Expressions such as $\kappa \to [\mu]^{<\lambda}_\gamma$ should be given the obvious meaning.

It is a theorem of Erdős and Hajnal [26] that $\kappa \nrightarrow [\kappa]^\omega_\kappa$ for every infinite cardinal κ (see [53, Sect. 23] for a nice proof due to Galvin and Prikry [37]). This result is a key ingredient in Kunen's proof [58] that there is no elementary embedding $j : V \to V$.

In this subsection, we will concentrate on colorings of pairs, that is, the case where $\lambda = 2$ in Definition 5.10. Our first result is an easy proposition due to Erdős, Hajnal, and Rado [27] which we mentioned in the discussion following Corollary 5.9.

5.11 Proposition. *If $2^\kappa = \kappa^+$, then $\kappa^+ \nrightarrow [\kappa^+]^2_{\kappa^+}$.*

Proof. Assume $2^\kappa = \kappa^+$, and let $\langle X_\alpha : \alpha < \kappa^+\rangle$ enumerate the bounded subsets of κ^+ in such a way that $X_\alpha \subseteq \alpha$. An easy construction yields a function $f : [\kappa^+]^2 \to \kappa^+$ with the property that whenever $\kappa \leq \alpha < \beta$ and $\gamma < \beta$, there is a $\xi \in X_\alpha$ such that $f(\xi, \beta) = \gamma$. If A is any unbounded subset of κ^+ and $\gamma < \kappa^+$, we can choose α with $X_\alpha \subseteq A$. If β is the least element of A greater than γ and α, then our construction guarantees that there is a $\xi \in A$ with $f(\xi, \beta) = \gamma$. ⊣

Todorčević [97] obtained the following significant strengthening of Theorem 5.4 using his technique of minimal walks. Shelah's paper [86] also contains a proof of this theorem, and Sect. 20 of Hajnal and Hamburger's book [42] gives a nice exposition.

5.12 Theorem. *If λ has a non-reflecting stationary subset, then $\lambda \nrightarrow [\lambda]^2_\lambda$.*

Proof. See [42, Sect. !20]. ⊣

5.13 Corollary. *If κ is a regular cardinal, then $\kappa^+ \nrightarrow [\kappa^+]^2_{\kappa^+}$.*

The following counterpart of Theorem 5.7 is also due to Todorčević, and Burke and Magidor [10] contains a nice treatment. The proof we give is based on their paper.

5.14 Theorem. *Let $(\vec{\mu}, \vec{f})$ be a scale for the singular cardinal μ. If*

$$\mu_i \nrightarrow [\mu_i]^2_{\mu_i} \tag{15.87}$$

for all $i < \mathrm{cf}(\mu)$, then

$$\mu^+ \nrightarrow [\mu^+]^2_{\mu^+}. \tag{15.88}$$

Proof. Assume $(\vec{\mu}, \vec{f})$ is a scale satisfying (15.87), with c_i the corresponding coloring on μ_i for each $i < \mathrm{cf}(\mu)$. Define $d : [\mu^+]^2 \to \mathrm{cf}(\mu)$ by setting $d(\alpha, \beta)$ equal to the maximal $i^* < \mathrm{cf}(\mu)$ for which $f_\beta(i^*) < f_\alpha(i^*)$ if such an i^* exists, and setting $d(\alpha, \beta)$ equal to 0 otherwise.

Now define $c : [\mu^+]^2 \to \mu^+$ by

$$c(\alpha, \beta) = c_{i^*}(f_\beta(i^*), f_\alpha(i^*))$$

where $\alpha < \beta$ and $i^* = d(\alpha, \beta)$. We now work to prove that c has the properties needed for us to conclude that $\mu^+ \nrightarrow [\mu^+]^2_{\mu^+}$.

Suppose that we are given a set $X \subseteq \mu^+$ of cardinality μ^+, and a color $\gamma < \mu^+$; we must produce $\alpha < \beta$ in X with $c(\alpha, \beta) = \gamma$. Let M be an elementary submodel of $H(\chi)$ such that

- μ, $(\vec{\mu}, \vec{f})$, and X are all in M,
- $\mathrm{cf}(\mu) \subseteq M$, and
- $|M| < \mu$

and let $\mathrm{Ch}^{\vec{\mu}}_M$ be defined as in (15.85).

There is an α_0 such that $\mathrm{Ch}^{\vec{\mu}}_M <^* f_\alpha$ for all $\alpha \geq \alpha_0$. Since μ^+ is regular and $|X| = \mu^+$, it follows that there is an $i_0 < \mathrm{cf}(\mu)$ and a set $Y \subseteq X$ of cardinality μ^+ such that

$$\sup(M \cap \mu_i) = \mathrm{Ch}^{\vec{\mu}}_M(i) < f_\alpha(i) \quad \text{for all } i \geq i_0 \text{ and } \alpha \in Y.$$

For each $\alpha < \mu^+$ and $i \geq i_0$, define

$$A(\alpha, i) = \{f_\xi(i) : \xi \in Y \setminus \alpha\}.$$

Note that $A(\alpha, i) \subseteq \mu_i$, and for each i the sequence $\langle A(\alpha, i) : \alpha < \mu^+\rangle$ is non-increasing, hence eventually constant. Thus, for $i_0 \leq i < \mathrm{cf}(\mu)$ there is a set $A_i \subseteq \mu_i$ and $\alpha_i < \mu^+$ such that

$$\alpha \geq \alpha_i \quad \Longrightarrow \quad A(\alpha, i) = A_i.$$

Since μ^+ is regular, it follows that there is a single $\alpha^* < \mu^+$ satisfying

$$\alpha \geq \alpha^* \quad \Longrightarrow \quad A(\alpha, i) = A_i \text{ for } i \geq i_0. \tag{15.89}$$

We can assume that $\alpha^* \geq \alpha_0$, as increasing α^* preserves (15.89).

Next, note that A_i is unbounded in μ_i for all sufficiently large $i < \mathrm{cf}(\mu)$. This has a straightforward proof by contradiction—if A_i is bounded below μ_i for arbitrarily large $i < \mathrm{cf}(\mu)$, then one easily contradicts the fact that $\vec{f}$ is a scale.

Choose $i^* \geq i_0$ large enough so that $\gamma < \mu_{i^*}$ and A_{i^*} is unbounded in μ_{i^*}. Our choice of c_{i^*} guarantees the existence of $\xi < \zeta$ in A_{i^*} for which

$$c_{i^*}(\xi, \zeta) = \gamma.$$

The definition of A_{i^*} implies that there is a $\beta \in Y$ such that

$$f_\beta(i^*) = \xi.$$

Now let $N = \mathrm{Sk}^{\mathfrak{A}}(M \cup \mu_{i^*})$. An application of Lemma 1.6 from the introduction tells us that

$$\mathrm{Ch}^{\vec{\mu}}_N(i) = \sup(N \cap \mu_i) = \mathrm{Ch}^{\vec{\mu}}_M(i) \quad \text{for } i > i^*,$$

and since $\beta \in Y$, it follows that

$$\mathrm{Ch}^{\vec{\mu}}_N(i) < f_\beta(i) \quad \text{for } i > i^*. \tag{15.90}$$

The ordinal ζ is in N, and by elementarity

$$N \models (\exists \alpha \in X)[f_\alpha(i^*) = \zeta],$$

so we can find a $\alpha \in N \cap X$ such that $f_\alpha(i^*) = \zeta$.

Since $f_\alpha(i) \in N \cap \mu_i$ for all i, it follows from (15.90) that

$$i > i^* \implies f_\alpha(i) < f_\beta(i).$$

Since $f_\beta(i^*) = \xi < \zeta = f_\alpha(i^*)$, we conclude that $d(\alpha, \beta) = i^*$ and therefore

$$c(\alpha, \beta) := c_{i^*}(f_\beta(i^*), f_\alpha(i^*)) = c_{i^*}(\xi, \zeta) = \gamma,$$

as desired. ⊣

The proof of the theorem just completed exploits a crucial property of the function d defined in the course of the demonstration. As we shall see, that particular function implies that certain square-bracket partition relations fail dramatically at successors of singular cardinals. To make this precise we need the following definition of Shelah, which is only one of an imposing family of related concepts. We refer to the reader to the first appendix of [89] for more information.

5.15 Definition. Let μ be a singular cardinal. $\mathrm{Pr}_1(\mu^+, \mathrm{cf}(\mu), \mathrm{cf}(\mu))$ says that there is a function $c : [\mu^+]^2 \to \mathrm{cf}(\mu)$ such that whenever we are given a sequence $\langle t_i : i < \mu^+\rangle$ of disjoint sets from $[\mu^+]^{<\mathrm{cf}(\mu)}$ and an ordinal $\gamma < \mathrm{cf}(\mu)$, we can find $\epsilon_1 < \epsilon_2$ such that $c(\alpha, \beta) = \gamma$ whenever $\alpha \in t_{\epsilon_1}$ and $\beta \in t_{\epsilon_2}$.

We point out that in the above definition, the coloring takes on only $\mathrm{cf}(\mu)$ possible values, and not μ^+. Also, note that

$$\mathrm{Pr}_1(\mu^+, \mathrm{cf}(\mu), \mathrm{cf}(\mu)) \implies \mu^+ \nrightarrow [\mathrm{cf}(\mu)]^2_{\mathrm{cf}(\mu)}$$

because each t_i can be taken to be a singleton. The following theorem is due to Shelah (see Conclusion 4.1 in Chap. II of [89]).

5.16 Theorem. $\mathrm{Pr}_1(\mu^+, \mathrm{cf}(\mu), \mathrm{cf}(\mu))$ *holds for every singular cardinal* μ.

Proof. Let $\lambda = \mu^+$ and $\kappa = \mathrm{cf}(\mu)$. By Theorem 3.53, we can find a scale $(\vec{\mu}, \vec{f})$ for μ with $\kappa < \mu_0$. Let us define $d : [\lambda]^2 \to \kappa$ just as in the proof of Theorem 5.14, that is $d(\alpha, \beta)$ is set (for $\alpha < \beta < \lambda$) equal to the maximal $i^* < \mathrm{cf}(\mu)$ for which $f_\beta(i^*) < f_\alpha(i^*)$ if such an i^* exists, and $d(\alpha, \beta) = 0$ otherwise.

Next, let $h : \kappa \to \kappa$ be a partition of κ into sets of size κ. We define (again for $\alpha < \beta < \lambda$)

$$c(\alpha, \beta) = h(d(\alpha, \beta)).$$

We claim that c has the property required by $\mathrm{Pr}_1(\lambda, \kappa, \kappa)$.

To see this, suppose that we are given a sequence $\langle t_i : i < \lambda\rangle$ of subsets of λ, each of size less than κ. Without loss of generality, we assume that all t_i have the same order-type $\xi < \kappa$, $i \leq \min(t_i)$, and that $\sup(t_i) < \min(t_j)$ for

$i < j < \kappa$. Given $\gamma < \kappa$, our task is to find $\epsilon_1 < \epsilon_2 < \lambda$ such that $c \restriction t_{\epsilon_1} \times t_{\epsilon_2}$ is constant with value γ.

For each $\beta < \lambda$, we define functions $f_\beta^{\inf}$ and $f_\beta^{\sup}$ mapping κ to μ by

$$f_\beta^{\inf}(i) = \inf\{f_\alpha(i) : \alpha \in t_\beta\}$$

and

$$f_\beta^{\sup}(i) = \sup\{f_\alpha(i) : \alpha \in t_\beta\}.$$

Note that $f_\beta^{\sup} \in \prod_{i<\kappa} \mu_i$ as $\xi < \kappa < \mu_0$ and each μ_i is regular, while

$$f_\beta^{\inf}(i) = f_{\min(t_\beta)}(i) \quad \text{for all sufficiently large } i < \kappa \tag{15.91}$$

as $\xi < \kappa$ and κ is regular.

Let M be an elementary submodel of $H(\chi)$ of size κ with $\kappa \subseteq M$ and containing λ, $(\vec{\mu}, \vec{f})$, and $\langle t_i : i < \lambda \rangle$. Finally, let $\mathrm{Ch}_M^{\vec{\mu}}$ be the characteristic function of M on $\vec{\mu}$, defined as in (15.85).

Since $\vec{f}$ forms a scale, by (15.91) there is an ordinal $\epsilon_1 < \lambda$ such that $\mathrm{Ch}_M^{\vec{\mu}} <^* f_{\epsilon_1}^{\inf}$. Also, we note that for all sufficiently large $i < \kappa$ we have

$$\mu_i = \sup\{f_\beta^{\inf}(i) : \beta < \lambda\}.$$

This follows easily from the fact that $(\vec{\mu}, \vec{f})$ is a scale.

After putting these two observations together, it follows that we can choose an $i^* < \kappa$ such that the following conditions hold:

1. $h(i^*) = \gamma$,
2. $\mu_{i^*} = \sup\{f_\beta^{\inf}(i^*) : \beta < \lambda\}$, and
3. $\mathrm{Ch}_M^{\vec{\mu}}(i) < f_{\epsilon_1}^{\inf}(i)$ for all $i \geq i^*$.

By condition (2), we can find an $\epsilon^* < \lambda$ such that

$$f_{\epsilon_1}^{\sup}(i^*) < \delta := f_{\epsilon^*}^{\inf}(i^*).$$

We now define $N = \mathrm{Sk}^{\mathfrak{A}}(M \cup \mu_{i^*})$. By Lemma 1.6, we know that

$$\sup(N \cap \sigma) = \sup(M \cap \sigma)$$

for every regular cardinal in M greater than μ_{i^*}. In particular,

$$\mathrm{Ch}_M^{\vec{\mu}} \restriction [i^* + 1, \kappa) = \mathrm{Ch}_N^{\vec{\mu}} \restriction [i^* + 1, \kappa).$$

By elementarity,

$$N \models (\exists \beta < \lambda)[f_\beta^{\inf}(i^*) = \delta],$$

and so there is an $\epsilon_2 \in N$ with $f_{\epsilon_2}^{\inf}(i^*) = \delta$. Thus

$$f_{\epsilon_1}^{\sup}(i^*) < f_{\epsilon_2}^{\inf}(i^*). \tag{15.92}$$

On the other hand, for $i > i^*$ we have

$$f^{\sup}_{\epsilon_2}(i) < \mathrm{Ch}^{\vec{\mu}}_N(i) = \mathrm{Ch}^{\vec{\mu}}_M(i) < f^{\inf}_{\epsilon_1}(i). \tag{15.93}$$

Thus for $\alpha \in t_{\epsilon_1}$ and $\beta \in t_{\epsilon_2}$, (15.92) and (15.93) imply

$$d(\alpha, \beta) = i^*,$$

and so

$$c(\alpha, \beta) = h(e(\alpha, \beta)) = h(i^*) = \gamma,$$

as required. ⊣

As a special case of the preceding theorem, we obtain the following.

5.17 Corollary. *If μ is singular, then $\mu^+ \nrightarrow [\mu^+]^2_{\mathrm{cf}(\mu)}$.*

Much more is known about colorings of pairs at successors of singular cardinals, but the techniques used involve club guessing in an essential way—see [25] and [24], for example. We discuss the interplay between club guessing and the existence of complicated colorings in the next subsection.

5.3. Colorings and Club Guessing

In the previous subsection, we have exploited the existence of scales to shed light on square-bracket partition relations at successors of singular cardinals. In this subsection, we get more results using a different technique—club guessing. We remark that all the results presented in this section are due to Shelah, and they can be found in his book [89]. Club guessing has already made a few brief appearances in earlier chapters, e.g., [49, Theorem 1.16] and [1, Theorem 2.17]. In the following subsections we develop the theory just enough to shed light on the question (15.82). We begin with some terminology.

5.18 Definition. Let κ be a regular cardinal and let $S \subseteq \kappa$ be a stationary set. A family $\bar{C} = \langle C_\delta : \delta \in S\rangle$ is an S-*club system* if the set of $\delta \in S$ for which C_δ is not closed and unbounded in δ is nonstationary.

Given an S-club system $\bar{C}$ for a cardinal κ, there are several senses in which $\bar{C}$ can be said to "guess clubs", but they all have the same general form—they all require that for every closed unbounded $E \subseteq \kappa$, the set $E \cap C_\delta$ is "large" for a "large" set of $\delta \in S$. For example, one might require for every closed unbounded $E \subseteq \kappa$ that $C_\delta \subseteq E$ for stationarily many $\delta \in S$—we used this sort of club guessing in our proof of Theorem 3.18. The hypotheses of the following theorem include another example of club guessing, and we shall use the theorem and its proof to motivate further investigations.

5.19 Theorem. *Suppose that $\lambda = \mu^+$ where μ is singular, and let $S \subseteq \lambda$ be stationary. Further suppose that there is an S-club system $\bar{C} = \langle C_\delta : \delta \in S\rangle$ with the property that for every closed unbounded $E \subseteq \lambda$, there is a stationary set of $\delta \in S$ such that for all $\beta < \delta$ and $\gamma < \mu$, there is an $\alpha \in E \cap \mathrm{nacc}(C_\delta)$ such that*

1. $\beta < \alpha$,

2. $\gamma < \mathrm{cf}(\alpha)$, *and*

3. $\mathrm{cf}(\alpha)$ *carries a Jónsson algebra.*

Then λ *carries a Jónsson algebra.*

Proof. Let M by an elementary submodel of $H(\chi)$ for some sufficiently large regular χ containing S and $\bar{C}$. Further suppose that $\lambda \in M$ and $|M \cap \lambda| = \lambda$. We must establish that $\lambda \subseteq M$.

Given $\delta \in S$, let us define β_δ to be the least member of $M \cap \lambda$ greater than or equal to δ. Clearly, $\delta < \beta_\delta$ if and only if $\delta \notin M$. Let $E \subseteq \lambda$ be the closed unbounded set of all $\alpha \in \lambda \setminus \mu$ satisfying $\alpha = \sup(M \cap \alpha)$, and fix $\delta \in S$ such that $E \cap \mathrm{nacc}(C_\delta)$ satisfies the assumptions of the theorem. The following crucial lemma tells us that M must contain many points of C_δ, even though δ itself need not be in M.

5.20 Lemma. *M contains all members of $E \cap \mathrm{nacc}(C_\delta)$ of cofinality greater than $\mathrm{cf}(\beta_\delta)$.*

Proof. We dispose of the easy case first—if $\delta \in M$ then $E \cap \mathrm{nacc}(C_\delta) \subseteq M$ as well. To see why, suppose that $\beta \in E \cap \mathrm{nacc}(C_\delta)$. Since $\beta = \sup(\beta \cap M)$, there is an ordinal $\beta^* \in M$ with $\sup(C_\delta \cap \beta) < \beta^* < \beta$. Thus, β is the least member of C_δ above β^*. Since C_δ and β^* are both in M (recall that we assumed $\delta \in M$), it follows that β must be in M as well.

The case where δ is not in M is more difficult as we do not have C_δ available in the model. In this case, recall that $\delta < \beta_\delta$.

Inside M, let d be a closed unbounded subset of β_δ of order-type $\mathrm{cf}(\beta_\delta)$. The same argument we used in the proof of Theorem 5.4 shows us that δ is an element of d.

Now let $\beta \in E \cap \mathrm{nacc}(C_\delta)$ satisfy $\mathrm{cf}(\beta) > |d| = \mathrm{cf}(\beta_\delta)$. It follows that β cannot be a limit point of d, and so (using the definition of E) there exists an ordinal β_0 with

- $\beta_0 \in M$,
- $\sup(C_\delta \cap \beta) < \beta_0 < \beta$, and
- $\sup(d \cap \beta) < \beta_0$.

Given β_0, we define A to be the set $\{\min(C_\epsilon \setminus \beta_0) : \epsilon \in d \cap S\}$. Notice that A is in M because all parameters used in its definition are available there. Also, $|A| \leq |d| < \mathrm{cf}(\beta)$ and so $A \cap \beta$ is bounded below β. Thus, there is an ordinal β_1 such that

- $\beta_1 \in M$,
- $\beta_0 < \beta_1 < \beta$, and
- $A \cap [\beta_1, \beta) = \emptyset$.

Let us now define

$$d^* = \{\epsilon \in d \cap S \setminus \beta_1 : \min(C_\epsilon \setminus \beta_0) = \min(C_\epsilon \setminus \beta_1)\}.$$

The set d^* is an element of M as it is definable from parameters in M. Clearly δ is in the set d^* as

$$\min(C_\delta \setminus \beta_0) = \min(C_\delta \setminus \beta_1) = \beta. \tag{15.94}$$

If $\epsilon \in d \cap S$ is such that $\min(C_\epsilon \setminus \beta_0) < \beta$, then our choice of β_1 implies $\min(C_\epsilon \setminus \beta_0) < \beta_1$ and hence $\epsilon \notin d^*$. Thus

$$\epsilon \in d^* \implies \beta \leq \min(C_\epsilon \setminus \beta_0). \tag{15.95}$$

Putting (15.94) and (15.95) together, we conclude

$$\beta = \min\left(\{\min(C_\epsilon \setminus \beta_0) : \epsilon \in d^*\}\right).$$

Thus β is definable from parameters in M, and so $\beta \in M$ as required. $\dashv$

To finish the proof that λ carries a Jónsson algebra, we note that it suffices to prove that $\sigma \subseteq M$ for arbitrarily large $\sigma < \mu$, as this implies $\mu \subseteq M$ which implies $\lambda = \mu^+ \subseteq M$.

Choose an ordinal $\delta \in S$ as guaranteed by the assumptions of the theorem. Given $\sigma < \mu$, our choice of δ together with the preceding lemma lets us find an $\alpha \in E \cap \mathrm{nacc}(C_\delta)$ such that

- $\sigma < \mathrm{cf}(\alpha)$,
- $\mathrm{cf}(\alpha)$ carries a Jónsson algebra, and, most importantly,
- $\alpha \in M$.

Since $M \cap \alpha$ is unbounded in α, it follows immediately that $M \cap \mathrm{cf}(\alpha)$ is unbounded in $\mathrm{cf}(\alpha)$. However, $\mathrm{cf}(\alpha)$ is in M and it also carries a Jónsson algebra. By Theorem 5.3, we must conclude $\mathrm{cf}(\alpha) \subseteq M$, and the proof is complete. $\dashv$

We mentioned prior to the statement of Theorem 5.19 that its hypotheses require the S-club sequence $\bar{C}$ to guess clubs in a certain sense. We will invest a little time in unpacking some notation of Shelah in order to make this more precise.

5.21 Definition. Let κ be a regular cardinal, and let $\bar{C}$ be an S-club system for some stationary $S \subseteq \kappa$. A sequence $\bar{I} = \langle I_\delta : \delta \in S\rangle$ is said to be an *ideal sequence associated with* $\bar{C}$ if each I_δ is a (not necessarily proper) ideal on C_δ extending $J^{\mathrm{bd}}[C_\delta]$, the ideal of bounded subsets of C_δ. When we write "let $(\bar{C}, \bar{I})$ be an S-club system" it is to be understood that $\bar{I}$ is an ideal sequence associated with $\bar{C}$.

Now associated to every pair $(\bar{C}, \bar{I})$ as in the preceding definition, we have two natural club guessing ideals.

5.22 Definition. Let κ be a regular cardinal, let $S \subseteq \kappa$ be stationary, and let $(\bar{C}, \bar{I})$ be an S-club system.

1. $\mathrm{id}^a(\bar{C}, \bar{I})$ is defined to be the set of all $A \subseteq \kappa$ for which there is a club $E \subseteq \lambda$ such that $\{\delta \in S \cap A : C_\delta \setminus E \in I_\delta\}$ is nonstationary.
2. $\mathrm{id}^p(\bar{C}, \bar{I})$ is defined to be the set of all $A \subseteq \kappa$ for which there is a club $E \subseteq \lambda$ such that $\{\delta \in S \cap A : E \cap C_\delta \notin I_\delta\}$ is nonstationary.

We pause here for a moment to consider the preceding definitions. Note that an S-club system $(\bar{C}, \bar{I})$ can be said to "guess clubs" if one or both of these ideals are proper—for example, if $I_\delta = J^{\mathrm{bd}}[C_\delta]$ for all $\delta \in S$ and $\mathrm{id}^a(\bar{C}, \bar{I})$ is a proper ideal, then for every closed unbounded $E \subseteq \kappa$ the set of δ such that E contains a tail of C_δ is stationary. With the same choice of $\bar{I}$, we see that $\mathrm{id}^p(\bar{C}, \bar{I})$ is a proper ideal if and only if for every closed unbounded $E \subseteq \kappa$ there is a stationary set of $\delta \in S$ with $E \cap C_\delta$ unbounded in δ. (This last statement is true for any $\delta \in S \cap \mathrm{acc}(E)$ of uncountable cofinality, so in practice we usually require the ideal I_δ to contain $\mathrm{acc}(C_\delta)$.) Note that in the case of $\mathrm{id}^a(\bar{C}, \bar{I})$, we require that $E \cap C_\delta$ contains almost all (in the sense of I_δ) elements of C_δ, while in the case of $\mathrm{id}^p(\bar{C}, \bar{I})$ we only require that $E \cap C_\delta$ is I_δ-positive.

We do not have room here for a full exposition of club guessing results, and accordingly we focus on the special case that is extremely relevant to square-bracket partition relations at successors of singular cardinals. In particular, we will not have an opportunity to discuss recent work of Foreman and Komjath [33] and Ishiu [47, 48] in this area; the reader is encouraged to look in these papers for more information.

5.23 Definition. Suppose that $\lambda = \mu^+$ for some singular cardinal μ, and let $\delta < \lambda$ be a limit ordinal. For C_δ closed and unbounded in δ, we define $J^{b[\mu]}[C_\delta]$ to be the ideal of subsets of C_δ generated sets of the following forms:

- $\mathrm{acc}(C_\delta)$
- $C_\delta \cap \beta$ for all $\beta < \delta$
- $\{\alpha \in C_\delta : \mathrm{cf}(\alpha) < \gamma\}$ for all $\gamma < \mu$

There are three comments that should be made here. First, the notation is due to Shelah, who first realized the relevance of these ideals to the problems we are considering. Second, note that a set A is in $J^{b[\mu]}[C_\delta]$ if and only if there are $\beta < \delta$ and $\gamma < \mu$ such that

$$A \subseteq \mathrm{acc}(C_\delta) \cup \beta \cup \{\epsilon < \delta : \mathrm{cf}(\epsilon) < \gamma\}. \tag{15.96}$$

This makes it clear that $J^{b[\mu]}[C_\delta]$ is τ-complete where $\tau = \min\{\mathrm{cf}(\delta), \mathrm{cf}(\mu)\}$. Finally, we point out that the ideal $J^{b[\mu]}[C_\delta]$ is perhaps easier to visualize when one considers what it means for a set to be $J^{b[\mu]}[C_\delta]$-positive—a set $A \subseteq C_\delta$ is *not in* $J^{b[\mu]}[C_\delta]$ if for any $\beta < \delta$ and $\gamma < \mu$, there is an ordinal $\alpha \in \mathrm{nacc}(C_\delta)$ such that $\beta < \alpha$ and $\mathrm{cf}(\alpha) > \gamma$.

In this terminology, we see that the hypothesis concerning $\bar{C}$ in Theorem 5.19 becomes "for every closed unbounded $E \subseteq \lambda$, there are stationarily many $\delta \in S$ such that the set $\{\alpha \in E \cap C_\delta : \mathrm{cf}(\alpha)$ carries a Jónsson algebra$\}$ is not in $J^{b[\mu]}[C_\delta]$". We now state without proof a club guessing result of Shelah taken from [89, Chap. III].

5.24 Theorem. *Let $\lambda = \mu^+$ for μ a singular cardinal, and let $S \subseteq S^{\lambda}_{\mathrm{cf}(\mu)}$ be stationary. There is an S-club system $\bar{C}$ such that for every closed unbounded $E \subseteq \lambda$, the set of $\delta \in S$ with $E \cap C_\delta \notin J^{b[\mu]}[C_\delta]$ is stationary.*

Said another way, the previous theorem states that $\mathrm{id}^p(\bar{C}, \bar{I})$ is a proper ideal, where I_δ is defined to be $J^{b[\mu]}[C_\delta]$. We remark that the theorem is never explicitly stated in [89], but it follows from piecing together various club guessing results appearing in Chap. III of that book, and the paper [40] contains an exposition of related results. From this theorem, we can see that the hypotheses of Theorem 5.19 are satisfied for any singular cardinal μ that is not a limit of regular Jónsson cardinals.

5.25 Theorem. *If μ is a singular cardinal that is not a limit of regular Jónsson cardinals, then μ^+ carries a Jónsson algebra.*

Proof. Let $\langle C_\delta : \delta \in S^{\mu^+}_{\mathrm{cf}(\mu)}\rangle$ be a club system as in Theorem 5.24. The hypotheses of Theorem 5.19 are then satisfied because of the definition of $J^{b[\mu]}[C_\delta]$. $\dashv$

Plowing through the notation associated with club guessing may seem a steep price to pay for the preceding theorem, especially as we obtained a similar result in a much neater way using scales. However, the club guessing proof seems to give more information, and we will spend the rest of the subsection illustrating this.

The ideals defined in Definition 5.22 are certainly natural ones to consider in association with club guessing, but for our purposes we need to also consider the following ideals:

5.26 Definition. Let κ be a regular cardinal, let $S \subseteq \kappa$ be stationary, and let $(\bar{C}, \bar{I})$ be an S-club system.

1. $\mathrm{id}_a(\bar{C}, \bar{I})$ is defined to be the set of all $A \subseteq \kappa$ for which there is a club $E \subseteq \lambda$ such that $\{\delta \in S : A \cap C_\delta \setminus E \in I_\delta\}$ is nonstationary.

2. $\mathrm{id}_p(\bar{C}, \bar{I})$ is defined to be the set of all $A \subseteq \kappa$ for which there is a club $E \subseteq \lambda$ such that $\{\delta \in S : E \cap A \cap C_\delta \notin I_\delta\}$ is nonstationary.

The notation above is due to Shelah and even though it is not terribly descriptive, we note that the switch from superscripts in $\mathrm{id}^p(\bar{C}, \bar{I})$ to subscripts in $\mathrm{id}_p(\bar{C}, \bar{I})$ is suggestive—the "superscript ideals" concentrate on the set S, while the "subscript ideals" concentrate instead on the set $\bigcup_{\delta\in S} C_\delta$.

To see the difference between the two, let us consider the case where $(\bar{C}, \bar{I})$ is an S-club system for some stationary $S \subseteq \kappa$. The ideal $\mathrm{id}^p(\bar{C}, \bar{I})$ is a proper ideal if and only if $\mathrm{id}_p(\bar{C}, \bar{I})$ is, and both these conditions happen if and only if the pair $(\bar{C}, \bar{I})$ guesses clubs in the "p-sense".

Now, given such $(\bar{C}, \bar{I})$, a set T is in $\mathrm{id}^p(\bar{C}, \bar{I})$ if and only if the sequence $\langle (C_\delta, I_\delta) : \delta \in S\cap T\rangle$ no longer guesses clubs, while T is in $\mathrm{id}_p(\bar{C}, \bar{I})$ precisely when the sequence $\langle (C_\delta \cap T, I_\delta \restriction (C_\delta \cap T)) : \delta \in S\rangle$ no longer guesses clubs. In both cases, T is used to "shrink" the sequence $(\bar{C}, \bar{I})$, but the shrinking is done in different senses.

The importance of this ideal is shown by the following theorem. Although this theorem was first stated explicitly in [22], its proof is the same as that of Theorem 5.19 and it is implicit in Claim 3.7 in Chap. III of [89] (which appears as Corollary 5.28 below).

5.27 Theorem. *Let $\lambda = \mu^+$ for μ a singular cardinal, and let $S \subseteq \lambda$ be stationary. Given an S-club sequence $\bar{C}$ as in the conclusion of Theorem 5.24, there is a function $F : [\lambda]^{<\omega} \to \lambda$ such that for any unbounded $A \subseteq \lambda$, the range of $F\restriction[A]^{<\omega}$ is in the filter dual to $\mathrm{id}_p(\bar{C}, \bar{I})$, that is*

$$A \in [\lambda]^\lambda \quad\Longrightarrow\quad [\lambda \setminus \mathrm{ran}(F\restriction[A]^{<\omega})] \in \mathrm{id}_p(\bar{C}, \bar{I}). \tag{15.97}$$

Proof. Let $x = \{S, \lambda, (\bar{C}, \bar{I})\}$, and let χ be a sufficiently large regular cardinal. The function $F : [\lambda]^{<\omega} \to \lambda$ is to code the Skolem functions of the structure $\mathfrak{A} = \langle H(\chi), \in, x, <_\chi\rangle$ just as in the proof of Theorem 5.3. This means, in particular, that for any $B \subseteq \lambda$ we have

$$\mathrm{ran}(F\restriction[B]^{<\omega}) = \mathrm{Sk}^{\mathfrak{A}}(B) \cap \lambda. \tag{15.98}$$

Now let A be an unbounded subset of λ, and let $B = \mathrm{ran}(F\restriction[A]^{<\omega})$. If $B = \lambda$, there is nothing to prove. If not, then $M = \mathrm{Sk}^{\mathfrak{A}}(A)$ is an elementary submodel of $H(\chi)$ satisfying

- $M \cap \lambda = B = \mathrm{ran}(F\restriction[A]^{<\omega})$,
- λ, S, and $(\bar{C}, \bar{I})$ are all in M,
- $|M \cap \lambda| = \lambda$, and
- $\lambda \not\subseteq M$.

Let E be the closed unbounded set of $\alpha < \lambda$ for which $\alpha = \sup(M \cap \alpha)$. By Lemma 5.20, if $\delta \in S$ is such that C_δ guesses E then M contains all members of $E \cap \mathrm{nacc}(C_\delta)$ of cardinality greater than β_δ. In other words,

$$\delta \in S \quad\Longrightarrow\quad E \cap (\lambda \setminus B) \cap C_\delta \in I_\delta.$$

Therefore $\lambda \setminus B$ is in $\mathrm{id}_p(\bar{C}, \bar{I})$, as was to be shown. $\dashv$

Thus, even though we as yet do not know whether the successor of a singular cardinal must carry a Jónsson algebra, the above theorem gives an approximation to a positive answer—for any unbounded $A \subseteq \lambda$, the function F takes on almost all values (in the sense of $\mathrm{id}_p(\bar{C}, \bar{I})$) when restricted to $[A]^{<\omega}$. As a corollary, we deduce the following result of Shelah.

5.28 Corollary. *Let λ, S, and $(\bar{C}, \bar{I})$ be as in the statement of Theorem 5.27. If there exists a partition of λ into θ sets, each of which is $\mathrm{id}_p(\bar{C}, \bar{I})$-positive, then $\lambda \nrightarrow [\theta]^{<\omega}_{\lambda}$.*

Proof. Let $\langle A_i : i < \theta \rangle$ be a partition of λ into $\mathrm{id}_p(\bar{C}, \bar{I})$ positive sets, and for $s \in [\lambda]^{<\omega}$ we define

$$c(s) = i \iff F(s) \in A_i.$$

Given an unbounded $A \subseteq \lambda$ an $i < \theta$, we know A_i meets the range of $F \restriction [A]^{<\omega}$. In particular, there must be an $s \in [A]^{<\omega}$ with $F(s) \in A_i$, and for this choice of s we have $c(s) = i$, as required. ⊣

If each C_δ is of cardinality less than μ (this can be guaranteed if the cofinality of μ is uncountable, but the question for countable cofinality is still open), then the function F from Theorem 5.27 can be improved to a function defined on pairs. This is shown in [24], where minimal walks are combined with combinatorics of scales to construct a complicated coloring of pairs. It then follows that the conclusion of the corollary can then be improved to $\lambda \nrightarrow [\lambda]^2_{\lambda}$ (and even to $\mathrm{Pr}_1(\lambda, \lambda, \mathrm{cf}(\mu))$ using a stronger argument). The fourth section of Chap. III from [89] also achieves this improvement of the corollary, but Shelah's colorings are constructed directly from a partition of λ into disjoint $\mathrm{id}_p(\bar{C}, \bar{I})$-positive sets.

We now close the section by remarking that the problem of partitioning λ into $\mathrm{id}_p(\bar{C}, \bar{I})$-positive sets is a very concrete one, and Shelah exploits this in [89] as a way of obtaining Jónsson algebras and colorings of pairs.

6. Concluding Remarks

In this final section, we make a few remarks concerning the overarching themes present in this chapter. As mentioned in the introduction, one can view successors of singular cardinals as a battleground between "compactness" and "non-compactness". On the one side, we have all the reflection phenomena associated with supercompact cardinals and their ilk, while squares act as a paradigmatic representative for the other side. In between, we find a gradation of combinatorial principles that can be used to measure the non-reflection inherent in a combinatorial statement.

There is more here to hold our interest than the simple weighing of combinatorial statements on scales of reflection, however, for the theory contains many surprises. We hope that this introduction to the topic adequately communicates the richness of this area of set theory, and that it will serve as an invitation for other researchers to join in the exploration.

DOI 10.1007/978-1-4020-5764-9_17,

One of the central topics of set theory since Cantor has been the study of the power function $\kappa \to 2^\kappa$. The basic problem is to determine all the possible values of 2^κ for a cardinal κ. Cohen [7] proved the independence of CH and invented the method of forcing. Easton [11] building on Cohen's results showed that the function $\kappa \to 2^\kappa$ for regular κ can behave in any prescribed way consistent with the Zermelo-König inequality, which entails $\mathrm{cf}(2^\kappa) > \kappa$. This reduces the study to singular cardinals.

It turned out that the situation with powers of singular cardinals is much more involved. Thus, for example, a remarkable theorem of Silver states that a singular cardinal of uncountable cofinality cannot be the first to violate GCH. The Singular Cardinals Problem is the problem of finding a complete set of rules describing the behavior of the function $\kappa \to 2^\kappa$ for singular κ's.

There are three main tools for dealing with the problem: pcf theory, inner model theory and forcing involving large cardinals. The purpose of this chapter is to present the main forcing tools for dealing with powers of singular cardinals. We refer to [19] or to [24] for detailed discussion of the Singular Cardinals Problem.

The chapter should be accessible to a reader with knowledge of forcing (say, Chaps. VII, VIII of Kunen's book [30]) and familiarity with ultrapowers and elementary embeddings. Thus §§5, 26 of Kanamori's book [26] will be more than enough. Only Sect. 6 requires in addition a familiarity with iterated forcing (for example Baumgartner's paper [5], §§0–2 of Sect. II of Shelah's book [54], or Cummings' chapter [8] in this Handbook). The following sections can be read independently: Sects. 1 and 2; Sects. 1.1, 3 and 4; Sects. 1.1 and 5.1, 5.2; Sect. 6.

Acknowledgments

We are grateful to Aki Kanamori, John Krueger, Andreas Liu and Carmi Merimovich for their remarks and corrections. We would like to thank to Assaf Rinot for his corrections and for his help with T_EX. We owe a special debt to Bill Mitchell for his critical reading of a previous version, culminating in a long list of improvements.

1. Prikry Forcings

We describe here the classical Prikry forcing and some variations of it. They were all introduced implicitly or explicitly by Karel Prikry in [47].

1.1. Basic Prikry Forcing

Let κ be a measurable cardinal and U a normal ultrafilter over κ.

1.1 Definition. Let $\mathcal{P}$ be the set of all pairs $\langle p, A\rangle$ such that

(1) p is a finite subset of κ,

(2) $A \in U$, and

(3) $\min(A) > \max(p)$.

It is convenient sometimes to view p as an increasing finite sequence of ordinals.

We define two partial orderings on $\mathcal{P}$, the first one conspicuously lacking any useful closure property and the second closed enough to compensate for the lack of closure of the first.

1.2 Definition. Let $\langle p, A\rangle, \langle q, B\rangle \in \mathcal{P}$. We say that $\langle p, A\rangle$ *is stronger than* $\langle q, B\rangle$ and denote this by $\langle p, A\rangle \geq \langle q, B\rangle$ iff

(1) p is an end extension of q, i.e. $p \cap (\max(q)+1) = q$,

(2) $A \subseteq B$, and

(3) $p \setminus q \subseteq B$.

We shall use $\leq$ with the corresponding meaning, and proceed analogously in similar definitions without further comment.

1.3 Definition. Let $\langle p, A\rangle, \langle q, B\rangle \in \mathcal{P}$. We say that $\langle p, A\rangle$ is *a direct (or Prikry) extension* of $\langle q, B\rangle$ and denote this by $\langle p, A\rangle \geq^* \langle q, B\rangle$ iff

(1) $p = q$, and

(2) $A \subseteq B$.

We will force with $\langle \mathcal{P}, \leq\rangle$, and $\langle \mathcal{P}, \leq^*\rangle$ will be used to show that no new bounded subsets are added to κ after the forcing with $\langle \mathcal{P}, \leq\rangle$.

Let us prove a few basic lemmas.

1.4 Lemma. *Let $G \subseteq \mathcal{P}$ be generic for $\langle \mathcal{P}, \leq\rangle$. Then $\bigcup\{p \mid \exists A(\langle p, A\rangle \in G)\}$ is an ω-sequence cofinal in κ.*

Proof. Just note that for every $\alpha < \kappa$ and $\langle q, B\rangle \in \mathcal{P}$ the set

$$D_\alpha = \{\langle p, A\rangle \in \mathcal{P} \mid \langle p, A\rangle \geq \langle q, B\rangle \text{ and } \max(p) > \alpha\}$$

is dense in $\langle \mathcal{P}, \leq\rangle$ above $\langle q, B\rangle$. ⊣

1.5 Lemma. *$\langle \mathcal{P}, \leq\rangle$ satisfies the κ^+-c.c.*

Proof. Note that any two conditions having the same first coordinate are compatible: If $\langle p, A\rangle, \langle p, B\rangle \in \mathcal{P}$, then $\langle p, A \cap B\rangle$ is stronger than both of them. ⊣

Let us now state three lemmas about $\leq^*$ and its relation to $\leq$. The third one contains the crucial idea of Prikry that makes everything work.

1.6 Lemma. $\leq^* \subseteq \leq$.

This is obvious from Definitions 1.2 and 1.3.

1.7 Lemma. *$\langle \mathcal{P}, \leq^* \rangle$ is κ-closed.*

Proof. Let $\langle \langle p_\alpha, A_\alpha \rangle \mid \alpha < \lambda \rangle$ be a $\leq^*$-increasing sequence of length λ for some $\lambda < \kappa$. Then all the p_α's are the same. Set $p = p_0$ and $A = \bigcap_{\alpha<\lambda} A_\alpha$. Then $A \in U$ by κ-completeness of U. So $\langle p, A \rangle \in \mathcal{P}$, and it is stronger than each $\langle p_\alpha, A_\alpha \rangle$ according to $\leq^*$. $\dashv$

1.8 Lemma (The Prikry condition). *Let $\langle q, B \rangle \in \mathcal{P}$ and σ be a statement of the forcing language of $\langle \mathcal{P}, \leq \rangle$. Then there is a $\langle p, A \rangle \geq^* \langle q, B \rangle$ such that $\langle p, A \rangle \parallel \sigma$ (i.e. $\langle p, A \rangle \Vdash \sigma$ or $\langle p, A \rangle \Vdash \neg\sigma$), where, again, we force with $\langle \mathcal{P}, \leq \rangle$ and not with $\langle \mathcal{P}, \leq^* \rangle$.*

Proof. We identify finite subsets of κ and finite increasing sequences of ordinals below κ, i.e. $[\kappa]^{<\omega}$. Define a partition $h : [B]^{<\omega} \to 2$ as follows:

$$h(s) = \begin{cases} 1, & \text{if there is a } C \text{ such that } \langle q \cup s, C \rangle \Vdash \sigma, \\ 0, & \text{otherwise.} \end{cases}$$

U is a normal ultrafilter, so by the Rowbottom theorem (see [26, 7.17] or [25, 70]) there is an $A \in U$, $A \subseteq B$ homogeneous for h, i.e. for every $n < \omega$ and every $s_1, s_2 \in [A]^n$, $h(s_1) = h(s_2)$. Now $\langle q, A \rangle$ will decide σ. Otherwise, there would be

$$\langle q \cup s_1, B_1 \rangle, \langle q \cup s_2, B_2 \rangle \geq \langle q, A \rangle$$

such that $\langle q \cup s_1, B_1 \rangle \Vdash \sigma$ and $\langle q \cup s_2, B_2 \rangle \Vdash \neg\sigma$. By extending one of these conditions if necessary, we can assume that $|s_1| = |s_2|$. But then $s_1, s_2 \in [A]^{|s_1|}$ and $h(s_1) \neq h(s_2)$, which contradicts the homogeneity of A. $\dashv$

The above lemma allows us to implement the κ-closure of $\langle \mathcal{P}, \leq^* \rangle$ in the actual forcing $\langle \mathcal{P}, \leq \rangle$. Thus we can conclude the following:

1.9 Lemma. *$\langle \mathcal{P}, \leq \rangle$ does not add new bounded subsets of κ.*

Proof. Let $t \in \mathcal{P}$, $\underset{\sim}{a}$ is a name, $\lambda < \kappa$ and

$$t \Vdash \underset{\sim}{a} \subseteq \check{\lambda}.$$

For every $\alpha < \lambda$ denote by σ_α the statement "$\check{\alpha} \in \underset{\sim}{a}$". We define by recursion a $\leq^*$-increasing sequence of conditions $\langle t_\alpha \mid \alpha < \lambda \rangle$ such that $t_\alpha \parallel \sigma_\alpha$ for each $\alpha < \lambda$. Let t_0 be a direct extension of t deciding σ_0; one exists by Lemma 1.8. Suppose that $\langle t_\beta \mid \beta < \alpha \rangle$ is defined. Define t_α. First, using Lemma 1.7 we find a direct extension t'_α of $\langle t_\beta \mid \beta < \alpha \rangle$. Then by Lemma 1.8 choose a direct extension t_α of t'_α deciding σ_α. This completes the definition of $\langle t_\alpha \mid \alpha < \lambda \rangle$. Now let t^* be a direct extension of $\langle t_\alpha \mid \alpha < \lambda \rangle$ (again Lemma 1.7 is used). Then $t^* \geq t$ (in fact $t^* \geq^* t$) and $t^* \Vdash \underset{\sim}{a} = \check{b}$ where $b = \{\alpha < \lambda \mid t^* \Vdash \alpha \in \underset{\sim}{a}\}$. $\dashv$

Let us summarize the situation.

1.10 Theorem. *The following holds in $V[G]$:*

(a) κ has cofinality $\aleph_0$.

(b) All the cardinals are preserved.

(c) No new bounded subsets are added to κ.

Proof. (a) Is established by Lemma 1.4, (c) by Lemma 1.9. Finally, (b) follows from (c) and Lemma 1.5. $\dashv$

If $2^\kappa > \kappa^+$ in V, then in $V[G]$ the Singular Cardinal Hypothesis will fail at κ.

Let $C = \bigcup\{p \mid \exists A(\langle p, A\rangle \in G)\}$. By Lemma 1.4, C is an ω-sequence cofinal in κ. It is called a *Prikry sequence for U*. The generic set G can be easily reconstructed from C:

$$G = \{\langle p, A\rangle \in \mathcal{P} \mid p \text{ is an initial segment of } C \text{ and } C \setminus (\max(p)+1) \subseteq A\}.$$

So, $V[G] = V[C]$.

1.11 Lemma. *C is almost contained in every set in U, i.e.*

$(*)$ *for every $A \in U$ the set $C \setminus A$ is finite.*

Proof. Let $A \in U$. Then the set

$$D = \{\langle p, B\rangle \in \mathcal{P} \mid B \subseteq A\}$$

is dense in $\mathcal{P}$. So, there is a $\langle q, S\rangle \in G \cap D$. But then, for every $\langle q', S'\rangle \geq \langle q, S\rangle$, $q' \setminus q \subseteq S \subseteq A$. Hence, also, $C \setminus q \subseteq A$. $\dashv$

The above implies that C generates U, i.e. $X \in U$ iff $X \in V$ and $C \setminus X$ is finite.

Mathias [38] pointed out that $(*)$ of Lemma 1.11 actually characterizes Prikry sequences:

1.12 Theorem. *Suppose that M is an inner model of* ZFC*, U a normal ultrafilter over κ in M. Assume that C is an ω-sequence satisfying* $(*)$*. Then C is a Prikry sequence for U over M.*

Proof. We need to show that the set

$$\begin{aligned} G(C) = \{\langle p, A\rangle \in \mathcal{P} \mid\ & p \text{ is an initial segment of } C \\ & \text{and } C \setminus (\max(p)+1) \subseteq A\} \end{aligned}$$

is a generic subset of $\mathcal{P}$ over M. The only non-trivial property to check is that $G(C) \cap D \neq \emptyset$ for every dense open subset $D \in M$ of $\mathcal{P}$. Let us first point out that the following holds in M:

1.13 Lemma. *Let $\langle q, B\rangle \in \mathcal{P}$ and $D \subseteq \mathcal{P}$ be dense open. Then there are $\langle q, A\rangle \geq^* \langle q, B\rangle$ and $m < \omega$ such that for every n with $m \leq n < \omega$ and every $s \in [A]^n$, we have $\langle q \cup s, A \setminus (\max(s)+1)\rangle \in D$.*

Proof. We define a partition $h : [B]^{<\omega} \to 2$ as in Lemma 1.8 only replacing "$\Vdash \sigma$" by "$\in D$". Let $A' \in U$, $A' \subseteq B$ be homogeneous for h. Then, starting with some m, for every $n \geq m$ and $s \in [A']^n$ we have $h(s) = 1$. Hence there will be a set $A_s \in U$ such that $\langle q \cup s, A_s\rangle \in D$. Set $A = A' \cap \Delta\{A_s \mid s \in [A']^n, m \leq n < \omega\}$, where

$$\begin{aligned}&\Delta\{A_s \mid s \in [A']^n, m \leq n < \omega\}\\ &\quad = \{\alpha < \kappa \mid \forall n \geq m \forall s \in [A']^n(\max(s) < \alpha \to \alpha \in A_s)\}.\end{aligned}$$

Then clearly $A \in U$. The condition $\langle q, A\rangle$ is as desired, since for each $n \geq m$ and $s \in [A]^n$ we have $A \setminus (\max(s)+1) \subseteq A_s$ and, so $\langle q \cup s,\ A \setminus (\max(s)+1)\rangle \in D$. ⊣

Now, let $D \in M$ be a dense open subset of $\mathcal{P}$. For every finite $q \subseteq \kappa$, using Lemma 1.13, we pick $m(q) < \omega$ and $A(q) \in U$ such that $\langle q, A(q)\rangle \geq^* \langle q, \kappa \setminus (\max(q)+1)\rangle$ and for every $n \geq m(q)$ and $s \in [A(q)]^n$, $\langle q \cup s, A(q) \setminus (\max(s)+1)\rangle \in D$. Set

$$A = \Delta\{A(q) \mid q \in [\kappa]^{<\omega}\} = \{\alpha < \kappa \mid \forall q \in [\kappa]^{<\omega}(\max q < \alpha \to \alpha \in A(q))\}.$$

There is a $\tau < \kappa$ such that $C \setminus \tau \subseteq A$. Consider $\langle C \cap \tau, A \setminus \tau\rangle$. Since $C \cap \tau$ is finite, $\langle C \cap \tau, A \setminus \tau\rangle \in \mathcal{P}$. Then, for every $n \geq \max(C \cap \tau)$ and $s \in [C \setminus \tau]^n$ we have

$$\langle (C \cap \tau) \cup s, A \setminus (\max(s)+1)\rangle \in D,$$

since $A \setminus \tau \subseteq A \setminus (C \cap \tau)$. But $C \setminus \tau \subseteq A$, so we can pick $s \in [C \setminus \tau]^n$ for some $n \geq \max(C \cap \tau)$. Then $(C \cap \tau) \cup s \subseteq C$ and $C \setminus (\max(s)+1) \subseteq A \setminus (\max(s)+1)$. Hence, $\langle (C \cap \tau) \cup s, A \setminus (\max(s)+1)\rangle \in G(C) \cap D$. ⊣

1.2. Tree Prikry Forcing

We would now like to eliminate the use of the normality of the ultrafilter U in the previous construction. Note that it was used only once in the proof of the Prikry condition 1.8.

Let us now assume only that U is a κ-complete ultrafilter over κ.

1.14 Definition. A set T is called a *U-tree with a trunk t* iff

(1) T consists of finite increasing sequences of ordinals below κ.

(2) $\langle T, \trianglelefteq\rangle$ is a tree, where $\trianglelefteq$ is the order of end extension of finite sequences, i.e. $\eta \trianglelefteq \nu$ iff $\nu \restriction \mathrm{dom}(\eta) = \eta$.

(3) t is a trunk of T, i.e. $t \in T$ and for every $\eta \in T$, $\eta \trianglerighteq t$ or $t \trianglerighteq \eta$.

(4) For every $\eta \trianglerighteq t$ the set $\mathrm{Suc}_T(\eta) = \{\alpha < \kappa \mid \eta^\frown\langle\alpha\rangle \in T\}$ is in U.

Define $\mathrm{Lev}_n(T) = \{\eta \in T \mid \mathrm{length}(\eta) = n\}$ for every $n < \omega$.

We now define the *tree Prikry forcing.*

1.15 Definition. The set $\mathcal{P}$ consists of all pairs $\langle t, T\rangle$ such that T is a U-tree with trunk t.

1.16 Definition. Let $\langle t, T\rangle, \langle s, S\rangle \in \mathcal{P}$. We say that $\langle t, T\rangle$ *is stronger than* $\langle s, S\rangle$ and denote this by $\langle t, T\rangle \geq \langle s, S\rangle$ iff $S \supseteq T$.

Note that $S \supseteq T$ implies that $t \trianglerighteq s$ and $t \in S$.

1.17 Definition. Let $\langle t, T\rangle, \langle s, S\rangle \in \mathcal{P}$. We say that $\langle t, T\rangle$ is *a direct (or Prikry) extension of* $\langle s, S\rangle$ and denote this by $\langle t, T\rangle \geq^* \langle s, S\rangle$ iff

(1) $S \supseteq T$, and

(2) $s = t$.

As in the previous section we will force with $\langle \mathcal{P}, \leq\rangle$ and the role of $\leq^*$ will be to provide closure.

1.18 Lemma. *Let $\langle T_\alpha \mid \alpha < \lambda\rangle$ be a sequence of U-trees with the same trunk and $\lambda < \kappa$. Then $T = \bigcap_{\alpha<\lambda} T_\alpha$ is a U-tree having that same trunk.*

Proof. Let t be the trunk of T_0 (and so of every T_α). Suppose that $\eta \in T$ and $\eta \trianglerighteq t$. Then

$$\mathrm{Suc}_T(\eta) = \bigcap\nolimits_{\alpha<\lambda} \mathrm{Suc}_{T_\alpha}(\eta).$$

By κ-completeness of U, $\mathrm{Suc}_T(\eta) \in U$. Hence T is a U-tree with trunk t. ⊣

Using Lemma 1.18 it is easy to prove lemmas analogous to Lemmas 1.4–1.7.

1.19 Lemma. *Let $G \subseteq \mathcal{P}$ be generic for $\langle \mathcal{P}, \leq\rangle$. Then*

$$\bigcup\{t \mid \exists T(\langle t, T\rangle \in G)\}$$

is an ω-sequence cofinal in κ.

1.20 Lemma. *$\langle \mathcal{P}, \leq\rangle$ satisfies the κ^+-c.c.*

1.21 Lemma. *$\leq^* \subseteq \leq$.*

1.22 Lemma. *$\langle \mathcal{P}, \leq^*\rangle$ is κ-closed.*

Let us show that $\langle \mathcal{P}, \leq, \leq^*\rangle$ satisfies the Prikry condition. The proof is based on the following Ramsey property:

If T is a U-tree and $f : T \to \lambda < \kappa$, then there is an U-tree $S \subseteq T$ such that $f\restriction\mathrm{Lev}_n(S)$ is constant for each $n < \omega$.

We prefer here and later to give a direct proof instead of deducing first a relevant Ramsey property and then proving it.

1.23 Lemma (The Prikry condition). *Let $\langle t, T\rangle \in \mathcal{P}$ and σ be a statement of the forcing language. Then there is a $\langle s, S\rangle \geq^* \langle t, T\rangle$ such that $\langle s, S\rangle \parallel \sigma$.*

Proof. Suppose otherwise. Consider the set $\mathrm{Suc}_T(t)$. We split it into three sets as follows:

$$\begin{aligned} X_0 &= \{\alpha \in \mathrm{Suc}_T(t) \mid \exists S_\alpha \subseteq T \text{ a } U\text{-tree with trunk } t^\frown\langle\alpha\rangle \\ &\qquad\qquad \text{such that } \langle t^\frown\langle\alpha\rangle, S_\alpha\rangle \Vdash \sigma\} \\ X_1 &= \{\alpha \in \mathrm{Suc}_T(t) \mid \exists S_\alpha \subseteq T \text{ a } U\text{-tree with trunk } t^\frown\langle\alpha\rangle \\ &\qquad\qquad \text{such that } \langle t^\frown\langle\alpha\rangle, S_\alpha\rangle \Vdash \neg\sigma\} \\ X_2 &= \mathrm{Suc}_T(t) \setminus (X_0 \cup X_1). \end{aligned}$$

Clearly, $X_0 \cap X_1 = \emptyset$, since by Lemma 1.18 any two conditions with the same trunk are compatible. Now U is an ultrafilter and $\mathrm{Suc}_T(t) \in U$, so for some $i < 3$, $X_i \in U$. We shrink T to a tree T_1 with the same trunk t, having $\mathrm{Suc}_{T_1}(t) = X_i$ and: If $i < 2$, then let T_1 be S_α above $t^\frown\langle\alpha\rangle$ for every $\alpha \in X_i$; if $i = 2$, then let T_1 be the same as T above $t^\frown\langle\alpha\rangle$ for every $\alpha \in X_2$. We continue by recursion to shrink the initial tree T level by level. Thus define a decreasing sequence $\langle T_n \mid n < \omega\rangle$ of U-trees with trunk t so that

(1) $T_0 = T$.

(2) For every $n > 0$ and $m > n$, $T_m \restriction (n + |t|) = T_n \restriction (n + |t|)$, i.e. after stage n the n-th level above the trunk remains unchanged in all T_m's for $m \geq n$.

(3) For every $n > 0$, if $i < 2$, $\eta \in \mathrm{Lev}_{n+|t|}(T_n)$ and for some U-tree S with trunk η we have $\langle \eta, S\rangle \Vdash {}^i\sigma$, then

  (3a) $\langle \eta, (T_n)_\eta\rangle \Vdash {}^i\sigma$, and

  (3b) For every $\nu \in \mathrm{Lev}_{n+|t|}(T_n)$ having the same immediate predecessor as η,

$$\langle \nu, (T_n)_\nu\rangle \Vdash {}^i\sigma.$$

Here, ${}^0\sigma$ denotes σ, ${}^1\sigma$ denotes $\neg\sigma$ and for a tree R with $r \in R$,

$$(R)_r = \{r' \in R \mid r' \trianglerighteq r\}.$$

Now we set $T^* = \bigcap_{n<\omega} T_n$. Clearly, T^* is a U-tree with a trunk t by (2) or by Lemma 1.18. Consider $\langle t, T^*\rangle \in \mathcal{P}$. By the assumption, $\langle t, T^*\rangle \nVdash \sigma$. Pick a condition $\langle s, S\rangle \geq \langle t, T^*\rangle$ forcing σ with $n = |s - t|$ as small as possible. Then $s \in \mathrm{Lev}_{n+|t|}(T^*) = \mathrm{Lev}_{n+|t|}(T_n)$. By (3) of the recursive construction,

$$\langle s, (T_n)_s\rangle \Vdash \sigma$$

and for every $s' \in \mathrm{Lev}_{n+|t|}(T_n)$ with the same predecessor as s, $\langle s', (T_n)_{s'}\rangle \Vdash \sigma$. But $T^* \subseteq T_n$, so

$$\langle s, (T^*)_s\rangle \Vdash \sigma \quad \text{and} \quad \langle s', (T^*)_{s'}\rangle \Vdash \sigma$$

for every s' as above.

Let s^* denote the immediate predecessor of s, i.e. s without its last element. Then $\langle s^*, (T^*)_{s^*}\rangle \Vdash \sigma$ since for every $\langle r, R\rangle \geq \langle s^*, (T^*)_{s^*}\rangle$, $r = s'{}^\frown r'$ for some $s' \in \mathrm{Lev}_{n+|t|}(T^*)$ and $s' \rhd s^*$. Hence, $\langle r, R\rangle \geq \langle s', (T^*)_{s'}\rangle \Vdash \sigma$.

But we chose s to be of minimal length such that for some S, $\langle s, S\rangle \Vdash \sigma$, yet $|s^*| = |s| - 1$. Contradiction. ⊣

Now, as in Lemma 1.9 the κ-closure of $\langle \mathcal{P}, \leq^*\rangle$ can be used to derive the following:

1.24 Lemma. *$\langle \mathcal{P}, \leq\rangle$ does not add new bounded subsets of κ.*

The conclusions are the same as those of the previous section.

1.25 Theorem. *The following holds in $V[G]$:*

(a) κ has cofinality $\aleph_0$.

(b) All the cardinals are preserved.

(c) No new bounded subsets are added to κ.

1.3. Adding a Prikry Sequence to a Singular Cardinal

Suppose that κ is a limit of an increasing sequence $\langle \kappa_n \mid n < \omega\rangle$ of measurable cardinals. We want to add an ω-sequence dominating every sequence in $\prod_{n<\omega} \kappa_n$, i.e. a sequence $\langle \tau_m \mid m < \omega\rangle \in \prod_{n<\omega} \kappa_n$ such that for every $\langle \rho_m \mid m < \omega\rangle \in (\prod_{n<\omega} \kappa_n) \cap V$ and for all but finitely many m's, $\tau_m > \rho_m$.

Fix a κ_n-complete ultrafilter U_n over κ_n for every $n < \omega$. One can assume normality but it is not necessary.

Let $n < \omega$. We describe first a very simple forcing for adding a one-element Prikry sequence.

1.26 Definition. Let $Q_n = U_n \cup \kappa_n$. If $p, q \in Q_n$ we define $p \geq_n q$ iff either

(1) $p, q \in U_n$ and $p \subseteq q$,

(2) $q \in U_n$ and $p \in q$, or

(3) $p = q \in \kappa_n$.

Thus we can pick a set in U_n, and then shrink it still in U_n or pick an element of this set. In particular, above every condition there is an atomic one. So, the forcing $\langle Q_n, \leq_n\rangle$ is trivial.

Nevertheless we also define a direct extension ordering:

1.27 Definition. Let $p, q \in Q_n$. Set $p \geq_n^* q$ iff $p = q$, or $p, q \in U_n$ and $p \subseteq q$.

The forcing $\langle Q_n, \leq_n, \leq_n^*\rangle$ is called the *one-element Prikry forcing*. The following lemma follows from the κ_n-completeness of U_n.

1.28 Lemma. *$\langle Q_n, \leq_n^*\rangle$ is κ_n-closed.*

1.29 Lemma. *$\langle Q_n, \leq_n, \leq_n^* \rangle$ satisfies the Prikry condition, i.e. for every $p \in Q_n$ and every statement σ of the forcing language there is a $q \geq_n^* p$ such that $q \parallel \sigma$.*

The proof repeats the first stage of the proof of Lemma 1.23.
We now combine Q_n's together.

1.30 Definition. Let $\mathcal{P}$ be the set of all sequences $p = \langle p_n \mid n < \omega \rangle$ so that

(1) For every $n < \omega$, $p_n \in Q_n$.

(2) There is an $\ell(p) < \omega$ so that for every $n < \ell(p)$, p_n is an ordinal below κ_n and for every $n \geq \ell(p)$, $p_n \in U_n$.

The orderings $\leq$ and $\leq^*$ are defined on $\mathcal{P}$ in obvious fashion:

1.31 Definition. Let $p = \langle p_n \mid n < \omega \rangle$, $q = \langle q_n \mid n < \omega \rangle \in \mathcal{P}$. We say that $p \geq q$ (resp. $p \geq^* q$) iff for every $n < \omega$, $p_n \geq_n q_n$ (resp. $p_n \geq_n^* q_n$).

For $p = \langle p_n \mid n < \omega \rangle \in \mathcal{P}$ we denote $\langle p_m \mid m < n \rangle$ by $p{\restriction}n$ and $\langle p_m \mid m \geq n \rangle$ by $p \setminus n$. Let $\mathcal{P}{\restriction}n = \{p{\restriction}n \mid p \in \mathcal{P}\}$ and $\mathcal{P} \setminus n = \{p \setminus n \mid p \in \mathcal{P}\}$.

The following splitting lemma is obvious:

1.32 Lemma. *$\mathcal{P} \simeq \mathcal{P}{\restriction}n \times \mathcal{P} \setminus n$ for every $n < \omega$.*

1.33 Lemma. *For every $n < \omega$, $\langle \mathcal{P} \setminus n, \leq^* \rangle$ is κ_n-closed.*

The above follows from the fact that each U_m with $m \geq n$ is κ_n-complete.

1.34 Lemma. *$\langle \mathcal{P}, \leq, \leq^* \rangle$ satisfies the Prikry condition.*

Proof. Let $p = \langle p_n \mid n < \omega \rangle$ be an element of $\mathcal{P}$ and σ be a statement of the forcing language. Suppose for simplicity that $\ell(p) = 0$. Then let $p_n = A_n \in U_n$ for every $n < \omega$. We want to find a direct extension of p deciding σ. Assume that there is no such extension. Define by recursion on $n < \omega$ a $\leq^*$-increasing sequence $\langle q(n) \mid n < \omega \rangle$ of $\leq^*$-extensions of p such that for every $n < \omega$ the following holds:

(1) If $m \geq n$, then $q(m){\restriction}n = q(n){\restriction}n$.

(2) If $q = \langle q_n \mid n < \omega \rangle \geq q(n)$ decides σ and $\ell(q) = n+1$ then already $\langle q_m \mid m \leq n \rangle^\frown \langle q(n)_m \mid m > n \rangle$ decides σ and in the same way as q; moreover, for every $\tau_n \in q(n)_n$ also $\langle q_m \mid m < n \rangle^\frown \langle \tau_n \rangle^\frown \langle q(n)_m \mid m > n \rangle$ makes the same decision.

The recursive construction is straightforward. At the nth stage, the κ_n-completeness of the U_m's for $m \geq n$ is used in order to take care of the possibilities for initial sequences of length $n-1$ below κ_n. The number of such possibilities is $|\prod_{i \leq n-1} \kappa_i| = \kappa_{n-1} < \kappa_n$. Now define $s = \langle s_n \mid n < \omega \rangle$ to be $\langle q(n)_n \mid n < \omega \rangle$. Clearly, $s \in \mathcal{P}$ and $s \geq^* p$. The conclusion is now as in Lemma 1.23. Thus let $q = \langle q_n \mid n < \omega \rangle$ be an extension of s forcing σ and with $\ell(q)$ as small as possible. By the assumption, $\ell(q) > 0$. Let $n = \ell(q) - 1$. Now, using (2) of the construction, we conclude that

$$\langle q_m \mid m < n\rangle^\frown\langle \tau_n\rangle^\frown\langle s_m \mid m > n\rangle \Vdash \sigma$$

for every $\tau_n \in q(n)_n = s_n$. But then also $\langle q_m \mid m < n\rangle^\frown\langle s_m \mid m \geq n\rangle \Vdash \sigma$, contradicting the minimality of $\ell(q)$. $\dashv$

Combining Lemmas 1.32, 1.33 and 1.34 we obtain the following:

1.35 Lemma. *$\langle \mathcal{P}, \leq\rangle$ does not add new bounded subsets to κ.*

Note that for each $n < \omega$, $\mathcal{P}\restriction n$ is just a trivial forcing "adding" a sequence of length n of ordinals in $\prod_{m \leq n-1} \kappa_m$.

1.36 Lemma. *$\langle \mathcal{P}, \leq\rangle$ satisfies the κ^+-c.c.*

Proof. Note that any two conditions $p = \langle p_n \mid n < \omega\rangle$ and $q = \langle q_n \mid n < \omega\rangle$ are compatible provided $\ell(p) = \ell(q)$ and $\langle p_n \mid n < \ell(p)\rangle = \langle q_n \mid n < \ell(q)\rangle$. $\dashv$

Now let $G \subseteq \mathcal{P}$ be generic for $\langle \mathcal{P}, \leq\rangle$. Define an ω-sequence $\langle t_n \mid n < \omega\rangle \in \prod_{n<\omega} \kappa_n$ as follows: $t_n = \tau$ if for some $p = \langle p_m \mid m < \omega\rangle \in G$ with $\ell(p) > n$ $p_n = \tau$.

Using density arguments it is easy to show the following:

1.37 Lemma. *For every $\langle s_n \mid n < \omega\rangle \in (\prod_{n<\omega} \kappa_n) \cap V$ there is an $n_0 < \omega$ such that for every $n \geq n_0$, $t_n > s_n$.*

Combining lemmas together we now obtain the following:

1.38 Theorem. *The following holds in $V[G]$:*

(a) All cardinals and cofinalities are preserved.

(b) No new bounded subsets are added to κ.

(c) There is a sequence in $\prod_{n<\omega} \kappa_n$ dominating every sequence in $(\prod_{n<\omega} \kappa_n) \cap V$.

1.4. Supercompact and Strongly Compact Prikry Forcings

In this section, we present Prikry forcings for supercompact and strongly compact cardinals. The main feature of these forcings is that not only κ changes its cofinality to ω, but also every regular cardinal in the interval $[\kappa, \lambda]$ does so, if we use a λ-supercompact (or strongly compact) cardinal κ. The presentation will follow that of Menachem Magidor who was the first to use these forcings in his celebrated papers [35, 36].

Fix cardinals $\kappa \leq \lambda$. Let $\mathcal{P}_\kappa(\lambda) = \{P \subseteq \lambda \mid |P| < \kappa\}$. Let us recall few basic definitions.

1.39 Definition. An ultrafilter U over $\mathcal{P}_\kappa(\lambda)$ is called *normal* iff

(1) U is κ-complete.

(2) U is fine, i.e. for every $\alpha < \lambda$, $\{P \in \mathcal{P}_\kappa(\lambda) \mid \alpha \in P\} \in U$.

(3) For every $A \in U$ and every $f : A \to \lambda$ satisfying $f(P) \in P$ for $P \in A$ there are $A' \in U$ and $\alpha' < \lambda$ such that for every $P \in A'$ we have $f(P) = \alpha'$.

1.40 Definition.

(1) κ is called λ-*strongly compact* iff there exists a κ-complete fine ultrafilter over $\mathcal{P}_\kappa(\lambda)$.

(2) κ is called λ-*supercompact* iff there exists a normal ultrafilter over $\mathcal{P}_\kappa(\lambda)$.

(3) If $P, Q \in \mathcal{P}_\kappa(\lambda)$, then P is *strongly included* in Q iff $P \subseteq Q$ and $\mathrm{otp}(P) < \mathrm{otp}(Q \cap \kappa)$. We denote this by $P \subsetneqq Q$.

Suppose now that κ is λ-supercompact cardinal and U is a normal ultrafilter over $\mathcal{P}_\kappa(\lambda)$. The normality of U easily implies the following:

(a) If F is function from a set in U into $\mathcal{P}_\kappa(\lambda)$ such that for all $P \neq \emptyset$ $F(P) \subsetneqq P$, then F is constant on a set in U.

(b) If for every $Q \in \mathcal{P}_\kappa(\lambda)$, $A_Q \in U$, then $\{P \mid \forall Q \subsetneqq P\ (P \in A_Q)\} \in U$. (This last set is called the *diagonal intersection* of the system $\{A_Q \mid Q \in \mathcal{P}_\kappa(\lambda)\}$.)

For $B \subseteq \mathcal{P}_\kappa(\lambda)$, denote by $[B]^{[n]}$ the set of all n element subsets of B totally ordered by $\subsetneqq$; denote $\bigcup_{n<\omega}[B]^{[n]}$ by $[B]^{[<\omega]}$. The following is a straightforward analog of the Rowbottom theorem:

If $F : [\mathcal{P}_\kappa(\lambda)]^{[<\omega]} \to 2$, then there is an $A \in U$ such that for every $n < \omega$, F is constant on $[A]^{[n]}$.

We are now ready to define the *supercompact Prikry forcing* with a normal ultrafilter U over $\mathcal{P}_\kappa(\lambda)$.

The definitions will be the same as in Definition 1.1 with only κ replaced by $\mathcal{P}_\kappa(\lambda)$ and the order on ordinals replaced by $\subsetneqq$.

1.41 Definition. Let $\mathcal{P}$ be the set of all pairs $\langle\langle P_1, \dots, P_n\rangle, A\rangle$ such that

(1) $\langle P_1, \dots, P_n\rangle$ is a finite $\subsetneqq$-increasing sequence of elements of $\mathcal{P}_\kappa(\lambda)$,

(2) $A \in U$, and

(3) for every $Q \in A$, $P_n \subsetneqq Q$.

1.42 Definition. Let $\langle\langle P_1, \dots, P_n\rangle, A\rangle$, $\langle\langle Q_1, \dots, Q_m\rangle, B\rangle \in \mathcal{P}$. Then define $\langle\langle P_1, \dots, P_n\rangle, A\rangle \geq \langle\langle Q_1, \dots, Q_m\rangle, B\rangle$ iff

(1) $n \geq m$,

(2) for every $k \leq m \quad P_k = Q_k$,

(3) $A \subseteq B$, and

(4) $\{P_{m+1}, \dots, P_n\} \subseteq B$.

1.43 Definition. Let $\langle\langle P_1, \dots, P_n\rangle, A\rangle, \langle\langle Q_1, \dots, Q_m\rangle, B\rangle \in \mathcal{P}$. Then $\langle\langle P_1, \dots, P_n\rangle, A\rangle \geq^* \langle\langle Q, \dots, Q_m\rangle, B\rangle$ iff

(1) $\langle P_1, \dots, P_n\rangle = \langle Q_1, \dots, Q_m\rangle$, and

(2) $A \subseteq B$.

The next lemmas are proved as in Definition 1.1 with obvious changes from κ to $\mathcal{P}_\kappa(\lambda)$.

1.44 Lemma. $\leq^* \subseteq \leq$.

1.45 Lemma. *$\langle \mathcal{P}, \leq^*\rangle$ is κ-closed.*

1.46 Lemma (The Prikry condition). *Let $\langle q, B\rangle \in \mathcal{P}$ and σ be a statement of the forcing language (i.e. of $\langle \mathcal{P}, \leq\rangle$). Then there is a $\langle p, A\rangle \geq^* \langle q, B\rangle$ such that $\langle p, A\rangle \parallel \sigma$.*

1.47 Lemma. *$\langle \mathcal{P}, \leq\rangle$ does not add new bounded subsets to κ.*

1.48 Lemma. *$\langle \mathcal{P}, \leq\rangle$ satisfies the $(\lambda^{<\kappa})^+$-c.c.*

Proof. As in Lemma 1.5, any two conditions with the same finite sequence, i.e. of the form $\langle p, A\rangle$ and $\langle p, B\rangle$ are compatible. The number of possibilities for p's now is $\lambda^{<\kappa}$. So we are done. $\dashv$

By the theorem of Solovay (see [55] or [27]), $\lambda^{<\kappa} = \lambda$ if λ is regular or of cofinality $\geq \kappa$, and $\lambda^{<\kappa} = \lambda^+$ if $\mathrm{cf}(\lambda) < \kappa$. Note that λ-supercompactness of κ actually implies its $\lambda^{<\kappa}$-supercompactness. We can restate Lemma 1.48 using Solovay's theorem as follows:

1.49 Lemma. *$\langle \mathcal{P}, \leq\rangle$ satisfies the μ^+-c.c., where*

$$\mu = \begin{cases} \lambda, & \text{if } \mathrm{cf}(\lambda) \geq \kappa \\ \lambda^+, & \text{if } \mathrm{cf}(\lambda) < \kappa. \end{cases}$$

Our next lemma presents the main property of the supercompact Prikry forcing. Also, it shows that Lemma 1.49 is sharp.

Let G be a generic subset of $\langle \mathcal{P}, \leq\rangle$ and let $\langle P_n \mid 1 \leq n < \omega\rangle$ be the Prikry sequence produced by G, i.e. the sequence such that for every $n < \omega$, there is an $A \in U$ with $\langle\langle P_1, \dots, P_n\rangle, A\rangle \in G$.

1.50 Lemma. *Every $\delta \in [\kappa, \mu]$ of cofinality $\geq \kappa$ (in V) changes its cofinality to ω in $V[G]$, where*

$$\mu = \begin{cases} \lambda, & \text{if } \operatorname{cf}(\lambda) \geq \kappa \\ \lambda^+, & \text{if } \operatorname{cf}(\lambda) < \kappa. \end{cases}$$

Moreover, for each $\delta \leq \lambda$, $\delta = \bigcup_{n<\omega}(P_n \cap \delta)$, i.e. it is a countable union of old sets each of cardinality less than κ.

Proof. Let $\alpha < \lambda$. The fineness of U implies that $\{P \in \mathcal{P}_\kappa(\lambda) \mid \alpha \in P\} \in U$. Then, by a density argument, $\alpha \in P_n$ for all but finitely many n's. Hence, for each $\delta \leq \lambda$

$$\delta = \bigcup_{n<\omega}(P_n \cap \delta).$$

This implies that each $\delta \leq \lambda$ of cofinality $\geq \kappa$ in V changes cofinality to ω in $V[G]$, as witnessed by $\langle \sup(P_n \cap \delta) \mid n < \omega \rangle$. In order to finish the proof, we need to deal with λ of cofinality below κ and to show that in this case λ^+ also changes its cofinality to ω. Fix in V a sequence cofinal in λ of regular cardinals $\langle \lambda_i \mid i < \operatorname{cf}(\lambda) \rangle$, a sequence of functions $\langle f_\alpha \mid \alpha < \lambda^+ \rangle$ in $\prod_{i<\operatorname{cf}(\lambda)} \lambda_i$ and an ultrafilter D over $\operatorname{cf}(\lambda)$ including all cobounded subsets of $\operatorname{cf}(\lambda)$, so that

(a) $\alpha < \beta < \lambda^+ \implies f_\alpha < f_\beta \pmod D$, and

(b) for every $g \in \prod_{i<\operatorname{cf}(\lambda)} \lambda_i$ there is an $i < \lambda^+$ such that $f_i > g \pmod D$.

Using $\lambda^{<\kappa} = \lambda^+$, it is not hard directly by induction to construct such sequence of f_i's. One can also appeal to general pcf considerations; see [1]. Now, by fineness and density again, for every $\alpha < \lambda^+$ and for all but finitely many $n < \omega$ we will have $P_n \supseteq \operatorname{ran}(f_\alpha)$. Hence, for such n's, $\langle \bigcup(P_n \cap \lambda_i) \mid i < \operatorname{cf}(\lambda) \rangle > f_\alpha$. So, $\{\langle \bigcup(P_n \cap \lambda_i) \mid i < \operatorname{cf}(\lambda) \rangle \mid n < \omega\}$ will be an ω-sequence of functions from $(\prod_{i<\operatorname{cf}(\lambda)} \lambda_i) \cap V$ unbounded in $(\prod_{i<\operatorname{cf}(\lambda)} \lambda_i) \cap V$. This implies that λ^+ should have cofinality ω in $V[G]$. ⊣

Let us now turn to *strongly compact Prikry forcing.* So, we give up normality and assume only that U is a κ-complete fine ultrafilter over $\mathcal{P}_\kappa(\lambda)$. The construction here is completely parallel to the construction of the tree Prikry forcing in Definition 1.2.

1.51 Definition. A set T is called a *U-tree with trunk t* iff

(1) T consists of finite sequences $\langle P_1, \ldots, P_n \rangle$ of elements of $\mathcal{P}_\kappa(\lambda)$ so that $P_1 \subsetneqq P_2 \subsetneqq \cdots \subsetneqq P_n$.

(2) $\langle T, \trianglelefteq \rangle$ is a tree, where $\trianglelefteq$ is the order of the end extension of finite sequences.

(3) t is a trunk of T, i.e. $t \in T$ and for every $\eta \in T$, $\eta \trianglerighteq t$ or $t \trianglerighteq \eta$.

(4) For every $\eta \trianglerighteq t$,

$$\mathrm{Suc}_T(\eta) = \{Q \in \mathcal{P}_\kappa(\lambda) \mid \eta^\frown\langle Q\rangle \in T\} \in U.$$

The definitions of the forcing notion $\mathcal{P}$ and the orders $\leq$ and $\leq^*$ are now exactly the same as those in Definitions 1.15, 1.16 and 1.17. $\langle \mathcal{P}, \leq, \leq^*\rangle$ here shares all the properties of the tree Prikry forcing of Sect. 1.2 except the κ^+-c.c. Thus the Lemmas 1.18, 1.21–1.24 are valid in the present context with basically the same proofs. Instead of the κ^+-c.c. we will have here the $(\lambda^{<\kappa})^+$-c.c. Also Lemmas 1.48–1.50 hold with the same proofs.

Let us summarize the properties of both supercompact and strongly compact Prikry forcings.

1.52 Theorem. *Let G be a generic set for $\langle \mathcal{P}, \leq, \leq^*\rangle$, where $\langle \mathcal{P}, \leq, \leq^*\rangle$ is either supercompact or strongly compact Prikry forcing over $\mathcal{P}_\kappa(\lambda)$. The following holds in $V[G]$:*

(a) No new bounded subsets are added to κ.

(b) Every cardinal in the interval $[\kappa, \mu]$ of cofinality $\geq \kappa$ (as computed in V) changes its cofinality to ω.

(c) All the cardinals above μ are preserved, where

$$\mu = \begin{cases} \lambda, & \text{if } \mathrm{cf}(\lambda) \geq \kappa \\ \lambda^+, & \text{if } \mathrm{cf}(\lambda) < \kappa. \end{cases}$$

2. Adding Many Prikry Sequences to a Singular Cardinal

In this section we present the extender-based Prikry forcing over a singular cardinal. It is probably the simplest direct way for violating the Singular Cardinal Hypothesis using minimal large cardinal hypotheses. This type of forcing first appeared in [20] in a more complicated form. The presentation here follows [17, Sect. 3].

Let, as in Definition 1.3, $\kappa = \bigcup_{n<\omega} \kappa_n$ with $\langle \kappa_n \mid n < \omega\rangle$ increasing and each κ_n measurable. The Prikry forcing described in Definition 1.3 produces basically one Prikry sequence. More precisely, if GCH holds in the ground model, then κ^+-many new ω-sequences are introduced but all of them are coded by the generic Prikry sequence. Here we present a way for adding any number of Prikry sequences into $\prod_{n<\omega} \kappa_n$. In particular, this will increase the power of κ as large as one likes without adding new bounded subsets and preserving all the cofinalities.

The basic idea is to use many ultrafilters over each of the κ_n's instead of a single one as in Definition 1.3. This leads naturally to extenders over the κ_n's. For the basics about extenders and corresponding large cardinal hypotheses, which are significantly weaker than λ-supercompactness of Lemma 1.4, see the fine structure and inner model chapters of this Handbook.

Assume GCH and let $\lambda \geq \kappa^+$ be a regular cardinal. Suppose that we want to add to κ or into $\prod_{n<\omega} \kappa_n$ at least λ many Prikry sequences. Our basic assumption will now be that each κ_n is a $(\lambda+1)$-strong cardinal. This means that for every $n < \omega$ there is a $(\kappa_n, \lambda+1)$-extender E_n over κ_n whose ultrapower contains $V_{\lambda+1}$ and which moves κ_n above λ. We fix such E_n and let $j_n : V \to M_n \simeq \mathrm{Ult}(V, E_n)$. For every $\alpha < \lambda$ we define a κ_n-complete ultrafilter $U_{n\alpha}$ over κ_n by setting $X \in U_{n\alpha}$ iff $\alpha \in j_n(X)$. Actually only $U_{n\alpha}$'s with $\alpha \geq \kappa_n$ will be important. Note that a lot of $U_{n\alpha}$'s are comparable in the Rudin-Keisler order $\leq_{\mathrm{RK}}$, recalling that

$$\begin{aligned} U \leq_{\mathrm{RK}} W \quad \text{iff} \quad & \exists f : \bigcup W \to \bigcup U \ \forall X \subseteq \bigcup U \\ & (X \in U \leftrightarrow f^{-1}(X) \in W). \end{aligned}$$

Thus for example, if α is a cardinal and $\beta \leq \alpha$, then $U_{n(\alpha+\beta)} \geq_{\mathrm{RK}} U_{n,\alpha}$ and $U_{n(\alpha+\beta)} \geq_{\mathrm{RK}} \ U_{n,\beta}$.

We will need a strengthening of the Rudin-Keisler order. For $\alpha, \beta < \lambda$ define

$$\begin{aligned} \alpha \leq_{E_n} \beta \quad \text{iff} \quad & \alpha \leq \beta \text{ and} \\ & \text{for some } f \in {}^{\kappa_n}\kappa_n,\ j_n(f)(\beta) = \alpha. \end{aligned}$$

Clearly, then $\alpha \leq_{E_n} \beta$ implies $U_{n\alpha} \leq_{\mathrm{RK}} U_{n\beta}$, as witnessed by any $f \in {}^{\kappa_n}\kappa_n$ with $j_n(f)(\beta) = \alpha$: If $A \in U_{n\beta}$, then $\beta \in j_n(A)$. So $\alpha = j_n(f)(\beta) \in j_n(f)``j_n(A) = j_n(f``A)$. Hence $f``A \in U_{n,\alpha}$. Note that, in general, $\alpha < \beta < \lambda$ and $U_{n\alpha} <_{\mathrm{RK}} U_{n\beta}$ does not imply $\alpha <_{E_n} \beta$.

The partial order $\langle \lambda, \leq_{E_n} \rangle$ is κ_n-directed, as we see in Lemma 2.1 below. Actually, it is κ_n^{++}-directed, but for our purposes κ_n-directness will suffice. Thus, using GCH, find some enumeration $\langle a_\alpha \mid \alpha < \kappa_n \rangle$ of $[\kappa_n]^{<\kappa_n}$ so that for every regular cardinal $\delta < \kappa_n$, $\langle a_\alpha \mid \alpha < \delta \rangle$ enumerates $[\delta]^{<\delta}$ and every element of $[\delta]^{<\delta}$ appears δ many times in the enumeration. Let $j_n(\langle a_\alpha \mid \alpha < \kappa_n \rangle) = \langle a_\alpha \mid \alpha < j_n(\kappa_n) \rangle$. Then, $\langle a_\alpha \mid \alpha < \lambda \rangle$ will enumerate $[\lambda]^{<\lambda} \supseteq [\lambda]^{<\kappa_n}$ in both M_n and V; this coding will be applied below.

The next lemma is a basic application of commutativity of diagrams corresponding to extenders and their ultrafilters.

2.1 Lemma. *Let $n < \omega$ and $\tau < \kappa_n$. Suppose that $\langle \alpha_\nu \mid \nu < \tau \rangle$ is a sequence of ordinals below λ and $\alpha \in \lambda \setminus (\bigcup_{\nu<\tau} \alpha_\nu + 1)$ codes this sequence, i.e. $a_\alpha = \{\alpha_\nu \mid \nu < \tau\}$. Then $\alpha >_{E_n} \alpha_\nu$ for every $\nu < \tau$.*

Proof. Fix $\nu < \tau$. Consider the following diagram

$$\begin{tikzcd}
& M_n \\
V \arrow[ur, "j_n"] \arrow[r, "i_\alpha"] \arrow[dr, "i_{\alpha_\nu}"'] & N_\alpha \arrow[u, "k_\alpha"'] \\
& N_{\alpha_\nu} \arrow[uu, bend right=60, "k_{\alpha_\nu}"']
\end{tikzcd}$$

where $N_\alpha \simeq \mathrm{Ult}(V, U_{n,\alpha})$, $k_\alpha([f]_{U_{n,\alpha}}) = j_n(f)(\alpha)$ and the same with α_ν replacing α. Then $j_n(\langle a_\beta \mid \beta < \kappa_n\rangle) = k_\alpha(i_\alpha(\langle a_\beta \mid \beta < \kappa_n\rangle))$ and $k_\alpha(i_\alpha(\langle a_\beta \mid \beta < \kappa_n\rangle)([\mathrm{id}])_{U_{n,\alpha}})) = j_n(\langle a_\beta \mid \beta < \kappa_n\rangle)(\alpha) = a_\alpha = \{\alpha_\mu \mid \mu < \tau\}$. But $\tau < \kappa_n$, so it is fixed by k_α, since $\mathrm{crit}(k_\alpha) \geq \kappa_n$. Hence $i_\alpha(\langle a_\beta \mid \beta < \kappa_n\rangle)([\mathrm{id}]_{U_{n,\alpha}})$ is a sequence of ordinals of length τ. Let α^*_ν denote its ν-th element. Then, by elementarity, $k_\alpha(\alpha^*_\nu) = \alpha_\nu$. We can hence define $k_{\alpha_\nu \alpha} : N_{\alpha_\nu} \longrightarrow N_\alpha$ by setting $k_{\alpha_\nu\alpha}([f]_{U_{\alpha_\nu}}) = i_\alpha(f)(\alpha^*_\nu)$. It is easy to see that $k_{\alpha_\nu\alpha}$ is elementary embedding and the following diagram is commutative.

$$\begin{tikzcd}
& M_n \\
V \arrow[ur, "j_n"] \arrow[r, "i_\alpha"] \arrow[dr, "i_{\alpha_\nu}"'] & N_\alpha \arrow[u, "k_\alpha"'] \\
& N_{\alpha_\nu} \arrow[u, "k_{\alpha_\nu\alpha}"'] \arrow[uu, bend right=60, "k_{\alpha_\nu}"']
\end{tikzcd}$$

Finally, we can define the desired projection $\pi_{\alpha\alpha_\nu}$ of $U_{n,\alpha}$ onto U_{n,α_ν}. Thus let $\pi_{\alpha\alpha_\nu} : \kappa_n \to \kappa_n$ be a function such that $[\pi_{\alpha\alpha_\nu}]_{U_{n,\alpha}} = \alpha^*_\nu$. Then, $j_n(\pi_{\alpha\alpha_\nu})(\alpha) = k_\alpha\ ([\pi_{\alpha,\alpha_\nu}]_{U_{n,\alpha}}) = k_\alpha(\alpha^*_\nu) = \alpha_\nu$. So, $\alpha >_{E_n} \alpha_\nu$. ⊣

Hence we obtain the following:

2.2 Lemma. *For every set $a \subseteq \lambda$ of cardinality less than κ_n, there are λ many α's below λ so that $\alpha >_{E_n} \beta$ for every $\beta \in a$.*

For every $\alpha, \beta < \lambda$ such that $\alpha >_{E_n} \beta$ we fix the projection $\pi_{\alpha\beta} : \kappa_n \to \kappa_n$ defined as in Lemma 2.1 witnessing this. Let $\pi_{\alpha\alpha} = \mathrm{id}$, the identity map: $\kappa_n \to \kappa_n$.

The following two lemmas are standard.

2.3 Lemma. *Let $\gamma < \beta \leq \alpha < \lambda$. If $\alpha \geq_{E_n} \beta$ and $\alpha \geq_{E_n} \gamma$, then $\{\nu < \kappa_n \mid \pi_{\alpha\beta}(\nu) > \pi_{\alpha\gamma}(\nu)\} \in U_{n\alpha}$.*

Proof. We consider the following commutative diagram

$$
\begin{tikzcd}
 & M_n \\
V \arrow[ur, "j_n"] \arrow[r, "i_\alpha"] \arrow[dr, "i_\beta"] \arrow[ddr, "i_\gamma"] & N_\alpha \arrow[u, "k_\alpha"'] \\
 & N_\beta \arrow[u, "k_{\beta\alpha}"'] \arrow[uu, bend right, "k_\beta"'] \\
 & N_\gamma \arrow[uu, bend right, "k_{\gamma\alpha}"'] \arrow[uuu, bend right=60, "k_\gamma"']
\end{tikzcd}
$$

where for $\delta', \delta \in \{\alpha, \beta, \gamma\}$

$$i_\delta : V \longrightarrow N_\delta \simeq \mathrm{Ult}(V, U_{n\delta})$$

$$k_\delta([f]_{U_{n\delta}}) = j_n(f)(\delta)$$

and

$$k_{\delta'\delta}([f]_{U_{n\delta'}}) = i_\delta(f)([\pi_{\delta\delta'}]_{U_{n\delta}}).$$

Then $k_\alpha([\pi_{\alpha\beta}]_{U_{n\alpha}}) = k_\alpha(k_{\beta\alpha}([\mathrm{id}]_{U_{n\beta}})) = k_\beta([\mathrm{id}]_{U_{n\beta}}) = j_n(\mathrm{id})(\beta) = \beta$. The same is true for γ, i.e.

$$k_\alpha([\pi_{\alpha\gamma}]_{U_{n\alpha}}) = \gamma.$$

But $M_n \vDash \gamma < \beta$ and k_α is elementary, so $N_\alpha \vDash [\pi_{\alpha\gamma}]_{U_{n\alpha}} < [\pi_{\alpha\beta}]_{U_{n\alpha}}$. Hence

$$\{\nu < \kappa_n \mid \pi_{\alpha\beta}(\nu) > \pi_{\alpha\gamma}(\nu)\} \in U_{n\alpha}.$$

$\dashv$

2.4 Lemma. *Let $\{\alpha_i \mid i < \tau\} \subseteq \alpha < \lambda$ for some $\tau < \kappa_n$. Assume that $\alpha \geq_{E_n} \alpha_i$ for every $i < \tau$. Then there is a set $A \in U_{n\alpha}$ so that for every $i, j < \tau$: $\alpha_i \geq_{E_n} \alpha_j$ implies $\pi_{\alpha\alpha j}(\nu) = \pi_{\alpha_i\alpha_j}(\pi_{\alpha\alpha_i}(\nu))$ for every $\nu \in A$.*

Proof. It is enough to prove the lemma for $\tau = 2$ and then to use the κ_n-completeness of $U_{n\alpha}$. So, let $\beta, \gamma < \alpha$ and assume that $\gamma \leq_{E_n} \beta \leq_{E_n} \alpha$.

Consider the following commutative diagram:

$$\begin{tikzcd}
 & M_n \\
 & N_\alpha \arrow[u, "k_\alpha"'] \\
V \arrow[uur, "j_n"] \arrow[ur, "i_\alpha"] \arrow[dr, "i_\beta"'] \arrow[ddr, "i_\gamma"'] & \\
 & N_\beta \arrow[uu, "k_{\beta\alpha}"'] \arrow[uuu, bend right, "k_\beta"'] \\
 & N_\gamma \arrow[u, "k_{\gamma\beta}"'] \arrow[uuu, bend right, "k_{\gamma\alpha}"'] \arrow[uuuu, bend right=60, "k_\gamma"']
\end{tikzcd}$$

where k's and i's are defined as in Lemma 2.3.

We need to show that

$$[\pi_{\alpha\gamma}]_{U_{n\alpha}} = [\pi_{\beta\gamma} \circ \pi_{\alpha\beta}]_{U_{n\alpha}}.$$

As in Lemma 2.3, $k_\alpha([\pi_{\alpha\gamma}]_{U_{n\alpha}}) = \gamma$. On the other hand, again as Lemma 2.3,

$$\begin{aligned} k_\alpha([\pi_{\beta\gamma} \circ \pi_{\alpha\beta}]_{U_{n\alpha}}) &= j_n(\pi_{\beta\gamma} \circ \pi_{\alpha\beta})(\alpha) = j_n(\pi_{\beta\gamma})(j_n(\pi_{\alpha\beta})(\alpha)) \\ &= j_n(\pi_{\beta\gamma})(\beta) = \gamma. \end{aligned}$$

Since k_α is elementary, we have in N_α the desired equality. ⊣

We are now ready to define our first forcing notion. It will resemble the one-element Prikry forcing considered in Definition 1.3 and will be built from two pieces. Fix $n < \omega$.

2.5 Definition. Let $Q_{n1} = \{f \mid f$ is a partial function from λ to κ_n of cardinality at most $\kappa\}$. We order Q_{n1} by inclusion, which here is denoted by $\leq_1$.

Thus Q_{n1} is basically the usual Cohen forcing for blowing up the power of κ^+ to λ. The only, and minor, change is that the functions take values inside κ_n rather than 2 or κ^+.

2.6 Definition. Let Q_{n0} be the set of triples $\langle a, A, f\rangle$ so that

(1) $f \in Q_{n1}$.

(2) $a \subseteq \lambda$ with

(2a) $|a| < \kappa_n$,

(2b) $a \cap \mathrm{dom}(f) = \emptyset$, and

(2c) a has a $\leq_{E_n}$-maximal element, i.e. an element $\alpha \in a$ such that $\alpha \geq_{E_n} \beta$ for every $\beta \in a$.

(3) $A \in U_{n\,\max(a)}$.

(4) For every $\alpha, \beta, \gamma \in a$, if $\alpha \geq_{E_n} \beta \geq_{E_n} \gamma$, then $\pi_{\alpha\gamma}(\rho) = \pi_{\beta\gamma}(\pi_{\alpha\beta}(\rho))$ for every $\rho \in \pi_{\max(a),\alpha}$"$A$.

(5) For every $\alpha > \beta$ in a and every $\nu \in A$,

$$\pi_{\max(a),\alpha}(\nu) > \pi_{\max(a),\beta}(\nu).$$

The last two conditions can be met by Lemmas 2.3, 2.4.

2.7 Definition. Let $\langle a, A, f\rangle$, $\langle b, B, g\rangle \in Q_{n0}$. We say that $\langle a, A, f\rangle$ *is stronger than* $\langle b, B, g\rangle$ and denote this by $\langle a, A, f\rangle \geq_0 \langle b, B, g\rangle$ iff

(1) $f \supseteq g$,

(2) $a \supseteq b$, and

(3) $\pi_{\max(a),\max(b)}$"$A \subseteq B$.

We now define a forcing notion Q_n which is an extender analog of the one-element Prikry forcing of Definition 1.3.

2.8 Definition. $Q_n = Q_{n0} \cup Q_{n1}$.

2.9 Definition. The direct extension ordering $\leq^*$ on Q_n is defined to be $\leq_0 \cup \leq_1$.

2.10 Definition. Let $p, q \in Q_n$. Then $p \leq q$ iff either

(1) $p \leq^* q$, or

(2) $p = \langle a, A, f\rangle \in Q_{n0}$, $q \in Q_{n1}$ and the following holds:

(2a) $q \supseteq f$,

(2b) $\mathrm{dom}(q) \supseteq a$,

(2c) $q(\max(a)) \in A$, and

(2d) for every $\beta \in a$, $q(\beta) = \pi_{\max(a),\beta}(q(\max(a)))$.

Clearly, the forcing $\langle Q_n, \leq\rangle$ is equivalent to $\langle Q_{n1}, \leq_1\rangle$, i.e. Cohen forcing. However, the following basic facts relate it to the Prikry-type forcing notion.

2.11 Lemma. *$\langle Q_n, \leq^*\rangle$ is κ_n-closed.*

2.12 Lemma. *$\langle Q_n, \leq, \leq^*\rangle$ satisfies the Prikry condition, i.e. for every $p \in Q_n$ and every statement σ of the forcing language there is a $q \geq^* p$ deciding σ.*

Proof. Let $p = \langle a, A, f\rangle$. Suppose otherwise. By recursion on $\nu \in A$ define an increasing sequence $\langle p_\nu \mid \nu \in A\rangle$ of elements of Q_{n1} with $\mathrm{dom}(p_\nu) \cap a = \emptyset$ as follows. Suppose that $\langle p_\rho \mid \rho \in A \cap \nu\rangle$ is defined and $\nu \in A$. Define p_ν as follows: Let $u = \bigcup_{\rho<\nu} p_\rho$. Then $u \in Q_{n1}$. Consider $q = \langle a, A, u\rangle$. Let $q^\frown\langle\nu\rangle = u \cup \{\langle \beta, \pi_{\max(a),\beta}(\nu)\rangle \mid \beta \in a\}$. If there is a $p \geq_1 q^\frown\langle\nu\rangle$ deciding σ, then let p_ν be some such p restricted to $\lambda \setminus a$. Otherwise, set $p_\nu = u$. Note that there will always be a condition deciding σ.

Finally, let $g = \bigcup_{\nu\in A} p_\nu$. Shrink A to a set $B \in U_{n\max(a)}$ so that $p_\nu{}^\frown\langle\nu\rangle = p_\nu \cup \{\langle\beta, \pi_{\max(a),\beta}(\nu)\rangle \mid \beta \in a\}$ decides σ the same way or does not decide σ at all, for every $\nu \in B$. By our assumption $\langle a, B, g\rangle \not\parallel \sigma$. However, pick some $h \geq \langle a, B, g\rangle$, $h \in Q_{n1}$ deciding on σ. Let $h(\max(a)) = \nu$. Then, $p_\nu{}^\frown\langle\nu\rangle$ decides σ. But this holds then for every $\nu \in B$. Hence, already $\langle a, B, g\rangle$ decides σ. Contradiction. $\dashv$

Let us now define the main forcing of this section by putting the blocks of Q_n's together. This forcing is called the *extender-based Prikry forcing* over a singular cardinal.

2.13 Definition. The set $\mathcal{P}$ consists of sequences $p = \langle p_n \mid n < \omega\rangle$ so that

(1) For every $n < \omega$, $p_n \in Q_n$.

(2) There is an $\ell(p) < \omega$ so that for every $n < \ell(p)$, $p_n \in Q_{n1}$, and for every $n \geq \ell(p)$, $p_n = \langle a_n, A_n, f_n\rangle \in Q_{n0}$ and $a_n \subseteq a_{n+1}$.

2.14 Definition. Let $p = \langle p_n \mid n < \omega\rangle$ and $q = \langle q_n \mid n < \omega\rangle \in \mathcal{P}$. We set $p \geq q$ (resp. $p \geq^* q$) iff for every $n < \omega$, $p_n \geq_{Q_n} q_n$ (resp. $p_n \geq^*_{Q_n} q_n$).

The forcing $\langle\mathcal{P}, \leq\rangle$ does not satisfy the κ^+-c.c. However:

2.15 Lemma. *$\langle\mathcal{P}, \leq\rangle$ satisfies the κ^{++}-c.c.*

Proof. Let $\{p(\alpha) \mid \alpha < \kappa^{++}\}$ be a set of elements of $\mathcal{P}$, with $p(\alpha) = \langle p(\alpha)_n \mid n < \omega\rangle$ and $p(\alpha)_n = \langle a(\alpha)_n, A(\alpha)_n, f(\alpha)_n\rangle$ for $n \geq \ell(p(\alpha))$. There is an $S \subseteq \kappa^{++}$ stationary such that for every $\alpha, \beta \in S$ the following holds:

(a) $\ell(p(\alpha)) = \ell(p(\beta)) = \ell$.

(b) For every $n < \ell$, $\{\mathrm{dom}(p(\alpha)_n) \mid \alpha \in S\}$ forms a Δ-system with $p(\alpha)_n$ and $p(\beta)_n$ having the same values on its kernel.

(c) For every $n \geq \ell$, $\{(a(\alpha)_n \cup \mathrm{dom}(f(\alpha)_n) \mid \alpha \in S\}$ forms a Δ-system with $f(\alpha)_n$, $f(\beta)_n$ having the same values on the kernel. Also, if $\alpha, \beta \in S$ then $a(\alpha)_n \cap \mathrm{dom}(f(\beta)_n) = \emptyset$.

Now let $\alpha < \beta$ be in S. We construct a condition $q = \langle q_n \mid n < \omega\rangle$ stronger than both $p(\alpha)$ and $p(\beta)$.

For every $n < \ell$ let $q_n = p(\alpha)_n \cup p(\beta)_n$. Now suppose that $n \geq \ell$. q_n will be of the form $\langle b_n, B_n, g_n\rangle$. Set $g_n = f(\alpha)_n \cup f(\beta)_n$. We would like to define

b_n as the union of $a(\alpha)_n$ and $a(\beta)_n$. But Definition 2.6(2(iii)) requires the existence of a maximal element in the $\leq_{E_n}$ order which need not be the case in the simple union of $a(\alpha)_n$ and $a(\beta)_n$. It is easy to fix this. Just pick some $\rho < \lambda$ above $a(\alpha)_n \cup a(\beta)_n$ in the $\leq_{E_n}$ order. Also let $\rho > \sup(\mathrm{dom}(f(\alpha)_n)) + \sup(\mathrm{dom}\ (f(\beta))_n)$. Lemma 2.2 insures that there are such ρ's. Now we set $b_n = a(\alpha)_n \cup a(\beta)_n \cup \{\rho\}$. Let $B'_n = \pi^{-1}_{\rho\alpha^*}(A(\alpha)_n) \cap \pi^{-1}_{\rho\beta^*}(A(\beta)_n)$, where $\alpha^* = \max(a(\alpha)_n)$ and $\beta^* = \max(a(\beta)_n)$. Finally we shrink B'_n to a set $B_n \in U_{n\rho}$ satisfying Definition 2.6((4), (5)). This is possible by Lemmas 2.3, 2.4. ⊣

For $p = \langle p_n \mid n < \omega\rangle \in \mathcal{P}$ set $p{\restriction}n = \langle p_m \mid m < n\rangle$ and $p \backslash n = \langle p_m \mid m \geq n\rangle$. Let $\mathcal{P}{\restriction}n = \{p{\restriction}n \mid p \in \mathcal{P}\}$ and $\mathcal{P} \setminus n = \{p \setminus n \mid p \in \mathcal{P}\}$. Then the following lemmas are obvious:

2.16 Lemma. *$\mathcal{P} \simeq \mathcal{P}{\restriction}n \times \mathcal{P} \setminus n$ for every $n < \omega$.*

2.17 Lemma. *$\langle \mathcal{P} \setminus n, \leq^*\rangle$ is κ_n-closed. Moreover, if $\langle p^\alpha \mid \alpha < \delta < \kappa\rangle$ is a $\leq^*$ increasing sequence with $\kappa_{\ell(p_0)} > \delta$, then there is a $p \geq^* p^\alpha$ for every $\alpha < \delta$.*

We will now turn to the Prikry condition and establish a more general statement which will allow us to deduce in addition that κ^+ is preserved after forcing with $\langle \mathcal{P}, \leq\rangle$.

Let us introduce first some notation. For $p = \langle p_n \mid n < \omega\rangle \in \mathcal{P}$ and m with $\ell(p) \leq m < \omega$, let $p_m = \langle a_m, A_m, f_m\rangle$. Denote a_m by $a_m(p)$, A_m by $A_m(p)$ and f_m by $f_m(p)$. Let $\langle \nu_{\ell(p)}, \dots, \nu_m\rangle \in \prod_{k=\ell(p)}^m A_k(p)$. We denote by

$$p^\frown\langle \nu_{\ell(p)}, \dots, \nu_m\rangle$$

the condition obtained from p by adding the sequence $\langle \nu_{\ell(p)}, \dots, \nu_m\rangle$, i.e. a condition $q = \langle q_n \mid n < \omega\rangle$ such that $q_n = p_n$ for every n, $n < \ell(p)$ or $n > m$, and if $\ell(p) \leq n \leq m$ then $q_n = f_n(p) \cup \{\langle \beta, \pi_{\max(a_n(p)),\beta}(\nu_n)\rangle \mid \beta \in a_n(p)\}$.

We prove the following analog of Lemma 1.13:

2.18 Lemma. *Let $p \in \mathcal{P}$ and D be a dense open subset of $\langle \mathcal{P}, \leq\rangle$ above p. Then there are $p^* \geq^* p$ and $n^* < \omega$ such that for every $\langle \nu_0, \dots, \nu_{n^*-1}\rangle \in \prod_{m=\ell(p)}^{\ell(p)+n^*-1} A_m(p^*)$, $p^{*\frown}\langle \nu_0, \dots, \nu_{n^*-1}\rangle \in D$.*

Let us first deduce the Prikry condition from this lemma.

2.19 Lemma. *Let $p \in \mathcal{P}$ and σ be a statement of the forcing language. Then there is a $p^* \geq^* p$ deciding σ.*

Proof of Lemma 2.19 from Lemma 2.18. Consider $D = \{q \in \mathcal{P} \mid q \geq p$ and $q \parallel \sigma\}$. Clearly, D is dense open above p. Apply Lemma 2.18 to this D and choose n^* as small as possible and $p^* \geq^* p$ such that for every $q \geq p^*$ with $\ell(q) \geq n^*$, $q \in D$. If $n^* = \ell(p)$, then we are done. Suppose otherwise.

Assume for simplicity that $\ell(p) = 0$ and $n^* = 2$. Then let $p^* = \langle p_n^* \mid n < \omega\rangle$ and for every $n < \omega$ let $p_n^* = \langle a_n^*, A_n^*, f_n^*\rangle$. Let $\alpha_0 = \max(a_0^*)$ and $\alpha_1 = \max(a_1^*)$. Then $A_0^* \in U_{0\alpha_0}$ and $A_1^* \in U_{1\alpha_1}$. Let $\nu_0 \in A_0^*$ and $\nu_1 \in A_1^*$. Consider $p^{*\frown}\langle \nu_0, \nu_1\rangle$ the condition obtained from p^* by adding ν_0 and ν_1. Clearly, $\ell(p^{*\frown}\langle \nu_0, \nu_1\rangle) = 2$. Hence it decides σ. Now we shrink A_1^* to $A_{1\nu_0}^*$ so that for every $\nu_1', \nu_1'' \in A_{1\nu_0}^*$ $p^{*\frown}\langle \nu_0, \nu_1'\rangle$ and $p^{*\frown}\langle \nu_0, \nu_1''\rangle$ decide σ the same way. Let $A_1^{**} = \bigcap\{A_{1\nu_0}^* \mid \nu_0 \in A_0^*\}$. We shrink now A_0^* to A_0^{**} so that for every $\nu_0', \nu_0'' \in A_0^{**}$ and for every $\nu_1 \in A_1^{**}$, $p^{*\frown}\langle \nu_0', \nu_1\rangle$ and $p^{*\frown}\langle \nu_0'', \nu_1\rangle$ decide σ in the same way. Let p^{**} be a condition obtained from p^* by replacing in it A_0^* by A_0^{**} and A_1^* by A_1^{**}. Then $p^{**} \geq^* p^*$ and $p^{**} \parallel \sigma$. Contradiction.

Proof of Lemma 2.18. The main objective is to reduce the problem to the point where we can use the argument of the corresponding fact in Sect. 1.3, as if we were forcing using $\langle U_{n\max(a_n)} \mid n < \omega\rangle$.

We first prove the following crucial claim:

Claim. *There is a $p' \geq^* p$, $p' = \langle p_n' \mid n < \omega\rangle$, such that for every $q \geq p'$, $q = \langle q_n \mid n < \omega\rangle$, if $q \in D$, then also*

$$\langle p_n' \mid n < \ell(p)\rangle^\frown\langle q_n\restriction a_n(p') \cup f_n(p') \mid \ell(p') \leq n < \ell(q)\rangle^\frown\langle p_n' \mid n \geq \ell(q)\rangle \in D,$$

where $p_n' = \langle a_n(p'), A_n(p'), f_n(p')\rangle$ for $n \geq \ell(p)$.

Proof of Claim. Choose a function $h : \kappa \leftrightarrow [\kappa]^{<\omega}$, such that for every $n < \omega$, $h\restriction\kappa_n : \kappa_n \leftrightarrow [\kappa_n]^{<\omega}$. Now define by recursion a $\leq^*$-increasing sequence $\langle p^\alpha \mid \alpha < \kappa\rangle$ of direct extensions of p, where $p^\alpha = \langle p_n^\alpha \mid n < \omega\rangle$ and, for $n \geq \ell(p)$, $p_n^\alpha = \langle a_n^\alpha, A_n^\alpha, f_n^\alpha\rangle$. Set $p^0 = p$. Suppose that $\alpha < \kappa$ and $\langle p^\beta \mid \beta < \alpha\rangle$ has been defined. As a recursive assumption we assume the following:

$$(*) \qquad \begin{array}{l}\text{For every } n < \omega \text{ and for } \beta, \gamma, \kappa_n \leq \beta, \gamma < \kappa,\\ \text{if } \ell(p) \leq m \leq n+1, \text{then } a_m^\beta = a_m^\gamma \text{ and } A_m^\beta = A_m^\gamma.\end{array}$$

Let $\tilde{p}^\alpha$ be $p^{\alpha-1}$ if α is successor ordinal, and a direct extension of $\langle p^\beta \mid \beta < \alpha\rangle$ satisfying $(*)$ if α is a limit ordinal. Note that if $n < \omega$ is the maximal such that $\alpha \geq \kappa_n$ then Lemma 2.17 applies, since the parts of p^β's below κ_{n+1} satisfy $(*)$. Now we consider $h(\alpha)$. Let $h(\alpha) = \langle \nu_1, \dots, \nu_k\rangle$. If $\langle \nu_0, \dots, \nu_{k-1}\rangle \notin \prod_{m=\ell(p)}^{\ell(p)+k-1} A_m(\tilde{p}^\alpha)$, then we set $p^\alpha = \tilde{p}^\alpha$, where for $m \geq \ell(p)$, $\tilde{p}_m^\alpha = \langle a_m(\tilde{p}^\alpha), A_m(\tilde{p}^\alpha), f_m(\tilde{p}^\alpha)\rangle$. If not, we consider $q = \tilde{p}^{\alpha\frown}\langle \nu_0, \dots, \nu_{k-1}\rangle$. If there is no direct extension of q inside D, then let $p^\alpha = \tilde{p}^\alpha$. Otherwise, let $s = \langle s_n \mid n < \omega\rangle \geq^* q$ be in D. Define $p^\alpha = \langle p_n^\alpha \mid n < \omega\rangle$ then as follows:

(a) For each n with $n \geq \ell(p) + k$ or $n < \ell(p)$, let $p_n^\alpha = s_n$, and

(b) For each n with $\ell(p) \leq n \leq \ell(p) + k - 1$, $a_n(p^\alpha) = a_n(\tilde{p}^\alpha)$, $A_n(p^\alpha) = A_n(\tilde{p}^\alpha)$, and $f_n(p^\alpha) = f_n(s)\restriction((\mathrm{dom}(f_n(s)) \setminus a_n(\tilde{p}^\alpha))$.

The meaning of this last part of the definition is that we extend for n with $\ell(p) \le n \le \ell(p)+k-1$ only $f_n(\tilde{p}^\alpha)$ and only outside of $a_n(\tilde{p}^\alpha)$. Clearly such defined p^α satisfies $(*)$.

Finally, $(*)$ allows us to put all the $\langle p^\alpha \mid \alpha < \kappa\rangle$ together. Thus we define $p' = \langle p'_n \mid n < \omega\rangle$ as follows:

(i) For $n < \ell(p)$, let $p'_n = \bigcup_{\alpha<\kappa} p^\alpha_n$.

(ii) For $n \ge \ell(p)$, let $f_n(p') = \bigcup_{\alpha<\kappa} f_n(p^\alpha)$, $a_n(p') = a_n(p^{\kappa_n})$, and $A_n(p') = A_n(p^{\kappa_n})$.

Obviously $p' \in \mathcal{P}$ and $p' \ge^* p$. This p' is as desired. Thus, if $q \ge p'$ is in D, then we consider $\alpha = h^{-1}(\langle q_n(\max(a_n(p'))) \mid \ell(p) \le n < \ell(q)\rangle)$. By the construction of $p^\alpha \le^* p'$, $p^{\alpha\frown}\langle q_n(\max(a_n(p'))) \mid \ell(p) \le n < \ell(q)\rangle$ will be in D. Then also $p'^\frown\langle q_n(\max(a_n(p')) \mid \ell(p) \le n < \ell(q)\rangle \in D$, since D is open.

This concludes the proof of the claim.

Now let $p' \ge^* p$ be given by the claim. Assume for simplicity that $\ell(p) = 0$. We would like to shrink the sets $A_n(p')$ in a certain way. Thus define $p(1) \ge^* p'$ such that:

$(*)_1$ For every $m < \omega$ and $\langle \nu_0, \ldots, \nu_{m-1}\rangle \in \prod_{n=0}^{m-1} A_n(p(1))$, if for some $\nu \in A_m(p(1))$, $p(1)^\frown\langle \nu_0, \ldots, \nu_{m-1}, \nu\rangle \in D$, then for every $\nu' \in A_m(p(1))$ $p(1)^\frown\langle \nu_0, \ldots, \nu_{m-1}, \nu'\rangle \in D$.

Let $m < \omega$ and $\vec{\nu} = \langle \nu_0, \ldots, \nu_{m-1}\rangle \in \prod_{n=0}^{m-1} A_n(p')$, where in case of $m = 0$, $\vec{\nu}$ is the empty sequence. Consider the set

$$X_{m,\vec{\nu}} = \{\nu \in A_m(p') \mid p'^\frown\langle \nu_0, \ldots, \nu_{m-1}, \nu\rangle \in D\}.$$

Define $A_{m\vec{\nu}}$ to be $X_{m,\vec{\nu}}$, if $X_{m\vec{\nu}} \in U_{m,\max(a_m(p'))}$ and $A_m(p') \setminus X_{m,\vec{\nu}}$, otherwise. Let $A_m = \bigcap\{A_{m,\vec{\nu}} \mid \vec{\nu} \in \prod_{n=0}^{m-1} A_n(p')\}$. Define now $p(1) = \langle p(1)_n \mid n < \omega\rangle$ as follows: for each $n < \omega$ let $p(1)_n = \langle a_n(p'), A_n, f(p')\rangle$. Clearly, such defined $p(1)$ satisfies $(*)_1$.

Then, in a similar fashion we chose $p(2) \ge^* p(1)$ satisfying:

$(*)_2$ For every $m < \omega$ and $\langle \nu_0, \ldots, \nu_{m-1}\rangle \in \prod_{n=0}^{m-1} A_n(p(2))$, if for some $\langle \nu_m, \nu_{m+1}\rangle \in A_m(p(2)) \times A_{m+1}(p(2))$,

$$p(2)^\frown\langle \nu_0, \ldots, \nu_{m-1}\rangle^\frown\langle \nu_m, \nu_{m+1}\rangle \in D,$$

then for every $\langle \nu'_m, \nu'_{m+1}\rangle \in A_m(p(2)) \times A_{m+1}(p(2))$,

$$p(2)^\frown\langle \nu_0, \ldots, \nu_{m-1}\rangle^\frown\langle \nu'_m, \nu'_{m+1}\rangle \in D.$$

Continue and define for every k with $2 \le k < \omega$ a $p(k) \ge^* p(k-1)$ satisfying $(*)_k$, where $(*)_k$ is defined analogously for k-sequences. Finally, let p^* be a direct extension of $\langle p(k) \mid 1 \le k < \omega\rangle$. Let $s \ge p^*$ be in D. Set

$n^* = \ell(s)$. Consider $\langle s_0(\max(a_0(p^*))), \ldots, s_{n^*-1}(\max(a_{n^*-1}(p^*)))\rangle$. Then the choice of p', $p' \leq^* p^*$ and openness of D imply that

$$p^{*\frown}\langle s_0(\max(a_0(p^*)), \ldots, s_{n^*-1}(\max(a_{n^*-1}(p^*)))\rangle \in D.$$

But $p^* \geq^* p(n^*)$. So, p^* satisfies $(*)_{n^*}$. It follows that for $\langle \nu_0, \ldots, \nu_{n^*-1}\rangle \in \prod_{m=0}^{n^*-1} A_m(p^*)$, $p^{*\frown}\langle \nu_0, \ldots, \nu_{n^*-1}\rangle \in D$. ⊣

Combining these lemmas we obtain the following:

2.20 Proposition. *The forcing $\langle \mathcal{P}, \leq\rangle$ does not add new bounded subsets to κ and preserves all the cardinals above κ^+.*

Actually, it is not hard now to show that κ^+ is preserved as well.

2.21 Lemma. *Forcing with $\langle \mathcal{P}, \leq\rangle$ preserves κ^+.*

Proof. Suppose that $(\kappa^+)^V$ is not a cardinal in a generic extension $V[G]$. Recall that $\mathrm{cf}(\kappa) = \aleph_0$ and by Proposition 2.20 it is preserved. So, $\mathrm{cf}((\kappa^+)^V) < \kappa$ in $V[G]$. Pick $p \in G$, $\delta < \kappa$ and a name $\underset{\sim}{g}$ so that $\kappa_{\ell(p)} > \delta$ and

$$p \Vdash (\underset{\sim}{g} : \check{\delta} \to (\kappa^+)^V \text{ and } \mathrm{ran}(\underset{\sim}{g}) \text{ is unbounded in } (\kappa^+)^V).$$

For every $\tau < \delta$ let

$$D_\tau = \{q \in \mathcal{P} \mid q \geq p \text{ and for some } \alpha < \kappa^+,\ q \Vdash \underset{\sim}{g}(\check{\tau}) = \check{\alpha}\}.$$

Define by recursion, using Lemma 2.17, a $\leq^*$-increasing sequence $\langle p^\tau \mid \tau < \delta\rangle$ of $\leq^*$-extensions of p so that p^τ satisfies the conclusion 2.18 with $D = D_\tau$. By Lemma 2.17, there is a $p^\delta \geq^* p^\tau$ for each $\tau < \delta$.

Now let $\tau < \delta$. By the choice of p^τ there is an $n(\tau) < \omega$ such that for every $\langle \nu_0, \ldots, \nu_{n(\tau)-1}\rangle \in \prod_{m=\ell(p)}^{\ell(p)+n(\tau)-1} A_m(p^\delta)$, $p^{\delta\frown}\langle \nu_0, \ldots, \nu_{n(\tau)-1}\rangle \in D_\tau$. This means that for some $\alpha(\nu_0, \ldots, \nu_{n(\tau)-1}) < \kappa^+$

$$p^{\delta\frown}\langle \nu_0, \ldots, \nu_{n(\tau)-1}\rangle \Vdash \underset{\sim}{g}(\check{\tau}) = \check{\alpha}(\nu_0, \ldots, \nu_{n(\tau)-1}).$$

Set

$$\alpha(\tau) = \sup\Big\{\alpha(\nu_0, \ldots, \nu_{n(\tau)-1}) \mid \langle \nu_0, \ldots, \nu_{n(\tau)-1}\rangle \in \prod_{m=\ell(p)}^{\ell(p)+n(\tau)-1} A_m(p^\delta)\Big\}.$$

Then clearly $\alpha(\tau) < \kappa^+$ and

$$p^\delta \Vdash \underset{\sim}{g}(\check{\tau}) < \check{\alpha}(\tau).$$

Now let $\alpha^* = \bigcup_{\tau<\delta} \alpha(\tau)$. Then again $\alpha^* < \kappa^+$ and

$$p^\delta \Vdash \forall \tau < \check{\delta}(\underset{\sim}{g}(\tau) < \check{\alpha}^*).$$

But this is impossible since $p \leq^* p^\delta$ forced that the range of g was unbounded in κ^+. Contradiction. ⊣

Finally, let us show that this forcing adds λ ω-sequences to κ. Thus, let $G \subseteq \mathcal{P}$ be generic. For every $n < \omega$ define a function $F_n : \lambda \to \kappa_n$ as follows:

$$F_n(\alpha) = \nu \quad \text{if for some } p = \langle p_m \mid m < \omega \rangle \in G \text{ with } \ell(p) > n,\ p_n(\alpha) = \nu.$$

Now for every $\alpha < \lambda$ set $t_\alpha = \langle F_n(\alpha) \mid n < \omega \rangle$. Let us show that the set $\{t_\alpha \mid \alpha < \lambda\}$ has cardinality λ. Notice that we cannot claim that all such sequences are new or even distinct due to the Cohen parts of conditions, i.e. the f_n's.

2.22 Lemma. *For every $\beta < \lambda$ there is an α with $\beta < \alpha < \lambda$ such that t_α dominates every t_γ with $\gamma \leq \beta$.*

Proof. Suppose otherwise. Then there is a $p = \langle p_n \mid n < \omega \rangle \in G$ and $\beta < \lambda$ such that

$$p \Vdash \forall \alpha(\beta < \alpha < \lambda \to \exists \gamma \leq \beta\ (\underset{\sim}{t_\alpha} \text{ does not dominate } \underset{\sim}{t_\gamma})).$$

For every $n \geq \ell(p)$ let $p_n = \langle a_n, A_n, f_n \rangle$. Pick some

$$\alpha \in \lambda \setminus \big(\bigcup_{n<\omega} a_n \cup \bigcup \mathrm{dom}(f_n) \cup (\beta + 1)\big).$$

We extend p to a condition q so that $q \geq^* p$ and for every $n \geq \ell(q) = \ell(p)$, $\alpha \in b_n$, where $q_n = \langle b_n, B_n, g_n \rangle$. Then q will force that t_α dominates every t_γ with $\gamma < \alpha$. This leads to the contradiction. Thus, let $\gamma < \alpha$ and assume that q belongs to the generic subset of $\mathcal{P}$. Then either $t_\gamma \in V$ or it is a new ω-sequence. If $t_\gamma \in V$ then it is dominated by t_α by the usual density arguments. If t_γ is new, then for some $r \geq q$ in the generic set $\gamma \in c_n$ for every $n \geq \ell(r)$, where $r_n = \langle c_n, C_n, h_n \rangle$. But also $\alpha \in c_n$ since $c_n \supseteq b_n$. This implies $F_n(\alpha) > F_n(\gamma)$ (by Definition 2.6(5)) and we are done. ⊣

We now have the following conclusion.

2.23 Theorem. *The following holds in $V[G]$:*

(a) All cardinals and cofinalities are preserved.

(b) No new bounded subsets are added to κ; in particular, GCH *holds below κ.*

(c) There are λ new ω-sequences in $\prod_{n<\omega} \kappa_n$. In particular, $2^\kappa \geq \lambda$.

2.24 Remark. The initial large cardinal assumptions used here are not optimal. We refer to Mitchell's chapter [41] on the Covering Lemma for matters of the consistency strength. In the next section another extender-based Prikry forcing requiring much weaker extenders will be introduced.

It is tempting to extend Lemma 2.22 and claim that $\langle t_\alpha \mid \alpha < \lambda$ and $t_\alpha \notin V \rangle$ is a scale in $\prod_{n<\omega} \kappa_n$, i.e. for every $t \in \prod_{n<\omega} \kappa_n$ there is an $\alpha < \lambda$ such $t_\alpha \notin V$ and t_α dominates t. Unfortunately this is not true in general.

We need to replace $\prod_{n<\omega}\kappa_n$ by the product of a sequence $\langle\lambda_n \mid n<\omega\rangle$ related to λ (basically the Prikry sequence for $U_{n\lambda}$ whenever it is defined). Assaf Sharon [50] made a full analysis of possible cofinalities structure for a similar forcing (the one that will be discussed in the next section). Let us now deal with a special case that cannot be covered by such forcing. Let us assume that for every $n<\omega$, $j_n(\kappa_n)=\lambda$, where $j_n: V\to M_n \simeq \mathrm{Ult}(V,E_n)$ is the canonical embedding. In particular, each κ_n is a superstrong cardinal. Then the following holds.

2.25 Lemma. *Let $t\in\prod_{n<\omega}\kappa_n$ in $V[G]$. Then there is an $\alpha<\lambda$ such that $t_\alpha\notin V$ and for all but finitely many $n<\omega$, $t_\alpha(n)>t(n)$.*

Proof. Let $\underset{\sim}{t}$ be a name of t. Pick $p\in G$ forcing "$\underset{\sim}{t}\in\prod_{n<\omega}\check{\kappa}_n$". Define for every $n<\omega$ a set dense open above p:

$$D_n=\{q\in\mathcal{P}\mid q\geq p \text{ and there is a } \nu_n<\kappa_n \text{ such that } q\Vdash \underset{\sim}{t}(n)=\check{\nu}_n\}.$$

Apply Lemma 2.18 to each of D_n's and construct a $\leq^*$-sequence $\langle p(k)\mid k<\omega\rangle$ of direct extensions of p such that $p(k)$ and D_k satisfy the conclusion of Lemma 2.18. Let p^* be a common direct extension of $p(k)$'s. Then for every k, $1\leq k<\omega$, there is an $n(k)<\omega$ such that for every $\langle\nu_0,\dots,\nu_{n(k)-1}\rangle\in\prod_{m=\ell(p)}^{\ell(p)+n(k)-1}A_m(p^*)$,

$$p^{*\frown}\langle\nu_0,\dots,\nu_{n(k)-1}\rangle\Vdash\underset{\sim}{t}(k-1)=\check{\xi}(\nu_0,\dots,\nu_{n(k)-1})$$

for some $\xi(\nu_0,\dots,\nu_{n(k)-1})<\kappa_{k-1}$. Assume for simplicity of notation that $\ell(p)=0$. Let $1\leq k<\omega$. We can assume that $\xi(\nu_0,\dots,\nu_{n(k)-1})$, defined above, depends really only on $\nu_0,\dots,\nu_{k-1}$, since its values are below κ_{k-1} and ultrafilters over κ_m's are κ_k-complete for $m\geq k$. Also assume that for every $m>0$ $A_m(p^*)\cap\kappa_{m-1}=\emptyset$. Now, we replace ξ by a bigger function η depending only on ν_{k-1}. Thus set

$$\eta(\nu_{k-1})=\bigcup\bigl\{\xi(\nu_0,\dots,\nu_{k-2},\nu_{k-1})\mid\langle\nu_0,\dots,\nu_{k-2}\rangle\in\textstyle\prod_{m=0}^{k-2}A_m(p^*)\bigr\}+\nu_{k-1}.$$

Clearly, $\eta(\nu_{k-1})<\kappa_{k-1}$. So,

$$p^{*\frown}\langle\nu_0,\dots,\nu_{k-1}\rangle\Vdash\underset{\sim}{t}(k-1)<\check{\eta}(\nu_{k-1})$$

for every k, $1\leq k<\omega$ and every $\langle\nu_0,\dots,\nu_{k-1}\rangle\in\prod_{m=0}^{k-1}A_m(p^*)$. For every $n<\omega$ let $\eta_n: A_n(p^*)\to\kappa_n$ be the restriction of η to κ_n. Let $\alpha_n=\max(a_n(p^*))$. Consider $j_n(\eta_n)(\alpha_n)$ where $j_n: V\to M_n$ is the embedding of the extender E_n. Then $j_n(\eta_n)(\alpha_n)<j_n(\kappa_n)=\lambda$. Choose some α below λ and above $\bigcup_{n<\omega}j_n(\eta_n)(\alpha_n)\cup(\mathrm{dom}(f_n(p^*)))$. Now extend p^* to a condition p^{**} such that $p^{**}\geq^* p^*$ and for every $n<\omega$ $\alpha\in a_n(p^{**})$. Then,

$$p^{**}\Vdash\forall n(\underset{\sim}{t_\alpha}(n)>\eta_n((\underset{\sim}{t_{\alpha_n}}(n))>\underset{\sim}{t}(n)).$$

So we are done. ⊣

The extender-based forcing described in this section can also be used with much stronger extenders than those used here. Thus with minor changes we can deal with E_n's such that $j_n(\kappa_n) < \lambda$ but requiring $j_n(\kappa_{n+1}) > \lambda$. Once $j_n(\kappa_{n+1}) \leq \lambda$ for infinitely many n's, the arguments like the one in the proof of the Prikry condition seem to break down completely.

Another probably more exciting direction is to use shorter extenders instead of long ones. Thus it turned out that for λ's below $\kappa^{+\omega_1}$ an extender of length κ_n^{+n} over κ_n for $n < \omega$ suffices. The basic idea is to replace in $p \in \mathcal{P}$ the subset $a_n(p)$ of λ by an order preserving function from λ to κ_n^{+n}. Such defined forcing fails to satisfy κ^{++}-c.c. and actually will collapse λ to κ^+. But using increasing with n similarity of ultrafilters involved in the extenders, it turns out that there is a subforcing satisfying the κ^{++}-c.c. and still producing λ new sequences in $\prod_{n<\omega} \kappa_n$. This approach was implemented in [17] for calculating the consistency strength of various instances of the failure of the Singular Cardinal Hypothesis and, as well, for constructing more complicated cardinal arithmetic configurations.

3. Extender-Based Prikry Forcing with a Single Extender

In this section we present a simplified version of the original extender-based Prikry forcing of [19, Sect. 1]. Our aim is simultaneously to change the cofinality of a regular cardinal to $\aleph_0$ and blow up its power. Recall that the Prikry forcing of Definitions 1.1 and 1.2 does the first part, i.e. change cofinality. As in the previous section, we would like to use an extender instead of a single ultrafilter in order to blow up the power.

Let κ, λ be regular cardinals with $\lambda \geq \kappa^{++}$. Assume that κ is $V_{\kappa+\delta}$-strong for a δ so that $\kappa^{+\delta} = \lambda$. Let E be an extender over κ witnessing this and $j : V \longrightarrow M \simeq \mathrm{Ult}(V, E)$ with $M \supseteq V_{\kappa+\delta}$ be the corresponding elementary embedding. Suppose also that there is a function $f_\lambda : \kappa \to \kappa$ such that $j(f_\lambda)(\kappa) = \lambda$. Notice that such a function always exists for small λ's like $\lambda = \kappa^{++}$, $\lambda = \kappa^{+116}$, $\lambda = \kappa^{+\kappa+1}$ etc., just take mappings $\alpha \to \alpha^{++}$, $\alpha \to \alpha^{+116}$, $\alpha \to \alpha^{+\alpha+1}$. In general, assuming $j(\kappa) > \lambda$, it is not hard to force such f_λ. The idea is to force for every inaccessible $\alpha \leq \kappa$ a generic function from α to α and then to extend the embedding specifying to κ the value λ under the generic function from $j(\kappa)$ to $j(\kappa)$ in M.

If κ is a strong cardinal then for every $\lambda > \kappa$ there is a (κ, λ)-extender E and a function $f : \kappa \to \kappa$ so that $j_E(f)(\kappa) = \lambda$, where $j_E : V \to M \simeq \mathrm{Ult}(V, E)$. The Solovay argument [56], originally used for a supercompact κ, works without change for a strong cardinal κ: Let κ be a strong cardinal and suppose that for some $\lambda > \kappa$ for every (κ, λ)-extender E and every function $f : \kappa \to \kappa$ we have $j_E(f)(\kappa) \neq \lambda$. Let λ be the least such ordinal. Pick a $(\kappa, 2^{2^\lambda})$-extender E^*. Let $j : V \to M \simeq \mathrm{Ult}(V, E^*)$. Then, in M, λ will be the least such that for every (κ, λ)-extender E and every function $f : \kappa \to \kappa$,

$j_E(f)(\kappa) \neq \lambda$, since $M \supseteq V_{2^{2^\lambda}}$. Now define a function $g : \kappa \to \kappa$ as follows: $g(\alpha) =$ the least $\beta > \alpha$ such that for every (α, β)-extender E and every function $f : \alpha \to \alpha$, $j_E(f)(\alpha) \neq \beta$, if there is such a β and let $g(\alpha) = 0$ otherwise. Then, clearly, $j(g)(\kappa) = \lambda$. But then $E^* \restriction \lambda$ and g provide the contradiction.

Suppose for simplicity that V satisfies GCH. Then we will have ${}^{\kappa^+}V_{\kappa+\delta} \subseteq M$. For every $\alpha < \lambda$ define a κ-complete ultrafilter U_α over κ by setting $X \in U_\alpha$ iff $\alpha \in j(X)$. Notice that U_κ will be normal and each U_α with $\alpha < \kappa$ will be trivial; we shall ignore such U_α and refer to U_κ as the least one. As in Sect. 2, we define a partial ordering $\leq_E$ on λ:

$$\alpha \leq_E \beta \quad \text{iff} \quad \alpha \leq \beta \text{ and for some } f \in^\kappa \kappa,\ j(f)(\beta) = \alpha.$$

Again, clearly, $\alpha \leq_E \beta$ implies that $U_\alpha \leq_{\mathrm{RK}} U_\beta$ as witnessed by any $f \in {}^\kappa\kappa$ with $j(f)(\beta) = \alpha$. In the previous section only the κ directedness (more precisely, κ_n directedness for every $n < \omega$) of the ordering was used. Here we will need more—κ^{++}-directedness. Thus, as in Sect. 2, fix an enumeration $\langle a_\alpha \mid \alpha < \kappa \rangle$ of $[\kappa]^{<\kappa}$ so that for every regular cardinal $\mu < \kappa$, $\langle a_\alpha \mid \alpha < \mu \rangle$ enumerates $[\mu]^{<\mu}$ and every element of $[\mu]^{<\mu}$ appears μ many times in the enumeration. Let $j(\langle a_\alpha \mid \alpha < \kappa \rangle) = \langle a_\alpha \mid \alpha < j(\kappa) \rangle$. Then, $\langle a_\alpha \mid \alpha < \lambda \rangle$ will enumerate $[\lambda]^{<\lambda} \supseteq [\lambda]^{<\kappa^{++}}$. For each $\alpha < \lambda$ we consider the following basic commutative diagram:

$$\begin{tikzcd} & M \\ V \arrow[ur, "j"] \arrow[dr, "i_\alpha"'] & \\ & N_\alpha \arrow[uu, "k_\alpha"'] \end{tikzcd}$$

where $i_\alpha : V \longrightarrow N_\alpha \simeq \mathrm{Ult}(V, U_\alpha)$ and $k_\alpha([f]_{U_\alpha}) = j(f)(\alpha)$.

3.1 Lemma. $\mathrm{crit}(k_\alpha) = (\kappa^{++})^{N_\alpha}$.

Proof. It is enough to show that $k_\alpha(\kappa) = \kappa$, since $k_\alpha((\kappa^+)^{N_\alpha}) = \kappa^+$ and $k_\alpha((\kappa^{++})^{N_\alpha}) = \kappa^{++}$ by elementarity. But ${}^\kappa N_\alpha \subseteq N_\alpha$. Hence $(\kappa^+)^{N_\alpha} = \kappa^+$. By $2^\kappa = \kappa^+$, $(\kappa^{++})^{N_\alpha} < \kappa^{++}$. So $(\kappa^{++})^{N_\alpha}$ is the first ordinal moved by k_α.

In order to show that κ is fixed let us use the function $f_\lambda : \kappa \to \kappa$ representing λ in M. Thus by commutativity, $k_\alpha(i_\alpha(f_\lambda)) = j(f_\lambda)$. Clearly, $i_\alpha(f_\lambda) : i_\alpha(\kappa) \to i_\alpha(\kappa)$ and $i_\alpha(f_\lambda) \restriction \kappa = f_\lambda$. Hence

$$N_\alpha \vDash \forall \tau < \kappa\ (i_\alpha(f_\lambda)(\tau) < \kappa).$$

Using k_α we obtain that

$$M \vDash \forall \tau < k_\alpha(\kappa)\ (j(f_\lambda)(\tau) < k_\alpha(\kappa)).$$

But $k_\alpha(\kappa) \le k_\alpha([\mathrm{id}]_{U_\alpha}) = \alpha < \lambda$. Hence,

$$M \vDash \forall \tau < k_\alpha(\kappa)\ (j(f_\lambda)(\tau) < \lambda).$$

But $k_\alpha(\kappa) \ge \kappa$ and $j(f_\lambda)(\kappa) = \lambda$. So, $k_\alpha(\kappa)$ must be equal to κ and we are done. $\dashv$

The following is a consequence of the previous lemma.

3.2 Lemma. *For every α with $\kappa \le \alpha < \lambda$, $\alpha \ge_E \kappa$.*

Proof. By Lemma 3.1, $k_\alpha(\kappa) = \kappa$. So, $k_\alpha([g]_{U_\alpha}) = \kappa$ for $g : \kappa \to \kappa$ representing κ in N_α. Then g projects U_α on U_κ and $j(g)(\alpha) = k_\alpha([g]_{U_\alpha}) = \kappa$. $\dashv$

We can now improve Lemma 2.1 to κ^{++}-directedness.

3.3 Lemma. *Let $\langle \alpha_\nu \mid \nu < \kappa^+ \rangle$ be a sequence of ordinals below λ. Suppose that $\alpha \in \lambda \setminus (\bigcup_{\nu < \kappa^+} \alpha_\nu + 1)$ codes $\{\alpha_\nu \mid \nu < \kappa^+\}$, i.e. $a_\alpha = \{\alpha_\nu \mid \nu < \kappa^+\}$. Then $\alpha >_E \alpha_\nu$ for every $\nu < \kappa^+$.*

Proof. Let $\nu < \kappa^+$. Consider the following commutative diagram:

$$\begin{tikzcd}
 & M \\
V \arrow[ur, "j"] \arrow[r, "i_\alpha"] \arrow[dr, "i_{\alpha_\nu}"'] & N_\alpha \arrow[u, "k_\alpha"'] \\
 & N_{\alpha_\nu} \arrow[uu, bend right, "k_{\alpha_\nu}"']
\end{tikzcd}$$

Then $j(\langle a_\beta \mid \beta < \kappa \rangle) = k_\alpha(i_\alpha(\langle a_\beta \mid \beta < \kappa \rangle))$. Let $\alpha^* = [\mathrm{id}]_{U_\alpha}$. Then $k_\alpha(\alpha^*) = \alpha$. So, $a_\alpha = k_\alpha(a^*_{\alpha^*})$, where $a^*_{\alpha^*} = i_\alpha(\langle a_\beta \mid \beta < \kappa \rangle)(\alpha^*)$. But $a_\alpha = \{\alpha_{\nu'} \mid \nu' < \kappa^+\}$ and, by Lemma 3.1, $k_\alpha(\kappa^+) = \kappa^+$. So, $a^*_{\alpha^*} = \{\alpha^*_{\nu'} \mid \nu' < \kappa^+\}$, where $k_\alpha(\alpha^*_{\nu'}) = \alpha_{\nu'}$. Now we can define an elementary embedding $k_{\alpha_\nu \alpha} : N_{\alpha_\nu} \longrightarrow N_\alpha$. Set

$$k_{\alpha_\nu \alpha}([f]_{U_{\alpha_\nu}}) = i_\alpha(f)(\alpha^*_\nu).$$

Finally, every function representing α^*_ν in N_α will be a projection of U_α onto U_{α_ν} and witness $\alpha_\nu <_E \alpha$. $\dashv$

For $\beta \le_E \alpha < \lambda$ we fix a projection $\pi_{\alpha\beta} : \kappa \to \kappa$ defined as in Lemma 3.3. Let $\pi_{\alpha\alpha} = \mathrm{id}$. The following two lemmas were actually proved in the previous section (Lemmas 2.3 and 2.4).

3.4 Lemma. *Let $\gamma < \beta \leq \alpha < \lambda$. If $\alpha \geq_E \beta$ and $\alpha \geq_E \gamma$, then $\{\nu < \kappa \mid \pi_{\alpha\beta}(\nu) > \pi_{\alpha\gamma}(\nu)\} \in U_\alpha$.*

3.5 Lemma. *Let $\alpha, \beta, \gamma < \lambda$ be so that $\alpha \geq_E \beta \geq_E \gamma$. Then there is an $A \in U_\alpha$ so that for every $\nu \in A$*

$$\pi_{\alpha\gamma}(\nu) = \pi_{\beta\gamma}(\pi_{\alpha\beta}(\nu)).$$

Consider the following set:

$$\begin{aligned}\overline{X} = \{\nu < \kappa \mid \exists \nu^* \leq \nu(&\nu^* \text{ is inaccessible}, \\ &f_\lambda \restriction \nu^* : \nu^* \longrightarrow \nu^*, \text{ and } f_\lambda(\nu^*) > \nu)\}.\end{aligned}$$

Clearly $\overline{X} \in U_\alpha$ for every $\alpha < \lambda$ (ignoring α's below κ). Also the function $g : \overline{X} \to \kappa$ defined by $g(\nu) =$ the maximal inaccessible $\nu^* \leq \nu$ closed under f_λ and with $f_\lambda(\nu^*) > \nu$, projects each U_α onto U_κ. Let us change each $\pi_{\alpha\kappa}$ to g on $\overline{X}$ and for $\nu \in \kappa \setminus \overline{X}$ let $\pi_{\alpha\kappa}(\nu) = 0$. Also change $\pi_{\alpha\beta}$'s a little for $\alpha, \beta > \kappa$. Thus for $\nu \in \kappa \setminus \overline{X}$ let $\pi_{\alpha\beta}(\nu) = 0$. If $\nu \in \overline{X}$ and $\pi_{\alpha\beta}(\nu)$ is below $\pi_{\alpha\kappa}(\nu)$ then change $\pi_{\alpha\beta}(\nu)$ to ν or any ordinal between $\pi_{\alpha\kappa}(\nu)$ and ν. Note that these changes are on a small set since $\kappa \setminus \overline{X} \notin U_\alpha$ for any $\alpha < \lambda$. Hence the changed $\pi_{\alpha\beta}$'s are still projections. The following summarizes the main properties of the U_α's and $\pi_{\alpha\beta}$'s:

(1) $\langle \lambda, \leq_E \rangle$ is a κ^{++}-directed partial ordering.

(2) $\langle U_\alpha \mid \alpha < \lambda \rangle$ is a Rudin-Keisler commutative sequence of κ-complete ultrafilters over κ with projections $\langle \pi_{\alpha\beta} \mid \beta \leq \alpha < \lambda, \alpha \geq_E \beta \rangle$.

(3) For every $\alpha < \lambda$, $\pi_{\alpha\alpha}$ is the identity on a fixed set $\overline{X}$ which belongs to every U_β for $\beta < \lambda$.

(4) (Commutativity) For every $\alpha, \beta, \gamma < \lambda$ such that $\alpha \geq_E \beta \geq_E \gamma$, there is a $Y \in U_\alpha$ so that for every $\nu \in Y$

$$\pi_{\alpha\gamma}(\nu) = \pi_{\beta\gamma}(\pi_{\alpha\beta}(\nu)).$$

(5) For every $\alpha < \beta$, $\gamma < \lambda$, if $\gamma \geq_E \alpha, \beta$ then

$$\{\nu < \kappa \mid \pi_{\gamma\alpha}(\nu) < \pi_{\gamma\beta}(\nu)\} \in U_\gamma.$$

(6) U_κ is a normal ultrafilter.

(7) $\kappa \leq_E \alpha$ when $\kappa \leq \alpha < \lambda$.

(8) (Full commutativity at κ) For every $\alpha, \beta < \lambda$ and $\nu < \kappa$, if $\alpha \geq_E \beta$ then $\pi_{\alpha\kappa}(\nu) = \pi_{\beta\kappa}(\pi_{\alpha\beta}(\nu))$.

(9) (Independence of the choice of projection to κ) For every $\alpha, \beta, \kappa \leq \alpha$, $\beta < \lambda$, and $\nu < \kappa$

$$\pi_{\alpha\kappa}(\nu) = \pi_{\beta\kappa}(\nu).$$

(10) Each U_α is a P-point ultrafilter, i.e. for every $f \in {}^\kappa\kappa$, if f is not constant mod U_α, then there is a $Y \in U_\alpha$ such that for every $\nu < \kappa$ $|Y \cap f^{-1}\{\nu\}| < \kappa$.

The last property just follows using the set $\overline{X}$ defined above and the normality of U_κ.

A system of ultrafilters and projections satisfying (1)–(10) was called in [19] a *nice system*. Its existence is a bit weaker than the strongness assumption used here. In what follows we will use only such a system in order to define extender-based Prikry forcing over κ.

Let us denote $\pi_{\alpha\kappa}(\nu)$ by ν^0, where $\kappa \le \alpha < \lambda$ and $\nu < \kappa$. By a $^\circ$-increasing sequence of ordinals we mean a sequence $\langle \nu_1, \dots, \nu_n\rangle$ of ordinals below κ so that

$$\nu_1^0 < \nu_2^0 < \cdots < \nu_n^0.$$

For every $\alpha < \lambda$ by $X \in U_\alpha$ we shall always mean that $X \subseteq \overline{X}$, in particular, it will imply that for $\nu_1, \nu_2 \in X$ if $\nu_1^0 < \nu_2^0$ then $|\{\alpha \in X \mid \alpha^0 = \nu_1^0\}| < \nu_2^0$. The following weak version of normality holds, since U_α is a P-point: if $X_i \in U_\alpha$ for $i < \kappa$ then also $X = \Delta^*_{i<\kappa} X_i = \{\nu \mid \forall i < \nu^0\ (\nu \in X_i)\} \in U_\alpha$.

Let $\nu < \kappa$ and $\langle \nu_1, \dots, \nu_n\rangle$ be a finite sequence of ordinals below κ. Then ν is called *permitted* for $\langle \nu_1, \dots, \nu_n\rangle$ if $\nu^0 > \max\{\nu_i^0 \mid 1 \le i \le n\}$.

We shall ignore U_α's with $\alpha < \kappa$ and denote U_κ by U_0.

Let us now define a forcing notion for adding λ ω-sequences to κ.

3.6 Definition. The set of forcing conditions $\mathcal{P}$ consists of all the elements p of the form $\{\langle \gamma, p^\gamma\rangle \mid \gamma \in g \setminus \{\max(g)\} \cup \{\langle \max(g), p^{\max(g)}, T\rangle\}$, where

(1) $g \subseteq \lambda$ of cardinality $\le \kappa$ which has a maximal element in $\le_E$-ordering and $0 \in g$. Further let us denote g by $\mathrm{supp}(p)$, $\max(g)$ by $mc(p)$, T by T^p, and $p^{\max(g)}$ by p^{mc} (mc for the maximal coordinate).

(2) For $\gamma \in g$, p^γ is a finite $^\circ$-increasing sequence of ordinals $< \kappa$.

(3) T is a tree with a trunk p^{mc} consisting of $^\circ$-increasing sequences. All the splittings in T are required to be on sets in $U_{mc(p)}$, i.e. for every $\eta \in T$, if $\eta \ge_T p^{mc}$ then the set

$$\mathrm{Suc}_T(\eta) = \{\nu < \kappa \mid \eta^\frown\langle \nu\rangle \in T\} \in U_{mc(p)}.$$

Also require that for $\eta_1 \ge_T \eta_2 \ge_T p^{mc}$

$$\mathrm{Suc}_T(\eta_1) \subseteq \mathrm{Suc}_T(\eta_2).$$

(4) For every $\gamma \in g$, $\pi_{mc(p),\gamma}(\max(p^{mc}))$ is not permitted for p^γ.

(5) For every $\nu \in \mathrm{Suc}_T(p^{mc})$

$$|\{\gamma \in g \mid \nu \text{ is permitted for } p^\gamma\}| \le \nu^0.$$

(6) $\pi_{mc(p),0}$ projects p^{mc} onto p^0 (so p^{mc} and p^0 are of the same length).

Let us give some intuitive motivation for the definition of forcing conditions. We want to add a Prikry sequence for every $U_\alpha(\alpha < \lambda)$. The finite sequences p^γ ($\gamma \in \text{supp}(p)$) are initial segments of such sequences. The support of p has two distinguished coordinates. The first is the 0-coordinate of p and the second is its maximal coordinate. The 0-coordinate or more precisely the Prikry sequence for the normal ultrafilter will be used further in order to push the present construction to $\aleph_\omega$. Also condition (6) will be used for this purpose. The maximal coordinate of p is responsible for extending the Prikry sequences for γ's in the support of p. The tree T^p is a set of possible candidates for extending p^{mc} and by using the projections map $\pi_{mc(p),\gamma}$ for $\gamma \in \text{supp}(p)$, T^p becomes also the set of candidates for extending the p^γ's. Instead of working with a tree, it is possible to replace it by a single set. The proof of the Prikry condition will then be a bit more complicated. Condition (4) means that the information carried by $\max(p^{mc})$ is impossible to project down. The reasons for such a condition are technical. Condition (5) is desired to allow the use of the diagonal intersections.

In contrast to the main forcing of the previous section, we deal with κ coordinates simultaneously (i.e. the support of the condition may have cardinality κ). This causes difficulties since we cannot hope to have full commutativity between κ many ultrafilters.

3.7 Definition. Let $p, q \in \mathcal{P}$. We say that p *extends* q and denote this by $p \geq q$ iff

(1) $\text{supp}(p) \supseteq \text{supp}(q)$.

(2) For every $\gamma \in \text{supp}(q)$, p^γ is an end-extension of q^γ.

(3) $p^{mc(q)} \in T^q$.

(4) For every $\gamma \in \text{supp}(q)$,

$$p^\gamma \setminus q^\gamma = \pi_{mc(q),\gamma}``((p^{mc(q)} \setminus q^{mc(q)}) \restriction (\text{length}(p^{mc}) \setminus (i+1)),$$

where $i \in \text{dom}(p^{mc(q)})$ is the largest such that $p^{mc(q)}(i)$ is not permitted for q^γ.

(5) $\pi_{mc(p),mc(q)}$ projects $T^p_{p^{mc}}$ into $T^q_{q^{mc}}$.

(6) For every $\gamma \in \text{supp}(q)$ and $\nu \in \text{Suc}_{T^p}(p^{mc})$, if ν is permitted for p^γ, then

$$\pi_{mc(p),\gamma}(\nu) = \pi_{mc(q),\gamma}(\pi_{mc(p),mc(q)}(\nu)).$$

In clause (5) above the following notation is used: let T be a tree and $\eta \in T$, then T_η consists of all finite sequences μ such that $\eta^\frown\mu$ is in T.

Intuitively, we are allowing almost everything to be added on the new coordinates and restrict ourselves to choosing extensions from the sets of measure one on the old coordinates. Actually here we are really extending only the maximal old coordinate and then we are using the projection map. This idea goes back to [13] and further to Mitchell [44].

3.8 Definition. Let $p, q \in \mathcal{P}$. We say that p is a *direct (or Prikry) extension of* q and denote this by $p \geq^* q$ iff

(1) $p \geq q$, and

(2) for every $\gamma \in \operatorname{supp}(q)$, $p^\gamma = q^\gamma$.

Our strategy is to show that $\langle \mathcal{P}, \leq, \leq^* \rangle$ satisfies the Prikry condition, that $\langle \mathcal{P}, \leq^* \rangle$ is κ-closed, and that $\langle \mathcal{P}, \leq \rangle$ satisfies the κ^{++}-c.c.

The Prikry condition together with κ closedness of $\langle \mathcal{P}, \leq^* \rangle$ insure that no new bounded subsets of κ are added. The κ^{++}-c.c. takes care of cardinals $\geq \kappa^{++}$. Since κ will change its cofinality to $\aleph_0$, an argument similar to Lemma 2.21 will be used to show that κ^+ is preserved. Clause 3.7(4) of the system of ultrafilters and projections insures that at least λ-many ω-sequences will be added to κ.

3.9 Lemma. *The relation $\leq$ is a partial order.*

Proof. Let us check the transitivity of $\leq$. Suppose that $r \leq q$ and $q \leq p$. Let us show that $r \leq p$. Conditions (1) and (2) of Definition 3.7 are obviously satisfied. Let us check (3), i.e. let us show that $p^{mc(r)} \in T^r$. Since $p \geq q \geq r$, $mc(r) \in \operatorname{supp}(q)$, $q^{mc(r)} \in T^r$ and

$$p^{mc(r)} \setminus q^{mc(r)} = \pi_{mc(q),mc(r)}``(p^{mc(q)} \setminus q^{mc(q)}).$$

Also $p^{mc(q)} \in T^q$. By (5) of Definition 3.7 (for q and r) $\pi_{mc(q),mc(r)}$ projects $T^q_{q^{mc}}$ into a subtree of $T^r_{q^{mc(r)}}$. Hence $p^{mc(r)} \in T^r$ and, so condition (3) is satisfied.

Let us check condition (4). Suppose that $\gamma \in \operatorname{supp}(r)$. We need to show that $p^\gamma \setminus r^\gamma = \pi_{mc(r),\gamma}``(p^{mc(r)} \setminus r^{mc(r)})$. In order to simplify the notation, we are assuming here that every element of $p^{mc(r)} \setminus r^{mc(r)}$ is permitted for $r^\gamma$. Since $q \geq r$, $q^\gamma \setminus r^\gamma = \pi_{mc(r),\gamma}``(q^{mc(r)} \setminus r^{mc(r)})$. So, we need to show only that $p^\gamma \setminus q^\gamma = \pi_{mc(r),\gamma}``(p^{mc(r)} \setminus q^{mc(r)})$. Since $p \geq q$, $p^{mc(q)} \in T^q$ and $p^\gamma \setminus q^\gamma = \pi_{mc(q),\gamma}``(p^{mc(q)} \setminus q^{mc(q)})$. Using condition (6) of Definition 3.7 for $q \geq r$ and the elements of $p^{mc(q)} \setminus q^{mc(q)}$, we obtain the following

$$\begin{aligned} p^\gamma \setminus q^\gamma &= \pi_{mc(q),\gamma}``(p^{mc(q)} \setminus q^{mc(q)}) \\ &= \pi_{mc(r),\gamma}``(\pi_{mc(q),mc(r)}``(p^{mc(q)} \setminus q^{mc(q)})) \\ &= \pi_{mc(r),\gamma}``(p^{mc(r)} \setminus q^{mc(r)}). \end{aligned}$$

The last equality holds by condition (4) of Definition 3.7 used for p and q.

Let us check condition (5), i.e. $\pi_{mc(p),mc(r)}$ projects $T^p_{p^{mc}}$ into $T^r_{p^{mc(r)}}$. Since $p \geq q$, $T^p_{p^{mc}}$ is projected by $\pi_{mc(p),mc(q)}$ into $T^q_{q^{mc}}$. Since $q \geq r$, $\pi_{mc(q),mc(r)}$ projects $T^q_{q^{mc}}$ into $T^r_{q^{mc(r)}}$. Now, using condition (6) for p and q with $\gamma = mc(r)$, we obtain condition (5) for p and r.

Finally, let us check condition (6). Let $\gamma \in \mathrm{supp}(r)$, $\nu \in \mathrm{Suc}_{T^p}(p^{mc})$ and suppose that ν is permitted for p^γ. Using condition (5) for p and q, we obtain that $\pi_{mc(p),mc(q)}(\nu) \in \mathrm{Suc}_{T^q}(q^{mc})$. Recall that it was required in Clause 3.6(3) that each splitting has a splitting below it in the tree. Denote $\pi_{mc(p),mc(q)}(\nu)$ by δ. By condition (6) for q and r, $\pi_{mc(q),\gamma}(\delta) = \pi_{mc(r),\gamma}(\pi_{mc(q),mc(r)}(\delta))$. Using (6) for p and q, we obtain

$$\begin{aligned}\pi_{mc(p),\gamma}(\nu) &= \pi_{mc(q),\gamma}(\pi_{mc(p),mc(q)}(\nu))\\ &= \pi_{mc(q),\gamma}(\delta)\\ &= \pi_{mc(r),\gamma}(\pi_{mc(q),mc(r)}(\delta)).\end{aligned}$$

Once more using (6) for p and q,

$$\pi_{mc(q),mc(r)}(\pi_{mc(p),mc(q)}(\nu)) = \pi_{mc(p),mc(r)}(\nu).$$

This completes the checking of (6) and also the proof of the lemma. $\dashv$

The main point of the proof appears in the next lemma.

3.10 Lemma. *Let $q \in \mathcal{P}$ and $\alpha < \lambda$. Then there is a $p \geq^* q$ so that $\alpha \in \mathrm{supp}(p)$.*

Proof. If $\alpha \leq_E mc(q)$, then it is obvious. Thus, if $\alpha \in \mathrm{supp}(q)$, then we can take $p = q$. Otherwise add to q a pair $\langle \alpha, t\rangle$ where t is any $^\circ$-increasing sequence so that $\max(q^{mc})$ is not permitted for t.

Now suppose that $\alpha \not\leq_E mc(q)$. Pick some $\beta < \lambda$ so that $\beta \geq_E \alpha$ and $\beta \geq_E mc(q)$. Without loss of generality we can assume that $\beta = \alpha$. We shall define p to be of the form

$$q' \cup \{\langle \alpha, t, T\rangle\}$$

where q' is derived from q by deleting T^q from the triple $\langle mc(q), q^{mc}, T^q\rangle$, t is an $^\circ$-increasing sequence which projects onto q^0 by $\pi_{\alpha 0}$ and the tree T will be defined below.

First consider the tree T_0 which is the inverse image of $T^q_{q^{mc}}$ by $\pi_{\alpha,mc(q)}$, with t added as the trunk. Then $p_0 = q' \cup \{\langle \alpha, t, T_0\rangle\}$ is a condition in $\mathcal{P}$ which is "almost" an extension and even a direct extension of q. The only concern is that condition (6) of Definition 3.7 may not be satisfied by p_0 and q. In order to repair this, let us shrink the tree T_0 a little.

Denote $\mathrm{Suc}_{T_0}(t)$ by A. For $\nu \in A$ set

$$B_\nu = \{\gamma \in \mathrm{supp}(q) \mid \gamma \neq mc(q) \text{ and } \nu \text{ is permitted for } q^\gamma\}.$$

Then we have $|B_\nu| \leq \nu^0$, since $\pi_{\alpha,mc(q)}(\nu) \in \mathrm{Suc}_{T^q}(q^{mc})$, $\nu^0 = \pi_{\alpha 0}(\nu) = \pi_{mc(q),0}(\pi_{\alpha mc(q)}(\nu))$, and q being in $\mathcal{P}$ satisfies condition (5) of Definition 3.6.

Clearly, for $\nu, \delta \in A$, if $\nu^0 = \delta^0$ then $B_\nu = B_\delta$, and if $\nu^0 > \delta^0$ then $B_\nu \supseteq B_\delta$. Also, if $\nu \in A$ and ν^0 is a limit point of $\{\delta^0 \mid \delta \in A\}$, then $B_\nu = \bigcup\{B_\delta \mid \delta \in A$ and $\delta^0 < \nu^0\}$. So the sequence $\langle B_\nu \mid \nu \in A\rangle$ is increasing and continuous (according to the ν^0's). Obviously, $\bigcup\{B_\nu \mid \nu \in A\} = \mathrm{supp}(q) \setminus \{mc(q)\}$. Let $\langle \xi_i \mid i < \kappa\rangle$ be an enumeration of $\mathrm{supp}(q) \setminus \{mc(q)\}$ such that for every $\nu \in A$

$$B_\nu \subseteq \{\xi_i \mid i < \nu^0\}.$$

Now pick for every $i \in A$ a set $C_i \subseteq A$, with $C_i \in U_\alpha$ so that for every $\nu \in C_i$ $\pi_{\alpha\xi_i}(\nu) = \pi_{mc(q),\xi_i}(\pi_{\alpha,mc(q)}(\nu))$. Let $C = A {}^\frown \Delta^*_{i<\kappa} C_i = \{\nu \in A \mid \forall i < \nu^0 (\nu \in C_i)\}$. Then $C \in U_\alpha$.

Now define T to be the tree obtained from T_0 by intersecting every level of T_0 with C. Let us show that condition (6) of Definition 3.7 is now satisfied. Suppose that $\gamma \in \mathrm{supp}(q)$. If $\gamma = mc(q)$, then everything is trivial. Assume that $\gamma \in \mathrm{supp}(q) \setminus \{mc(q)\}$. Then for some $i_0 < \kappa$, $\gamma = \xi_{i_0}$. Suppose that some $\nu \in C$ is permitted for q^γ. Then $\xi_{i_0} = \gamma \in B_\nu$. Since $B_\nu \subseteq \{\xi_i \mid i < \nu^0\}$, $i_0 < \nu^0$. Then $\nu \in C_{i_0}$. Hence

$$\pi_{\alpha\xi_{i_0}}(\nu) = \pi_{mc(q),\xi_{i_0}}(\pi_{\alpha,mc(q)}(\nu)).$$

So condition (6) is satisfied by p. Hence, $p \geq^* q$. ⊣

3.11 Lemma.

(a) $\langle \mathcal{P}, \geq\rangle$ *satisfies the* κ^{++}*-c.c.*

(b) $\langle \mathcal{P}, \geq^*\rangle$ *is* κ*-closed.*

Proof of (a). Let $\{p_\alpha \mid \alpha < \kappa^{++}\} \subseteq \mathcal{P}$. Without loss of generality, we can assume their supports form a Δ-system and are contained in κ^{++}. Also, we can assume that there are s and $\langle t, T\rangle$ so that for every $\alpha < \kappa^{++}$, $p_\alpha \restriction \alpha = s$ and $\langle p_\alpha^{mc}, T^{p_\alpha}\rangle = \langle t, T\rangle$. Let us then show that p_α and p_β are compatible for every $\alpha, \beta < \kappa^{++}$.

Let $\alpha, \beta < \kappa^{++}$ be fixed. We would like simply to take the union $p_\alpha \cup p_\beta$ and to show that this is a condition stronger than both p_α and p_β. The first problem is that $p_\alpha \cup p_\beta$ may not be in $\mathcal{P}$, since $\mathrm{supp}(p_\alpha \cup p_\beta) = \mathrm{supp}(p_\alpha) \cup \mathrm{supp}(p_\beta)$ may not have a maximal element. In order to fix this, let us add say to p_α some new coordinate δ so that $\delta \geq_E mc(p_\alpha), mc(p_\beta)$. Let p^*_α be the extension of p_α defined in the previous lemma by adding δ as a new coordinate to p_α. Then $p^*_\alpha \cup p_\beta \in \mathcal{P}$. But we do need a condition stronger than both p_α and p_β. The condition $p^*_\alpha \cup p_\beta$ is a good candidate for it. The only concerns here are (5) and (6) of Definition 3.6. Actually, (5) can be easily satisfied by intersecting $T^{p^*_\alpha}_{(p^*_\alpha)^{mc}}$ with $\pi^{-1}_{\delta,mc(p_\beta)}$ “$(T^{p_\beta}_{p^{mc}_\beta})$. In order to satisfy (6), we need to shrink $T^{p^*_\alpha}$ more. The argument of the previous lemma can be used for this.

Proof of (b). Let $\delta < \kappa$ and let $\langle p_i \mid i < \delta\rangle$ be an $\leq^*$-increasing sequence of elements of $\mathcal{P}$. Pick $\alpha < \lambda$ above $\{mc(p_i) \mid i < \delta\}$. Let p be the union of p_i's with T^{p_i} removed. Set $T = \bigcap_{i<\delta} \pi^{-1}_{\alpha,mc(p_i)}$"$T^{p_i}$. Also remove all τ's with $\tau^0 \leq \delta$ from this tree. Let t be a $^\circ$-increasing sequence so that $\pi_{\alpha 0}$"$t = p^0_0$. Consider $p \cup \{\langle \alpha, t, T\rangle\}$. Clearly, it belongs to $\mathcal{P}$. Now, as in Lemma 3.9, shrink T to a tree T^i so that $p \cup \{\langle \alpha, t, T^i\rangle\}^* \geq p_i$, where $i < \delta$. Let $T^* = \bigcap_{i<\delta} T^i$ and consider $r = p \cup \{\langle \alpha, t, T^*\rangle\}$. Then $r \geq^* p_i$ for every $i < \delta$. ⊣

3.12 Lemma. *$\langle \mathcal{P}, \leq, \leq^*\rangle$ satisfies the Prikry condition, i.e. for every statement σ of the forcing language, for every $q \in \mathcal{P}$ there exists a $p \geq^* q$ deciding σ.*

Proof. Let σ be a statement and $q \in \mathcal{P}$. In order to simplify the notation we assume that $q = \emptyset$. The object in this proof is to reduce the problem to that of Prikry forcing on some U_α, so the arguments of Sect. 1.1 can be applied. In order to find a suitable ordinal α, which will be p^{mc}, pick an elementary submodel N of V_μ for μ sufficiently large to contain all the relevant information of cardinality κ^+ and closed under κ-sequences of its elements. Pick $\alpha < \lambda$ above (in the $\leq_E$-ordering) all the elements of $N \cap \lambda$. Let T be a tree so that $\{\langle \alpha, \emptyset, T\rangle\} \in \mathcal{P}$. More precisely, we should write $\{\langle 0, \emptyset\rangle\} \cup \{\langle \alpha, \emptyset, T\rangle\}$. But let us omit the least coordinate when the meaning is clear. If there is a $p \in N$ so that $p \cup \{\langle \alpha, \emptyset, T'\rangle\} \in \mathcal{P}$ and decides σ, for some $T' \subseteq T$, then we are done. Suppose otherwise. Denote $\mathrm{Suc}_T(\langle\rangle)$ by A. We shall define by recursion sequences $\langle p_\nu \mid \nu \in A\rangle$ and $\langle T^\nu \mid \nu \in A\rangle$.

Let $\nu = \min(A)$. Consider $\{\langle \alpha, \langle \nu\rangle, T_{\langle \nu\rangle}\rangle\}$. If there is no $p \in N$ and $T' \subseteq T_{\langle \nu\rangle}$ such that $p \cup \{\langle \alpha, \langle \nu\rangle, T'\rangle\}$ is in $\mathcal{P}$ and decides σ, then set $p_\nu = \emptyset$ and $T^\nu = T_{\langle \nu\rangle}$. Otherwise, pick some p and $T' \subseteq T_{\langle \nu\rangle}$ so that $p \cup \{\langle \alpha, \langle \nu\rangle, T'\rangle\}$ is in $\mathcal{P}$ and decides σ. Set $p_\nu = p$ and $T^\nu = T'$.

Suppose now that p_ξ and T^ξ are defined for every $\xi < \nu$ in A. We shall define p_ν and T^ν. But let us first define p'_ν and p''_ν. Define p''_ν to be the union of all p_ξ's with $\xi \in A \cap \nu$. Let $p'_\nu = \{\langle \gamma, p'^{\gamma}_\nu\rangle \mid \gamma \in \mathrm{supp}(p''_\nu)\}$, where for $\gamma \in \mathrm{supp}(p''_\nu)$, $p'^{\gamma}_\nu = p''^{\gamma}_\nu$ unless ν is permitted for p''^{γ}_ν and then $p'^{\gamma}_\nu = p''^{\gamma}_\nu {}^\frown \langle \pi_{\alpha\gamma}(\nu)\rangle$. If there is no $p \in N$ and T' so that $q = p \cup \{\langle \alpha, \langle \nu\rangle, T'\rangle\} \in \mathcal{P}$, $q \geq^* p'_\nu \cup \{\langle \alpha, \langle \nu\rangle, T_{\langle \nu\rangle}\rangle\}$ and $q \parallel \sigma$, then set $p_\nu = p''_\nu$ and $T^\nu = T_{\langle \nu\rangle}$. Suppose otherwise. Let p, T' be witnessing this. Then set $T^\nu = T'$ and $p_\nu = p''_\nu \cup (p \setminus p'_\nu)$.

This completes the recursive definition. Set $p = \bigcup_{\nu \in A} p_\nu$. For $i < \kappa$ let

$$C_i = \begin{cases} A, & \text{if there is no } \delta \in A \text{ such that } \delta^0 = i, \\ \bigcap\{\mathrm{Suc}_{T^\delta}(\langle \delta\rangle) \mid \delta \in A \text{ and } \delta^0 = i\}, & \text{otherwise.} \end{cases}$$

Note that $C_i \in U_\alpha$ since $A \in U_\alpha$ and this means by our agreement that for $\nu_1, \nu_2 \in A$, if $\nu^0_1 < \nu^0_2$ then $|\{\gamma \in A \mid \gamma^0 = \nu^0_1\}| < \nu^0_2$. Set $A^* = A \cap \Delta^*_{i<\kappa} C_i$. Then for every $\nu \in A^*$ for every $\delta \in A$ if $\delta^0 < \nu^0$ then $\nu \in \mathrm{Suc}_{T^\delta}(\langle \delta\rangle)$. Let S be the tree obtained from T by first replacing $T_{\langle \nu\rangle}$ by T^ν for every $\nu \in A^*$ and then intersecting all levels of it with A^*. ⊣

3.12.1 Claim. *$p \cup \{\langle \alpha, \emptyset, S\rangle\}$ belongs to $\mathcal{P}$.*

Proof. The only non-trivial point here is to show that $p \cup \{\langle \alpha, \emptyset, S\rangle\}$ satisfies condition (5) of the definition of $\mathcal{P}$. So let $\nu \in \mathrm{Suc}_S(\langle\rangle)$. By the definition of $S, \mathrm{Suc}_S(\langle\rangle) = A^*$. Consider the set

$$B_\nu = \{\gamma \in \mathrm{supp}(p) \mid \nu \text{ is permitted for } \underset{\sim}{p}^\gamma\}.$$

For every $\delta \in A$ let $B_{\nu,\delta} = \{\gamma \in \mathrm{supp}(p_\delta) \mid \nu \text{ is permitted for } p^\gamma\}$. Then $B_\nu = \bigcup_{\delta \in A} B_{\nu,\delta}$. But, actually the definition of the sequence $\langle p_\delta \mid \delta \in A\rangle$ implies that $B_\nu = \bigcup \{B_{\nu,\delta} \mid \delta \in A \text{ and } \delta^0 < \nu^0\}$. The number of δ's in A with $\delta^0 < \nu^0$ is $\leq \nu^0$, since for $\delta, \nu \in A$, $\delta^0 < \nu^0$ implies $\delta < \nu^0$, and it means in particular that for every $\xi < \nu^0$, $|\{\delta \in A \mid \delta^0 = \xi\}| < \nu^0$. So it is enough to show that for every $\delta \in A$, $\delta^0 < \nu^0$ implies $|B_{\nu,\delta} | \leq \nu^0$. Fix some $\delta \in A$ such that $\delta^0 < \nu^0$. Since $\nu \in A^*$ and $\delta^0 < \nu^0$, $\nu \in \mathrm{Suc}_{T^\delta}(\langle\delta\rangle)$. But $p_\delta \cup \{\langle \alpha, \langle\delta\rangle, T^\delta\rangle\} \in \mathcal{P}$. So, by the definition of $\mathcal{P}, |B_{\nu,\delta}| \leq \nu^0$. $\dashv$

Then, clearly $p \cup \{\langle \alpha, \emptyset, S\rangle\} \geq^* \langle \alpha, \emptyset, T\rangle\}$.

For $\delta \in \mathrm{Suc}_S(\langle\rangle) = A^*$ let us denote by $(p \cup \{\langle \alpha, \emptyset, S\rangle\})_\delta$ the sequence $\{\langle \gamma, (p^\gamma)_{\pi_{\alpha\gamma}(\delta)}\rangle \mid \gamma \in \mathrm{supp}(p)\} \cup \{\langle \alpha, \langle\delta\rangle, S_{\langle\delta\rangle}\rangle\}$, where

$$(p^\gamma)_{\pi_{\alpha\gamma}(\delta)} = \begin{cases} p^{\gamma\frown}\pi_{\alpha\gamma}(\delta), & \text{if } \delta \text{ is permitted for } p^\gamma, \\ p^\gamma, & \text{otherwise.} \end{cases}$$

Note that $(p \cup \{\langle \alpha, \emptyset, S\rangle\})_\delta$ is a condition and $\pi_{\alpha\gamma}(\delta)$ is added only for γ's which appear in the support of some p_ξ with $\xi^0 < \delta^0$ and hence, with $\xi < \delta$. Also $(p \cup \{\langle \alpha, \emptyset, S\rangle\})_\delta{}^* \geq p_\delta \cup \{\langle \alpha, \langle\delta\rangle, T^\delta\rangle\}$.

3.12.2 Claim. *For every $\delta \in \mathrm{Suc}_S(\langle\rangle)$ if for some $q, R \in N$,*

$$(p \cup \{\langle \alpha, \emptyset, S\rangle\})_\delta \leq^* q \cup \{\langle \alpha, \langle\delta\rangle, R\rangle\} \quad \textit{and} \quad q \cup \{\langle \alpha, \langle\delta\rangle, R\rangle\} \Vdash \sigma (\textit{resp. } \neg\sigma),$$

then $(p \cup \{\langle \alpha, \emptyset, S\rangle\})_\delta \Vdash \sigma$ (resp. $\neg\sigma$).

Proof. Such a $q \cup \{\langle \alpha, \langle\delta\rangle, R\rangle\}$ is a direct extension of $p_\delta \cup \{\langle \alpha, \langle\delta\rangle, T^\delta\rangle\}$. By the choice of p_δ and T^δ, $p_\delta \cup \{\langle \alpha, \langle\delta\rangle, T^\delta\rangle\}$ decides σ. But $(p \cup \{\langle \alpha, \emptyset, S\rangle\})_\delta{}^* \geq p_\delta \cup \{\langle \alpha, \langle\delta\rangle, T^\delta\rangle\}$. $\dashv$

Let us now shrink the first level of S in order to insure that for every δ_1 and δ_2 in the new first level

$$(p \cup \{\langle \alpha, \emptyset, S\rangle\})_{\delta_1} \Vdash \sigma \text{ (resp. } \neg\sigma) \quad \text{iff} \quad (p \cup \{\langle \alpha, \emptyset, S\rangle\})_{\delta_2} \Vdash \sigma \text{ (resp. } \neg\sigma).$$

Let us denote the shrunken tree again by S.

3.12.3 Claim. *For every $\delta \in \mathrm{Suc}_S(\langle\rangle)$, $(p \cup \{\langle \alpha, \emptyset\rangle\})_\delta \not\parallel \sigma$.*

Proof. Suppose otherwise. Then every δ in $\mathrm{Suc}_S(\langle\rangle)$ will force the same truth value of σ. Suppose, for example, that σ is forced. Then $p \cup \{\langle \alpha, \emptyset, S\rangle\}$ will force σ. Since every $q \geq p \cup \{\langle \alpha, \emptyset, S\rangle\}$ is compatible with one of $(p \cup \{\langle \alpha, \emptyset, S\rangle\})_\delta$ for $\delta \in \mathrm{Suc}_S(\langle\rangle)$. This contradicts the initial assumption. $\dashv$

Now, climbing up level by level in the fashion described above for the first level, construct a direct extension $p^* \cup \{\langle \alpha, \emptyset, S^* \rangle\}$ of $p \cup \{\langle \alpha, \emptyset, S \rangle\}$ so that:

(a) For every $\eta \in S^*$, if for some $q, R \in N$, $(p^* \cup \{\alpha, \emptyset, S^*\rangle\})_\eta \leq^* q \cup \{\langle \alpha, \langle \eta \rangle, R \rangle\}$ and $q \cup \{\langle \alpha, \langle \eta \rangle, R\rangle\} \Vdash \sigma$ (resp. $\neg\sigma$), then $(p^* \cup \{\langle \alpha, \emptyset, S^* \rangle\})_\eta \Vdash \sigma$ (resp. $\neg\sigma$).

(b) If $\eta_1, \eta_2 \in S^*$ are of the same length, then

$$(p^* \cup \{\langle \alpha, \emptyset, S^*\rangle\})_{\eta_1} \Vdash \sigma \text{ (resp. } \neg\sigma) \quad \text{iff} \quad (p^* \cup \{\langle \alpha, \emptyset, S^*\rangle\})_{\eta_2} \Vdash \sigma \text{ (resp. } \neg\sigma).$$

As in Claim 3.12.3, it is impossible to have any $\eta \in S^*$ so that $(p^* \cup \{\langle \alpha, \emptyset, S^* \rangle\})_\eta$ decides σ. Combining this with (a) we obtain the following.

3.12.4 Claim. *For every $q, R, t \in N$, if $q \cup \{\langle \alpha, t, R\rangle\} \geq p^* \cup \{\langle \alpha, \emptyset, S^*\rangle\}$ then $q \cup \{\langle \alpha, t, R \rangle\}$ does not decide σ.*

Proof. Just note that $q \cup \{\langle \alpha, t, R\rangle\} \geq^* (p^* \cup \{\langle \alpha, \emptyset, S\rangle\})_t$ and use (a). ⊣

Pick some $\beta \in N \cap \lambda$ which is $\leq_E$ above every element of $\operatorname{supp}(p^*)$. This is possible since $\operatorname{supp}(p^*) \in N$. Shrink S^* to a tree S^{**}, as in Lemma 3.10 in order to insure the following:

$$\text{For every } \nu \in \operatorname{Suc}_{S^{**}}(\langle\rangle) \text{ and } \gamma \in \operatorname{supp}(p^*), \quad \text{if } \nu \text{ is permitted for } (p^*)^\gamma, \text{ then } \pi_{\alpha\gamma}(\nu) = \pi_{\beta\gamma}(\pi_{\alpha\beta}(\nu)).$$

Let S^{***} be the projection of S^{**} to β via $\pi_{\alpha,\beta}$. Denote $p^* \cup \{\langle \beta, \emptyset, S^{***}\rangle\}$ by p^{**}. Then $p^{**} \in N$ and $p^{**} \cup \{\langle \alpha, \emptyset, S^{**}\rangle\} \geq^* p^* \cup \{\langle \alpha, \emptyset, S^*\rangle\}$. Since N is an elementary submodel there is some $q \in N$ with $q \geq p^{**}$ deciding σ. Let, for example, $q \Vdash \sigma$. Pick some $t \in S^{**}$ so that $\pi_{\alpha\beta}``t = q^\beta$. Such t exists, since by Definition 3.7 q^β belongs to S^{***} which is the image of S^{**} under $\pi_{\alpha\beta}$. Note also that $mc(q) <_E \alpha$ by the choice of N. Let R be a from S^{**}_t by intersecting S^{**}_t with $\pi^{-1}_{\alpha, mc(q)}(T^q)$ and shrinking, if necessary, as in Lemma 3.10 in order to insure the equality of projections $\pi_{\alpha\gamma}$ and $\pi_{mc(q),\gamma} \circ \pi_{\alpha, mc(q)}$ for permitted γ's in $\operatorname{supp}(q)$. Then $q \cup \{\langle \alpha, t, R\rangle\}$ will be a condition stronger than q. Hence, it forces σ. But this contradicts Claim 3.12.4, since $q \cup \{\langle \alpha, t, R\rangle\} \geq p^* \cup \{\langle \alpha, \emptyset, S^*\rangle\}$. This contradiction finishes the proof of Lemma 3.12. ⊣

Let G be a generic subset of $\mathcal{P}$. By Lemma 3.10, for every $\alpha < \lambda$ there is a $p \in G$ with $\alpha \in \operatorname{supp}(p)$. Let us denote $\bigcup\{p^\alpha \mid p \in G\}$ by G^α.

3.13 Lemma.

(a) For every $\alpha < \lambda$, G^α is a Prikry sequence for U_α, i.e. an ω-sequence almost contained in every set in U_α.

(b) G^0 is an ω-sequence unbounded in κ.

(c) If $\alpha \neq \beta$ then $G^\alpha \neq G^\beta$, moreover $\alpha < \beta$ implies that G^β dominates G^α.

Proof. (a) Follows from the definition of $\mathcal{P}$. (b) Is a trivial consequence of (a). For (c) note that there is a $\gamma < \lambda$ such that $\gamma \geq_E \alpha, \beta$. By Lemma 3.4 then $\{\nu < \kappa \mid \pi_{\gamma\alpha}(\nu) < \pi_{\gamma\beta}(\nu)\} \in U_\gamma$. This together with the definition of $\mathcal{P}$ implies that G^α is dominated by G^β. ⊣

3.14 Lemma. *κ^+ remains a cardinal in $V[G]$.*

Proof. Suppose otherwise. Then it changes its cofinality to some $\mu < \kappa$. Let $g : \mu \to (\kappa^+)^V$ be unbounded in $(\kappa^+)^V$. Pick $p \in G$ forcing this. Suppose for simplicity that $\emptyset \Vdash \underset{\sim}{g} : \check{\mu} \to \check{\kappa}^+$ unbounded. Pick an elementary submodel N as in Lemma 3.12. Let $\alpha < \lambda$ be above every element of $N \setminus \lambda$. Pick a tree T so that $\{\langle \alpha, \emptyset, T\rangle\} \in \mathcal{P}$. As in Lemma 3.12, define by induction an $\leq^*$ increasing sequence of direct extensions of $\{\langle \alpha, \emptyset, T\rangle\}$ $\langle q_i \cup \{\langle \alpha, \emptyset, S^i\rangle\} \mid i < \mu\rangle$ so that

(a) $q_i \in N$.

(b) If for some $q, R, t \in N$ and $j < \kappa^+$, $q \cup \{\langle \alpha, t, R\rangle\} \geq q_i \cup \{\langle \alpha, \emptyset, S^i\rangle\}$ and $q \cup \{\langle \alpha, t, R\rangle\} \Vdash \underset{\sim}{g}(\check{i}) = \check{j}$, then
$$(q_i \cup \{\langle \alpha, \emptyset, S^i\rangle\})_t \Vdash \underset{\sim}{g}(\check{i}) = \check{j}.$$

Using Lemma 3.11, find S so that $\bigcup_{i<\mu} q_i \cup \{\langle \alpha, \emptyset, S\rangle\} \geq^* q_i \cup \{\langle \alpha, \emptyset, S^i\rangle\}$ for every $i < \mu$. Denote $\bigcup_{i<\mu} q_i$ by p. As in Lemma 3.12, choose $\beta \in N \setminus \lambda$ above $\mathrm{supp}(p)$ and project S into β using $\pi_{\alpha\beta}$. Denote the projection by S^*. Let $p^* = p \cup \{\langle \beta, \emptyset, S^*\rangle\}$. Then $p^* \in N$ and $p^* \cup \{\langle \alpha, \emptyset, S\rangle\} \geq^* p \cup \{\langle \alpha, \emptyset, S\rangle\}$. Since N is an elementary submodel, for every $i < \mu$ there will be a $q \in N$, $q \geq p^*$ forcing a value for $\underset{\sim}{g}(i)$. Then, using (b), as in Lemma 3.12 for some $t \in S$ $(p \cup \{\langle \beta, \emptyset, S\rangle\})_t$ will force the same value for $\underset{\sim}{g}(i)$. But $|S| = \kappa$. So, all such values are bounded in κ^+ by some ordinal δ which is impossible, since $N \supseteq \kappa^+$ and $N \vDash (\phi \Vdash (\underset{\sim}{g} : \check{\mu} \to \check{\kappa}^+ \text{ unbounded}))$. Contradiction. ⊣

Now combining the lemmas together, we obtain the following.

3.15 Theorem. *The following holds in $V[G]$:*

(a) κ has cofinality $\aleph_0$ and $\kappa^{\aleph_0} \geq \lambda$.

(b) All the cardinals are preserved.

(c) No new bounded subsets are added to κ.

If κ is a strong cardinal and $\lambda > \kappa$, then by the Solovay argument, described in the beginning of the section, there is a function $f : \kappa \to \kappa$ and a λ-strong embedding $j : V \to M$ so that $j(f)(\kappa) = \lambda$. Now, having f and j we can use the extender-based Prikry forcing over κ, as it was defined above. So, the following holds.

3.16 Theorem. *Let V be a model of* GCH *and let κ be a strong cardinal. Then for every λ there exists a cardinal preserving set generic extension $V[G]$ of V so that*

(a) No new bounded subsets are added to κ.

(b) κ changes its cofinality to $\aleph_0$.

(c) $2^\kappa \geq \lambda$.

4. Down to $\aleph_\omega$

The forcings of Sects. 2 and 3 produce models with κ of cofinality $\aleph_0$, GCH below κ, and 2^κ arbitrarily large. But such κ are quite large. Thus, in Sect. 2, it is a limit of measurables. In Sect. 3, it is a former measurable and no cardinals below it were collapsed. We should now like to collapse cardinals below κ and to move it to $\aleph_\omega$. Note that it is impossible to keep 2^κ arbitrarily large once κ is $\aleph_\omega$, since by the celebrated results of Shelah [53] $2^{\aleph_\omega} < \min(\aleph_{(2^{\aleph_0})^+}, \aleph_{\omega_4})$ provided that $\aleph_\omega$ is a strong limit. Our goal will be only to produce a finite gap between $\kappa = \aleph_\omega$ and 2^κ. It is possible to generalize this to countable gaps and for this we refer to [19, Sect. 3]. The possibility of getting uncountable gaps between $\aleph_\omega$ and $2^{\aleph_\omega}$ is a major open problem of cardinal arithmetic.

Let $2 \leq m < \omega$. We construct a model satisfying "$2^{\aleph_n} = \aleph_{n+1}$ for every $n < \omega$ and $2^{\aleph_\omega} = \aleph_{\omega+m}$" based on the forcing of the previous section.

The basic ideas for moving down to a small cardinal like $\aleph_\omega$ are due to Magidor [35, 36]. Hugh Woodin, see [9] or [15] was able to replace the use of supercompacts and huge cardinals by Magidor in [15] by strong cardinals. We present here a simplified version of [20, Sect. 2]. The main simplification is an elimination of M-generic sets used there. Another simplification, suggested by Assaf Sharon, allows the removal of bounds $b(p, \gamma)$ of [20, Sect. 2].

Fix a $(\kappa, \kappa+m)$-extender E over κ. Let $j : V \to M \simeq \mathrm{Ult}(V, E)$, $\mathrm{crit}(j) = \kappa$, $M \supseteq V_{\kappa+m}$, be the canonical embedding. Assume GCH. Let $\langle U_\alpha \mid \alpha < \lambda\rangle$, $\langle \pi_{\alpha\beta} \mid \alpha, \beta < \lambda,\ \beta \leq_E \alpha\rangle$ be as in the previous section with $\lambda = \kappa^{+m}$ and $f_\lambda : \kappa \to \kappa$ defined by $f_\lambda(\nu) = \nu^{+m}$.

We now define the set of forcing conditions.

4.1 Definition. The set of forcing conditions $\mathcal{P}$ consists of all elements p of the form

$$\begin{aligned}&\{\langle 0, \langle \tau_1, \ldots, \tau_n\rangle, \langle f_0, \ldots, f_n\rangle, F\rangle\}\\ &\quad \cup \{\langle \gamma, p^\gamma\rangle \mid \gamma \in g \setminus \{\max(g), 0\}\} \cup \{\langle \max(g), p^{\max(g)}, T\rangle\},\end{aligned}$$

where

(1) $\{\langle 0, \langle \tau_1, \ldots, \tau_n\rangle\rangle\} \cup \{\langle \gamma, p^\gamma\rangle \mid \gamma \in g \setminus \{\max(g), 0\}\} \cup \{\langle \max(g), p^{\max(g)}, T\rangle\}$ is as in Definition 3.6. Let us use the notations introduced there.

So, we denote g by $\mathrm{supp}(p), \max(g)$ by $mc(p)$, T by T^p and $p^{\max(g)}$ by p^{mc}. Also, let us denote further $\langle \tau_1, \ldots, \tau_n \rangle$ by p^0, $\langle f_0, \ldots, f_n \rangle$ by f^p, for $i < n$ f_i by f_i^p, n by n^p and F by F^p.

(2) $f_0 \in \mathrm{Col}(\omega, \tau_1)$, $f_i \in \mathrm{Col}(\tau_i^{+m+1}, \tau_{i+1})$ for $0 < i < n$, and $f_n \in \mathrm{Col}(\tau_n^{+m+1}, \kappa)$.

(3) F is a function on the projection of $T_{p^{mc}}$ by $\pi_{mc(p),0}$ so that

$$F(\langle \nu_0, \ldots, \nu_{i-1} \rangle) \in \mathrm{Col}(\nu_{i-1}^{+m+1}, \kappa).$$

Let us denote by $T^{p,0}$ the projection of T by π_{mc0}. For every $\eta \in T^{p,0}_{p^0}$ let F_η be defined by $F_\eta(\nu) = F(\eta^\frown \langle \nu \rangle)$.

Intuitively, the forcing $\mathcal{P}$ is intended to turn κ to $\aleph_\omega$ and simultaneously blowing up its power to κ^{+m+1}. The part of $\mathcal{P}$, which is responsible for blowing up the power of κ is the forcing used in Sect. 3. The function $f_0, \ldots, f_{n-1}$ provides partial information about collapsing already known elements of the Prikry sequence for U_0. F is a set of possible candidates for collapsing between further, still unknown elements of this sequence. Note, that for $i < n$ we are starting the collapse with τ_i^{+m+1}, i.e. we intend to preserve all $\tau_i, \tau_i^+, \ldots, \tau_i^{+m+1}$. The reason for this appears in the proof of the κ^{++}-c.c. and of the Prikry condition. It looks technical but what is hidden behind is that collapsing indiscernibles (i.e. members of Prikry's sequences for U_α's ($\alpha < \lambda$)) causes collapsing generators, i.e. cardinals between κ and λ. Shelah's bounds on the power of $\aleph_\omega$, [53] suggest that there is no freedom in using collapses below κ without effecting the structure of cardinals above κ as well.

4.2 Definition. Let $p, q \in \mathcal{P}$. We say that p *extends* q and denote this by $p \geq q$ iff

(1) $\{\langle 0, p^0 \rangle\} \cup \{\langle \gamma, p^\gamma \rangle \mid \gamma \in \mathrm{supp}(p) \setminus \{mc(p), 0\}\} \cup \{\langle mc(p), p^{mc}, T^p \rangle\}$
extends
$\{\langle 0, q^0 \rangle\} \cup \{\langle \gamma, q^\gamma \rangle \mid \gamma \in \mathrm{supp}(q) \setminus \{mc(q), 0\}\} \cup \{\langle mc(q), q^{mc}, T^q \rangle\}$
in the sense of Definition 3.7.

(2) For every $i < \mathrm{length}(q^0) = n^q$, $f_i^p \geq f_i^q$.

(3) For every $\eta \in T^{p,0}_{p^0}$, $F^p(\eta) \supseteq F^q(\eta)$.

(4) For every i with $n^q \leq i < n^p$,

$$f_i^p \supseteq F^q((p^0 \setminus q^0) \restriction i + 1).$$

(5) $\min(p^0 \setminus q^0) > \sup(\mathrm{ran}(f_{n^q}))$.

4.3 Definition. Let $p, q \in \mathcal{P}$. We say that p is a *direct extension of* q and denote this by $p \geq^* q$ iff

(1) $p \geq q$, and

(2) for every $\gamma \in \mathrm{supp}(q)$, $p^\gamma = q^\gamma$.

The following lemmas are analogous to the corresponding lemmas of the previous section and they have analogous proofs.

4.4 Lemma. *The relation $\leq$ is a partial order.*

4.5 Lemma. *Let $q \in \mathcal{P}$ and $\alpha < \kappa^{+m}$. Then there is a $p \geq^* q$ so that $\alpha \in \mathrm{supp}(p)$.*

4.6 Lemma. *$\langle \mathcal{P}, \leq \rangle$ satisfies the κ^{++}-c.c.*

For the proof of the last lemma, note only that the number of possibilities for the collapsing part $\langle f_0, , \dots, f_n \rangle, F$ of a condition (in the form of Definition 4.1) is κ^+. It is important that F depends only on the normal ultrafilter of the extender. This way F can be viewed as an element of $\mathrm{Col}(\kappa, i_\kappa(\kappa))$ of $N_\kappa \simeq \mathrm{Ult}(V, U_\kappa)$, which (in V) has cardinality κ^+. Once allowing F to depend on the extender itself, say on the maximal coordinate of a condition, we will have the correspondence to $\mathrm{Col}(\kappa, j(\kappa))$ of $M \simeq \mathrm{Ult}(V, E)$. This set is of cardinality $> \kappa^+$ (in V) and using it, it is easy to produce κ^{++} incompatible conditions.

If $p \in \mathcal{P}$ and $\tau \in p^0$, then the set $\mathcal{P}/p$ of all extensions of p in $\mathcal{P}$ can be split in the obvious fashion into two parts: one everything above τ and the second everything below τ. Denote them by $(\mathcal{P}/p)^{\geq \tau}$ and $(\mathcal{P}/p)^{<\tau}$. Then $\mathcal{P}/p$ can be viewed as $(\mathcal{P}/p)^{\geq \tau} \times (\mathcal{P}/p)^{<\tau}$. The part $(\mathcal{P}/p)^{<\tau}$ consists of finitely many Levy collapses and the part $(\mathcal{P}/p)^{\geq \tau}$ is similar to $\mathcal{P}$ but has a slight advantage, namely the Levy collapses used in it are τ^{+m+1}-closed. Using this observation, one can show the following analog of Lemma 3.11(b):

4.7 Lemma. *If $p \in \mathcal{P}$ and $\tau \in p^0$, then $\langle (\mathcal{P}/p)^{\geq \tau}, \leq^* \rangle$ is τ^{+m+1}-closed.*

Let us now turn to the Prikry condition.

4.8 Lemma. *$\langle \mathcal{P}, \leq, \leq^* \rangle$ satisfies the Prikry condition.*

Proof. Let σ be a statement of the forcing language and $q \in \mathcal{P}$. We shall find $p \geq^* q$ deciding σ. In order to simplify notation, assume that $q = \emptyset$.

Pick an elementary submodel N, $\alpha < \kappa^{+m}$ and T as in Lemma 3.12. Consider condition $\{\langle \alpha, \emptyset, T \rangle\}$. More precisely, we should write $\{\langle 0, \emptyset, \emptyset, \emptyset \rangle \cup \{\langle \alpha, \emptyset, T \rangle\}$. But when the meaning is clear we shall omit $\{\langle 0, \emptyset, \emptyset, \emptyset \rangle\}$. If for some $p \in N$ $\{\langle 0, \emptyset, f, F \rangle\} \cup p \cup \{\langle \alpha, \emptyset, T' \rangle\} \in \mathcal{P}$ and decides σ, for some $T' \subseteq T, f$ and F, then we are done. Suppose otherwise.

As in the proof of Lemma 3.12 we first show that it is possible to deal with conditions having fixed support. Once the support is fixed the proof will be more or less like that of Lemma 1.20, with small complications due to the involvement of collapses.

4.8.1 Claim. *There are p, F and S in N so that*

(a) $\{\langle 0,\emptyset,\emptyset,F\rangle\}\cup p\cup\{\langle\alpha,\emptyset,S\rangle\}\geq^*\{\langle\alpha,\emptyset,T\rangle\}$.

(b) If for some $q\in N$, q^0, q^α, F', T' and $\vec{f}$,

$$\{\langle 0,q^0,\vec{f},F'\rangle\}\cup q\cup\{\langle\alpha,q^\alpha,T'\rangle\}$$

is a an extension of $\{\langle 0,\emptyset,\emptyset,F\rangle\}\cup p\cup\{\langle\alpha,\emptyset,T^*\rangle\}$ and forces σ (or $\neg\sigma$) then also

$$\{\langle 0,q^0,(\vec{f}\restriction\mathrm{length}(q^0))^\frown F(q^0),F\rangle\}\cup(p)_{q^\alpha}\cup\{\langle\alpha,q^\alpha,S_{q^\alpha}\rangle\}$$

forces the same, where $(p)_{q^\alpha}$ is the set $\{\langle\gamma,p^{\gamma\frown}t^\gamma\rangle\mid\gamma\in\mathrm{supp}(p)\}$ with t^γ the maximal final segment of $\pi_{\alpha\gamma}$"q^α permitted for p^γ.

Proof. Let A denote $\mathrm{Suc}_T(\langle\rangle)$. Assume that $A\subseteq\kappa$ and for $\nu_1,\nu_2\in A$, $\nu_1<\nu_2$ implies $\nu_1^0<\nu_2^0$. Also assume that only the elements of A appear in T, i.e. $T\subseteq[A]^{<\omega}$. Let $\{\langle q_i^0,\vec{f}_i,q_i^\alpha\rangle\mid i<\kappa\}$ be an enumeration of all triples $\langle q^0,\vec{f},q^\alpha\rangle$ such that

(i) $q^\alpha\in T$.

(ii) $q^0=\pi_{\alpha 0}$"q^α.

(iii) If $q^0=\langle\tau_0,\dots,\tau_{n-1}\rangle$ then $\mathrm{dom}(\vec{f})=n$ and $\vec{f}(0)\in\mathrm{Col}(\omega,\tau_0)$, $\vec{f}(1)\in\mathrm{Col}(\tau_0^{+m+1},\tau_1),\dots,\vec{f}(n-1)\in\mathrm{Col}(\tau_{n-2}^{+m+1},\tau_{n-1})$. (Note that we do not enumerate the "last" function from $\mathrm{Col}(\tau_{n-1}^{+m+1},\kappa)$.)

For every $\nu\in A$, $|\{\rho\in A\mid\rho^0=\nu^0\}|\leq(\nu^0)^{+m}$. So, the number of such triples satisfying $q^0(i)\leq\nu^0$ for every $i\leq$ length(q^0) is at most $(\nu^0)^{+m}$. We can assume that $\{\langle q_i^0,\vec{f}_i,q_i^\alpha\rangle\mid i<(\nu^0)^{+m}\}=\{\langle q^0,\vec{f},q^\alpha\rangle\mid\langle q^0,\vec{f},q^\alpha\rangle$ satisfy the conditions (i), (ii), (iii) above and $q^0(i)\leq\nu^0$ for every $i\leq\mathrm{length}(q^0)\}$.

Define by recursion sequences $\langle p_i\mid i<\kappa\rangle$, $\langle T^i\mid i<\kappa\rangle,\langle f^i\mid i<\kappa\rangle$ and $\langle F^i\mid i<\kappa\rangle$. Set $p_0=\emptyset$, $T^0=T$, $f^0=\emptyset$ and $F^0=\emptyset$.

Suppose that p_j, T^j and F^j are defined for every $j<i$. Define p_i, T^i, f^i and F^i.

Set first $p_i''=\bigcup_{j<i}p_j$. Let $p_i'=\{\langle\gamma,p'^\gamma\rangle\mid\gamma\in\mathrm{supp}(p_i'')\}$, where for $\gamma\in\mathrm{supp}(p_i'')$, $p_i'^\gamma=p_i''^\gamma$ unless there is a $\nu\in q_i^\alpha$ permitted for $p_i''^\gamma$ and then $p_i'^\gamma=p_i''^{\gamma\frown}$ the maximal final segment of $\pi_{\alpha\gamma}$"q_i^α permitted for $p_i''^\gamma$.

We now wish to define a function F' on the set $q_i^{0\frown}(T_{q_i^\alpha})^0=_{df}\{q_i^{0\frown}\langle\eta\rangle\mid\langle\eta\rangle\in(T_{q_i^\alpha})^0\}$. Let $\langle\eta\rangle\in(T_{q_i^\alpha a})^0$ (it may be just the empty sequence). Consider the set

$$C=\{j<i\mid q_i^{0\frown}\langle\eta\rangle\text{ extends }q_j^0\text{ and }q_i^{0\frown}\langle\eta\rangle\in q_j^{0\frown}(T^j)^0\}.$$

For every $j\in C$ we have

$$q_j^0(\mathrm{length}(q_j^0)-1)\leq q_i^{0\frown}\langle\eta\rangle(\mathrm{length}(q_i^{0\frown}\langle\eta\rangle)-1).$$

Then, by the properties of the enumeration $\{\langle q^0_\nu, \vec{f}_\nu, q^\alpha_\nu\rangle \mid \nu < \kappa\}$ we have $j < (q^0_i{}^\frown\langle\eta\rangle(\mathrm{length}(q^0_i{}^\frown\langle\eta\rangle) - 1))^{+m}$. So

$$C \subseteq (q^0_i{}^\frown\langle\eta\rangle(\mathrm{length}(q^0_i{}^\frown\langle\eta\rangle) - 1))^{+m}.$$

Now define

$$F'(q^0_i{}^\frown\langle\eta\rangle) = \bigcup_{j\in C} F^j(q^0_i{}^\frown\langle\eta\rangle).$$

Then

$$F'(q^0_i{}^\frown\langle\eta\rangle) \in \mathrm{Col}(q^0_i{}^\frown\langle\eta\rangle(\mathrm{length}(q^0_i{}^\frown\langle\eta\rangle) - 1)^{+m+1}, \kappa),$$

since $|C| \le q^0_i{}^\frown\langle\eta\rangle(\mathrm{length}(q^0_i{}^\frown\langle\eta\rangle) - 1)^{+m}$. Define

$$r^i = \{\langle q^0_i, \vec{f}_i{}^\frown F'(q^0_i), F'\rangle\} \cup p'_i \cup \{\langle \alpha, q^\alpha_i, T_{q^\alpha_i}\rangle\}.$$

If $r^i \notin \mathcal{P}$ or it belongs to $\mathcal{P}$ and there is no $p \in N, T', g$ and F so that $\{\langle 0, q^0_i, \vec{f}_i{}^\frown g, F\rangle\} \cup p \cup \{\langle\alpha, q^\alpha_i, T'\rangle\} \in \mathcal{P}$ extends r^i and decides σ, then set $p_i = p''_i$, $T^i = T_{q^\alpha_i}$, $f^i = F'(q^0_i)$ and $F^i = F'$. Otherwise, pick some p, T', g and F witnessing this. Then define $T^i = T'$, $F^i = F$, $f^i = g$, $F^i(q^0_i) = f^i$. Set $p_i = p''_i \cup p^*$, where $p^* = p \setminus p'_i$.

This completes the recursive definition. Set $p = \bigcup_{i<\kappa} p_i$. Now define a subtree S of T by putting together all the T^i's for $i < \kappa$. The definition is level by level. Thus, if S is defined up to level n and t sits in S on this level, then set

$$\begin{aligned}\mathrm{Suc}_S(t) = \{\nu \in A \mid \nu^0 > \max(t),\ &\text{and for every } i < \nu^0,\\ &\nu \in \mathrm{Suc}_{T^i}(\langle\rangle) \text{ and } \nu \in \mathrm{Suc}_{T^i}(t) \text{ when } t \in T^i\}.\end{aligned}$$

So $\mathrm{Suc}_S(t) \in U_\alpha$.

Let us now put together all the F^i's. Define a function F on a tree $(S)^0$.

Thus let $\eta \in S^0$. Consider the set $C = \{j < \kappa \mid q^0_j \subseteq \eta \in q^0_j{}^\frown(T^j)^0\}$. Let $\ell = \mathrm{length}(\eta) - 1$. Then for each $j \in C$ $q^0_j(\mathrm{length}(q^0_j) - 1) \le \eta(\ell)$. So, by the choice of the enumeration $\{\langle q^0_\nu, \vec{f}_\nu, q^\alpha_\nu\rangle \mid \nu < \kappa\}$ we have $j < \eta(\ell)^{+m}$. Hence $C \subseteq \eta(\ell)^{+m}$. Define $F(\eta) = \bigcup_{j\in C} F^j(\eta)$. Then $F(\eta) \in \mathrm{Col}(\eta(\ell)^{+m+1}, \kappa)$.

4.8.2 Subclaim. $\{\langle 0, \emptyset, \emptyset, F\rangle\} \cup p \cup \{\langle\alpha, \emptyset, S\rangle\} \in \mathcal{P}$.

Proof. The only problem is to show that for every $\nu \in \mathrm{Suc}_S(\langle\rangle)$,

$$|\{\gamma \in \mathrm{supp}(p) \mid \nu \text{ is permitted for } p^\gamma\}| \le \nu^0.$$

Thus let $\nu \in \mathrm{Suc}_S(\langle\rangle)$ and $i < \kappa$. If $\langle q^0_i, \vec{f}_i, q^\alpha_i\rangle$ satisfies $\max(q^0_i) < \nu^0$, then $i < \max(q^0_i)^{+m} < \nu^0$. Hence for every $i \ge \nu^0$, ν is not permitted for q^0_i. So after the stage ν^0 we did not add any new coordinate γ with ν permitted for $(p_i)^\gamma$. This means that $\{\gamma \in \mathrm{supp}(p) \mid \nu$ is permitted for $p^\gamma\} = \bigcup_{i<\nu^0}\{\gamma \in \mathrm{supp}(p_i) \mid \nu$ is permitted for $p^\gamma\}$ and we are done. ⊣

Denote $\{\langle 0, \emptyset, \emptyset, F\rangle\} \cup p \cup \{\langle \alpha, \emptyset, S\rangle\}$ by p^*. We now show that p^* is as desired. Clearly, $p^* \geq^* \{\langle \alpha, \emptyset, T\rangle\}$. Suppose that for some $q \in N$, q^0, q^α, G R and $\vec{f}$

$$\{\langle 0, q^0, \vec{f}, G\rangle\} \cup q \cup \{\langle \alpha, q^\alpha, R\rangle\} \geq p^*$$

and

$$\{\langle 0, q^0, \vec{f}, G\rangle\} \cup q \cup \{\langle \alpha, q^\alpha, R\rangle\} \Vdash \sigma \quad (\text{or } \neg\sigma)$$

Let $q^0 = \langle \tau_1, \ldots, \tau_n\rangle$ and $\vec{f} = \langle f_0, \ldots, f_n\rangle$. Obviously, $n > 0$ since otherwise we will have a direct extension of p^* (and hence of $\{\langle \alpha, \emptyset, T\rangle\}$) deciding σ contrary to the initial assumption. Find $i < \tau_n^{+m}$ such that $\langle q^0, \langle f_0, \ldots, f_{n-1}\rangle, q^\alpha\rangle = \langle q_i^0, \vec{f_i}, q_i^\alpha\rangle$. Consider the condition

$$r^i = \{\langle q_i^0, \vec{f_i}{}^\frown F'(q_i^0), F'\rangle\} \cup p_i' \cup \{\langle \alpha, q_i^\alpha, T_{q_i^\alpha}\rangle\},$$

defined at stage i of the construction. We have

$$\{\langle 0, q^0, \vec{f}, G\rangle\} \cup q \cup \{\langle \alpha, q^\alpha, R\rangle\} \geq^* r^i,$$

since $R \subseteq S_{q^\alpha} \subseteq T_{q^\alpha}$, $F'(\eta) \subseteq F(\eta)$ for η's from the common domain, so that in particular, $F'(q_i^0) \subseteq F(q_i^0) \subseteq f_n$. But then

$$\{\langle 0, q_i^0, \vec{f_i}{}^\frown f^i, F^i\rangle\} \cup (p_i)_{q_i^\alpha} \cup \{\langle \alpha, q_i^\alpha, T^i_{q_i^\alpha}\rangle\} \Vdash \sigma \quad (\text{or } \neg\sigma)$$

by the choice of f^i, F^i, T^i and p_i at the stage i of the construction. Hence also

$$\{\langle 0, q^0, \langle f_0, \ldots, f_{n-1}, F(q^0)\rangle, F\rangle\} \cup (p)_{q^\alpha} \cup \{\langle \alpha, q^\alpha, S_{q^\alpha}\rangle\}$$

forces the same. This completes the proof Claim 4.8.1. ⊣

Fix $p^* = \{\langle 0, \emptyset, \emptyset, F\rangle\} \cup p \cup \{\langle \alpha, \emptyset, S\rangle\}$ satisfying the conclusion of Claim 4.8.1.

As in Lemma 3.12, it is possible to show that the assumption "$q \in N$" is not really restrictive. Briefly, if there is some q outside of N which is used to decide σ, then there exists one also inside N. So the following claim will provide the desired contradiction.

4.8.3 Claim. *There is a*

$$p^{**} = \{\langle 0, \emptyset, \emptyset, F{\restriction}T^*\rangle\} \cup p \cup \{\langle \alpha, \emptyset, T^*\rangle\} \geq^* p^*$$

such that the following holds:

$(*)$ *There are no $q \in N, q^0, q^\alpha, \vec{f}, F'$ and T' such that*

$$p^{**} \leq \{\langle 0, q^0, \vec{f}, F'\rangle\} \cup q \cup \{\langle \alpha, q^\alpha, T'\rangle\} \parallel \sigma.$$

Proof. We shall construct by recursion a $\le^*$-increasing sequence $\langle p(\ell) \mid \ell \le \omega\rangle$ of direct extensions of p^* satisfying for every $\ell \le \omega$ the following condition:

$(*)_\ell$ There are no $q \in N$, q^0, q^α, $\vec{f}$, F' and T' such that length$(q^0) \le \ell$ and

$$p(\ell) \le \{\langle 0, q^0, \vec{f}, F'\rangle\} \cup q \cup \{\langle \alpha, q^\alpha, T'\rangle\} \parallel \sigma.$$

Clearly, then $p(\omega)$ will be as desired.

Set $p(0) = p^*$. Define $p(1)$ to be a condition of the form $\{\langle 0, \emptyset, \emptyset, F\restriction T_1\rangle\} \cup p \cup \{\langle \alpha, \emptyset, T_1\rangle\}$ with T_1 defined below. Consider the three sets

$$\begin{aligned} X_i = \big\{&\nu \in \mathrm{Suc}_S(\langle\rangle) \mid \exists f_0^\nu \in \mathrm{Col}(\omega, \nu^0) \\ &\big(\{\langle 0, \langle \nu^0\rangle, f_0^\nu{}^\frown F(\langle \nu^0\rangle), F\rangle\} \cup p_{\langle\nu\rangle} \cup \{\langle \alpha, \langle\nu\rangle, S_{\langle\nu\rangle}\rangle\} \ \Vdash {}^i\sigma\big)\big\}, \end{aligned}$$

where $i < 2$, ${}^0\sigma = \sigma$ and ${}^1\sigma = \neg\sigma$, and

$$X_2 = \mathrm{Suc}_S(\langle\rangle) \setminus (X_0 \cup X_1).$$

There is an $i < 3$ such that $X_i \in U_\alpha$. Let T_1' be the tree obtained from S by intersecting all its levels with X_i. Let $r = \{\langle 0, \emptyset, \emptyset, F\restriction T_1'\rangle\} \cup p \cup \{\langle \alpha, \emptyset, T_1'\rangle\}$. If there is no $q \in N, \vec{f}, \nu, F'$ and T' such that

$$r \le \{\langle 0, \langle \nu^0\rangle, \vec{f}, F'\rangle\} \cup q \cup \{\langle \alpha, \langle\nu\rangle, T'\rangle\} \parallel \sigma,$$

then set $T_1 = T_1'$ and $p(1) = r$. We claim that this is the only possible case. Otherwise, pick $q, \vec{f} = \langle f_0, f_1\rangle, \nu, F'$ and T' witnessing this and, say, forcing σ. By the previous claim, then

$$\{\langle 0, \langle \nu^0\rangle, f_0{}^\frown F(\nu^0), F\rangle\} \cup p_{\langle\nu\rangle} \cup \{\langle \alpha, \langle\nu\rangle, (T_1')_{\langle\nu\rangle}\rangle\} \Vdash \sigma.$$

By the choice of T_1', then $X_0 \in U_\alpha$. Hence, for every $\nu \in \mathrm{Suc}_{T_1}(\langle\rangle)$ there is an $f_0^\nu \in \mathrm{Col}(\omega, \nu^0)$ such that

$$\{\langle 0, \langle \nu^0\rangle, f_0^\nu{}^\frown F(\langle \nu^0\rangle), F\rangle \cup p_{\langle\nu\rangle} \cup \{\langle \alpha, \langle\nu\rangle, (T_1')_{\langle\nu\rangle}\rangle\} \Vdash \sigma.$$

Note that the function taking ν^0 to f_0^ν is actually a regressive function on $(X_0)^0$. Find $Y \in U_\alpha$ and $f^* \in \mathrm{Col}(\omega, \kappa)$ such that for every $\nu \in Y$, $f_0^\nu = f^*$. Let T_1 be a tree obtained from T_1' by shrinking all its levels to Y. Set $F_1 = F\restriction T_1$. Finally, let

$$p(1) = \{\langle 0, \emptyset, f^*, F_1\rangle\} \cup p \cup \{\langle \alpha, \emptyset, T_1\rangle\}.$$

By the construction, $p^* \le^* p(1) \Vdash \sigma$, which contradicts the assumption that it is impossible to decide σ by direct extensions of p^*.

Let us define $p(2) = \langle 0, \emptyset, \emptyset, F\restriction T_2\rangle \cup p \cup \{\langle \alpha, \emptyset, T_2\rangle\}$ now. Fix a $\nu \in \mathrm{Suc}_{T^1}(\langle\rangle)$. Let $\{\langle f_i, \nu_i\rangle \mid 1 \le i < (\nu^0)^{+m}\}$ be the enumeration of all pairs $\langle f, \rho\rangle$ such that $\rho \in \mathrm{Suc}_{T_1}(\langle\rangle)$, $\rho^0 = \nu^0$ and $f \in \mathrm{Col}(\omega, \nu^0)$. We would first like to define $T_{2\langle\rho\rangle}$ for every $\rho \in \mathrm{Suc}_{T_1}(\langle\rangle)$ with $\rho^0 = \nu^0$. In order to do this define by recursion on $i < (\nu^0)^{+m}$ sets S_i as follows: for $i = 0$ let $S_0 = (T_1)_{\langle\nu\rangle}$. Suppose that S_j is defined for every $j < i$. Set $S = (\bigcap_{j<i} S_j) \cap (T_1)_{\langle\nu_i\rangle}$. Consider a condition

$$r = \{\langle 0, \langle\nu^0\rangle, f_i, F(\langle\nu^0\rangle), F{\restriction}S\rangle\} \cup (p)_{\langle\nu_i\rangle} \cup \{\langle\alpha, \langle\nu_i\rangle, S\rangle\}.$$

Clearly, $r \geq p(1)$. By the choice of $p(1)$, neither r or its direct extensions decide σ. Then, the construction of $p(1)$ from $p(0)$ applied to r (instead of $p(0)$) will produce

$$r^i = \{\langle 0, \langle\nu^0\rangle, f_i, F(\langle\nu^0\rangle), F{\restriction}S_i\rangle\} \cup (p)_{\nu_i} \cup \{\langle\alpha, \langle\nu_i\rangle, S_i\rangle\} \geq^* r$$

satisfying the following: There are no $q \in N, \rho, g_1, g_2, F', S'$ such that

$$r^i \leq \{\langle 0, \langle\nu^0, \rho^0\rangle, \langle f_i, g_1, g_2\rangle, F'\rangle\} \cup (p)_{\langle\nu_i,\rho\rangle} \cup \{\langle\alpha, \langle\nu_i, \rho\rangle, S'\rangle\} \parallel \sigma.$$

Now let $(T_2)_{\langle\nu^0\rangle} = \bigcap_{j<(\nu_0)^{+m}} S_j$. Define T_2 to be the tree obtained from T_1 by replacing $(T_1)_{\langle\nu\rangle}$ by $(T_2)_{\langle\nu^0\rangle}$ for each $\nu \in \mathrm{Suc}_{T_1}(\langle\rangle)$. Set $p(2) = \{\langle 0, \emptyset, \emptyset, F{\restriction}T_2\rangle\} \cup p \cup \{\langle\alpha, \emptyset, T_2\rangle\}$. It is easy to see that $p(2)$ satisfies $(*)_2$.

We continue in the same fashion and define $p(n) = \{\langle 0, \emptyset, \emptyset, F{\restriction}T_n\rangle\} \cup p \cup \{\langle\alpha, \emptyset, T_n\rangle\}$ satisfying $(*)_n$ for every n, $2 \leq n < \omega$. Finally let $T_\omega = \bigcap_{n<\omega} T_n$. Set $p(\omega) = \{\langle 0, \emptyset, \emptyset, F{\restriction}T_\omega\rangle \cup p \cup \{\langle\alpha, \emptyset, T_\omega\}$. Then $p(\omega)$ will satisfy $(*)_n$ for every $n < \omega$ and hence $(*)$. ⊣

This completes the proof of Lemma 4.8. ⊣

Using Lemma 4.8 as a replacement for Lemma 3.12, the arguments of Lemma 3.12 show the following:

4.9 Lemma. *κ^+ remains a cardinal in $V^{\mathcal{P}}$.*

Lemma 3.13 transfers directly to the present forcing notion. Thus for G a generic subset of $\mathcal{P}$ and $\alpha < \kappa^{+m}$ define and G^α, as in Sect. 3, as to be $\bigcup\{p^\alpha \mid p \in G\}$. Let $G^0 = \langle\kappa_0, \kappa_1, \ldots, \kappa_n, \ldots\rangle$.

4.10 Lemma.

(a) For every $\alpha < \kappa^{+m}$, G^α is a Prikry sequence for U_α.

(b) G^0 is an ω-sequence unbounded in κ.

(c) If $\alpha \neq \beta$ are then $G^\alpha \neq G^\beta$.

Let $\alpha < \kappa^{+m}$ and $G^\alpha = \langle\nu_0, \nu_1, \ldots, \nu_n, \ldots\rangle$. An easy density argument provides an $n(\alpha) < \omega$ such that either

(i) for all but finitely many n's, $\nu^0_{n+n(\alpha)} = \kappa_n$, or

(ii) for all but finitely many n's, $\nu^0_n = \kappa_{n+n(\alpha)}$.

Transform G^α into a sequence $G'^\alpha = \langle \nu'_0, \nu'_1, \ldots, \nu'_n, \ldots\rangle$ defined as follows:

$$\nu'_n = \begin{cases} \nu_{n+n(\alpha)}, & \text{if (a) holds,} \\ \nu_{n-n(\alpha)}, & \text{if (b) holds and } n \geq n(\alpha)\text{, and} \\ \kappa_n, & \text{if (b) holds and } n < n(\alpha). \end{cases}$$

Then, for every $n < \omega$, $(\nu'_n)^0 = \kappa_n$.

Assaf Sharon [50] showed that $\langle G'^\alpha \mid \alpha < \kappa^{+m}\rangle$ is a scale in $\prod_{n<\omega} \kappa_n^{+m}$, i.e. every member of $\prod_{n<\omega} \kappa_n^{+m}$ is dominated by one of the G'^α's and $\alpha < \beta$ implies that G'^β dominates G'^α.

The next lemma is obvious.

4.11 Lemma. *If $\aleph_0 < \tau < \kappa$ and τ remains a cardinal in $V[G]$, then for some n and for some $m' \leq m$, $\tau = \kappa_n^{+m'+1}$.*

Implementing $\mathrm{Col}(\nu, \nu^+)$'s also, Sharon [50] was able to collapse each κ_n^+ as well. Thus in his model $\kappa_n^{+m'+1}$ for $1 \leq m' \leq m$ are the only uncountable cardinals below κ. Notice that $\langle \kappa_n^+ \mid n < \omega\rangle$ and $\langle \kappa_n^{+m+1} \mid n < \omega\rangle$ are Prikry sequences for U_{κ^+} and $U_{\kappa^{+m+1}}$ and so correspond to κ^+ and κ^{+m+1} of the ultrapower M by $(\kappa, \kappa+m)$-extender E. So, in V, $\mathrm{cf}((\kappa^{+m+1})^M) = \kappa^+$. Also $\langle \kappa_{n+1} \mid n < \omega\rangle$ may be viewed as a sequence corresponding to $j(\kappa)$ which again has cofinality κ^+. Hence, the collapses involved collapse between members of the same cofinality.

Now combining all the lemmas, we obtain the following.

4.12 Theorem. *In a generic extension $V[G]$, $2^{\aleph_n} = \aleph_{n+1}$ for every $n < \omega$ and $2^{\aleph_\omega} = \aleph_{\omega+m}$.*

5. Forcing Uncountable Cofinalities

In the previous sections we dealt with a singular κ of cofinality $\aleph_0$ or changed the cofinality of a regular κ to $\aleph_0$. Here we would like to deal with forcings changing cofinality to an uncountable value. The first such forcing was introduced by Magidor [37]. It changed the cofinality of a regular κ to any prescribed regular value δ below κ. The Magidor forcing adds a closed unbounded in κ sequence of order type δ instead of an ω-sequence added by the Prikry forcing in Definition 1.1. The initial assumption used for this was stronger than just measurability. A measurable cardinal κ of the Mitchell order δ, i.e. $o(\kappa) = \delta$, was used. Later Mitchell [45] showed that this assumption is optimal. Lon Radin [48] defined a forcing of the same flavor which not only could change the cofinality of κ to $\delta < \kappa$ by shooting a closed unbounded δ-sequence, but also adding a closed unbounded κ-sequence preserving regularity and even measurability of κ. It is not a big deal to add a closed unbounded subset to a regular κ preserving its regularity and also measurability. But what is special about the Radin club is that it consists of cardinals which were regular in the ground model and this way combines together a variety of ways of changing cofinalities. This feature allows results of global character in the cardinal arithmetic. Thus, shortly after the discovery of the Radin forcing, Foreman and Woodin [12] constructed a model satisfying $2^\tau > \tau^+$ for every τ and Woodin produced a model with $2^\tau = \tau^{++}$ for every τ. Later James Cummings [9] constructed a model with $2^\tau = \tau^+$ for every regular τ and $2^\tau = \tau^{++}$ for every singular cardinal τ. Recently, Carmi Merimovich [39, 40] obtained additional results of this type introducing extender-based Radin forcing.

5.1. Radin Forcing

Here we will give the basics of Radin forcing. A comprehensive account on the matter containing various beautiful results of Woodin using Radin forcing should appear in the book by Cummings and Woodin [10]. Originally Radin [48] and then Mitchell [42] defined this forcing axiomatically. We will follow a more concrete approach due to Woodin.

Let $j : V \to M$ be an elementary embedding of V into transitive inner model M, with critical point κ. Define a normal ultrafilter $U(0)$ over κ:

$$X \in U(0) \quad \text{iff} \quad \kappa \in j(X).$$

If $U(0) \in M$, then we define a κ-complete ultrafilter $U(1)$, only not over κ but over V_κ:

$$X \in U(1) \quad \text{iff} \quad \langle \kappa,\ U(0)\rangle \in j(X).$$

Such defined $U(1)$ concentrate on pairs $\langle \nu, F\rangle$ so that ν is a measurable cardinal below κ and F is a normal ultrafilter over ν.

If $U(1) \in M$, then we can continue and define a κ-complete ultrafilter $U(2)$ over V_κ:

$$X \in U(2) \quad \text{iff} \quad \langle \kappa, U(0), U(1)\rangle \in j(X).$$

Continue by recursion and define a sequence

$$\vec{U} = \langle \kappa, U(0), U(1), \ldots, U(\alpha), \ldots \mid \alpha < \operatorname{length}(\vec{U})\rangle,$$

where each $U(\alpha)$ will be a κ-complete ultrafilter over V_κ:

$$X \in U(\alpha) \quad \text{iff} \quad \vec{U}\restriction\alpha = \langle \kappa, U(0), U(1), \ldots, U(\beta), \ldots \mid \beta < \alpha\rangle \in j(X),$$

and $\operatorname{length}(\vec{U})$ will be the least α with $\vec{U}\restriction\alpha \notin M$. For example, if $M \supseteq \mathcal{P}(\mathcal{P}(\kappa))$, then $\operatorname{length}(\vec{U})$ will be at least $(2^\kappa)^+$, as we will see below. Let us call $\vec{U}$ and $\vec{U}\restriction\alpha$ $(0 < \alpha < \operatorname{length}(\vec{U}))$ *j-sequences of ultrafilters*.

Fix some α^* with $0 < \alpha^* \le \operatorname{length}(\vec{U})$. Let $\vec{V} = \vec{U}\restriction\alpha^*$. We want to define Radin forcing with the ultrafilter sequence $\vec{V}$. Denote it by $R_{\vec{V}}$. As usual, it will have two orders $\le$ and $\le^*$.

Let us deal first with $\alpha^* = 1$ and $\alpha^* = 2$. Thus, for $\alpha^* = 1$, $\vec{V} = \langle \kappa, U(0)\rangle$. Let $\langle R_{\vec{V}}, \le, \le^*\rangle$ be the usual Prikry forcing with $U(0)$ of Definition 1.1, only instead of writing $\langle t, A\rangle$ (where t is an increasing finite sequence and $A \in U(0)$) we shall write $\langle t, \langle \kappa, U(0)\rangle, A\rangle$.

Now let $\alpha^* = 2$. Then $\vec{V} = \langle \kappa, U(0), U(1)\rangle$. We would like to incorporate both $U(0)$ and $U(1)$ in the process generating the generic cofinal sequence. Thus instead of $A \in U(0)$ in the previous case we allow two sets $A_0 \in U(0)$ and $A_1 \in U(1)$, or equivalently, a set in $U(0) \cap U(1)$. Notice, that we can separate $U(0)$ and $U(1)$ since $U(0)$ concentrates on ordinals and $U(1)$ on pairs $\langle \nu, F\rangle$ with F a normal ultrafilter over ν. An initial condition in $R_{\vec{V}}$ will have a form

$$p = \langle\langle \kappa, U(0), U(1)\rangle, A\rangle$$

with $A \in U(0) \cap U(1)$ and require also that each $a \in A$ is either an ordinal or a pair consisting of a measurable cardinal and a normal ultrafilter over it. In order to extend p pick $a \in A$ and $B \subseteq A$, with $B \in U(0) \cap U(1)$ such that the rank of each member of B is above $\text{rank}(a) + 1$. If a is an ordinal then just add it. We will obtain a one-step extension of p

$$\langle a, \langle\langle \kappa, U(0), U(1)\rangle, B\rangle\rangle.$$

If $a = \langle \nu, F\rangle$, then consider $A \cap \nu$. a can be added to p only if this set is in F. Notice that the set $X_A = \{\langle \nu', F'\rangle \mid A \cap \nu' \in F'\} \in U(1)$ since $A \cap \kappa \in U_0$ and so in M, $\langle \kappa, U_0\rangle \in j(X_A)$. If $A \cap \nu \in F$, then let $B_\nu \in F$ be a subset of $A \cap \nu$. The following will be one-step extension of p:

$$\langle\langle\langle \nu, F\rangle, B_\nu\rangle, \langle\langle \kappa, U(0), U(1)\rangle, B\rangle\rangle.$$

Consider a one-step extension $\langle d, \langle\langle \kappa, U(0), U(1)\rangle, B\rangle\rangle$. If d is an ordinal then repeat the recipe of one-step extension described above. Suppose that $d = \langle\langle \nu, F\rangle, B_\nu\rangle$. We now have two alternatives. The first, just as at step one, is to add an ordinal or a pair but between ν and κ. The second is to add an element of B_ν. Thus $\langle \nu, F\rangle$ will be responsible for producing a Prikry sequence for F. This way, generically a sequence of the type ω^2 will be produced.

We now turn to the general case and give a formal definition of $R_{\vec{V}}$ the Radin forcing with the sequence of ultrafilters $\vec{V}$. First let us introduce some notation. Thus, for a sequence $\vec{F} = \langle F(0), \ldots, F(\tau), \ldots \mid \tau < \text{length}(\vec{F})\rangle$ let $\bigcap \vec{F} = \bigcap\{F(\tau) \mid \tau < \text{length}(\vec{F})\}$. For an ordinal $d = \nu$ or pair $d = \langle \nu, \vec{F}\rangle$ or a triple $d = \langle \nu, \vec{F}, B\rangle$ let us denote ν by $\kappa(d)$. For a triple $d = \langle \nu, \vec{F}, B\rangle$ by $d \in A$ we shall mean that the two first coordinates of d, i.e. $\langle \nu, \vec{F}\rangle$ belong to A.

The main idea behind this forcing is to use members of finite sequences (that it produces) to give rise to separate blocks that are themselves Radin forcings. In order to realize this idea let us first shrink a bit the possibilities of choosing these finite sequences. Let $\vec{F}$ be a sequence of ultrafilters over ν. We would like to use only $\vec{F}$'s which are j-sequences of ultrafilters for some $j : V \to M$. Also, we like to have a set $B \in \bigcap \vec{F}$ such that each member d of it is a j-sequence for some j with critical point $\kappa(d)$.

To achieve this let us define by recursion classes of sequences:

$$A^{(0)} = \{\vec{F} \mid \vec{F} \text{ is a } j\text{-sequence of ultrafilters for some } j : V \to M\}$$

$$A^{(n+1)} = \{\vec{F} \in A^{(n)} \mid \forall\alpha\ 0 < \alpha < \text{length}(\vec{F})\ (A^{(n)} \cap V_{\kappa(\vec{F})} \in F(\alpha))\}$$

$$\overline{A} = \bigcap\nolimits_{n<\omega} A^{(n)}.$$

The main feature of $\overline{A}$ is that if $\vec{F} \in \overline{A}$ then, for $0 < \alpha < \text{length}(\vec{F})$, $F(\alpha)$ concentrates on $\overline{A} \cap V_{\kappa(\vec{F})}$, since then $A^{(n)} \cap V_{\kappa(\vec{F})} \in F(\alpha)$ for every n and hence by countable completeness of $F(\alpha)$, also $\overline{A} \cap V_{\kappa(\vec{F})} \in F(\alpha)$.

Note that each measurable cardinal is in $\overline{A}$. But in the presence of stronger large cardinals, $\overline{A}$ turns out to be much wider. We will need the following statement proved by Cummings and Woodin [10]:

5.1 Lemma. *Let E be a (κ, λ)-extender and $j : V \to M \simeq \text{Ult}(V, E)$ the corresponding elementary embedding, so that $M \supseteq V_{\kappa+2}$ and ${}^{\kappa}M \subseteq M$. Let $\vec{U}$ be the j-sequence of ultrafilters of the maximal length. Then*

(a) $\text{length}(\vec{U}) \geq (2^\kappa)^+$.

(b) For every $\alpha < (2^\kappa)^+$, $\vec{U}{\restriction}\alpha \in \overline{A}$.

Proof. Note that ${}^{\alpha}V_{\kappa+2} \subseteq M$ for every $\alpha < (2^\kappa)^+$. Hence $\vec{U}{\restriction}\alpha \in M$ for every such α.

Let us first show that for every $\alpha < (2^\kappa)^+$, $\vec{U}{\restriction}\alpha \in A^{(1)}$. Equivalently, for every β, $0 < \beta < (2^\kappa)^+$, we need to show that $A^{(0)} \cap V_\kappa \in U(\beta)$. By the definition $\vec{U}$, this means that in M, $\vec{U}{\restriction}\beta \in j(A^0)$. So we need to find in M an embedding constructing $\vec{U}{\restriction}\beta$. Let E' be the extender $E{\restriction}[\beta]^{<\omega}$. Then $E' \in M$, since ${}^{\beta}V_{\kappa+2} \subseteq M$. Consider the following commutative diagram:

$$\begin{tikzcd} V \arrow[r, "j"] \arrow[dr, "j'"'] & M \arrow[r, "i"] & N \simeq \text{Ult}(M, E') \\ & M' \simeq \text{Ult}(V, E') \arrow[u, "k"'] & \end{tikzcd}$$

Now, it is not hard to see that $i = j'{\restriction}M$, since ${}^{\kappa}M \subseteq M$ and E' is an extender over κ. In particular, $i(\kappa) = j'(\kappa)$. Since ${}^{\kappa}V_{\kappa+2} \cap M = {}^{\kappa}V_{\kappa+2} \cap V$, we have $V_{j'(\kappa)+2} \cap N = V_{j'(\kappa)+2} \cap M'$. In addition, $\beta \subseteq \text{ran}(k)$, so $\text{crit}(k) \geq \max(\beta, \kappa^+)$. Let $\vec{U^*}$ be the i-sequence of ultrafilters constructed in M. We show by induction that $U^*(\gamma) = U(\gamma)$ for every $\gamma < \beta$. First note that $k(U) = U$ for every ultrafilter U over κ. Thus $\text{crit}(k) > \kappa$ implies that $U = k``U$. Also, clearly, $k``U \subseteq k(U)$. Finally, using $V_{\kappa+1} \cap M' = V_{\kappa+1} \cap M = V_{\kappa+1}$ and maximality of U as a filter we have $U = k(U)$.

Suppose now that $\gamma < \beta$ and we have already shown $\vec{U^*}{\restriction}\gamma = \vec{U}{\restriction}\gamma$. Let $X \subseteq V_\kappa$. Then $X \in U^*(\gamma)$ iff $\vec{U^*}{\restriction}\gamma \in i(X)$ iff $\vec{U}{\restriction}\gamma \in i(X)$ iff $\vec{U}{\restriction}\gamma \in j'(X)$ iff

$k(\vec{U}\restriction\gamma) \in j(X)$ (by elementarity of k and since $\vec{U}\restriction\gamma \in M'$) iff $\vec{U}\restriction\gamma \in j(X)$ iff $X \in U(\gamma)$ (since $k(\gamma) = \gamma$ and $k(U(\delta)) = U(\delta)$ for every $\delta < \gamma$).

This concludes the proof of $\vec{U}\restriction\alpha \in A^{(1)}$, for $\alpha < (2^\kappa)^+$. Let us show that $\vec{U}\restriction\alpha \in A^{(n)}$ for every n, $2 \leq n < \omega$ and $\alpha < (2^\kappa)^+$. First, for $n = 2$ we have

$$\begin{aligned} \vec{U}\restriction\alpha \in A^{(2)} \quad & \text{iff} \quad \forall\beta < \alpha\ A^{(1)} \cap V_\kappa \in \vec{U}\restriction\beta \\ & \text{iff} \quad \forall\beta < \alpha\ \vec{U}\restriction\beta \in j(A^{(1)}) \\ & \text{iff} \quad \forall\beta < \alpha \forall\gamma < \beta\ j(A^{(0)}) \cap V_\kappa \in U(\gamma). \end{aligned}$$

It is enough to show that $j(A^{(0)}) \cap V_\kappa = A^{(0)} \cap V_\kappa$, since we already proved that $A^{(0)} \cap V_\kappa \in U(\gamma)$ for every $\gamma < (2^\kappa)^+$. Let $\vec{F} \in V_\kappa$ be an i-sequence of ultrafilters for an embedding of either V or M with critical point $\nu = \kappa(\vec{F}) < \kappa$. The length of $\vec{F}$ is below κ, and κ is an inaccessible, so it is easy to find an extender inside V_κ such that the elementary embedding i' of it agrees with i long enough and constructs $\vec{F}$. Hence i' will witness both $\vec{F} \in j(A^{(0)})$ and $\vec{F} \in A^{(0)}$. The same argument works for any $n \geq 2$. Thus we will have

$$\vec{U}\restriction\alpha \in A^{(n)} \quad \text{iff} \quad \forall\gamma(\gamma + n \leq \alpha \to j^{n-1}(A^{(0)}) \cap V_\kappa \in U(\gamma)),$$

where j^{n-1} is an application of j $n-1$ many times, or equivalently the embedding $j_{0n-1} : V \to M_{n-1}$ of V into the $n-1$ times iterated ultrapower M_{n-1} of V by E. Again, as above $j^{n-1}(A^{(0)}) \cap V_\kappa = A^{(0)} \cap V_\kappa$. ⊣

Note that using stronger j's it is possible to show that longer ultrafilter sequences are in $\overline{A}$.

We are now ready to define Radin forcing. Let $\vec{V} = \langle U(\alpha) \mid \alpha < \text{length}(\vec{V})\rangle$ be a j-sequence of ultrafilters in $\overline{A}$ for some $j : V \to M$ with $\text{crit}(j) = \kappa$.

5.2 Definition. Let $R_{\vec{V}}$ be the set of finite sequences $\langle d_1, \ldots, d_n, \langle\kappa, \vec{V}\rangle, A\rangle$ such that

(1) $A \in \bigcap \vec{V}$ and $A \subseteq \overline{A}$.

(2) $A \cap V_{\kappa(d_n)+1} = \emptyset$.

(3) For every m with $1 \leq m \leq n$, either

(3a) d_m is an ordinal, or

(3b) $d_m = \langle\nu, \vec{F}_\nu, A_\nu\rangle$ for some $\vec{F}_\nu \in \overline{A}$, $A_\nu \subseteq \overline{A}$ and $A_\nu \in \bigcap \vec{F}_\nu$.

(4) For every $1 \leq i < j \leq n$,

(4a) $\kappa(d_i) < \kappa(d_j)$, and

(4b) if d_j is of the form $\langle\nu, F_\nu, A_\nu\rangle$ then $A_\nu \cap V_{\kappa(d_i)+1} = \emptyset$.

Each d_m of the form $\langle \nu, \vec{F}_\nu, A_\nu \rangle$ will give rise to Radin forcing $R_{\vec{F}_\nu}$ with $\vec{F}_\nu$ playing the same role as $\vec{V}$ in $R_{\vec{V}}$.

We define two orders $\leq$ and $\leq^*$ on $R_{\vec{V}}$, where, as usual, $\leq$ will be used to force and $\leq^*$ will provide the closure.

5.3 Definition. Let $p = \langle d_1, \ldots, d_n, \langle \kappa, \vec{V} \rangle, A \rangle$, $q = \langle e_1, \ldots, e_m, \langle \kappa, \vec{V} \rangle, B \rangle \in R_{\vec{V}}$. We say that p *is stronger than* q and denote this by $p \geq q$ iff

(1) $A \subseteq B$.

(2) $n \geq m$.

(3) There are $1 \leq i_1 < i_2 < \cdots < i_m \leq n$ such that for $1 \leq k \leq m$, either

  (3a) $e_k = d_{i_k}$, or

  (3b) $e_k = \langle \nu, \vec{F}_\nu, B_\nu \rangle$ and then $d_{i_k} = \langle \nu, \vec{F}_\nu, C_\nu \rangle$ with $C_\nu \subseteq B_\nu$.

(4) Let $i_1, \ldots, i_m$ be as in (3). Then the following holds for every j, $1 \leq j \leq n$:

  (4a) if $j > i_m$, then $d_j \in B$ or d_j is of the form $\langle \nu, \vec{F}_\nu, C_\nu \rangle$ with $\langle \nu, \vec{F}_\nu \rangle \in B$ and $C_\nu \subseteq B \cap \nu$;

  (4b) if $j < i_m$, then for the least k with $j < i_k$, e_k is of the form $\langle \nu, \vec{F}_\nu, B_\nu \rangle$ so that

    (i) if d_j is an ordinal then $d_j \in B_\nu$, and

    (ii) if $d_j = \langle \rho, \vec{T}, S \rangle$ then $\langle \rho, \vec{T} \rangle \in B_\nu$ and $S \subseteq B_\nu$.

5.4 Definition. Let $p = \langle d_1, \ldots, d_n, \langle \kappa, \vec{V} \rangle, A \rangle$, $q = \langle e_1, \ldots, e_m, \langle \kappa, \vec{V} \rangle, B \rangle \in R_{\vec{V}}$. We say that p *is a direct extension of* q and denote this by $p \geq^* q$ iff

(1) $p \geq q$, and

(2) $n = m$.

Intuitively, $\langle R_{\vec{V}}, \leq, \leq^* \rangle$ is like Prikry forcing once some point of the form $\langle \nu, \vec{F}_\nu \rangle$ is produced, when it starts to act completely autonomously and eventually adds its own sequence.

As in the case of the Prikry forcing, any two conditions in $R_{\vec{V}}$ having the same finite sequences are compatible. So we obtain the following analogue of Lemma 1.5:

5.5 Lemma. $\langle R_{\vec{V}}, \leq \rangle$ *satisfies the* κ^+*-c.c.*

Suppose that $p = \langle d_1, \dots, d_n, \langle \kappa, \vec{V} \rangle, A \rangle \in R_{\vec{V}}$. Let, for some m with $1 \le m \le n$, $d_m = \langle \nu_m, \vec{V}_m, A_m \rangle$. Set $p^{\le m} = \langle d_1, \dots, d_m \rangle$ and

$$p^{>m} = \langle d_{m+1}, \dots, d_n, \langle \kappa, \vec{V} \rangle, A \rangle.$$

Then $p^{\le m} \in R_{\vec{V}_m}$ and $p^{>m} \in R_{\vec{V}}$. Let for $\vec{W} \in \overline{A}$ and $q \in R_{\vec{W}}$

$$R_{\vec{W}}/q = \{ r \in R_{\vec{W}} \mid r \ge q \}.$$

5.6 Lemma. *$R_{\vec{V}}/p \simeq R_{\vec{V}_m}/p^{\le m} \times R_{\vec{V}}/p^{>m}$.*

5.7 Lemma. *$\langle R_{\vec{V}}/p^{>m}, \le^* \rangle$ is ν_m-closed.*

This together with the Prikry condition (the next lemma) will suffice to prove the preservation of cardinals. Thus let $p = \langle d_1, \dots, d_n, \langle \kappa, \vec{V} \rangle, A \rangle \in R_{\vec{V}}$ and ξ be a cardinal. If $\xi > \kappa$, then we use Lemma 5.5. Let $\xi \le \kappa$. Then we pick the last m, $1 \le m \le n$ with d_m of the form $\langle \nu_m, \vec{V}_m, A_m \rangle$ such that $\nu_m < \xi$, if it exists. Work with $R_{\vec{V}}/p^{>m}$ in this case. Otherwise we continue to deal with $R_{\vec{V}}$. Suppose for simplicity that such an m does not exist, i.e. $\xi \le \nu_m$ for every m, $1 \le m \le n$ with $d_m = \langle \nu_m, \vec{V}_m, A_m \rangle$.

Let

$$\rho = \min(\{ \kappa, \kappa(d_m) \mid 1 \le m \le n \text{ and } d_m \text{ is of form } \langle \nu_m, \vec{V}_m, A_m \rangle \} \setminus \xi).$$

Assume for simplicity that $\rho = \kappa$. If $\operatorname{length}(\vec{V}) = 1$, then $R_{\vec{V}}$ is just the Prikry forcing and it preserves cardinals. Suppose that $\operatorname{length}(\vec{V}) > 1$. Let $\delta < \kappa$. Extend p to p^* by shrinking A to $A \setminus V_{\delta+1}$. Then $\langle R_{\vec{V}}/p^*, \le^* \rangle$ will be δ-closed. Using the Prikry condition, one can see that $\langle R_{\vec{V}}/p^*, \le \rangle$ does not add new subsets to δ. But δ was any cardinal below κ. So ξ is not collapsed even if $\xi = \kappa$ and we are done.

Let us now turn to the Prikry condition. The main new point here is that we are allowed to extend a given condition by picking elements from different ultrafilters of the sequence $\vec{V}$. So maybe different choices will decide some statement σ differently. The heart of the matter will be to show that this really does not happen. Actually, we can pass from one choice of an ultrafilter to another, remaining with compatible conditions.

5.8 Lemma. *$\langle R_{\vec{V}}, \le, \le^* \rangle$ satisfies the Prikry condition.*

Proof. Let $p \in R_{\vec{V}}$ and σ be a statement of the forcing language. We need to find $p^* \ge^* p$ that decides σ. Suppose that there is no such p^*. Assume for simplicity that $p = \langle \langle \kappa, \vec{V} \rangle, A \rangle$.

For every $\vec{d} = \langle d_1, \dots, d_n \rangle \in [V_\kappa]^n$ consider

$$\langle d_1, \dots, d_n \rangle^\frown p =_{df} \langle d_1, \dots, d_n, \langle \kappa, \vec{V} \rangle, A \setminus V_{\kappa(d_n)+1} \rangle.$$

Suppose that it is a condition in $R_{\vec{V}}$. Let

$$\widetilde{A}(\vec{d}) = \{d \in A \mid \text{ either } d \text{ is an ordinal and then } \vec{d}^\frown d^\frown p \in R_{\vec{V}} \\ \text{or } d \text{ is of the form } \langle \nu, \vec{F}_\nu \rangle \text{ and then } \vec{d}^\frown \langle \nu, \vec{F}_\nu, A \cap V_\nu \rangle^\frown p \in R_{\vec{V}}\}.$$

Clearly, $\widetilde{A}(\vec{d}) \in \bigcap \vec{V}$. We split $\widetilde{A}$ into three sets: First, set

$$A_0(\vec{d}) = \{d \in \widetilde{A}(\vec{d}) \mid \text{either (i) or (ii)}\}$$

where

(i) d is an ordinal and there is a B_d such that

$$\vec{d}^\frown d^\frown p \leq^* \langle \vec{d}^\frown d, \langle \kappa, \vec{V} \rangle, B_d \rangle \Vdash \sigma, \text{ or}$$

(ii) d is of the form $\langle \nu, \vec{F}_\nu \rangle$ and there are B_d and b_d such that

$$\vec{d}^\frown \langle \nu, \vec{F}_\nu, A \cap V_\nu \rangle^\frown p \leq^* \langle \vec{d}^\frown \langle \nu, \vec{F}_\nu, b_d \rangle, \langle \kappa, \vec{V} \rangle, B_d \rangle \Vdash \sigma.$$

Then, let $A_1(\vec{d})$ be the same as $A_0(\vec{d})$ but with σ replaced by $\neg\sigma$. Finally, set

$$A_2(\vec{d}) = \widetilde{A}(\vec{d}) \setminus (A_0(\vec{d}) \cup A_1(\vec{d})).$$

For every $\alpha < \text{length}(\vec{V})$ choose an $i_\alpha \leq 2$ such that $A_{i_\alpha}(\vec{d}) \in U(\alpha)$. Set $A(\alpha, \vec{d}) = A_{i_\alpha}(\vec{d})$. If $\vec{d}^\frown p \notin R_{\vec{V}}$ then let $A(\alpha, \vec{d}) = A$. Set

$$A(\alpha) = \big\{d \in A \mid \forall \vec{d} = \langle d_1, \ldots, d_n \rangle \in [V_\kappa]^n \\ \big(\text{if } \max\{\kappa(d_k) \mid 1 \leq k \leq n\} < \kappa(d), \text{ then } d \in A(\alpha, \vec{d})\big)\big\}.$$

This is the kind of diagonal intersection which is appropriate for our setting. We claim that $A(\alpha) \in U(\alpha)$. Thus, for every $\vec{d} \in [V_\kappa]^n$ we have $A(\alpha, \vec{d}) \in U(\alpha)$. So, in M, $\langle \kappa, V{\restriction}\alpha \rangle \in j(A(\alpha, \vec{d}))$ for every $\vec{d} \in [V_\kappa]^n$. Clearly $\kappa(\langle \kappa, U{\restriction}\alpha \rangle) = \kappa$. Hence, by the definition of $A(\alpha)$, $\langle \kappa, V{\restriction}\alpha \rangle \in j(A(\alpha))$.

Define now $A^* = \bigcup_{\alpha < \text{length}(\vec{V})} A(\alpha)$. Obviously $A^* \in \bigcap_{\alpha < \text{length}(\vec{V})} U(\alpha)$. Consider $p^* = \langle \langle \kappa, \vec{V} \rangle, A^* \rangle$. By our initial assumption there is no direct extension of p^* deciding σ. Pick $\langle \langle d_1, \ldots, d_{n+1} \rangle, \langle \kappa, \vec{V} \rangle, B \rangle$ to be an extension of p^* deciding σ with n as small as possible. Suppose, for example, that it forces σ. Pick $\alpha < \text{length}(\vec{V})$ such that $d_{n+1} \in A(\alpha)$. Let $\vec{d} = \langle d_1, \ldots, d_n \rangle$. Then $\vec{d}^\frown p \in R_{\vec{V}}$. By the definition of $A(\alpha)$, $d_{n+1} \in A(\alpha, \vec{d})$. By the choice of $A(\alpha, \vec{d})$, then $A(\alpha, \vec{d}) = A_0(\vec{d})$. This means that for every $d \in A(\alpha) \setminus V_{\kappa(d_n)+1}$ there are $\widetilde{d}$ and B such that

$$\vec{d}^\frown d^\frown p \leq^* \langle \vec{d}^\frown \widetilde{d}, \langle \kappa, \vec{V} \rangle, B \rangle \Vdash \sigma.$$

Obviously we can replace p by p^* here. In what follows we show that for some C

$$p^* \leq \langle\langle d_1, \ldots, d_n\rangle, \langle\kappa, \vec{V}\rangle, C\rangle \Vdash \sigma.$$

This will contradict the minimality of n and, in turn, our initial assumption.

We shrink first the sets in $U(\beta)$ for every $\beta < \alpha$ (if there are any). Suppose that $\alpha > 0$. The case $\alpha = 0$ is similar and slightly easier. For every $d \in A(\alpha) \setminus V_{\kappa(d_n)+1}$ of the form $\langle\nu, \vec{F}_\nu\rangle$ pick some b_d and B_d so that $\vec{d}^\frown d^\frown p^* \leq^* \langle\vec{d}, \langle\langle\nu, \vec{F}_\nu\rangle, b_d\rangle, \langle\kappa, \vec{V}\rangle, B_d\rangle \Vdash \sigma$. We take a diagonal intersection of the B_d's. Thus, let

$$B^* = \{e \in A^* \mid \forall d \in V_{\kappa(e)}\,(\text{if } B_d \text{ is defined then } e \in B_d)\}.$$

For every $\beta < \mathrm{length}(\vec{V})$, $B^* \in U(\beta)$, since clearly for every $d \in V_\kappa$ with B_d defined $\langle\kappa, \vec{V}\restriction\beta\rangle \in j(B_d)$ due to $B_d \in \bigcap\vec{V}$, so $\langle\kappa, \vec{V}\restriction\beta\rangle \in j(B^*)$.

Note that by the choice of $\overline{A}$ and Lemma 5.1(3(b)), $b_d \in \bigcap_{W\in\vec{F}_\nu} W$, where each $W \in \vec{F}_\nu$ is a ν-complete ultrafilter over V_ν. Consider $A^{<\alpha} = j(\langle b_d \mid d \in A(\alpha)\rangle)(\vec{V}\restriction\alpha)$ (recall that $A(\alpha) \in U(\alpha)$ implies that $\vec{V}\restriction\alpha \in j(A(\alpha))$). Then, by elementarity, $A^{<\alpha} \in U(\beta)$ for every $\beta < \alpha$. Also, note that the set $A'(\alpha) = \{d \in A(\alpha) \mid A^{<\alpha} \cap V_{\kappa(d)} = b_d\} \in U(\alpha)$, since $j(A^{<\alpha}) \cap V_{\kappa(\vec{V}\restriction\alpha)} = j(A^{<\alpha}) \cap V_\kappa = A^{<\alpha} = j(\langle b_d \mid d \in A(\alpha)\rangle)(\vec{V}\restriction\alpha)$ and hence $\vec{V}\restriction\alpha \in j(A'(\alpha))$.

Set $A^{\leq\alpha} = (A^{<\alpha} \cup A'(\alpha)) \cap A^*$. Then $A^{\leq\alpha} \in U(\beta)$ for every $\beta \leq \alpha$.

Now let us shrink the sets in $U(\beta)$ for all $\beta > \alpha$ (if there are any). Actually, we need to care for only β's with $A^{\leq\alpha} \notin U(\beta)$. Consider the set

$$A^{>\alpha} = \{\langle\nu, \vec{F}\rangle \in A^* \mid \exists\xi < \mathrm{length}(\vec{F})(A'(\alpha) \cap V_\nu \in F(\xi))\}.$$

Then $A^{>\alpha} \in U(\beta)$ for every β with $\alpha < \beta < \mathrm{length}(\vec{V})$. Set

$$A^{**} = (A^{\leq\alpha} \cup A^{>\alpha}) \cap B^*.$$

Clearly, $A^{**} \in \bigcap\vec{V}$. Consider a condition $p^{**} = \langle\langle\kappa, \vec{V}\rangle, A^{**}\rangle$ and $q = \langle d_1, \ldots, d_n\rangle^\frown p^{**}$. By the choice of n, neither q nor its direct extensions can decide σ. Pick some $r \geq q$ forcing $\neg\sigma$. Let $r = \langle e_1, \ldots, e_m, \langle\kappa, \vec{V}\rangle, C\rangle$. There is a $k \leq m$ such that $\kappa(d_n) = \kappa(e_k)$, by Definition 5.2(3). Consider three cases.

Case 1. $k = m$.

Then choose some $d \in A(\alpha) \cap C$ such that $C \cap \nu \in \bigcap\vec{F}_\nu$ where $d = \langle\nu, \vec{F}_\nu\rangle$. By the choice of $A(\alpha)$ and B^* there is a b_d such that

$$\langle d_1, \ldots, d_n, \langle\langle\nu, \vec{F}_\nu\rangle, b_d\rangle, \langle\kappa, \vec{V}\rangle, A^{**} \setminus V_{\kappa(d)+1}\rangle \Vdash \sigma.$$

Clearly we can shrink $A^{**} \setminus V_{\kappa(d)+1}$ to C. Then,

$$\langle e_1, \ldots, e_m, \langle\langle\nu, \vec{F}_\nu\rangle, b_d \cap C\rangle, \langle\kappa, \vec{V}\rangle, A^{**} \cap C \setminus V_{\kappa(d)}\rangle$$

will be a common extension of r and $\langle d_1,\dots,d_n, \langle\langle\nu,\vec{F}_\nu\rangle, b_d\rangle\langle\kappa,\vec{V}\rangle, A^{**}\cap C\setminus V_{\kappa(d)}\rangle$, which is clearly impossible since they disagree about σ.

Case 2. $k<m$ and for $k<j\le m$, $e_j\in A^{<\alpha}$.

Pick $d\in A'(\alpha)\cap C$, $d=\langle\nu,\vec{F}_\nu\rangle$ such that $C\cap A^{<\alpha}\cap V_\nu\in\cap\vec{F}_\nu$. Then, by the choice of $A'(\alpha)$, $b_d=A^{<\alpha}\cap V_\nu$. So,

$$\langle d_1,\dots,d_n,\langle\langle\nu,\vec{F}_\nu\rangle,A^{<\alpha}\cap V_\nu\rangle,\langle\kappa,\vec{V}\rangle,A^{**}\setminus V_{\kappa(d)+1}\rangle\rangle\Vdash\sigma.$$

But

$$\begin{aligned}&\langle\langle e_1,\dots,e_m\rangle,\langle\langle\nu,\vec{F}_\nu\rangle,C\cap A^{<\alpha}\cap V_\nu\rangle,\langle\kappa,\vec{V}\rangle,A^{**}\cap C\setminus V_{\kappa(d)+1}\rangle\\&\quad\ge\langle d_1,\dots,d_n,\langle\langle\nu,\vec{F}_\nu\rangle,A^{<\alpha}\cap\nu\rangle,\langle\kappa,\vec{V}\rangle,A^{**}\cap C\setminus V_{\kappa(d)+1}\rangle,\end{aligned}$$

since $e_j\in A^{<\alpha}$ for every $k<j\le m$, $\kappa(d_n)=\kappa(e_k)$ and $r\ge q$. Also, clearly,

$$\langle\langle e_1,\dots,e_m\rangle,\langle\langle\nu,\vec{F}_\nu\rangle,C\cap A^{<\alpha}\cap\nu\rangle,\langle\kappa,\vec{V}\rangle,A^{**}\cap C\setminus V_{\kappa(d)+1}\rangle\rangle\ge r.$$

But this is impossible, since $r\Vdash\neg\sigma$.

Case 3. $k<m$ and there is a j with $k<j\le m$ such that $e_j\notin A^{<\alpha}$.

Let j^* be the minimal j with $k<j\le m$ and $e_j\notin A^{<\alpha}$. Then $e_{j^*}\in A'(\alpha)\cup A^{>\alpha}$. If $e_{j^*}\in A'(\alpha)$, then

$$\begin{aligned}&\langle e_1,\dots,e_{j^*-1},\langle\langle\nu,\vec{F}_\nu\rangle,E\cap A^{<\alpha}\rangle,\langle\kappa,\vec{V}\rangle,A^{**}\setminus V_{\kappa(e_{j^*})+1}\rangle\\&\quad\ge\langle d_1,\dots,d_n,\langle\langle\nu,\vec{F}_\nu\rangle,A^{<\alpha}\cap V_\nu\rangle\ \langle\kappa,\vec{V}\rangle,A^{**}\setminus V_{\nu+1}\rangle\Vdash\sigma,\end{aligned}$$

by minimality of j^*, where $e_{j^*}=\langle\langle\nu,\vec{F}_\nu\rangle,E\rangle$. But, $\langle e_1,\dots,e_{j^*-1},\langle\langle\nu,\vec{F}_\nu\rangle, E\cap A^{<\alpha}\rangle,\langle\kappa,\vec{V}\rangle,A^{**}\setminus V_{\kappa(e_{j^*})+1}\rangle$ and r are compatible, which is impossible since $r\Vdash\neg\sigma$.

So, assume that $\langle\nu,\vec{F}_\nu\rangle\in A^{>\alpha}\setminus A^{\le(\alpha)}$, where $e_{j^*}=\langle\langle\nu,\vec{F}_\nu\rangle,E\rangle$. We have $E\in\bigcap\vec{F}_\nu$. By the choice of $A^{>\alpha}$, for some $\xi<\text{length}(\vec{F}_\nu)$ $A'(\alpha)\cap V_\nu\in F_\nu(\xi)$. Hence $A'(\alpha)\cap E\in F_\nu(\xi)$. Pick some $\langle\tau,\vec{G}_\tau\rangle\in(A'(\alpha)\cap E)\setminus V_{\kappa(e_{j^*-1})+1}$ such that $E\cap\tau\in\cap\vec{G}_\tau$. This can be done since $\vec{F}_\nu$ is a j'-sequence for some j' and $E\in\bigcap\vec{F}_\nu$. Now we can extend r by adding to it $\langle\tau,\vec{G}_\tau\rangle$. This will reduce the situation to the one considered above, i.e. $e_{j^*}\in A'(\alpha)$. This completes the proof of the lemma. ⊣

Now let G be a generic subset of $R_{\vec{V}}$. Combining the previous lemmas together, we obtain the following:

5.9 Theorem. *$V[G]$ is a cardinal preserving extension of V.*

Consider the following crucial set:

$$C_G=\big\{\kappa(d)<\kappa\mid\exists p\in G\ (d\text{ is one of the elements of the finite sequence of }p)\big\}.$$

5.10 Lemma. *C_G is a closed unbounded subset of κ.*

Proof. C_G is unbounded since for every condition $p = \langle d_1, \dots, d_n, \langle \kappa, \vec{V} \rangle, A \rangle$ and every ordinal $\tau < \kappa$ we can find some $\nu \in A \cap (\kappa \setminus \tau)$ and extend p by adding ν to its finite sequence $\langle d_1, \dots, d_n \rangle$.

Let us show that C_G is closed. Thus, let for some $\tau < \kappa$ some

$$p = \langle d_1, \dots, d_n, \langle \kappa, \vec{V} \rangle, A \rangle \Vdash \check{\tau} \notin \underset{\sim}{C}_G.$$

Clearly, $\tau \neq \kappa(d_i)$ for any i, $1 \leq i \leq n$. If $\tau > \kappa(d_n)$, then we shrink A to $A \setminus (\tau + 1)$. By the definition of the forcing ordering $\leq$,

$$\langle d_1, \dots, d_n, \langle \kappa, \vec{V} \rangle, A \setminus (\tau + 1) \rangle \Vdash \sup(\underset{\sim}{C}_G \cap \check{\tau}) = \check{\kappa}(d_n).$$

Suppose now that $\tau < \kappa(d_n)$. Let $i^* < n$ be the least such that $\tau < \kappa(d_{i^*+1})$. If d_{i^*+1} is an ordinal, then again by the definition of the forcing ordering $\leq$, p forces that $\underset{\sim}{C}_G$ will not have elements in the open interval $(\kappa(d_{i^*}), d_{i^*+1})$, where $d_0 = 0$. So, let $d_{i^*+1} = \langle \nu, \vec{F}_\nu, B_\nu \rangle$. Then $B_\nu \setminus (\tau+1) \in \bigcap \vec{F}_\nu$ and the extension of p

$$\begin{aligned} &\bigl\langle d_1, \dots, d_{i^*}, \langle \nu, \vec{F}_\nu, B_\nu \setminus (\tau + 1) \rangle, d_{i^*+2}, \dots, d_n, \langle \kappa, \vec{V} \rangle, A \bigr\rangle \\ &\quad \Vdash \sup(\underset{\sim}{C}_G \cap \check{\tau}) = \check{\kappa}(d_{i^*}). \end{aligned}$$

Combining all the cases together we conclude that there is always an extension of p forcing that τ is not a limit of elements of C_G. ⊣

The next question will be crucial for the issue of changing cofinalities:

What is the order type of C_G?

For every τ with $0 < \tau < \kappa$, $U(\tau)$ concentrates on the set $X_\tau = \{\langle \nu, \vec{F}_\nu \rangle \mid \vec{F}_\nu$ is a sequence of ν-complete ultrafilters over V_ν of length $\tau < \nu\}$. Clearly, $\{X_\tau \mid 0 < \tau < \kappa\}$ are disjoint. We can add to them also $X_0 = \kappa$ and $X_\kappa = \{\langle \nu, \vec{F}_\nu \rangle \mid \vec{F}_\nu$ is a sequence of ν-complete ultrafilters over ν of length $\nu\}$. Using this partition and an easy induction it is not hard to see the following.

5.11 Lemma. *Let δ, $0 < \delta < \kappa$, $\mathrm{length}(\vec{V}) = \delta$, and $G \subseteq R_{\vec{V}}$ be generic. Then, in $V[G]$, a final segment of C_G has order type ω^δ, where ω^δ is the ordinal power. Moreover, $\langle \kappa, \vec{V}, \bigcup \{X_\tau \mid 0 < \tau < \delta\} \rangle$ forces the order type of C_G to be ω^δ. In particular, $\mathrm{otp}(C_G) = \delta$ if δ is an uncountable cardinal.*

Combining this with Theorem 5.9 we obtain the following:

5.12 Theorem. *Let $\mathrm{length}(\vec{V}) = \delta < \kappa$ be a cardinal, and let $G \subseteq R_{\vec{V}}$ be generic. Then $V[G]$ is a cardinal preserving extension of V in which κ changes its cofinality to $\mathrm{cf}(\delta)^V$.*

Notice that if $\delta > 0$ then $R_{\vec{V}}$ changes cofinalities also below κ. Hence new bounded subsets are added to κ. Mitchell [45] showed that once one changes the cofinality of κ to some uncountable $\delta < \kappa$ preserving cardinals, then new bounded subsets of κ must appear, provided the ground model was the core model. On the other hand, it is possible to prepare a ground model and then force in order to change cofinality of κ to an uncountable δ without adding new bounded subsets. This was first done by Mitchell [44], combining iterated ultrapowers and forcing. A pure forcing construction was given in [13].

If we force with $R_{\vec{V}}$ having $\mathrm{length}(\vec{V}) = \kappa$, then κ changes its cofinality to ω again.

5.13 Lemma. *Suppose that* $\mathrm{length}(\vec{V}) = \kappa$ *and* $G \subseteq R_{\vec{V}}$ *generic. Then, in* $V[G]$, $\mathrm{cf}(\kappa) = \aleph_0$.

Proof. Let $\langle X_\tau \mid \tau < \kappa\rangle$ be the partition defined before Lemma 5.11. Then, $\bigcup_{\tau<\kappa} X_\tau \in \bigcap \vec{V}$, since for every $\tau < \kappa$ $X_\tau \in U(\tau)$ and $\vec{V} = \langle U(0), \ldots, U(\tau), \ldots \mid \tau < \kappa\rangle$. Let $X = \bigcup_{\tau<\kappa} X_\tau$. Consider

$$Y = \big\{\langle \nu, \vec{F}_\nu\rangle \in X \mid \bigcup\{X_\tau \mid \tau < \mathrm{length}(\vec{F}_\nu)\} \cap V_\nu \in \cap \vec{F}_\nu\big\} \cup \kappa.$$

Clearly, $Y \in \bigcap \vec{V}$. Now pick some $p = \langle d_1, \ldots, d_n, \langle \kappa, \vec{V}\rangle, A\rangle \in G$ with $A \subseteq Y$. Let

$$C = \big\{\langle \nu, \vec{F}_\nu\rangle \in V_\kappa \mid \exists E \in \bigcap \vec{F}_\nu(\langle \nu, \vec{F}_\nu, E\rangle \text{ appears in a condition in } G)\big\}.$$

Then, $C \setminus (\kappa(d_n) + 1) \subseteq A$. A simple density argument shows that for every $\tau < \kappa$, C will contain unboundedly many members of X_τ. Let

$$C' = \{\nu < \kappa \mid \exists \vec{F}(\langle \nu, \vec{F}\rangle \in C)\}.$$

Clearly, C' is just the set of all limit points of C_G. Also, for every $\nu \in C'$ there is a unique $\vec{F}_\nu$ with $\langle \nu, \vec{F}_\nu\rangle \in C$. We define an increasing sequence $\langle \nu_n \mid n < \omega\rangle$ of elements of C' as follows: $\nu_0 = \min(C')$, $\nu_{n+1} = \min\{\nu \in C' \mid \exists \vec{F}_\nu \langle \nu, \vec{F}_\nu\rangle \in X_{\nu_n}\} \setminus (\nu_n + 1))$.

Set $\nu_\omega = \bigcup_{n<\omega} \nu_n$. We claim that $\nu_\omega = \kappa$. Otherwise there is a $\tau < \kappa$ such that $\langle \nu_\omega, \vec{F}\rangle \in C \cap X_\tau$ for some (unique) $\vec{F}$, since C' is closed and $C \subseteq A \subseteq Y \subseteq X = \bigcup_{\tau<\kappa} X_\tau$. Then there is a $q \geq p$ in G with $\langle\langle \nu_\omega, \vec{F}\rangle, B\rangle$ appearing in q for some $B \in \cap \vec{F}$. We require also $B \subseteq \bigcup\{X_{\tau'} \mid \tau' < \tau\} \cap V_{\nu_\omega}$. This is possible since $q \geq p$, $A \subseteq Y$, $\nu_\omega > \kappa(d_n)$, and hence $\bigcup\{X_{\tau'} \mid \tau' < \tau\} \cap V_{\nu_\omega} \in \bigcap \vec{F}$. Now, by the definition of X_τ, we have $\tau < \nu_\omega$. So, there is an $n < \omega$ with $\nu_n > \max(\tau, \min(B))$. But $\nu_n \in C'$, hence $\langle \nu_n, \vec{F}_{\nu_n}\rangle$ should be in B, for some (unique) $\vec{F}_{\nu_n}$. The same holds for each ν_m with $n \leq m < \omega$. In particular, $\langle \nu_{n+1}, \vec{F}_{\nu_{n+1}}\rangle \in \bigcup_{\tau'<\tau} X_{\tau'}$. But it was picked to be in X_{ν_n} which is disjoint to each $X_{\tau'}$ for $\tau' < \nu_n$. Contradiction. ⊣

Similar arguments show that for every $\delta < \kappa^+$, if $\mathrm{length}(\vec{V}) = \delta$ then the forcing $R_{\vec{V}}$ changes the cofinality of κ. If δ is a successor ordinal, then to $\aleph_0$; if δ is limit and $\mathrm{cf}(\delta) \neq \kappa$ then to $\mathrm{cf}(\delta)$ and, finally, if $\mathrm{cf}(\delta) = \kappa$ then to $\aleph_0$.

Let us now show that if $\vec{V}$ is long enough then $R_{\vec{V}}$ can preserve measurability of κ. Later it will be shown that length$(\vec{V}) = \kappa^+$ suffices to keep κ regular and so inaccessible. The ability of keeping κ regular turned out to be very important in applications to the cardinal arithmetic. Thus a basic common theme used there is to arrange some particular pattern of the power function over C_G, sometimes adding Cohen subsets or collapsing cardinals in between and then to cut the universe at κ. This type of constructions were used by Foreman-Woodin [12], Cummings [9] and recently by Merimovich [40].

5.14 Definition. An ordinal $\gamma <$ length$(\vec{V})$ is called a *repeat point* for $\vec{V}$ if for every δ with $\gamma \leq \delta <$ length$(\vec{V})$ and for every $A \in U(\delta)$, there is a $\delta' < \gamma$ such that $A \in U(\delta')$. Equivalently, $\bigcup \vec{V} = \bigcup \vec{V} \restriction \gamma$.

Note that if $2^\kappa = \kappa^+$ and our sequence has length κ^{++}, then there will be κ^{++} repeat points between κ^+ and κ^{++}. This implies that also $\vec{V} = \vec{U} \restriction \alpha$ will have a repeat point for unboundedly many α's below κ^{++}.

5.15 Theorem. *If γ is a repeat point for $\vec{V}$ and $G \subseteq R_{\vec{V}}$ is generic, then κ remains measurable in $V[G]$.*

Proof. Recall that $\vec{V} = \langle U(\alpha) \mid \alpha < \text{length}(\vec{V})\rangle$ is a j-sequence for some elementary embedding $j : V \to M$ with $\text{crit}(j) = \kappa$. By the definition of a repeat point, the forcing $R_{\vec{V}}$ and $R_{\vec{V}\restriction\gamma}$ are basically the same (we need only to replace $\langle \kappa, \vec{V}\rangle$ in each condition of $R_{\vec{V}}$ by $\langle \kappa, \vec{V}\restriction\gamma\rangle$ in order to pass to $R_{\vec{V}\restriction\gamma}$). So we can view G as a generic subset of $R_{\vec{V}\restriction\gamma}$. Define now an ultrafilter F over κ in $V[G]$. Let $\underset{\sim}{X}$ be a name of a subset of κ. Set $\underset{\sim}{X}[G] \in F$ iff for some $\langle d_1, \dots, d_n, \langle \kappa, \vec{V}\rangle, A\rangle \in G$ the following holds in M: For some $B \in \bigcap j(\vec{V})$,

$$\langle d_1, \dots, d_n, \langle\langle \kappa, \vec{V}\restriction\gamma\rangle, A\rangle, \langle j(\kappa), j(\vec{V})\rangle, B\rangle \Vdash_{R_{j(\vec{V})}} \check{\kappa} \in j(\underset{\sim}{X}).$$

First note that F is well defined. Thus, let some $\langle d_1, \dots, d_n, \langle \kappa, \vec{V}\rangle, A\rangle \in G$ forces "$\underset{\sim}{X} = \underset{\sim}{Y}$". Then, in M

$$\langle d_1, \dots, d_n, \langle j(\kappa), j(\vec{V}), j(A)\rangle\rangle \Vdash j(\underset{\sim}{X}) = j(\underset{\sim}{Y}).$$

But $A \in \bigcap \vec{V}$. In particular, $A \in U(\gamma)$. Hence, $\langle \kappa, \vec{V}\restriction\gamma\rangle \in j(A)$. Also, $j(A) \cap V_\kappa = A$. So, $\langle\langle \kappa, \vec{V}\restriction\gamma\rangle, A\rangle$ is addible to $\langle d_1, \dots, d_n, \langle j(\kappa), j(\vec{V}), j(A)\rangle$. But if for some $B \in \bigcap j(\vec{V})$,

$$\langle d_1, \dots, d_n, \langle\langle \kappa, \vec{V}\restriction\gamma\rangle, A\rangle, \langle j(\kappa), j(\vec{V})\rangle, B\rangle \Vdash_{R_{j(\vec{V})}} \check{\kappa} \in j(\underset{\sim}{X}),$$

then

$$\begin{aligned}&\langle d_1, \dots, d_n, \langle\langle \kappa, \vec{V}\restriction\gamma\rangle, A\rangle, \langle j(\kappa), j(\vec{V})\rangle, B \cap j(A)\rangle \\ &\quad \Vdash_{R_{j(\vec{V})}} \check{\kappa} \in j(\underset{\sim}{X}) \wedge j(\underset{\sim}{X}) = j(\underset{\sim}{Y}).\end{aligned}$$

Let us establish normality for F. Suppose that $\langle d_1, \ldots, d_n, \langle \kappa, \vec{V}\rangle, A\rangle\rangle \in G$ and $\langle d_1, \ldots, d_n, \langle \kappa, \vec{V}\rangle, A\rangle\rangle \Vdash (\{\nu < \kappa \mid \underset{\sim}{f}(\nu) < \nu\} \in \underset{\sim}{F})$. Then, in M, for some $B \in \bigcap j(\vec{V})$

$$\langle d_1, \ldots, d_n, \langle\langle \kappa, \vec{V}\restriction\gamma\rangle, A\rangle, \langle j(\kappa), j(\vec{V})\rangle, B\rangle \Vdash_{R_{j(\vec{V})}} j(\underset{\sim}{f})(\check{\kappa}) < \check{\kappa}.$$

Working in M, construct $B' \in \bigcap j(\vec{V})$ such that: If for some $\nu < \kappa$, we have a condition $\langle x_1, \ldots, x_\ell, \langle\langle \kappa, \vec{V}\restriction\gamma\rangle, C\rangle, \langle j(\kappa), j(\vec{V})\rangle, E\rangle$ forcing "$j(\underset{\sim}{f})(\check{\kappa}) = \check{\nu}$", then $\langle x_1, \ldots, x_\ell, \langle\langle \kappa, \vec{V}\restriction\gamma\rangle, C\rangle, \langle j(\kappa), j(\vec{V})\rangle, B'\rangle$ forces the same.

Back in V, the set

$$\begin{aligned} D = \big\{&\langle x_1, \ldots, x_\ell, \langle\langle \kappa, \vec{V}\restriction\gamma\rangle, C\rangle\rangle \mid \text{for some } \nu < \kappa, \\ &\langle x_1, \ldots, x_\ell, \langle\langle \kappa, \vec{V}\restriction\gamma\rangle, C\rangle, \langle j(\kappa), j(\vec{V})\rangle, B'\rangle \Vdash_{R_{j(\vec{V})}} j(\underset{\sim}{f})(\check{\kappa}) = \check{\nu}\big\} \end{aligned}$$

will be dense in $R_{\vec{V}\restriction\gamma}$ above $\langle d_1, \ldots, d_n, \langle \kappa, \vec{V}\rangle, A\rangle$. Thus, if some $p \in R_{\vec{V}\restriction\gamma}$ with $p \geq \langle d_1, \ldots, d_n, \langle \kappa, \vec{V}\rangle, A\rangle$ has no extension in D, then we consider the statement

$$\begin{aligned} \varphi \equiv \text{“There is a } q \in R_{\vec{V}} \text{ stronger than } p, \text{ a } \nu < \kappa, \text{ and} \\ \text{an } r \text{ in } \underset{\sim}{G}(R_{j(\vec{V})\setminus\kappa+1}) \text{ such that } \langle q, r\rangle \Vdash_{R_{j(\vec{V})}} j(\underset{\sim}{f})(\check{\kappa}) = \check{\nu}\text{”}, \end{aligned}$$

where $\underset{\sim}{G}(R_{j(\vec{V})\setminus\kappa+1})$ is the canonical name of a generic subset of $R_{j(\vec{V})\setminus\kappa+1}$. Let, in M, $s \geq^* \langle\langle j(\kappa), j(\vec{V})\rangle, B'\rangle$ deciding φ. Then s must force φ. Find some $s_1 \geq^* s$ deciding the values of ν and q in φ. This leads to the contradiction.

So, pick some $\langle e_1, \ldots, e_m, \langle \kappa, \vec{V}\rangle, A'\rangle \geq \langle d_1, \ldots, d_n, \langle \kappa, \vec{V}\rangle, A\rangle$ in $G \cap D$. There is a $\delta < \kappa$ such that

$$\langle\langle e_1, \ldots, e_m\rangle, \langle\langle \kappa, \vec{V}\restriction\gamma\rangle, A'\rangle, \langle j(\kappa), j(\vec{V})\rangle, B'\rangle \Vdash j(\underset{\sim}{f})(\check{\kappa}) = \check{\delta}.$$

Then $\{\nu < \kappa \mid f(\nu) = \delta\} \in F$, by the definition of F. ⊣

Similar arguments show that it is possible to preserve the degree of strongness and even of supercompactness of j. Notice also that F defined above extends $U(0)$, but the elementary embedding of F does not extend that of $U(0)$. Instead, it extends a certain iterated ultrapower embedding using ultrafilters of $\mathrm{Ult}(V, U(0))$ between κ and $i_{U(0)}(\kappa)$.

We now want to show that κ remains regular in $V^{R_{\vec{V}}}$ when we have $\mathrm{cf}(\mathrm{length}(\vec{V})) \geq \kappa^+$. But first we need to extend a bit the Prikry condition Lemma 5.8 in the spirit of Lemma 2.18. This will allow us to deal with dense sets. The situation here is more involved due to the possibility of extending a given condition by adding to it elements from different ultrafilters $U(\alpha)$'s. We start with the following definition.

5.16 Definition. Let $\vec{F}$ be a sequence of ultrafilters over some $\nu \leq \kappa$. A tree $T \subseteq [V_\nu]^{\leq n}$ with $n < \omega$ levels is called $\vec{F}$-*fat* iff

(1) For every $\langle \nu_1, \dots, \nu_k \rangle \in T$, $\kappa(\nu_1) < \kappa(\nu_2) < \dots < \kappa(\nu_k)$.

(2) For every $\langle \nu_1, \dots, \nu_k \rangle \in T$ with $k < n$, there is an $\alpha < \mathrm{length}(\vec{F})$ so that $\mathrm{Suc}_T(\langle \nu_1, \dots, \nu_k \rangle) \in F(\alpha)$.

Let T be as in Definition 5.16 and η a maximal branch in T. A sequence $\vec{A} = \langle \vec{A}(1), \dots, \vec{A}(n) \rangle \in [V_\nu]^n$ will be called a *sequence of η-measure one* if, for every i, $1 \le i \le n$ with $\eta(i)$ of form $\langle \tau_i, \vec{G}_{\tau_i} \rangle$ we have $\vec{A}(i) \in \bigcap \vec{G}_{\tau_i}$. Let $p = \langle d_1, \dots, d_n, \langle \kappa, \vec{V} \rangle, A \rangle \in R_{\vec{V}}$ and $d_i = \langle \langle \nu_i, \vec{F}_i \rangle, A_i \rangle$ or $d_i = \nu_i < \kappa$ for each i, $1 \le i \le n$. Here also denote $\langle \langle \kappa, \vec{V} \rangle, A \rangle$ by $\langle \langle \nu_{n+1}, \vec{F}_{n+1} \rangle, A_{n+1} \rangle$. Let $1 \le i_1 < \dots < i_m \le n+1$ be some elements of the set $\{ i \mid 1 \le i \le n+1, d_i = \langle \langle \nu_i, \vec{F}_i \rangle, A_i \rangle \}$.

Let for each k with $1 \le k \le m$ and some $n_k < \omega$, $T_k \subseteq [V_{\nu_{i_k}}]^{n_k}$ be a $\vec{F}_{\nu_{i_k}}$-fat tree, η_k a maximal branch in T_k, and $\vec{A}_k \in [V_{\nu_{i_k}}]^{\le n_k}$ a sequence of η_k-measure one. Let $q = \langle t_1, \dots, t_\ell, t_{\ell+1} \rangle$ be obtained from p by adding to it between $d_{i_k - 1}$ and d_{i_k}, for each k, $1 \le k \le m$, the following n_k-sequence $\langle s_j \mid 1 \le j \le n_k \rangle$, where $s_j = \eta_k(j)$, if $\eta_k(j)$ is an ordinal, or $s_j = \langle \tau_j, \vec{G}_{\tau_j}, \vec{A}_k(j) \rangle$, if $\eta_k(j) = \langle \tau_i, G_{\tau_i} \rangle$. Denote by $p^\frown \langle \eta_1, \vec{A}_1 \rangle^\frown \cdots ^\frown \langle \eta_m, \vec{A}_m \rangle$ the condition in $R_{\vec{V}}$ obtained from q by the obvious shrinking of sets of measure one needed in order to satisfy Definition 5.2, i.e. for every i with $1 < i \le \ell + 1$, if $t_i = \langle \delta_i, \vec{H}_i, B_i \rangle$, then we replace B_i by $B_i \setminus V_{\kappa(t_{i-1})+1}$.

5.17 Lemma. *Let D be a dense open subset of $R_{\vec{V}}$ and $p = \langle d_1, \dots, d_n, \langle \kappa, \vec{V} \rangle, A \rangle \in R_{\vec{V}}$. Then there are $p^* = \langle d_1^*, \dots, d_n^*, \langle \kappa, \vec{V} \rangle, A^* \rangle \ge^* p$; $1 \le i_1 < \dots < i_m \le n + 1$; and for $1 \le k \le m$, $T_k \subseteq [V_{\nu_{i_k}}]^{n_k}$ $\vec{F}_{\nu_{i_k}}$-fat trees so that the following holds:*

For every sequence $\langle \eta_k \mid 1 \le k \le m \rangle$ such that η_k is a maximal branch in T_k, there exists a sequence $\langle \vec{A}_k \mid 1 \le k \le m \rangle$ such that

(1) $\vec{A}_k \in [V_{i_k}]^{n_k}$ is a sequence of η_k-measure one, and

(2) $p^{*\frown} \langle \eta_1, \vec{A}_1 \rangle^\frown \cdots ^\frown \langle \eta_m, \vec{A}_m \rangle \in D$.

5.18 Remark. Roughly, the meaning of this is that in order to get into D we need to specify certain $U(\alpha)$'s (or $F(\alpha)$'s, if below κ) and sets A_α's in these ultrafilters. Then any choice of elements in A_α's will put us into D.

Proof. The proof is very similar to that of Lemma 5.8. Suppose for simplicity that $p = \langle \langle \kappa, \vec{V} \rangle, A \rangle$. We need to find a direct extension $p^* = \langle \langle \kappa, \vec{V} \rangle, A^* \rangle$ of p and a $\vec{V}$-fat tree T of some finite height m such that the following holds: for every maximal branch $\eta = \langle f_1, \dots, f_m \rangle$ through T there are sets $\vec{A} = \langle a_1, \dots, a_m \rangle$ of η-measure one (i.e. for every i with $1 \le i \le m$, if $f_i = \langle \tau_i, \vec{G}_{\tau_i} \rangle$ then $a_i \in \bigcap \vec{G}_{\tau_i}$) such that $p^{*\frown} \langle \eta, \vec{A} \rangle \in D$, where

$$p^{*\frown} \langle \eta, \vec{A} \rangle = \langle f_1', \dots, f_m', \langle \kappa, \vec{V} \rangle, A^* \setminus V_{\kappa(f_m)} \rangle$$

and for every i with $1 \le i \le m$, either

(α) f_i is an ordinal and then $f_i' = f_i$, or

(β) $f_i = \langle \tau_i, \vec{G}_{\tau_i}\rangle$ and then $f_i' = \langle \tau_i, \vec{G}_{\tau_i}, a_i\rangle$.

If p already has a direct extension in D, then we take such an extension and set $T = \{\langle\rangle\}$. Suppose that this is not the case. Define $\widetilde{A}(\vec{d})$ as in Lemma 5.8. Here we split it only into two sets $A_0(\vec{d}) = \{d \in \widetilde{A}(\vec{d}) |$ either (i) or (ii)$\}$ and $A_1(d) = \widetilde{A}(\vec{d}) \setminus A_0(\vec{d})$, where:

(i) d is an ordinal and then there is a $B_{\vec{d}}$ such that

$$\vec{d}^\frown d^\frown p \leq^* \langle \vec{d}^\frown d, \langle \kappa, \vec{V}\rangle, B_{\vec{d}}\rangle \in D.$$

(ii) d is of form $\langle \nu, \vec{F}_\nu\rangle$ and then there are $B_{\vec{d}}$ and $b_{\vec{d}}$ such that

$$\vec{d}^\frown \langle \nu, \vec{F}_\nu, A \cap V_\nu\rangle^\frown p \leq^* \langle \vec{d}^\frown \langle \nu, \vec{F}_\nu, b_{\vec{d}}\rangle, \langle \kappa, \vec{V}\rangle, B_{\vec{d}}\rangle \in D.$$

As in Lemma 5.8, define $A(\alpha, \vec{d})$'s and $A(\alpha) \in U(\alpha)$ for $\alpha < \text{length}(\vec{V})$. Set $A^1 = \bigcup\{A(\alpha) \mid \alpha < \text{length}(\vec{V})\}$ and $p^1 = \langle\langle \kappa, \vec{V}\rangle, A^1\rangle$. Then p^1 satisfies the following:

$(*)_1$ If $p^1 \leq q = \langle e_0, \ldots, e_m, \langle \kappa, \vec{V}\rangle, B\rangle \in D$, then there is an $\alpha < \text{length}(\vec{V})$ such that for every $e_m' \in A(\alpha) \setminus V_{\kappa(e_{m-1})+1}$, $\langle e_0, \ldots, e_{m-1}, e_m', \langle \kappa, \vec{V}\rangle, A^1\rangle$ has a direct extension of form $\langle e_0, \ldots, e_{m-1}, e_m'', \langle \kappa, \vec{V}\rangle, A''\rangle$ in D.

Just pick α with $e_m \in A(\alpha)$ (more precisely, only $\langle \nu, \vec{F}_\nu\rangle$ if $e_m = \langle \nu, \vec{F}_\nu, B_\nu\rangle$). Then $e_m \in A(\alpha, \langle e_0, \ldots, e_{m-1}\rangle)$ and so by choice of $A(\alpha, \langle e_0, \ldots, e_{m-1}\rangle)$, for every $e_m' \in A(\alpha, \langle e_0, \ldots, e_{m-1}\rangle)$ a direct extension of $\langle e_0, \ldots, e_{m-1}, e_m'$, $\langle \kappa, \vec{V}\rangle, A^1\rangle$ will be in D. But if we were to take $e \in A(\alpha) \setminus V_{\kappa(e_{m-1})+1}$, then $e \in A(\alpha, \langle e_0, \ldots, e_{m-1}\rangle)$, by the definition of the diagonal intersection.

If for some $d \in A^1$, $d^\frown p^1$ has a direct extension in D, then we are done. Thus choose $\alpha < \text{length}(\vec{V})$ with $d \in A(\alpha)$. By the choice of $A(\alpha)$, then for every $d' \in A(\alpha)$ some direct extension of $d'^\frown p^1$ will be in D. Let us fix for every $d \in A(\alpha)$ a direct extension $\langle \widetilde{d}, \langle \kappa, \vec{V}\rangle, B_d\rangle$ of $d^\frown p^1$ in D, where $\widetilde{d}$ is either d, if d is an ordinal or $\langle \nu, \vec{F}_\nu, b_d\rangle$ if $d = \langle \nu, \vec{F}_\nu\rangle$. Set $A^* = \{e \in A^1 \mid \forall e' \in V_e(e \in B_{e'})\}$. Clearly, $A^* \in \bigcap \vec{V}$ and for every $d \in A^*$, $A^* \setminus V_{\kappa(d)+1} \subseteq B_d$. So, for every $d \in A(\alpha) \cap A^*$, $\langle \widetilde{d}, \langle \kappa, \vec{V}\rangle, B_d\rangle \leq^* \langle \widetilde{d}, \langle \kappa, \vec{V}\rangle, A^* \setminus V_{\kappa(d)+1}\rangle$. Hence, also $\langle \widetilde{d}, \langle \kappa, \vec{V}\rangle, A^* \setminus V_{\kappa(d)+1}\rangle$ is in D. Then we can take $p^* = \langle\langle \kappa, \vec{V}\rangle, A^*\rangle$ and T to be a one level tree which level consists of $A(\alpha) \cap A^*$.

Suppose now that there is no $d \in A^1$ with $d^\frown p^1$ having a direct extension in D. We continue to two steps extensions. Replacing A by A^1 we define $\widetilde{A}(\vec{d})$ as above. Let $A_0(\vec{d}) = \{d \in \widetilde{A}(\vec{d}) \mid$ there are $\alpha(\vec{d}) < \text{length}(\vec{V})$ and $C(\vec{d}) \subseteq \widetilde{A}(d) \setminus \kappa(d)$, $C(\vec{d}) \in U(\alpha(\vec{d}))$ such that for every $c \in C(\vec{d})$ there is in D a direct extension of the condition $\vec{d}^\frown d^\frown c^\frown p^1$ (i.e. the one obtained by adding $\vec{d}$, d and c to $p^1)\}$ and $A_1(\vec{d}) = A^1 \setminus A_0(\vec{d})$. Define $A(\alpha, \vec{d})$'s, $A(\alpha)$'s, A^2 and p^2 as was done above. Now, if for some $d_1, d_2 \in A^2$ some direct extension of $d_1{}^\frown d_2{}^\frown p^2$ is in D, then by $(*)_1$ for some $\beta < \text{length}(\vec{V})$, for every $d'_2 \in A^1(\beta) \setminus V_{\kappa(d_1)+1}$, $d_1{}^\frown d'_2{}^\frown p^2$ will have a direct extension in D. But then for $\alpha < \text{length}(\vec{V})$ with $d_1 \in A(\alpha)$ we will have that $d_1 \in A_0(\langle\,\rangle)$, i.e. for every $d'_1 \in A(\alpha)$ for some $\beta' < \text{length}(\vec{V})$ for every $d'_2 \in A^1(\beta') \setminus V_{\kappa(d'_1)+1}$, $d'_1{}^\frown d'_2{}^\frown p'$ will have a direct extension in D. In this case we can define p^* and two levels tree T. The definition is similar to those given above. Otherwise we consider $(*)_2$ the two-step analogue of $(*)_1$. Continue in a similar fashion. Thus at stage n we will have sets $A^n(\alpha) \in U(\alpha)$, $A^n = \bigcup\{A^n(\alpha) \mid \alpha < \text{length}(\vec{V})\}$ and $p^n = \langle\langle\kappa, \vec{V}\rangle, A^n\rangle$. Also the following n-dimension version of $(*)_1$ will hold:

$(*)_n$ If $p^n \leq q = \langle e_0, \ldots, e_{m-1}, d_1, \ldots, d_n, \langle\kappa, \vec{V}\rangle, B\rangle \in D$, then there is an n-levels $\vec{V}$-fat tree T_q such that for every maximal branch $\eta = \langle f_1, \ldots, f_n\rangle$ of T_q there are sets $\vec{A} = \langle a_1, \ldots, a_n\rangle$ of η-measure one and $B_\eta \in \bigcap \vec{V}$ such that

$$\langle e_0, \ldots, e_{m-1}\rangle^\frown\langle\eta, \vec{A}\rangle^\frown\langle\langle\kappa, \vec{V}\rangle, B_\eta\rangle \in D.$$

Again, if for some $d_1, \ldots, d_n \in A^n$, a direct extension q of $\langle d_1, \ldots, d_n\rangle^\frown p^n$ is in D, then we can easily finish. Just use T_q given by $(*)_n$ as T and let $A^* = \{e \in A^n \mid \forall\eta \in V_{\kappa(e)}(e \in B_\eta)\}$.

Suppose that the process does not stop at any $n < \omega$. Set

$$p^* = \big\langle\langle\kappa, \vec{V}\rangle, \textstyle\bigcap_{n<\omega} A_n\big\rangle.$$

Then $p^* \geq^* p$. By our assumption, no direct extension of p (and so of p^*) is in D. Pick some q, $q = \langle d_1, \ldots, d_n, \langle\kappa, \vec{V}\rangle, B\rangle \geq p^*$ and $q \in D$. Then $q \geq^* \langle d_1, \ldots, d_n\rangle^\frown p^n$. So, by the choice of p^n, we were supposed to stop at stage n. Contradiction. ⊣

We are now ready to show the following:

5.19 Theorem. *If* $\text{cf}(\text{length}(\vec{V})) \geq \kappa^+$ *then* κ *remains regular* (*and hence inaccessible*) *in* $V^{R_{\vec{V}}}$.

5.20 Remark. In view of Theorem 5.15 the converse of Theorem 5.19 is false.

Proof. Suppose that $\delta < \kappa$ and $\underset{\sim}{f}$ is an $R_{\vec{V}}$-name so that the weakest condition forces

$$\underset{\sim}{f} : \check{\delta} \longrightarrow \check{\kappa}.$$

Let $t = \langle\mu_1, \ldots, \mu_s, \langle\kappa, \vec{V}\rangle, E\rangle \in R_{\vec{V}}$. We find a $p \geq t$ forcing "$\text{ran}\underset{\sim}{f}$ is bounded in κ". Let $\xi < \delta$. Consider the set

$$D_\xi = \big\{p \in R_{\vec{V}} \mid \text{for some } d \in V_\kappa \setminus V_{\mu_3+1} \text{ appearing in } p,\ (p \Vdash \underset{\sim}{f}(\check{\xi}) < \check{\kappa}(d))\big\}.$$

Clearly, D_ξ is a dense subset of $R_{\vec{V}}$. For every $\vec{d} = \langle d_1, \dots, d_n\rangle \in V_\kappa$ with $\vec{d}^\frown\langle\langle\kappa,\vec{V}\rangle, V_\kappa\backslash V_{\kappa(d_n)+1}\rangle \in R_{\vec{V}}$ apply Lemma 5.17 to $\vec{d}^\frown\langle\langle\kappa,\vec{V}\rangle, V_\kappa\backslash V_{\kappa(d_n)+1}\rangle$ and to D_ξ. We are interested only in the last T_m and only if $i_m = n+1$ there. Such a T_m is a $\vec{V}$-fat tree of the height $n_m < \omega$. Denote T_m further as $T(\xi,\vec{d})$. By Definition 5.16, for every $\eta \in T_m \setminus \mathrm{Lev}_{n_m}(T_m)$ there is an $\alpha(\eta) < \mathrm{length}(\vec{V})$ such that $\mathrm{Suc}_{T_m}(\eta) \in U(\alpha(\eta))$. Define $\alpha(\vec{d}) = \bigcup\{\alpha(\eta) \mid \eta \in T_m \setminus \mathrm{Lev}_{n_m}(T_m)\}$. Then $\alpha(\vec{d}) < \mathrm{length}(\vec{V})$, since $\mathrm{cf}(\mathrm{length}(\vec{V})) = \kappa^+$. Pick $\alpha(\xi) < \mathrm{length}(\vec{V})$ to be larger than each $\alpha(\vec{d})$ with $\vec{d}$ as above. Finally let $\alpha < \mathrm{length}(\vec{V})$ be above each $\alpha(\xi)$. Consider the following set:

$$B = \{\langle\nu,\vec{F}_\nu\rangle \in V_\kappa \mid \forall\xi<\delta\forall\vec{d}\in V_\nu(T(\xi,\vec{d})\cap V_\nu \text{ is } \vec{F}_\nu\text{-fat})\}.$$

By the choice of $\alpha, B \in U(\alpha)$. For every $\xi < \delta$, let $A^*_\xi \in \bigcap\vec{V}$ be the set given by Lemma 5.17 applied to D_ξ and t. Let $A^* = \bigcap_{\xi<\delta} A^*_\xi$. Every condition of $R_{\vec{V}}$ can be extended to one containing elements of $B \setminus V_{\mu_s+1}$. Hence the following will conclude the proof:

Claim. *Let $p \geq \langle\mu_1,\dots,\mu_s,\langle\kappa,\vec{V}\rangle, A^*\setminus V_{\mu_s+1}\rangle$ and some $\langle\nu,\vec{F}_\nu\rangle \in B\setminus V_{\mu_s+1}$ appears in p. Then*

$$p \Vdash \forall\xi < \check{\delta}\ (\underset{\sim}{f}(\xi) < \check{\nu}).$$

Proof. Suppose otherwise. Let

$$p \geq \langle\mu_1,\dots,\mu_s,\langle\kappa,\vec{V}\rangle, A^*\setminus V_{\mu_s+1}\rangle,$$

some $\langle\nu,\vec{F}_\nu\rangle \in B\setminus V_{\mu_s+1}$ appears in p and for some $\xi<\delta$ $p \Vdash \underset{\sim}{f}(\check{\xi}) \geq \check{\nu}$. Let $p = \langle d_1,\dots,d_\ell,\langle\langle\nu,\vec{F}_\nu\rangle,a_\nu\rangle, d_{\ell+2},\dots,d_n,\langle\kappa,\vec{V}\rangle, A\rangle$. Consider

$$p' = \langle d_1,\dots,d_\ell,\langle\kappa,\vec{V}\rangle, A^*\setminus V_{\kappa(d_\ell)+1}\rangle.$$

We would like to apply Remark 5.18. By the definition of B, $T(\xi,\langle d_1,\dots, d_\ell\rangle)\cap V_\nu$ is $\vec{F}_\nu$-fat. Since $a_\nu \in \bigcap\vec{F}_\nu$, we can find a maximal branch $\langle f_1,\dots,f_m\rangle$ through $T(\xi,\langle d_1,\dots,d_\ell\rangle)$ inside a_ν. By Lemma 5.17, there is a $q \geq p'$ with $q\in D_\xi$ of form

$$\langle e_1,\dots,e_i,\widetilde{f}_1,\dots,\widetilde{f}_m, A^*\setminus V_{\kappa(f_m)+1}\rangle$$

where $\kappa(e_i) = \kappa(d_\ell)$ and for every j, $1\leq j\leq m$, $\widetilde{f}_j$ is f_j, if f_j is an ordinal, or $\widetilde{f}_j = \langle f_j, b_j\rangle$ for some b_j, otherwise. $q \in D_\xi$ implies that $q \Vdash \underset{\sim}{f}(\check{\xi}) < \check{\kappa}(f_m)$. Obviously, $\kappa(f_m) < \nu$, since $f_m \in a_\nu \subseteq V_\nu$. On the other hand, q and p are compatible, since $p \geq \langle\mu_1,\dots,\mu_s,\langle\kappa,\vec{V}\rangle, A^*\setminus V_{\mu_s+1}\rangle$,

$$p = \langle d_1,\dots,d_\ell,\langle\langle\nu,\vec{F}_\nu\rangle,a_\nu\rangle, d_{\ell+2},\dots,d_n,\langle\kappa,\vec{V}\rangle, A\rangle$$

and, hence $\langle\nu,\vec{F}_\nu\rangle, d_{\ell+2},\dots,d_n$ come from A^*. So they are addible to q. Hence

$$\langle e_1,\dots,e_i,\widetilde{f}_1,\dots,\widetilde{f}_m,\langle\langle\nu,\vec{F}_\nu\rangle,a_\nu\setminus V_{\kappa(f_m)+1}\rangle, d_{\ell+2},\dots,d_n,\langle\kappa,\vec{V}\rangle, A\rangle$$

is a common extension of q and p. But this is impossible since $p \Vdash \underset{\sim}{f}(\check{\xi}) \geq \check{\nu}$ and $q \Vdash \underset{\sim}{f}(\check{\xi}) < \check{\nu}$. Contradiction. ⊣

5.2. Magidor Forcing and Coherent Sequences of Measures

Magidor [37] invented a forcing for changing the cofinality of a cardinal κ to an uncountable value $\delta < \kappa$. As an initial assumption, his forcing uses a coherent sequence of measures of length δ. Coherent sequences of measures were introduced by Mitchell [43]. In [42] Mitchell showed that it is possible to do Radin forcing with coherent sequences of measures replacing an elementary embedding $j : V \to M$. The main advantage of this approach is reducing initial assumptions to weaker ones that in turn also provide equiconsistency results. This allows the simultaneous treatment of both the Magidor and the Radin forcings.

5.21 Definition. A *coherent sequence of measures* (ultrafilters) $\vec{U}$ is a function with domain of form

$$\{(\alpha, \beta) \mid \alpha < \ell^{\vec{U}} \text{ and } \beta < o^{\vec{U}}(\alpha)\}$$

for an ordinal $\ell^{\vec{U}}$, the length of $\vec{U}$, and a function $o^{\vec{U}}(\alpha)$, called the *order* of $\vec{U}$ at α. For each pair $(\alpha, \beta) \in \mathrm{dom}(\vec{U})$,

(1) $U(\alpha, \beta)$ is a normal ultrafilter over α, and

(2) if $j^\alpha_\beta : V \longrightarrow N^\alpha_\beta \simeq \mathrm{Ult}(V, (\alpha, \beta))$ is the canonical embedding, then

$$j^\alpha_\beta(\vec{U}) \restriction \alpha + 1 = \vec{U} \restriction (\alpha, \beta),$$

where

$$\vec{U} \restriction \alpha = \vec{U} \restriction \{(\alpha', \beta') \mid \alpha' < \alpha \text{ and } \beta' < o^{\vec{U}}(\alpha')\}$$

and

$$\vec{U} \restriction (\alpha, \beta) = \vec{U} \restriction \big\{(\alpha', \beta') \mid (\alpha' < \alpha \text{ and } \beta' < o^{\vec{U}}(\alpha')) \\ \text{or } (\alpha' = \alpha \text{ and } \beta' < \beta)\big\}.$$

Suppose that $\vec{U}$ is a coherent sequence of measures with $\ell^{\vec{U}} = \kappa + 1$ and $o^{\vec{U}}(\kappa) = \delta > 0$. We will now use $\vec{U}$ as a replacement for $\vec{V}$ of the previous section. Thus, over κ, $\vec{U}(\kappa) = \langle \vec{U}(\kappa, \alpha) \mid \alpha < \delta \rangle$ is used. Let $A \in \bigcap \vec{U}(\kappa) = \bigcap_{\alpha < \delta} U(\kappa, \alpha)$. Elements of A are ordinals only, no more pairs of form $\langle \nu, \vec{F}_\nu \rangle$ with ν an ordinal and $\vec{F}_\nu$ a sequence of ultrafilters over V_ν. But actually, if $\nu \in A$ and $o^{\vec{U}}(\nu) > 0$, then we have a sequence of measures $\vec{U}(\nu) = \langle \vec{U}(\nu, \alpha) \mid \alpha < o^{\vec{U}}(\nu) \rangle$ over ν. And it can be used exactly as $\vec{F}_\nu$ of the previous section. Note that here $\vec{U}(\nu)$ is determined uniquely from ν and $\vec{U}$. Also, because of coherence, namely Definition 5.21(2), there is no need to define the set $\overline{A}$ as it was done in the previous section before the definition of $R_{\vec{V}}$ (Lemma 5.1).

Let us denote for an ordinal $d = \nu$ or pair $d = \langle \nu, B \rangle$, ν by $\kappa(d)$. Using the above observations we define $\mathcal{P}_{\vec{U}}$ a coherent sequences analogue of $R_{\vec{V}}$.

5.22 Definition. Let $\mathcal{P}_{\vec{U}}$ be the set of finite sequences $\langle d_1, \dots, d_n, \langle \kappa, A \rangle \rangle$ such that:

(1) $A \in \bigcap \vec{U}(\kappa)$.

(2) $\min(A) > \kappa(d_n)$.

(3) For every m with $1 \leq m \leq n$, either

(3a) d_m is an ordinal and then $o^{\vec{U}}(d_m) = 0$, or

(3b) $d_m = \langle \nu, A_\nu \rangle$ for some ν with $o^{\vec{U}}(\nu) > 0$ and $A_\nu \in \bigcap_{\alpha < 0^{\vec{U}}(\nu)} U(\nu, \alpha)$.

(4) For every $1 \leq i \leq j \leq m$,

(4a) $\kappa(d_i) < \kappa(d_j)$, and

(4b) if d_j is of form $\langle \nu, A_\nu \rangle$ then $\min(A_\nu) > \kappa(d_i)$.

The definition of orders $\leq, \leq^*$ on $\mathcal{P}_{\vec{U}}$ repeats those of $R_{\vec{V}}$ (5.2), only ultrafilter sequences $\vec{F}_\nu$'s and $\vec{V}$ are removed from the conditions there.

5.23 Definition. Let $p = \langle d_1, \dots, d_n, \langle \kappa, A \rangle \rangle, q = \langle e_1, \dots, e_m, \langle \kappa, B \rangle \rangle \in \mathcal{P}_{\vec{U}}$. We say that p *is stronger than* q and denote this by $p \geq q$ iff

(1) $A \subseteq B$.

(2) $n \geq m$.

(3) There are $1 \leq i_1 < i_2 < \cdots < i_m \leq n$ such that for every k with $1 \leq k \leq m$, either

(3a) $e_k = d_{i_k}$, or

(3b) $e_k = \langle \nu, B_\nu \rangle$ and then $d_{i_k} = \langle \nu, C_\nu \rangle$ with $C_\nu \subseteq B_\nu$.

(4) Let $i_1, \dots, i_m$ be as in (3). Then the following holds for every j with $1 \leq j \leq n$ and $j \notin \{i_1, \dots, i_k\}$:

(4a) If $j > i_m$, then $d_j \in B$ or d_j is of form $\langle \nu, C_\nu \rangle$ with $\nu \in B$ and $C_\nu \subseteq B \cap \nu$.

(4b) If $j < i_m$, then for the least k with $j < i_k$, e_k is of form $\langle \nu, B_\nu \rangle$ so that

(i) if d_j is an ordinal then $d_j \in B_\nu$, and

(ii) if $d_j = \langle \rho, S \rangle$ then $\rho \in B_\nu$ and $S \subseteq B_\nu$.

5.24 Definition. Let $p = \langle d_1, \dots, d_n, \langle \kappa, A \rangle \rangle, q = \langle e_1, \dots, e_m, \langle \kappa, B \rangle \rangle \in \mathcal{P}_{\vec{U}}$. We say that p is a *direct extension* of q and denote this by $p \geq^* q$ iff

(1) $p \geq q$, and

(2) $n = m$.

Now all the results of the previous section are valid in the present context with $\mathcal{P}_{\vec{U}}$ replacing $R_{\vec{V}}$. Also their proofs require only trivial changes.

If $\delta < \kappa$, then $\langle U(\kappa,\alpha) \mid \alpha < \delta\rangle$ can be split. Thus for every $\alpha < \delta$, $U(\kappa,\alpha)$ concentrates on the set $Y_\alpha = \{\nu < \kappa \mid o^{\vec{U}}(\nu) = \alpha\}$. $\mathcal{P}_{\vec{U}}$, above the condition $\langle\langle\kappa, \bigcup_{\alpha<\delta} Y_\alpha\rangle\rangle$ is then the Magidor forcing for changing cofinality of κ to $\mathrm{cf}(\delta)$.

5.3. Extender-Based Radin Forcing

In this section we give a brief description of the extender-based Radin forcing developed by Merimovich [39]. Previously, extender-based Magidor forcing was introduced by Miri Segal [49]. The basic idea is to combine the forcing of Sect. 3 with those of Sect. 5.1.

Assume GCH and let $j : V \longrightarrow M \supseteq V_{\kappa+4}$ be an elementary embedding with $\mathrm{crit}(j) = \kappa$. First, as in Sect. 3, but with $\lambda = \kappa^{++}$, for every $\alpha < \kappa^{++}$, we consider U_α an ultrafilter over κ defined by:

$$X \in U_\alpha \quad \text{iff} \quad \alpha \in j(X).$$

Define a partial order $\leq_j$ on λ:

$$\alpha \leq_j \beta \quad \text{iff} \quad \alpha \leq \beta \text{ and for some } f \in {}^\kappa\kappa,\ j(f)(\beta) = \alpha.$$

Let $\langle \pi_{\alpha\beta} \mid \beta \leq \alpha < \kappa^{++},\ \alpha \geq_j \beta\rangle$ be the sequence of projections defined in Sect. 3. The whole system (i.e. the extender)

$$\langle\langle U_\alpha \mid \alpha < \kappa^{++}\rangle, \langle \pi_{\alpha\beta} \mid \beta \leq \alpha < \kappa^{++}, \alpha \geq_j \beta\rangle\rangle$$

is in M, as ${}^{\kappa^{++}}V_{\kappa+3} \subseteq V_{\kappa+3} \subseteq M$. Denote this system by $E(0)$ and U_α by $E_\alpha(0)$ for every $\alpha < \kappa^{++}$. Now, as in Lemma 5.1, we use the fact that $E(0) \in M$ in order to define $E(1)$. Thus for every $\alpha < \kappa^{++}$, we define over V_κ the following ultrafilter:

$$A \in E_{\langle\alpha,E(0)\rangle}(1) \quad \text{iff} \quad \langle\alpha, E(0)\rangle \in j(A).$$

It is possible to use only α as an index instead of $\langle\alpha, E(0)\rangle$, but it turns out that the latter notation is more convenient. Note that $E_{\langle\alpha,E(0)\rangle}(1)$ concentrates on elements of form $\langle\xi, e(0)\rangle$, where $e(0)$ is an extender over ξ^0 (recall, that in the notation of Sect. 3, ξ^0 denotes the projection of ξ to the normal ultrafilter by $\pi_{\alpha\kappa}$) of length $(\xi^0)^{++}$ including projections between its measures. Also note that σ_α defined by $\sigma_\alpha(\xi, e(0)) = \xi$ projects $E_{\langle\alpha,E(0)\rangle}(1)$ onto $E_\alpha(0) = U_\alpha$.

We define projections $\pi_{\langle\alpha,E(0)\rangle,\langle\beta,E(0)\rangle}$ for $\kappa^{++} > \alpha \geq \beta$ with $\alpha \geq_j \beta$ as follows:

$$\pi_{\langle\alpha,E(0)\rangle,\langle\beta,E(0)\rangle}(\langle\xi, e(0)\rangle) = \langle\pi_{\alpha\beta}(\xi), e(0)\rangle.$$

Then, in M,

$$j(\pi_{\langle\alpha,E(0)\rangle,\langle\beta,E(0)\rangle})(\langle\alpha, E(0)\rangle) = \langle\beta, E(0)\rangle.$$

This defines an extender

$$E(1) = \big\langle \langle E_{\langle \alpha, E(0)\rangle}(1) \mid \alpha < \kappa^{++}\rangle, \\ \langle \pi_{\langle \alpha, E(0)\rangle, \langle \beta, E(0)\rangle} \mid \kappa^{++} > \alpha \geq \beta,\ \alpha \geq_j \beta \rangle \big\rangle.$$

Continue by recursion. Suppose that $\tau < \kappa^{+4}$ and a sequence of extenders $\langle E(\tau') \mid \tau' < \tau\rangle$ is already defined. Again, as ${}^{\kappa^{++}}V_{\kappa+4} \subseteq V_{\kappa+4} \subseteq M$, $\langle E(\tau') \mid \tau' < \tau\rangle \in M$. So, for every $\alpha < \kappa^{++}$ we can define an ultrafilter over V_κ as follows

$$A \in E_{\langle \alpha, E(0), \ldots, E(\tau'), \ldots \mid \tau' < \tau\rangle}(\tau) \\ \text{iff} \quad \langle \alpha, E(0), \ldots, E(\tau'), \ldots \mid \tau' < \tau\rangle \in j(A).$$

Define projections:

$$\pi_{\langle \alpha, E(0), \ldots, E(\tau), \ldots \mid \tau' < \tau\rangle, \langle \beta, E(0), \ldots, E(\tau'), \ldots \mid \tau' < \tau\rangle}(\langle \xi, d\rangle) = \langle \pi_{\alpha\beta}(\xi), d\rangle,$$

for every α, β, with $\kappa^+ > \alpha \geq \beta$ and $\alpha \geq_j \beta$. Further, let us suppress these long indexes and use only α and β, i.e. the above projection will be denote by $\pi_{\alpha\beta}$ and $E_{\langle \alpha, E(0), \ldots, E(\tau'), \ldots \mid \tau' < \tau\rangle}(\tau)$ by $E_\alpha(\tau)$. Define

$$E(\tau) = \big\langle \langle E_\alpha(\tau) \mid \alpha < \kappa^{++}\rangle, \langle \pi_{\alpha\beta} \mid \kappa^{++} > \alpha \geq \beta, \alpha \geq_j \beta\rangle \big\rangle.$$

Fix some $\tau^* \leq \kappa^{+4}$. Let $\vec{E} = \langle E(\tau) \mid \tau < \tau^*\rangle$.

In [24] and [25] Merimovich used such $\vec{E}$ to define the extender-based Radin forcing. The general definition is quite complicated and we will not reproduce it here. Instead let us concentrate on the case length$(\vec{E}) = 2$. This exhibits the idea of the Merimovich construction. So let $\vec{E} = \langle E(0), E(1)\rangle$. For each $\alpha < \kappa^{++}$ let $\overline{\alpha} = \langle \alpha, E(0), E(1)\rangle$. Set $\overline{E} = \{\langle \alpha, E(0), E(1)\rangle \mid \alpha < \kappa^{++}\}$.

5.25 Definition. A *basic condition* in $\mathcal{P}_{\vec{E}}$ over κ is one of form

$$p = \{\langle \overline{\gamma}, p^{\overline{\gamma}}\rangle \mid \overline{\gamma} \in s\} \cup \{\langle \overline{\alpha}, p^{\overline{\alpha}}\rangle, T\}$$

so that

(1) $s \subseteq \overline{E}$, $|s| \leq \kappa$ and $\overline{\kappa} \in s$.

This s is the support of the condition and here, instead of just ordinals used as supports in the extender-based Prikry forcing of Sect. 3, its elements are of form $\overline{\gamma} = \langle \gamma, E(0), E(1)\rangle$.

(2) $p^{\overline{\gamma}} \in V_\kappa$ is a finite sequence of elements of form an ordinal ν or a pair $\langle \nu, e_\nu(0)\rangle$ with $e_\nu(0)$ and extender of length $(\nu^0)^{++}$ over ν^0 (recall that, as in Sect. 3, ν^0 denotes the projection of ν by $\pi_{\gamma,\kappa}$, i.e. to the normal measure). We require that the ν^0's of elements of $p^{\overline{\gamma}}$ are increasing. Denote the ν of the last element of $p^{\overline{\gamma}}$ by $\kappa(p^{\overline{\gamma}})$, if $p^{\overline{\gamma}}$ is nonempty and let $\kappa(p^{\overline{\gamma}}) = 0$ otherwise.

(3) $\overline{\alpha}$ is above every $\overline{\gamma} \in s$ in the $\leq_j$ order (i.e. $\gamma \leq_j \alpha$).

(4) $\kappa(p^{\overline{\alpha}}) \leq \kappa(p^{\overline{\gamma}})$.

(5) $T \in E_\alpha(0) \cap E_\alpha(1) \setminus V_{\kappa(p^{\overline{\kappa}})+1}$.

(6) For every $\overline{\nu} \in T$,

$$|\{\overline{\gamma} \in s \mid (\kappa(p^{\overline{\gamma}}))^0 < (\kappa(\overline{\nu}))^0\}| \leq (\kappa(\overline{\nu}))^0.$$

(7) For every $\overline{\nu} \in T$, $\overline{\beta}, \overline{\gamma} \in \overline{s}$, if $(\kappa(p^{\overline{\beta}}))^0, (\kappa(p^{\overline{\gamma}}))^0 < (\kappa(\overline{\nu}))^0$ and $\overline{\beta} \neq \overline{\gamma}$ then

$$\pi_{\overline{\alpha},\overline{\beta}}(\overline{\nu}) \neq \pi_{\overline{\alpha},\overline{\gamma}}(\overline{\nu}).$$

As in Sect. 3, we write $T^p, mc(p), \mathrm{supp}(p)$ for $T, \overline{\alpha}$ and $s \cup \{\overline{\alpha}\}$ respectively.

5.26 Definition. For basic conditions p, q of $\mathcal{P}_{\vec{E}}$ over κ, define $p \geq^* q$ iff

(1) $\mathrm{supp}(p) \supseteq \mathrm{supp}(q)$.

(2) For every $\overline{\gamma} \in \mathrm{supp}(q)$, $p^{\overline{\gamma}} = q^{\overline{\gamma}}$.

(3) $T^p \subseteq \pi^{-1}_{mc(p),mc(q)}$ "T^q.

(4) For every $\overline{\gamma} \in \mathrm{supp}(q)$ and $\overline{\nu} \in T^p$, if $(\kappa(p^{\overline{\gamma}}))^0 < (\kappa(\overline{\nu}))^0$ then

$$\pi_{mc(p),\overline{\gamma}}(\overline{\nu}) = \pi_{mc(q),\overline{\gamma}}(\pi_{mc(p),mc(q)}(\overline{\nu})).$$

Now let p_0 be a basic condition over κ and $\overline{\nu} \in T^{p_0}$. We define $p_0{}^\frown\overline{\nu}$, a one-element extension of p_0 by $\overline{\nu}$.

5.27 Definition. $p_0{}^\frown\langle\overline{\nu}\rangle$ will be of form $p'_1{}^\frown p'_0$ where

(1) $\mathrm{supp}(p'_0) = \mathrm{supp}(p_0)$.

(2) For every $\overline{\gamma} \in \mathrm{supp}(p'_0)$

$$p'^{\overline{\gamma}}_0 = \begin{cases} \pi_{mc(p_0),\overline{\gamma}}(\overline{\nu}), & \\ \qquad \text{if } (\kappa(p_0^{\overline{\gamma}}))^0 < (\kappa(\overline{\nu}))^0 \text{ and } \overline{\nu} \text{ is of form } \langle \nu, e_\nu(0)\rangle, & \\ p_0^{\overline{\gamma}}{}^\frown \pi_{mc(p_0),\overline{\gamma}}(\overline{\nu}), & \\ \qquad \text{if } (\kappa(p_0^{\overline{\gamma}}))^0 < (\kappa(\overline{\nu}))^0 \text{ and } \overline{\nu} \text{ is an ordinal}, & \\ p_0^{\overline{\gamma}}, \quad \text{otherwise}. & \end{cases}$$

(3) $T^{p'_0} = T^{p_0} \setminus V_{(\kappa(\overline{\nu}))^0+1}$.

If $\overline{\nu}$ is an ordinal then p'_1 is empty, otherwise the following holds:

(4) $mc(p'_1) = \overline{\nu}$.

(5) $\mathrm{supp}(p_1') =$
$\{\pi_{mc(p_0),\overline{\gamma}}(\overline{\nu}) \mid \overline{\gamma} \in \mathrm{supp}(p_0) \text{ and } (\kappa(p_0^{\overline{\gamma}}))^0 < (\kappa(\overline{\nu}))^0\} \cup \{\overline{\nu}\}$.

(6) $p_1'^{\pi_{mc(p_0),\overline{\gamma}}(\overline{\nu})} = p_0^{\overline{\gamma}}$.

(7) $T^{p_1'} = T^{p_0} \cap V_{(\kappa(\overline{\nu}))^0}$.

Definition 5.27 is the crucial step of the definition of $\mathcal{P}_{\vec{E}}$. If $\overline{\nu}$ was an ordinal then $p^\frown\langle\overline{\nu}\rangle = p_0'$ is generated as in Sect. 3. But if $\overline{\nu}$ is of form $\langle \nu, e_\nu(0)\rangle$ then after adding $\overline{\nu}$, p_0 splits into two blocks p_0' and p_1'. p_0' is still a basic condition over κ generated in the fashion of Sect. 3. But p_1' is a new block. We just separate and move to the new block every $p_0^{\overline{\gamma}}$ to which $\overline{\nu}$ can be added. The actual addition, $\pi_{mc(p_0),\overline{\gamma}}(\overline{\nu})$, is kept both in the support of p_1' and on the new $p_0'^{\overline{\gamma}}$. T^{p_0} is moved down to ν and p_1' is a basic condition over ν^0. We can extend it further using measures of the extender $e_\nu(0)$. It acts from now autonomously and as a condition in the extender-based Prikry forcing of Sect. 3. Note that we still keep some connection with the upper block p_0'. Thus $\pi_{mc(p_0),\overline{\gamma}}(\overline{\nu})$'s appear in both $\mathrm{supp}(p_1')$ and p_0', as $p_0'^{\overline{\gamma}}$. See the figure below which gives an example of such p_0, p_0', p_1'.

$$\begin{array}{lllll}
 & & \overline{\mu}_{32} & & \\
 & \overline{\mu}_{11} & \overline{\mu}_{31} & & \\
\overline{\mu}_0 & \overline{\mu}_{10} & \overline{\mu}_{30} & \overline{\mu}_4 & T \cap V_\kappa(\overline{\nu}) \\
\hline
\overline{\nu}^0 & \pi_{\alpha_4\alpha_1}(\overline{\nu}) & \pi_{\alpha_4\alpha_3}(\overline{\nu}) & \overline{\nu} &
\end{array} \quad p_1'$$

$$\begin{array}{llllll}
 & & \overline{\mu}_{21} & & & \\
\overline{\nu}^0 & \pi_{\alpha_4\alpha_1}(\overline{\nu}) & \overline{\mu}_{20} & \pi_{\alpha_4\alpha_3}(\overline{\nu}) & \overline{\nu} & T \setminus V_{\kappa(\overline{\nu})+1} \\
\hline
\overline{\kappa} & \overline{\alpha}_1 & \overline{\alpha}_2 & \overline{\alpha}_3 & \overline{\alpha}_4 = mc &
\end{array} \quad p_0'$$

$$\begin{array}{llllll}
 & & & \overline{\mu}_{32} & & \\
 & \overline{\mu}_{11} & \overline{\mu}_{21} & \overline{\mu}_{31} & & \\
\overline{\mu}_0 & \overline{\mu}_{10} & \overline{\mu}_{20} & \overline{\mu}_{30} & \overline{\mu}_4 & T \\
\hline
\overline{\kappa} & \overline{\alpha}_1 & \overline{\alpha}_2 & \overline{\alpha}_3 & \overline{\alpha}_4 = mc &
\end{array} \quad p_0$$

Once we have a two-block condition $p_1{}^\frown p_0$ we can extend it further in the same way by adding either $\overline{\nu} \in T_{p_0}$ or $\overline{\nu} \in T_{p_1}$. In the first case this will generate a new block between p_1 and p_0 and the second below p_1. We are allowed to repeat this any finite number of times. Thus a general condition in $P_{\vec{E}}$ will be of form $p = p_n{}^\frown p_{n-1}{}^\frown \cdots {}^\frown p_0$ where p_0 is a basic condition over κ, p_1 over some $\nu_0 < \kappa, \ldots$ and, p_n over some $\nu_{n-1} < \nu_{n-2}$.

An example of a condition in $P_{\vec{E}}$:

$$\begin{array}{lllllll}
 & \overline{\tau}_{12} & & & & & \\
 & \overline{\tau}_{11} & & & & & \\
\overline{\tau}_0 & \overline{\tau}_{10} & \overline{\tau}_2 & \overline{\tau}_3 & \overline{\tau}_4 & \overline{\tau}_5 & R \\
\hline
\overline{\mu}_0 & \overline{\mu}_1 & \overline{\mu}_2 & \overline{\mu}_3 & \overline{\mu}_4 & \overline{\mu}_5 = mc &
\end{array} \quad p_2$$

$$\begin{array}{ccccccc} & & \overline{\mu}_{71} & & & & \\ \overline{\mu}_0 & \overline{\mu}_1 & \overline{\mu}_{70} & \overline{\mu}_8 & \overline{\mu}_6 & \overline{\mu}_5 & S \\ \hline \overline{\nu}_0 & \overline{\nu}_1 & \overline{\nu}_2 & \overline{\nu}_3 & \overline{\nu}_4 & \overline{\nu}_5 = mc & \end{array} \quad p_1$$

$$\begin{array}{cccccc} & & & \overline{\nu}_{71} & & \\ \overline{\nu}_0 & \overline{\nu}_1 & \overline{\nu}_6 & \overline{\nu}_{70} & \overline{\nu}_4 & T \\ \hline \overline{\kappa} & \overline{\alpha}_1 & \overline{\alpha}_2 & \overline{\alpha}_3 & \overline{\alpha}_4 = mc & \end{array} \quad p_0$$

Each block may grow separately. Thus in the example the maximal coordinate of p_1 changed from $\overline{\nu}_4$, corresponding to $\overline{\alpha}_4$, to a new value $\overline{\nu}_5$. New coordinates $\overline{\nu}_2, \overline{\nu}_3$ were added in p_1 and $\overline{\mu}_2, \overline{\mu}_3, \overline{\mu}_4$ in p_2.

The following is a straightforward generalization of Definition 5.27.

5.28 Definition. Let $p, q \in P_{\overline{E}}$. We say that p is a *one-point extension* of q and denote this by $p \geq_1 q$ iff p and q are of form

$$\begin{aligned} p &= p_{n+1}{}^\frown p_n{}^\frown \cdots {}^\frown p_0 \\ q &= q_n{}^\frown \cdots {}^\frown q_0 \end{aligned}$$

and there is a k with $0 \leq k \leq n$ such that

(1) p_i and q_i are basic conditions over some ν_i with $p_i \geq^* q_i$ for $i < k$.

(2) p_{i+1} and q_i are basic conditions over some ν_i with $p_{i+1} \geq^* q_i$ for each $k < i \leq n$.

(3) There is a $\overline{\nu} \in T^{q_k}$ such that $p_{k+1}{}^\frown p_k \geq^* q_k{}^\frown \langle \overline{\nu} \rangle$.

We now define n-point extension for every $n < \omega$.

5.29 Definition. Let $p, q \in P_{\vec{E}}$. We say that p is an *n-point extension* of q and denote this by $p \geq_n q$ iff either $n = 0$ and $p \geq^* q$, or else $n > 0$ and there are $p^n, \ldots, p^0$ such that

$$p = p^n \geq_1 \cdots \geq_1 p^0 = q.$$

Finally, we can define the order $\leq$ on $P_{\vec{E}}$.

5.30 Definition. Let $p, q \in P_{\vec{E}}$. Define $p \geq q$ iff there is $n < \omega$ such that $p \geq_n q$.

Let G be a generic subset of $\langle \mathcal{P}_{\vec{E}}, \leq \rangle$. For every α with $\kappa \leq \alpha < \kappa^{++}$ we want to collect together all the ordinals corresponding to α into a set which we call G^α. Define

$$\begin{aligned} G^\alpha = \bigl\{ \kappa(p^{\vec{E}_\alpha}) \mid \exists p \in G\, (&p \text{ is a basic condition} \\ &\text{over } \kappa \text{ with } \vec{E}_\alpha \in \operatorname{supp}(p) \text{ and } p^{\vec{E}_\alpha} \neq \emptyset) \bigr\}. \end{aligned}$$

It is not hard to see using the definition of the order on $P_{\vec{E}}$ that G^α will be unbounded in κ sequence of order type ω^2. Also $\alpha \neq \beta$ will imply $G^\alpha \neq G^\beta$.

In addition, the sequence G^κ (the one corresponding to the normal ultrafilter) will be closed.

Now let length($\vec{E}$) be any ordinal $\leq \kappa^{+4}$. Merimovich [39] showed that his forcing $P_{\vec{E}}$ shares all the properties of the Radin forcing of Lemma 5.1, only κ^+-c.c. should be replaced by κ^{++}-c.c. This causes a new problem to show that κ^+ is preserved in cases of regular κ. In order to preserve measurability of κ the following variation of repeat point is used:

> $\tau <$ length($\vec{E}$) is called a *repeat point* of $\vec{E}$ if for every
>
> $\xi <$ length($\vec{E}$) and $\alpha < \kappa^{++}$, $A \in E_\alpha(\xi)$ implies that for some
>
> $\xi' < \tau$ $A \in E_\alpha(\xi')$.

That is, τ acts simultaneously as a repeat point of the sequence of ultrafilters $\langle E_\alpha(\xi') \mid \xi < \text{length}(\vec{E})\rangle$ for each $\alpha < \kappa^{++}$. Clearly, there will be lots of repeat points below κ^{+4}. The κ^{++} sets G^α defined above for a generic $G \subseteq P_{\vec{E}}$ will witness $2^\kappa = \kappa^{++}$; G^κ will be a club in κ.

In further work [40], Merimovich added collapses to the extender-based Radin forcing. This allowed him to reprove results of Foreman-Woodin [12], and Woodin and obtain new interesting patterns of global behavior of the power function.

6. Iterations of Prikry-Type Forcing Notions

In this section we present two basic techniques for iterating Prikry-type forcing notions. The first one is called the Magidor or full support iteration and the second, Easton support iteration.

A set with two partial orders $\langle \mathcal{P}, \leq, \leq^* \rangle$ is called a *Prikry-type forcing notion* iff

(a) $\leq \supseteq \leq^*$.

(b) (The Prikry condition) For every $p \in \mathcal{P}$ and statement σ of the forcing language of $\langle \mathcal{P}, \leq \rangle$ there is a $p^* \geq^* p$ deciding σ.

Notice that any forcing $\langle \mathcal{P}, \leq \rangle$ can be turned into a Prikry-type by defining $\leq^* = \leq$. In this case the iterations below coincide with the usual iterations with full or Easton support.

6.1. Magidor Iteration

The presentation below follows [16] and is a bit different from Magidor's original version [34].

Let ρ be an ordinal. We define an iteration $\langle \mathcal{P}_\alpha, \underset{\sim}{Q}_\alpha \mid \alpha < \rho\rangle$. For every $\alpha < \rho$ define by recursion $\mathcal{P}_\alpha$ to be the set of all p of form $\langle \underset{\sim}{p}_\gamma \mid \gamma < \alpha\rangle$ so that for every $\gamma < \alpha$,

(a) $p\restriction\gamma = \langle \underset{\sim}{p}_\beta \mid \beta < \gamma\rangle \in \mathcal{P}_\gamma$, and

(b) $p\restriction\gamma \Vdash_{\mathcal{P}_\gamma}$ "$\underset{\sim}{p}_\gamma$ is a condition in the forcing $\langle \underset{\sim}{Q}_\gamma, \underset{\sim}{\leq}_\gamma, \underset{\sim}{\leq}^*_\gamma\rangle$ of Prikry-type".

We next define two orderings $\leq_{\mathcal{P}_\alpha}$ and $\leq^*_{\mathcal{P}_\alpha}$ on $\mathcal{P}_\alpha$.

6.1 Definition. Let $p = \langle \underset{\sim}{p}_\gamma \mid \gamma < \alpha\rangle$, $q = \langle \underset{\sim}{q}_\gamma \mid \gamma < \alpha\rangle \in \mathcal{P}_\alpha$. Then $p \geq_{\mathcal{P}_\alpha} q$ iff

(1) For every $\gamma < \alpha$, $p\restriction\gamma \Vdash_{\mathcal{P}_\gamma}$ "$\underset{\sim}{p}_\gamma \geq_\gamma \underset{\sim}{q}_\gamma$ in the forcing $\underset{\sim}{Q}_\gamma$".

(2) There exists a finite $b \subseteq \alpha$ such that for every $\gamma \in \alpha \setminus b$, $p\restriction\gamma \Vdash_{\mathcal{P}_\gamma}$ "$\underset{\sim}{p}_\gamma \geq^*_\gamma \underset{\sim}{q}_\gamma$ in the forcing $\underset{\sim}{Q}_\gamma$".

If the set b in (2) is empty, then we call p a *direct extension* of q and denote this by $p \geq^*_{\mathcal{P}_\alpha} q$.

Thus we use full support iteration here, but in order to pass from a condition $q \in \mathcal{P}_\alpha$ to a stronger one, we are allowed to take non-direct extensions only at finitely many places. A typical example and the one originally used by Magidor in [34], is an iteration of Prikry forcings at each measurable below α. Here, in order to extend a condition we may shrink sets of measure one at each measurable $\beta < \alpha$ but only for finitely many β's is it allowed to add new elements of the Prikry sequence. We further discuss this important example in detail. Let us now show that $\langle \mathcal{P}_\alpha, \leq, \leq^*\rangle$ is itself of Prikry-type.

6.2 Lemma. *Let $p = \langle \underset{\sim}{p}_\gamma \mid \gamma < \alpha\rangle \in \mathcal{P}_\alpha$ and σ be a statement of the forcing language of $\langle \mathcal{P}_\alpha, \leq\rangle$. Then there is a direct extension of p deciding σ.*

Proof. We deal first with the successor case. Let $\alpha = \alpha' + 1$. Assume that $\mathcal{P}_{\alpha'}$ has the Prikry property, $\mathcal{P}_\alpha = \mathcal{P}_{\alpha'} * \underset{\sim}{Q}_{\alpha'}$, and $\Vdash_{\mathcal{P}_{\alpha'}} (\langle \underset{\sim}{Q}_{\alpha'}, \underset{\sim}{\leq}_{\alpha'}, \underset{\sim}{\leq}^*_{\alpha'}\rangle$ has the Prikry property). Let $G_{\alpha'} \subseteq \mathcal{P}_{\alpha'}$ be generic for $\langle \mathcal{P}_{\alpha'}, \leq\rangle$ with $p\restriction\alpha' = \langle \underset{\sim}{p}_\gamma \mid \gamma < \alpha'\rangle \in G_{\alpha'}$. Find $p^*_{\alpha'} \geq^*_{\alpha'} p_{\alpha'}$ in $Q_{\alpha'}$ which decides $\sigma[G_{\alpha'}]$. Back in V, let $\underset{\sim}{p}^*_{\alpha'}$ be a name of such $p^*_{\alpha'}$ so that

$$p\restriction\alpha' \Vdash_{\mathcal{P}_{\alpha'}} \underset{\sim}{p}^*_{\alpha'} \text{ decides } \sigma.$$

Use the Prikry property of $\langle \mathcal{P}_{\alpha'}, \leq, \leq^*\rangle$ to find a $q \geq^* p\restriction\alpha'$ such that $q \Vdash_{\mathcal{P}_{\alpha'}} (\underset{\sim}{p}^*_{\alpha'} \Vdash_{\underset{\sim}{Q}^*_{\alpha'}} {}^i\sigma)$, for some $i < 2$, where ${}^0\sigma = \sigma$ and ${}^1\sigma = \neg\sigma$. Then, with $r = q^\frown \underset{\sim}{p}^*_{\alpha'}$, we have $r \Vdash_{\mathcal{P}_\alpha} {}^i\sigma$.

Suppose now that α is a limit ordinal. Assume that there is no direct extension of p deciding σ. We define by recursion on $\beta < \alpha$

$$p(\beta) = \langle \underset{\sim}{p}^*_\gamma \mid \gamma < \beta\rangle^\frown \langle \underset{\sim}{p}_\gamma \mid \beta \leq \gamma < \alpha\rangle \geq^* p$$

so that $p(\beta)\restriction\beta = \langle \underset{\sim}{p}^*_\gamma \mid \gamma < \beta\rangle \Vdash_{\mathcal{P}_\beta} \neg\sigma_\beta$ where $\sigma_\beta \equiv (\exists \underset{\sim}{q} \in \mathcal{P}_\alpha \setminus \beta(\underset{\sim}{q} \geq^* p \setminus \beta$ and $\underset{\sim}{q} \Vert \sigma))$.

Suppose that $\langle p(\gamma) \mid \gamma < \beta\rangle$ are defined and $\leq^*$-increasing. Define $p(\beta)$:

Case 1. $\beta = \beta' + 1$.

Force with $\mathcal{P}_{\beta'} = \mathcal{P}_\alpha \restriction \beta'$, i.e. with $\langle \mathcal{P}_{\beta'}, \leq \rangle$. Let $G_{\beta'} \subseteq \mathcal{P}_{\beta'}$ be generic with $p(\beta') \restriction \beta' \in G_{\beta'}$. At stage β' we use $\langle Q_{\beta'}, \leq_{\beta'}, \leq^*_{\beta'} \rangle$. It satisfies the Prikry condition. So there is a $p^*_{\beta'} \geq^*_{\beta'} p_{\beta'}$ deciding σ_β.

6.2.1 Claim. $p^*_{\beta'} \Vdash_{Q_{\beta'}} \neg \sigma_\beta$.

Proof. Suppose otherwise. Then there is a $p^{**}_{\beta'} \geq^* p^*_{\beta'}$ with

$$p^{**}_{\beta'} \Vdash_{Q_{\beta'}} (\exists \underset{\sim}{q} \in \mathcal{P}_\alpha \setminus \beta (\underset{\sim}{q} \geq^* p \setminus \beta \text{ and } \underset{\sim}{q} \Vdash_{\mathcal{P}_\alpha \setminus \beta} {}^i\sigma))$$

for some $i < 2$, where ${}^o\sigma = \sigma$ and ${}^1\sigma = \neg\sigma$. Without loss of generality assume $i = 0$. Then there are $r = \langle \underset{\sim}{r}_\gamma \mid \gamma < \beta' \rangle \in G_{\beta'}$ and $\underset{\sim}{q}$ such that $p(\beta') \restriction \beta' \leq r$ and

$$r \Vdash_{\mathcal{P}_{\beta'}} (\underset{\sim}{p}_{\beta'} \leq^*_{\beta'} \underset{\sim}{p}^{**}_{\beta'} \Vdash_{\underset{\sim}{Q}_{\beta'}} (\underset{\sim}{q} \geq^* p \setminus \beta \text{ and } \underset{\sim}{q} \Vdash_{\mathcal{P}_\alpha \setminus \beta} \sigma)).$$

Hence, $r \Vdash_{\mathcal{P}_{\beta'}} (\underset{\sim}{p}^{**}_{\beta'} {}^\frown \underset{\sim}{q} \geq^* p \setminus \beta'$ and $\underset{\sim}{p}^{**}_{\beta'} {}^\frown \underset{\sim}{q} \Vdash_{\mathcal{P}_\alpha \setminus \beta'} \sigma)$. In particular, $p(\beta') \restriction \beta' \leq r \Vdash_{\mathcal{P}_{\beta'}} \sigma_{\beta'}$ which contradicts the choice of $p(\beta')$. ⊣

Now, since $G_{\beta'}$ was arbitrary, we can take a name $\underset{\sim}{p}^*_{\beta'}$ of $p^*_{\beta'}$ such that $p(\beta') \restriction \beta' \Vdash (\underset{\sim}{p}^*_{\beta'} \Vdash_{\underset{\sim}{Q}_{\beta'}} \neg \sigma_\beta)$. Set $p(\beta) = p(\beta') \restriction \beta' {}^\frown \underset{\sim}{p}^*_{\beta'} {}^\frown \langle \underset{\sim}{p}_\gamma \mid \beta \leq \gamma < \alpha \rangle$.

Case 2. β is a limit ordinal.

Then we need to show that

$$p(\beta) = \langle \underset{\sim}{p}^*_\gamma \mid \gamma < \beta \rangle {}^\frown \langle \underset{\sim}{p}_\gamma \mid \beta \leq \gamma < \alpha \rangle$$

is as desired, i.e. $p(\beta) \restriction \beta \Vdash \neg \sigma_\beta$. Suppose otherwise; then there is an $r = \langle \underset{\sim}{r}_\gamma \mid \gamma < \beta \rangle \in \mathcal{P}_\beta$ such that $r \geq p(\beta) \restriction \beta$ and $r \Vdash \sigma_\beta$. Extend it, if necessary, so that for some $\underset{\sim}{q}$ and $i < 2$

$$r \Vdash (\underset{\sim}{q} \geq^* p \setminus \beta \text{ and } \underset{\sim}{q} \Vdash_{\mathcal{P}_\alpha \setminus \beta} {}^i\sigma)$$

where ${}^0\sigma = \sigma$ and ${}^1\sigma = \neg\sigma$. Let us assume that $i = 0$. By the definition of order on $\mathcal{P}_\beta$ (Definition 6.1(2)), there is a $\beta^* < \beta$ such that for every γ with $\beta^* \leq \gamma < \beta$, $r \restriction \gamma \Vdash \underset{\sim}{r}_\gamma \geq^*_\gamma \underset{\sim}{p}^*_\gamma$. Consider a $\mathcal{P}_{\beta^*}$-name $\underset{\sim}{q}' = \langle \underset{\sim}{r}_\gamma \mid \beta^* \leq \gamma < \beta \rangle {}^\frown \underset{\sim}{q}$. Then, $r \restriction \beta^* \Vdash (\underset{\sim}{q}' \geq^* p \setminus \beta^*$ and $\underset{\sim}{q}' \Vdash_{\mathcal{P}_\alpha \setminus \beta^*} \sigma)$. But $r \restriction \beta^* \geq p(\beta^*) \restriction \beta^* \Vdash \neg \sigma_{\beta^*}$. Contradiction.

This completes the construction. Consider $p(\alpha) = \langle \underset{\sim}{p}^*_\gamma \mid \gamma < \alpha \rangle$. Pick some $r \geq p(\alpha)$ deciding σ. Now we obtain a contradiction as in Case 2. This completes the proof of the lemma. ⊣

Let us now use this type of iteration to prove the following result of Magidor [34]:

6.3 Theorem. *Let κ be a strongly compact cardinal. Then there is a cardinal preserving extension in which κ is the least strongly compact and also the least measurable.*

Proof. We use the Magidor iteration $\langle \mathcal{P}_\alpha, \underset{\sim}{Q}_\beta \mid \alpha \leq \kappa, \beta < \kappa\rangle$ defined by recursion on α as follows:

(a) If $\Vdash_{\mathcal{P}_\alpha}$ (α is not measurable), then take $\langle \underset{\sim}{Q}_\alpha, \underset{\sim}{\leq}_\alpha, \underset{\sim}{\leq}^*_\alpha\rangle$ to be the trivial forcing

(b) If $\Vdash_{\mathcal{P}_\alpha}$ (α is a measurable cardinal), then let $\langle \underset{\sim}{Q}_\alpha, \underset{\sim}{\leq}_\alpha, \underset{\sim}{\leq}^*_\alpha\rangle$ be the Prikry forcing over α with some normal ultrafilter.

(c) If $\neg(a)$ and $\neg(b)$, then we pick a maximal antichain $\langle p^i \mid i < \tau\rangle$ of elements of $\mathcal{P}_\alpha$ so that each p^i decides measurability of α. Above each p^i forcing (α is not measurable) we take $\langle \underset{\sim}{Q}_\alpha, \underset{\sim}{\leq}_\alpha, \underset{\sim}{\leq}^*_\alpha\rangle$ to be the trivial forcing. Above every p^i forcing measurability of α let $\langle \underset{\sim}{Q}_\alpha, \underset{\sim}{\leq}_\alpha, \underset{\sim}{\leq}^*_\alpha\rangle$ be the Prikry forcing over α with some normal ultrafilter.

This means that $\langle \underset{\sim}{Q}_\alpha, \underset{\sim}{\leq}_\alpha, \underset{\sim}{\leq}^*_\alpha\rangle$ is a $\mathcal{P}_\alpha$-name such that $\mathcal{P}_\alpha$ forces: "if α is a measurable then $\langle \underset{\sim}{Q}_\alpha, \underset{\sim}{\leq}_\alpha, \underset{\sim}{\leq}^*_\alpha\rangle$ is Prikry forcing, and otherwise $\langle \underset{\sim}{Q}_\alpha, \underset{\sim}{\leq}_\alpha, \underset{\sim}{\leq}^*_\alpha\rangle$ is trivial.

Let us now force with $\langle \mathcal{P}_\kappa, \leq\rangle$. Let $G_\kappa \subseteq \mathcal{P}_\kappa$ be generic. Then, in $V[G_\kappa]$, all measurable cardinals below κ are destroyed. Note that for $\alpha < \kappa$ the iteration past stage $\alpha + 1$ does not add measurables below α, since it is itself a Prikry-type iteration with $\leq^*$-order more than 2^α-closed. So, no new subsets are added to α. We need only show that κ remains strongly compact. This will follow from the next more general statement. ⊣

Note that the above proof is a simplification of Magidor's proof, which showed that the measures to be killed are exactly the unique normal extensions of measures of order 0 in V.

6.4 Lemma. *Suppose that $\langle \mathcal{P}_\alpha, \underset{\sim}{Q}_\beta \mid \alpha \leq \kappa, \beta < \kappa\rangle$ is the Magidor iteration of Prikry-type forcing notions such that $\mathcal{P}_\alpha \subseteq {}^\alpha V_\alpha$ for unboundedly many α's. Then κ is strongly compact in $V^{\mathcal{P}_\kappa}$ provided it was such in V and for every $\alpha < \kappa$, $\Vdash_{\mathcal{P}_\alpha}$ ((a) $\langle \underset{\sim}{Q}_\alpha, \underset{\sim}{\leqslant}_\alpha{}^*\rangle$ is $|\alpha|$-closed, and (b) for all $p, q, r \in \underset{\sim}{Q}_\alpha$, if $p, q \geq^* r$ there is a $t \in \underset{\sim}{Q}_\alpha$ such that $t \geq^* p, q$).*

6.5 Remark. The requirement (a) holds for most of the Prikry-type forcing notions. But we refer the reader to [16] and [46] for doing without closure but still preserving measurability. The requirement (b) is much more restrictive. For example extender-based Prikry forcings of Sects. 2 and 3 do not satisfy it. Also the Easton support iteration that will be defined later fails to satisfy (b). It will be shown in Lemma 6.8 in non trivial cases (a) + (b) imply existence of a measurable cardinal $\geq |\alpha|$.

Proof. Let $G_\kappa \subseteq \mathcal{P}_\kappa$ be generic, i.e. generic for $\langle \mathcal{P}_\kappa, \leq\rangle$. Let $\lambda \geq \kappa$. We want to establish the λ-strong compactness of κ. In V pick a κ-complete fine ultrafilter U over $\mathcal{P}_\kappa(\lambda)$ (recall that U is fine if for every $\alpha < \lambda$ the set

$\{P \in \mathcal{P}_\kappa(\lambda) \mid \alpha \in P\}$ is in U). Let $j : V \longrightarrow M \simeq \mathrm{Ult}(V, U)$. Back in $V[G_\kappa]$, let us define $U^* \supseteq U$ over $\mathcal{P}_\kappa(\lambda)$ as follows:

$$X \in U^* \quad \text{iff} \quad \begin{array}{l} \text{for some } p \in G_\kappa, \text{ in } M \text{ there is a } q \in \mathcal{P}_{j(\kappa)} \setminus \kappa \text{ with} \\ q \geq^* j(p) \setminus \kappa \text{ so that } p^\frown q \Vdash_{\mathcal{P}_{j(\kappa)}} [\check{\mathrm{id}}]_U \in j(\underset{\sim}{X}) \\ \text{for some name } \underset{\sim}{X} \text{ of } X. \end{array}$$

Note that $\mathcal{P}_\kappa = j(\mathcal{P}_\kappa){\restriction}\kappa$, since, in M, $j(\mathcal{P}_\kappa){\restriction}\kappa \subseteq {}^\kappa V_\kappa$ and $j``V_\kappa = V_\kappa$. So G_κ is an M-generic subset of $\mathcal{P}_\kappa$. Also $j(p){\restriction}\kappa = p$ for every $p \in \mathcal{P}_\kappa$. We need to first check that U^* is well defined. By (b) any two q's as above are compatible. Note also that if p, $p' \in \mathcal{P}_\kappa$ are $\leq$-compatible, then, in M, $j(p) \setminus \kappa$ and $j(p') \setminus \kappa$ are $\leq^*$-compatible. To see this, let $r \in \mathcal{P}_\kappa$, $r \geq p, p'$. Then there is a $\beta < \kappa$ such that for $\beta \leq \alpha < \kappa$, $r{\restriction}\beta \Vdash_{\mathcal{P}_\beta} \underset{\sim}{r}_\beta \geq^*_\beta \underset{\sim}{p}_\beta, \underset{\sim}{p}'_\beta$, where $r = \langle \underset{\sim}{r}_\gamma \mid \gamma < \kappa\rangle$, $p = \langle \underset{\sim}{p}_\gamma \mid \gamma < \kappa\rangle$, and $p' = \langle \underset{\sim}{p}'_\gamma \mid \gamma < \kappa\rangle$. So, in M, the same is true for $j(r)$, $j(p)$ and $j(p')$. Hence, r forces $\leq^*$-compatibility of $j(p) \setminus \kappa$ and $j(p') \setminus \kappa$ witnessed by $j(r) \setminus \kappa$. In particular, this shows using (b) that $q \geq^* j(p) \setminus \kappa$ is $\leq^*$-compatible with every $j(p') \setminus \kappa$ with p, $p' \in G$.

Now applying above, if $p \in G$ forces "$\underset{\sim}{X} \in \underset{\sim}{U}^*$ and $\underset{\sim}{X} = \underset{\sim}{Y}$", then for some $q \in \mathcal{P}_{j(\kappa)} \setminus \kappa$, $q \geq^* j(p) \setminus \kappa$ we have

$$j(p){\restriction}\kappa^\frown q \ \Vdash_{\mathcal{P}_{j(\kappa)}} [\check{\mathrm{id}}]_U \in j(\underset{\sim}{X}).$$

But by elementarity, $j(p) \Vdash j(\underset{\sim}{X}) = j(\underset{\sim}{Y})$. Also, $j(p){\restriction}\kappa^\frown q \geq^* j(p)$. Hence

$$j(p){\restriction}\kappa^\frown q \ \Vdash_{\mathcal{P}_{j(\kappa)}} [\check{\mathrm{id}}]_U \in j(\underset{\sim}{Y}).$$

Clearly, $U^* \supseteq U$, and so it is fine. Let $\langle X_\nu \mid \nu < \delta < \kappa\rangle$ be a partition of $\mathcal{P}_\kappa(\lambda)$. We need to show that then for some $\nu < \delta$, $X_\nu \in U^*$. Pick some $p \in G_\kappa$ and names $\langle \underset{\sim}{X}_\nu \mid \nu < \delta\rangle$ such that $p \Vdash \langle \underset{\sim}{X}_\nu \mid \nu < \delta\rangle$ is a partition of $\mathcal{P}_\kappa(\lambda)$.

Then in M, $j(p) \Vdash (\langle j(\underset{\sim}{X}_\nu) \mid \nu < \delta\rangle$ is a partition of $\mathcal{P}_{j(\kappa)}(j(\lambda))$. Now we use κ-completeness of $\langle \mathcal{P}_{j(\kappa)} \setminus \kappa, \leq^*\rangle$ in order to find $\nu^* < \delta$ and $q \in \mathcal{P}_{j(\kappa)} \setminus \kappa$ with $q \geq^* j(p) \setminus \kappa$ such that for some $r \in G_\kappa$,

$$r^\frown q \Vdash_{\mathcal{P}_{j(\kappa)}} [\check{\mathrm{id}}] \in j(\underset{\sim}{X}_{\nu^*}).$$

Hence $X_{\nu^*} \in U^*$ and we are done. $\dashv$

Note that once the ultrafilter U (in the proof above) is normal and the forcing $\langle \mathcal{P}_{j(\kappa)} \setminus \kappa, \leq^*\rangle$ is λ^+-closed, then the ultrafilter U^* extending U will be normal as well. Just use a regressive function instead of a partition in the proof of Lemma 6.4.

In particular, if we change the cofinality of each measurable cardinal below a measurable cardinal κ using the Magidor iteration of Prikry forcings, then the normal measure U over κ in V extends to a normal measure in the extension, provided $\langle \mathcal{P}_{j(\kappa)} \setminus \kappa, \leq^* \rangle$ is κ^+-closed. In order to insure this degree of closure, we may take U which concentrates on non-measurables, i.e.

$$\{\alpha < \kappa \mid \alpha \text{ is not a measurable }\} \in U.$$

It is still necessary to check that the iteration $\mathcal{P}_\kappa$ does not turn κ into a measurable in M (the ultrapower by U). This will follow from the following general statement. The proof of it is based on [34].

6.6 Lemma. *Suppose that $\langle \mathcal{P}_\alpha, \underset{\sim}{Q}_\beta \mid \alpha \leq \kappa, \beta < \kappa \rangle$ is the Magidor iteration of Prikry-type forcing notions such that*

(a) $\mathcal{P}_\alpha \subseteq {}^\alpha V_\alpha$ for unboundedly many α's.

(b) For every $\alpha < \kappa$, $\Vdash_{\mathcal{P}_\alpha} (\langle \underset{\sim}{Q}_\alpha, \underset{\sim}{\leqslant}_\alpha{}^* \rangle$ is $|\alpha|$-closed, and: for all $p, q, r \in \underset{\sim}{Q}_\alpha$, if $p, q \geq^* r$ there is a $t \in \underset{\sim}{Q}_\alpha$ such that $t \geq^* p, q)$.

(c) The forcing in the interval $[\alpha, (2^\alpha)^+]$ is trivial for stationary many α's.

If κ is measurable in $V^{\mathcal{P}_\kappa}$ then it was measurable in V.

6.7 Remark. We do not know if there is a non-trivial Prikry-type forcing $\langle Q, \leq, \leq^* \rangle$ satisfying the clause 2 for a non-measurable cardinal α, assuming that $\langle Q, \leq^* \rangle$ is not α^+-closed. So, the clause 3 may hold automatically.

Proof. Let G be a generic subset of $\mathcal{P}_\kappa$ and W a κ-complete ultrafilter over κ in $V[G]$. Then, clearly, κ is at least a Mahlo cardinal in V. So, the following set is stationary in V:

$$S = \big\{\alpha < \kappa \mid \mathcal{P}_\alpha \subseteq {}^\alpha V_\alpha, |V_\alpha| = \alpha, \\ \text{the forcing is trivial in the interval } [\alpha, (2^\alpha)^+]\big\}.$$

Suppose for simplicity that $0_{\mathcal{P}_\kappa} = \langle 0_{\underset{\sim}{Q}_\gamma} \mid \gamma < \kappa \rangle \in G$ and it forces that W is a κ-complete ultrafilter over κ in $V[G]$; otherwise, just work above a condition forcing this. Note that in our setting, $0_{\mathcal{P}_\kappa}$ need not be weaker than every other condition in $\mathcal{P}_\kappa$: We may have a $t = \langle \underset{\sim}{t}_\gamma \mid \gamma < \kappa \rangle \in \mathcal{P}_\kappa$ such that for infinitely many γ's $\underset{\sim}{t}_\gamma$ is a non-direct extension of $\underset{\sim}{0}_\gamma$ in $\underset{\sim}{Q}_\gamma$; such a t would be incompatible with $0_{\mathcal{P}_\kappa}$.

Let $\alpha \in S$. Define an ultrafilter U_α over κ in $V[G{\restriction}\alpha]$ as follows:

$$X \in U_\alpha \quad \text{iff} \quad \text{for some } p \in G{\restriction}\alpha \text{ there is a } q \in \mathcal{P}_\kappa \setminus \alpha \text{ with } q \geq^* 0_{\mathcal{P}_\kappa} \setminus \alpha \\ \text{so that } p^\frown q \Vdash_{\mathcal{P}_\kappa} \underset{\sim}{X} \in \underset{\sim}{W} \text{ for some name } \underset{\sim}{X} \text{ of } X.$$

Trivially, U_α is well-defined. $\alpha \in S$ implies that U_α is at least a $(2^\alpha)^+$-complete ultrafilter over κ in $V[G{\restriction}\alpha]$ (just use the $\leq^*$-completeness of the forcing $\mathcal{P}_\kappa \setminus \alpha$ to deal with partitions of κ into $\leq (2^\alpha)^+$ many pieces).

We use now the argument of Levy-Solovay [33] to find a condition $t(\alpha) \in \mathcal{P}_\alpha$ with $t(\alpha) \geq 0_{\mathcal{P}_\alpha}$ so that for every set $X \in V$ with $X \subseteq \kappa$, either

$$t(\alpha) \Vdash_{\mathcal{P}_\alpha} X \in \underset{\sim}{U}_\alpha \quad \text{or} \quad t(\alpha) \Vdash_{\mathcal{P}_\alpha} X \notin \underset{\sim}{U}_\alpha.$$

Thus, suppose that there is no such $t(\alpha)$. Work in V. For each $q \in \mathcal{P}_\alpha$ with $q \geq 0_{\mathcal{P}_\alpha}$, we pick a set $A_q \subseteq \kappa$ such that q does not decide whether $A_q \in \underset{\sim}{U}_\alpha$. Define a function from κ into a set of cardinality at most 2^α as follows:

$$F(\nu) = \langle \langle q, i \rangle \mid q \in \mathcal{P}_\alpha,\ i < 2, \text{ and: } i = 0 \text{ if } \nu \in A_q,\ i = 1 \text{ otherwise} \rangle.$$

Now, in $V[G{\restriction}\alpha]$, U_α is $(2^\alpha)^+$-complete ultrafilter, hence there is an $X \in V \cap U_\alpha$ such that $F(\nu) = F(\mu)$, for any $\nu, \mu \in X$. Pick some $q \in G{\restriction}\alpha$ forcing this. Finally, back in V, there is an $i < 2$ such that for each $\nu \in X$ the pair $\langle q, i \rangle$ appears in $F(\nu)$. Then, $i = 0$ implies $X \subseteq A_q$ and $i = 1$ implies $X \subseteq \kappa \setminus A_q$. But $q \Vdash_{\mathcal{P}_\alpha} X \in \underset{\sim}{U}_\alpha$. Hence, either $q \Vdash_{\mathcal{P}_\alpha} A_q \in \underset{\sim}{U}_\alpha$ or $q \Vdash_{\mathcal{P}_\alpha} \kappa \setminus A_q \in \underset{\sim}{U}_\alpha$, which contradicts the choice of A_q.

Set now (in V)

$$U(\alpha) = \{X \subseteq \kappa \mid t(\alpha) \Vdash_{\mathcal{P}_\alpha} X \in \underset{\sim}{U}_\alpha\}.$$

Clearly, $U(\alpha)$ is a $(2^\alpha)^+$-complete ultrafilter over κ.

We shall find a stationary subset S' of S such that for every $\alpha < \beta \in S'$, $U(\alpha) = U(\beta)$. Then, $\alpha \in S'$ will imply that $U(\alpha)$ is a κ-complete ultrafilter over κ.

Thus, consider the sequence of conditions $\langle t(\alpha) \mid \alpha \in S \rangle$. For each $\alpha \in S$ we have $t(\alpha) \geq 0_{\mathcal{P}_\alpha}$. Hence, by the definition of the order $\leq$, there is a finite set $b(\alpha) \subseteq \alpha$ such that for each $\gamma \in \alpha \setminus b(\alpha)$,

$$t(\alpha){\restriction}\gamma \Vdash_{\mathcal{P}_\gamma} t(\underset{\sim}{\alpha})_\gamma \geq^* \underset{\sim}{0}_\gamma \text{ in the forcing } \underset{\sim}{Q}_\gamma.$$

Now, we shrink S to a stationary set S_1 such that for each $\alpha, \beta \in S_1$, $b(\alpha) = b(\beta)$. Denote $b(\alpha)$ for $\alpha \in S_1$ by b. Let $\delta = \max(b) + 1$. The cardinality of the forcing $\mathcal{P}_\delta$ is less than α, for each $\alpha \in S_1$, since $\alpha = |V_\alpha|$ and $\mathcal{P}_\delta \in V_\alpha$. Hence, there are a stationary $S' \subseteq S_1$ and $t \in \mathcal{P}_\delta$ such that for each $\alpha \in S'$ we have $t(\alpha){\restriction}\delta = t$. It follows that $t(\alpha)$ and $t(\beta)$ are compatible in the order $\leq^*$, for any $\alpha, \beta \in S'$. We claim that $U(\alpha) = U(\beta)$, for each $\alpha, \beta \in S'$.

Recall the definition of $U(\alpha)$. Thus,

$$\begin{aligned} X \in U(\alpha) \quad &\text{iff} \quad t(\alpha) \Vdash_{\mathcal{P}_\alpha} X \in \underset{\sim}{U}_\alpha \\ &\text{iff} \quad \exists q \in \mathcal{P}_\kappa \setminus \alpha \text{ with } q \geq^* 0_{\mathcal{P}_\kappa} \setminus \alpha \\ &\qquad\ \text{such that } t(\alpha)^\frown q \Vdash_{\mathcal{P}_\kappa} X \in \underset{\sim}{W}. \end{aligned}$$

Suppose for a moment that there is an $X \in U(\alpha) \setminus U(\beta)$. Find $q_\alpha \in \mathcal{P}_\kappa \setminus \alpha$ with $q_\alpha \geq^* 0_{\mathcal{P}_\kappa} \setminus \alpha$ such that $t(\alpha)^\frown q_\alpha \Vdash_{\mathcal{P}_\kappa} X \in \underset{\sim}{W}$ and $q_\beta \in \mathcal{P}_\kappa \setminus \alpha, q_\beta \geq^* 0_{\mathcal{P}_\kappa} \setminus \alpha$ such that $t(\beta)^\frown q_\beta \Vdash_{\mathcal{P}_\kappa} \kappa \setminus X \in \underset{\sim}{W}$. But $t(\alpha)^\frown q_\alpha$ and $t(\beta)^\frown q_\beta$ are $\leq^*$-compatible, which is impossible since they force contradictory assertions. $\dashv$

The next simple observation shows that the conditions (a) and (b) of Lemma 6.4 already imply some strength.

6.8 Lemma. *Let $\langle Q, \leq, \leq^* \rangle$ be a non-trivial Prikry-type forcing notion and κ be an uncountable cardinal such that*

(1) $\langle Q, \leq^* \rangle$ is κ-closed.

(2) For all $p, q, r \in Q$, if $p, q \geq^* r$ there is a $t \in Q$ such that $t \geq^* p, q$.

Then there is a measurable cardinal $\geq \kappa$.

Proof. Let λ be a cardinal which contains a new subset. Fix a name $\underset{\sim}{a}$ of such a subset of λ. We assume that 0_Q already forces this.

Set

$$A = \{\rho < \lambda \mid \exists t \geq^* 0_Q \ t \Vdash_Q \check{\rho} \in \underset{\sim}{a}\}.$$

Then

$$0_Q \Vdash_Q \underset{\sim}{a} \neq \check{A}$$

just since A is old but a is new. Now define U to be the set of all $X \subseteq \lambda$ such that

$$\exists t \geq^* 0_Q \ t \Vdash_Q (\rho \in \check{X} \text{ for the least } \rho \text{ such that } \rho \in \underset{\sim}{a} \Delta \check{A}).$$

Then, clearly, U is a κ-complete ultrafilter over λ. Let us show that it is a non-principal one. Suppose otherwise. Then, for some $\rho < \lambda$ we will have $\{\rho\} \in U$. Hence there is a $t \geq^* 0_Q$ such that $t \Vdash \check{\rho} \in \underset{\sim}{a} \Delta \check{A}$. Extend t to some $s \geq^* t$ such that

$$s \Vdash_Q \check{\rho} \in \underset{\sim}{a} \quad \text{or} \quad s \Vdash_Q \check{\rho} \in \check{A}.$$

The former possibility implies that $\rho \in A$, by the definition of A, which is impossible. If the later possibility occurs, then, again by the definition of A, we will have an $r \geq^* 0_Q$ such that $r \Vdash_Q \check{\rho} \in \underset{\sim}{a}$. But r is compatible with s, so we arrive to a contradiction. Hence, U is non-principal and we are done. $\dashv$

6.9 Example. Let us show how the Magidor iteration may destroy stationarity. Fix a regular cardinal κ, and set $Z = \{\alpha < \kappa \mid \alpha \text{ is a measurable}\}$. Assume that Z is stationary. Change the cofinality of each measurable cardinal below κ to ω using the Magidor iteration $\langle \mathcal{P}_\alpha, \underset{\sim}{Q}_\beta \mid \alpha \leq \kappa, \beta < \kappa \rangle$ of Prikry forcings. By Lemma 6.6, only the members of Z change their cofinality. Let G be a generic subset of $\mathcal{P}_\kappa$ with $0_{\mathcal{P}_\kappa} \in G$. Let C_α denote the Prikry sequence for α deduced from G, where $\alpha \in Z$. Define a function $f : Z \to \kappa$ by setting $f(\alpha) = \min(C_\alpha)$.

6.10 Claim. *There is a finite $b \subseteq \kappa$ such that the elements of the sequence $\langle C_\alpha \mid \alpha \in Z \setminus b \rangle$ are pairwise disjoint. In particular, f is one-to-one on $Z \setminus b$ and, so Z is not stationary in $V[G]$.*

Proof. Work in V. Let $t \in \mathcal{P}_\kappa$ with $t \geq 0_{\mathcal{P}_\kappa}$. Suppose for simplicity that $t \geq^* 0_{\mathcal{P}_\kappa}$; otherwise, we work only with the coordinates where the extension is direct. Let $t = \langle \underset{\sim}{t}_\gamma \mid \gamma < \kappa \rangle$ and for each $\gamma \in Z$ we have $\underset{\sim}{t}_\gamma = \langle \langle \rangle, \underset{\sim}{A}_\gamma \rangle$, where $\underset{\sim}{A}_\gamma$ is a $\mathcal{P}_\gamma$-name of a set in the normal ultrafilter $\underset{\sim}{U}^*_\gamma$ over γ which extends a normal ultrafilter U_γ, as in Lemma 6.4. Note that by Lemma 6.6, the forcing at each $\gamma \in \kappa \setminus Z$ is trivial.

Fix $\gamma \in Z$. Let G_γ be a generic subset of $\mathcal{P}_\gamma$ with $r = t \restriction \gamma \in G_\gamma$. Turn to $V[G_\gamma]$. Let us show that the set

$$B_\gamma = \{\nu \in A_\gamma \mid \forall \delta \in Z \cap \gamma\, (\nu \notin C_\delta)\}$$

must be in U^*_γ. Consider $j(r) \setminus \kappa$ in M, where $j : V \to M$ is the canonical embedding into the ultrapower of V by U_γ. Let $q \geq^* j(r) \setminus \kappa$ be obtained from $j(r) \setminus \kappa$ by replacing each set of measure one $\underset{\sim}{A}_\delta$ (for $\delta \in j(Z) \setminus (\kappa+1)$) of $j(r) \setminus \kappa$ by $\underset{\sim}{A}_\delta \setminus (\kappa+1)$. Then

$$r^\frown q \Vdash_{\mathcal{P}_{j(\kappa)}} [\check{\gamma}] \in j(\underset{\sim}{B}_\gamma).$$

Hence, $B_\gamma \in U^*_\gamma$.

Finally, back in V, we define $t^* \geq^* t$ by replacing each $\underset{\sim}{A}_\gamma$ by $\underset{\sim}{B}_\gamma$. Then t^* will force that C_γ's are pairwise disjoint. ⊣

Suppose now that κ above was measurable and there was a measure U on κ concentrating on measurables. Then $Z \in U$. But in $V[G]$, Z is not stationary any more. Hence U does not extend to a normal ultrafilter.

6.2. Leaning's Forcing

Jeffrey Leaning [32] suggested a new and interesting way to put together Prikry forcings over different cardinals avoiding iteration. Below, we will briefly describe his forcing.

Fix a set Z of measurable cardinals, and set $\kappa = \sup(Z)$. For each $\delta \in Z$ pick a normal ultrafilter U_δ over δ. Set $\vec{U} = \langle U_\delta \mid \delta \in Z\rangle$.

6.11 Definition. Let the *filter of long measure one sets* be

$$\mathfrak{L}(\vec{U}) = \{X \subseteq \kappa \mid X \cap \delta \in U_\delta \text{ for all } \delta \in Z\}.$$

6.12 Definition. Let $\mathbf{D}(\vec{U})$ be the set of all the pairs $\langle s, X\rangle$ such that

(1) $s \in [\kappa]^{<\omega}$.

(2) $X \in \mathfrak{L}(\vec{U})$.

6.13 Definition. Let $\langle s, X\rangle, \langle t, Y\rangle \in \mathbf{D}(\vec{U})$. Then $\langle s, X\rangle \geq \langle t, Y\rangle$ iff

(1) $s \subseteq t$.

(2) $X \subseteq Y$.

(3) $s \setminus t \subseteq Y$.

If $s = t$ then $\langle s, X\rangle \geq^* \langle t, Y\rangle$.

In [32] Leaning showed that $\langle \mathbf{D}(\vec{U}), \leq, \leq^* \rangle$ satisfies the Prikry condition, and so it is a Prikry-type forcing notion. He found a very interesting application of this forcing. Thus, starting from an assumption weaker than $o(\kappa) = 2$, Leaning constructed a forcing extension in which the first measurable cardinal κ may have any number $\lambda \leq \kappa$ normal measures.

Note that if Z does not include its limit points (for example, if there is no measurable which is a limit of measurables), then this forcing is equivalent to the Magidor iteration of Prikry forcings for elements of Z. Crucially for each $\delta \in Z$, the forcing $\mathcal{P}_\delta$ below δ has cardinality less than δ. Hence, it is not hard to replace a name of a set of measure one by an actual set in U_δ; see [33] or just apply the corresponding argument from Lemma 6.6. Also, for each $\delta \in Z$ the set $A_\delta = \delta \setminus \sup(Z \cap \delta)$ is in U_δ and these sets are disjoint. Hence, we can link between finite sequences s and measurable cardinals in Z.

Leaning's forcing is equivalent for a while to a kind of the Magidor "iteration" of Prikry forcings, where instead of names of sets of measure one actual sets of measure one (i.e. those from U_δ's) are used. But once the set Z includes δ such that

$$\text{for all } X \in U_\delta, \text{ there is a } \mu < \kappa \text{ such that } X \cap \mu \in U_\mu,$$

the forcing $\langle \mathbf{D}(\vec{U}), \leq, \leq^* \rangle$ is different. Namely, at this stage the Magidor "iteration" of Prikry forcings without names fails to satisfy the Prikry condition. Thus, for example, there is no direct extension of the condition $\langle \langle \langle \rangle, \gamma \rangle \mid \gamma \in Z \rangle$ which can decide the following statement: "The first element of the Prikry sequence for δ belongs to the Prikry sequence of some $\mu < \delta$".

6.3. Easton Support Iteration

In many applications of iterated forcings it is important to have the κ-c.c. at stage κ of an iteration. The Magidor iteration or full support iteration, as well as the usual full support iterations in different contexts, fail to have this property. The common approach is to replace a full support by an Easton one. In the present section we show how to realize this dealing with iterations of Prikry-type forcing notions. The method was introduced in [13] and simplified in [16]. Shelah [51] found generalizations and applied them to small cardinals.

Let us give one example that illuminates the difference between full and Easton support iteration.

6.14 Example. Suppose that κ is inaccessible and the limit of a set A of measurable cardinals. Assume for simplicity that A does not contain any of its limit points. Either iteration can be used to add a Prikry sequence C_γ for each $\gamma \in A$. In case of the full support iteration this sequence is uniform (below a certain condition) in the sense that if $\langle X_\gamma \mid \gamma \in A \rangle$ is any sequence in V such that X_γ is in a normal ultrafilter U_γ over γ, then $\bigcup_{\gamma \in A} (C_\gamma \setminus X_\gamma)$

is finite. Just the definition of the Magidor iteration and an easy density argument imply this. Thus let $p = \langle \underset{\sim}{p}_\gamma \mid \gamma \in A\rangle$ be a condition in this iteration. A does not contain its limit points, so we can assume that each $\underset{\sim}{p}_\gamma$ is in V. Then p_γ is just a condition in the Prikry forcing with U_γ. Hence $p_\gamma = \langle t_\gamma, A_\gamma\rangle$, where $t_\gamma \in [\gamma]^{<\omega}$ and $A_\gamma \in U_\gamma$. Suppose now that we force only with extensions of the condition $\{\langle \emptyset, \gamma\rangle \mid \gamma \in A\}$. Then all but finitely many t_γ's are empty. Let $t_{\gamma_1}, \dots, t_{\gamma_n}$ be the only nonempty t_γ's. Extend p to a condition $q = \{\langle t_\gamma, X_\gamma \cap A_\gamma\rangle \mid \gamma \in A\}$. Then $q \Vdash (\bigcup_{\gamma\in A} \underset{\sim}{C}_\gamma \setminus \check{X}_\gamma) \subseteq \bigcup_{i=1}^n t_{\gamma_i}$.

In the case of Easton support iteration this will not be true: for example the set $\{\min(C_\gamma) \mid \gamma \in A\}$ will be essentially an Easton support Cohen subset of κ, and in fact $V[\langle C_\gamma \mid \gamma \in A\rangle]$ will not have uniform sequence of Prikry sequences as in the full support iteration.

Let us now turn to the definition of the Easton iteration of Prikry-type forcing notions.

Let ρ be an ordinal. We define an iteration $\langle \mathcal{P}_\alpha, \underset{\sim}{Q}_\alpha \mid \alpha < \rho\rangle$ with Easton support. For every $\alpha < \rho$ define by recursion $\mathcal{P}_\alpha$ to be the set of all elements p of form $\langle \underset{\sim}{p}_\gamma \mid \gamma \in g\rangle$, where

(1) $g \subseteq \alpha$.

(2) g has an Easton support, i.e. for every inaccessible $\beta \le \alpha$, $\beta > |g \cap \beta|$, provided that for every $\gamma < \beta$, $|\mathcal{P}_\gamma| < \beta$.

(3) For every $\gamma \in \mathrm{dom}(g)$,

$$p \restriction \gamma = \langle \underset{\sim}{p}_\beta \mid \beta \in g \cap \gamma\rangle \in \mathcal{P}_\gamma$$

and $p\restriction\gamma \Vdash_{\mathcal{P}_\gamma}$ "$\underset{\sim}{p}_\gamma$ is a condition in the forcing $\langle \underset{\sim}{Q}_\gamma, \underset{\sim}{\le}_\gamma, \underset{\sim}{\le}^*_\gamma\rangle$ of Prikry-type".

Let $p = \langle \underset{\sim}{p}_\gamma \mid \gamma \in g\rangle$ and $q = \langle \underset{\sim}{q}_\gamma \mid \gamma \in f\rangle$ be elements of $\mathcal{P}_\alpha$. Then $p \ge q$ iff

(1) $g \supseteq f$.

(2) For every $\gamma \in f$, $p\restriction\gamma \Vdash_{\mathcal{P}_\gamma}$ "$\underset{\sim}{p}_\gamma \ge_\gamma \underset{\sim}{q}_\gamma$ in the forcing $\underset{\sim}{Q}_\gamma$".

(3) There exists a finite subset b of f so that for every $\gamma \in f \setminus b$, $p\restriction\gamma \Vdash_{\mathcal{P}_\gamma}$ "$\underset{\sim}{p}_\gamma \ge^*_\gamma \underset{\sim}{q}_\gamma$ in the forcing $\underset{\sim}{Q}_\gamma$".

If the set b in (3) is empty, then we call p a *direct extension* of q, and denote this by $p \ge^* q$.

Notice that in contrast to Definition 6.1, we are allowed to take non-direct extensions in both $\le$ and $\le^*$ orderings for infinitely many coordinates $\gamma < \alpha$ provided that they are outside of the support (i.e. outside of f for extensions of $q = \langle \underset{\sim}{q}_\gamma \mid \gamma \in f\rangle$). Inside the support, as in Definition 6.1, only for finitely many γ's can a non-direct extension be taken.

Let $p = \langle \underset{\sim}{p}_\gamma \mid \gamma \in g\rangle \in \mathcal{P}_\alpha$ and $\beta < \alpha$. Consider $p\restriction\beta = \langle \underset{\sim}{p}_\gamma \mid \gamma \in g \cap \beta\rangle$. Let $G_\beta \subseteq \mathcal{P}_\beta$ be generic with $p\restriction\beta \in G_\beta$. Then $p \setminus \beta = \langle \underset{\sim}{p}_\gamma \mid \gamma \in g \setminus \beta\rangle \in \mathcal{P} \setminus \beta =$

$\mathcal{P}_\alpha/G_\beta$. Let $t = \langle t_\gamma \mid \gamma \in f\rangle \in \mathcal{P}_\alpha/G_\beta$ be an extension of $p \setminus \beta$. The support f of t need not be in V. But we can always find an $f^* \in V$, $f \subseteq f^* \subseteq \alpha \setminus \beta$ satisfying (2) of the definition of the conditions. Thus let $\underset{\sim}{t}, \underset{\sim}{f}$ be a $\mathcal{P}_\beta$-names of t, f so that

$$p{\restriction}\beta \Vdash \underset{\sim}{t} = \langle \underset{\sim}{t}_\gamma \mid \gamma \in \underset{\sim}{f}\rangle \geq p \setminus \beta.$$

Work in V. Define $f^* \subseteq \alpha$ covering $\underset{\sim}{f}$ and satisfying (2) of the definition of the conditions. The construction of f^* is recursive. Let $f^* \cap \beta = \emptyset$. Suppose that $\beta < \gamma < \alpha$ and $f^* \cap \delta$ is already defined for each $\delta < \gamma$. If γ is a limit ordinal then let $f^* \cap \gamma = \bigcup_{\delta<\gamma} f^* \cap \delta$. If $\gamma = \gamma' + 1$, then we include γ' in f^* only in the case if some extension of $p{\restriction}\beta$ forces (in $\mathcal{P}_\beta$) "$\check{\gamma}' \in \underset{\sim}{f}$". This completes the definition of f^*. It is easy to check that for every $\gamma \lneqq \alpha$,

$$p{\restriction}\beta \Vdash_{\mathcal{P}_\beta} (\check{f}^* \supseteq \underset{\sim}{f} \quad \text{and} \quad |\check{f}^* \cap \check{\gamma}| \leq |\underset{\sim}{f} \cap \check{\gamma}| + |\mathcal{P}_\beta|).$$

Now, if γ with $\beta < \gamma \leq \alpha$ is inaccessible and for every $\delta < \gamma$, $|\mathcal{P}_\delta| < \gamma$, then $|f^* \cap \gamma| < \gamma$, since, back in $V[G_\beta]$ we have $|f \cap \gamma| < \gamma$ and $|\mathcal{P}_\beta| < \gamma$. So γ remains inaccessible and $|f^* \cap \gamma| \leq |f \cap \gamma| + |\mathcal{P}_\beta| < \gamma$. Clearly, in V, $|f^* \cap \gamma| < \gamma$ holds then as well.

Using the observation above, we can establish the Prikry condition for $\langle \mathcal{P}_\alpha, \leq, \leq^*\rangle$ repeating the argument of Lemma 6.2.

6.15 Lemma. *Suppose that $\langle \mathcal{P}_\alpha, \underset{\sim}{Q}_\beta \mid \alpha \leq \kappa, \beta < \kappa\rangle$ is an Easton iteration of Prikry-type forcing notions such that for unboundedly many α's $\mathcal{P}_\alpha \subseteq {}^\alpha V_\alpha$. Then κ is measurable in $V^{\mathcal{P}_\kappa}$, provided:*

(a) κ is measurable in V.

(b) $V \vDash 2^\kappa = \kappa^+$.

(c) For every cardinal $\alpha < \kappa$ we have

(i) $\Vdash_{\mathcal{P}_\alpha} (\langle \underset{\sim}{Q}_\alpha, \underset{\sim}{\leq}^*_\alpha\rangle$ is $|\alpha|$-closed).

(ii) for every β with $\alpha < \beta < \alpha^+$, $\Vdash_{\mathcal{P}_\alpha} (\langle \underset{\sim}{Q}_\alpha, \underset{\sim}{\leq}^*_\alpha\rangle$ is α^+-closed).

(d) For a closed unbounded set of α's below κ,
$\Vdash_{\mathcal{P}_\alpha}$ either

(i) $\langle \underset{\sim}{Q}_\alpha, \underset{\sim}{\leq}^*_\alpha\rangle$ is $|\alpha|^+$-closed, or

(ii) for all $p, q \in \underset{\sim}{Q}^*_\alpha$, if $p, q \underset{\sim}{\geq}^*_\alpha 0_{\underset{\sim}{Q}_\alpha}$ there is a $t \in \underset{\sim}{Q}_\alpha$ such that $t \underset{\sim}{\geq}^*_\alpha p, q$

where $0_{\underset{\sim}{Q}_\alpha}$ is the weakest element of $\underset{\sim}{Q}_\alpha$.

6.16 Remark.

(1) The requirement $\mathcal{P}_\alpha \subseteq {}^\alpha V_\alpha$ for unboundedly many $\alpha < \kappa$ easily implies here that $\mathcal{P}_\alpha \subseteq V_\alpha$, for every inaccessible α in a closed unbounded subset of κ, due to the Easton support of conditions.

(2) If at each $\alpha < \kappa$, $\leq_\alpha = \leq^*_\alpha$, then also $\leq = \leq^*$ for $\mathcal{P}_\kappa$ and the lemma is actually the Kunen-Paris [31] result on preservation of measurability. Also our argument is very close to the Kunen-Paris one.

(3) If κ was a supercompact then as in [4] it is possible to show that κ remains strongly compact. Clearly, the supercompactness may be lost by iterating the Prikry forcing at each measurable below κ.

(4) Even if the alternative (ii) of the conclusion holds for each $\alpha < \kappa$, $\langle \mathcal{P}_\kappa, \leq^* \rangle$ fails to satisfy it, i.e. in $\mathcal{P}_\kappa$ there are lots of incompatible direct extensions of a fixed condition.

Proof. Let U be a κ-complete ultrafilter over κ. Consider its elementary embedding

$$j : V \to M \simeq \mathrm{Ult}(V, U).$$

Then ${}^\kappa M \subseteq M$.

Let $G_\kappa \subseteq \mathcal{P}_\kappa$ be generic. The set of $\alpha < \kappa$ such that $\mathcal{P}_\alpha \subseteq V_\alpha$ is a member of U. Hence $\mathcal{P}_\kappa \subseteq V_\kappa$, $\mathcal{P}_\kappa = \mathcal{P}_{j(\kappa)} \restriction \kappa$ and for every $p \in \mathcal{P}_\kappa$ we have $j(p) = p$. Using $2^\kappa = \kappa^+$, we chose an enumeration $\langle \underset{\sim}{A}_\alpha \mid \alpha < \kappa^+ \rangle$ of all canonical names of subsets of κ. In M, at κ either $\langle Q_\kappa, \leq^*_\kappa \rangle$ is κ^+-closed, or for every $p, q \in Q_\kappa$, if $p, q \geq^*_\kappa 0_{Q_\kappa}$ then there is a $t \in Q_\kappa$ with $t \geq^*_\kappa p, q$. Suppose first that $\langle Q_\kappa, \leq^*_\kappa \rangle$ is κ^+-closed. Define by recursion a $\leq^*$-increasing sequence $\langle r_\alpha \mid \alpha < \kappa^+ \rangle$ of conditions in $\mathcal{P}_{j(\kappa)} \setminus \kappa$ such that for every $\alpha < \kappa^+$ there is a $p \in G_\kappa$ satisfying

$$p^\frown r_\alpha \parallel \check{\kappa} \in j(\underset{\sim}{A}_\alpha).$$

Let $U^* = \{A_\alpha \mid \alpha < \kappa^+$, for some $p \in G_\kappa$ $p^\frown r_\alpha \Vdash \check{\kappa} \in j(\underset{\sim}{A}_\alpha)\}$. It is routine to check that U^* is well-defined and is a normal ultrafilter over κ extending U.

We now turn to the second possibility, i.e. any two $\leq^*_\kappa$-extensions of $0_{\underset{\sim}{Q}_\kappa}$ in Q_κ are $\leq^*_\kappa$-compatible. Define by recursion an $\leq^*$-increasing sequence $\langle \underset{\sim}{r}_\alpha \mid \alpha < \kappa^+ \rangle$ of conditions in $\mathcal{P}_{j(\kappa)} \setminus (\kappa + 1)$ such that for every $\alpha < \kappa^+$ there are $p \in G_\kappa$ and $\underset{\sim}{t}$ such that $p \Vdash_{\mathcal{P}_\kappa} \underset{\sim}{t} \underset{\sim}{\geq}^*_\kappa 0_{\underset{\sim}{Q}_\kappa}$ and

$$p^\frown \underset{\sim}{t}^\frown \underset{\sim}{r}_\alpha \parallel \kappa \in j(\underset{\sim}{A}_\alpha).$$

Let

$$U^* = \big\{A_\alpha \mid \alpha < \kappa^+, \text{ and for some } p \in G_\kappa \text{ and } \underset{\sim}{t},\; p \Vdash_{\mathcal{P}_\kappa} \underset{\sim}{t} \underset{\sim}{\geq}^*_\kappa 0_{\underset{\sim}{Q}_\kappa} \text{ and } p^\frown \underset{\sim}{t}^\frown \underset{\sim}{r}_\alpha \Vdash \check{\kappa} \in j(\underset{\sim}{A})\big\}.$$

Using the compatibility in $\langle Q_\kappa, \leq^* \rangle$ of any two extensions of 0_{Q_κ}, it is routine to check that U^* is well defined and is a κ-complete ultrafilter extending U. Note that U^* need not be normal anymore. $\dashv$

Using a similar idea a bit more general result can be shown.

6.17 Lemma. *Suppose that $\langle \mathcal{P}_\alpha, \underset{\sim}{Q}_\beta \mid \alpha \le \kappa, \beta < \kappa\rangle$ is an Easton iteration of Prikry-type forcing notions such that for unboundedly many α's $\mathcal{P}_\alpha \subseteq {}^\alpha V_\alpha$. Let U_1 be a κ-complete ultrafilter over κ and U_0 a normal ultrafilter over κ such that $U_0 \trianglelefteq U_1$ in the Mitchell order (i.e. $U_0 = U_1$ or $U_0 \in \mathrm{Ult}(V, U_1)$). Then U_1 extends to a κ-complete ultrafilter in $V^{\mathcal{P}_\kappa}$ provided:*

(a) $V \vDash 2^\kappa = \kappa^+$.

(b) For every cardinal $\alpha < \kappa$ we have

(i) $\Vdash_{\mathcal{P}_\alpha} (\langle \underset{\sim}{Q}_\alpha, \underset{\sim}{\le}^*_\alpha\rangle$ is $|\alpha|$-closed).

(ii) For every β with $\alpha < \beta < \alpha^+$, $\Vdash_{\mathcal{P}_\alpha} (\langle \underset{\sim}{Q}_\alpha, \underset{\sim}{\le}^*_\alpha\rangle$ is α^+-closed).

(c) The set of $\alpha < \kappa$ satisfying the condition below is in U_0: $\Vdash_{\mathcal{P}_\alpha}$ either

(i) $\langle \underset{\sim}{Q}_\alpha, \underset{\sim}{\le}^*_\alpha\rangle$ is $|\alpha|^+$-closed, or

(ii) for all $p, q \in \underset{\sim}{Q}^*_\alpha$, if $p, q \underset{\sim}{\ge}^*_\alpha 0_{\underset{\sim}{Q}_\alpha}$ there is a $t \in \underset{\sim}{Q}_\alpha$ with $t \underset{\sim}{\ge}^*_\alpha p, q$.

Proof. If $U_1 = U_0$, then this was proved in Lemma 6.15. Suppose then that $U_0 \in \mathrm{Ult}(V, U_1)$. Let $M_1 = \mathrm{Ult}(V, U_1)$ and $j_1 : V \to M_1$ be the corresponding elementary embedding. Consider $M = \mathrm{Ult}(M_1, U_0)$ and $j_{10} : M_1 \to M$ the corresponding elementary embedding. Set $j = j_{10} \circ j_1$. Clearly, $j : V \to M$ is an elementary embedding, $U_0 = \{X \subseteq \kappa \mid \kappa \in j(X)\}$ and $U_1 = \{X \subseteq \kappa \mid j_{10}([\mathrm{id}]_{U_1}) \in j(X)\}$. We use j, M as in the proof of Lemma 6.15 to define a $\le^*$-increasing sequence $\langle \underset{\sim}{r}_\alpha \mid \alpha < \kappa^+\rangle$, but now deciding statements "$j_{10}([\mathrm{id}]_{U_1}) \in j(\underset{\sim}{A}_\alpha)$" and not "$\check\kappa \in j(\underset{\sim}{A}_\alpha)$" as in that lemma. The κ-complete ultrafilter defined using this sequence will then be as desired. ⊣

The above lemma turned out to be useful for iterations of extender-based Prikry and Radin forcings for which the $\le^*_\alpha$-compatibility condition (i.e. the alternative (ii) of the conclusion of the lemma) fails.

The next lemma is a basic tool our Easton support iteration and has the same proof as that for the usual Easton support iteration. See Baumgartner [5], Jech [25] or Shelah [54] for the proof.

6.18 Lemma. *Suppose that $\langle \mathcal{P}_\alpha, \underset{\sim}{Q}_\beta \mid \alpha \le \kappa, \beta < \kappa\rangle$ is an Easton iteration of Prikry-type forcing notions such that for unboundedly many α's $\mathcal{P}_\alpha \subseteq {}^\alpha V_\alpha$. If κ is a Mahlo cardinal, then $\mathcal{P}_\kappa$ satisfies the κ-c.c.*

Let us show now an analog of Lemma 6.6 that Easton iterations of Prikry-type forcing notions do not create new measurable cardinals. The proof is based on an argument of Kimchi and Magidor [28]; see also Apter [3].

6.19 Lemma. *Suppose that $\langle \mathcal{P}_\alpha, \underset{\sim}{Q}_\beta \mid \alpha \le \kappa, \beta < \kappa\rangle$ is an Easton iteration of Prikry-type forcing notions such that for unboundedly many α's $\mathcal{P}_\alpha \subseteq {}^\alpha V_\alpha$. Let G be a generic subset of $\mathcal{P}_\kappa$. If κ is a measurable cardinal in $V[G]$, then it was measurable already in V.*

Proof. Let W be a normal ultrafilter over κ in $V[G]$. Fix a $p \in G$ such that $p \Vdash_{\mathcal{P}_\kappa} (\underset{\sim}{W}$ is a normal ultrafilter over $\kappa)$. Work in V. Clearly, κ is a Mahlo cardinal. It is enough to find a $q \geq p$ such that for every $X \subseteq \kappa$, q decides the statement "$\check{X} \in \underset{\sim}{W}$".

Suppose that there is no such q. We build a binary κ-tree T of height κ. Star with $\langle p, \kappa \rangle$.

Successor Levels

Let the pair $\langle r, A \rangle$ be on level α of T. We assume that $r \geq p$, $A \subseteq \kappa$ and $r \Vdash_{\mathcal{P}_\kappa} (\check{A} \in \underset{\sim}{W})$. Pick some partition A_0, A_1 of A and incompatible extensions r_0, r_1 of r such that $r_0 \Vdash_{\mathcal{P}_\kappa} (\check{A}_0 \in \underset{\sim}{W})$ and $r_1 \Vdash_{\mathcal{P}_\kappa} (\check{A}_1 \in \underset{\sim}{W})$. Place both $\langle r_0, A_0 \rangle$ and $\langle r_1, A_1 \rangle$ in T at the level $\alpha + 1$ to be the successors of $\langle r, A \rangle$.

Limit Levels

Let $\alpha < \kappa$ be a limit ordinal. For each branch in T of height α, we take the intersection of all second coordinates of elements along the branch. We thus obtain a partition of κ into at most 2^α many sets. But κ is Mahlo, hence $2^\alpha < \kappa$. Also,

$$p \Vdash_{\mathcal{P}_\kappa} (\underset{\sim}{W} \text{ is a normal ultrafilter over } \kappa).$$

Hence, there are an element A of this partition and $r \geq p$ such that

$$r \Vdash_{\mathcal{P}_\kappa} \check{A} \in \underset{\sim}{W}.$$

For all such A, we place a pair of form $\langle r, A \rangle$ into T at level α as the successor of each element of the branch generating A.

This completes the construction of T.

Turn now to $V[G]$. κ is measurable and so weakly compact. Hence T must have a κ-branch. Let $\langle \langle r_\alpha, A_\alpha \rangle \mid \alpha < \kappa \rangle$ be such a branch. For each $\alpha < \kappa$ set $B_\alpha = A_\alpha \setminus A_{\alpha+1}$. By the construction of T, then there is an s_α such that $\langle s_\alpha, B_\alpha \rangle$ is an immediate successor of $\langle r_\alpha, A_\alpha \rangle$. In addition, $s_\alpha \geq r_\alpha$ and the conditions $r_{\alpha+1}$, s_α are incompatible. Also, for each $\beta > \alpha$, we have $A_\beta \subseteq A_{\alpha+1}$. So, $A_\beta \cap B_\alpha = \emptyset$. But

$$r_\beta \Vdash_{\mathcal{P}_\kappa} \check{A}_\beta \in \underset{\sim}{W} \quad \text{and} \quad s_\alpha \Vdash_{\mathcal{P}_\kappa} \check{B}_\alpha \in \underset{\sim}{W},$$

hence r_β and s_α are incompatible. This implies that s_β and s_α are incompatible as well, since $s_\beta \geq r_\beta$.

Hence, $\langle s_\alpha \mid \alpha < \kappa \rangle$ forms an antichain of size κ in $V[G]$. But this is impossible, since we can run the usual Δ-system argument for the Easton support iteration $(\mathcal{P}_\kappa)^V$ inside $V[G]$ and this will give the κ-c.c. Contradiction. $\dashv$

Let us conclude with two applications. The first one will be a construction of a κ^+-saturated ideal over an inaccessible κ concentrating on cardinals of cofinality $\aleph_0$. Such an ideal was first constructed by Woodin starting from a supercompact and using a beautiful construction involving passing to a model without AC and then restoring the choice by forcing. Mitchell in [44] gave another construction from the optimal assumptions. The construction below follows the lines of [13]. Let $U_0 \triangleleft U_1$ be normal ultrafilters over κ (i.e. $U_0 \in \mathrm{Ult}(V, U_1)$). Suppose GCH for simplicity. Fix a sequence of normal ultrafilters $\langle U(\beta) \mid \beta < \kappa\rangle$ representing U_0 in the ultrapower by U_1. Pick some $A \subseteq \kappa$, $A \in U_1 \setminus U_0$ such that for every $\beta \in A$, $A \cap \beta \notin U(\beta)$. We define $\langle \mathcal{P}_\kappa, \leq, \leq^*\rangle$ by taking the Easton iteration of Prikry forcings with $U(\beta)$ (or more precisely with the extension of $U(\beta)$ defined in Remark 6.7) for every $\beta \in A$. Let $j : V \longrightarrow M_1 \simeq \mathrm{Ult}(V, U_1)$ and let $G_\kappa \subseteq \mathcal{P}_\kappa$ be generic. Fix an enumeration $\langle \underset{\sim}{A}_\alpha \mid \alpha < \kappa^+\rangle$ of all canonical names of subsets of κ. As in Lemma 6.15, we define a $\leq^*$-increasing sequence $\langle \underset{\sim}{r}_\alpha \mid \alpha < \kappa^+\rangle$ of elements of $\mathcal{P}_{j(\kappa)} \setminus \kappa+1$ such that for every $\alpha < \kappa^+$ there are $p \in G_\kappa$ and $t \in Q_\kappa$ with

$$p^\frown t^\frown \underset{\sim}{r}_\alpha \parallel \check{\kappa} \in j(\underset{\sim}{A}_\alpha).$$

Define

$$F_1 = \big\{B \subseteq \kappa \mid \text{there are } p \in G_\kappa \text{ and } \alpha < \kappa^+ \\ \text{such that } p^\frown 0_{\underset{\sim}{Q}_\kappa}{}^\frown \underset{\sim}{r}_\alpha \Vdash \check{\kappa} \in j(\underset{\sim}{B})\big\}.$$

It is not hard to see that F_1 is a well-defined normal filter over κ extending U_1.

Let us establish the normality. Suppose that $\langle B_\beta \mid \beta < \kappa\rangle$ is a sequence of elements of F_1. We need to show that $B = \Delta\{B_\beta \mid \beta < \kappa\} \in F_1$. By the definition of F_1, for each $i < \kappa$ there are $p_\beta \in G_\kappa$ and $\alpha_\beta < \kappa^+$ such that

$$p_\beta{}^\frown 0_{\underset{\sim}{Q}_\kappa}{}^\frown \underset{\sim}{r}_{\alpha_\beta} \Vdash \check{\kappa} \in j(\underset{\sim}{B}_\beta).$$

Let $\alpha \geq \bigcup_{\beta<\kappa} \alpha_\beta$. We would like to show that for some $p \in G_\kappa$,

$$p^\frown 0_{\underset{\sim}{Q}_\kappa}{}^\frown \underset{\sim}{r}_\alpha \ \Vdash \ \check{\kappa} \in j(\underset{\sim}{B}).$$

Suppose otherwise. Then for some $p \in G_\kappa$, $t \in Q_\kappa$ and $\underset{\sim}{r} \geq \underset{\sim}{r}_\alpha$,

$$p^\frown t^\frown \underset{\sim}{r} \ \Vdash \ \check{\kappa} \notin j(\underset{\sim}{B}).$$

Then, by the definition of the diagonal intersection, there would be $\beta < \kappa$, $p' \in G$, $t' \in Q_\kappa$, and $\underset{\sim}{r}'$ such that

$$p^\frown t^\frown \underset{\sim}{r} \leqslant p'^\frown t'^\frown \underset{\sim}{r}' \ \Vdash \ \check{\kappa} \notin j(\underset{\sim}{B}_\beta).$$

But this is impossible, since $p_\beta{}^\frown 0_{Q_\kappa}{}^\frown \underset{\sim}{r}_{\alpha_\beta} \Vdash \check{\kappa} \in j(\underset{\sim}{B}_\beta)$, there is a $q \in G_\kappa$ which is stronger than both p and p_β, and so $q^\frown t^\frown \underset{\sim}{r} \geq p_\beta{}^\frown 0_{Q_\kappa}{}^\frown 0_{Q_\kappa}{}^\frown \underset{\sim}{r}_{\alpha_\beta}$. Contradiction.

Forcing with F_1-positive sets is equivalent to forcing with $\langle Q_\kappa, \leq_\kappa\rangle$. The last forcing is just Prikry forcing with an extension of U_0. Hence it satisfies the κ^+-c.c. Clearly, F_1 concentrates on cardinals of cofinality $\aleph_0$, since each member of A is such a cardinal in $V[G_\kappa]$. Reference [13] contains generalizations of the above construction for cofinalities different from $\aleph_0$ and to the nonstationary ideal. Thus it was shown there that $NS_\kappa \restriction S$ can be κ^+-saturated for a stationary set $S \subseteq \kappa$ so that for every regular cardinal $\delta < \kappa$ $S \cap \{\beta < \kappa \mid \mathrm{cf}(\beta) = \delta\}$ is stationary.

If we define a function $f : A \to \kappa$ by $f(\alpha) = \min(C_\alpha)$, where C_α is the Prikry sequence for α, then for every $\gamma < \kappa$ the set $\{\alpha < \kappa \mid f(\alpha) = \gamma\}$ will be F_1-positive. This is in contrast to a similar construction in Sect. 6.2. There, f is one-to-one. Below, we will see that this f may be a projection function from a non-normal extension of U_1 to a normal extension of U_0.

Let us now turn to the second application. Consider $U_0 \triangleleft U_1$ as above. Perform the same iteration. Let $j_1 : V \longrightarrow M_1 \simeq \mathrm{Ult}(V, U_1)$. In $M_1[G_\kappa]$, at stage κ we are supposed to use the Prikry forcing with a normal ultrafilter U_0^* extending U_0. Clearly, U_0^* is such also in $V[G_\kappa]$. Obviously, any two direct extensions of the weakest condition in Prikry forcing are compatible. Hence, by Lemma 6.6 or Lemma 6.8, there is a κ-complete ultrafilter U_1^* extending U_1. We pick U_1^* as it was defined in Lemma 6.17 using the embedding j_1.

6.20 Lemma. $U_1^* >_{\mathrm{RK}} U_0^*$.

Proof. Define the projection map $f : A \longrightarrow \kappa$ as follows: $f(\alpha) =$ the first element of the Prikry sequence of α, where $A \in U_1 \setminus U_0$ is as in the first application. In order to show that this f projects U_1^* onto U_0^*, it is enough to prove that for every $B \in U_0^*$ and $C \in U_1^*$

$$f^{-1}(B) \cap C \neq \emptyset.$$

So let $C \in U_1^*$ and $B \in U_0^*$. By the definition of U_1^* there are $p \in G_\kappa$, $t = \langle \emptyset, D \rangle \in Q_\kappa$ and $\alpha < \kappa^+$ so that $p^\frown t^\frown \underset{\sim}{r}_\alpha \Vdash \check{\kappa} \in j_1(\underset{\sim}{C})$. Then also, $p^\frown \langle \emptyset, D \cap B \rangle^\frown \underset{\sim}{r}_\alpha \Vdash \check{\kappa} \in j_1(\underset{\sim}{C})$ and in addition $\langle \emptyset, D \cap B \rangle \Vdash_{Q_\kappa}$ (the first element of the Prikry sequence of κ is in B). Hence,

$$p^\frown \langle \emptyset, D \cap B \rangle^\frown \underset{\sim}{r}_\alpha \Vdash \check{\kappa} \in j_1(\underset{\sim}{C}) \cap j_1(\underset{\sim}{f}^{-1})(j_1(\underset{\sim}{B})) = j_1(\underset{\sim}{C} \cap \underset{\sim}{f}^{-1}(\underset{\sim}{B})).$$

So, $C \cap f^{-1}(B) \in U_1^*$. In particular, $C \cap f^{-1}(B) \neq \emptyset$.

Notice now that U_1^* cannot be isomorphic to U_0^* or in other words, f cannot be one-to-one on a set in U_1^*. Thus, by the κ-c.c. every closed unbounded subset of κ in $V[G_\kappa]$ contains a closed unbounded subset of κ which is in V. U_1 was normal in V, hence U_1^* containing U_1 contains as well all closed unbounded subsets of κ. Clearly, f is regressive. So, if it is one-to-one on a set $E \in U_1^*$ then E is nonstationary which is impossible. Hence $U_1^* >_{\mathrm{RK}} U_0^*$ and we are done. $\dashv$

The construction above turns the Mitchell order into the Rudin Keisler order for two ultrafilters. Longer sequences were dealt in [13], and the consistency correlation between these orderings was studied in [14]. In [15], the construction above was extended further in order to turn a Mitchell increasing sequence of length κ^{++} into a Rudin-Keisler increasing sequence of the same length. Such a sequence (with minor changes) can be used in the extender-based Prikry forcing of Sect. 3 for changing the cofinality of κ to $\aleph_0$ blowing simultaneously its power to κ^{++}. This way, the consistency strength of the negation of the Singular Cardinal Hypothesis is reduced to the optimal value $o(\kappa) = \kappa^{++}$, i.e. a measurable cardinal of Mitchell order κ^{++}.

6.4. An Application to Distributive Forcing Notions

We would like to apply the iteration techniques of Sects. 6.1 and 6.2 to distributive forcing notions.

Let $\langle Q, \leq\rangle$ be (κ, ∞)-distributive, i.e. it does not add new sequences of ordinals of length less than κ or, equivalently, the intersection of any less than κ dense open subsets of Q is dense open. If κ is $2^{|Q|}$-supercompact (or $2^{|Q|}$-strongly compact) then it is possible to turn Q into a Prikry-type forcing $\langle Q, \leq, \leq^*\rangle$ with $\langle Q, \leq^*\rangle$ κ-closed.

Recall that a map $\pi : \mathcal{P}_1 \to \mathcal{P}_2$ between forcing notions is called a *projection* if

(a) $q \leq r$ implies $\pi(q) \leq \pi(r)$.

(b) $\pi(0_{\mathcal{P}_1}) = 0_{\mathcal{P}_2}$.

(c) If $p \geq \pi(q)$, then there is an $r \geq q$ with $\pi(r) \geq p$.

If $G_1 \subseteq \mathcal{P}_1$ is generic then $\pi``G_1$ generates a generic subset of $\mathcal{P}_2$. We say that in this case $\mathcal{P}_2$ is a subforcing of $\mathcal{P}_1$.

6.21 Lemma. *Assume that $\langle Q, \leq\rangle$ is a (κ, ∞)-distributive forcing notion where κ is $2^{|Q|}$-supercompact. Let $\langle \mathcal{P}, \leq, \leq^*\rangle$ be the supercompact Prikry forcing with a normal ultrafilter over $\mathcal{P}_\kappa(2^{|Q|})$. Then $\langle Q, \leq\rangle$ is a subforcing of $\langle \mathcal{P}, \leq\rangle$.*

Proof. Let $\lambda = 2^{|Q|}$. Fix $\langle D_\alpha \mid \alpha < \lambda\rangle$ a list of all dense open subsets of Q. Let G be a generic subset of $\mathcal{P}$ and $\langle P_n \mid n < \omega\rangle$ its Prikry sequence. Then, by Lemma 1.50, $\lambda = \bigcup_{n<\omega} P_n$. Each $P_n \in V$ and has cardinality less than κ. Hence, by distributivity, $D(n) = \bigcap\{D_\alpha | \alpha \in P_n\} \in V$ is dense open subset of Q. Also, $D(n+1) \subseteq D(n)$, since $P_{n+1} \supseteq P_n$. Now, we pick an increasing sequence $\langle q_n \mid n < \omega\rangle$ with $q_n \in D(n)$. It will generate a generic subset of Q. ⊣

Let $\pi : \mathcal{P} \to Q$ be a projection map, which exists by the previous lemma. Define now a forcing ordering (quasiorder) $\leq_Q$ over $\mathcal{P}$:

$$p \leq_Q r \quad \text{iff} \quad \pi(p) \leq \pi(r).$$

Then $\langle \mathcal{P}, \leq_Q\rangle$ is a forcing equivalent to $\langle Q, \leq\rangle$.

6.22 Lemma. *$\langle \mathcal{P}, \leq_Q, \leq^* \rangle$ is a Prikry-type forcing notion.*

Proof. Clearly, $\leq_Q \supseteq \leq \supseteq \leq^*$. So we need to check that for every $p \in \mathcal{P}$ and a statement σ of the forcing $\langle \mathcal{P}, \leq_Q \rangle$ there is a $p^* \geq^* p$ deciding σ in $\langle \mathcal{P}, \leq_Q \rangle$. Set

$$A_0 = \{q \in \mathcal{P} \mid q \geq_Q p \text{ and } q \Vdash_{\langle \mathcal{P}, \leq_Q \rangle} \sigma\}, \quad \text{and}$$
$$A_1 = \{q \in \mathcal{P} \mid q \geq_Q p \text{ and } q \Vdash_{\langle \mathcal{P}, \leq_Q \rangle} \neg\sigma\}.$$

Note that any $q_0 \in A_0$ and $q_1 \in A_1$ are incompatible in $\langle \mathcal{P}, \leq \rangle$, since $\leq \subseteq \leq_Q$. Also, each $r \in \mathcal{P}$ has a $\leq_Q$-extension in A_0 or in A_1. Thus, it must have a $\leq$-extension in one of these sets. Let, for example, $r \leq_Q s \in A_0$. So, $\pi(r) \leq \pi(s)$ and by (3) of the definition of projection there is an $r' \geq r$ such that $\pi(r') \geq \pi(s)$. Hence, $r' \geq_Q s \in A_0$ and so $r' \in A_0$. The above means that $A_0 \cup A_1$ is dense $\langle \mathcal{P}, \leq \rangle$. The Prikry condition for $\langle \mathcal{P}, \leq, \leq^* \rangle$ implies then that there is a $p^* \geq^* p$ forcing in $\langle \mathcal{P}, \leq \rangle$ "$\underset{\sim}{G} \cap A_i \neq \emptyset$" for some $i \in 2$, where $\underset{\sim}{G}$ is the canonical name for a $\langle \mathcal{P}, \leq \rangle$-generic set. Without loss of generality suppose that $i = 0$. Then, $p^* \Vdash_{\langle \mathcal{P}, \leq_Q \rangle} \sigma$. Otherwise, there will be a $q \in A_1$ such that $q \geq_Q p^*$. But, then, using the property (3) of the projection, there will be a $q' \geq p^*$ such that $q' \geq_Q q$. Hence $q' \in A_1$ which means $q' \Vdash_{\langle \mathcal{P}, \leq \rangle} \underset{\sim}{G} \cap A_1 \neq \emptyset$. This contradicts the choice of p^*. $\dashv$

Let us conclude with an example of iterating distributive forcing notions. We refer to [16, 13, 46] and [29] for more sophisticated applications.

A subset E of a regular $\kappa > \aleph_0$ is called *fat* if for every $\delta < \kappa$ and every closed unbounded subset C of κ there is a closed subset $s \subseteq E \cap C$ of order type δ. It is not hard to obtain a fat subset with fat complement. For example, just force a Cohen subset to κ. It will be as desired. Suppose now that $E \subseteq \kappa$ is fat. Consider the usual forcing for adding a club to E: $P[E] = \{d \mid d \text{ is a closed bounded subset of } E\}$ ordered by the end extension, i.e. $d_1 \geq d_2$ iff $d_1 \cap \max(d_2) + 1 = d_2$. By Abraham and Shelah [2], or just directly, the forcing $\langle P[E], \leq \rangle$ is (κ, ∞)-distributive.

Suppose now that for every $n < \omega$, κ_n is a κ_n^+-supercompact cardinal, $2^{\kappa_n} = \kappa_n^+$ and E_n is a fat subset of κ_n. We would like to produce a cardinal preserving extension in which every E_n will contain a club.

By Lemma 6.22, for every $n < \omega$ there is a Prikry-type forcing $\langle Q_n, \leq_n, \leq_n^* \rangle$ such that $\langle Q_n, \leq_n \rangle$ is equivalent to $\langle P[E_n], \leq \rangle$ and $\langle Q_n, \leq_n^* \rangle$ is κ_n-closed. Let $\langle \mathcal{P}_n, \underset{\sim}{Q}_n \mid n < \omega \rangle$, $\langle \mathcal{P}_\omega, \leq, \leq^* \rangle$ be the Magidor iteration (the Easton iteration is just the same in case of ω stages) of $\langle Q_n, \leq_n, \leq_n^* \rangle$'s. It certainly will add clubs to each E_n. We need to show only that cardinals are preserved. Let $m < \omega$. We use an obvious splitting $\mathcal{P}_\omega = \mathcal{P}_{\leq m} * \mathcal{P}_{>m}$ of $\mathcal{P}_\omega$ into the part of the iteration up to m and those above m. Then, $\langle \mathcal{P}_{>m}, \leq^* \rangle$ will be κ_{m+1}-closed. So the Prikry condition will imply that it does not add new bounded subsets to κ_{m+1}. $\mathcal{P}_{\leq m}$ is a finite iteration $P[E_0] * P[E_1] * \cdots * P[E_m]$. For every $k \leq m$, $|\mathcal{P}_{\leq k}| = \kappa_k$. So each E_{k+1} remains fat in $V^{\mathcal{P}_{\leq k}}$. Hence, $\mathcal{P}_{\leq m}$ preserves all the cardinals.

7. Some Open Problems

We conclude this chapter with several open problems on cardinal arithmetic. Some of them are well known; others are less so, but seem to us important for the further understanding of the power function.

The first and probably the most well known:

1 Problem. Suppose that $\aleph_\omega$ is strong limit or even $2^{\aleph_n} = \aleph_{n+1}$ for every $n < \omega$. Is it possible to have $2^{\aleph_\omega} > \aleph_{\omega_1}$?

By Shelah [53], an upper bound is $\min(\aleph_{\omega_4}, \aleph_{(2^{\aleph_0})^+})$. It is shown in [21] that "$2^{\aleph_\omega} > \aleph_{\omega_1}$" implies an inner model with overlapping extenders. Recently this was improved in [23] to Projective Determinacy.

The next problem is probably a bit less well known, but according to Shelah it is the crucial for cardinal arithmetic.

2 Problem. Let a be a set of regular cardinals with $|a| < \min(a)$. Can $|\mathrm{pcf}(a)| > |a|$?

Recall that $\mathrm{pcf}(a) = \{\mathrm{cf}(\prod a/D) \mid D \text{ an ultrafilter over } a\}$. By the basics of pcf theory, $|\mathrm{pcf}(a)\ | \leq 2^{|a|}$ (see [53], [6] or [1]). It is unknown even for countable a's whether "$|\mathrm{pcf}(a)| > |a|$" implies an inner model with a strong cardinal. But in [18], it was shown that if for a set a of regular cardinals above $2^{|a|^+ + \aleph_2}$ we have $|\mathrm{pcf}(a)| > |a| + \aleph_1$, then there is an inner model with a strong cardinal.

Recall that $\mathrm{pp}(\kappa) = \sup\{\mathrm{cf}(\prod a/D) \mid a \subseteq \kappa$ is a set of at most $\mathrm{cf}(\kappa)$ of regular cardinals, unbounded in κ and D an ultrafilter over a including all cobounded subsets of $a\}$. The next problem was proposed by Shelah in [52] and deals with the following strengthening of "$|\mathrm{pcf}(a)| = |a|$" called the Shelah Weak Hypothesis:

For every cardinal λ the number of singular cardinals $\kappa < \lambda$ with $\mathrm{pp}(\kappa) \geq \lambda$ is at most countable.

Also, for uncountable cofinality an even stronger statement is claimed:

For every cardinal λ the number of singular cardinals $\kappa < \lambda$ of uncountable cofinality with $\mathrm{pp}(\kappa) \geq \lambda$ is finite.

3 Problem. Is the negation of the Shelah Weak Hypothesis consistent?

In [22] was shown that much more complicated forcing notions than those of Sects. 2 and 3 seem to be needed in order to deal with the negation of the Weak Hypothesis.

The general formulation of the Singular Cardinals Problem (SCP) is as follows: Find a complete set of rules describing the behavior of the power (or more generally, the pseudo-power (pp)) function on singular cardinals. In terms of core models (see the inner model chapters of this Handbook) we can reformulate SCP in a more concrete form: Given a core model K with certain large cardinals, which functions in K can be realized as the power set function in a set generic extension of K, i.e. if $F : \lambda \to \lambda \in K$ for some ordinal λ, is there a generic extension of K satisfying $2^{\aleph_\alpha} = \aleph_{F(\alpha)}$ for all $\alpha < \lambda$?

If we restrict ourselves to finite gaps between singular cardinals and its power then, at present, the most general results on possible behavior of the power function are due Merimovich [40]. They extend previous results by Foreman-Woodin [12], Woodin, Cummings [9] and Segal [49]. However lots of possibilities are still open. Let us state a few of the simplest:

4 Problem. Is it possible to have $2^{\aleph_{\omega_1}} = \aleph_{\omega_1+2}$ and two stationary sets $S_1, S_2 \subseteq \omega_1$ with $S_1 \cup S_2 = \omega_1$ such that

$$\begin{aligned} \alpha \in S_1 \quad &\text{implies} \quad 2^{\aleph_\alpha} = \aleph_{\alpha+2} \quad \text{and} \\ \alpha \in S_2 \quad &\text{implies} \quad 2^{\aleph_\alpha} = \aleph_{\alpha+3}? \end{aligned}$$

5 Problem. Is it possible to have two stationary sets $S_1, S_2 \subseteq \omega_2$ with $S_1 \cup S_2 = \omega_2$ and $S_2 \cap \{\alpha < \omega_2 \mid \mathrm{cf}(\alpha) = \omega_1\}$ stationary such that

$$\begin{aligned} \alpha \in S_1 \quad &\text{implies} \quad 2^{\aleph_\alpha} = \aleph_{\alpha+1} \quad \text{and} \\ \alpha \in S_2 \quad &\text{implies} \quad 2^{\aleph_\alpha} = \aleph_{\alpha+2}? \end{aligned}$$

The usual approach via Magidor or Radin forcing produces a club set of αs with the same cardinal behavior, and here we would like to have different behaviors on relatively big sets. The first of these two problems may be the easier one, since we need only GCH on S_1 and, so starting with the GCH in the ground model nothing special should be done on S_1. Note also that in view of Silver's Theorem (see [25, Sect. 1.8]) we must have $2^{\aleph_{\omega_1}} = \aleph_{\omega_1+1}$ in models of Problem 5 and $2^{\aleph_{\omega_1}} \leq \aleph_{\omega_1+2}$ in those of Problem 4. Methods of [21] can be used to show that at least a strong cardinal is needed for constructing a model of Problem 4. By [23], the strength of at least Projective Determinacy is needed for constructing a model of Problem 5.

DOI 10.1007/978-1-4020-5764-9_18,

This chapter provides an introduction to the basic theory of inner models without fine structure. It assumes that the reader is familiar with Gödel's class L of constructible sets; however Sect. 1 begins by recalling the definition and basic theory of L with an emphasis on the condensation property. This discussion leads to a consideration of relative constructibility—that is, models of the form $L[A]$—and then to $L[U]$, the minimal model with a measurable cardinal. A discussion of $0^{\#}$, and of sharps in general, leads up to a brief description of the Dodd-Jensen core model K^{DJ}, which links the models L and $L[U]$.

Sections 2 and 3 discuss generalizations of the ideas of Sect. 1 to larger cardinals. Section 2 looks at sequences of measurable cardinals and the models $L[\mathcal{U}]$ constructed from such sequences. The use of iterated ultrapowers to compare pairs of models, introduced in Sect. 1 for the model $L[U]$, is extended to these models $L[\mathcal{U}]$. Section 3 introduces the notion of an *extender*, a generalized form of ultrafilter used to express cardinal properties stronger than measurability. Extenders are combined with the ideas of Sect. 2 to obtain models $L[\mathcal{E}]$, constructed from a sequence $\mathcal{E}$ of extenders, which can contain cardinals up to a strong cardinal.

The definition of models for still stronger cardinals requires an understanding of iteration trees and fine structure, which are not covered in this chapter. Section 4 gives a brief survey of such larger cardinals, and the current status of their inner model theory.

The principal goal of research in inner models is to define a *core model* K which can coexist with larger cardinals in the universe V. The construction of the core model is not described in this chapter except for a brief description of K^{DJ} (which is the core model if there is no model with a measurable cardinal) in Sect. 1.2. Because of its centrality, however, the core model itself is mentioned frequently. Briefly, the *core model* K should have two properties: (1) it is like L, and (2) it is close to V. The first property is satisfied by defining it as one of the models $L[\mathcal{U}]$ or $L[\mathcal{E}]$ described in this chapter. For the second property we can ask for some form of a *covering lemma*. In the case when L is the core model—that is, when the only large cardinal properties which hold anywhere are those which hold in L—the second criteria is satisfied by Jensen's covering lemma, which states that every uncountable set x of ordinals in V is contained in a set $y \in L$ of the same cardinality. This also holds of K^{DJ} when it is the core model—that is, when there is no model with a measurable cardinal—but for larger cardinals the core model K can only be expected to satisfy some form of the *weak covering lemma*: that $(\lambda^{+})^{K} = \lambda^{+}$ for every singular cardinal λ.

In the final Sect. 5 there is a further discussion of the core model, but from a somewhat different perspective. This is not an attempt to describe the construction of an existing model, but instead is an attempt to answer the questions "how do we decide that a particular model is 'the core model' " and "how will we recognize a model, newly discovered in the future, as the core model". This attempt is, of course, highly speculative: new discoveries may show that models with the properties we are expecting are impossible or even uninteresting, or a newly discovered model with properties substantially different from what we expect may play a critical role with respect to larger cardinals, which demands that it be recognized as the core model.

Most of the topics related to inner model theory which are not covered in this chapter can be found elsewhere in this Handbook. The core model and covering lemma are introduced in the chapters [24, 33, 38]. An excellent source for further information on large cardinals is Kanamori's book [15, 16]. For more information on L, the standard reference is [3]. The more recent book [42] is an excellent introduction to inner models and core model techniques. In this Handbook, fine structure is covered in the chapters [36, 40].

One other approach to inner models which is not covered in this chapter is the class HOD of hereditarily definable sets and its variants. The model HOD has the serious disadvantage that it is not canonical—for example, it can easily be changed by forcing. However it is frequently used for models in which the axiom of choice fails, where it usually gives more readable proofs than do symmetric models, and has been used in studies of determinacy and of cardinals large enough that the inner models described in this chapter are unknown or poorly understood.

The major goal of this introduction is to establish notation and a certain amount of background for other topics in this Handbook. Where sketches of proofs are given, the intention is not so much to present the proof itself as to introduce techniques which are important to the further development of the theory of inner models and core models.

1. The Constructible Sets

1.1 Definition. Gödel's class L of constructible sets is defined to be $L = \bigcup_{\alpha\in\mathrm{On}} L_\alpha$, where the sets L_α are defined by recursion on α as follows:

1. $L_0 = \varnothing$,
2. $L_{\alpha+1} = \operatorname{def}(L_\alpha, \in)$,
3. $L_\lambda = \bigcup_{\alpha<\lambda} L_\alpha$ if λ is a limit ordinal.

Here $\operatorname{def}(L_\alpha, \in)$ is the set of subsets of L_α which are first-order definable in the structure $(L_\alpha, \in)$, using parameters from L_α.

The most basic property of L is the following:

1.2 Lemma. *There is a Π_2 sentence of set theory, which we denote by "$V = L$", such that the transitive models of the sentence "$V = L$" are exactly the sets L_α and the class L itself. Furthermore, if α is any ordinal then $\langle L_\nu : \nu < \alpha\rangle$ is definable in L_α by a Σ_1 formula.*

The main content of the sentence "$V = L$" is the statement $\forall x \exists \alpha \exists y$ $(y = L_\alpha \ \& \ x \in L_\alpha)$. See Jech [14, Lemma 13.17] for a proof of Lemma 1.2 in the case that α is a limit ordinal, which is sufficient for most uses which do not involve fine structure. The use of fine structure goes beyond Lemma 1.2 by splitting the successor interval between L_α and $L_{\alpha+1}$ into infinitely many levels of definability.

The most important property of the constructible hierarchy follows from Lemma 1.2:

1.3 Lemma (Condensation Lemma).

1. *If $X \prec_1 L_\alpha$ for some ordinal α, then there is an ordinal $\alpha' \leq \alpha$ such that $X \cong L_{\alpha'}$.*

2. *If X is a proper class such that $X \prec_1 L$, then $X \cong L$.*

That is, if X is a Σ_1 elementary substructure of L or of any L_α, then X is isomorphic, via its transitive collapse, to L or some $L_{\alpha'}$.

The simplest application of Lemma 1.3 is Gödel's proof that GCH holds in L.

1.4 Definition. If $\mathcal{M}$ is any structure and X is a subset of the universe of $\mathcal{M}$ then the *Skolem hull* of X in $\mathcal{M}$ is the smallest elementary submodel of $\mathcal{M}$ containing X. We write $\mathcal{H}^{\mathcal{M}}(X)$ for the Skolem hull of X in $\mathcal{M}$.

This definition assumes the existence of such a unique minimal submodel of $\mathcal{M}$ containing X. In all of our applications the model $\mathcal{M}$ will have a definable well-ordering which provides Skolem functions that ensure this. Definition 1.4 can also be used in cases when $\mathcal{M}$ is a well-founded class model of ZF. In this case, provided X contains a proper class of ordinals, the Skolem hull $\mathcal{H}^{\mathcal{M}}(X)$ is equal to $\bigcup_{\alpha \in X} \mathcal{H}^{V_\alpha \cap \mathcal{M}}(X \cap V_\alpha)$, and hence is definable in $\mathcal{M}$.

1.5 Theorem. $L \models \mathrm{GCH}$.

Proof. We work inside L. An easy induction on α shows that $|L_\alpha| = |\alpha|$ for all infinite ordinals α. Hence, to establish $2^\kappa = \kappa^+$ it is enough to show that any set $x \subseteq \kappa$ is a member of L_{κ^+}. To this end, pick τ large enough that $x \in L_\tau$ and set $X = \mathcal{H}^{L_\tau}(\kappa \cup \{x\})$. By Lemma 1.3 there is an ordinal α such that $\pi : (X, \in) \cong L_\alpha$ where π is the transitive collapse map. Then $x = \pi(x) \in L_\alpha$, and $|L_\alpha| = |X| = \kappa$ so $\alpha < \kappa^+$. $\dashv$

The aim of the inner model theory which we will outline in this chapter is to extend this result to a more general class of models. We will describe (informally, and without attempting a precise definition) a hierarchy satisfying the analog of Lemma 1.3 as a *hierarchy with condensation*.

1.1. Relative Constructibility

Each of the inner models which we will consider is defined as the class of all sets which are *constructible from* some specified set or class A. Two notions of relative constructibility are in general use:

1.6 Definition.

1. If A is a transitive set then $L(A) = \bigcup_{\alpha\in\mathrm{On}} L_\alpha(A)$, where the sets $L_\alpha(A)$ are defined exactly like the hierarchy L_α except that rule 1.1(1) is replaced by $L_0(A) = A$.

2. If A is any set or class, then $L[A] = \bigcup_{\alpha\in\mathrm{On}} L_\alpha[A]$, where the sets $L_\alpha[A]$ are defined exactly like the hierarchy L_α, except that rule 1.1(2) is replaced by
$$L_{\alpha+1}[A] = \mathrm{def}(L_\alpha[A], \in, A),$$
where $\mathrm{def}(L_\alpha[A], \in, A)$ is the set of subsets of $L_\alpha[A]$ first-order definable with parameters from $L_\alpha[A]$, using $A \cap L_\alpha[A]$ as a predicate.

The class $L(A)$ satisfies ZF and contains the set A, and it can be characterized as the smallest such class which contains the ordinals. It need not satisfy the axiom of choice, and indeed it is usually used in cases where the axiom of choice is intended to fail. The most important example is $L(\mathbb{R})$, the smallest model of ZF containing all the reals.[1] This model is heavily used in studies of the axiom of determinacy (AD), where it reconciles that axiom with the axiom of choice in the sense that the axiom "$L(\mathbb{R}) \models \mathrm{AD}$" implies many of the same consequences as the full axiom of determinacy, but is consistent with the axiom of choice in V. We will not consider models of the form $L(A)$ further in this chapter.

If A is a set then the model $L[A]$ always satisfies ZFC. It need not have A itself as a member, but the restriction $A \cap L[A]$ of A to the model $L[A]$ is in $L[A]$. The model $L[A]$ can be characterized as the smallest model M of ZF which contains all the ordinals and has $A \cap M$ as a member. The case when A is a class is similar, provided that replacement holds for formulas with a predicate for A.

In one sense the models $L[A]$ can be fully as complex as any other model of set theory. This is clear in the case that A is a class, since (assuming the axiom of global choice) the universe V can be coded by a class A of ordinals, so that $L[A] = V$. However, a surprising result of Jensen ([2], see [10, Theorem 5.1]) shows that A need not be a proper class: he defines a class generic extension $V[G]$ of the universe V such that $V[G] = L[a]$ for some $a \subseteq \omega$. Thus any class can be contained in a model of the form $L[a]$, with $a \subseteq \omega$.

[1] Strictly speaking Definition 1.6 does not apply to $L(\mathbb{R})$, since $\mathbb{R}$ is not transitive. Taking $L(\mathbb{R})$ to be $L(V_{\omega+1})$ repairs this defect and also gives a more convenient form to the low levels of the $L_\alpha(\mathbb{R})$ hierarchy.

In another sense the models $L[A]$ are quite simple when A is a set—nearly as simple as L itself. This simplicity appears when working above the set A, for submodels M of $L[A]$ such that $A \cap L[A] \in M$. For example, the sentence "$V = L$" can be generalized straightforwardly to a sentence "$V = L[A]$" which satisfies the following generalization of the Condensation Lemma 1.3:

1.7 Lemma. *Suppose that A is a set, and that $X \prec_1 L_\alpha[A]$, where $\alpha \in \mathrm{On} \cup \{\mathrm{On}\}$, and the transitive closure of $A \cap L_\alpha[A]$ is contained in X. Then there is an $\alpha' \leq \alpha$ such that $X \cong L_{\alpha'}[A]$.*

Hence the sets $L_\alpha[A]$, with $\alpha \geq \mathrm{rank}(A)$, also form a hierarchy with condensation, and it follows that all of the basic properties of L, such as GCH, $\Diamond_\kappa$ and $\Box_\kappa$, hold in $L[A]$—at least above $\mathrm{rank}(A)$—for the same reason that they hold in L

Lemma 1.7 does not give any information about the set A itself, and it says nothing about how models $L[A]$ and $L[A']$ might be related when $A \neq A'$. If we are to use the techniques of inner model theory to study the set A, then we need a version of Lemma 1.7 which does not assume $A \cap L[A] \in X$. Any such lemma will require some restriction on the class of sets A for which it is valid.

Elementary embeddings (or, rather, sets A encoding elementary embeddings) have proved to be especially fruitful for this purpose. One reason for this fruitfulness is that when A and A' encode different elementary embeddings of $L[A]$ and $L[A']$, respectively, then it is possible, under suitable conditions, to use the embeddings themselves to modify the models so that they can be compared. This gives at least a start on the goal of understanding the relationships between distinct models $L[A]$ and $L[A']$. This idea may be seen in the proof of Theorem 1.9 and in the comparison Lemma 2.8 for sequences of measures.

A second reason for this fruitfulness arises in the consideration of the embeddings $\pi : L_{\bar\alpha}[\bar A] \cong X \prec_1 L_\alpha[A]$ arising from a transitive collapse. If embeddings coded by A are suitably chosen, then the embedding π will be closely related to the embeddings encoded into A. In this case an analog of the Condensation Lemma 1.3 may hold without the restriction $A \cap L[A] \subseteq X$ needed for Lemma 1.7. This phenomenon often occurs, and is heavily used, in the analysis of inner models for large cardinals.

1.2. Measurable Cardinals

The simplest, and oldest, example of a model $L[A]$ in which A encodes an embedding of $L[A]$ is $L[U]$, the minimal inner model for a measurable cardinal.

1.8 Definition. Recall that a cardinal κ is *measurable* if there is an elementary embedding $i : V \to M$, where M is a well-founded class and $\kappa = \mathrm{crit}(i)$. Here $\mathrm{crit}(i)$ is the *critical point* of i, that is, the least ordinal α such that $i(\alpha) > \alpha$.

The *ultrafilter* associated with such an embedding i is the set

$$U = \{x \subseteq \kappa : \kappa \in i(x)\}.$$

This set U is a *κ-complete ultrafilter* on κ, where κ-completeness means that $\bigcap X \in U$ whenever $X \subseteq U$ and $|X| < \kappa$. Indeed, U is *normal*, which is a stronger property: for any function $f : \kappa \to \kappa$, if $\{\nu < \kappa : f(\nu) < \nu\} \in U$ then there is an ordinal $\gamma < \kappa$ such that $\{\nu : f(\nu) = \gamma\} \in U$.

A normal ultrafilter is frequently called a *measure*. The analogy with Lebesgue measure on the real line, from which this terminology is derived, is slightly strained since neither normality nor the property of being two-valued has an analog in the real line; however this usage has a strong historical basis (evidenced by the term "measurable cardinal") and it is useful in a context such as the present chapter, in which non-normal ultrafilters never appear.

In the other direction, from an ultrafilter to an embedding, the *ultrapower* construction gives, for any normal ultrafilter U on κ, an embedding $i^U : V \to M = \mathrm{Ult}(V, U)$ with critical point κ such that U is the ultrafilter associated with i^U. The ultrapower has the property that $M = \{i^U(f)(\kappa) : f \in V \cap {}^\kappa V\}$, and as a consequence i^U is minimal among all embeddings related to U in the following sense: Any other embedding $i : V \to N$ with the same associated ultrafilter U can be factored as

$$i : V \xrightarrow{i^U} \mathrm{Ult}(V, U) \xrightarrow{k} N,$$

where the embedding k is defined by $k([f]_U) = k(i^U(f)(\kappa)) = i(f)(\kappa)$.

It is easy to see that if U is a normal ultrafilter on κ, then $U \cap L[U]$ is a normal ultrafilter in $L[U]$. On its face, the model $L[U]$ appears to depend on the choice of the ultrafilter U; however Kunen [18] showed that it depends only on the critical point of U.

The proof, which we outline below, uses iterated ultrapowers. We write $i^U_\alpha : V \to \mathrm{Ult}_\alpha(V, U)$ for the α-fold iterated ultrapower by U, which is defined by setting $\mathrm{Ult}_0(V, U) = V$, $\mathrm{Ult}_{\alpha+1}(V, U) = \mathrm{Ult}(\mathrm{Ult}_\alpha(V, U), i^U_\alpha(U))$, and $\mathrm{Ult}_\alpha(V, U) = \operatorname{dir\,lim}_{\alpha' < \alpha} \mathrm{Ult}_{\alpha'}(V, U)$ if α is a limit ordinal.

We will need the fact that every iterated ultrapower $\mathrm{Ult}_\alpha(L[U], U)$ is well-founded. This is easily proved by induction on α: more generally, let M be any well-founded model containing the ordinals, and suppose that M satisfies that U is a countably complete ultrafilter. A useful observation is that all iterated ultrapowers of M are definable subsets of M, and hence we can work inside M. It is easy to see that $\mathrm{Ult}(M, U)$ is well-founded. For any ordinal α such that $\mathrm{Ult}_\alpha(M, U)$ is well-founded, it then follows, by working inside $\mathrm{Ult}_\alpha(M, U)$, that $\mathrm{Ult}_{\alpha+1}(M, U)$ is also well-founded. Hence the least ordinal α such that $\mathrm{Ult}_\alpha(M, U)$ is ill-founded would be a limit ordinal. Now call an ordinal γ *U-soft in M* if there is an iterated ultrapower i^U_α by U such that the set of ordinals in $\mathrm{Ult}_\alpha(M, U)$ below $i^U_\alpha(\gamma)$ is ill-founded. Let γ be the least U-soft ordinal in M, and let α be least such that i^U_α witnesses that

γ is soft. Now if α' is any ordinal in the interval $0 \leq \alpha' < \alpha$, then $i^U_{\alpha'}(\gamma)$ is, by elementarity, the least $i^U_{\alpha'}(U)$-soft ordinal in $\mathrm{Ult}_{\alpha'}(M, U)$. But this is impossible, since for sufficiently large $\alpha' < \alpha$ there is an ordinal $\xi < i^U_{\alpha'}(\gamma)$ in $\mathrm{Ult}_{\alpha'}(M, U)$ such that $i_{\alpha',\alpha}(\xi)$ is a member of an infinite descending sequence below $i_\alpha(\gamma)$. Then $i^U_{\alpha',\alpha}$ is an iterated ultrapower of $\mathrm{Ult}_{\alpha'}(M, U)$ by $i^U_{\alpha'}(U)$ which witnesses that ξ is $i^U_{\alpha'}(U)$-soft in $\mathrm{Ult}_{\alpha'}(M, U)$.

The proof above can be generalized to any well-founded model M with $\omega_1 \subseteq M$, and to any iterated ultrapower of M by arbitrary measures in M rather than by the single ultrafilter U. We will later see that the situation is much more difficult for iterations involving cardinals beyond a strong cardinal.

1.9 Theorem. *Suppose that U and U' are normal ultrafilters in $L[U]$ and $L[U']$, respectively.*

1. *If* $\mathrm{crit}(U) = \mathrm{crit}(U')$ *then $U = U'$, and hence $L[U] = L[U']$.*
2. *If* $\mathrm{crit}(U) < \mathrm{crit}(U')$ *then $L[U'] = \mathrm{Ult}_\alpha(L[U], U)$ for some ordinal α.*

1.10 Corollary. *The model $L[U]$ has only the one normal ultrafilter U.*

Sketch of Proof of Theorem 1.9(1). The proof of Theorem 1.9 uses the following two observations about the iterated ultrapower $\mathrm{Ult}_\lambda(L[U], U)$, where $\lambda > \kappa^+$ is a cardinal of uncountable cofinality.

(1) The set $C = \{i^U_\alpha(\kappa) : \alpha < \lambda\}$ is a closed, unbounded set of indiscernibles for $\mathrm{Ult}_\lambda(L[U], U)$ which generates its measure $i^U_\lambda(U)$ in the sense that

$$i^U_\lambda(U) = \{x \subseteq \lambda : \sup(C - x) < i^U_\lambda(\kappa)\}, \tag{17.1}$$

and therefore $\mathrm{Ult}_\lambda(L[U], U) = L[i^U_\lambda(U)] = L[\mathcal{C}_\lambda]$ where $\mathcal{C}_\lambda$ is the filter of closed unbounded subsets of λ. To see that (17.1) holds, let x be any subset of $i_\lambda(\kappa)$ in $\mathrm{Ult}_\lambda(L[U], U)$. Then there is some $\alpha_0 < \lambda$ and $x_{\alpha_0} \in \mathrm{Ult}_{\alpha_0}(L[U], U)$ such that $x = i_{\alpha_0,\lambda}(x_{\alpha_0})$. For ordinals α in the interval $\alpha_0 < \alpha < \lambda$ set $x_\alpha = i_{\alpha_0,\alpha}(x_{\alpha_0})$, so that $x = i_{\alpha,\lambda}(x_\alpha)$. Then $i^U_\alpha(\kappa) \in x \iff i^U_\alpha(\kappa) \in x_{\alpha+1} = i_{\alpha,\alpha+1}(x_\alpha) \iff x_\alpha \in i^U_\alpha(U) \iff x \in i^U_\lambda(U)$.

(2) Let Γ be the class of ordinals $\xi > \lambda$ such that $i^U_\lambda(\xi) = \xi$. Then simple cardinal arithmetic shows that Γ is a proper class, and contains all of its limit points of cofinality greater than λ.

Now suppose that the models $L[U]$ and $L[U']$ are as in the hypothesis of Theorem 1.9(1), with $\kappa = \mathrm{crit}(U) = \mathrm{crit}(U')$. Let $\lambda = (2^\kappa)^+$. By the first observation, $\mathrm{Ult}_\lambda(L[U], U) = \mathrm{Ult}_\lambda(L[U'], U') = L[\mathcal{C}_\lambda]$, with $i^U_\lambda(U) = i^{U'}_\lambda(U') = \mathcal{C}_\lambda \cap L[\mathcal{C}_\lambda]$. By the second observation $\Gamma = \{\xi > \lambda : i^U_\lambda(\xi) = i^{U'}_\lambda(\xi) = \xi\}$ is a proper class.

Let $X = \mathcal{H}^{L[\mathcal{C}_\lambda]}(\kappa \cup \Gamma \cup \{\mathcal{C}_\lambda \cap L[\mathcal{C}_\lambda]\}) \prec L[\mathcal{C}_\lambda]$ be the Skolem hull, and let $\pi : M \cong X$ be its transitive collapse. Then $X \subseteq \mathrm{ran}(i^U_\lambda)$, so $M \prec L[U]$. However $U = \pi^{-1}(\mathcal{C}_\lambda \cap L[\mathcal{C}_\lambda]) \in M$, and the proper class Γ is a subset of M. It follows by Lemma 1.7 that $M = L[U]$. By the same argument $M = L[U']$ and $U' = \pi^{-1}(\mathcal{C}_\lambda \cap L[\mathcal{C}_\lambda])$, so $L[U] = L[U']$ and $U = U'$. $\dashv$

1.11 Theorem (Silver). $L[U] \models \mathrm{GCH}$.

Sketch of Proof. First we recall Gödel's proof of GCH for L. Assume $V = L$, and fix any set $x \in \mathcal{P}^L(\lambda)$. Now pick some $\tau > \lambda$ such that $x \in L_\tau$, and let $\pi : M_x \cong X \prec_1 L_\tau$ where $|X| = \lambda$, $\lambda \cup \{x\} \subseteq X$, and M_x is transitive. Then the Condensation Lemma 1.3 implies that $M_x = L_\alpha$ for some $\alpha < \lambda^+$, so that $x = \pi^{-1}(x) \in L_\alpha$. Thus $\{z \subseteq \lambda : z \leq^L x\} \subseteq L_\alpha$, and since $|L_\alpha| = \lambda$ it follows that no set in $\mathcal{P}(\lambda)$ has more than λ many $<^L$-predecessors. Hence $\operatorname{otp}(\mathcal{P}(\lambda), \leq^L) = \lambda^+$, so $L \models 2^\lambda = \lambda^+$.

Now assume $V = L[U]$, where U is a normal ultrafilter on κ, and fix a cardinal λ. If $\lambda \geq \kappa$ then Gödel's proof for L can be easily adapted to $L[U]$ by substituting Lemma 1.7 for Lemma 1.3. Thus we only need to consider the case $\lambda < \kappa$.

Fix a set $x \subseteq \lambda$, and pick τ such that $x \in L_\tau[U]$. For convenience, also let $L_\tau[U]$ satisfy ZF^-, the axioms of ZF without the Power Set Axiom; this will be true if τ is any successor cardinal. Now let $X \prec L_\tau[U]$ where $x \in X$, $\lambda \subseteq X$, and $|X| = \lambda$. If $M_x \cong X$ is the transitive collapse of X, then $M_x = L_{\alpha_x}[U_x]$ for some $\alpha_x < \lambda^+$ and some filter U_x which is a normal ultrafilter in M_x.

In order to conclude, as in the proof for L, that $\operatorname{otp}\bigl(\mathcal{P}(\lambda), <^{L[U]}\bigr) = \lambda^+$, we need to show that $\{z \subseteq \lambda : z \leq^{L[U]} x\} \subseteq M_x$. The fact that $U_x \neq U$ is a complication which is not present in L, and we will use the techniques from the proof of Theorem 1.9 to deal with it. The assumption that $L_\tau[U]$, and hence M_x, satisfies ZF^- makes it is easy to verify that the iterated ultrapower $i^{U_x}_\kappa : L_{\alpha_x}[U_x] \to \operatorname{Ult}_\kappa(L_{\alpha_x}[U_x], U_x)$ can be defined and has all of the required properties: In particular, $\operatorname{Ult}_\kappa(L_{\alpha_x}[U_x], U_x) = L_{\alpha'_x}[i^{U_x}_\kappa(U_x)]$ for some $\alpha'_x < \kappa^+$, and $i^{U_x}_\kappa(U_x) \subseteq U$ since $i^{U_x}_\kappa(U_x)$ is generated by the set $C_x = \{i^{U_x}_\nu(\lambda) : \nu < \kappa\}$, which is in U since it is closed and unbounded. Since $i^{U_x}_\lambda {\restriction} \mathcal{P}^{M_x}(\lambda)$ is the identity, it follows that $\{z \subseteq \lambda : z <^{L[U]} x\} \subseteq \mathcal{P}^{L_{\alpha'_x}[U_x]}(\lambda) \subseteq M_x$, as desired. ⊣

This proof can be interpreted as showing that $L[U]$ contains a hierarchy with condensation; however this hierarchy has two flaws: (i) the very existence of the model $L[U]$, and hence of this hierarchy, is conditional on the existence of the normal ultrafilter U, and (ii) unlike the structures L_α, the structures M_x do not actually satisfy condensation. That is, the model M_x is not actually an initial segment of $L[U]$, but only a structure which can be compared to an initial segment of $L[U]$ by means of an iterated ultrapower. The first, and more important, of these two flaws was fixed by the Dodd and Jensen [4, 6, 5] with their introduction of the original core model K^{DJ}. They defined a *mouse* to be a structure $M = L_{\alpha^M}[U_M]$ such that (i) M satisfies the sentence "U_M is a normal ultrafilter", (ii) all of the iterated ultrapowers of M are well-founded, and (iii) M satisfies a fine structure condition which implies that there is a $\rho \leq \operatorname{crit}(U_M)$ such that $L_{\alpha^M+1}[U_M] \models \bigl|\alpha^M\bigr| = \rho$. The Dodd-Jensen core model K^{DJ} is defined to be $L[\mathcal{M}]$, where $\mathcal{M}$ is the class of all mice. With the emergence of a general concept of "the core model" (see Sect. 5), K^{DJ} came to be seen as the core model below $L[U]$, that is, it is the core model provided that there is no model with a measurable cardinal.

The weakest mouse is equi-constructible with $0^{\#}$, which is described in the next subsection. The model M_x in the proof of Theorem 1.11 is an example of a mouse; however its construction required starting with the model $L[U]$ and it is difficult to prove that such a model exists using any assumption weaker than a measurable cardinal. Dodd and Jensen threw out the assumption $M_x \models \mathrm{ZF}^-$ of Theorem 1.11, and replaced it with clauses (i) and (ii); they then used fine structure to show that iterated ultraproducts of mice can still be defined and have the required properties.

The second flaw, the lack of condensation, is only a minor technical problem at the level of one measurable cardinal but leads to serious difficulties at higher levels. This problem is corrected by the modern presentation of the core model. As adapted to the special case of the Dodd-Jensen core model K^{DJ}, this presentation works as follows: First note that K^{DJ} does satisfy a form of condensation, for if $\pi : L_{\alpha'}[\mathcal{M}'] \cong X \prec_1 L_\alpha[\mathcal{M}]$, then π preserves the property of being a mouse. It follows that $\mathcal{M}'$ is contained in $\mathcal{M}$, and since the Dodd-Jensen mice are well-ordered by relative constructibility it follows that $\mathcal{M}'$ is an initial sequence of the class $\mathcal{M}$. We can extend this to $L[U]$ as follows: each mouse is a model $L_{\alpha_M}[U_M]$. Since U_M and $L_{\alpha_M}[U_M]$ are equi-constructible, K^{DJ} can be equivalently written as $L[\langle U_M : M \in \mathcal{M}\rangle]$ instead of as $L[\mathcal{M}]$, and then $L[U]$ is equal to $L[\mathcal{M}, U] = L[\langle U_M : M \in \mathcal{M}\rangle, U]$. If we let $\mathcal{U}$ be the sequence $\langle U_M : M \in \mathcal{M}\rangle^\frown\langle U\rangle$, then $L[U] = L[\mathcal{U}]$, and the transitive collapse of a substructure $X \prec_1 L_\alpha[\mathcal{U}]$ has the form $L_{\alpha'}[\mathcal{U}']$ where, as in the case of K^{DJ}, the sequence $\mathcal{U}'$ is an initial segment of $\mathcal{U}$. Thus $X \cong L_{\alpha'}[\mathcal{U}\restriction\alpha']$, which is an initial segment of $L[\mathcal{U}] = L[U]$.

Notice that this construction has the further advantage of smoothly joining the construction of K^{DJ} with $L[U]$ at one extreme and (taking $\mathcal{U}$ to be empty) L at the other.

1.3. $0^{\#}$, and Sharps in General

This subsection covers the first steps of the core model hierarchy suggested by the proof of Theorem 1.11. They are the first steps historically, since the model $L[0^{\#}]$ was the first canonical inner model to be extensively studied other than L and $L[U]$. They are also the first steps in the sense that they lie at the bottom of the core model hierarchy: $0^{\#}$ is, as we will see later, essentially the same as the first Dodd-Jensen mouse.

Lemma 1.2 implies that if $i : L \to M$, where M is a well-founded class, then $M = L$. As Scott [37] observed, it follows that there are no measurable cardinals in L: otherwise let $U \in L$ be a normal ultrafilter on the least measurable cardinal κ of L. Then $i^U(\kappa) > \kappa$; but this is impossible since $i^U(\kappa)$ is, by the elementarity of the embedding i^U, the least measurable cardinal in $\mathrm{Ult}(L, U) = L$, and that is κ.

Nontrivial embeddings from L into L can, however, exist in V: for example, if U is a normal ultrafilter and $i^U : V \to \mathrm{Ult}(V,U)$ then $i^U \restriction L : L \to L$. Silver's $0^\#$ gives a complete analysis of such embeddings. We say that a class I of ordinals is a class of indiscernibles for a model M if for any formula $\varphi(v_0, \dots, v_{n-1})$ of the language of set theory and any increasing sequences $(c_0, \dots, c_{n-1})$ and $(c'_0, \dots, c'_{n-1})$ of members of I we have $M \models \varphi(c_0, \dots, c_{n-1}) \iff \varphi(c'_0, \dots, c'_{n-1})$.

1.12 Definition. We say that $0^\#$ *exists* if there is closed proper class I of indiscernibles for L. In this case we define $0^\# \subseteq \omega$ to be the set of Gödel numbers of formulas $\varphi(v_0, \dots, v_{n-1})$ such that $L \models \varphi(c_0, \dots, c_{n-1})$ for any increasing sequence $\langle c_0, \dots, c_{n-1} \rangle \in [I]^n$.

Since I is a class of indiscernibles for L, this characterization of the set $0^\#$ does not depend on the choice of the sequence $\vec{c} \in [I]^n$. The fact that I is required to be closed implies that the definition of $0^\#$ does not depend on the choice of the class I. It also implies that the members of I possess the following normality property, which Silver called *remarkability*: if η is any ordinal and $f : \mathrm{On} \to \mathrm{On}$ is any map definable in L from parameters in L_η such that $f(c_0, \dots, c_{n-1}) = \xi < c_0$ for some sequence $\vec{c} = (c_0, \dots, c_{n-1}) \in [I - \eta]^n$, then $f(\vec{d}) = \xi$ for every sequence $\vec{d} \in [I - \eta]^n$.

Silver showed that if $0^\#$ exists then there is a unique maximal class I, the *Silver indiscernibles* such that $L = \mathcal{H}^L(I)$, that is, every set in L is definable in L from parameters in I. This class can be obtained by starting with any remarkable class I' of indiscernibles. Then $\mathcal{H}^L(I') \prec L$ is a proper class and hence is isomorphic to L. If $\pi : \mathcal{H}^L(I') \cong L$ is the transitive collapse map, then $I = \pi``I'$ is a closed class of indiscernibles and $\mathcal{H}^L(I) = L$.

Our Definition 1.12 requires that I be a proper class, but Silver showed that this is not necessary:

1.13 Theorem. *If there is an uncountable set of indiscernibles for L then $0^\#$ exists. Furthermore, there is a Π^1_2 formula ψ such that if a is any subset of ω, then $\psi(a)$ holds if and only if $a = 0^\#$.*

Thus for example, the existence of $0^\#$ is an immediate consequence of the existence of a Ramsey cardinal. The following result shows how $0^\#$ can be used to characterize the elementary embeddings from L into L:

1.14 Theorem (Silver). *Assume that $0^\#$ exists. Then (i) for any strictly increasing map $\pi : I \to I$ there is a unique elementary embedding $i : L \to L$ such that $\pi = i \restriction I$, and (ii) if $i : L \to L$ then $i``I \subseteq I$, and i is determined by $i \restriction I : I \to I$.*

The proof follows easily from the indiscernibility of the members of I and the fact that every constructible set is definable from members of I: if x is the unique set satisfying a formula $\varphi(x, \alpha_0, \dots, \alpha_{n-1})$ for some sequence $(\alpha_0, \dots, \alpha_{n-1}) \in [I]^{<\omega}$, then $i(x)$ must be the unique set x' satisfying $\varphi(x', \pi(\alpha_0), \dots, \pi(\alpha_{n-1}))$.

This leaves open one gap in the use of $0^\#$ to characterize embeddings from L into L: the question of whether the existence of such an embedding implies the existence of $0^\#$. This question was settled by Kunen; the version of the proof which we sketch below is largely due to Silver and is included because it involves ideas which are basic to the proof of the covering lemma:

1.15 Theorem. *If $i : L \to L$ is a nontrivial elementary embedding then $0^\#$ exists.*

Sketch of Proof. Let $\kappa = \mathrm{crit}(i)$. We can assume without loss of generality that i is continuous at every ordinal of cofinality greater than κ: if it is not, then factor the embedding i as $i : L \to X := \{i(f)(\kappa) : f \in L\} \prec L$ and replace i with $i' : L \xrightarrow{i} X \xrightarrow{\pi} L$, where $\pi : X \cong L$ is the transitive collapse.

We will define, for each $\nu \in \mathrm{On}$, a class Γ_ν of ordinals which is unbounded and contains all of its limit points of cofinality greater than κ. If we set $\kappa_\nu = \inf(\Gamma_\nu - \kappa)$ then the class $J = \{\kappa_\nu : \nu \in \mathrm{On}\}$ will be a class of indiscernibles for L, and by Silver's results this implies that $0^\#$ exists.

Set $\Gamma_0 = \mathrm{On} \cap \mathrm{ran}(i)$, and if λ is a limit ordinal then set $\Gamma_\lambda = \bigcap_{\nu<\lambda} \Gamma_\nu$. Now suppose that Γ_ν has been defined, and write $\mathcal{H}^L(X) \prec L$ for the class of sets definable in L from parameters in X. Then $\mathcal{H}^L(\Gamma_\nu) \cong L$ since Γ_ν is a proper class, so consider the map

$$i_\nu : L \cong \mathcal{H}^L(\Gamma_\nu) \prec L.$$

Then $\Gamma_{\nu+1}$ is defined to be the set of ordinals ξ such that $i_\nu(\xi) = \xi$.

Notice that $\Gamma_\nu = \mathrm{On} \cap \mathcal{H}^L(\Gamma_\nu)$, that $\kappa_\nu = \inf(\Gamma_\nu - \kappa) = i_\nu(\kappa)$, and that if $\nu > \nu'$ then $i_{\nu'}(\kappa_\nu) = \kappa_\nu$. Now define, for each pair $\nu' < \nu$ of ordinals, the embedding $i_{\nu',\nu} : L \cong \mathcal{H}^L(\kappa_{\nu'} \cup \Gamma_\nu) \prec L$ to be the inverse of the transitive collapse of $\mathcal{H}^L(\kappa_{\nu'} \cup \Gamma_\nu)$. Thus $i_{\nu',\nu}$ is the identity on $\kappa_{\nu'} \cup \Gamma_{\nu+1}$.

We claim that $i_{\nu',\nu}(\kappa_{\nu'}) = \kappa_\nu$. This claim is equivalent to the statement that $\kappa_\nu \cap \mathcal{H}^L(\kappa_{\nu'} \cup \Gamma_\nu) = \kappa_{\nu'}$, and if it were false then there would be $\vec{\alpha} \in [\Gamma_\nu]^{<\omega}$ and a formula φ such that

$$L \models \exists \eta \in \kappa_\nu - \kappa_{\nu'} \exists \vec{\gamma} \in [\kappa_{\nu'}]^{<\omega} \big(\varphi(\vec{\gamma}, \eta, \vec{\alpha}) \ \& \ \forall \eta' < \eta \, \neg\varphi(\vec{\gamma}, \eta', \vec{\alpha})\big). \quad (17.2)$$

Now the embedding $i_{\nu'} : L \cong \mathcal{H}^L(\Gamma_{\nu'}) \prec L$ is elementary, and $i_{\nu'}(\kappa) = \kappa_{\nu'}$, but $i_{\nu'}(\kappa_\nu) = \kappa_\nu$ and $i_\nu(\vec{\alpha}) = \vec{\alpha}$ since $i_{\nu'} {\restriction} \Gamma_\nu$ is the identity. Thus formula (17.2) implies that

$$L \models \exists \eta \in \kappa_\nu - \kappa \exists \vec{\gamma} \in [\kappa]^{<\omega} \big(\varphi(\vec{\gamma}, \eta, \vec{\alpha}) \ \& \ \forall \eta' < \eta \, \neg\varphi(\vec{\gamma}, \eta', \vec{\alpha})\big).$$

But this is impossible, since any such ordinal η would be in Γ_ν and $\kappa_\nu = \min(\Gamma_\nu - \kappa)$.

This completes the proof of the claim. Now suppose that $\vec{c}$ and $\vec{c}\,'$ are two increasing sequences in $[J]^{<\omega}$ which differ only in the ith place; say that, $c'_i = \kappa_{\nu'} < c_i = \kappa_\nu$ while $c_j = c'_j$ for $j \neq i$. Then $i_{\nu',\nu}(\vec{c}\,') = \vec{c}$, and since $i_{\nu',\nu} : L \to L$ is elementary it follows that $\vec{c}\,'$ and $\vec{c}\,'$ satisfy the same formulas over L. But if $\vec{c}\,'$ and $\vec{c}$ are any two increasing sequences of the same length from $[J]^{<\omega}$, then one can be obtained from the other in a finite sequence of steps in such a way that each step changes only one element of the sequence. Hence J is a class of indiscernibles for L. ⊣

The following result of Silver states that if $0^{\#}$ exists then the class L of constructible sets is much smaller than V:

1.16 Theorem (Silver). *Assume that $0^{\#}$ exists, and let I be the class of Silver indiscernibles. Then (i) every uncountable cardinal κ of V is a member of I, and indeed $|I \cap \kappa| = \kappa$, (ii) every Silver indiscernible is weakly compact in L, (iii) $\forall \eta \ \left|\mathcal{P}^L(\eta)\right| = |\eta|$, and (iv) $\forall \eta \ \mathrm{cf}(\eta^{+L}) = \omega$.*

Clause (ii) can be strengthened by replacing "weakly compact" with any large cardinal property which can consistently hold in L. This fact suggests that the existence of $0^{\#}$ can be viewed as the weakest large cardinal property which cannot consistently be true in L, and further experience has supported this view. Such a statement cannot be proved, or even stated precisely, without a precise definition of "large cardinal property"; however it is true for large cardinals inside the core model, and the covering lemma provides other senses in which $L[0^{\#}]$ is a minimal extension of L. For example, if M is any class model such that $M \models \lambda^+ \neq (\lambda^+)^L$ for some singular cardinal λ of M, then $L[0^{\#}]$ is contained in M.

Solovay once suggested that $L[0^{\#}]$ might be minimal in another sense: that every real $a \in L[0^{\#}]$ such that $0^{\#} \notin L[a]$ would be set generic over L. This suggestion was refuted by Jensen [2], who used class forcing to construct a counterexample. A weaker conjecture might be that $0^{\#}$ is the minimal real which is easily definable; however Friedman [11] has shown that if $0^{\#}$ exists then there is a set a such that $0 <_L a <_L 0^{\#}$ and a is a Π^1_2 singleton; furthermore, the set defined by this Π^1_2 formula remains a singleton in any extension with the same ordinals. See [10, Theorem 6.5] for more on this subject.

1.4. Other Sharps

The process used to define $0^{\#}$ can also be applied to models larger than L. This process is commonly used in two slightly different contexts: in order to define the sharp of a large cardinal property, and in order to define the sharp of a set.

In order to construct the sharp of a large cardinal property, we need to start with a minimal inner model M for the property such that M has a suitable inner model theory. For a measurable cardinal, for example, we could take any model of the form $M = L[U]$ such that U is a normal ultrafilter in M. If J is a closed proper class of indiscernibles for M, then we can define a new real, just as with $0^{\#}$, to be the set of Gödel numbers of formulas $\varphi(x_0, \ldots, x_{n-1})$ such that $M \models \varphi(c_0, \ldots, c_{n-1})$ for any $(c_0, \ldots, c_{n-1}) \in [J]^n$.

By using the inner model theory for the model M in question, together with Silver's techniques from the theory of $0^\#$, it can be shown that this construction yields a unique real even though (as in the case of $L[U]$) the model M may not itself be unique.

This procedure is not limited to properties involving a single cardinal. As we will see shortly, the ideas of $L[U]$ can be extended to a model $M = L[\mathcal{U}]$, having a proper class of measurable cardinals, so that M has an inner model theory similar to that of $L[U]$. The procedure described above, applied to the model M, will then yield a real which is the sharp for a proper class of measurable cardinals.

The sharp construction was first applied to $L[U]$ by Solovay, who gave the name $0^\dagger$ to the resulting sharp for a measurable cardinal. This precedent has had the effect of leading to a proliferation of typographical symbols for sharps of various large cardinal properties, the most common of which is $0^\P$, used for the sharp of a strong cardinal. The use of these symbols, apparently chosen on a whim and with no relation to the cardinals they are supposed to represent, places an unfortunate and unnecessary burden on the reader's memory. Fortunately the most important example, the sharp for a Woodin cardinal, has escaped the use of such symbols. This sharp is important because a number of applications of Woodin cardinals, particularly to inner model theory, appear to require the sharp for a Woodin cardinal, rather than simply a Woodin cardinal itself. It is commonly denoted by $M_1^\#$, where M_1 is the standard symbol for the minimal model with one Woodin cardinal.

It is straightforward to generalize the construction of $0^\#$ to obtain the sharp $A^\#$ for an arbitrary set A of ordinals: If $A \subseteq \gamma$, and J is a closed, proper class of indiscernibles for $L[A]$, then $A^\#$ is the set of pairs $(n, \vec{a})$ where $n = \ulcorner\varphi\urcorner$ is the Gödel number of a formula $\varphi(\vec{v}, z, \vec{u})$, $\vec{a} \in [\gamma]^{<\omega}$, and $L[A] \models \varphi(\vec{c}, A, \vec{a})$ for any $\vec{c} \in [J]^n$. By use of an appropriate coding, we can regard $A^\#$ as a subset of γ.

In particular, this construction can be used to iterate the sharp operation: Starting with $0^{\#^1} = 0^\#$, we define $0^{\#^{\alpha+1}} = (0^{\#^\alpha})^\#$. If α is a limit ordinal then $0^{\#^\alpha}$ is defined to be a set encoding $\langle 0^{\#^\gamma} : \gamma < \alpha\rangle$.

Assuming the existence of a large cardinal (a Ramsey cardinal is much more than enough) it can be shown to be consistent that $0^{\#^\alpha}$ exists for all ordinals α. The model $L[\langle 0^{\#^\alpha} : \alpha \in \mathrm{On}\rangle]$ forms a hierarchy with condensation, and this hierarchy is an initial segment of the core model hierarchy toward which we are working. This process can easily be continued: the model $M = L[\langle 0^{\#^\alpha} : \alpha \in \mathrm{On}\rangle]$ is a minimal model for the large cardinal property "$A^\#$ exists for all sets A", and (given a class of indiscernibles for this model) we can define the sharp for this property. This sharp will be a subset of ω and it is the next step $0^{\#^{\mathrm{On}}}$ in the desired hierarchy.

On the one hand there seems to be no obvious bound determining how far the hierarchy obtained through this process can be extended, but on the other hand it is not clear how to generalize the process to give a uniform definition, using indiscernibles, of such a hierarchy. The core model provides such a definition by replacing the indiscernibles by ultrafilters, as suggested by the proof of Theorem 1.11. We will conclude this section by discussing the relationship between ultrafilters and sets of indiscernibles.

1.5. From Sharps to the Core Model

The Dodd-Jensen core model K^{DJ} was briefly described at the end of Sect. 1.3. This subsection will explain how the concept of a mouse, which they invented for this model, generalizes and extends the concept of sharps.

Recall that they defined a *mouse* to be a model $L_{\alpha^M}[U_M]$, similar to the models M_x used in the proof of Theorem 1.11, but with the strong theory ZF^- replaced with a fine structural condition. One of the uses of this fine structural condition was to allow them to define iterated ultrapowers of mice and to show that they have the required properties. Silver, Magidor and others later gave a construction of K^{DJ} without the need for fine structure, but fine structure is still needed to define core models for larger cardinals.

As in the proof of Theorem 1.11, iterated ultrapowers can be used to compare two mice. This comparison process prewellorders the class of mice, and shows that they form, in an appropriate sense, a hierarchy with condensation. The Dodd-Jensen core model is defined to be the model $K = L[\mathcal{M}]$, where $\mathcal{M}$ is the class of all mice; the well-ordering of mice and their condensation properties imply that $L[\mathcal{M}]$ is a model of ZF + GCH.

This model cannot contain a measurable cardinal, but Dodd and Jensen proved a covering lemma for K which asserts that a model $L[U]$ with a measurable cardinal has approximately the same relation to K that $0^{\#}$ has to L.

The Dodd-Jensen core model can be better understood by considering a translation from mice to sharps and vice versa. Suppose first that $M = L_\alpha[U]$ is a mouse. Then the result of the iterated ultrapower $i^U_{\mathrm{On}} : M \to M^* = \mathrm{Ult}_{\mathrm{On}}(M, U)$ is a well-founded model by clause (ii) of the definition of a mouse. The ordinals On^{M^*} of M^* have length greater than On, and On is the measurable cardinal in M^*. If we write i^U_λ for the embedding from $L_\alpha[U]$ to $\mathrm{Ult}_\lambda(L_\alpha[U], U)$, then the class $I = \{i^U_\lambda(\kappa) : \lambda \in \mathrm{On}\}$ is a class of indiscernibles for M^*.

This class I can be used, as described in the last subsection, to define an initial sequence of the class of sharps. This sequence of sharps can be defined by recursion over On^{M^*}, so that the length of On^{M^*} provides an indication of how long a hierarchy of sharps will be generated before the process generates a model for which I is not a class of indiscernibles. Clause (iii) of the definition of a mouse can be used to show that this final model is M^*.

In discussing the other direction, from sharps to mice, we will use Kunen's notion of a M-ultrafilter:

1.17 Definition. A *normal M-ultrafilter* in Kunen's sense is an ultrafilter on $\mathcal{P}(\kappa) \cap M$, for some κ in M, such that

1. If $f : \kappa \to \kappa$ is in M and $\{\nu < \lambda : f(\nu) < \nu\} \in U$, then there is γ such that $\{\nu : f(\nu) = \gamma\} \in U$, and
2. If $x \subseteq \mathcal{P}(\kappa)$ is a member of M, and $|x|^M = \kappa$, then $U \cap x \in M$.

The second condition enables the ultrapower by U to be iterated, even though $U \notin M$. If $i^U : M \to \mathrm{Ult}(M, U)$ then $U_1 = \{[f]_U : f \in ({}^{\kappa}U) \cap M\}$ is an $\mathrm{Ult}(M, U)$-ultrafilter, which can be used as $i^U(U)$.

A member of the sharp hierarchy is a set which encodes the theory of a model M^*, with parameters taken from a class I of indiscernibles for M^*. A mouse will be a model $L_\alpha[U]$, where α is the least ordinal such that U is not a normal ultrafilter in $L_{\alpha+1}[U]$. We could easily get an M^*-ultrafilter U on any limit point of I by setting $U = \{x \subseteq \lambda : \sup((I \cap \lambda) - x) < \lambda\}$, the filter on λ generated by $I \cap \lambda$. A better construction, however, uses the analog of Theorem 1.14 for M^* to get an M^*-ultrafilter on $\lambda = \min(I)$: let $i : I \to I$ be an increasing map such that $i(\lambda) > \lambda$. By Theorem 1.14 the embedding i extends to a map $i^* : M^* \to M^*$ such that $i = i^* \restriction I$, and $U = \{x \subseteq \lambda : \lambda \in i^*(x)\}$ is a normal M^*-ultrafilter.

2. Beyond One Measurable Cardinal

The next step beyond $L[U]$ is to develop an inner model theory for models with many measurable cardinals. This is straightforward so long as all of the measures have different critical points: If $\mathcal{U} = \langle U_\nu : \nu < \lambda \rangle$ is a sequence of measures, with increasing critical points κ_ν, then the model $L[\mathcal{U}]$ has measures $U_\nu \cap L[\mathcal{U}]$, and (as with the model $L[U]$) no other measures. If it is desired to have several measures on the same cardinal then the answer is less obvious: if U_0 and U_1 are two measures on a cardinal κ then $U_0 \cap L[U_0, U_1] = U_1 \cap L[U_0, U_1]$ by Kunen's Theorem 1.10, so the model $L[U_0, U_1]$ has only one normal ultrafilter.

A way to proceed is suggested by the following observation of Kunen:

2.1 Proposition. *Every measurable cardinal κ has a normal ultrafilter U_κ which concentrates on nonmeasurable cardinals.*

Proof. Suppose as an induction hypothesis that for each measurable cardinal $\lambda < \kappa$ there is a normal ultrafilter U_λ concentrating on nonmeasurable cardinals, and let U be a normal ultrafilter on κ. If U concentrates on nonmeasurable cardinals then set $U_\kappa = U$; otherwise

$$U' = [\langle U_\lambda : \lambda < \kappa \rangle]_U = \{x \subseteq \kappa : \{\lambda < \kappa : x \cap \lambda \in U_\lambda\} \in U\}$$

is a second normal ultrafilter on κ which concentrates on nonmeasurable cardinals. In this case set $U_\kappa = U'$. ⊣

Note that in the second case of the proof, the model $L[\langle U_\lambda : \lambda < \kappa \rangle, U', U]$ is a model with at least two normal ultrafilters U' and U on κ. The following partial order captures the relation between U' and U:

2.2 Definition. If U and U' are normal ultrafilters on a cardinal κ then we write $U' \lhd U$ if $U' \in \mathrm{Ult}(V, U)$.

Thus $U' \lhd U$ if and only if there is a function f such that

$$\{\alpha < \kappa : f(\alpha) \text{ is a normal ultrafilter on } \alpha\} \in U$$

and

$$U' = \{x \subseteq \kappa : \{\lambda < \kappa : x \cap \lambda \in f(\lambda)\} \in U\}.$$

The argument which Scott used to prove that there are no measurable cardinals in L proves the follow proposition:

2.3 Proposition. *The ordering $\lhd$ is well-founded.*

Proof. Assuming the contrary, let κ be the least cardinal such that the normal ultrafilters on κ are not well-founded by $\lhd$. Then there is a normal ultrafilter U on κ so that $\{U' : U' \lhd U\}$ is not well-founded by $\lhd$. The normal ultrafilters on κ in $\mathrm{Ult}(V, U)$ are exactly the normal ultrafilters U' on κ in V such that $U' \lhd U$, and the $\lhd$-ordering on these normal ultrafilters in $\mathrm{Ult}(V, U)$ is the same as in V since V and $\mathrm{Ult}(V, U)$ have the same functions from κ to V_κ. Thus the measures on κ in $\mathrm{Ult}(V, U)$ are not well-founded under $\lhd$. Since $\mathrm{Ult}(V, U)$ is well-founded it follows that $\mathrm{Ult}(V, U)$ satisfies that the measures on κ are not well-founded by $\lhd$, but this is impossible since, by the elementarity of the embedding i, there is no cardinal $\lambda < i(\kappa)$ in $\mathrm{Ult}(V, U)$ such that the measures on λ are not well-founded by $\lhd$. $\dashv$

2.4 Definition. The order $o(U)$ of a normal ultrafilter U is its rank in the ordering $\lhd$, that is, $o(U) = \sup\{o(U') + 1 : U' \lhd U\}$. The order of a cardinal κ is $o(\kappa) = \sup\{o(U) + 1 : U \text{ is a normal ultrafilter on } \kappa\}$.

Thus a measure U has order 0 if and only if the set of smaller measurable cardinals is not a member of U. A cardinal κ has order 0 if it is not measurable, and order 1 if it is measurable, but has no measures concentrating on smaller measurable cardinals. Since each measure $U' \lhd U$ is equal to $[f]_U$ for some $f : \kappa \to V_\kappa$, we have the following upper bound:

2.5 Proposition (Solovay). *If U is a normal ultrafilter on a measurable cardinal κ then $o(U) < (2^\kappa)^+$, and hence $o(\kappa) \leq (2^\kappa)^+$.*

Under the GCH, it follows that $o(\kappa) \leq \kappa^{++}$.

The inner models $L[\mathcal{U}]$ for sequences of measures utilize this ordering $\lhd$. We give here the original presentation of these models as in [25]. This presentation is the simplest way to approach these models, and we will show that it can be generalized with the use of extenders to define inner models with a strong cardinal. However it is not adequate for dealing with cardinals very much larger than this; and in Sect. 3 we will follow up by giving a brief description of the modified presentation now used for the core model and for inner models with larger cardinals.

2.6 Definition. A *coherent sequence of measures* is a function $\mathcal{U}$ such that

1. $\mathrm{dom}(\mathcal{U}) = \{(\kappa,\beta) : \kappa < \mathrm{len}(\mathcal{U}) \text{ and } \beta < o^{\mathcal{U}}(\kappa)\}$, where $\mathrm{len}(\mathcal{U})$ is a cardinal and $o^{\mathcal{U}}$ is a function mapping cardinals $\kappa < \mathrm{len}(\mathcal{U})$ to ordinals.

2. If $(\kappa,\beta) \in \mathrm{dom}(\mathcal{U})$ then $U = \mathcal{U}(\kappa,\beta)$ is a normal ultrafilter on κ.

3. If $U = \mathcal{U}(\kappa,\beta)$ then $o^{i^U(\mathcal{U})}(\kappa) = \beta$ and $i^U(\mathcal{U})(\kappa,\beta') = \mathcal{U}(\kappa,\beta')$ for all $\beta' < \beta$.

The final clause of this definition is the *coherence condition*, which can also be expressed by saying that $(i^{\mathcal{U}(\kappa,\beta)}(\mathcal{U}))\restriction\kappa+1 = \mathcal{U}\restriction(\kappa,\beta)$. Here we write $\mathcal{U}\restriction(\kappa,\beta)$ for the restriction of $\mathcal{U}$ to

$$\{(\kappa',\beta') \in \mathrm{dom}(\mathcal{U}) : \kappa' < \kappa \vee (\kappa' = \kappa \wedge \beta' < \beta)\}$$

and $\mathcal{U}\restriction\lambda$ for $\mathcal{U}\restriction(\lambda,0)$. Notice that the coherence condition implies that $\mathcal{U}(\kappa,\beta') \lhd \mathcal{U}(\kappa,\beta)$ for all $\beta' < \beta < o^{\mathcal{U}}(\kappa)$, so that $o(\mathcal{U}(\kappa,\beta)) \geq \beta$.

The following theorem is the main result of [25]; it is a generalization of the Corollary 1.10 to Theorem 1.9:

2.7 Theorem. *If $\mathcal{U}$ is a coherent sequence of measures in $L[\mathcal{U}]$, then the only normal ultrafilters in $L[\mathcal{U}]$ are the members of the sequence $\mathcal{U}$.*

It follows from Theorem 2.7 that $o(\mathcal{U}(\kappa,\beta))$ is exactly equal to β in $L[\mathcal{U}]$, and that each cardinal κ has exactly $|o^{\mathcal{U}}(\kappa)|$ many normal ultrafilters in $L[\mathcal{U}]$. Theorem 1.9 itself does not generalize to $L[\mathcal{U}]$: starting in a model with κ^+ measurable cardinals, where κ is measurable, it is possible to construct sequences $\mathcal{U}$ and $\mathcal{U}'$ with the same domain such that $L[\mathcal{U}] \neq L[\mathcal{U}']$.

2.1. The Comparison Process

The main difficulty in generalizing the proofs of Theorem 1.9 and Theorem 1.11 to the models $L[\mathcal{U}]$ is in adapting the iterated ultrapowers used in those proofs. Recall that they used the iterated ultrapower $\mathrm{Ult}_\lambda(L_\alpha[U], U)$, where λ is some larger cardinal, so that the image i^U_λ of U is contained in the closed unbounded filter $\mathcal{C}_\lambda$ on λ. Thus two normal ultrafilters U and U' were compared indirectly, via the filter $\mathcal{C}_\lambda$. In adapting this construction to the models $L[\mathcal{U}]$ we use iterated ultrapowers to compare sequences $\mathcal{U}$ and $\mathcal{U}'$ directly, through a process known as *iterating the least difference*.

2.8 Lemma (Comparison). *Suppose that $L_\alpha[\mathcal{U}]$ and $L_{\alpha'}[\mathcal{U}']$ satisfy* ZF$^-$, *and that $\mathcal{U}$ and $\mathcal{U}'$ are coherent in $L_\alpha[\mathcal{U}]$ and $L_{\alpha'}[\mathcal{U}']$ respectively. Then for some sequence $\mathcal{W}$ and some ordinals $\bar\alpha$ and $\bar\alpha'$, there are iterated ultrapowers $i : L_\alpha[\mathcal{U}] \to L_{\bar\alpha}[\mathcal{W}\restriction\bar\alpha]$ and $i' : L_{\alpha'}[\mathcal{U}'] \to L_{\bar\alpha'}[\mathcal{W}\restriction\bar\alpha']$.*

Notice that the sequence $\mathcal{W}$ plays the role of the closed unbounded filter in the proof of Theorem 1.9

For simplicity, this statement of Lemma 2.8 assumes that the models being compared are sets; however the process can also be used if one or both of the models is a proper class, that is, if one or both of $L_\alpha[\mathcal{U}]$ or $L_{\alpha'}[\mathcal{U}]$ is replaced by $L[\mathcal{U}]$ or $L[\mathcal{U}']$. In this case one or both of the iterated ultrapowers may have length On, and one (but never both) of the models $L_{\bar\alpha}[\mathcal{W}\restriction\bar\alpha]$ or $L_{\bar\alpha'}[\mathcal{W}\restriction\bar\alpha']$ may have length larger than On. The simplest example of this is when $L[\mathcal{U}] = L[U]$, with a single normal ultrafilter, and $L[\mathcal{U}'] = L$. Then the comparison consists of iterating U, the only ultrapower available, and U must be iterated On many times to move it past L. Thus $L_{\bar\alpha}[\mathcal{W}\restriction\bar\alpha] = \mathrm{Ult}_{\mathrm{On}}(L[U], U)$, which has On as its measurable cardinal and has length greater than On.

Proof of Lemma 2.8. An iterated ultrapower of length θ of a model M is a family of maps $i_{\nu,\nu'} : M = M_\nu \to M_{\nu'}$, commuting in the sense that $i_{\nu,\nu''} = i_{\nu',\nu''} \circ i_{\nu,\nu'}$ whenever $\nu < \nu' < \nu'' < \theta$, which is defined by recursion on ordinals $\nu < \nu' < \theta$ by setting $M_0 = M$ and $M_\nu = \operatorname{dir\,lim}_{\nu'<\nu} M_{\nu'}$ for each limit $\nu \le \theta$, and for successor ordinals $\nu+1 < \theta$ letting either $M_{\nu+1} = M_\nu$ or else $M_{\nu+1} = \mathrm{Ult}(M_\nu, U_\nu)$ for some M_ν-measure U_ν. The iterated ultrapowers used in this proof are *internal*, which means that $U_\nu \in M_\nu$ for all $\nu < \theta$. We write i_ν for $i_{0,\nu}$.

The proof given before Lemma 1.9 that the model $L[U]$ is iterable relied on the fact that every iterated ultrapower of $L[U]$ is internal to $L[U]$ in the stronger sense that every iterated ultrapower of $L[U]$ is definable in $L[U]$. That is not true for the models $L[\mathcal{U}]$ described here, since the choice of which ultrafilters to use in the iteration may be made externally to $L[\mathcal{U}]$; however, every iterated ultrapower of $L[\mathcal{U}]$ can be embedded into an iterated ultrapower which is definable in $L[\mathcal{U}]$, and thus the argument before Lemma 1.9 shows that every iterated ultrapower of $L[\mathcal{U}]$ is well-founded.

We define two iterated ultrapowers: $i_{\nu',\nu} : M_{\nu'} \to M_\nu$ on $L[\mathcal{U}]$ and $i'_{\nu',\nu} : M'_{\nu'} \to M'_\nu$ on $L[\mathcal{U}']$, as follows: Suppose that $i_\nu : M_0 = L_\alpha[\mathcal{U}] \to M_\nu = L_{\alpha_\nu}[\mathcal{U}_\nu]$ and $i'_\nu : M'_0 = L_{\alpha'}[\mathcal{U}'] \to M'_\nu = L_{\alpha'_\nu}[\mathcal{U}'_\nu]$ have already been defined, where $\mathcal{U}_\nu = i_\nu(\mathcal{U})$ and $\mathcal{U}'_\nu = i'_\nu(\mathcal{U}')$. Let $\gamma = \min\{\alpha_\nu, \alpha'_\nu\}$. If $\mathcal{U}'_\nu\restriction\gamma = \mathcal{U}_\nu\restriction\gamma$ then we are finished, since we can take $\bar\alpha = \alpha_\nu$ and $\bar\alpha' = \alpha'_\nu$ and let $\mathcal{W}$ be the longer of the sequences $\mathcal{U}_\nu$ and $\mathcal{U}'_\nu$. In this case we say that the comparison *terminates at stage* ν.

Otherwise we define $M_{\nu+1}$ and $M'_{\nu+1}$ by the process of *iterating the least difference*: Let (κ_ν, β_ν) be the lexicographically least pair of ordinals such that $\kappa_\nu < \gamma$, $\beta_\nu \le \min\{o^{\mathcal{U}_\nu}(\kappa_\nu), o^{\mathcal{U}'_\nu}(\kappa_\nu)\}$, and

$$\mathcal{U}_\nu(\kappa_\nu, \beta_\nu) \ne \mathcal{U}'_\nu(\kappa_\nu, \beta_\nu), \tag{17.3}$$

where the inequality (17.3) may hold either because $o^{\mathcal{U}_\nu}(\kappa_\nu) \ne o^{\mathcal{U}'_\nu}(\kappa_\nu)$ and $\beta_\nu = \min\{o^{\mathcal{U}_\nu}(\kappa_\nu), o^{\mathcal{U}'_\nu}(\kappa_\nu)\}$ (so that only one side of (17.3) is defined) or because there is a set $x_\nu \in M_\nu \cap M'_\nu$ such that $x_\nu \in \mathcal{U}_\nu(\kappa_\nu, \beta_\nu) \not\Longleftrightarrow x_\nu \in \mathcal{U}'_\nu(\kappa_\nu, \beta_\nu)$. If $\beta_\nu = o^{\mathcal{U}_\nu}(\kappa_\nu)$ then set $M_{\nu+1} = M_\nu$; otherwise set $M_{\nu+1} = \mathrm{Ult}(M_\nu, \mathcal{U}(\kappa_\nu, \beta_\nu))$. Similarly, $M'_{\nu+1} = \mathrm{Ult}(M'_\nu, \mathcal{U}'_\nu(\kappa_\nu, \beta_\nu))$ if $\beta_\nu < o^{\mathcal{U}'_\nu}(\kappa_\nu)$, and $M'_{\nu+1} = M'_\nu$ otherwise.

Note that the ordinals κ_ν are strictly increasing: we have $\mathcal{U}_{\nu+1}{\restriction}\kappa_\nu + 1 = \mathcal{U}_\nu{\restriction}(\kappa_\nu, \beta_\nu) = \mathcal{U}'_\nu{\restriction}(\kappa_\nu, \beta_\nu) = \mathcal{U}'_{\nu+1}{\restriction}\kappa_\nu + 1$, where the outer equalities follow from the coherence condition and the inner equality follows from the minimality of the pair (κ_ν, β_ν). It follows that $i_{\nu+1,\nu'}(\kappa_\nu) = i'_{\nu+1,\nu'}(\kappa_\nu) = \kappa_\nu$ for all $\nu' > \nu$.

In order to complete the proof of the lemma, we need to show that this comparison eventually terminates. The proof relies on the following observation:

2.9 Claim. *Suppose that τ is an infinite regular cardinal and $\langle N_\nu : \nu < \tau\rangle$ is an iterated ultrapower with embeddings $j_{\nu,\nu'} : N_\nu \to N_{\nu'}$. Further suppose that $|N_0| < \tau$, that $S \subseteq \tau$ is stationary, and that $y_\nu \in N_\nu$ for each $\nu \in S$. Then there is a stationary set $S' \subseteq S$ such that $j_{\nu,\nu'}(y_\nu) = y_{\nu'}$ for all $\nu < \nu'$ in S'.*

Proof. For each limit $\nu \in S$ there is an ordinal $\gamma < \nu$ such that $y_\nu \in \operatorname{ran}(j_{\gamma,\nu})$, so by Fodor's Lemma there is a fixed $\gamma_0 < \tau$ such that the set of $\nu \in S$ such that $y_\nu \in \operatorname{ran}(j_{\gamma_0,\nu})$ is stationary. Since $|N_{\gamma_0}| \le \max\{|N_0|, |\gamma_0|\} < \tau$, there is a fixed $\bar{y} \in N_{\gamma_0}$ such that $S' = \{\nu \in S : y_\nu = j_{\gamma_0,\nu}(\bar{y})\}$ is stationary. Now if $\nu < \nu'$ are in S' then $y_{\nu'} = j_{\gamma_0,\nu'}(\bar{y}) = j_{\nu,\nu'} j_{\gamma_0,\nu}(\bar{y}) = j_{\nu,\nu'}(y_\nu)$. ⊣

Set $\tau = (\max\{\alpha, \alpha'\})^+$, and suppose for the sake of contradiction that the comparison does not terminate in fewer then τ steps. By applying the claim successively to the two iterations of the comparison we get a stationary subset S_0 of τ such that for any two ordinals $\nu < \nu'$ in S_0 we have $i_{\nu,\nu'}(\kappa_\nu) = i'_{\nu,\nu'}(\kappa_\nu) = \kappa_{\nu'}$. It follows that $\beta_\nu < \min\{o^{\mathcal{U}_\nu}(\kappa_\nu), o^{\mathcal{U}'_\nu}(\kappa_\nu)\}$ for all $\nu \in S_0$, for otherwise if we take any $\nu' > \nu$ in S_0, then either $i_{\nu,\nu'}(\kappa_\nu) = \kappa_\nu < \kappa_{\nu'}$ or $i'_{\nu,\nu'}(\kappa_\nu) = \kappa_\nu < \kappa_{\nu'}$.

Thus x_ν is defined for each $\nu \in S_0$, and by applying the claim twice again we get a stationary set $S_1 \subseteq S_0$ such that $i_{\nu,\nu'}(x_\nu) = i'_{\nu,\nu'}(x_\nu) = x_{\nu'}$ for each $\nu < \nu'$ in S_1. But this is impossible, for since $i_{\nu+1,\nu'}(\kappa_\nu) = i'_{\nu+1,\nu'}(\kappa_\nu) = \kappa_\nu$ it follows that

$$\begin{aligned}
x_\nu \in \mathcal{U}_\nu(\kappa_\nu, \beta_\nu) \quad &\iff \quad \kappa_\nu \in i_{\nu,\nu+1}(x_\nu) \\
&\iff \quad \kappa_\nu \in i_{\nu,\nu'}(x_\nu) = x_{\nu'} = i'_{\nu,\nu'}(x_\nu) \\
&\iff \quad \kappa_\nu \in i'_{\nu,\nu+1}(x_\nu) \\
&\iff \quad x_\nu \in \mathcal{U}'_\nu(\kappa_\nu, \beta_\nu),
\end{aligned}$$

contradicting the choice of x_ν and thus completing the proof of Lemma 2.8. ⊣

As an example of the use of Lemma 2.8, we sketch the proof of Theorem 2.7:

Sketch of Proof. Suppose that Theorem 2.7 is false, so that there is a sequence $\mathcal{U}$ such that $\mathcal{U}$ is coherent in $L[\mathcal{U}]$ and $L[\mathcal{U}]$ contains a normal ultrafilter U which is not a member of the sequence $\mathcal{U}$. We can assume that

Lemma 2.7 does hold for every proper initial segment of the sequence $\mathcal{U}$, that κ and $\beta = o(U)$ are the smallest ordinals such that there is a normal ultrafilter U on κ in $L[\mathcal{U}]$ with $o(U) = \beta$ which is not in the sequence $\mathcal{U}$, and that U is the first such ultrafilter in the order of construction of $L[\mathcal{U}]$. Note that all of these statements can be expressed by sentences in $L[\mathcal{U}]$.

Now apply Lemma 2.8 to the models $L[\mathcal{U}]$ and $\mathrm{Ult}(L[\mathcal{U}], U)$ (with $\alpha = \alpha' = \mathrm{On}$). We must also have $\bar{\alpha} = \bar{\alpha}' = \mathrm{On}$; otherwise if, for example, $\mathrm{On} = \bar{\alpha} < \bar{\alpha}'$, then the lemma would fail in $L_{\bar{\alpha}}[\mathcal{W}{\restriction}\bar{\alpha}] = L[\mathcal{W}{\restriction}\mathrm{On}]$, which contradicts the fact that $L_{\bar{\alpha}'}[\mathcal{W}]$ satisfies the sentence stating that Lemma 2.7 does hold for every proper initial segment of $\mathcal{W}$. Thus we have the following diagram:

$$\begin{tikzcd} & \mathrm{Ult}(L[\mathcal{U}], U) \arrow[dr, "i"] & \\ L[\mathcal{U}] \arrow[ur, "i^U"] \arrow[rr, "i'"] & & L[\mathcal{W}] \end{tikzcd} \tag{17.4}$$

This diagram obviously commutes on definable members of $L[\mathcal{U}]$, but since the diagram itself is definable in $L[\mathcal{U}]$, the least element of $L[\mathcal{U}]$ for which it failed to commute would be definable. Hence diagram (17.4) commutes.

In particular $i'(\kappa) = i\, i^U(\kappa)$, so $i'(\kappa) > \kappa$. Since $i{\restriction}\kappa$ and $i'{\restriction}\kappa$ are the identity it follows that i' begins with an ultrapower by a normal ultrafilter on κ; that is, $\beta_0 = \beta = o(U) < o^{\mathcal{U}}(\kappa)$ and $i' = i'_\theta = i'_{1,\theta}\, i^{\mathcal{U}(\kappa,\beta)}$. But now $U = \mathcal{U}(\kappa, \beta)$, for if x is any subset of κ in $L[\mathcal{U}]$ then $i\, i^U(x) = i'(x) = i'_{1,\theta} i^{\mathcal{U}(\kappa,\beta)}(x)$, so

$$\begin{aligned} x \in U \quad &\Longleftrightarrow \quad \kappa \in i i^U(x) \quad \Longleftrightarrow \quad \kappa \in i'_{1,\theta}\, i^{\mathcal{U}(\kappa,\beta)}(x) \\ &\Longleftrightarrow \quad x \in \mathcal{U}(\kappa, \beta). \end{aligned}$$

$\dashv$

Models $L[\mathcal{U}]$ with higher order measures are more difficult to obtain than the model $L[U]$ with one measure. One might try to proceed by analogy with the model $L[U]$, choosing a coherent sequence $\mathcal{U}$ in V and using the model $L[\mathcal{U}]$, but this fails on two counts. In the first place it is not clear that there is a coherent sequence $\mathcal{U}$ in V, for example it is not known whether $o(\kappa) = \omega$ implies that there is a coherent sequence $\mathcal{U}$ of measures in V with $o^{\mathcal{U}}(\kappa) = \omega$. In the second place, if $o(\kappa) > \kappa^+$ then it is not clear that a sequence which is coherent in V need be coherent in $L[\mathcal{U}]$. The first construction of an inner model of $o(\kappa) = \omega$ from the assumption $o^V(\kappa) = \omega$ used the covering lemma; however we outline a proof which avoids this. Call a sequence $\mathcal{U}$ *weakly coherent* if it satisfies conditions 1 and 2 of Definition 2.6, together with the following weakened coherence condition: if $(\kappa, \beta) \in \mathrm{dom}(\mathcal{U})$ and $U = \mathcal{U}(\kappa, \beta)$ then $o^V(U) = \beta$.

We first show that the comparison process can be modified to use sequences which are only weakly coherent. Notice that this proof requires that $\mathcal{U}$ and $\mathcal{W}$ be sequences of measures in V, not just in $L[\mathcal{U}]$ and $L[\mathcal{W}]$. The example described following Theorem 2.7 shows that this hypothesis cannot be eliminated.

2.10 Lemma. *Suppose that $\mathcal{U}$ and $\mathcal{W}$ are weakly coherent sequences of measures in V with the same domain. Then $L[\mathcal{U}] = L[\mathcal{W}]$, and $\mathcal{U}(\kappa,\beta) \cap L[\mathcal{U}] = \mathcal{W}(\kappa,\beta) \cap L[\mathcal{W}]$ for every (κ,β) in their common domain.*

Proof. We compare the model V with itself, using iterated ultrapowers $i_\nu : V = M_0 \to M_\nu$ and $j_\nu : V = N_0 \to N_\nu$. The comparison process is similar to that in Lemma 2.8 except that we simultaneously compare each of the sequences $i_\nu(\mathcal{U})$ and $i_\nu(\mathcal{W})$ in M_ν with each of the sequences $j_\nu(\mathcal{U})$ and $j_\nu(\mathcal{W})$ in N_ν. Thus, condition (17.3) of the proof of Lemma 2.8 is modified as follows: Suppose that M_ν and N_ν have been defined. Define o^{M_ν} and o^{N_ν} by setting $o^{M_\nu}(\kappa) = o^{i_\nu(\mathcal{U})}(\kappa) = o^{i_\nu(\mathcal{W})}(\kappa)$ and $o^{N_\nu}(\kappa) = o^{j_\nu(\mathcal{U})}(\kappa) = o^{j_\nu(\mathcal{W})}(\kappa)$. Now let (κ_ν, β_ν) be the least pair (κ,β) such that one of the following hold:

1. $\beta < \min\{o^{M_\nu}(\kappa), o^{N_\nu}(\kappa)\}$ and there is a set in $M_\nu \cap N_\nu$ on which the four filters $i_\nu(\mathcal{U})(\kappa,\beta)$, $i_\nu(\mathcal{W})(\kappa,\beta)$, $j_\nu(\mathcal{U})(\kappa,\beta)$ and $j_\nu(\mathcal{W})(\kappa,\beta)$ do not all agree.

2. $\beta = \min\{o^{M_\nu}(\kappa), o^{N_\nu}(\kappa)\}$ and $o^{M_\nu}(\kappa) \neq o^{N_\nu}(\kappa)$.

Now proceed with a slightly modified version of the proof of Lemma 2.8. In case 1 pick U_ν to be one of $\{i_\nu(\mathcal{U})(\kappa,\beta), i_\nu(\mathcal{W})(\kappa,\beta)\}$ and U'_ν to be one of $\{j_\nu(\mathcal{U})(\kappa,\beta), j_\nu(\mathcal{W})(\kappa,\beta)\}$ so that $U_\nu \cap M_\nu \cap N_\nu \neq U'_\nu \cap M_\nu \cap N_\nu$, and set $M_{\nu+1} = \mathrm{Ult}(M_\nu, U_\nu)$ and $N_{\nu+1} = \mathrm{Ult}(N_\nu, U'_\nu)$. In case 2 let $M_{\nu+1} = M_\nu$ if $o^{M_\nu}(\kappa) = \beta$ and $M_{\nu+1} = \mathrm{Ult}(M_\nu, i_\nu(\mathcal{U})(\kappa,\beta))$ if $\beta < o^{M_\nu}(\kappa)$, and define $N_{\nu+1}$ similarly.

Unlike the proof of Lemma 2.8, the sequence of ordinals κ_ν need not be strictly increasing; however the sequence is nondecreasing and the fact that $\beta_{\nu+1} < \beta_\nu$ whenever $\kappa_{\nu+1} = \kappa_\nu$ implies that for each ν there is an $n < \omega$ such that $\kappa_{\nu+n} > \kappa_\nu$. This, together with the weak coherence of $\mathcal{U}$ and $\mathcal{W}$, is enough to show that the comparison terminates at some stage θ.

There is a λ such that either $o^{i_\theta(\mathcal{U})} = o^{j_\theta(\mathcal{U})} \restriction \lambda$ or $o^{j_\theta(\mathcal{U})} = o^{i_\theta(\mathcal{U})} \restriction \lambda$; we may assume the former. We will show that $L[i_\theta(\mathcal{U})] = L[i_\theta(\mathcal{W})]$, and since i_θ is an elementary embedding it follows that $L[\mathcal{U}] = L[\mathcal{W}]$, as was to be shown.

The four sequences $i_\theta(\mathcal{U}) \restriction \lambda$, $i_\theta(\mathcal{W}) \restriction \lambda$, $j_\theta(\mathcal{U})$ and $j_\theta(\mathcal{W})$ agree on sets in $M_\theta \cap N_\theta$, and thus $L[i_\theta(\mathcal{U})] = L[i_\theta(\mathcal{W})]$ will follow if we can show that $L[i_\theta(\mathcal{U})] \subseteq M_\theta \cap N_\theta$. Suppose the contrary, and let α be least such that there is a set in $L_{\alpha+1}[i_\theta(\mathcal{U})]$ which is not in $M_\theta \cap N_\theta$. Now $i_\theta(\mathcal{U})$ and $j_\theta(\mathcal{U})$ agree on all sets in $L_\alpha[i_\theta(\mathcal{U})]$. Thus $L_\alpha[i_\theta(\mathcal{U})] = L_\alpha[j_\theta(\mathcal{U})]$, and the restrictions of $i_\theta(\mathcal{U})$ and $j_\theta(\mathcal{U})$ to this set are equal. However $L_{\alpha+1}[i_\theta(\mathcal{U})]$ is equal to the set of subsets of $L_\alpha[i_\theta(\mathcal{U})]$ definable over $L_\alpha[i_\theta(\mathcal{U})]$ using as a predicate the restriction of $i_\theta(\mathcal{U})$ to $L_\alpha[i_\theta(\mathcal{U})]$, and similarly for $L_{\alpha+1}[j_\theta(\mathcal{U})]$. Hence $L_{\alpha+1}[i_\theta(\mathcal{U})] = L_{\alpha+1}[j_\theta(\mathcal{U})]$, and it follows that $L_{\alpha+1}[i_\theta(\mathcal{U})] \subseteq M_\theta \cap N_\theta$, contradicting the choice of α. This contradiction completes the proof of Lemma 2.10. $\dashv$

2.11 Corollary. *If $\mathcal{U}$ is weakly coherent in V, then either $\mathcal{U}$ is coherent in $L[\mathcal{U}]$ or there is an inner model of $\exists\kappa(o(\kappa) = \kappa^{++})$.*

Sketch of Proof. Let $\mathcal{U}$ be any weakly coherent sequence which is not coherent in $L[\mathcal{U}]$. Since initial segments of $\mathcal{U}$ are also weakly coherent, we may assume that $\mathcal{U}$ has minimal length, so that $\mathcal{U}\restriction(\kappa,\beta)$ is coherent in $L[\mathcal{U}\restriction(\kappa,\beta)]$ for all (κ,β) in the domain of $\mathcal{U}$. In particular, if (κ,β) is the least place at which $\mathcal{U}$ is not coherent in $L[\mathcal{U}]$ then $\mathcal{U}\restriction(\kappa,\beta)$ is coherent in $L[\mathcal{U}\restriction(\kappa,\beta)]$, and it will be sufficient to show that $L[\mathcal{U}\restriction(\kappa,\beta)] \models o(\kappa) = \beta = \kappa^{++}$.

To this end, set $U = \mathcal{U}(\kappa,\beta)$ and consider the following triangle:

$$\begin{tikzcd}
L[\mathcal{U}] \arrow[r, "j"] \arrow[dr, "i^U\restriction L[\mathcal{U}]"'] & \mathrm{Ult}(L[\mathcal{U}], U) \arrow[d, "k"] \\
& L[i^U(\mathcal{U})]
\end{tikzcd}$$

where $i^U : V \to \mathrm{Ult}(V, U)$, j is the ultrapower of $L[\mathcal{U}]$ using functions in $L[\mathcal{U}]$, and k is defined by $k\big(j(f)(\kappa)\big) = i^U(f)(\kappa)$.

We claim that $i^U(\mathcal{U})\restriction\kappa+1$ agrees with $\mathcal{U}\restriction(\kappa,\beta)$ on all sets in $L[\mathcal{U}]$. To see this, let $\mathcal{U}'$ be the sequence obtained from $\mathcal{U}$ by replacing $\mathcal{U}\restriction(\kappa,\beta)$ with $i^U(\mathcal{U})\restriction\kappa+1$. Then $\mathcal{U}'$ is weakly coherent, and has the same domain as $\mathcal{U}$, so by Lemma 2.10 it is equal to $\mathcal{U}$ on sets in $L[\mathcal{U}]$.

This implies that k is not the identity on $o^{j(\mathcal{U})}(\kappa)+1$, since otherwise we would have $k(j(\mathcal{U})\restriction\kappa+1) = i^U(\mathcal{U})\restriction\kappa+1$. Since $L[\mathcal{U}]$ and $L[j(\mathcal{U})]$ have the same subsets of κ, and $i^U(\mathcal{U})\restriction\kappa+1$ agrees with $\mathcal{U}$ on these subsets, this would contradict the assumption that $\mathcal{U}$ is not coherent in $L[\mathcal{U}]$ at (κ,β).

Now let $\eta = \mathrm{crit}(k)$. Then $\eta \le o^{L[j(\mathcal{U})]}(\kappa)$, and since $\beta = k(o^{L[j(\mathcal{U})]}(\kappa))$ it follows that $k(\eta) \le \beta$. Also $\eta > \kappa$, and η is a cardinal in $L[j(\mathcal{U})]$ and hence in $L[\mathcal{U}]$. But $k(\eta)$ is a cardinal in $L[i^U(\mathcal{U})]$, and hence also in $L[i^U(\mathcal{U})\restriction\kappa+1] = L[\mathcal{U}\restriction(\kappa,\beta)]$. Thus $\beta \ge k(\eta) \ge \kappa^{++}$ in $L[\mathcal{U}\restriction(\kappa,\beta)]$. ⊣

2.2. Indiscernibles from Iterated Ultrapowers

We now look at the use of iterated ultrapowers to generate systems of indiscernibles, and at the relation between these indiscernibles and those added generically by Prikry forcing and its variants. Such forcing is covered extensively in chapter [12].

The simplest case is Prikry forcing [31], which involves only one normal ultrafilter. Let U be a normal ultrafilter on a cardinal κ, and let $i^U_\omega : V \to M_\omega = \mathrm{Ult}_\omega(V, U)$ be the iterated ultrapower of length ω. Then the set $C = \{i^U_n(\kappa) : n < \omega\}$ is a set of indiscernibles over M_ω in the following sense: if x is any subset of $i_\omega(\kappa)$ in M_ω, then there are $n < \omega$ and $x' \subseteq i_n(\kappa)$ in M_n such that $x = i_{n,\omega}(x')$. Then for all $m \ge n$ we have $i_m(\kappa) \in x$ if and only if $x' \in i_n(U)$, which is to say if and only if $x \in i_\omega(U)$. Hence C is almost contained in any set $x \in \mathcal{P}^{M_\omega}(i_\omega(\kappa))$ such that $x \in i_\omega(U)$. By

Mathias's genericity criterion [23], this implies that the sequence C is generic for Prikry forcing over M_ω.

In order to extend this construction to the variants of Prikry forcing discovered by Magidor [21] and Radin [32], let $\mathcal{U} = \langle U_\beta : \beta < \eta \rangle$ be a $\triangleleft$-increasing sequence of measures on κ, with $o(U_\beta) = \beta$ for $\beta < \eta$ and define an iterated ultrapower $i_\nu : V \to M_\nu$, of length θ, as follows:

As usual, set $M_0 = V$ and set $M_\nu = \operatorname{dir}\lim_{\nu' < \nu} M_{\nu'}$ whenever ν is a limit ordinal. Now suppose that M_ν has been defined. Set $\kappa_\nu = i_\nu(\kappa)$, and let $M_{\nu+1} = \mathrm{Ult}(M_\nu, i_\nu(\mathcal{U})_{\beta_\nu})$ where $\beta_\nu < i_\nu(\eta)$ is the least ordinal β such that $\{\nu' < \nu : i_{\nu',\nu}(\beta_{\nu'}) = \beta\}$ is bounded in ν. If there is no such ordinal β then set $\theta = \nu$ and stop the process.

Assuming $\eta < \kappa^{++}$ and $2^\kappa = \kappa^+$, Fodor's Lemma implies that $\theta < \kappa^{++}$. If $\eta < \kappa$ then a straightforward induction shows that $\theta = \omega^\eta$, and that β_ν is always the least ordinal β such that $\nu = \nu' + \omega^\beta$ for some ordinal $\nu' < \nu$. In particular $\beta_\nu = 0$ if ν is a successor ordinal.

The set $C = \{i_\nu(\kappa) : \nu < \theta\}$ is a closed unbounded subset of $i_\theta(\kappa)$, since the sequence $\langle i_\nu(\kappa) : \nu < \theta \rangle$ is continuous. If $x \in M_\nu$ and $x \subseteq \kappa_\nu$ then $\kappa_\nu \in i_{\nu,\theta}(x) \iff x \in i_\nu(\mathcal{U})_{\beta_\nu} \iff i_{\nu,\theta}(x) \in i_\theta(\mathcal{U})_\beta$, where $\beta = i_{\nu,\theta}(\beta_\nu)$. Thus the sets $C_\beta = \{\kappa_\nu : \nu < \theta \text{ and } i_{\nu,\theta}(\beta_\nu) = \beta\}$ are sets of indiscernibles for the normal ultrafilters $i_\theta(\mathcal{U})_\beta$ on $i_\theta(\kappa)$.

We have already considered the case $n = 1$, when $C = C_0$ is a Prikry sequence for the normal ultrafilter $i(\mathcal{U}_0)$ on $i_\omega(\kappa)$. If $\eta < \kappa$ is an uncountable regular cardinal then $M_\theta[C]$ is a generic extension of the model M_θ by Magidor's generalization [21] of Prikry forcing: the cardinals of $M_\theta[C]$ are the same as those of M_θ, while κ_θ is regular in M_θ and has cofinality η in $M_\theta[C]$. Notice that $\vec{C} = \langle C_\beta : \beta < \eta \rangle \in M_\theta[C]$, since $C_\beta = \{\lambda \in C : o(\lambda) = \beta\}$.

The covering lemma, which is discussed in a separate chapter [24], implies that these results are the best possible in the sense that if there is a cardinal κ which is regular in the core model but is singular of cofinality $\eta > \omega$ in V, then $o(\kappa) \geq \eta$ in the core model. Furthermore, the singularity of κ is witnessed by a set which is similar to the Prikry-Magidor generic set C described above, but which may be more irregular: it satisfies $o(\nu) \geq \limsup\{o(\nu') + 1 : \nu' \in C \cap \nu\}$, while the Prikry-Magidor generic set satisfies the stronger condition $\forall \nu \in C\ o(\nu) = \limsup\{o(\nu') + 1 : \nu' \in C \cap \nu\}$. The case of $\mathrm{cf}(\kappa) = \omega$ can be somewhat more complicated.

If $\kappa < \eta \leq \kappa^{++}$ then the set C obtained from the iterated ultrapower described above is generic for Radin forcing [32], or rather for the variant of Radin forcing described in [26]. It is a closed unbounded subset of $i_\theta(\kappa)$ and it is eventually contained in every member x of the filter $\bigcap i_\theta(\mathcal{U})$ on $\mathcal{P}^{M_\theta}(i_\theta(\kappa))$. If $\eta \geq \kappa^+$ then the sequence $\langle C_\beta : \beta < i_\theta(\eta) \rangle \notin M_\theta[C]$, and the cardinals of $M_\theta[C]$ are the same as those of M_θ. If $\mathrm{cf}(\eta) = \kappa^+$ then κ_θ remains inaccessible in $M_\theta[C]$, and κ can have stronger larger cardinal properties in $M_\theta[C]$ as the ordinal η becomes larger. For the most important example, define β to be a weak repeat point in the sequence $\mathcal{U}$ if for each set $A \in U_\beta$ there is $\beta' < \beta$ such that $A \in U_{\beta'}$. If $\eta = \beta + 1$, where β is a weak repeat point in $\mathcal{U}$, then $i_\theta(\kappa)$ is measurable in $M_\theta[C]$, with a measure on $i_\theta(\kappa)$ in $M_\theta[C]$ which extends the measure $i(U_\beta)$ in M_θ.

If the set C is obtained by Radin forcing or, equivalently, by an iterated ultrapower as described above, then C is eventually contained in any closed unbounded subset of κ which is a member of the ground model M. It can be shown [28] that if this additional condition is imposed, then neither the hypothesis $o(\kappa) \geq \kappa^+$ for preserving the inaccessibility of κ nor the hypothesis of a weak repeat point for preserving measurability can be weakened. If this condition is removed, however, then work of Gitik [13], improved by Mitchell [28], has shown that if $M \models o(\kappa) = \kappa$ then there is a forcing to add a closed, unbounded set $C \subseteq \kappa$ such that every member of C is inaccessible in M, while κ is still measurable in $M[C]$. Gitik also shows that if $\{\nu < \kappa : o(\kappa) > \beta\}$ is stationary in κ for all $\beta < \kappa$ then κ remains inaccessible in κ. Such sets cannot be obtained by iterated ultrapowers alone, without forcing. Both of these results are the best possible.

3. Extender Models

The next step above the hierarchy of measurable cardinals is the hierarchy leading to a strong cardinal:

3.1 Definition. A cardinal κ is λ-*strong* if there is an elementary embedding $j : V \to M$ such that $\kappa = \operatorname{crit}(j)$, $\lambda < j(\kappa)$, and $\mathcal{P}^\lambda(\kappa) \subseteq M$. A cardinal κ is *strong* if it is λ-strong for every ordinal λ.

A cardinal is 1-strong if and only if it is measurable; however an embedding of the form i^U, where U is an ultrafilter on κ, will never witness that a cardinal κ is 2-strong since $U \in \mathcal{P}^2(\kappa) - \operatorname{Ult}(V, U)$. An *extender* is a generalized ultrafilter designed to represent the stronger embeddings needed for strong cardinals. Extenders can be equivalently defined in either of two different ways, as elementary embeddings or as sequences of ultrafilters. We will begin with the simpler of the two:

3.2 Definition. A (κ, λ)-*extender* is an elementary embedding $\pi : M \to N$ where M and N are transitive models of ZF^-, $\kappa = \operatorname{crit}(\pi)$, and $\lambda \leq \pi(\kappa)$.

The model M need not be a model of ZF; indeed we can typically assume that κ is the largest cardinal in M since $\mathcal{P}^M(\kappa)$ is the only part of M which will be used for the ultrapower construction. Extenders are so called because the embedding π can be extended to an embedding on a full model M' of set theory, provided that the subsets of κ in M' are contained in those of M:

3.3 Definition. Suppose that $\pi : M \to N$ is an extender and M' is a model of set theory such that $\mathcal{P}^{M'}(\kappa) \subseteq \mathcal{P}^M(\kappa)$.

If $a, a' \in [\lambda]^{<\omega}$, and f and f' are functions in M' with domains $[\kappa]^{|a|}$ and $[\kappa]^{|a'|}$ respectively, then we say that $(f, a) \sim_\pi (f', a')$ if and only if

$(a, a') \in \pi(\{(v, v') \in [\kappa]^{|a|} \times [\kappa]^{|a'|} : f(v) = f'(v')\})$. We write $[f, a]_\pi$ for the equivalence class $\{(f', a') : (f, a) \sim_\pi (f', a')\}$.

Finally we write $\mathrm{Ult}(M', \pi)$ for the model with universe

$$\{[f, a]_\pi : f \in {}^\kappa M' \cap M' \;\;\&\;\; a \in {}^{<\omega}\lambda\},$$

and with the membership relation $\in_\pi$ defined by $[f, a]_\pi \in_\pi [f', a']_\pi$ if $(a, a') \in \pi(\{(v, v') : f(v) \in f'(v')\}$.

The ultrapower embedding $i^\pi : M' \to \mathrm{Ult}(M', \pi)$ is defined by $i^\pi(x) = [x, \varnothing]_\pi$. Here x is regarded as a constant, that is, a 0-ary function.

We will only be interested in extenders such that $\mathrm{Ult}(M', \pi)$ is well-founded and hence isomorphic to a transitive model, and we will identify $\mathrm{Ult}(M', \pi)$ with the transitive model to which it is isomorphic.

The ordinal λ is called the *length* of the (κ, λ)-extender π, and is written $\mathrm{len}(\pi)$. The embedding π does not actually itself determine the value of λ, since the same embedding π could be used as to represent a (κ, λ') extender for any $\lambda' < \pi(\kappa)$. When necessary, the ordinal λ may be explicitly specified, for example by writing $\mathrm{Ult}(M', \pi, \lambda)$ instead of $\mathrm{Ult}(M', \pi)$ or $[f, a]_{\pi,\lambda}$ instead of $[f, a]_\pi$.

If $\lambda < \lambda'$ then a natural elementary embedding

$$k : \mathrm{Ult}(M', \pi, \lambda) \to \mathrm{Ult}(M', \pi, \lambda')$$

can be defined by setting $k([f, a]_{\pi,\lambda}) = [f, a]_{\pi,\lambda'}$. It can be that $\mathrm{Ult}(M', \pi, \lambda) = \mathrm{Ult}(M', \pi, \lambda')$ and k is the identity, in which case we will say that the (κ, λ)- and (κ, λ')-extenders defined by π are equivalent. This will happen whenever there is, for each $\nu \in \lambda'$, some $a \in [\lambda]^{<\omega}$ and $f \in M$ such that $[f, a]_\pi = [\mathrm{id}, \nu]_\pi$. For example, the $(\kappa, \lambda + 1)$- and $(\kappa, \lambda + 2)$-extenders determined by π will always be equivalent, since if s is the successor function, $s(\nu) = \nu + 1$, then $[s, \{\lambda\}]_\pi = [\mathrm{id}, \{\lambda + 1\}]_\pi$.

Łoś's Theorem for extender ultrapowers is proved in the same way as the Łoś's Theorem for ultrafilters:

3.4 Proposition (Łoś's Theorem). *Suppose that $\varphi(v_0, \dots, v_{n-1})$ is any formula of set theory, and that $a_i \in [\lambda]^{<\omega}$ for $i < n$ and $f_i : [\kappa]^{|a_i|} \to \lambda$. Then*

$$\mathrm{Ult}(M', \pi) \models \varphi([f_0, a_0]_\pi, \dots, [f_{n-1}, a_{n-1}]_\pi)$$

if and only if

$$(a_0, \dots, a_{n-1}) \in \pi\big(\{(v_0, \dots, v_{n-1}) : M' \models \varphi(f_0(v_0), \dots, f_{n-1}(v_{n-1}))\}\big).$$

This statement suggests the alternate definition of an extender as a sequence E of ultrafilters:

3.5 Definition. The ultrafilter sequence representing a (κ, λ)-extender π is the sequence $E^\pi = \langle E_a : a \in [\lambda]^{<\omega}\rangle$ of ultrafilters defined by

$$E_a = \{x \subseteq {}^a\kappa : a \in \pi(\{\mathrm{ran}(v) : v \in x\})\}. \tag{17.5}$$

Here we write ran(v) for the sequence $\langle v(a_i) : i < |a|\rangle \in {}^{|a|}\kappa$, where $a = \langle a_i : i < |a|\rangle$. The use of ran$(v)$ instead of v in the right side of (17.5) is necessary because a need not be a member of M. This complication could have been avoided by equivalently defining E_a to be an ultrafilter on subsets of $[\kappa]^{|a|}$ or ${}^{|a|}\kappa$ instead of on ${}^a\kappa$; however the use of ${}^a\kappa$ simplifies some later notation.

3.6 Definition. The ultrapower $\mathrm{Ult}(M', E)$ is defined to be the direct limit of the commuting system of maps

$$\big(\langle \mathrm{Ult}(M', E_a) : a \in {}^{<\omega}\lambda\rangle, \langle \pi_{a,a'} : \mathrm{ran}(a) \subseteq \mathrm{ran}(a')\rangle\big),$$

where $\pi_{a,a'} : \mathrm{Ult}(M', E_a) \to \mathrm{Ult}(M, E_{a'})$ is defined by setting $\pi_{a,a'}([f]_{E_a}) = [v \mapsto f(v{\restriction}a)]_{E_{a'}}$.

It can easily be shown that if π is a (κ, λ)-extender then $\mathrm{Ult}(M, E^\pi) = \mathrm{Ult}(M, \pi, \lambda)$.

In the future we will follow the usual practice of using the ultrafilter representation for extenders. This generally makes for clearer notation, which among other things does not tie down the variables M and N. It also has the advantage of explicitly incorporating the length λ of the extender, but requires additional notation for the shortened extender: if $E = \langle E_a : a \in [\lambda]^{<\omega}\rangle$ is a (κ, λ)-extender and $\lambda' < \lambda$, then we write $E|\lambda'$ for the subsequence $\langle E_a : a \in [\lambda']^{<\omega}\rangle$ of E. Thus $E|\lambda'$ is the (κ, λ')-extender represented by the embedding π^E.

It may happen that $\mathrm{Ult}(V, E|\lambda') = \mathrm{Ult}(V, E)$, in which case we say that the two extenders are equivalent. This will be true whenever there is, for each $\alpha \in \lambda - \lambda'$, a function f and finite set $a \in [\lambda']^{<\omega}$ such that $[f, a]_E = [\mathrm{id}, \{a\}]_E$ or, equivalently, such that $\{v \in {}^{a\cup\{\alpha\}}\kappa : f(v{\restriction}a) = v(\alpha)\} \in E_{a\cup\{\alpha\}}$. As a simple example, by taking f to be the successor function we can see that $E|(\lambda + 1)$ is always equivalent to $E|(\lambda + 2)$.

The notion of countable completeness is somewhat more complicated for extenders than for ultrafilters:

3.7 Definition. An (κ, λ)-extender E is *countably complete* if for each sequence $(a_i : i \in \omega)$ of sets $a_i \in [\lambda]^{<\omega}$ and each sequence $(X_i : i < \omega)$ of sets $X_i \in E_{a_i}$ there is a function $v : \bigcup_i a_i \to \kappa$ such that $v{\restriction}a_i \in X_i$ for each $i < \omega$.

As in the case of ultrafilters, countably complete extenders are important because they ensure well-foundedness of iterated ultrapowers.

3.8 Definition. Suppose that M is a model of set theory and $\mathcal{E}$ is a collection of extenders in M. An iterated ultrapower of M by extenders in $\mathcal{E}$ is a pair of sequences $\langle M_\nu : \nu \leq \theta\rangle$ and $\langle E_\nu : \nu < \theta\rangle$, together with a commuting system of elementary embeddings $i_{\nu,\nu'} : M_\nu \to M_{\nu'}$, such that $M_0 = M$, if ν is a limit ordinal then M_ν is the direct limit of the models $\langle M_{\nu'} : \nu' < \nu\rangle$ under the embeddings $i_{\nu',\nu''}$, and if $\nu < \theta$ then $E_\nu \in i_{0,\nu}(\mathcal{E})$ and $i_{\nu,\nu+1} : M_\nu \to \mathrm{Ult}(M_\nu, E_\nu) = M_{\nu+1}$.

3.9 Lemma. *If $\mathcal{E}$ is a collection of countably complete extenders then any iterated ultrapower using extenders in $\mathcal{E}$ is well-founded.*

Proof. Suppose to the contrary that we have an iterated ultrapower as in Definition 3.8 with M_θ ill-founded. The initial model M_0 could be a proper class, but in that case M_0 can be replaced by an initial segment of M_0 satisfying ZF^- which exhibits the ill-foundedness; thus we can assume that M_0 is a set.

Fix a regular cardinal τ such that the ill-founded iterated ultrapower is a member of $H(\tau)$, the set of sets which are hereditarily of size less than τ, let $X \prec H(\tau)$ be a countable elementary substructure containing the iterated ultrapower, and let $\sigma : P \cong X$ be the inverse of the transitive collapse map. Set $\bar\theta = \sigma^{-1}(\theta)$, and set $\bar E_\nu = \sigma^{-1}(E_{\sigma(\nu)})$ and $\bar M_\nu = \sigma^{-1}(M_{\sigma(\nu)})$ for each $\nu < \bar\theta$.

Set $\bar{\mathcal{E}} = \sigma^{-1}(\mathcal{E})$. Then $(\langle \bar M_\nu : \nu \leq \bar\theta\rangle, \langle \bar E_\nu : \nu < \bar\theta\rangle)$ is an ill-founded iterated ultrapower of $\bar M_0$ of countable length $\bar\theta$, using only extenders from $\bar{\mathcal{E}}$.

We will define a commuting sequence of elementary embeddings

$$\begin{tikzcd}
V & & & & \\
\bar M_0 \arrow[u, "\sigma_0"] \arrow[r, "i_{0,1}"] & \bar M_1 \arrow[ul, "\sigma_1"'] \arrow[r, "i_{1,2}"] & \bar M_2 \arrow[ull, "\sigma_2"'] \arrow[r, "i_{2,3}"] & \cdots \arrow[r] & \bar M_{\bar\theta} \arrow[ullll, "\sigma_{\bar\theta}"']
\end{tikzcd} \tag{17.6}$$

with $\sigma_0 = \sigma \restriction \bar M_0$. Thus $\sigma_{\bar\theta}$ embeds $\bar M_{\bar\theta}$ into V, contradicting the assumption that $\bar M_{\bar\theta}$ is ill-founded and thus completing the proof of the lemma.

The embedding σ_0 has already been defined, and the requirement that the diagram (17.6) commutes determines the choice of σ_α for limit ordinals $\alpha \leq \bar\theta$: if $x \in \bar M_\alpha$ then $\sigma_\alpha(x) = \sigma_{\alpha'}(i^{-1}_{\alpha,\alpha'}(x))$ where α' is any ordinal less than α such that $x \in i_{\alpha',\alpha}``\bar M_{\alpha'}$.

To define $\sigma_{\alpha+1}$, supposing that $\sigma_\alpha : M_\alpha \to H(\tau)$ has been defined, set $\bar\lambda = \operatorname{len}(\bar E_\alpha)$, and let $\langle (\bar X_i, \bar a_i) : i < \omega\rangle$ be an enumeration of the set of pairs (X, a) in M_α such that $a \in [\bar\lambda]^{<\omega}$ and $X \in (\bar E_\alpha)_a$. Then $\sigma_\alpha(\bar X_i) \in (\sigma_\alpha(\bar E_\alpha))_{\sigma_\alpha(\bar a_i)}$, and since $\sigma_\alpha(\bar E_\alpha)$ is a member of the collection $\mathcal{E}$ of countably complete extenders there is a function $v : \bigcup_i \sigma_\alpha(\bar a_i) \to \sigma_\alpha(\bar\kappa)$ such that $v \restriction \sigma_\alpha(\bar a_i) \in \sigma_\alpha(\bar X_i)$ for each $i \in \omega$. Then a straightforward induction shows that the map $\sigma_{\alpha+1} : \bar M_{\alpha+1} \to H(\tau)$ defined by setting $\sigma_{\alpha+1}(x) = \sigma_\alpha(f)(v \restriction \sigma_\alpha(a))$ for each $x = [f, a]_{\bar E_\alpha} \in \bar M_{\alpha+1}$ is an elementary embedding such that $\sigma_\alpha = \sigma_{\alpha+1} \circ \bar i_{\alpha,\alpha+1}$. $\dashv$

This completes the preliminary exposition of extenders, and we now discuss sequences of extenders. The following definition is almost the same as that of a coherent sequence of ultrafilters:

3.10 Definition. A *coherent sequence of nonoverlapping extenders* is a function $\mathcal{E}$ with domain of the form $\{(\kappa, \beta) : \beta < o^{\mathcal{E}}(\kappa)\}$ such that

1. if $o^{\mathcal{E}}(\kappa) > 0$ then $o^{\mathcal{E}}(\lambda) < \kappa$ for every $\lambda < \kappa$,

and if $\beta < o^{\mathcal{E}}(\kappa)$ then

2. $\mathcal{E}(\kappa, \beta)$ is a $(\kappa, \kappa+1+\beta)$-extender E, and
3. $i^{\mathcal{E}(\kappa,\beta)}(\mathcal{E})\restriction(\kappa+1) = \mathcal{E}\restriction(\kappa, \beta)$.

Here $\mathcal{E}\restriction(\kappa, \beta)$ is the restriction of $\mathcal{E}$ to those pairs (κ', β') in its domain which are lexicographically less than (κ, β).

The term *nonoverlapping* refers to clause 1. We will show that nonoverlapping sequences are adequate to construct models with a strong cardinal. It is possible to obtain models with somewhat larger cardinals by weakening clause 1 and modifying the comparison iteration; Baldwin [1] describes a general method of constructing such models. Cardinals very much larger than a strong cardinal, however, require extender sequences $\mathcal{E}$ with overlapping extenders, which greatly complicates the theory of iterated ultrapowers on $L[\mathcal{E}]$, and usually requires the use of iteration trees rather than the linear iterations described in Definition 3.8.

Note that the indexing of the sequences described in Definition 3.10 is the same as that used for sequences of ultrafilters: $\mathcal{E}(\kappa, \beta)$ is the βth extender with critical point κ. This indexing works well for nonoverlapping extenders but fails to be meaningful for sequences with overlapping extenders, where there may be a proper class of extenders with the same critical point κ, and there may be extenders which have critical point κ, but which are stronger than all of the extenders with critical point κ.

All sequences of extenders referred to in this section will be nonoverlapping.

One useful difference between sequences of ultrafilters and sequences of extenders is the fact that the coherence functions for extenders are trivial. The coherence property for a sequence $\mathcal{U}$ of measures depends on the presence, for each $\beta' < \beta < o(\kappa)$, of a function f such that $\beta' = [f]_{\mathcal{U}(\kappa,\beta)}$, or equivalently, such that $\beta' = i^{\mathcal{U}(\kappa,\beta)}(f)(\kappa)$; thus the sequence $\mathcal{U}$ may, for example, be coherent in V but not in $L[\mathcal{U}]$. In the case of a sequence $\mathcal{E}$ of extenders, however, the only coherence function needed is the identity function: if $\beta' < \beta < o^{\mathcal{E}}(\kappa)$ then $\beta' = [\mathrm{id}, \{\beta'\}]_{\mathcal{E}(\kappa,\beta)}$, that is, $\beta' = i^{\mathcal{E}(\kappa,\beta)}(\mathrm{id})(\beta')$. The following proposition, which is not true for sequences of measures, follows immediately:

3.11 Proposition. *If $\mathcal{E}$ is a coherent nonoverlapping sequence of extenders in V and M is an inner model such that the restriction of $\mathcal{E}$ to M is a member of M, then $\mathcal{E}$ is coherent in M.*

In order to define the class $L[\mathcal{E}]$ of sets constructible from $\mathcal{E}$, we can code $\mathcal{E}$ as $\{(\kappa, \beta, a, x) : x \in (\mathcal{E}_{\kappa.\beta})_a\}$. Using this coding, if M is an inner model then $\mathcal{E} \cap M$ is the code for the sequence of restrictions $\langle E_a \cap M : a \in \operatorname{dom} E\rangle$ to M of the extenders E in $\mathcal{E}$.

As we did with sequences of ultrafilters, we need to start with a weaker version of coherence in order to obtain long extender sequences which are coherent in $L[\mathcal{E}]$:

3.12 Definition. A sequence $\mathcal{E}$ of extenders is *weakly coherent* if each extender $E = \mathcal{E}(\kappa,\beta)$ is a $(\kappa,\kappa+1+\beta)$-extender such that $o^{i^E(\mathcal{E})}(\kappa) = \beta$.

3.13 Definition. Suppose that N_0 and M_0 are models with countably complete weakly coherent extender sequences $\mathcal{E}_0$ and $\mathcal{F}_0$, respectively. The *comparison iterations* of N_0 and M_0 are defined as follows: Assume $i_\alpha : M_0 \to M_\alpha$ and $j_\alpha : N_0 \to N_\alpha$ have been defined, and let (κ,β) be the least pair such that one of the following holds:

1. $\beta = o^{i_\alpha(\mathcal{E})}(\kappa) < o^{j_\alpha(\mathcal{F})}(\kappa)$.
2. $\beta = o^{j_\alpha(\mathcal{F})}(\kappa) < o^{i_\alpha(\mathcal{E})}(\kappa)$.
3. $\beta < \min\{o^{j_\alpha(\mathcal{F})}(\kappa), o^{i_\alpha(\mathcal{E})}(\kappa)\}$ and there is an $a \in [\kappa+1+\beta]^{<\omega}$ and $x \in \mathcal{P}({}^a\kappa) \cap M_\alpha \cap N_\alpha$ such that $x \in (i_\alpha(\mathcal{E})(\kappa,\beta))_a - (j_\alpha(\mathcal{F})(\kappa,\beta))_a$.

If there is no such pair (κ,β) then the sequences $i_\alpha(\mathcal{E})$ and $j_\alpha(\mathcal{F})$ have the same domain and are equal, at least with respect to sets which are in both models. If κ is greater than the length of one of the sequences $i_\alpha(\mathcal{E})$ or $j_\alpha(\mathcal{E})$, that is, if $o^{i_\alpha(\mathcal{E})}(\mu) = 0$ for all $\mu \geq \kappa$ or $o^{j_\alpha(\mathcal{F})}(\mu) = 0$ for all $\mu \geq \kappa$, then one of the sequences is an initial segment of the other (again, at least with respect to sets which are in both models). In either case the process is terminated at this stage.

Otherwise define $i_{\alpha,\alpha+1} : M_\alpha \to M_{\alpha+1}$ to be the ultrapower embedding $i^{i_\alpha(\mathcal{E})(\kappa,\beta)} : M_\alpha \to \mathrm{Ult}(M_\alpha, i_\alpha(\mathcal{E})(\kappa,\beta))$ in cases 2 and 3, and in case 1 define $M_{\alpha+1} = M_\alpha$ and let $i_{\alpha,\alpha+1}$ be the identity. Similarly define $N_{\alpha+1}$ by using the extender $j_\alpha(\mathcal{F})(\kappa,\beta)$ in cases 1 and 3, and set $N_{\alpha+1} = N_\alpha$ in case 2.

The proof that this comparison iteration terminates will use the following proposition, which is proved just like Claim 2.9.

3.14 Proposition. *Suppose that θ is an uncountable regular cardinal, and that we have an iterated extender ultrapower $\langle M_\alpha : \alpha < \theta\rangle$ with iteration embeddings $i_{\alpha',\alpha} : M_{\alpha'} \to M_\alpha$. If X is a set in M_0 such that $|i_\lambda(X)| < \theta$ for each $\lambda < \theta$, and $y_\alpha \in i_{0,\alpha}(X)$ for all $\alpha < \theta$, then for every stationary set $S \subseteq \theta$ there is a stationary set $S' \subseteq S$ such that if $\alpha' < \alpha$ are in S' then $y_\alpha = i_{\alpha',\alpha}(y_{\alpha'})$.*

3.15 Lemma. *If M_0, N_0, $\mathcal{E}$ and $\mathcal{F}$ are as in Definition 3.13, and θ is a regular cardinal such that $\theta \geq \sup\{\, 2^\kappa : o^{\mathcal{E}}(\kappa) > 0$ or $o^{\mathcal{F}}(\kappa) > 0\}$, then the comparison process terminates in fewer than θ steps.*

Proof. Assume the contrary, and at each $\alpha < \theta$ let κ_α and β_α be as in the definition of $M_{\alpha+1}$ and $N_{\alpha+1}$. By applying Proposition 3.14 twice, once to the iterated ultrapower of M_0 and then to that of N_0, we can find a stationary set $S \subseteq \theta$ such that if $\alpha' < \alpha$ are in S then $\kappa_\alpha = i_{\alpha',\alpha}(\kappa_{\alpha'}) = j_{\alpha',\alpha}(\kappa_{\alpha'})$.

Now the sequence $\langle \kappa_\alpha : \alpha < \theta\rangle$ is nondecreasing. Furthermore, whenever $\kappa_{\alpha+1} = \kappa_\alpha$ we have $\beta_{\alpha+1} < \beta_\alpha$, and it follows that for each α there is $k < \omega$

such that $\kappa_\alpha < \kappa_{\alpha+k}$. It follows that $\kappa_{\alpha'} < \kappa_\alpha$ whenever $\alpha' < \alpha$ are limit ordinals.

Now $o^{i_{\alpha+1}(\mathcal{E})}(\kappa_\alpha) = o^{j_{\alpha+1}(\mathcal{F})}(\kappa_\alpha) = \beta_\alpha$ for each $\alpha < \theta$, so case 1 or 2 can only occur at stages α such that $\kappa_{\alpha'} < \kappa_\alpha$ for all $\alpha' < \alpha$. In particular, it never happens that cases 1 and 2 both occur at stages with the same critical point κ_α. For ordinals $\alpha < \alpha'$ in S we have $i_{\alpha,\alpha'}(\kappa_\alpha) = j_{\alpha,\alpha'}(\kappa_\alpha) = \kappa_{\alpha'} > \kappa_\alpha$, so if $\alpha \in S$ and $\alpha^* \geq \alpha$ is the last stage for which $\kappa_{\alpha^*} = \kappa_\alpha$ then case 3 must occur at stage α^*. Finally, let $a_{\alpha^*} \in [\beta_{\alpha^*}]^{<\omega}$ and $x_{\alpha^*} \subseteq [\kappa_\alpha]^{|a_{\alpha^*}|}$ be as in the definition of the comparison at stage α^*. Two more applications of Proposition 3.14 give a stationary $S' \subseteq S$ such that if $\alpha < \gamma$ are in S' then $x_{\gamma^*} = i_{\alpha,\gamma}(x_{\alpha^*}) = j_{\alpha,\gamma}(x_{\alpha^*})$. Set $E_\alpha = i_{0,\alpha}(\mathcal{E})(\kappa_\alpha, \beta_\alpha)$ and $F_\alpha = j_{0,\alpha}(\mathcal{F})(\kappa_\alpha, \beta_\alpha)$. Then we have

$$\begin{aligned} x_\alpha \in (E_{\alpha^*})_{a_{\alpha^*}} &\iff a_{\alpha^*} \in i_{\alpha^*,\alpha^*+1}(x_\alpha) \\ &\iff a_{\alpha^*} \in i_{\alpha^*+1,\gamma} \circ i_{\alpha^*,\alpha^*+1} \circ i_{\alpha,\alpha^*}(x_\alpha) \\ &\qquad\quad = i_{\alpha,\gamma}(x_\alpha) = x_\gamma, \end{aligned}$$

since $i_{\alpha,\alpha^*}(x_\alpha) \cap [\kappa_\alpha]^{|a_{\alpha^*}|} = x_\alpha$ and $i_{\alpha^*+1,\gamma}(a_{\alpha^*}) = a_\alpha$. Similarly, $x_\alpha \in (F_{\alpha^*})_{a_{\alpha^*}}$ if and only if $a_{\alpha^*} \in j_{\alpha,\gamma}(x_\alpha) = x_\gamma$, and hence $x_{\alpha^*} \in (E_{\alpha^*})_{a_{\alpha^*}}$ if and only if $x_{\alpha^*} \in (F_{\alpha^*})_{a_{\alpha^*}}$. This contradicts the choice of x_{α^*} and hence completes the proof of the lemma. ⊣

The proof of Lemma 3.15 relied crucially on the fact that $i_{\alpha^*+1,\gamma}(a_{\alpha^*}) = j_{\alpha^*+1,\gamma}(a_{\alpha^*}) = a_{\alpha^*}$ for all $\alpha < \gamma$ in S; that is, none of the generators arising from a use of an extender in the iteration is moved by the remainder of the iteration. This problem of *moving generators* is the reason that linear iterations like those used in the proof of Lemma 3.15 are not adequate for comparisons of sequences having overlapping extenders. Thus iteration trees are needed for the analysis of inner models with larger cardinals.

When the comparison process terminates, it is only guaranteed that the sequences match with respect to sets which are in both models, so it is important to observe that this is true of all relevant sets:

3.16 Proposition. *Suppose that the comparison maps $i_\theta : L[\mathcal{E}] \to L[i_\theta(\mathcal{E})]$ and $j_\theta : L[\mathcal{F}] \to L[i_\theta(\mathcal{F})]$ terminate with $i_\theta(\mathcal{E})$ equal to $j_\theta(\mathcal{F})\restriction\eta$ in the sense that $o^{i_\theta(\mathcal{E})} = o^{j_\theta(\mathcal{F})}\restriction\eta$ and*

$$i_\theta(\mathcal{E}) \cap L[i_\theta(\mathcal{E})] \cap L[j_\theta(\mathcal{F})] = (j_\theta(\mathcal{F}))\restriction\eta \cap L[i_\theta(\mathcal{E})] \cap L[j_\theta(\mathcal{F})].$$

Then $L[i_\theta(\mathcal{E})] \subseteq L[j_\theta(\mathcal{F})]$, so that $i_\theta(\mathcal{E}) = (j_\theta(\mathcal{F})\restriction\eta) \cap L[i_\theta(\mathcal{E})]$.

Proof. We prove by induction on α that $L_\alpha[i_\theta(\mathcal{E})] \subseteq L_\alpha[j_\theta(\mathcal{F})]$ for all ordinals α. It is only the successor case that could be problematic: assume as an induction hypothesis that $\alpha < \eta$ and $L_\alpha[i_\theta(\mathcal{E})] \subseteq L_\alpha[j_\theta(\mathcal{F})]$. Notice that it follows that $i_\theta(\mathcal{E}) \cap L_\alpha[i_\theta(\mathcal{E})] = j_\theta(\mathcal{F}) \cap L_\alpha[j_\theta(\mathcal{F})]$ if $\alpha \leq \eta$, and $i_\theta(\mathcal{E}) \cap L_\alpha[i_\theta(\mathcal{E})] = (j_\theta(\mathcal{F})\restriction\eta) \cap L_\alpha[j_\theta(\mathcal{E})]$ if $\alpha > \eta$. In either case both $L_\alpha[i_\theta(\mathcal{E})]$ and $i_\theta(\mathcal{E}) \cap L[i_\theta(\mathcal{E})]$ are definable in $L_\alpha[j_\theta(\mathcal{F})]$, and it follows that $L_{\alpha+1}[i_\theta(\mathcal{E})] \subseteq L_{\alpha+1}[j_\theta(\mathcal{F})]$. ⊣

3.17 Definition. Suppose that $\mathcal{E}$ is a weakly coherent sequence and $\varphi(\mathcal{E})$ is a sentence in the language of set theory. Then $L[\mathcal{E}]$ is said to be *φ-minimal* if $L[\mathcal{E}] \models \varphi(\mathcal{E})$ but there is no proper initial segment $\mathcal{E}' = \mathcal{E}\restriction(\kappa, \beta)$ of $\mathcal{E}$ such that $L[\mathcal{E}'] \models \varphi(\mathcal{E}')$.

3.18 Proposition. *Suppose that $\mathcal{E}$ is weakly coherent and $L[\mathcal{E}]$ is φ-minimal for some formula φ, and suppose that $\pi : L[\mathcal{E}] \to L[\mathcal{E}']$ is an elementary embedding. Then the comparison of $L[\mathcal{E}]$ and $L[\mathcal{E}']$ gives the following diagram:*

$$\begin{tikzcd} L[\mathcal{E}] \arrow[rr, "j_\theta"] \arrow[dr, "\pi"'] & & L[j_\theta(\mathcal{E})] \\ & L[\mathcal{E}'] \arrow[ur, "k_\theta"'] & \end{tikzcd} \tag{17.7}$$

Furthermore, if π is definable in $L[\mathcal{E}]$ then this diagram commutes.

Proof. If $j_\theta : L[\mathcal{E}] \to L[j_\theta(\mathcal{E})]$ and $k_\theta : L[\mathcal{E}'] \to L[k_\theta(\mathcal{E}')]$ are the two embeddings generated by the comparison process, then Proposition 3.16 implies that one of the two sequences $j_\theta(\mathcal{E})$ and $k_\theta(\mathcal{E}')$ is an initial segment of the other. Since φ-minimality is a first order property, both of the models $L[j_\theta(\mathcal{E})]$ and $L[k_\theta(\mathcal{E}')]$ are φ-minimal; and it follows that neither can be a proper initial segment of the other. Thus $j_\theta(\mathcal{E}) = k_\theta(\mathcal{E}')$.

It follows that the comparison yields the diagram (17.7). To see that the diagram commutes whenever π is definable, suppose the contrary and let x be the least set in the order of construction of $L[\mathcal{E}]$ such that $j_\theta(x) \neq k_\theta \circ \pi(x)$. Since π is definable in $L[\mathcal{E}]$, the set x is also definable, but this is impossible since then $j_\theta(x)$ and $k_\theta \circ \pi(x)$ are both defined in $L[j_\theta(\mathcal{E})]$ by the same formula and hence must be equal. $\dashv$

3.19 Lemma. *Suppose that $\mathcal{E}$ is a weakly coherent extender sequence and that E is a countably complete $(\kappa, \kappa + 1 + \beta)$-extender in $L[\mathcal{E}]$ such that $o^{i^E(\mathcal{E})}(\kappa) = \beta$. Then $E = \mathcal{E}(\kappa, \beta)$.*

Proof. If this fails then we may assume that $\mathcal{E}$ is φ-minimal for the formula φ asserting that it fails. Pick a counterexample $E \in L[\mathcal{E}]$ with (κ, β) as small as possible and let j_θ and k_θ be the maps arising from the comparison of $L[\mathcal{E}]$ with the model $\mathrm{Ult}(L[\mathcal{E}], E)$. By Proposition 3.18 this gives rise to the following commutative diagram:

$$\begin{tikzcd} L[\mathcal{E}] \arrow[rr, "j_\theta"] \arrow[dr, "i^E"'] & & L[j_\theta(\mathcal{E})] \\ & L[i^E(\mathcal{E})] \arrow[ur, "k_\theta"'] & \end{tikzcd} \tag{17.8}$$

Now all of the extenders $i^E(\mathcal{E})(\kappa, \beta')$ for $\beta' < o^{i^E(\mathcal{E})}(\kappa) = \beta$ are members of $L[\mathcal{E}]$, and by the minimality of (κ, β) it follows that $i^E(\mathcal{E})\restriction(\kappa+1) = \mathcal{E}\restriction(\kappa, \beta)$.

If $o^{\mathcal{E}}(\kappa) = \beta$ then this would imply $j_\theta(\kappa) = \kappa < i^E(\kappa)$, contradicting the commutativity of diagram (17.8). Hence the comparison starts with case 1, so that $j_{0,1} = i^{E'}$, where $E' = \mathcal{E}(\kappa, \beta)$, and $k_{0,1}$ is the identity. Furthermore, $i^{E'}(\mathcal{E}){\upharpoonright}\kappa + 1 = \mathcal{E}{\upharpoonright}(\kappa, \beta) = i^E(\mathcal{E}){\upharpoonright}\kappa + 1$, so $\kappa_1 > \kappa$. Now suppose that $a \in [\kappa+1+\beta]^{<\omega}$ and $x \subseteq [\kappa]^{|a|}$. Then $x \in E_a \iff a \in i^E(x) \iff a \in k_\theta \circ i^E(x)$ and $x \in E'_a \iff a \in i^{E'}(x) = j_{0,1}(x) \iff a \in j_{1,\theta} \circ j_{0,1}(x) = j_\theta(x)$. Since $j_\theta(x) = k_\theta \circ i^E(x)$ it follows that $E = E'$, contrary to the choice of E. ⊣

3.20 Corollary. *If $\mathcal{E}$ is a weakly coherent extender sequence of countably complete extenders, then $\mathcal{E}$ is coherent in $L[\mathcal{E}]$.*

Proof. Suppose to the contrary that $\gamma < o^{\mathcal{E}}(\alpha)$ and $i^{\mathcal{E}(\alpha,\gamma)}(\mathcal{E}){\upharpoonright}\gamma \neq \mathcal{E}{\upharpoonright}(\alpha, \gamma)$. Let $\beta < \gamma$ be such that $\mathcal{E}(\alpha, \beta) \neq i^{\mathcal{E}(\alpha,\gamma)}(\mathcal{E})(\alpha, \beta)$, and apply Lemma 3.19 with $E = i^{\mathcal{E}(\alpha,\gamma)}(\mathcal{E})(\alpha, \beta)$. ⊣

It should be noted that the assumption that the extenders in $\mathcal{E}$ are countably complete is used only to assure that any iterated ultrapower using extenders in $\mathcal{E}$ is well-founded.

3.21 Theorem. *If κ is a strong cardinal, then there is a weakly coherent sequence $\mathcal{E}$ of countably complete extenders such that there is a strong cardinal $\kappa' \leq \kappa$ in $L[\mathcal{E}]$.*

Proof. We define the domain $o^{\mathcal{E}}$ of $\mathcal{E}$ and the extenders $\mathcal{E}(\lambda, \beta)$ using recursion on λ with an inner recursion on β. Suppose that $o^{\mathcal{E}}{\upharpoonright}\lambda$ and $\mathcal{E}{\upharpoonright}\lambda$ have been defined. If λ is not measurable, or if there is some $\lambda' < \lambda$ such that $o^{\mathcal{E}}(\lambda') \geq \lambda$, then set $o^{\mathcal{E}}(\lambda) = 0$. Otherwise define extenders $\mathcal{E}(\lambda, \beta)$ by recursion on β. Suppose that $\mathcal{E}{\upharpoonright}(\lambda, \beta)$ has been defined. If there is a countably complete $(\lambda, \lambda + 1 + \beta)$-extender E such that $o^{i^E(\mathcal{E}{\upharpoonright}\lambda)}(\lambda) = \beta$, then let $\mathcal{E}(\lambda, \beta)$ be any such extender. If there is no such extender E then the inner recursion terminates and $o^{\mathcal{E}}(\lambda)$ is defined to be β.

The sequence $\mathcal{E}$ is coherent in $L[\mathcal{E}]$ by Corollary 3.20. Now a cardinal κ' is strong in $L[\mathcal{E}]$ if and only if $o^{\mathcal{E}}(\kappa') = \mathrm{On}$. The necessity follows from the fact that if $o^{\mathcal{E}}(\kappa') \in \mathrm{On}$ then $\mathcal{E}{\upharpoonright}\kappa' + 1$ is a set, but there is no extender E on κ' in $L[\mathcal{E}]$ such that $\mathcal{E}{\upharpoonright}\kappa' + 1 \in \mathrm{Ult}(L[\mathcal{E}], E)$. To see that the condition $o^{\mathcal{E}}(\kappa') = \mathrm{On}$ is sufficient, let X be any set in $L[\mathcal{E}]$ and fix τ so that $X \in L_\tau[\mathcal{E}]$. Now set $E = \mathcal{E}_{\kappa,\tau}$. Then by coherence $\mathcal{E}{\upharpoonright}(\kappa, \tau) = i^E(\mathcal{E}){\upharpoonright}\kappa + 1$, so $X \in L_\tau[\mathcal{E}] = L_\tau[\mathcal{E}{\upharpoonright}(\kappa, \tau)] = L_\tau[i^E(\mathcal{E})] \in \mathrm{Ult}(L[\mathcal{E}], E)$.

To finish the proof we need to show that there is some $\kappa' \leq \kappa$ such that $o^{\mathcal{E}}(\kappa') = \mathrm{On}$. We may suppose that $o^{\mathcal{E}}(\kappa') < \mathrm{On}$ for all $\kappa' < \kappa$. This implies that $o^{\mathcal{E}}(\kappa') < \kappa$ for all $\kappa' < \kappa$: otherwise there is, for all ordinals β, an extender F on κ so that $i(\kappa) > \beta$ and $V_\beta \subseteq \mathrm{Ult}(V, F)$. Then $o^{i^F(\mathcal{E})}(\kappa') = i^F(o^{\mathcal{E}}(\kappa')) > \beta$, but $i^F(\mathcal{E}){\upharpoonright}\beta = \mathcal{E}{\upharpoonright}\beta$. Since β was arbitrary, this implies that $o^{\mathcal{E}}(\kappa') = \mathrm{On}$, contrary to assumption.

Now suppose that $\mathcal{E}{\upharpoonright}(\kappa, \beta)$ has been defined. We must show that there is a countably complete $(\kappa, \kappa + 1 + \beta)$-extender E such that $i^E(o^{\mathcal{E}})(\kappa) = \beta$.

Since κ is strong in V, there is a countably complete extender F on κ such that $\mathcal{E}\upharpoonright(\kappa,\beta) \in \mathrm{Ult}(V,F)$. Now $i^F(\mathcal{E})$ is defined in $\mathrm{Ult}(V,F)$ in the same way as $\mathcal{E}$ is defined in V. Since $\mathcal{E}(\kappa,\gamma) \in \mathrm{Ult}(V,F)$ for each $\gamma < \beta$, and $\mathcal{E}(\kappa,\gamma)$ is a possible choice for $i^F(\mathcal{E})(\kappa,\gamma)$, we must have $o^{i^F(\mathcal{E})}(\kappa) \geq \beta$.

If $o^{i^F(\mathcal{E})} > \beta$ then set $E = i^F(\mathcal{E})(\kappa,\beta)$. Since V and $\mathrm{Ult}(V,F)$ have the same subsets of κ and $E\upharpoonright\kappa = i^F(\mathcal{E})\upharpoonright\kappa$, E is also a countably complete extender on V and satisfies $o^{i^E(\mathcal{E})} = \beta$. Otherwise, if $o^{i^F(\mathcal{E})}(\kappa) = \beta$, let $E = F|(\kappa+1+\beta)$, the $(\kappa,\kappa+1+\beta)$-extender given by the embedding $i^F : V \to \mathrm{Ult}(V,F)$. Since the identity functions serve as coherence functions for extenders, $i^E(o^{\mathcal{E}})(\kappa) = i^F(o^{\mathcal{E}})(\kappa) = \beta$, and hence E is a suitable choice for $\mathcal{E}(\kappa,\beta)$. ⊣

Theorem 3.21 can be generalized to smaller cardinals: If κ is λ-strong in V then there is a sequence $\mathcal{E}$ such that $o^{\mathcal{E}}(\kappa) > (\kappa^{+\lambda})^{L[\mathcal{E}]}$, and this holds if and only if κ is λ-strong in $L[\mathcal{E}]$.

The next result shows that, as was the case for sequences of measures, the sequence $\mathcal{E} \cap L[\mathcal{E}]$ is uniquely determined by its domain, provided that the extenders $\mathcal{E}(\kappa,\beta)$ are countably complete extenders in V, not merely in $L[\mathcal{E}]$.

3.22 Theorem. *Suppose that $\mathcal{E}$ is a weakly coherent sequence of extenders in V, $\beta < o^{\mathcal{E}}(\kappa)$, and F is a countably complete extender of length $\kappa+1+\beta$ such that $o^{i^F(\mathcal{E})}(\kappa) = \beta$. Then $F \cap L[\mathcal{E}] = \mathcal{E}(\kappa,\beta)$.*

Proof. Let $i_\theta : M_0 := L[\mathcal{E},F] \to M_\theta$ and $j_\theta : N_0 := L[\mathcal{E},F] \to N_\theta$ be iterated ultrapowers comparing the model $L[\mathcal{E},F]$ with itself, with the comparison process modified to include F as an alternative to $\mathcal{E}(\kappa,\beta)$. This means that case 3 of Definition 3.13 is modified to allow $M_{\nu+1}$ to be either of $\mathrm{Ult}(M_\nu, i_\nu(\mathcal{E}(\kappa,\beta)))$ or $\mathrm{Ult}(M_\nu, i_\nu(F))$ if the ultrafilter in question differs on a set in $M_\nu \cap N_\nu$ either from $j_\nu(\mathcal{E})(i_\nu(\kappa), i_\nu(\beta))$ or (in the case $i_\nu(\kappa) = j_\nu(\kappa)$ and $i_\nu(\beta) = j_\nu(\beta)$) from $j_\nu(F)$. Similarly, $j_\nu(F)$ is a candidate for use in defining $N_{\nu+1}$.

Lemma 3.15, asserting that the comparison terminates, is still valid for this comparison. Consider the final models $M_\theta = L[i_\theta(\mathcal{E}), i_\theta(F)]$ and $N_\theta = L[j_\theta(\mathcal{E}), j_\theta(F)]$ of this comparison. One of the sequences $i_\theta(\mathcal{E})$ and $j_\theta(\mathcal{E})$ will be an initial segment (possibly proper) of the other; suppose that $i_\theta(\mathcal{E})$ is an initial segment of $j_\theta(\mathcal{E})$. Then we have that $i_\theta(\mathcal{E}(\kappa,\beta))$ and $i_\theta(F)$ agree with $j_\theta(\mathcal{F})(i_\theta(\kappa), i_\theta(\beta))$, and hence with each other, on all sets in $M_\theta \cap N_\theta$. By the elementarity of i_θ there is a set $x \in M_\theta$ on which $i_\theta(F)$ and $i_\theta(\mathcal{E}(\kappa,\beta))$ differ. Let x be the first such set in the order of construction of M_θ, and suppose that $x \in L_{\tau+1}[i_\theta(\mathcal{E}), i_\theta(F)] - L_\tau[i_\theta(\mathcal{E}), i_\theta(F)]$. Then $L_\tau[i_\theta(\mathcal{E}), i_\theta(F)] = L_\tau[i_\theta(\mathcal{E})] = L_\theta[j_\theta(\mathcal{E})]$ so, as in the proof of Lemma 3.19, $x \in L_{\tau+1}[i_\theta(\mathcal{E})] \subseteq N_\theta$. Thus $x \in M_\theta \cap N_\theta$, contradicting the assumption that $i_\theta(F)$ and $i_\theta(\mathcal{E}(\kappa,\beta))$ differ about x. ⊣

3.23 Corollary. *If $\mathcal{E}$ and $\mathcal{E}'$ are weakly coherent sequences of extenders in V with the same domain then $L[\mathcal{E}] = L[\mathcal{E}']$ and $\mathcal{E} \cap L[\mathcal{E}] = \mathcal{E}' \cap L[\mathcal{E}']$.*

It was previously observed that this statement is false, even for ultrapowers of order 0, if the requirement that $\mathcal{E}$ be a sequence of extenders in V is weakened to require only that they be extenders in $L[\mathcal{E}]$.

We conclude this section by showing that the Generalized Continuum Hypothesis holds in $L[\mathcal{E}]$. The same argument shows that other consequences of condensation such as $\Diamond_\kappa$ and $\Box_\kappa$ also hold in $L[\mathcal{E}]$.

3.24 Theorem. *If $\mathcal{E}$ is a coherent sequence of countably complete extenders in $L[\mathcal{E}]$ then $L[\mathcal{E}] \models \mathrm{GCH}$.*

Proof. The proof of Theorem 3.24 will require the proof of a condensation lemma for $L[\mathcal{E}]$. Let us say that a model M is a *coarse mouse* in $L[\mathcal{E}]$ with projectum ρ if $\pi : M \cong X \prec L_\tau[\mathcal{E}]$ where $L_\tau[\mathcal{E}] \models \mathrm{ZF}^-$ and $X = \mathcal{H}^{L_\tau[\mathcal{E}]}(\{\mathcal{E}\} \cup \rho \cup p)$ for some finite set $p \in L_\tau[\mathcal{E}]$ of parameters. As in the proof of GCH for L, every subset of ρ in $L[\mathcal{E}]$ is in some coarse mouse with projectum ρ, and each such mouse has cardinality $|\rho|$. Hence it will be enough to show that if M and N are coarse mice in $L[\mathcal{E}]$ with the same projectum ρ, then either $\mathcal{P}(\rho) \cap M \subseteq N$ or $\mathcal{P}(\rho) \cap N \subseteq M$.

First, suppose that $o^{\mathcal{E}}(\kappa) \leq \rho$ for all $\kappa < \rho$ and let $i_\theta : M \to P$ and $j_\theta : N \to Q$ be the maps arising from the comparison of $M = L_{\tau_0}[\mathcal{F}_0]$ and $N = L_{\tau_1}[\mathcal{F}_1]$. Then $\mathcal{F}_0 \restriction \rho = \mathcal{F}_1 \restriction \rho = \mathcal{E} \restriction \rho$ and hence both $i_\theta \restriction \rho$ and $j_\theta \restriction \rho$ are the identity. Therefore $\mathcal{P}^M(\rho) = \mathcal{P}^P(\rho)$ and $\mathcal{P}^N(\rho) = \mathcal{P}^Q(\rho)$; and since one of P and Q is contained in the other it follows that one of $\mathcal{P}^M(\rho)$ and $\mathcal{P}^N(\rho)$ is contained in the other, as was to be proved.

In particular, the assumption that there is no overlapping in the sequence $\mathcal{E}$ implies that $2^\kappa = \kappa^+$ in $L[\mathcal{E}]$ for any κ such that $o^{\mathcal{E}}(\kappa) > 0$.

Now suppose that there is $\kappa < \rho$ with $o^{\mathcal{E}}(\kappa) > \rho$, and let $M = L_\alpha[\mathcal{F}]$ be any coarse ρ-mouse in $L[\mathcal{E}]$. If we set $\beta = o^{\mathcal{F}}(\kappa)$, then because $L[\mathcal{E}]$ satisfies GCH at κ we have $\mathcal{P}^{L[\mathcal{E}]}(\kappa) \subseteq M$ and hence the extenders $\mathcal{F}(\kappa, \gamma)$ for $\gamma < \beta$ are all extenders in $L[\mathcal{E}]$. It follows by Lemma 3.19 that $\mathcal{F}(\kappa, \gamma) = \mathcal{E}(\kappa, \gamma)$ for all $\gamma < \beta$, and hence $\mathcal{F} \restriction \kappa + 1 = \mathcal{E} \restriction (\kappa, \beta)$.

Now if M and N are two coarse ρ-mice in $L[\mathcal{E}]$ with $\beta^M = \beta^N$, then the same argument as that used for the case when $o^{\mathcal{E}}(\kappa) \leq \rho$ for all $\kappa < \rho$ implies that one of $\mathcal{P}^M(\rho)$ and $\mathcal{P}^N(\rho)$ is a subset of the other. Thus, if we hold β fixed then there are at most ρ^+ many subsets of ρ which are in some coarse mouse M for $L[\mathcal{E}]$ with projectum ρ and which have $\beta^M = \beta$. Now $\beta^M < \rho^+$ in $L[\mathcal{E}]$ for any such coarse mouse with projectum ρ, so there can be at most ρ^+-many subsets of ρ in $L[\mathcal{E}]$. ⊣

The natural well-ordering of $\mathcal{P}^{L[\mathcal{E}]}(\rho)$ suggested by this proof is given by setting $x \prec y$ if there is $\beta < o^{\mathcal{E}}(\kappa)$ such that x, but not y, is a member of $\mathrm{Ult}(L[\mathcal{E}], \mathcal{E}(\kappa, \beta))$; and otherwise setting $x \prec y$ if x is less than y in the order of construction either of $\mathrm{Ult}(L([\mathcal{E}], \mathcal{E}(\kappa, \beta))$ where β is least such that $x, y \in \mathrm{Ult}(L([\mathcal{E}], \mathcal{E}(\kappa, \beta))$, or of $L[\mathcal{E}]$ if there is no such β. Note that $i^{\mathcal{E}(\kappa,\beta)}(\rho) < \rho^+$ for any $\beta < \rho^+$, and hence this well-ordering has ordertype ρ^+.

3.1. The Modern Presentation of $L[\mathcal{E}]$

Almost all of the description of $L[\mathcal{U}]$ and $L[\mathcal{E}]$ given so far has followed the original style of [25]; the only exception being the brief description at the end of Sect. 1.2 of the application of the modern presentation to $L[U]$ and K^{DJ}. This presentation was invented in order to accommodate larger cardinals than those considered here, but it has several advantages even for models with smaller cardinals, especially when core model and fine structural techniques are being used.

We will now outline some aspects of this new presentation. There are three major changes.

(1) As was pointed out previously, the method of indexing used in the models of this chapter breaks down beyond a strong cardinal. Instead we index extenders in the sequence with a single ordinal. In the original indexing of these models, the index γ for a extender $E = \mathcal{E}_\gamma$ on the sequence is given by $\gamma = (\nu^+)^{L[\mathcal{E}\restriction\gamma]}$ where ν is the larger of κ^+ and the length of the extender E. This choice of ν ensures that E can easily be coded as a subset of ν.

As part of this indexing, the class coding the sequence $\vec{\mathcal{E}}$ is chosen so that $L_\gamma[\mathcal{E}] = L_\gamma[\mathcal{E}\restriction\gamma]$, while $L_{\gamma+1}[\mathcal{E}]$ is the collection of subsets of $L_\gamma[\mathcal{E}]$ which are definable in the structure $(L_\gamma[\mathcal{E}], \mathcal{E}\restriction\gamma, \mathcal{E}_\gamma)$.

This indexing is still commonly used, but Jensen and others have also worked with indexing schemes using indices as large as $i^E(\kappa^+)$.

(2) More importantly, an extender $E = \mathcal{E}_\gamma$ of the sequence $\mathcal{E}$ does not measure all of the sets in $L[\mathcal{E}]$, but instead only measures the sets in $L_\gamma[\mathcal{E}\restriction\gamma]$, that is, the sets already constructed at the time E appears. This is in contrast to the models of this chapter, in which an extender E is expected to measure sets in $L[\mathcal{E}]$ which require E, and even larger extenders, for their construction. Note that if $\kappa = \mathrm{crit}(\mathcal{E}_\gamma)$ then the choice of $\gamma = (\nu^+)^{L_\gamma[\mathcal{E}\restriction\gamma]}$ implies that $\mathcal{P}(\nu) \cap L[\mathcal{E}\restriction\gamma] \subseteq L_\gamma[\mathcal{E}\restriction\gamma] = L_\gamma[\mathcal{E}]$. Thus $\mathcal{E}_\gamma \subseteq L_\gamma[\mathcal{E}]$, and hence $\mathcal{E}_\gamma$ is a member of $L_{\gamma+1}[\mathcal{E}]$.

An extender $\mathcal{E}_\gamma$ with critical point κ_γ will be a full extender in the final model $L[\mathcal{E}]$ if and only if no new subsets of κ_γ are constructed in $L[\mathcal{E}] - L_\gamma[\mathcal{E}]$. The other extenders, those extenders $\mathcal{E}_\gamma$ for which $\mathcal{P}(\kappa_\gamma) \cap L[\mathcal{E}] \not\subseteq L_\gamma[\mathcal{E}]$, are only partial extenders in $L[\mathcal{E}]$; however (as in the discussion of K^{DJ} at the end of Sect. 1.2) they serve as full extenders inside the mice by which these new subsets of κ_γ are constructed. In fact these mice turn out to be exactly the initial segments $L_\alpha[\mathcal{E}] = L_\alpha[\mathcal{E}\restriction\alpha]$ of the model $L[\mathcal{E}]$.

(3) This use of the partial extenders in mice requires the definition and use of a fine structure which is essentially identical to Jensen's fine structure for L. Fine structure is beyond the purview of this chapter, but one important consequence has already been mentioned in connection with K^{DJ}: whenever $\rho < \alpha$ and there is a set $x \in \mathcal{P}(\rho) \cap L_{\alpha+1}[\mathcal{E}] - L_\alpha[\mathcal{E}]$, then $L_{\alpha+1}[\mathcal{E}] \models |\alpha| \leq \rho$.

This discussion ignores one further difference: the model $L[\mathcal{E}]$ (like all recent fine structural arguments) is defined using Jensen's rudimentary hierarchy $J_\alpha[\mathcal{E}]$ instead of the hierarchy $L_\alpha[\mathcal{E}]$ used in this chapter. This change yields a substantial technical simplification, but makes no conceptual difference.

The main disadvantage of the newer approach is evident. The use of fine structure makes the newer models $L[\mathcal{E}]$ more complex than the models $L[\mathcal{U}]$, and furthermore, the extra complexity cannot be delayed, since the model $L[\mathcal{E}]$ cannot even be defined without it.[2] Thus one would want to have a good understanding of the simpler models described here, as well as of fine structure in the simpler setting of L, before studying the newer extender models.

We list below some of the advantages which justify the extra complexity. It should be noted that for larger cardinals there is no choice: the inner models require the newer style—which was in fact invented in order to make inner models for these cardinals possible. However it turns out that arguments using the newer $L[\mathcal{E}]$ style models are simpler, even though the older style $L[\mathcal{U}]$ could have been used instead. The discussion below indicates some of the reasons for this.

(1) A much stronger condensation property holds for the new fine structural models than for those discussed in this chapter. This point was briefly touched on during the discussion of the model $L[U]$ in Sect. 1.2.

(2) The coherence property is simpler and more robust in the fine structural models. We have already seen this as an advantage of using extenders instead of ultrafilters, and this sometimes gives reason to use extender models even when all extenders used turn out to be equivalent to ultrafilters. This advantage is strengthened in the fine structural models, in which all relevant functions have already been constructed before the extender is added.

(3) The use of partial extenders helps to simplify and strengthen the comparison process. Suppose that the two sequences $\mathcal{E}$ and $\mathcal{E}'$ being compared differ first at an ordinal γ, so that $\mathcal{E}\restriction\gamma = \mathcal{E}'\restriction\gamma$ but $\mathcal{E}_\gamma \neq \mathcal{E}'_\gamma$. Then $\mathcal{E}_\gamma$ measures only the sets in $L_\gamma[\mathcal{E}] = L_\gamma[\mathcal{E}\restriction\gamma] = L_\gamma[\mathcal{E}'\restriction\gamma] = L_\gamma[\mathcal{E}']$, which contains the sets measured by $\mathcal{E}'_\gamma$. Hence there is no need for the maneuver used in Definition 3.13, in which two extenders are deemed to differ for the purposes of defining the iterated ultrapower only if they differ on a set in the intersection $L[\mathcal{E}] \cap L[\mathcal{E}']$ of the two models: If $\mathcal{E}_\gamma$ and $\mathcal{E}_{\gamma'}$ differ at all, then they disagree on a member of their common domain $L_\gamma[\mathcal{E}] = L_\gamma[\mathcal{E}']$.

(4) The development of the core model is greatly simplified in fine structural models, because there is no need to treat mice and ultrafilters separately. Under the old approach, the core model was a structure of the form $K = L[\mathcal{U}, \mathcal{M}]$ where $\mathcal{U}$ is a coherent sequence of measures and $\mathcal{M}$ is the

[2] There do exist inner models for larger cardinals which do not use fine structure. These include the original Martin-Steel model [22] for a Woodin cardinal, the HOD models having Woodin cardinals which Woodin obtained from determinacy hypotheses, and Woodin's recent models for cardinals beyond a supercompact. However all of these models fall badly short of being the L-like models we are looking for: for example, it is still not known whether the Martin-Steel models satisfy GCH.

class of mice over $\mathcal{U}$. In fine structural models the core model K has the form $L[\mathcal{E}]$, and the mice used to construct the model are simply the initial segments $L_\gamma[\mathcal{E}]$ of $L[\mathcal{E}]$, with some of the partial measures of $\mathcal{E}$ being used as full measures in the mouse $L_\gamma[\mathcal{E}]$.

This point becomes more important for core models for larger cardinals. In order for the construction to work properly, the mice must reflect the properties of the full core model, and in particular they must be allowed to recursively contain smaller mice. This seems almost prohibitively complicated when working with a core model in the form $K = L[\mathcal{U}, \mathcal{M}]$, with the measures and the mice treated separately, but it falls out naturally in the fine structural model $K = L[\mathcal{E}]$ where a mouse $M = L_\gamma[\mathcal{E}]$ will contain as smaller mice all its initial segments $L_{\gamma'}[\mathcal{E}]$ for $\gamma' < \gamma$.

(5) The fine structural models come much closer to satisfying the analog of Theorem 1.9 than do the models described in this chapter. To see why this is so, consider an argument like that given for Lemma 3.22, where $\mathcal{E}\restriction\gamma$ has been defined and $E = \mathcal{E}_\gamma$ and F is a second extender which could have been chosen as $\mathcal{E}_\gamma$. In the fine structural model both of these extenders measure the same collection of sets, namely the members of the structure $L_\gamma[\mathcal{E}\restriction\gamma]$. Thus instead of using an iterated ultrapower of the structure $L[\mathcal{E}, F]$, in which both extenders are used in the construction, one can use the *bicephelus* $(L_\gamma, \mathcal{E}\restriction\gamma, E, F)$, in which both extenders are available as predicates but neither is used in the construction. The only extra hypothesis on E and F which is needed, beyond the requirement that each extender individually satisfies the conditions to be $\mathcal{E}_\gamma$, is that they are jointly iterable in the sense that all ultrapowers of this structure are well-founded.

One further point should be noted: the principal disadvantage of the fine structural approach, the need to introduce the extra complexity of fine structure at the very beginning, is not an issue in the development of the core model because the fine structure will be required in any case. Indeed incorporating fine structure into the initial definition of $L[\mathcal{E}]$ allows for a much more natural presentation and development of the core model and its fine structure.

4. Remarks on Larger Cardinals

In this section we briefly list some of the most important large cardinals above measurability, in increasing order of size. The primary focus is on the inner model theory available for these large cardinal properties; more information on some of these inner models can be found in later chapters in this Handbook.

All of the large cardinal properties described here are defined by elementary embeddings. Throughout this section, i is always an elementary embedding and M is a well-founded class.

Strong cardinals

Strong cardinals, together with their inner models, have already been introduced and an inner model has been described. It was also pointed out that such simple models, with comparison defined by linear iterations, are inadequate to handle very much larger cardinals. The line beyond which iteration trees are needed is not sharp. Baldwin [1] uses modified linear iterations to handle cardinals substantially larger than strong cardinals, and Schindler [35] has used nearly linear iterations to define a fine structural core model up to the sharp of a proper class of strong cardinals. In the other direction, a careful analysis shows that fine structural models actually use a simple form of iteration tree even down at the level of a 2-strong cardinal, that is, one with an extender E on κ such that $\mathcal{P}^2(\kappa) \subseteq \mathrm{Ult}(V, E)$.

Because of the need for iteration trees rather than linear iterations, it is much more difficult to obtain iterable models for larger cardinals in this range. Indeed, it is not known[3] whether a core model larger than those constructed by Schindler in [35] can be constructed without an added assumption of some large cardinal strength in the universe. Chapter [33] covers the core model and the covering lemma up to a Woodin cardinal.

Woodin cardinals

A cardinal δ is said to be *Woodin* if for all functions $f : \delta \to \delta$ there is an embedding $i : V \to M$ with critical point $\kappa < \delta$ such that $f``\kappa \subseteq \kappa$ and $V_{i(f)(\kappa)} \subseteq M$.

Woodin cardinals were defined by Woodin in 1984, following work of Foreman, Magidor and Shelah [8], and are the most important large cardinal property for current research in set theory. The most notable result concerning Woodin cardinals is probably the equiconsistency of the axiom of determinacy with the existence of infinitely many Woodin cardinals, due to Woodin, Martin and Steel, which is discussed in chapters [29] and [17].

This, and other consequences of Woodin cardinals, depend largely on two forcing notions which can be used to prove that inner models for Woodin and stronger cardinals must differ in important respects from those for smaller cardinals. The first of these forcing notions is *stationary tower forcing*, which was defined by Woodin using ideas from Foreman, Magidor and Shelah [9, 8]. In one form, this forcing will preserve a Woodin cardinal δ, while making massive changes to the cardinal structure below δ: for example, there is a stationary subset of singular cardinals below δ whose successors are collapsed by the forcing. Hence there cannot be a core model satisfying the weak covering property for (exactly) a Woodin cardinal, although there is one for the sharp of a Woodin cardinal. In addition, stationary tower forcing

[3] It is now known, by a recent unpublished result of Jensen and Steel, that if there is no model with a Woodin cardinal then the core model K can be constructed with no extra large cardinal hypothesis.

can collapse ω_1, and in the process will add new countable mice. This forcing is discussed in the book [20].

The second forcing notion, invented by Woodin, is the remarkable "all sets are generic" forcing: If M is a model with a Woodin cardinal δ, and M is iterable in V, then there is a forcing notion $P \in M$ of size δ such that for any set x in V there is a tree iteration of M, with final model N and embedding $i: M \to N$, such that $N[x]$ is a generic extension of N by the forcing $i(P)$. This forcing can be used to show that the minimal model M for a Woodin cardinal cannot satisfy the sentence asserting that M is iterable, even when M is iterable in the universe V. The implications of this for the core model are discussed further at the end of this chapter.

At present it is not known how to construct core models for cardinals in this range without some large cardinal properties holding in the universe. Jensen has shown that a subtle cardinal, a property weak enough to hold in L, is enough to show prove that the core model exists and satisfies the covering lemma; however it is an open question whether this assumption is needed. Other than this gap, the core model theory through ω many Woodin cardinals is well understood [39]. The strongest current result on existence of iterable inner models is due to Neeman, who has constructed [30] iterable extender models with a Woodin limit of Woodin cardinals. These models, however, are not fine structural, and no core model results are known in this region.

Superstrong Cardinals

A cardinal κ is *superstrong* if there is an embedding $i: V \to M$ with critical point κ such that $V_{i(\kappa)} \subseteq M$.

As was pointed out previously, a superstrong cardinal is at the outer limits of our understanding of inner models. Much of the basic inner model theory is understood up to a superstrong cardinal: for example it is known [34] that $\square_\kappa$ holds in any extender model up through a superstrong cardinal. Indeed they show that $\square_\kappa$ holds in an extender model $L[\mathcal{E}]$ for any cardinal κ short of what Jensen has labeled a *subcompact cardinal.* Jensen has shown that $\square_\kappa$ cannot hold if κ is subcompact. However it is not known, under any large cardinal assumption, that there are any iterable extender models with anything near a superstrong cardinal.

Supercompact Cardinals

A cardinal κ is λ-*supercompact* if there is an embedding $i: V \to M$ with critical point κ such that ${}^{\lambda}M \subseteq M$, and κ is *supercompact* if κ is λ-supercompact for all cardinals λ.

None of the models described in this chapter give any promise of yielding models with a supercompact cardinal. However Woodin has recently proposed a form of model, using what he calls *suitable extender sequences* which can include supercompact cardinals and even the larger cardinals discussed in the next paragraph, and which he hopes to show have many of the properties enjoyed by the extender models $L[\mathcal{E}]$ which have been discussed in this chapter.

Like these models, Woodin's models have the form $L[\mathcal{E}]$, the class of sets constructible from a sequence of extenders. An important difference is that not all of the extenders witnessing large cardinal properties are members of the sequence $\mathcal{E}$; in fact all of the critical points of extenders on the sequence are below the first supercompact cardinal. It is still not known whether these models have an analog of the comparison process of Lemma 2.8, and no proofs are known for their iterability.

Larger Cardinals

A number of cardinals larger than supercompact have been defined. Some of these have important consequences, notably huge cardinals and variants of these. A cardinal κ is *huge* if there is an elementary embedding $i : V \to M$ with critical point κ such that ${}^{i(\kappa)}M \subseteq M$.

Catalogs of large cardinal properties, such as this one, traditionally end with a nontrivial elementary embedding from V into V, which Kunen proved in [19] to be inconsistent. It is still open whether such an embedding is consistent with ZF without the axiom of choice.

5. What is the Core Model?

This section is not intended to be a description of existing core models, but rather an examination of the term "core model" itself. We will try to determine the meaning of the phrase "the core model", and in particular explain the difference between it and the term "extender model". The structure, construction and properties of known core models is described elsewhere in this chapter and in chapters [24, 33, 38] and [36]. In addition the reader may want to look at [27], which discusses from a relatively non-technical point of view the use of iteration trees and the construction of the Steel core model up to a Woodin cardinal.

Our first approach will be to look at the history of the term "core model", which was introduced by Dodd and Jensen [5, 6] for the model which is variously referred to as the Dodd-Jensen core model, K^{DJ}, or the core model below a measurable cardinal. The history, however, begins earlier—at least as far back as Jensen's discovery of the covering lemma for L, since the Dodd-Jensen core model generalizes this result. The model $L[U]$ also predated K^{DJ}, and although $L[U]$ is not contained in the structure K^{DJ} which Dodd and Jensen referred to as the core model, they proved [7] the covering lemma for $L[U]$ and hence brought this model into the modern pantheon of core models. Their work was extended by Mitchell to include sequences of measures. The core model to this point is described in chapter [24]. The use of extenders as a generalization of normal ultrafilters, and of iteration trees as a generalization of iterated ultrapowers, led to the Steel core model, which is described in chapters [33, 38]. This model is currently at the frontier of the subject.

Of the two terms under consideration, only "extender model" has a precise meaning: an extender model is a model of the form $L[\mathcal{E}]$ where $\mathcal{E}$ is a good sequence of extenders as defined in chapter [38]. Every known core model is an extender model, but this should not be assumed to be true for larger cardinals; indeed it seems unwise to be dogmatic about the properties of as yet unknown core models until we have a better idea of what is possible.

Even keeping this caveat in mind, "the core model" is always singular: there is at most one core model in any given model of set theory, and in particular there is at most one true core model in the true universe of sets.

Some authors have used the term "core model" to mean the same as "extender model". While it is true that every known core model is an extender model, and that generally, or arguably always, an extender model is its own core model, the distinction between the terms is important and should be preserved. The term *extender model* describes the interior structure of the model, while the term *core model* refers to the relation between the model and the class of all sets.

Some illumination on this point can be gained by looking at cases in which we find it useful, in apparent contradiction to the dictum in the last paragraph, to speak of "*a* core model". It is often useful to refer to a model as "a core model" if it is the core model as defined inside some model which is of particular interest, but is not necessarily the universe of all sets. In a related usage, the term "core model" is often used for a model obtained by a particular construction which is known to yield the core model under additional assumptions such as the nonexistence of some large cardinal property. The Dodd-Jensen core model K^{DJ} is an example of both usages: It is characterized by its mode of construction, which is an initial segment of the core model construction in every model for which such a construction is known. It is also characterized by the fact that it (or at least $K^{\mathrm{DJ}} \cap M$) is *the* core model inside *any* model M, so long as M does not have an inner model with a measurable cardinal. Core models for larger cardinals are less clear cut, since the core model for a model M varies with the particular extenders which are members of M, even though the large cardinal strength of the model is held fixed. There is a unique core model, however, for the sharps of such large cardinal properties.

The second approach to understanding the term "core model" is through consideration of the properties of the known core models. These properties fall into two classes. The properties in the first class are those which hold in any extender model: These models are built up from below, in a manner analogous to the construction of L, and as a consequence they satisfy some sort of condensation. They satisfy combinatorial principles such as $\Diamond_\kappa$ and (for cardinals small enough that we currently have a core model) $\Box_\kappa$. They satisfy the generalized continuum hypothesis, they satisfy the global axiom of choice and their well-ordering, both of their reals, and of their full universe, has a logical form which is as simple as possible in any model with the same large cardinal properties.

The other class of properties of the core models are those which might be seen as asserting that the model is close to V. The most important of these is the covering lemma, or at the least some form of the weak covering lemma. A second is rigidity: there is no nontrivial elementary embedding $i : K \to K$. A third is absoluteness: the core model is absolute for a class of sentences which falls just short of including the sentence asserting that there is a set not in that core model.

It is unclear to what extent we should assume that these properties will necessarily hold for larger core models. Even down at the level of a Woodin cardinal, without the sharp of a Woodin cardinal, there is no inner model which satisfies both weak covering and invariance under forcing; and properties which seem close to rigidity fail well below a Woodin cardinal.

A final property bridges these two classes: The core models are uniquely defined by a formula which is absolute under set generic extensions. This formula says on the one hand that the model is built up from below as an extender model $L[\mathcal{E}]$, and on the other that the construction is greedy, including everything appropriate into the sequence $\mathcal{E}$. If we take the first class of properties as evidence of minimality then we could take something like the following as the definition of the core model:

5.1 Definition. The *core model* is the minimal class inner model of ZF which contains all of the large cardinal structure which exists in the universe.

We could modify the statement by requiring ZFC rather than ZF, but it seems better to regard the axiom of choice as a consequence (so far, at least) of minimality.

Although it is labeled a “definition”, Definition 5.1 is not intended to be a precise mathematical definition. Neither “minimal” nor “large cardinal structure” have a precise meaning. The phrase “minimal class inner model of ZF” is, perhaps, reasonably clear. We can take “minimal” to mean $\subseteq$-minimal, which works for all known core models—provided a suitable meaning for the term “large cardinal structure” is understood.

The meaning of this term is somewhat more problematic. One important point is that “large cardinal structure” is not the same as “large cardinal properties”. The model $L[U]$ is not $\subseteq$-minimal among all models having a measurable cardinal; for example $\mathrm{Ult}(L[U], U)$ is a proper subclass of $L[U]$. However $L[U]$ is the minimal model containing the filter $U \cap L[U]$, and it seems quite clear that the ultrafilter U should be included as part of the large cardinal structure. There are more doubtful cases in which Definition 5.1 may be at least potentially circular: once a particular model K has been anointed as “the core model” there will be a tendency to take the “large cardinal structure” of the universe to be just that structure which is contained in K.

As a case study to illustrate how the line might be drawn, we consider the situation when there is a Woodin cardinal δ, but no sharp for a model with a Woodin cardinal. There is an obvious candidate for the core model in this case, namely the extender model $L[\mathcal{E}]$ given by Steel's core model construction described in chapter [33]. It might be objected that this model is not really obtained by Steel's construction of the core model, but rather as a limiting case of that construction: Steel's construction gives a sequence of models $K_\theta = L_\theta[\mathcal{E}_\theta]$ for measurable cardinals $\theta < \delta$. Each of the models K_θ is unequivocally the core model in V_θ, and the extender sequences $\mathcal{E}_\theta$ of the models K_θ agree so as to yield a combined sequence $\mathcal{E} = \bigcup_\theta \mathcal{E}_\theta$ such that δ is Woodin in $L[\mathcal{E}]$. This objection is a reason for caution, but is irrelevant to the application of Definition 5.1, which deliberately avoids specifying a particular means of construction. A second objection to the model $L[\mathcal{E}]$ is that it is not iterable: Woodin's "all sets are generic" forcing demonstrates that there is an iteration tree of height δ which can be defined in $L[\mathcal{E}]$, but which has no well-founded branch in $L[\mathcal{E}]$. Again this is a reason for caution but is not necessarily fatal: the iterability of the model might well be considered as large cardinal structure, but it is large cardinal structure which does not exist in the universe and thus cannot be expected to exist in the core model. In fact, for example, the existence of a model $L[\mathcal{E}]$ with a Woodin cardinal such that every iteration tree in $L[\mathcal{E}]$ has a well-founded branch in V implies the existence of a class of indiscernibles for $L[E]$.

A more significant question is raised by Woodin's stationary tower forcing, which massively violates the weak covering lemma. The cardinal δ is still Woodin in the generic extension, but it is possible to arrange (and is possibly impossible to avoid) that every sufficiently large successor cardinal below δ is collapsed. This probably should not bother us: we can consider this to be analogous to Prikry forcing at a measurable cardinal, which shows that if there is a measurable cardinal then no core model will satisfy the covering lemma in all generic extensions. It is true that the situation at a measurable cardinal is well understood while that at a Woodin cardinal is quite hazy, but the analogy seems reasonable.

It has been argued that it is not really necessary to give up the weak covering lemma because there is a second candidate for the core model. If we assume that the ground model is $L[\mathcal{E}]$, then an $L[\mathcal{E}]$-generic set G for the stationary tower forcing is essentially an extender which gives an elementary embedding $i^G : L[\mathcal{E}] \to L[i^G(\mathcal{E})]$ with the property that $V_\delta \cap L[\mathcal{E}][G] \subseteq L[i^G(\mathcal{E})]$. In particular, $L[i^G(\mathcal{E})]$ does satisfy the covering lemma in the generic extension $L[\mathcal{E}][G]$, and furthermore, $L[i^G(\mathcal{E})]$ is the model obtained as described above using Steel's construction inside $L[\mathcal{E}][G]$. We could take $L[i^G(\mathcal{E})]$ as the core model, provided that we are willing to give up invariance under forcing. In favor of $L[\mathcal{E}]$, we could assert that $i : L[\mathcal{E}] \to L[i^G(\mathcal{E})]$ should be regarded as analogous to $\mathrm{Ult}(L[U], U) = L[i^U(U)]$, and note that $L[i^U(U)]$ is certainly not the core model. This view is supported by Woodin's [41] extensive and fruitful theory of iterated ultrapowers using generic embeddings such as i^G, but it is weakened by the fact that it throws no light on the failure of the weak covering lemma.

The model $L[\mathcal{E}]$ is certainly the core model according to Definition 5.1, at least inside the ground model $L[\mathcal{E}]$ itself. The question is whether the mice in $L[i^G(\mathcal{E})] - L[\mathcal{E}]$ should be included as part of the large cardinal structure of $L[\mathcal{E}][G]$. For an answer to this question we consider another analogy with $L[U]$: Jensen has proved (see Theorem 3.43 in chapter [24]) that if H is a $L[U]$ generic Levy collapse, then in $L[U][H]$ there is an embedding $i : K^{\mathrm{DJ}} \to K^{\mathrm{DJ}}$ such that $\mathrm{crit}(i)$ is smaller than $\mathrm{crit}(U)$. The embedding is constructed from a model $N = L_\alpha[U^N]$ in $L[U][H] - L[U]$ which is iterable and satisfies ZF^-. In fact N is a mouse; however it is not a mouse in the sense of K^{DJ} because there is no subset of $\mathrm{crit}(U^N)$ in $L_{\alpha+1}[U^N] - L_\alpha[U^N]$. Now U^N is not an ultrafilter in $L[U^N]$, so let $\alpha' > \alpha$ be the least ordinal such that there is a subset of $\mathrm{crit}(U^N)$ in $L_{\alpha'+1}[U^N] - L_{\alpha'}[U^N]$. If $N' = L_{\alpha'}[U^N]$ were iterable then it would be a member of K^{DJ}, and that is not true because U^N measures all sets in K^{DJ} while there is a set in $L_{\alpha'+1}[U^N]$ which U^N does not measure. Thus N' is not iterable; in fact the set in $L_{\alpha'+1}[U^N]$ which is not measured by U^N can be constructed from a sequence of functions in N' which witnesses that $\mathrm{Ult}(N', U^N)$ is not well-founded.

The extra information given by the ordinal $\alpha' > \alpha$ shows that $L_\alpha[U^N]$ is, in an extended sense, not really iterable. Similarly, the information given by the extender sequence $\mathcal{E}$ shows that the supposed mice M which are in $L[i^G(\mathcal{E})]$ but not in $L[\mathcal{E}]$ are not really iterable: if we attempt to compare M with $L[\mathcal{E}]$ then the tree on M has height δ and has no well-founded cofinal branch, as any such branch could be used to construct the sharp for a Woodin cardinal. Thus it seems appropriate to conclude that M is not part of the large cardinal structure of $L[\mathcal{E}][G]$, and hence that $L[\mathcal{E}]$ is the core model in $L[\mathcal{E}][G]$.

Why then does Steel's construction seem to go wrong here? As was suggested earlier, it is not the construction which is in error: If θ is a measurable cardinal below δ then every mouse in the model $K_\theta = L_\theta[i^G(\mathcal{E})\restriction\theta]$ is iterable in $V_\theta^{L[\mathcal{E}][G]}$, and hence K_θ really is the core model in the universe $V_\theta^{L[\mathcal{E}][G]}$. The only error is in assuming that the limit of these local core models will be a core model in $V^{L[\mathcal{E}][G]}$: it is not, because its "mice" are not iterable there.

1. The Statement

Ronald Jensen's discovery of the covering lemma arose out of work on the singular cardinals problem. Paul Cohen published his proof of the independence of the continuum hypothesis [4, 5] in 1963, and one year later William Easton's thesis [13, 14] completely settled the question of the size of the continuum for regular cardinals. The continuum problem for singular cardinals remained open, and the *Singular Cardinal Hypothesis* (SCH), stating (in its simplest form) that $2^\lambda = \lambda^+$ for every singular strong limit cardinal, became one of the most important problems in set theory. It was ten years before Jack Silver made the first significant advance on the problem: In a sharp contrast to Easton's result, which stated that the only constraints on the size of the continuum for regular cardinals are the obvious ones, Silver [56] proved that SCH cannot fail at a singular cardinal of uncountable cofinality unless it already fails at all but a nonstationary set of smaller cardinals. Silver's proof, which depends heavily on the use of the filter of closed unbounded subsets of λ, fails badly at cardinals of cofinality ω and attention turned immediately to understanding this case. A year later, in 1974, Jensen distributed a series of handwritten notes titled *Marginalia to a Theorem of Silver*.[1] These notes, later revised by Keith Devlin and Jensen and published [7] under the same title, stated and proved the basic covering lemma for L:

1.1 Theorem (Covering Lemma for L). *If $0^\#$ does not exist then for any set x of ordinals there is a set $y \in L$ such that $y \supseteq x$ and $|y| = |x| + \aleph_1$.*

It is an immediate corollary that $\neg 0^\#$ implies SCH: Theorem 1.1 implies that any function $f : \mathrm{cf}(\lambda) \to \lambda$ is determined by a covering set $y \supseteq \mathrm{ran}(f)$ in L of size at most $\max\{\aleph_1, \mathrm{cf}(\lambda)\}$, together with a function from $\mathrm{cf}(\lambda)$ into y. Thus $\lambda^{\mathrm{cf}(\lambda)} \leq (\lambda^{\mathrm{cf}(\lambda)})^L \, \tau^{\mathrm{cf}(\lambda)} = \lambda^+ 2^{\mathrm{cf}(\lambda)} = \max\{\lambda^+, 2^{\mathrm{cf}(\lambda)}\}$, where $\tau = \max\{\aleph_1, \mathrm{cf}(\lambda)\}$. This implies the more general form of SCH, $\lambda^{\mathrm{cf}(\lambda)} = \lambda^+ \, 2^{\mathrm{cf}(\lambda)}$ for every singular cardinal λ, and this in turn implies $2^\lambda = \lambda^+$ if λ is a singular strong limit cardinal.

The most obvious direction in which to extend the covering lemma is by weakening the assumption $\neg 0^\#$ to allow larger cardinals in the universe. The first step in this direction was due to Anthony Dodd and Jensen, who constructed a core model K^{DJ} under the assumption that there is no inner model with a measurable cardinal [9, 10, 8]. The Dodd-Jensen core model is, in many ways, similar to L: it satisfies GCH along with most of the combinatorial properties of L, and it satisfies an analogous covering lemma:

1.2 Theorem (Covering Lemma for K^{DJ}). *Assume that there is no inner model with a measurable cardinal, and let K^{DJ} be the Dodd-Jensen core model. Then for any set x of ordinals there is a set $y \in K^{\mathrm{DJ}}$ such that $y \supseteq x$ and $|y| = |x| + \aleph_1$.*

---

[1] It is worth pointing out that about 20 years later, during the 1990's, this same problem led to another of the major advances in set theory, Saharon Shelah's pcf theory ([53], see chapter [1]).

The statement cannot be extended directly to larger cardinals, as Prikry forcing [46] gives a counterexample. However, Dodd and Jensen generalize Theorem 1.2 to show that Prikry forcing is the only possible counterexample [11]:

1.3 Theorem (Covering Lemma for $L[U]$). *Assume that $0^\dagger$ does not exist but that there is an inner model with a measurable cardinal, and that the model $L[U]$ is chosen so that $\kappa = \mathrm{crit}(U)$ is as small as possible. Then one of the following two statements holds:*

1. *For every set x of ordinals there is a set $y \in L[U]$ with $y \supseteq x$ and $|y| = |x| + \aleph_1$.*
2. *There is a sequence $C \subseteq \kappa$, which is Prikry generic over $L[U]$, such that for all sets x of ordinals there is a set $y \in L[U, C]$ such that $y \supseteq x$ and $|y| = |x| + \aleph_1$.*

Furthermore, the sequence C of clause 2 is unique up to finite initial segments.

Theorem 1.3 can easily be generalized to models with no inaccessible limit of measurable cardinals, but two problems have to be overcome to extend it to larger cardinals: (i) it is necessary to construct a core model which can consistently contain larger cardinals and for which the basic argument of the proof of the covering lemma can be made to work, and (ii) it is necessary to find a useful statement of the covering lemma for this core model which can be proved from the basic argument. The construction and basic properties of the core model are given in chapters [47] and [57], or in [29]. In addition the current chapter includes, in Sect. 4, an outline of the theory of the core model for sequences of measures and for non-overlapping extenders.

A statement of the full covering lemma for these models will be deferred to Sect. 4 of this chapter, but Theorem 1.8 below states a simplified version which generalizes the result of Dodd and Jensen by showing that a singular cardinal which is regular in K is made singular by a set which approximates a Prikry-Magidor generic set (see [32, Sect. 2.2]). This statement requires some preliminary definitions.

Say that a cardinal κ is *μ-measurable* if there is an embedding $i : V \to M$ such that the measure $\{x \subseteq \kappa : \kappa \in i(x)\}$ associated with i is a member of M. This is the weakest large cardinal property which requires the existence of something more than normal ultrafilters.

For the rest of this subsection we assume that there is no inner model with a μ-measurable cardinal, and we assume that K is the core model. If κ is a cardinal of K and $\beta < o(\kappa)$ then use $\mathcal{U}(\kappa, \beta)$ to denote the measure of order β on κ in K. First we define what appears to be a rather weak notion of indiscernibility:

1.4 Definition. Assume that κ is a singular cardinal which is regular in K. A closed unbounded subset C of κ is a *weak Prikry-Magidor set* for K if (i) $|C| < \kappa$, and (ii) if x is any closed unbounded subset of κ with $x \in K$ then $C - x$ is bounded in κ.

Any Prikry-Magidor generic subset of κ is a weak Prikry-Magidor set.

1.5 Theorem. *If there is no model with a μ-measurable cardinal then any weak Prikry-Magidor set $C \subseteq \kappa$ for K has the following two properties:*

1. *C is eventually contained in any set $a \in K$ such that $a \in \mathcal{U}(\kappa, \beta)$ for all $\beta < o(\kappa)$.*
2. *$C \cap \lambda$ is a weak Prikry-Magidor set over K for every sufficiently large limit point λ of C.*

1.6 Definition. A function σ is an *assignment function in K* for C if

1. There is an $h \in K$ such that $\sigma(\nu) = h(\nu)$ for all sufficiently large $\nu \in C$.
2. C is a set of indiscernibles for $\mathcal{U}(\kappa, \sigma(\nu))$ in the sense that for any sequence $\langle a_\xi : \xi < \kappa \rangle \in K \cap {}^\kappa\mathcal{P}(\kappa)$ of subsets of κ, and for all sufficiently large $\nu \in C$, we have $\forall \xi < \nu \, (\nu \in a_\xi \iff a_\xi \in \mathcal{U}(\kappa, \sigma(\nu)))$.

If $o(\kappa) < \kappa$, as in Prikry-Magidor forcing, then we can always take σ to be the function $\sigma(\nu) = o(\nu)$. If $o(\kappa) \geq \kappa^+$ then Radin forcing (cf. chapter [15]) can be used to add a set C which satisfies the definition of a weak Prikry-Magidor set except that κ remains regular, and hence $|C| = \kappa$. Clearly such a set does not have an assignment function, since any assignment function would be bounded in κ^+. Thus the following theorem would be false if the requirement that $|C| < \kappa$ were dropped from Definition 1.4.

1.7 Theorem. *Any weak Prikry-Magidor set $C \subseteq \kappa$ for K has an assignment function in K. Furthermore*

1. *The assignment function σ is unique except for initial segments.*
2. *The assignment function is weakly increasing in the sense that $\sigma(\nu) \geq \limsup\{\sigma(\xi) + 1 : \xi \in C \cap \nu\}$ for every sufficiently large limit point ν of C.*

Any weak Prikry-Magidor set C which satisfies the stronger version of clause 2 obtained by changing the inequality to an equality, and in particular has $\sigma(\xi) = 0$ for each successor member ξ of C, is a Prikry-Magidor generic set.

We cannot hope to actually cover subsets of κ using indiscernibles for only a single cardinal κ, but the following theorem, which is our promised version of the covering lemma, generalizes Dodd and Jensen's Theorem 1.3 to say that any small subset of κ can be approximated by a weak Prikry-Magidor set:

1.8 Theorem. *If a singular cardinal κ is regular in K then for any set $x \subseteq \kappa$ with $|x| < \kappa$ there is a weak Prikry-Magidor set $C \subseteq \kappa$ for K and a function $g : \kappa \to \kappa$ in K such that $x - \bigcup_{\nu \in C} (g(\nu) - \nu)$ is bounded in κ.*

The Weak Covering Lemma

No satisfactory statement of the full covering lemma is known for cardinals much larger than a single strong cardinal: the indiscernibles are too complicated to use to approximate arbitrary sets in the manner of Theorem 1.3 or Theorem 1.8. What remains is known as the weak covering lemma, which is proved by using the same basic proof as that used below a strong cardinal, but applying it only to subsets of the interval $(\lambda, (\lambda^+)^K)$, in which there cannot be any indiscernibles.

1.9 Definition. A class model M of set theory satisfies the *weak covering property* if $(\lambda^+)^M = \lambda^+$ for every singular cardinal λ of V.

The weak covering lemma, stating that K has the weak covering property, is among the most important consequences of the covering lemma. If K contains more than a few measurable cardinals then the weak covering property is needed to prove the basic properties of the core model, including the full covering lemma; indeed the weak covering property may be taken as part of the definition of what it means to be a "core model". The best results known to date are as follows:[2]

1.10 Theorem.

1. *If the sharp for a model with a class of strong cardinals does not exist, then there is a core model K of the form $L[\mathcal{E}]$ which satisfies the weak covering property (see [50]).*

2. *If there are no inner models with a Woodin cardinal and there is a subtle cardinal θ, then the Steel core model $K_\theta = L_\theta[\mathcal{E}]$ below θ exists, and satisfies the weak covering property for $\lambda < \theta$ (see chapter [47]).*

The proof of clause 1 will be sketched in Sect. 4. The proof of clause 2 is given in [45].

It is not clear what, if anything, can be done in the actual vicinity of a Woodin cardinal. Mitchell [42] reports some unsatisfactory results from

[2] It is now known, by recent unpublished work of Jensen and Steel, that if there is no model with a Woodin cardinal then there is a core model K as in clause 1. This new result supersedes clauses 1 and 2.

The proof uses a new technique which was discovered by Jensen and is described in the recent paper [27], which deals with a model K^c of the form $L[\mathcal{E}]$ under the assumption that there is no model with a cardinal κ which is simultaneously a limit of Woodin cardinals and of cardinals strong to κ. Although this paper does not actually show that the weak covering lemma holds in K^c, it does show that a weak covering property holds in the structures which Jensen calls "stacks". This is sufficient to show that many core model arguments can be extended to such large cardinals. Indeed the technique works up to a superstrong cardinal; however, it is not known that the model K^c exists for such cardinals.

applying the standard proof at a Woodin cardinal, but the following result of Woodin may suggest a more useful direction. The theorem only applies below $2^{\aleph}$ (assuming AC in V) but that is the region where the large cardinals implied by AD exist. This result also goes beyond the large cardinal limit of $\neg$AD imposed by Theorem 1.10.

1.11 Theorem (Woodin [64]). *Suppose that the nonstationary ideal on ω_1 is $\aleph_2$-saturated, and suppose that M is a transitive inner model of* ZF + DC + AD *containing all reals and ordinals such that every set of reals in M is, in V, weakly homogeneously Souslin. Let X be a bounded subset of Θ^M such that $|X| = \aleph_1$. Then there exists a $Y \supseteq X$ in M such that $|Y|^M = \aleph_1$.*

Here Θ^M is the supremum of the ordinals δ in M such that there is a map in M from the reals onto δ.

The Strong Covering Lemma

This concludes, until Sect. 4, the discussion of cardinals larger than a measurable cardinal. We now return to the models L and $L[U]$ in order to look at another direction in which the original covering lemma has been extended. The *strong covering lemmas* use Jensen's proof but show that more can be extracted from it. Theorem 1.12, which is our version of the strong covering lemma for the Dodd-Jensen core model, is essentially taken from unpublished notes of Timothy Carlson, who proved it for L by using a variant, influenced by ideas of Silver, of Jensen's proof. The idea, as well as the name, comes from work of Shelah (see [53, Theorem VII.0.1] and [54]) who obtains the strong covering property in a more general setting by assuming the ordinary covering property together with some extra combinatorial structure. We will describe his main application in the next section.

1.12 Theorem (Strong Covering Lemma). *Assume that there is no inner model with a measurable cardinal. Then there is a class $\mathbf{C} \subseteq K^{\mathrm{DJ}}$, definable in K^{DJ}, such that the following statements hold:*

1. *If x is any uncountable set of ordinals then there is a set $X \in \mathbf{C}$ such that $x \subseteq X$ and $|x| = |X|$.*

2. *The class $\mathbf{C}$ is closed in V under increasing unions of uncountable cofinality; that is, if $\langle X_\nu : \nu < \eta \rangle$ is an increasing sequence of members of $\mathbf{C}$ and $\mathrm{cf}(\eta) > \omega$ then $\bigcup_{\nu<\eta} X_\nu \in \mathbf{C}$.*

Notice that clause 2 holds for all sequences $\langle X_\nu : \nu < \eta \rangle$, not only for those which are members of K.

The statement of Theorem 1.12 remains valid if $L[U]$ exists but $0^\dagger$ does not, provided that K is replaced by the appropriate model $L[U]$ or $L[U, C]$ from Theorem 1.3. The following statement, however, is stronger and is easier to generalize to larger core models (see Sect. 4).

1.13 Theorem. *Assume that $0^\dagger$ does not exist, and that the measure U and Prikry sequence C are as in Theorem 1.3(2). Then there is a class $\mathbf{C} \subseteq L[U, C]$ which satisfies clauses 1 and 2 of Theorem 1.12, and in addition*

3. *For each set $X \in \mathbf{C}$ there is an ordinal $\rho < \max\{\aleph_2, |X|^+\}$ and a function $h \in L[U]$ such that $X = \mathcal{H}^h(\rho \cup C)$, the smallest set containing $\rho \cup C$ and closed under h.*

4. *The class $\mathbf{C}$ is definable in $L[U]$ in the sense that there is a formula φ such that a set X is in $\mathbf{C}$ if and only if there is a set $A \in U$, a function $h \in L[U]$ and an ordinal ρ such that $L[U] \models \varphi(A, h, \rho)$ and $X = \mathcal{H}^h(\rho \cup (C \cap A))$.*

Clause 4 follows from the definability of forcing: the formula $\varphi(A, h, \rho)$ asserts that $(\varnothing, A) \Vdash \mathcal{H}^h(\check{\rho} \cup \dot{C}) \in \dot{\mathbf{C}}$, where the forcing is Prikry forcing for the measure U, $\dot{C}$ is a name for the resulting Prikry sequence, and $\dot{\mathbf{C}}$ is a name, derived from the proof of the covering lemma, for the class $\mathbf{C}$.

The following proposition gives a very useful property of the function h. It is also true for L, for the Dodd-Jensen core model, and for the core model for sequences of measures.

1.14 Proposition. *Let h be as in Theorem 1.13 for $X \in \mathbf{C}$. Then h can be written as $h = \bigcup_{\nu<\alpha} h_\alpha$ for some functions $h_\nu \in X$ such that $h_\nu \subseteq h_{\nu'}$ whenever $\nu < \nu' < \alpha$.*

The Covering Lemma without Second-Order Closure

The strong covering lemma can be viewed as asserting that if $0^\#$ does not exist then every sufficiently closed set is a member of L. The precise statement of the requirement that X be sufficiently closed has both first-order and second-order components. Magidor's covering lemma [31] for L weakens the conclusion of the covering lemma in order to eliminate the second-order components:

1.15 Theorem (Magidor [31]). *If $0^\#$ does not exist and x is a set of ordinals which is closed under the primitive recursive set functions, then there are sets $y_n \in L$ for $n < \omega$ such that $x = \bigcup_{n<\omega} y_n$.*

Magidor also extends Theorem 1.15 to the Dodd-Jensen core model by requiring closure under a larger set of functions in K^{DJ} and assuming that there is no inner model with an ω_1-Erdős cardinal. He points out that this assumption is necessary, since if there is an ω_1-Erdős cardinal in K then there is a generic extension M of K such that for any countable set $\mathcal{F}$ of functions in K there is a set $X \in M$ which is closed under the functions in $\mathcal{F}$, but is not a countable union of sets in K.

The following theorem was proved independently of Theorem 1.15, but the same idea lies behind both theorems.

1.16 Theorem (Mitchell [33, 41], Jensen [12]). *If there is no model with a Woodin cardinal then every regular Jónsson cardinal is Ramsey in the core model K. Furthermore, if κ is δ-Jónsson for some uncountable ordinal $\delta < \kappa$ then κ is δ-Erdős in K.*

A cardinal κ is said to be *δ-Jónsson* if any structure with universe κ and countably many predicates has an elementary substructure with order type δ; and κ is said to be *δ-Erdős* [3] if for any such structure and any closed unbounded subset C of κ there is a normal set of indiscernibles of order type δ contained in C.

A similar proof shows that Chang's conjecture implies that ω_2 is ω_1-Erdős in K, and together with a result of Silver (1967, unpublished) proves the equiconsistency of the two notions.

This concludes our discussion of the various statements of the covering lemma. In Sect. 2 we will briefly describe some of the basic applications of the core model, and in Sect. 3 we will outline the basic proof of the covering lemma and its variants under the hypothesis that $0^\dagger$ does not exist. The final section looks at larger cardinals, giving the statement and an outline of the proof of the covering lemma for sequences of ultrafilters or extenders. The basic proof is taken almost unchanged from Sect. 3, but the analysis of the resulting system of indiscernibles is much more difficult.

2. Basic Applications

We pointed out earlier that the source of the covering lemma, as well as its first application, is the Singular Cardinal Hypothesis:

2.1 Theorem (Jensen [7]). *If $0^\#$ does not exist, $\lambda^{\mathrm{cf}(\lambda)} = \max\{\lambda^+, 2^{\mathrm{cf}(\lambda)}\}$ for every singular cardinal λ and hence $2^\lambda = \lambda^+$ for every singular strong limit cardinal λ.*

Jensen's proof can be generalized to larger cardinals, but the full strength of the failure of SCH was not discovered until Moti Gitik combined the covering lemma with Shelah's pcf theory:

2.2 Theorem (Gitik [17, 20]). *The failure of the Singular Cardinal Hypothesis is equiconsistent with $\exists\kappa(o(\kappa) = \kappa^{++})$.*

In Sect. 4.3 we present Gitik's proof that the failure of the singular cardinal hypothesis implies that there is an inner model satisfying $\exists\kappa(o(\kappa) = \kappa^{++})$. Gitik's proof that this is sufficient is given in [16]; in this Handbook [15] he describes a later method of forcing which is simpler and more general, but which gives slightly weaker results in this case.

The following theorem is Shelah's main application of the Strong Covering Lemma 1.12. The sufficiency of slightly stronger large cardinal assumptions is proved in [55].

2.3 Theorem. *If M is a model containing K such that $M \models \mathrm{GCH}$, and r is a real such that $M[r] \models \neg\mathrm{CH}$, then there is an inner model with an inaccessible cardinal. If, in addition, the cardinals of $M[r]$ are the same as those of M then there is an inner model with a measurable cardinal.*

The Weak Covering Lemma

By far the most important consequence of the covering lemma is the weak covering property, Definition 1.9. Indeed it is arguably more accurate to turn the statement around: the covering lemma is an application, and not necessarily the most important application, of the weak covering lemma. Below a strong cardinal the proof of the weak covering lemma is a special case of the proof of the full covering lemma, so that the importance of the weak covering lemma is not immediately apparent. Beyond a strong cardinal, in Steel's core model, we do not know how to even begin the proof of the covering lemma without first proving, by an entirely different method using a weak large cardinal hypothesis, a slightly weaker version of the weak covering lemma.

Among the most important properties of the core model K (stated under the assumption that $0^\P$ does not exist) which follow from the weak covering lemma are the following:

- The construction of K from the countably complete core model K^{c}.
- If $i : K \to M$ is an elementary embedding, where M is well-founded, then i is an iterated ultrapower of K.
- If U is a normal K-ultrafilter on κ and $\mathrm{Ult}(K,U)$ is well-founded then $U \in K$. If $\mathrm{crit}(U) > \omega_2$ then the hypothesis that $\mathrm{Ult}(K,U)$ is well-founded can be omitted.

Many results which are usually regarded as consequences of the covering lemma in fact use only these basic properties of the core model. Among such results are the lower bounds in the following theorem:

2.4 Theorem.

1. *The failure of* GCH *at a measurable cardinal κ is equiconsistent with $\exists\kappa(o(\kappa) = \kappa^{++})$.*
2. *If κ is weakly compact and $o^K(\kappa) < \kappa^{++}$ then $(\kappa^+)^K = \kappa^+$.*
3. *If κ is Jónsson, there is no model with a Woodin cardinal, and the Steel core model exists (in particular, if there is no model with a strong cardinal), then $(\kappa^+)^K = \kappa^+$; furthermore $(\lambda^+)^K = \lambda^+$ for stationarily many $\lambda < \kappa$ [62].*
4. *The consistency of a Woodin cardinal implies that of the existence of a saturated ideal on ω_1. If the Steel core model exists then the existence*

of such an ideal implies in turn that there is a Woodin cardinal in an inner model [58].

Sketch of Proof. We prove, as an example, the lower bound for clause 1. The upper bound is proved in Gitik [16]. Suppose that U is a measure on κ and $2^\kappa \geq \kappa^{++}$, but that $o(\kappa) < \kappa^{++}$ in K. Let $i^U : V \to M = \mathrm{Ult}(V, U)$, and consider $i = i^U \restriction K : K \to K^M$. Then i is an iterated ultrapower of K, so let $i = i_{0,\theta}$ where $i_{\nu,\nu'} : N_\nu \to N_{\nu'}$. If $\nu < \theta$ is a limit ordinal then there are $\xi_\nu < \nu$ and $U_\nu \in N_{\xi_\nu}$ such that $N_{\nu+1} = \mathrm{Ult}(N_\nu, i_{\xi_\nu,\nu}(U_\nu))$. Since $o(\kappa) < \kappa^{++} \leq \theta$, there is a stationary class $S \subseteq \kappa^{++}$ of ordinals of cofinality ω such that $\xi_\nu = \bar{\xi}$ and $U_\nu = \bar{U}$ are constant for $\nu \in S$. Now fix $\nu \in S \cap \lim(S)$. If $\vec{\kappa} = \langle \nu_n : n < \omega \rangle$ is a cofinal sequence in $S \cap \nu$ and $\kappa_n = \mathrm{crit}(i_{\nu_n,\nu})$, then the sequence $\vec{\kappa}$ generates the measure $i_{\bar{\xi},\nu}(\bar{U})$. Since ${}^\omega M \subseteq M$, the sequence $\vec{\kappa}$ and hence the measure $i_{\bar{\xi},\nu}(\bar{U})$ is a member of M. It follows that $i_{\bar{\xi},\nu}(\bar{U}) \in K^M$; but this is impossible since $i_{\bar{\xi},\nu}(\bar{U})$ is not in $N_{\nu+1}$ and hence not in $N_\theta = K^M$. This contradiction completes the proof that $o(\kappa) \not< \kappa^{++}$ in K. ⊣

The naïve proof of clause 2 uses the fact that κ is inaccessible; however, Ralf Schindler [49] has adapted it to successor cardinals, showing that if κ has the tree property and $2^\kappa > \kappa^+$ then κ is strong in K.

The main reason for the importance of the weak covering property is that it can be used to adapt to K techniques which Kunen (see [28, §21]) originally used in proving that $0^\#$ follows from the existence of a nontrivial elementary embedding from L into L. As applied to L these techniques make use of the fact that any proper class $\Gamma \prec L$ is isomorphic to L. The corresponding fact for K is that any class $\Gamma \prec K$ is isomorphic to K, provided that the class

$$\{\lambda : \mathrm{ot}(\Gamma \cap (\lambda^+)^K) = (\lambda^+)^K\} \tag{18.1}$$

is stationary. Cardinal calculations show that the classes Γ used in Kunen's arguments satisfy that

$$\{\lambda : 2^{<\lambda} = \lambda \wedge \mathrm{cf}(\lambda) < \lambda \wedge |\Gamma \cap \lambda^+| = \lambda^+\} \tag{18.2}$$

is stationary. The weak covering lemma implies that the class (18.2) is contained in the class (18.1) and hence implies that $\Gamma \cong K$.

The Full Covering Lemma

The Singular Cardinal Hypothesis has already been mentioned as a result which requires the full covering lemma. We now look at other such results.

2.5 Theorem (Dodd-Jensen [11], Mitchell [37]). *Let κ be a singular cardinal of cofinality λ which is regular in K. Then κ is measurable in K, and if $\lambda > \omega$ then $o(\kappa) \geq \lambda$ in K.*

The proof, using Theorems 1.7 and 1.8, is easy, and a more careful analysis yields a classification of singular cardinals [38]:

2.6 Theorem (Mitchell [38]). *Assume that* $\neg\exists\kappa\,(o(\kappa) = \kappa^{++})$. *Let* κ *be a singular cardinal which is regular in* K. *Then there is a cofinal set* $C \subseteq \kappa$ *of ordertype* $\mathrm{cf}(\kappa)$ *such that*

1. *If* $\mathrm{cf}(\kappa) > \omega$ *then* C *is a weak Prikry-Magidor set (Definition 1.4).*
2. *If* $\mathrm{cf}(\kappa) = \omega$ *then let* $\beta \leq o(\kappa)$ *be the least ordinal such that* $o(\nu) < \beta$ *for all but boundedly many* $\nu \in C$. *Then*
   - *(a) If* β *is a successor ordinal then* C *is Prikry generic over* K.
   - *(b) If* $\mathrm{cf}^K(\beta) < \kappa$ *then* $\mathrm{cf}(\beta) = \omega$, *and* C *is a weak Prikry-Magidor sequence.*
   - *(c) If* $\mathrm{cf}^K(\beta) = \kappa$, *witnessed by* $\tau : \kappa \to \beta$, *then there is a weak Prikry-Magidor sequence* D *with assignment function* σ *such that the increasing enumeration* $\langle c_n : n < \omega\rangle$ *of* C *is definable recursively from* D *by letting* c_{n+1} *be the least member* c *of* D *such that* $\sigma(c) \geq \tau(c_n)$.
   - *(d) If* $\mathrm{cf}^K(\beta) = \kappa^+$ *then* C *is a sequence of accumulation points for* κ *(the definition of an accumulation point is given in Definition 4.18).*

Further, the set C *can be chosen to be maximal in a sense which makes it definable up to initial segment, except in case (2d) where any two such sequences eventually alternate.*

A measure U on κ is a *weak repeat point* if for every set $A \in U$ there is a $U' \lhd U$ with $A \in U'$. Results similar to the following theorem have been proved by Gitik [19, 22] for the nonstationary ideal.

2.7 Theorem (Mitchell [34]). *If the closed, unbounded filter on* ω_1 *is an ultrafilter, then there is a weak repeat point in* K.

2.8 Theorem (Sureson [60], Mitchell [36]). *The following four statements are equiconsistent, where* $\delta < \kappa$ *is a regular cardinal.*

1. *There is a* κ*-complete ultrafilter* U *on* κ *extending the closed, unbounded filter such that* $\{\alpha : \mathrm{cf}(\alpha) = \delta\} \in U$.
2. *There is a* κ*-complete ultrafilter* U *on* κ *with* δ *skies; that is, there is an increasing sequence* $\langle\alpha_\nu : \nu < \delta\rangle$ *of ordinals between* κ *and* $i^U(\kappa)$ *with the property that* $i^U(f)(\alpha_\nu) < \alpha_{\nu'}$ *for all* $\nu < \nu' < \delta$ *and all* $f : \kappa \to \kappa$.
3. *There is a* κ^+*-saturated normal filter* F *with* $\{\alpha : \mathrm{cf}(\alpha) = \delta\} \in F$.
4. $o(\kappa) = \delta + 1$ *if* $\delta > \omega$, *and* $o(\kappa) = 2$ *if* $\delta = \omega$.

The covering lemma is used to prove that each of clauses 1–3 imply that clause 4 holds in K. The forcing used in [36] to prove the other direction has been simplified and extensively generalized by Gitik; in particular it is used to give the upper bounds for the consistency strength of the failure of SCH.

The $\mathbf{\Sigma}^1_3$-absoluteness theorem, Theorem 2.9 below, was originally proved by Jensen assuming $\neg 0^\dagger$; Magidor (unpublished, see [59, §4]) has given a simpler proof but one which gives slightly less information. Clause 1 was proved under the assumption that $\neg\exists\kappa\,(o(\kappa)=\kappa^{++})$ by Mitchell [39] using Jensen's method. Steel and Welch [59] later proved clause 1 using Magidor's method, and Steel, using results of Hjorth, extended it [58, Theorem 7.9] to prove clause 2.

We say that a model M is $\mathbf{\Sigma}^1_3$-*correct* if for any Σ^1_3 formula φ and any real $r\in M$ we have $M\models\varphi(r)$ if and only if $V\models\varphi(r)$.

2.9 Theorem ($\mathbf{\Sigma}^1_3$-absoluteness).

1. *Suppose that there is no inner model of $\exists\kappa\,(o(\kappa)=\kappa^{++})$ and that $r^\#$ exists for every real r. Then any model M of* ZFC *such that $M\supseteq K$ is $\mathbf{\Sigma}^1_3$-correct.*

2. *Assume that there are two measurable cardinals and no inner model with a Woodin cardinal. Then any model M of* ZFC *such that $M\supseteq K$ is $\mathbf{\Sigma}^1_3$-correct.*

The conclusion can be equivalently stated as "$\mathbf{\Sigma}^1_3$ formulas are absolute for models containing K".

3. The Proof

This section outlines the proof of the Jensen and Dodd-Jensen covering lemmas up through a single measurable cardinal. Section 4 will continue, using the same basic ideas, to describe the covering lemmas for larger cardinals.

Section 3.1 briefly describes the basic tools, including fine structure, needed for the proof. Section 3.2 gives the proof of Jensen's covering lemma for L, Theorem 1.1 (including the proof of the strong variant, Theorem 1.12). Section 3.3 extends this proof to the Dodd-Jensen covering lemma, Theorems 1.2 and 1.3. Finally Sect. 3.4 looks at the two major variants on the covering lemma: Magidor's Theorem 1.15 and Theorem 1.16, stating that Jónsson cardinals are Ramsey in K.

The proofs given in this section are not complete, but enough details are given so that a reader with some understanding of fine structure should be able to fill in the rest. Complete proofs may be found in the original sources, [7–11, 26, 31], or in later references such as Devlin [6].

3.1. Fine Structure and Other Tools

This section has two incompatible aims: the first is to be accessible to a reader without a sophisticated knowledge of fine structure, and the second is to present a proof which is sufficiently complete that a reader with a understanding of fine structure can fill in the details.

One very interesting approach to this dilemma was invented by Silver (see [28, 31]), who gave a proof of the Jensen covering lemma which essentially eliminates any need for fine structure. He has extended this method to yield the Dodd-Jensen covering lemma, and it has been further extended and publicized by Magidor. In unpublished work, Magidor and Silver have used this approach at least up a model with a cardinal α such that $o(\alpha)$ is measurable. It is not known whether this approach works up to $o(\alpha) = \alpha^{++}$, and it seems unlikely that it will work for the newer models containing cardinals up to a Woodin cardinal. This rules out its use here, since this section is intended to serve as an introduction to covering lemmas for larger models.

The approach we have used is very close than that presented by Schindler and Zeman earlier in this Handbook [52]. We have attempted to make this section accessible without such an introduction: The hope is that this presentation will be sufficiently generic that a knowledgeable reader will be readily able to translate it to his preferred version, while at the same time it is sufficiently specific (without being too detailed) that it is understandable to a naïve reader. However, any reader wanting a full understanding of the subject is encouraged to read [52] before or after this section.

Our presentation of fine structure, like Jensen's original papers, is based directly on master code structures. We follow current practice in using Jensen's J_α hierarchy, rather than the L_α hierarchy. This newer hierarchy yields substantial advantages, some of which will be pointed out in the text, for a complete exposition of the fine structure; however, the differences are not apparent at this level of detail and the naïve reader will lose little, if anything, by simply reading J_α as L_α.

One unfortunate exception to this equivalence comes from the fact that members $M = J_\alpha$ of the J_α hierarchy are conventionally indexed by $\alpha = \mathrm{On}(M)$, which is always a limit ordinal. Thus the γth member of this hierarchy is $J_{\omega\cdot\gamma}$, which is nearly the same as L_γ. In particular $J_{\omega\cdot\gamma+n}$ does not exist for $0 < n < \omega$: the successor of a member $J_{\omega\cdot\gamma}$ of the hierarchy is $J_{\omega\cdot\gamma+\omega}$.

At some points in the arguments, primarily those involving the Downward Extension Lemma, it did not seem possible to give the full proof without being more specific about the fine structure; in these cases we restrict ourselves to giving the proof in the simplest case, which is Σ_1 definability over J_α for a limit ordinal α. This case may seem very special, but in fact it essentially contains the general case. See [52] for a more complete discussion of fine structure.

As stated earlier, we take the basic models of our fine structure to be the sets J_α. We will call these models *mice* in anticipation of larger core models.

Two concepts are basic to the fine structure of a mouse $M = J_\alpha$: the Σ_n projectum ρ^M_n and the Σ_n-Skolem function h^M_n. A third concept which is central to the proof of the covering lemma is the Σ_n-ultrafilter $\mathrm{Ult}_n(M, \pi, \kappa)$ of M, obtained by using the embedding π as an extender. A fourth concept, the use of substructures of mice, is used in the definition of fine structure and is central to the proof of $\square_\kappa$ and other combinatorial applications of fine structure; however, it is more peripheral to the proof of the covering lemma, where it is only needed for the non-countably closed case.

We discuss these four concepts further before beginning the actual proof. We begin with the definition of the fine structure of J_α in the special case when $n = 1$ and α is a limit ordinal.

3.1 Definition. Assume that α is a limit ordinal, and that $M = (J_\alpha, A)$ is *amenable*, that is, $A \cap x \in J_\alpha$ for all $x \in J_\alpha$.

1. The Σ_1 *projectum* ρ^M_1 of an amenable structure $M = (J_\alpha, A)$ is the least ordinal ρ such that there is a Σ_1 subset x of ρ which is not a member of J_α, but is Σ_1-definable in M using a finite set $p \subseteq \alpha$ as a parameter.

2. The Σ_1 *standard parameter* p^M_1 of M is the least finite sequence $p \in [\alpha]^{<\omega}$ of ordinals such that there is some set $x \subseteq \rho^M_1$ so that $x \notin J_\alpha$, but x is Σ_1-definable in M from parameters in $\rho^M_1 \cup p$.

   The ordering of the parameters is lexicographical on descending sequences of ordinals; that is, $p < p'$ if $\max(p \triangle p') \in p'$.

3. The Σ_1 *standard master code* is the set A^M_1 of pairs $(\ulcorner\varphi\urcorner, \xi)$ such that $\xi < \rho^M_1$ and $\ulcorner\varphi\urcorner$ is the Gödel number of a Σ_1 formula φ over M, with parameter p^M_1, such that $M \models \varphi(\xi)$.

4. The Σ_1-*Skolem function* h^M_1 of M is defined as follows: fix an enumeration $\langle \exists z \varphi_n : n < \omega \rangle$ of the Σ_1 formulas of set theory. Then $h^M_1(\langle n, x \rangle)$ is defined if and only if there are z and y such that $M \models \varphi_n(x, y, z, p^M_1)$. In this case $h^M_1(\langle n, x \rangle) = y$ where (α', z, y) is the lexicographically least triple such that $(J_{\alpha'}, A \cap \alpha') \models \varphi_n(x, y, z, p^M_1)$.

5. The Σ_1-*code* $\mathfrak{C}_1(M)$ of M is the structure $(J_{\rho^M_1}, A^M_1)$.

It should be noticed that the Σ_1-Skolem function is itself Σ_1-definable over M. The Σ_1-Skolem function is a function of one variable; however, we will frequently abuse the notation by writing it as a function with a variable number of arguments. Thus $h^M_1(x_1, x_2, x_3)$ should be understood to mean $h^M_1(\ulcorner x_1, x_2, x_3 \urcorner)$ where $\ulcorner \ldots \urcorner$ is an appropriate coding of finite sequences. In addition, we will abuse notation by writing h_1"x to mean h_1"$^{<\omega}x$, the closure of x under the Skolem function h_1.

We will rarely be using the function h_1^M as a Skolem function for any particular formula φ_n, and so will not normally mention the parameter n explicitly, regarding it instead as being coded into the stated parameters.

If α is a successor ordinal, $\alpha = \gamma + 1$, then the definitions are the same, except that the hierarchy $\langle J_{\alpha'} : \alpha' < \alpha \rangle$ used for the definition of h_1^M is replaced by a hierarchy, with length ω, of the sets in $J_{\omega\cdot\gamma+\omega} - J_{\omega\cdot\gamma}$. The hierarchy depends on the specific fine structure being used. Jensen originally used the Levy hierarchy on L_γ, the kth level of which contains the subsets of L_γ which are Σ_k-definable in (L_γ, A). Later he invented the rudimentary functions and the hierarchy of sets $J_{\omega\cdot\alpha}$ in order to avoid technical complications caused by the use of the Levy hierarchy. See chapter [52] for a detailed presentation of the rudimentary functions and their use in setting up the fine structure.

One major advantage of the J_α hierarchy over the L_α hierarchy is that $[J_\alpha]^{<\omega} \subseteq J_\alpha$ even for successor ordinals α. Thus a finite set of ordinals $\alpha_0, \ldots, \alpha_{k-1}$ can be freely treated as a single parameter, the finite sequence $\langle \alpha_0, \ldots, \alpha_{k-1} \rangle$. In the case of the L_α hierarchy some awkward and painful coding is necessary to achieve the same result.

We will not say more about the successor case, except to mention that arguments involving fine structure generally treat the case of successor α as simpler special cases of the arguments for limit ordinals α. This characterization of the case of successor α as "simpler" assumes, of course, an understanding of the detailed definition of the fine structure.

We now turn to consider the fine structure for $n > 1$. The central theme of fine structure is that it is never necessary to deal directly with Σ_{n+1} definability for any n greater than zero; instead a Σ_{n+1} formula is reduced to an equivalent Σ_1 formula over the Σ_n-code of J_α. The definition of the Σ_n-code $\mathfrak{C}_n(J_\alpha)$ is itself a good example of this theme.

3.2 Definition. We define the Σ_n-codes of J_α by recursion on $n < \omega$. We set $\mathfrak{C}_0(J_\alpha) = (J_\alpha, \varnothing)$, and for $n \geq 0$

$$\rho_{n+1}^{J_\alpha} = \rho_1^{\mathfrak{C}_n(J_\alpha)} \qquad p_{n+1}^{J_\alpha} = p_1^{\mathfrak{C}_n(J_\alpha)} \qquad h_{n+1}^{J_\alpha} = h_1^{\mathfrak{C}_n(J_\alpha)}$$
$$A_{n+1}^{J_\alpha} = A_1^{\mathfrak{C}_n(J_\alpha)} \qquad \mathfrak{C}_{n+1}(J_\alpha) = \mathfrak{C}_1(\mathfrak{C}_n(J_\alpha))$$

Finally, the projectum of J_α is defined to be $\mathrm{proj}(J_\alpha) = \rho^{J_\alpha} = \inf_n \rho_n^{J_\alpha}$. Since the sequence of projecti $\langle \rho_n^{J_\alpha} : n < \omega \rangle$ is nonincreasing, $\rho_n^{J_\alpha} = \mathrm{proj}(J_\alpha)$ for all sufficiently large $n < \omega$.

Note that if $n > 1$ then the Σ_n-Skolem function h_n^M need not be Σ_n-definable over M. Jensen's Σ_n-uniformization theorem states that this construction can be used to define a Skolem function for Σ_n formulas over J_α which is Σ_n-definable in J_α (though not uniformly so). This Σ_n-uniformization theorem was an important part of the motivation for Jensen's invention of fine structure, but it has turned out to have little direct importance because it is simpler and more useful to work directly with the fine structure.

We now consider the problem of recovering the original structure $M = (J_\alpha, A)$ from its code $M_1 = \mathfrak{C}_1(M) = (J_{\rho_1^M}, A_1^M)$. In order to do so, recall that the Skolem function h_1^M is Σ_1-definable in M from the parameter p_1^M, and that $A_1^M = \{\ulcorner \varphi_n(a, p_1^M) \urcorner : n < \omega \;\; \& \;\; a \in (\rho^{M_1})^{<\omega}\}$, the set of Gödel numbers of the Σ_1 theory of M with parameters from $\rho_1^M \cup p_1^M$. Now define X to be the set of equivalence classes $[\xi]_\sim$, where $\xi \in \rho_1^M \cap \mathrm{dom}(h_1^M)$ and $\xi \sim \xi'$ if and only if $\ulcorner h_1^M(\xi) = h_1^M(\xi') \urcorner \in A_1^M$. The membership relation E on X is defined by $[\xi] \mathrel{\mathrm{E}} [\xi']$ if and only if $\ulcorner h_1^M(\xi) \in h_\xi^M(\xi') \urcorner \in A_1^M$; and the subset $\bar{A} \subseteq X$ is defined by setting $[\xi] \in \bar{A}$ if and only if $\ulcorner h_1^M(\xi) \in A \urcorner \in A_1^M$.

It is straightforward to verify that we can define a Σ_1-elementary embedding $i : (X, \mathrm{E}, \bar{A}) \to (J_\alpha, \in, A)$ by setting $i([\xi]) = h_1^M(\xi)$. This embedding i is an isomorphism if and only if $M = h_1^M$“ρ_1^M, in which case we can say that this construction *recovers M from its Σ_1-code* $\mathfrak{C}_1(M)$.

3.3 Definition. The structure $M = (J_\alpha, A)$ is said to be *1-sound* if $J_\alpha = h_1^M$“ρ_1^M. Further, M is said to be *n-sound* if it is $(n-1)$-sound and $\mathfrak{C}_{n-1}(M)$ is 1-sound; and M is said to be *sound* if M is n-sound for all n.

We will say that the model J_α is *n-sound* or *sound*, respectively, if the structure $(J_\alpha, \varnothing)$ is n-sound or sound.

Notice that if M is sound then one can repeat the process described above n times in order to recover M from any of its codes $\mathfrak{C}_n(M)$. Thus the following lemma is the basic fact of fine structure:

3.4 Lemma. *If α is any ordinal then the structure J_α is sound.*

We will only consider the case when α is a limit ordinal, and begin with the proof that J_α is 1-sound.

Sketch of Proof. Let $Z = h_1^M$“$\rho_1^M \prec_1 J_\alpha$, and let i be the collapse map $i : \bar{M} \cong Z \prec_1 J_\alpha$. Since $\bar{M} \models$ “$V = L$”, we must have $\bar{M} = J_{\bar{\alpha}}$ for some $\bar{\alpha} \leq \alpha$. Since i is Σ_1-elementary and $\rho_1^M \cup p_1^M \subseteq Z$, the set $A_1^{J_\alpha}$ is Σ_1-definable in $J_{\bar{\alpha}}$. Since $A_1^{J_\alpha} \notin J_\alpha$ it follows that $\bar{\alpha} = \alpha$.

Similarly, p_1^M is the least parameter which can be used to define A_1^M in J_α, and $i^{-1}(p_1^M) \leq p_1^M$, so $p_1^M = i(p_1^M)$. But every member of $\mathrm{dom}(i)$ is Σ_1-definable in $J_{\bar{\alpha}}$ from parameters in $\rho_1^M \cup p_1^M$, and it follows that i is the identity. Thus h_1^M“$\rho_1^M = Z = \mathrm{ran}(i) = J_\alpha$. This completes the proof that J_α is 1-sound. $\dashv$

It should be noted that this proof is closely related to the proof that GCH holds in L. Both rely on the following condensation lemma:

3.5 Lemma. *If $Z \prec_0 J_\alpha$ then there is an $\bar{\alpha} \leq \alpha$ such that $Z \cong J_{\bar{\alpha}}$.*

The proof here is somewhat more delicate than that of GCH, as the sentence “$V = L$” needs to be carefully formulated so that it is satisfied by J_α

even for successor α. The hypothesis of Lemma 3.5, stating that Z is Σ_0-elementary, is meant be interpreted in the terms of the J_α hierarchy as meaning that Z is closed under rudimentary functions. This is slightly stronger than the assertion that it is Σ_0-elementary in the sense of the Levy hierarchy. This observation is another example of the superiority of the J_α hierarchy: when using the L_α hierarchy, the hypothesis must be strengthened to require that Z be Σ_1-elementary.

In order to prove Lemma 3.4 for arbitrary n we need an extension of Lemma 3.5 in which the model J_α is replaced by the Σ_{n-1}-code $\mathfrak{C}_{n-1}(J_\alpha)$. This generalization is given by the *downward extension* or *condensation* property, stated in the following lemma, and is central to many applications of fine structure.

3.6 Lemma (Downward Extension Lemma). *Suppose that* $i : (J_{\rho'}, A') \prec_0 \mathfrak{C}_n(J_\alpha)$. *Then there is an* $\alpha' \leq \alpha$ *such that* $(J_{\rho'}, A') = \mathfrak{C}_n(J_{\alpha'})$, *and* i *extends to a* Σ_n*-embedding* $\tilde{\imath} : J_{\alpha'} \to J_\alpha$. *Furthermore* $\tilde{\imath}$ *preserves the first* n *stages of the fine structure, so that* $\tilde{\imath}\, h_k^{J_{\alpha'}} = h_k^{J_\alpha}\, \tilde{\imath}$ *for all* $k \leq n$.

Sketch of Proof. Lemmas 3.4 and 3.6 are proved by a joint induction on n. First we assume that Lemma 3.6 is true for $\mathfrak{C}_n(J_\alpha)$, and use this to prove that J_α is $(n+1)$-sound. The proof is essentially identical to the proof given above that J_α is 1-sound. The collapse map $i : J_{\bar{\alpha}} \cong Z \prec_0 J_\alpha$ becomes $i : (J_{\bar{\rho}}, \bar{A}) \cong Z \prec_0 (J_{\rho_n^M}, A_n^M) = \mathfrak{C}_n(J_\alpha)$. Since Lemma 3.6 holds for $\mathfrak{C}_n(J_\alpha)$ this can be written as $i : \mathfrak{C}_n(J_{\alpha'}) \to \mathfrak{C}_n(J_\alpha)$ for some $\alpha' \leq \alpha$. Since $A_{n+1}^{J_\alpha}$ is Σ_1-definable in $\mathfrak{C}_n(J_{\alpha'})$ we must have $\alpha' = \alpha$, and since $i^{-1}(p_{n+1}^{J_\alpha}) \leq p_{n+1}^{J_\alpha}$, which is the least parameter which can be used to define $A_{n+1}^{J_\alpha}$, we must have $i(p_{n+1}) = p_{n+1}$. Hence i is the identity on $\mathfrak{C}_n(J_\alpha)$, so J_α is $(n+1)$-sound.

To complete the proof, we show that if J_α is $(n+1)$-sound, and Lemma 3.6 holds for $\mathfrak{C}_n(J_\alpha)$, then Lemma 3.6 also holds for $\mathfrak{C}_{n+1}(J_\alpha)$. Suppose that $i : (J_{\rho'}, A') \prec_0 \mathfrak{C}_{n+1}(J_\alpha)$.

Apply to the structure $(J_{\rho'}, A')$ the construction described before Definition 3.3 to recover a structure (J_α, A) from its Σ_1-code $\mathfrak{C}_1(J_\alpha, A)$. The assumption that i is Σ_0-elementary implies that the construction succeeds to the extent of defining a model $(X, \mathrm{E}, \bar{A})$ and an embedding $i' : (X, \mathrm{E}, \bar{A}) \to \mathfrak{C}_n(J_\alpha)$. The existence of the embedding i' ensures that (X, E) is well-founded, and therefore $X \cong J_{\rho''}$ for some ordinal ρ''. If A'' is the image of $\bar{A}$ under this isomorphism, then i' induces an embedding $\tilde{\imath}_n : (J_{\rho''}, A'') \to \mathfrak{C}_n(J_\alpha)$.

By the construction, the set A' encodes the Σ_1 theory of $(J_{\rho''}, A'')$, and since i is Σ_0-elementary and A encodes the Σ_1 theory of $\mathfrak{C}_n(J_\alpha)$ it follows that $\tilde{\imath}_n$ is a Σ_1-elementary embedding. By the induction hypothesis it follows that there is an ordinal α' such that $(J_{\rho''}, A'') = \mathfrak{C}_n(J_{\alpha'})$, and an embedding $\tilde{\imath}_0 : J_{\alpha'} \to J_\alpha$ which extends $\tilde{\imath}_n$ and which preserves the first n stages of the fine structure, as far as $\mathfrak{C}_n(J_{\alpha'})$.

Now it only remains to verify that $(J_{\rho'}, A') = \mathfrak{C}_1(J_{\rho''}, A'')$, which entails verifying that $\rho_1^{(J_{\rho''},A'')} = \rho'$ and $p_1^{(J_{\rho''},A'')} = \tilde{\imath}_n^{-1}(p_1^{\mathfrak{C}_n(J_\alpha)})$. The inequality $\rho_1^{(J_{\alpha''},A'')} \leq \rho'$ follows from the fact that $A' \notin J_{\rho''}$, which is proved by the argument of the Russell paradox: If $A' \in J_{\rho''}$ then so is $y = \{\nu : \ulcorner \nu \notin h(\nu)\urcorner \in A'\}$, where $h : \rho' \to J_{\rho''}$ is the Skolem function coded by A'. But this is impossible, as then $y = h(\nu)$ for some ν and then $\nu \in y \iff \nu \notin y$.

The inequality $\rho' \leq \rho_1^{(J_{\alpha''},A'')}$ follows from the fact that $A' \cap \xi \in J_{\rho'}$ for $\xi < \rho'$, which follows from the assumption that $(J_{\rho'}, A') \prec_0 \mathfrak{C}_{n+1}(J_\alpha)$. Thus $\rho' = \rho_1^{(j_{\alpha''},A'')}$, and this implies the inequality $p_1^{(J_{\rho''},A'')} \leq \tilde{\imath}_n^{-1}(p_1^{\mathfrak{C}_n(J_\alpha)})$ since $p_1^{(J''_\rho,A'')}$ is, by definition, the least parameter which can be used to define A''.

The final inequality $p_1^{(J_{\rho''},A'')} \geq \tilde{\imath}_n^{-1}(p_1^{\mathfrak{C}_n(J_\alpha)})$ is the point in the proof of Lemma 3.6 which requires the joint induction with Lemma 3.4: assume for the sake of contradiction that $p_{n+1}^{J_{\bar\alpha}} < \tilde{\imath}_n^{-1}(p_{n+1})^{J_\alpha}$ and apply Lemma 3.4 to $J_{\bar\alpha}$. This implies that $\tilde{\imath}_n^{-1}(p_{n+1}^{J_\alpha})$ is Σ_1-definable in $(J_{\alpha'}, A')$ from $p_{n+1}^{J_{\bar\alpha}}$. It follows that $p_{n+1}^{J_\alpha}$ is Σ_1-definable in $\mathfrak{C}_n(J_\alpha)$ from $\tilde{\imath}_{n+1}(p_{n+1}^{J_{\bar\alpha}}) < p_{n+1}^{J_\alpha}$, but this contradicts the definition of $p_{n+1}^{J_\alpha}$.

This completes the proof of Lemma 3.6, except for the claim that $\tilde{\imath}$ is Σ_{n+1}-elementary. To see this, notice that the embedding i'' constructed in the induction step is one quantifier stronger than i'. The map $\tilde{\imath}$ is obtained by repeating this process $n+1$ times, and hence the original Σ_0 embedding is strengthened to a Σ_{n+1}-elementary embedding $\tilde{\imath} : J_{\alpha'} \to J_\alpha$. $\dashv$

It should be noted that the statement that the embedding $\tilde{\imath}$ preserves the fine structure is stronger—and usually more useful—than the statement that $\tilde{\imath}$ is Σ_n-elementary.

If we define $\bar{h}_n^{J_\alpha} = h_1^{J_\alpha} \ldots h_n^{J_\alpha}$, then $\bar{h}^{J_\alpha} : \rho_n^{J_\alpha} \to J_\alpha$ and an induction using Lemma 3.4 shows that $J_\alpha = \bar{h}_n^{J_\alpha} ``\rho_n^{J_\alpha}$. In order to avoid considering detailed fine structure as much as possible, we make the following convention:

Notation. Unless stated otherwise, we abuse notation by using $h_n^{J_\alpha}$ to denote the function $\bar{h}_n^{J_\alpha}$ described above, and we call it the Σ_n-Skolem function of J_α.

We end the discussion of Lemma 3.6 with Lemma 3.7, which is frequently useful in applications of the covering lemma and in particular proves, used along with the proof of the covering lemma itself, Proposition 1.14 from the introduction.

3.7 Lemma. *The Σ_n-Skolem function $h_n^{J_\alpha}$ of J_α can be written as an increasing union $h_n^{J_\alpha} = \bigcup_{\nu<\eta} g_\nu$ of functions $g_\nu \in J_\alpha$, with $\eta \leq \rho_n^{J_\alpha}$.*

Sketch of Proof. First consider the case when $n = 1$ and α is a limit ordinal. Pick a sequence of ordinals α_ν cofinal in α, and define g_ν to be the function defined in J_{α_ν} by the same Σ_1 formula (with the same parameter $p_1^{J_\alpha}$) as was used to define $h_1^{J_\alpha}$ in J_α. Thus $g_\nu(x) = y$ if and only if $h_1^{J_\alpha}(x) = y$, both x and y are in J_{α_ν}, and in addition the witness to the Σ_1 fact "$h_1^{J_\alpha}(x) = y$" is a member of J_{α_ν}.

For $n > 1$, apply the construction above to $\mathfrak{C}_{n-1}(J_\alpha)$, noting that $\rho_n^{J_\alpha}$ is always a limit ordinal for $n > 0$. ⊣

The importance of Lemma 3.6 to fine structure theory extends far beyond the arguments above; however, its importance in the proof of the covering lemma is secondary to the that of the upward extension property, Lemma 3.10, described below.

Embeddings of Mice

In this subsection we define a generalized ultrapower which is central to the proof of the covering lemma. This ultrapower, which is used to extend a given embedding $\pi : J_{\bar\kappa} \to J_\kappa$ to an embedding $\tilde\pi : J_{\bar\alpha} \to J_{\alpha'}$ with a larger domain, can be described in modern terms as the ultrapower by the extender $E_{\pi,\beta}$ of length β which is associated with the embedding π. It should be noted, however, that this construction of Jensen is older than, and in fact is ancestral to, the modern notion of an extender. Extenders are more completely described in chapter [32].

We first explain the extender construction by defining the Σ_0-ultrapower $\mathrm{Ult}(M, \pi, \beta)$ of a model M.

3.8 Definition. Assume that M and N are transitive models of a fragment of set theory, and that $\pi : N \to N'$ is a Σ_0-elementary embedding such that $\mathcal{P}(\nu) \cap M \subseteq N$ for all $\nu < \mathrm{On}(N)$ such that $\sup(\pi``\nu) < \beta$. Then

$$\begin{aligned}\mathrm{Ult}(M, \pi, \beta) = \{[a, f]_\pi : f \in M \text{ and } \mathrm{dom}(f) \in \mathrm{dom}(\pi) \\ \text{and } a \in [\beta]^{<\omega} \cap \pi(\mathrm{dom}(f))\}\end{aligned} \tag{18.3}$$

where $[a, f]_\pi$ is the equivalence class of the pair (a, f) under the relation

$$(a, f) \sim_\pi (a', f') \iff (a, a') \in \pi(\{(\vec\nu, \vec\nu') : f(\vec\nu) = f'(\vec\nu')\}). \tag{18.4}$$

The membership relation E_π and any other predicates of $\mathrm{Ult}(M, \pi, \beta)$ are defined similarly, and the embedding $i : M \to \mathrm{Ult}(M, \pi, \beta)$ is defined as usual by $i(x) = [a, C_x]_\pi$ where a is arbitrary and C_x is the constant function, $\forall z\, C_x(z) = x$.

The embedding $i : M \to \mathrm{Ult}(M, \pi, \beta)$ satisfies Łos's theorem for Σ_0 formulas:

3.9 Proposition. *If φ is a Σ_0 formula, then for any $f_0, \dots, f_n$ in M and $a_0, \dots, a_n$ in β we have $\mathrm{Ult}(M, \pi, \beta) \models \varphi([f_0, a_0], \dots, [f_n, a_n])$ if and only if $\langle a_0, \dots, a_n\rangle \in \pi(\{\langle u_0, \dots, u_n\rangle : M \models \varphi(f_0(u_0), \dots, f_n(u_n))\})$.*

If $M = J_\alpha$ for some ordinal α then $\mathrm{ran}(i)$ is cofinal in $\mathrm{Ult}(M, \pi, \beta)$, and it follows that i is Σ_1-elementary. In particular, i preserves the Σ_1-Skolem function of J_α.

We will need to define Σ_n ultrapowers, for arbitrary $n \in \omega$, so that they preserve Σ_{n+1}-Skolem functions. The obvious way to define such an ultrapower is to modify Definition 3.8 by replacing the condition "$f \in M$" of (18.3) with "f is Σ_n-definable in J_α"; however, doing so would require first proving Jensen's uniformization theorem, which states that there is a Σ_n-definable Skolem function for Σ_n formulas on J_α. A second possible approach is that of Silver, who showed that it is possible to define $\mathrm{Ult}_n(J_\alpha, \pi, \beta)$ by using compositions of the naïve Σ_n-Skolem function, and that the naïve Skolem function is preserved by the resulting embedding even though it is not defined by a Σ_n formula. This is the simplest approach, as it avoids the use of fine structure, but it appears to have difficulties with models for larger cardinals.

Our approach will be closer to the first one, but will use the fine structure directly. The notion of Σ_n ultrapower which we use can be defined in two different, but equivalent, ways. One way is to define $\mathrm{Ult}_n(J_\alpha, \pi, \beta)$ directly, using Definition 3.8, but allowing any function f of the form $f(x) = h_n(x, q)$ where h_n is the Σ_n-Skolem function mapping a subset of $J_{\rho_n^{J_\alpha}}$ onto J_α, and $q \in J_{\rho_n^{J_\alpha}}$ is an arbitrary parameter. The other way is indirect, by taking the ordinary Σ_0 ultrapower $i : \mathfrak{C}_n(J_\alpha) \to \mathrm{Ult}(\mathfrak{C}_n(J_\alpha), \pi, \beta)$ of the Σ_n-code of J_α, and then extending this to a map $\tilde{i} : J_\alpha \to J_{\tilde{\alpha}}$. This approach has the advantage that most arguments can be carried out at the level of the Σ_n-code of J_α, which involves the easily understandable Σ_0 ultrapower and Σ_1-Skolem function.

The extension of π to an embedding $\tilde{\pi}$ with the larger domain J_α depends on Lemma 3.10 below, which is the counterpart of the Downward Extension Lemma 3.6 given earlier. One major difference between the Upward and Downward Extension Lemmas concerns the well-foundedness of the new structure. In the Downward Extension Lemma, this structure is a substructure of a given well-founded structure and hence is automatically well-founded. In the Upward Extension Lemma the well-foundedness of $\mathrm{Ult}_n(J_\alpha, \pi, \beta)$ must be explicitly assumed.

3.10 Lemma (Upward Extension Lemma). *Suppose that $\pi : J_{\bar{\kappa}} \to J_\kappa$, that $\beta \leq \kappa$, and either $\rho_n^{J_\alpha} > \min\{\nu : \pi(\nu) \geq \beta\}$ or $\mathrm{ran}(\pi)$ is cofinal in β and $\pi(\rho_n^{J_\alpha}) \geq \beta$. Set $M_n = \mathfrak{C}_n(J_\alpha)$ and $\widetilde{M}_n = \mathrm{Ult}(M_n, \pi, \beta)$.*

1. *There is a structure $\widetilde{M}_0$ such that $\widetilde{M}_n$ is, formally, equal to $\mathfrak{C}_n(\widetilde{M}_0)$. If this structure $\widetilde{M}_0$ is well-founded then there is an ordinal $\tilde{\alpha}$ such that $\widetilde{M}_0 = J_{\tilde{\alpha}}$ and $\widetilde{M}_n = \mathfrak{C}_n(J_{\tilde{\alpha}})$.*

2. *There is an embedding $\tilde{\pi} : J_\alpha \to \widetilde{M}_0$ such that $\pi{\restriction}J_{\bar{\beta}} = \tilde{\pi}{\restriction}J_{\bar{\beta}}$, where $\bar{\beta}$ is the least ordinal such that $\pi(\bar{\beta}) \geq \beta$ if $\beta < \kappa$, or $\bar{\beta} = \bar{\kappa}$ if $\beta = \kappa$.*

3. *The embedding $\tilde{\pi}$ preserves the Σ_k codes for $k \leq n$: in particular, $\tilde{\pi} \circ h_k^{J_\alpha}(x) = h_k^{\widetilde{M}_0} \circ \tilde{\pi}(x)$ for all x for which either side is defined.*

4. *The embedding $\tilde{\pi}$ preserves the Σ_1-Skolem function of M_n in the sense*

that there is a function $\tilde{h}$, which is Σ_1-definable over $\widetilde{M}_n$, such that $\tilde{\pi}\, h^M_{n+1}(x) = \tilde{h}\,\tilde{\pi}(x)$ for all $x \in M$ such that either side is defined.

The proof of the Upward Extension Lemma is nearly the same as that of the Downward Extension Lemma 3.6. The models $\widetilde{M}_{n-k}$, and embeddings $\tilde{\pi}_{n-k} : \mathfrak{C}_{n-k}(J_\alpha) \to \widetilde{M}_{n-k}$ are defined by recursion on $k \leq n$: The embedding $\tilde{\pi}_0 : \mathfrak{C}_n(J_\alpha) \to \widetilde{M}_n$ is the Σ_0 ultrapower, and $\widetilde{M}_{n-(k+1)}$ is constructed from $\widetilde{M}_{n-k}$ by the same recovery process as was used for the Downward Extension Lemma. This process uses the fact that $\widetilde{M}_{n-k}$ has the form $(\widetilde{M}_{n-k}, \mathrm{E}, \tilde{A}_{n-k})$ and satisfies the first-order sentences asserting that $(\widetilde{M}_{n-k}, \mathrm{E})$ is a model of $V = L$, and that $\tilde{A}_{n-k}$ is the Σ_n theory of a larger model $\widetilde{M}_{n-(k+1)}$ of which $\widetilde{M}_{n-k}$ is the Σ_1-code.

The embedding $\tilde{\pi}$ does not, in general, preserve fine structure below ρ^M_n; for example if β is a cardinal in L then $\rho^{\widetilde{M}} \geq \beta$, since every bounded subset of β in L is a member of J_β, but it may happen that $\rho^M_{n+1} < \bar{\beta}$. In this case $\tilde{\pi}(\rho^M_{n+1}) = \pi(\rho^M_{n+1}) < \beta$. It follows that the function $\tilde{h}$ will not, in general, be the Σ_1-Skolem function $h_1^{\widetilde{M}_n}$. It is defined by the same formula as $h_1^{\widetilde{M}_n}$, but using the image $\tilde{\pi}_0(p_1^{J_{M_n}})$ of the standard parameter of M_n instead of the standard parameter $p_1^{\widetilde{M}_n}$ of $\widetilde{M}_n$.

In order for the ultrapower $\mathrm{Ult}_n(M, \pi, \beta)$ described above to be defined, the set $\{(\vec{\nu}, \vec{\nu}') : f(\vec{\nu}) = f'(\vec{\nu}')\}$ must be in the domain of π for each pair (f, f') of functions in $\Sigma_n(M)$. This yields the following condition for the existence of $\mathrm{Ult}_n(M, \pi, \beta)$:

3.11 Proposition. *Let M, π and β be as above, and let $\bar{\beta}$ be the least ordinal such that $\pi(\bar{\beta}) \geq \beta$ (or $\bar{\beta} = \mathrm{On}(N)$ if $\beta = \sup(\mathrm{ran}(\pi))$). Then the ultrapower $\mathrm{Ult}_n(M, \pi, \beta)$ is defined if and only if either $\rho^M_n > \bar{\beta}$, or else $\rho^M_n \geq \bar{\beta}$ and $\mathrm{ran}(\pi)$ is cofinal in β.*

Equivalently, the ultrapower is defined if and only if either

1. *Every subset of $\bar{\kappa}$ which is Σ_n-definable in M is a member of $J_{\bar{\kappa}}$, or*
2. *$\mathrm{ran}(\pi)$ is cofinal in β and every bounded subset of $\bar{\kappa}$ which is Σ_n-definable in M is a member of $J_{\bar{\kappa}}$.*

3.2. Proof of the Covering Lemma for L

The main part of the proof of the covering lemma for L is a construction which shows that any set $X \prec_1 J_\kappa$, which is suitable in a sense to be made precise in Definition 3.14, is a member of L. The concluding part of the proof is an analysis of the notion of suitability showing that every uncountable set of ordinals is contained in a suitable set of the same cardinality.

The construction, together with the Definition 3.14 of suitability, will prove the following lemma:

3.12 Lemma.

1. *If* $X \prec_1 J_\kappa$ *is suitable then there is a cardinal* $\rho < \kappa$ *of* L *and a function* $h \in L$ *such that* $X = h``(\rho \cap X)$.

2. *If* $X \prec_1 J_\kappa$ *is suitable and* $\rho < \kappa$ *is a cardinal of* L *then* $X \cap J_\rho$ *is also suitable.*

3.13 Corollary. *Any suitable set* $X \prec_1 J_\kappa$ *is a member of* L.

Proof. The proof is by induction on κ. Let $X \subseteq \kappa$ be suitable, and let h and ρ be as in clause 1. Then $X \cap J_\rho$ is suitable by clause 2 and hence is in L by the induction hypothesis, but then $X = h``(X \cap \rho) \in L$. ⊣

In order to describe the basic construction, we fix a cardinal κ of L and a set $X \prec_1 J_\kappa$ with $\sup(X) = \kappa \not\subseteq X$. Let $\pi : N \to X$ be the collapse map, so that $N = J_{\bar\kappa}$ for some ordinal $\bar\kappa$, and let (α, n) be the lexicographically largest pair such that $\mathrm{Ult}_n(J_\alpha, \pi, \kappa)$ is defined. There are two cases:

1. If $\mathcal{P}(\delta) \cap L \subseteq N$ for all $\delta < \bar\kappa$ then $J_\alpha = L$ and $n = 0$.

2. Otherwise α is the least ordinal such that there is a bounded subset of $\bar\kappa$ in $J_{\alpha+\omega} - J_{\bar\kappa}$, and n is the least integer such there is such a subset which is Σ_{n+1}-definable in J_α. That is, $\rho_{n+1}^{J_\alpha} < \bar\kappa \leq \rho_n^{J_\alpha}$, and $\rho_m^{J_{\alpha'}} \geq \bar\kappa$ whenever $\bar\kappa \leq \alpha' < \alpha$ and $m < \omega$.

The basic construction will succeed whenever $\widetilde{M} = \mathrm{Ult}_n(J_\alpha, \pi, \kappa)$ is well-founded; the Definition 3.14 of suitability, given in the next subsection, is a generalization of this requirement. If case (1) occurs for some suitable set X then $\tilde\pi : L \to \mathrm{Ult}(L, \pi, \kappa) = L$ is a nontrivial embedding from L into L, which implies by Kunen's theorem (see chapter [32, Theorem 1.13]) that $0^\#$ exists. This contradicts our current assumption that the core model is equal to L, so we can assume that case (2) occurs for all suitable sets X. Then by Lemma 3.10, $\mathrm{Ult}_n(J_\alpha, \pi, \kappa) = J_{\tilde\alpha}$ for some ordinal $\tilde\alpha$, and the following diagram commutes:

$$\begin{tikzcd} J_\alpha \arrow[r, "\tilde\pi"] & \widetilde{\mathcal{M}} = \mathrm{Ult}_n(J_\alpha, \pi, \kappa) = J_{\tilde\alpha} \\ J_{\bar\kappa} \arrow[u, hook] \arrow[r, "\pi"] & X \prec_1 J_\kappa \arrow[u, hook] \end{tikzcd} \tag{18.5}$$

Now let $\bar\rho = \rho_{n+1}^{J_\alpha}$. Then $\bar\rho < \bar\kappa$, and $J_\alpha = \bar h``\bar\rho$ where $\bar h = h_{n+1}^{J_\alpha}$, so

$$X = \pi``J_{\bar\kappa} = \pi``(\bar\kappa \cap \bar h``(\bar\rho)), \tag{18.6}$$

and furthermore

$$\tilde h \circ \tilde\pi = \tilde\pi \circ \bar h \tag{18.7}$$

where $\tilde{h}$ is the function given by Lemma 3.10(4). Putting equations (18.6) and (18.7) together, we get

$$X = J_\kappa \cap (\widetilde{\pi} \circ \bar{h}``\bar{\rho}) = J_\kappa \cap (\tilde{h} \circ \widetilde{\pi}``\bar{\rho}) = J_\kappa \cap \tilde{h}``(X \cap \rho) \tag{18.8}$$

where $\rho = \sup(\pi``\bar{\rho}) < \kappa$. Since $\tilde{h} \in L$, this completes the basic construction.

Suitable Sets

Here is the formal definition of suitability:

3.14 Definition. Suppose $X \subseteq L$ and let $\pi : N \cong X$ be the inverse of the transitive collapse. Then X is *suitable* if $X \prec_1 J_\kappa$ for some ordinal κ and $\mathrm{Ult}_n(J_\alpha, \pi, \beta)$ is well-founded for all triples (α, n, β) such that the ultrapower is defined.

We write $\mathbf{C}$ for the class of suitable sets.

Proof of Lemma 3.12. If $X \prec_1 J_\kappa$ is any set in $\mathbf{C}$ then the basic construction succeeds for X, and hence clause 1 of Lemma 3.12 holds for X. Clause 2 of that lemma is clear. ⊣

It follows by Corollary 3.13 that every suitable set is in L, so Jensen's covering Lemma 1.1 for L will follow if we can show that every uncountable set is contained in a suitable set of the same cardinality. For the Strong Covering Lemma 1.12 we additionally need to show that the class $\mathbf{C}$ is closed under increasing unions of uncountable cofinality. Notice that Definition 3.14 is absolute, so that the class $\mathbf{C}$ is definable in L.

The countably closed sets give a easy, but useful, special case:

3.15 Definition. We will call a set $X \prec_1 J_\kappa$ *countably closed* if there is a set $Y \prec H(\lambda)$, for some $\lambda \geq \kappa$, such that ${}^\omega Y \subseteq Y$ and $X = Y \cap J_\kappa$.

If $|x|^\omega < \kappa$ then it is always possible to find a countably closed $X \supseteq x$ with $|X| = |x|^\omega$, so the following easily proved observation is often all that is needed.

3.16 Proposition. *Every countably closed set $X \prec_1 J_\kappa$ is suitable, and hence is a member of L.*

It follows that if $0^\#$ does not exist then every set x is contained in a set $y \in L$ such that $|y| \leq |x|^\omega$. This result gives much of the strength of the covering lemma, and moreover its proof highlights the most important ideas of the proof of the full covering lemma while omitting the most delicate part of the argument. This by itself would be sufficient reason to consider the countably closed case, but for core models involving measurable cardinals or non-overlapping extenders the countably closed case of the covering lemma is a necessary step in the proof of the full lemma: it is used to prove that the weak covering lemma, Definition 1.9, holds in a variant K^{c} of the core model. The weak covering lemma for K^{c} is then used to prove the existence and essential properties of the true core model K, and only after this can the full covering lemma be proved for K.

The following lemma will conclude the proof of Theorem 1.1 and of Theorem 1.12 in the case $0^{\#}$ does not exist: the covering lemma and the strong covering lemma for L:

3.17 Lemma. *The class* $\mathbf{C}$ *is unbounded in* $[J_\kappa]^\delta$ *for every uncountable cardinal* δ*, and* $\bigcup_{\nu<\eta} X_\nu \in \mathbf{C}$ *whenever* $\langle X_\nu : \nu < \eta\rangle$ *is an increasing sequence of sets in* $\mathbf{C}$ *with* $\mathrm{cf}(\eta) > \omega$*.*

The proof of this lemma will take up the remainder of Sect. 3.2.

Fix, for the moment, a set X which is not suitable, and let α, n and β be such that $\widetilde{M} = \mathrm{Ult}_n(J_\alpha, \pi, \beta)$ is defined but not well-founded. This ill-foundedness is witnessed by a descending E-chain, $\dots \mathrel{\mathrm{E}} z_2 \mathrel{\mathrm{E}} z_1 \mathrel{\mathrm{E}} z_0$, of members of $\widetilde{M}$, where E is the membership relation of $\widetilde{M}$. In order to prove Lemma 3.17 we need to incorporate additional structure into such a witness:

3.18 Definition. A *witness* w *to the unsuitability* of $X \prec_1 J_\kappa$ is a ω-chain of Σ_0-elementary embeddings $i_k : m_k \to m_{k+1}$ such that

1. $i_k \in X$ and $m_k \in X$ for each $k < \omega$.
2. $\operatorname{dir\,lim}(\pi^{-1}[w]) = \mathfrak{C}_n(J_\alpha)$ for some ordinal α and some $n \in \omega$.
3. $\operatorname{dir\,lim}(w)$ is not the Σ_n-code of any well-founded model $J_{\tilde{\alpha}}$.
4. Write β_k for the critical point of i_k. Then the sequence $\langle \beta_k : k < \omega\rangle$ is nondecreasing.
5. For each k we have $m_k \in m_{k+1}$, and there is a function $f \in m_{k+1}$ such that $f``\beta_k = i_k``m_k$.

We will call $\beta = \sup_k(\beta_k)$ the *support* of the witness w, and we will call the pair (α, n) the *height* of w in X. We will say that a witness w is *minimal* in X if it has minimal height in X among all witnesses with the same support β.

There may be more than one minimal witness for X with the same support β. It is possible, with some care, to modify the definition so that this minimal witness is unique; however, we do not need to do so.

3.19 Lemma. *A set* $X \prec_1 J_\kappa$ *is unsuitable if and only if it has a witness to its unsuitability. Furthermore, if* w *is a witness to the unsuitability of* X *then*

1. *If* $w \subseteq X' \prec_1 X$ *then* w *is also a witness to the unsuitability of* X'*.*
2. *If, in clause 1,* w *is a minimal witness for* X *then it is also a minimal witness for* X'*, and furthermore any other minimal witness for* X' *with the same support is also a minimal witness for* X*.*
3. *If* $X = Y \cap J_\kappa$*, where* $Y \prec_1 H(\tau)$ *for some cardinal* $\tau > \kappa$*, then* $w \notin Y$*.*

We will give some immediate consequences of Lemma 3.19 and then use it to finish the proof of the covering lemma. We will then give the proof of Lemma 3.19.

3.20 Corollary. *If $\langle X_\nu : \nu < \eta \rangle$ is an increasing sequence of sets in $\mathbf{C}$, with $\mathrm{cf}(\eta) > \omega$, then $X = \bigcup_{\nu<\eta} X_\nu \in \mathbf{C}$.*

Proof. Otherwise there would be a witness w to the unsuitability of X; but since $\mathrm{cf}(\eta) > \omega$ this would imply that $w \subseteq X_\nu$ for some $\nu < \eta$ and hence w is a witness to the unsuitably of X_ν by clause 1. $\dashv$

We can use Lemma 3.19 to give a proof of Proposition 3.16, although a direct proof is somewhat simpler.

3.21 Corollary. *Every countably closed set $X \prec_1 J_\kappa$ is suitable, and hence is a member of L.*

Proof. By definition, X is countably closed if and only if $X = Y \cap J_\kappa$ for some $Y \prec_1 H(\tau)$ where ${}^\omega Y \subseteq Y$. Then any witness to the unsuitability of X would have to be a member of Y, contrary to clause 3 of Lemma 3.19. $\dashv$

The following lemma will complete the proof of the covering lemma except for the proof of Lemma 3.19.

3.22 Lemma. *The class $\mathbf{C}$ is unbounded in $[J_\kappa]^\delta$ for any cardinal δ with $\omega < \delta < \kappa$.*

Proof. Jensen's proof of this result begins by generically collapsing the cardinal κ onto δ^+. The proof given here is essentially the same, but the presentation is slightly different: instead of carrying out the generic collapse we work with the set $\mathrm{Col}(\delta^+, J_\kappa)$ of forcing conditions for the collapse. The members of $\mathrm{Col}(\delta^+, J_\kappa)$ are functions $\sigma : \xi \to J_\kappa$ with $\xi < \delta^+$. With the obvious notions of "closed" and "unbounded" this space satisfies Fodor's Lemma: if $S \subseteq \mathrm{Col}(\kappa^+, J_\kappa)$ is a stationary set and F is a function with domain S such that $F(\sigma) \in \mathrm{ran}(\sigma)$ for all $\sigma \in S$, then F is constant on a stationary subset of S. The reason for using the space $\mathrm{Col}(\delta^+, J_\kappa)$ instead of $[J_\kappa]^\kappa$ is that $\mathrm{Col}(\delta^+, J_\kappa)$ also satisfies the following variant of Fodor's Lemma:

3.23 Proposition. *Suppose that $S \subseteq \mathrm{Col}(\delta^+, J_\kappa)$ is a stationary set such that $\mathrm{cf}(\mathrm{dom}(\sigma)) > \omega$ for all $\sigma \in S$, and that F is a function defined on S such that $F(\sigma)$ is a countable subset of $\mathrm{ran}(\sigma)$ for all $\sigma \in S$. Then there is a stationary subset S' of S and a function $\sigma_0 \in S'$ such that*

$$\forall \sigma \in S' \, (\sigma_0 \subseteq \sigma \text{ and } F(\sigma) \subseteq \mathrm{ran}(\sigma_0)).$$

Proof. Let $f(\sigma) < \mathrm{dom}(\sigma)$ be the least ordinal η such that $F(\sigma) \subseteq \sigma``\eta$, and let $S_0 \subseteq S$ be a stationary set on which $f(\sigma)$ is constant. Pick any $\sigma_0 \in S_0$ and let $S' = \{\sigma \in S_0 : \sigma_0 \subseteq \sigma\}$. Then S' and σ_0 are as required. $\dashv$

Let S_0 be the set of functions $\sigma \in \mathrm{Col}(\delta^+, J_\kappa)$ such that $\mathrm{ran}(\sigma) \notin \mathbf{C}$, $\mathrm{cf}(\mathrm{dom}(\sigma)) > \omega$ and $\mathrm{ran}(\sigma) \prec_1 J_\kappa$. We will prove that S_0 is nonstationary, which implies that $\mathbf{C}$ is unbounded in $[J_\kappa]^\delta$.

Suppose to the contrary that S_0 is stationary. It follows by Lemma 3.19 that there is, for each $\sigma \in S_0$, a minimal witness w^σ to the unsuitability of $\mathrm{ran}(\sigma)$. Let β^s be the support of w^σ. By the ordinary Fodor's Lemma there is a stationary set $S_1 \subseteq S_0$ such that $\beta = \beta^\sigma$ is constant for $\sigma \in S_1$, and by Proposition 3.23 there is a stationary set $S_2 \subseteq S_1$ and $\sigma_0 \in S_2$ such that $\sigma_0 \subseteq \sigma$ and $w^\sigma \subseteq \mathrm{ran}(\sigma_0)$ for all $\sigma \in S_2$. It follows that w^{σ_0} is a minimal witness to the unsuitability of $\mathrm{ran}(\sigma)$ for each $\sigma \in S_2$. Now consider the class $\mathcal{Y}$ of sets $Y \prec_{\Sigma_1} H(\kappa^+)$ such that $w^{\sigma_0} \in Y$. Then

$$\mathcal{X} = \{\sigma \in \mathrm{Col}(\delta^+, J_\kappa) : \exists Y \in \mathcal{Y}\ \mathrm{ran}(\sigma) = Y \cap J_\kappa\}$$

contains a closed unbounded subset of $\mathrm{Col}(\delta^+, J_\kappa)$, and hence $S_2 \cap \mathcal{X} \neq \varnothing$. However, this contradicts Lemma 3.19(3), and this contradiction completes the proof of Lemma 3.22. $\dashv$

This completes the proof of the covering lemma, except for the proof of Lemma 3.19:

Proof of Lemma 3.19. First, notice that if w is a witness with support β to the unsuitability of X, then clauses 4 and 5 imply that $\mathrm{dir\,lim}(w) = \mathrm{Ult}(\mathrm{dir\,lim}(\pi^{-1}[w]), \pi, \beta)$, and hence clause 3.18(3) implies that X is in fact unsuitable.

Now suppose that X is unsuitable, so that there are α, n and β such that $\mathrm{Ult}_n(J_\alpha, \pi, \beta)$ is defined, but not well-founded. If we write $M_n = \mathfrak{C}_n(J_\alpha)$ then this means that $\mathrm{Ult}(M_n, \pi, \beta)$ is defined, but is not the Σ_n-code of any well-founded structure $J_{\tilde{\alpha}}$. We will find a witness w to the unsuitability of X, such that w has height and support less than or equal to (α, n) and β, respectively.

If $\mathrm{Ult}(M_n, \pi, \beta)$ is not well-founded then there are $f_k \in M_n$ and $a_k \in \beta$ so that $z_{k+1}\ \mathrm{E}\ z_k$, where $z_k = [a_k, f_k]_\pi = \tilde{\pi}(f_k)(a_k)$, and E is the membership relation of $\mathrm{Ult}(M_n, \pi, \beta)$. If on the other hand $\mathrm{Ult}(M_n, \pi, \beta)$ is well-founded, then, since $\tilde{\pi} : M_n \to \widetilde{M}_n = \mathrm{Ult}(M_n, \pi, \beta)$ is Σ_1-elementary, there is a (ill-founded) structure $\widetilde{M}$ such that $\widetilde{M}_n = \mathfrak{C}_n(\widetilde{M})$, along with a map $\tilde{h}_n$, the Σ_n-Skolem function of $\widetilde{M}$, mapping $\widetilde{M}_n$ onto $\widetilde{M}$. Then we can find $z_k = [a_k, f_k]_\pi$ so that $\tilde{h}_n(z_{k+1})\ \mathrm{E}\ \tilde{h}_n(z_k)$ for each $k < \omega$.

Write $M_n = (J_{\rho_n}, A_n)$ (if $n = 0$ then $\rho_n = \alpha$ and $A_n = \varnothing$, in which case we assume as usual that α is a limit ordinal). Let $\alpha_k < \rho_n$ be the least ordinal $\xi > \alpha_{k-1}$ such that $\{f_1, \dots, f_k\} \subseteq J_\xi$, and let β_k be the least member of X such that $\{a_0, \dots, a_k\} \subseteq \beta_k$. Finally let $\bar{\beta}_k = \pi^{-1}(\beta_k)$ and let $\bar{j}_k : \bar{m}_k \cong \mathcal{H}_{\Sigma_1}^{(J_{\alpha_k}, A_n \cap J_{\alpha_k})}(\bar{\beta}_k \cup \{f_1, \dots, f_k\})$ be the transitive collapse of the Σ_1 hull of $\bar{\beta}_k \cap \{f_1, \dots, f_k\}$ in $(J_{\alpha_k}, A_n \cap J_{\alpha_k})$, with $\bar{i}_k = \bar{j}_{k+1}^{-1} \bar{j}_k : \bar{m}_k \to \bar{m}_{k+1}$.

Then $\bar{m}_k, \bar{i}_k \in J_{\bar{\kappa}}$ for each $k < \omega$. Set $w = \langle \pi(\bar{m}_k), \pi(\bar{i}_k) : k < \omega \rangle$, with $m_k = \pi(\bar{m}_k)$ and $i_k = \pi(\bar{i}_k)$, and set $\beta' = \sup_k(\beta_k) \leq \beta$.

If $\bar{w} = \langle \bar{m}_k, \bar{i}_k : k < \omega \rangle = \pi^{-1}[w]$ then $\operatorname{dir}\lim(\bar{w}) \prec_0 M_n = \mathfrak{C}_n(J_\alpha)$ and hence, by Lemma 3.6, $\operatorname{dir}\lim(\bar{w})$ is the Σ_n-code of $J_{\alpha'}$ for some $\alpha' \leq \alpha$, but w was constructed so that $\operatorname{dir}\lim(w)$ is not the Σ_n-code of any well-founded model. Finally, since $\alpha_{k+1} > \alpha_k$, the Skolem function mapping β_k onto j_k"$m_k \prec_{\Sigma_1} J_{\alpha_k}$, with parameters $\{f_1, \ldots, f_k\}$, is a member of $J_{\alpha_{\kappa+1}}$. This gives the functions f required by clause 3.18(5).

Thus w is the desired witness to the unsuitability of X.

To prove clause 3.19(3), note that by the absoluteness of well-foundedness we can find, working in Y, a sequence $a'_k < \beta'$ of ordinals and a sequence $f'_k \in m_{k+1}$ of functions such that if f''_k is the image $j_k(f'_k)$ of f'_k in $\operatorname{dir}\lim(w)$ then the sets $z'_k = f''_k(a'_k)$ demonstrate, in the same way that $\langle z_k : k < \omega \rangle$ above did for $\widetilde{M}_n$, that $\operatorname{dir}\lim(w)$ is not the Σ_n-code of a well-founded structure. Then the sets a'_k and f'_k are members of $Y \cap J_\kappa = X$, so the sets $\bar{z}'_k = \bar{i}_k\, \pi^{-1}(f'_k)(\pi^{-1}(\alpha'_k))$ demonstrate that $\operatorname{dir}\lim(\pi^{-1}[w])$ is not the Σ_n-code of a well-founded structure, contradicting clause 3.18(2).

Clause 3.19(1), stating that any witness $w \subseteq X' \prec_1 X$ to the unsuitability of X is also a witness that X' is not suitable, is straightforward. Finally, to prove clause 3.19(2), suppose that w is minimal, and that w' is a minimal witness for X' having the same support β.

Let (α', n') and (α'', n) be the heights of w' and w, respectively, in X', and let $\bar{\pi} = (\pi^X)^{-1}\pi^{X'}$. Then $(\alpha', n') \leq (\alpha'', n)$ since w' is minimal, so

$$\begin{aligned}
\operatorname{dir}\lim((\pi^X)^{-1}\text{``}w') &= \operatorname{Ult}_{n'}(\operatorname{dir}\lim((\pi^{X'})^{-1}\text{``}w'), \bar{\pi}, \bar{\beta}) \\
&= \operatorname{Ult}_{n'}(J_{\alpha'}, \bar{\pi}, \bar{\beta}) \\
&\subseteq \operatorname{Ult}_n(J_{\alpha''}, \bar{\pi}, \bar{\beta}) = \operatorname{dir}\lim((\pi^X)^{-1}\text{``}w).
\end{aligned}$$

Hence $\operatorname{dir}\lim((\pi^X)^{-1}\text{``}w')$ is well-founded, and it follows that w' is a witness to the unsuitability of X with support β, and by the minimality of w we must have $\operatorname{Ult}_{n'}(J_{\alpha'}, \bar{\pi}, \bar{\beta}) = J_\alpha$ and $n' = n$. Hence the height of w' in X is (α, n), so that w' is also a minimal witness for X. ⊣

This completes the proof of the covering lemma for L. In the rest of this section we consider two variations on this proof. The first, and most important, extends the argument to models with a measurable cardinal in order to obtain the Dodd-Jensen covering lemma; the second variation applies the argument to unsuitable sets X, obtaining Magidor's Covering Lemma 1.15 and the absoluteness theorem for Jónsson cardinals, Theorem 1.16.

3.3. Measurable Cardinals

The primary aim of this subsection is to prove the Dodd-Jensen covering lemma, and an important secondary aim is to prepare the way for Sect. 4 which describes the covering lemma for larger core models. In accordance with this secondary aim we do not assume $\neg 0^\dagger$ except when it is explicitly specified. For simplicity we do assume that there is no model of $\exists\kappa\, o(\kappa) =$

κ^{++}, but much of our discussion is true in general (though not always in detail) for the larger core models described in chapter [57].

In Dodd and Jensen's original papers [9–11], the minimal model $L[U]$ for a measurable cardinal is treated separately from the Dodd-Jensen core model K^{DJ}. The model $L[U]$ is the simplest natural analogue of L and was already well understood long before the core model was invented. While $L[U]$ has many of the properties of L, there is one vital difference: The existence of the model L is implied by the axioms of set theory, but the construction of the model $L[U]$ depends on being first given the filter U which will be the measure in the model $L[U]$.

If $L[U]$ does exist then K^{DJ} can easily be obtained by "iterating the measure U out of the universe":

$$K^{\mathrm{DJ}} = \bigcap_{\nu\in\mathrm{On}} \mathrm{Ult}^{\nu}(L[U],U) = \bigcup_{\nu\in\mathrm{On}}(\mathrm{Ult}^{\nu}(L[U],U) \cap V_{i_\nu(\kappa)})$$

where $i_\nu : L[U] \to \mathrm{Ult}^{\nu}(L[U],U)$ is the ν-fold iteration of the ultrapower by U. In order to define an inner model which would exist even in the absence of a model $L[U]$, Dodd and Jensen defined the core model K^{DJ} to be $L[\mathcal{M}]$, where $\mathcal{M}$ is a class of approximations, called *mice*, to models of the form $L[U]$. The mice are structures $M = J_\alpha[W]$ with the properties (i) $M \models$ "W is a measure", (ii) M is iterable (in the sense that every iterated ultrapower of M is well-founded) and (iii) M is sound and has projectum smaller than $\mathrm{crit}(W)$. Note that condition (iii) implies that $J_{\alpha+\omega}[W] \models |\alpha| < \mathrm{crit}(W)$, so that W is not a measure in any model larger than M.

In [35], the Dodd-Jensen core model was extended to obtain a core model for sequences of measures. This extended core model had the form $K[\mathcal{U}] = L[\mathcal{U},\mathcal{M}]$, where $\mathcal{U}$ was the sequence of measures in $K[\mathcal{U}]$ and $\mathcal{M}$ was a class of mice. The mice $M \in \mathcal{M}$ were models of the form $M = J_\alpha[\mathcal{U}']$ where the sequence $\mathcal{U}'$ was a concatenation $\mathcal{U}' = \mathcal{U}^\frown\mathcal{W}$ of the sequence of measures of $K[\mathcal{U}]$ with a sequence $\mathcal{W}$ of filters which are measures in M but not in $J_{\alpha+\omega}[\mathcal{U}']$. The sequence $\mathcal{W}$ corresponded to the measure W in a Dodd-Jensen mouse $J_\alpha[W]$.

The modern approach to mice, which we follow here, originated in attempts to extend the core model to cardinals approaching a supercompact cardinal. This program has many difficulties, some of which are still not solved, but a key to making a beginning was the observation that the original notion of a mouse was too simple. A key fact in the theory of the constructible sets is that all of the models J_α, as well as L itself, have the same structure, so that they differ only in length. It became clear in course of the investigation that the mice for an extended core model should similarly have the same structure as the full core model. That is, the mice are themselves constructed from smaller mice, like a well-founded version of Swift's well known flea, which

> hath smaller fleas that on him prey
> And these have smaller still to bit 'em;
> And so proceed *ad infinitum.*

This seemed prohibitively complicated, but a suggestion of S. Baldwin made it possible to realize the desired situation while simplifying, instead of complicating, the construction: The mice and the core model would be structures of the form $M = J_\alpha[\mathcal{E}]$ or $M = L[\mathcal{E}]$, respectively. The members of the sequence $\mathcal{E}$ would be extenders, but some would be only partial extenders, not measuring all of the sets in M. These partial extenders would be the full extenders of those mice which are members of M; thus the sequence $\mathcal{E}$ codes both the mice and the extenders in the structure M.

For the rest of this section we limit ourselves to sequences of measures, with no extenders, and we mark this restriction by using the letter $\mathcal{U}$ to denote the sequence instead of $\mathcal{E}$.

As hoped, this approach leads to a feasible fine structure for the extended core models, but surprisingly it also simplifies the fine structure for the previously existing core models. This is particularly surprising for the Dodd-Jensen core model, the mice of which have at most one measurable cardinal. It would seem at first glance that nothing could be simpler than a mouse of the form $J_\alpha[U]$, but the apparent simplicity of this model hides a complicated fine structure. For example, consider the key fact of the fine structure of L—and even of Gödel's proof of the continuum hypothesis—that every constructible subset of ω is a member of J_{ω_1}. This fact fails badly in the model $L[U]$: if $\kappa = \mathrm{crit}(U)$ then $J_\alpha[U] = J_\alpha$ for all $\alpha \leq \kappa + 1$. The first nonconstructible set to be constructed is $0^\#$, which is a subset of ω and is Δ_1-definable over $J_{\kappa+\omega}[U]$, so that $0^\# \in J_{\kappa+\omega\cdot 2}[U] - J_{\kappa+\omega}[U]$.

The newer fine structure avoids this problem because the subsets of ω in $L[\mathcal{U}]$ are all in $J_{\omega_1}[\mathcal{U}]$ and hence are constructed from the restriction $\mathcal{U}\restriction\omega_1$ of $\mathcal{U}$ to (partial) measures on countable ordinals. In fact, the first nontrivial member of $\mathcal{U}$ is the L-ultrafilter on the first Silver indiscernible c_0 which is induced by, and which constructs, the real $0^\#$. In the case $L[\mathcal{U}] = L[U]$, the sequence $\mathcal{U}$ has as its last nontrivial member the measure U, which is the only member of the sequence $\mathcal{U}$ which is a full measure on $L[\mathcal{U}]$.

The benefit of the new approach to the core model is suggested by the fact that the following two modifications are all that is necessary to adapt Definition 3.1 of fine structure for L to the core model.

1. An added predicate is needed to represent the sequence of measures, so that the Σ_1-code is a structure of the form $(J_\alpha[\mathcal{U}], \mathcal{U}\restriction\alpha, A)$ instead of (J_α, A).

2. For ordinals α such that $\mathcal{U}_\alpha \neq \varnothing$ it is necessary to begin the construction with a special *amenable code*, defined to be $\mathfrak{C}_0(J_\alpha[\mathcal{U}]) = (J_{\rho_0}, \mathcal{U}\restriction\rho_0, \mathcal{U}_\alpha)$ where, if $\kappa = \mathrm{crit}(\mathcal{U}_\alpha)$, then ρ_0 is defined to be κ^+ of $L[\mathcal{U}\restriction\alpha]$.

The "Skolem function" $h_0^{J_\alpha[\mathcal{U}]}$ mapping $\rho_0 = \rho_0^{J_\alpha[\mathcal{U}]} = \kappa^{+J_\alpha[\mathcal{U}]}$ onto $J_\alpha[\mathcal{U}]$ is derived from the function mapping functions $f : \kappa \to J_\kappa[\mathcal{U}]$ in $J_{\rho_0}[\mathcal{U}]$ to their equivalence classes $[f]_{\mathcal{U}_\alpha} \in J_\alpha[\mathcal{U}] = J_\alpha[\mathcal{U}\restriction\alpha] \subseteq \mathrm{Ult}(J_\kappa[\mathcal{U}], \mathcal{U}_\alpha)$.

The analogous structure in the fine structure of L was simply $\mathfrak{C}_0(J_\alpha) = (J_\alpha, \varnothing)$. The amenable code is needed here because the obvious structure $(J_\alpha[\mathcal{U}], \in, \mathcal{U}{\restriction}\alpha, \mathcal{U}_\alpha)$ is not amenable: $\mathcal{P}(\alpha)^{J_\alpha[\mathcal{U}]} \in J_\alpha[U]$, but $\mathcal{U}_\alpha \cap \mathcal{P}(\alpha)^{J_\alpha[\mathcal{U}]} = \mathcal{U}_\alpha \notin J_\alpha[\mathcal{U}]$. If $\mathcal{U}_\alpha = \varnothing$ then the amenable code is simply $(J_\alpha[\mathcal{U}], \mathcal{U}{\restriction}\alpha, \varnothing)$, as in L.

Some additional change is necessary for cardinals larger than measurable cardinals:

3. In models where iteration trees are needed instead of linear iterated ultrapowers, the standard parameter is augmented to included a *witness* to its minimality. This witness, which is discussed later, is used in the models of this section, but does not need to be explicitly included in the structure.

4. The amenable code is somewhat more complicated in the case of sequences $L[\mathcal{E}]$ involving extenders instead of only measures. See chapter [47] for details.

The proof that the fine structure given by this definition satisfies the necessary properties is, of course, more complicated than the proof in L. We begin with the definition of a mouse. Recall that U is a M*-ultrafilter* on κ if it is a normal M-ultrafilter in the sense of Kunen, that is, U is a normal ultrafilter on $\mathcal{P}^M(\kappa)$ and $U \cap X \in M$ whenever $X \in M$ and $M \models |X| = \kappa$. If M is a structure $J_\alpha[\mathcal{U}]$ and $\gamma < \alpha$ then we write $M|\gamma$ for the initial segment $J_\gamma[\mathcal{U}]$ of M.

3.24 Definition. A *mouse* is a premouse which is iterable and sound.

We define the terms *premouse* and *sound* by a simultaneous recursion on α:

1. A *premouse* is a model $J_\alpha[\mathcal{U}]$ (or $L[\mathcal{U}]$, allowing $\alpha = \mathrm{On}$) which satisfies the following three conditions:

   (a) For each γ such that $\mathcal{U}_\gamma \neq \varnothing$, there is a cardinal κ of $J_\alpha[\mathcal{U}{\restriction}\gamma]$ such that $(J_\gamma[\mathcal{U}{\restriction}\gamma], \mathcal{U}_\gamma) \models (\gamma = \kappa^{++}$ and $\mathcal{U}_\gamma$ is a normal $J_\gamma[\mathcal{U}{\restriction}\gamma]$-measure on $\kappa)$.

   (b) (Coherence) If $\mathcal{U}_\gamma \neq \varnothing$ then $(i^{\mathcal{U}_\gamma}(\mathcal{U}{\restriction}\gamma)){\restriction}\gamma + 1 = \mathcal{U}{\restriction}\gamma$.

   (c) (Soundness) The structure $(J_{\alpha'}[\mathcal{U}], \mathcal{U}{\restriction}\alpha', \mathcal{U}_{\alpha'})$ is sound for every ordinal $\alpha' < \alpha$.

   We say that a sequence $\mathcal{U}$ is *good* if $L[\mathcal{U}]$ is a premouse.

2. A premouse $\mathcal{M} = (J_\alpha[\mathcal{U}], \mathcal{U}{\restriction}\alpha, \mathcal{U}_\alpha)$ is said to be n*-sound* if $h^{\mathcal{M}}_m$“$\rho_m = J_\alpha[\mathcal{U}]$ for each $m \leq n$, where $h^{\mathcal{M}}_m$ and $\rho^{\mathcal{M}}_m$ are the Σ_m-Skolem functions and Σ_m projectum of $\mathcal{M}$, respectively. The model $\mathcal{M}$ is *sound* if it is n-sound for all $n \in \omega$.

   We will say that $\mathcal{M}$ is *sound above* η if either $\mathcal{M}$ is sound or there is n such that $\rho^{\mathcal{M}}_{n+1} \leq \eta$, $\mathcal{M}$ is n-sound and $h^{\mathcal{M}}_{n+1}$“$\eta = J_\alpha[\mathcal{U}]$.

3. (Iterability) A premouse $J_\alpha[\mathcal{U}]$ is *iterable* if every iterated ultrapower of $J_\alpha[\mathcal{U}]$ is well-founded.

   Note that this definition of the term *iterable* needs to be supplemented by Definition 3.30, given later, of an iterated ultrapower of a premouse.

Again, see chapter [47] for the somewhat more complicated conditions on the sequence $\mathcal{U}$ when it is allowed to contain extenders.

3.25 Remark. Notice that any premouse satisfies GCH, since the soundness condition implies that whenever $x \subseteq \eta < \alpha$ and $x \in J_{\alpha+\omega}[\mathcal{U}] - J_\alpha[\mathcal{U}]$, then $J_{\alpha+\omega}[\mathcal{U}] \models |\alpha| \leq \eta$. This property is often called *acceptability* in the literature, where it is used as a placeholder for soundness in the definition of a premouse in order to avoid the use of simultaneous recursion as in Definition 3.24.

If $J_\alpha[\mathcal{U}]$ is a n-sound premouse then the ultrapower $\mathrm{Ult}_n(J_\alpha[\mathcal{U}], \pi, \beta)$ of $M = J_\alpha[\mathcal{U}]$ by the extender derived from an embedding π is defined just like that for L, by taking the ultrapower $\mathrm{Ult}_0(\mathfrak{C}_n(M), \pi, \beta)$ of the Σ_n-code using functions in $\mathfrak{C}_n(M)$ and then using the upward extension property to extend the embedding to all of M. In particular the upward extension property, Lemma 3.10 (which we will not restate here) is still valid for these models. Since not every premouse $J_\alpha[\mathcal{U}]$ is sound, the Proposition 3.11 giving the conditions for the existence of $\mathrm{Ult}_n(J_\alpha[\mathcal{U}], \pi, \beta)$ needs to be supplemented with the requirement that $J_\alpha[\mathcal{U}]$ be n-sound. In addition, we now have the possibility of taking an ultrapower by one of the ultrafilters $U = \mathcal{U}_\gamma$ in $M = J_\alpha[\mathcal{U}]$. The ultrapower $\mathrm{Ult}_n(M, U)$, like $\mathrm{Ult}_n(M, \pi, \beta)$, is obtained by taking the ordinary ultrapower $\mathrm{Ult}(\mathfrak{C}_n(M), U)$ of the nth code of M and using Lemma 3.10.

3.26 Lemma. *Suppose that $M = J_\alpha[\mathcal{U}]$ is an n-sound iterable premouse, and U is a M-ultrafilter with* $\mathrm{crit}(U) \geq \rho^M_{n+1}$*. Then the embedding $i^U : M \to M' = \mathrm{Ult}_n(M, U)$ satisfies the following two properties:*

1. $A^M_{n+1} \notin M'$, and hence $\rho^{M'}_{n+1} = \rho^M_{n+1}$.

2. $i^U(p^M_{n+1}) = p^{M'}_{n+1}$.

Furthermore, any embedding $i : M \to M'$ which is given by the Upward Extension Lemma from a Σ_0-elementary embedding from $\mathfrak{C}_n(M)$ and which satisfies clause 1 also satisfies clause 2.

The thing which makes the conclusion stronger than that of Lemma 3.10 is the assertion that $\rho^{M'}_{n+1} = \rho^M_{n+1}$. This may be contrasted with diagram (18.5) in the proof of the covering lemma, in which $\tilde{\pi} : J_\alpha \to J_{\tilde{\alpha}} = \mathrm{Ult}(J_\alpha, \pi, \kappa)$ and $\rho^{J_\alpha} < \bar{\kappa}$, while $\rho^{J_{\tilde{\alpha}}}_{n+1} = \kappa = \tilde{\pi}(\bar{\kappa})$.

A part of the proof of clause 2 will be deferred until after the discussion of iterated ultrapowers.

Sketch of Proof. To see that $\rho^{M'}_{n+1} = \rho^{M}_{n+1}$ we need to verify that the master code $A = A^M_{n+1} \subseteq \rho^M_{n+1}$ is not a member of M'. Suppose to the contrary that $A = [f]_U \in M' = \mathrm{Ult}_n(M, U)$. Then A can be written as $\{\beta < \rho^M_{n+1} : \{\xi : \beta \in f(\xi)\} \in U\}$, which is a member of M since the assumptions that U is a M-ultrafilter and $\rho^M_{n+1} \leq \kappa$ imply that

$$U \cap \{\{\xi < \kappa : \beta \in f(\xi)\} : \beta < \rho^M_{n+1}\} \in M.$$

This contradiction concludes the proof that $A \notin M'$.

One direction of clause 2 is straightforward: clearly $i^U(p^M_{n+1}) \geq p^{M'}_{n+1}$, since A^M_{n+1} can be defined using the parameter $i^U(p^M_{n+1})$. The hard part is to see that $i^U(p^M_{n+1}) \leq p^{M'}_{n+1}$. The proof proceeds by induction on n, and we will only present the case $n = 0$. If to the contrary $p^{M'}_1 < i^U(p^M_1)$, then there is an ordinal $i^U(\nu) \in i^U(p^M_1) - p^{M'}_1$ such that $p^{M'}_1 - i^U(\nu) = i^U(p^M_1) - (i^U(\nu)+1)$. Set $p = p^M - (\nu+1)$ and $p' = i^U(p) = p^{M'}_1 - i^U(\nu)$, and set $A' = \{\xi < i^U(\nu) : M' \models \Phi(\xi, p')\}$ where Φ is the universal Σ_1 formula. Any subset of $i(\nu)$ which is Σ_1-definable in M' from p' is rudimentary in A', so if we can show that $A' \in M'$, then it will follow that any set Σ_1-definable from parameters in $p' \cup \nu$ is also a member of M'. This will contradict the assumption that $p' = p^{M'}_1 - \nu$.

Set $A = \{\xi < \nu : \Phi(\xi, p)\}$. Then $A \in M$, so $i^U(A) \in M'$. Unfortunately it may not be the case that $A' = i^U(A)$, so we need to analyze this set further. Let $M = J^{\mathcal{U}}_\alpha$, and define a prewellordering R on A by $\xi' \, R \, \xi$ if $\xi \in A$ and $\exists\gamma \, (J^{\mathcal{U}}_\gamma \models \Phi(\xi', p) \,\&\, \forall\gamma' < \gamma \; J^{\mathcal{U}}_\gamma \not\models \Phi(\xi, p))$. Then R is also Σ_1-definable from p, and hence is a member of M. Define R' in M' similarly. Then the prewellordering R' on A' is an initial segment of the preordering $i(R)$ on $i(A)$. Now $i(R) \in M'$, and if $i(R)$ is a prewellordering then all initial segments of $i(R)$ are also in M'. The following definition will be used to show that $i(R)$ is a prewellordering:

3.27 Definition. A *solidity witness that* $\nu \in p^M_1$ is a function $\tau \in M$ which maps A into the ordinals of M so that $\forall \xi', \xi \in A \; (\xi' \, R \, \xi \iff \tau(\xi') \leq \tau(\xi))$.

If τ is a solidity witness that ν is in p^M_{n+1} then $i(\tau)$ is an order preserving embedding from $i(R)$ into the ordinals of M'. Since M' is well-founded it follows that $i(R)$ is a prewellordering.

The general proof of the existence of a solidity witness will be deferred until after the introduction of iterated ultrapowers; however, we note here that the construction of a solidity witness τ can be carried out in any admissible set containing R; in fact this is the central element of the standard proof that well-foundedness is absolute. This leads to two easy cases, in which the solidity witness for a mouse $M = J_\alpha(\mathcal{U}^M)$ can be found in an admissible initial segment $M|\gamma = J_\gamma(\mathcal{U}^M \restriction \gamma)$ of M. If M has a measurable cardinal $\mu \geq \nu$ then $(\nu^+)^M$ exists, so there is a solidity witness in the admissible set $M|(\nu^+)^M$; and if M has a full measure $\mathcal{U}_\gamma$ with $\mathrm{crit}(\mathcal{U}_\gamma) < \nu < \gamma$ and $R \in \mathrm{Ult}(M, \mathcal{U}_\gamma)$ then M has a solidity witness in the admissible set $M|\gamma$. $\dashv$

Note that the hypothesis that U is a normal M-ultrafilter holds whenever $U = \mathcal{U}^M_\gamma$ for some $\gamma \leq \alpha$. If $\gamma < \alpha$ then a slightly stronger result holds, since the hypothesis that $\kappa \geq \rho^M_{n+1}$ can be eliminated (with some adjustment to the conclusion). Even then, however, not all of the fine structure of M is preserved by the ultrapower i^U. First, and most important, the ultrapower $M' = \mathrm{Ult}_n(M, U)$ is never sound above $\kappa = \mathrm{crit}(U)$, even if M is, since $\kappa \notin (i^U h^M_{n+1})``\mathrm{crit}(U) = h^{M'}_{n+1}``\mathrm{crit}(U) = h^{M'}_{n+1}``\rho_{n+1}$. The model $M'$ *is* sound above $\kappa + 1$. Second, the two projecti $\rho^M_n$ and $\rho^M_{n+1}$ need not be preserved by the embedding $i$: if $\mathrm{crit}(U) = \rho^M_{n+1}$ then $\rho^{M'}_{n+1} = \rho^M_{n+1} < i^U(\rho^M_{n+1})$; and in any case $\rho^{M'}_n = \sup(i^U\, ``\rho^M_n)$, which may be smaller then $i^U(\rho^M_n)$.

The existence of unsound premice is an important difference between the fine structure of L and that of larger core models. The counterpart of Lemma 3.4, which states that J_α is sound, is given by the following lemma:

3.28 Lemma. *Any iterable premouse $M = J_\alpha[\mathcal{U}]$ is an iterated ultrapower of a mouse.*

The mouse is given by the following definition:

3.29 Definition. The nth *core* of a premouse M, written $\mathrm{core}_n(M)$, is the model obtained by decoding the nth code $M_n = \mathfrak{C}_n(M)$ of M. The *core* of M, written $\mathrm{core}(M)$, is $\mathrm{core}_n(M)$ where n is least such that $\rho^M_n = \rho^M$.

Note that the definition of $\mathfrak{C}_n(M)$ is not hindered by the possibility that M is not sound. The structure $\mathrm{core}(M)$ will be equal to the transitive collapse of the substructure of M containing those elements which are, in an appropriate sense, definable in M. In particular, if we define $\mathrm{core}_1(M)$ to be the model obtained by decoding the Σ_1-code $M_1 = \mathfrak{C}_1(M)$, and then decoding M_1, then $\mathrm{core}_1(M)$ is the transitive collapse of $h^M_1``\rho^M_1$, the set of $x \in M$ which are Σ_1-definable using parameters from $\rho^M_1 \cup p^M_1$.

Any further sketch of the proof will clearly depend on the definition and properties of iterated ultrapowers. These were described in chapter [32], but are complicated here by the fact that they may involve ultrapowers of differing degrees and since they may involve filters $\mathcal{U}^{M_\nu}_\gamma$ which are not full ultrafilters on M_ν. Both of these situations result in the *drops* mentioned in the following definition.

The situation is slightly simpler in the case when $0^\dagger$ does not exist, so that the premice $J_\alpha[\mathcal{U}]$ have at most one full ultrafilter, than it is in the more general case needed in Sect. 4. At stage ν of the iterated ultrapowers being considered here there are only two possible choices. One is to use the single full ultrafilter in the model M_ν, which will be the last member of the sequence $\mathcal{U}^{\mathcal{M}_\nu}$; this is case 3a of the definition. The other is to use one of the earlier filters in the sequence $\mathcal{U}^M$. This earlier filter is not a full ultrafilter in M_ν and hence must be applied to a smaller mouse in M_ν on which it is an ultrafilter; this is case 3c. Case 3b does not arise in the absence of $0^\dagger$.

3.30 Definition. An *iterated ultrapower of a premouse* $M = J_\alpha[\mathcal{U}]$ is a sequence of models M_ν for $\nu \leq \theta$, together with a finite set $D \subseteq \theta+1$, called the set of *drops*, and embeddings $i_{\nu,\nu'} : M_\nu \to M_{\nu'}$ defined for all pairs $\nu < \nu' \leq \theta$ such that $D \cap (\nu, \nu'] = \varnothing$.

All of these are determined by a sequence of filters $U_\nu = \mathcal{U}^{M_\nu}_{\gamma_\nu} \in M_\nu$, with a strictly increasing sequence of critical points $\operatorname{crit}(U_\nu)$, as follows:

1. $M_0 = J_\alpha[\mathcal{U}]$.
2. If ν is a limit ordinal then $M_\nu = \operatorname{dir\,lim}_{\nu_0 \leq \nu' < \nu} M_{\nu'}$ where $\nu_0 = \sup(D \cap \nu)$. Note that this direct limit exists since the finiteness of D implies that $D \cap \nu$ is bounded in ν, so that the embeddings $i_{\nu'',\nu'} : M_{\nu''} \to M_{\nu'}$ exist for all sufficiently large $\nu'' < \nu' < \nu$.
3. If $\nu + 1 \leq \theta$ then $M_{\nu+1}$ is determined by the choice of the ultrafilter $U_\nu = \mathcal{U}^{M_\nu}_{\gamma_\nu}$, where $\gamma_\nu > \gamma_{\nu'}$ for all $\nu' < \nu$. There are three cases:
   (a) If U_ν is a full ultrafilter on M_ν then set $n_\nu = n$ where n is the largest number such that $\operatorname{Ult}_n(M_\nu, U_\nu)$ is defined. If $n_\nu = n_{\nu'}$ for all sufficiently large $\nu' < \nu$, then $M_{\nu+1} = \operatorname{Ult}_{n_\nu}(M_\nu, U_\nu)$. In this case $i_{\nu,\nu+1}$ is the canonical embedding.

       Note that since the critical points of the ultrafilters U_ν are increasing, M_ν is sound above $\operatorname{crit}(U_\nu)$ and hence the soundness hypothesis of Lemma 3.26 is satisfied.

   (b) If U_ν is a full ultrafilter on M_ν, but $n_\nu < n_{\nu'}$ for all $\nu' \in \nu - \max(D \cap \nu)$, then $M_{\nu+1} = \operatorname{Ult}_{n_\nu}(M_\nu, U_\nu)$. In this case we add $\nu + 1$ to D, so that $i_{\nu,\nu+1}$ is not defined.

       Note that this happens when $\operatorname{crit}(U_\nu) \geq \rho^{M_\nu}_{n_{\nu'}}$, but $\operatorname{crit}(U_{\nu'}) < \rho^{M_{\nu'}}_{n_{\nu'}}$, for $\sup(D \cap \nu) < \nu' < \nu$. This case is known as a *drop in degree*.

   (c) If U_ν is not a full ultrafilter on M_ν, then let $M^*_{\nu+1}$ be the largest initial segment of M_ν on which U_ν is an ultrafilter. Thus $M^*_{\nu+1} = J_{\alpha^*_\nu}[\mathcal{U}_\nu]$ where α^*_ν is the least ordinal $\beta < \alpha$ such that there is a subset x of $\operatorname{crit}(U_\nu)$ in $J_{\beta+\omega}[\mathcal{U}_\nu] - J_\beta[\mathcal{U}_\nu]$ which is not measured by U_ν.

       In this case, which is known as a *normal drop*, we set $M_{\nu+1} = \operatorname{Ult}(M^*_{\nu+1}, U_\nu)$, and we add $\nu+1$ to D so that $i_{\nu,\nu+1}$ is not defined.

We say that M is *iterable* if every model in any iterated ultrapower of M is well-founded and no attempt to create an iterated ultrapower leads to infinitely many drops.

Here again the situation becomes more complicated in the case of extenders, where *iteration trees* are needed instead of the linear iterated ultrapowers described above. See chapter [47] or [57].

3.31 Remark. In practice we will frequently make the trivial modification that $U_\nu = \mathcal{U}^{M_\nu}_{\gamma_\nu} = \varnothing$ is also allowed in an iterated ultrapower, and set $M_{\nu+1} = M_\nu$ in this case. This gives what is known as *padded* iterated ultrapowers.

3.32 Lemma. *The formula asserting that a set M is a mouse is absolute for models N containing ω_1.*

Proof. The statement that M is a premouse is first-order over M, as is the assertion that M is sound, so we only need verify that the iterability of M is absolute. If M is countable in N then this can be proved using the Shoenfield absoluteness theorem, as the statement that there is an ill-founded iterated ultrapower of M, with the iterated ultrapower indexed by a countable well-order, is a Σ^1_2 statement. The proof for general M is similar to the proof of Shoenfield's theorem: for each countable ordinal α one builds a "tree of attempts to find a ill-founded iterated ultrapower of length at most α", that is to say, a tree T_α such that the infinite branches of T_α correspond exactly to the ill-founded iterated ultrapowers of M of length at most α. If there is an ill-founded iteration of length $\alpha < \omega_1$ in V, then T_α has an infinite branch and hence is ill-founded. Assuming that the tree T_α can be constructed in N just as it was constructed in V (this relies on the fact that $\omega_1 \subseteq N$, so that α is countable in N) the tree T_α is in N. By the absoluteness of well-foundedness it is ill-founded there, so there is, in N, an infinite branch of T_α which specifies an ill-founded iterated ultrapower of M.

Since this is a very important technique, we suggest here one method of constructing such a tree. In order to simplify the construction we first ignore the possibility of drops. A node at the nth level of the tree T_α will be a 4-tuple $p = \langle x, \vec{U}, \vec{M}, \vec{\xi}\rangle$ such that

1. $\{0, \alpha\} \subseteq x \in [\alpha+1]^{<\omega}$,
2. $\vec{M}$ is a finite iterated ultrapower of $M_0 = M$ indexed by the ordinals in x and using the ultrafilters $\vec{U}$. That is, if $\nu \in x$ and $\nu' = \min(x-(\nu+1))$ then $U_\nu \in M_\nu$ and $M_{\nu'} = \mathrm{Ult}(M_\nu, U_\nu)$.
3. $\vec{\xi}$ is a descending sequence of ordinals, $\vec{\xi}$ has length n, and $\vec{\xi} \in M_\alpha$.

We will say that a node $p' = \langle x', \vec{U}', \vec{M}', \vec{\xi}\rangle$ at the $n+1$st level of T_α is *below p in T_α* if $x' \supseteq x$ and for each $\nu \in x$ there is $\sigma_\nu : M_\nu \to M'_\nu$ such that

1. σ_0 is the identity.
2. $\sigma_\nu(U_\nu) = U'_\nu$.
3. If $\nu \in x$, $\nu' = \min(x - (\nu+1))$ and $\nu'' = \min(x' - (\nu+1))$ then $\sigma_{\nu'}([f]_{U_\nu}) = i'_{\nu',\nu''}([\sigma_\nu(f)]_{U'_\nu})$, where $i'_{\nu',\nu''} : M_{\nu'} \to M_{\nu''}$ is the embedding associated with the iteration $\vec{M}'$.
4. $\xi'_k = i'_{\nu,\nu'}(\sigma_\nu(\xi_k))$ for each $k < n$, where $\nu = \max(x)$ and $\nu' = \max(x')$.

In order to see how an ill-founded iteration $\langle M_\nu : \nu < \alpha\rangle$ yields an infinite branch in T_α we need the concept of a *support*:

3.33 Definition. If $\langle M_\nu : \nu \le \eta\rangle$ is an iterated ultrapower, then the notion of a *support* is defined by recursion on η: a finite set $y \subseteq \eta + 1$ is a support for $z \in M_\eta$ if

1. $\{0, \eta\} \subseteq y$.
2. If η is a limit ordinal then there are $\nu < \eta$ in y and $z' \in M_\nu$ such that $z = i_{\nu,\eta}(z')$ and $y \cap (\nu + 1)$ is a support for z' in $\vec{M}\restriction(\nu + 1)$.
3. If $\eta = \nu + 1$ then $\nu \in y$ and $y \cap \eta$ is a support for $\{U_\nu, f\}$, where $M_\eta = \mathrm{Ult}(M_\nu, U_\nu)$ and $z = [f]_{U_\nu}$.

Suppose that $y \subseteq \eta + 1$ is a support in $\langle M_\nu : \nu \le \eta\rangle$. We will construct a finite iterated ultrapower $\langle M'_\nu : \nu \in x\rangle$, together with embeddings $\sigma_\nu : M'_\nu \to M_\nu$ for $\nu \in x$, with the key property that the range of each embedding σ_ν is exactly the set of $z \in M_\nu$ such that $y \cap (\nu + 1)$ is a support for z.

The index set x for the iteration is the set of $\nu \in y$ such that $\nu = 0$, $\nu = \eta$, or $\nu + 1 \in y$. The models M'_ν and embeddings $\sigma_\nu : M'_\nu \to M_\nu$ for $\nu \in x$, and the ultrafilters $U'_\nu \in M'_\nu$ for $\nu \in x \cap \eta$, are defined by recursion on ν. To start out, $M'_0 = M_0$ and σ_0 is the identity. If $\nu \in x \cap \eta$ then $U'_\nu = \sigma_\nu^{-1}(U_\nu)$, which exists because $y \cap (\nu + 1)$ is a support for U_ν in M_ν, and $M'_{\nu'} = \mathrm{Ult}(M_\nu, U_\nu)$ where $\nu' = \min(x - (\nu + 1))$. If $\nu' = \nu + 1 \in x$ then $\sigma_{\nu+1}$ is defined by setting $\sigma_{\nu+1}([f]_{U'_\nu}) = [\sigma_\nu(f)]_{U_\nu}$. Otherwise ν' is a limit ordinal and $\sigma_{\nu'}([f]_{U'_\nu}) = i_{\nu+1,\nu'}([\sigma_\nu(f)]_{U_\nu})$.

Now if $\langle M_\nu : \nu \le \alpha\rangle$ is an ill-founded iterated ultrapower, then let $\vec{\xi} = \langle \xi_n : n < \omega\rangle$ be an infinite descending sequence of ordinals in the final model M_α, and pick an increasing sequence $\{y_n : n < \omega\}$ such that y_n is a support for $\vec{\xi}\restriction n$. Then the construction in the last paragraph gives a sequence $\langle (x_n, \vec{U}_n, \vec{M}_n, \vec{\xi}_n) : n \in \omega\rangle$ which is an infinite branch in the tree T_α.

To go the other direction, if $\langle\langle x_n, \vec{U}_n, \vec{M}_n, \vec{\xi}_n\rangle : n \in \omega\rangle$ is an infinite branch of T_α then we can obtain, by a direct limit construction, an iterated ultrapower which is indexed by $\bigcup_n x_n$ and hence has length at most α. Clause 4 of the definition implies that the direct limit maps $\sigma_{n,\alpha} : M_{n,\alpha} \to M_\alpha$ satisfy $\sigma_{n,\alpha}(\vec{\xi}_n) = \sigma_{n',\alpha}(\vec{\xi}_{n'})\restriction n$ for all $n < n' < \omega$. Thus $\bigcup_n \sigma_{n,\alpha}(\vec{\xi}_n)$ is an infinite descending sequence of ordinals which witnesses that the final model M_α is ill-founded.

In order to allow for iterated ultrapowers including drops, the definition of T_α must be modified: first, the definition of a node allows iterations with drops, and in the definition of the tree ordering the maps σ_ν is required to preserve the drops; furthermore any $\nu \in x' - x$ at which $\vec{M}'_\nu$ drops are required to be larger than $\max(x \cap \alpha)$. Finally, clause 4 of that definition is modified to state that either clause 4 holds as stated previously, or else the iteration $\vec{M}'$ has a drop in $x' - x$.

An infinite branch of T_α describes a presumptive iteration which is indexed by a subset of α, and hence has length at most α. If a new drop is added at infinitely many levels in the branch then the presumptive iteration has infinitely many drops; otherwise the presumptive iteration is a real iteration and hence has a last model, but the levels of the branch beyond the last drop provide a witness $\vec{\xi}$ that the last model of the iteration is ill-founded. In either case this presumptive iteration demonstrates that the model M_0 is not iterable. ⊣

Comparisons of Mice

In the case of L, the only mice are the structures J_α, and hence it is trivial that, given two mice M and N, one is an initial segment of the other. Under appropriate conditions the same crucial fact is true of the mice for higher core models, but the proof requires the use of iterated ultrapowers to compare the two mice. We describe this process below, using the notation of Definition 3.30 for the iterated ultrapowers. Superscripts M and N are used to distinguish the iterated ultrapower on M from that on N.

3.34 Definition (Comparison for Premice). We will say that two premice M and N *strongly agree up to* τ if $\operatorname{crit}(\mathcal{U}^M_{\gamma'}) \geq \tau$ and $\operatorname{crit}(\mathcal{U}^N_{\gamma'}) \geq \tau$ for all $\gamma' \geq \gamma$, where γ is the least ordinal such that $\mathcal{U}^M_\gamma \neq \mathcal{U}^N_\gamma$. Assume strongly agree up to τ. Then the comparison of M and N is defined by the use of iterated ultrapowers on M and N, which we distinguish by means of superscripts M and N.

Start the comparison by setting $M_0 = M$ and $N_0 = N$. Now suppose that M_ν and N_ν have been defined. If either of the models N_ν or M_ν is an initial segment of the other then the comparison is complete, and the iterated ultrapower is terminated with $\theta = \nu$. Otherwise let γ_ν be the least ordinal γ such that $\mathcal{U}^{N_\nu}_\gamma \neq \mathcal{U}^{M_\nu}_\gamma$, and set $U^M_\nu = \mathcal{U}^{M_\nu}_{\gamma_\nu}$ and $U^N_\nu = \mathcal{U}^{N_\nu}_{\gamma_\nu}$. Now use these ultrafilters to define $M_{\nu+1}$ and $N_{\nu+1}$ as in Definition 3.30 of an iterated ultrapower.

Note that Definition 3.34 uses padded iterated ultrapowers, since it may be that $\mathcal{U}^{N_\nu}_\gamma \neq \mathcal{U}^{M_\nu}_\gamma$ because one of the two is equal to $\varnothing$.

The coherence property of premice ensures that both the indices γ_ν and the critical points of the ultrafilters U^M_ν and U^N_ν are strictly increasing.

3.35 Lemma. *This comparison process always stops after fewer than τ^+ steps, with one of M_θ and N_θ an initial segment of the other.*

Proof. Suppose to the contrary that the comparison continues for τ^+ steps, and let $i_{\nu,\nu'} : N_\nu \to N_{\nu'}$ and $j_{\nu,\nu'} : M_\nu \to M_{\nu'}$ be the iteration embeddings. Set $\nu_0 = \max(D^N \cap D^M)$, the last place at which either iteration drops. Then for each $\nu < \tau^+ - \nu_0$ at least one of $i_{\nu,\nu+1}$ and $j_{\nu,\nu+1}$ is nontrivial; let κ_ν be the critical point of this embedding. If one of these embeddings is trivial then set $x_\nu = \varnothing$; otherwise pick $x_\nu \subseteq \kappa_\nu$ so that $x_\nu \in M_\nu \cap N_\nu$ and $x_\nu \in U^M_\nu \not\Longleftrightarrow x_\nu \in U^N_\nu$.

Now for each limit ordinal $\nu \in \tau^+ - \nu_0$ there is some $\eta_\nu < \nu$ such that κ_ν and x_ν are in the range of $i_{\eta_\nu,\nu}$, say $\kappa_\nu = i_{\eta_\nu,\nu}(\kappa'_\nu)$ and $x_\nu = i_{\eta_\nu,\nu}(x'_\nu)$. By Fodor's Lemma there is a stationary set $S_0 \subseteq \tau^+$ on which η_ν is constant, say $\eta_\nu = \eta$, and since $|N_\eta| < \tau^+$ there is a stationary $S_1 \subseteq S_0$ on which κ'_ν and x'_ν are also constant, say $\kappa'_\nu = \kappa'$ and $x'_\nu = x'$. Then for any $\nu' < \nu$ in S_1 we have $i_{\nu,\nu'}(\kappa_\nu) = i_{\nu,\nu'} i_{\eta,\nu}(\kappa') = i_{\eta,\nu'}(\kappa') = \kappa_{\nu'}$, and similarly $i_{\nu,\nu'}(x_\nu) = x_{\nu'}$. In particular $i_{\nu,\nu+1}$ is not the identity for $\nu \in S_1$, since otherwise we would have $\kappa_{\nu'} = i_{\nu,\nu'}(\kappa_\nu) = i_{\nu+1,\nu'} i_{\nu,\nu+1}(\kappa_\nu) = i_{\nu+1,\nu'}(\kappa_\nu) = \kappa_\nu$. Similarly there is a stationary set $S_2 \subseteq S_1$ such that if $\nu < \nu'$ are in S_2 then $j_{\nu,\nu'}(\kappa_\nu) = \kappa_{\nu'}$ and $j_{\nu,\nu'}(x_\nu) = x_{\nu'}$. But this is impossible, for if $\nu < \nu'$ are in S_2 then $x_\nu \in U^N_\nu \Longleftrightarrow \nu \in i_{\nu,\nu'}(x_\nu) = x_{\nu'} = j_{\nu,\nu'}(x_\nu) \Longleftrightarrow \kappa_\nu \in U^M_\nu$, contrary to the choice of x_ν. ⊣

The next few results analyze some of the possible outcomes of this comparison. All results assume that M and N satisfy the requirements for Definition 3.34: that is, they strongly agree up to τ and are sound above τ.

3.36 Lemma. *Suppose that M_θ is a proper initial segment of N_θ. Then M is sound, and the only ultrafilters U^M_ν used in the iteration of M are full ultrafilters with* $\operatorname{crit}(U^M_\nu) < \rho^{M_\nu}$. *Thus $D^M = \varnothing$.*

Sketch of Proof. Since M_θ is an initial segment of the premouse N_θ, the definition of a premouse implies that it is sound. Any model $\operatorname{Ult}(M_\nu, U)$ obtained by taking the ultrapower by an ultrafilter U with $\operatorname{crit}(U) \geq \rho^{M_\nu}$ is unsound, and this unsoundness is preserved by any further iterated ultrapowers.

If $D^M \neq \varnothing$ then let $\nu + 1 = \max(D^M)$. Then $M_{\nu+1} = \operatorname{Ult}(M^*_{\nu+1}, U^M_\nu)$ where $\operatorname{crit}(U^M_\nu) \geq \rho^{M^*_{\nu+1}}$, and hence $M_{\nu'}$ is unsound for all $\nu' \geq \nu + 1$. Similarly, if any of the models $M_{\nu+1}$ arise as ultrapowers by an ultrafilter $U^M_\nu \in M_\nu$ with $\operatorname{crit}(U^M_\nu) \geq \rho^{M_\nu}$, or if $M = M_0$ is unsound, then all succeeding models $M_{\nu'}$ are unsound. In either case this contradicts the fact that M_θ is sound. ⊣

3.37 Lemma. *Suppose that $M_\theta = N_\theta$, that $D^M = D^N = \varnothing$, and that $\tau \geq \max\{\rho^M, \rho^N\}$. Then $M = N$.*

Sketch of Proof. Since $D^M = D^N = \varnothing$, both $i^M_{0,\theta} : M \to M_\theta$ and $i^N_{0,\theta} : N \to N_\theta$ are defined. Since $\tau \geq \rho^M$ we have $M = h^M “\tau$. By Lemma 3.26, we have $i^M_{0,\theta} h^M = h^{M_\theta}$ so it follows that $M \cong h^{M_\theta} “\tau$. Similarly $N \cong h^{N_\theta} “\tau$, and since $N_\theta = M_\theta$ it follows that $M = N$. ⊣

3.38 Corollary. *At least one of D^M and D^N are empty.*

Sketch of Proof. Assume to the contrary that both iterated ultrapowers drop. Then Lemma 3.36 implies that neither of M_θ and N_θ is a proper initial segment of the other, so $M_\theta = N_\theta$. Now let $\nu + 1$ be the largest member of

$D^M \cup D^N$, and suppose for example that $\nu + 1 \in D^M$. Then the remainder of the iterated ultrapower can be regarded as a comparison of $M^*_{\nu+1}$ with either N_ν or $N^*_{\nu+1}$, depending on whether $\nu + 1 \in D^N$. Furthermore, since D^N contains some ordinal $\nu' \leq \nu+1$, this comparison satisfies the hypothesis of Lemma 3.37, with $\tau = \operatorname{crit}(U^M_\nu)$, so $M^*_{\nu+1} = N_\nu$ or $M^*_{\nu+1} = N^*_{\nu+1}$. This is impossible since $U^M_\nu = \mathcal{U}^{M_\nu}_{\gamma_\nu} \neq \mathcal{U}^{N_\nu}_{\gamma_\nu}$. ⊣

3.39 Lemma. *Suppose that M and N are mice with* $\max\{\rho^N, \rho^M\} \leq \tau$*, and that M and N strongly agree up to τ. Then one of M and N is an initial segment of the other.*

Sketch of Proof. We prove the lemma by induction on the lengths of the mice M and N. First suppose that $M_\theta = N_\theta$. If $D^M = D^N = \varnothing$ then $M = N$ by Lemma 3.37. Otherwise, suppose that $D^N \neq \varnothing$ and let $\nu + 1$ be the largest member of D^N. If this is a drop in degree, then the remainders $\langle M_\xi : \nu \leq \xi < \theta\rangle$ and $\langle N_\xi : \nu \leq \xi < \theta\rangle$ of the two iterated ultrapowers form the comparison of M_ν with N_ν. This comparison has no drops, so we can apply Lemma 3.37 to conclude that $M_\nu = N_\nu$, contradicting the fact that $\nu < \theta$. Similarly, if this is a normal drop, then the remainders of the two iterated ultrapowers form the comparison of M_ν with the mouse $N^*_{\nu+1}$ to which the iteration on N drops at that point. Again, Lemma 3.37 shows that $M_\nu = N^*_{\nu+1}$, which is an initial segment of N_ν, so that the comparison would have terminated at $\nu < \theta$.

Thus we can assume without loss of generality that M_θ is a proper initial segment of N_θ. It follows by Lemma 3.36 that the iteration of M uses only ultrafilters with critical point smaller than the projectum; however, since the M and N strongly agree to τ the comparison uses only ultrafilters with critical point larger than τ, which in turn is larger then the projectum ρ^M. Thus M is never moved in the comparison, that is, $M_\theta = M$. ⊣

We are now ready to sketch a proof of Lemma 3.28 together with the existence of solidity witnesses:

3.40 Lemma. *If M is an iterable premouse then M is an iterated ultrapower of the mouse* $\operatorname{core}(M)$*, and M has a solidity witness for each $\nu \in p^M_k$ and $k < \omega$.*

Sketch of Proof of Lemmas 3.28 and 3.40. The proof is an induction over n, showing for each n that $\operatorname{core}_n(M)$ is an iterated ultrapower of $\operatorname{core}_{n+1}(M)$ and that p^M_{n+1} has solidity witnesses. We will give the proof for the case $n = 0$, beginning by showing that $M = \operatorname{core}_0(M)$ is an iterated ultrapower of $N = \operatorname{core}_1(M)$ (with critical point at least ρ^M_1) and will assume for the moment that N has solidity witnesses for all $\nu \in p^N_1$. Let $\pi : N \to M$ be the collapse map, and let $i : N \to N_\theta$ and $j : M \to M_\theta$ be the iterated ultrapowers comparing N and M. We begin by assuming that both maps have critical point at least ρ^M_1. Then neither side of the comparison can drop: if, say, the iterated ultrapower on M dropped then M_θ would be a proper initial segment of N_θ since A_1^M is definable in N_θ, but not in M_θ; however, this contradicts Lemma 3.36. Furthermore $N_\theta = M_\theta$ since A_1^M is definable in, but not a member of, each. Now the existence of solidity witnesses for p_1^N implies that $i(p_1^N) = p_1^{N_\theta} = j\pi(p_1^N)$, but this implies that $ih_1^N(\xi) = j\pi h_1^N(\xi)$ for all $\xi < \rho_1^M$. Since N is 1-sound it follows that $i = j\pi$.

If M is not an iterated ultrapower of N, then $M \neq M_\theta$ and j is not the identity. Let ν be the least stage in the ultrapower that $j_{\nu,\nu+1}$ is nontrivial, let U'_ν be the ultrafilter used at this point, and let $\eta = \mathrm{crit}(j)$ be its critical point. Then $\eta \notin j\pi h_1^N$"$\eta = ih_1^N$"η, and it follows that η is also the critical point of an ultrapower in i: that is, $i_{\nu,\nu+1} = i^{U_\nu}$ for an ultrafilter U_ν in N_ν, as in diagram (18.9):

$$\begin{tikzcd} N \arrow[r, "i_{0,\nu}"] \arrow[dr, "\pi"] & N_\nu \arrow[r, "i^{U_\nu}"] & N_{\nu+1} \arrow[r, "i_{\nu+1,\theta}"] & N_\theta \arrow[d, equal] \\ & M \arrow[r, "j_{0,\nu}"] & M_\nu \arrow[r, "j^{U'_\nu}"] & M_{\nu+1} \arrow[r, "j_{\nu+1,\theta}"] & M_\theta \end{tikzcd} \tag{18.9}$$

Let $x \subseteq \eta$ be a set in $N_\nu \cap M_\nu$ such that $x \in U_\nu \not\Longleftrightarrow x \in U'_\nu$. Then $x = h_1^{N_\nu}(\xi)$ for some $\xi < \eta$. We claim that $x = h_1^{M_\nu}(\xi)$ as well: to see this, note that $j_{\nu,\theta}(h_1^{M_\nu}(\xi)) = h_1^{M_\theta}(\xi) = h_1^{N_\theta}(\xi) = j_{\nu,\theta}(x)$, and each of $i_{\nu,\theta}$ and $j_{\nu,\theta}$ are the identity on η. Thus $i_{\nu,\theta}(x) = j_{\nu,\theta}(x)$, but this is impossible since then $x \in U_\nu \iff \nu \in i_{\nu,\theta}(x) \iff \nu \in j_{\nu,\theta}(x) \iff x \in U'_\nu$, contradicting the choice of x.

This completes the proof that M is an iterated ultrapower of $\mathfrak{C}_1(M)$, except for verifying that neither i nor j have critical point smaller than ρ_1^M. If this is false, then it must be that $\rho_1^M = \mu^{+M}$, where $\mu = \mathrm{crit}(\mathcal{U}_\gamma^M)$ for some $\gamma > \rho_1^M$, and $(\mu^{++})^N = (\mu^{++})^M \cap h_1^M$"$\rho_1^M < (\mu^{++})^M$. If $\gamma \geq (\mu^{++})^N$ is least such that $\mathcal{U}_\gamma^M$ is a measure on μ, then the measures in N with critical point μ are exactly the measures in $\mathcal{U}^M \restriction \gamma$. It follows that none of these measures will be applied in the comparison, and hence $\mathrm{crit}(i) \geq \rho_1^M$.

To see that $\mathrm{crit}(j) \geq \rho_1^M$ we need to use another basic result, the proof of which will be delayed until after the current proof is completed.

3.41 Lemma (Dodd-Jensen Lemma). *Suppose that N is an iterable premouse, $i : N \to P$ is an iterated ultrapower, and $k : N \to P$ is any Σ_0-elementary embedding. Then the range of k is cofinal in P, i does not drop, and $i(\alpha) \geq k(\alpha)$ for all $\alpha \in N$.*

Now if $\mathrm{crit}(j) = \mu < \mathrm{crit}(i)$, then $i(\mu) = \mu < j(\mu) = j\pi(\mu)$. This contradicts Lemma 3.41 with $P = N_\theta$, $k = i\pi$, and $\alpha = \mu$, and this contradiction completes the proof that M is an iterated ultrapower of $\mathrm{core}_1(M)$.

The proof that M has solidity witnesses is similar. Fix $\nu \in p_1^M$, set $p = p_1^M - (\nu + 1)$, and let $\pi : N \to M$ be the transitive collapse of the Σ_1

hull h_1^M"ν of $\nu \cup p$ in M. Recall that $A = \{\xi < \nu : M \models \Phi(\xi, p)\}$, the Σ_1 theory of $\nu \cup p$ in M, and R is the prewellordering of A defined by letting $\xi \, R \, \xi'$ if there is γ such that $J_\gamma^{\mathcal{U}} \models \Phi(\xi, p)$ and $\forall \gamma' < \gamma \; J_{\gamma'}^{\mathcal{U}} \models \neg\Phi(\xi', p)$ where Φ is the universal Σ_1 formula. Clearly A and R are Σ_1-definable in N. Let $i : N \to N_\theta$ and $j : M \to M_\theta$ be the iterated ultrapowers comparing N and M. By the same argument as before, $\mathrm{crit}(i) \geq \nu$. We claim that N_θ is a proper initial segment of M_θ, for if not, then Lemma 3.41 implies $\mathrm{crit}(j) \geq \nu$ by the same argument as before, and hence A is a member of M_θ; however, $A \notin N_\theta$ and hence $M_\theta \not\subseteq N_\theta$.

Now there is a $\tau \in M_\theta$ mapping A into the ordinals of N_θ such that $\forall \xi, \xi' \in A \; (\tau(\xi) \leq \tau(\xi') \iff \xi \, R \, \xi')$, namely the map defined by letting $\tau(\xi)$ be the least ordinal γ such that $J_\gamma^{\mathcal{U}^{M_\theta}} \models \Phi(\xi, i\pi^{-1}(p))$. This map is Σ_1-definable in N_θ and hence is a member of M_θ.

If j is the identity, then $M_\theta = M$ and hence $\tau \in M$ is the desired solidity witness. If j is not the identity, then it does not drop by Lemma 3.36 so either M has a full measure U with $\mathrm{crit}(U) \geq \nu$ or else there is a full measure $U \in M$ with $\mathrm{crit}(U) < \nu$ but $R \in \mathrm{Ult}(M, U)$. We observed following Definition 3.27 that either of these implies that M has a solidity witness that ν is in p_1^M, and this completes the proof of Lemma 3.40. $\dashv$

We outline the proof of Lemma 3.41. A full proof is given in Sect. 4 of chapter [57].

Sketch of the Proof of Lemma 3.41. Suppose that i and k are as in the hypothesis. We will define iterations $i_n : N_n \to N_{n+1}$ so that the direct limit $i^* = \dots i_3 i_2 i_1 i_0 : N_0 \to N_\omega$ is an iterated ultrapower on N. We will then see that if the conclusion fails then the iteration i^* contradicts the assumption that N is iterable.

The maps i_n and k_n are defined by recursion on n, starting by setting $N_1 = P$, $i_0 = i$ and $k_0 = k$. The recursion step uses a general copy process: using the notation of diagram (18.10), we set $i_{n+1} = k_n(i_n)$ and $k_{n+1} = i_n * k_n$.

To describe the copy process leading to diagram (18.10), suppose that $e : N \to P$ is an iterated ultrapower and $j : N \to P$ is a Σ_0-elementary embedding. We will define the copy map $j(e)$ and a map $e * j$ so that the following diagram commutes:

$$\begin{tikzcd}
P \arrow[r, "j(e)"] & N' \\
N \arrow[u, "j"] \arrow[r, "e"] & P \arrow[u, "e*j"']
\end{tikzcd} \tag{18.10}$$

The definition is by recursion on length of the iterated ultrapower e, with the induction step using the following diagram:

$$\begin{tikzcd} P_\nu \arrow[r, "e^{j_\nu(U_\nu)}"] & P_{\nu+1} \\ N_\nu \arrow[u, "j_\nu"] \arrow[r, "e^{U_\nu}"] & N_{\nu+1} \arrow[u, "j_{\nu+1}"'] \end{tikzcd} \tag{18.11}$$

Here $e^{U_\nu} : N_\nu \to N_{\nu+1}$ is the νth stage of the iteration e on N, $j_0 = j$, and $j_{\nu+1}$ is defined by $j_{\nu+1}([f]_{U_\nu}) = [j_\nu(f)]_{j_\nu(U_\nu)}$. The maps of diagram (18.10) are defined by letting $j(e)$ be the iteration using the maps $e^{j_\nu(U_\nu)}$ on the top row of diagram (18.11), and setting $e * j = j_\theta$ where θ is the length of the iteration.

Now suppose that the map i does contain a drop. Then each of the maps i_n contains a drop, and hence $i^* = \dots i_3 i_2 i_1 i_0 : N_0 \to N_\omega$ is a presumptive iteration on N containing infinitely many drops, contrary to the assumption that N is iterable. Hence i does not drop.

Now we will show that if either of the other clauses of the conclusion is false, then there are ordinals $\alpha_n \in N_n$ such that $i_n(\alpha_n) > \alpha_{n+1}$, so that the ordinals $\alpha'_n = \dots i_{n+1} i_n(\alpha_n)$ form an infinitely descending sequence of ordinals in N_ω, again contradicting the assumption that N is iterable. In the case that the range of k is bounded in $P = N_1$ a simple induction shows that the ordinals $\alpha_{n+1} = \sup(\mathrm{ran}(k_n)) \in N_{n_1}$ are as required. If $i(\alpha) > k(\alpha)$ for some $\alpha \in N$, then the ordinals $\alpha_n \in N_n$ are defined by recursion on n, setting $\alpha_0 = \alpha$ and $\alpha_{n+1} = k_n(\alpha_n)$. Then by induction on n we have $\alpha_{n+1} = k_n(\alpha_n) < i_n(\alpha_n)$ and $k_{n+1}(\alpha_{n+1}) = k_{n+1}k_n(\alpha_n) < k_{n+1}i_n(\alpha_n) = i_{n+1}k_n(\alpha_n) = i_{n+1}(\alpha_{n+1})$. ⊣

The Dodd-Jensen Core Model

The discussion above is valid for the core model up through $\exists\kappa\,(o(\kappa) = \kappa^{++})$. We now turn our attention to the Dodd-Jensen core model, and for this purpose we assume that $0^\dagger$ does not exist, and hence no mouse has any full measures except possibly for the final nontrivial measure on its sequence.

3.42 Definition. We will define the Dodd-Jensen core $K^{\mathrm{DJ}} = L[\mathcal{U}]$ by recursion as follows: Suppose $K^{\mathrm{DJ}}_\kappa = J_\kappa[\mathcal{U}\restriction\kappa]$ has been defined. Let $\mathcal{M}$ be the set of mice $M = J_{\alpha^M}[\mathcal{U}^M]$ such that M has no full measures, $\rho^M = \kappa$ and $\mathcal{U}^M\restriction\kappa = \mathcal{U}\restriction\kappa$. Then $K^{\mathrm{DJ}}_{\bar\kappa} = \bigcup\mathcal{M}$, where $\bar\kappa = \sup\{\alpha^M : M \in \mathcal{M}\}$.

To justify this definition of K^{DJ}, notice that Lemma 3.39 implies that of any two members M_0 and M_1 of $\mathcal{M}$, one is an initial segment of the other. Thus $K^{\mathrm{DJ}}_{\bar\kappa} = J_{\bar\kappa}[\mathcal{U}\restriction\bar\kappa]$ where $\mathcal{U}\restriction\bar\kappa = \bigcup\{\mathcal{U}^M : M \in \mathcal{M}\}$. The ordinal $\bar\kappa$ will be equal to κ^+ in K^{DJ}.

If there is no inner model with a measurable cardinal, then the core model K is equal to K^{DJ}. If there is an inner model with a measurable cardinal, but $0^\dagger$ does not exist, then $K = L[U]$, where the model $L[U]$ is chosen so that the critical point of the measure U of $L[U]$ is as small as possible.

Note that $K^{\mathrm{DJ}} = L$ if $0^{\#}$ does not exist. If $K = L[U]$, with U a measure on κ, then we can write $L[U] = L[\mathcal{U}]$ where, setting $\gamma = (\kappa^{++})^{K^{\mathrm{DJ}}}$, the sequence $\mathcal{U}$ has a largest member $\mathcal{U}_\gamma = U$ and $\mathcal{U}\restriction\gamma = \mathcal{U}^{\mathrm{DJ}}\restriction\gamma$.

The fact that a mouse is required to be iterable, while a level J_α of the L hierarchy is only required to be well-founded, makes the definition of a mouse logically more complicated than that of the sets J_α. For example, the statement $\exists\alpha\ (\omega, \mathrm{E}) \cong (J_\alpha, \in)$ is a Π^1_1 statement about the set $\mathrm{E} \subseteq \omega^2$, while the statement that (ω, E) is isomorphic to a mouse $J_\alpha[\mathcal{U}]$ is Π^1_2.

However, $(K^{\mathrm{DJ}})^M = K^{\mathrm{DJ}} \cap M$ whenever M is a transitive model of ZF containing ω_1, since the definition of a mouse is absolute for models containing ω_1 by Lemma 3.32.

It is not the case, as it is for L, that there is a sentence $V = K$ such that every class model of $V = K$ is equal to K. This can be seen by considering the class L, which may or may not be equal to K^{DJ}, depending on whether $0^{\#}$ exists. A more general example can be obtained by taking any mouse M in K^{DJ} with a measure U on κ, and let $\widetilde{M} = \mathrm{Ult}_{\mathrm{On}}(M, U)$. Then $i^U_{\mathrm{On}}(\kappa) = \mathrm{On}$, and the initial segment $\widetilde{M}|\,\mathrm{On} = V^{\widetilde{M}}_{\mathrm{On}}$ of $\widetilde{M}$ is a class model of ZFC $+\ V = K$ which is not equal to K^{DJ}. Notice, for example, that the critical points of the iteration form a closed and unbounded class of indiscernibles for $\widetilde{M}|\,\mathrm{On}$ which is definable in $L[M]$, and hence in K^{DJ}.

Vickers and Welch have observed [61] that the existence of a Ramsey cardinal implies that it is consistent that there is a proper class $X \prec K^{\mathrm{DJ}}$ such that $X \not\cong K^{\mathrm{DJ}}$.

The proof of Jensen's covering lemma for L relied on Kunen's result that the existence of a nontrivial embedding $i : L \to L$ implies that $0^{\#}$ exists. The proof of the covering lemma for K^{DJ} will rely on an analogous result, Lemma 3.47, stating that if $0^{\dagger}$ does not exist and there is a nontrivial elementary embedding $i : K^{\mathrm{DJ}} \to M$, then $K = L[U]$ for some measure U in K. In particular, if there is a nontrivial embedding $i : K^{\mathrm{DJ}} \to K^{\mathrm{DJ}}$, then $K \neq K^{\mathrm{DJ}}$, so that (assuming $0^{\dagger}$ does not exist) $K = L[U]$ for some measure U in K. However, Jensen has shown that it is not necessarily true, as one might expect, that U is the ultrafilter associated with i, or even that $\mathrm{crit}(U) = \mathrm{crit}(i)$. Notice that the model N of this proof gives an example of a mouse which is not a member of K, and of a mouse which is added by a set forcing.

3.43 Theorem. *Suppose that $L[U]$ satisfies that U is a measure on κ, and let G be $L[U]$-generic for the collapse of $\lambda = (\kappa^+)^{L[U]}$ onto ω. Then in $L[U, G]$ there is a fully iterable premouse N with measurable cardinal less than κ such that $J_\lambda(U)$ is an ultrapower of N. Hence there is an elementary embedding $i : K^{\mathrm{DJ}} \to K^{\mathrm{DJ}}$ with* $\mathrm{crit}(i) < \kappa$.

Proof. We will prove that the theorem is true in $\mathrm{Ult}(L[U], U)$, so that by elementarity it is true in $L[U]$ as well. Let $j : L[U] \to M = \mathrm{Ult}(L[U], U)$, let

$$\kappa' = j(\kappa), \qquad \lambda' = j(\lambda), \quad \text{and} \quad U' = j(U),$$

and let G be M-generic for the collapse of λ' onto ω. Let $\mathcal{L}$ be the infinitary language with a constant $\mathbf{x}$ for each member x of $J_{\lambda'}[U', G]$ and one additional constant $\mathbf{W}$ which will denote a measure on κ. Let T be the theory with sentences

$$\forall z\big(z \in \mathbf{x} \iff \textstyle\bigvee_{y \in x}(z = \mathbf{y})\big)$$

for each $x \in J_{\lambda'}[U', G]$, together with a sentence asserting that $\mathbf{W}$ is an amenable measure in $J_\lambda[\mathbf{W}]$ such that $\mathrm{Ult}(J_\lambda[\mathbf{W}], \mathbf{W}) \cong J_{\lambda'}[U']$. This theory is consistent because it is true in $L[U]$, so by the Barwise compactness theorem it has a model $\mathcal{A}$. Let $W = \mathbf{W}^{\mathcal{A}}$ and let N be the premouse $J_\lambda[W]$. Then $\mathrm{Ult}(N, W) = J_{\lambda'}[U']$ by the construction of W, and it follows that N is fully iterable since $J_{\lambda'}[U']$ is fully iterable.

Now K^{DJ} is equal to the initial segment of $\mathrm{Ult}_{\mathrm{On}}(N, W)$ below On, its measurable cardinal, and hence it follows easily that there is an embedding from K^{DJ} into K^{DJ} with critical point κ. $\dashv$

A major difference between the proof of the covering lemma for L and the proof of the covering lemma for $L[U]$ is that the proof of the analog Lemma 3.47 of Kunen's result itself uses the covering lemma. In order to avoid circularity we prove the covering lemma in two steps: the first step proves enough of the strength of the covering lemma to prove Lemma 3.47, using the following observation:

3.44 Lemma. *If U is a countably complete normal K^{DJ}-ultrafilter then U is a measure in $L[U]$, and $K^{\mathrm{DJ}} \subseteq L[U]$.*

Proof. Let $\kappa = \mathrm{crit}(U)$ and set $\gamma = (\kappa^{++})^{K^{\mathrm{DJ}}}$. Take $\mathcal{U}$ to be the sequence such that $K^{\mathrm{DJ}} = L[\mathcal{U}]$ and let $\mathcal{U}'$ be the good sequence defined by $\mathcal{U}' \restriction \gamma = \mathcal{U} \restriction \gamma$ and $\mathcal{U}'_\gamma = U$. We will show that $\mathcal{P}(\kappa)^{L[\mathcal{U}']} = \mathcal{P}(\kappa)^{K^{\mathrm{DJ}}}$, which implies that U is a measure in $L[\mathcal{U}']$, and hence in $L[U]$.

Suppose the contrary, and let α be the least ordinal such that there is a set $x \in \mathcal{P}(\kappa) \cap J_{\alpha+\omega}[\mathcal{U}'] - K^{\mathrm{DJ}}$. Now the model $J_\alpha[\mathcal{U}']$ need not be sound, but the iterability of $L[\mathcal{U}]$ and the countable completeness of U ensure that $J_{\alpha'}[\mathcal{U}]$ is iterable. Hence Lemma 3.28 implies that $J_\alpha[\mathcal{U}']$ is an iterated ultrapower of a mouse N, but this is impossible since any such mouse would be a member of K^{DJ}.

To see that $K^{\mathrm{DJ}} \subseteq L[U]$, suppose the contrary and use iterated ultrapowers to compare K^{DJ} with $K^{L[U]}$. Note that the latter is equal to $L[U]$, and can be written $L[\mathcal{U}'']$, where $\mathcal{U}''$ is constructed like the sequence $\mathcal{U}'$ above, but using $(K^{\mathrm{DJ}})^{L[U]}$ instead of the true K^{DJ}. If the iterated ultrapower beginning with K^{DJ} does not drop, then it must be trivial since there are no full measures in K^{DJ}, and this would imply $K^{\mathrm{DJ}} \subseteq L[U]$. If it does drop, on the other hand, then the iterated ultrapower of $L[U]$ does not drop, and the final model $L[U_\theta]$ of that iteration is an initial segment of the final model of the iteration on K^{DJ}.

Then that iteration would construct a class of indiscernibles for $L[U_\theta]$, which implies that $0^\dagger$ exists and in fact is a member of K^{DJ}, which is absurd. $\dashv$

The second part of the proof will use the following analog of the Condensation Lemma for L:

3.45 Lemma. *Assume that there is no inner model with a measurable cardinal, and that $X \prec K^{\mathrm{DJ}}$ is a class such that* $\mathrm{ot}(X \cap (\lambda^+)^{K^{\mathrm{DJ}}}) = (\lambda^+)^{K^{\mathrm{DJ}}} = \lambda^+$ *for a proper class of cardinals λ of K^{DJ}. Then $X \cong K^{\mathrm{DJ}}$.*

Sketch of Proof. Let N be the transitive collapse of X, and suppose to the contrary that $N \neq K^{\mathrm{DJ}}$. Then there is a mouse $M \in K^{\mathrm{DJ}} - N$. Now use iterated ultrapowers to compare the models M and N, and let M_θ and N_θ be the final models of the iterated ultrapower of M and N, respectively. Then N_θ must be a proper initial segment of M_θ, since there is a set $x \subseteq \rho^M$ which is definable in M but not in N. Then x is definable in M_θ, but not in N_θ so N_θ is a proper initial segment of M_θ and it follows by Corollary 3.38 that the iterated ultrapower on N does not drop. Since N does not contain any full ultrafilters it follows that the iterated ultrapower on N must be trivial, that is, $N = N_\theta$, and this implies that $\mathrm{ot}(X \cap (\lambda^+)^{K^{\mathrm{DJ}}}) = (\lambda^+)^N = (\lambda^+)^{M_\theta} < \lambda^+$ for every cardinal $\lambda > |M_\theta|$, contradicting the hypothesis. This contradiction completes the proof of Proposition 3.45. $\dashv$

The assumption that $(\lambda^+)^{K^{\mathrm{DJ}}} = \lambda^+$ is actually unnecessary here: any iterated ultrapower of K^{DJ} is a member of K^{DJ}, since it is a finite sequence of drops, separated by an iterated ultrapower by a single ultrafilter. In particular $M_\theta \in K^{\mathrm{DJ}}$.

The set Γ from Kunen's proof satisfies $|\Gamma \cap \lambda^+| = \lambda^+$ on a stationary set. Hence the importance of the weak covering property:

3.46 Definition. A cardinal λ is *countably closed* if $\eta^\omega < \lambda$ for all $\eta < \lambda$, and a model M has the *countably closed weak covering property* if for all sufficiently large countably closed singular cardinals λ we have $(\lambda^+)^M = \lambda^+$.

3.47 Lemma. *Suppose that $0^\dagger$ does not exist, and that K satisfies the countably closed weak covering property. If there is a nontrivial elementary embedding $i : K \to M$, then $K = L[U]$ where U is a measure in $L[U]$ with* $\mathrm{crit}(U) = \mathrm{crit}(i)$.

Proof. Set $\kappa = \mathrm{crit}(i)$. We can assume that $M = \{i(f)(\kappa) : f \in K\}$, for otherwise we could factor i as

$$i : K \xrightarrow{i'} M' \cong \{i(f)(\kappa) : f \in K\} \prec M,$$

and work with $i' : K \to M'$ instead of $i : K \to M$.

First we show that $K \neq K^{\mathrm{DJ}}$, so that $K = L[U]$ for some measure U. Suppose to the contrary that $K = K^{\mathrm{DJ}}$. We claim that in this case M also equals K^{DJ}: to see this, assume $M \neq K^{\mathrm{DJ}}$ and use iterated ultrapowers to compare M with K^{DJ}. The iteration on M is trivial, and the iteration on K^{DJ} drops and generates a closed and unbounded class I of indiscernibles for M. Then our assumption on i implies that $i^{-1}[I]$ is a class of indiscernibles for K^{DJ}, which would generate a countably complete K^{DJ}-measure U_{ω_1} on the limit of the first ω_1 members of I. By Lemma 3.47, it follows that U_{ω_1} is a measure in $L[U_{\omega_1}]$, contrary to our assumption that $K = K^{\mathrm{DJ}}$.

Thus $i : K^{\mathrm{DJ}} \to K^{\mathrm{DJ}}$, and we can apply the proof, sketched in chapter [32, Theorem 1.13], of Kunen's corresponding result for L. This involves defining a continuously descending sequence of classes Γ_α, beginning with $\Gamma_0 = \mathrm{ran}(i)$ and setting $\Gamma_{\alpha+1} = \{x \in \Gamma_\alpha : i_\alpha(x) = x\}$ where i_α is the transitive collapse of $\Gamma_\alpha \prec K$. The classes Γ_α contain all of their limit points of cofinality greater than κ, and if $\kappa < \nu \in \Gamma_\alpha$ then $|\Gamma_\alpha \cap \nu^+| = \nu^+$. Since $\nu^+ = \nu^{+K}$ by the weak covering property, it follows by Lemma 3.45 that $\Gamma_\alpha \cong K^{\mathrm{DJ}}$ for each ordinal α. Now the same argument as for L shows that if we set $\kappa = \mathrm{crit}(i)$ and $\kappa_\alpha = \min(\Gamma_\alpha - \kappa)$ then the class of ordinals $(\kappa_\alpha : \alpha \in \mathrm{On})$ is a closed and unbounded class of indiscernibles for K^{DJ}. It follows that $\{\kappa_\alpha : \alpha < \omega_1\}$ generates a normal K^{DJ}-measure U_{ω_1} on κ_{ω_1}, and since U_{ω_1} is countably complete it follows by Lemma 3.44 that U_{ω_1} is a measure in $L[U_{\omega_1}]$.

This completes the proof that $K = L[U]$ for some measure U. We must have $\mathrm{crit}(U) \geq \mathrm{crit}(i)$, for otherwise Kunen's argument for L implies directly that $0^\dagger$ exists. To see that $\mathrm{crit}(U) \leq \mathrm{crit}(i)$, assume to the contrary that $\lambda = \mathrm{crit}(U) > \kappa = \mathrm{crit}(i)$ and observe that it is true for $L[U]$, as it is for L, that $\mathcal{H}^{L[U]}(\Gamma) \cong L[U]$ for any proper class Γ of ordinals. Now $M = L[U']$, with $\lambda' = \mathrm{crit}(U') \geq \lambda = \mathrm{crit}(U)$, so there is an iterated ultrapower $j : K \to M$. Let $\Gamma = \{\nu : i(\nu) = j(\nu)\}$. Then Γ is a proper class, it contains its limit points of cofinality greater than λ, and $\kappa \notin \mathcal{H}^K(\Gamma) = \mathrm{On} \cap \Gamma$.

We will complete the proof by showing that this is impossible. First, note that the family of proper classes $\Gamma \prec L[U]$ which contain all of their limit points of cofinality greater than λ is closed under intersections of size at most λ. Hence there is such a class Γ' such that $\Gamma' \cap \lambda$ is as small as possible. Now if $k : L[U''] \cong \mathcal{H}^K(\Gamma')$ is the transitive collapse then, since $\mathrm{crit}(U)$ is as small as possible, $\mathrm{crit}(U'') = \mathrm{crit}(U) = \lambda$. However, there is some $\eta < \lambda$ so that $k(\eta) > \eta$. Then $k(\eta) \in \kappa \cap \mathcal{H}^K(\Gamma') - \mathcal{H}^K(\Gamma'')$, where $\Gamma'' = \{\nu : k(\nu) = \nu\}$, contrary to the choice of Γ'. $\dashv$

Part 1 of the Proof

The proof of the Dodd-Jensen covering lemma can be divided into two parts. The first part is a direct generalization of the proof of the covering lemma for L: it involves defining the basic construction for suitable sets $X \prec K_\kappa$, and showing that the class of suitable sets is unbounded. One of the two major novelties in this stage of the proof is the possible use of an iterated ultrapower in the construction. The second part of the proof, which has no analog for L, is used to analyze the indiscernibles generated by this iterated ultrapower.

In the case when this iterated ultrapower is infinite, these indiscernibles will yield a sequence C which is Prikry generic over $K = L[U]$.

The other major novelty arises from the fact that Lemma 3.47, which is needed in the proof, has the hypothesis that K satisfies the countably closed weak covering property. Thus we will, during part one of the proof, simultaneously prove two results, the first of which is the hypothesis to the second.

3.48 Lemma. *Assume that* $0^\dagger$ *does not exist.*

1. *The core model* K *satisfies the countably closed weak covering property.*
2. *If* K *satisfies the countably closed weak covering property, then it also satisfies the full Dodd-Jensen covering lemma, Theorems 1.12 and 1.13.*

Most of this proof will be reused in proving the covering lemma for sequences of measures; however, certain segments of the proof are substantially simplified by our assumption that $0^\dagger$ does not exist. This extra assumption is equivalent to the assumption that no premouse has more than one full ultrafilter.

The following definition will be valid up to a strong cardinal. We write K_κ for $J_\kappa[\mathcal{U}] = K \cap V_\kappa$.

3.49 Definition. Let $X \prec_1 K_\kappa$, with transitive collapse $\pi : \overline{K} \to X$, where $\overline{K} = L_{\bar\kappa}[\overline{\mathcal{U}}]$. We say that X is *suitable* if $\mathrm{Ult}_n(M, \pi, \beta)$ is iterable whenever $n \in \omega$, $\beta \leq \kappa$, and $M = J_\alpha[\mathcal{U}']$ is an iterable premouse (possibly with $\alpha = \mathrm{On}$) such that $\mathrm{Ult}_n(M, \pi, \beta)$ is defined and $\mathcal{U}'{\upharpoonright}\bar\beta = \overline{\mathcal{U}}{\upharpoonright}\bar\beta$ where $\bar\beta$ is the least ordinal such that $\pi(\bar\beta) \geq \beta$.

As in the proof of the covering lemma for L, we say that $X \prec_1 K_\kappa$ is *countably closed* if $X = Y \cap K_\kappa$, where ${}^\omega Y \subseteq Y$ and $Y \prec H(\tau)$ for some $\tau > \kappa$.

3.50 Lemma.

(i) Every countably closed set $X \prec_1 K_\kappa$ *is suitable, and*

(ii) the class of suitable sets X *is closed under increasing unions of uncountable cofinality, and is unbounded in* $H(\delta)^{(K_\kappa)}$ *for any uncountable cardinal* δ.

Sketch of Proof. The only difference between the proof of this lemma and the corresponding lemma for L is that we need to check that the model $\widetilde{M} = \mathrm{Ult}_n(M, \pi, \beta)$ is iterable rather than merely well-founded. This is straightforward for clause (i). For clause (ii) this involves changing Definition 3.18 of a witness to the unsuitability of X: Clause 3.18(2), stating that $\operatorname{dir\,lim}(\pi^{-1}(w)) = \mathfrak{C}_n(J_\alpha)$ for some ordinal α, is modified to require that $\operatorname{dir\,lim}(\pi^{-1}(w))$ be the Σ_n-code for some mouse. Clause 3.18(3), is modified to state that the witness w either the structure $\widetilde{M}_0$ of which $\operatorname{dir\,lim}(w)$ is the Σ_n-code is ill-founded, or else there is an ill-founded iteration of this structure.

The proof for both clauses relies on the fact that if there is an ill-founded iteration then there is one of countable length. $\dashv$

We are now ready to describe the basic construction. As in the proof of the covering lemma for L, we are given a suitable set $X \prec_1 K_\kappa$, and we let $\pi : \overline{K} = J_{\bar\kappa}[\overline{\mathcal{U}}] \cong X \prec_1 K_\kappa$ be the transitive collapse. We assume that X is not transitive, so that π is not the identity, and furthermore we assume that either X is countably closed or else K satisfies the countably closed weak covering property.

In order to postpone some complications which arise in the proof of the covering lemma for sequences of measures, we make the following additional assumption:

$$\begin{gathered}\text{If } K = L[U]\text{, where } U \text{ is a measure on a cardinal } \mu \text{ of } K\text{,}\\ \text{then either } (\mu^+)^K \subseteq X \text{ or else } \kappa \le (\mu^+)^K.\end{gathered} \tag{18.12}$$

This assumption does not involve any loss of generality: the case $(\mu^+)^K \subseteq X$ shows that any set x of size at most $(\mu^+)^K$ is contained in a set $y' \in K$ of size $(\mu^+)^K$, and then the case $\kappa \le (\mu^+)^K$ shows that x can be covered by a set $y \subseteq y'$ which satisfies Theorem 1.3. The case $(\mu^+)^K \subseteq X$ is a relativization of the proof for L and requires no new ideas.

In the proof for L, the next step was to set $M = J_\alpha$, where $\alpha \ge \bar\kappa$ was the least ordinal such that there is a bounded subset of $\bar\kappa$ in $J_\alpha - J_{\bar\kappa}$. If it happens that $\overline{\mathcal{U}} = \mathcal{U}{\restriction}\bar\kappa$ then we can similarly take $J_\alpha[\mathcal{U}]$, but in general we need to modify the construction by using iterated ultrapowers to compare the models $\overline{K} = J_{\bar\kappa}[\overline{\mathcal{U}}]$ and $K = L[\mathcal{U}]$. A key step of the proof is showing (see Lemma 3.51(2)) that $\overline{K}$ is never moved in this comparison, so that the final model of the iterated ultrapower on K is a model $M_\theta = J_{\alpha_\theta}[\mathcal{U}_\theta]$ such that $\overline{\mathcal{U}} = \mathcal{U}_\theta{\restriction}\bar\kappa$.

Thus we obtain the following variant of diagram (18.5), where each of the subset symbols indicate containment as an initial segment:

$$\begin{tikzcd} K \arrow[r, squiggly, "i"] & M_\theta \supseteq M \arrow[r, "\tilde\pi"] & \mathrm{Ult}_n(M,\pi,\kappa) = \widetilde{M} \\ & \overline{K} = J_{\bar\kappa}[\overline{\mathcal{U}}] \arrow[u, hook] \arrow[r, "\pi"] & X \prec K_\kappa \arrow[u, hook] \end{tikzcd} \tag{18.13}$$

We will write $M = J_\alpha[\mathcal{U}^M]$ and $\widetilde{M} = J_{\tilde\alpha}[\widetilde{\mathcal{U}}]$. As in diagram (18.5), $\overline{K}$ is the transitive collapse of the set X and π is the inverse of the collapse map. The iterated ultrapower is indicated by the wavy line from K to M_θ. Since this iteration drops whenever it is nontrivial (see Lemma 3.51(3)), the wavy line does not represent an embedding.

Once the model $M_\theta = J_{\alpha_\theta}[\mathcal{U}^{M_\theta}]$ has been constructed, diagram (18.13) is completed like diagram (18.5): Let $M = J_\alpha[\mathcal{U}^{M_\theta}]$, where (α, n) is the largest pair $(\alpha, n) \leq (\alpha_\theta, n_\theta)$ such that $\mathrm{Ult}_n(J_\alpha[\mathcal{U}^{M_\theta}], \pi, \kappa)$ is defined. Thus α is the least ordinal such that there is a bounded subset x of κ which is definable in $J_\alpha[\mathcal{U}_\theta]$ but is not a member of $\overline{K}$. Finally, set $\widetilde{M} = \mathrm{Ult}_n(M, \pi, \kappa)$.

3.51 Lemma. *Assume that $0^\dagger$ does not exist. Let $X \prec_1 K_\kappa$ be a suitable set which is not transitive, so that the collapse $\pi : \overline{K} \cong X \prec_1 K_\kappa$ is not the identity. Finally, assume that either X is countably complete or else K has the countably closed weak covering property.*

1. *$\mathcal{P}^K(\eta) \not\subseteq \overline{K}$, where $\eta = \mathrm{crit}(\pi)$.*
2. *In the comparison of K and $\overline{K}$, the iterated ultrapower on the model $\overline{K}$ is trivial.*
3. *Either $\overline{K}$ is an initial segment of K, or else $1 \in D$, so that the iterated ultrapower on K drops immediately.*
4. *$\overline{K}$ is an initial segment of the final model M_θ of the iteration of K.*
5. *$\widetilde{M} \in K$.*

Sketch of Proof. If clause 1 fails then $U' = \{x \in \mathcal{P}^{\overline{K}}(\eta) : \eta \in \pi(x)\}$ is a K-ultrafilter. If X is countably closed then U' is countably complete, so Lemma 3.44 implies that U' is a measure in $L[U']$. If K has the countably closed weak covering property then $\mathrm{Ult}(K, U')$ is well-founded since it can be embedded into $\mathrm{Ult}(K, \pi, \kappa)$, which is well-founded by the definition of suitability, so Lemma 3.47 implies that $K = L[U]$ where $\mathrm{crit}(U) \leq \mathrm{crit}(U')$. Thus, under the hypothesis of either clause of Lemma 3.48, $K = L[U]$ for some measure U with $\mathrm{crit}(U) \leq \mathrm{crit}(i)$; but this is impossible: if $\mathrm{crit}(U) < \mathrm{crit}(i)$ then it would follow that $0^\dagger$ exists, contrary to the hypothesis, while if $\mathrm{crit}(U) = \mathrm{crit}(i)$ then $\mathrm{crit}(U)$ would be definable in K_κ as the only measurable cardinal, and hence would be in X.

To see that the ultrapower on $\overline{K}$ is trivial, first note that the extra assumption (18.12) on X implies that any full measure in $\overline{K}$ is contained in K_η. Thus the iterated ultrapower on $\overline{K}$ must be trivial unless it drops. By Lemma 3.38 this would imply that the iterated ultrapower on K does not drop, and its final model M_θ is an initial segment of the final model above $\overline{K}$; but this is absurd, since $\overline{K}$ is a set and M_θ is a proper class.

To verify clause 3, note that if $\overline{K}$ is not an initial segment of K then the iterated ultrapower on K is nontrivial; however, again using (18.12), any full ultrafilter in K with critical point smaller than η would also be in $\overline{K}$, and hence would not be used in the iteration. Thus the iterated ultrapower on K must drop immediately.

Clause 4 follows from clause 2, so it only remains to check clause 5, stating that $\widetilde{M} \in K$. If $\widetilde{M}$ has no full measure $U = \mathcal{U}^{\widetilde{M}}_\gamma$ with $\mathrm{crit}(U) < \kappa$, then $\widetilde{M}$

is iterable because of the suitability of X. Now $\widetilde{M}$ is sound above κ, because of its construction as an ultrapower $\mathrm{Ult}(M, \pi, \kappa)$. On the other hand, the projectum ρ of $\widetilde{M}$ cannot be smaller that κ, as otherwise $\widetilde{M}$ would be an iterated ultrapower of a mouse M' of size at most ρ, but this is impossible since then $M' \in K_\kappa \subseteq M$. It follows that $\widetilde{M}$ is sound, and hence is a member of K.

Now it will be sufficient to show that there is no full measure U in $\widetilde{M}$ with $\mu = \mathrm{crit}(U) < \kappa$. First, we observe that any such measure U would have to satisfy $\kappa = {\mu^+}^K$: otherwise $\kappa > (\mu^+)^K$, so $U = \mathcal{U}^{\widetilde{M}}_\gamma$ for some $\gamma < \kappa$. Then $\tilde{\pi}^{-1}(U) = \mathcal{U}^M_{\pi^{-1}(\gamma)}$, with $\pi^{-1}(\gamma) < \bar{\kappa}$. By the construction it follows that $\tilde{\pi}^{-1}(U) \in \overline{K}$, so $U \in K$, contradicting the special assumption (18.12).

Hence the following lemma will prove that there is no full measure U in $\widetilde{M}$ with $\mu = \mathrm{crit}(U) < \kappa$, and hence will complete the proof of Lemma 3.51:

3.52 Lemma. *κ is not a successor cardinal in K.*

Proof. We will first assume that there is no measure in $\widetilde{M}$ with critical point below κ. We will show that if κ is a successor in K then there is an $\eta < \kappa$ such that $X = \tilde{h}``(X \cap \eta)$, which implies that κ is singular in K and hence is not a successor. To do so we will need to consider the indiscernibles generated by the iteration i.

If $M \neq M_\theta$ then M is a proper initial segment of the potential premouse M_θ. It follows that M is sound and is hence a mouse. In this case the proof proceeds exactly as in that of the covering lemma for L, and leads to the conclusion that $X = \tilde{h}``(X \cap \rho)$, where $\tilde{h}$ comes from Lemma 3.10 and $\rho = \pi(\rho^M_{m+1})$ where m is least such that $\rho^M_{m+1} < \bar{\kappa}$.

Thus we can assume that $M = M_\theta$. Then Lemma 3.51(3) states that $1 \in D$, so $D \neq \varnothing$. Let $\nu_0 + 1 < \theta$ be the largest member of D. Then M_θ is an iterated ultrapower (without drops) of the potential premouse $M^*_{\nu_0+1}$, which is an initial segment of M_{ν_0}. All of the remaining ultrapowers have the same degree n, and $M^*_{\nu_0+1}$ is n-sound. Let $\overline{C} = \{i_{\nu_0,\nu}(\kappa_{\nu_0}) : \nu_0 < \nu < \theta\}$, where $i_{\nu_0,\nu} : M^*_{\nu_0+1} \to M_\nu$. Then $\overline{C}$ is a sequence of indiscernibles for M_θ.

Let $\bar{\rho}$ be the Σ_n projectum of M, which is equal to the Σ_n projectum of $M^*_{\nu_0+1}$, and let $\bar{h}$ be the Σ_n-Skolem function of M_θ. Then

$$M_\theta = \bar{h}``(\bar{\rho} \cup \overline{C}) \tag{18.14}$$

by the soundness of $M^*_{\nu_0+1}$ and Lemma 3.26. Now let $\rho = \sup(\pi``\bar{\rho})$ and $C = \pi``\overline{C}$. If $\tilde{h} = \tilde{h}^X$ is the function given by Lemma 3.10, then it follows that $X = K_\kappa \cap \tilde{\pi}``M_\theta = K_\kappa \cap \tilde{\pi}h``(\bar{\rho} \cup \overline{C}) = \tilde{h}\pi``(\bar{\rho} \cup \overline{C}) \subseteq \tilde{h}``(\rho \cup C)$.

Now $\overline{C}$ cannot be unbounded in $\bar{\kappa}$: $\bar{\kappa}$ is not a limit cardinal in M since κ is not a limit cardinal in K, but each member of $\overline{C}$ is a cardinal in M. Thus $X \subseteq \tilde{h}``\eta$ where $\eta = \sup(\rho \cup C) < \kappa$, as claimed.

This completes the proof in the case that there is no measure $U \in \widetilde{M}$ with $\mathrm{crit}(U) < \kappa$. If there is such a measure then, as was pointed out at the end of the proof of Lemma 3.51, $\kappa = (\mu^+)^K$ where $\mu = \mathrm{crit}(U)$. In this case set $M' = \mathrm{Ult}_n(M, \overline{U})$ where $\overline{U} = \tilde{\pi}^{-1}(U)$. The same argument as above shows that $\widetilde{M'} = \mathrm{Ult}(M', \pi, \kappa) \in K$. In this case M' and $\widetilde{M'}$ should be used in place of M and $\widetilde{M}$ in proof above. Note that M' is the result of carrying out one more step in the iteration i of which M_θ is the last model. ⊣

This completes the proof of Lemma 3.52, and hence of Lemma 3.51, and we can now finish the proof of clause 1 of Lemma 3.48:

3.53 Corollary. *If* $0^\dagger$ *does not exist then* K *satisfies the countably closed weak covering property.*

Sketch of Proof. Suppose to the contrary that λ is a countably closed singular cardinal, and that $\kappa = \lambda^{+K} < \lambda^+$. Then $\mathrm{cf}(\kappa) \leq \lambda$, and since λ is singular it follows that $\mathrm{cf}(\kappa) < \lambda$. Since λ is countably closed it follows that $\mathrm{cf}(\kappa)^\omega < \lambda$, so there is a set $Y \prec H(\kappa^+)$ with $Y^\omega \subseteq Y$ and $|Y| = \mathrm{cf}(\lambda)^\omega < \kappa$ such that $Y \cap \kappa$ is cofinal in κ. Thus $X = Y \cap K_\kappa$ is countably closed, and hence is suitable, contradicting Lemma 3.52. ⊣

Part 2 of the Proof: Analyzing the Indiscernibles

We have now constructed all of the elements of diagram (18.13) and we have proved the countably closed weak covering lemma. In order to complete the proof of Lemma 3.48(2), and hence of Theorems 1.12 and 1.13, the strong covering lemma below $0^\dagger$, we need to study in more detail the indiscernibles C introduced in the proof of Lemma 3.52. The use of indiscernibles from an iterated ultrapower as a Prikry sequence is discussed in Sect. 2.2 of chapter [32].

Fix, for the moment, an arbitrary suitable set X. We need to find $f \in K$ and $\eta < \kappa$ such that either $X = f``(\eta \cap X)$ or else $C$ is a Prikry sequence and $X = f``(C \cup (\eta \cap X))$. Furthermore, we want to show that the Prikry sequence C, if it is exists, is unique modulo finite differences.

Equation (18.14) states that $M = h``(\rho \cup \overline{C})$. This statement can be strengthened:

$$\forall \xi \in \bar{\kappa} - \overline{C} \;\; \xi \in \bar{h}``(\bar{\rho} \cup (\overline{C} \cap \xi)). \tag{18.15}$$

Now let $\rho = \sup(\pi``\bar{\rho})$ and $C = \pi``\overline{C}$. If $\tilde{h} = \tilde{h}^X$ is the function given by Lemma 3.10, then it follows that $X = \tilde{h}``((X \cap \rho) \cup C)$, and if $\xi \in X \cap \kappa$ then $\xi \in \tilde{h}``((X \cap \rho) \cup (C \cap \xi + 1))$.

If $\overline{C}$ is finite then we can define $f(x) = \tilde{h}^X(x, C)$, so that $f \in K$ and $X = f``(X \cap \rho^X)$. Thus the first of the desired alternatives hold.

For the remainder of the proof, we will assume that C is infinite. We use a superscript X to designate the results of applying this construction to the arbitrary suitable set X.

3.54 Definition. Let $\mathbf{C}$ be the class of suitable sets X such that either C^X is finite or else $K = L[U]$, the set C^X is a Prikry sequence for U, and C^X is maximal in the sense that $C - C^X$ is finite whenever C is any other Prikry sequence for $L[U]$.

Notice that C^X and $C^{X'}$ differ only finitely for any two sets $X, X' \in \mathbf{C}$ such that C^X and $C^{X'}$ are both infinite.

The following lemma will complete the proof of the Dodd-Jensen covering lemma:

3.55 Lemma. *If $0^\dagger$ does not exist then the class $\mathbf{C}$ is closed under increasing unions of uncountable cofinality, and is unbounded in $[K_\kappa]^\delta$ whenever κ is a cardinal of K and δ is an uncountable regular cardinal.*

The proof of this lemma will take up the rest of Sect. 3.3. We already know that the class of unsuitable sets is nonstationary, and by the comments above, we can assume that C^X is infinite for all but a nonstationary set of sets X.

First we show, assuming Lemma 3.55 is true for all cardinals $\mu < \kappa$, that $\mathrm{ot}(C^X) = \omega$ on all but a nonstationary set. Assume the contrary; then there is a $\mu < \kappa$ such that the ω^{th} member C^X of C^X is equal to μ for stationarily many sets X. Since the induction hypothesis states that the covering lemma holds for $C \cap K_\mu$, there is a X with $\mu^X = \mu$ such that $X \cap K_\mu \in \mathbf{C}$, but this implies that $K = L[U]$ where U is a measure on μ. Now this measure U must be in X, and is generated by $C^X \cap \mu$. Thus the iterated ultrapower from diagram (18.13) which was used to generate $\overline{C}$ would not continue past $(\pi^X)^{-1}(\mu)$, and hence $\overline{C}^X \subseteq (\pi^X)^{-1}(\mu)$. This contradicts the assumption that $C^X \not\subseteq \mu$, and completes the proof that C^X has order type ω except on a nonstationary set.

The proof of Lemma 3.55 is based on the following observation:

3.56 Proposition. *Suppose that X is suitable and $X = Y \cap K_\kappa$ where $Y \prec H(\kappa^+)$ and $C^X \in Y$. Then $X \in \mathbf{C}$.*

Proof. First we show that U is a measure in $L[U]$. Since the members of $\overline{C} = \pi^{-1}(C^X)$ come from the iteration of the unique full measure of M_θ, they generate the final measure $\overline{U}$ of the measure sequence of that model. Thus the filter U is the final measure in the measure sequence $\widetilde{\mathcal{U}}$ of $\widetilde{M} = J_{\tilde{\alpha}}[\widetilde{\mathcal{U}}]$. It follows that $\widetilde{\mathcal{U}} \in Y$ since $U \in Y$. If γ is the least ordinal such that U is not a measure in $J_\gamma[\widetilde{\mathcal{U}}]$, then $\gamma \in Y$ and hence $(\pi^N)^{-1}(J_\gamma[\widetilde{\mathcal{U}}]) = J_{\bar{\gamma}}[\mathcal{U}^M]$ is in the transitive collapse N of Y. Evidently $\bar{\gamma} \geq \mathrm{On}(M)$ since $\overline{U}$ is a measure in M, but this is impossible since there is a bounded subset of $\bar{\kappa}$ which is definable in M but is not in $\overline{K} = H(\bar{\kappa})^N$.

Thus C^X is a Prikry sequence for the measure U, and if C^X fails to satisfy Definition 3.54 then it is because there is another Prikry sequence C' such that $C' - C$ is infinite. Then by elementarity there is such a sequence C' which is a member of Y. Then $C' \subseteq X$, so any member α of $C' - C^X$ is in $\tilde{h}^X``(\tilde{\rho}^X \cup (C \cap \alpha)) \subseteq h^X``\alpha$, and since $\tilde{h}^X \in K = L[U]$ it follows that $C' - C^X$ is finite since C' is a Prikry sequence. ⊣

3.57 Corollary. *If X is countably closed then $X \in \mathbf{C}$.*

Now we will deal with the proof of Lemma 3.55 for non-countably closed sets X. This proof uses the ideas of the proof of Lemma 3.50, stating that the class of suitable sets is unbounded, but is significantly more difficult. We use the notation $a \subseteq^* b$ to mean that $a - b$ is finite, and $a =^* b$ to mean that $a \subseteq^* b$ and $b \subseteq^* a$.

3.58 Lemma. *If X_0, X_1 are suitable and $X_0 \subseteq X_1$, then $C^{X_1} \cap X_0 \subseteq^* C^{X_0}$.*

Proof. We will use subscripts 0 and 1 to distinguish objects defined from X_0 or X_1; for example we write $\pi_0 = \pi^{X_0}$ and $\pi_1 = \pi^{X_1}$. We will find a function h^*, definable in $M_1 = M^{X_1}$, such that $\xi \in h^*``\xi$ for all but boundedly many $\xi \in \pi_1^{-1}((C_1 \cap X_0) - C_0)$. Since this can only hold for finitely many $\xi \in \pi_1^{-1}(C_1)$, this will imply that $C_1 \cap X_0 \subseteq^* C_0$.

To this end, let ν be any member of $X_0 \cap (C_1 - C_0)$ and set $\nu_0 = \pi_0^{-1}(\nu)$. Then $\nu_0 \notin \overline{C}_0$, so $\nu_0 \in h_0``\nu_0$ where h_0 is the Skolem function of $M_0 = M^{X_0}$. Now let $\tau = \pi_1^{-1} \circ \pi_0 : \overline{K}_0 \to \overline{K}_1$, and let

$$\tilde{\tau} : M_0 \to M^* = \mathrm{Ult}(M_0, \tau, \bar{\kappa}_1).$$

Then $\nu_1 = \tau(\nu_0) \in h^*``\nu_1$ where h^* is given by Lemma 3.10. But M^* is sound above $\bar{\kappa}_1$, and agrees with $\bar{K}_1$ up to $\bar{\kappa}_1$, so by Lemma 3.39 one of M^* and M_1 is an initial segment of the other. Since every bounded subset of $\bar{\kappa}$ in M^* is a member of $\bar{K}_1$, it must be that M^* is an initial segment of M_1 and it follows that h^* is definable in M_1 from some parameter q. Since $\nu \in X_0 \cap (C_1 - C_0)$ was arbitrary, it follows that $X_0 \cap (C_1 - C_0)$ is finite, that is, $C_1 \cap X_0 \subseteq^* C_0$. ⊣

3.59 Corollary. *The class $\mathbf{C}$ is uncountably upward closed.*

Proof. Suppose that $X = \bigcup_{\xi<\eta} X_\xi$ is an increasing union of sets $X_\xi \in \mathbf{C}$ such that $\mathrm{cf}(\eta) > \omega$. Then X is suitable since the class of suitable sets is closed under uncountable increasing unions, and $C^X \subseteq X_\xi$ for some $\xi < \eta$ so $C^X \subseteq^* C^{X_\xi}$ by Lemma 3.58. In particular, the fact that C^{X_ξ} is a Prikry sequence for the measure U implies that C^X is a Prikry sequence for the same measure.

To complete the proof that $X \in \mathbf{C}$ we need to show that C^X is maximal, and since C^{X_ξ} is maximal it is sufficient to show that $C^{X_\xi} \subseteq^* C^X$. Now if ν is any member of $C^{X_\xi} - C^X$, then $\nu \in \tilde{h}``\nu$ where $\tilde{h}$ is the function given by Lemma 3.10. But since $C^{X_\xi}$ is a Prikry sequence over $K$ and $\tilde{h} \in K$, it follows that $C^{X_\xi} - C^X \subseteq \{\nu \in C^{X_\xi} : \nu \in \tilde{h}``\nu\}$ is finite, so $C^{X_\xi} \subseteq^* C^X$. ⊣

The following lemma completes the proof of the Dodd-Jensen covering lemma. We give a proof which is somewhat different from that given by Dodd and Jensen in [11], as that proof does not easily adapt to larger core models.

3.60 Lemma. *If δ is a regular cardinal and κ is a cardinal of K then $\mathbf{C}$ is unbounded in $[K_\kappa]^\delta$.*

Proof. As in the proof of the covering lemma for L, we work in the space $\mathrm{Col}(\delta, K_\kappa)$. If $\sigma \in \mathrm{Col}(\delta, K_\kappa)$ then we will sometimes identify σ with $\mathrm{ran}(\sigma)$, especially when it appears as a superscript. Let S be the set of functions $\sigma \in \mathrm{Col}(\delta, K_\kappa)$ such that $\mathrm{cf}(\mathrm{dom}(\sigma)) > \omega$ and $\mathrm{ran}(\sigma)$ is suitable, but $\mathrm{ran}(\sigma) \notin \mathbf{C}$, and suppose for the sake of contradiction that S is stationary in $\mathrm{Col}(\delta, K_\kappa)$. By Lemma 3.23 there is a $\sigma_0 \in S$ and a stationary set $S_0 \subseteq S$ such that $\sigma \supseteq \sigma_0$ and $C^\sigma \subseteq \mathrm{ran}(\sigma_0)$ for all $\sigma \in S_0$. Thus $C^\sigma \subseteq^* C^{\sigma_0}$ for all $\sigma \in S_0$ by Lemma 3.58. Set $C_0 = C^{\sigma_0}$.

As in the proof of the covering lemma for L, we define, for each member of S_0, a witness $w(\sigma)$ to the fact that $\mathrm{ran}(\sigma) \notin \mathbf{C}$:

3.61 Claim. *There is a function w mapping each member σ of S_0 to a countable subset of $\mathrm{ran}(\sigma)$ such that for any $\sigma_1, \sigma_2 \in S_0$ such that $\sigma_1 \subseteq \sigma_2$ and $w(\sigma_2) \subseteq \mathrm{ran}(\sigma_1)$ we have $C^{\sigma_1} \subseteq^* C^{\sigma_2}$.*

First we show that the lemma follows from this claim. By applying Lemma 3.23 a second time, we can find an $\sigma_1 \in S_0$ and a stationary set $S_1 \subseteq S_0$ so that $\sigma_1 \subseteq \sigma$ and $w(\sigma) \subseteq \mathrm{ran}(\sigma_1)$ for all $\sigma \in S_1$. If σ is any member of S_1 then $C^{\sigma_1} \subseteq^* C^\sigma$ by Claim 3.61 and $C^\sigma \subseteq^* C^{\sigma_1}$ by Lemma 3.58. Thus $C^\sigma =^* C^{\sigma_1}$ for all $\sigma \in S_1$.

Since S_1 is stationary, there is a $\sigma \in S_1$ such that $\mathrm{ran}(\sigma) = Y \cap K_\kappa$ for some $Y \prec H(\kappa^+)$ with $C^{\sigma_1} \in Y$. Since $C^\sigma =^* C^{\sigma_1}$ it follows that $C^\sigma \in Y$. This implies $\mathrm{ran}(\sigma) \in \mathbf{C}$ by Lemma 3.56, contradicting the fact that $\sigma \in S_1 \subseteq S_0$. This contradiction shows that S_0 is not stationary, and hence $\mathbf{C}$ is unbounded.

Proof of Claim 3.61. We will fix $\sigma \in S_1$ for the moment in order to define $w(\sigma)$. The critical point is that $C^\sigma \subseteq^* C^{\sigma_0}$, so that C^σ is determined, up to a finite set, by $D = C^{\sigma_0} - C^\sigma$. If D is finite then we can set $w(\sigma) = \varnothing$, so we will assume that D is infinite. Let $\langle d_k : k < \omega \rangle$ enumerate D in increasing order, and set $\bar{d}_k = \pi^{-1}(d_k)$. Then $\bar{d}_k \in h^M$ "d_k, where h^M is the Skolem function for the premouse M of diagram (18.13).

To define the function w we modify Definition 3.18 of a witness to the unsuitability of X by replacing clause 3 with the statement that there is a function h which is Σ_n-definable over $\operatorname{dir\,lim}(w)$ such that $d \in h$"d for all $d \in D$.

To see that this witness function $w(\sigma)$ satisfies Claim 3.61, let $\sigma_1 \subseteq \sigma$ be a member of S_0 with $w(\sigma) \subseteq \mathrm{ran}(\sigma_1)$. Write π_1 for π^{σ_1}, and set $\tau = \pi_1^{-1}\pi : \overline{K}^{\sigma_1} \to \overline{K}^{\sigma}$. If $\bar{\mathfrak{m}} = \operatorname{dir\,lim}(\pi_1^{-1}(w(\sigma)))$ then the map τ extends to an elementary embedding $\tilde{\tau} : \bar{\mathfrak{m}} \to \mathfrak{m}$, so $\bar{\mathfrak{m}}$ is also a premouse. The measure on $\bar{\kappa}_1$ in $\bar{\mathfrak{m}}$ is generated by the indiscernibles $\tau^{-1}(\overline{C}^{\sigma}) = \pi_1^{-1}(C^\sigma)$, and since $C^\sigma \subseteq^* C^{\sigma_1}$ it follows that this measure is equal to the measure in M^{σ_1}. Thus $\bar{\mathfrak{m}}$ strongly agrees with M^{σ_1} up to $\bar{\kappa}_1$. Since both premice are sound above $\bar{\kappa}_1$ it follows that one is an initial segment of the other. Now if M^{σ_1} were a proper initial segment of $\bar{\mathfrak{m}}$, then there would be a bounded subset x of $\bar{\kappa}_1$

in $\bar{\mathfrak{m}} - \overline{K}^{\sigma_1}$. This is not the case, since every bounded subset of $\bar{\kappa}_1$ in $\bar{\mathfrak{m}}$ is in some $\bar{\mathfrak{m}}_k \in \overline{K}^{\sigma_1}$, so $\bar{\mathfrak{m}}$ must be an initial segment of M^{σ_1}. Hence, the Skolem function of $\bar{\mathfrak{m}}$ is definable in M^{σ_1}, and thus every sufficiently large member d of $\pi_1^{-1}(D)$ is in $h^{M^{\sigma_1}}$ "d. It follows that $D \cap C^{\sigma_1}$ is finite, which is to say that $C^{\sigma_1} \subseteq^* C^{\sigma}$, as was to be proved. ⊣

This completes the proof of Lemma 3.60, and hence of the Dodd-Jensen covering lemma, Theorems 1.2 and 1.3. ⊣

3.4. Unsuitable Covering Sets

As we have seen, the proof of the covering lemma for L shows, assuming $\neg 0^{\#}$, that every suitable set is in L. This striking fact suggests that the proof may also have something to say about sets X which are not suitable. Some restrictions on X are certainly needed: for example, if X is a Cohen generic subset of some uncountable regular cardinal τ then any unbounded $y \subseteq \tau$ in L intersects both X and its complement $\tau - X$. Thus we will retain the first order part of the definition of suitability: we assume that $X \prec_1 J_\kappa$ (or $X \prec_1 K_\kappa$ in the case of larger core models) but omit the second-order condition that $\widetilde{M}^X$ is well-founded and (in the case of K) that C^X is a maximal Prikry sequence. This one idea leads to two separate results: For L, or more generally if there is no ω_1-Erdős cardinal in K, it gives Magidor's Covering Lemma, 1.15, while in the presence of larger cardinals it gives Theorem 1.16 stating that Jónsson and Ramsey cardinals relativize to K.

We recall the statement of Magidor's Covering Lemma 1.15 for L. This statement follows [31] in using the hypothesis that X is primitive recursively closed instead of $X \prec_1 J_\kappa$, but we do not verify that this weaker condition is sufficient.

3.62 Theorem. *Suppose that $0^{\#}$ does not exist and that X is a primitive recursively closed subset of J_κ, and let $\delta = \inf(\kappa - X)$. Then there are functions $h_i \in L$ for $i < \omega$ such that $X \cap \kappa = \bigcup_{i<\omega} h_i$ "δ.*

Sketch of Proof. Like the covering lemma, this theorem is proved by induction on κ. Suppose that $X \prec_1 J_\kappa$. If $\operatorname{cf}(\kappa) = \omega$, say $\kappa = \bigcup_{n<\omega} \kappa_n$, then $X = \bigcup_{n<\omega}(J_{\kappa_n} \cap X)$, so the truth of the theorem for X follows from its truth for each of the sets $X \cap J_{\kappa_n}$ for $n < \omega$. Thus we can assume that $\operatorname{cf}(\kappa) > \omega$. In addition we can assume that κ is a cardinal in L, that X is cofinal in κ, and that $\kappa \not\subseteq X$. Note that we do not assume that $|X| < \kappa$.

The proof begins exactly like that of the covering lemma, with the transitive collapse $\pi : N = J_{\bar{\kappa}} \cong X \subseteq J_\kappa$. Thus $\delta = \operatorname{crit}(\pi) < \kappa$.

If X is suitable then $X \in L$ by the proof of the covering lemma, so we can assume that X is not suitable. We recall the construction, given in Lemma 3.19, of a witness to the unsuitability of X. There is a triple (α, n, β), with $\beta < \kappa$, such that $\operatorname{Ult}_n(J_\alpha, \pi, \beta)$ is defined but not well-founded. Let (α, n, β) be the least such triple, in the lexicographic ordering, and pick

$f_i \in J_\alpha$ and $a_i \in [\beta]^{<\omega}$ for $i < \omega$ so that $[a_{i+1}, f_{i+1}]_\pi \mathrel{\mathrm{E}} [a_i, f_i]_\pi$, where E is the membership relation in the ultrapower. Then $\beta = \sup(\bigcup_i a_i)$, and since $\mathrm{cf}(\kappa) > \omega$ it follows that $\beta < \kappa$. We will show that there are functions $h_i \in L$ such that $X = \bigcup_{i<\omega} h_i``(X \cap \beta)$. The truth of the theorem for X then follows by applying the induction hypothesis to the set $X \cap \beta$.

In order to simplify notation we will assume that $n = 0$ and that α is a limit ordinal. We make two observations:

1. We can choose $\langle f_i : i < \omega\rangle$ so that $J_\alpha = \mathcal{H}^{J_\alpha}_{\Sigma_1}(\beta \cup \{f_i : i < \omega\})$. If this is not true for the original choice of functions f_i, then let $\mathcal{M}' = J_{\alpha'}$ be the transitive collapse of $\mathcal{H}^{J_{\alpha_i}}_{\Sigma_1}(\beta \cup \{f_i : i < \omega\})$. Then $\alpha' \le \alpha$ and $\mathrm{Ult}(J_{\alpha'}, \pi, \beta)$ is ill-founded, so $\alpha' = \alpha$ by the minimality of α. The original functions f_i may be moved in the collapse, but we can replace them by their images under the collapse.

2. If $\alpha_i < \alpha$ is the least ordinal such that $f_i \in J_{\alpha_i}$ and $\mathcal{M}_i$ is the transitive collapse of $\mathcal{H}^{J_{\alpha_i}}_{\Sigma_1}(\bar\kappa \cup \{f_0, \ldots, f_i\})$, then $\widetilde{\mathcal{M}}_i = \mathrm{Ult}(\mathcal{M}_i, \pi, \kappa)$ is well-founded. To see this, note that $\mathrm{Ult}(J_{\alpha_i}, \pi, \kappa)$ is well-founded by the minimality of the triple (α, n, β), and $\widetilde{\mathcal{M}}_i$ is a substructure of $\mathrm{Ult}(J_{\alpha_i}, \pi, \kappa)$.

It follows that $\widetilde{\mathcal{M}}_i = \mathrm{Ult}(\mathcal{M}_i, \pi, \kappa) \in L$ for each $i < \omega$, and $X = \pi``\bar\kappa = J_\kappa \cap \bigcup_{i<\omega} h_i``(X \cap \beta)$ where $h_i \in L$ is the function given by Lemma 3.10. This completes the proof of Theorem 3.62. $\dashv$

This argument, applied to K^{DJ} in the absence of a model with a ω_1-Erdős cardinal, yields Magidor's generalization of Theorem 1.15 to K^{DJ}, while applied to larger core models K it yields the absoluteness to K of Jónsson and Ramsey cardinals, Theorem 1.16. This extension of the argument to K requires that the iterated ultrapower constructed in Definition 3.30 be modified by adding a second type of drop: Suppose that $M_\nu = J_{\alpha_\nu}[\mathcal{U}_\nu]$ has been defined, and let $\bar\beta_\nu$ be the largest ordinal such that $\mathcal{U}_\nu \restriction \bar\beta_\nu = \overline{\mathcal{U}} \restriction \bar\beta_\nu$. The next model, $M_{\nu+1}$, is defined normally, following Definition 3.30, except in the special case when $D \cap \nu = \varnothing$ and there is a triple (α, n, β) with $\beta \le \pi(\beta_\nu)$ such that $\mathrm{Ult}_n(J_\alpha[\mathcal{U}_\nu], \pi, \beta)$ is defined but not iterable. In this case put ν into D and set $M_{\nu+1} = J_\alpha[\mathcal{U}_\nu]$, where (α, n, β) is the least such triple. It is still true that if $X = Y \cap K_\kappa$ and N is the transitive collapse of Y then K^N is an initial segment of the final model M_θ of this iteration: either as in the original proof because M_θ defines a bounded subset of $\bar\kappa$ which is not in $H(\kappa)^{(N)} = \overline{K}$, or else because $\mathrm{Ult}_n(M_\theta, \pi, \kappa)$ is not iterable, while $\mathrm{Ult}(K^N, \pi, \kappa)$ can be embedded into $K_{\sup(Y)}$ which is iterable.

Let C^X be the set of putative indiscernibles generated by this proof, that is, the image under π of the critical points (after the last drop) of the iterated ultrapower. Then we get, as in the proof of Theorem 3.62, a set of functions

$h_k \in K$ for $k < \kappa$ so that

$$\begin{aligned}\widetilde{M} &= \bigcup\{\mathcal{H}^{h_k}(\rho \cup C^X) : k \in \omega\}\\ &= \bigcup\{h_k``(\rho \cup \vec{c}) : k < \omega \wedge \vec{c} \in [C^X]^{<\omega}\}\end{aligned}$$

where $\rho = \inf(\kappa - X)$.

If C^X is finite or countable then this gives X as a countable union of sets in K, so we can assume that C^X is uncountable. There is no reason to expect C^X to be a set of indiscernibles for K, but it *is* a set of indiscernibles for any structure in the range of $\tilde{\pi}$. This observation explains the importance of the following proposition:

3.63 Proposition. *Suppose that $X = Y \cap K_\kappa$ where $\kappa \in Y$, Y is cofinal in κ, and $Y \cap K_\lambda \prec_1 K_\lambda$ for some cardinal $\lambda > \kappa$. Then $\mathcal{P}(\kappa) \cap Y \subseteq \operatorname{ran}(\tilde{\pi}^X)$.*

Proof. Let $\pi^Y : N^Y \cong Y$ be the transitive collapse of Y, so that $N^Y \cap K_{\bar{\kappa}} = \overline{K}$ and $\pi^Y \restriction \overline{K} = \pi^X$. Fix any member z of $\mathcal{P}^K(\kappa) \cap Y$, let $\mathfrak{m} \in Y$ be the least mouse such that $z \in \mathfrak{m}$, and set $\bar{\mathfrak{m}} = (\pi^X)^{-1}(\mathfrak{m}) \in N^Y$. By Lemma 3.39 one of $\bar{\mathfrak{m}}$ and M^X is an initial segment of the other. Every bounded subset of $\bar{\kappa}$ in $\bar{\mathfrak{m}}$ is a member of N^X since $X = Y \cap K_\kappa$, but there is a bounded subset of $\bar{\kappa}$ which is definable in M^X and not a member of N^X. It follows that M^X is not a proper initial segment of $\bar{\mathfrak{m}}$, so $\bar{\mathfrak{m}}$ must be an initial segment of M^X. It follows that $\bar{z} = (\pi^Y)^{-1}(z) \in M^X$, and hence $z = \tilde{\pi}^Y(\bar{z}) = \tilde{\pi}^X(\bar{z}) \in \operatorname{ran}\tilde{\pi}^X$. ⊣

3.64 Corollary. *Suppose that $X = Y \cap K_\kappa$ where $Y \prec H(\lambda)$ for some $\lambda > \kappa$, and that $\mathcal{A} \in Y \cap K$ is a structure with universe κ. Then C^X is a set of indiscernibles for $\mathcal{A}$.*

Furthermore, if $D \in K \cap Y$ is a closed and unbounded subset of κ then $C^X - D$ is bounded in $\sup(C^X)$.

We will use this proposition to show that any Jónsson cardinal is Ramsey in K. The argument that every δ-Jónsson cardinal is δ-Erdős in K is similar, as is Magidor's argument that Theorem 1.15 holds for K^{DJ} unless there is an ω_1-Erdős cardinal in K^{DJ}.

Let $\mathcal{A}$ be any structure in K with universe κ. Since X is Jónsson there are sets Y and X as in the hypothesis of Proposition 3.64 such that $|X| = \kappa$ but $\kappa \not\subseteq X$.

It follows from the construction of the set C^X that $|C^X| = \kappa$. To show that κ is Ramsey in K we will show that there is a $\rho < \kappa$ and a set $C \in K$ of indiscernibles for $\mathcal{A}$ such that $(C^X - \rho) \subseteq C$. To this end let U be the filter on κ generated by C^X, that is, $z \in U$ if and only if $C^X - z$ is bounded in κ. Let $\mathfrak{m}$ be the least mouse with projectum κ such that $\mathcal{A} \in \mathfrak{m}$. Then $\mathfrak{m} \in Y$, so U is a normal ultrafilter on $\mathfrak{m}$. Furthermore $\operatorname{Ult}(\mathfrak{m}, U)$ is iterable since U is countably complete, so $\operatorname{Ult}(\mathfrak{m}, U) \in K$ and hence $U \cap \mathfrak{m} \in K$. Let h be the Skolem function of $\mathfrak{m}$ and define C to be the set of $\nu < \kappa$ such that, for each

$k < \omega$ and each set $z \in \kappa^{1+k} \cap h``\nu$,

$$\begin{array}{rcll} z \in U & \iff & \nu \in z & \text{if } k = 0 \\ z \in U^{1+k} & \iff & \{\vec{\gamma} \in (\kappa - \nu)^k : \nu^\frown\vec{\gamma} \in z\} \in U^k & \text{if } k > 0. \end{array}$$

Then C is a set of indiscernibles for $\widetilde{M}^X$, and hence for $\mathcal{A}$. Furthermore $C \in K$, and $C^X - C$ is bounded in κ since $h \in Y$. Then C is the required set of indiscernibles in K for $\mathcal{A}$, and since $\mathcal{A}$ was arbitrary this completes the proof that every Jónsson cardinal is Ramsey in K.

4. Sequences of Measures

This section concerns the covering lemma in the presence of models containing large cardinals. Most of the section will concentrate on the core model for sequences of measures; the remainder will describe, with less detail, what is known about the covering lemma up to a strong cardinal and then for overlapping extenders in the Steel core model up to and beyond a Woodin cardinal. We begin with a general survey, which is followed by a precise statement of the covering lemma for sequences of measures and some indications as to its proof.

The two large cardinal properties which critically affect the statement of the covering lemma are measurable cardinals and Woodin cardinals. Measurable cardinals are critical because they provide, via Prikry forcing, the first counterexample to the full covering property. Woodin cardinals are critical because they provide, via stationary tower forcing, a counterexample to the weak covering property as described in Sect. 4 of chapter [32].

The Covering Lemma and Sequences of Measures

The Dodd-Jensen covering lemma neatly accommodates the covering lemma to models $L[U]$ with a single measure; indeed the hypotheses $\neg\exists 0^\dagger$ and $K = L[U]$ are as well understood as is the hypothesis $\neg\exists 0^\#$ of the Jensen covering lemma. The situation for larger core models is both more complicated and less elegant. We begin this section by describing some of these complications, in rough order of the size of the core model at which they first appear.

The first three observations are relevant even in models in which $o(\kappa) \leq 1$ for all κ, that is, when no cardinal has more than one measure. To simplify the notation for this case we use an increasing enumeration $\vec{\kappa} = \langle \kappa_\nu : \nu < \theta \rangle$ of the measurable cardinals in $K = L[\mathcal{U}]$, and write U_ν for the full measure on κ_ν. A system of indiscernibles for this model K is a sequence $\mathcal{C} = \langle C_\nu : \nu < \theta \rangle$, with $C_\nu \subseteq \kappa_\nu$. Each set C_ν is either finite or a Prikry sequence, but in addition the sequence $\mathcal{C}$ as a whole is uniformly a system of indiscernibles:

$$\forall \vec{x} \in K \ \big((\forall \nu < \theta \, x_\nu \in U_\nu) \implies \big|\bigcup\{C_\nu - x_\nu : \nu < \theta\}\big| < \omega \big). \tag{18.16}$$

This leads to our first observation:

1. The sets C_ν need not be infinite: formula (18.16) is meaningful even if some or all of the sets C_ν are finite.

The only constraint on the function $f(\nu) = |C_\nu|$ when $o(\kappa_\nu) = 1$ for all ν is that ot $C_\nu \leq \omega$. For any predetermined function f, there is a straightforward modification of Prikry forcing which can be used to obtain a sequence such that $|C_\nu| = f(\nu)$ for all $\nu \in \mathrm{dom}(\mathcal{U})$: the conditions are pairs $(a, \vec{A})$ such that $A_\nu \in U_\nu$, $a_\nu \subseteq \kappa_\nu$ and $|a_\nu| \leq f(\nu)$ for each $\nu < \theta$, and $\bigcup_\nu a_\nu$ is finite. The order is defined by $(a', \vec{A}') \leq (a, \vec{A})$ if $a'_\nu \supseteq a_\nu$, $A'_\nu \subseteq A_\nu$, and $a'_\nu - a_\nu \subseteq A_\nu$ for each $\nu < \theta$.

As a consequence the relation between $L[\mathcal{U}]$ and $L[\mathcal{U}, \mathcal{C}]$ is more complicated than that between $L[U]$ and $L[U, C]$:

2. The function $f(\nu) = |C_\nu|$ need not be a member of K.

As an example, suppose that $\theta \geq \omega$ and let $a \subseteq \omega$ be a real which is Cohen generic over K. Then each of the measures U_n can be extended to a measure in $K[a]$, so we can modify Prikry forcing as described above to obtain a system $\mathcal{C}$ of indiscernibles for $K[a]$ such that $|C_n| = 1$ (or, alternatively, $|C_n| = \omega$) for each $n \in a$ and $C_n = \varnothing$ for each $n \in \omega - a$. Thus $a \in K[\mathcal{C}]$. If $|C_n| = \omega$ for each $n \in \omega$ then a is definable in $K[\mathcal{C}]$ as $\{n \in \omega : \mathrm{cf}(\kappa_n) = \omega\}$. If $|C_n| = 1$ for $n \in a$ then the covering lemma can be used to show that the system $\mathcal{C}$, and hence the set a, is definable in $K[\mathcal{C}]$ up to a finite set.

Note that a can be any set so long as the measures U_n can be extended to measures in $K[a]$.

In the Dodd-Jensen covering lemma for $L[U]$, the Prikry sequence C, if it exists, does not depend on the set x to be covered. This is not true for longer sequences:

3. If there is an inaccessible limit of measurable cardinals in K, then there is a cardinal preserving generic extension $K[G]$ of K in which each measure in K has a Prikry sequence, but there is no sequence $\mathcal{C} = \langle C_\nu : \nu < \kappa \rangle$ of Prikry sequences which satisfies (18.16) [36, Theorem 1.3].

An inaccessible limit of measurable cardinals is needed to obtain such a sequence: it is shown in [40, Theorem 4.1] that if there is no model with an inaccessible limit of measurable cardinals then, as in the Dodd-Jensen covering lemma, there is a single sequence $\mathcal{C}$ which can be used to cover any set x.

Since the remaining observations only apply in the presence of cardinals κ with $o(\kappa) > 1$, we now revert to the notation for sequences of measures described in chapter [32] and in the last section: the core model K is a structure of the form $L[\mathcal{U}]$, where $\mathcal{U}$ is a sequence of filters such that each member $\mathcal{U}_\gamma$ of the sequence is a normal measure on $L[\mathcal{U}{\restriction}\gamma] \cap \mathcal{P}(\kappa)$, where $\gamma = \kappa^{++}$ in $L[\mathcal{U}{\restriction}\gamma]$. Not all of the filters $\mathcal{U}_\gamma$ are full measures in K, but we only need to consider those measures which are full.

We frequently write $\mathcal{U}(\alpha,\beta)$ for the βth full measure on α in $L[\mathcal{U}]$; that is, $\mathcal{U}(\alpha,\beta)=\mathcal{U}_{\gamma_\beta}$ where $\langle\gamma_\nu : \nu < o(\alpha)\rangle$ is the increasing enumeration of the ordinals γ such that $\mathcal{U}_\gamma$ is a full measure on α in $L[\mathcal{U}]$. We write $o(\alpha)$, as above, for the least ordinal β such that $\mathcal{U}(\alpha,\beta)$ is undefined. The sequence $\mathcal{U}$ has the following *coherence* property: if $i : K \to \mathrm{Ult}(K,\mathcal{U}(\alpha,\beta))$ then $o^{i(\mathcal{U})}(\alpha)=\beta$ and $i(\mathcal{U})(\alpha,\beta')=\mathcal{U}(\alpha,\beta')$ for all $\beta'<\beta$.

For the next three observations we assume that the core model does not contain any extenders, so that K always satisfies $o(\alpha)\le\alpha^{++}$.

Corresponding to a sequence $\mathcal{U}$ of measures we will use $\mathcal{C}$ to denote a system of indiscernibles: if $\gamma\in\mathrm{dom}(\mathcal{C})$ then $\mathcal{C}_\gamma\subseteq\mathrm{crit}(\mathcal{U}_\gamma)$ is a set of indiscernibles for the measure $\mathcal{U}_\gamma$ (or, in the other notation, $\mathcal{C}(\alpha,\beta)\subseteq\alpha$ is a set of indiscernibles for $\mathcal{U}(\alpha,\beta)$). The precise definition of a system of indiscernibles will be given later, in Definitions 4.15 through 4.18 and in the covering lemma, Theorem 4.19.

4. The sets $\mathcal{C}(\kappa,\beta)$ may have order type greater than ω. In general, the set $\bigcup_{\beta<o(\kappa)}\mathcal{C}(\kappa,\beta)$ of indiscernibles for measures on a cardinal κ is a closed subset of κ which may have any order type up to $\min\{\kappa,\omega^{o(\kappa)}\}$.

In [30] Magidor generalizes Prikry forcing in order to add such a sequence of indiscernibles and hence change the cofinality of a cardinal κ to any smaller regular cardinal λ, provided that $o(\kappa)\ge\lambda$ in the ground model. This forcing is discussed briefly in chapter [32] and extensively in chapter [15].

For longer sequences of measures, and in particular when $o(\kappa)>\kappa$, it is important in applications that the domain of the sequence $\mathcal{C}^X$ is contained in the covering set X. For this reason, we assume a slightly different context for the covering lemma for sequences than was used for the Dodd-Jensen covering lemma. Let $\kappa=\sup(x)$ be a cardinal of K, where x is the set which we are trying to cover. We will look for a covering set $X\supseteq x$ such that $X\prec_1 K_{\breve\kappa}$, where $\breve\kappa$ is the least cardinal of K such that $\breve\kappa\ge\max\{\kappa,o(\kappa)\}$.

This requirement that $\mathrm{dom}(\mathcal{C}^X)\subseteq X$ leads to two somewhat technical problems in the study of longer sequences of measures:

5. It need not be that every suitable set X can be written as $X=h``(\rho;\mathcal{C}^X)$ where $\rho=\min(\kappa-X)$ and $h\in K$.

The notation $h``(\rho;\mathcal{C}^X)$ (which is defined in Definition 4.17) corresponds to the notation $h``(\rho\cup C)$ used when $K=L[U]$, but takes account of the fact that $\mathcal{C}^X$ is a function rather than a set. Recall that the strong version of the Jensen covering lemma states that if $0^\#$ does not exist then every suitable set X is in L, and the Dodd-Jensen covering lemma for $L[U]$ states (assuming there is a Prikry sequence C) that any such set can be written as $h``(\rho\cup C)$ where $\rho=\min(\kappa-X)$.

The covering lemma for longer sequences states that $X=h``(\rho\cap X;\mathcal{C}^X)$ for some $\rho<\kappa$, however, the induction used to show that ρ can be taken to be $\inf(\kappa-X)$ breaks down for sequences of measures: it depends on the fact that $X \cap K_\rho$ is suitable as a subset of K_ρ, but in the case of sequences of measures it may be that ρ is measurable, but is not a member of X. In this case $X' = X \cap K_{\breve{\rho}}$ is not suitable since $\operatorname{dom}(\mathcal{C}^{X'})$ is not contained in X'.

So far this limitation has not caused problems in applications, nor has the next difficulty:

6. If $o(\alpha) \geq \alpha^+$ then it is not known whether countable completeness of a set X is enough to ensure that X is a suitable covering set. What is known is stated in Theorem 4.19, which requires that the set X be $\operatorname{cf}(\kappa)$-closed. In particular it is not known whether there always exist suitable covering sets of size less than $\operatorname{cf}(\kappa)^+$.

The problem, again, comes from the requirement that $\operatorname{dom}(\mathcal{C}) \subseteq X$, but in this case it is the measures on κ which are in question. These measures are generated by cofinal subsets of $\bigcup_\beta \mathcal{C}(\kappa, \beta)$, so the assumption that X contains its subsets of size at most $\operatorname{cf}(\kappa)$ implies that these subsets, and hence the corresponding measures, are in X.

Extenders

If $o(\kappa) > \kappa^{++}$ then the core model is built using extenders, and we will write $K = L[\mathcal{E}]$ to denote the core model. Below $0^\P$, the sharp for a strong cardinal, the extenders do not overlap and the covering lemma as stated for sequences of measures remains true with two modifications. One of these is primarily notational, but the following situation is unexpected:

7. If $\operatorname{cf}(\kappa) = \omega$ and $\{\alpha < \kappa : o(\alpha) \geq \alpha^{+n}\}$ is unbounded in κ for all $n < \omega$, then the fact that a set X is countably closed does not ensure that X contains all of the extenders on κ which are generated by the system $\mathcal{C}^X$ of indiscernibles for X.

   If $\operatorname{cf}(\kappa) \geq \omega_1$ and ${}^{\operatorname{cf}(\kappa)}X \subseteq X$, however, in this case X does contain all such extenders. As a result the covering lemma up to $0^\P$ is similar to the result of substituting "ω_1" and "countable" for "ω" and "finite" in the covering lemma for sequences of measures.

Both parts of this observation are due to Gitik. In [18] he defines a game which can be used to reconstruct a extender E on a cardinal of uncountable cofinality from the sequences of ordinals which generate the constituent ultrafilters, and in [21] he constructs a model in which this is not possible for extenders on a cardinal of cofinality ω.

The set $0^\P$ marks the introduction of overlapping extenders, and thus of a dramatic shift in our understanding of the covering lemma:

8. If $0^\P$ exists then we cannot prove much more than the weak covering lemma and the absoluteness theorem for Jónsson and Ramsey cardinals (Theorem 1.16).

The basic construction of the proof of the covering lemma does still go through for overlapping extenders, with considerably increased technical difficulties [45, 43], but it uses iteration trees rather than the linear iteration of Definition 3.30. The indiscernibles generated by such iterations are very poorly understood, and the proofs for the known results above $0^\P$ rely on avoiding indiscernibles rather than on analyzing them.

9. No core model with cardinals very much larger than $0^\P$ is known to exist and satisfy the weak covering lemma without an additional assumption that there is a subtle cardinal in the universe. It is known that there is no model for a Woodin cardinal which satisfies the weak covering lemma in set generic extensions.

Even the weak covering lemma is false for any model with a Woodin cardinal δ, since stationary tower forcing can be used to collapse successors of many singular cardinals below δ. The situation between $0^\P$ and a Woodin cardinal is still under investigation.

Of course any statement such as these must rely on implicit assumptions about what it means to be a "core model". Section 4 of chapter [32] explores the assumptions lying behind the statement here.

The use of $0^\P$ as the dividing line is an oversimplification: it is possible to use tricks to push some of the results somewhat further. In fact Schindler [50] has constructed a core model under the assumption that there is no sharp for a model with a class of strong cardinals. More importantly, there are some suggestions that it is the presence of actual overlapping extenders in K which cause the difficulty, not partial extenders such as those which appear in the countable mouse $0^\P$. Schimmerling and Woodin have shown that in certain special cases the core model can be proved to have the full covering property, even though it contains inner models with several Woodin cardinals. See [48], where Schimmerling and Woodin show that this result is not limited to the Steel core models, but has consequences for the existence of core-like models.

This concludes our summary. The next subsection contains a more detailed discussion of the covering lemma for sequences of measures.

4.1. The Core Model for Sequences of Measures

See chapter [32] for a discussion of the inner models for sequences of measures, and Sect. 3.3 of this chapter on the Dodd-Jensen core model for its discussion of the core model K in particular. Recall that $K = L[\mathcal{U}]$, where $\mathcal{U}$ is a coherent sequence with members $\mathcal{U}_\gamma$ which are $J_\gamma[\mathcal{U}{\restriction}\gamma]$-measures. We will define the sequence $\mathcal{U}$, and hence the core model, by recursion on γ. The main problem in designing this recursion is to ensure that the final model $L[\mathcal{U}]$ is iterable: when $\mathcal{U}{\restriction}\gamma$ has been defined, then the decision whether to set $\mathcal{U}_\gamma = U$ for some measure U must take into account the requirement that any iterated ultrapower of the as yet undefined model $L[\mathcal{U}]$ must be well-founded. This is accomplished by defining two core models: the first, the *countably complete* core model K^c, has the weak covering property and is iterable because its full measures are countably complete; the second, the *true* core model K, has the full covering property and is iterable because it is an elementary substructure of K^c.

4.1 Definition. Either the core model K, or the countably complete core model K^c, are defined as $L[\mathcal{U}]$ where the sequence $\mathcal{U}$ is defined by recursion on γ as follows. Assume that $\mathcal{U}\restriction\gamma$ has already been defined:

1. If there is a mouse $M = J_{\gamma'}[\mathcal{U}']$ such that $\mathcal{U}'\restriction\gamma = \mathcal{U}\restriction\gamma$, the projectum of M is smaller than γ, and no measure in $\mathcal{U}' - \mathcal{U}$ is full in M, then set $\mathcal{U}\restriction\gamma' = \mathcal{U}'$.

2. If there is no mouse as in clause 1, and if $J_\gamma[\mathcal{U}] \models \gamma = \kappa^{++}$ for some $\kappa < \gamma$ such that there is a $J_\gamma[\mathcal{U}]$-ultrafilter U on κ with $i^U(\mathcal{U})\restriction\gamma+1 = \mathcal{U}\restriction\gamma$, then set $\mathcal{U}_\gamma = U$, provided it satisfies an iterability condition depending on which model is being constructed:

   (a) For the model K^c, the ultrafilter U is added to the sequence only if U is countably complete and $\operatorname{cf}(\operatorname{crit}(U)) = \omega_1$.

   (b) For the true core model K, the ultrafilter U is added to the sequence only if $\operatorname{Ult}(L[\mathcal{W}], U)$ is well-founded for every iterable inner model $L[\mathcal{W}]$ such that $\mathcal{W}\restriction\gamma = \mathcal{U}$.

3. If neither of the previous clauses apply then $\mathcal{U}_\gamma = \varnothing$.

The construction in clause 1 apparently depends on the choice of the mouse M to be added; however, if two mice $J_{\alpha_0}[\mathcal{W}_0]$ and $J_{\alpha_1}[\mathcal{W}_1]$ satisfy clause 1, then one of them is an initial segment of the other. Thus clause 1 could be equivalently restated by specifying that $\mathcal{U}\restriction\gamma$ is to be extended to the longest good sequence $\mathcal{U}' \supseteq \mathcal{U}\restriction\gamma$ such that $L_{\gamma'}[\mathcal{U}']$ is iterable, the largest cardinal in $L[\mathcal{U}']$ below $\sup(\operatorname{dom}(\mathcal{U}'))$ is smaller than γ, and no measures in $\mathcal{U}' - \mathcal{U}\restriction\gamma$ are full in $L[\mathcal{U}']$.

It can be shown that there is never more than one choice of the measure $\mathcal{U}_\gamma$ satisfying clause 2. One way of doing so is to pick a mouse M with projectum κ containing a set x on which two candidate measures U and U' differ, and compare $\operatorname{Ult}(M, U)$ and $\operatorname{Ult}(M, U')$. Another is by using a *bicephelus*, which is a structure $\mathcal{B} = (J_\gamma[\mathcal{U}], \mathcal{U}, U, U')$ which is like a mouse except that both of U and U' are used as the top measure $\mathcal{U}_\gamma$ of $\mathcal{U}$. As in the proof of [32, Theorem 3.22], an iterated ultrapower is used to compare $\mathcal{B}$ with itself and conclude that in fact U is equal to U'. The construction is simpler than that of [32, Theorem 3.22] since $\mathcal{B}$ is a perfectly normal mouse except for the doubled top measures U and U', which are used only as predicates, not in the construction of $J_\gamma[\mathcal{U}]$.

4.2 Lemma. *The model K^c is iterable.*

Proof. We present a proof which seems slightly oblique compared to the original proof, but which extends naturally to models with sequences of extenders. First we show that if $\sigma : M \to K^{\mathrm{c}}_\theta$ is an elementary embedding, where M is a countable transitive set and θ is a sufficiently large cardinal, and if U is a full measure in M, then σ can be extended to obtain an elementary embedding $\tilde\sigma : \mathrm{Ult}(M,U) \to K^{\mathrm{c}}_\theta$ such that $\sigma = \tilde\sigma i^U$. To define $\tilde\sigma$ let $A = \bigcap \sigma``U$. Then $A \neq \varnothing$ since $\sigma``U$ is a countable subset of the countably complete ultrafilter $\sigma(U)$, so choose $\lambda \in A$ and define $\tilde\sigma([f]_U) = \sigma(f)(\lambda)$. Then $\tilde\sigma$ is elementary because $\mathrm{Ult}(M,U) \models \varphi([f]_U)$ if and only if $M \models \{\nu : \varphi(f(\nu))\} \in U$, and by the choice of λ this holds if and only if $K^{\mathrm{c}}_\theta \models \varphi(f(\lambda))$.

Now suppose that K^{c} is not iterable. Then for sufficiently large θ there is a countable elementary substructure $X \prec V_\theta$ containing an iteration witnessing this failure. If $\sigma : M \cong X \cap K^{\mathrm{c}}_\theta$ is the transitive collapse then M is not iterable, and there is a countable iteration of M witnessing this failure. If this iteration does not contain any drops then the construction of the last paragraph can be repeated countably many times to obtain embeddings $\tilde\sigma_\nu : M_\nu \to K^{\mathrm{c}}_\theta$ of the models M_ν of this iteration into K^{c}_θ, but this is impossible because the final ill-founded model M_δ of the iteration is embedded by $\tilde\sigma_\delta$ into the well-founded set K^{c}_θ. If the iteration does contain a drop, with the first drop occurring at ν_0, then $\tilde\sigma_{\nu_0} \restriction M^*_{\nu_0+1}$ embeds $M^*_{\nu_0+1}$ into an iterable mouse $\widetilde{M} = \tilde\sigma_{\nu_0}(M^*_{\nu_0+1})$ of K^{c}_θ. The remainder of the iteration on $M = M_0$ can then be copied to obtain an ill-behaved iteration on $\widetilde{M}$, which contradicts the fact that $\widetilde{M}$ is iterable. ⊣

We will show that K is iterable by giving, in Lemma 4.11, a characterization of K as the transitive collapse of an elementary substructure of K^{c}. This characterization, which depends on the weak covering lemma for K^{c}, begins with the following preliminary definitions generalizing the fact that the weak covering lemma for K^{DJ} implies that any elementary substructure $X \prec K^{\mathrm{DJ}}$ with $|X \cap \lambda^+| = \lambda^+$ is isomorphic to K^{DJ}.

4.3 Definition. An iterable premouse $M = L[\mathcal{U}]$ is said to be *universal* if, whenever M is compared with any other iterable premouse M', the iterated ultrapower on M' does not drop and the final model in that iteration is a (possibly proper) initial segment of the final model of the iteration on M.

Note that a universal premouse M must be a proper class, since if $M = J_\alpha[\mathcal{U}]$ is an iterable premouse which is a set then Lemma 3.28 implies that M is the iterated ultrapower of a mouse $M' = J_{\alpha'}[\mathcal{U}']$. Thus $L[\mathcal{U}']$ is an iterable premouse, and M comes out shorter than $L[\mathcal{U}']$ when they are compared because the iteration on $L[\mathcal{U}']$ consists of an initial drop to the mouse M', followed by the iterated ultrapower of M' to M.

4.4 Proposition. *If M is a iterable class premouse and $\lambda^{+M} = \lambda^+$ for a stationary class of cardinals, then M is universal.*

Proof. If M is not universal then there is an iterable premouse M' and iterated ultrapowers $i : M \to P$ and $i' : M' \to P'$ such that P is a proper initial segment of P'. Thus the class of ordinals of P is the class Ω of actual ordinals, and since P' is longer, we have $\Omega \in P'$. The iteration i does not drop by Lemma 3.36. We can assume that i' also does not drop, since if it did drop we could consider only the tail of the iteration starting after the last drop. If ν_0 and κ are chosen so that $\Omega = i'_{\nu_0,\Omega}(\kappa)$ then the class Γ of ordinals λ such that $i_{0,\lambda}``\lambda \subseteq \lambda$ and $\lambda = i'_{\nu_0,\lambda}(\kappa)$ is closed and unbounded. Fix $\lambda \in \Gamma$ such that $(\lambda^+)^M = \lambda^+$. Then $\lambda^{+^{P'}} = \lambda^{+^{M'_\lambda}} = i'_{\nu_0,\lambda}(\kappa^{+^{M'_{\nu_0}}}) < \lambda^+$. This implies that $\lambda^{+^P} = \lambda^{+^{M_\lambda}} < \lambda^+$. We will obtain a contradiction by showing that $\kappa^{+^{M_\lambda}} = \lambda^+$. If $i_{0,\lambda}(\lambda) = \lambda$ then this follows immediately since $\lambda^{+^{M_\lambda}} = i_{0,\lambda}(\lambda^+) \geq \lambda^+$. Otherwise there is a unique $\nu < \lambda$ such that $i_{0,\nu}(\lambda) = \lambda$ and $i_{\nu+1,\lambda}(\lambda) = \lambda$, but $\mathrm{crit}(i_{\nu,\nu+1}) = \mathrm{cf}^{M_\nu}(\lambda)$. Then $\lambda^{+^{M_\lambda}} = \lambda^{+^{M_{\nu+1}}} = \lambda^{+^{M_\nu}} = \lambda^{+^M}$, with the first and last equalities being proved as in the case when λ is never moved. ⊣

We will prove the following lemma later, simultaneously with the full covering lemma:

4.5 Lemma (Weak Covering Lemma for K^{c}). *Suppose that there is no inner model of $\exists\kappa\,(o(\kappa) = \kappa^{++})$ and that λ is a singular strong limit cardinal. Then $(\lambda^+)^{K^c} = \lambda^+$.*

4.6 Definition. A class Γ is *thick* if Γ is a proper class, there is some τ such that Γ contains its limit points of cofinality greater than τ, and $|\Gamma \cap \lambda^+| = \lambda^+$ for all sufficiently large singular strong limit cardinals $\lambda \in \Gamma$.

4.7 Proposition. *Any set sized intersection of thick classes is thick.*

The following observation explains the definition of a thick class, and also the decision to require that every measurable cardinal in K^{c} have cofinality ω_1.

4.8 Proposition. *Suppose that W is an iterable, class length premouse, τ is an ordinal, and Γ is a thick class such that for any singular cardinal $\lambda \in \Gamma$ with $\mathrm{cf}(\lambda) > \tau$ we have that $\mathrm{cf}^W(\lambda)$ is not measurable, and $\lambda^{+^W} = \lambda^+$.*

Then any (nondropping) iterated ultrapower $i : W \to N$ is continuous at points $\xi \in \Gamma$ of cofinality greater than τ. Hence, the class Γ' of ordinals $\xi \in \Gamma$ such that $i(\xi) = \xi$ is thick.

Proof. If $i(\xi) > \sup(i``\xi)$, then it must be that at some stage ν in the iteration, $W_{\nu+1} = \mathrm{Ult}(W_\nu, U_\nu)$ where U_ν is a measure in W_ν on a cardinal κ_ν with $\mathrm{cf}^{W_\nu}(i_\nu(\xi)) = \kappa_\nu$. Since $\kappa_\nu = i_\nu(\mathrm{cf}^W(\xi))$ it follows that $\mathrm{cf}^W(\xi)$ is measurable in W. By the assumption on W, it follows that ξ is not a member of Γ of cofinality greater than τ.

For the final sentence, consider the class X of cardinals ξ such that ξ is a limit point of Γ of cofinality at least τ, and $i``\xi \subseteq \xi$. Then X is a proper class, and Γ' contains all of the limit points of X of cofinality at least τ.

Finally, if $\lambda \in \Gamma'$ and $\lambda^{+W} = \lambda^+$ then $i(\lambda^+) = \lambda^+$, and an argument like that in the last paragraph shows that $|\{\xi \in \lambda^+ : i(\xi) = \xi\}| = \lambda^+$. Thus $|\Gamma' \cap \lambda^+| = \lambda^+$, so Γ' is thick. $\dashv$

4.9 Lemma. *Assume that K^c satisfies the weak covering lemma, that λ is a limit cardinal and Γ is thick. Then for each $x \in \mathcal{P}^{K^c}(\lambda)$ there is a $y \in \mathcal{H}^{K^c}(\Gamma \cup \lambda)$, the Skolem hull of $\Gamma \cup \lambda$, such that $x = y \cap \lambda$.*

Proof. Let $\pi : N \cong \mathcal{H}^{K^c}(\Gamma \cup \lambda)$ be the transitive collapse. Then $\xi^{+N} \geq |\Gamma \cap \xi^+| = \xi^+$ for all singular limit cardinals ξ of sufficiently large cofinality, so N is universal by Lemma 4.4. It follows that the comparison of N with K^c will result in iterated ultrapowers with no drops and a common final model P. Furthermore, the critical point of each of the associated embeddings $i : N \to P$ and $j : K^c \to P$ is at least λ, since N and K^c agree on all measures with critical point below λ. Thus $x \in \mathcal{P}^P(\lambda) = \mathcal{P}^N(\lambda) \subseteq \mathrm{dom}(\pi)$, and the set $y = \pi(x)$ satisfies the requirements. $\dashv$

4.10 Lemma. *If K^c satisfies Lemma 4.5, Γ is thick and $\lambda > \omega_1$ is a strong limit cardinal of cofinality ω_1, then $\lambda \in \mathcal{H}^{K^c}(\lambda \cup \Gamma)$.*

Proof. Let $X = \mathcal{H}^{K^c}(\lambda \cup \Gamma)$, and suppose to the contrary that $\lambda \notin X$. Let $\pi : N \cong X$ be the transitive collapse, and let $U = \{x \subseteq \lambda : \lambda \in i(x)\}$. Then U is a K^c-ultrafilter, since $\mathcal{P}^{K^c}(\lambda) \subseteq N$. Furthermore U is countably complete. To see this, let A be any countable subset of U. Since $\mathrm{cf}(\lambda^{+K^c}) = \mathrm{cf}(\lambda^+) = \lambda^+ > \omega$ there is $B \in K^c$ of size κ such that $A \subseteq B$, and since $\mathrm{cf}(\lambda) > \omega$ it follows that there is $B' \in K^c$ of size less than κ such that $A \subseteq B' \subseteq B$. Then $\bigcap A \supseteq \bigcap(B' \cap U)$, but the latter is nonempty since $B' \cap U \in K^c$ and U is a K^c-ultrafilter.

Thus $U \in K^c$, which is impossible since $o(U) = o^{K^c}(\lambda)$. The contradiction shows that $\lambda \in X$. $\dashv$

4.11 Lemma. *If K^c satisfies Lemma 4.5 then K is isomorphic to the class $X = \bigcap\{\mathcal{H}^{K^c}(\Gamma) : \Gamma$ is thick$\}$.*

Sketch of Proof. Let $\pi : \widetilde{K} \cong X$ be the transitive collapse of X. First we show that X is a proper class. Suppose to the contrary that X is a set and let $\kappa = \sup(X \cap \mathrm{On})$. Now use Proposition 4.7 to define a descending sequence $\langle \Gamma_\nu : \nu < \omega_1 \rangle$ of thick classes such that $X = \mathcal{H}^{K^c}(\Gamma_0) \cap V_{\kappa+1}$, the sequence of ordinals $\kappa_\nu = \inf(\mathcal{H}^{K^c}(\Gamma_\nu) - \kappa)$ is strictly increasing, and $\lambda = \sup\{\kappa_\nu : \nu < \omega_1\}$ is a strong limit cardinal. We will show that $\lambda \in X$, contradicting the choice of κ.

Suppose the contrary, and pick $\Gamma_{\omega_1} \subseteq \bigcap_{\nu<\omega_1} \Gamma_\nu$ so that $\lambda \notin \mathcal{H}^{K^c}(\Gamma_{\omega_1})$. By Lemma 4.10 there is a parameter $a \in \Gamma_{\omega_1}$, an ordinal $\xi < \lambda$, and a formula φ such that λ is the unique η such that $K^c \models \varphi(a, \xi, \eta)$. Let $\tau \in K$ be the

Skolem function for φ (with parameter a) so that $K^{\mathrm{c}} \models \forall\iota\,(\exists\eta\,\varphi(a,\iota,\eta) \implies \varphi(a,\iota,\tau(\iota)))$.

Now, notice that if $\nu < \omega_1$ then $\tau``\kappa_\nu \cap \lambda \subseteq \kappa_\nu$: otherwise there is some $\nu' > \nu$ and $\xi' < \kappa_\nu$ so that $\kappa_\nu \leq \tau(\xi') < \kappa_{\nu'}$. Then the least such ξ' is definable from κ_ν, $\kappa_{\nu'}$ and a, so $\xi' \in \mathcal{H}^{K^{\mathrm{c}}}(\Gamma_\nu) \cap \kappa_\nu = X \cap \kappa$, but this is impossible since in that case $\tau(\xi') \in \mathcal{H}^{K^{\mathrm{c}}}(\Gamma_{\nu'})$.

Now let ξ_0 be the least ordinal ξ such that $\lambda = \tau(\xi)$, and fix $\nu_0 < \omega_1$ so $\xi_0 < \kappa_{\nu_0}$. Then $\lambda = \min(\tau``\kappa_{\nu_0} - \kappa_{\nu_0}) \in \mathcal{H}^{K^{\mathrm{c}}}(\Gamma_{\nu_0})$. However, this implies that $\xi_0 \in \mathcal{H}^{K^{\mathrm{c}}}(\Gamma_{\nu_0}) \cap \kappa_{\nu_0} = X \cap \kappa \subseteq \mathcal{H}^{K^{\mathrm{c}}}(\Gamma_{\omega_1})$. Hence $\lambda \in \mathcal{H}^{K^{\mathrm{c}}}(\Gamma_{\omega_1})$, contrary to the choice of Γ_{ω_1}.

Now we show that $\widetilde{K} = K$. Else, fix λ such that $\widetilde{K}_\lambda \neq K_\lambda$, and fix a thick class Γ small enough that if $\pi : W \cong \mathcal{H}^{K^{\mathrm{c}}}(\Gamma)$ is the collapse map then $\pi``\widetilde{K}_\lambda = X \cap K^{\mathrm{c}}_{\pi(\lambda)}$. Note that W, with the class $\pi^{-1}[\Gamma]$, satisfies the conditions of Proposition 4.8. If we consider the least place at which K differs from $\widetilde{K}$, and hence from W, then there are two possibilities: $\widetilde{K}$ is missing a mouse which is in K, or $\widetilde{K}$ is missing a full measure which is in K. The first is impossible, since it would contradict the universality of W. Thus there must be a measure $U = \mathcal{U}_\gamma$ on some cardinal $\kappa < \lambda$ in K such that $U \notin W$, but K and W agree up to $\gamma = \kappa^{++W}$. Now consider the following diagram:

$$\begin{tikzcd} W \arrow[r, "i^U"] \arrow[dr, "j"'] & \mathrm{Ult}(W,U) \arrow[d, "k"] \\ & \overline{N} \end{tikzcd}$$

where $\overline{N}$ is the common final model of the iterated ultrapowers coming from the comparison of the universal models W and $\mathrm{Ult}(W,U)$, and j and k are the embeddings from these iterated ultrapowers. Let Γ' be the set of $\xi \in \pi^{-1}[\Gamma]$ such that $ki^U\pi^{-1}(x) = j\pi^{-1}(x)$. Then Γ' is thick, but $\pi(\kappa) \notin \mathcal{H}^W(\Gamma')$, contradicting the assumption that $\pi(\kappa) \in X$. ⊣

The trick used at the end of the last proof, using an approximation W which agrees with the relevant initial segment of K but which satisfies the hypothesis of Proposition 4.8, is often necessary. The following theorem gives another example:

4.12 Theorem. *If K^{c} satisfies the weak covering lemma then any universal iterable premouse M is an iterated ultrapower of K.*

Proof. Suppose that M is a counterexample, and let ν be the first stage in the comparison with K at which the iterated ultrapower on M becomes nontrivial. Thus $M_\nu = M$ and $M_{\nu+1} = \mathrm{Ult}(M,U)$, and the ultrafilter $U = \mathcal{U}^{M_\nu}_\gamma$ is not in the νth model N_ν in the iterated ultrapower on K.

Fix η large enough that $i_\nu(\eta) > \gamma$, where $i_\nu : K = N_0 \to N_\nu$ is the embedding coming from the iterated ultrapower on K, and as in the last proof choose W satisfying the hypothesis of Proposition 4.8 which agrees with K

up to η, so that $W_\eta = K_\eta$. Thus the description in the last paragraph of the comparison between K and M applies equally to the comparison between W and M, and for the rest of the proof we use the latter.

Since both W and M are universal, the comparison of these two models gives iterated ultrapowers of length $\theta \leq \mathrm{On}$ with no drops and with a common final model P, as in the left half of the following diagram:

$$\begin{tikzcd} W = N_0 \arrow[rr, "i_\nu"] & & N_\nu \arrow[r, "i^U"] \arrow[d, "i_{\nu,\theta}"'] \arrow[dr, "s"] & \mathrm{Ult}(N_\nu, U) \arrow[d, "t"] \\ M \arrow[r, equal, "j_\nu"] & M_\nu \arrow[r, "j_{\nu,\theta}"'] & P & Q \end{tikzcd} \tag{18.17}$$

Since there are no drops, the models N_ν, P and M_ν all have the same subsets of κ, so U is an N_ν-ultrafilter. Furthermore, $\mathrm{Ult}(N_\nu, U)$ is well-founded: otherwise $\mathrm{Ult}(P, U)$ would be ill-founded, but the iterated ultrapower $j_{\nu,\theta}$ can be copied to an iterated ultrapower on $\mathrm{Ult}(M_\nu, U)$ with last model $\mathrm{Ult}(P, U)$, so the iterability of M_ν implies that $\mathrm{Ult}(P, U)$ is well-founded. Now compare N_ν and $\mathrm{Ult}(N_\nu, U)$. Again, both models are universal so this comparison gives embeddings s and t as in diagram (18.17) with the same final model Q.

Let $\Gamma = \{\xi > \eta : ti^U i_\nu(\xi) = si_\nu(\xi)\}$. Then Γ is thick, so Theorem 4.11 implies that $K_\eta = W_\eta \subseteq \mathcal{H}^W(\Gamma)$. It follows that $i_\nu(K_\eta) \subseteq \mathcal{H}^{N_\nu}(\Gamma \cup \kappa)$, so $ti^U \restriction W_{i_\nu(\eta)} = s \restriction W_{i_\nu(\eta)}$. In particular, $s(\kappa) > \kappa$ since $ti^U(\kappa) > \kappa$, so the iteration s begins with an ultrapower by some measure $U' = \mathcal{U}_\gamma^{N_\nu} \in N_\nu$ with critical point κ. But then $U = U'$, since if x is any subset of κ in N_ν then $x \in U \iff \kappa \in ti^U(x) = s(x) \iff x \in U'$. This contradicts the assumption that $U \notin N_\nu$. ⊣

4.13 Corollary. *If K^c satisfies the weak covering property and U is a normal ultrafilter on K such that $\mathrm{Ult}(K, U)$ is well-founded, then there is some γ such that $U = \mathcal{U}_\gamma$, where $K = L[\mathcal{U}]$.*

Proof. Apply Theorem 4.12 to $\mathrm{Ult}(K, U)$. ⊣

Note that the hypothesis that M is universal cannot be eliminated from Theorem 4.12: The model N constructed in the proof of Jensen's Theorem 3.43 provides a counterexample in which N is a set, and a similar argument, starting with an assumption somewhat weaker than two measurable cardinals, gives a counterexample in which N is a proper class. However, such situations can only occur below ω_2: If $\lambda \geq \omega_2$ then the covering lemma implies that $\mathrm{cf}((\lambda^+)^K) > \omega$, and it follows that any K-ultrafilter on λ is countably complete.

4.2. The Covering Lemma up to $o(\kappa) = \kappa^{++}$

We use the following setting for the covering lemma for sequences of measures: We take κ to be a cardinal of K which is singular in V, and we consider covering sets $X \prec_1 K_{\breve{\kappa}}$ where $\breve{\kappa}$ is a cardinal of K with $\breve{\kappa} \geq \max\{\kappa, o(\kappa)\}$. The covering lemma asserts that for suitable sets X there is a system $\mathcal{C}^X$ of indiscernibles, a function h in K, and a $\rho < \kappa$ such that $X = h``(X \cap \rho; \mathcal{C})$, the smallest set containing $X \cap \rho$ and closed under h and $\mathcal{C}$. We will call such a set X a *covering set.*

Some definitions are required before we can give a precise statement of the covering lemma. Here is a general definition for a system of indiscernibles:

4.14 Definition.

1. If U is a measure, then $\operatorname{crit}(U)$ is the cardinal κ such that U is a measure on κ.

2. If $\gamma < \gamma'$, with $\gamma' \in \operatorname{dom}(\mathcal{U})$, then $\operatorname{Coh}_{\gamma,\gamma'}$ is the least function f in the ordering of $L[\mathcal{U}]$ such that $\gamma = [f]_{\mathcal{U}_{\gamma'}}$ in $\operatorname{Ult}(L[\mathcal{U}], \mathcal{U}_{\gamma'})$.

4.15 Definition. If $\mathcal{U}$ is a sequence of measures then a *system of indiscernibles* for $M = L[\mathcal{U}]$ is a function $\mathcal{C}$ such that

1. $\operatorname{dom}(\mathcal{C}) \subseteq \operatorname{dom}(\mathcal{U})$, and $\mathcal{C}_\gamma \subseteq \operatorname{crit}(\mathcal{U}_\gamma)$ for all $\gamma \in \operatorname{dom}(\mathcal{C})$.

2. For any function $f \in M$ there is a finite set a of ordinals such that if $\gamma \in \operatorname{dom}(\mathcal{U})$ and $\lambda = \operatorname{crit}(\mathcal{U}_\gamma)$ then

$$\forall \nu \in (\mathcal{C}_\gamma - \sup(a \cap \lambda)) \forall x \in f``(\nu \times \{\lambda\}) \, (\nu \in x \iff x \cap \lambda \in \mathcal{U}_\gamma).$$

The indiscernible sequences rising from the covering lemma have some additional structure:

4.16 Definition. If $\mathcal{C}$ is a system of indiscernibles for M, then $\mathcal{C}$ is said to be *h-coherent* if $h \in M$ is a function and the following conditions hold:

1. For all $\nu \in \bigcup_\gamma \mathcal{C}_\gamma$ there is a unique $\gamma \in h``\nu$ such that $\nu \in \mathcal{C}_\gamma$.

2. Suppose that $\nu \in \mathcal{C}_\gamma \cap \mathcal{C}_{\gamma'}$ and $\gamma \in h``\nu$. If $\gamma' \neq \gamma$ then $\operatorname{crit}(\mathcal{U}_{\gamma'}) < \operatorname{crit}(\mathcal{U}_\gamma)$, and $\operatorname{crit}(\mathcal{U}_{\gamma'}) \in \mathcal{C}_{\gamma''}$ for some $\gamma'' < \gamma$ with $\operatorname{crit}(\mathcal{U}_{\gamma''}) = \operatorname{crit}(\mathcal{U}_\gamma)$.

3. Suppose $\gamma_\nu = \operatorname{Coh}_{\gamma',\gamma}(\nu)$, where $\gamma' < \gamma$ with $\operatorname{crit}(\mathcal{U}_{\gamma'}) = \operatorname{crit}(\mathcal{U}_\gamma)$; and suppose that $\nu \in \mathcal{C}_\gamma$ with $\gamma' \in h``\nu$. Then $\mathcal{C}_{\gamma_\nu} = \mathcal{C}_{\gamma'} \cap (\nu - \nu')$, where $\nu'$ is least such that $\gamma \in h``\nu'$.

For a simple example, consider a set $C \subseteq \kappa$ which is Magidor generic over M, making $\operatorname{cf}(\kappa) = o^M(\kappa) = \lambda$ for some cardinal $\lambda < \kappa$. In this case we can take h to be the function such that $h(\beta)$ is the index of the βth full measure on κ, that is, such that $\mathcal{U}(\kappa, \beta) = \mathcal{U}_{h(\beta)}$ for all $\beta < o(\kappa)$. Then $\mathcal{C}_{h(\beta)} = \{\nu \in C : o(\nu) = \beta\}$. If we take C to be Radin generic, with $o(\kappa) < \kappa^+$, then we could define h so that $\mathcal{U}(\kappa, \sigma(\xi)) = \mathcal{U}_{h(\xi)}$, where σ is the canonical function taking κ onto $o(\kappa) < \kappa^+$. If C is Radin generic with $o(\kappa) = \kappa^+$, on the other hand, then there is no $h \in M$ and h-coherent system

$\mathcal{C}$ of indiscernibles such that $C = \bigcup_\gamma \mathcal{C}_\gamma$, for having such a system $\mathcal{C}$ would require that h maps κ onto κ^+.

The function $h``(x;\mathcal{C})$ provides a weak sense in which a covering set X is generated by a function $h \in K$ and a sequence $\mathcal{C}$ of indiscernibles:

4.17 Definition. Suppose that $\mathcal{C}$ is a system of indiscernibles and x is a set. Then $h``(x;\mathcal{C})$ is the smallest set $X$ such that $x \subseteq X$ and $X = h``(X \cup \bigcup_{\gamma \in X} \mathcal{C}_\gamma)$.

Definition 4.17 is too weak, since it does not provide any bounds on the size of the sets $\mathcal{C}_\gamma$. The functions defined below are used in clause 4 of Theorem 4.19 to describe a stronger sense in which X is generated by $\mathcal{C}$:

4.18 Definition. If $\mathcal{C}$ is a g-coherent system of indiscernibles and X is a set then we define

1. $s^{\mathcal{C}}(\gamma, \xi)$ is the least member of $\mathcal{C}_\gamma - (\xi + 1)$.
2. $s_*^{\mathcal{C}}(\gamma, \xi)$ is the least member of $\bigcup_{\gamma' \geq \gamma} \mathcal{C}_{\gamma'} - (\xi + 1)$.
3. If λ is measurable in K and $\gamma \leq \lambda^{++K}$ then an ordinal ξ is an *accumulation point* of $\mathcal{C}$ in X for γ if the ordinals γ, ξ are in X, and the set $\bigcup\{\mathcal{C}_{\gamma''} : \mathrm{crit}(\mathcal{U}_{\gamma''}) = \lambda \text{ and } \gamma'' \geq \gamma'\}$ is unbounded in $X \cap \xi$ for all $\gamma' < \gamma$ in $X \cap g``\nu$.
4. $a^{\mathcal{C},X}(\gamma, \xi)$ is the least accumulation point of $\mathcal{C}$ in X for γ above ξ.

This definition of an accumulation point does not seem to be entirely satisfactory, since it depends on the set X and the function g as well as on the system $\mathcal{C}$; however, clause 5 of Theorem 4.19 gives a sense in which the functions $s^{\mathcal{C}}$ and $a^{\mathcal{C},X}$ are, up to finite differences, independent of g, X and $\mathcal{C}$.

4.19 Theorem (Covering Lemma for Sequences of Measures). *Assume there is no inner model of $\exists\kappa\,(o(\kappa) = \kappa^{++})$. Let κ be a cardinal of the core model K, and let $\breve{\kappa}$ be a cardinal of K such that $\breve{\kappa} \geq \max\{\kappa, o(\kappa)\}$. Finally, let X be a set such that $\kappa \not\subseteq X = Y \cap K_{\breve{\kappa}}$ for some set Y such that $Y \prec_1 H(\breve{\kappa}^+)$ and ${}^{\mathrm{cf}(\kappa)}Y \subseteq Y$.*

Then there is an ordinal $\rho < \kappa$, a function $h \in K$, and a function $\mathcal{C}$ such that

1. *$\mathcal{C}$ is an h-coherent system of indiscernibles for K.*
2. *$\mathrm{dom}(\mathcal{C}) \subseteq X$ and $\bigcup_\gamma \mathcal{C}_\gamma \subseteq X$.*
3. *$X = h``(X \cap \rho; \mathcal{C})$, and hence $X \subseteq h``(\rho; \mathcal{C})$.*
4. *For all $\nu \in X \cap \kappa$, either $\nu \in h``(X \cap \nu)$ or else there is a γ such that $\nu \in \mathcal{C}_\gamma$. In the latter case there is $\xi \in X \cap \nu$ such that either*

    (a) $\nu = s^{\mathcal{C}}(\gamma, \xi) = s_*^{\mathcal{C}}(\gamma, \xi)$, or else

(b) $\nu = a^{\mathcal{C},X}(\gamma', \xi)$ *for some* $\gamma' > \gamma$ *in* $h``(X \cap \nu)$*.*

Furthermore, clause (a) holds if ν *is a limit point of* X*.*

5. *If* X' *is another set satisfying the hypothesis of the theorem, then there is a finite set* a *of ordinals such that for any* $\xi, \gamma \in X \cap X'$ *with* $a \cap \mathrm{crit}(\mathcal{U}_\gamma) \subseteq \xi$ *and* $\xi > \max\{\rho^X, \rho^{X'}\}$ *we have*

$$s^{\mathcal{C}}(\gamma, \xi) = s^{\mathcal{C}'}(\gamma, \xi)$$
$$s_*^{\mathcal{C}}(\gamma, \xi) = s_*^{\mathcal{C}'}(\gamma, \xi)$$
$$a^{\mathcal{C},X}(\gamma, \xi) = a^{\mathcal{C}',X'}(\gamma, \xi)$$

whenever either is defined.

To see that Theorem 4.19 implies the Dodd-Jensen covering lemma as a special case, notice that if $K = L[U]$ then $\mathcal{C}$ contains only a single set C of indiscernibles for the unique measure U. Then clause 4 asserts that $\mathrm{ot}(C) \leq \omega$, and clause 5 asserts that C is maximal.

4.20 Remark. As with the Dodd-Jensen covering lemma, the hypothesis ${}^{\mathrm{cf}(\kappa)}X \subseteq X$ can be weakened: If $\mathrm{cf}(\kappa) < \delta < \kappa$ and δ is the successor of a regular cardinal, then there is an unbounded class $\mathbf{C} \subseteq \mathcal{P}_\delta(K_{\breve{\kappa}})$ of sets X satisfying the conclusion of Theorem 4.19 such that if $\vec{X}$ is an increasing chain of members of $\mathbf{C}$ such that $\mathrm{cf}(\kappa) < \mathrm{cf}(\mathrm{len}(\vec{X})) < \kappa$ then $\bigcup \vec{X} \in \mathbf{C}$.

4.21 Remark. The assumption that ${}^{\mathrm{cf}(\kappa)}Y \subseteq Y$ is used to ensure that the measures on κ generated by $\mathcal{C}$ are members of X. As was pointed out in observation 6 at the beginning of this section, this assumption can be weakened to ${}^{\omega}Y \subseteq Y$ if $o(\kappa) < \kappa^+$.

Similarly, if $o(\kappa) < \kappa^+$ then Remark 4.20 can be improved to state that $\mathbf{C}$ is closed under increasing unions of uncountable cofinality.

4.22 Remark. If every measurable limit point of X is a member of X then the condition $\rho < \kappa$ can be strengthened to $\rho = \inf(\kappa - X)$, so that $X = h``(\rho; \mathcal{C})$. In particular, $\rho = \inf(\kappa - X)$ whenever $o(\alpha) < \inf(\kappa - X)$ for all $\alpha < \kappa$.

Introduction to the Proof

Before beginning to sketch the proof of the covering lemma we pause to look at three complications and digressions:

1. It was pointed out earlier that in order to ensure that $\mathrm{dom}(\mathcal{C}) \subseteq X$ we are assuming that $X \prec_1 K_{\breve{\kappa}}$, rather than $X \prec_1 K_\kappa$ as in the last section. This change, however, appears only in the very last step of the proof: until then we work only with $X \cap K_\kappa$ and use arguments which closely parallel those of the Dodd-Jensen covering lemma.

Similarly, this final step is the only place where the closure condition ${}^{\mathrm{cf}(\kappa)}Y \subseteq Y$ is used: up until then countable closure, ${}^{\omega}Y \subseteq Y$, is all that is needed.

2. The proof we give is for the $\mathrm{cf}(\kappa)$-closed case, with ${}^{\mathrm{cf}(\kappa)}Y \subseteq Y$, as in the statement of Lemma 4.19. With one exception, the extension of the proof to the stronger result of Remark 4.20 is relatively straightforward, using the ideas outlined in the proof of the Dodd-Jensen covering lemma. The exception is Lemma 4.28, and we will digress from the main line of the proof to state Lemma 4.29, the analogue of Lemma 4.28 for the unclosed case, and to sketch its proof. The reader may, if desired, skip this digression.

3. As was explained in Sect. 4.1 an essential complication arises from the special role which the weak covering lemma plays in the definition of the core model. Beyond $0^\dagger$, the core model K is constructed in two stages: The first stage constructs the *countably complete* core model K^{c}, for which iterability is guaranteed (below the sharp for a class of strong cardinals) by the fact that every full measure of K^{c} is countably complete in V. After Lemma 4.5 is proved for K^{c}, the true model K is shown to be an elementary substructure of K^{c}, so that the iterability of K^{c} implies the iterability of K.

Part 1 of the Proof

Here we give the first part of the proof of the covering lemma for the true core model K. At the end of this subsection we will show how to adapt this proof to prove the Weak Covering Lemma 4.5 for K^{c}. As in the proof of the Dodd-Jensen covering lemma we begin with the following diagram:

$$\begin{tikzcd} M_0 \arrow[r, rightsquigarrow, "i"] & M_\theta \supseteq M \arrow[r, "\tilde{\pi}"] & \widetilde{M} = \mathrm{Ult}_n(M, \pi, \kappa) \\ & \overline{K} \arrow[u, hook] \arrow[r, "\pi"] & X \cap K_\kappa \prec_1 K_\kappa \arrow[u, hook] \end{tikzcd} \tag{18.18}$$

The construction of this diagram is identical to the construction for the Dodd-Jensen covering lemma: M_θ is obtained as the last model of the iterated ultrapower of $M_0 = K$ arising from the comparison of K with the transitive collapse $\overline{K}$ of $X \cap K_\kappa$; and $\widetilde{M} = \mathrm{Ult}_n(M, \pi, \kappa)$ where M is the largest initial segment of M_θ, and n is the largest integer, such that the ultrapower is defined.

The proof of the analogue of Lemma 3.51, which states that the construction of diagram (18.18) succeeds, is the same as for the Dodd-Jensen covering lemma except for two items. The first is clause 3.51(3):

4.23 Claim. *Either $\theta = 0$ and M is a proper initial segment of $M_0 = K$, or else 1 is in the set D of drops in the iteration on M_0. That is, either the iteration is trivial or it drops immediately.*

Proof. Set $\eta = \mathrm{crit}(\pi)$ and let ρ be least such that $\mathcal{P}^K(\rho) \not\subseteq \overline{K}$. As in the proof of Lemma 3.17 it will be sufficient to show that $\rho \leq \eta$ and that any ultrafilter U in $K - \overline{K}$ has critical point $\mathrm{crit}(U) \geq \rho$.

We will show the second half first: suppose to the contrary that $U \in K - \overline{K}$ and $\tau = \mathrm{crit}(U) < \min\{\eta, \rho\}$. Evidently $\eta > \tau^{+\overline{K}}$, since otherwise $\tau^{+K} > \tau^{+\overline{K}}$, which contradicts the assumption that $\mathcal{P}^K(\tau) \subseteq \overline{K}$. Then $\eta \geq \tau^{++\overline{K}}$, and since $K \models o(\tau) < \tau^{++}$ it follows that $o^{\overline{K}}(\tau) < \eta$. Thus $o(\tau) = \pi(o^{\overline{K}}(\tau)) = o^{\overline{K}}(\tau)$ and $o(\tau) \subseteq \mathrm{ran}(\pi)$, which implies that every measure on τ in K is in $\overline{K}$, contradicting the choice of U.

Now suppose that $\rho > \eta$, that is, that $\mathcal{P}^K(\eta) \subseteq \overline{K}$. Then the filter $U = \{x \subseteq \tau : \eta \in \pi(x)\}$ is a normal ultrafilter on $\mathcal{P}^K(\tau)$, and hence is a member of K. Now factor π into $\pi : \overline{K} \xrightarrow{i^U} \mathrm{Ult}(\overline{K}, U) \xrightarrow{k} K$ and apply the argument from the last paragraph to the map k to conclude that every ultrafilter on η in K is in $\mathrm{Ult}(\overline{K}, U)$. In particular $U \lhd U$, which is impossible since $\lhd$ is well-founded. $\dashv$

The second item to consider is clause 3.51(2):

4.24 Claim. *The model $\overline{K}$ is not moved in the comparison of $\overline{K}$ with K.*

Proof. Since the iterated ultrapower on K drops, that on $\overline{K}$ does not. Suppose for the sake of contradiction that the claim is false, and let ν be the least stage at which the iterated ultrapower on $\overline{K}$ is nontrivial. Thus $N_\nu = N_0 = \overline{K}$, and $N_{\nu+1} = \mathrm{Ult}(\overline{K}, \overline{U})$ for some measure $\overline{U} = \mathcal{U}^{\overline{K}}_\gamma$ which is not in the νth model M_ν of the iteration on K. If $\overline{U}$ is an ultrafilter on M_ν then set $\overline{M}_\nu = M_\nu$; otherwise let $\overline{M}_\nu$ be the largest initial segment of M_ν such that every set in $\overline{M}_\nu$ is measured by $\overline{U}$. In either case $\overline{U}$ is an $\overline{M}_\nu$-ultrafilter, and $\overline{M}_\nu$ is a mouse with projectum at most $\mathrm{crit}(\overline{U})$.

First we show that $\mathrm{Ult}_n(\overline{M}_\nu, \overline{U})$ is iterable, where n is largest for which the ultrapower is defined. To see this, let $\mu = \mathrm{crit}(\overline{U})$ and note that $\pi(\overline{U}) = \mathcal{U}_{\pi(\gamma)}$ is a measure on $\pi(\mu)$ in K, while $\widetilde{M}_\nu = \mathrm{Ult}_n(\overline{M}_\nu, \pi, \pi(\mu)+1)$ is an initial segment of K by the same argument as for $\widetilde{M} = \widetilde{M}_\theta$. Since $\mathcal{U}_{\pi(\gamma)}$ is a full measure in K it follows that $\mathrm{Ult}_n(\widetilde{M}_n, \mathcal{U}_{\pi(\gamma)})$ is iterable. Then $\mathrm{Ult}_n(M_\nu, \overline{U})$ must also be iterable, since it can be embedded into $\mathrm{Ult}_n(\widetilde{M}_n, \mathcal{U}_{\pi(\gamma)})$ and hence any witness to the contrary could be copied to a witness that $\mathrm{Ult}_n(\widetilde{M}_\nu, \mathcal{U}_{\pi(\gamma)})$ is not iterable.

Thus we can use iterated ultrapowers to compare the models M_ν and $\mathrm{Ult}_n(M_\nu, \overline{U})$. An argument like that for Lemma 3.39 shows that neither of the two iterated ultrapowers drops and that they have the same last model N, giving rise to the following diagram, where s and t are the embeddings of the two iterated ultrapowers.

$$\begin{tikzcd} M_\nu \arrow[rr, "s"] \arrow[dr, "i^U"'] & & N \\ & \mathrm{Ult}_n(M_\nu, \overline{U}) \arrow[ur, "t"'] & \end{tikzcd} \tag{18.19}$$

Furthermore diagram (18.19) commutes, since every member of M_ν can be written as $h^{M_\nu}_{n+1}(\xi)$ for some $\xi < \mu$, and both of the embeddings s and $ti^{\overline{U}}$ are the identity on μ and both embeddings map $h^{M_\nu}_{n+1}$ to h^{N}_{n+1} by Lemma 3.26. It follows that $\mathrm{crit}(s) = \mathrm{crit}(ti^{\overline{U}}) = \mu$, so that the ultrapower s on M_ν starts with an ultrapower using a measure $\mathcal{U}^{M_\nu}_\gamma$. Furthermore, for every set $x \subseteq \kappa$ in M_ν we have $x \in \overline{U} \iff \mu \in ti^{\overline{U}}(x) \iff \mu \in i(x) \iff x \in \mathcal{U}^{M_\nu}_\gamma$. Thus $U = \mathcal{U}^{M_\nu}_\gamma \in M_\nu$. ⊣

This completes part one of the proof of the covering lemma for K, and we are now ready to prove the Weak Covering Lemma 4.5 for K^{c}:

Proof of Lemma 4.5. The proof is similar to the proof of the weak covering lemma for K^{DJ}. Suppose to the contrary that λ is a singular cardinal with $\mu^\omega < \lambda$ for all $\mu < \lambda$, and that $\kappa = \lambda^{+K^{\mathrm{c}}} < \lambda^+$. Then $\mathrm{cf}(\kappa) < \lambda$, and hence there is a set $X \prec_1 K_\kappa$, cofinal in κ, such that $\lambda \not\subseteq X$, ${}^\omega X \subseteq X$ and if $\eta = \min(\lambda - X)$ then $\mathrm{cf}(\eta) = \omega_1$. The final condition is obtained by constructing X as the union of an increasing chain of sets of length ω_1.

Now apply the construction above of part one of the proof to the set X, using K^{c} for K. The constraint $\mathrm{cf}(\eta) = \omega_1$ is needed to ensure that the measure U of the first paragraph of the proof of Claim 4.23 would be in K^{c} if it existed.

Now, as in the proof of the weak covering lemma for K^{DJ}, the fact that $\kappa = (\lambda^+)^{K^{\mathrm{c}}}$ implies that the set of indiscernibles generated by the construction is bounded by $\lambda + 1$. It follows that $X = h^X``(X \cap \lambda)$, which is impossible since it would imply that $\mathrm{cf}^{K^{\mathrm{c}}}(\lambda^{+K^{\mathrm{c}}}) \leq \lambda$. This contradiction completes the proof of Lemma 4.5. ⊣

We now turn to the main subject of this section, the analysis of indiscernibles which will complete the proof of the full covering lemma.

Part 2 of the Proof: Analyzing the Indiscernibles

As in the proof of the Dodd-Jensen covering lemma, the $\widetilde{M} = \mathrm{Ult}_n(M, \pi, \kappa)$ of diagram (18.18) is a mouse in K. It follows that $\widetilde{M}$ is an initial segment of K; that is, $\widetilde{M} = J_{\tilde{\alpha}}[\mathcal{U}{\restriction}\tilde{\alpha}]$ for some ordinal $\tilde{\alpha} < \kappa^+$.

Still following the proof of the Dodd-Jensen covering lemma, let ν_0 be the largest member of the set D of drops, and let $\bar{\rho} < \bar{\kappa}$ be the Σ_n projectum of $M^*_{\nu_0+1}$ and hence of M_ν for every ordinal ν in the interval $\nu_0 < \nu \leq \theta$. The ordinal ρ required by Lemma 4.19 must satisfy

$$\rho \geq \sup(\pi``\bar{\rho}). \tag{A}$$

In the proof of the Dodd-Jensen covering lemma we could set $\rho = \sup(\pi``\bar{\rho})$, but in the present proof there are several other things which can go wrong, and each of these will determine a separate lower bound for ρ. Rather than specifying ρ at this point we will, at various points during the course of the proof, specify a series (A)–(E) of lower bounds on ρ. At any point in the proof we will assume that ρ is an ordinal less than κ which satisfies all the lower bounds specified up to that point.

Let $\overline{\mathcal{C}}$ be the system of indiscernibles on $\overline{K}$ given by the iteration of K, and define $\widetilde{\mathcal{C}}$ with $\mathrm{dom}(\widetilde{\mathcal{C}}) = \tilde{\pi}``\mathrm{dom}(\overline{\mathcal{C}})$ by setting $\widetilde{\mathcal{C}}_{\tilde{\pi}(\gamma)} = \pi``\overline{\mathcal{C}}_\gamma - \rho$ for each $\gamma \in \mathrm{dom}(\overline{\mathcal{C}})$. This is nearly the desired set of indiscernibles: it is an $\tilde{h}$-coherent system of indiscernibles at least for $\mathrm{ran}(\tilde{\pi})$, and $X \cap K_\kappa = K_\kappa \cap \pi``h(\bar{\rho} \cap X; \overline{\mathcal{C}}) = K_\kappa \cap \tilde{h}(X \cap \rho; \widetilde{\mathcal{C}})$ where $\tilde{h}$ is the Skolem function of $\widetilde{M}$.

In order to convert $\widetilde{\mathcal{C}}$ into a system of indiscernibles for K we will show that $\widetilde{\mathcal{C}}$ generates a sequence of normal ultrafilters $\mathcal{U}^*_\gamma$ on K such that $\mathrm{Ult}(K, U)$ is well-founded. It will follow that $\mathcal{U}^*_\gamma$ is equal to some full measure $\mathcal{U}_{\tau(\gamma)}$ in K, and will define a sequence $\mathcal{C}$ of indiscernibles for K by setting $\mathcal{C}_{\tau(\gamma)} = \mathcal{C}^*_\gamma$. Finally, in order to show that $\mathcal{C}$ is a sequence of indiscernibles, we will use the assumption ${}^{\mathrm{cf}(\kappa)}Y \subseteq Y$ to show that the range of τ is contained in Y, and obtain the required function h by combining $\tilde{h}$ with a function g obtained by applying the covering lemma to $X \cap (\breve{\kappa} - \kappa)$.

The coherence function $\mathrm{Coh}^{\gamma'}_{\gamma,}$ was defined in Definition 4.14. Note that this definition does make sense even though the measures $\mathcal{U}_{\gamma'}$ and $\mathcal{U}_\gamma$ are partial in K, and are full measures only in $\widetilde{M}$.

4.25 Definition. Define the relation $\nu \in_\gamma x$, for $x \in K$ and γ an ordinal, as follows:

$$\nu \in_\gamma x \quad \Longleftrightarrow \quad \begin{cases} \nu \in x & \text{if } \nu \in \widetilde{\mathcal{C}}_\gamma \\ x \cap \nu \in \mathcal{U}_{\gamma''} & \text{if } \nu \in \mathcal{C}_{\gamma'} \text{ where } \gamma < \gamma' \text{ and } \gamma'' = \mathrm{Coh}_{\gamma,\gamma'}(\nu) \\ \text{undefined} & \text{otherwise} \end{cases}$$

4.26 Definition. If $\gamma \in \mathrm{dom}(\widetilde{\mathcal{C}})$ then define

$$\mathcal{C}^+_\gamma = \bigcup\{\widetilde{\mathcal{C}}_{\gamma'} : \gamma' \geq \gamma \ \ \& \ \ \mathrm{crit}(\widetilde{\mathcal{U}}_{\gamma'}) = \mathrm{crit}(\mathcal{U}_\gamma)\}.$$

If $\mathcal{C}^+_\gamma$ is cofinal in $\mathrm{crit}(\mathcal{U}_\gamma)$, then we write $\mathcal{U}^*_\gamma$ for the set of $x \in \mathcal{P}^K(\mathrm{crit}(\mathcal{U}_\gamma))$ such that $\nu \in_\gamma x$ for all sufficiently large $\nu \in \mathcal{C}^+_\gamma$.

In order to show that the filters $\mathcal{U}^*_\gamma$ are K-ultrafilters we use the idea of an *indiscernible sequence*:

4.27 Definition. A sequence $\vec{\alpha} = \langle \alpha_n : n < \omega \rangle$ is a *$\widetilde{\mathcal{C}}$-indiscernible sequence* for $\vec{\gamma} = \langle \gamma_n : n < \omega \rangle$ if $\vec{\alpha}$ is strictly increasing, $\alpha_n \in \widetilde{\mathcal{C}}_{\gamma_n}$ for all but finitely many $n < \omega$, and either (i) $\sup_n(\gamma_n) = \sup_n(\alpha_n)$, or (ii) $\mathrm{crit}(\mathcal{U}_{\gamma_n}) = \sup_{n\in\omega}(\alpha_n)$ for all $n < \omega$.

The following lemma corresponds to the argument that C^X is a Prikry sequence in the proof of the Dodd-Jensen covering lemma.

4.28 Lemma. *If $\vec{\alpha}$ is a $\widetilde{\mathcal{C}}$-indiscernible sequence for $\vec{\gamma}$ in $\widetilde{\mathcal{C}}$ then for any function $f \in K$ there is an $n_0 < \omega$ such that:*

1. *If* $n_0 \leq n < n' < \omega$ *and* $\operatorname{crit}(\mathcal{U}_{\gamma_{n'}}) < \gamma_m \leq \min\{\gamma_n, \gamma_{n'}\}$, *then for all* $\xi < \alpha_n$ *we have* $\alpha_n \in_{\gamma_m} f(\xi) \iff \alpha_{n'} \in_{\gamma_m} f(\xi)$.

2. *If* $n_0 < n$ *and* $\gamma_n < \kappa$ *then for all* $\xi < \alpha_n$ *we have* $\alpha_n \in f(\xi)$ *if and only if* $f(\xi) \cap \operatorname{crit}(\mathcal{U}_{\gamma_n}) \in \mathcal{U}_{\gamma_n}$.

Proof. Suppose that the lemma fails for some $\widetilde{\mathcal{C}}$-indiscernible sequence $\vec{\alpha}$ for $\vec{\gamma}$. The assertion that clause 2 fails uses parameters $\vec{\alpha}$ and $\{\gamma_n : \gamma_n < \kappa\}$, both of which are contained in X, and since ${}^{\omega}Y \subseteq Y$ it follows that both parameters are members of Y. By elementarity it follows that there is such a function f which is a member of Y. Then $f \in \operatorname{ran}(\tilde{\pi})$ by Proposition 3.63, so $\tilde{\pi}^{-1}(f)$ is in M and contradicts the fact that $\bar{\mathcal{C}}$ is a sequence of indiscernibles for M.

For clause 1, define $\gamma_{n',n} = \operatorname{Coh}_{\gamma_{n'},\gamma_n}(\alpha_n)$ whenever this is defined. Then the statement "$\alpha_n \in_{\gamma_m} f(\xi)$" is equivalent to the statement "Either $\gamma_n = \gamma_m$ and $\alpha_n \in f(\xi)$ or else $\gamma_{m,n}$ is defined and $f(\xi) \cap \alpha_n \in \mathcal{U}_{\gamma_{m,n}}$", so the statement that the lemma does not hold for $\vec{\alpha}$, $\vec{\gamma}$ and f can be stated using as parameters $\vec{\alpha}$, the ordinals $\gamma_{n',n}$, and $\{(n,n') \in \omega^2 : \gamma_n = \gamma_{n'}\}$. All of these are contained in X, so the same argument as in the last paragraph yields a contradiction. $\dashv$

Before using Lemma 4.28 to show that the sets $\mathcal{U}^*$ are K-ultrafilters, we digress to look at the analog of Lemma 4.28 for the case when X is not countably closed.

Digression for Non-Countably Closed Sets X

It was pointed out in the introduction to the proof of Theorem 4.19 that Lemma 4.28 is the one point in the proof where a new idea, beyond those presented in the proof of the Dodd-Jensen covering lemma, is needed in order to strengthen Theorem 4.19 as in Remark 4.20 by removing the assumption that $X = Y \cap K_{\breve{\kappa}}$ for some countably closed set Y. Lemma 4.29 below substitutes for Lemma 4.28 in this case. Lemma 4.29 and its proof may be skipped without affecting the proof of the covering lemma as stated in Theorem 4.19.

4.29 Lemma. *Suppose that* $\delta = \tau^+$ *where* τ *is a uncountable regular cardinal, and let* $\mathbf{C}$ *be the set of* $X \in \mathcal{P}_\delta(K_{\breve{\kappa}})$ *such that* $\mathcal{C}^X$ *satisfies Lemma 4.28. Then* $\mathbf{C}$ *is unbounded in* $X \in \mathcal{P}_\delta(K_{\breve{\kappa}})$ *and is closed under unions of increasing sequences of uncountable cofinality.*

Note that the requirement on δ is stronger than is needed for the corresponding results in the proof of the Dodd-Jensen covering lemma, for which δ could be any uncountable cardinal.

Sketch of Proof. The proof of the following analogue of Lemma 3.58 is direct:

4.30 Lemma. *If $X_0 \subseteq X_1$, and $\vec{\alpha}$ and $\vec{\gamma}$ are sequences with range contained in X_0 such that $\vec{\alpha}$ is a $\mathcal{C}^{X_1}$-indiscernible sequence for $\vec{\gamma}$, then $\vec{\alpha}$ is also a $\mathcal{C}^{X_0}$-indiscernible sequence for $\vec{\gamma}$.*

As in the Dodd-Jensen covering lemma, it easily follows that $\mathbf{C}$ is closed under increasing unions of uncountable cofinality. Thus we only need to prove that $\mathbf{C}$ is unbounded.

Let S be the set of $\sigma \in \operatorname{Col}(\delta, K_\lambda)$ such that $\operatorname{cf}(\operatorname{dom}(\sigma)) = \tau$ and $\operatorname{ran}(\sigma)$ fails to satisfy Lemma 4.28. As in the Dodd-Jensen covering lemma, we will finish the proof of Lemma 4.29 by showing that S is nonstationary. Suppose toward a contradiction that S is stationary, and for each function $\sigma \in S$ let $\vec{\alpha}^\sigma$ and $\vec{\gamma}^\sigma$ be sequences which witness that Lemma 4.29 fails for $X^\sigma = \operatorname{ran}(\sigma)$; that is, $\vec{\alpha}^\sigma$ is a $\mathcal{C}^\sigma$-indiscernible sequence for $\vec{\gamma}^\sigma$, but $\vec{\alpha}$ and $\vec{\gamma}$ fail to satisfy one of clauses 1 or 2 of Lemma 4.28. Now continue following the proof of Lemma 3.60, which was the analog in the proof of the Dodd-Jensen covering lemma of Lemma 4.29: Let A^σ be the set

$$\bigl\{\vec{\alpha}^\sigma, \{\gamma^\sigma_n : \gamma^\sigma_n < \kappa\}, \{(n', n) : \gamma^\sigma_{n',n} \text{ is defined}\}, \{(n', n) : \gamma^\sigma_{n'} = \gamma^\sigma_n\}\bigr\}$$

of parameters used in the proof of Lemma 4.28, and find $\sigma_0 \in S$ and a stationary set $S_0 \subseteq S$ so that $\sigma \supseteq \sigma_0$ and $A^\sigma \subseteq \operatorname{ran}(\sigma_0)$ for all $\sigma \in S_0$.

Recall that the key point in the proof of Lemma 3.60 was that, because $C^\sigma \subseteq^* C^{\sigma_0}$ for every $\sigma \in S_0$, each of the sets C^σ were determined (up to a finite set) by the subset $D^\sigma = C^{\sigma_0} - C^\sigma$ of C^{σ_0}. The key step in the current proof is to use Fodor's Lemma and the hypothesis that $\delta = \tau^+$ to find a set Z which fills the role of C^{σ_0}. Toward this end, choose an function $k : \tau \cong \operatorname{dom}(\sigma_0) < \tau^+$. Since $\operatorname{cf}(\tau) > \omega$ there is, for each $\sigma \in S$, an ordinal $\xi^\sigma < \tau$ such that $\bigcup A^\sigma \subseteq \sigma_0 k``\xi^\sigma$. By Fodor's Lemma there is a stationary subset $S_0' \subseteq S_0$ such that $\xi^\sigma$ is constant, say $\xi^\sigma = \xi$ for each $\sigma \in S_0'$. Set $Z = (\sigma_0 \circ k)``\xi$, so that $|Z| < \tau$ and $\bigcup A^\sigma \subseteq Z$ for every $\sigma \in S_0'$.

The rest of the proof parallels the proof of Lemma 3.60 for the Dodd-Jensen covering lemma. First define, for each $\sigma \in S_0'$, a set $w(\sigma)$ which witnesses that the restriction of $\widetilde{\mathcal{C}}$ to Z is as large as possible. This set is obtained by modifying Definition 3.18 as follows: Set the support β^σ of $w(\sigma)$ to be $\beta^\sigma = \max\{\sup(Z), \rho^\sigma + 1\} < \kappa$, and replace the requirement that $w(\sigma)$ be countable with the condition $|w(\sigma)| = |Z|$. Finally, modify clause 3 of Definition 3.18 to state that $\mathfrak{m}^\sigma = \operatorname{dir\,lim}(w(\sigma))$ is the Σ_n-code of a mouse of K, and there is a function $f = f^\sigma$ which is Σ_1-definable in $\mathfrak{m}^\sigma$ such that (i) for any $\alpha, \gamma \in Z$ such that $\gamma < \kappa$ and $\alpha \notin \widetilde{\mathcal{C}}^\sigma(\gamma)$, there is a set $x \in f``\alpha$ such that $x \in \mathcal{U}(\gamma)$ but $\alpha \notin x$, and (ii) for any $\alpha < \alpha'$ in $Z$ which are not members of the same set $\mathcal{C}^\sigma(\gamma)$, there is $x \in f``(\alpha \cap w(\sigma))$ such that $\alpha \in x$ and $\alpha' \notin x$.

Thus $w(\sigma)$ gives a complete description of the restriction of $\mathcal{C}^\sigma$ to Z.

Now, since $|w(\sigma)| = |Z| < \tau$ and $\operatorname{cf}(\operatorname{dom}(\sigma)) = \tau$ for every member σ of S_0', Lemma 3.23 implies that there is $\sigma_1 \in S_0'$ and a stationary set $S_1 \subseteq S_0'$ such that if $\sigma \in S_1$ then $\sigma_1 \subseteq \sigma$ and $w(\sigma) \subseteq \operatorname{ran}(\sigma_1)$. By shrinking S_1 further, if necessary, we can ensure that $\beta^\sigma = \beta$ is constant for $\sigma \in S_1$.

Now since S_1 is unbounded and the sequences $\vec{\alpha}^{\sigma_1}$ and $\vec{\gamma}^{\sigma_1}$ do not satisfy the conclusion of Lemma 4.28, there is some $\sigma \in S_1$ with a function $f \in \operatorname{ran}(\sigma)$ which witnesses this failure. It follows that $\vec{\alpha}^{\sigma_1}$ is not a $\widetilde{\mathcal{C}}^{\sigma}$-indiscernible sequence, and by the definition of $w(\sigma)$ it follows that there is a function f' which is Σ_1-definable in $\operatorname{dir lim}(w(\sigma))$ which witnesses this failure. Now $w(\sigma) \subseteq \operatorname{ran}(\sigma_1)$, and it follows that $\operatorname{dir lim}(w(\sigma)) \subseteq \widetilde{M}^{\sigma_1}$. To see this, notice that $\bar{\mathfrak{m}} = \operatorname{dir lim}((\pi^{\sigma_1})^{-1} w(\sigma)) \subseteq M$, since every subset of $\bar{\rho} = (\pi^{\sigma_1})^{-1}(\rho^{\sigma_1})$ in $\mathfrak{m}$ is a member of M and there is a subset of $\bar{\rho}$ definable in M which is not a member of M.

Thus $\vec{\alpha}^{\sigma_1}$ is not a $\widetilde{\mathcal{C}}^{\sigma_1}$-indiscernible sequence for $\vec{\gamma}^{\sigma_1}$. This contradicts the choice of $\vec{\alpha}^{\sigma_1}$ and $\vec{\gamma}^{\sigma_1}$, and hence completes the proof of Lemma 4.29. ⊣

Continuation of the Main Proof

This completes the digression for non-countably closed covering sets X, and we now return to the basic proof of the covering lemma.

4.31 Lemma. *Suppose that $\mathcal{C}^+(\gamma)$ is cofinal in $\alpha = \operatorname{crit}(\mathcal{U}_\gamma)$. Then $\mathcal{U}^*_\gamma$ is a normal ultrafilter on K, and $\operatorname{Ult}(K, \mathcal{U}^*_\gamma)$ is well-founded. Hence $\mathcal{U}^*_\gamma = \mathcal{U}_{\tau(\gamma)}$ in K for some ordinal $\tau(\gamma)$.*

Furthermore, for any function $f \in K$ there is an $\eta < \alpha$ such that

$$\begin{aligned} &\forall \nu, \gamma \big(\eta < \nu < \alpha < \gamma \ \ \& \ \ \nu \in \mathcal{C}^+_\gamma \\ &\qquad \implies \ \forall \xi < \nu \,(\nu \in_\gamma f(\xi) \iff f(\xi) \in \mathcal{U}^*_\gamma)\big). \end{aligned} \tag{18.20}$$

We break up the proof of Lemma 4.31 into two parts, depending on the cofinality of α.

4.32 Lemma. *The conclusion of Lemma 4.31 holds whenever $\operatorname{cf}(\alpha) = \omega$. Furthermore if $\alpha < \kappa$ then $\tau(\gamma) = \gamma$, and if $\alpha = \kappa$ then $\tau(\gamma) \in Y$.*

Proof. In this case everything except the existence of $\tau(\gamma)$ follows immediately from Lemma 4.28, as any counterexample could be witnessed by a $\widetilde{\mathcal{C}}$-indiscernible sequence. The assertion that $\tau(\gamma) = \gamma$ if $\alpha < \kappa$ follows from clause 2 of that lemma, and the assertion that $\tau(\gamma) \in Y$ if $\gamma > \kappa$ follows from its proof.

The existence of $\tau(\gamma)$ follows from Corollary 4.13, which states that $\mathcal{U}^*_\gamma$ is equal to some full measure $\mathcal{U}_{\gamma'}$ on the K-sequence provided that $\operatorname{Ult}(K, \mathcal{U}^*_\gamma)$ is well-founded. If it is not well-founded then there are functions $f_n \in K \cap H(\alpha^+)$ such that $[f_{n+1}]_{\mathcal{U}^*_\gamma} < [f_n]_{\mathcal{U}^*_\gamma}$ for each $n < \omega$. As in the proof of Lemma 4.28 we can assert this condition on the functions f_n by a statement in Y, and by elementarity there must be such a sequence in Y. This is impossible, as it would imply that $\operatorname{Ult}(M, \tilde{\pi}^{-1}(\mathcal{U}_\gamma))$ is ill-founded, but $\tilde{\pi}^{-1}(\mathcal{U}_\gamma) = \mathcal{U}^M_{\pi^{-1}(\gamma)} \in M$, and hence $\operatorname{Ult}(M, \tilde{\pi}^{-1}(\mathcal{U}_\gamma))$ must be well-founded since M is an iterable model obtained by an iteration on K. ⊣

Before proving Lemma 4.31 when $\operatorname{cf}(\alpha) > \omega$ we need to make the following important observation:

4.33 Lemma. *Suppose $\vec{\alpha}$ is an increasing sequence with $\alpha_n \in \widetilde{\mathcal{C}}_{\gamma_n}$ for each $n < \omega$, and that* $\operatorname{crit}(\mathcal{U}_{\gamma_n}) = \alpha$ *for all $n < \omega$. If $\alpha' = \lim_n \alpha_n < \alpha$ then $\alpha' \in \widetilde{\mathcal{C}}_{\gamma'}$ for some $\gamma' \geq \limsup\{\gamma_n + 1 : n < \omega\}$.*

Proof. We can assume that $\gamma_n < \limsup_{m<\omega}(\gamma_m + 1)$ for all $n < \omega$. We want to use Lemma 4.32, using α' for α. This can be done by using $X \cap K_{\breve{\alpha}'}$, which is a suitable set for the covering lemma at α'. The iteration used in the construction of diagram (18.18) for $X \cap K_{\breve{\alpha}'}$ is an initial segment of that for X: let θ' be the least ordinal such that $\operatorname{crit}(i_{\theta',\theta}) > \pi^{-1}(\alpha')$ where the embeddings $i_{\xi',\xi}$ come from the iteration of K with last model M_θ. The first θ' stages of this iteration are exactly those which are used in the proof of the covering lemma for α', using the suitable set $X \cap K_{\breve{\alpha}'}$. By Lemma 4.32 it follows that this sequence generates measures $\mathcal{U}_{\gamma'}$, with critical point α', on the K-sequence; and furthermore $\mathcal{U}_{\gamma'} \in X$ since it is generated by countable sequences contained in X. Now the embedding $i_{\theta',\theta'+1}$ comes from an ultrapower of $M_{\theta'}$ using a measure $\mathcal{U}_{\bar{\gamma}'}^{M'_\theta}$ larger than all of those in N. Thus $\bar{\gamma}' > \pi^{-1}(\gamma'_n)$ for each $n < \omega$. But $\gamma_n = \tilde{\pi} i_{\theta',\theta}(\pi^{-1}(\gamma'_n))$ and $\alpha' \in \widetilde{\mathcal{C}}_{\gamma'}$ where $\gamma' = \tilde{\pi} i_{\theta',\theta}(\bar{\gamma}')$. Thus $\gamma' > \gamma_n$ for each $n < \omega$. ⊣

Proof of 4.31 for $\operatorname{cf}(\alpha) > \omega$. Suppose that $\operatorname{cf}(\alpha) > \omega$. We will first prove that for any function $f \in K$ there is an η satisfying (18.20).

Suppose to the contrary that f is a function for which no η exists as required. Define sequences ξ_n, ν_n and γ_n so that $\vec{\gamma}$ is nondecreasing, $\xi_n < \nu_n \in \mathcal{C}^+_{\gamma_n}$, and $\nu_n \in_{\gamma_n} f(\xi_n) \not\Longleftrightarrow f(\xi_n) \in \mathcal{U}^*_{\gamma_n}$ but for all $\nu \in \mathcal{C}^+_{\gamma_n} - \nu_{n+1}$ we have $\nu \in_{\gamma_n} f(\xi_n) \Longleftrightarrow f(\xi_n) \in \mathcal{U}^*_{\gamma_n}$.

Now set $\alpha' = \sup_n(\nu_n)$. By Lemma 4.33 $\alpha' \in \mathcal{C}_{\gamma'}$ for some $\gamma' \geq \sup_n(\gamma_n + 1)$, and if we set $\gamma'_n = \operatorname{Coh}_{\gamma_n,\gamma'}(\nu_n)$ then $\vec{\nu}$ is a $\widetilde{\mathcal{C}}$-indiscernible sequence for $\vec{\gamma}'$. Hence the lemma fails at α', contradicting Lemma 4.32. A similar argument shows that $\mathcal{U}^*_\gamma$ is normal.

Finally $\mathcal{U}^*_\gamma$ is countably complete when $\operatorname{cf}(\alpha) > \omega$, so $\operatorname{Ult}(K, \mathcal{U}^*_\gamma)$ is well-founded. Hence Corollary 4.13 implies that $\mathcal{U}^*_\gamma = \mathcal{U}_{\tau(\gamma)}$ for some ordinal $\tau(\gamma)$. ⊣

We are now ready to specify the second and third of the lower bounds on ρ:

$$\rho > \sup\{\gamma \in \operatorname{dom}(\mathcal{U}^*) \cap \kappa : \mathcal{U}_\gamma \neq \mathcal{U}^*_\gamma\}. \tag{B}$$

Condition (B) holds for all sufficiently large $\rho < \kappa$ since Lemma 4.28 implies that $\{\operatorname{crit}(\mathcal{U}^*_\gamma) : \mathcal{U}_\gamma \neq \mathcal{U}^*_\gamma\}$ is finite.

$$\rho > \sup \bigcup\{\widetilde{\mathcal{C}}_\gamma : \kappa < \gamma \ \& \ \mathcal{U}^*_\gamma \text{ is not defined}\}. \tag{C}$$

To see that the right-hand side of condition (C) is smaller than κ, suppose to the contrary that there is a cofinal set $C \subseteq \kappa$ such that for each $\nu \in C$ there is $\gamma_\nu > \kappa$ such that $\nu \in \widetilde{\mathcal{C}}_{\gamma_\nu}$ and $\mathcal{U}^*_{\gamma_\nu}$ is not defined. By taking a subsequence if necessary, we can assume that $\langle \gamma_\nu : \nu \in C \rangle$ is nondecreasing, but this implies that $\mathcal{U}^*_{\gamma_\nu}$ is defined for each $\nu \in C$.

Conditions (B) and (C) enable us to complete the definition of $\mathcal{C}$:

4.34 Definition. If $\gamma \in \operatorname{dom}\widetilde{\mathcal{C}}$ then let $\tau(\gamma)$ be the ordinal such that $\mathcal{U}^*_\gamma = \mathcal{U}_{\tau(\gamma)}$.

Define $\mathcal{C}$ by setting $\mathcal{C}_{\tau(\gamma)} = \widetilde{\mathcal{C}}_\gamma$ for all γ such that $\tau(\sigma)$ is defined.

Condition (A) ensures that $\tau(\gamma) = \gamma$ for all $\gamma < \kappa$. We now make our single use of the assumption that X is $\mathrm{cf}(\kappa)$-closed, that is, that $X = Y \cap K_{\breve\kappa}$ for some $Y \prec H(\lambda)$ with ${}^{\mathrm{cf}(\kappa)}Y \subseteq Y$

4.35 Claim. *If $\mathcal{U}^*_\gamma$ is defined then $\mathcal{U}^*_\gamma \in X$, and hence $\tau(\beta) \in X$.*

Proof. As in the proof of Lemma 4.28, the filter $\mathcal{U}^*_\gamma$ is generated in X by any cofinal subsequence of $\mathcal{C}^+_\gamma$. Since ${}^{\mathrm{cf}(\kappa)}\kappa \subseteq Y$, there is such a subsequence in Y. ⊣

4.36 Remark. If $o(\kappa) < \kappa^{+K}$ then the assumption that X is $\mathrm{cf}(\kappa)$-closed is unnecessary, for in that case there is a partition of κ into disjoint sets $\langle A_\beta : \beta < o(\kappa)\rangle$ such that $A_\beta \in \mathcal{U}(\kappa,\beta)$ for each $\beta < o(\kappa)$. If $\vec{A} \in Y$ then there is an $\eta < \kappa$ so that $\mathcal{C}(\kappa,\beta) - A_\beta \subseteq \eta$ for all $\beta < o(\kappa)$. If $\nu \in \mathcal{C}(\kappa,\beta) - \eta$ then β is definable from $\vec{A}$ as the unique ordinal β such that $\nu \in A_\beta$, so Claim 4.35 holds for all $X = Y \cap K_{\breve\kappa}$ with $\vec{A} \in Y$.

It is easy to see from the construction that $\mathcal{C}$ is a sequence of indiscernibles for K. Thus $\mathcal{C}$ satisfies clauses 1 and 2 of Theorem 4.19.

4.37 Claim. *There is a function $g \in K$ such that $X \subseteq g``(X \cap \kappa)$.*

Proof. Apply the proof of the covering lemma to the full set $X \prec_1 K_{\breve\kappa}$ (rather than to $X \cap K_\kappa$). Notice that, as in the proof of Lemma 4.5, there are no measurable cardinals in the interval $(\kappa, \breve\kappa]$ and hence any indiscernibles which come up in the construction must be smaller than κ. It follows, just as in the proof of the covering lemma for L, that there is a function $g \in K$ such that $X = g``(X \cap \kappa)$. ⊣

We now put the fourth lower bound on ρ:

$$\rho > \sup\bigl\{\nu : \exists\beta\,(\nu \in \mathcal{C}(\kappa,\beta) \wedge \beta \notin g``(X \cap \nu))\bigr\}. \tag{D}$$

The following claim justifies this bound:

4.38 Claim. *There is an ordinal $\eta < \kappa$ such that $\gamma \in g``(X \cap \nu)$ whenever $\gamma > \kappa$ and $\eta < \nu \in \mathcal{C}_\gamma$*

Proof. Define, in K, a disjoint sequence of sets $\langle A_\gamma : \gamma \in \operatorname{ran}(g)\rangle$ such that $A_\gamma \in \mathcal{U}_\gamma$ whenever $\gamma \in \operatorname{ran}(g)$ and $\mathcal{U}_\gamma$ is a full ultrafilter on κ in K. By Lemma 4.31 there is an $\eta < \kappa$ so that for all $\gamma \in \operatorname{dom}(\mathcal{C}) - \kappa$ and all $\nu \in \mathcal{C}_\gamma - \eta$ and $\xi < \nu$ we have $\nu \in A_{g(\xi)} \iff A_{g(\xi)} \in \mathcal{U}_\gamma$. Since the diagonal union $B = \{\nu < \kappa : \exists\xi < \nu \;\; \nu \in A_{g(\xi)}\}$ is a member of each measure $\mathcal{U}_{g(\xi)}$, we can also assume $\bigcup\{\mathcal{C}_\gamma - \eta : \gamma \in \operatorname{ran}(g)\} \subseteq B$. It follows that this choice of η will satisfy the statement of the lemma. ⊣

This completes the proof of the first three clauses of Theorem 4.19. For the rest of the proof of the theorem it will be convenient to use the notation $\mathcal{U}(\alpha, \beta)$, which explicitly names the critical point of the measure, rather than the notation $\mathcal{U}_\gamma$. In doing so we will consistently adjust the notation described earlier by replacing γ with the pair (α, β): for example, we will write $s^{\mathcal{C}}(\alpha, \beta, \xi)$ instead of $s^{\mathcal{C}}(\gamma, \xi)$, we will say that $\vec{\nu}$ is an indiscernible sequence for $(\vec{\alpha}, \vec{\beta})$ instead of $\vec{\gamma}$, and we will write $\mathrm{Coh}_{\alpha,\beta,\beta'}$ for the coherence function relating $\mathcal{U}(\alpha, \beta)$ and $\mathcal{U}(\alpha, \beta')$.

It will also be useful to have a notion of an indiscernible sequence which, like that of a Prikry sequence, depends directly on the sequence $\mathcal{U}$ of measures rather than on a system of indiscernibles.

4.39 Definition. We say that $\vec{\nu}$ is an *indiscernible sequence* for $(\vec{\alpha}, \vec{\beta})$ if (i) $\vec{\nu}$ is a strictly increasing sequence of ordinals of length ω, (ii) either $\sup_n(\nu_n) = \sup_n(\alpha_n)$ or else $\alpha_n = \sup_n(\nu_n)$ for all n, and (iii) for any function $f \in K$ there is $n_0 < \omega$ such that $\forall n > n_0 \forall \xi < \alpha_n\, (\nu_n \in f(\xi) \iff f(\xi) \cap \alpha_n \in \mathcal{U}_{\alpha_n, \beta_n})$.

Notice that Lemma 4.28 implies that any $\widetilde{\mathcal{C}}$-indiscernible sequence for $(\vec{\alpha}, \vec{\beta})$ is an indiscernible sequence for $(\vec{\alpha}, \vec{\beta}')$ where $\beta'_n = \tau(\beta_n)$.

In the rest of this proof we will say $\vec{\nu} <^* \vec{\nu}'$ to mean that $\nu_n < \nu'_n$ for all but finitely many $n < \omega$; and we will use $>^*$, $\leq^*$ and $\geq^*$ similarly.

We will first prove clause 4 of Theorem 4.19 in the case when $\mathrm{cf}(\nu) = \omega$. Suppose that $\nu \in \mathcal{C}_{\alpha,\beta}$; we want to show that there is an $\xi < \nu$ so that $\nu = s(\alpha, \beta, \xi) = s_*(\alpha, \beta, \xi)$. If this is not so then there is a cofinal sequence of ordinals $\nu_n \in \mathcal{C}_{\alpha,\beta_n}$ with $\beta_n \geq \beta$, and this contradicts Lemma 4.33 which implies that $\beta \geq \limsup_n(\beta_n + 1)$.

Now let $\nu \in \mathcal{C}_{\alpha,\beta_0}$ be arbitrary and let β_1 be the largest ordinal such that ν is an accumulation point in X for (α, β_1). Then $\bigcup_{\beta_1 \leq \beta < o(\alpha)} \mathcal{C}(\alpha, \beta)$ is bounded in $\nu \cap X$, say by $\xi \in X \cap \nu$. If $\beta_0 \geq \beta_1$ then $\nu = s(\alpha, \beta_0, \xi) = s_*(\alpha, \beta_0, \xi)$, so we can suppose that $\beta_0 < \beta_1$. We claim that there are only finitely many accumulation points in X for (α, β_1) in the interval (ξ, ν), so that $\nu = a(\alpha, \beta_1, \xi')$ for some ξ' in $[\xi, \nu) \cap X$. If, to the contrary, there are infinitely many such accumulation points, then let ν' be the least member of the interval $(\xi, \nu]$ which is a limit of accumulation points for (α, β_1). Then $\mathrm{cf}(\nu') = \omega$ and it follows from the last paragraph that $\nu' \in \mathcal{C}(\alpha, \beta')$ for some $\beta' \geq \beta_1$, contradicting the choice of ξ. This contradiction completes the proof of clause 4, except for the last sentence which states that $\nu = s(\alpha, \beta_0, \xi_0) = s_*(\alpha, \beta_0, \xi_0)$ whenever ν is a limit point of X. We will defer the proof of this for the case $\mathrm{cf}(\nu) > \omega$ until after the proof of clause 5, on which its proof depends.

Notice that any increasing ω-sequence $\vec{\nu}$ of indiscernibles from $\mathcal{C}$ is an indiscernible sequence for some $\vec{\alpha}, \vec{\beta}$. To see this, suppose that $\nu_n \in \mathcal{C}(\alpha_n, \beta_n)$, with $\alpha_n, \beta_n \in g``\nu_n$. If $\alpha_n \leq \sup_n(\nu_n)$ for each n, then $\vec{\nu}$ is an indiscernible sequence for $(\vec{\alpha}, \vec{\beta})$. Otherwise $\alpha_n = \alpha$ is constant for sufficiently large n with $\alpha_n > \alpha' = \sup_n(\nu_n)$, and Lemma 4.33 implies that $\alpha' \in \mathcal{C}(\alpha, \beta)$ for some $\beta < o(\alpha)$ such that $\beta_n > \beta$ for all sufficiently large $n < \omega$. Then $\vec{\nu}$ is an indiscernible sequence for $(\vec{\alpha}', \vec{\beta}')$ where $\alpha'_n = \alpha'$ and $\beta'_n = \mathrm{Coh}_{\alpha,\beta_n,\beta}(ga')$ for all n such that $\alpha_n = \alpha$.

The proof of clause 5 relies on Lemma 4.28(2), which implies for any sequences $\vec{\nu}, (\vec{\alpha}, \vec{\beta}) \in X$ that $\vec{\nu}$ is a $\mathcal{C}^X$-indiscernible sequence for $(\vec{\alpha}, \vec{\beta})$ if and only if it is an indiscernible sequence for $(\vec{\alpha}, \vec{\beta})$ in the sense of Definition 4.39; and similarly for X'. Suppose that clause 5 is false for the function $s^{\mathcal{C}}$. Then we can assume, without loss of generality, that there are infinite sequences $\vec{\alpha}, \vec{\beta}$ and $\vec{\xi}$ in $X \cap X'$ such that for each $n < \omega$ we have (i) $\nu'_n = s^{\mathcal{C}'}(\alpha_n, \beta_n, \xi_n)$ exists, (ii) $\xi_{n+1} \geq \nu'_n$, and (iii) $s^{\mathcal{C}}(\alpha_n, \beta_n, \xi_n)$ either does not exist or is strictly larger than $s^{\mathcal{C}'}(\alpha_n, \beta_n, \xi_n)$. Then $\vec{\nu}'$ is an indiscernible sequence for $(\vec{\alpha}, \vec{\beta})$, and since $Y \prec H(\lambda)$ it follows that Y satisfies that there is an indiscernible sequence $\vec{\nu}$ for $(\vec{\alpha}, \vec{\beta})$ such that $\nu_n > \xi_n$ for all n. Thus, by Lemma 4.28, $s^{\mathcal{C}}(\alpha_n, \beta_n, \xi_n)$ exists for all but finitely many $n < \omega$, so we can set $\nu_n = s^{\mathcal{C}}(\alpha_n, \beta_n, \xi_n)$. By the choice of $\vec{\alpha}, \vec{\beta}$ and $\vec{\xi}$, we must have $\vec{\nu} >^* \vec{\nu}'$, but then again Y satisfies that there is an indiscernible sequence ν'' for $(\vec{\alpha}, \vec{\gamma})$ such that $\vec{\xi} <^* \vec{\nu}'' <^* \vec{\nu}$, so that $\vec{\nu}''$ is an indiscernible sequence for $(\vec{\alpha}, \vec{\beta})$ in $\mathcal{C}$, which contradicts the choice of $\vec{\nu}$.

The proof of clause 5 for the function $s^{\mathcal{C}}_*$ is similar, except that $\vec{\nu}'$ is an indiscernible sequence for some $(\vec{\alpha}, \vec{\beta}')$ with $\vec{\beta}' \geq^* \vec{\beta}$, instead of for $(\vec{\alpha}, \vec{\beta})$ itself.

The proof that clause 5 holds for the function $a^{\mathcal{C}}$ is similar but slightly more complicated. We say that $\vec{\nu}$ is an *accumulation point sequence* for $(\vec{\alpha}, \vec{\gamma})$ if for all sequences $\vec{\gamma}' <^* \vec{\gamma}$ and $\vec{\nu}' <^* \vec{\nu}$ there are sequences $\vec{\nu}''$ and $\vec{\beta}''$ with $\vec{\nu}' <^* \vec{\nu}'' <^* \vec{\nu}$ and $\vec{\beta}' \leq \vec{\beta}''$ such that $\vec{\nu}''$ is an indiscernible sequence for $(\vec{\alpha}, \vec{\beta}'')$. By using the elementarity of Y and the fact that being an indiscernible sequence is absolute between Y and V, it follows that being an accumulation point sequence is also absolute between Y and V. The rest of clause 5 follows as for the functions $s^{\mathcal{C}}$ and $s^{\mathcal{C}}_*$.

This completes the proof of clause 5, and we now return to the proof of the final sentence of clause 4, which states that if ν is any limit point of X such that $\nu \in \mathcal{C}(\alpha, \beta)$ for some $\beta < o(\alpha)$ then $\nu = s(\alpha, \beta, \xi)$ for some $\xi \in X \cap \nu$. Let Z be the set of ordinals $\nu \in X \cap \lim(X)$ such that $\nu \notin h``\nu$ and there is no α, β and ξ in X such that $\nu = s(\alpha, \beta, \xi) = s_*(\alpha, \beta, \xi)$.

We specify the last lower bound on ρ:

$$\rho \geq \sup(Z). \tag{E}$$

This is justified by the following claim:

4.40 Claim. *The set Z is finite.*

Sketch of Proof. Suppose to the contrary that $\vec{\nu}$ is an increasing ω-sequence of members of Z. Then $\alpha = \sup_n(\nu_n) \notin Z$ since clause 4 holds for ordinals of cofinality ω, so $\vec{\nu}$ is an indiscernible sequence in $\mathcal{C}$ for some pair $(\vec{\alpha}, \vec{\beta})$ with

$\alpha_n \leq \alpha$. Since $\nu_n \in Z$, $\nu_n = a^{\mathcal{C}}(\alpha_n, \beta'_n, \xi_n)$ for some β'_n with $\beta_n < \beta'_n \leq o(\alpha_n)$ and $\xi_n \in X \cap \nu_n$.

Now proceed as in the proof of Lemma 4.33 for each of the ordinals ν_n. Let $C_n = \bigcup\{\mathcal{C}(\alpha_n, \beta) : \beta_n \leq \beta < \beta'_n\}$ and for each $\nu \in C_n$ let $\beta_{n,\nu}$ be the ordinal β such that $\nu \in \mathcal{C}(\alpha_n, \beta)$. Set $\vec{\beta}_n = \langle \beta_{n,\nu} : \nu \in C_n \rangle$. If the sequences $\vec{C}_n$ and $\vec{\beta}_n$ are in X then we can use the argument of Lemma 4.33 to conclude that $\beta_n \geq \sup_{\nu \in C_n} \beta_{n,\nu}$, contrary to assumption.

To deal with the general case, pick a set $X' = Y' \cap K_{\breve{\kappa}}$ as in the hypothesis of the Covering Lemma 4.19 so that $C_n \in Y'$ and $\vec{\beta}_n \in Y'$ for each $n < \omega$. Then the argument in the last paragraph shows that it cannot be true that $\nu_n \in \mathcal{C}^{X'}(\alpha_n, \beta_n)$ and at the same time $\nu \in \mathcal{C}^{X'}(\alpha_n, \beta_{n,\nu})$ for unboundedly many $\nu \in C_n$. But by clause 5, for sufficiently large $n < \omega$ we have $\nu_n \in \mathcal{C}^{X}(\alpha_n, \beta_n) \implies \nu_n \in \mathcal{C}^{X'}(\alpha_n, \beta_n)$ and $\nu \in \mathcal{C}^{X}(\alpha_n, \beta_{n,\nu}) \implies \nu \in \mathcal{C}^{X'}(\alpha_n, \beta_{n,\nu})$ for all $\nu \in C_n$. This contradiction completes the proof of Claim 4.40. $\dashv$

This completes the proof of the last sentence of clause 4, which is the end of the proof of Theorem 4.19, the covering lemma for sequences of measures.

4.3. The Singular Cardinal Hypothesis

We will now use Theorem 4.19 to establish the lower bound for the strength of a failure of the Singular Cardinal Hypothesis:

4.41 Theorem (Gitik [17]). *If there is a singular cardinal κ with $2^\kappa > \max\{\kappa^+, 2^{\mathrm{cf}(\kappa)}\}$ then there is a cardinal κ with $o(\kappa) \geq \kappa^{++}$ in K.*

The proof combines the use of the covering lemma with two theorems from Shelah's pcf theory. The first can be found as Conclusion 5.10(2) on page 410 of [53].

4.42 Theorem. *If κ is the least cardinal satisfying $\kappa^{\mathrm{cf}(\kappa)} > \kappa^+ + 2^{\mathrm{cf}(\kappa)}$ then $\mathrm{pp}(\kappa) \geq \kappa^{++}$, $\mathrm{cf}(\kappa) = \omega$, and $\forall \mu < \kappa\, \mu^\omega \leq \max\{\mu^+, 2^\omega\}$.*

We will assume that $o^K(\kappa) < \kappa^{++}$, where κ is given by the conclusion of Theorem 4.42, and derive a contradiction. Note that the conclusion implies that $\kappa > 2^\omega$ and $\mu^\omega = \mu$ for each cardinal μ of uncountable cofinality in the interval $2^\omega \leq \mu < \kappa$.

The statement that $\mathrm{pp}(\kappa) \geq \kappa^{++}$ implies that there is a sequence $\vec{\kappa} = \langle \kappa_n : n < \omega \rangle$ of regular cardinals smaller than κ, together with a sequence $\vec{f} = \langle f_\alpha : \alpha < \kappa^{++} \rangle$ of functions in $\prod \vec{\kappa}$ which is $<^*$-increasing and $<^*$-cofinal in $\prod \vec{\kappa}$. We will call such a sequence a *scale* and will use it to derive the contradiction. The first part of the proof will use the covering lemma to obtain from the given scale a scale in which each of the functions f_α is what Gitik calls a *diagonal sequence*. The exact meaning of this term will be given in Lemma 4.44 after some notation has been established, but a typical example, requiring $o(\kappa_{n+1}) \geq \kappa_n$ for each n, would be a sequence $f \in \prod \vec{\kappa}$

such that $f(n+1) = s_*(\kappa_{n+1}, f(n), \kappa_n)$ for each $n < \omega$. This construction requires separate covering sets for each sequence f_α, and relies heavily on the fact that any two such covering sets agree (on their common domain) for all but finitely many κ_n. The final contradiction, however, requires finding an appropriate collection of covering sets which agree for some particular fixed κ_n, and for this a second result of Shelah will be needed. A proof is in Jech [25, Lemma 24.10].

4.43 Lemma. *If $\langle f_\alpha : \alpha < \kappa^{++} \rangle$ is a scale, then for each $\alpha < \kappa^{++}$ with* $\mathrm{cf}(\alpha) = \kappa^+$ *there is an* exact upper bound *(eub) of $\langle f_{\alpha'} : \alpha' < \alpha \rangle$; that is, a function $g \in \prod \vec{\kappa}$ such that $f_{\alpha'} <^* g$ for all $\alpha' < \alpha$, and for any function $g' <^* g$ there is an $\alpha' < \alpha$ such that $g' <^* f_{\alpha'}$.*

In what follows we say that a set X is a *covering set* if it satisfies the hypothesis of the covering lemma, Theorem 4.19. All covering sets have cardinality 2^ω unless stated otherwise. We will be using a number of different covering sets, and will heavily use the next indiscernible function $s^X_*(\kappa, \beta, \xi)$ and next accumulation point function $a^X(\gamma, \beta, \xi)$ from that lemma. These functions depend on the choice of covering set X, but by clause 5 of Theorem 4.19 there is, for any two covering sets X and X', an $n_0 < \omega$ such that the functions defined using the two sets agree (whenever the arguments are in both sets) above κ_{n_0}. Keeping this in mind, we will normally simplify the notation by omitting the superscripts X. In addition we will use a standard, fixed covering set X for many of our calculations, but we will want this set to include a number of objects which are not defined until later in the course of the proof. To see that we can do so without loss of generality, note that if some desired object is not a member of X then we can choose a new, larger covering set X' which does include it. If we were to redo the proof up to this point using X' instead of X then there is some $n < \omega$ such that the X agrees with X' about indiscernibles above κ_n, and hence about everything defined in the proof so far which lies above κ_n. In this case we can throw out a finite initial segment $\vec{\kappa} \restriction n+1$ of the sequence $\vec{\kappa}$. By restricting the functions f_α in the original scale to this reduced sequence we obtain a scale for which X and X' agree. This will cause no problems so long as it occurs only finitely often.

We begin by assuming that $\{\vec{\kappa}, \vec{f}\} \subseteq X$. Set $\kappa'_n = \min(h^X``\kappa_n)$, so $\kappa_n \leq \kappa'_n \leq \kappa$. If $\kappa'_n > \kappa_n$ then κ_n will be an indiscernible for κ'_n. Let $\beta_n \leq o(\kappa_n)$ be the largest ordinal such that κ_n is an accumulation point for (κ'_n, β_n) in $\mathcal{C}^X$, noting that Definition 4.18 of an accumulation point makes perfectly good sense even if $\kappa'_n = \kappa_n$. Pick $g^*(n) < \kappa_n$ in X large enough that $\kappa'_n \in h^X``g^*(n)$, $\bigcup_{\beta \geq \beta_n} \mathcal{C}_{\kappa'_n, \beta} \subset g^*(n)$, and $\mathcal{C}^X$ has no accumulation points for (κ'_n, β_n) in $\kappa_n - g^*(n)$. The latter is possible because it follows from $\mathrm{cf}(\kappa_n) > \omega$ that there are only boundedly many accumulation points for (κ'_n, β_n) below κ_n

Now choose, for each $\alpha < \kappa^{++}$, a covering set X_α with $f_\alpha \in X_\alpha$. Since $o(\kappa) < \kappa^{++}$ implies that there are only κ^+ many possible Skolem functions h^{X_α}, there is a function h such that $\{\alpha < \kappa^+ : h^{X_\alpha} = h\}$ is cofinal in κ^{++}.

By throwing away the rest of the sequence $\vec{f}$ we can assume without loss of generality that $h^{X_\alpha} = h$ for all $\alpha < \kappa^{++}$. Similarly we can assume that there is an $n_0 < \omega$ such that $\rho^{X_\alpha} = \rho$ is constant and that the ordinals κ'_n, β_n and $g^*(n)$ computed using any X_α are the same as those computed using X for all $n > n_0$. By cutting off the start of the sequence $\vec{\kappa}$ we can assume that $n_0 = 0$. We will also assume that $h \in X$.

Define, for each $\alpha < \kappa^{++}$, a function f'_α by taking $f'_\alpha(n)$ to be the least ordinal $\xi \leq f_\alpha(n)$ such that $\kappa'_n \cap h^X``(\{\kappa'_n\} \cup (\xi+1)) \not\subseteq f_\alpha(n)$. The functions $f'_\alpha$ are unbounded in $\prod_n \kappa_n$: to see this, let $g$ be any member of $\prod \vec{\kappa}$ and pick $\alpha$ so that $f_\alpha(n) > \sup(\kappa_n \cap h``g(n))$ for almost all n. Then $f'_\alpha >^* g$.

Thus we can assume that $f'_\alpha = f_\alpha$ for all α, which implies that $f_\alpha(n)$ is an indiscernible in $\mathcal{C}_{\kappa'_n,\beta}$ for some $\beta < o(\kappa'_n)$. We now show that we can assume that the functions f_α are what Gitik calls *diagonal sequences*:

4.44 Lemma. *Under the assumptions of Theorem 4.42 there is a sequence $\vec{\kappa}$ of regular cardinals and a scale $\langle f_\alpha : \alpha < \kappa^{++}\rangle$ in $\prod \vec{\kappa}$ such that, using the notation introduced above, $\operatorname{cf}(\beta_n) = \kappa_{n-1}$. Furthermore, if we fix continuous, cofinal functions $t_n : \kappa_{n-1} \to \beta_n$, then each of the functions f_α satisfies $f_\alpha(n) = s_*(\kappa'_n, t_n(f_\alpha(n-1)), g^*(n))$ for almost all n.*

Note that the cofinalities are computed in V, and the maps t_n need not be in K.

Proof. Each of the ordinals β_n is a limit ordinal, for if $\beta_n = \beta + 1$ then $\mathcal{C}_{\kappa'_n,\beta}$ is cofinal in κ_n and $\mathcal{C}_{\kappa'_n,\beta+1} \cap \kappa_n \subseteq g^*(n)$, but this implies that $\operatorname{cf}(\kappa_n) = \omega$, contrary to assumption.

For any $\alpha < \kappa^{++}$ we know that each of the ordinals $f_\alpha(n)$ is equal to either $a(\kappa'_n, \beta, \gamma)$ or $s(\kappa'_n, \beta, \gamma)$ for some $\gamma < f(n)$ and $\beta \in h``f_\alpha(n)$. Since there is always some $\beta' \in \beta_n \cap h``f_\alpha(n)$ such that $s_*(\kappa'_n, \beta, g^*(n))$ is larger than either of these, we can assume that $f_\alpha(n) = s_*(\kappa'_n, \beta_{\alpha,n}, g^*(n))$ for some $\beta_{\alpha,n} \in \beta_n \cap h``f_\alpha(n)$.

4.45 Claim. *For any $\delta < \kappa$ there are at most finitely many $n < \omega$ such that $\operatorname{cf}(\beta_n) < \delta$; and there are at most finitely many n such that $\operatorname{cf}(\beta_n) = \kappa_n$.*

Proof. First suppose that $\operatorname{cf}(\beta_n) < \delta < \kappa$ for all n in an infinite set A, and let $\sigma_n : \operatorname{cf}(\beta_n) \to \beta_n$ be cofinal maps. For each $s \in \prod_{n\in A} \delta_n$ define $g_s \in \prod_{n \in A} \kappa_n$ (up to a finite set) by $g_s(n) = s_*(\kappa'_n, \sigma_n(s(n)), g^*(n))$. Then the maps g_s are cofinal in $\prod_{n\in A} \kappa_n$, but this is impossible since $\prod_{n\in A} \kappa_n$ has cofinality κ^{++} and there are at most $\delta^\omega < \kappa$ many functions g_s.

Now suppose that $\operatorname{cf}(\beta_n) = \kappa_n$ for all n in an infinite set A. We will use the assumption that $h \in X$ to show that for all $\alpha < \kappa^{++}$ we have $f_\alpha(n) < \sup(X \cap \kappa_n)$ for all but finitely many $n \in A$. This is impossible since $|X| = 2^\omega < \kappa_n = \operatorname{cf}(\kappa_n)$, and hence $X \cap \kappa_n$ is bounded in κ_n.

Recall that each f_α is covered by the covering set X_α in the sense that $f_\alpha(n) = \gamma_k$ for some sequence $\langle \gamma_0, \ldots, \gamma_k\rangle$ of indiscernibles in $\mathcal{C}^{X_\alpha}$ such that for each $i \leq k$ either $\gamma_i = s(\alpha_i, \eta_i, \xi_i)$ or $\gamma_i = a(\alpha_i, \eta_i, \xi_i)$ for some α_i, η_i and ξ_i

in $h``(\rho \cup \vec{\gamma}\restriction i)$. Let $i \leq \kappa$ be least such that $\gamma_i \geq \sup(X \cap \kappa_n)$. If $\alpha_i < \kappa_n$ then $\gamma_i < \alpha_i < \sup(X \cap \kappa_n)$, contrary to the choice of i, so it must be that $\alpha_i \geq \kappa_n$ which implies $\alpha_i = \kappa'_n$. In that case we have $\eta_i < \sup(\beta_n \cap h``(X \cap \kappa_n))$ and $\xi_i < \sup(X \cap \kappa_n)$. Thus we can find $\beta > \eta_i$ in $X \cap \beta_n$ and $\xi > \xi_i$ in $X \cap \kappa_n$, and then $\gamma_i \leq s_*(\kappa'_n, \beta, \xi) < \sup(X \cap \kappa_n)$ for all n sufficiently large that X agrees with X_α at κ_n. This again contradicts the choice of i. ⊣

Now define D to be the smallest set such that each of the ordinals κ_n is in D and D is closed under the function σ defined as follows: Suppose that $\gamma \in D$, let γ' be largest such that either $\gamma' = \gamma$ or $\gamma \in \mathcal{C}_{\gamma',\beta}$ for some β, and let $\beta = \beta(\gamma) > 0$ be the largest ordinal such that γ is an accumulation point for (γ', β). If $\mathrm{cf}(\beta) > \omega$ then define $\sigma(\gamma) = \mathrm{cf}(\beta)$; otherwise leave $\sigma(\gamma)$ undefined.

4.46 Claim. $\mathrm{ot}(D) = \omega$.

Proof. Otherwise let δ be the least limit point of D. Then the set $D' = \{\gamma \in D - \delta : \sigma(\gamma) < \delta\}$ is infinite. Now consider a covering set $X' \supseteq X$ of size δ^ω with $\delta \subseteq X$. Then $\sigma^{X'}(\gamma) = \sigma^X(\gamma)$ for infinitely many of the $\gamma \in D'$, and X' is cofinal in any γ with $\sigma^{X'}(\gamma) < \delta$. This contradicts the fact that every $\gamma \in D$ is regular. ⊣

If $\gamma \in D$ and $\sigma(\gamma)$ is defined then let $t_\gamma : \sigma(\gamma) \to \beta(\gamma)$ be continuous, increasing and cofinal. Note that we do not assume that $t_\gamma \in K$. Also let $g^{**}(\gamma) < \gamma$ be large enough that $\mathcal{C}_{\gamma',\beta} \cap \gamma \subseteq g^{**}(\gamma)$ for all $\beta \geq \beta(\gamma)$. Define $\mathcal{F}$ to be the set of functions $f \in \prod D$ such that for all but finitely many $\gamma \in D$ such that $\sigma(\gamma)$ is defined we have $f(\gamma) = s(\gamma', t_\gamma(f(\sigma(\gamma)), g^{**}(\gamma)))$.

4.47 Claim. *For each $\alpha < \kappa^{++}$ there is an $f \in \mathcal{F}$ such that $f_\alpha <^* f\restriction\vec{\kappa}$.*

Proof. Fix $\alpha < \kappa^{++}$, and work in the covering set X_α for f_α. Define a sequence of functions $g_k \in \prod D$ by recursion on $k \in \omega$ as follows: set $g_0(\kappa_n) = f_\alpha(\kappa_n)$ for $n < \omega$, and $g_0(\gamma) = 0$ for $\gamma \in D - \vec{\kappa}$. Now define g_{k+1} so that the inequalities

$$\begin{aligned} g_{k+1}(\gamma) &\geq s_*(\gamma', t_\gamma(g_k(\sigma(\gamma))), g^{**}(\gamma)) \\ s_*(\gamma', t_\gamma(g_{k+1}(\sigma(\gamma))), g^{**}(\gamma)) &\geq g_k(\gamma) \end{aligned}$$

hold for all $\gamma \in D$ such that $\sigma(\gamma)$ is defined. Then the function $f \in \prod D$ defined by $f(\gamma) = \sup_k(g_k(\gamma))$ is as required. ⊣

Define a tree order on D by letting the immediate successors of a ordinal $\gamma' \in D$ be the ordinals $\gamma \in D$ such that $\gamma' = \sigma(\gamma)$. This tree is infinite and finitely branching, so it has an infinite branch. This branch is an infinite subset $D' \subseteq D$ such that $\sigma(\gamma) = \max(D' \cap \gamma)$ for each $\gamma \in D' - \{\min(D')\}$. This set D' satisfies all of the original assumptions on $\vec{\kappa}$, and $\prod D'$ has a scale $\vec{f}'$ of functions satisfying the equation

$$f'_\alpha(n) = s_*(\kappa'_n, t_n(f_\alpha(n-1)), g^*(n)) \tag{18.21}$$

for all $\alpha < \kappa^{++}$ and all sufficiently large $n < \omega$, so the scale $\vec{f}'$ consists of diagonal sequences. This completes the proof of Lemma 4.44. $\dashv$

Now modify the sequence $\vec{f}$ by replacing the functions f_α such that $\mathrm{cf}(\alpha) = \kappa^+$ with an exact upper bound (given by Lemma 4.43) of the sequence $\langle f_{\alpha'} : \alpha' < \alpha\rangle$. These functions need not satisfy (18.21), but they do satisfy the following:

4.48 Claim. *If* $\mathrm{cf}(\alpha) = \kappa^+$ *then* $f_\alpha(n) = a(\kappa'_n, t_n(f_\alpha(n-1)), g^*(n))$ *for all but finitely many* $n < \omega$. *Furthermore* $\mathrm{cf}(f_\alpha(n)) > \mathrm{cf}(f_\alpha(n-1))$ *for infinitely many* $n < \omega$.

Note that we do not exclude the possibility that $f_\alpha(n)$ is also equal to $s_*(\kappa'_n, \beta_{\alpha,n}, g^*(n))$.

Proof. Let $\vec{\xi}$ be any sequence such that $\xi_{n-1} < f_\alpha(n-1)$ for almost all $n < \omega$. Since f_α is an exact upper bound of $\vec{f}\upharpoonright\alpha$, there is an $\alpha' < \alpha$ so that $f_\alpha(n-1) > f_{\alpha'}(n-1) > \xi_n$ for almost all n. Then $f_\alpha(n) > f_{\alpha'}(n) \geq s_*(\kappa'_n, t_n(\xi_n), g^*(n))$ for almost all n.

This shows that there is an accumulation point sequence $\vec{\eta}$ for the sequence $\langle(\kappa'_n, t_n(f_\alpha(n-1))) : n < \omega\rangle$ such that $\vec{\eta} \leq^* f_\alpha$. We now show that no accumulation point sequence $\vec{\eta}$ can satisfy $g^*(n) <^* \eta(n) <^* f_\alpha(n)$ for infinitely many n. To this end let $\vec{\eta}$ be any sequence such that $f_\alpha(n) > \eta_n$ for almost all n, and pick $\alpha' < \alpha$ so large that $f_{\alpha'}(n) > s_*(\kappa_n, t_n(\eta_{n-1}), g^*(n))$ for almost all n. Then $s_*(\kappa'_n, t_n(f_{\alpha'}(n-1)), g^*(n)) = f_{\alpha'}(n) > \eta_n$ for almost all n.

Finally, if $\mathrm{cf}(f_\alpha(n)) \leq \mathrm{cf}(f_\alpha(n-1))$ for all but finitely many $n < \omega$ then the set $\{\mathrm{cf}(f_\alpha(n)) : n < \omega\}$ is bounded by some $\delta < \kappa$, but in this case $\prod_n f_\alpha(n)$ would have cofinality at most $\delta^\omega < \kappa$, when in fact it has true cofinality $\mathrm{cf}(\alpha) = \kappa^+$. $\dashv$

There is a certain tension implicit in the statement of Claim 4.48: the first sentence appears to say that $\{s_*(\kappa'_n, t_n(\xi), g^*(n)) : \xi < f_\alpha(n-1)\}$ is cofinal in $f_\alpha(n)$, but that would contradict the second sentence. This is not yet an actual contradiction because the covering set in which $s_*(\kappa'_n, t_n(\xi), g^*(n))$ is evaluated varies with ξ. In the remainder of the proof we will realize this contradiction. Towards this end, pick a set $A \subseteq \omega$ such that

$$\big\{\alpha < \kappa^{++} : \mathrm{cf}(\alpha) = \kappa^+ \ \ \& \ \ A = \{n : \mathrm{cf}(f_\alpha(n)) > \mathrm{cf}(f_\alpha(n-1))\}\big\} \quad (18.22)$$

has cardinality κ^{++}, and then use the case $(2^\omega)^+ \to (\omega_1)^2_\omega$ of the Erdős-Rado theorem to find an uncountable subset S of the set (18.22) and an $n_0 \in \omega$ such that $f_{\alpha'}(n) < f_\alpha(n)$ for all $\alpha' < \alpha$ in S and all $n > n_0$. Let $\langle \delta_\iota : \iota < \omega_1\rangle$ enumerate S, set $g_\iota = f_{\delta_\iota}$ and write τ_n for $\sup_{\iota<\omega_1}(g_\iota(n))$.

Enlarge the covering set X, if necessary, so that $S \cup \{S\} \subseteq X$. Note that $\{g_\iota(n) : \iota < \omega_1\} \subseteq X$ for each n, so X is cofinal in τ_n. It follows by the final sentence of Theorem 4.19.4 that $\tau_n = s(\kappa'_n, \beta'_n, g^*(n))$ for some β'_n, for all but finitely many $n < \omega$, and that $\beta'_n \geq \sup_{\iota<\omega_1}(t_n(g_\iota(n-1)))$. As a consequence we can work with indiscernibles for τ_n rather than for κ'_n, as follows: Let $t^*_n : \tau_n \to \beta'_n$ be defined by $t^*_n(\xi) = \mathrm{Coh}_{\kappa'_n, t_n(\xi), \beta'_n}(\tau_n)$. Then $s_*(\kappa'_n, t_n(\gamma), g^*_n) = s_*(\tau_n, t^*_n(\gamma), g^*_n)$.

For each $n < \omega$ let Y_n be a covering set containing all of the data so far which has $\tau_{n-1} \subseteq Y_n$ and $|Y_n| = |\tau_{n-1}|^\omega \leq \tau^+_{n-1} \leq \kappa_{n-1} < \tau_n$. Define maps $d_{\iota,n}(\gamma)$ by setting $d_{\iota,n}(\gamma) = s^{Y_n}_*(\tau_n, t^*_n(\gamma), g^*(n))$ for each ordinal $\gamma < g_\iota(n-1)$, and set $d^*_{\iota,n} = \sup\{d_{\iota,n}(\gamma) : \gamma < g_\iota(n-1)\}$. Notice that $d^*_{\iota,n} < g_\iota(n)$ for all $n \in A$. This is clear if the nondecreasing sequence $\langle d_{\iota,n}(\gamma) : \gamma < g_\iota(n)\rangle$ is eventually constant; and if it is not constant then $\mathrm{cf}(d^*_{\iota,n}) = \mathrm{cf}(g_\iota(n-1)) < \mathrm{cf}(g_\iota(n))$, and since $d^*_{\iota,n} \leq g_\iota(n)$ it follows that $d^*_{\iota,n} < g_\iota(n)$.

Fix, for each $\iota < \omega_1$, some $\alpha_\iota < \delta_\iota$ and $n_\iota < \omega$ so that $d^*_{\iota,n} < f_{\alpha_\iota}(n) < g_\iota(n)$ for all $n \geq n_\iota$ in A. Then for each $\iota < \omega_1$ we have, for sufficiently large $n < \omega$,

$$\begin{aligned} &s^{Y_n}_*(\tau_n, t^*_n(f_{\alpha_\iota}(n-1)), g^*(n)) \\ &\quad = d_{\iota,n}(f_{\alpha_\iota}(n-1) \leq d^*_{n,\gamma} < f_{\alpha_\iota} = s^{X_{\alpha_\iota}}_*(\tau_n, t^*_n(f_{\alpha_\iota}(n-1)), g^*(n)). \end{aligned} \tag{18.23}$$

By enlarging X if necessary, we can assume that all ordinals mentioned in the inequality (18.23) are in X. Then for all $n < \omega$ there is ι_n such that for all $\iota > \iota_n$

$$s^{Y_n}_*(\tau_n, t^*_n(f_{\alpha_\iota}(n-1)), g^*(n)) = s^X_*(\tau_n, t^*_n(f_{\alpha_\iota}(n-1)), g^*(n)) \tag{18.24}$$

and for every $\iota < \omega_1$ there is $n_\iota < \omega$ such that for all $n > n_\iota$

$$s^{X_{\alpha_\iota}}_*(\tau_n, t^*_n(f_{\alpha_\iota}(n-1)), g^*(n)) = s^X_*(\tau_n, t^*_n(f_{\alpha_\iota}(n-1)), g^*(n)). \tag{18.25}$$

Now fix $\iota > \sup_{n<\omega}(\iota_n)$, and then pick $n > n_\iota$ large enough that inequality (18.23) holds for this n and ι. Then all three of (18.23), (18.24) and (18.25) hold, and this contradiction completes the proof of Theorem 4.41.

4.4. The Covering Lemma for Extenders

This subsection is unevenly divided into three parts. The largest part concerns the covering lemma up to $0^\P$, which is understood nearly as well as that for sequences of measures. A smaller part covers the covering lemma for the Steel core model, for which little is known beyond the weak covering lemma, and the final part describes what is known beyond this. No proofs are given. See [28] or chapter [57] for definitions and basic properties of extenders.

Up to a Strong Cardinal

This subsection covers the covering lemma when $o(\kappa) > \kappa^{++}$ but $0^\P$ does not exist; that is, when the core model contains extenders, but not overlapping extenders. More information may be found in [23].

It was remarked in the introduction to Sect. 4 that the extension of the covering lemma to this region involves two significant changes: one which is easy and largely notational, and another which is rather surprising. We will begin with the notational considerations, which come into play whenever extenders are present. These considerations are all that is needed for Theorem 4.50, which deals with extenders of length less than $\kappa^{+\omega}$ where κ is the critical point of the extender. We will consider the more surprising change following this theorem.

The first observation is that since there are no overlapping extenders, the notations $\mathcal{E}(\alpha,\beta)$ and $o(\alpha)$ are still meaningful: $\mathcal{E}(\alpha,\beta)$ is the βth full extender on α, and $o(\alpha)$ is the order type of the set of full extenders on α. Some care is required in the use of this notation: it is not true, as it is for sequences of measures, that $E = \mathcal{E}(\alpha,\beta)$ implies $o^{i^E(\mathcal{E})}(\alpha) = \beta$. For an example of this, let $E = \mathcal{E}(\alpha,\beta)$ where $\beta \geq \alpha^{++}$, and let U be the associated ultrafilter, that is, $x \in U$ if and only if $\alpha \in i^E(x)$. Then $U = \mathcal{E}(\alpha,\beta')$ for some $\beta' < \beta$. In fact $\mathcal{E}(\alpha,\beta') = \mathcal{E}_{\gamma'}$ where (since $\mathcal{E}(\alpha,\beta')$ is a measure) $\gamma' = (\alpha^{++})^{L[i^U(\mathcal{E})]}$. There are β' many ordinals $\gamma'' < \gamma'$ such that $\mathcal{E}_{\gamma''}$ is a full extender, so we must have $\beta' \leq (\alpha^{++})^{L[i^U(\mathcal{E})]}$. Now $\{\nu : o(\nu) > \nu^{++}\} \in U$, so $o^{i^U(\mathcal{E})}(\alpha) > (\alpha^{++})^{L[i^U(\mathcal{E})]}$. Thus $o^{i^U(\mathcal{E})}(\alpha) > (\alpha^{++})^{L[i^U(\mathcal{E})]} \geq \beta'$.

Because of this, it is not strictly true that comparisons of these models use only linear iterations; however, the tree iterations which they do use have a particularly simple form: there is a single trunk with no side branches of length more than one, and furthermore each extender used in the iteration tree is a member of (though not necessarily on the extender sequence of) the model to which it is applied. These simple trees can be modified to obtain linear iterations (cf. [2, 23]) or they can be handled directly without using the stronger techniques required for larger extenders (cf. [59]). Schindler [50] has extended such linearization techniques to work for cardinals below the sharp for a class of strong cardinals, and it is not known how much further they can be stretched.

Before we can state a covering lemma for models with extenders, we need to develop some notation for dealing with indiscernibles for extenders. Consider for contrast the more familiar case of indiscernibles for measures. If U is an ultrafilter on κ in some model M, and $i = i^U : M \to \mathrm{Ult}(M,U)$ is the canonical embedding, then κ is an indiscernible for $i(U)$ in the sense that

$$\forall x \in i``\mathcal{P}(\kappa)\bigl(\kappa \in x \iff i^{-1}(x) \in U \iff x \in i(U)\bigr),$$

and κ generates $\mathrm{Ult}(M,U)$ in the sense that

$$\mathrm{Ult}(M,U) = \{i^U(f)(\kappa) : f \in M\}.$$

Now let E be a (κ,λ)-extender, and let $i = i^E : M \to \mathrm{Ult}(M,E)$ be the canonical embedding. In this case the role previously played by the ordinal κ is played by the interval $[\kappa,\lambda)$: if we write E_a for the ultrafilter corresponding to $a \in [\lambda]^{<\omega}$ then

$$\forall x \in i``\mathcal{P}(\kappa^{|a|})\bigl(a \in x \iff i^{-1}(x) \in E_a \iff x \in i(E_a)\bigr),$$

and

$$\mathrm{Ult}(M,E) = \{i(f)(a) : f \in M \wedge a \in [\kappa,\lambda)^{<\omega}\}.$$

Thus a plays the role of an indiscernible for $i(E_a) = i(E)_{i(a)}$. Since $i(a) = i``a$ it will be sufficient to consider individual ordinals in the interval $[\kappa,\lambda)$.

In the example above we regard the critical point κ of i as a *principal indiscernible* for $i(E)$, and we will call an ordinal $\alpha \in [\kappa,\lambda)$ the *indiscernible for* $i(E)_{i(\alpha)}$ *belonging to* κ. In order to extend these concepts to an iterated ultrapower, we will write a system of indiscernibles for a model $M = L[\mathcal{E}]$ as a pair $(\mathcal{C}, b)$ of functions, where $\mathcal{C}_\gamma$ is the set of principal indiscernibles for the extender $\mathcal{E}_\gamma$ and $b(\gamma,\alpha,\xi)$ is the indiscernible (if there is one) for $(\mathcal{E}(\gamma))_\xi$ which belongs to α. Here is the precise definition:

4.49 Definition. If $i_{0,\theta} : M_0 \to M_\theta = M$ is an iterated ultrapower then the system $(\vec{\mathcal{C}}, b)$ of indiscernibles for M_θ generated by $i_{0,\theta}$ is defined as follows:

1. $\alpha \in \mathcal{C}_\gamma$ if and only if there are $\nu < \nu' \le \theta$ such that $\alpha = \mathrm{crit}(i_{\nu,\nu'})$ and $\mathcal{E}_\gamma = \mathcal{E}_\gamma^{M_{\nu'}} = i_{\nu,\nu'}(E_\nu)$ where E_ν is the extender such that $M_{\nu+1} = \mathrm{Ult}(M_\nu, E_\nu)$.

2. If $\alpha \in \mathcal{C}(\gamma)$, with ν and ν' as in clause 1, then $b(\gamma,\alpha,\eta)$ is defined if and only if $\eta \in i``[\alpha,\lambda)$ where E_ν is a (α,λ)-extender. In this case $b(\gamma,\alpha,\eta) = i^{-1}_{\nu,\nu'}(\eta)$.

In order to obtain an abstract definition of a system of indiscernibles for a model $M = L[\mathcal{E}]$, without any assumption that the system came from an iterated ultrapower, we replace clause 4.15(2) of Definition 4.15 of a system of indiscernibles for sequences of measures with clause $2'$ below.

$2'$ For any function $f \in M$ there is a finite sequence $\vec{a}$ of ordinals such that if $\alpha \in \mathcal{C}(\gamma)$, with $\vec{a} \cap [\alpha,\gamma) = \varnothing$, and $\bar{b} = b(\gamma,\alpha,b)$, then $\bar{b} \in x \iff x \cap V_\gamma \in (\mathcal{E}(\gamma))_b$.

Some obvious changes need to be made to the definition of a h-coherent system of indiscernibles, and the definition of $X = h``(\rho;\mathcal{C})$ needs to be modified to $h``(\rho;\mathcal{C},b)$.

4.50 Theorem (Covering Lemma for Short Extenders). *Assume that $n < \omega$ and that there is no inner model M such that $\{\alpha < \kappa : o^M(\alpha) = \alpha^{+n}\}$ is unbounded in κ for any cardinal κ. Let κ be a cardinal of K, set $\lambda = \kappa^{+n}$, and suppose $X = Y \cap K_\lambda$ where $Y \prec H(\lambda^+)$ and ${}^{\mathrm{cf}(\kappa)}Y \subseteq Y$. Then there is a pair $(\mathcal{C}, b)$, a function $h \in K$, and an ordinal $\rho < \kappa$ such that*

1. *The pair $(\mathcal{C}, b)$ is a h-coherent system of indiscernibles for K.*

2. $\mathrm{dom}(\mathcal{C}) \cup \mathrm{dom}(b) \subseteq X$, *and* $\mathrm{ran}(b) \cup \bigcup \mathrm{ran}(\mathcal{C}) \subseteq X$.

3. *For all $\nu \in X - \rho$, one of the following four conditions hold:*

   (a) $\nu \in h``(X \cap \nu)$.

(b) $\nu = s^{\mathcal{C}}(\gamma, \xi)$ *for some* $\xi \in X \cap \nu$ *and* $\gamma \in h``(X \cap \nu)$.

(c) $\nu = a^{\mathcal{C},X}(\gamma, \xi)$ *for some* $\xi \in X \cap \nu$ *and* $\gamma \in h``(X \cap \nu)$. *Furthermore, this clause never holds if* ν *is a limit point of* X.

(d) $\nu = b(\gamma, \alpha, a)$ *for some* $\alpha \in X \cap \nu$ *and* $\gamma, a \in h``\alpha$.

4. *If* X' *is another set satisfying the hypothesis of the theorem, and* $\mathcal{C}'$, b', X' *satisfy clauses 1–4, then there is a finite set* $\vec{d}$ *of ordinals such that if* $\xi, \gamma \in X \cap X'$ *with* $[\xi, \gamma) \cap \vec{d} = \varnothing$, *then*

$$s^{\mathcal{C}}(\gamma, \xi) \le s^{\mathcal{C}'}(\gamma, \xi)$$
$$a^{\mathcal{C},X}(\gamma, \xi) \le a^{\mathcal{C}',X'}(\gamma, \xi)$$
$$b(\gamma, \alpha, \nu) = b'(\gamma, \alpha, \nu).$$

In particular, the left side of the above relations is defined whenever the right side is defined.

Longer extenders require the second, and more interesting, modification to the covering lemma which was alluded to in observation 7 at the beginning of this section: an extender can not necessarily be reconstructed from its countable sequences of indiscernibles. Again we contrast indiscernibles for extenders with those for measures. Suppose that M is a model of set theory and $C \subseteq \kappa$ is an ω-sequence of indiscernibles for M, in the sense that $U = \{x \subseteq \kappa : C - x \text{ is finite}\}$ is a normal M-ultrafilter on κ. Then the added hypothesis ${}^{\omega}M \subseteq M$ implies that $C \in M$, so that $U \in M$ and hence $U \in K^M$.

Now if (C, b) is similarly a system of indiscernibles for a M-extender E, then the situation is more complicated. Again, C is an ω-sequence of indiscernibles which generates the normal measure $U = E_\kappa$ associated with E. In fact all of the ultrafilters E_a are members of M, since E_a is generated by the ω-sequence $\langle b(\nu, \alpha, a) : \nu \in C\rangle$). It is not clear, however, that these ultrafilters E_a can be reassembled in M to obtain the extender E, and in fact Gitik showed in [21] (see chapter [15]) that this reassembly is not always possible. He also showed that it is possible under the stronger hypothesis of Theorem 4.50, namely that $\{\alpha < \kappa : o(\alpha) > \alpha^{+n}\}$ is bounded in κ for some $n < \omega$. In addition he discovered a game which does provide the desired reassembly, provided that it is applied to a sequence (C, b) of indiscernibles such that $\mathrm{ot}(C)$ has uncountable cofinality. Hence a version of the covering lemma can be obtained for these longer extenders by systematically replacing ω with ω_1 [23]:

4.51 Theorem (Covering Lemma up to $0^{\P}$). *Assume that* $0^{\P}$ *does not exist. Let* κ *be a cardinal of* K *with* $\mathrm{cf}(\kappa) > \omega$, *and set* $\lambda = o(\kappa)^{+K}$. *Then if* $\kappa \not\subseteq X = Y \cap K_\lambda$, *where* $Y \prec H(\lambda)$ *and* ${}^{\mathrm{cf}(\kappa)}Y \subseteq Y$, *then there is a pair* $(\mathcal{C}, b)$ *such that the conclusion of Theorem 4.50 holds, except that clause 3c is modified as follows, where we write* $a^{\mathcal{C},X}_\iota(\gamma, \xi)$ *for the* ι*th accumulation point for* E_γ *above* ξ*:*

(3c′) $\nu = a^{\mathcal{C},X}_{\iota}(\gamma,\xi)$ *for some* $\xi \in X \cap \nu$*, some* $\gamma \in h``(X \cap \nu)$*, and some* $\iota < \omega_1$*.*

Furthermore clause (3c′) *does not hold for any limit point* ν *of* X *with* $\mathrm{cf}(\nu) > \omega$*.*

For details, see [23], which shows that these results are strong enough to give the correct lower bound for the consistency strength of a failure of the Singular Cardinal Hypothesis at a cardinal of cofinality greater than ω.

Up to a Woodin Cardinal

The following form of the weak covering lemma is proved for countably closed cardinals in chapter [47]. This proof originally appeared in [45], and the general case is proved in [43].

4.52 Theorem (Weak Covering Lemma up to a Woodin). *Suppose that there is no inner model with a Woodin cardinal, and that the Steel core model* K *exists.*[3] *Then* $(\lambda^+)^K = \lambda^+$ *for every singular cardinal* λ*.*

By "the Steel core model K exists" we mean that Steel's construction of the core model up to a Woodin cardinal, described in chapter [47], succeeds in constructing a class model K satisfying the weak covering lemma. It is known that this follows from the assumption that there is a class of subtle cardinals.

The proof involves several technical difficulties which either do not occur or are easily dealt with below $0^\P$, but it closely parallels the earlier proofs. Like the first part of the proof of Theorem 4.19 it gives, for any suitable covering set X, a mouse $\widetilde{M}$, a system $\widetilde{\mathcal{C}}$ of indiscernibles for $\widetilde{M}$, and an ordinal $\rho < \kappa$ such that $X = h^{\widetilde{M}}``(X \cap \rho; \widetilde{\mathcal{C}})$. However, the system $\widetilde{\mathcal{C}}$ of indiscernibles comes from an iteration tree, not a linear iteration, and no known analysis of such indiscernibles yields any useful information. The proof of Lemma 4.52 sidesteps this problem: like the proof of the Covering Lemma 4.5 for sequences of measures, it relies on the observation that there are no measures, and hence no indiscernibles, in the interval $(\lambda, (\lambda^+)^K]$.

Theorem 4.52 is actually weaker than it appears at first: its hypothesis that the Steel core model exists has no parallel in the covering lemmas for smaller cardinals. Recall that the proof of the full covering lemma for sequences of measures involved first proving the weak covering lemma for the model K^{c} constructed using countably complete measures, and then defining the true core model K as a elementary submodel of K^{c}. There are at least two problems in extending this procedure past $0^\P$. The most important of

[3] Jensen and Steel have recently shown that this extra assumption that K exists in unnecessary, as it follows from the assumption that there is no inner model with a Woodin cardinal. This work is as of yet unpublished.

these is the fact that countable completeness is not, so far as is known, sufficient to ensure iterability of extender sequences significantly beyond a strong cardinal. Steel, in his construction of K^{c}, replaces countable completeness with a stronger notions, which he calls *countable certification*. However, the proof of the weak covering lemma, as given for sequences of measures, does not work for K^{c} as defined from countably certified measures. Instead Steel defines K^{c} by using a measurable cardinal in V, which provides the certification needed to prove that K^{c} satisfies a form of the weak covering lemma which is slightly weaker than the countably closed weak covering property, Definition 3.46, but is sufficiently strong to support the definition of K and the proof of the full covering lemma. Further work by Steel, Jensen and others has weakened the strength required to a subtle cardinal; however, there is no clear strategy for obtaining the weak covering property with any weaker assumptions. In contrast, Mitchell and Schindler [44] have obtained a model which is iterable and (in what appear to be the appropriate senses) universal with no large cardinal assumptions.[4]

The second problem involves the proof that the iteration from the basic construction in the proof of the core model drops immediately, that is, that $1 \in D$. In the case of the covering lemma for extenders below $0^{\P}$ this argument splits. The argument used to show that the weak covering lemma holds for countably complete cardinals λ is similar to that for sequences of measures but requires an extra assumption that $o(\alpha) < \lambda$ for all $\alpha < \lambda$. The proof of the full covering lemma, on the other hand, uses a different proof relying on the weak covering lemma; it does not show that the iteration drops, but instead shows that even when the iteration does not drop there is still a Skolem function $g^X \in K$ (derived, for a suitable set X, from an extender $\mathcal{E}_\gamma$ of length κ and critical point less than $\inf(\kappa - X)$) such that $X = g^X``(X \cap \rho^X; \mathcal{C}^X)$ for some $\rho^X < \lambda$. Beyond $0^{\P}$ the notion of $o(\alpha)$ is not meaningful, so only the second argument, which requires the weak covering lemma, is usable.

A few other results are known which use the ideas of the covering lemma. One of these is Theorem 1.16, asserting that any Jónsson cardinal κ is Ramsey in K. This proof avoids a measurable cardinal at κ, since if κ were measurable then it would be Ramsey, and it avoids smaller measurable cardinals by selecting a set of indiscernibles witnessing that κ is Ramsey which contains only nonmeasurable cardinals. Others such results demonstrate that certain properties of the smaller core models extend to larger cardinals: Schindler proves in [51] that if M is a model which contains all of its countable subsets then the core model K^M defined inside M is an iterated ultrapower of K, and Gitik, Schindler and Shelah prove in [24] that if $\kappa > \omega_2$ is a cardinal in K then any sound mouse M extending $K\|\kappa$ and projecting to κ is an initial segment of K.

[4] In recent work to appear in [27], Jensen has shown that such a model also has a form of the weak covering property.

Beyond a Woodin Cardinal

As was pointed out earlier, not even the weak covering lemma is valid for a model containing a Woodin cardinal δ: Woodin has defined a notion of forcing, the stationary tower forcing [63], such that the cardinal δ is still Woodin in the generic extension $L[\mathcal{E}][G]$ but there are cofinally many singular cardinals $\lambda < \delta$ such that $(\lambda^+)^{L[\mathcal{E}]} < (\lambda^+)^{L[\mathcal{E}][G]}$. Indeed it seems likely that every sufficiently large successor cardinal less than δ is collapsed by this forcing.

It is possible that this situation is analogous to that of Prikry forcing at a measurable cardinal, in that one could hope for an analogue of the Dodd-Jensen lemma stating that any failure of the weak covering lemma is achieved by some variant of stationary tower forcing. Some very weak results in this direction are proved in [42], but there are many more questions than theorems. One difficulty is that the stationary tower forcing, unlike Prikry forcing, has a number of variants; furthermore there are other forcings, notably Woodin's "all sets generic" forcing, which require a Woodin cardinal in the universe and which may be relevant to this question.

More promising developments deal with core models which do not contain Woodin cardinals, but which are large in the sense that they have inner models with Woodin cardinals. The best result so far is due to Schimmerling and Woodin, in [48]:

4.53 Theorem. *Suppose that $\mathcal{E}$ is a good extender sequence and the model $W = L[\mathcal{E}, x]$ is sufficiently iterable. Then either there is an amenable ultrafilter U on W with* $\mathrm{crit}(W) > \mathrm{rank}(x)$ *such that* $\mathrm{Ult}(W, U)$ *is well-founded, or else W has the weak covering property above* $\mathrm{rank}(x)$.

1. Introduction

This chapter is an exposition of the theory of canonical inner models for large cardinal hypotheses, or *extender models*. We hope to convey the most important ideas and methods of this theory without sinking into the morass of fine-structural detail surrounding them. The resulting outline should be accessible to anyone familiar with the theory of iterated ultrapowers and $L[U]$ contained in Kenneth Kunen's paper [14], and with the fine structure theory for L contained in Ronald Jensen's paper [10].

We shall present basic inner model theory in what is roughly the greatest generality in which it is currently known. This means that the theory we shall outline applies to extender models which may satisfy large cardinal hypotheses as strong as "There is a Woodin cardinal which is a limit of Woodin cardinals". Indeed, granted the iterability Conjecture 6.5, the theory applies to extender models satisfying "There is a superstrong cardinal". Measuring the scope of the theory descriptive-set-theoretically, we can say that it applies to any extender model containing only reals which are ordinal definable over $L(\mathbb{R})$, and in fact to extender models containing somewhat more complicated reals. One can obtain a deeper analysis of a smaller class of inner models by restricting to models satisfying at most "There is a strong cardinal" (and therefore having only Δ^1_3 reals). The basic theory of this smaller class of models is significantly simpler, especially with regard to the structure of the iterated ultrapowers it uses. One can find expositions of this special case in the papers [19] and [20], and in the book [50].

Our outline of basic inner model theory occupies Sects. 2 through 6 of this chapter. In Sects. 7 and 8 we present an application of this theory in descriptive set theory: we show that the model $\mathrm{HOD}^{L(\mathbb{R})}$ of all sets hereditarily ordinal definable in $L(\mathbb{R})$ is (essentially) an extender model.

The reader can find in [15] an exposition of basic inner model theory which is similar to this one, but somewhat less detailed. That paper then turns toward applications of inner model theory in the realm of consistency-strength lower bounds, an important area driving much of the evolution of the subject which we shall, nevertheless, avoid here. There is a more thorough and modern exposition of this area in [32]. We shall also abstain here from any extended discussion of the history of inner model theory. The reader can find philosophical/historical essays on the subject in the introductory sections of [18] and [15], and in [11, 24, 44], and in the chapter notes of [50].

2. Premice

The models we consider will be of the form $L[\vec{E}]$, where $\vec{E}$ is a coherent sequence of extenders. This framework seems quite general; indeed, it is plausible that there are models of the $L[\vec{E}]$ form for all the known large cardinal hypotheses. The framework is due, for the most part, to William Mitchell [21, 22].

2.1. Extenders

An *extender* is a system of ultrafilters which fit together in such a way that they generate a single elementary embedding. The concept was originally introduced by Mitchell [22], and then simplified to its present form by Jensen.

2.1 Definition. Let $\kappa < \lambda$ and suppose that M is transitive and rudimentarily closed. We call E a (κ, λ)-*extender over* M iff there is a nontrivial Σ_0-elementary embedding $j : M \to N$, with N transitive and rudimentarily closed, such that $\kappa = \text{crit}(j)$, $\lambda < j(\kappa)$, and

$$E = \{(a, x) \mid a \in [\lambda]^{<\omega} \wedge x \subseteq [\kappa]^{|a|} \wedge x \in M \wedge a \in j(x)\}.$$

We say in this case that E is *derived from* j, and write $\kappa = \text{crit}(E)$, $\lambda = \text{lh}(E)$.

If the requirement that N be transitive is weakened to $\lambda \subseteq \text{wfp}(N)$, where $\text{wfp}(N)$ is the wellfounded part of N, then we call E a (κ, λ)-*pre-extender over* M. For the most part, this weakening is important only in the sort of details we intend to suppress.

If E is a (κ, λ)-pre-extender over M and $a \in [\lambda]^{<\omega}$, then setting $E_a = \{x \mid (a, x) \in E\}$, we have that E_a is an M, κ-complete nonprincipal ultrafilter on the field of sets $P([\kappa]^{|a|}) \cap M$. Thus we can form the ultrapower $\text{Ult}(M, E_a)$. The fact that all the E_a's come from the same embedding implies that there is a natural direct limit of the $\text{Ult}(M, E_a)$'s, and we call this direct limit $\text{Ult}(M, E)$. We can present $\text{Ult}(M, E)$ more concretely as follows.

Let E be a (κ, λ)-pre-extender over M. Let us identify finite sets of ordinals with their increasing enumerations. Let $a, c \in [\lambda]^{<\omega}$ with $a \subseteq c$, and let s be the increasing enumeration of $\{i \mid c(i) \in a\}$. For $x \subseteq [\kappa]^{|a|}$, we set

$$x_{ac} = \{u \in [\kappa]^{|c|} \mid u \circ s \in x\}.$$

If we think of x as a $|a|$-ary predicate on κ, then x_{ac} is just the result of blowing it up to a $|c|$-ary predicate by adding dummy variables at spots corresponding to ordinals in $c \setminus a$. It is easy to see that

$$x \in E_a \iff x_{ac} \in E_c.$$

That this is true of all x, a, c is a property of E known as *compatibility*. Notice that it really is a property of E alone; M only enters in through $P(\kappa) \cap M$, and E determines $P(\kappa) \cap M$. Similarly, if f is a function with domain $[\kappa]^{|a|}$, then f_{ac} is the function with domain $[\kappa]^{|c|}$ given by $f_{ac}(u) = f(u \circ s)$, which comes from f by adding the appropriate dummy variables. It is easy to see that E has the following property, known as *normality*: if $a \in [\lambda]^{<\omega}$, $i < |a|$, $f \in M$ is a function with $\text{dom}(f) = [\kappa]^{|a|}$, and[1]

$$\text{for } E_a \text{ a.e. } u, \quad f(u) \in u(i),$$

[1] Here and in the future we use the "almost every" quantifier: given a filter F, we say $\phi(u)$ holds for F a.e. u iff $\{u \mid \phi(u)\} \in F$.

then

$$\exists\xi < a(i)(f_{a,a\cup\{\xi\}}(v) = v(j) \text{ for } E_{a\cup\{\xi\}} \text{ a.e. } v),$$

where j is such that ξ is the jth element of $a \cup \{\xi\}$. (Just take $\xi = j(f)(a)$, where E is derived from j.) Again, normality is a property of E alone.

Suppose that M is transitive and rudimentarily closed, and that $E = \langle E_a \mid a \in [\lambda]^{<\omega}\rangle$ is a family of M-κ-complete ultrafilters E_a on $[\kappa]^{|a|}$, having the compatibility and normality properties. We construct $\mathrm{Ult}(M, E)$ as follows. Suppose that $a, b \in [\kappa]^{<\omega}$ and f, g are functions in M with domains $[\kappa]^{|a|}$ and $[\kappa]^{|b|}$; then we put

$$\langle a, f\rangle \sim \langle b, g\rangle \quad \text{iff} \quad \text{for } E_{a\cup b} \text{ a.e. } u\ (f_{a,a\cup b}(u) = g_{b,a\cup b}(u)).$$

It is easy to check that $\sim$ is an equivalence relation; we use $[a, f]^M_E$ to denote the equivalence class of $\langle a, f\rangle$, and omit the subscript and superscript when context permits. Let

$$[a, f] \mathrel{\tilde{\in}} [b, g] \quad \text{iff} \quad \text{for } E_{a\cup b} \text{ a.e. } u\ (f_{a,a\cup b}(u) \in g_{b,a\cup b}(u)).$$

Then $\mathrm{Ult}(M, E)$ is the structure consisting of the set of all $[a, f]$ together with $\tilde{\in}$. We shall identify the wellfounded part of $\mathrm{Ult}(M, E)$ with its transitive isomorph, so that $\tilde{\in} = \in$ on the wellfounded part.

Suppose also that M satisfies the Axiom of Choice, as will indeed be the case in our applications. We then have Łoś's theorem for Σ_0 formulae, in that if φ is Σ_0 and $c = \bigcup_{i=1}^n a_i$, then

$$\mathrm{Ult}(M, E) \models \varphi[[a_1, f_1], \ldots, [a_n, f_n]]$$

if and only if

$$\text{for } E_c \text{ a.e. } u\ (M \models \varphi[(f_1)_{a_1 c}(u), \ldots, (f_n)_{a_n c}(u)]).$$

(The full Łoś's theorem may fail, as M may not satisfy enough ZFC.) It follows that the canonical embedding

$$i^M_E : M \to \mathrm{Ult}(M, E)$$

is Σ_1-elementary, where i^M_E is given by $i^M_E(x) = [\{0\}, c_x]$, with $c_x(\alpha) = x$ for all α.

We have $[a, \mathrm{id}] = a$ for all $a \in [\lambda]^{<\omega}$ by an easy induction using the normality of E. From this and Łoś's theorem we get

$$x \in E_a \iff a \in i^M_E(x),$$

for all a, x, and

$$[a, f] = i^M_E(f)(a),$$

for all a, f. The first of these facts implies that E is the (κ, λ)-pre-extender over M derived from i^M_E. Thus compatibility and normality are equivalent to pre-extenderhood; moreover, if E is a (κ, λ)-pre-extender over Q, then E is also a (κ, λ)-pre-extender over any transitive, rudimentarily closed M such that $P(\kappa) \cap M = P(\kappa) \cap Q$. It is definitely not the case, however, that the wellfoundedness of $\mathrm{Ult}(Q, E)$ implies the wellfoundedness of $\mathrm{Ult}(M, E)$.

If E is derived from $j : M \to N$, then there is a natural embedding $k : \mathrm{Ult}(M, E) \to N$ given by $k([a, f]) = j(f)(a)$, and the diagram

$$\begin{tikzcd} M \arrow[rr, "j"] \arrow[dr, "i_E"'] & & N \\ & \mathrm{Ult}(M, E) \arrow[ur, "k"'] & \end{tikzcd}$$

commutes. It is easy to see that $k{\restriction}\lambda = \mathrm{id}$.

If E is a (κ, λ)-pre-extender over M and $\xi \leq \lambda$, then we set $E{\restriction}\xi = \{(a, x) \in E \mid a \subseteq \xi\}$. There is a natural embedding σ from $\mathrm{Ult}(M, E{\restriction}\xi)$ into $\mathrm{Ult}(M, E)$ given by: $\sigma([a, f]^M_{E{\restriction}\xi}) = [a, f]^M_E$. We call ξ a *generator* of E just in case $\xi = \mathrm{crit}(\sigma)$; that is, $\xi \neq [a, f]^M_E$ for all $f \in M$ and $a \subseteq \xi$. The idea is that in this case $E{\restriction}(\xi + 1)$ has more information than $E{\restriction}\xi$, in that it determines a "bigger" ultrapower. The smallest generator of E is κ. All other generators are $> \kappa^{+M}$.

2.2 Definition. If E is a (κ, λ)-pre-extender over M, then

$$\nu(E) = \sup(\kappa^{+M} \cup \{\xi + 1 \mid \xi \text{ is a generator of } E\}).$$

We call $\nu(E)$ the *support* of E.

The (κ, λ)-extender derived from j can capture significantly more of the strength of j than the normal measure (that is, $(\kappa, \kappa + 1)$-extender) derived from j. For example, if $|V^N_\alpha|^N \leq \lambda$, then the existence of the factor map k implies that $V^N_\alpha = V^{\mathrm{Ult}(M,E)}_\alpha$. So if there is an embedding $j : V \to N$ such that $V_{\mathrm{crit}(j)+2} \subseteq N$, then there is an extender whose ultrapower gives rise to such an embedding. Indeed, if we remove the requirement that $\lambda < j(\kappa)$ from the definition of "extender", the results just discussed still go through, and we see that any embedding can be fully captured by such a generalized extender. We have included the restriction $\lambda < j(\kappa)$ in Definition 3.1 only because nothing we shall prove here requires these "long" extenders, and it simplifies the exposition.

2.2. Fine Extender Sequences

Our models are to be constructed from *coherent sequences* of extenders. Roughly speaking, this means that each E_α is either trivial (i.e. $E_\alpha = \emptyset$), or is an extender over $L[\vec{E}{\restriction}\alpha]$ satisfying certain conditions. The extenders in a coherent sequence must appear in order of increasing strength, in that $\beta < \alpha$ implies $i_{E_\alpha}(\vec{E})_\beta = \vec{E}_\beta$. There can be no gaps, in that $i_{E_\alpha}(\vec{E})_\alpha = \emptyset$.

These two conditions constitute *coherence*, a key idea which goes back to [21]. There are further conditions on the extender sequences we consider which insure that if $E_\alpha \neq \emptyset$, then α is completely determined by the embedding coded in E_α; this prevents us from coding random information into our model via the indexing of its extenders. There are different ways of handling the details here, all of which lead to the same class of models in the end. We shall adopt the indexing scheme of [25].

We shall use the Jensen J hierarchy to stratify our models. If A is any set or class,

$$L[A] = \bigcup_{\alpha \in \mathrm{On}} J^A_\alpha,$$

where $J^A_0 = \emptyset$, $J^A_\lambda = \bigcup_{\alpha<\lambda} J^A_\alpha$ for λ limit, and

$$J^A_{\alpha+1} = \ \mathrm{rud}^A(J^A_\alpha),$$

the closure of $J^A_\alpha \cup \{J^A_\alpha\}$ under rudimentary functions and the function $x \mapsto A \cap x$. If $\vec{E}$ is a sequence, then we shall abuse notation slightly by writing $J^{\vec{E}}_\alpha$ for J^A_α, where $A = \{(\beta, z) \mid z \in E_\beta\}$. In the case of interest to us, each E_α is either $\emptyset$ or a pre-extender over $J^{\vec{E}}_\alpha$ of length α, and $E_\alpha = \emptyset$ if α is a successor ordinal. It follows then that $J^A_\alpha = J^{\vec{E}\restriction\alpha}_\alpha$ and $E_\alpha \subseteq J^{\vec{E}\restriction\alpha}_\alpha$; from this we get that for all $X \subseteq J^{\vec{E}}_\alpha$,

$$X \in J^{\vec{E}}_{\alpha+1} \quad \text{iff} \quad X \text{ is definable over } (J^{\vec{E}}_\alpha, \in, \vec{E}\restriction\alpha, E_\alpha),$$

where the definition of X may use parameters from $J^{\vec{E}}_\alpha$. (See [38, 1.4].) Although we are officially using the J hierarchy, we might have used Gödel's L hierarchy instead, and the reader who prefers can change the J's to L's in what follows. (The advantages of using the J hierarchy show up in details we shall suppress.)

There is one important point here: in our setup, if $E_\alpha \neq \emptyset$, then E_α is an extender *over* $J^{\vec{E}}_\alpha$; it only measures the subsets of its critical point constructed before stage α. There may or may not be subsets of $\mathrm{crit}(E_\alpha)$ constructed in $L[\vec{E}]$ after stage α; if there are, then E_α does not measure them, and so fails to be an extender over all of $L[\vec{E}]$. The idea of adding such "partial" extenders to our sequences $\vec{E}$ is due to Stewart Baldwin and Mitchell. It leads to a stratification of core models much simpler than the sort studied previously. In particular, the hierarchies we shall study are (strongly) acceptable in the sense of [6].

2.3 Definition. A set A is *acceptable at* α iff

$$\forall\beta < \alpha\forall\kappa((P(\kappa) \cap (J^A_{\beta+1} \setminus J^A_\beta) \neq \emptyset) \longrightarrow J^A_{\beta+1} \models |J^A_\beta| \leq \kappa).$$

Notice that if A is acceptable at α and $J^A_\alpha \models$ "κ^+ exists", then $J^A_\alpha \models$ "$P(\kappa)$ exists and $P(\kappa) \subseteq J^A_{\kappa^+}$". It follows that GCH is true in J^A_α.

It is a basic fact in the fine structure of L that $\emptyset$ is acceptable at all α. On the other hand, if μ is a normal measure on κ, then μ is not acceptable at $\kappa + 2$, since there are subsets of ω in $J^\mu_{\kappa+2} \setminus J^\mu_{\kappa+1}$ (such as $0^\#$), while κ is not countable in $J^\mu_{\kappa+2}$ (or anywhere else).

Suppose that E is a pre-extender over M, and that $M \models \kappa^+$ exists, where $\kappa = \mathrm{crit}(E)$. Let $\nu = \nu(E)$ and $\eta = (\nu^+)^{\mathrm{Ult}(M,E)}$ be in the wellfounded part of $\mathrm{Ult}(M, E)$. We shall use the ordinal η to index E in extender sequences. Let E^* be the (κ, η)-pre-extender derived from E. It is easy to check that $\nu = \nu(E^*)$ and $E{\restriction}\nu = E^*{\restriction}\nu$, so that E and E^* are equivalent. For a minor technical reason, it is E^* which we shall index at η. We call E^* the *trivial completion* of E.

We shall need the following very technical concept. Let E be an extender over M. We say that E is of *type Z* iff $\nu(E) = \lambda + 1$ for some limit ordinal λ such that (a) $\lambda = \nu(E{\restriction}\lambda)$, and (b) $(\lambda^+)^{\mathrm{Ult}(M,E)} = (\lambda^+)^{\mathrm{Ult}(M,E{\restriction}\lambda)}$. Notice that our indexing convention would require that the trivial completions E^* and $(E{\restriction}\lambda)^*$ be indexed at the same place, if E is type Z. We resolve this conflict by giving $(E{\restriction}\lambda)^*$ preference, and therefore putting no type Z extenders on our sequences.

We are ready for one of the most important definitions in this chapter.

2.4 Definition. A *fine extender sequence* is a sequence $\vec{E}$ such that for each $\alpha \in \mathrm{dom}(\vec{E})$, $\vec{E}$ is acceptable at α, and either $\vec{E}_\alpha = \emptyset$, or E_α is a (κ, α)-pre-extender over $J^{\vec{E}}_\alpha$ for some κ such that $J^{\vec{E}}_\alpha \models \kappa^+$ exists, and:

1. E_α is the trivial completion of $E_\alpha{\restriction}\nu(E_\alpha)$, and hence $\alpha = (\nu(E_\alpha)^+)^{\mathrm{Ult}(J^{\vec{E}}_\alpha, E_\alpha)}$, and E_α is not of type Z,
2. (Coherence) $i(\vec{E}{\restriction}\kappa){\restriction}\alpha = \vec{E}{\restriction}\alpha$ and $i(\vec{E}{\restriction}\kappa)_\alpha = \emptyset$, where $i : J^{\vec{E}}_\alpha \to \mathrm{Ult}(J^{\vec{E}}_\alpha, E_\alpha)$ is the canonical embedding, and
3. (Closure under initial segment) for any η such that $(\kappa^+)^{J^{\vec{E}}_\alpha} \leq \eta < \nu(E_\alpha)$, $\eta = \nu(E_\alpha{\restriction}\eta)$, and $E_\alpha{\restriction}\eta$ is not of type Z, one of the following holds:
   (a) there is a $\gamma < \alpha$ such that E_γ is the trivial completion of $E_\alpha{\restriction}\eta$, or
   (b) $E_\eta \neq \emptyset$, and letting $j : J^{\vec{E}}_\eta \to \mathrm{Ult}(J^{\vec{E}}_\eta, E_\eta)$ be the canonical embedding and $\mu = \mathrm{crit}(j)$, there is a $\gamma < \alpha$ such that $j(\vec{E}{\restriction}\mu)_\gamma$ is the trivial completion of $E_\alpha{\restriction}\eta$.

2.5 Remarks. Let $\vec{E}$ be a fine extender sequence, $E_\alpha \neq \emptyset$, and let $i : J^{\vec{E}}_\alpha \to \mathrm{Ult}(J^{\vec{E}}_\alpha, E_\alpha)$ be the canonical embedding.

1. Although $\mathrm{Ult}(J^{\vec{E}}_\alpha, E_\alpha)$ may be illfounded, it must be that $\alpha + 1$ is contained in the wellfounded part of the ultrapower, and this is enough to make sense of the conditions in Definition 2.4. Also, $\vec{E}{\restriction}\beta \in J^{\vec{E}}_\alpha$ for all $\beta < \alpha$, and it is natural then to set $i(\vec{E}{\restriction}\alpha) = \bigcup_{\beta<\alpha} i(\vec{E}{\restriction}\beta)$.

2. Let $\nu = \nu(E_\alpha)$. By coherence, $J_\alpha^{i(\vec{E}\restriction\alpha)} = J_\alpha^{\vec{E}}$. Since $\alpha = \nu^+$ in $\mathrm{Ult}(J_\alpha^{\vec{E}}, E_\alpha)$, and since $i(\vec{E}\restriction\alpha)$ is acceptable at all $\beta < \sup_{\gamma<\alpha} i(\gamma)$ by Łoś's theorem (acceptability being a Π_1 property of $\vec{E}\restriction\alpha$ whenever α is a limit), there are no cardinals $> \nu$ in $J_\alpha^{\vec{E}}$. The ordinal ν itself may be a successor ordinal. It is not hard to show that if ν is a limit ordinal, then ν is a cardinal in both $J_\alpha^{\vec{E}}$ and $\mathrm{Ult}(J_\alpha^{\vec{E}}, E_\alpha)$.

3. Let $\kappa = \mathrm{crit}(E_\alpha)$. By clause 1 of Definition 2.4, there is a map of $(P(\kappa) \cap J_\nu^{\vec{E}}) \times [\nu]^{<\omega}$ onto α, the map being in $J_{\alpha+1}^{\vec{E}}$. Thus α is not a cardinal in $J_{\alpha+1}^{\vec{E}}$.

4. For the fine sequences $\vec{E}$ we construct, E_α is an extender over $L[\vec{E}\restriction\alpha]$, and $\alpha = \nu(E_\alpha)^+$ in both $L[\vec{E}\restriction\alpha]$ and $\mathrm{Ult}(L[\vec{E}\restriction\alpha], E_\alpha)$. This in fact follows from the clauses of Definition 2.4 if we can iterate from $J_\alpha^{\vec{E}}$ via E_α and its images On times.

Definition 2.4 diverges slightly from the definition of "good extender sequence" in [25, Sect. 1]. The latter definition is wrong, in that the extender sequences constructed in Sect. 11 of [25] and Sect. 6 of the present chapter do not satisfy it. This was shown by Martin Zeman. The problem lies in the initial segment condition of [25], which does not contain the proviso in clause 3 of Definition 2.4 that $E_\alpha\restriction\eta$ is not of type Z. Zeman showed that on any reasonably rich sequence of the sort constructed in [25] or Sect. 6 of this chapter, there must be extenders E such that for some $\eta < \nu(E)$, $\eta = \nu(E\restriction\eta)$ and $E\restriction\eta$ is of type Z.[2] Our indexing scheme implies that the conclusion of clause 3 of Definition 2.4 must then fail for one of $E\restriction\eta$ and $E\restriction(\eta-1)$. Ralf Schindler and Hugh Woodin independently found the correct axiomatization of the properties of the extender sequences constructed in [25] and here: one simply adds that type Z extenders do not occur on the sequence, and weakens the initial segment condition to take this into account.[3]

It might be hoped that alternative 3(b) of Definition 2.4 could be dropped, but Farmer Schlutzenberg has recently proved that if $\vec{E}$ is a fine extender sequence such that $L[\vec{E}]$ has two strong cardinals, then case 3(b) does occur somewhere in $\vec{E}$. The initial segment condition in Definition 2.4 is crucial in the proof that the comparison process terminates. We need some form of it as an axiom on our extender sequences in order to get a decent theory going. Other forms of this axiom are discussed in [39].

Following a suggestion of Sy Friedman, Jensen has investigated an indexing of extenders different from the sort described in Definition 2.4 (cf. [50]). In this framework, the extender E is indexed at the cardinal successor of

[2] See [39], which also corrects some further errors in [25] and [33].

[3] The "proof" in [25] of the stronger initial segment condition goes wrong in the proof of Theorem 10.1, where on p. 98, in the "$\eta = \gamma$" case, the authors ignore the possibility that G might be of type Z. Schindler found this error. What the argument of [25] does prove is the weaker initial segment condition of Definition 2.4.

$i_E(\mathrm{crit}(E))$ in its ultrapower. For any fine extender sequence $\vec{E}$ there is a Friedman-Jensen sequence $\vec{F}$ such that $L[\vec{E}] = L[\vec{F}]$, and vice-versa, so both approaches lead to the same class of models. The Friedman-Jensen hierarchy grows more slowly than the one we are using, in that certain extenders are put on a Friedman-Jensen sequence which only appear on ultrapowers of its translation to a fine extender sequence. In particular, one can drop the counterpart of clause 3(b) of Definition 2.4 in the Friedman-Jensen approach.

2.6 Definition. A *potential premouse* (or ppm) is a structure of the form $(J_\alpha^{\vec{E}}, \in, \vec{E}\restriction\alpha, E_\alpha)$, where $\vec{E}$ is a fine extender sequence. We use $\mathcal{J}_\alpha^{\vec{E}}$ to denote this structure.

2.7 Definition. Let $\mathcal{M} = \mathcal{J}_\alpha^{\vec{E}}$ be a ppm. We say $\mathcal{M}$ is *active* if $E_\alpha \neq \emptyset$, and passive otherwise. If $\mathcal{M}$ is active, then letting $\nu = \nu(E_\alpha)$ and $\kappa = \mathrm{crit}(E_\alpha)$, we say $\mathcal{M}$ is *type* I if $\nu = (\kappa^+)^{\mathcal{M}}$, $\mathcal{M}$ is *type* II if ν is a successor ordinal, and $\mathcal{M}$ is *type* III if ν is a limit ordinal $> (\kappa^+)^{\mathcal{M}}$.

The distinctions among potential premice introduced in Definition 2.7 are mostly important in the sort of details we shall suppress, but we need them in order to make certain definitions formally correct.

2.3. The Levy Hierarchy, Cores, and Soundness

Although it is possible to avoid fine structure theory entirely in the proofs of basic facts about smaller core models (for example, in the proof that $L[U] \models \mathsf{GCH}$), there is little one can show about larger core models (such as the minimal model satisfying "There is a Woodin cardinal") without fine structure theory.[4] It seems that one must marshall all one's forces in good order in order to advance; indeed, the very definition of the models requires fine structural notions. Therefore, in order to be able even to state precise definitions and theorems, we must lay out some of the fine structure theory of definability over potential premice.

We shall simplify matters by concentrating on the representative special case of Σ_1 definability, and indicating only briefly the appropriate notions at higher levels of the Levy hierarchy. In those few places where fine structural details crop up in proofs we give in later sections, the reader will lose little by considering only the special case $\Sigma_{n+1} = \Sigma_1$. The reader should see [38]

[4] Fine structure theory begins with Jensen's landmark paper [10]. Solovay (unpublished manuscript) extended Jensen's work to $L[U]$, and then Dodd and Jensen showed in [6–8], and [5] just how remarkably fruitful this extension could be. Dodd, Jensen, and Mitchell extended this older fine structure theory to still larger core models (in [23], and unpublished work), but the complexities became unmanageable just past core models with strong cardinals. The Baldwin-Mitchell idea of putting partial extenders on a coherent sequence cut through these difficulties. Ref. [25] was the first account to develop the Baldwin-Mitchell idea.

for an excellent full account of the fine structural underpinnings of the theory we present here.[5]

The subsets of $J_\alpha^{\vec{E}}$ belonging to $J_{\alpha+1}^{\vec{E}}$ are precisely those first-order definable over the ppm $\mathcal{J}_\alpha^{\vec{E}}$, but unfortunately, this structure is not amenable if $E_\alpha \neq \emptyset$.

2.8 Definition. A structure $(M, \in, A_1, A_2, \ldots)$ is *amenable* iff

$$\forall x \in M \forall i (A_i \cap x \in M).$$

Since amenability is important in basic ways,[6] we need an amenable structure with the same definable subsets as $(J_\alpha^{\vec{E}}, \in, \vec{E}\restriction\alpha, E_\alpha)$; that is, we need an amenable predicate coding E_α. The following lemma is the key.

2.9 Lemma. *Let $\vec{E}$ be a fine extender sequence, $E_\alpha \neq \emptyset$, $\kappa = \mathrm{crit}(E_\alpha)$, and $\nu = \nu(E_\alpha)$; then for any $\eta < \alpha$ and $\xi < (\kappa^+)^{J_\alpha^{\vec{E}}}$, $E_\alpha \cap ([\eta]^{<\omega} \times J_\xi^{\vec{E}}) \in J_\alpha^{\vec{E}}$. Moreover, if for $\xi < (\kappa^+)^{J_\alpha^{\vec{E}}}$ we set*

$$\gamma_\xi = \text{ least } \gamma < \alpha \text{ such that } E_\alpha \cap ([\nu]^{<\omega} \times J_\xi^{\vec{E}}) \in J_\gamma^{\vec{E}},$$

then

$$\sup(\{\gamma_\xi \mid \xi < (\kappa^+)^{J_\alpha^{\vec{E}}}\}) = \alpha.$$

Proof. Fix $\xi < (\kappa^+)^{J_\alpha^{\vec{E}}}$. Let $\langle A_\beta \mid \beta < \kappa\rangle$ be an enumeration of $\bigcup_{n<\omega}(P([\kappa]^n) \cap J_\xi^{\vec{E}})$ belonging to $J_\alpha^{\vec{E}}$. Let

$$i : J_\alpha^{\vec{E}} \to \mathrm{Ult}(J_\alpha^{\vec{E}}, E_\alpha)$$

be the canonical embedding, and notice that

$$\langle i(A_\beta) \mid \beta < \kappa\rangle \in \mathrm{Ult}(J_\alpha^{\vec{E}}, E_\alpha),$$

since $\langle i(A_\beta) \mid \beta < \kappa\rangle = i(\langle A_\beta \mid \beta < \kappa\rangle)\restriction\kappa$. But

$$E_\alpha \cap ([\eta]^{<\omega} \times J_\xi^{\vec{E}}) = \{(a, A_\beta) \mid a \in [\eta]^{<\omega} \wedge a \in i(A_\beta)\},$$

so $E_\alpha \cap ([\eta]^{<\omega} \times J_\xi^{\vec{E}}) \in \mathrm{Ult}(J_\alpha^{\vec{E}}, E_\alpha)$. Since α is a cardinal in this ultrapower, we have by acceptability that $E_\alpha \cap ([\eta]^{<\omega} \times J_\xi^{\vec{E}}) \in J_\alpha^{i(\vec{E}\restriction\alpha)}$. But $J_\alpha^{i(\vec{E}\restriction\alpha)} = J_\alpha^{\vec{E}}$ by coherence, so we are done with the first part of the lemma.

In order to show the γ_ξ are cofinal in α, it suffices to show that whenever $A \subseteq \nu$ and $A \in \mathrm{Ult}(J_\alpha^{\vec{E}}, E_\alpha)$, then there is a ξ such that $A \in J_{\gamma_\xi+1}^{\vec{E}}$. So fix

[5] Jensen has developed a more general fine structure theory, using terminology somewhat different from that used here. See [47] or [50]. We shall not need this extra generality here.
[6] For example, in the proof that satisfaction for Σ_1 formulae is Σ_1, and in the proof of the Łoś's theorem for Σ_0 formulae. See [38, 1.12, 8.4].

such an A, and let $A = [a, f]$, where $a \subseteq \nu$ and, without loss of generality, $f \in J_\alpha^{\vec{E}}$ and $f : J_\kappa^{\vec{E}} \to J_\kappa^{\vec{E}}$. By acceptability, we have $\xi < (\kappa^+)^{J_\alpha^{\vec{E}}}$ such that $f \in J_\xi^{\vec{E}}$. Now for $\eta < \nu$, $\eta \in A$ iff for $(E_\alpha)_{a \cup \{\eta\}}$ a.e. u, $\mathrm{id}_{\{\eta\}, a \cup \{\eta\}}(u) \in f(u)$, and the set to be measured in answering this question about η is in $J_\xi^{\vec{E}}$. Thus A can be computed from $E_\alpha \cap ([\nu]^{<\omega} \times J_\xi^{\vec{E}})$, so $A \in J_{\gamma_\xi + 1}^{\vec{E}}$. ⊣

Given now a fine extender sequence $\vec{E}$ with $E_\alpha \neq \emptyset$, we can code E_α as follows: let E_α^c be the set of quadruples (γ, ξ, a, x) such that

$$\begin{aligned}&\big(\nu(E_\alpha) < \gamma < \alpha\big) \wedge (\mathrm{crit}(E_\alpha) < \xi < (\mathrm{crit}(E_\alpha)^+)^{J_\alpha^{\vec{E}}})\\ &\quad \wedge \big(E_\alpha \cap ([\nu(E_\alpha)]^{<\omega} \times J_\xi^{\vec{E}}) \in J_\gamma^{\vec{E}}\big) \wedge \big((a, x) \in (E_\alpha \cap ([\gamma]^{<\omega} \times J_\xi^{\vec{E}}))\big).\end{aligned}$$

It follows from Lemma 2.9 that $(J_\alpha^{\vec{E}}, \in, \vec{E}\restriction\alpha, E_\alpha^c)$ is amenable.

Certain ordinal parameters are important in the description of a ppm. Let $\mathcal{M} = \mathcal{J}_\alpha^{\vec{E}}$. If $\mathcal{M}$ is active, then we set

$$\nu^{\mathcal{M}} = \nu(E_\alpha) \quad \text{and} \quad \mu^{\mathcal{M}} = \mathrm{crit}(E_\alpha).$$

If $\mathcal{M}$ is passive, set $\nu^{\mathcal{M}} = \mu^{\mathcal{M}} = 0$. If $\mathcal{M}$ is active of type II, then there is a longest non-type-Z proper initial segment F of E_α containing properly less information than E_α itself, and we let $\gamma^{\mathcal{M}}$ determine where F appears on $\vec{E}$ or an ultrapower of $\vec{E}$. More precisely, set

$$F = \begin{cases} (E_\alpha\restriction(\nu^{\mathcal{M}} - 1))^* & \text{if } (E_\alpha\restriction(\nu^{\mathcal{M}} - 1))^* \text{ is not type Z} \\ (E_\alpha\restriction\nu(E_\alpha\restriction(\nu^{\mathcal{M}} - 1)) - 1)^* & \text{otherwise.} \end{cases}$$

Then we let

$$\gamma^{\mathcal{M}} = \text{the unique } \xi \in \mathrm{dom}(\vec{E}) \quad \text{such that} \quad F = E_\xi,$$

if there is such a ξ.[7] If there is no such ξ, then setting $\eta = \nu(F)$, we have by 3(b) of Definition 2.4 that F is on the extender sequence of $\mathrm{Ult}(J_\eta^{\vec{E}}, E_\eta)$. We then let

$$\gamma^{\mathcal{M}} = (\eta, a, f), \quad \text{where } F = [a, f]_{E_\eta}^{J_\eta^{\vec{E}}},$$

and (a, f) is least in the order of construction on $J_\eta^{\vec{E}}$ with this property. Finally, if $\mathcal{M}$ is not active type II, then we set $\gamma^{\mathcal{M}} = 0$.

Since we shall put these parameters in all hulls we form, we might as well have names for them in our language.

2.10 Definition. $\mathcal{L}$ is the language of set theory with additional constant symbols $\dot{\mu}, \dot{\nu}, \dot{\gamma}$, and additional unary predicate symbols $\dot{E}$ and $\dot{F}$.

[7] $\gamma^{\mathcal{M}} = \mathrm{lh}(F)$ in this case.

2.11 Definition. Let $\mathcal{M} = \mathcal{J}_\alpha^{\vec{E}}$ be a ppm; then the Σ_0 *code* of $\mathcal{M}$, or $\mathcal{C}_0(\mathcal{M})$, is the $\mathcal{L}$-structure $\mathcal{N}$ given by:

1. if $\mathcal{M}$ is passive, then $\mathcal{N}$ has universe $J_\alpha^{\vec{E}}$, $\dot{E}^{\mathcal{N}} = \vec{E}\restriction\alpha$, $\dot{F}^{\mathcal{N}} = \emptyset$, and $\dot{\mu}^{\mathcal{N}} = \dot{\nu}^{\mathcal{N}} = \dot{\gamma}^{\mathcal{N}} = 0$;

2. if $\mathcal{M}$ is active of types I or II, then $\mathcal{N}$ has universe $J_\alpha^{\vec{E}}$, $\dot{E}^{\mathcal{N}} = \vec{E}\restriction\alpha$, $\dot{F}^{\mathcal{N}} = E_\alpha^*$ (where E_α^* is the amenable coding of E_α), and $\dot{\mu}^{\mathcal{N}} = \mu^{\mathcal{M}}$, $\dot{\nu}^{\mathcal{N}} = \nu^{\mathcal{M}}$, and $\dot{\gamma}^{\mathcal{N}} = \gamma^{\mathcal{M}}$;

3. if $\mathcal{M}$ is active type III, then letting $\nu = \nu(E_\alpha)$, $\mathcal{N}$ has universe $J_\nu^{\vec{E}}$, $\dot{E}^{\mathcal{N}} = \vec{E}\restriction\nu$, $\dot{F}^{\mathcal{N}} = E_\alpha\restriction\nu$, $\dot{\mu}^{\mathcal{N}} = \mu^{\mathcal{M}}$, and $\dot{\nu}^{\mathcal{N}} = \dot{\gamma}^{\mathcal{N}} = 0$.

The Σ_0 code $\mathcal{C}_0(\mathcal{M})$ is amenable; this follows from our lemma unless $\mathcal{M}$ is active type III, in which case it follows at once from the initial segment condition of Definition 2.4. The reader may wonder why we treated the type III ppm differently in the definition above, but fortunately, the answer lies in fine structural details we shall avoid here.[8] The reader will lose nothing of importance if he pretends that all active premice are of type II. Notice that $\mathcal{M}$ is indeed coded into $\mathcal{C}_0(\mathcal{M})$; this is obvious unless $\mathcal{M}$ is active type III, and in that case we can recover $\mathcal{M}$ by forming $\mathrm{Ult}(\mathcal{C}_0(\mathcal{M}), \dot{F}^{\mathcal{C}_0(\mathcal{M})})$, then adding the trivial completion of $\dot{F}^{\mathcal{C}_0(\mathcal{M})}$ to its sequence at the proper place. There is little harm in identifying $\mathcal{M}$ with $\mathcal{C}_0(\mathcal{M})$.

We can now define the Σ_1 projectum, first standard parameter, and first core of a ppm $\mathcal{M}$.

2.12 Definition. Let $\mathcal{M}$ be a ppm; then the Σ_1 *projectum* of $\mathcal{M}$, or $\rho_1(\mathcal{M})$, is the least ordinal α such that for some boldface $\mathbf{\Sigma_1^{\mathcal{C}_0(\mathcal{M})}}$ set $A \subseteq \alpha$, $A \notin \mathcal{C}_0(\mathcal{M})$. (Thus $\rho_1(\mathcal{M}) \leq \mathrm{On} \cap \mathcal{C}_0(\mathcal{M})$.)

Notice that the new set A may not be (lightface) Σ_1-definable. Since there is a $\Sigma_1^{\mathcal{C}_0(\mathcal{M})}$ map from the class of finite sets of ordinals onto $\mathcal{C}_0(\mathcal{M})$, we can take the parameter from which A is defined to be a finite set of ordinals. We standardize the parameter by minimizing it in a certain wellorder.

2.13 Definition. A *parameter* is a finite sequence $\langle \alpha_0, \ldots, \alpha_n \rangle$ of ordinals such that $\alpha_0 > \cdots > \alpha_n$ (and could be empty). If $\mathcal{M}$ is a ppm, then the *first standard parameter of* $\mathcal{M}$, or $p_1(\mathcal{M})$, is the lexicographically least parameter p such that there is a $\Sigma_1^{\mathcal{C}_0(\mathcal{M})}(\{p\})$ set A such that $(A \cap \rho_1(\mathcal{M})) \notin \mathcal{C}_0(\mathcal{M})$.

2.14 Definition.

1. For any $\mathcal{L}$ structure $\mathcal{Q}$ and set $X \subseteq |\mathcal{Q}|$, $\mathcal{H}_1^{\mathcal{Q}}(X)$ is the transitive collapse of the substructure of $\mathcal{Q}$ whose universe consists of all $y \in |\mathcal{Q}|$ such that $\{y\}$ is $\Sigma_1^{\mathcal{Q}}$ definable from parameters in X.

[8] See [25, Sect. 3].

2. For any ppm $\mathcal{M}$, the *first core* of $\mathcal{M}$, $\mathcal{C}_1(\mathcal{M})$, is defined by: $\mathcal{C}_1(\mathcal{M}) = \mathcal{H}_1^{\mathcal{C}_0(\mathcal{M})}(\rho_1(\mathcal{M}) \cup \{p_1(\mathcal{M})\})$.

It is a routine matter to show that for any ppm $\mathcal{M}$, $\mathcal{C}_1(\mathcal{M})$ is the Σ_0 code of some ppm $\mathcal{N}$. One need only check that being a Σ_0 code can be expressed using Π_2 sentences of $\mathcal{L}$. (See [25, 2.5].)

We introduce two important ways in which the standard parameter $p_1(\mathcal{M})$ can behave well.

2.15 Definition. Let $\mathcal{M}$ be a ppm.

1. We say $p_1(\mathcal{M})$ is *1-universal* iff whenever $A \subseteq \rho_1(\mathcal{M})$ and $A \in \mathcal{C}_0(\mathcal{M})$, then $A \in \mathcal{C}_1(\mathcal{M})$.

2. Let $p_1(\mathcal{M}) = \langle \alpha_0, \ldots, \alpha_n \rangle$. We say $p_1(\mathcal{M})$ is *1-solid* iff whenever $i \leq n$ and A is $\Sigma_1^{\mathcal{C}_0(\mathcal{M})}(\{\alpha_0, \ldots, \alpha_{i-1}\})$, then $A \cap \alpha_i \in \mathcal{C}_0(\mathcal{M})$.

3. We say $\mathcal{M}$ is *1-solid* just in case $p_1(\mathcal{M})$ is 1-solid and 1-universal.

If $p_1(\mathcal{M})$ is 1-universal, then letting $\mathcal{C}_1(\mathcal{M}) = \mathcal{C}_0(\mathcal{N})$, we have $\rho_1(\mathcal{N}) = \rho_1(\mathcal{M})$, and $p_1(\mathcal{N})$ is the image of $p_1(\mathcal{M})$ under the transitive collapse.[9] The 1-solidity of $p_1(\mathcal{M})$ is important in showing that $i(p_1(\mathcal{M})) = p_1(\mathcal{Q})$ for certain ultrapower embeddings $i : \mathcal{M} \to \mathcal{Q}$.[10]

2.16 Definition. $\mathcal{M}$ is 1-*sound* iff $\mathcal{M}$ is 1-solid and $\mathcal{C}_1(\mathcal{M}) = \mathcal{C}_0(\mathcal{M})$.

Let $\mathcal{N}$ be the ppm whose Σ_0 code is $\mathcal{C}_1(\mathcal{M})$. It is easy to see that $\mathcal{C}_1(\mathcal{N}) = \mathcal{C}_1(\mathcal{M})$, so that if $\mathcal{N}$ is 1-solid, then $\mathcal{N}$ is 1-sound. We should now go on and define the nth projectum $\rho_n(\mathcal{M})$, the nth standard parameter $p_n(\mathcal{M})$, and the nth core $\mathcal{C}_n(\mathcal{M})$, as well as the notions of n-solidity and n-universality for $p_n(\mathcal{M})$ and n-soundness for $\mathcal{M}$, in the case $n > 1$. The definitions run parallel to those in the $n = 1$ case, but there are enough annoying details that we prefer to shirk our duty and refer the conscientious reader to [25, Sect. 2]. (Formally speaking, these objects and notions are defined by induction on n in such a way that $\rho_n(\mathcal{M})$, $p_n(\mathcal{M})$, etc., only make sense if $\mathcal{M}$ is $(n-1)$-solid.) There is one point worth mentioning here, namely, $\rho_n(\mathcal{M})$, $p_n(\mathcal{M})$, $\mathcal{C}_n(\mathcal{M})$, etc., are defined *from the viewpoint of* $\mathcal{C}_{n-1}(\mathcal{M})$. For example, $\rho_2(\mathcal{M})$ is the least ordinal α such that there is an $r\Sigma_2^{\mathcal{C}_1(\mathcal{M})}$-in-parameters set $A \subseteq \alpha$ such

[9] Let r be the image of $p_1(\mathcal{M})$ under the collapse. As the collapse is the identity on $\rho_1(\mathcal{M})$, r defines over $\mathcal{C}_0(\mathcal{N})$ a new Σ_1 subset of $\rho_1(\mathcal{M})$, so that $\rho_1(\mathcal{N}) \leq \rho_1(\mathcal{M})$ and $p_1(\mathcal{N}) \leq_{\text{lex}} r$. It is easy to see $\rho_1(\mathcal{N}) \geq \rho_1(\mathcal{M})$. Finally, if $s <_{\text{lex}} r$ and $A \subseteq \rho_1(\mathcal{M})$ is $\Sigma_1^{\mathcal{C}_0(\mathcal{N})}$ definable from s, then $A \in \mathcal{M}$ by the minimality of $p_1(\mathcal{M})$, so $A \in \mathcal{N}$ by the universality of $p_1(\mathcal{M})$. Thus $r \leq_{\text{lex}} p_1(\mathcal{N})$.

[10] For any parameter $s <_{\text{lex}} p_1(\mathcal{M})$, let T_s be the Σ_1 theory in $\mathcal{C}_0(\mathcal{M})$ of parameters from $\rho_1(\mathcal{M}) \cup \{s\}$; then $T_s \in \mathcal{M}$ by the definition of $p_1(\mathcal{M})$. The solidity of $p_1(\mathcal{M})$ is equivalent to the assertion that the map $s \mapsto T_s$ is a member of $\mathcal{M}$.

that $A \notin \mathcal{C}_1(\mathcal{M})$.[11] The class of $\Sigma_2^{\mathcal{C}_0(\mathcal{M})}$-definable relations is not relevant at this (or any) point, since random information can be coded into such relations by iterating some $\mathcal{C}_0(\mathcal{N})$ above $\rho_1(\mathcal{N})$.[12]

2.17 Definition. Let $\mathcal{M}$ be a ppm; then $\mathcal{M}$ is *ω-solid* iff $\mathcal{M}$ is n-solid for all $n < \omega$, and $\mathcal{M}$ is *ω-sound* iff $\mathcal{M}$ is n-sound for all $n < \omega$. If $\mathcal{M}$ is ω-solid, then we let $\rho_\omega(\mathcal{M})$ be the eventual value of $\rho_n(\mathcal{M})$ and $\mathcal{C}_\omega(\mathcal{M})$ the eventual value of $\mathcal{C}_n(\mathcal{M})$ as $n \to \omega$.

If $n < m$, then $\rho_n(\mathcal{M}) \geq \rho_m(\mathcal{M})$, so there is indeed an eventual value for $\rho_n(\mathcal{M})$, and hence $\mathcal{C}_n(\mathcal{M})$. Clearly, $\mathcal{M}$ is ω-sound iff $\mathcal{C}_0(\mathcal{M}) = \mathcal{C}_\omega(\mathcal{M})$. All levels of the core models we shall construct will be ω-sound. Nevertheless, we must study potential premice which are not ω-sound, since these can be produced from ω-sound potential premice by taking ultrapowers. (See Lemma 2.23 below.) However, all proper initial segments of such an ultrapower are ω-sound, so we can restrict ourselves to ppm all of whose proper initial segments are ω-sound.

2.18 Definition. Let $\mathcal{M} = \mathcal{J}_\alpha^{\vec{E}}$ be a ppm, and let $\beta \leq \alpha$; then we write $\mathcal{J}_\beta^{\mathcal{M}}$ for $\mathcal{J}_\beta^{\vec{E}}$, and call $\mathcal{J}_\beta^{\mathcal{M}}$ an *initial segment* of $\mathcal{M}$. We write $\mathcal{N} \trianglelefteq \mathcal{M}$ ($\mathcal{N}$ is an initial segment of $\mathcal{M}$) iff $\exists\beta(\mathcal{N} = \mathcal{J}_\beta^{\mathcal{M}})$, and $\mathcal{N} \triangleleft \mathcal{M}$ ($\mathcal{N}$ is a proper initial segment of $\mathcal{M}$) iff $\exists\beta < \alpha(\mathcal{N} = \mathcal{J}_\beta^{\mathcal{M}})$.

2.19 Definition. A *premouse* is a potential premouse all of whose proper initial segments are ω-sound. A *coded premouse* is a structure of the form $\mathcal{C}_0(\mathcal{M})$, where $\mathcal{M}$ is a premouse.

It is easy to see that if $\vec{E}$ is an extender sequence with domain α such that all proper initial segments of $\mathcal{J}_\alpha^{\vec{E}}$ are ω-sound then $\vec{E}$ is acceptable at α. Indeed, soundness is simply a refinement of acceptability, in that we demand that whenever a new subset of κ appears in $J_{\tau+1}^{\vec{E}} - J_\tau^{\vec{E}}$, the surjection $f \in J_{\tau+1}^{\vec{E}}$ from κ onto $J_\tau^{\vec{E}}$ required by acceptability must actually be definable over $\mathcal{J}_\tau^{\vec{E}}$ at the same quantifier level that the new subset was. The acceptability of the fine extender sequences we shall construct will come from soundness in this way.

Perhaps the first substantial theorem in the fine structural analysis of L is Jensen's result that if $E_\beta = \emptyset$ for all $\beta \leq \alpha$, then $\mathcal{J}_\alpha^{\vec{E}}$ is ω-sound [10]. If μ is a normal ultrafilter on κ, then $(J_{\kappa+1}^\mu, \in, \mu)$ is not 1-sound (in the naturally

[11] The $r\Sigma_2$ relations are, roughly speaking, just those which are Σ_1-definable from the function T, where $T(\eta, q) = \Sigma_1$ theory of parameters in $\eta \cup \{q\}$, for $\eta < \rho_1$, and $T(\eta, q) = 0$ if $\eta \geq \rho_1$.

[12] The following example is due to Mitchell. Suppose that $\langle \kappa_i \mid i \in \omega \rangle$ is an increasing sequence of measurable cardinals of $\mathcal{N}$ with $\rho_1(\mathcal{N}) \leq \kappa_0$, and suppose that $\mathcal{N}$ is 1-sound and iterable. Let $a \subseteq \omega$ be arbitrary. Let $\mathcal{M}$ result from iterating $\mathcal{N}$ by hitting a normal measure with critical point κ_i iff $i \in a$. Then a is $\Sigma_2^{\mathcal{M}}$ since $i \in a$ iff κ_i is not $\Sigma_1^{\mathcal{M}}$-definable from parameters in $\kappa_i \cup \{p_i(\mathcal{M})\}$.

adapted meaning of the term). It is because we have followed the Baldwin-Mitchell approach in putting partial extenders on $\vec{E}$ that we have the very useful L-like fact that all levels of $L[\vec{E}]$ are ω-sound.

2.4. Fine Structure and Ultrapowers

If $\mathcal{M}$ is a premouse and E is an extender over $\mathcal{C}_0(\mathcal{M})$, then we can form $\mathrm{Ult}(\mathcal{C}_0(\mathcal{M}), E)$. One can show without too much difficulty that this structure is the Σ_0 code of a premouse. The key here is that the canonical embedding i into the ultrapower is not just Σ_1-elementary, but *cofinal*, in that both $i``(\mathrm{On} \cap \mathcal{C}_0(\mathcal{M}))$ is cofinal in $\mathrm{On} \cap \mathrm{Ult}(\mathcal{C}_0(\mathcal{M}), E)$, and $i``(\dot{\mu}^+)^{\mathcal{C}_0(\mathcal{M})}$ is cofinal in $i((\dot{\mu}^+)^{\mathcal{C}_0(\mathcal{M})})$. The second condition is of course only interesting if $\mathcal{M}$ is active.[13] If $\mathrm{crit}(E) < \rho_n(\mathcal{M})$, where $1 \leq n \leq \omega$, one can form a stronger ultrapower of $\mathcal{M}$, one for which Łoś's theorem holds for $r\Sigma_n$ formulae. Roughly speaking, instead of using only functions $f \in \mathcal{C}_0(\mathcal{M})$, one uses all functions f which are $r\Sigma_n$-definable from parameters over $\mathcal{C}_0(\mathcal{M})$. (See [25, Sect. 4] and [38] for details, and generally for the $r\Sigma_n$ hierarchy.) Since $\mathrm{crit}(E) < \rho_n(\mathcal{M})$, E measures enough sets that the construction makes sense, and Łoś's theorem holds for $r\Sigma_n$ formulae. We call this stronger ultrapower $\mathrm{Ult}_n(\mathcal{C}_0(\mathcal{M}), E)$, and sometimes call the earlier ultrapower $\mathrm{Ult}_0(\mathcal{C}_0(\mathcal{M}), E)$.

We shall only form $\mathrm{Ult}_n(\mathcal{C}_0(\mathcal{M}), E)$ in the case that $\mathcal{M}$ is n-sound. In this case, all of $\mathcal{C}_0(\mathcal{M})$ can be coded by the $r\Sigma_n$ theory of $\rho_n(\mathcal{M}) \cup \{p_n(\mathcal{M})\}$, which we can regard as a subset A_n of $\rho_n(\mathcal{M})$. The structure $(J^{\mathcal{M}}_{\rho_n}, A_n)$ is amenable. If one decodes $\mathrm{Ult}_0((J^{\mathcal{M}}_{\rho_n(\mathcal{M})}, A_n), E)$ in the natural way, one gets $\mathrm{Ult}_n(\mathcal{C}_0(\mathcal{M}), E)$. This is how Σ_n ultrapowers were treated by Dodd and Jensen [6], and the reader can find an exposition of their method in [38, §8]. The equivalence of the two approaches in the case that $\mathcal{M}$ is n-sound is proved in [25, §2].

We wish to record some basic facts concerning the elementarity of the canonical embedding associated to a Σ_n ultrapower. As a notational convenience, for any ppm $\mathcal{M}$ we let $\rho_0(\mathcal{M}) = \mathrm{On} \cap \mathcal{C}_0(\mathcal{M})$ and $p_0(\mathcal{M}) = \emptyset$, and we say $\mathcal{M}$ is 0-sound. Again, the concept of being $r\Sigma_n$ is treated in [25] and [38].

2.20 Definition. Let $\pi : \mathcal{C}_0(\mathcal{M}) \to \mathcal{C}_0(\mathcal{N})$, and let $n < \omega$. We call π an *n-embedding* iff

1. $\mathcal{M}$ and $\mathcal{N}$ are n-sound,
2. π is $r\Sigma_{n+1}$-elementary,
3. $\pi(p_i(\mathcal{M})) = p_i(\mathcal{N})$ for all $i \leq n$, and
4. $\pi(\rho_i(\mathcal{M})) = \rho_i(\mathcal{N})$ for all $i < n$ and $\sup(\pi``\rho_n(\mathcal{M})) = \rho_n(\mathcal{N})$.

[13] This is why we defined $\mathcal{C}_0(\mathcal{M})$ as we did in the case $\mathcal{M}$ is of type III. Had we defined it as in the type II case, the fact that i might not be continuous at $\nu^{\mathcal{M}}$ might lead to a failure of the initial segment condition for $\mathrm{Ult}(\mathcal{C}_0(\mathcal{M}), E)$. Having said this, we ask the reader to once again forget the type III case, and go back to identifying $\mathcal{C}_0(\mathcal{M})$ with $\mathcal{M}$.

We call π an *ω-embedding* iff π is fully elementary. Such an embedding preserves all projecta and standard parameters.

2.21 Lemma. *For any $n \leq \omega$, the canonical embedding associated to a Σ_n ultrapower is an n-embedding.*

We must also consider the behavior of $\rho_{n+1}(\mathcal{M})$ and $p_{n+1}(\mathcal{M})$ in Σ_n ultrapowers. Here we must impose an additional condition on the extender used to form the ultrapower.

2.22 Definition. Let E be a (κ,λ)-extender over $\mathcal{C}_0(\mathcal{M})$; then we say E *is close to* $\mathcal{C}_0(\mathcal{M})$ (or to $\mathcal{M}$ itself) iff for every $a \in [\lambda]^{<\omega}$

1. E_a is Σ_1-definable over $\mathcal{C}_0(\mathcal{M})$ from parameters, and
2. if $\mathcal{A} \in \mathcal{C}_0(\mathcal{M})$ and $\mathcal{C}_0(\mathcal{M}) \models |\mathcal{A}| \leq \kappa$, then $E_a \cap \mathcal{A} \in \mathcal{C}_0(\mathcal{M})$.

2.23 Lemma. *Let $\mathcal{M}$ be a premouse, and E a (κ,λ)-extender over $\mathcal{C}_0(\mathcal{M})$ which is close to $\mathcal{C}_0(\mathcal{M})$, with $\kappa < \rho_n(\mathcal{M})$ where $n \leq \omega$. Let $\mathcal{N}$ be such that $\mathcal{C}_0(\mathcal{N}) = \mathrm{Ult}_n(\mathcal{C}_0(\mathcal{M}), E)$. Then*

$$P(\kappa) \cap \mathcal{M} = P(\kappa) \cap \mathcal{N}.$$

If in addition $n < \omega$, $\mathcal{M}$ is n-sound and $(n+1)$-solid, and $\rho_{n+1}(\mathcal{M}) \leq \kappa$, then the canonical embedding $\pi : \mathcal{C}_0(\mathcal{M}) \to \mathcal{C}_0(\mathcal{N})$ satisfies

$$\rho_{n+1}(\mathcal{M}) = \rho_{n+1}(\mathcal{N}) \quad \textit{and} \quad \pi(p_{n+1}(\mathcal{M})) = p_{n+1}(\mathcal{N}),$$

so that

$$\mathcal{C}_{n+1}(\mathcal{M}) = \mathcal{C}_{n+1}(\mathcal{N}),$$

and $\pi \restriction \mathcal{C}_{n+1}(\mathcal{M})$ is (an isomorphic copy of) the uncollapse map from $\mathcal{C}_{n+1}(\mathcal{N})$ to $\mathcal{C}_n(\mathcal{N})$. In particular, $\mathcal{N}$ is n-sound but not $(n+1)$-sound.

We omit the proof of Definition 2.23, which the reader can find in [25, 4.5, 4.6]. See also [38, 8.10]. It is a reasonable exercise to prove the lemma in the case $n = 0$. Here the only tricky part is showing that $\pi(p_1(\mathcal{M})) = p_1(\mathcal{N})$. At that point one uses heavily the solidity of $p_1(\mathcal{M})$. The prewellordering property for $\Sigma_1^{\mathcal{C}_0(\mathcal{M})}$ relations is also used.[14]

Let $\mathcal{M}$ be a premouse, and E an extender over $\mathcal{C}_0(\mathcal{M})$ with $\mathrm{crit}(E) < \rho_n(\mathcal{M})$; then by $\mathrm{Ult}_n(\mathcal{M}, E)$ we shall mean the unique premouse $\mathcal{N}$ such that $\mathcal{C}_0(\mathcal{N}) = \mathrm{Ult}_n(\mathcal{C}_0(\mathcal{M}), E)$.[15]

[14] Let $p_1(\mathcal{M}) = \langle \alpha_0, \ldots, \alpha_k \rangle$, and let T be a universal $\Sigma_1^{\mathcal{M}}(\{\alpha_0, \ldots, \alpha_{i-1}\})$ subset of α_i. Let $\leq$ be the prewellorder of T given by the stages at which Σ_1 formulae are verified. Then the universal $\Sigma_1^{\mathcal{N}}(\{\pi(\alpha_0), \ldots, \pi(\alpha_{i-1})\})$ subset of $\pi(\alpha_i)$ is an initial segment of $\pi(T)$ under $\pi(\leq)$, and is therefore in $\mathcal{N}$. Thus $\pi(p_1(\mathcal{M}))$ is solid, and from this we easily see that $\pi(p_1(\mathcal{M})) = p_1(\mathcal{N})$.

[15] This gives us two definitions of $\mathrm{Ult}_0(\mathcal{M}, E)$, but they clearly agree with one another except possibly when $\mathcal{M}$ is active type III. In that case, we are now discarding the earlier definition.

3. Iteration Trees and Comparison

The key to Kunen's theory of $L[U]$ is the method of *iterated ultrapowers*. Given a structure $\mathcal{M}_0 = \langle L_\zeta[U], \in, U\rangle$ with appropriate ultrafilter U, one can form ultrapowers by U and its images under the canonical embeddings repeatedly, taking direct limits at limit ordinals. One obtains thereby structures $\mathcal{M}_\alpha$ and embeddings $i_{\alpha,\beta} : \mathcal{M}_\alpha \to \mathcal{M}_\beta$ for $\alpha < \beta$. We call the structures $\mathcal{M}_\alpha$ *iterates* of $\mathcal{M}_0$, and say that $\mathcal{M}_0$ is *iterable* just in case all its iterates are wellfounded. Kunen's key *comparison lemma* states that if $\mathcal{M}_0$ and $\mathcal{N}_0$ are two iterable structures of this form, then there are iterates $\mathcal{M}_\alpha$ and $\mathcal{N}_\alpha$ such that one of the two is an initial segment of the other.[16]

One can form iterated ultrapowers of an arbitrary premouse $\mathcal{M}_0$ similarly. In this case, the $\mathcal{M}_\alpha$-sequence may have more than one extender, and we are allowed to choose any one of them to continue. If E_α is the extender chosen, then we take $\mathcal{M}_{\alpha+1}$ to be $\mathrm{Ult}(\mathcal{M}_\alpha, E_\alpha)$.[17] At limit stages we form direct limits and continue. We call any such sequence $\langle(\mathcal{M}_\alpha, E_\alpha) : \alpha < \beta\rangle$ a *linear iteration* of $\mathcal{M}_0$, and the structures $\mathcal{M}_\alpha$ in it *linear iterates* of $\mathcal{M}_0$. We say $\mathcal{M}_0$ is *linearly iterable* just in case all its linear iterates are wellfounded.[18]

Given linearly iterable premice $\mathcal{M}_0$ and $\mathcal{N}_0$, there is a natural way to try to compare the two via linear iteration. Having reached $\mathcal{M}_\alpha$ and $\mathcal{N}_\alpha$, and supposing neither is an initial segment of the other (as otherwise our work is finished), we pick extenders E and F representing the least disagreement between $\mathcal{M}_\alpha$ and $\mathcal{N}_\alpha$, and use these to form $\mathcal{M}_{\alpha+1}$ and $\mathcal{N}_{\alpha+1}$.

If the extenders of the coherent sequence of $\mathcal{M}_0$ do not overlap one another too much, and similarly for $\mathcal{N}_0$, then this process must terminate with all disagreements between some $\mathcal{M}_\alpha$ and $\mathcal{N}_\alpha$ eliminated, so that one is an initial segment of the other. This is the key to core model theory at the level of strong cardinals. At bottom, the reason this comparison process must terminate is the following: if E and F are the extenders used at a typical stage α, then there will be a finite set a of generators and sets $\overline{X}$ and $\tilde{X}$ such that $X = i_{\eta,\alpha}(\overline{X}) = j_{\xi,\alpha}(\tilde{X})$, and X is measured differently by E_a and F_a.[19] But then $a \in i_{\alpha,\alpha+1}(X) \iff a \notin j_{\alpha,\alpha+1}(X)$, so $i_{\eta,\alpha+1}(\overline{X}) \neq j_{\xi,\alpha+1}(\tilde{X})$, and

[16] This means that there is a filter F such that $\mathcal{M}_\alpha$ and $\mathcal{N}_\alpha$ are of the form

$$\langle L_\xi[F], \in, F\rangle$$

and

$$\langle L_\eta[F], \in, F\rangle$$

for some ξ and η. (Here and elsewhere we identify wellfounded, extensional structures with their transitive isomorphs.) In fact, in this simple case we can take α to be $\sup(|\mathcal{M}_0|, |\mathcal{N}_0|)^+$ and F to be the club filter on α.

[17] This must be qualified, since if E_α does not measure all subsets of its critical point in $\mathcal{M}_\alpha$, then $\mathrm{Ult}(\mathcal{M}_\alpha, E_\alpha)$ makes no sense. In this case we take the "largest" E_α ultrapower of an initial segment of $\mathcal{M}_\alpha$ we can in order to form $\mathcal{M}_{\alpha+1}$. See below.

[18] In which case we identify these iterates with the premice to which they are isomorphic. Linear iterability should be taken to include the condition that no linear iteration of $\mathcal{M}_0$ drops to proper initial segments infinitely often.

[19] We use i for the embeddings in the $\mathcal{M}$-iteration, and j in the $\mathcal{N}$-iteration.

the images of $\overline{X}$ and $\tilde{X}$ do not participate in a disagreement at stage $\alpha+1$ the way they did at stage α. *If* all future extenders used in either iteration have critical point above $\sup(a)$, then $i_{\eta,\beta}(\overline{X}) \neq j_{\xi,\beta}(\tilde{X})$ for all β, so the images of $\overline{X}$ and $\tilde{X}$ never again participate in a disagreement, and we have made real progress at stage α. A simple reflection argument shows that if we never "move generators" in one of our iterations,[20] then eventually all disagreements are removed.[21] The lack of overlaps in the sequences of mice below a strong cardinal means that this process of iterating away the least disagreement does not move generators, and hence terminates in a successful comparison.

However, beyond a strong cardinal this linear comparison process definitely will lead to moving generators. There are tricks for making do with linear iterations a bit beyond strong cardinals, but the right solution is to give up linearity. If the extender E_α from the $\mathcal{M}_\alpha$-sequence we want to use has critical point less than $\nu(E_\beta)$ for some $\beta < \alpha$, then we apply E_α not to $\mathcal{M}_\alpha$, but to $\mathcal{M}_\beta$, for the least such β: i.e., we set $\mathcal{M}_{\alpha+1} = \mathrm{Ult}(\mathcal{M}_\beta, E_\alpha)$, where β is least such that $\mathrm{crit}(E_\alpha) < \nu(E_\beta)$.[22] We have an embedding $i_{\beta,\alpha+1} : \mathcal{M}_\beta \to \mathcal{M}_{\alpha+1}$. Thus this new iteration process gives rise to a *tree* of models, with embeddings along each branch of the tree. Along each branch the generators of the extenders used are not moved by later embeddings, and this is good enough to show that if a comparison process involving the formation of such "iteration trees" goes on long enough, it must eventually succeed.

What one needs to keep the construction of an iteration tree going past some limit ordinal λ is a branch of the tree which has been visited cofinally often before λ and is such that the direct limit of the premice along the branch is wellfounded. Thus the iterability we need for comparison amounts to the existence of some method for choosing such branches. We can formalize this as the existence of a winning strategy in a certain game. In giving the details of the necessary definitions, it is more convenient to introduce this "iteration game" first. We turn to this now.

3.1. Iteration Trees

Let $\mathcal{M}$ be a k-sound premouse, and let θ be an ordinal; we shall define the *iteration game* $\mathcal{G}_k(\mathcal{M}, \theta)$.

3.1 Definition. A *tree order on* α (for α an ordinal) is a strict partial order T of α with least element 0 such that for all $\gamma < \alpha$

1. $\beta \, T \, \gamma \implies \beta < \gamma$,
2. $\{\beta \mid \beta \, T \, \gamma\}$ is wellordered by T,

[20] That is, if $\nu(E) \leq \mathrm{crit}(E')$ whenever E is used before E' in the $\mathcal{M}$ iteration, and similarly on the $\mathcal{N}$ side.

[21] More precisely, there must be a stage $\alpha < \sup(|\mathcal{M}_0|, |\mathcal{N}_0|)^+$ at which $\mathcal{M}_\alpha$ is an initial segment of $\mathcal{N}_\alpha$, or *vice versa*.

[22] Again, if E_α fails to measure all sets in $\mathcal{M}_\beta$, we take the ultrapower of the longest possible initial segment of $\mathcal{M}_\beta$.

3. γ is a successor ordinal $\iff \gamma$ is a T-successor, and

4. γ is a limit ordinal $\implies \{\beta \mid \beta\, T\, \gamma\}$ is $\in$-cofinal in γ.

3.2 Definition. If T is a tree order then

$$[\beta, \gamma]_T = \{\eta \mid \eta = \beta \vee \beta\, T\, \eta\, T\, \gamma \vee \eta = \gamma\},$$

and similarly for $(\beta, \gamma]_T$, $[\beta, \gamma)_T$, and $(\beta, \gamma)_T$. Also, if γ is a successor ordinal, we let $\mathrm{pred}_T(\gamma)$ be the unique ordinal $\eta\, T\, \gamma$ such that $(\eta, \gamma)_T = \emptyset$.

3.3 Definition. Premice $\mathcal{M}$ and $\mathcal{N}$ *agree below* γ iff $\mathcal{J}_\beta^{\mathcal{M}} = \mathcal{J}_\beta^{\mathcal{N}}$ for all $\beta < \gamma$.

We now describe a typical run of $\mathcal{G}_k(\mathcal{M}, \theta)$. As play proceeds the players determine

- a tree order T on θ,
- premice $\mathcal{M}_\alpha$ for $\alpha < \theta$, with $\mathcal{M}_0 = \mathcal{M}$,
- an extender F_α from the $\mathcal{M}_\alpha$ sequence, for $\alpha < \theta$, and
- a set $D \subseteq \theta$, and embeddings $i_{\alpha,\beta} : \mathcal{C}_0(\mathcal{M}_\alpha) \to \mathcal{C}_0(\mathcal{M}_\beta)$ defined whenever $\alpha\, T\, \beta$ and $D \cap (\alpha, \beta]_T = \emptyset$.

The rules of the game guarantee the following agreement among the premice produced:

- $\alpha \le \beta \implies \mathcal{M}_\alpha$ agrees with $\mathcal{M}_\beta$ below $\mathrm{lh}(F_\alpha)$,
- $\alpha < \beta \implies \mathrm{lh}(F_\alpha)$ is a cardinal of $\mathcal{M}_\beta$.

Notice that the last condition implies that if $\alpha < \beta$, then $\mathcal{M}_\alpha$ does not agree with $\mathcal{M}_\beta$ below $\mathrm{lh}(F_\alpha) + 1$. This is because from F_α one can easily compute a map from $\nu(F_\alpha)$ onto $\mathrm{lh}(F_\alpha)$.

The game is played as follows. Suppose first that we are at move $\alpha + 1$, and have already defined F_ξ for $\xi < \alpha$, $\mathcal{M}_\xi$ for $\xi \le \alpha$, and T and D on $\alpha + 1$. (The first move is move 1, and in this case all we need is $\mathcal{M} = \mathcal{M}_0$ to get going.) At move $\alpha + 1$, I must pick an extender F_α from the $\mathcal{M}_\alpha$ sequence such that $\mathrm{lh}(F_\xi) < \mathrm{lh}(F_\alpha)$ for all $\xi < \alpha$. (If he does not, the game is over and he loses.) Now let $\beta \le \alpha$ be least such that $\mathrm{crit}(F_\alpha) < \nu(F_\beta)$. Let

$$\mathcal{M}^*_{\alpha+1} := \mathcal{J}_\gamma^{\mathcal{M}_\beta}, \quad \text{where } \gamma \text{ is the largest } \eta \text{ such that } F_\alpha \text{ is a pre-extender over } \mathcal{J}_\eta^{\mathcal{M}_\beta}.$$

Our agreement hypotheses imply that γ exists, $\mathrm{lh}(F_\beta) \le \gamma$, and F_α is a pre-extender over $\mathcal{C}_0(\mathcal{J}_\gamma^{\mathcal{M}_\beta})$. [Proof: this is clear if $\beta = \alpha$, so let $\beta < \alpha$. Let $\kappa = \mathrm{crit}(F_\alpha)$. Since $\mathrm{lh}(F_\beta) < \mathrm{lh}(F_\alpha)$ and $\mathrm{lh}(F_\beta)$ is a cardinal of $\mathcal{M}_\alpha$,

$$P(\kappa) \cap \mathcal{J}^{\mathcal{M}_\beta}_{\mathrm{lh}(F_\beta)} = P(\kappa) \cap \mathcal{M}_\alpha = P(\kappa) \cap \mathcal{J}^{\mathcal{M}_\alpha}_{\mathrm{lh}(F_\alpha)}.$$

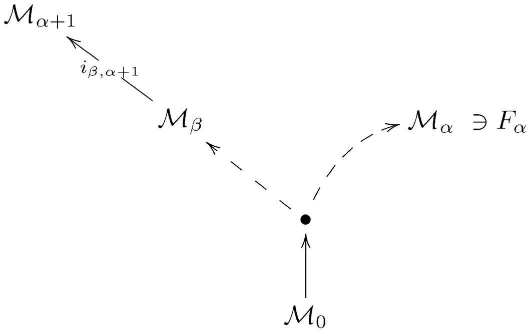
Thus F_α is a pre-extender over $\mathcal{J}^{\mathcal{M}_\beta}_{\mathrm{lh}(F_\beta)}$, so γ exists and $\mathrm{lh}(F_\beta) \le \gamma$. The last statement needs proof only in the case $\mathcal{J}^{\mathcal{M}_\beta}_\gamma$ is of type III. In this case, $\nu := \nu(\mathcal{J}^{\mathcal{M}_\beta}_\gamma)$ is the largest cardinal of $\mathcal{J}^{\mathcal{M}_\beta}_\gamma$. Thus if $\mathrm{lh}(F_\beta) < \gamma$, then $\mathrm{lh}(F_\beta) \le \nu$, so that $\kappa < \nu$, as desired. If $\mathrm{lh}(F_\beta) = \gamma$, then $\nu = \nu(F_\beta)$, so once again $\kappa < \nu$, as desired.] We put

$$\alpha + 1 \in D \iff \mathcal{M}^*_{\alpha+1} \text{ is a proper initial segment of } \mathcal{M}_\beta.$$

Let $n \le \omega$ be largest such that: (i) $\mathrm{crit}(F_\alpha) < \rho_n(\mathcal{M}^*_{\alpha+1})$ and (ii) if $D \cap [0, \alpha+1]_T = \emptyset$, then $n \le k$. Set

$$\mathcal{M}_{\alpha+1} := \mathrm{Ult}_n(\mathcal{M}^*_{\alpha+1}, F_\alpha),$$

if this ultrapower is wellfounded. (If the ultrapower is not wellfounded, then the game is over and II has lost.) Finally, we let $\beta\, T\, (\alpha+1)$, and if $\alpha + 1 \notin D$, then $i_{\beta,\alpha+1} : \mathcal{C}_0(\mathcal{M}_\beta) \to \mathcal{C}_0(\mathcal{M}_{\alpha+1})$ is the canonical ultrapower embedding, and $i_{\gamma,\alpha+1} = i_{\beta,\alpha+1} \circ i_{\gamma,\beta}$ whenever $\gamma\, T\, \beta$ and $D \cap (\gamma, \beta]_T = \emptyset$. If $\alpha + 1 \in D$, then we leave $i_{\beta,\alpha+1}$ undefined.



We must verify the agreement hypothesis we have carried along. For this, it suffices by induction to show that $\mathcal{M}_\alpha$ and $\mathcal{M}_{\alpha+1}$ have the necessary agreement. Let $\kappa = \mathrm{crit}(F_\alpha)$, and let $i : \mathcal{M}^*_{\alpha+1} \to \mathcal{M}_{\alpha+1}$, $j : \mathcal{M}^*_{\alpha+1} \to \mathrm{Ult}_0(\mathcal{M}^*_{\alpha+1}, F_\alpha) := \mathcal{P}$, and $h : \mathcal{J}^{\mathcal{M}_\alpha}_{\mathrm{lh}(F_\alpha)} \to \mathrm{Ult}_0(\mathcal{J}^{\mathcal{M}_\alpha}_{\mathrm{lh}(F_\alpha)}, F_\alpha) := \mathcal{Q}$ be the canonical embeddings. We have just shown, in effect, that $\mathcal{M}^*_{\alpha+1}$ and $\mathcal{J}^{\mathcal{M}_\alpha}_{\mathrm{lh}(F_\alpha)}$ agree below their common value λ for κ^+. It follows at once that $\mathcal{P}$ and $\mathcal{Q}$ agree below $j(\lambda) = h(\lambda)$. But $\mathcal{P}$ agrees below $i(\lambda) = j(\lambda)$ with $\mathcal{M}_{\alpha+1}$ because $\kappa < \rho_n(\mathcal{M}^*_{\alpha+1})$ (so that the $r\Sigma_n^{\mathcal{M}^*_{\alpha+1}}$ functions from κ to itself are all in $\mathcal{M}^*_{\alpha+1}$). Finally, $\mathcal{Q}$ agrees with $\mathcal{M}_\alpha$ below $\mathrm{lh}(F_\alpha)$, which is a cardinal of $\mathcal{Q}$, from the definition of fine extender sequences. Since $\mathrm{lh}(F_\alpha) < h(\lambda)$ we have the required agreement.

At a limit move λ, II picks a branch b of the tree T on λ determined by the play thus far. The branch b must be *cofinal* (i.e. $\in$-cofinal in λ), and *wellfounded*; otherwise II loses. (We say b is wellfounded iff $D \cap b$ is bounded below λ, and the direct limit of the $\mathcal{C}_0(\mathcal{M}_\beta)$ for $\beta \in (b \setminus \sup(D \cap \beta))$ under the embeddings $i_{\alpha,\beta}$ along b is wellfounded.) If II picks such a b, we set

$$\mathcal{M}_\lambda := \operatorname*{dirlim}_{\alpha \in b} \mathcal{M}_\alpha,$$

where we understand the direct limit here to be the premouse whose Σ_0 code is the direct limit of the $\mathcal{C}_0(\mathcal{M}_\alpha)$, for $\alpha \in b$ sufficiently large. We put $\alpha \, T \, \lambda$ for all $\alpha \in b$, and let $i_{\alpha,\lambda}$ be the canonical embedding into the direct limit for $\alpha \in b \setminus \sup(D \cap b)$.

This completes the rules of play for $\mathcal{G}_k(\mathcal{M}, \theta)$. If no one has lost after θ moves, then II wins.

3.4 Definition. A *k-maximal iteration tree on $\mathcal{M}$* is a partial play of the game $\mathcal{G}_k(\mathcal{M}, \theta)$ in which neither player has yet lost.[23]

We shall use calligraphic letters (e.g. $\mathcal{T}$) for iteration trees, and the corresponding roman letters (e.g. T) for their associated tree orders. ($\mathcal{T}$ is an *iteration tree* if it is a k-maximal iteration tree for some $k \leq \omega$.) We use $\mathcal{M}_\alpha^\mathcal{T}$ for the αth premouse of $\mathcal{T}$, $E_\alpha^\mathcal{T}$ for the αth extender used in $\mathcal{T}$, and $i_{\alpha,\beta}^\mathcal{T}$ for the canonical embeddings. (So $E_\alpha^\mathcal{T}$ is on the sequence of $\mathcal{M}_\alpha^\mathcal{T}$.) We use $D^\mathcal{T}$ for the set of all $\alpha+1$ such that $\mathcal{M}_{\alpha+1}^{*\mathcal{T}} \neq \mathcal{M}_{\mathrm{pred}_T(\alpha+1)}^\mathcal{T}$. In order to avoid a forest of superscripts, we shall often say "$\mathcal{T}$ is an iteration tree with models $\mathcal{N}_\alpha$, extenders F_α, and embeddings $j_{\alpha,\beta}$" when $\mathcal{N}_\alpha = \mathcal{M}_\alpha^\mathcal{T}$, $F_\alpha = E_\alpha^\mathcal{T}$, and $j_{\alpha,\beta} = i_{\alpha,\beta}^\mathcal{T}$. We will then write $\mathcal{N}_{\alpha+1}^*$ for $\mathcal{M}_{\alpha+1}^{*\mathcal{T}}$, and so forth. In general, we drop superscripts keeping track of an iteration tree whenever it seems like a good idea.

The *length* $\mathrm{lh}(\mathcal{T})$ of an iteration tree $\mathcal{T}$ is the domain of the associated tree order, so that $\mathrm{lh}(\mathcal{T}) = \alpha + 1$ iff $\mathcal{T}$ has last model $\mathcal{M}_\alpha^\mathcal{T}$.

In the course of describing $\mathcal{G}_k(\mathcal{M}, \theta)$ we proved the following lemma.

3.5 Lemma. *Let $\mathcal{T}$ be an iteration tree with models $\mathcal{M}_\alpha$ and extenders E_α, and let $\alpha < \beta < \mathrm{lh}(\mathcal{T})$; then*

1. *$\mathcal{M}_\alpha$ and $\mathcal{M}_\beta$ agree below $\mathrm{lh}(E_\alpha)$, and*
2. *$\mathrm{lh}(E_\alpha)$ is a cardinal of $\mathcal{M}_\beta$, so that $\mathcal{M}_\alpha$ and $\mathcal{M}_\beta$ do not agree below $\mathrm{lh}(E_\alpha) + 1$.*

Here is another elementary fact:

3.6 Lemma. *Let $\mathcal{T}$ be an iteration tree, and let $\alpha + 1 < \mathrm{lh}(\mathcal{T})$; then E_α is close to $\mathcal{M}_{\alpha+1}^*$.*

The proof is a straightforward induction (see [25, 6.1.5]). This lemma puts the elementarity Lemma 2.23 at our disposal, and we can then describe the elementarity of the embeddings along the branches of an iteration tree as follows.

[23] More commonly now, such a tree is called *k-normal*. The word "maximal" is used for an entirely different descriptive set-theoretic property of iteration trees.

3.7 Definition. If $\mathcal{T}$ is an iteration tree with models $\mathcal{M}_\alpha$ and extenders E_α, and $\alpha+1 < \mathrm{lh}(\mathcal{T})$, then $\deg^{\mathcal{T}}(\alpha+1)$ is the largest $n \leq \omega$ such that $\mathcal{M}_{\alpha+1} = \mathrm{Ult}_n(\mathcal{M}^*_{\alpha+1}, E_\alpha)$. Also, we use $i^{*\mathcal{T}}_{\alpha+1}$ for the canonical embedding from $\mathcal{M}^*_{\alpha+1}$ into this ultrapower.

3.8 Theorem. *Let $\mathcal{T}$ be a k-maximal iteration tree on a k-sound premouse, with models $\mathcal{M}_\alpha$ and embeddings $i_{\alpha,\beta}$, and let $(\alpha+1)\, T\, \beta$ and $D^{\mathcal{T}} \cap (\alpha+1, \beta]_T = \emptyset$; then*

1. $\deg^{\mathcal{T}}(\alpha+1) \geq \deg^{\mathcal{T}}(\xi+1)$ *for all* $\xi+1 \in (\alpha+1, \beta]_T$*, and*
2. *if* $\deg^{\mathcal{T}}(\alpha+1) = \deg^{\mathcal{T}}(\xi+1) = n$ *for all* $\xi+1 \in (\alpha+1,\beta]_T$*, then*

$$i_{\alpha+1,\beta} \circ i^*_{\alpha+1} \quad \textit{is an } n\textit{-embedding;}$$

moreover if $D^{\mathcal{T}} \cap [0, \alpha+1] \neq \emptyset$ *or* $n < k$*, then*

$$\rho_{n+1}(\mathcal{M}^*_{\alpha+1}) = \rho_{n+1}(\mathcal{M}_\beta) \leq \mathrm{crit}(i_{\alpha+1,\beta} \circ i^*_{\alpha+1}),$$

$$i_{\alpha+1,\beta} \circ i^*_{\alpha+1}(p_{n+1}(\mathcal{M}^*_{\alpha+1})) = p_{n+1}(\mathcal{M}_\beta),$$

and

$$\mathcal{C}_{n+1}(\mathcal{M}^*_{\alpha+1}) = \mathcal{C}_{n+1}(\mathcal{M}_\beta).$$

We omit the proof (see [25, 4.7]), which proceeds by induction on β, using the proof (not just the statement) of Lemma 2.23. Because of Theorem 3.8, we can for limit λ set $\deg^{\mathcal{T}}(\lambda)$ = eventual value of $\deg^{\mathcal{T}}(\alpha+1)$, for $(\alpha+1)\, T\, \lambda$ sufficiently large. When we are considering $\mathcal{T}$ as a play in $\mathcal{G}_k(\mathcal{M}, \theta)$, we set also $\deg^{\mathcal{T}}(0) = k$.[24] We then have that for any $\alpha < \mathrm{lh}(\mathcal{T})$, $\deg^{\mathcal{T}}(\alpha)$ is the largest $n \leq \omega$ such that $\mathcal{M}_\alpha$ is n-sound and $n \leq \deg^{\mathcal{T}}(0)$ if $D \cap [0, \alpha+1]_T = \emptyset$. If $\mathcal{M}^*_{\alpha+1}$ is $(n+1)$-sound, where $n+1 \leq \deg^{\mathcal{T}}(0)$ if $D \cap [0, \alpha+1]_T = \emptyset$, and $D \cap (\alpha+1, \beta]_T = \emptyset$ and $\deg^{\mathcal{T}}(\alpha+1) = \deg^{\mathcal{T}}(\beta) = n$, then by Theorem 3.8 the branch embedding $i_{\alpha+1,\beta} \circ i^*_{\alpha+1}$ is just the uncollapse map from $\mathcal{C}_{n+1}(\mathcal{M}_\beta)$ to $\mathcal{C}_n(\mathcal{M}_\beta)$.

3.9 Definition. A (k, θ)-*iteration strategy for* $\mathcal{M}$ is a winning strategy for II in $\mathcal{G}_k(\mathcal{M}, \theta)$. We say $\mathcal{M}$ *is* (k, θ)-*iterable* iff there is such a strategy.

The iteration trees we have introduced have some special properties. If one drops the restriction on I in $\mathcal{G}_k(\mathcal{M}, \theta)$ that he pick extenders of increasing lengths, and allow him to apply the extender chosen to any initial segment of any earlier model over which it is an extender, one obtains a stronger notion of iterability which is perhaps more natural. We shall need an approximation to this stronger notion later.

It is customary to call an iterable premouse a *mouse*, and we shall follow this custom in informal discussion. We shall make no formal definition

[24] It is an awkward feature of our terminology that an iteration tree may be a play of $\mathcal{G}_k(\mathcal{M}, \theta)$ for more than one k.

of "mouse", however, as it is not clear what sort of iterability one should demand. The definition above captures only one variety of iterability. The question of iterability and its applications is of central importance and, at the same time, not very well understood. For this reason, we prefer to spell out in each instance how much iterability we can prove, or how much we need for a given purpose.

3.2. The Comparison Process

The most important use of iterability lies in the *comparison process* for mice. There are certainly mice $\mathcal{M}$ and $\mathcal{N}$ such that neither is an initial segment of the other, but if $\mathcal{M}$ and $\mathcal{N}$ are sufficiently iterable, then one can form iteration trees on $\mathcal{M}$ and $\mathcal{N}$ with last models $\mathcal{P}$ and $\mathcal{Q}$ respectively such that $\mathcal{P}$ is an initial segment of $\mathcal{Q}$ or vice-versa. Moreover, one can arrange that if, say, $\mathcal{P}$ is an initial segment of $\mathcal{Q}$, then the branch of the tree on $\mathcal{M}$ leading to $\mathcal{P}$ does not drop, and thus gives rise to an elementary embedding from $\mathcal{M}$ to $\mathcal{P}$. Intuitively, this means that $\mathcal{M}$ has been compared with $\mathcal{N}$, and found to be no stronger.

3.10 Definition. A branch b of the iteration tree $\mathcal{T}$ *drops (in model or degree)* iff $D^{\mathcal{T}} \cap b \neq \emptyset$ or $\deg^{\mathcal{T}}(b) < \deg^{\mathcal{T}}(0)$.

If b does not drop in model, then $i_{0,b}$ exists, and if in addition b does not drop in degree, then $i_{0,b}$ is a $\deg^{\mathcal{T}}(0)$-embedding. We shall also speak of "partial branches" of the form $[0,\alpha]_T$ dropping (in model or degree), with the obvious meaning. Again, if there is no such dropping, then $i_{0,\alpha}$ exists and is a $\deg^{\mathcal{T}}(0)$-embedding.

3.11 Theorem (The Comparison Lemma). *Let $\mathcal{M}$ and $\mathcal{N}$ be k-sound premice of size $\leq \theta$, and suppose that Σ and Γ are $(k, \theta^+ + 1)$-iteration strategies for $\mathcal{M}$ and $\mathcal{N}$ respectively; then there are iteration trees $\mathcal{T}$ and $\mathcal{U}$ played according to Σ and Γ respectively, and having last models $\mathcal{M}^{\mathcal{T}}_\alpha$ and $\mathcal{M}^{\mathcal{U}}_\eta$, such that either*

1. *$[0,\alpha]_T$ does not drop in model or degree, and $\mathcal{M}^{\mathcal{T}}_\alpha$ is an initial segment of $\mathcal{M}^{\mathcal{U}}_\eta$, or*
2. *$[0,\eta]_U$ does not drop in model or degree, and $\mathcal{M}^{\mathcal{U}}_\eta$ is an initial segment of $\mathcal{M}^{\mathcal{T}}_\alpha$.*

Proof. We build $\mathcal{T}$ and $\mathcal{U}$ by an inductive process known as "iterating away the least disagreement". Before step $\alpha + 1$ of the construction we have initial segments $\mathcal{T}_\alpha$ and $\mathcal{U}_\alpha$ of the trees we shall eventually construct, and these have last models $\mathcal{P}$ and $\mathcal{Q}$ respectively. ($\mathcal{T}_0$ and $\mathcal{U}_0$ are one-model trees with last models $\mathcal{P} = \mathcal{M}$ and $\mathcal{Q} = \mathcal{N}$.) If one of $\mathcal{P}$ and $\mathcal{Q}$ is an initial segment of the other, then the construction of $\mathcal{T}$ and $\mathcal{U}$ is finished. Otherwise, let

$$\lambda = \text{least } \gamma \text{ such that } \mathcal{J}^{\mathcal{P}}_\gamma \neq \mathcal{J}^{\mathcal{Q}}_\gamma.$$

This means that the predicates $\dot{F}^{\mathcal{J}^{\mathcal{P}}_\lambda}$ and $\dot{F}^{\mathcal{J}^{\mathcal{Q}}_\lambda}$ are different. If $\dot{F}^{\mathcal{J}^{\mathcal{P}}_\lambda} \neq \emptyset$, then letting $\mathrm{lh}(\mathcal{T}_\alpha) = \beta + 1$, we set

$$E^{\mathcal{T}_{\alpha+1}}_\beta := \text{pre-extender coded by } \dot{F}^{\mathcal{J}^{\mathcal{P}}_\lambda}$$

and let $\mathcal{T}_{\alpha+1}$ be the unique one-model extension of $\mathcal{T}_\alpha$ determined by this and the rules of $\mathcal{G}_k(\mathcal{M}, \theta^+ + 1)$. If $\dot{F}^{\mathcal{J}^{\mathcal{P}}_\lambda} = \emptyset$, then we just let $\mathcal{T}_{\alpha+1} = \mathcal{T}_\alpha$. Similarly, if $\dot{F}^{\mathcal{J}^{\mathcal{Q}}_\lambda} \neq \emptyset$, then letting $\mathrm{lh}(\mathcal{U}_\alpha) = \eta + 1$, we set

$$E^{\mathcal{U}_{\alpha+1}}_\eta := \text{pre-extender coded by } \dot{F}^{\mathcal{J}^{\mathcal{Q}}_\lambda}$$

and let $\mathcal{U}_{\alpha+1}$ be the one model extension of $\mathcal{U}_\alpha$ thereby determined; otherwise we let $\mathcal{U}_{\alpha+1} = \mathcal{U}_\alpha$. Notice that in any case, the last models of $\mathcal{T}_{\alpha+1}$ and $\mathcal{U}_{\alpha+1}$ agree below $\lambda + 1$. This means that future extenders used in the two trees will have length $> \lambda$, so that player I is not losing one of the iteration games by failing to play extenders increasing in length.

At limit steps λ in our construction, we set $\mathcal{T}_\lambda = \bigcup_{\alpha<\lambda} \mathcal{T}_\alpha$ if this tree has a last model, that is, if $\mathcal{T}_\alpha$ is eventually constant as $\alpha \to \lambda$. Otherwise we let $\mathcal{T}_\lambda$ be the one-model extension of $\bigcup_{\alpha<\lambda} \mathcal{T}_\alpha$ determined by the cofinal, wellfounded branch of this tree chosen by Σ. We define $\mathcal{U}_\lambda$ in parallel fashion.

The main thing we need to prove is that the inductive process just described stops at some step $\alpha < \theta^+$.

Claim. *There is an $\alpha < \theta^+$ such that the last model of $\mathcal{T}_\alpha$ is an initial segment of the last model of $\mathcal{U}_\alpha$, or vice-versa.*

Proof. If not, then we have trees $\mathcal{T} = \mathcal{T}_{\theta^+}$ and $\mathcal{U} = \mathcal{U}_{\theta^+}$. It is easy to see that, since $\mathcal{M}$ and $\mathcal{N}$ have size $\leq \theta$, both $\mathcal{T}$ and $\mathcal{U}$ have length $\theta^+ + 1$.

Let us say that extenders E and F are *compatible* iff for some η, E is the trivial completion of $F \restriction \eta$ or F is the trivial completion of $E \restriction \eta$. (This implies that the extenders have the same critical point, and measure the same subsets of that critical point.)

Subclaim. *For any $\alpha, \beta < \theta^+$, $E^{\mathcal{T}}_\alpha$ is incompatible with $E^{\mathcal{U}}_\beta$.*

Proof. Let $E = E^{\mathcal{T}}_\alpha$, $F = E^{\mathcal{U}}_\beta$, and suppose E is the trivial completion of $F \restriction \eta$, for some η. Let ξ be such that E is the extender used to go from $\mathcal{T}_\xi$ to $\mathcal{T}_{\xi+1}$, and let γ be such that F is used to go from $\mathcal{U}_\gamma$ to $\mathcal{U}_{\gamma+1}$. Since $\mathrm{lh}(E) \leq \mathrm{lh}(F)$, we have $\xi \leq \gamma$. But if $\xi = \gamma$, then E and F are used at the same stage in our process, so $\mathrm{lh}(E) = \mathrm{lh}(F)$, so $E = F$, contrary to the fact that we were iterating away disagreements. Thus $\xi < \gamma$, and hence $\mathrm{lh}(E) < \mathrm{lh}(F)$. Now let $\mathcal{P}$ and $\mathcal{Q}$ be the last models of $\mathcal{T}_\gamma$ and $\mathcal{U}_\gamma$ respectively. By Lemma 3.5, $\mathrm{lh}(E)$ is a cardinal of $\mathcal{P}$, and since $\mathcal{P}$ agrees with $\mathcal{Q}$ below $\mathrm{lh}(F)$, this means $\mathrm{lh}(E)$ is a cardinal of $\mathcal{J}^{\mathcal{Q}}_{\mathrm{lh}(F)}$. On the other hand, the initial segment condition of Definition 2.4 implies (in both its cases) that $E \in \mathcal{J}^{\mathcal{Q}}_{\mathrm{lh}(F)}$. Since E collapses its length in an easily computable way, this is a contradiction. $\dashv$

We now use a reflection argument to produce compatible extenders used on the branches $[0, \theta^+]_T$ and $[0, \theta^+]_U$, the desired contradiction. Let $X \prec V_\eta$ for some large η, with $\mathcal{T}, \mathcal{U} \in X$, $|X| = \theta$, and $X \cap \theta^+$ transitive. Let H be the transitive collapse of X, $\pi : H \to V_\eta$ the collapse map, and $\alpha = \mathrm{crit}(\pi) = X \cap \theta^+$. (Note that $\theta < \alpha$.) Let $\bar{\mathcal{T}} = \pi^{-1}(\mathcal{T})$ and $\bar{\mathcal{U}} = \pi^{-1}(\mathcal{U})$.

Since $\mathcal{M}$ and $\mathcal{N}$ have size $\leq \theta$, $\bar{\mathcal{T}}$ and $\bar{\mathcal{U}}$ are trees on $\mathcal{M}$ and $\mathcal{N}$ respectively. Similarly, $\bar{\mathcal{T}} \restriction \alpha = \mathcal{T} \restriction \alpha$ and $\bar{\mathcal{U}} \restriction \alpha = \mathcal{U} \restriction \alpha$. Also, $[0, \alpha]_{\bar{T}} = [0, \theta^+]_T \cap \alpha$ and $[0, \alpha]_{\bar{U}} = [0, \theta^+]_U \cap \alpha$. Since $[0, \alpha]_{\bar{T}}$ has limit order type, and any branch of an iteration tree must be closed below its sup (by clauses 3 and 4 of Definition 3.1), we have $\alpha \in [0, \theta^+]_T$, and thus $[0, \alpha]_{\bar{T}} = [0, \alpha]_T$. Similarly $\alpha \in [0, \theta^+]_U$ and $[0, \alpha]_{\bar{U}} = [0, \alpha]_U$. Since the direct limit construction is absolute to H, these facts imply that $\bar{\mathcal{T}} = \mathcal{T} \restriction (\alpha + 1)$ and $\bar{\mathcal{U}} = \mathcal{U} \restriction (\alpha + 1)$.

We can find a $\gamma \in [0, \alpha]_T$ such that $D^{\mathcal{T}} \cap [0, \alpha]_T \subseteq \gamma$, and using π we see that $D^{\mathcal{T}} \cap [0, \theta^+]_T \subseteq \gamma$. This means that $i^{\mathcal{T}}_{\alpha, \theta^+}$ is defined. In fact, if $x \in \mathcal{C}_0(\mathcal{M}^{\mathcal{T}}_\alpha)$, then letting

$$x = i^{\mathcal{T}}_{\gamma, \alpha}(\bar{x}) = i^{\bar{\mathcal{T}}}_{\gamma, \alpha}(\bar{x}),$$

we have

$$\pi(x) = i^{\mathcal{T}}_{\gamma, \theta^+}(\bar{x}) = i^{\mathcal{T}}_{\alpha, \theta^+}(i^{\mathcal{T}}_{\gamma, \alpha}(\bar{x})) = i^{\mathcal{T}}_{\alpha, \theta^+}(x).$$

In other words

$$i^{\mathcal{T}}_{\alpha, \theta^+} = \pi \restriction \mathcal{C}_0(\mathcal{M}^{\mathcal{T}}_\alpha).$$

Similarly, we get

$$i^{\mathcal{U}}_{\alpha, \theta^+} = \pi \restriction \mathcal{C}_0(\mathcal{M}^{\mathcal{U}}_\alpha).$$

Thus $i^{\mathcal{T}}_{\alpha, \theta^+}$ and $i^{\mathcal{U}}_{\alpha, \theta^+}$ agree wherever both are defined. Notice that they are defined on the same subsets of α, since

$$P(\alpha)^{\mathcal{M}^{\mathcal{T}}_\alpha} = P(\alpha)^{\mathcal{M}^{\mathcal{T}}_{\theta^+}} = P(\alpha)^{\mathcal{M}^{\mathcal{U}}_{\theta^+}} = P(\alpha)^{\mathcal{M}^{\mathcal{U}}_\alpha}.$$

Here the first and third identities hold because $\mathrm{crit}(i^{\mathcal{T}}_{\alpha, \theta^+}) = \mathrm{crit}(i^{\mathcal{U}}_{\alpha, \theta^+}) = \alpha$, and the second holds because $\mathcal{M}^{\mathcal{T}}_{\theta^+}$ agrees with $\mathcal{M}^{\mathcal{U}}_{\theta^+}$ below θ^+.

Now let $\xi + 1 \in [0, \theta^+]_T$ be such that $\mathrm{pred}_T(\xi + 1) = \alpha$, and $\gamma + 1 \in [0, \theta^+]_U$ be such that $\mathrm{pred}_U(\gamma + 1) = \alpha$. Let $\nu = \inf(\nu(E^{\mathcal{T}}_\xi), \nu(E^{\mathcal{U}}_\gamma))$. Then for any $a \in [\nu]^{<\omega}$ and $B \in \mathcal{C}_0(\mathcal{M}^{\mathcal{T}}_\alpha) \cap \mathcal{C}_0(\mathcal{M}^{\mathcal{U}}_\alpha)$,

$$\begin{aligned} B \in (E^{\mathcal{T}}_\xi)_a \quad &\Longleftrightarrow \quad a \in i^{\mathcal{T}}_{\alpha, \xi+1}(B) \\ &\Longleftrightarrow \quad a \in i^{\mathcal{T}}_{\alpha, \theta^+}(B) \\ &\Longleftrightarrow \quad a \in i^{\mathcal{U}}_{\alpha, \theta^+}(B) \\ &\Longleftrightarrow \quad a \in i^{\mathcal{U}}_{\alpha, \gamma+1}(B) \\ &\Longleftrightarrow \quad B \in (E^{\mathcal{U}}_\gamma)_a. \end{aligned}$$

The first and last equivalences displayed come from the relationship of an extender to its embedding, and the middle equivalence comes from the agreement between $i^{\mathcal{T}}_{\alpha, \theta^+}$ and $i^{\mathcal{U}}_{\alpha, \theta^+}$ our reflection argument produced. The second and fourth equivalences come from the fact that $\nu(E^{\mathcal{T}}_\xi) \leq \mathrm{crit}(i^{\mathcal{T}}_{\xi+1, \theta^+})$ and

$\nu(E_\gamma^{\mathcal{U}}) \leq \mathrm{crit}(i_{\gamma+1,\theta^+}^{\mathcal{U}})$. This is because *generators are not moved* along the branches of an iteration tree: if e.g. $(\xi+1)T(\eta+1)$, then $E_\eta^{\mathcal{T}}$ has been applied to a model with index $> \xi$, so $\nu(E_\xi^{\mathcal{T}}) \leq \mathrm{crit}(E_\eta^{\mathcal{T}})$.

This completes the proof of the claim. ⊣

Now let α be as in the claim, and set $\mathcal{T} = \mathcal{T}_\alpha$, $\mathcal{U} = \mathcal{U}_\alpha$, $\beta+1 = \mathrm{lh}(\mathcal{T})$, and $\gamma + 1 = \mathrm{lh}(\mathcal{U})$. In order to complete our proof, we must show that we have not dropped in model or degree in a way which would make our comparison meaningless. Now if $\mathcal{M}_\beta^{\mathcal{T}}$ is a proper initial segment of $\mathcal{M}_\gamma^{\mathcal{U}}$, then $\mathcal{M}_\beta^{\mathcal{T}}$ is ω-sound, and hence by the remarks following Theorem 3.8 there can have been no dropping in model or degree along $[0,\beta]_T$, so that $i_{0,\beta}^{\mathcal{T}}$ exists and is a k-embedding, as desired. Similarly, if $\mathcal{M}_\gamma^{\mathcal{U}}$ is a proper initial segment of $\mathcal{M}_\beta^{\mathcal{T}}$, then $i_{0,\gamma}^{\mathcal{U}}$ exists and is a k-embedding. Thus we may assume $\mathcal{M}_\beta^{\mathcal{T}} = \mathcal{M}_\gamma^{\mathcal{U}}$. If $D^{\mathcal{T}} \cap [0,\beta]_T = \emptyset$ and $\deg^{\mathcal{T}}(\beta) = k$, then we are done, so let us assume otherwise. Similarly, we may assume that $D^{\mathcal{U}} \cap [0,\gamma]_U \neq \emptyset$ or $\deg^{\mathcal{U}}(\gamma) < k$. It follows from these assumptions that $\deg^{\mathcal{T}}(\beta) = \deg^{\mathcal{U}}(\gamma) = n$, where n is largest such that $\mathcal{M}_\beta^{\mathcal{T}} = \mathcal{M}_\gamma^{\mathcal{U}}$ is n-sound. (See Theorem 3.8.) But then, from Theorem 3.8 and the remarks following it, we see that there are $\xi+1 \in [0,\beta]_T$ and $\eta + 1 \in [0,\gamma]_U$ such that

$$\begin{aligned} i_{\xi+1,\beta}^{\mathcal{T}} \circ i_{\xi+1}^{*\mathcal{T}} &= \text{uncollapse map from } \mathcal{C}_{n+1}(\mathcal{M}_\beta^{\mathcal{T}}) \text{ to } \mathcal{C}_n(\mathcal{M}_\beta^{\mathcal{T}}) \\ &= \text{uncollapse map from } \mathcal{C}_{n+1}(\mathcal{M}_\gamma^{\mathcal{U}}) \text{ to } \mathcal{C}_n(\mathcal{M}_\gamma^{\mathcal{U}}) \\ &= i_{\eta+1,\gamma}^{\mathcal{U}} \circ i_{\eta+1}^{*\mathcal{U}}. \end{aligned}$$

Because generators are not moved along the branches of an iteration tree, we get as in the proof of the claim that the extender $E_\xi^{\mathcal{T}}$ giving rise to $i_{\xi+1}^{*\mathcal{T}}$ is compatible with the extender $E_\eta^{\mathcal{U}}$ giving rise to $i_{\eta+1}^{*\mathcal{U}}$. This contradicts the subclaim, and thereby completes the proof of the comparison theorem. ⊣

We note that the conclusion of the Comparison Lemma can be strengthened a bit in the case that one is comparing ω-sound mice using ω-maximal trees, which is the case of greatest interest. In this case, if $\mathcal{T}$ drops in model or degree along the branch leading to its last model, then $\mathcal{U}$ does not, and the last model of $\mathcal{U}$ is a proper initial segment of the last model of $\mathcal{T}$. This follows at once from the proof of the Comparison Lemma 3.11 and the observation that the last model of $\mathcal{T}$ cannot be ω-sound in this case.

We can draw some simple corollaries concerning the definability of the reals belonging to mice.

3.12 Corollary. *Let $\mathcal{M}$ and $\mathcal{N}$ be ω-sound (ω,ω_1+1)-iterable premice such that $\rho_\omega(\mathcal{M}) = \rho_\omega(\mathcal{N}) = \omega$; then $\mathcal{M}$ is an initial segment of $\mathcal{N}$, or vice-versa.*

Proof. Since $\mathcal{M}$ and $\mathcal{N}$ are ω-sound and project to ω, they are countable, and so we have enough iterability to compare them. Let $\mathcal{T}$ on $\mathcal{M}$ and $\mathcal{U}$ on $\mathcal{N}$ be as in the conclusion of the Comparison Lemma 3.11, with last models $\mathcal{M}_\alpha$

and $\mathcal{N}_\eta$ respectively, and suppose without loss of generality that $\mathcal{M}_\alpha \trianglelefteq \mathcal{N}_\eta$ and $[0,\alpha]$ does not drop in model or degree. Since $\rho_\omega(\mathcal{M}) = \omega$, there are no extenders over $\mathcal{M}$ with critical point $< \rho_\omega(\mathcal{M})$, and therefore $\alpha > 0$ implies that $[0,\alpha]$ must drop in model or degree. So $\alpha = 0$. If $\eta = 0$ we are done, so assume $\eta > 0$. Since $\rho_\omega(\mathcal{N}) = \omega$, this implies $\mathcal{N}_\eta$ is not ω-sound. Thus $\mathcal{M}$ is a *proper* initial segment of $\mathcal{N}_\eta$, and $\mathcal{M}$ is countable in $\mathcal{N}_\eta$ because $\rho_\omega(\mathcal{M}) = \omega$. It is easy to see that this implies that $\mathcal{M}$ is an initial segment of $\mathcal{N}$, as desired. (One cannot gain reals by iterating, although one can lose them along some branch that drops.) ⊣

3.13 Corollary. *If $\mathcal{M}$ and $\mathcal{N}$ are (ω, ω_1+1)-iterable premice, then the $\mathcal{M}$-constructibility order on $\mathbb{R}\cap\mathcal{M}$ is an initial segment of the $\mathcal{N}$-constructibility order on $\mathbb{R}\cap\mathcal{N}$, or vice-versa.*

Proof. If $x \in \mathbb{R} \cap (\mathcal{J}^{\mathcal{M}}_{\alpha+1} \setminus \mathcal{J}^{\mathcal{M}}_{\alpha})$, then $\rho_\omega(\mathcal{J}^{\mathcal{M}}_{\alpha}) = \omega$. This observation and Corollary 3.12 easily yield the desired conclusion. ⊣

3.14 Corollary. *If $x \in \mathbb{R} \cap \mathcal{M}$ for some $(\omega, \omega_1 + 1)$-iterable premouse $\mathcal{M}$, then x is ordinal definable, and in fact x is Δ^2_2-definable from some countable ordinal.*

Proof. Say x is the αth real in the $\mathcal{M}$-constructibility order. By Corollary 3.13 we know that the formula "v is the αth real of some $(\omega, \omega_1 + 1)$-iterable premouse" characterizes x uniquely, so x is definable from α. In fact, by simply counting quantifiers one sees that $(\omega, \omega_1 + 1)$-iterability is Σ^2_3-definable, so x is Δ^2_3-definable from α. To see that x is Δ^2_2-definable, one uses the following equivalence:

$$\begin{aligned} y = x \quad \iff \quad & \exists\mathcal{M}\exists\Sigma(\mathcal{M} \text{ is a countable premouse and} \\ & \Sigma \text{ is an } (\omega,\omega_1)\text{-iteration strategy for } \mathcal{M} \text{ and} \\ & \forall\mathcal{N}\forall\Gamma(\text{if } \mathcal{N} \text{ is a countable premouse which} \\ & \text{has an } \alpha\text{th real } z \neq y, \text{ and} \\ & \Gamma \text{ is an } \omega_1\text{-iteration strategy for } \mathcal{N}, \text{ then} \\ & \text{if } (\mathcal{T},\mathcal{U}) \text{ is the } (\Sigma,\Gamma)\text{-coiteration of } \mathcal{M} \text{ with } \mathcal{N}, \\ & \text{then } \mathcal{U} \text{ has no cofinal branch})). \end{aligned}$$

Here by the (Σ, Γ)-coiteration we mean the pair of iteration trees determined by Σ and Γ through the process of iterating away the least disagreement, as in the Comparison Lemma 3.11. Since an ω_1-iteration strategy is essentially a set of reals, and the property of being an ω_1-iteration strategy is expressible using only real quantifiers, the formula displayed above is Σ^2_2, and hence x is Δ^2_2 in α. ⊣

We shall refine the proof of Corollary 3.14 later, and thereby obtain sharper upper bounds on the complexity of the reals in certain small mice. The refinement involves producing a logically simpler condition equivalent to $(\omega_1 + 1)$-iterability in the case of these small mice.

4. The Dodd-Jensen Lemma

The Dodd-Jensen Lemma on the minimality of iteration maps is a fundamental, often-used tool in inner model theory.

4.1. The Copying Construction

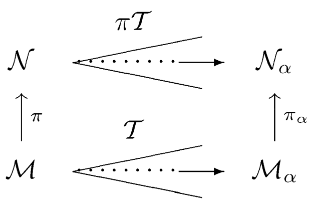
Given a k-embedding $\pi : \mathcal{M} \to \mathcal{N}$ and a k-maximal iteration tree $\mathcal{T}$ on $\mathcal{M}$ with models $\mathcal{M}_\alpha$, we can lift $\mathcal{T}$ to a k-maximal iteration tree $\pi\mathcal{T}$ on $\mathcal{N}$ with models $\mathcal{N}_\alpha$. In fact, we need slightly less elementarity for π in order to construct $\pi\mathcal{T}$.

4.1 Definition. Let $\pi : \mathcal{C}_0(\mathcal{M}) \to \mathcal{C}_0(\mathcal{N})$ and let $k < \omega$. We call π a *weak k-embedding* iff

1. $\mathcal{M}$ and $\mathcal{N}$ are k-sound,
2. π is $r\Sigma_k$-elementary, and $r\Sigma_{k+1}$-elementary on parameters from some set X cofinal in $\rho_k(\mathcal{M})$,
3. $\pi(p_i(\mathcal{M})) = p_i(\mathcal{N})$, for all $i \leq k$, and
4. $\pi(\rho_i(\mathcal{M})) = \rho_i(\mathcal{N})$ for all $i < k$, and $\sup(\pi``\rho_k(\mathcal{M})) \leq \rho_k(\mathcal{N})$.

A *weak ω-embedding* is just an ω-embedding, that is, a fully elementary map.

We shall construct $\pi\mathcal{T}$ by induction; at stage α we define its αth model $\mathcal{N}_\alpha$, together with an embedding π_α from $\mathcal{C}_0(\mathcal{M}_\alpha)$ to $\mathcal{C}_0(\mathcal{N}_\alpha)$, as in the following figure:



The next lemma describes the successor steps of this construction.

4.2 Lemma (Shift Lemma). *Let $\bar{\mathcal{M}}$ and $\bar{\mathcal{N}}$ be premice, let $\bar{\kappa} = \mathrm{crit}(\dot{F}^{\bar{\mathcal{N}}})$, and let*

$$\psi : \mathcal{C}_0(\bar{\mathcal{N}}) \to \mathcal{C}_0(\mathcal{N})$$

be a weak 0*-embedding, and*

$$\pi : \mathcal{C}_0(\bar{\mathcal{M}}) \to \mathcal{C}_0(\mathcal{M})$$

be a weak n-embedding. Suppose that $\bar{\mathcal{M}}$ and $\bar{\mathcal{N}}$ agree below $(\bar{\kappa}^+)^{\bar{\mathcal{M}}}$ and $(\bar{\kappa}^+)^{\bar{\mathcal{M}}} \le (\bar{\kappa}^+)^{\bar{\mathcal{N}}}$, while $\mathcal{M}$ and $\mathcal{N}$ agree below $(\kappa^+)^{\mathcal{M}}$ and $(\kappa^+)^{\mathcal{M}} \le (\kappa^+)^{\mathcal{N}}$, where $\kappa = \psi(\bar{\kappa})$. Suppose also

$$\pi\restriction(\bar{\kappa}^+)^{\bar{\mathcal{M}}} = \psi\restriction(\bar{\kappa}^+)^{\bar{\mathcal{M}}}.$$

Let $\bar{\kappa} < \rho_n(\bar{\mathcal{M}})$, so that $\mathrm{Ult}_n(\mathcal{C}_0(\bar{\mathcal{M}}), \dot{F}^{\bar{\mathcal{N}}})$ and $\mathrm{Ult}_n(\mathcal{C}_0(\mathcal{M}), \dot{F}^{\mathcal{N}})$ make sense, and suppose the latter ultrapower is wellfounded. Then the former ultrapower is wellfounded; moreover, there is a unique embedding

$$\sigma : \mathrm{Ult}_n(\mathcal{C}_0(\bar{\mathcal{M}}), \dot{F}^{\bar{\mathcal{N}}}) \to \mathrm{Ult}_n(\mathcal{C}_0(\mathcal{M}), \dot{F}^{\mathcal{N}})$$

satisfying the conditions:

1. *σ is a weak n-embedding,*
2. *$\mathrm{Ult}_n(\mathcal{C}_0(\bar{\mathcal{M}}), \dot{F}^{\bar{\mathcal{N}}})$ agrees with $\bar{\mathcal{N}}$ below $\rho_0(\bar{\mathcal{N}})$, and $\mathrm{Ult}_n(\mathcal{C}_0(\mathcal{M}), \dot{F}^{\mathcal{N}})$ agrees with $\mathcal{N}$ below $\rho_0(\mathcal{N})$,*
3. *$\sigma\restriction(\rho_0(\bar{\mathcal{N}})) = \psi\restriction(\rho_0(\bar{\mathcal{N}}))$,*
4. *the diagram*

$$\begin{tikzcd} \mathrm{Ult}_n(\mathcal{C}_0(\bar{\mathcal{M}}), \dot{F}^{\bar{\mathcal{N}}}) \arrow[r, "\sigma"] & \mathrm{Ult}_n(\mathcal{C}_0(\mathcal{M}), \dot{F}^{\mathcal{N}}) \\ \mathcal{C}_0(\bar{\mathcal{M}}) \arrow[u, "i"] \arrow[r, "\pi"'] & \mathcal{C}_0(\mathcal{M}) \arrow[u, "j"'] \end{tikzcd}$$

commutes, where i and j are the canonical ultrapower embeddings.

The proof of the lemma is straightforward, so we omit it. In the representative special case $n = 0$, the desired map σ is defined by

$$\sigma([a, f]^{\bar{\mathcal{M}}}_{\dot{F}^{\bar{\mathcal{N}}}}) = [\psi(a), \pi(f)]^{\mathcal{M}}_{\dot{F}^{\mathcal{N}}}.$$

This is of course how it must be defined if we are to have conditions 3 and 4.

Now let $\pi : \mathcal{C}_0(\mathcal{M}) \to \mathcal{C}_0(\mathcal{N})$ be a weak k-embedding, and let $\mathcal{T}$ be a k-maximal iteration tree on $\mathcal{M}$. We define the models of a k-maximal copied tree $\pi\mathcal{T}$ on $\mathcal{N}$ by induction. In order to avoid some fine structural details, we shall assume first that no model on $\mathcal{T}$ is a type III premouse. In that case, $\pi\mathcal{T}$ will be a tree with the same order and drop structure as $\mathcal{T}$, and we shall have embeddings

$$\pi_\alpha : \mathcal{C}_0(\mathcal{M}_\alpha) \to \mathcal{C}_0(\mathcal{N}_\alpha).$$

We shall have $\deg^{\mathcal{T}}(\alpha) \le \deg^{\pi\mathcal{T}}(\alpha)$, with perhaps strict inequality being forced on us by the desire that $\pi\mathcal{T}$ be k-maximal. We use E_β and $i_{\beta,\alpha}$ for the extenders and embeddings of $\mathcal{T}$, and F_β and $j_{\beta,\alpha}$ for the extenders and embeddings of $\pi\mathcal{T}$, and we maintain inductively:

- π_α is a weak $\deg^{\mathcal{T}}(\alpha)$-embedding,
- if $\beta < \alpha$ and E_β is the last extender of the initial segment $\mathcal{P}$ of $\mathcal{M}_\beta$, then $\pi_\beta \restriction \rho_0(\mathcal{P}) = \pi_\alpha \restriction \rho_0(\mathcal{P})$, and
- if $\beta\, T\, \alpha$ and $(\beta, \alpha]_T \cap D = \emptyset$, then the following diagram commutes:

$$\begin{tikzcd}
\mathcal{C}_0(\mathcal{N}_\beta) \arrow[r, "j_{\beta,\alpha}"] & \mathcal{C}_0(\mathcal{N}_\alpha) \\
\mathcal{C}_0(\mathcal{M}_\beta) \arrow[u, "\pi_\beta"] \arrow[r, "i_{\beta,\alpha}"'] & \mathcal{C}_0(\mathcal{M}_\alpha) \arrow[u, "\pi_\alpha"']
\end{tikzcd}$$

We define $\mathcal{N}_{\alpha+1}$ and $\pi_{\alpha+1}$ by applying the Shift Lemma. Following the notation of the lemma, we take $\bar{\mathcal{N}}$ to be the initial segment of $\mathcal{M}_\alpha$ whose last extender is E_α, and $\mathcal{N}$ to be $\pi_\alpha(\bar{\mathcal{N}})$ if $\bar{\mathcal{N}}$ is a proper initial segment of $\mathcal{M}_\alpha$, and $\mathcal{N} = \mathcal{N}_\alpha$ otherwise. (Because we have assumed $\mathcal{M}_\alpha$ is not of type III, $\mathcal{M}_\alpha$ is contained in the domain of π_α.) We take ψ to be the embedding with domain $\mathcal{C}_0(\bar{\mathcal{N}})$ induced by π_α. We let $F_\alpha = \dot{F}^{\mathcal{N}}$. Following further the Shift Lemma notation, $\bar{\mathcal{M}}$ is the initial segment $\mathcal{M}^*_{\alpha+1}$ of $\mathcal{M}_{\mathrm{pred}_T(\alpha+1)}$ to which E_α is applied, and $\pi : \mathcal{C}_0(\bar{\mathcal{M}}) \to \mathcal{C}_0(\mathcal{M})$ is the map induced by π_β, for $\beta = \mathrm{pred}_T(\alpha+1)$.) Let $n = \deg^{\mathcal{T}}(\alpha+1)$, and let $m = \deg^{\pi\mathcal{T}}(\alpha+1)$ be the degree dictated by F_α and our requirement that $\pi\mathcal{T}$ be k-maximal. One can check $n \le m$. If the ultrapower $\mathrm{Ult}_m(\mathcal{C}_0(\mathcal{N}), F_\alpha)$ giving rise to $\mathcal{N}_{\alpha+1}$ is illfounded, as may very well happen, then we stop the construction of $\pi\mathcal{T}$. Otherwise, let $\pi_{\alpha+1} = \tau \circ \sigma$, where σ is given by the Shift Lemma, and $\tau : \mathrm{Ult}_n(\mathcal{C}_0(\mathcal{N}), F_\alpha) \to \mathrm{Ult}_m(\mathcal{C}_0(\mathcal{N}), F_\alpha)$ is the natural map. It is easy to verify the induction hypotheses, and so we can continue.

At limit steps $\lambda < \mathrm{lh}(\mathcal{T})$ we let $\mathcal{N}_\lambda$ be the direct limit over all $\alpha \in [0, \lambda)_T$, α sufficiently large, of the $\mathcal{N}_\alpha$, provided that this limit is wellfounded. We let π_λ be the embedding given by our induction hypothesis (3): $\pi_\lambda(i_{\alpha,\lambda}(x)) = j_{\alpha,\lambda}(\pi_\alpha(x))$. It is easy to verify the induction hypotheses. If the direct limit is illfounded, as may very well happen, we stop the construction of $\pi\mathcal{T}$.

Suppose now that α is such that $\mathcal{M}_\alpha$ is type III. Letting $\bar{\mathcal{N}}$ be the initial segment of $\mathcal{M}_\alpha$ whose last extender is E_α, it is possible then that π_α does not act on $\mathcal{N}$, because the domain of π_α is only the squashed structure $\mathcal{C}_0(\mathcal{M}_\alpha)$. In the next paragraph, we include an outline of how to deal with this case, as a service to the scrupulous reader. We advise the unscrupulous reader to skip it.[25]

Let α be least such that $\mathcal{M}_\alpha$ is type III and let $\beta = \mathrm{pred}_T(\alpha+1)$. If $\bar{\mathcal{N}} = \mathcal{M}_\alpha$, then we can just take F_α to be the last extender of $\mathcal{N}_\alpha$, and everything works out. The problem comes when $\bar{\mathcal{N}}$ is a proper initial segment of $\mathcal{M}_\alpha$, but not in the domain of π_α. But notice then that "un-squashing" upstairs gives $\psi : \mathrm{Ult}(\mathcal{C}_0(\mathcal{M}_\alpha), \bar{F}) \to \mathrm{Ult}(\mathcal{C}_0(\mathcal{N}_\alpha), F)$ which extends π_α, where $\bar{F}$ and

[25] We ignored this problem in [25]. Schlutzenberg found that error, and its repair.

F are the last extenders of $\mathcal{M}_\alpha$ and $\mathcal{N}_\alpha$ respectively. Let $\mathcal{N} = \psi(\bar{\mathcal{N}})$. The problem is that $\mathcal{N}$ may not be an initial segment of $\mathcal{N}_\alpha$. So we extend $\pi\mathcal{T}$ by two steps: first apply F to the appropriate initial segment of the appropriate model (as dictated by maximality), forming $\mathcal{N}_{\alpha+1} = \mathrm{Ult}(\mathcal{Q}, F)$. It is easy to see that $\mathcal{N}$ is a proper initial segment of $\mathcal{P}$. We then take the last extender from $\mathcal{N}$ and apply it to the appropriate initial segment of $\mathcal{N}_\beta$ to get $\mathcal{N}_{\alpha+2}$. We have $\pi_{\alpha+1} : \mathcal{M}_{\alpha+1} \to \mathcal{N}_{\alpha+2}$ given by $\pi_{\alpha+1}([a, f]) = [\psi(a), \pi_\beta(f)]$. Again, everything works out. Thus in general, one step forward in $\mathcal{T}$ may correspond to two steps forward in $\pi\mathcal{T}$, and our copy maps π_γ map $\mathcal{M}^{\mathcal{T}}_\gamma$ to $\mathcal{N}^{\pi\mathcal{T}}_{\tau(\gamma)}$, where $\gamma < \tau(\gamma)$ is possible.

This completes the definition of $\pi\mathcal{T}$.

4.3 Remark. A *near k-embedding* is a weak k-embedding which is fully $r\Sigma_{k+1}$-elementary. If π_0 is a *near* k-embedding, then all π_α are near $\deg^{\mathcal{T}}$-embeddings, and moreover $\deg^{\mathcal{T}}(\alpha) = \deg^{\pi\mathcal{T}}(\alpha)$. See [35, 1.3]. There is an error in [25], where it is claimed that one can copy under weak embeddings, while maintaining both $\deg^{\mathcal{T}}(\alpha) = \deg^{\pi\mathcal{T}}(\alpha)$ and that $\pi\mathcal{T}$ is maximal.[26] See [35] for more on how various degrees of elementarity are propagated in the copying construction.

The Dodd-Jensen Lemma applies only to mice with a slightly stronger iterability property than the one we have introduced. In order to describe this property, we introduce an elaboration of the iteration game $\mathcal{G}_k(\mathcal{M}, \theta)$; a run of the new game is a linear composition of appropriately maximal iteration trees, rather than just a single such tree.

Let θ be an ordinal. In $\mathcal{G}_k(\mathcal{M}, \alpha, \theta)$, there are α rounds, the βth being played as follows: Let $\mathcal{Q}$ be the last model in the linear composition produced before round β; that is, let $\mathcal{Q} = \mathcal{M}$ if $\beta = 0$, $\mathcal{Q}$ be the last model of the tree played during round $\beta - 1$ if $\beta > 0$ is a successor, and $\mathcal{Q}$ be the direct limit along the unique cofinal branch in the linear composition of trees produced before β, if β is a limit ordinal. (I wins if this branch is illfounded.) We let q, the degree of $\mathcal{Q}$, be k if $\beta = 0$, the degree of $\mathcal{Q}$ as a model of the tree played during round $\beta - 1$ (see Definition 3.7) if $\beta > 0$ is a successor, and the eventual value of the degrees of previous rounds if β is a limit ordinal. I begins round β by choosing an initial segment $\mathcal{P}$ of $\mathcal{Q}$, and an $i \leq \omega$ such that if $\mathcal{P} = \mathcal{Q}$ then $i \leq q$, where q is the degree of $\mathcal{Q}$. The rest of round β is a run of $\mathcal{G}_i(\mathcal{P}, \theta)$,[27] except that we allow I to exit to round $\beta + 1$ before all θ moves have been played, and we require him to do so, on pain of losing, if θ is limit ordinal. (So if I has not lost, then when round β ends there will be in any case a last model to serve as $\mathcal{Q}$ for round $\beta + 1$.) II wins $\mathcal{G}_k(\mathcal{M}, \alpha, \theta)$ just in case he does not lose any of the component games and, for $\beta \leq \alpha$ a limit ordinal, the unique cofinal branch in the composition of trees previously produced is wellfounded. A play of this game in which II has not yet lost is called a *k-bounded* iteration tree on $\mathcal{M}$. More commonly now,

[26] Schlutzenberg also found this error, and its repair.

[27] So by our earlier conventions, i is the degree of $\mathcal{P}$.

it is called a *stack of normal trees on $\mathcal{M}$.* Notice that any winning strategy Γ for II in $\mathcal{G}_k(\mathcal{M},\alpha,\theta)$ determines a winning strategy Σ for II in $\mathcal{G}_k(\mathcal{M},\theta)$ in an obvious way: Σ calls for II to play as if he were using Γ in the first round of $\mathcal{G}_k(\mathcal{M},\alpha,\theta)$, and I had not dropped to begin that round.

4.4 Definition. Let $\mathcal{M}$ be a k-sound premouse, where $k \le \omega$; then a (k,α,θ)-*iteration strategy* for $\mathcal{M}$ is a winning strategy for II in $\mathcal{G}_k(\mathcal{M},\alpha,\theta)$, and $\mathcal{M}$ is (k,α,θ)-*iterable* just in case there is such a strategy.

The copying construction enables us to pull back iteration strategies for $\mathcal{N}$ to iteration strategies for premice embedded in $\mathcal{N}$.

4.5 Definition. Let $\pi : \mathcal{M} \to \mathcal{N}$ be a weak k-embedding, and Σ a strategy for II in $\mathcal{G}_k(\mathcal{N},\theta)$, or in $\mathcal{G}_i(\mathcal{P},\alpha,\theta)$ for some $\mathcal{P}$ such that $\mathcal{N}$ is an initial segment of $\mathcal{P}$ and i such that $i \le k$ if $\mathcal{N} = \mathcal{P}$; then the *pullback of* Σ *under* π is the strategy Σ^π in the corresponding game on $\mathcal{M}$ such that for any k-bounded $\mathcal{T}$ on $\mathcal{M}$,

$$\mathcal{T} \textit{ is by } \Sigma^\pi \iff \pi\mathcal{T} \textit{ is by } \Sigma.$$

Clearly, if Σ is a winning strategy for II an iteration game on $\mathcal{N}$, and $\pi : \mathcal{M} \to \mathcal{N}$ is sufficiently elementary, then Σ^π is a winning strategy for II in the corresponding game on $\mathcal{M}$. Thus

4.6 Theorem. *Suppose $\mathcal{N}$ is (k,θ)-iterable (respectively, (k,α,θ)-iterable), and there is a weak k-embedding from $\mathcal{M}$ into $\mathcal{N}$; then $\mathcal{M}$ is (k,θ)-iterable (respectively, (k,α,θ)-iterable).*

4.2. The Dodd-Jensen Lemma

The following definition enables us to state an abstract form of the Dodd-Jensen Lemma.

4.7 Definition. Let Σ be a (k,λ,θ)-iteration strategy for $\mathcal{M}$, where λ is additively closed, and let $\mathcal{T}$ be an iteration tree played according to Σ; then we say $\mathcal{T}$ *is* (k,λ,θ)-*unambiguous* iff whenever $\alpha < \mathrm{lh}(\mathcal{T})$ is a limit ordinal, then $[0,\alpha]_T$ is the unique cofinal branch b of $\mathcal{T}\restriction\alpha$ such that $\mathcal{M}^\mathcal{T}_b$ is $(\deg(b),\lambda,\theta)$-iterable.

So the unambiguous trees are just those which are played according to *every* (k,λ,θ)-iteration strategy for $\mathcal{M}$.

4.8 Theorem (The Dodd-Jensen Lemma). *Let λ be additively closed, let Σ be a (k,λ,θ)-iteration strategy for $\mathcal{M}$, and let $\mathcal{T}$ be an unambiguous iteration tree of length $\alpha+1$ played according to Σ. Suppose* $\deg^\mathcal{T}(\alpha) = k$, *and $\pi : \mathcal{M} \to \mathcal{N}$ is a weak k-embedding, where $\mathcal{N}$ is an initial segment of $\mathcal{M}^\mathcal{T}_\alpha$; then*

1. *$\mathcal{N} = \mathcal{M}^\mathcal{T}_\alpha$,*

2. $[0, \alpha]_T$ *does not drop (in model or degree), and*

3. *for all* $x \in \mathcal{M}$, $i^{\mathcal{T}}_{0,\alpha}(x) \leq_L \pi(x)$, *where* $\leq_L$ *is the order of construction.*

Proof. Assume first toward contradiction that $\mathcal{N}$ is a proper initial segment of $\mathcal{M}^{\mathcal{T}}_\alpha$. We shall construct a run r of $\mathcal{G}_k(\mathcal{M}, \lambda, \theta)$ which is a loss for Σ. The run r is divided into ω blocks, each consisting of a number of rounds of $\mathcal{G}_k(\mathcal{M}, \lambda, \theta)$ equal to the number of rounds in $\mathcal{T}$. We shall use $\mathcal{T}_n$ for the iteration tree played in the nth block of r, and $\mathcal{M}_n$ for the base model of $\mathcal{T}_n$. Thus $\mathcal{M}_{n+1}$ is the model player I drops to at the beginning of the first round in block $n+1$ of r; we have I drop to the degree k at the beginning of this round. We shall arrange that $\mathcal{M}_{n+1}$ is a proper initial segment of the last model of $\mathcal{T}_n$, so that the unique cofinal branch of the composition of the $\mathcal{T}_n$'s is illfounded, and r is indeed a loss for Σ. As an auxiliary we define maps $\pi_n : \mathcal{M}_n \to \mathcal{M}_{n+1}$ as we proceed.

Set $\mathcal{M}_0 = \mathcal{M}$, $\mathcal{T}_0 = \mathcal{T}$, $\mathcal{M}_1 = \mathcal{N}$, and $\pi_0 = \pi$.

Now suppose that $\mathcal{M}_n$, $\mathcal{T}_n$, $\mathcal{M}_{n+1}$, and π_n are given. Set $\mathcal{T}_{n+1} = \pi_n \mathcal{T}_n$. We shall check shortly that $\mathcal{T}_{n+1}$ is played according to Σ, so that $\mathrm{lh}(\mathcal{T}_{n+1}) = \mathrm{lh}(\mathcal{T}_n)$, and we have from the copying construction an embedding σ from the last model of $\mathcal{T}_n$ to the last model of $\mathcal{T}_{n+1}$. Now $\mathcal{M}_{n+1} \in \mathrm{dom}(\sigma)$, so we can set $\mathcal{M}_{n+2} = \sigma(\mathcal{M}_{n+1})$ and $\pi_{n+1} = \sigma \restriction \mathcal{M}_{n+1}$. This completes the construction of r, and thereby gives the desired contradiction.

We now show that $\mathcal{T}_{n+1}$ is a play according to Σ. Let us call a position u which is according to Σ *transitional* if $u = (s, (\mathcal{P}, i))$ where s represents some number $\beta < \lambda$ of complete rounds of play according to Σ in which I has not lost, and $(\mathcal{P}, i)$ is a way I might legally begin round β. Notice that in this situation, Σ determines an (i, λ, θ)-iteration strategy for $\mathcal{P}$. We call this strategy Σ_u. Now let u and v be the transitional initial segments of r ending with $(\mathcal{M}_n, k)$ and $(\mathcal{M}_{n+1}, k)$ respectively. Let $\psi = \pi_{n-1} \circ \cdots \circ \pi_0$ and $\tau = \pi_n \circ \cdots \circ \pi_0$, so that $\psi : \mathcal{M} \to \mathcal{M}_n$ and $\tau : \mathcal{M} \to \mathcal{M}_{n+1}$ are weak k embeddings. Since $(\Sigma_u)^\psi$ and $(\Sigma_v)^\tau$ are (k, λ, θ)-iteration strategies for $\mathcal{M}$ and $\mathcal{T}$ is unambiguous, $\mathcal{T}$ is a play by each of $(\Sigma_u)^\psi$ and $(\Sigma_v)^\tau$. Therefore $\psi\mathcal{T}$ and $\tau\mathcal{T}$ are plays according to Σ, and since $\tau\mathcal{T} = \pi_n \circ \psi\mathcal{T} = \pi_n \mathcal{T}_n = \mathcal{T}_{n+1}$, we are done.

The proofs of conclusions 2 and 3 of the Dodd-Jensen Lemma are similar. We construct $\mathcal{M}_n$, $\mathcal{T}_n$, and π_n as above, but now we have that $\mathcal{M}_{n+1}$ is the last model of $\mathcal{T}_n$. If the branch of $\mathcal{T}$ from $\mathcal{M}$ to $\mathcal{N} = \mathcal{M}_1$ drops, then the branch of $\mathcal{T}_n$ from $\mathcal{M}_n$ to $\mathcal{M}_{n+1}$ drops for each n, and the unique cofinal branch of the composition of the $\mathcal{T}_n$'s is illfounded. Thus we may assume that the branch of $\mathcal{T}$ from $\mathcal{M}$ to $\mathcal{N}$ does not drop, so that 2 holds. This implies that for all n, the branch of $\mathcal{T}_n$ from $\mathcal{M}_n$ to $\mathcal{M}_{n+1}$ does not drop, so that we have an iteration map $i_n : \mathcal{M}_n \to \mathcal{M}_{n+1}$ given by $\mathcal{T}_n$. Assume that conclusion 3 fails, and fix $x_0 \in \mathcal{M}_0$ such that $\pi_0(x_0) <_L i_0(x_0)$. For any $n \geq 0$, define x_{n+1} by: $x_{n+1} = \pi_n(x_n)$. It is easy to check that $x_{n+1} <_L i_n(x_n)$ for all n. (This is true for $n = 0$ by hypothesis. But if $x_{n+1} <_L i_n(x_n)$,

then

$$x_{n+2} = \pi_{n+1}(x_{n+1}) <_L \pi_{n+1}(i_n(x_n)) = i_{n+1}(\pi_n(x_n)) = i_{n+1}(x_{n+1}),$$

because $\pi_{n+1} \circ i_n = i_{n+1} \circ \pi_n$ by the commutativity of the copy maps.) Thus again, the unique cofinal branch of the composition of the $\mathcal{T}_n$'s is illfounded, and we have a loss for Σ.

The following diagram illustrates the proof given for conclusion 3.

$$\begin{tikzcd}
\mathcal{M}_0 \arrow[r, "i_0=i^{\mathcal{T}}_{0\alpha}"] & \mathcal{M}_1 x \arrow[r, "i_1"] & \mathcal{M}_2 \arrow[r, "i_2"] & \mathcal{M}_3 \arrow[r, "i_3"] & \cdots \\
& \mathcal{M}_0 \arrow[u, "\pi_0=\pi"] \arrow[r, "i_0"] & \mathcal{M}_1 \arrow[u, "\pi_1"] \arrow[r, "i_1"] & \mathcal{M}_2 \arrow[u, "\pi_2"] \arrow[r, "i_2"] & \cdots \\
& & \mathcal{M}_0 \arrow[u, "\pi_0"] \arrow[r, "i_0"] & \mathcal{M}_1 \arrow[u, "\pi_1"] \arrow[r, "i_1"] & \cdots \\
& & & \mathcal{M}_0 \arrow[u, "\pi_0"] \arrow[r, "i_0"] & \cdots
\end{tikzcd}$$

$\dashv$

4.3. The Weak Dodd-Jensen Property

Unfortunately, there are important contexts in which one wants to use the Dodd-Jensen Lemma, but in which one does not know that the given iteration strategy is unambiguous. One such context is the proof of the key fine structural fact that the standard parameters of a sufficiently iterable mouse are solid and universal. (We shall prove this in the next section.) Fortunately, one can construct from any iteration strategy for a countable mouse another iteration strategy which satisfies a weak version of the Dodd-Jensen Lemma, and this weak version suffices for the proof of solidity and universality. Since the construction is simple and natural, we shall give it here.

The notions and results in this subsection come from [31].

Let $\mathcal{M}$ and $\mathcal{P}$ be premice; then we say that $\mathcal{P}$ is $(\mathcal{M}, k)$-*large* just in case there is a near k-embedding from $\mathcal{M}$ to an initial segment of $\mathcal{P}$. (A near k-embedding is a weak k-embedding which is $r\Sigma_{k+1}$ elementary. See [35, 1.2, 1.3], where it is shown that the copying construction gives rise to such embeddings. We could make do with weak k-embeddings here, but it would be a bit awkward at one point.) Let $\vec{e} = \langle e_i \mid i < \omega \rangle$ enumerate the universe of a countable premouse $\mathcal{M}$, and $\pi : \mathcal{M} \to \mathcal{P}$ be a near k-embedding; then we say π is $(k, \vec{e})$-*minimal* iff whenever σ is a near k-embedding from $\mathcal{M}$ to an initial segment $\mathcal{N}$ of $\mathcal{P}$, then $\mathcal{N} = \mathcal{P}$ and either $\sigma = \pi$, or $\sigma(e_i) >_L \pi(e_i)$ where i is least such that $\sigma(e_i) \neq \pi(e_i)$. Notice that if $\mathcal{P}$ is $(\mathcal{M}, k)$-large but no proper initial segment of $\mathcal{P}$ is $(\mathcal{M}, k)$-large, then there is a $(k, \vec{e})$-minimal embedding from $\mathcal{M}$ to $\mathcal{P}$. This embedding is just the leftmost branch through a certain tree.

4.9 Definition. Let Σ be a (k, α, θ)-iteration strategy for a countable premouse $\mathcal{M}$, and let $\vec{e} = \langle e_i \mid i < \omega \rangle$ enumerate the universe of $\mathcal{M}$ in order type ω; then we say Σ has the *weak Dodd-Jensen property* (relative to $\vec{e}$) iff whenever $\mathcal{T}$ is an iteration tree on $\mathcal{M}$ played according to Σ, and $\beta < lh(\mathcal{T})$ is such that $\mathcal{M}_\beta^\mathcal{T}$ is $(\mathcal{M}, k)$-large, then $i_{0,\beta}^\mathcal{T}$ exists and is $(k, \vec{e})$-minimal.

4.10 Theorem (The Weak Dodd-Jensen Lemma). *Suppose $\mathcal{M}$ is (k, ω_1, θ)-iterable, and that $\vec{e}$ enumerates the universe of $\mathcal{M}$ in order type ω; then there is a (k, ω_1, θ)-iteration strategy for $\mathcal{M}$ which has the weak Dodd-Jensen property relative to $\vec{e}$.*

Proof. Let Σ be any (k, ω_1, θ)-iteration strategy for $\mathcal{M}$. We shall construct a transitional position $u = (r, (\mathcal{P}, k))$ of Σ and a $(k, \vec{e})$-minimal embedding $\pi : \mathcal{M} \to \mathcal{P}$ such that π is strongly $(k, \vec{e})$ minimal, in the sense that whenever $\mathcal{R}$ is an $(\mathcal{M}, k)$-large Σ_u-iterate of $\mathcal{P}$, then there is no dropping in the iteration from $\mathcal{P}$ to $\mathcal{R}$, and if $i : \mathcal{P} \to \mathcal{R}$ is the iteration map, then $i \circ \pi$ is $(k, \vec{e})$ minimal. It is then easy to see that the π-pullback of Σ_u has the weak Dodd-Jensen property.

Let us call a pair $(r, \mathcal{Q})$ *suitable* if $(r, (\mathcal{Q}, k))$ is transitional, and $\mathcal{Q}$ is $(\mathcal{M}, k)$-large but no proper initial segment of $\mathcal{Q}$ is $(\mathcal{M}, k)$-large. In order to obtain the desired u and π, we define by induction on $n < \omega$ suitable pairs $(r_n, \mathcal{P}_n)$. We maintain inductively that r_{n+1} extends $(r_n, (\mathcal{P}_n, k))$. We begin by letting r_0 be the empty position, and $\mathcal{P}_0 = \mathcal{M}$. Now suppose that r_n and $\mathcal{P}_n$ have been defined.

Case 1. There is a suitable $(s, \mathcal{Q})$ such that s extends $(r_n, (\mathcal{P}_n, k))$ and the branch $\mathcal{P}_n$-to-$\mathcal{Q}$ in the iteration given by s has a drop.

In this case, we simply let $(r_{n+1}, \mathcal{P}_{n+1})$ be any such $(s, \mathcal{Q})$.

Case 2. Otherwise.

Let $\tau : \mathcal{M} \to \mathcal{P}_n$ be $(k, \vec{e})$-minimal.

Subcase 2a. There is a suitable $(s, \mathcal{Q})$ such that s extends $(r_n, (\mathcal{P}_n, k))$, and letting $i : \mathcal{P}_n \to \mathcal{Q}$ be the iteration map given by s, $i \circ \tau$ is not $(k, \vec{e})$-minimal.

In this case, let $m < \omega$ be least such that for some such s, $\mathcal{Q}$, and i we have, letting $\sigma : \mathcal{M} \to \mathcal{Q}$ be $(k, \vec{e})$-minimal, that $\sigma(e_m) \neq i \circ \tau(e_m)$ (and thus $\sigma(e_m) <_L i \circ \tau(e_m)$). We then let $(r_{n+1}, \mathcal{P}_{n+1})$ be a suitable pair $(s, \mathcal{Q})$ witnessing this property of m.

Subcase 2b. Otherwise.

In this case τ is strongly $(k, \vec{e})$-minimal in the sense advertised earlier, so we set $u = (r_n, (\mathcal{P}_n, k))$ and $\pi = \tau$, and stop the construction.

Now suppose that the construction never stops. Notice that case 1 can only apply finitely often, since otherwise we get an iteration tree played according to Σ whose unique cofinal branch has infinitely many drops. Suppose then that case 2 applies at all $n \geq n_0$, so that for all $n_0 \leq n \leq m$ we have a k-embedding $i_{n,m} : \mathcal{P}_n \to \mathcal{P}_m$ given by r_m. For $n \geq n_0$, let $\pi_n : \mathcal{M} \to \mathcal{P}_n$ be $(k, \vec{e})$-minimal; then if $n_0 \leq n < m$, π_m is "to the left" of $i_{n,m} \circ \pi_n$. It follows that for any j, $i_{n,m}(\pi_n(e_j)) = \pi_m(e_j)$ for all sufficiently large n, m (by induction on j). Let

$$r = \bigcup_{n<\omega} r_n, \qquad \mathcal{P} = \lim_{n\to\infty} \mathcal{P}_n, \qquad u = (r, (\mathcal{P}, k)),$$

let $i_{n,\infty} : \mathcal{P}_n \to \mathcal{P}$ be the direct limit map (a k-embedding), and define $\pi : \mathcal{M} \to \mathcal{P}$ by

$$\pi(e_j) = \text{ eventual value of } i_{n,\infty}(\pi_n(e_j)), \quad \text{as } n \to \infty.$$

We claim that u and π are as advertised earlier.

Clearly π is a near k-embedding, and so $\mathcal{P}$ is $(\mathcal{M}, k)$-large. No proper initial segment $\mathcal{R}$ of $\mathcal{P}$ can be $(\mathcal{M}, k)$-large, as then $(u, \mathcal{R})$ could serve as the $(s, \mathcal{Q})$ witnessing the occurrence of case 1 at a stage $n > n_0$. Similarly, π is $(k, \vec{e})$-minimal. For if σ is a near k-embedding of $\mathcal{M}$ into $\mathcal{P}$ which is to the left of π, then take m_0 to be the least j such that $\sigma(e_j) \neq \pi(e_j)$, and let $l < \omega$ be so large that $n_0 < l$ and $\pi(e_j) = i_{l,\infty}(\pi_l(e_j))$ for all $j \leq m_0$ (and so $m > m_0$, where m is as in case 2a at stage l). Then r, $\mathcal{P}$, and σ could serve as the s, $\mathcal{Q}$, and σ witnessing $m \leq m_0$ at stage l, contradiction. Finally, let $\mathcal{R}$ be any $(\mathcal{M}, k)$-large iterate of $\mathcal{P}$ via Σ_u. Clearly, there is a transitional position $(v, (\mathcal{R}, k))$ such that v extends u. We can argue as above that there is no dropping in the iteration tree given by v from $\mathcal{P}$ to $\mathcal{R}$, and that if $i : \mathcal{P} \to \mathcal{R}$ is the iteration map, then $i \circ \pi$ is $(k, \vec{e})$-minimal. Thus u and π are as advertised.

We leave to the reader the easy verification that $(\Sigma_u)^\pi$ has the weak Dodd-Jensen property. ⊣

The weak Dodd-Jensen property isolates a unique iteration strategy, modulo the enumeration $\vec{e}$. Since the main ideas in the proof of this fact are used very often in inner model theory, we give it here.

4.11 Theorem. *Let $\vec{e}$ enumerate the universe of the k-sound premouse $\mathcal{M}$ in order type ω; then there is at most one $(k, \omega_1 + 1)$-iteration strategy for $\mathcal{M}$ which has the weak Dodd-Jensen property relative to $\vec{e}$.*

Proof. Suppose that Σ and Γ are distinct such strategies. We can find a k-maximal iteration tree $\mathcal{T}$ on $\mathcal{M}$ such that $\mathcal{T}$ has limit length $\lambda < \omega_1$, $\mathcal{T}$ is played according to both Σ and Γ, and $\Sigma(\mathcal{T}) \neq \Gamma(\mathcal{T})$. Let $\mathcal{U}^*$ and $\mathcal{V}^*$ be the iteration trees of length $\lambda + 1$ extending $\mathcal{T}$ produced by Σ and Γ respectively. We now proceed as if we had produced $\mathcal{U}^*$ and $\mathcal{V}^*$ on the two sides of a coiteration, and continue "iterating the least disagreement". We thereby extend $\mathcal{U}^*$ and $\mathcal{V}^*$ to k-maximal trees $\mathcal{U}$ and $\mathcal{V}$, played according to Σ and Γ respectively, in such a way that the last model of one is an initial segment of the last model of the other. We may as well assume that $\mathcal{M}^{\mathcal{U}}_\alpha$ is an initial segment of $\mathcal{M}^{\mathcal{V}}_\beta$. As in the Comparison Lemma 3.11, one of the two trees does not drop along the branch leading to its last model, so we can assume that $D^{\mathcal{U}} \cap [0,\alpha]_U = \emptyset$ and $\deg^{\mathcal{U}}(\alpha) = k$, and hence $i^{\mathcal{U}}_{0,\alpha}$ exists and is a k-embedding.

It follows that $\mathcal{M}^{\mathcal{V}}_\beta$ is $(\mathcal{M}, k)$-large. Since Γ has the weak Dodd-Jensen property relative to $\vec{e}$, $i^{\mathcal{V}}_{0,\beta}$ exists and is $(k,\vec{e})$-minimal. This implies that no proper initial segment of $\mathcal{M}^{\mathcal{V}}_\beta$ is $(\mathcal{M}, k)$-large, so $\mathcal{M}^{\mathcal{U}}_\alpha = \mathcal{M}^{\mathcal{V}}_\beta$. Because Σ also has the weak Dodd-Jensen property relative to $\vec{e}$, $i^{\mathcal{U}}_{0,\alpha}$ is also $(k,\vec{e})$-minimal. It follows that $i^{\mathcal{U}}_{0,\alpha} = i^{\mathcal{V}}_{0,\beta}$.

Notice that since $\Sigma(\mathcal{T}) \neq \Gamma(\mathcal{T})$, $[0,\alpha]_U \cap [0,\beta]_V$ is bounded in λ. As branches in an iteration tree are closed below their sups, we have a largest ordinal γ such that $\gamma \in [0,\alpha]_U \cap [0,\beta]_V \cap \lambda$. Let $\nu = \sup\{\nu(E^{\mathcal{T}}_\xi) \mid \xi\, T\, \gamma\}$. Every member of $\mathcal{M}^{\mathcal{T}}_\gamma$ is of the form $i^{\mathcal{T}}_{0,\gamma}(f)(a)$, for some $f \in \mathcal{M}$ and $a \in [\nu]^{<\omega}$. (We take $k = 0$ for notational simplicity; otherwise we have f $r\Sigma_k$ over $\mathcal{M}$.) Since $i^{\mathcal{U}}_{\gamma,\alpha}$ and $i^{\mathcal{V}}_{\gamma,\beta}$ have critical point at least ν, this representation of $\mathcal{M}^{\mathcal{T}}_\gamma$ and the fact that $i^{\mathcal{U}}_{0,\alpha} = i^{\mathcal{V}}_{0,\beta}$ yield that $i^{\mathcal{U}}_{\gamma,\alpha} = i^{\mathcal{V}}_{\gamma,\beta}$.

Let $\xi + 1 \in (\gamma,\alpha]_U$ be such that $\mathrm{pred}_U(\xi+1) = \gamma$. Let $\sigma + 1 \in (\gamma,\beta]_V$ be such that $\mathrm{pred}_V(\sigma+1) = \gamma$. Since $i^{\mathcal{U}}_{\gamma,\alpha} = i^{\mathcal{V}}_{\gamma,\beta}$, the extenders $E^{\mathcal{U}}_\xi$ and $E^{\mathcal{V}}_\sigma$ are compatible, that is, they agree up to the inf of the sups of their generators. If $\xi < \lambda$ or $\sigma < \lambda$, this is impossible as no extender used in an iteration tree is compatible with any extender used later in the same tree. (If $\alpha < \beta$ and E_α is compatible with E_β, then $E_\alpha \in \mathcal{M}_\beta$ by the initial segment condition. This implies that $\mathrm{lh}(E_\alpha)$ is not a cardinal in $\mathcal{M}_\beta$, contrary to Lemma 3.5.) If $\lambda \le \xi$ and $\lambda \le \sigma$, this is impossible as no two extenders used in a coiteration are compatible. (This was a subclaim in the proof of the Comparison Lemma 3.11.) This contradiction completes the proof. ⊣

5. Solidity and Condensation

In this section we shall sketch the proofs of two theorems which are central in the fine structural analysis of definability over mice. These results are much deeper than the fine structural results of Sect. 2. Their proofs involve comparison arguments, and hence require an iterability hypothesis. The proofs also use the weak Dodd-Jensen property, and they illustrate a very useful technique for insuring that in certain comparisons, the critical point of the embedding from the first to the last model in one of the trees is not too small.

Our first theorem is a condensation result.

5.1 Theorem. *Let $\mathcal{M}$ be ω-sound and $(\omega,\omega_1,\omega_1+1)$-iterable. Suppose that $\pi : \mathcal{H} \to \mathcal{M}$ is fully elementary, and* $\mathrm{crit}(\pi) = \rho^{\mathcal{H}}_\omega$*; then either*

1. *$\mathcal{H}$ is a proper initial segment of $\mathcal{M}$, or*

2. *there is an extender E on the $\mathcal{M}$-sequence such that $\mathrm{lh}(E) = \rho^{\mathcal{H}}_\omega$, and $\mathcal{H}$ is a proper initial segment of* $\mathrm{Ult}_0(\mathcal{M}, E)$.

5.2 Remarks. The complexities in the statement of Theorem 5.1 are necessary.

1. The hypothesis that $\mathrm{crit}(\pi) = \rho_\omega^{\mathcal{H}}$ is necessary in Theorem 5.1. For notice that $\mathrm{crit}(\pi) > \rho_\omega^{\mathcal{H}}$ is impossible since otherwise we would have $\rho_\omega^{\mathcal{H}} = \rho_\omega^{\mathcal{M}}$, and since $\mathcal{M}$ is ω-sound, this would imply that $\mathrm{crit}(\pi)$ is definable over $\mathcal{M}$ from points in the range of π. On the other hand, $\mathrm{crit}(\pi) < \rho_\omega^{\mathcal{H}}$ can occur while the conclusions of Theorem 5.1 fail: for example, let $\mathcal{M} = \mathrm{Ult}_\omega(\mathcal{H}, E)$, where E is on the $\mathcal{H}$-sequence and $\mathrm{crit}(E) < \rho_\omega^{\mathcal{H}}$, and let π be the canonical embedding.

2. The alternatives in the conclusion of Theorem 5.1 are mutually exclusive, since in the second case the extender E is on the $\mathcal{M}$-sequence, but not on the $\mathcal{H}$-sequence. The following example shows that the second alternative can occur. Suppose that $\mathcal{P}$ is an active, ω-sound mouse, and F is the last extender on the $\mathcal{P}$-sequence. Let $\kappa = \mathrm{crit}(F)$, and suppose $F{\restriction}\alpha$ is on the $\mathcal{P}$-sequence, where $\alpha > (\kappa^+)^{\mathcal{P}}$. (Under weak large cardinal hypotheses, there is such a $\mathcal{P}$.) Let

$$\sigma : \mathrm{Ult}_0(\mathcal{P}, F{\restriction}\alpha) \to \mathrm{Ult}_0(\mathcal{P}, F)$$

be the natural embedding. Since α is a cardinal in $\mathrm{Ult}_0(\mathcal{P}, F{\restriction}\alpha)$ by clause 1 of Definition 2.4, and not a cardinal in $\mathrm{Ult}_0(\mathcal{P}, F)$ because $F{\restriction}\alpha$ is in this model and collapses α, we have that $\alpha = \mathrm{crit}(\sigma)$. Let

$$\mathcal{H} = \mathcal{J}_{\alpha+1}^{\mathrm{Ult}_0(\mathcal{P}, F{\restriction}\alpha)}$$

and

$$\mathcal{M} = \sigma(\mathcal{H}), \pi = \sigma{\restriction}\mathcal{H}.$$

Clearly $\alpha = \mathrm{crit}(\pi) = \rho_\omega^{\mathcal{H}}$, π is fully elementary, and $\mathcal{H}$ is not an initial segment of $\mathcal{M}$.

Proof of Theorem 5.1. Let $\mathcal{H}$ and $\mathcal{M}$ constitute a counterexample. Let $X \prec V_\lambda$ for some limit ordinal λ, with X countable and $\mathcal{H}, \mathcal{M} \in X$, and let $\bar{\mathcal{H}}$ and $\bar{\mathcal{M}}$ be the images of $\mathcal{H}$ and $\mathcal{M}$ under the transitive collapse of X. It is easy to see that $\bar{\mathcal{H}}$ and $\bar{\mathcal{M}}$ still constitute a counterexample to Theorem 5.1. Thus we may assume without loss of generality that $\mathcal{M}$ is countable. We can therefore fix an enumeration $\vec{e}$ of $\mathcal{M}$ in order type ω, and an $(\omega, \omega_1, \omega_1 + 1)$-iteration strategy Σ for $\mathcal{M}$ having the weak Dodd-Jensen property relative to $\vec{e}$.

The natural plan is to compare $\mathcal{H}$ with $\mathcal{M}$, using Σ to iterate $\mathcal{M}$ and Σ^π to iterate $\mathcal{H}$. Suppose that $\mathcal{P}$ is the last model of the tree $\mathcal{T}$ on $\mathcal{H}$ and $\mathcal{Q}$ is the last model of the tree $\mathcal{U}$ on $\mathcal{M}$ in this comparison. We would like to see that $\mathcal{P} = \mathcal{H}$, for then it is clear that $\mathcal{H}$ is an initial segment of $\mathcal{Q}$, and a little further argument, given below, shows that $\mathcal{U}$ uses at most one extender, so that one of the alternatives in the conclusion of Theorem 5.1 must hold. Assume then that $\mathcal{P} \neq \mathcal{H}$.

If the branch $\mathcal{H}$-to-$\mathcal{P}$ of $\mathcal{T}$ drops in model or degree, then $\mathcal{M}$-to-$\mathcal{Q}$ does not drop in model or degree, and $\mathcal{Q}$ is a proper initial segment of $\mathcal{P}$. (Here we use that $\mathcal{T}$ and $\mathcal{U}$ are ω-maximal.) But then, letting $j : \mathcal{M} \to \mathcal{Q}$ be the iteration map, and $\tau : \mathcal{P} \to \mathcal{R}$ be the copy map from $\mathcal{P}$ to the last model of $\pi\mathcal{T}$, we have that $\tau \circ j$ maps $\mathcal{M}$ to a proper initial segment of $\mathcal{R}$, and $\mathcal{R}$ is a Σ-iterate of $\mathcal{M}$. This contradicts the weak Dodd-Jensen property of Σ. Thus $\mathcal{H}$-to-$\mathcal{P}$ does not drop in model or degree, and we have a fully elementary iteration map $i : \mathcal{H} \to \mathcal{P}$.

Since the branch $\mathcal{H}$-to-$\mathcal{P}$ does not drop in model or degree, we must have $\text{crit}(i) < \rho_\omega^{\mathcal{H}}$. Let $\rho = \rho_\omega^{\mathcal{H}}$. Since $\text{crit}(\pi) = \rho$, $\mathcal{H}$ and $\mathcal{M}$ agree below ρ, so that all extenders used in their comparison have length at least ρ. Nevertheless, it is possible that the first extender E used along $\mathcal{H}$-to-$\mathcal{P}$ is such that $\text{crit}(E) < \rho \leq \text{lh}(E)$. This possibility ruins our proof, so we must modify the construction of $\mathcal{T}$ so as to avoid it.

We modify the construction so that if E is an extender used in $\mathcal{T}$ and $\text{crit}(E) < \rho$, then E is used in $\mathcal{T}$ to take an ultrapower of $\mathcal{M}$, or rather the longest initial segment of $\mathcal{M}$ containing only subsets of $\text{crit}(E)$ measured by E, instead of being used to take an ultrapower of $\mathcal{H}$, as it would be in a tree on $\mathcal{H}$. This modification is possible because $\mathcal{M}$ and $\mathcal{H}$ agree below ρ. The system $\mathcal{T}$ we form in this way is not an ordinary iteration tree, but rather a "double-rooted" iteration tree whose base is the pair of models $(\mathcal{M}, \mathcal{H})$. We shall use $\mathcal{P}_\alpha$ for the αth model of $\mathcal{T}$, and E_α for the extender taken from the $\mathcal{P}_\alpha$-sequence and used to form $\mathcal{P}_{\alpha+1}$. Let

$$\mathcal{P}_0 = \mathcal{M}, \quad \text{and} \quad \mathcal{P}_1 = \mathcal{H}.$$

Let $E_0 = \emptyset$, and

$$\nu(E_0) = \rho.$$

For $\alpha \geq 1$, E_α is the extender on the $\mathcal{P}_\alpha$-sequence which participates in its least disagreement with the sequence of the current last model in $\mathcal{U}$. As in an ordinary iteration tree,

$$\text{pred}_T(\alpha + 1) = \text{least } \beta \text{ such that } \text{crit}(E_\alpha) < \nu(E_\beta),$$

and

$$\mathcal{P}_{\alpha+1} = \text{Ult}_n(\mathcal{P}^*_{\alpha+1}, E_\alpha),$$

where $\mathcal{P}^*_{\alpha+1}$ is the longest initial segment of $\mathcal{P}_\beta$ and n is the largest number $\leq \omega$ such that the ultrapower in question makes sense. (That is, we do so in all but one anomalous case, which we shall explain in the next paragraph.) Our convention on $\nu(E_0)$ and the fact that the $\nu(E_\alpha)$ are increasing then implies that if $\text{crit}(E_\alpha) < \rho$, then $\text{pred}_T(\alpha + 1) = 0$, so that E_α is applied in $\mathcal{T}$ to an initial segment of $\mathcal{M}$.

There is one anomalous case here.[28] Suppose that $\text{crit}(E_\alpha) := \kappa < \rho$, and let $\mathcal{P}^*_{\alpha+1}$ be the longest initial segment $\mathcal{Q}$ of $\mathcal{M}$ such that $P(\kappa) \cap \mathcal{Q} \subseteq \mathcal{P}_\alpha$. It

[28] This case was overlooked in [25]. It was discovered by Jensen. Our method of dealing with it is due to Schindler and Zeman; cf. [39].

can happen that $\mathcal{P}^*_{\alpha+1}$ is of type III, with $\nu(\mathcal{P}^*_{\alpha+1}) = \kappa$. (One can show easily then that $\rho = (\kappa^+)^{\mathcal{H}}$, and $\mathcal{P}^*_{\alpha+1} = \mathcal{J}^{\mathcal{M}}_\rho$.) In this case, $\mathrm{Ult}_0(\mathcal{C}_0(\mathcal{P}^*_{\alpha+1}), E_\alpha)$ does not make sense, because $\mathcal{C}_0(\mathcal{P}^*_{\alpha+1})$ has ordinal height $\mathrm{crit}(E_\alpha)$.[29] We must therefore return to our old, naïve meaning for $\mathrm{Ult}_0(\mathcal{P}^*_{\alpha+1}, E_\alpha)$. Let k be the canonical embedding associated to this ultrapower, and let F be the last extender of $\mathcal{P}^*_{\alpha+1}$. Then we set

$$\mathcal{P}_{\alpha+1} = \mathrm{Ult}_\omega(\mathcal{M}, k(F)).$$

Note here that $k(F)$ is indeed a total extender over $\mathcal{M}$ with critical point strictly less than $\rho_\omega(\mathcal{M})$.

Unfortunately, the extender $k(F)$ does not satisfy the initial segment condition, since $F{\restriction}\kappa$ is an initial segment of it not present in $\mathrm{Ult}_0(\mathcal{P}^*_{\alpha+1}, E_\alpha)$. This complicates the comparison argument to follow. We advise the reader who is going through this argument for the first time to simply ignore the anomalous case in the definition of $\mathcal{P}_{\alpha+1}$.

We can lift $\mathcal{T}$ to an ordinary iteration tree on $\mathcal{M}$ as follows. Let

$$\mathcal{R}_0 = \mathcal{R}_1 = \mathcal{M},$$

and let

$$\pi_0 : \mathcal{P}_0 \to \mathcal{R}_0 \quad \text{and} \quad \pi_1 : \mathcal{P}_1 \to \mathcal{R}_1$$

be given by: $\pi_0 =$ identity and $\pi_1 = \pi$. Note that π_0 and π_1 agree below $\nu(E_0)$. We can use (π_0, π_1) to lift $\mathcal{T}$ to a double-rooted tree $(\pi_0, \pi_1)\mathcal{T}$ on the pair $(\mathcal{R}_0, \mathcal{R}_1)$ just as we did in the copying construction for ordinary iteration trees. Since $\mathcal{R}_0 = \mathcal{R}_1 = \mathcal{M}$, the tree $(\pi_0, \pi_1)\mathcal{T}$, which we shall call $\mathcal{S}$, is nothing but an ordinary iteration tree on $\mathcal{M}$.[30]

We form $\mathcal{T}$ and $\mathcal{S}$ at limit stages as follows. Suppose that the initial segment $\mathcal{S}^*$ of $\mathcal{S}$ built so far is a play by Σ; then we can use Σ to obtain a cofinal wellfounded branch of $\mathcal{S}^*$, and as in the ordinary copying construction, the pullback of this branch is a cofinal wellfounded branch of the initial segment $\mathcal{T}^*$ of $\mathcal{T}$ built so far. We extend $\mathcal{S}^*$ and $\mathcal{T}^*$ by choosing these branches. Thus $\mathcal{S}$ is a play by Σ, and $\mathcal{T}$ is a play by its pullback $\Sigma^{(\pi_0,\pi_1)}$.

Since Σ is an $(\omega, \omega_1, \omega_1+1)$ iteration strategy, this inductive construction of $\mathcal{S}$, $\mathcal{T}$, and $\mathcal{U}$ can last as many as ω_1+1 steps. But $\mathcal{H}$ and $\mathcal{M}$ are countable, so as in the proof of the Comparison Lemma 3.11, the comparison represented by $\mathcal{T}$ and $\mathcal{U}$ actually terminates successfully at some countable stage. Let $\mathcal{P}$ and $\mathcal{Q}$ be the last models of $\mathcal{T}$ and $\mathcal{U}$ respectively. Let $\mathcal{R}$ be the last model of $\mathcal{S}$, and $\tau : \mathcal{P} \to \mathcal{R}$ the copy map. The key claim is:

Claim. *$\mathcal{P}$ is above $\mathcal{H}$ in $\mathcal{T}$.*

Proof. If not, then $\mathcal{P}$ is above $\mathcal{M}$ in $\mathcal{T}$. Suppose that the branch $\mathcal{M}$-to-$\mathcal{Q}$ of $\mathcal{U}$ drops in model or degree. Since $\mathcal{T}$ and $\mathcal{U}$ are ω-maximal trees on ω-sound mice, we then have that $\mathcal{P}$ is a proper initial segment of $\mathcal{Q}$, and the

[29] This problem cannot occur in the construction of an ordinary iteration tree, as we verified in the course of describing the successor steps in an iteration game.

[30] We are ignoring here some complications in the anomalous case.

branch $\mathcal{M}$-to-$\mathcal{P}$ of $\mathcal{T}$ does not drop in model or degree, so that there is a fully elementary iteration map $i : \mathcal{M} \to \mathcal{P}$. But then i maps $\mathcal{M}$ to a proper initial segment of a Σ-iterate of $\mathcal{M}$, which contradicts the weak Dodd-Jensen property of Σ. Thus $\mathcal{M}$-to-$\mathcal{Q}$ does not drop, and we have a fully elementary iteration map $j : \mathcal{M} \to \mathcal{Q}$ given by $\mathcal{U}$.

Suppose that the branch $\mathcal{M}$-to-$\mathcal{P}$ of $\mathcal{T}$ drops in model or degree. In this case $\mathcal{Q}$ must be a proper initial segment of $\mathcal{P}$. But then $\tau \circ j$ is a fully elementary map from $\mathcal{M}$ to a proper initial segment of $\mathcal{R}$, which is a Σ-iterate of $\mathcal{M}$. This contradicts the weak Dodd-Jensen property of Σ. Thus $\mathcal{M}$-to-$\mathcal{P}$ does not drop, and we have a fully elementary iteration map $i : \mathcal{M} \to \mathcal{P}$ given by $\mathcal{T}$.

These arguments also show that $\mathcal{P}$ is not a proper initial segment of $\mathcal{Q}$ and $\mathcal{Q}$ is not a proper initial segment of $\mathcal{P}$, so that $\mathcal{P} = \mathcal{Q}$. We claim that $i = j$ as well. For let x be first in the enumeration $\vec{e}$ of $\mathcal{M}$ such that $i(x) \neq j(x)$. If $i(x) <_L j(x)$, then j is an iteration map produced by Σ which is not $\vec{e}$-minimal, contrary to the weak Dodd-Jensen property of Σ. So $j(x) <_L i(x)$. But now, since $\mathcal{M}$-to-$\mathcal{P}$ did not drop in $\mathcal{T}$, the branch $\mathcal{M}$-to-$\mathcal{R}$ does not drop in the copied tree $\mathcal{S}$, and so we have an iteration map $k : \mathcal{M} \to \mathcal{R}$ given by $\mathcal{S}$. The copy maps commute with the tree embeddings, so we have $\tau \circ i = k \circ \pi_0 = k$. But then

$$\tau(j(x)) <_L \tau(i(x)) = k(x),$$

and $\tau \circ j$ witnesses that k is not $\vec{e}$-minimal, contrary to the fact that k is an iteration map produced by Σ. Thus $i = j$.

As in the proofs of Theorems 3.11 and 4.11, this implies that the first extenders used along the branches giving rise to i and j are compatible with each other. If these extenders satisfy the initial segment condition, then as in Theorems 3.11 and 4.11, that is a contradiction because they participated in disagreements when they were used.

We are left with the possibility that the first extender G used in i comes from our anomalous case. Here $G = k(F)$, where $k : \mathcal{J}_\rho^{\mathcal{M}} \to \mathrm{Ult}_0(\mathcal{J}_\rho^{\mathcal{M}}, E_\alpha)$ is the canonical embedding, and F is the last extender of $\mathcal{J}_\rho^{\mathcal{M}}$. We also have $\mathrm{crit}(k) = \nu(F)$, so that $F{\restriction}\nu(F)$ is an initial segment of G. It is in fact the first initial segment of G which is not in $\mathcal{P}$, and since it is compatible with the first extender used in j (which itself satisfies the initial segment condition), the trivial completion of $F{\restriction}\nu(F)$ *is* the first extender used in j. One can now show that the second extender used in j is compatible with E_α, and that is a contradiction because both of these extenders satisfy the initial segment condition. To prove the compatibility, one uses that for $A \subseteq \mathrm{crit}(G)$, $i_G(A) = k(i_F(A))$. The reader can find the remaining details in [39]. ⊣

So $\mathcal{P}$ is above $\mathcal{H}$ in $\mathcal{T}$. The branch $\mathcal{H}$-to-$\mathcal{P}$ cannot drop in model or degree, since otherwise $\mathcal{Q}$ is a proper initial segment of $\mathcal{P}$ and we have a fully elementary iteration map $j : \mathcal{M} \to \mathcal{Q}$, so that $\tau \circ j$ maps $\mathcal{M}$ into a proper initial segment of the Σ-iterate $\mathcal{R}$. Thus we have a fully elementary iteration map $i : \mathcal{H} \to \mathcal{P}$ given by $\mathcal{T}$. If i is not the identity, then the rules for $\mathcal{T}$ guarantee $\mathrm{crit}(i) \geq \rho$, so that $\mathcal{H}$-to-$\mathcal{P}$ would have to drop in model or degree at its first step. Therefore i is the identity; that is, $\mathcal{H} = \mathcal{P}$.

$\mathcal{Q}$ cannot be a proper initial segment of $\mathcal{H}$, for otherwise $\mathcal{M}$-to-$\mathcal{Q}$ does not drop, and letting j be the iteration map, $\tau \circ j$ maps $\mathcal{M}$ to a proper initial segment of itself. It cannot be that $\mathcal{H} = \mathcal{Q}$, for if so, then $\mathcal{M}$-to-$\mathcal{Q}$ does not drop, and letting j be the iteration map, $\rho_\omega^{\mathcal{H}} < \rho_\omega^{\mathcal{M}} \leq j(\rho_\omega^{\mathcal{M}}) = \rho_\omega^{\mathcal{Q}}$. Thus $\mathcal{H}$ is a proper initial segment of $\mathcal{Q}$.

We can now complete the proof of Theorem 5.1. Suppose that $\mathcal{H}$ is not an initial segment of $\mathcal{M}$, so that $\mathcal{U}$ uses at least one extender $E_0^{\mathcal{U}}$. Now $\rho \leq \mathrm{lh}(E_0^{\mathcal{U}})$ because $\mathcal{H}$ and $\mathcal{M}$ agree below ρ, while $\mathrm{lh}(E_0^{\mathcal{U}}) \leq \mathrm{On}^{\mathcal{H}}$ because $\mathcal{H}$ is not an initial segment of $\mathcal{M}$. But $\mathrm{lh}(E_0^{\mathcal{U}})$ is a cardinal of $\mathcal{Q}$, and $\mathcal{H}$ is a proper initial segment of $\mathcal{Q}$, so that $|\,\mathrm{On}^{\mathcal{H}}\,| \leq \rho_\omega^{\mathcal{H}}$ in $\mathcal{Q}$. It follows that $\mathrm{lh}(E_0^{\mathcal{U}}) = \rho$. Similarly, if $E_1^{\mathcal{U}}$ exists, then we must have $\mathrm{On}^{\mathcal{H}} < \mathrm{lh}(E_1^{\mathcal{U}})$, so in fact $E_1^{\mathcal{U}}$ does not exist. This means that $\mathcal{Q} = \mathrm{Ult}_k(\mathcal{M}, E_0^{\mathcal{U}})$ for some k. We can take $k = 0$ because $\mathrm{Ult}_0(\mathcal{M}, E_0^{\mathcal{U}})$ and $\mathrm{Ult}_k(\mathcal{M}, E_0^{\mathcal{U}})$ agree to their common value for ρ^+ and beyond. ⊣

One can prove a version of Theorem 5.1 in which $\rho_\omega^{\mathcal{H}}$ is replaced by $\rho_n^{\mathcal{H}}$, for some $n < \omega$. See [25, Sect. 8].

The technique by which Theorem 5.1 is proved is useful in many circumstances. One wants to compare two mice $\mathcal{H}$ and $\mathcal{M}$ in such a way that the iteration map on the $\mathcal{H}$ side has critical point at least ρ. An ordinary comparison might not have this property, but one finds models (such as $\mathcal{M}$ itself in the proof above) which agree with $\mathcal{H}$ to various extents below ρ, yet in some sense carry more information than $\mathcal{H}$. One then forms a many-rooted iteration tree on $\mathcal{H}$ "backed up" by these other models, and argues that the final model on this tree lies above the root $\mathcal{H}$. One can view the proof of Theorem 4.11 in this light.[31] Another important application of the technique lies in the proof of the following central fine-structural result concerning the good behavior of the standard parameter.

5.3 Theorem. *Let $k < \omega$, and let $\mathcal{M}$ be a k-sound, $(k, \omega_1, \omega_1 + 1)$-iterable premouse; then $\mathcal{C}_{k+1}(\mathcal{M})$ exists, and agrees with $\mathcal{M}$ below γ, for all γ of $\mathcal{M}$-cardinality $\rho_{k+1}(\mathcal{M})$.*

Sketch of Proof. We assume $k = 0$ for notational simplicity, and because only in that case have we given full definitions anyway. Let $r = p_1(\mathcal{M})$ be the first standard parameter of $\mathcal{M}$; we must show that r is 1-solid and 1-universal, so that $\mathcal{C}_1(\mathcal{M})$ exists, and that $\mathcal{C}_1(\mathcal{M})$ agrees with $\mathcal{M}$ as claimed. These properties of r and $\mathcal{M}$ are expressed by sentences in the first order theory of $\mathcal{M}$, so if they fail, they fail in some countable fully elementary

[31] In Theorem 4.11 one wanted to compare the last models of $\mathcal{U}^*$ and $\mathcal{V}^*$, but for the proof it was important to back them up with the earlier models of $\mathcal{T}$. Many-rooted iteration trees are also important in the inductive definition of K [43, Sect. 6], and in the proof of weak covering for K [26].

submodel of $\mathcal{M}$. Any countable elementary submodel of $\mathcal{M}$ inherits its $(0, \omega_1, \omega_1 + 1)$-iterability. Thus we may assume without loss of generality that $\mathcal{M}$ is countable.

We shall assume that r is solid, and briefly sketch the proof that r is universal and $\mathcal{C}_1(\mathcal{M})$ agrees with $\mathcal{M}$ below the cardinal successor of $\rho_1(\mathcal{M})$ in $\mathcal{M}$. So let $\rho = \rho_1(\mathcal{M})$, and let

$$\mathcal{H} = \mathcal{H}_1^{\mathcal{M}}(\rho \cup \{r\}).$$

We wish to show that $P(\rho) \cap \mathcal{M} \subseteq \mathcal{H}$, and for this the natural strategy is to compare $\mathcal{H}$ with $\mathcal{M}$. If the critical point of the embedding i from $\mathcal{H}$ to the last model $\mathcal{P}$ on the $\mathcal{H}$ side is at least ρ, then the $\Sigma_1^{\mathcal{H}}$ set $A \subseteq \rho$ which is not in $\mathcal{M}$ (witnessing that $\rho = \rho_1^{\mathcal{M}}$) is also $\Sigma_1^{\mathcal{P}}$. Since A is not in the last model $\mathcal{Q}$ on the $\mathcal{M}$ side, $\mathcal{Q}$ is an initial segment of $\mathcal{P}$, and one can then argue that

$$P(\rho)^{\mathcal{M}} = P(\rho)^{\mathcal{Q}} \subseteq P(\rho)^{\mathcal{P}} = P(\rho)^{\mathcal{H}},$$

as desired. In order to insure that $\mathrm{crit}(i) \geq \rho$, we once again form a double-rooted tree on the pair $(\mathcal{M}, \mathcal{H})$ on the $\mathcal{H}$ side of our comparison, going back to $\mathcal{M}$ whenever we use an extender with critical point $< \rho$.

Let $r = \langle \alpha_0, \dots, \alpha_n \rangle$, where the ordinals α_i are listed in decreasing order. Let $\vec{e}$ be an enumeration of the universe of $\mathcal{M}$ such that $e_i = \alpha_i$ for all $i \leq n$. Let Σ be a $(0, \omega_1, \omega_1 + 1)$ iteration strategy for $\mathcal{M}$ having the weak Dodd-Jensen property relative to $\vec{e}$. Let $\pi_0 =$ identity and $\pi_1 : \mathcal{H} \to \mathcal{M}$ be the collapse embedding. We form the double-rooted tree $\mathcal{T}$ on $(\mathcal{M}, \mathcal{H})$ using the pullback $\Sigma^{(\pi_0, \pi_1)}$ of Σ to choose branches at limit stages, and iterating the least disagreement with the last model of the tree $\mathcal{U}$ on $\mathcal{M}$ at successor stages. Let $\mathcal{P}$ and $\mathcal{Q}$ be the last models of $\mathcal{T}$ and $\mathcal{U}$.

As in the proof of Theorem 5.1, the weak Dodd-Jensen property of Σ implies that $\mathcal{P}$ is above $\mathcal{H}$, and not above $\mathcal{M}$, and that $\mathcal{H}$-to-$\mathcal{P}$ does not drop, and that $\mathcal{Q}$ is not a proper initial segment of $\mathcal{P}$. Thus we have a 0-embedding $i : \mathcal{H} \to \mathcal{P}$ given by $\mathcal{T}$. Since $\mathrm{crit}(i) \geq \rho$, A is $\Sigma_1^{\mathcal{P}}$, and since $A \notin \mathcal{Q}$, $\mathcal{P}$ is not a proper initial segment of $\mathcal{Q}$. Thus $\mathcal{P} = \mathcal{Q}$. We also get that $\mathcal{M}$-to-$\mathcal{Q}$ does not drop, so that $\mathcal{U}$ gives us an embedding $j : \mathcal{M} \to \mathcal{Q}$.

Let $\bar{\alpha}_e = \pi_1^{-1}(\alpha_e)$ be the image of α_e under collapse, for $e \leq n$. One can show by induction on e that

$$i(\bar{\alpha}_e) = j(\alpha_e),$$

using the solidity of $j(r)$ to show $i(\bar{\alpha}_e) \geq j(\alpha_e)$, and using the weak Dodd-Jensen property for the copied tree $(\pi_0, \pi_1)\mathcal{T}$ to show $i(\bar{\alpha}_e) \leq j(\alpha_e)$. (This is where we use the fact that $e_i = \alpha_i$ for all $i \leq n$.)

It follows that $\mathrm{crit}(j) \geq \rho$. For otherwise, letting $\kappa = \mathrm{crit}(j)$, and S be the Σ_1 theory in $\mathcal{M}$ of parameters from $\kappa \cup \{r\}$, then $S \in \mathcal{M}$. But then $j(S) \in \mathcal{Q}$, and from $j(S)$ one can compute the Σ_1 theory in $\mathcal{Q}$ of parameters from $j(\kappa) \cup \{j(r)\}$. (This is like the proof of Lemma 2.23 which we hinted at earlier.) Now $\rho < j(\kappa)$, $\mathcal{P} = \mathcal{Q}$, and $i(\bar{r}) = j(r)$, so this means the Σ_1 theory of $\rho \cup \{i(\bar{r})\}$ is in $\mathcal{P}$. This implies $A \in \mathcal{P}$, a contradiction.

Since i and j have critical point above ρ, $P(\rho)^{\mathcal{H}} = P(\rho)^{\mathcal{P}} = P(\rho)^{\mathcal{Q}} = P(\rho)^{\mathcal{M}}$, as desired. Also, $\mathcal{H} = \mathcal{C}_{k+1}(\mathcal{M})$ agrees with $\mathcal{P}$, hence $\mathcal{Q}$, hence $\mathcal{M}$, below any γ of $\mathcal{M}$-cardinality ρ, as desired. ⊣

One can use fine-structural condensation results such as Theorem 5.1 to show that iterable mice satisfy many of the useful combinatorial principles which Jensen has shown are true in L. For example

5.4 Theorem. *Let $\mathcal{M}$ be an $(\omega, \omega_1, \omega_1 + 1)$-iterable premouse satisfying the axioms of* ZF*, except perhaps Power Set; then the following are true in $\mathcal{M}$:*

1. *for all uncountable regular κ, $\diamondsuit_\kappa$,*
2. *for all uncountable regular κ ($\diamondsuit_\kappa^+ \iff \kappa$ is not ineffable),*
3. *for all infinite cardinals κ, $\square_\kappa$.*

Clause 1 follows immediately from Theorem 5.1 and Jensen's argument for L. Clause 2 is due to Ernest Schimmerling [33]. Clause 3 is work of Schimmerling and Zeman [37], building on the earlier work of Jensen, Solovay, Welch, Wylie, and Schimmerling. (See [10, 48, 49, 33], and [34].)

It follows immediately from Theorem 5.3 that if $\mathcal{M}$ is sufficiently iterable, then $\mathcal{C}_\omega(\mathcal{M})$ exists. We shall use this heavily in the construction of an iterable model, all of whose levels are ω-sound. We turn to that construction now.

6. Background-Certified Fine Extender Sequences

We have been studying mice in the abstract, but we have yet to produce any! In this section we shall describe a certain family of mouse constructions which we call, for obscure reasons, K^c*-constructions*. Such constructions are sufficiently cautious about adding extenders to the model that one gets an iterable model in the end,[32] yet can be sufficiently daring that they can capture the large cardinal strength present in the universe.[33]

6.1. K^c-Constructions

The natural idea is to construct a fine extender sequence $\vec{E}$ by induction. Given $\vec{E}\restriction\alpha$, we set $E_\alpha = \emptyset$ unless there is a certified[34] extender F such that $(\vec{E}\restriction\alpha)^\frown F$ is still a fine extender sequence; if there is such an F we may either set $E_\alpha = F$ or set $E_\alpha = \emptyset$. Here "certified" means roughly that F

[32] This is something between a conjecture and a theorem; see below.
[33] Again, there are qualifications to come.
[34] Whence the "c" in K^c.

is the restriction to $J_\alpha^{\vec{E}\restriction\alpha}$ of a "background extender" F^* which measures a broader collection of subsets of its critical point than does F, and whose ultrapower agrees with V a bit past $\nu(F)$. This background-certificate demand is necessary in order to insure that the premice we are constructing are iterable. Unfortunately, the background certificate demand conflicts with the demand that all levels of the model we are constructing be ω-sound.[35] K^c-constructions deal with this conflict by continually replacing the premouse $\mathcal{N}_\alpha$ currently approximating the model being built by its core $\mathcal{C}_\omega(\mathcal{N}_\alpha)$. Taking cores insures soundness, while the background extenders one can resurrect by going back into the history of the construction insure iterability.

This last claim must be qualified. We do not have a general proof of iterability for the premice $\mathcal{N}_\alpha$ produced in K^c-constructions. At the moment, in order to prove that such a premouse is appropriately iterable, we need to make an additional "smallness" assumption. One assumption that suffices, and which we shall spell out in more detail shortly, is that no initial segment of $\mathcal{N}_\alpha$ satisfies "There is an extender E on my sequence such that $\nu(E)$ is a Woodin cardinal". We shall call this property of $\mathcal{N}_\alpha$ *tameness*. Iterability is essential from the very beginning, for our proof that $\mathcal{C}_\omega(\mathcal{N}_\alpha)$ exists involves comparison arguments, and hence relies on the iterability of $\mathcal{N}_\alpha$. Thus, for all we know, a K^c-construction might simply break down by reaching a non-tame premouse $\mathcal{N}_\alpha$ such that $\mathcal{C}_\omega(\mathcal{N}_\alpha)$ does not exist.

The following definitions describe our background certificate condition. They come from [43, Sect. 1].

6.1 Definition. Let $\mathcal{M}$ be an active premouse, F the extender coded by $\dot{F}^{\mathcal{M}}$ (i.e. its last extender), $\kappa = \mathrm{crit}(F)$, and $\nu = \nu(F)$. Let $\mathcal{A} \subseteq \bigcup_{n<\omega} P([\kappa]^n)^{\mathcal{M}}$; then an *$\mathcal{A}$-certificate for $\mathcal{M}$* is a pair (N, G) such that

1. N is a transitive, power admissible set, $V_\kappa \cup \mathcal{A} \subseteq N$, N is closed under ω-sequences, and G is an extender over N,
2. $F \cap ([\nu]^{<\omega} \times \mathcal{A}) = G \cap ([\nu]^{<\omega} \times \mathcal{A})$,
3. $V_{\nu+1} \subseteq \mathrm{Ult}(N, G)$, and
4. $\forall\gamma(\omega\gamma < \mathrm{On}^{\mathcal{M}} \longrightarrow \mathcal{J}_\gamma^{\mathcal{M}} = \mathcal{J}_\gamma^{i(\mathcal{J}_\kappa^{\mathcal{M}})})$, where $i = i_G^N$ is the canonical embedding from N to $\mathrm{Ult}(N, G)$.

6.2 Definition. Let $\mathcal{M}$ be an active premouse, and κ the critical point of its last extender. We say $\mathcal{M}$ *is countably certified* iff for every countable $\mathcal{A} \subseteq \bigcup_{n<\omega} P([\kappa]^n)^{\mathcal{M}}$, there is an $\mathcal{A}$-certificate for $\mathcal{M}$.

In the situation described in Definition 6.1, we shall typically have $|N| = \kappa$, so that $\mathrm{On}^N < \mathrm{lh}(G)$. We are therefore not thinking of (N, G) as a structure

[35] Part of the requirement on F^* is that it be countably complete, and so $\mathrm{crit}(F^*)$ must be uncountable; on the other hand, if α is least so that $E_\alpha \neq \emptyset$, then $(J_\alpha^{\vec{E}\restriction\alpha}, \in, \vec{E}\restriction\alpha, E_\alpha)$ has Σ_1 projectum ω, so that $\mathrm{crit}(E_\alpha)$ must be countable if this structure is even 1-sound.

to be iterated; N simply provides a reasonably large collection of sets to be measured by G. The conditions $V_\kappa \subseteq N$ and $V_{\nu+1} \subseteq \mathrm{Ult}(N, G)$ are crucial (although the former can be weakened in a useful way; cf. [36, 2.1]). Power admissibility is simply a convenient fragment of ZFC; it can probably be weakened substantially.

6.3 Definition. A K^c*-construction* is a sequence $\langle \mathcal{N}_\alpha \mid \alpha < \theta \rangle$ of premice such that

1. $\mathcal{N}_0 = (V_\omega, \in, \emptyset, \emptyset)$;
2. if $\alpha + 1 < \theta$, then $\mathcal{N}_\alpha$ is ω-solid, and letting $\mathcal{M}$ be the unique ω-sound premouse such that $\mathcal{C}_\omega(\mathcal{N}_\alpha) = \mathcal{C}_\omega(\mathcal{M})$, either
   (a) $\mathcal{M}$ is passive, and $\mathcal{N}_{\alpha+1}$ is a countably certified premouse of the form $(|\mathcal{M}|, \in, \dot{E}^{\mathcal{M}}, F)$, for some F, or
   (b) letting $\omega\gamma = \mathrm{On}^{\mathcal{M}}$ and $\vec{E} = \dot{E}^{\mathcal{M}} \oplus \dot{F}^{\mathcal{M}}$, we have that $\mathcal{N}_{\alpha+1} = (J^{\vec{E}}_{\gamma+1}, \in, \vec{E}, \emptyset)$;
3. if $\lambda < \theta$ is a limit ordinal, then $\mathcal{N}_\lambda$ is the unique passive premouse $\mathcal{P}$ such that for all β, $\omega\beta < \mathrm{On}^{\mathcal{P}}$ iff $\mathcal{J}^{\mathcal{N}_\alpha}_\beta$ is defined and eventually constant as $\alpha \to \lambda$, and for all β such that $\omega\beta < \mathrm{On}^{\mathcal{P}}$, $\mathcal{J}^{\mathcal{P}}_\beta =$ eventual value of $\mathcal{J}^{\mathcal{N}_\alpha}_\beta$, as $\alpha \to \lambda$.

So at successor steps in a K^c-construction one replaces the previous model with its ωth core, and then either adds a countably certified extender to the resulting extender sequence or takes one step in its constructible closure. At limit steps one forms the natural "lim inf" of the previous premice.

Because we replace $\mathcal{N}_\alpha$ by its core at each step in a K^c-construction, the models of the construction may not grow by end-extension, and we need a little argument to show, for example, that a construction of proper class length converges to a premouse of proper class size. Our Theorem 5.3 on the agreement of $\mathcal{N}$ with $\mathcal{C}_\omega(\mathcal{N})$ is the key here.

6.4 Theorem. *Let κ be an uncountable regular cardinal or $\kappa = \mathrm{On}$, and let $\langle \mathcal{N}_\alpha \mid \alpha < \kappa \rangle$ be a K^c-construction; then there is a unique premouse $\mathcal{N}_\kappa$ of ordinal height κ such that $\langle \mathcal{N}_\alpha \mid \alpha \leq \kappa \rangle$ is a K^c-construction.*

Proof. For any limit ordinal κ and K^c-construction $\langle \mathcal{N}_\alpha \mid \alpha < \kappa \rangle$, there is a unique premouse $\mathcal{N}_\kappa$ satisfying the limit ordinal clause of Definition 6.3. We need only show that $\mathcal{N}_\kappa$ has ordinal height κ in the case κ is an uncountable cardinal or $\kappa = \mathrm{On}$. It is clear that $|\mathcal{N}_\alpha| < \kappa$ for all $\alpha < \kappa$, so $\mathcal{N}_\kappa$ has ordinal height $\leq \kappa$.

For $\nu < \kappa$, let

$$\vartheta_\nu = \inf\{\rho_\omega(\mathcal{N}_\alpha) \mid \nu \leq \alpha < \kappa\}.$$

So $\vartheta_0 = \omega$, and the ϑ's are nondecreasing. By Theorem 5.3, $\mathcal{N}_\nu$ agrees with all later $\mathcal{N}_\alpha$ below ϑ_ν, so if $\kappa = \sup(\{\vartheta_\nu \mid \nu < \kappa\})$, we are done. Since κ is regular, the alternative is that the ϑ's are eventually constant; say $\vartheta_\nu = \rho$ for all ν such that $\eta \le \nu < \kappa$. Now notice that if $\eta \le \nu < \kappa$ and $\rho_\omega(\mathcal{N}_\nu) = \rho$, then $\mathcal{C}_\omega(\mathcal{N}_\nu)$ is a proper initial segment of $\mathcal{N}_{\nu+1}$.[36] Moreover, $\mathcal{C}_\omega(\mathcal{N}_\nu)$ has cardinality ρ in $\mathcal{N}_{\nu+1}$ by soundness. It follows from Theorem 5.3 that $\mathcal{C}_\omega(\mathcal{N}_\nu)$ is an initial segment of $\mathcal{N}_\alpha$, for all $\alpha \ge \nu$. Since there are cofinally many $\nu < \kappa$ such that $\rho = \rho_\omega(\mathcal{N}_\nu)$, we again get that $\mathcal{N}_\kappa$ has height κ. ⊣

It is not hard to see that the ϑ_ν defined in the proof above are just the infinite cardinals of $\mathcal{N}_\kappa$.

6.2. The Iterability of K^c

It is clear by now that we have gotten nowhere unless we can prove that the premice we have constructed are sufficiently iterable. Here we encounter the central open problem of inner model theory. We formulate one instance of it as a conjecture:

6.5 Conjecture. Suppose $\mathcal{N}$ is a premouse occurring in a K^c-construction, that $k \le \omega$, and that $\mathcal{M}$ is a countable premouse such that there is a weak k-embedding from $\mathcal{M}$ into $\mathcal{C}_k(\mathcal{N})$; then $\mathcal{M}$ is $(k, \omega_1, \omega_1 + 1)$-iterable.

A proof of this conjecture would yield at once the basics of inner model theory at the level of models with superstrong cardinals.[37] At present we can prove the conjecture only for certain small mice.

In general, iterability proofs break up into an *existence* proof and a *uniqueness* proof for "sufficiently good" branches in iteration trees on the premice under consideration. The existence proof itself breaks into two parts, a direct existence argument in the countable case and a reflection argument in the uncountable case.

The direct existence argument applies to countable iteration trees on countable elementary submodels of the premice under consideration, and proceeds by using something like the countable completeness of the extenders involved in the iteration to transform an ill-behaved iteration into an infinite descending $\in$-chain. When coupled with the uniqueness proof, this shows that any countable elementary submodel of a premouse under consideration has an ω_1-iteration strategy, namely, the strategy of choosing the unique cofinal "sufficiently good" branch.[38]

The reflection argument extends this method of iterating to the uncountable: given an iteration tree $\mathcal{T}$ on $\mathcal{M}$, we go to $V[G]$ where G is $\mathrm{Col}(\omega, \kappa)$-generic over V and κ is large enough that $\mathcal{M}$ and $\mathcal{T}$ have become countable, and find a sufficiently good branch there. This branch is unique, and hence

[36] Assume the last extender predicate of $\mathcal{N}_\nu$ is empty here, as it obviously is for cofinally many such ν.

[37] New problems arise between superstrong and supercompact cardinals.

[38] Of course a sufficiently good branch must be wellfounded, but in general more is required, for we want to be able to find cofinal wellfounded branches later in the iteration game as well.

by the homogeneity of the collapse it is in V. In order to execute this argument one needs a certain level of absoluteness between V and $V[G]$. Once one gets past mice with Woodin cardinals, "sufficiently good" can no longer be taken simply to mean "wellfounded", and in fact "sufficiently good" is no longer a Σ^1_2 notion at all. Because of this, the generic absoluteness required by our reflection argument needs large cardinal/mouse existence principles that go beyond ZFC.[39]

The conjecture above overlaps slightly with the uncountable case because it is (ω_1+1)-iterability, rather than ω_1-iterability, which is at stake. One needs (ω_1+1)-iterability to guarantee the comparability of countable mice; the reflection argument that shows coiterations terminate requires a wellfounded branch of length ω_1. Nevertheless, we believe that the conjecture is provable in ZFC.[40]

At present, the strongest partial results on Conjecture 6.5 are those of [1] and [30], which show that it holds for levels $\mathcal{N}$ of K^c which are of limited complexity, in that they do not have too many extenders overlapping local Woodin cardinals. (Ref. [30] goes further than Conjecture 6.5, to levels with Woodin limits of Woodin cardinals, but it applies only to K^c constructions in which the background extenders measure all sets in V.) In this chapter we shall consider only premice having no extenders overlapping local Woodin cardinals. We call these special premice "tame". We shall outline a proof of Conjecture 6.5 for the tame levels of K^c. Our direct existence argument in the countable case seems perfectly general, but our uniqueness results are less definitive, and it is here that we resort to the tameness assumption. We begin by stating the existence theorem in the countable case.

We say that a branch b of an iteration tree $\mathcal{T}$ is *maximal* iff b has limit order type but is not continued in $\mathcal{T}$. Such a b must be $\in$-cofinal in some $\lambda \leq \mathrm{lh}(\mathcal{T})$, but different from $[0,\lambda]_T$ if $\lambda < \mathrm{lh}(\mathcal{T})$. Notice that any cofinal branch of $\mathcal{T}$ is maximal; the converse fails in general. Finally, a *putative* iteration tree is just like an ordinary iteration tree, except that we allow the last model, if there is one, to be illfounded.

6.6 Theorem (Branch Existence Theorem). *Let $\pi : \mathcal{M} \to \mathcal{C}_k(\mathcal{N}_\alpha)$ be a weak k-embedding, where $\mathcal{M}$ is countable and $\langle \mathcal{N}_\beta \mid \beta < \theta \rangle$ is a K^c-construction. Let $\mathcal{T}$ be a countable, k-maximal, putative iteration tree on $\mathcal{M}$; then either*

1. *There is a maximal branch b of $\mathcal{T}$ such that, letting $l = \deg^{\mathcal{T}}(b)$,*

    (a) *$D^{\mathcal{T}} \cap b = \emptyset$ and $l = k$, and there is a weak l-embedding $\sigma : \mathcal{M}_b^{\mathcal{T}} \to \mathcal{C}_l(\mathcal{N}_\alpha)$ such that*

---

[39] For example, if it is consistent that there is a Woodin cardinal, then it is consistent that there is a premouse $\mathcal{N}$ occurring on a K^c-construction which is not θ-iterable for some θ.

[40] We suspect that if κ is strictly less than the infimum of the critical points of the background extenders, then the κ-iterability of the size κ elementary submodels of premice in a K^c-construction is provable in ZFC.

$$\begin{tikzcd} \mathcal{M} \arrow[r, "\pi"] \arrow[dr, "i_{0,b}"'] & \mathcal{C}_l(\mathcal{N}_\alpha) \\ & \mathcal{M}_b^{\mathcal{T}} \arrow[u, "\sigma"'] \end{tikzcd}$$

commutes, or

(b) $D^{\mathcal{T}} \cap b \neq \emptyset$ *or* $l < k$*, and there is a* $\beta \leq \alpha$ *and weak* l*-embedding* $\sigma : \mathcal{M}_b^{\mathcal{T}} \to \mathcal{C}_l(\mathcal{N}_\beta)$*, with* $\beta < \alpha$ *if* $D^{\mathcal{T}} \cap b \neq \emptyset$*, or*

2. $\mathcal{T}$ *has a last model* $\mathcal{M}_\gamma^{\mathcal{T}}$ *such that, letting* $l = \deg^{\mathcal{T}}(\gamma)$*,*

(a) $D^{\mathcal{T}} \cap [0, \gamma]_T = \emptyset$ *and* $l = k$*, and there is a weak* l*-embedding* $\sigma : \mathcal{M}_\gamma^{\mathcal{T}} \to \mathcal{C}_l(\mathcal{N}_\alpha)$ *such that*

$$\begin{tikzcd} \mathcal{M} \arrow[r, "\pi"] \arrow[dr, "i_{0,\gamma}"'] & \mathcal{C}_l(\mathcal{N}_\alpha) \\ & \mathcal{M}_\gamma^{\mathcal{T}} \arrow[u, "\sigma"'] \end{tikzcd}$$

commutes, or

(b) $D^{\mathcal{T}}[0, \gamma]_T \neq \emptyset$ *or* $l < k$*, and there is a* $\beta \leq \alpha$ *and weak* l*-embedding* $\sigma : \mathcal{M}_b^{\mathcal{T}} \to \mathcal{C}_l(\mathcal{N}_\beta)$*, with* $\beta < \alpha$ *if* $D^{\mathcal{T}} \cap [0, \gamma]_T \neq \emptyset$*.*

We shall not attempt to prove this theorem here. The reader can find a proof in [43, Sects. 2 and 9]. The theorem in the form stated here evolved from earlier results of [18] and [25].

If b is a branch satisfying clause 1 of the conclusion of the Branch Existence Theorem, then we say b (or $\mathcal{M}_b^{\mathcal{T}}$) is π-*realizable*, and call the map σ described in clause 1 a π-*realization* of b (or $\mathcal{M}_b^{\mathcal{T}}$). Similarly, if γ satisfies clause 2 of the conclusion, then we say γ (or $\mathcal{M}_\gamma^{\mathcal{T}}$) is π-realizable, and call the associated map σ a π-realization.

Given $\mathcal{M}$ and π as in the hypotheses of the Branch Existence Theorem, it is natural to attempt to iterate $\mathcal{M}$ using the following strategy: given $\mathcal{T}$ on $\mathcal{M}$ of countable limit length, pick the unique cofinal π-realizable branch of $\mathcal{T}$ with which to continue. Clause 2 in the conclusion of the Branch Existence Theorem guarantees that this strategy cannot break down at any countable successor stage. Clause 1 guarantees that if this strategy breaks down at some countable limit stage, then there are distinct cofinal π-realizable branches at that stage, since the uniqueness of the branches chosen at earlier stages implies that any maximal π-realizable branch of $\mathcal{T}$ must be cofinal. However, if we ever reach a stage at which our tree has distinct cofinal π-realizable branches (this is possible for some $\mathcal{M}$ and π; see [18, Sect. 5]), our troubles start. The best we can do, it seems, is to choose one such branch b and a π-realization σ of $\mathcal{M}_b^{\mathcal{T}}$. If our opponent in the iteration game is kind enough to continue by playing extenders which can be interpreted as forming a tree on $\mathcal{M}_b^{\mathcal{T}}$, then we can choose unique σ-realizable branches to continue, until we get distinct such branches and must pick one, realize it, and continue, etc. However, we are done for if our opponent applies an extender to a model from $\mathcal{T}$ (that is, a model with index $< \sup(b)$). Nothing in the Branch Existence Theorem even guarantees that the associated ultrapower will be wellfounded.[41]

Clearly, we need a uniqueness theorem to accompany our existence theorem. What we can show, roughly speaking, is that at a non-uniqueness stage in the process just described we pass a local Woodin cardinal.

6.7 Definition. Let $\kappa < \delta$ and $A \subseteq V_\delta$; then we say κ is *A-reflecting in δ* iff for all $\nu < \delta$ there is an extender E over V such that $\mathrm{crit}(E) = \kappa$, $i_E(\kappa) > \nu$, and $i_E(A) \cap V_\nu = A \cap V_\nu$.

6.8 Definition. A cardinal δ is a *Woodin cardinal* iff for all $A \subseteq \delta$ there is a $\kappa < \delta$ which is A-reflecting in δ.

It is perhaps no surprise to the reader that Woodin cardinals were discovered by Woodin. Woodin was inspired by the results of [9], and by earlier work of Saharon Shelah reducing the large cardinal hypotheses employed in [9]. The definition of Woodinness given above is different from Woodin's original one, but equivalent to it by an argument essentially due to Mitchell. (See [21, Theorem 4.1].) Mitchell's argument can also be used to show that if δ is Woodin, then δ is witnessed to be Woodin by extenders in V_δ.[42] It follows that the Woodinness of δ can be expressed by a Π_1 sentence about $(V_{\delta+1}, \in)$, so that the least Woodin cardinal is not weakly compact. It is easy to see that all Woodin cardinals are Mahlo.

The (local) Woodin cardinal we get from an iteration tree $\mathcal{T}$ having distinct good branches is the supremum of the lengths of the extenders used in $\mathcal{T}$.

6.9 Definition. Let $\mathcal{T}$ be a k-maximal iteration tree on $\mathcal{M}$ such that $\mathrm{lh}(\mathcal{T})$ is a limit ordinal; then we set

$$\delta(\mathcal{T}) = \sup\{\mathrm{lh}(E_\alpha^{\mathcal{T}}) \mid \alpha < \mathrm{lh}(\mathcal{T})\},$$

and

$$\begin{aligned}\mathcal{M}(\mathcal{T}) = {} & \text{unique passive } \mathcal{P} \text{ such that } \mathrm{On}^{\mathcal{P}} = \delta(\mathcal{T}) \text{ and} \\ & \forall \alpha < \delta(\mathcal{T})(\mathcal{M}(\mathcal{T}) \text{ agrees with } \mathcal{M}_\alpha^{\mathcal{T}} \text{ below } \mathrm{lh}(E_\alpha^{\mathcal{T}})).\end{aligned}$$

It is clear that if b is a cofinal branch of $\mathcal{T}$ such that $\delta(\mathcal{T}) \in \mathcal{M}_b^{\mathcal{T}}$, then $\delta(\mathcal{T})$ is a limit cardinal of $\mathcal{M}_b^{\mathcal{T}}$.

The main result connecting Woodin cardinals with the uniqueness of cofinal wellfounded branches in iteration trees is the following theorem of [18].

[41] We have described here how the Branch Existence Theorem yields a winning strategy for II in a game that requires less of him, the *weak iteration game.* We shall introduce this game formally in the next section.

[42] This observation is due to Woodin.

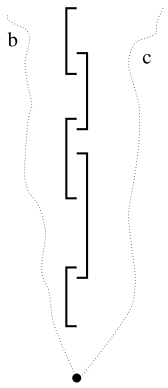


Figure 19.1: The overlapping pattern of two distinct wellfounded branches

6.10 Theorem (Branch Uniqueness Theorem). *Let b and c be distinct cofinal branches of the k-maximal iteration tree $\mathcal{T}$, let $\delta = \delta(\mathcal{T})$, and suppose that $A \subseteq \delta$ is such that $\delta, A \in \mathrm{wfp}(\mathcal{M}_b^{\mathcal{T}}) \cap \mathrm{wfp}(\mathcal{M}_c^{\mathcal{T}})$; then*

$$\mathcal{M}_b^{\mathcal{T}} \models \exists\kappa < \delta(\kappa \textit{ is } A\textit{-reflecting in } \delta).$$

Sketch of Proof. The extenders used on b and c have an overlapping pattern pictured in Fig. 19.1:

To see this, pick any successor ordinal

$$\alpha_0 + 1 \in b \setminus c,$$

and then let

$$\beta_n + 1 = \min\{\gamma \in c : \gamma > \alpha_n + 1\}$$

and

$$\alpha_{n+1} + 1 = \min\{\eta \in b : \eta > \beta_n + 1\},$$

for all $n < \omega$. Now for any n, the T-predecessor of β_n+1 is on c and $\leq \alpha_n+1$, hence $\leq \alpha_n$, so by the rules of the iteration game

$$\mathrm{crit}(F_{\beta_n}) < \nu(F_{\alpha_n}).$$

Similarly, for any n

$$\mathrm{crit}(F_{\alpha_{n+1}}) < \nu(F_{\beta_n}).$$

Now extenders used along the same branch of an iteration tree do not overlap (i.e., if E is used before F, then $\nu(E) \leq \mathrm{crit}(F)$), so we have

$$\begin{aligned}\mathrm{crit}(F_{\beta_n}) < \nu(F_{\alpha_n}) \leq \mathrm{crit}(F_{\alpha_{n+1}}) < \nu(F_{\beta_n})\\ \leq \mathrm{crit}(F_{\beta_{n+1}}) < \nu(F_{\alpha_{n+1}}) \leq \mathrm{crit}(F_{\alpha_{n+2}}),\end{aligned}$$

which is the overlapping pattern pictured.

Now $\sup(\{\alpha_n : n < \omega\}) = \sup(\{\beta_n : n < \omega\})$, and since branches of iteration trees are closed below their suprema in the order topology on On, the common supremum of the α_n and β_n is λ. Let us assume α_0 was chosen large enough that letting

$$\xi = \mathrm{pred}_T(\beta_0 + 1) \quad \text{and} \quad \eta = \mathrm{pred}_T(\alpha_1 + 1),$$

we have

$$A = i_{\xi,c}(A^*) = i_{\eta,b}(A^{**})$$

for some A^* and A^{**}. Let

$$\kappa = \mathrm{crit}(F_{\beta_0}) = \mathrm{crit}(i_{\xi,c});$$

we shall show that κ is A-reflecting in δ in the model $\mathcal{M}_b$.

Let $E_0 = F_{\beta_0} \restriction \mathrm{crit}(F_{\alpha_1})$. Because of the overlapping pattern, E_0 is a proper initial segment of F_{β_0}, and by initial segment condition on premice and the agreement of the models of an iteration tree, $E_0 \in \mathcal{M}_b$. Moreover, if $j : \mathcal{M}_b \to \mathrm{Ult}(\mathcal{M}_b, E_0)$ is the canonical embedding, then because A and A^* agree below κ, $j(A)$ and $i_{\xi,c}(A^*)$ agree below $\mathrm{crit}(F_{\alpha_1})$. That is, $j(A)$ agrees with A below $\mathrm{crit}(F_{\alpha_1})$, and hence E_0 witnesses that κ is A-reflecting up to $\mathrm{crit}(F_{\alpha_1})$ in $\mathcal{M}_b$.

To get A-reflection all the way up to δ, we set

$$E_{2n} = F_{\beta_n} \restriction \mathrm{crit}(F_{\alpha_{n+1}}) \quad \text{and} \quad E_{2n+1} = F_{\alpha_{n+1}} \restriction \mathrm{crit}(F_{\beta_{n+1}}),$$

for all n. Each of the E_n is in $\mathcal{M}_b$ for the same reason E_0 is in $\mathcal{M}_b$. Therefore the extender E which represents the embedding coming from "composing" the ultrapowers by the E_i for $0 \le i \le 2n$, is in $\mathcal{M}_b$. The argument above generalizes easily to show that E witnesses that κ is A-reflecting up to $\mathrm{crit}(F_{\alpha_{n+1}})$. Since $\mathrm{crit}(F_{\alpha_{n+1}}) \to \delta$ as $n \to \omega$, κ is A-reflecting in δ in the model $\mathcal{M}_b$. $\dashv$

We shall need a fine-structural refinement of Theorem 6.10. For this, we have to look closely at the first level of $\mathcal{M}_b^{\mathcal{T}}$ at which $\delta(\mathcal{T})$ is seen not to be Woodin, if there is one.

6.11 Definition. Let $\mathcal{T}$ be a k-maximal iteration tree on $\mathcal{M}$ of limit length, and let b be a cofinal wellfounded branch of $\mathcal{T}$. Let γ be the least ordinal, if there is one, such that either

$$\omega\gamma < \mathrm{On}^{\mathcal{M}_b} \quad \text{and} \quad \mathcal{J}_{\gamma+1}^{\mathcal{M}_b} \models \delta(\mathcal{T}) \text{ is not Woodin},$$

or

$$\omega\gamma = \mathrm{On}^{\mathcal{M}_b} \quad \text{and} \quad \rho_{n+1}(\mathcal{J}_\gamma^{\mathcal{M}_b}) < \delta(\mathcal{T})$$

for some $n < \omega$ such that $n + 1 \le k$ if $D^{\mathcal{T}} \cap b = \emptyset$. We set

$$\mathcal{Q}(b, \mathcal{T}) := \mathcal{J}_\gamma^{\mathcal{M}_b}$$

if there is such a γ, and let $\mathcal{Q}(b, \mathcal{T})$ be undefined otherwise.

Notice that if $\mathcal{Q}(b,\mathcal{T})$ exists and $\delta(\mathcal{T}) \in \mathcal{Q}(b,\mathcal{T})$, then $\mathcal{Q}(b,\mathcal{T})$ is just the longest initial segment $\mathcal{Q}$ of $\mathcal{M}_b^{\mathcal{T}}$ such that $\mathcal{Q} \models \delta(\mathcal{T})$ is Woodin. There is a failure of $\delta(\mathcal{T})$ to be Woodin definable over $\mathcal{Q}(b,\mathcal{T})$.[43] Notice also that if b drops in either model or degree, then $\rho_n(\mathcal{M}_b^{\mathcal{T}}) < \delta(\mathcal{T})$ for some appropriate n, and therefore $\mathcal{Q}(b,\mathcal{T})$ exists.[44]

Suppose that $\mathcal{Q}(b,\mathcal{T}) = \mathcal{Q}(c,\mathcal{T})$ (so both exist), and $\mathcal{Q}(b,\mathcal{T})$ is a proper initial segment of $\mathcal{M}_b^{\mathcal{T}}$ and $\mathcal{M}_c^{\mathcal{T}}$. Since $\mathcal{Q}(b,\mathcal{T})$ codes up a failure of Woodinness, Theorem 6.10 implies $b = c$. The following is a fine-structural strengthening of this fact.

6.12 Theorem. *Let $\mathcal{T}$ be k-maximal, and let b and c be distinct cofinal wellfounded branches of $\mathcal{T}$ such that $\mathcal{Q}(b,\mathcal{T})$ and $\mathcal{Q}(c,\mathcal{T})$ exist; then neither is an initial segment of the other.*

Proof. If one is an initial segment of the other, then since they are minimal with respect to the same first-order property, $\mathcal{Q}(b,\mathcal{T}) = \mathcal{Q}(c,\mathcal{T})$. Since this property involves a failure of $\delta(\mathcal{T})$ to be Woodin, $\mathcal{Q}(b,\mathcal{T}) \notin \mathcal{M}_b$ and $\mathcal{Q}(c,\mathcal{T}) \notin \mathcal{M}_c$ by Theorem 6.10. Thus $\mathcal{M}_b = \mathcal{Q}(b,\mathcal{T}) = \mathcal{Q}(c,\mathcal{T}) = \mathcal{M}_c$.

It follows that $\mathcal{Q}(b,\mathcal{T})$ and $\mathcal{Q}(c,\mathcal{T})$ are defined by the second clause of Definition 6.11. If we let n be least such that $\rho_{n+1}(\mathcal{M}_b) < \delta(\mathcal{T})$, then there are $\eta \in b$ and $\xi \in c$ such that

$$\mathcal{M}_\eta^* = \mathcal{C}_{n+1}(\mathcal{M}_b) = \mathcal{C}_{n+1}(\mathcal{M}_c) = \mathcal{M}_\xi^*,$$

and $i_{\eta,b} \circ i_\eta^*$ and $i_{\xi,c} \circ i_\xi^*$ exist, and are n-embeddings with critical point at least $\rho_{n+1}(\mathcal{M}_\eta^*)$. But then, as in the fine structure argument at the end of the proof of the Comparison Lemma 3.11,

$$i_{\eta,b} \circ i_\eta^* = i_{\xi,c} \circ i_\xi^*,$$

since each is the core embedding from $\mathcal{C}_{n+1}(\mathcal{M}_b) = \mathcal{C}_{n+1}(\mathcal{M}_c)$ to $\mathcal{M}_b = \mathcal{M}_c$. Thus the extender applied to $\mathcal{M}_\eta^*$ in b is compatible with the extender applied to $\mathcal{M}_\xi^*$ in c, so that $\eta = \xi$.

Let α be the largest ordinal in $b \cap c$, so that $\alpha > \eta$ by the argument above. As usual, let us assume $n = 0$ to simplify matters a bit; the general case is essentially the same. Letting $\nu = \sup\{\nu(E_\beta) \mid \beta \, T \, \alpha\}$, we then have

$$\mathcal{M}_\alpha = \{i_{\eta,\alpha} \circ i_\eta^*(f)(a) \mid f \in \mathcal{M}_\eta^* \text{ and } a \in [\nu]^{<\omega}\}.$$

Since $i_{\alpha,b}$ and $i_{\alpha,c}$ are the identity on ν and agree on the range of $i_{\eta,\alpha} \circ i_\eta^*$, we have $i_{\alpha,b} = i_{\alpha,c}$. But this means the extender applied to $\mathcal{M}_\alpha$ in b is compatible with the extender applied to $\mathcal{M}_\alpha$ in c, so that α is not the largest element of $b \cap c$, a contradiction. $\dashv$

[43] The case $\rho_{n+1}(\mathcal{Q}(b,\mathcal{T})) < \delta(\mathcal{T})$ represents a failure of $\delta(\mathcal{T})$ to be a cardinal at all.

[44] Because $\mathcal{T}$ is maximal, b only drops when some extender used on b has critical point at least a projectum of the model to which it is applied. At the last drop, this projectum is preserved as a projectum of $\mathcal{M}_b^{\mathcal{T}}$.

6.13 Definition. We say η is a *cutpoint* of $\mathcal{M}$ iff for all extenders E on the $\mathcal{M}$-sequence, if $\text{crit}(E) < \eta$ then $\text{lh}(E) < \eta$.

6.14 Corollary. *Let $\mathcal{T}$ be k-maximal; then there is at most one cofinal, wellfounded branch b of $\mathcal{T}$ such that*

1. *$\mathcal{Q}(b, \mathcal{T})$ exists,*
2. *$\delta(\mathcal{T})$ is a cutpoint of $\mathcal{Q}(b, \mathcal{T})$, and*
3. *$\mathcal{Q}(b, \mathcal{T})$ is $\delta(\mathcal{T})^+ + 1$-iterable.*

Proof. Suppose that b and c are distinct such branches. $\mathcal{Q}(b, \mathcal{T})$ and $\mathcal{Q}(c, \mathcal{T})$ have cardinality $\delta(\mathcal{T})$, so they are sufficiently iterable that their coiteration terminates successfully. Since $\delta(\mathcal{T})$ is a cutpoint of each model, and the two models agree below $\delta(\mathcal{T})$, all extenders used in this coiteration have critical point above $\delta(\mathcal{T})$. Also, each model is $\delta(\mathcal{T})$-sound and projects to $\delta(\mathcal{T})$, in the sense that there is an $n < \omega$ such that $\rho_{n+1}(\mathcal{Q}(b, \mathcal{T})) \leq \delta(\mathcal{T})$ and $\mathcal{Q}(b, \mathcal{T}) = \mathcal{H}_{n+1}^{\mathcal{Q}(b,\mathcal{T})}(\delta(\mathcal{T}) \cup \{p_{n+1}(\mathcal{Q}(b, \mathcal{T}))\})$, and similarly for $\mathcal{Q}(c, \mathcal{T})$. Just as in the proof of Corollary 3.12, this means that the side which comes out shorter does not move at all in the comparison, so that $\mathcal{Q}(b, \mathcal{T})$ is an initial segment of $\mathcal{Q}(c, \mathcal{T})$ or vice-versa. This contradicts Theorem 6.12. ⊣

Notice that all we needed in this argument was that $\mathcal{Q}(b, \mathcal{T})$ and $\mathcal{Q}(c, \mathcal{T})$ be iterable enough that we can compare them successfully. We can think of the structure $\mathcal{Q}(b, \mathcal{T})$ as a *branch oracle*, in that the fact that it is sufficiently iterable to be compared with other $\mathcal{Q}$-structures identifies b as the good branch of $\mathcal{T}$, the one any iteration strategy ought to choose. The sufficient-iterability-for-comparison of $\mathcal{Q}(b, \mathcal{T})$ only identifies b as the good branch, however, when $\delta(\mathcal{T})$ is a cutpoint of $\mathcal{Q}(b, \mathcal{T})$. This leads us to restrict our attention to mice all of whose Woodin cardinals are cutpoints.

6.15 Definition. A premouse $\mathcal{M}$ is *tame* iff whenever E is an extender on the $\mathcal{M}$-sequence, and $\lambda = \text{lh}(E)$, then

$$\mathcal{J}_\lambda^{\mathcal{M}} \models \forall \delta \geq \text{crit}(E)(\delta \text{ is not Woodin}).$$

In other words, tame mice cannot have extenders overlapping local Woodin cardinals. It is clear from the definition that any initial segment of a tame mouse is tame. Tame mice can satisfy large cardinal hypotheses as strong as "There is a strong cardinal which is a limit of Woodin cardinals". No tame mouse can satisfy "There is a Woodin cardinal which is a limit of Woodin cardinals".

The iterability conjecture above becomes a theorem when it is restricted to tame premice.

6.16 Theorem. *Let $\mathcal{N}$ be a tame premouse occurring on a K^c-construction, let $k \leq \omega$, and let $\mathcal{M}$ be countable and such that there is a weak k-embedding from $\mathcal{M}$ to $\mathcal{C}_k(\mathcal{N})$; then $\mathcal{M}$ is $(k, \omega_1, \omega_1 + 1)$-iterable.*

We shall not prove this theorem here, but in the next section we shall prove a fairly representative special case of it.

6.3. Large Cardinals in K^c

The iterability conjectures and theorems above show that K^c-constructions are sufficiently conservative about putting extenders on their sequences. We need also to know that they can be sufficiently liberal.

6.17 Definition. A K^c-construction $\langle \mathcal{N}_\alpha \mid \alpha < \theta \rangle$ is *maximal* iff $\mathcal{N}_{\alpha+1}$ is defined by case (2)(a) of Definition 6.3 whenever possible; that is, a new extender is added to the current sequence whenever there is one meeting all the requirements of (2)(a) in Definition 6.3.

One evidence of liberality is that large cardinal hypotheses true in V must also hold in K^c. Here is one such theorem.

6.18 Theorem. *Let δ be Woodin; then either*

1. *there is a maximal K^c-construction $\langle \mathcal{N}_\alpha \mid \alpha < \theta + 1 \rangle$ such that $\mathcal{N}_\theta$ is not tame, or*

2. *there is a maximal K^c-construction of length* $\mathrm{On} + 1$*, and for any such construction $\langle \mathcal{N}_\alpha \mid \alpha \leq \mathrm{On} \rangle$,*

$$\mathcal{N}_{\mathrm{On}} \models \delta \textit{ is Woodin.}$$

Sketch of Proof. If no maximal K^c-construction ever reaches a non-tame premouse, then by Theorems 6.16 and 5.3, every premouse occurring in a K^c-construction is ω-solid, and hence there are maximal K^c-constructions of length $\mathrm{On} + 1$.

Let $\langle \mathcal{N}_\alpha \mid \alpha \leq \mathrm{On} \rangle$ be such a construction, and let $\mathcal{N}_{\mathrm{On}} = (L[\vec{E}], \in, \vec{E})$. Let $A \subseteq \delta$ and $A \in L[\vec{E}]$; we must find a $\kappa < \delta$ which is satisfied by $L[\vec{E}]$ to be A-reflecting in δ.

Since δ is Woodin in V, we can find a $\kappa < \delta$ which is $(A, \vec{E} \restriction \delta)$-reflecting in δ. Now if F is an extender over V which witnesses this reflection up to η, where $\kappa < \eta < \delta$ and η is, say, inaccessible, then we can show that for any $\xi < \eta$,

$$G_\xi := F \restriction \xi \cap L[\vec{E}] \in L[\vec{E}].$$

This is enough, for the extenders G_ξ to witness that κ is A-reflecting in δ up to ξ in $L[\vec{E}]$.

To show that $G_\xi \in L[\vec{E}]$, we show by induction on ξ that if G_ξ is not of type Z, then the trivial completion of G_ξ is either on the sequence $\vec{E}$ or on an ultrapower of it, as in the initial segment condition in the definition of fine extender sequences. It is easy to see that G_ξ satisfies the requirements for being added to $\vec{E}$: coherence comes from the fact that F witnesses $\vec{E}\restriction\delta$-reflection,[45] the initial segment condition comes from our induction hypothesis, and F provides the necessary background certificates. However, there are some problems. First, there is a *timing* problem: the above shows that G_ξ could be added to the $L[\vec{E}]$ sequence somewhere, but we need to find an actual stage $\mathcal{N}_\alpha$ of the construction at which it can be added. Second, there is a *uniqueness of the next extender* problem: we need to conclude from the fact that G_ξ could be added to produce $\mathcal{N}_\alpha + 1$ that it *was* added to produce $\mathcal{N}_\alpha + 1$. For these arguments, we refer the reader to [25, Theorem 11.4]. $\dashv$

We note that the proof of Theorem 6.18 would have gone through if we had been even more conservative and required in Definition 6.3 that our background extenders measure all sets in V. This requirement simplifies the iterability proof for the resulting model, as it allows us to lift trees on it to trees on V.[46] It is important in some contexts, however, to allow partial background extenders. For example, in proving relative consistency results in which the theory assumed consistent does not imply the existence of measurable cardinals, we must construct core models satisfying large cardinal hypotheses without assuming there are any extenders which are total over V. What assures us that maximal K^c-constructions are sufficiently liberal in that situation is the following.

6.19 Theorem. *Suppose that μ is a normal measure on the measurable cardinal Ω, and that no K^c-construction reaches a non-tame premouse. Let $\langle \mathcal{N}_\alpha \mid \alpha \leq \Omega\rangle$ be a maximal K^c-construction; then for μ-almost every $\alpha < \Omega$, $(\alpha^+)^{\mathcal{N}_\Omega} = \alpha^+$.*

This is essentially Theorem 1.4 of [43]. That is in turn an extension of earlier work of Jensen and Mitchell which in effect proved Theorem 6.19 under the hypothesis that no K^c-construction reaches the sharp for an inner model with a strong cardinal. Jensen and Mitchell did not require the measurable cardinal. Jensen and the author have recently proved in ZFC a version of Theorem 6.19 under the hypothesis that there is no proper class model with a Woodin cardinal, and used it to develop core model theory up to a Woodin cardinal in ZFC. See [32].

Our focus for the rest of this chapter will be on applications of core model theory in descriptive set theory, and so for simplicity we shall generally assume that there are Woodin cardinals in V. Therefore it will be Theorem 6.18 rather than Theorem 6.19 which is important for us. The reader should

[45] This is not actually as obvious as it might seem at first, because the G_ξ ultrapower of $L[\vec{E}]$ only obviously agrees with the F ultrapower (and hence $L[\vec{E}]$) out to $\nu(G_\xi)$, rather than to the successor of $\nu(G_\xi)$ in the G_ξ ultrapower, as required by coherence. The stronger agreement can be proved using the Condensation Theorem 5.1, applied to the natural embedding of the G_ξ ultrapower into the F ultrapower.

[46] This is the iterability proof given in [25, Sect. 12]. Of course, it only applies to tame mice; that is, it only proves a version of Theorem 6.16.

see [15] for an introductory article which turns at this point toward relative consistency results, results which make use of Theorem 6.19 rather than Theorem 6.18. See also [32] for a much more thorough survey of this area.

7. The Reals of M_ω

We shall show that the reals in the minimal iterable proper class model satisfying "There are ω Woodin cardinals" are precisely those reals which are ordinal definable over $L(\mathbb{R})$. Of course, in order to do this we must assume that there is such a model. It will simplify matters if we assume something a bit stronger, namely, that there are ω Woodin cardinals with a measurable cardinal above them all (in V). We shall do so throughout the rest of this chapter, sometimes without explicitly mentioning the assumption. One useful consequence of our assumption is $\mathsf{AD}^{L(\mathbb{R})}$, the axiom of determinacy restricted to sets of reals in $L(\mathbb{R})$.[47]

7.1 Definition. A premouse $\mathcal{M}$ is *ω-small* iff whenever κ is the critical point of an extender on the $\mathcal{M}$-sequence, then

$$\mathcal{J}_\kappa^{\mathcal{M}} \not\models \text{There are } \omega \text{ Woodin cardinals.}$$

An ω-small mouse can satisfy "There are ω Woodin cardinals", but it cannot satisfy any significantly stronger large cardinal hypotheses.

7.2 Theorem. *If there are ω Woodin cardinals with a measurable cardinal above them all, then there is a $(\omega, \omega_1, \omega_1 + 1)$-iterable premouse which is not ω-small.*

Sketch of Proof. If a K^c construction reaches a nontame premouse, then it reaches a nontame premouse that is not ω-small, and we can apply Theorem 6.16. So, we may assume our maximal K^c construction reaches only tame mice. Let $j : V \to M$ witness the measurability of some κ below which there are ω Woodin cardinals. By Theorem 6.18, the Woodin cardinals of M are Woodin in $j(K^c)$, and hence there are ω Woodin cardinals of $j(K^c)$ below κ. Now for any $A \subseteq V_{\kappa+1}$ of cardinality κ, the fragment $E_j \cap (A \times [j(\kappa)]^{<\omega})$ of the extender determined by j is in M. These fragments provide sufficient background certificates to show that there is an extender on the K^c sequence whose critical point is above all the Woodin cardinals of $j(K^c)$ which are below κ. Thus our maximal K^c-construction reaches an $\mathcal{N}_\alpha$ which is not ω-small. By Theorem 6.16, any countable elementary submodel of $\mathcal{C}_\omega(\mathcal{N}_\alpha)$ witnesses the truth of the theorem. ⊣

7.3 Definition. $M_\omega^\#$ is the unique sound, $(\omega, \omega_1, \omega_1+1)$-iterable mouse which is not ω-small, but all of whose proper initial segments are ω-small.

[47] This is a result of Woodin, building on the work of [9] and [17]. See [28] for a proof.

It is easy to see that $\rho_1(M_\omega^\#) = \omega$, so that $M_\omega^\#$ is countable, and in fact every $x \in M_\omega^\#$ is Σ_1-definable over $M_\omega^\#$.[48] The uniqueness of $M_\omega^\#$ follows from Corollary 3.12. It is also clear that $M_\omega^\#$ is active; that is, it has a nonempty last extender predicate. We let M_ω be the proper class model left behind when the last extender of $M_\omega^\#$ is iterated out of the universe.

7.4 Definition. $M_\omega = \mathcal{J}^{\mathcal{P}}_{\mathrm{On}}$, where $\mathcal{P}$ is the Onth iterate of $M_\omega^\#$ by the last extender on its sequence.

It is clear that M_ω is an ω-small proper class model with ω Woodin cardinals, and that the Woodin cardinals of M_ω are countable in V. Their supremum is the supremum of the lengths of the extenders on the M_ω-sequence. The iterability of $M_\omega^\#$ easily implies that M_ω is $(\omega, \omega_1, \omega_1 + 1)$-iterable.

We shall show that the reals of M_ω are precisely the reals which are ordinal definable in $L(\mathbb{R})$.[49] We begin by showing that every real in M_ω is $\mathrm{OD}^{L(\mathbb{R})}$. Following the proof of Corollary 3.14, we see that for this it is enough to show that if $\alpha = \omega_1^{M_\omega}$, then $L(\mathbb{R})$ satisfies "$\mathcal{J}_\alpha^{\mathcal{M}_\omega}$ is $(\omega_1 + 1)$-iterable".[50]

7.1. Iteration Strategies in $L(\mathbb{R})$

Our task is complicated by the fact that M_ω is not itself $(\omega, \omega_1 + 1)$-iterable in $L(\mathbb{R})$, as we shall show later. We must drop to slightly smaller mice in order to find iteration strategies in $L(\mathbb{R})$.

7.5 Definition. A premouse $\mathcal{P}$ is *properly small* iff

1. $\mathcal{P}$ is ω-small,
2. $\mathcal{P} \models$ There are no Woodin cardinals, and
3. $\mathcal{P} \models$ There is a largest cardinal + ZF^-.

Here ZF^- is ZF without the Power Set Axiom. It is clear that if α is a successor cardinal of M_ω below its least Woodin cardinal, then $\mathcal{J}_\alpha^{M_\omega}$ is properly small. In particular, this is true when $\alpha = \omega_1^{M_\omega}$.

7.6 Lemma. *Let $\mathcal{T}$ be an ω-maximal iteration tree of limit length on a properly small premouse, and let b be a cofinal wellfounded branch of $\mathcal{T}$; then $\mathcal{Q}(b, \mathcal{T})$ exists.*

[48] Suppose that $\mathcal{M}$ is sufficiently iterable, not ω-small, and has only ω-small proper initial segments. The Σ_1 hull $\mathcal{H} := \mathcal{H}_1^{\mathcal{M}}(\emptyset)$ of $\mathcal{M}$ is sufficiently iterable that it can be compared with $\mathcal{J}_\alpha^{\mathcal{M}}$, for any $\alpha < \omega_1^{\mathcal{M}}$. Since $\mathcal{J}_\alpha^{\mathcal{M}}$ is ω-small, $\mathcal{H}$ must iterate past it, and it follows that for $\gamma = \omega_1^{\mathcal{M}}$, $\mathcal{J}_\gamma^{\mathcal{M}}$ is an initial segment of $\mathcal{H}$. Since we can easily compute a counting of $\mathcal{J}_\gamma^{\mathcal{H}}$ from the Σ_1 theory of $\mathcal{M}$, this theory is not a member of $\mathcal{M}$. Thus if $\mathcal{M}$ is 1-sound, $\mathcal{M} = \mathcal{H}$.

[49] Of course, M_ω and $M_\omega^\#$ have the same reals as members. $M_\omega^\#$ *is* (coded by) the simplest canonical real which is not $\mathrm{OD}^{L(\mathbb{R})}$; it is definable over $L(\mathbb{R} \cup \{\mathbb{R}^\#\})$ in a simple way.

[50] We are regarding this as a statement about the *parameter* $\mathcal{J}_\alpha^{M_\omega}$, which is in $L(\mathbb{R})$ because it is hereditarily countable. $L(\mathbb{R})$ need not believe that $\mathcal{J}_\alpha^{M_\omega}$ is obtained by implementing the definition of M_ω we gave in V.

Proof. We have already observed that if b drops in model or degree, then $\rho_{n+1}(\mathcal{M}_b) < \delta(\mathcal{T})$ for some n, so that $\mathcal{Q}(b, \mathcal{T})$ exists. Let $\mathcal{M} = \mathcal{M}_0^{\mathcal{T}}$. The requirement that $\mathcal{M}$ satisfy ZF^- insures that $\rho_\omega(\mathcal{M}) = \mathrm{On}^{\mathcal{M}}$, so that any iteration map along a non-dropping branch of an ω-maximal tree on $\mathcal{M}$ is fully elementary. The requirement that there are no Woodin cardinals in $\mathcal{M}$ then implies that there are none in $\mathcal{M}_b$, so that if $\delta(\mathcal{T}) < \mathrm{On}^{\mathcal{M}_b}$ then $\mathcal{Q}(b, \mathcal{T})$ exists. But we must have $\delta(\mathcal{T}) < \mathrm{On}^{\mathcal{M}_b}$, since if $\delta(\mathcal{T}) = \mathrm{On}^{\mathcal{M}_b}$, then as $\mathrm{lh}(E_\alpha^{\mathcal{T}})$ is a cardinal of $\mathcal{M}_b$ for all $\alpha < \mathrm{lh}(\mathcal{T})$, there is no largest cardinal of $\mathcal{M}_b$. $\dashv$

This lemma will, together with Theorem 6.12, guarantee that there is at most one iteration strategy for a properly small $\mathcal{M}$, and ultimately the $L(\mathbb{R})$-definability of this strategy when it exists.

It is useful to introduce yet another iteration game, one which requires less of player II than $\mathcal{G}_k(\mathcal{M}, \lambda, \theta)$. We call this new game the *weak iteration game*. Suppose that $\mathcal{M}$ is a k-sound premouse; then the weak iteration game $\mathcal{W}_k(\mathcal{M}, \omega)$ is played in ω rounds as follows:

$$\begin{array}{c|cccccccc}
I & \mathcal{T}_0 & & \mathcal{P}_1, i_1, \mathcal{T}_1 & & \mathcal{P}_2, i_2, \mathcal{T}_2 & & \dots & \\
\hline
II & & b_0 & & b_1 & & b_2 & & \dots
\end{array}$$

Here I begins by playing a countable, k-maximal, putative iteration tree $\mathcal{T}_0$ on $\mathcal{M}$, after which II plays b_0, which may be either "accept" or a maximal wellfounded branch of $\mathcal{T}_0$, with the proviso that II cannot accept unless $\mathcal{T}_0$ has a last model, and this model is wellfounded. Let $\mathcal{Q}_1$ be this last model, if II accepts, and let $\mathcal{Q}_1 = \mathcal{M}_{b_0}^{\mathcal{T}_0}$ otherwise. Let k_1 be the degree of $\mathcal{Q}_1$. Play now goes into the next round as it did in $\mathcal{G}_k(\mathcal{M}, \lambda, \theta)$: I picks an initial segment $\mathcal{P}_1$ of $\mathcal{Q}_1$, and an $i_1 \leq \omega$ such that $i_1 \leq k_1$ if $\mathcal{P}_1 = \mathcal{Q}_1$, together with a countable, i_1-maximal, putative iteration tree on $\mathcal{P}_1$. Then II either accepts or plays a maximal wellfounded branch of $\mathcal{T}_1$, with the proviso that he can only accept if $\mathcal{T}_1$ has a last, wellfounded model. Etc.

If no one breaks any of these rules along the way, then we say II wins this run of $\mathcal{W}_k(\mathcal{M}, \omega)$ iff for all sufficiently large i, $\mathcal{P}_i = \mathcal{Q}_i$, the branch of $\mathcal{T}_i$ from $\mathcal{P}_i$ to $\mathcal{Q}_{i+1}$ does not drop, and the direct limit of the $\mathcal{P}_i$ under the iteration maps given by the $\mathcal{T}_i$ is wellfounded.

7.7 Definition. A *weak (k, ω)-iteration strategy* for $\mathcal{M}$ is a winning strategy for II in $\mathcal{W}_k(\mathcal{M}, \omega)$, and we say $\mathcal{M}$ is *weakly (k, ω)-iterable* (or $\Game^{\mathbb{R}}\Pi_1^1$*-iterable*) just in case there is such a strategy.

It is an immediate consequence of the Branch Existence Theorem 6.6 that every countable elementary submodel $\mathcal{M}$ of $\mathcal{C}_k(\mathcal{N}_\alpha)$, where $\mathcal{N}_\alpha$ occurs in a K^c-construction, is weakly (k, ω)-iterable. In fact, such mice are weakly (k, ω_1)-iterable, in the obvious sense.[51] Weak (k, ω_1)-iteration strategies suf-

[51] In $\mathcal{W}_k(\mathcal{M}, \omega_1)$, player I must play at limit $\lambda < \omega_1$ a tree $\mathcal{T}_\lambda$ on the direct limit of the models $\mathcal{P}_\eta$ for $\eta < \lambda$. Player II must insure that this direct limit is wellfounded.

fice for the comparison of tame mice, and this fact is what lies behind our iterability Theorem 6.16 for tame mice.[52]

If $\mathcal{M}$ is countable, and coded by the real x, then the weak iteration game $\mathcal{W}_k(\mathcal{M}, \omega)$ is (can be coded as) a game of length ω on $\mathbb{R}$ with $\Pi^1_1(x)$ payoff. Thus the set of reals coding weakly iterable premice is $\Game^{\mathbb{R}}\Pi^1_1$, which explains the alternate terminology. By [16], $\Game^{\mathbb{R}}\Pi^1_1$ statements are absolute between V and $L(\mathbb{R})$, so we have:

7.8 Theorem. *Let $\mathcal{M}$ be countable and weakly (k, ω)-iterable; then $L(\mathbb{R}) \models \mathcal{M}$ is weakly (k, ω)-iterable.*

It is also shown in [16] that $\Game^{\mathbb{R}}\Pi^1_1 = \Sigma_1^{L(\mathbb{R})}$, that is, that definitions in each form can be translated into the other.[53] We shall do our definability calculations below with Σ_1 formulae interpreted in $L(\mathbb{R})$. It is important here that we allow such formulae to contain a name $\dot{\mathbb{R}}$ for $\mathbb{R}$, so that quantification over $\mathbb{R}$ counts as bounded quantification. (Without this provision, we would have $\Sigma_1^{L(\mathbb{R})} = \Sigma^1_2$.) The sets whose definability we are calculating are generally subsets of HC, the class of hereditarily countable sets. Notice here that a set $A \subseteq \mathrm{HC}$ is $\Sigma_1^{L(\mathbb{R})}$ iff the set A^* of all reals coding (in some natural system) a member of A is $\Sigma_1^{L(\mathbb{R})}$. So we have:

7.9 Lemma. *The set of countable, weakly (k, ω)-iterable premice is $\Sigma_1^{L(\mathbb{R})}$.*

If we restrict our attention to properly small premice, weak (k, ω)-iterability suffices for comparison.

7.10 Theorem. *Assume $\mathsf{AD}^{L(\mathbb{R})}$, and let $\mathcal{M}$ be countable, properly small, and weakly (k, ω)-iterable; then*

$$L(\mathbb{R}) \models \mathcal{M} \textit{ is } (k, \omega_1 + 1)\textit{-iterable.}$$

Proof. We first note

7.11 Lemma. *In $L(\mathbb{R})$, every iteration tree of length ω_1 on a countable premouse has a cofinal, wellfounded branch.*

Proof. Let $\mathcal{T}$ be such a tree. Let j be the embedding coming from the club ultrafilter on ω_1. Now $\mathcal{T}$ can be coded by a subset of ω_1, so $\mathcal{T} \in L[\mathcal{T}]$. As $L[\mathcal{T}]$ is wellordered, $j \restriction L[\mathcal{T}]$ is elementary from $L[\mathcal{T}]$ to $L[j(\mathcal{T})]$. Thus $j(\mathcal{T})$ is an iteration tree of length $j(\omega_1) > \omega_1$, so that $j(\mathcal{T}) \restriction \omega_1$ has a cofinal, wellfounded branch. But $j(\mathcal{T}) \restriction \omega_1 = \mathcal{T}$. $\dashv$

Because of this, it is enough to show that $\mathcal{M}$ is (k, ω_1)-iterable in $L(\mathbb{R})$. We claim that the following is a (k, ω_1)-iteration strategy for $\mathcal{M}$: given that

[52] See [40, Theorem 1.1] for the comparison proof. The proof of our unique strategies result Theorem 4.11 is the other main ingredient in the proof of Theorem 6.16.

[53] We only need here that $\Game^{\mathbb{R}}\Pi^1_1 \subseteq \Sigma_1^{L(\mathbb{R})}$, and this is trivial.

you have reached $\mathcal{T}$ of countable limit length, pick the unique cofinal branch b of $\mathcal{T}$ such that $\mathcal{Q}(b,\mathcal{T})$ is weakly $(\deg^{\mathcal{T}}(b),\omega)$-iterable. Let us call this putative iteration strategy Γ.

Let $\mathcal{T}$ be played according to Γ, and of minimal length such that Γ breaks down at $\mathcal{T}$, either because $\mathcal{T}$ has limit length and there is no such unique branch to serve as $\Gamma(\mathcal{T})$, or because $\mathcal{T}$ has a last, illfounded model. Let Σ be a weak (k,ω)-iteration strategy for $\mathcal{M}$. If $\mathcal{T}$ has a last, illfounded model, then Σ cannot accept $\mathcal{T}$ as I's first move, so $\Sigma(\mathcal{T}) = b$ is a maximal branch of $\mathcal{T}$. Clearly, $\mathcal{Q}(b,\mathcal{T})$ is weakly $(\deg^{\mathcal{T}}(b),\omega)$-iterable, as witnessed by Σ. Letting $\lambda = \sup(b)$, we have from the definition of Γ that $b = \Gamma(\mathcal{T}\restriction\lambda)$, so $b = [0,\lambda]_T$, contrary to the maximality of b. Thus $\mathcal{T}$ has limit length. The argument just given shows that $b := \Sigma(\mathcal{T})$ is a cofinal branch of $\mathcal{T}$, and that $\mathcal{Q}(b,\mathcal{T})$ is weakly $(\deg^{\mathcal{T}}(b),\omega)$-iterable. Therefore there must be a second such branch; call it c. By Theorem 6.12 and the proof of Corollary 6.14, $\mathcal{Q}(b,\mathcal{T})$ and $\mathcal{Q}(c,\mathcal{T})$ cannot be compared. We shall use their weak iterability to compare them.

Let

$$\delta_0 = \sup\{\mathrm{lh}(E_\alpha^{\mathcal{T}}) \mid \alpha < \mathrm{lh}(\mathcal{T})\}.$$

Since δ_0 is Woodin in both $\mathcal{Q}(b,\mathcal{T})$ and $\mathcal{Q}(c,\mathcal{T})$, it is a cutpoint of each model. Since $\mathcal{Q}(b,\mathcal{T})$ and $\mathcal{Q}(c,\mathcal{T})$ agree below δ_0, the comparison we are doing uses only extenders with critical point strictly greater than δ_0.

Let $\Sigma_0 = \Sigma$ and Σ_1 be any weak $(\deg(c),\omega)$-iteration strategy for $\mathcal{Q}(c,\mathcal{T})$. Let $\mathcal{T}_0^0 = \mathcal{T}$, $b_0^0 = b$, and $c_0 = c$. We coiterate $\mathcal{Q}(b,\mathcal{T})$ and $\mathcal{Q}(c,\mathcal{T})$ by iterating the least disagreement at successor steps, and choosing the unique cofinal branch with a weakly iterable $\mathcal{Q}$-structure at limit steps. This process is $L(\mathbb{R})$-definable, and must break down at some countable stage, as otherwise by Lemma 7.11 and the proof of the Comparison Lemma 3.11 we shall succeed in comparing $\mathcal{Q}(b,\mathcal{T})$ with $\mathcal{Q}(c,\mathcal{T})$. By the argument given above, the weak iterability of $\mathcal{Q}(b,\mathcal{T})$ and $\mathcal{Q}(c,\mathcal{T})$ implies that uniqueness is what breaks down. (It does not literally follow from Lemma 7.6 that cofinal branches always have $\mathcal{Q}$-structures, as the models we are comparing may no longer be properly small. But if, say, $\mathcal{Q}(b,\mathcal{T})$ is not properly small, then we have dropped along b getting to it, and this guarantees that in the tree on $\mathcal{Q}(b,\mathcal{T})$ we are now building, cofinal branches always have $\mathcal{Q}$-structures.) Let $\mathcal{T}_1^0$ on $\mathcal{Q}(b,\mathcal{T})$ and $\mathcal{T}_1^1$ on $\mathcal{Q}(c,\mathcal{T})$ be the trees produced by this process. Let

$$\begin{aligned}\delta_1 &= \sup\{\mathrm{lh}(E_\alpha^{\mathcal{T}_1^0}) \mid \alpha < \mathrm{lh}(\mathcal{T}_1^0)\}\\ &= \sup\{\mathrm{lh}(E_\alpha^{\mathcal{T}_1^1}) \mid \alpha < \mathrm{lh}(\mathcal{T}_1^1)\}.\end{aligned}$$

Let

$$b_1^0 = \Sigma_0\big(\langle \mathcal{T}_0^0, (\mathcal{Q}(b_0^0,\mathcal{T}_0^0), \deg(\mathcal{Q}(b_0^0,\mathcal{T}_0^0)), \mathcal{T}_1^0)\rangle\big)$$

and

$$b_1^1 = \Sigma_1(\mathcal{T}_1^1)$$

be the cofinal, weakly iterable branches of $\mathcal{T}_1^0$ and $\mathcal{T}_1^1$ chosen by Σ_0 and Σ_1. By hypothesis we have a third branch c_1 of some $\mathcal{T}_1^i$ (it does not matter which) such that $\mathcal{Q}(c_1, \mathcal{T}_1^i)$ is weakly $(\deg(c_1), \omega)$-iterable, say via the strategy Σ_2. It follows that the premice $\mathcal{Q}(b_1^0, \mathcal{T}_1^0)$, $\mathcal{Q}(b_1^1, \mathcal{T}_1^1)$, and $\mathcal{Q}(c_1, \mathcal{T}_1^i)$ cannot be compared.

We attempt to reach a contradiction by simultaneously comparing these three premice. (This means that we form three iteration trees simultaneously, iterating by the shortest extender on the sequence of any of the three last models which is not present on the sequences of both of the other two last models.) Again, we choose unique weakly iterable branches at limit ordinals, and again this process must break down due to non-uniqueness, giving trees $\mathcal{T}_2^0, \mathcal{T}_2^1$, and $\mathcal{T}_2^2$, with cofinal branches b_2^0, b_2^1, and b_2^2 chosen by Σ_0, Σ_1, and Σ_2. (It is because the $\mathcal{T}_2^i$ use only extenders with critical point above δ_1 that we can interpret them as played by the Σ_i.) We also have a new branch c_2 of some $\mathcal{T}_2^i$, and a weak iteration strategy Σ_3 for $\mathcal{Q}(c_2, \mathcal{T}_2^i)$. We let δ_2 be the sup of the lengths of the extenders used in the $\mathcal{T}_2^i$. And so on.

After ω steps in the process we have for each $i < \omega$ a weak iteration strategy Σ_i and a play by Σ_i in which the iteration trees played by I are the $\mathcal{T}_j^i$ for $j \geq i$ and the branches chosen by II are the b_j^i for $j \geq i$. Let $\mathcal{P}_i$ be the direct limit of the $\mathcal{M}_{b_j^i}^{\mathcal{T}_j^i}$. Since each Σ_i is winning, these direct limits are wellfounded. Clearly, all the δ_k are Woodin in each $\mathcal{P}_i$. Since $\mathcal{P}_i$ is ω-small, it has no extenders with index above the sup of the δ_k, and thus $\mathcal{P}_i$ is an initial segment of $\mathcal{P}_n$ or vice-versa, for all i and n. Since all $\mathcal{P}_i$ project below the sup of the δ_k, they must all be the same. Moreover, as in the proof of the Comparison Lemma 3.11, we can show that for no i does the composition of the trees $\mathcal{T}_j^i$ drop in model or degree on the branch leading to $\mathcal{P}_i$. But this means that $\mathcal{P}_0$ and $\mathcal{P}_1$ are the last models of a successful comparison of $\mathcal{Q}(b, \mathcal{T})$ with $\mathcal{Q}(c, \mathcal{T})$, a contradiction. ⊣

We have at once

7.12 Corollary. *Every real in M_ω is ordinal definable in $L(\mathbb{R})$.*

Proof. Let x be the αth real in the order of constructibility of M_ω; then

$$\begin{aligned} y = x \quad \iff \quad & L(\mathbb{R}) \models \exists \mathcal{M}(\mathcal{M} \text{ is countable, properly small,} \\ & (\omega, \omega_1 + 1)\text{-iterable, and } y \text{ is the } \alpha\text{th real} \\ & \text{in the constructibility order of } \mathcal{M}). \end{aligned}$$

⊣

The proof of Theorem 7.10 gives at once:

7.13 Corollary. *Assume $\mathsf{AD}^{L(\mathbb{R})}$, and let $\mathcal{M}$ be countable, properly small, and weakly (k, ω)-iterable; then in $L(\mathbb{R})$, $\mathcal{M}$ has a unique (k, ω_1)-iteration strategy Σ; moreover, Σ is $\Sigma_1^{L(\mathbb{R})}(\{\mathcal{M}\})$ definable, uniformly in $\mathcal{M}$, and Σ extends, in $L(\mathbb{R})$, to a $(k, \omega_1 + 1)$-iteration strategy for $\mathcal{M}$.*

7.2. Correctness and Genericity Iterations

We shall prove some correctness results for M_ω, and use them to show that every real ordinal definable over $L(\mathbb{R})$ is in M_ω. The key to these results is the following remarkable theorem of Woodin.

7.14 Theorem. *Let Σ be an (ω, ω_1+1)-iteration strategy for $\mathcal{M}$, and suppose that δ is a countable ordinal such that $\mathcal{M} \models \mathsf{ZF}^- +\ \delta$ is Woodin; then there is a $\mathbb{Q} \subseteq V_\delta^{\mathcal{M}}$ such that*

1. *$\mathcal{M} \models \mathbb{Q}$ is a δ-c.c. complete Boolean algebra, and*

2. *for any real x, there is a countable iteration tree $\mathcal{T}$ on $\mathcal{M}$ played according to Σ with last model $\mathcal{M}_\alpha$ such that $i_{0,\alpha}$ exists and x is $i_{0,\alpha}(\mathbb{Q})$-generic over $\mathcal{M}_\alpha$.*

Proof. Working in $\mathcal{M}$, let $L_{\delta,0}$ be the infinitary language whose formulae are built up by means of conjunctions and disjunctions of size $< \delta$, and negation, from the propositional letters A_n, for $n < \omega$. (So all formulae are quantifier-free.) Any real x, regarded as a subset of ω, gives us an interpretation of $L_{\delta,0}$:

$$x \models A_n \iff n \in x.$$

We can then define $x \models \varphi$, for arbitrary formulae φ, by the obvious induction.

Still working in $\mathcal{M}$, consider the $L_{\delta,0}$ theory S which has the axioms

$$\bigvee\nolimits_{\alpha<\kappa} \varphi_\alpha \longleftrightarrow \bigvee\nolimits_{\alpha<\lambda} i_E(\langle \varphi_\xi \mid \xi < \kappa \rangle) \restriction \lambda$$

whenever E is on the $\mathcal{M}$-sequence, $\mathrm{crit}(E) = \kappa \leq \lambda$, and $\nu(E)$ is an $\mathcal{M}$-cardinal such that $i_E(\langle \varphi_\xi \mid \xi < \kappa \rangle) \restriction \lambda \in \mathcal{J}^{\mathcal{M}}_{\nu(E)}$.

We let $\mathbb{Q}$ be the Lindenbaum algebra of S. That is, we let

$$\varphi \sim \psi \quad \text{iff} \quad S \vdash \varphi \leftrightarrow \psi,$$

and

$$[\varphi] \leq [\psi] \quad \text{iff} \quad S \vdash \varphi \rightarrow \psi,$$

and we let

$$\mathbb{Q} := (\{[\varphi] \mid \varphi \in L_{\delta,0}\}, \leq).$$

Here provability in S means provability using the usual finitary rules together with the rule: from φ_α for all $\alpha < \kappa$ (where $\kappa < \delta$) infer $\bigwedge_{\alpha<\kappa} \varphi_\alpha$. Equivalently, $S \vdash \tau$ iff whenever x is a real in $\mathcal{M}[G]$ for some G generic over $\mathcal{M}$ and $x \models S$, then $x \models \tau$. (See [2]. Clearly, if $S \vdash \tau$, then *any* real which satisfies S satisfies τ.)

1 Claim. *$\mathbb{Q}$ is δ-c.c. in $\mathcal{M}$.*

Proof. We work in $\mathcal{M}$. Let $\langle[\varphi_\alpha] \mid \alpha < \delta\rangle$ be an antichain in $\mathbb{Q}$. Let $\kappa < \delta$ be $\langle\varphi_\alpha \mid \alpha < \delta\rangle$-reflecting. Let ν be a cardinal such that $\langle\varphi_\alpha : \alpha < \kappa+1\rangle \in \mathcal{J}_\nu^{\mathcal{M}}$, and let F on the $\mathcal{M}$-sequence witness the reflection of κ at this ν.[54] Let E be the trivial completion of $F{\restriction}\nu$. We then have

$$i_E\big(\textstyle\bigvee_{\alpha<\kappa}\varphi_\alpha\big){\restriction}(\kappa+1) = \textstyle\bigvee_{\alpha\leq\kappa}\varphi_\alpha,$$

so that

$$\textstyle\bigvee_{\alpha<\kappa}\varphi_\alpha \longleftrightarrow \textstyle\bigvee_{\alpha\leq\kappa}\varphi_\alpha$$

is provable in S. It follows that $[\varphi_\kappa] \leq \bigvee_{\alpha<\kappa}[\varphi_\alpha]$ in $\mathbb{Q}$, a contradiction. $\dashv$

2 Claim. *$\mathbb{Q}$ is a complete Boolean algebra in $\mathcal{M}$.*

Proof. $\mathbb{Q}$ is closed under sums of size $< \delta$ since $\bigvee_{\alpha<\kappa}[\varphi_\alpha] = [\bigvee_{\alpha<\kappa}\varphi_\alpha]$ for all $\kappa < \delta$. By Claim 1, $\mathbb{Q}$ is closed under arbitrary sums. $\dashv$

3 Claim. *If $x \models S$, then setting $G_x := \{[\varphi] \mid x \models \varphi\}$, we have that G_x is $\mathbb{Q}$-generic over $\mathcal{M}$ and $x \in \mathcal{M}[G_x]$.*

Proof. Since $x \models S$, G_x is well-defined on equivalence classes: if $S \vdash (\varphi \leftrightarrow \psi)$, then $x \models \varphi$ iff $x \models \psi$. It is also clear that G_x is an ultrafilter on $\mathbb{Q}$. To see that G_x is $\mathcal{M}$-generic, let $\langle[\varphi_\alpha] \mid \alpha < \nu\rangle$ be a maximal antichain. Since $[\bigvee_{\alpha<\nu}\varphi_\alpha] = 1$, we have $S \vdash \bigvee_{\alpha<\nu}\varphi_\alpha$. Since $x \models S$, we have $x \models \varphi_\alpha$ for some α; that is, $[\varphi_\alpha] \in G_x$ for some α. Finally, $n \in x$ iff $[A_n] \in G_x$, so $x \in \mathcal{M}[G_x]$. $\dashv$

An arbitrary real x may not satisfy S, but one can iterate $\mathcal{M}$ in such a way that x satisfies some image of S.

4 Claim. *For any real x, there is a countable iteration tree $\mathcal{T}$ on $\mathcal{M}$ which is played according to Σ, has last model $\mathcal{M}_\alpha$, and is such that $[0,\alpha]_T$ does not drop and $x \models i_{0,\alpha}(S)$.*

Proof. We keep iterating away the first extender which induces an axiom not satisfied by x. More precisely, set $\mathcal{M}_0 = \mathcal{M}$, and now suppose that we have constructed the model $\mathcal{M}_\beta$ of $\mathcal{T}$, where $\beta < \omega_1$. Suppose also that $\mathcal{T}$ has not dropped anywhere yet; that is, $D^{\mathcal{T}} = \emptyset$ as of now. If $x \models i_{0,\beta}(S)$ we are done, so suppose not. Let E on the $\mathcal{M}_\beta$-sequence be such that E induces an axiom of $i_{0,\beta}(S)$ which is false of x, and $\mathrm{lh}(E)$ is minimal among all extenders on the $\mathcal{M}_\beta$-sequence with this property. We set $E_\beta^{\mathcal{T}} := E$, and use E according to the rules for ω-maximal iteration trees to extend $\mathcal{T}$ one more step.

We must check here that $\gamma < \beta \implies \mathrm{lh}(E_\gamma) < \mathrm{lh}(E_\beta)$. But if not, the agreement of models in an ω-maximal iteration tree implies that E_β is on

[54] We are using here the fact that the Woodinness of δ in $\mathcal{M}$ is witnessed by extenders on the $\mathcal{M}$-sequence. We might just have added this to the hypotheses of Theorem 7.14, but we need not do so because, by [36], it follows from the other hypotheses.

the sequence of $\mathcal{M}_\gamma$, and it is not hard to check that the false axiom of $i_{0,\beta}(S)$ it induces in $\mathcal{M}_\beta$ is also induced by it in $\mathcal{M}_\gamma$. (To see that $\nu(E_\beta)$ is a cardinal of $\mathcal{M}_\gamma$ in this situation, note that since $\nu(E_\gamma)$ is a cardinal of $\mathcal{M}_\gamma$, any cardinal of $\mathcal{M}_\beta$ which is $\leq \nu(E_\gamma)$ is a cardinal of $\mathcal{M}_\gamma$. But $\nu(E_\beta) < \mathrm{lh}(E_\beta) \leq \mathrm{lh}(E_\gamma)$ and there are no cardinals of $\mathcal{M}_\beta$ in the interval $(\nu(E_\gamma), \mathrm{lh}(E_\gamma))$, so $\nu(E_\beta) \leq \nu(E_\gamma)$.)

We must also check that $[0, \beta+1]$ does not drop; that is, that E_β measures all subsets of its critical point κ in the model $\mathcal{M}_\gamma$ to which it is applied. This is true because $\kappa < \nu(E_\gamma)$, $\nu(E_\gamma)$ is a cardinal of $\mathcal{M}_\gamma$, and $\mathcal{M}_\beta$ agrees with $\mathcal{M}_\gamma$ below $\nu(E_\gamma)$.

This finishes the successor step in the construction of $\mathcal{T}$. At limit ordinals $\lambda \leq \omega_1$ we use Σ to extend $\mathcal{T}$.

It is enough to show this process terminates at some countable ordinal, so suppose not. We reach a contradiction much as in the proof that the comparison process terminates. As in that argument, let

$$\pi : H \to V_\eta$$

be elementary, where H is a countable, transitive set, and V_η and the range of π are large enough to contain everything of interest. Let $\pi(\bar{\mathcal{T}}) = \mathcal{T}$, etc., and let $\alpha = \mathrm{crit}(\pi) = \omega_1^H$. We get as before, setting $\delta^* = i^{\mathcal{T}}_{0,\alpha}(\delta) = i^{\bar{\mathcal{T}}}_{0,\alpha}(\delta)$,

$$V_{\delta^*}^{\mathcal{M}_\alpha^{\bar{\mathcal{T}}}} = V_{\delta^*}^{\mathcal{M}_\alpha^{\mathcal{T}}}$$

and

$$\pi \restriction V_{\delta^*}^{\mathcal{M}_\alpha^{\bar{\mathcal{T}}}} = i^{\mathcal{T}}_{\alpha,\omega_1} \restriction V_{\delta^*}^{\mathcal{M}_\alpha^{\mathcal{T}}}.$$

Now let $\beta + 1$ be the T-successor of α on $[0, \omega_1]_T$. We have $\mathrm{crit}(E_\beta) = \mathrm{crit}(i_{\alpha,\omega_1}) = \alpha$, and we have an axiom

$$\bigvee\nolimits_{\gamma<\alpha} \varphi_\gamma \longleftrightarrow i_{E_\beta}\big(\bigvee\nolimits_{\gamma<\alpha} \varphi_\gamma\big) \restriction \lambda$$

of $i_{0,\beta}(S)$ induced by E_β and false of x. The falsity of this axiom means that the right hand side is true of x, but the left hand side is not. But now $\bigvee_{\gamma<\alpha} \varphi_\gamma$ is essentially a subset of α, and therefore is small enough that it is in $\mathcal{M}_\alpha$. Moreover, $\lambda < \nu(E_\beta)$, and since generators are not moved on $\mathcal{T}$

$$i_{E_\beta}\big(\bigvee\nolimits_{\gamma<\alpha} \varphi_\gamma\big) \restriction \lambda = i_{\alpha,\omega_1}\big(\bigvee\nolimits_{\gamma<\alpha} \varphi_\gamma\big) \restriction \lambda = \pi\big(\bigvee\nolimits_{\gamma<\alpha} \varphi_\gamma\big) \restriction \lambda.$$

But $x \in H$ and $\pi(x) = x$. Since $L_{\delta,0}$ satisfaction is sufficiently absolute and $x \not\models \bigvee_{\gamma<\alpha} \varphi_\gamma$, we have $x \not\models \pi(\bigvee_{\gamma<\alpha} \varphi_\gamma)$. This contradicts the fact that x satisfies the initial segment $i_{E_\beta}(\bigvee_{\gamma<\alpha} \varphi_\gamma) \restriction \lambda$ of this disjunction. ⊣

If $\mathcal{M}_\alpha$ is as in Claim 4, then we can replace $\mathcal{M}$ by $\mathcal{M}_\alpha$ in Claims 1, 2, and 3, and we see then that $\mathcal{T}$ and $\mathcal{M}_\alpha$ witness the conclusion of Theorem 7.14. ⊣

The complete Boolean algebra $\mathbb{Q}$ of Theorem 7.14 is known as the *extender algebra*.

We drop for a moment to smaller mice, and use the extender algebra to prove a correctness result for the minimal proper class model with one Woodin cardinal. (This was Woodin's original application of Theorem 7.14.) Let us call a premouse $\mathcal{M}$ *1-small* iff whenever κ is the critical point of an extender on the $\mathcal{M}$-sequence, then $\mathcal{J}_\kappa^{\mathcal{M}} \models$ "There are no Woodin cardinals". Let $M_1^\#$ be the least mouse which is not 1-small, and M_1 the result of iterating the last extender of $M_1^\#$ out of the universe. (Granted that there is a Woodin cardinal with a measurable above it in V, $M_1^\#$ exists and is (ω, ω_1+1)-iterable.) Let $\mathbb{Q}$ be the extender algebra of M_1; then for any Σ_3^1 sentence φ, possibly involving real parameters from M_1, we have

$$\varphi \iff M_1 \models \exists p(p \Vdash \varphi).$$

The right-to-left direction comes from the fact that $P(\mathbb{Q}) \cap M_1$ is countable in V, so that any condition is extended by a generic filter in V. For the left-to-right direction: let x witness the outer existential quantifier of φ, and let $\mathcal{M}_\alpha$ be an iterate of M_1 over which x is $i_{0,\alpha}(\mathbb{Q})$-generic. Clearly, $\mathcal{M}_\alpha[G_x] \models \varphi$, so $\mathcal{M}_\alpha \models \exists p(p \Vdash \varphi)$, so by elementarity $M_1 \models \exists p(p \Vdash \varphi)$.

Thus M_1 can compute Σ_3^1 truth by asking what is forced in its extender algebra. (M_1 is not itself Σ_3^1-correct.) This easily implies that every real which is Δ_3^1 in a countable ordinal is in M_1. A careful look at the sort of iterability needed to compare "properly 1-small" mice (like $\mathcal{J}_\alpha^{M_1}$, for $\alpha = \omega_1^{M_1}$) shows every real in M_1 is Δ_3^1 in a countable ordinal, so we have a descriptive-set-theoretic characterization of the reals in M_1.[55]

$M_1^\#$ is essentially a real, and from this real we can recursively construct generic objects for the extender algebra of M_1 below any condition. It follows that every nonempty Σ_3^1 set of reals has a member recursive in $M_1^\#$. We can relativize the $M_1^\#$ construction to an arbitrary real x and obtain $M_1^\#(x)$; simply throw x into the model at the bottom. We get that any nonempty $\Sigma_3^1(x)$ set of reals has a member recursive in $M_1^\#(x)$, and therefore any premouse closed under the function $x \mapsto M_1^\#(x)$ is Σ_3^1-correct. In particular, M_ω is Σ_3^1-correct.

If we give M_n and $M_n^\#$ the obvious meaning, then we can show that the reals of M_n are precisely those which are Δ_{n+2}^1 in a countable ordinal, and that every nonempty Σ_{n+2}^1 set of reals has a member recursive in $M_n^\#$. (See [42].) Since M_ω is closed under $x \mapsto M_n^\#(x)$ for all $n < \omega$, M_ω is projectively correct. The following theorem gives us much more; it says that M_ω can compute $L(\mathbb{R})$ truth in much the same way that M_1 can compute Σ_3^1 truth.

We let $\mathrm{Col}(\omega, X)$ be the collapsing poset of all finite partial functions from ω into X. Notice that Theorem 7.14 implies that if $\mathcal{M}$, Σ, and δ satisfy its hypotheses, then for any real x there is a countable $\mathcal{T}$ played by Σ, with last model $\mathcal{M}_\alpha$, such that x is $\mathrm{Col}(\omega, i_{0,\alpha}(\delta))$-generic over $\mathcal{M}_\alpha$. This is true

[55] This set of reals is known in descriptive set theory as Q_3, and it has many other characterizations. $M_1^\#$ is also known from descriptive set theory; it is Turing equivalent to y_0. See [12].

because $\mathrm{Col}(\omega, \kappa)$ is universal for forcings of size κ. Unlike the extender algebra, $\mathrm{Col}(\omega, \delta)$ is not δ-c.c.; on the other hand, it is homogeneous.

By $\mathrm{Col}(\omega, <\lambda)$ we mean the finite support product of all $\mathrm{Col}(\omega, \alpha)$ such that $\alpha < \lambda$. If G is $\mathcal{M}$-generic over $\mathrm{Col}(\omega, <\lambda)$, then we set

$$\mathbb{R}^*_G := \bigcup_{\alpha<\lambda} \mathbb{R} \cap \mathcal{M}[G \cap \mathrm{Col}(\omega, <\alpha)],$$

and say that $\mathbb{R}^*_G$ is the set of reals of a symmetric collapse of $\mathcal{M}$ below λ.

7.15 Theorem. *Suppose that $\mathcal{M} \models \lambda$ is a limit of Woodin cardinals, where λ is countable in V, and that Σ is an $(\omega, \omega_1 + 1)$-iteration strategy for $\mathcal{M}$. Let H be $\mathrm{Col}(\omega, \mathbb{R})$-generic over V; then in $V[H]$ there is an iteration map $i : \mathcal{M} \to \mathcal{N}$ coming from an iteration tree all of whose proper initial segments are played by Σ, and a G which is $\mathrm{Col}(\omega, <i(\lambda))$-generic over $\mathcal{N}$, such that*

$$\mathbb{R}^*_G = \mathbb{R}^V.$$

Proof. We shall need the following slight refinement of Theorem 7.14.

7.16 Lemma. *Let $\mathcal{M} \models \delta$ is Woodin, where δ is countable in V, and let Σ be an (ω, ω_1+1)-iteration strategy for $\mathcal{M}$. Let $\kappa < \delta$, and let G be $\mathcal{M}$-generic for a poset $\mathbb{P} \in V^{\mathcal{M}}_\kappa$. Then for any $x \subseteq \omega$, there is a countable iteration tree $\mathcal{T}$ played by Σ and having last model $\mathcal{M}_\alpha$ such that*

1. *$D^{\mathcal{T}} = \emptyset$ and $\mathrm{crit}(E^{\mathcal{T}}_\beta) > \kappa$ for all β, and*
2. *x is in some $\mathrm{Col}(\omega, \delta)$-generic extension of $\mathcal{M}_\alpha[G]$.*

Sketch of Proof. In $\mathcal{M}[G]$, δ is still Woodin via the extenders over $\mathcal{M}[G]$ which are "completions" of extenders on the $\mathcal{M}$-sequence with critical point $> \kappa$. So in $\mathcal{M}[G]$, the version of the extender algebra which uses only these extenders is a δ-c.c. complete Boolean algebra. The iteration $\mathcal{U}$ of $\mathcal{M}[G]$ we need to do to make x generic can be obtained from an iteration $\mathcal{T}$ of $\mathcal{M}$: $\mathcal{M}^{\mathcal{U}}_\beta = \mathcal{M}^{\mathcal{T}}_\beta[G]$ for all β. We omit further details. ⊣

We can now prove the theorem. Working in $V[H]$, let $\langle x_n \mid n < \omega\rangle$ be an enumeration of $\mathbb{R}^V$. Let $\langle \delta_n \mid n < \omega\rangle$ be an increasing sequence of Woodin cardinals of $\mathcal{M}$ which is cofinal in λ. We shall use Lemma 7.16 to successively absorb the x_n into the collapse of some image of δ_n in an iterate of $\mathcal{M}$.

More precisely, working in V we find a countable iteration tree $\mathcal{T}_0$ on $\mathcal{M}$ played by Σ with last model $\mathcal{P}_0$, and a G_0 which is $\mathcal{P}_0$-generic over $\mathrm{Col}(\omega, i_0(\delta_0))$, where $i_0 : \mathcal{M} \to \mathcal{P}_0$ is the iteration map, so that $x_0 \in \mathcal{P}_0[G_0]$. We then find an iteration tree $\mathcal{T}_1$ on $\mathcal{P}_0$ such that $\mathcal{T}_0 \oplus \mathcal{T}_1$ is according to Σ, and if $i_1 : \mathcal{P}_0 \to \mathcal{P}_1$ is the iteration map, then $\mathrm{crit}(i_1) > i_0(\delta_0)$, and there is a G_1 which is $\mathcal{P}_1[G_0]$-generic over $\mathrm{Col}(\omega, i_1 \circ i_0(\delta_1))$ such that $x_1 \in \mathcal{P}_1[G_0][G_1]$. And so on: given $\mathcal{P}_n$, we use Lemma 7.16 in V to obtain an iteration tree $\mathcal{T}_{n+1}$ on $\mathcal{P}_n$ such that $\mathcal{T}_0 \oplus \cdots \oplus \mathcal{T}_{n+1}$ is according to Σ, and if $i_{n+1} : \mathcal{P}_n \to \mathcal{P}_{n+1}$ is the iteration map, then $\mathrm{crit}(i_{n+1}) > i_n \circ \ldots \circ i_0(\delta_n)$, and there is a G_{n+1}

which is $\mathcal{P}_{n+1}[G_0, \ldots, G_n]$-generic over $\mathrm{Col}(\omega, i_{n+1} \circ \ldots \circ i_0(\delta_{n+1}))$ such that $x_{n+1} \in \mathcal{P}_{n+1}[G_0, \ldots, G_n][G_{n+1}]$.

Let $\mathcal{T} = \left(\bigoplus_n \mathcal{T}_n\right) \oplus b$, where b is the branch of $\bigoplus_n \mathcal{T}_n$ containing the $\mathcal{P}_n$. By construction, b is the unique cofinal branch of $\bigoplus_n \mathcal{T}_n$, and the $\mathcal{T}_n$ constitute a play by Σ. Let $\mathcal{N}$ be the last model of $\mathcal{T}$; clearly $\mathcal{N}$ is just the direct limit of the $\mathcal{P}_n$ under the i_n. A simple absoluteness argument shows that $\mathcal{N}$ is wellfounded: if not, then the tree of attempts to produce a sequence $\langle \mathcal{U}_n \mid n \in \omega \rangle$ which constitutes a play of ω rounds of $\mathcal{G}_\omega(\mathcal{M}, \omega, \omega_1+1)$ by Σ, together with a descending chain of ordinals in the direct limit along the unique cofinal branch, would have a branch in V. Let $i : \mathcal{M} \to \mathcal{N}$ be the direct limit map. By construction, each G_n is in V, so we have $x_n \in (\mathbb{R} \cap \mathcal{N}[G_0, \ldots, G_{n+1}]) \subseteq \mathbb{R}^V$, and therefore $\bigcup_n (\mathbb{R} \cap \mathcal{N}[G_0, \ldots, G_n]) = \mathbb{R}^V$. It is easy to see that $\bigcup_n (\mathbb{R} \cap \mathcal{N}[G_0, \ldots, G_n])$ is the set of reals of a symmetric collapse of $\mathcal{N}$ below $i(\lambda)$, so we are done. $\dashv$

7.17 Corollary. *Let $\mathcal{M}$ be a proper class premouse such that $\mathcal{M} \models \lambda$ is a limit of Woodin cardinals, where λ is countable in V, and suppose that $\mathcal{M}$ is (ω, ω_1+1)-iterable; then every real which is ordinal definable over $L(\mathbb{R})$ belongs to $\mathcal{M}$.*

Proof. Let $i : \mathcal{M} \to \mathcal{N}$ be as in Theorem 7.15, and let x be $\mathrm{OD}^{L(\mathbb{R})}$. We have, by the symmetry of $\mathrm{Col}(\omega, {<}i(\lambda))$ and the fact that $L(\mathbb{R})^V$ is realized as some $L(\mathbb{R}^*_G)$, that $x \in \mathcal{N}$. It follows that $x \in \mathcal{M}$. $\dashv$

The proof of Theorem 6.16 shows that if λ is a limit of Woodin cardinals and there is a measurable cardinal above λ, then $M_\omega^\#$ exists and is $(\omega, \omega_1, \omega_1+1)$-iterable, not just in V, but in $V^{\mathbb{P}}$, for any poset $\mathbb{P}$ of cardinality $< \lambda$. So we get at once:

7.18 Corollary. *If there are ω Woodin cardinals with a measurable above them all in V, then $\mathbb{R} \cap M_\omega = \{x \in \mathbb{R} \mid x$ is $\mathrm{OD}^{L(\mathbb{R})}\}$.*

We are in a position now to see that M_ω has no (ω, ω_1)-iteration strategy in $L(\mathbb{R})$. (We assume here that there are in V ω Woodin cardinals with a measurable above them all.) For if there were such a strategy in $L(\mathbb{R})$, then the set of reals which are not in M_ω would be a $\Sigma_1^{L(\mathbb{R})}$ set: $z \notin M_\omega$ iff $L(\mathbb{R}) \models$ (there is an (ω, ω_1)-iterable, ω-small premouse $\mathcal{N}$ of ordinal height ω_1 such that for some countable λ, $\mathcal{N} \models \lambda$ is a limit of Woodin cardinals, and such that $z \notin \mathcal{N}$). However, by [16], any nonempty $\Sigma_1^{L(\mathbb{R})}$ set of reals has an $\mathrm{OD}^{L(\mathbb{R})}$ member.[56] So there is an $\mathrm{OD}^{L(\mathbb{R})}$ real not in M_ω, contrary to Corollary 7.18.

The proof of Theorem 7.15 shows that any sufficiently iterable proper class model with ω Woodin cardinals can compute $L(\mathbb{R})$ truth by consulting its symmetric collapse; in fact

[56] We shall give a purely inner-model-theoretic proof of this result immediately after Theorem 7.20.

7.19 Theorem. *Let $\mathcal{M}$ be a proper class premouse such that $\mathcal{M} \models \lambda$ is a limit of Woodin cardinals, where λ is countable in V, and suppose that $\mathcal{M}$ is (ω, ω_1+1)-iterable. Let $\mathbb{R}^*$ be the set of reals of a symmetric collapse of $\mathcal{M}$ below λ; then in $V^{\mathrm{Col}(\omega,\mathbb{R})}$ there is an elementary $j : L(\mathbb{R}^*) \to L(\mathbb{R})^V$.*

Sketch of Proof. Let $\langle \delta_n \mid n < \omega \rangle$ be a sequence of Woodin cardinals with limit λ, and let G_n be $\mathrm{Col}(\omega, \delta_n)$-generic over $\mathcal{M}$ and such that

$$\mathbb{R}^* = \bigcup_n (\mathbb{R} \cap \mathcal{M}[G_n]).$$

Working in $V[H]$, where H is $\mathrm{Col}(\omega, \mathbb{R})$-generic over V, the proof of Theorem 7.15 gives for each n an iteration map

$$i_n : \mathcal{M} \to \mathcal{P}_n, \quad \text{with } \mathrm{crit}(i_n) > \delta_n,$$

such that $\mathbb{R}^V$ is the set of reals of a symmetric collapse of $\mathcal{P}_n$ below $i_n(\lambda)$. Let

$$\Gamma = \{\alpha \in \mathrm{On} \mid \forall n (i_n(\alpha) = \alpha)\},$$

and

$$X = \{x \mid x \text{ is definable over } L(\mathbb{R}) \text{ from elements of } \mathbb{R}^* \cup \Gamma\}.$$

Since the i_n are iteration maps, Γ is a proper class. Now i_n induces an elementary embedding $i_n^* : \mathcal{M}[G_n] \to \mathcal{P}_n[G_n]$, and by the homogeneity of the symmetric collapses we get, for all reals $\vec{x}$ in $\mathcal{M}[G_n]$, ordinals $\vec{\alpha}$, and formulae φ,

$$L(\mathbb{R}^*) \models \varphi[\vec{x}, \vec{\alpha}] \iff L(\mathbb{R})^V \models \varphi[\vec{x}, i_n(\vec{\alpha})].$$

It follows easily that

$$\mathbb{R} \cap X = \mathbb{R}^*.$$

Thus it suffices to show that $X \prec L(\mathbb{R})$, for then the inverse of the transitive collapse of X is the desired elementary embedding. So suppose

$$L(\mathbb{R}) \models \exists v \sigma[\vec{y}, \vec{\alpha}],$$

where $\vec{y} \in (\mathbb{R}^*)^{<\omega}$ and $\vec{\alpha} \in \Gamma^{<\omega}$. Pick n such that $\vec{y} \in M[G_n]$. Using the partial elementarity of i_n displayed above, we get

$$L(\mathbb{R}^*) \models \exists v \sigma[\vec{y}, \vec{\alpha}].$$

Since Γ is a proper class, we can take the witness v from $L(\mathbb{R}^*)$ to be definable over $L(\mathbb{R}^*)$ from z and $\vec{\beta}$, where $z \in \mathbb{R}^*$ and $\vec{\beta} \in \Gamma^{<\omega}$. Let $k \geq n$ be such that $z \in M[G_k]$; then the partial elementarity of i_k guarantees that there is a witness v to σ which is $L(\mathbb{R})$-definable from $z, \vec{y}, \vec{\beta}$, and $\vec{\alpha}$. This shows $X \prec L(\mathbb{R})$, as desired. ⊣

Although iterable class models with ω Woodin cardinals can compute $L(\mathbb{R})$ truth, they need not be correct for arbitrary statements about $L(\mathbb{R})$. We do have, however:

7.20 Theorem. *Let $\mathcal{M}$ be a proper class premouse such that $\mathcal{M} \models \eta$ is a limit of Woodin cardinals, for some $\eta < \omega_1^V$. Suppose that $\mathcal{M}$ is $(\omega, \omega_1 + 1)$-iterable; then for any real $x \in \mathcal{M}$ and Σ_1 formula φ, containing perhaps a name $\dot{\mathbb{R}}$ for $\mathbb{R}$,*

$$(L(\mathbb{R}) \models \varphi[x]) \quad \Longrightarrow \quad (L(\mathbb{R})^{\mathcal{M}} \models \varphi[x]).$$

Proof. We shall assume $x \in M_\omega$; the argument in general is only slightly more complicated.

Fix an ω-small proper class premouse $\mathcal{N}$ whose extender sequence is an initial segment of that of $\mathcal{M}$, and such that there is a $\lambda \leq \eta$ such that λ is a limit of Woodin cardinals in $\mathcal{N}$. To see that there is such an $\mathcal{N}$, note that either $\mathcal{M}$ is ω-small, in which case we can take $\mathcal{N} = \mathcal{M}$, or $M_\omega^\# = \mathcal{J}_\alpha^{\mathcal{M}}$ for some α, in which case we can take $\mathcal{N} = M_\omega$. The iterability of $\mathcal{M}$ implies that of $\mathcal{N}$. From Theorem 7.19 we get some α such that $J_\alpha^{\mathcal{N}} \models \mathsf{ZF}^- +$ "There is a λ which is a limit of Woodin cardinals, and $L(\mathbb{R}^*) \models \varphi[x]$, where $\mathbb{R}^*$ is the set of reals of a symmetric collapse below λ". By taking a Skolem hull inside $\mathcal{N}$ and comparing the result with $\mathcal{N}$, we see that if $\bar{\alpha}$ is the least such α, then $\bar{\alpha}$ is countable in $\mathcal{N}$. Define $\bar{\lambda}$ to be least λ such that $J_{\bar{\alpha}}^{\mathcal{N}} \models \lambda$ is a limit of Woodin cardinals.

We claim that $\mathcal{J}_{\bar{\alpha}}^{\mathcal{N}}$ is $(\omega, \omega_1 + 1)$-iterable in $\mathcal{M}$. (This is why we dropped from $\mathcal{M}$ to $\mathcal{N}$.) For $\mathcal{Q} := \mathcal{J}_{\bar{\alpha}+1}^{\mathcal{N}}$ is properly small, and therefore by Corollary 7.13, has a (ω, ω_1^V)-iteration strategy Σ which is $\Sigma_1^{L(\mathbb{R})}(\{\mathcal{Q}\})$. By Theorem 7.19, and the homogeneity of $\mathrm{Col}(\omega, {<}\eta)$, $V_\eta^{\mathcal{M}}$ is closed under Σ, and $\Sigma \restriction V_\eta^{\mathcal{M}} \in \mathcal{M}$.

We can now run the construction of Theorem 7.15 in $\mathcal{M}[H]$, where H is $\mathcal{M}$-generic over $\mathrm{Col}(\omega, \mathbb{R})$. We obtain an iteration map

$$i : \mathcal{J}_{\bar{\alpha}}^{\mathcal{N}} \to \mathcal{P}$$

such that for some $\mathrm{Col}(\omega, {<}i(\bar{\lambda}))$-generic G over $\mathcal{P}$

$$\mathbb{R}^{\mathcal{M}} = \mathbb{R}^*_G.$$

Thus, for $\xi = \mathrm{On}^{\mathcal{P}}$, $L_\xi(\mathbb{R}^{\mathcal{M}}) \models \varphi[x]$, and hence $L(\mathbb{R}^{\mathcal{M}}) \models \varphi[x]$ since φ is Σ_1. $\dashv$

One can also prove this theorem using stationary tower forcing. (By Theorem 7.15 we have an iteration map $i : \mathcal{M} \to \mathcal{P}$ such that for some G which is $\mathrm{Col}(\omega, {<}i(\eta))$-generic over $\mathcal{P}$, $\mathbb{R}^V = \mathbb{R}^*_G$. Via stationary tower forcing over $\mathcal{P}$ one gets, for any α, a $\mathcal{P}$-generic elementary embedding $j : \mathcal{P} \to \mathcal{Q}$ with $\mathbb{R}^{\mathcal{Q}} = \mathbb{R}^*_G$ and $\alpha \in \mathrm{wfp}(\mathcal{Q})$. Then any Σ_1 fact true in $L(\mathbb{R})^V$ is true in some such $L(\mathbb{R})^{\mathcal{Q}}$, hence in $L(\mathbb{R})^{\mathcal{P}}$, and hence in $L(\mathbb{R})^{\mathcal{M}}$.) It is often the case that stationary tower forcing and genericity iterations can be made to do the same work.[57]

The argument of Theorem 7.20 yields another proof of the standard basis theorem for $\Sigma_1^{L(\mathbb{R})}$: every nonempty $\Sigma_1^{L(\mathbb{R})}$ set of reals has a $\Delta_1^{L(\mathbb{R})}$ member. For if φ defines our set over $L(\mathbb{R})$, then as in Theorem 7.20 we get an initial segment $\mathcal{Q}$ of M_ω of height $< \omega_1^{M_\omega}$ such that for some λ, $\mathcal{Q} \models \lambda$ is a limit of Woodin cardinals and it is forced in the symmetric collapse over $\mathcal{Q}$ below λ that $L(\mathbb{R}^*) \models \exists z \varphi(z)$. Working in M_ω, where λ is countable, we can find a generic object G for some $\mathrm{Col}(\omega, \delta)$, where $\delta < \lambda$, such that $\mathcal{Q}[G] \models \exists z(\mathrm{Col}(\omega, {<}\lambda) \Vdash \varphi(\check{z})^{L(\mathbb{R})})$. Picking such a $z \in \mathcal{Q}[G]$, we see from the iterability of $\mathcal{Q}$ in $V^{\mathrm{Col}(\omega,\mathbb{R})}$ that $L(\mathbb{R})^V \models \varphi[z]$. But z is in M_ω, hence z is $\mathrm{OD}^{L(\mathbb{R})}$. If we pick the least such z in the canonical wellorder of the reals of M_ω, we get that z is $\Delta_1^{L(\mathbb{R})}$.

The argument just given is closely related to the proof we gave that every nonempty Σ_3^1 set of reals has a member recursive in $M_1^\#$. One can extend the argument so as to show via inner model theory that the pointclass $\Sigma_1^{L(\mathbb{R})}$ has the scale property. (See [16] for the original proof, which used methods involving games and determinacy due to Yiannis Moschovakis.) In recent unpublished work, Itay Neeman has found a general method which uses definability over mice to produce many pointclasses with the scale property. Neeman's work gives a new proof that Σ_{2n}^1 and Π_{2n+1}^1 have the scale property, for any $n \geq 1$. Neeman's work builds on earlier ideas of Woodin (unpublished, but see [42]), who found a purely inner-model-theoretic proof of the weaker fact that Σ_{2n}^1 and Π_{2n+1}^1 have the prewellordering property, for all n.

7.21 Corollary. *Suppose that there are ω Woodin cardinals with a measurable above them all. Then $M_\omega \models \mathbb{R}$ has a $\Delta_1^{L(\mathbb{R})}$ wellorder.*

Proof. By the reflection theorem,

$$x \in \mathrm{OD}^{L(\mathbb{R})} \iff \exists \alpha (x \in \mathrm{OD}^{L_\alpha(\mathbb{R})}).$$

So being $\mathrm{OD}^{L(\mathbb{R})}$ is a $\Sigma_1^{L(\mathbb{R})}$ property. Thus, by Corollary 7.18 and Theorem 7.20,

$$M_\omega \models \forall x \in \mathbb{R}(x \text{ is } \mathrm{OD}^{L(\mathbb{R})}).$$

The reals can now be wellordered in M_ω via their definitions in $L(\mathbb{R})^{M_\omega}$. ⊣

One can also prove Corollary 7.21 by showing that the natural wellorder of $\mathbb{R} \cap M_\omega$ given by the stages of construction is Δ_1 over $L(\mathbb{R})^{M_\omega}$. The proof of this is implicit in the arguments just given.

[57] One can also show using the scale property for $\Sigma_1^{L(\mathbb{R})}$ that if $\mathcal{M}$ is any model of set theory such that $\mathbb{R}^{\mathcal{M}}$ is countable, and every $\mathrm{OD}^{L(\mathbb{R})}(\{\mathbb{R}^{\mathcal{M}}\})$ set $X \subseteq \mathbb{R}^{\mathcal{M}}$ is in $\mathcal{M}$, then the conclusion of Theorem 7.20 holds. Combining this with the natural extension of Corollary 7.17 to sets of reals, we get yet another proof of Theorem 7.20.

The author (unpublished) has shown that $M_\omega \models V = \mathrm{HOD}$. The proof builds on that of Corollary 7.21, but more is required.[58]

The correctness theorem 7.20 is best possible, in the sense that, if there are ω Woodin cardinals with a measurable cardinal above them all, then the statement "There is a wellorder of the reals" is a Σ_1 statement which is true in $L(\mathbb{R})^{M_\omega}$, but not true in $L(\mathbb{R})$. Another such statement is "Every real is ordinal definable over some $L_\alpha(\mathbb{R})$".

Iterations to make reals generic can be used to prove the generic absoluteness theorems one gets from stationary tower forcing. For example:

7.22 Theorem (Woodin). *Suppose that λ is a limit of Woodin cardinals, and there is a measurable cardinal above λ. Let G be $\mathbb{P}$-generic over V, where $|\mathbb{P}| < \lambda$, and let H be* $\mathrm{Col}(\omega, \mathbb{R})^{V[G]}$*-generic over $V[G]$; then in $V[G][H]$ there is an elementary*

$$j : L(\mathbb{R})^V \to L(\mathbb{R})^{V[G]}.$$

In particular, $L(\mathbb{R})^V$ is elementarily equivalent to $L(\mathbb{R})^{V[G]}$.

Proof. Let $\langle (i_n, \mathcal{P}_n) \mid n < \omega \rangle$ be a genericity iteration of M_ω such that setting $\mathcal{P} =$ dirlim $\mathcal{P}_n$, we have that $\mathbb{R}^V$ can be realized as the reals $\mathbb{R}^*_K$ of a symmetric collapse of $\mathcal{P}$ below the sup of its Woodin cardinals. We get such an iteration in $V[G][H]$ from the proof of Theorem 7.15, and we have from that proof that each $\mathcal{P}_n$ is countable in V, and $\mathbb{R}^*_K = \bigcup_n \mathbb{R} \cap \mathcal{P}_n[K_n]$, where K_n is in V and $\mathrm{Col}(\omega, i_n \circ \cdots \circ i_0(\delta_n))$-generic over $\mathcal{P}_n$. (Here δ_n is the nth Woodin cardinal of M_ω.) Applying Theorem 7.15 again, we have for each n an iteration map $j_n : \mathcal{P}_n \to \mathcal{Q}_n$ such that $\mathrm{crit}(j_n) > i_n \circ \cdots \circ i_0(\delta_n)$ and $\mathbb{R}^{V[G]}$ is the set of reals of a symmetric collapse of $\mathcal{Q}_n$. Note that j_n lifts to an elementary $\hat{j}_n$ from $\mathcal{P}_n[K_n]$ to $\mathcal{Q}_n[K_n]$. From the homogeneity of the two collapses it then follows that for any real $x \in \mathcal{P}_n[K_n]$, formula φ, and ordinal α, $L(\mathbb{R})^V \models \varphi[x, i_{n,\omega}(\alpha)]$ iff $L(\mathbb{R})^{V[G]} \models \varphi[x, j_n(\alpha)]$. As in the proof of Theorem 7.19, this means that if we let $X = \{\alpha \mid \forall n(j_n(\alpha) = \alpha = i_{n,\omega}(\alpha))\}$, and let j be the inverse of the transitive collapse of the hull in $L(\mathbb{R})^{V[G]}$ of $X \cup \mathbb{R}^V$, then $j : L(\mathbb{R})^V \to L(\mathbb{R})^{V[G]}$ elementarily. $\dashv$

One can also use genericity iterations to eliminate stationary tower forcing from the proof of $\mathsf{AD}^{L(\mathbb{R})}$, and in fact this can be done in several different ways. See for example [29, 28], and [45].

The connection between correctness of mice and definability of their iteration strategies extends much further. How much further is one of the central open problems of inner model theory.

7.23 Definition. *Mouse capturing* is the following statement: for all $x, y \in \mathbb{R}$, x is ordinal definable from y if and only if for some (ω, ω_1)-iterable y-premouse $\mathcal{M}$, $x \in \mathcal{M}$.

[58] One shows that the inductive definition of K from [43] relativizes in such a way that one can define over M_ω its extender sequence in each interval between successive Woodin cardinals of M_ω.

Here a y-premouse is just like an ordinary premouse, except that we put y in at the bottom of its hierarchy. We have shown in this section that the existence of $M_\omega^\#$ implies that mouse capturing holds in $L(\mathbb{R})$. Results of Woodin show that $\mathsf{AD}^{L(\mathbb{R})}$ implies that mouse capturing holds in $L(\mathbb{R})$, and in fact, appropriately interpreted, it holds in every $J_\alpha(\mathbb{R})$. (See [13] and [46].) Woodin has also shown that mouse capturing holds in models of determinacy beyond $L(\mathbb{R})$: in any model of AD in which all ω_1-iterable mice are tame (see [46]), and even beyond that, in the minimal model of $\mathsf{AD}_\mathbb{R} + \mathsf{DC}$.[59]

In his PhD thesis (Berkeley 2009), Grigor Sargsyan has shown that in fact mouse capturing holds in the minimal model of $\mathsf{AD}_\mathbb{R}$ + "Θ is regular".[60] These results have local refinements: mouse capturing holds in any reasonably closed Wadge initial segment of the minimal model of $\mathsf{AD}_\mathbb{R}$ + "Θ is regular".[61] The capturing mice in the minimal model of $\mathsf{AD}_\mathbb{R} + \mathsf{DC}$ can be nontame, but all capturing mice in the minimal model of $\mathsf{AD}_\mathbb{R}$ + "Θ is regular" are below a Woodin limit of Woodin cardinals.

This leads us to the

Mouse Set Conjecture. Assume AD^+, and that there is no ω_1-iteration strategy for a premouse satisfying "There is a superstrong cardinal"; then mouse capturing holds.

AD^+ is a strengthening of AD which holds in all the models of AD we have constructed under large cardinal hypotheses. See for example [13, §8] for a precise definition. We might have stated the mouse set conjecture with AD as its hypothesis, but preferred to separate it from the open technical question as to whether AD implies AD^+.

It might be possible to drop the hypothesis that there is no ω_1-iteration strategy for a premouse satisfying "There is a superstrong cardinal" from the mouse set conjecture. One would presumably then have to enlarge the notion of mouse, so as to accommodate canonical models with supercompacts and more. The hypothesis that there is no ω_1-iteration strategy for a premouse satisfying "There is a superstrong cardinal" is a convenient way to say that we are in the initial segment of AD^+ models in which the capturing mice are premice in the sense of this chapter.

The author believes that it is unlikely that one can construct (ω_1+1)-iterable premice satisfying "There is a superstrong cardinal" under any hypothesis, even the hypothesis that there are superstrong cardinals, without proving the mouse set conjecture.

---

59 $\mathsf{AD}_\mathbb{R}$ is the assertion that all games on $\mathbb{R}$ are determined.

60 This is a well-known, strong determinacy hypothesis. Θ is the least ordinal that is not the surjective image of $\mathbb{R}$. Θ for $L(\mathbb{R})$ is officially defined at the beginning of the next section.

61 Sargsyan also shows that if there is an iterable mouse with a Woodin limit of Woodin cardinals, then there is an inner model of $\mathsf{AD}_\mathbb{R}$ + "Θ is regular".

8. $\mathrm{HOD}^{L(\mathbb{R})}$ below Θ

Having characterized the reals in $\mathrm{HOD}^{L(\mathbb{R})}$ in terms of mice, it is natural to look for a similar characterization of the full model $\mathrm{HOD}^{L(\mathbb{R})}$. In this section we shall describe some work of the author [41] and Woodin (unpublished) which provides such a characterization.

The arguments of the last section give more in this direction than we stated there. Let $\mathcal{N}$ be the linear iterate of M_ω obtained by taking ultrapowers by the unique normal measure on the least measurable cardinal, and its images, ω_1^V times. Thus the least measurable cardinal of $\mathcal{N}$ is ω_1^V. One can show by the methods of the last section that $P(\omega_1^V) \cap \mathrm{HOD}^{L(\mathbb{R})} = P(\omega_1^V) \cap \mathcal{N}$. (See [40, Sect. 4].) This clearly suggests that the whole of $\mathrm{HOD}^{L(\mathbb{R})}$ might be an iterate of M_ω. We shall show in this section that is almost true.

8.1 Definition.

$$\Theta = \sup\{\alpha \mid \exists f \in L(\mathbb{R})(f : \mathbb{R} \to \alpha \text{ and } f \text{ is surjective})\}.$$

8.2 Definition.

$$\underset{\sim}{\delta}_1^2 = \sup\big\{\alpha \mid \exists f(f : \mathbb{R} \to \alpha \text{ and } f \text{ is surjective and } \boldsymbol{\Delta}_1^{L(\mathbb{R})}\big\}.$$

Standard notation would require that we write $\Theta^{L(\mathbb{R})}$ and $(\underset{\sim}{\delta}_1^2)^{L(\mathbb{R})}$ here, but since we shall only interpret the notions in question in $L(\mathbb{R})$, we have chosen to drop the superscripts. Similarly, we shall occasionally write HOD for $\mathrm{HOD}^{L(\mathbb{R})}$ in this section. We have nothing to say about HOD^V here.

We shall show that below $\underset{\sim}{\delta}_1^2$, HOD is the direct limit of a certain class $\mathcal{F}$ of countable, iterable mice, under the iteration maps given by the comparison process. (One gets a typical element of $\mathcal{F}$ by iterating M_ω, then cutting the iterate off at a successor cardinal below its bottom Woodin cardinal.) The mice in $\mathcal{F}$ are properly small, so that $L(\mathbb{R})$ knows how to iterate them correctly. They are as "full" as possible, given this smallness condition. Fullness guarantees that in the comparison of two mice in $\mathcal{F}$, neither side drops along the branch leading to the final model, and thus we have iteration maps on both sides. The Dodd-Jensen Lemma guarantees that these maps commute, so that we can indeed form a direct limit. The whole direct limit system is definable over $L(\mathbb{R})$ in a way that insures its direct limit M_∞ is included in $\mathrm{HOD} \cap V_{\underset{\sim}{\delta}_1^2}$. On the other hand, we shall see that in the bigger universe $V^{\mathrm{Col}(\omega_1,\mathbb{R})}$ there is an iterate N of $\mathcal{M}_\omega$ such that M_∞ is just N cut off at the least cardinal κ which is β-strong for all β below the bottom Woodin cardinal of N. The correctness properties of N can then be used to show that $\mathrm{HOD} \cap V_{\underset{\sim}{\delta}_1^2} \subseteq M_\infty$.

The maps in our direct limit system will come from compositions of iteration trees. In order to make the Dodd-Jensen Lemma applicable, we need to take care of some details regarding unique iterability. Let $\mathcal{M}$ be properly small. By $\mathcal{G}^*(\mathcal{M},\lambda,\theta)$ we mean the variant of the iteration game $\mathcal{G}_\omega(\mathcal{M},\lambda,\theta)$ in which player I is not allowed to drop at the beginning of a new round. That is, if $\mathcal{Q}$ is the model we get at the end of round α and q is its degree (with $\mathcal{Q}=\mathcal{M}$ and $q=\omega$ if $\alpha=0$), then round $\alpha+1$ of $\mathcal{G}^*(\mathcal{M},\lambda,\theta)$ must be a play of $\mathcal{G}_q(\mathcal{Q},\theta)$. Let us call a play of $\mathcal{G}^*(\mathcal{M},\lambda,\theta)$ in which II has not yet lost an *almost ω-maximal* iteration tree on $\mathcal{M}$; such a tree is just a linear composition of appropriately maximal trees, where "appropriately" means that the composition is itself maximal. Our proof of Corollary 7.13 gives

8.3 Lemma. *Let $\mathcal{M}$ be countable, properly small, and $\Game^{\mathbb{R}}\Pi^1_1$-iterable; then in $L(\mathbb{R})$, there is a unique winning strategy Σ for $\mathcal{G}^*(\mathcal{M},\omega_1,\omega_1)$; moreover, Σ is $\Sigma_1^{L(\mathbb{R})}(\{\mathcal{M}\})$ definable, uniformly in $\mathcal{M}$.*

8.4 Definition. Let $\mathcal{M}$ be countable, properly small, and $\Game^{\mathbb{R}}\Pi^1_1$-iterable. An almost ω-maximal iteration tree on $\mathcal{M}$ is *correct* just in case it is played according to the unique winning strategy for II in $\mathcal{G}^*(\mathcal{M},\omega_1,\omega_1)$. We say that $\mathcal{M}$ *iterates correctly* to $\mathcal{N}$ iff $\mathcal{N}$ is the last model of some correct $\mathcal{T}$ on $\mathcal{M}$ such that the branch $\mathcal{M}$-to-$\mathcal{N}$ of $\mathcal{T}$ has no drops.

From the last lemma we have at once:

8.5 Lemma. *The relations*

$$\{(\mathcal{M},\mathcal{T}) \mid \mathcal{T} \textit{ is a correct tree on } \mathcal{M}\}$$

and

$$\{(\mathcal{M},\mathcal{N}) \mid \mathcal{M} \textit{ iterates correctly to } \mathcal{N}\}$$

on HC *are Σ_1-definable over $L(\mathbb{R})$.*

There may in fact be more than one iteration tree witnessing that $\mathcal{M}$ iterates correctly to $\mathcal{N}$, but our proof of the Dodd-Jensen Lemma, together with the Uniqueness Lemma 8.3 above, easily implies that all such trees give rise to the same iteration map $\pi:\mathcal{M}\to\mathcal{N}$. Because properly small $\mathcal{M}$ satisfy ZF^-, π is fully elementary.

8.6 Definition. A properly small mouse $\mathcal{M}$ is *full* iff whenever $\mathcal{M}$ iterates correctly to $\mathcal{N}$, A is a bounded subset of $\mathrm{On}\cap\mathcal{N}$, and A is ordinal definable over $L(\mathbb{R})$ from the parameter $\mathcal{N}$, then $A\in\mathcal{N}$.

Fullness is clearly Π_1-definable over $L(\mathbb{R})$.[62] Since the $\mathrm{OD}^{L(\mathbb{R})}(\{\mathcal{N}\})$ sets are captured by mice, we can reformulate fullness in purely inner-model-theoretic terms.

8.7 Definition. We write $\mathcal{N}\trianglelefteq^*\mathcal{P}$ iff $\mathcal{N}=\mathcal{J}^{\mathcal{P}}_\eta$ for some cutpoint η of $\mathcal{P}$. In this case, we also call $\mathcal{N}$ a cutpoint of $\mathcal{P}$.

[62] Notice that a premouse which is not $\Game^{\mathbb{R}}\Pi^1_1$-iterable is vacuously full, since there are no correct trees on it. Of course, we are only interested in the full mice which *are* $\Game^{\mathbb{R}}\Pi^1_1$-iterable.

8.8 Lemma. *The following are equivalent:*

1. *$\mathcal{M}$ is full,*
2. *if $\mathcal{M}$ iterates correctly to $\mathcal{N}$, and $\mathcal{N} \trianglelefteq^* \mathcal{P}$, and $\mathcal{P}$ is $\Game^{\mathbb{R}}\Pi^1_1$-iterable above $\mathrm{On} \cap \mathcal{N}$,[63] then $\rho_\omega(\mathcal{P}) \geq \mathrm{On} \cap \mathcal{N}$.*

Proof. To see that $1 \Longrightarrow 2$, notice that the proof of Corollary 7.12 relativizes, and thus if $\mathcal{P}$ and $\mathcal{N}$ are as in clause 2, then $\mathcal{P}$ is $\mathrm{OD}^{L(\mathbb{R})}$ from $\mathcal{N}$ as a parameter.

For the converse, suppose that $\mathcal{N}$ is a correct iterate of $\mathcal{M}$, and let A be a bounded subset of $\lambda := \mathrm{On} \cap \mathcal{N}$ which is $\mathrm{OD}^{L(\mathbb{R})}$ from $\mathcal{N}$. We can modify the K^c construction by starting with $\mathcal{N}$ instead of $(V_\omega, \in, \emptyset, \emptyset)$ as our initial structure, and by adding only extenders with critical point strictly greater than λ. All ω-small structures we produce in such a construction are $\Game^{\mathbb{R}}\Pi^1_1$-iterable above λ, and so by clause 2 no such structure projects strictly below λ. It follows that $\mathcal{N}$ is an initial segment of all structures in the construction; indeed, λ is included in every core we take. Since $\mathcal{N}$ has a largest cardinal, λ is not the critical point of any extender in such a core, so that $\Game^{\mathbb{R}}\Pi^1_1$-iterability above λ is enough for comparison. We therefore get a proper class premouse $M_\omega(\mathcal{N})$ with ω Woodin cardinals which is iterable above λ and has $\mathcal{N}$ as a cutpoint. The proof of Corollary 7.18 relativizes so as to show that $A \in M_\omega(\mathcal{N})$. But by 2, no level of $M_\omega(\mathcal{N})$ projects strictly below λ, and therefore $A \in \mathcal{N}$. ⊣

We can now define our direct limit system. Set

$$\mathcal{F} := \{\mathcal{M} \mid \mathcal{M} \text{ is properly small, } \Game^{\mathbb{R}}\Pi^1_1\text{-iterable, and full}\},$$

and for $\mathcal{M}, \mathcal{N}$ in $\mathcal{F}$, let

$$\mathcal{M} \prec^* \mathcal{N} \iff \exists \mathcal{P}(\mathcal{M} \text{ iterates correctly to } \mathcal{P} \text{ and } \mathcal{P} \trianglelefteq^* \mathcal{N}).$$

The Dodd-Jensen Lemma implies that if $\mathcal{M} \prec^* \mathcal{N}$, then there is a unique $\mathcal{P} \trianglelefteq^* \mathcal{N}$ and a unique fully elementary $\pi : \mathcal{M} \to \mathcal{P}$ which is the iteration map given by some play of $\mathcal{G}^*(\mathcal{M}, \omega_1, \omega_1)$ according to the unique winning strategy for II. (There may be more than one such play giving rise to π.) We let

$$\pi_{\mathcal{M},\mathcal{N}} := \text{unique correct iteration map from } \mathcal{M} \text{ to some } \mathcal{P} \trianglelefteq^* \mathcal{N}.$$

It is clear that $\mathcal{F}$,$\prec^*$, and the function $(\mathcal{M}, \mathcal{N}) \mapsto \pi_{\mathcal{M},\mathcal{N}}$ are $\mathrm{OD}^{L(\mathbb{R})}$.

8.9 Lemma. *The relation $\prec^*$ is transitive; moreover, if $\mathcal{M} \prec^* \mathcal{N} \prec^* \mathcal{P}$, then $\pi_{\mathcal{M},\mathcal{P}} = \pi_{\mathcal{N},\mathcal{P}} \circ \pi_{\mathcal{M},\mathcal{N}}$.*

---

[63] This means that II wins the variant of $\mathcal{W}_\omega(\mathcal{N}, \omega)$ in which I is constrained to play only extenders with critical point above $\mathrm{On} \cap \mathcal{N}$.

Proof. Let $\mathcal{T}$ and $\mathcal{U}$ be correct trees witnessing that $\mathcal{M} \prec^* \mathcal{N}$ and $\mathcal{N} \prec^* \mathcal{P}$ respectively. Let $\mathcal{Q}$ be the last model of $\mathcal{T}$. Since $\mathcal{Q}$ is a cutpoint in $\mathcal{N}$, we can re-arrange $\mathcal{U}$ as an iteration tree $\mathcal{R}$ on $\mathcal{N}$ which uses only extenders from the image of $\mathcal{Q}$, followed by an iteration tree $\mathcal{S}$ on the last model $\mathcal{M}_\alpha^{\mathcal{R}}$ of $\mathcal{R}$ which uses no extenders from $i_{0,\alpha}^{\mathcal{R}}(\mathcal{Q})$. (We leave the details to the reader.) But then $\mathcal{T} \oplus \mathcal{R}$ witnesses that $\mathcal{M} \prec^* \mathcal{P}$. Moreover, the embedding given by $\mathcal{T} \oplus \mathcal{R}$ from $\mathcal{M}$ to its last model is just $i_{0,\alpha}^{\mathcal{R}} \circ \pi_{\mathcal{M},\mathcal{N}}$. Since $i_{0,\alpha}^{\mathcal{R}} = \pi_{\mathcal{N},\mathcal{P}} \restriction \mathcal{Q}$ by construction, the embedding given by $\mathcal{T} \oplus \mathcal{R}$ is $\pi_{\mathcal{N},\mathcal{P}} \circ \pi_{\mathcal{M},\mathcal{N}}$, as desired. ⊣

The Comparison Lemma and fullness imply that $\prec^*$ is directed. For suppose that $\mathcal{M}, \mathcal{N} \in \mathcal{F}$, and let $\mathcal{T}$ and $\mathcal{U}$ be the correct trees on $\mathcal{M}$ and $\mathcal{N}$ constituting their coiteration. Let $\mathcal{P}$ and $\mathcal{Q}$ be their respective last models, and suppose for example that $\mathcal{P} \trianglelefteq^* \mathcal{Q}$. (We can always take one more ultrapower so as to guarantee that $\trianglelefteq^*$, rather than just $\trianglelefteq$, holds between the last models.) From the Comparison Lemma we get that $\mathcal{M}$-to-$\mathcal{P}$ has no drops, so that $\mathcal{M}$ iterates correctly to $\mathcal{P}$. But $\mathcal{M}$ is full, so $\rho_\omega(\mathcal{Q}) \geq \mathrm{On} \cap \mathcal{P}$. Now if $\mathcal{N}$-to-$\mathcal{Q}$ drops, then letting κ be the extender used at the last drop, we have $\rho_\omega(\mathcal{Q}) \leq \kappa < \mathrm{On} \cap \mathcal{P}$. Thus $\mathcal{N}$-to-$\mathcal{Q}$ has no drops, so that $\mathcal{N}$ iterates correctly to $\mathcal{Q}$, and we have $\mathcal{M} \prec^* \mathcal{Q}$ and $\mathcal{N} \prec^* \mathcal{Q}$.

We wish to show that $\prec^*$ is countably directed, and for this it is most convenient to first relate the system $(\mathcal{F}, \prec^*)$ to a natural system $(\mathcal{F}^+, \prec^+)$ of iterates of M_ω.

8.10 Definition. Let Σ_0 be the unique winning strategy for II in the game $\mathcal{G}^*(M_\omega, \omega_1, \omega_1 + 1)$.

We can extend Definition 8.4 from properly small mice to iterates of M_ω in the natural way. In general, let us say that $\mathcal{M}$ *iterates correctly* to $\mathcal{Q}$, or $\mathcal{Q}$ is a *correct iterate* of $\mathcal{M}$, iff there is a unique winning strategy for II in $\mathcal{G}^*(\mathcal{M}, \omega_1, \omega_1 + 1)$, and $\mathcal{Q}$ is the last model of a countable iteration tree $\mathcal{T}$ on $\mathcal{M}$ played according to this strategy such that the branch $\mathcal{M}$-to-$\mathcal{Q}$ of $\mathcal{T}$ does not drop.

8.11 Definition. We call an iteration tree on a premouse $\mathcal{M}$ which satisfies "There is a Woodin cardinal" δ_0*-bounded* if it uses only extenders from the image of $\mathcal{J}_\delta^{\mathcal{M}}$, where δ is the least Woodin cardinal of $\mathcal{M}$.

Thus a δ_0-bounded tree on $\mathcal{M}$ is just one which can be interpreted as a tree on $\mathcal{J}_\delta^{\mathcal{M}}$, where δ is the least Woodin cardinal of $\mathcal{M}$.

8.12 Definition. We set

$$\mathcal{F}^+ = \{\mathcal{Q} \mid M_\omega \text{ iterates correctly to } \mathcal{Q} \text{ via a } \delta_0\text{-bounded tree}\},$$

and for $\mathcal{P}, \mathcal{Q} \in \mathcal{F}^+$, put

$$\mathcal{P} \prec^+ \mathcal{Q} \iff \mathcal{P} \text{ iterates correctly via a } \delta_0\text{-bounded tree to } \mathcal{Q}.$$

In this case, we let

$$\pi^+_{\mathcal{P},\mathcal{Q}} := \text{unique iteration map from } \mathcal{P} \text{ to } \mathcal{Q}.$$

The uniqueness of the iteration map from $\mathcal{P}$ to $\mathcal{Q}$ follows from the Dodd-Jensen Lemma.

The pair $(\mathcal{F}^+, \prec^+)$ is not lightface definable over $L(\mathbb{R})$, since from it we can define M_ω. It does happen to be definable over $L(\mathbb{R})$ from M_ω as a parameter, but this is of no use to us now. The function $(\mathcal{P}, \mathcal{Q}) \mapsto \pi^+_{\mathcal{P},\mathcal{Q}}$ does not even belong to $L(\mathbb{R})$. One can regard the system $(\mathcal{F}, \prec^*)$, with its maps, as an $L(\mathbb{R})$-definable approximation to the direct limit system $(\mathcal{F}^+, \prec^+)$, with its maps. We shall spell this out in more detail momentarily, but first we should verify:

8.13 Lemma. *The relation $\prec^+$ is transitive and countably directed; moreover, if $\mathcal{M} \prec^+ \mathcal{N} \prec^+ \mathcal{Q}$, then $\pi^+_{\mathcal{M},\mathcal{Q}} = \pi^+_{\mathcal{N},\mathcal{Q}} \circ \pi^+_{\mathcal{M},\mathcal{N}}$.*

Proof. Transitivity is obvious because we can compose iterations. (The situation here is a little simpler than it was with $\prec^*$.) The commutativity of the maps is clear.

Let $\mathcal{P}_i \in \mathcal{F}^+$ for all $i \in \omega$. Let $\mathcal{Q}_0 = M_\omega$, and given $\mathcal{Q}_i$, let $\mathcal{Q}_{i+1}$ be the last model of the iteration tree $\mathcal{T}_i$ on $\mathcal{Q}_i$ which results from comparing $\mathcal{Q}_i$ with $\mathcal{P}_i$, using their unique iteration strategies in both cases. Let $\mathcal{U}_i$ be the tree on $\mathcal{P}_i$ in this comparison. Clearly, neither $\mathcal{T}_i$ nor $\mathcal{U}_i$ drops along the branch to its last model, so $\mathcal{Q}_{i+1}$ is a correct iterate of both $\mathcal{Q}_i$ and $\mathcal{P}_i$. Letting $\mathcal{Q}$ be the direct limit of the $\mathcal{Q}_i$, we have that for all i, $\mathcal{Q}$ is a correct iterate of $\mathcal{P}_i$. In order to show $\mathcal{P}_i \prec^+ \mathcal{Q}$ for all i, it is enough to show that all $\mathcal{T}_i$ and $\mathcal{U}_i$ are δ_0-bounded.

Suppose that this is true for all $j < i$. Now we can regard M_ω as an initial segment of $M_\omega^\#$, and the latter is ω-sound and has Σ_1 projectum ω. The iteration strategy Σ_0 is the restriction to M_ω of a winning strategy in $\mathcal{G}^*(M_\omega^\#, \omega_1, \omega_1 + 1)$. Thus $\mathcal{P}_i$ and $\mathcal{Q}_i$ are initial segments of Σ_0-iterates $\mathcal{P}_i^*$ and $\mathcal{Q}_i^*$ of $M_\omega^\#$, and since the iterations are δ_0-bounded, each of $\mathcal{P}_i^*$ and $\mathcal{Q}_i^*$ is Σ_1-generated by the ordinals below its bottom Woodin cardinal. Now let $\mathcal{T}$ and $\mathcal{U}$ be the longest δ_0-bounded initial segments of $\mathcal{T}_i$ and $\mathcal{U}_i$, let $\mathcal{R}$ and $\mathcal{S}$ be their last models, and let $\mathcal{R}^*$ and $\mathcal{S}^*$ be the corresponding iterates of $M_\omega^\#$. Then $\mathcal{R}^*$ and $\mathcal{S}^*$ agree below their common value δ for the least Woodin cardinal (because this least Woodin is a cutpoint in each, and the last models of $\mathcal{T}_i$ and $\mathcal{U}_i$ so agree). Moreover, each is Σ_1-generated by δ, and they have a common iterate $\mathcal{Q}_{i+1}^*$ obtained from the rest of $\mathcal{T}_i$ and $\mathcal{U}_i$, which is above δ. It follows that $\mathcal{R}^* = \mathcal{S}^*$, so that $\mathcal{R} = \mathcal{S} = \mathcal{Q}_{i+1}$, and $\mathcal{T}_i$ and $\mathcal{U}_i$ are δ_0-bounded. $\dashv$

We now relate our two direct limit systems.

8.14 Lemma.

1. *Let $\mathcal{T}$ be an iteration according to Σ_0 of M_ω with last model $\mathcal{Q}$, and suppose that M_ω-to-$\mathcal{Q}$ does not drop. If η is a successor cardinal of $\mathcal{Q}$ below its bottom Woodin cardinal, then $\mathcal{J}_\eta^{\mathcal{Q}}$ is full, and therefore in $\mathcal{F}$.*

2. *Let $\mathcal{P} \in \mathcal{F}$, and let $\mathcal{M}$ be a correct iterate of M_ω; then there is a correct iterate $\mathcal{Q}$ of $\mathcal{M}$, given by a δ_0-bounded iteration tree, such that $\mathcal{P} \prec^* \mathcal{J}_\eta^{\mathcal{Q}}$ for some successor cardinal cutpoint η of $\mathcal{Q}$ below its bottom Woodin cardinal.*

3. *If $\mathcal{P} \prec^+ \mathcal{Q}$, and $\mathcal{M}$ is a cutpoint of $\mathcal{P}$ at some successor cardinal below its bottom Woodin cardinal, and $\mathcal{N} = \pi^+_{\mathcal{P},\mathcal{Q}}(\mathcal{M})$, then $\mathcal{M} \prec^* \mathcal{N}$, and $\pi_{\mathcal{M},\mathcal{N}} = \pi^+_{\mathcal{P},\mathcal{Q}} \restriction \mathcal{M}$.*

Proof. Clause 1 follows easily from Lemma 8.8: suppose that $\mathcal{J}_\eta^{\mathcal{Q}}$ iterates correctly to $\mathcal{N}$, and $\mathcal{N} \trianglelefteq^* \mathcal{P}$, where $\mathcal{P}$ is ω-small and $\Game^{\mathbb{R}}\Pi^1_1$-iterable above $\lambda := \mathrm{On} \cap \mathcal{N}$. We must show $\rho_\omega(\mathcal{P}) \geq \lambda$. Now, since η is a successor cardinal cutpoint of $\mathcal{Q}$, our correct iteration $\mathcal{J}_\eta^{\mathcal{Q}}$-to-$\mathcal{N}$ lifts to an iteration $\mathcal{Q}$-to-$\mathcal{R}$ according to Σ_0; moreover λ is a successor cardinal cutpoint of $\mathcal{R}$. We can now compare $\mathcal{P}$ and $\mathcal{R}$, and the comparison is above λ since it is a cutpoint of each. If $\rho_\omega(\mathcal{P}) < \lambda$, then we must have $\mathcal{P} \trianglelefteq \mathcal{R}$, but this contradicts the fact that λ is a cardinal of $\mathcal{R}$.

For 2, we simply compare $\mathcal{P}$ with $\mathcal{M}$, forming iterations according to the unique (ω, ω_1+1)-iteration strategy on both sides. Since $\mathcal{P}$ is properly small, it must iterate into an initial segment $\mathcal{R}$ of the last model $\mathcal{Q}$ on the $\mathcal{M}$ side, with no dropping from $\mathcal{P}$ to $\mathcal{R}$. Since $\mathcal{P}$ is full, $\mathcal{M}$-to-$\mathcal{Q}$ does not drop. Since $\mathcal{R}$ is properly small and full, it must have the form described.

For 3, notice that the iteration from $\mathcal{P}$ to $\mathcal{Q}$ can be factored so as to give an iteration from $\mathcal{M}$ to $\mathcal{N}$ because $\mathcal{M}$ is a cutpoint in $\mathcal{P}$. The uniqueness of the iteration strategies gives the rest. ⊣

8.15 Definition. We let M_∞ be the direct limit of $(\mathcal{F}, \prec^*)$ under the $\pi_{\mathcal{M},\mathcal{N}}$, and M_∞^+ be the direct limit of $(\mathcal{F}^+, \prec^+)$ under the $\pi^+_{\mathcal{M},\mathcal{N}}$, transitively collapsed in each case.

Since $\prec^+$ is countably directed, M_∞^+ is wellfounded, so we can regard it as transitive. But Lemma 8.14 shows that M_∞ is an initial segment of M_∞^+, so it too is wellfounded. In fact

8.16 Corollary. *Let δ be the least Woodin cardinal of M_∞^+, and let $\kappa < \delta$ be the least cardinal of M_∞^+ which is $<\delta$-strong in M_∞^+; then $M_\infty = \mathcal{J}_\kappa^{M_\infty^+}$.*

Proof. By Lemma 8.14, the set of all $\mathcal{M}$ which are cutpoints of some $\mathcal{Q} \in \mathcal{F}^+$ at a successor cardinal below its bottom Woodin cardinal (and hence below the least cardinal strong to its bottom Woodin) are cofinal in $(\mathcal{F}, \prec^*)$; moreover, the π^+ maps act on these $\mathcal{M}$ the same way that the π maps act. Thus M_∞ is the direct limit of all such $\mathcal{M}$ under the π^+ maps. Clearly, this direct limit is M_∞^+ cut at the sup of all its successor cardinal cutpoints below δ. That sup is just κ. ⊣

We shall now show that the ordinal height of M_∞ is $\underset{\sim}{\delta}^2_1$.

8.17 Definition. Let $\mathcal{M}$ be a premouse, $\varphi(v)$ a Σ_1 formula, and $x \in \mathbb{R}$. We call $\mathcal{M}$ a (φ, x)-*witness* just in case $\mathcal{M}$ has ω Woodin cardinals with supremum λ, and for some set $\mathbb{R}^*$ of reals of a symmetric collapse below λ over $\mathcal{M}$, we have $x \in \mathbb{R}^*$ and $L_\alpha(\mathbb{R}^*) \models \varphi[x]$, where $\alpha = \mathrm{On} \cap \mathcal{M}$.

8.18 Lemma. *Let φ be Σ_1 and $x \in \mathbb{R}$. The following are equivalent:*

1. $L(\mathbb{R}) \models \varphi[x]$,
2. *There is an $(\omega, \omega_1 + 1)$-iterable (φ, x)-witness,*
3. $\exists \mathcal{M} \in \mathcal{F} \exists \beta (\mathcal{J}_\beta^{\mathcal{M}}$ *is a (φ, x)-witness*$)$.

Proof. For $3 \Longrightarrow 2$, notice that $\mathcal{J}_\beta^{\mathcal{M}}$ is $(\omega, \omega_1 + 1)$-iterable, because $\mathcal{M}$ is. For $2 \Longrightarrow 1$, we can easily adapt the proofs of Theorems 7.19 and 7.15 to mice of set size with ω Woodin cardinals. We get, in some generic extension of V, an iterate of our witness $\mathcal{P}$ which has a symmetric collapse of the form $L_\alpha(\mathbb{R}^V)$ such that $L_\alpha(\mathbb{R}^V) \models \varphi[x]$. Since φ is Σ_1, this implies that $L(\mathbb{R}^V) \models \varphi[x]$.

We now prove $1 \Longrightarrow 3$. Let $\mathcal{Q}$ be a correct iterate of M_ω such that x is generic over $\mathcal{Q}$ for the extender algebra at its least Woodin cardinal δ. Now $\mathcal{Q}$ is a (φ, x)-witness by Theorem 7.19, but it is not an initial segment of any $\mathcal{M} \in \mathcal{F}$. We must therefore take some Skolem hulls.

Since φ is Σ_1, we can fix α such that $\mathcal{J}_\alpha^{\mathcal{Q}}$ is a (φ, x)-witness. Let $G_x^{\mathcal{Q}}$ be the generic object on the extender algebra of $\mathcal{Q}$ at δ determined by x. (That is, $[\psi] \in G_x^{\mathcal{Q}}$ iff $x \models \psi$.) We then have some $p \in G_x^{\mathcal{Q}}$ such that

$$\mathcal{J}_\alpha^{\mathcal{Q}} \models \exists \lambda [\lambda \text{ is a limit of Woodins and } p \Vdash (1 \Vdash (L(\mathbb{R}^*) \models \varphi[\check{\dot{x}}]))],$$

where the first forcing is the extender algebra, the second is the symmetric collapse, and $\dot{x}$ is the canonical name for the real determined by the extender algebra generic. This is a Σ_1 fact about p and δ, so we may assume that $\mathcal{J}_\alpha^{\mathcal{Q}}$ is Σ_1-generated by $\delta \cup \{\delta\}$. (The Σ_1 hull of these parameters collapses to an initial segment of $\mathcal{Q}$ by a simple comparison argument. The extender algebra is definable over $\mathcal{J}_\delta^{\mathcal{Q}}$, hence contained in the hull, so that $G_x^{\mathcal{Q}}$ is still generic over the collapse of the hull.)

Now, working in $\mathcal{Q}[x]$, where δ is still a regular cardinal, we can find an η and an elementary submodel $Y \prec \mathcal{J}_\eta^{\mathcal{Q}}[x]$ such that $\delta, \alpha, p, x \in Y$ and $Y \cap \delta \in \delta$. Let N be the transitive collapse of Y, and $\mathcal{P}$ be the image of $\mathcal{J}_\alpha^{\mathcal{Q}}$ under the collapse. Letting $\bar{\delta} = Y \cap \delta$, we have that $\mathcal{P}$ is iterable, Σ_1 projects to $\bar{\delta}$, and agrees with $\mathcal{Q}$ below $\bar{\delta}$. It follows that $\mathcal{P}$ is an initial segment of $\mathcal{J}_\delta^{\mathcal{Q}}$, by comparison, and therefore $\mathcal{P}$ is an initial segment of some $\mathcal{M} \in \mathcal{F}$. Since the property of being a (φ, x)-witness is first-order over $\mathcal{J}_\eta^{\mathcal{Q}}[x]$, we have that $\mathcal{P}$ is a (φ, x)-witness, as desired. ⊣

8.19 Lemma. $\mathrm{On} \cap M_\infty = \underset{\sim}{\delta}_1^2$.

Proof. A direct computation shows that $\mathrm{On} \cap M_\infty \leq \underset{\sim}{\delta}_1^2$. For let $\alpha \in \mathrm{On} \cap M_\infty$, and fix $\mathcal{M} \in \mathcal{F}$ so that $\pi_{\mathcal{M},\infty}(\bar{\alpha}) = \alpha$ for some $\bar{\alpha}$. Let $\mathcal{G} := \{\mathcal{P} \mid \mathcal{M}$ iterates correctly to $\mathcal{P}\}$. Then $\mathcal{G} \subseteq \mathcal{F}$, and one can easily check that $\mathcal{G}$ is $\Delta_1^{L(\mathbb{R})}(\{\mathcal{M}\})$. Also, the relation R is $\Delta_1^{L(\mathbb{R})}(\{\mathcal{M}\})$, where

$$\begin{aligned} &R(\langle \mathcal{P}, \bar{\beta}\rangle, \langle \mathcal{Q}, \bar{\gamma}\rangle) \\ &\quad\iff \quad (\mathcal{P}, \mathcal{Q} \in \mathcal{G} \wedge \bar{\beta} \in \mathrm{On}^{\mathcal{P}} \wedge \bar{\gamma} \in \mathrm{On}^{\mathcal{Q}} \wedge \pi_{\mathcal{P},\infty}(\bar{\beta}) \leq \pi_{\mathcal{Q},\infty}(\bar{\gamma})). \end{aligned}$$

This is because we can check whether $R(\langle \mathcal{P}, \bar{\beta}\rangle, \langle \mathcal{Q}, \bar{\gamma}\rangle)$ by comparing $\mathcal{P}$ with $\mathcal{Q}$, using their unique $\Sigma_1^{L(\mathbb{R})}(\{\mathcal{P}, \mathcal{Q}\})$ iteration strategies. Since every $\beta < \alpha$ is of the form $\pi_{\mathcal{P},\infty}(\bar{\beta})$ for some $\mathcal{P} \in \mathcal{G}$, there is a $\Delta_1^{L(\mathbb{R})}(\{\mathcal{M}\})$ prewellorder of H_{ω_1} of order type at least α. Thus $\alpha \leq \underset{\sim}{\delta}_1^2$.

Now suppose that $\mathrm{On} \cap M_\infty < \underset{\sim}{\delta}_1^2$. Since M_∞ can be coded simply by a subset of $\mathrm{On} \cap M_\infty$, we have by the Coding Lemma [27, Chap. 7] that for some real z, M_∞ is coded by a $\Delta_1^{L(\mathbb{R})}(\{z\})$ set of reals. But Lemma 8.18 implies that the universal $\Sigma_1^{L(\mathbb{R})}$ set of reals is projective in any set of reals coding M_∞, for we have, for all Σ_1 formulae φ and reals x:

$$L(\mathbb{R}) \models \varphi[x] \quad\iff\quad \exists \mathcal{M} \exists \beta \exists \pi (\mathcal{M} \text{ is a } (\varphi, x) \text{ witness and } \pi : \mathcal{M} \to \mathcal{J}_\beta^{M_\infty}).$$

(The left-to-right direction follows at once from $1 \Longrightarrow 3$ of Lemma 8.18, and the right-to-left direction follows from $2 \Longrightarrow 1$ of Lemma 8.18.) This implies that the universal $\Sigma_1^{L(\mathbb{R})}$ set of reals is $\Delta_1^{L(\mathbb{R})}(\{z\})$, a contradiction. ⊣

8.20 Theorem. $\mathrm{HOD} \cap V_{\underset{\sim}{\delta}_1^2} = M_\infty \cap V_{\underset{\sim}{\delta}_1^2}$.

Proof. We have shown that $\mathcal{F}, \prec^*$, and the function $(\mathcal{M}, \mathcal{N}) \mapsto \pi_{\mathcal{M},\mathcal{N}}$ are definable over $L(\mathbb{R})$. It follows that $M_\infty \in \mathrm{HOD}$. It is enough, then, to show that every bounded subset A of $\underset{\sim}{\delta}_1^2$ which is $\mathrm{OD}^{L(\mathbb{R})}$ is in M_∞. (Note here that $\underset{\sim}{\delta}_1^2$ is strongly inaccessible in HOD, by work of Harvey Friedman and Moschovakis.) So fix such an A. By the reflection theorem, we can fix a Σ_1 formula $\varphi(v_0, v_1)$ and an ordinal $\beta < \underset{\sim}{\delta}_1^2$ such that $A \subseteq \beta$, and for all $\alpha < \beta$

$$\alpha \in A \quad\iff\quad L(\mathbb{R}) \models \varphi[\alpha, \beta].$$

Since $M_\infty = \mathcal{J}_{\underset{\sim}{\delta}_1^2}^{M_\infty^+}$, and $\underset{\sim}{\delta}_1^2$ is a cardinal of M_∞^+ by Corollary 8.16, it will be enough to show that $A \in M_\infty^+$. Let λ be the sup of the Woodin cardinals of M_∞^+. By asking what is true in its own symmetric collapse below λ, M_∞^+ will be able to answer membership questions about A. More precisely, let $\bar{\varphi}(u)$ be the Σ_1 formula:

$$\text{“}u \in \mathbb{R} \text{ codes } (\mathcal{N}, \gamma, \delta) \text{ where } \mathcal{N} \in \mathcal{F} \text{ and } \varphi(\pi_{\mathcal{N},\infty}(\gamma), \pi_{\mathcal{N},\infty}(\delta))\text{”}.$$

Let η be a successor cardinal of M_∞ above β, and for each $\alpha < \beta$ let τ_α be a term for a real in the symmetric collapse below λ over M_∞^+ such that for all generic objects H for this collapse

$$\tau_\alpha^H \text{ codes } (\mathcal{J}_\eta^{M_\infty}, \alpha, \beta).$$

The map $\alpha \mapsto \tau_\alpha$, if chosen naturally, is definable over M_∞^+ from η and β. We claim that for all $\alpha < \beta$,

$$\alpha \in A \iff M_\infty^+ \models (1 \Vdash \bar{\varphi}(\tau_\alpha)^{L(\mathbb{R}^*)}).$$

It clearly suffices to prove this claim.

Fix $\alpha < \beta$. By Lemma 8.14, we can find $\mathcal{Q} \in \mathcal{F}^+$ and ordinals $\bar{\eta}$, $\bar{\beta}$, and $\bar{\alpha}$ in $\mathcal{Q}$ such that

$$\pi^+_{\mathcal{Q},\infty}(\langle \bar{\eta}, \bar{\beta}, \bar{\alpha}\rangle) = \langle \eta, \beta, \alpha\rangle.$$

Let $\bar{\tau}_{\bar{\alpha}}$ be definable over $\mathcal{Q}$ from $\bar{\eta}$, $\bar{\beta}$, and $\bar{\alpha}$ the way τ_α was from η, β, and α over M_∞^+, so that for any H generic over $\mathcal{Q}$ for the symmetric collapse below the sup $\bar{\lambda}$ of its Woodin cardinals, $\bar{\tau}^H_{\bar{\alpha}}$ is a real coding $(\mathcal{J}^{\mathcal{Q}}_{\bar{\eta}}, \bar{\alpha}, \bar{\beta})$. We have

$$\begin{aligned}
\alpha \in A \quad &\iff \quad L(\mathbb{R}) \models \varphi[\alpha, \beta]\\
&\iff \quad \forall H (H \text{ is } \mathrm{Col}(\omega, <\bar{\lambda}), \mathcal{Q}\text{-generic } \Rightarrow L(\mathbb{R}^*_H) \models \bar{\varphi}(\bar{\tau}^H_{\bar{\alpha}}))\\
&\iff \quad \mathcal{Q} \models (1 \Vdash \bar{\varphi}(\bar{\tau}_{\bar{\alpha}})^{L(\mathbb{R}^*)})\\
&\iff \quad M_\infty^+ \models (1 \Vdash \bar{\varphi}(\tau_\alpha)^{L(\mathbb{R}^*)}).
\end{aligned}$$

The second equivalence above follows from the correctness of $L(\mathbb{R}^*_H)$ and the fact that $\pi_{\mathcal{M},\infty}(\langle \bar{\alpha}, \bar{\beta}\rangle) = \langle \alpha, \beta\rangle$, for $\mathcal{M} = \mathcal{J}^{\mathcal{Q}}_{\bar{\eta}}$; this is true because the π and π^+ maps agree.

The displayed equivalences contain our claim. This completes the proof. $\dashv$

A different proof of Theorem 8.20 is sketched in [41]. One shows that in $L[M_\infty]$ there is a tree T on $\omega \times \underset{\sim}{\delta}^2_1$ projecting to the universal $\Sigma_1^{L(\mathbb{R})}$ set of reals, and that this tree is enough like the tree of a $\Sigma_1^{L(\mathbb{R})}$ scale that, by arguments of Martin, Becker, and Kechris [4], $\mathrm{HOD} \cap V_{\underset{\sim}{\delta}^2_1} \subseteq L[T]$. The tree T attempts to verify $\varphi(x)$ by building a (φ, x)-witness and embedding it into M_∞. In this version of the proof, the Dodd-Jensen Lemma corresponds nicely to the lower semi-continuity of a certain semi-scale.

Assuming sufficient determinacy, and given a pointclass Γ which resembles Π^1_1 in a certain technical sense, Moschovakis has defined a submodel of HOD corresponding to Γ-definability which he calls H_Γ. See [27, 8G]. Becker and Kechris show in [4] that $H_\Gamma = L[T]$, whenever T is the tree of a Γ-scale on a universal Γ set. The argument of the last paragraph actually shows that $L[M_\infty] = H_\Gamma$, where $\Gamma = \Sigma_1^{L(\mathbb{R})}$. The argument generalizes to many other Γ, with M_∞ replaced by a direct limit of mice whose iteration strategies and degree of correctness match Γ appropriately. This gives

8.21 Theorem. *Assume $\mathsf{AD}^{L(\mathbb{R})}$, and let Γ be either Π^1_n for n odd, or the pointclass $\Sigma_1^{L(\mathbb{R})}$; then H_Γ is an extender model.*

The theorem probably holds for all Γ resembling Π^1_1, but this has not been fully proved.

One immediate consequence of Theorem 8.20 is

8.22 Corollary. $\mathrm{HOD} \models \mathsf{GCH}$.

Proof. By Theorem 8.20, GCH holds in HOD at all $\alpha < \underset{\sim}{\delta}^2_1$. But Woodin [13] has shown that $\underset{\sim}{\delta}^2_1$ is $<\Theta$-strong in HOD, and thus GCH holds in HOD at all $\alpha < \Theta$. Since $\mathrm{HOD} = L(P)$ for some $P \subseteq \Theta$,[64] GCH holds in HOD at all α. $\dashv$

We emphasize that $\mathrm{HOD} = \mathrm{HOD}^{L(\mathbb{R})}$ in the statement of Corollary 8.22, and that $\mathsf{AD}^{L(\mathbb{R})}$ is a tacit hypothesis there.[65] Whether $\mathsf{AD}^{L(\mathbb{R})}$ implies that GCH holds in HOD was open for some time, and various partial results were obtained using the methods of "neo-classical" descriptive set theory, such as games and scales.[66] Our proof of Theorem 8.20 is evidence of what inner model theory can contribute to this mix. One gets not just GCH, of course, but the other consequences of fine structure theory, such as $\diamondsuit$ and $\square$.

It is natural to ask whether the full $\mathrm{HOD}^{L(\mathbb{R})}$ is a core model. Building on the proof of Theorem 8.20, Woodin has shown that this is essentially, but not literally, the case. We shall state Woodin's results, although it is beyond the scope of this chapter to prove them. The first is

8.23 Theorem (Woodin). *$M^+_\infty \subseteq \mathrm{HOD}$; moreover, the least Woodin cardinal of M^+_∞ is Θ, and $V_\Theta \cap \mathrm{HOD} = V_\Theta \cap M^+_\infty$.*

Since the full HOD is of the form $L(P)$ for some $P \subseteq \Theta$, M^+_∞ is not far from the full HOD. What is missing can be represented in inner-model-theoretic terms. Let X be the class of all δ_0-bounded iteration trees on M^+_∞ which belong to M^+_∞ and are satisfied to have cardinality strictly less than the sup of the Woodin cardinals in M^+_∞. There is a unique iteration strategy for M^+_∞; let us call it Σ.[67] Let $\Sigma^* := \{(\mathcal{T}, \alpha) \mid \mathcal{T} \in X$ and $\mathcal{T}$ is according to Σ and $\mathrm{lh}(\mathcal{T})$ is a limit ordinal, and $\alpha \in \Sigma(\mathcal{T})\}$. We then have

8.24 Theorem (Woodin). $\mathrm{HOD} = M^+_\infty[\Sigma^*]$.

Woodin has obtained results on HOD^M for M a model of AD larger than $L(\mathbb{R})$; for example, the Mouse Set Conjecture implies that $\mathrm{HOD}^M {\restriction} \Theta^M_0$ is an extender model. (Here Θ_0 is the supremum of the lengths of prewellorders of $\mathbb{R}$ which are ordinal definable from a real. If $V = L(\mathbb{R})$, then $\Theta_0 = \Theta$.) Woodin has also obtained an analysis of the full HOD^M analogous to that in

[64] This is another result of Woodin; P is a version of the Vopenka algebra which can add $\mathbb{R}$ to HOD.

[65] The proof we have given used a bit more, namely, that $M^\#_\omega$ exists and is $(\omega, \omega_1 + 1)$-iterable in $V^{\mathrm{Col}(\omega,\mathbb{R})}$. The proof can be made to work under the weaker hypothesis $\mathsf{AD}^{L(\mathbb{R})}$, however. The key is to prove the existence of mouse-witnesses, as stated in Lemma 8.18, assuming only $\mathsf{AD}^{L(\mathbb{R})}$. This is a result of Woodin. The method behind the original proof is described in [13]; there is another proof using the core model induction method.

[66] For example, Becker [3] showed that GCH holds in HOD at all $\alpha < \omega^V_1$.

[67] Granted ω Woodins plus a measurable above in V, Σ_0 prolongs uniquely to trees in $V^{\mathrm{Col}(\omega,\mathbb{R})}$.

Theorem 8.24. See [13, §8] for something on these results, on local forms of Theorem 8.24, and on open questions in the area.

We conclude with some applications of these results on HOD.

8.25 Lemma. *Let $\kappa < \Theta$ and suppose that* HOD $\models \kappa$ *is regular; then exactly one of the following holds:*

1. HOD $\models \kappa$ *is measurable,*

2. $\mathrm{cf}^{L(\mathbb{R})}(\kappa) = \omega$.

Proof. Let $\mathcal{Q} \in \mathcal{F}^+$ and $\bar{\kappa} \in \mathcal{Q}$ be such that $\pi^+_{\mathcal{Q},\infty}(\bar{\kappa}) = \kappa$. Thus $\mathcal{Q} \models$ $\bar{\kappa}$ is regular.

Suppose first that $\bar{\kappa}$ is not measurable in $\mathcal{Q}$. Now since $\pi^+_{\mathcal{Q},\infty}$ is essentially an iteration map, it is continuous at all regular, non-measurable cardinals of $\mathcal{Q}$. (In $V^{\mathrm{Col}(\omega,\mathbb{R})}$ we can find a $\prec^+$-increasing ω sequence starting with $\mathcal{Q}$ and cofinal in $\prec^+$. The map $\pi^+_{\mathcal{Q},\infty}$ is just the iteration map coming from composing iteration trees witnessing the $\prec^+$ relations along this sequence. So $\pi^+_{\mathcal{Q},\infty}$ is an iteration map in $V^{\mathrm{Col}(\omega,\mathbb{R})}$, which is good enough.) In particular, $\pi^+_{\mathcal{Q},\infty}$"$\bar{\kappa}$ is cofinal in κ. Since $\bar{\kappa}$ is below the least Woodin cardinal of $\mathcal{Q}$ by Theorem 8.23, and hence countable, $\mathrm{cf}^V(\kappa) = \omega$. But clearly, V and $L(\mathbb{R})$ have the same ω-sequences of ordinals $< \mu$, whenever $\mu < \Theta$. Thus $\mathrm{cf}^{L(\mathbb{R})}(\kappa) = \omega$. Note also that we have in this case that κ is not measurable in HOD.

Suppose next that $\bar{\kappa}$ is measurable in $\mathcal{Q}$. It is clear then that κ is measurable in HOD, and we need only show that $\mathrm{cf}^V(\kappa) > \omega$. Let X be a countable subset of κ. By the countable directedness of $\prec^+$, we can find an $\mathcal{R} \in \mathcal{F}^+$ such that $\mathcal{Q} \prec^+ \mathcal{R}$ and $X \subseteq \mathrm{dom}(\pi^+_{\mathcal{R},\infty})$. Let $\check{\kappa} = \pi^+_{\mathcal{Q},\mathcal{R}}(\bar{\kappa})$, and let $\mathcal{S}$ be the ultrapower of $\mathcal{R}$ by some normal measure on $\check{\kappa}$. Then $\mathcal{R} \prec^+ \mathcal{S}$, and it is easy to see that $X \subseteq \pi^+_{\mathcal{S},\infty}(\check{\kappa}) < \kappa$, so that X is bounded in κ, as desired. ⊣

We remark that the restriction of Lemma 8.25 to ordinals $\kappa < \underset{\sim}{\delta}^2_1$ requires only Theorem 8.20, rather than the full Theorem 8.23.

It follows from Lemma 8.25 that all successor cardinals of HOD below Θ have cofinality ω in $L(\mathbb{R})$, or equivalently, V. This is also true if we replace HOD by HOD_x, the sets hereditarily ordinal definable over $L(\mathbb{R})$ from x, for x a real. This is because our results relativize routinely to arbitrary reals x; we simply extend the notion of mouse by requiring that x be put in $\mathcal{J}^{\vec{E}}_0(x)$. The relativization of our dichotomy Lemma 8.25 gives the following result, known as the "boldface GCH" for $L(\mathbb{R})$.

8.26 Theorem. *Assume* AD *and* $V = L(\mathbb{R})$*; then for any* $\kappa < \Theta$*, every wellordered family of subsets of* κ *has cardinality at most* κ.

Proof. If not, we have some $A \subseteq \kappa^+$ which codes up a sequence of κ^+ distinct subsets of κ. Since $V = L(\mathbb{R})$, we can find a real x such that $A \in \mathrm{HOD}_x$. We have just observed that $(\kappa^+)^{\mathrm{HOD}_x} < \kappa^+$, by the relativization of our dichotomy Lemma 8.25 to x. But then A witnesses that GCH fails in HOD_x, contrary to the relativized version of Corollary 8.22. ⊣

Although we have quoted Corollary 8.22 in our proof of Theorem 8.26, we really only need Theorem 8.20. This is because "the boldface GCH fails at κ" is a $\Sigma_1^{L(\mathbb{R})}$ assertion about κ. Since $L_{\underset{\sim}{\delta}^2_1}(\mathbb{R})$ is a Σ_1 elementary substructure of $L(\mathbb{R})$, if the boldface GCH fails at some κ, it fails at some $\kappa < \underset{\sim}{\delta}^2_1$. But we can use Theorem 8.20 in the proof of Theorem 8.26 to see that this is not the case.

Finally, if $\kappa < \Theta$ is regular in $L(\mathbb{R})$, then by our dichotomy result, κ is measurable in HOD, and in fact, κ is measurable in HOD_x for all reals x. We can put the order zero measures on κ from the various HOD_x together, and we obtain:

8.27 Theorem. *Assume* AD *and* $V = L(\mathbb{R})$*; then for any regular* $\kappa < \Theta$*, the* ω*-closed unbounded filter on* κ *is a* κ*-complete, normal ultrafilter on* κ*. Thus all regular cardinals below* Θ *are measurable.*

Proof. For any real x, let μ_x be the order zero measure on κ of HOD_x, that is, the unique measure giving the set of measurable cardinals measure zero. There is such a measure by Lemma 8.25; it is unique because HOD_x is a core model. It will be enough to show that there is an ω-closed, unbounded set C which generates μ_x, in the sense that for all $A \subseteq \kappa$ such that $A \in \mathrm{HOD}_x$,

$$A \in \mu_x \quad \Longrightarrow \quad \exists \alpha < \kappa (C \setminus \alpha \subseteq A).$$

For this implies that the union over x of the μ_x is just the ω-closed unbounded filter on κ. Since every $A \subseteq \kappa$ is in some HOD_x, this union is an ultrafilter. Since every $f : \kappa \to \kappa$ is in some HOD_x, that ultrafilter is normal, and hence κ-complete.

We now construct the desired generating set for μ_x. Let us assume $x = 0$, so that we can use our earlier notation for the direct limit system giving $\mathrm{HOD}_x = \mathrm{HOD}$; the general case is only notationally different. Fix $\mathcal{Q} \in \mathcal{F}^+$ such that $\kappa \in \mathrm{ran}(\pi^+_{\mathcal{Q},\infty})$. Let

$$C := \{\alpha \mid \mathrm{cf}(\alpha) = \omega \text{ and } \mathrm{Hull}^{M^+_\infty}(\alpha \cup \mathrm{ran}(\pi^+_{\mathcal{Q},\infty})) \cap \kappa \subseteq \alpha\},$$

where the hull in question is the "uncollapsed" set of all points definable over M^+_∞ from parameters in $\mathrm{ran}(\pi^+_{\mathcal{Q},\infty})$ and ordinals $< \alpha$. Clearly, C is ω-closed and unbounded in κ. To see that C works, fix $A \in \mu_x = \mu_0$.

For any $\mathcal{S}$ such that $\mathcal{Q} \prec^+ \mathcal{S}$, let

$$\kappa(\mathcal{S}) := \text{ unique } \nu \in \mathcal{S} \text{ such that } \pi^+_{\mathcal{S},\infty}(\nu) = \kappa.$$

Fix $\mathcal{R}$ such that $\mathcal{Q} \prec^+ \mathcal{R}$ and $A \in \mathrm{ran}(\pi^+_{\mathcal{R},\infty})$, and for $\mathcal{S}$ such that $\mathcal{R} \prec^+ \mathcal{S}$ put

$$A(\mathcal{S}) := \text{ unique } B \in \mathcal{S} \text{ such that } \pi^+_{\mathcal{S},\infty}(B) = A.$$

We shall show that

$$C \setminus \sup(\mathrm{ran}(\pi^+_{\mathcal{R},\infty}) \cap \kappa) \subseteq A,$$

which will then finish the proof.

We need the following general fact about iterated ultrapower constructions.

1 Claim. *If $g \in \mathcal{R}$ and $g : [\kappa(\mathcal{R})]^{<\omega} \to \kappa(\mathcal{R})$, then there is a function $f \in \mathcal{Q}$ such that $g = \pi^+_{\mathcal{Q},\mathcal{R}}(f)(b)$ for some finite $b \subseteq \kappa(\mathcal{R})$.*

Proof. Let $\mathcal{T}$ be an iteration tree on $\mathcal{Q}$ with last model $\mathcal{R}$. One can show by an easy induction that if $\mathcal{R}^*$ is on the branch of $\mathcal{T}$ leading to $\mathcal{R}$, then the claim holds with $\mathcal{R}^*$ replacing $\mathcal{R}$. ⊣

Because our mice do not reach superstrong cardinals, we also have

2 Claim. *If $\mathcal{M}$ is a premouse, E is on the $\mathcal{M}$-sequence, $\mathrm{crit}(E) = \kappa$, and $i : \mathcal{M} \to \mathrm{Ult}_0(\mathcal{M}, E)$ is the canonical embedding, then $i(\kappa) = \sup\{i(f)(\kappa) \mid f : \kappa \to \kappa \wedge f \in \mathcal{M}\}$.*

Proof. Let λ be the sup in question. Clearly, $\lambda \leq i(\kappa)$, so suppose that $\lambda < i(\kappa)$ toward contradiction. Let $\nu = \nu(E)$.

Suppose that $\nu \leq \lambda$. Let $a \subseteq \nu$ and g be such that $\lambda = i(g)(a)$. Let h be such that $a \subseteq i(h)(\kappa)$. Now define $f : \kappa \to \kappa$ by

$$f(\alpha) := \sup\{g(u) \mid u \in [h(\alpha)]^{|a|}\}.$$

Then clearly, $\lambda \leq i(f)(\kappa)$, a contradiction. Therefore $\lambda < \nu$.

Arguing as in the last paragraph, we get that $i(g)(a) < \lambda$ for all finite $a \subseteq \lambda$ and $g : [\kappa]^{|a|} \to \kappa$. This means that $\lambda = j(\kappa)$, where $j : \mathcal{M} \to \mathrm{Ult}_0(\mathcal{M}, E{\restriction}\lambda)$ is the canonical embedding. But the initial segment condition on premice implies that the trivial completion E^* of $E{\restriction}\lambda$ is on the sequence of some premouse. Since $i_{E^*}(\kappa) < \mathrm{lh}(E^*)$, we do not allow such "long extenders" in a fine extender sequence, so this is a contradiction. ⊣

Now fix any $\alpha \in C \setminus \sup(\mathrm{ran}(\pi^+_{\mathcal{R},\infty}) \cap \kappa)$. Fix any $\mathcal{B}^* \in \mathcal{F}^+$ such that $\alpha \in \mathrm{ran}(\pi^+_{\mathcal{B}^*,\infty})$, and let $\mathcal{T}$ be the ω-maximal iteration tree on $\mathcal{R}$ which results from the coiteration of $\mathcal{B}^*$ with $\mathcal{R}$, using Σ_0 on both sides, and let $\mathcal{B}$ be the last model of $\mathcal{T}$. Since neither side drops, $\mathcal{B} \in \mathcal{F}^+$ and $\alpha \in \mathrm{ran}(\pi^+_{\mathcal{B},\infty})$; say

$$\alpha = \pi^+_{\mathcal{B},\infty}(\bar{\alpha}).$$

It will be enough to show that $\bar{\alpha} \in A(\mathcal{B})$.

Let us look closely at the tree $\mathcal{T}$ leading from $\mathcal{R}$ to $\mathcal{B}$. We use $\mathcal{M}_\xi, E_\xi$, and $i_{\xi,\gamma}$ for the models, extenders, and embeddings of $\mathcal{T}$. Let $\mathcal{B} = \mathcal{M}_\eta$. Now $i_{0,\eta}(\kappa(\mathcal{R})) = \kappa(\mathcal{B}) > \bar{\alpha}$, so we can set

$$\xi := \text{ least } \nu \in [0,\eta]_T \text{ such that } i_{0,\nu}(\kappa(\mathcal{R})) > \bar{\alpha}.$$

Note here that $\kappa(\mathcal{R}) \le \bar{\alpha}$, so that $\xi > 0$; this is because if $\gamma < \kappa(\mathcal{R})$, then $\pi^+_{\mathcal{R},\infty}(\gamma) < \alpha$, so $\pi^+_{\mathcal{R},\mathcal{B}}(\gamma) < \bar{\alpha}$, so $\gamma < \bar{\alpha}$.

Let $(\nu+1)\,T\,\xi$; we claim that $\mathrm{lh}(E_\nu) < \bar{\alpha}$. For letting $\beta = \mathrm{pred}_T(\nu+1)$, we have $\mathrm{crit}(E_\nu) = \mathrm{crit}(i_{\beta,\xi})$ because $\mathcal{T}$ is ω-maximal, and $\mathrm{crit}(i_{\beta,\xi}) \le \kappa(\mathcal{M}_\beta)$ by the minimality of ξ. But then $\mathrm{lh}(E_\nu) < i_{0,\nu+1}(\kappa(\mathcal{R})) \le \bar{\alpha}$ by the minimality of ξ.

It follows that ξ is a successor ordinal, for otherwise, since $\bar{\alpha} < i_{0,\xi}(\kappa(\mathcal{R}))$, we would get that $\bar{\alpha} = i_{0,\xi}(g)(a)$ for some $a \subseteq \mathrm{crit}(i_{\xi,\eta}) \cap \bar{\alpha}$ finite and $g : [\kappa(\mathcal{R})]^{|a|} \to \kappa(\mathcal{R})$. (We get $a \subseteq \mathrm{crit}(i_{\xi,\eta})$ because $\mathcal{T}$ is ω-maximal, and $a \subseteq \bar{\alpha}$ from the preceding paragraph and the assumption that ξ is a limit ordinal.) But by our first claim, we have $g = \pi^+_{\mathcal{Q},\mathcal{R}}(f)(b)$ for some $f \in \mathcal{Q}$ and $b \subseteq \kappa(\mathcal{R})$. We then have that

$$i_{\xi,\eta}(\bar{\alpha}) = i_{\xi,\eta}(i_{0,\xi}(g)(a)) = i_{0,\eta}(g)(a) = \pi^+_{\mathcal{Q},\mathcal{B}}(f)(\pi^+_{\mathcal{R},\mathcal{B}}(b))(a).$$

Since $\bar{\alpha} \le i_{\xi,\eta}(\bar{\alpha})$, we can apply $\pi^+_{\mathcal{B},\infty}$ to the identity above and obtain

$$\alpha \le \pi^+_{\mathcal{Q},\infty}(f)(\pi^+_{\mathcal{R},\infty}(b))(\pi^+_{\mathcal{B},\infty}(a)).$$

Now $\pi^+_{\mathcal{R},\infty}(b) \subseteq \alpha$ because we chose α as large as we did, and $\pi^+_{\mathcal{B},\infty}(a) \subseteq \alpha$ because $a \subseteq \bar{\alpha}$. Thus the ordinal named on the right side of the line just displayed witnesses that $\alpha \notin C$. This is a contradiction, and hence ξ is a successor ordinal.

Let $\xi = \gamma + 1$, $E = E_\gamma$, and $\beta = \mathrm{pred}_T(\xi)$. If $\nu(E) \le \bar{\alpha}$, then we get the same contradiction we got in the last paragraph, so we have $\nu(E) > \bar{\alpha}$. By the minimality of ξ, $\mathrm{crit}(E) \le \kappa(\mathcal{M}_\beta)$. We claim that $\mathrm{crit}(E) = \bar{\alpha}$. This is true because otherwise Claim 2 gives some $h : \kappa(\mathcal{M}_\beta) \to \kappa(\mathcal{M}_\beta)$ such that $\bar{\alpha} < i_{\beta,\xi}(h)(c)$, where $c = \{\mathrm{crit}(E)\} \subseteq \bar{\alpha}$. One can then proceed to a contradiction as in the last paragraph: represent h as $i_{0,\beta}(g)(d)$ where $d \subseteq \mathrm{crit}(E)$, so that $\bar{\alpha} = i_{0,\xi}(g)(a)$, where $a := c \cup d \subseteq \mathrm{crit}(i_{\xi,\eta}) \cap \bar{\alpha}$. Then let f, b be such that $\pi^+_{\mathcal{Q},\mathcal{R}}(f) = g$ and $b \subseteq \kappa(\mathcal{R})$, etc.

Since $\kappa(\mathcal{M}_\beta) \le \bar{\alpha}$ by the minimality of ξ, we have $\kappa(\mathcal{M}_\beta) = \mathrm{crit}(E) = \bar{\alpha}$. Now $\bar{\alpha}$ cannot be measurable in $\mathcal{M}_\xi = \mathrm{Ult}(\mathcal{M}_\beta, E)$, since then $\alpha = \pi^+_{\mathcal{B},\infty}(\bar{\alpha}) = \pi^+_{\mathcal{B},\infty}(i_{\xi,\eta}(\bar{\alpha}))$ is measurable in HOD. Since $\mathrm{cf}(\alpha) = \omega$, our dichotomy Lemma 8.25 rules this out. It follows that E is the order zero measure on $\kappa(\mathcal{M}_\gamma)$, and since using the order zero measure cannot move generators, that $\beta = \gamma$. We have then that $A(\mathcal{M}_\beta) \in E_a$, for $a = \{\kappa(\mathcal{M}_\beta)\}$, so $\bar{\alpha} = \kappa(\mathcal{M}_\beta) \in A(\mathcal{M}_\xi)$, so $\bar{\alpha} \in A(\mathcal{B})$, so $\alpha \in A$, as desired. ⊣

We remark that, once again, the negation of Theorem 8.27 is a Σ_1 statement about $L(\mathbb{R})$ by the Coding Lemma, so that if Theorem 8.27 fails, it fails below $\underset{\sim}{\delta}^2_1$. Therefore, we really needed only Theorem 8.20 for its proof. It is also worth noting that Theorems 8.26 and 8.27 make no mention of mice, or even HOD, in their statements.

1. Introduction

The subject of this chapter is core model theory at a level where it involves iteration trees. Our toolbox includes a list of fundamental theorems that set theorists can use off the shelf in applications; see Sect. 3. It also contains a catalog of applications of this sort of core model theory; see Sect. 5. The odd sections have no proofs and are basically independent of the even sections. For those interested in the nuts and bolts of core model theory, we offer a guide to the monograph *The Core Model Iterability Problem* [42] by John Steel in Sect. 2. We also provide an outline of the paper *The covering lemma up to a Woodin cardinal* by William Mitchell, Steel and the author [21] in Sect. 4.

What developed into the theory of core models began in earnest with theorems of Ronald Jensen L under the hypothesis that $0^{\#}$ does not exist. Jensen showed that if $0^{\#}$ does not exist, then L is the canonical core model, which is written $K = L$. He also showed that if $0^{\#}$ exists but $0^{\#\#}$ does not exist, then $K = L[0^{\#}]$ is the canonical core model. In general, K^V is the canonical core model (if there is one) whereas W is a core model if $W = K^M$ where M is a transitive class model of ZFC. Unfortunately, we must ask the reader to pay close attention to articles in the sense of grammar.

Whether or not it is possible to give a definition of K that allows us to make sense of K^M for all M is unknown. Up until recently, for those M for which K^M has been defined, K^M has turned out to be an extender model. Backing up slightly, recall that the existence of $0^{\#}$ is equivalent to the existence of an ordinal κ and an ultrafilter F over $\wp(\kappa) \cap L$ that gives rise to a non-trivial elementary embedding from L to itself. *Large cardinal axioms* such as the existence of $0^{\#}$ can all be phrased in terms of the existence of filters or systems of filters. Some of these systems are known as *extenders.* A *model* is a transitive set or proper class transitive model of ZFC. *Extender models* are models of the form J^E_Ω where $\Omega \le \mathrm{On}$, E is a sequence of length Ω and E_α is an extender for each $\alpha < \Omega$.[1]

Statements asserting that certain models with large cardinals do not exist are called *anti-large cardinal hypotheses.* Instead of making this precise, we list the four examples most relevant to our introduction.

- $0^{\#}$ does not exist.
- There is no proper class model with a measurable cardinal.
- There is no proper class model with a measurable cardinal κ with Mitchell order $o(\kappa) = \kappa^{++}$.
- There is no proper class model with a Woodin cardinal.

[1] Is every core model an extender model? Since we do not know how to define K in the abstract, it is impossible to answer this question. There are models that are not extender models that most likely will be accepted as core models but these are beyond the scope of this introduction.

For the last three examples, it would be equivalent to replace “model” by “extender model” although this is not obvious.

Much of core model theory deals with generalizations of Jensen’s theorems about L. The core model theorist adopts an anti-large cardinal hypothesis, possibly for the sake of obtaining a contradiction. Then he defines K and shows that K has many of the same useful properties that L has if $0^{\#}$ does not exist. With some exceptions, these properties fall into the following categories.

- Fine structure with the consequence, for example, that GCH and combinatorial principles such as $\diamondsuit$ and $\Box$ hold in K.

- Universality with the consequence, for example, that the existence of certain extender models is absolute to K.

- Maximality with the consequence, for example, that certain large cardinal properties of κ are downward absolute to K.

- Definability in a way that makes K absolute to set forcing extensions.

- Covering with the consequence, for example, that K computes successors of singular cardinals correctly.

Often, such properties of K are used in elaborate proofs by contradiction. In order to prove that a principle P implies the existence of a model with large cardinal C, one may assume that there is no model of C and use P to show that one of the basic properties of K fails. When this accomplished, it follows that the large cardinal consistency strength of P is at least C.

Dodd and Jensen developed the theory of K under the anti-large cardinal hypothesis that there is no proper class model with a measurable cardinal. Mitchell did this under the hypothesis that there is no proper class model with a measurable cardinal κ of order κ^{++}. Steel did this under the hypothesis that there is no proper class model with a Woodin cardinal except that he added a technical hypothesis, which we discuss momentarily.

It is important to emphasize that we do not know how to define K without an anti-large cardinal hypothesis. We do not refer to the Dodd-Jensen, Mitchell or Steel core model without the corresponding anti-large cardinal hypothesis. It is also important to know that the various definitions of K are consistent with each other. For example, if there is no transitive class model with a measurable cardinal, then the Dodd-Jensen, Mitchell and Steel definitions of K coincide. Quite reasonably, if $0^{\#}$ does not exist, then $K = L$ under all three definitions.

For all but the last section of this paper we assume:

Anti-Large Cardinal Hypothesis. *There is no proper class model with a Woodin cardinal.*

From what we said about the core model theories predating Steel's, the reader might expect that we could go straight into a discussion of K. But it is not known if the theory of K can be developed under this anti-large cardinal hypothesis alone. Following Steel, we add:

Technical Hypothesis. *Ω is a measurable cardinal and U is a normal measure over Ω.*

This means that U is a non-principal Ω-complete normal ultrafilter on $\wp(\Omega)$. Except in the last section, we also assume this Technical Hypothesis throughout this paper. Of course, by adding the Technical Hypothesis to ZFC we obtain a stronger theory. But, in this setting, it is not much stronger as measurable cardinals are much weaker than Woodin cardinals.[2]

The author thanks Paul Larson, Itay Neeman, Ralf Schindler, John Steel, Stuart Zoble and the anonymous referee for their help.

2. Basic Theory of K

2.1. Second-Order Definition of K

All of the results and proofs in Sects. 2.1 and 2.2 are due to Steel and come from [42]. But we only assume that the reader is familiar with [41] through the theory of countably certified construction.[3] Recall from [41, §6] that a countably certified construction is a sequence of premice $\langle \mathcal{N}_\alpha \mid \alpha \leq \Omega \rangle$ where either

$$\mathcal{N}_{\alpha+1} = \mathrm{rud}(\mathfrak{C}(\mathcal{N}_\alpha))$$

or

$$\mathcal{N}_{\alpha+1} = \mathrm{rud}(\mathfrak{C}(\mathcal{N}_\alpha)^\frown \langle F \rangle),$$

where the second option (adding an extender) is permitted if

$$\mathfrak{C}(\mathcal{N}_\alpha)^\frown \langle F \rangle$$

is a countably certified mouse. When β is a limit ordinal, we define

$$\mathcal{N}_\beta = \liminf \langle \mathcal{N}_\alpha \mid \alpha < \beta \rangle.$$

The gist of [41, §6] as it applies to us is that the following statements hold for all $\gamma \leq \Omega$.

---

[2] In the Fall of 2007, Jensen and Steel found a way around the Technical Hypothesis. Their new idea does not supersede the core model theory described in this chapter; rather, it is an additional layer on top of what we are about to present.

[3] Countably certified constructions are called *K^c-constructions* in [41]. There, K^c-constructions are studied in generality before a particular maximal K^c-construction

$$\langle \mathcal{N}_\alpha \mid \alpha \leq \Omega \rangle$$

is fixed, at which point K^c is defined to be $\mathcal{N}_\Omega$. The terminology here is slightly different in this respect, and so is the definition of K^c.

1. $\mathcal{N}_\gamma$ is a 1-small premouse. In other words, no initial segment of $\mathcal{N}_\gamma$ has the first-order properties of a sharp for an inner model with one Woodin cardinal.

2. If $\mathcal{P}$ is a countable premouse that embeds into $\mathcal{N}_\gamma$, then $\mathcal{P}$ is ω_1+1 iterable.

3. Let $\alpha<\gamma$. Suppose that $\kappa \le \rho_\omega^{\mathcal{N}_\beta}$ for all β such that $\alpha<\beta<\gamma$. Then $\mathcal{N}_\alpha$ and $\mathcal{N}_\gamma$ agree below $(\kappa^+)^{\mathcal{N}_\alpha}$.

The proof of clause 1 uses our Anti-Large Cardinal Hypothesis. Countable certificates are used in the proof of clause 2. Clause 3 implies that $\mathcal{N}_\Omega$ has height Ω. Another important fact that we revisit in this paper is Theorem 6.19 of [41], which implies that if $\langle \mathcal{N}_\alpha \mid \alpha \le \Omega\rangle$ is a maximal countably certified construction, then $\mathcal{N}_\Omega$ computes κ^+ correctly for U almost all $\kappa<\Omega$. In this context, *maximal* means that at all successor stages of the construction, if it is possible to add an extender, then we do.

To define K^c, we consider a kind of countably certified construction that is not maximal but still computes the successors of U almost all cardinals correctly. The new condition is that we add an extender to form

$$\mathcal{N}_{\alpha+1} = \mathrm{rud}(\mathfrak{C}(\mathcal{N}_\alpha)^\frown\langle F\rangle)$$

whenever it is permitted so long as

$$\mathrm{crit}(F) \text{ is an inaccessible cardinal}$$

and, if

$$(\mathrm{crit}(F)^+)^{\mathfrak{C}(\mathcal{N}_\alpha)} = \mathrm{crit}(F)^+$$

then

$$\{\kappa < \mathrm{crit}(F) \mid \kappa \text{ is an inaccessible cardinal and } (\kappa^+)^{\mathfrak{C}(\mathcal{N}_\alpha)} = \kappa^+\}$$

is stationary in $\mathrm{crit}(F)$. For the rest of this section, fix such a countably certified construction and let $K^c = \mathcal{N}_\Omega$.

2.1 Definition. A *weasel* is an $(\omega, \Omega+1)$ iterable premouse of height Ω.

This is slightly different from the notation in [42] where weasels are not required to be iterable at all.[4] The meaning of $(\omega,\Omega+1)$ *iterable* is given by Definition 4.4 of [41]. It says that there is a strategy for picking cofinal branches at limit stages that avoids illfounded models at all stages when building almost normal iteration trees. These are iteration trees obtained as follows.

- Build a normal iteration tree $\mathcal{T}_0$ of length $\le \Omega+1$.

[4] Following the convention on premice versus mice, a structure with the first-order properties of a weasel should have been called a *preweasel*.

- If $\mathcal{T}_n$ has successor length $\theta_n + 1 < \Omega + 1$, then build a normal iteration tree $\mathcal{T}_n$ on an initial segment of $\mathcal{M}^{\mathcal{T}_n}_{\theta_n}$.
- If $\mathcal{T}_n$ is defined for all $n < \omega$, then form the concatenation

$$\mathcal{T}_0{}^\frown\mathcal{T}_1{}^\frown\cdots{}^\frown\mathcal{T}_n{}^\frown\cdots.$$

In particular, the unique cofinal branch of the infinite concatenation may have only finitely many drops and its corresponding direct limit must be wellfounded. The original *raison d'être* for almost normal iteration trees is the Dodd-Jensen Lemma, Theorem 4.8 of [41]. The reader must forgive us for not saying whether we mean *normal* or *almost normal* when we write *iteration tree* in this basic account except at key places when the difference is most pronounced.

By the next theorem, the only way to iterate a weasel is to pick the unique cofinal wellfounded branch through an iteration tree of limit length $< \Omega$.

2.2 Theorem. *Let $\mathcal{P}$ be a premouse with no Woodin cardinals. Suppose that $\mathcal{T}$ is an iteration tree of limit length on $\mathcal{P}$. Assume that*

$$\delta(\mathcal{T}) < \mathrm{On} \cap \mathcal{P}.$$

Then $\mathcal{T}$ has at most one cofinal wellfounded branch.

Sketch. Let $\theta = \mathrm{lh}(\mathcal{T})$. Recall from Definition 6.9 of [41] that

$$\delta(\mathcal{T}) = \sup(\{\mathrm{lh}(E^{\mathcal{T}}_\eta) \mid \eta < \theta\})$$

and $\mathcal{M}(\mathcal{T})$ is the unique passive mouse of height $\delta(\mathcal{T})$ that agrees with $\mathcal{M}^{\mathcal{T}}_\eta$ below $\mathrm{lh}(E^{\mathcal{T}}_\eta)$ for all $\eta < \theta$. Our Anti-Large Cardinal Hypothesis implies that $\delta(\mathcal{T})$ is not a Woodin cardinal in $L[\mathcal{M}(\mathcal{T})]$. Let $\mathcal{Q}(\mathcal{M}(\mathcal{T}))$ be the premouse $\mathcal{R}$ of minimum height such that

$$\mathcal{M}(\mathcal{T}) \trianglelefteq \mathcal{R} \triangleleft L[\mathcal{M}(\mathcal{T})]$$

and $\delta(\mathcal{T})$ is not a Woodin cardinal in $\mathrm{rud}(\mathcal{R})$. By Theorem 6.10 of [41], there is at most one cofinal branch b of $\mathcal{T}$ with the property that

$$\mathcal{Q}(\mathcal{M}(\mathcal{T})) \trianglelefteq \mathrm{wfp}(\mathcal{M}^{\mathcal{T}}_b).^{5}$$

Our assumptions about $\mathcal{P}$ and $\mathcal{T}$ imply that if b is a cofinal wellfounded branch of $\mathcal{T}$, then

$$\mathcal{Q}(\mathcal{M}(\mathcal{T})) \trianglelefteq \mathcal{M}^{\mathcal{T}}_b.$$

⊣

[5] We define $\mathcal{M}^{\mathcal{T}}_b$ to be the Mostowski collapse of the direct limit of $\mathcal{M}^{\mathcal{T}}_\eta$ for $\eta \in b$ even if this direct limit is illfounded. By $\mathrm{wfp}(\mathcal{M}^{\mathcal{T}}_b)$ we mean the wellfounded part of $\mathcal{M}^{\mathcal{T}}_b$. In this case, the wellfounded part and the transitive part are the same because $\mathcal{M}^{\mathcal{T}}_b$ is its own Mostowski collapse.

2.3 Theorem. *K^c is a weasel.*

Sketch. We already know that K^c is a premouse of height Ω. It remains to see that K^c is $(\omega, \Omega+1)$ iterable. Here we show that it is Ω iterable. Our strategy is to pick the unique cofinal wellfounded branch through iteration trees of length $< \Omega$ and to use the fact that Ω is measurable to find a branch through iteration trees of length Ω.

First suppose that $\mathcal{T}$ is an iteration tree on K^c of length $\theta < \Omega$. Recalling that $H(\lambda)$ denotes the collection of sets hereditarily of cardinality $< \lambda$, let

$$\pi : N \to H(\Omega^+)$$

be an elementary embedding with N countable and transitive. Say $\pi(\mathcal{P}) = K^c$ and $\pi(\mathcal{S}) = \mathcal{T}$. By Theorem 6.16 of [41], $\mathcal{P}$ has an $\omega_1 + 1$ iteration strategy. Then $\mathcal{S}$ is consistent with this strategy because there is only one strategy: by Theorem 2.2, $[0, \eta)_S$ is the unique cofinal wellfounded branch of $\mathcal{S} \restriction \eta$ whenever η is a limit ordinal $< \mathrm{lh}(\mathcal{S})$.

Assume that $\theta = \eta + 1$ and F is an extender from the $\mathcal{M}^{\mathcal{T}}_\eta$ sequence such that $\mathrm{lh}(F) > \mathrm{lh}(E^{\mathcal{T}}_\zeta)$ for all $\zeta \leq \eta$. We claim that

$$\mathrm{Ult}(\mathcal{M}^*_{\zeta+1}, F)$$

is wellfounded where $\zeta \leq \eta$ is least so that $\mathrm{crit}(F) < \nu(E^{\mathcal{T}}_\zeta)$, $\mathcal{M}^*_{\zeta+1}$ is the maximal level of $\mathcal{M}^{\mathcal{T}}_\zeta$ that is measured by F, and the degree of the ultrapower is as large as possible. Otherwise, there exists such an F and a witness to illfoundedness in the range of π, so the corresponding extension of $\mathcal{S}$ using $\pi^{-1}(F)$ is also illfounded. This contradicts that $\mathcal{P}$ is $\mathrm{lh}(\mathcal{S}) + 1$ iterable.

Now assume that θ is a limit ordinal $< \Omega$. Let b be the unique cofinal wellfounded branch of $\mathcal{S}$. We know that b is the unique cofinal branch of $\mathcal{S}$ with the property that

$$\mathcal{Q}(\mathcal{M}(\mathcal{S})) \trianglelefteq \mathrm{wfp}(\mathcal{M}^{\mathcal{S}}_b).$$

By our Technical Hypothesis,

$$\mathcal{Q}(\mathcal{M}(\mathcal{T})) \triangleleft L_\Omega[\mathcal{M}(\mathcal{T})].$$

Therefore,

$$\mathcal{Q}(\mathcal{M}(\mathcal{S})) = \pi^{-1}(\mathcal{Q}(\mathcal{M}(\mathcal{T}))) \in N.$$

Let $\kappa < \pi^{-1}(\Omega)$ be a regular cardinal of N greater than the cardinality of $\mathcal{Q}(\mathcal{M}(\mathcal{S}))$ in N. For example, we may simply take

$$\kappa = (|\delta(\mathcal{S})|^+)^N.$$

Let $\mathcal{S}^*$ be $\mathcal{S}$ construed as an iteration tree on $\mathcal{J}^{\mathcal{P}}_\kappa$ and G be an N-generic filter over $\mathrm{Col}(\omega, \kappa)$.[6] Then $\mathcal{S}^*$ and $\mathcal{Q}(\mathcal{M}(\mathcal{S})) = \mathcal{Q}(\mathcal{M}(\mathcal{S}^*))$ are hereditarily

[6] We recall that $\mathrm{Col}\,(\omega, \kappa)$ is the collapsing poset consisting of the finite partial functions from ω to κ.

countable in $N[G]$. Moreover, in $N[G]$, there is a set Z and a subtree $\mathcal{U}$ of ${}^{<\omega}Z$ whose infinite branches correspond to picking an ordinal $\eta < \pi^{-1}(\theta)$ and a level $\mathcal{Q} \lhd \mathcal{M}_\eta^{\mathcal{S}^*}$, then, in infinitely many steps, picking a cofinal branch c of $\mathcal{S}^*$ and simultaneously defining an isomorphism

$$f : \mathcal{Q}(\mathcal{M}(\mathcal{S})) \simeq i_{\eta,c}^{\mathcal{S}^*}(\mathcal{Q}).$$

By being slightly more precise about the definition of $\mathcal{U}$, we guarantee that $\mathcal{U}$ has a unique branch, namely the one determined by b and the least ordinal $\eta \in b$ such that

$$\mathcal{Q}(\mathcal{M}(\mathcal{S})) \in \operatorname{ran}(i_{\eta,b}).$$

By the absoluteness of wellfoundedness, $b \in N[G]$. Then $b \in N$ by the uniqueness of b and the homogeneity of the poset $\operatorname{Col}(\omega, \kappa)$. The fact that b is a cofinal wellfounded branch of $\mathcal{S}$ is absolute to N. Therefore, $\pi(b)$ is a cofinal wellfounded branch of $\mathcal{T}$.

Finally, suppose that $\mathcal{T}$ is an iteration tree on K^c of length Ω. Let

$$b = [0, \Omega)_{j(T)}$$

where j is the ultrapower map corresponding to U. There is an elementary embedding from $\mathcal{M}_b^{\mathcal{T}}$ to $\mathcal{M}_\Omega^{j(\mathcal{T})}$. Since $\mathcal{M}_\Omega^{j(\mathcal{T})}$ is wellfounded, so is $\mathcal{M}_b^{\mathcal{T}}$. $\dashv$

2.4 Theorem. $\{\kappa < \Omega \mid (\kappa^+)^{K^c} = \kappa^+\} \in U$.

Sketch. Let $V' = \operatorname{Ult}(V, U)$ and $j : V \to V'$ be the ultrapower embedding. Then for all $\mathcal{A} \subseteq \wp(\Omega)$, if $|\mathcal{A}| \leq \Omega$, then $j \restriction \mathcal{A} \in V'$. Assume for contradiction that

$$(\Omega^+)^{j(K^c)} < \Omega^+.$$

Let F be the extender of length $j(\Omega)$ derived from $j \restriction j(K^c)$. Then $F \in V'$ and F is countably certified in V'. Now an elaborate induction similar to the proof of Theorem 6.18 of [41] shows that for all $\nu < j(\Omega)$, either the trivial completion of $F \restriction \nu$ is on the $j(K^c)$ sequence, or something close enough that still implies

$$F \restriction \nu \in j(K^c).$$

We could add F itself to $j(K^c)$ to get a model with a superstrong cardinal but it is enough to note that the initial segments of F witness that Ω is a Shelah cardinal in $j(K^c)$ for a contradiction. $\dashv$

2.5 Definition. Let

$$A_1 = \{\kappa < \Omega \mid \kappa \text{ is an inaccessible cardinal and } (\kappa^+)^{K^c} = \kappa^+\}$$

and

$$A_0 = \{\lambda \in A_1 \mid A_1 \cap \lambda \text{ is not stationary in } \lambda\}.$$

2.6 Theorem. *The following hold.*

(1) $A_0 \notin U$.

(2) A_0 *is stationary.*

(3) If $\lambda \in A_0$*, then there are no total-on-*K^c *extenders on the* K^c *sequence with critical point* λ.

Sketch. From Theorem 2.4 it follows that $A_1 \in U$. Suppose for contradiction that $A_0 \in U$. Then $\Omega \in j(A_0)$. So $j(A_0) \cap \Omega$ is not stationary in Ω. But $A_0 = j(A_0) \cap \Omega$. Thus A_0 is not stationary in Ω. Since U is normal, $A_0 \notin U$, which is a contradiction.

Suppose for contradiction that A_0 is not stationary. Then there exists a C club in Ω such that for all $\lambda < \Omega$, if $\lambda \in A_1 \cap C$, then $A_1 \cap \lambda$ is stationary in λ. Let λ be the least element of $A_1 \cap \lim(C)$. Then $C \cap \lambda$ is club in λ and λ is an inaccessible cardinal, so $\lim(C) \cap \lambda$ is club in λ. Since $A_1 \cap \lambda$ is stationary in λ, there exists a $\kappa < \lambda$ such that $\kappa \in A_1 \cap \lim(C)$, which is a contradiction.

Let $\lambda \in A_0$. For all sufficiently large $\alpha < \Omega$,

$$(\lambda^+)^{\mathcal{N}_\alpha} = (\lambda^+)^{K^c}$$

and $\mathcal{N}_\alpha$ and K^c agree below their common λ^+. For such α,

$$(\lambda^+)^{\mathfrak{C}(\mathcal{N}_\alpha)} = (\lambda^+)^{\mathcal{N}_\alpha}$$

and $\mathfrak{C}(\mathcal{N}_\alpha)$ and $\mathcal{N}_\alpha$ agree below their common λ^+. Therefore,

$$(\lambda^+)^{\mathfrak{C}(\mathcal{N}_\alpha)} = \lambda^+$$

and

$$\{\kappa < \lambda \mid \kappa \text{ is an inaccessible cardinal and } (\kappa^+)^{\mathfrak{C}(\mathcal{N}_\alpha)} = \kappa^+\}$$

is not stationary in λ. By the definition of K^c, we cannot add an extender with critical point λ to $\mathfrak{C}(\mathcal{N}_\alpha)$ in forming $\mathcal{N}_{\alpha+1}$. It follows that if $\lambda^+ < \xi < \Omega$, then $\mathrm{crit}(E_\xi^{K^c}) \neq \lambda$. Thus there are no total-on-K^c extenders on the K^c sequence with critical point λ. ⊣

Next we discuss some basic facts about coiteration. Suppose that $(\mathcal{P}, \mathcal{Q})$ is a pair of mice. Let $(\mathcal{S}, \mathcal{T})$ be the coiteration of $(\mathcal{P}, \mathcal{Q})$ determined by their respective iteration strategies. Say $\eta + 1 = \mathrm{lh}(\mathcal{S})$ and $\theta + 1 = \mathrm{lh}(\mathcal{T})$. By Theorem 3.11 of [41], there are two possibly overlapping cases.

1. $\mathcal{P} \leq^* \mathcal{Q}$. That is, $[0, \eta]_S$ does not drop in model or degree and

$$\mathcal{M}_\eta^{\mathcal{S}} \trianglelefteq \mathcal{M}_\theta^{\mathcal{T}}.$$

2. $\mathcal{P} \geq^* \mathcal{Q}$. That is, $[0, \theta]_T$ does not drop in model or degree and

$$\mathcal{M}_\eta^{\mathcal{S}} \trianglerighteq \mathcal{M}_\theta^{\mathcal{T}}.$$

Moreover, by the proof of Theorem 3.11 of [41],

$$\eta, \theta < \max(|\mathcal{P}|, |\mathcal{Q}|)^+.$$

We continue the discussion above but assume instead that $\mathcal{P}$ and $\mathcal{Q}$ both have height $\leq \Omega$ and are $\Omega+1$ iterable. Using the fact that Ω is inaccessible, we can modify the proof of Theorem 3.11 of [41] to show that the coiteration of $(\mathcal{P}, \mathcal{Q})$ is successful. Moreover, with the same notation as above, $\eta, \theta \leq \Omega$ and, if

$$\max(\eta, \theta) = \Omega,$$

then at least one of the following holds.

1. $\mathcal{P} \leq^* \mathcal{Q}$, $\mathcal{P}$ is a weasel and $i^{\mathcal{S}}_{0,\eta}$"$\Omega \subseteq \Omega$.
2. $\mathcal{P} \geq^* \mathcal{Q}$, $\mathcal{Q}$ is a weasel and $i^{\mathcal{T}}_{0,\theta}$"$\Omega \subseteq \Omega$.

We leave it to the reader to fill in these details.

2.7 Definition. A weasel $\mathcal{Q}$ is *universal* iff $\mathcal{P} \leq^* \mathcal{Q}$ for all $\Omega+1$ iterable premice $\mathcal{P}$ of height $\leq \Omega$.

By the next theorem, K^c is a universal weasel.

2.8 Theorem. *If $\mathcal{Q}$ is a weasel and $\{\kappa < \Omega \mid (\kappa^+)^{\mathcal{Q}} = \kappa^+\}$ is stationary, then Q is universal.*

Sketch. Otherwise, there is an $\Omega+1$ iterable mouse $\mathcal{P}$ of height $\leq \Omega$ such that not $\mathcal{P} \leq^* \mathcal{Q}$. Therefore, $\mathcal{P} \geq^* \mathcal{Q}$ and, with notation as in our discussion on coiteration, $\eta = \Omega$. Moreover, for some $\xi \in [0, \Omega]_S$ and $\kappa < \Omega$,

$$i^{\mathcal{S}}_{\xi,\Omega}(\kappa) = \Omega.$$

Then the set

$$\{\lambda \in (\xi, \Omega)_S \mid i^{\mathcal{S}}_{\xi,\lambda}(\kappa) = \lambda\}$$

is club. Let us assume for simplicity that $\theta = \Omega$. Then also

$$\{\lambda \in (0, \Omega)_T \mid i^{\mathcal{T}}_{0,\lambda}\text{“}\lambda \subseteq \lambda\}$$

is club because $i^{\mathcal{T}}_{0,\Omega}$"$\Omega \subseteq \Omega$. Let λ be a regular cardinal in both these clubs with

$$(\lambda^+)^{\mathcal{Q}} = \lambda^+.$$

Then

$$i^{\mathcal{T}}_{0,\lambda}(\lambda) = \sup(i^{\mathcal{T}}_{0,\lambda}\text{“}\lambda) = \lambda$$

so

$$i^{\mathcal{T}}_{0,\lambda}(\lambda^+) = \lambda^+$$

and

$$(\lambda^+)^{\mathcal{M}^{\mathcal{T}}_\lambda} = \lambda^+.$$

On the other hand,

$$(\lambda^+)^{\mathcal{M}^{\mathcal{S}}_\lambda} = i^{\mathcal{S}}_{\xi,\lambda}((\kappa^+)^{\mathcal{M}^{\mathcal{S}}_\xi}) = \sup(i^{\mathcal{S}}_{\xi,\lambda}``(\kappa^+)^{\mathcal{M}^{\mathcal{S}}_\xi}) < \lambda^+.$$

Because $i^{\mathcal{S}}_{\lambda,\Omega}$ has critical point λ and $i^{\mathcal{T}}_{\lambda,\Omega}$ has critical point $\geq \lambda$,

$$(\lambda^+)^{\mathcal{M}^{\mathcal{S}}_\Omega} = (\lambda^+)^{\mathcal{M}^{\mathcal{S}}_\lambda} < (\lambda^+)^{\mathcal{M}^{\mathcal{T}}_\lambda} = (\lambda^+)^{\mathcal{M}^{\mathcal{T}}_\Omega}.$$

This contradicts that $\mathcal{M}^{\mathcal{T}}_\Omega \trianglelefteq \mathcal{M}^{\mathcal{S}}_\Omega$. ⊣

We are leading up to the definitions of the definability and hull properties for weasels. Historically, these derive from familiar properties of mice that have gone unnamed. Before dealing with weasels, we digress to discuss the analogous properties of mice as motivation. The fundamental intuition from fine-structure theory of mice is that cores and ultrapowers are inverse operations. Let us give an illustrative example. Suppose that $\mathcal{Q}$ is a 1-sound mouse, $E = \dot{F}^{\mathcal{Q}}$ and

$$\rho_1^{\mathcal{Q}} \leq \mathrm{crit}(E) = \kappa < \mathrm{On} \cap \mathcal{Q}.$$

Let

$$i : \mathcal{Q} \to \mathcal{R} = \mathrm{Ult}(\mathcal{Q}, E)$$

be the ultrapower map. Then i is a Σ_1-elementary embedding and cofinal in the sense that

$$\mathrm{On} \cap \mathcal{R} = \sup(i``(\mathrm{On} \cap \mathcal{Q})).$$

Moreover, $\rho_1^{\mathcal{R}} = \rho_1^{\mathcal{Q}}$ and $p_1^{\mathcal{R}} = i(p_1^{\mathcal{Q}})$. By the definition of 1-soundness,

$$\mathcal{Q} = \mathrm{Hull}_1^{\mathcal{Q}}(\rho_1^{\mathcal{Q}} \cup p_1^{\mathcal{Q}}).$$

By definition, $\mathrm{Hull}_1^{\mathcal{Q}}(X)$ has elements $\tau^{\mathcal{Q}}[c]$ where τ is a Σ_1-Skolem term and $c \in X^{<\omega}$. Therefore,

$$\mathrm{ran}(i) = \mathrm{Hull}_1^{\mathcal{R}}(\rho_1^{\mathcal{R}} \cup p_1^{\mathcal{R}}).$$

The moral is that by deriving an extender from the inverse of the Mostowski collapse of this hull, we recover E. We abstract two key notions from this example. Observe that κ is the least ordinal α such that

$$\alpha \notin \mathrm{Hull}_1^{\mathcal{R}}(\alpha \cup p_1^{\mathcal{R}}).$$

This says that κ is the least ordinal $\alpha \geq \rho_1^{\mathcal{R}}$ such that $\mathcal{R}$ fails to have a certain *definability property* at α. Observe also that

$$\wp(\kappa) \cap \mathcal{R} \subseteq \text{the Mostowski collapse of } \mathrm{Hull}_1^{\mathcal{R}}(\kappa \cup p_1^{\mathcal{R}}).$$

This says that $\mathcal{R}$ has a certain *hull property* at κ. The combination of the two observations above is the minimum required to derive an extender over $\mathcal{R}$ with critical point κ from the inverse of the Mostowski collapse of

$$\mathrm{Hull}_1^{\mathcal{R}}(\kappa \cup p_1^{\mathcal{R}}).$$

Of course, $\mathcal{Q}$ has the definability and hull properties at all $\alpha \geq \rho_1^{\mathcal{Q}}$ since we assumed that $\mathcal{Q}$ is 1-sound. We could go on to show that for all $\alpha \geq \rho_1^{\mathcal{R}}$, $\mathcal{R}$ fails to have the definability property at α iff α is a generator of E. And that $\mathcal{R}$ has the hull property at α iff $\alpha \leq \kappa$ or $\alpha \geq \nu(E)$ where

$$\nu(E) = \sup(\{(\kappa^+)^{\mathcal{Q}}\} \cup \{\xi + 1 \mid \xi \text{ is a generator of } E\}).$$

Taking our discussion to the next level, suppose instead that $\mathcal{Q}$ is a weasel. This is fundamentally different because

$$\rho_1^{\mathcal{Q}} = \mathrm{On} \cap \mathcal{Q} = \Omega.$$

Nevertheless, it is important to find an analogous way of undoing iterations of $\mathcal{Q}$. What we need are versions of the definability and hull properties that are appropriate for weasels. And we need a way to take hulls in K^c that produces weasels with these properties.

2.9 Definition. Let $\mathcal{Q}$ be a weasel and $\Gamma \subseteq \mathcal{Q}$. Then Γ *is thick in* $\mathcal{Q}$ iff there is a club C in Ω such that for all $\lambda \in A_0 \cap C$,

1. $(\lambda^+)^{\mathcal{Q}} = \lambda^+$,
2. λ is not the critical point of a total-on-$\mathcal{Q}$ extender on the $\mathcal{Q}$ sequence, and
3. there is a λ-club in $\Gamma \cap \lambda^+$.

2.10 Definition. $\mathcal{Q}$ is a *thick* weasel iff Ω is thick in $\mathcal{Q}$.

The reader will not find the expression *thick weasel* in the literature but the concept needed a name so we picked one. Clearly K^c is a thick weasel. The next three results are useful closure properties of thick sets.

2.11 Theorem. *Let $\mathcal{Q}$ be a thick weasel. Then*

$$\{\Gamma \subseteq \mathcal{Q} \mid \Gamma \text{ is thick in } \mathcal{Q}\}$$

is an Ω-complete filter.

2.12 Theorem. *Suppose that $\pi : \mathcal{P} \to \mathcal{Q}$ is an elementary embedding and* $\mathrm{ran}(\pi)$ *is thick in $\mathcal{Q}$. Let*

$$\Phi = \{\alpha < \Omega \mid \pi(\alpha) = \alpha\}.$$

Then Φ is thick in both $\mathcal{P}$ and $\mathcal{Q}$.

2.13 Theorem. *Let $\mathcal{T}$ be an iteration tree on a thick weasel $\mathcal{Q}$ with*

$$\mathrm{lh}(\mathcal{T}) = \theta + 1 \leq \Omega + 1.$$

Assume that there is no dropping along $[0, \theta]_T$ and $i^{\mathcal{T}}_{0,\theta}$“$\Omega \subseteq \Omega$. Let

$$\Phi = \{\alpha < \Omega \mid i^{\mathcal{T}}_{0,\theta}(\alpha) = \alpha\}.$$

Then Φ is thick in both $\mathcal{Q}$ and $\mathcal{M}^{\mathcal{T}}_\theta$.

The proofs of the previous three theorems are reasonable exercises for the reader. The $\theta = \Omega$ case of the Theorem 2.13 is why we used A_0 instead of A_1.

2.14 Definition. A thick weasel $\mathcal{Q}$ has the *definability property* at α iff

$$\alpha \in \mathrm{Hull}^{\mathcal{Q}}(\alpha \cup \Gamma)$$

whenever Γ is thick in $\mathcal{Q}$.

By definition, the elements of $\mathrm{Hull}^{\mathcal{Q}}(X)$ are those of the form $\tau^{\mathcal{Q}}[c]$ where τ is a Skolem term and $c \in X^{<\omega}$. Equivalently, $a \in \mathrm{Hull}^{\mathcal{Q}}(X)$ iff $\{a\}$ is first-order definable over $\mathcal{Q}$ with parameters from X.

2.15 Definition. A thick weasel $\mathcal{Q}$ has the *hull property* at α iff

$$\wp(\alpha) \cap \mathcal{Q} \subseteq \text{the Mostowski collapse of } \mathrm{Hull}^{\mathcal{Q}}(\alpha \cup \Gamma)$$

whenever Γ is thick in $\mathcal{Q}$.

2.16 Theorem. *Let $\beta < \Omega$ and $\mathcal{Q}$ be a thick weasel with the definability and hull properties for all $\alpha < \beta$. Suppose that $\mathcal{T}$ is an iteration tree on $\mathcal{Q}$ with*

$$\mathrm{lh}(\mathcal{T}) = \theta + 1 \leq \Omega + 1.$$

Assume that there is no dropping along $[0, \theta]_T$ and $i^{\mathcal{T}}_{0,\theta}$"$\Omega \subseteq \Omega$. Then the following hold for all $\alpha < \beta$.

(1) $\mathcal{M}^{\mathcal{T}}_{\theta}$ does not have the definability property at α iff there exists an

$$\eta + 1 \in [0, \theta]_T$$

such that α is a generator of $E^{\mathcal{T}}_{\eta}$.

(2) $\mathcal{M}^{\mathcal{T}}_{\theta}$ does not have the hull property at α iff there exists an $\eta + 1 \in [0, \theta]_T$ such that

$$(\mathrm{crit}(E^{\mathcal{T}}_{\eta})^{+})^{\mathcal{M}^{\mathcal{T}}_{\theta}} \leq \alpha < \nu(E^{\mathcal{T}}_{\eta}).$$

Sketch. For simplicity, we deal only with the case of a single ultrapower. In other words, $\theta = 2$. Let $E = E^{\mathcal{T}}_0$ and consider the following diagram.

$$\begin{tikzcd}
\mathcal{Q} \arrow[r, "j"] \arrow[dr, "i"'] & \mathrm{Ult}(\mathcal{Q}, E) \\
 & \mathrm{Ult}(\mathcal{Q}, E \restriction \alpha) \arrow[u, "k"']
\end{tikzcd}$$

Then $\mathrm{crit}(k) = \alpha$ iff α is a generator of E. Let $\Phi = \{\xi < \Omega \mid j(\xi) = \xi\}$. Then Φ is thick in all three models. Of course, $j(\xi) = \xi$ implies $k(\xi) = \xi$ and $i(\xi) = \xi$.

First we prove the *if* direction of (1). Assume that α is a generator of E. Equivalently, that $\alpha = \mathrm{crit}(k)$. Suppose for contradiction that $\mathrm{Ult}(\mathcal{Q}, E)$ has the definability property at α. Then there is a Skolem term τ and a parameter $c \in (\alpha \cup \Phi)^{<\omega}$ such that

$$\alpha = \tau^{\mathrm{Ult}(\mathcal{Q},E)}[c] = k(\tau^{\mathrm{Ult}(\mathcal{Q},E\restriction\alpha)}[c]\,).$$

This is a contradiction since $\alpha \notin \mathrm{ran}(k)$.

Second we prove the *if* direction of (2). Assume that

$$(\mathrm{crit}(E)^+)^{\mathcal{Q}} \leq \alpha < \nu(E).$$

The main point is that

$$E\restriction\alpha \in \mathrm{Ult}(\mathcal{Q}, E)$$

whereas

$$E\restriction\alpha \notin \mathrm{Ult}(\mathcal{Q}, E\restriction\alpha).$$

We know this because E is on the $\mathcal{Q}$ sequence, which is a good extender sequence. Since

$$(\mathrm{crit}(E)^+)^{\mathcal{Q}} \leq \alpha,$$

it is possible to code $E\restriction\alpha$ by $A \subseteq \alpha$ with $A \in \mathrm{Ult}(\mathcal{Q}, E)$. Suppose for contradiction that $\mathrm{Ult}(\mathcal{Q}, E)$ has the hull property at α. Then there is a Skolem term τ and a parameter $c \in (\alpha \cup \Phi)^{<\omega}$ such that

$$A = \tau^{\mathrm{Ult}(\mathcal{Q},E)}[c] \cap \alpha.$$

Since $\mathrm{crit}(k) \geq \alpha$,

$$A = \tau^{\mathrm{Ult}(\mathcal{Q},E\restriction\alpha)}[c] \cap \alpha \in \mathrm{Ult}(\mathcal{Q}, E\restriction\alpha),$$

so

$$E\restriction\alpha \in \mathrm{Ult}(\mathcal{Q}, E\restriction\alpha),$$

which is a contradiction.

Notice that the two *if* directions did not use the hypothesis that $\mathcal{Q}$ has the definability and hull properties at all ordinals $< \beta$. These are used for the two *only if* directions, which we leave to the reader. ⊣

The next theorem explains how the definability property and hull property are related, and its proof is a good example of how they are used.

2.17 Theorem. *For all $\beta < \Omega$, if $\mathcal{Q}$ has the definability property at all $\alpha < \beta$, then $\mathcal{Q}$ has the hull property at β.*

Sketch. By induction, we may assume that $\mathcal{Q}$ has the definability and hull properties at all $\alpha < \beta$. Suppose that Γ is thick in $\mathcal{Q}$. Let

$$\pi : \mathcal{P} \simeq \mathrm{Hull}^{\mathcal{Q}}(\beta \cup \Gamma)$$

be the inverse of the Mostowski collapse. We must show that

$$\wp(\beta) \cap \mathcal{P} = \wp(\beta) \cap \mathcal{Q}.$$

If Δ is thick in $\mathcal{P}$, then $\{\xi \in \Delta \mid \pi(\xi) = \xi\}$ is thick in $\mathcal{Q}$. From this it follows that $\mathcal{P}$ has the definability and hull properties at all $\alpha < \beta$. Let $(\mathcal{S}, \mathcal{T})$ be the coiteration of $(\mathcal{P}, \mathcal{Q})$. Both $\mathcal{P}$ and $\mathcal{Q}$ are universal, so

$$\mathcal{M}^{\mathcal{S}}_{\eta} = \mathcal{M}^{\mathcal{T}}_{\theta}$$

where $\eta + 1 = \mathrm{lh}(\mathcal{S})$ and $\theta + 1 = \mathrm{lh}(\mathcal{T})$. Moreover, there is no dropping along $[0, \eta]_S$ and $[0, \theta]_T$. It is enough to see that

$$\mathrm{crit}(i^{\mathcal{S}}_{0,\eta}), \mathrm{crit}(i^{\mathcal{T}}_{0,\theta}) \geq \beta.$$

For contradiction, suppose that

$$\mathrm{crit}(i^{\mathcal{S}}_{0,\eta}) < \beta.$$

Apply Theorem 2.16 to $\mathcal{S}$ to see that $\mathrm{crit}(i^{\mathcal{S}}_{0,\eta})$ is equal to the least α such that $\mathcal{M}^{\mathcal{S}}_{\eta}$ does not have the definability property at α. And apply Theorem 2.16 to $\mathcal{T}$ to see that

$$\mathrm{crit}(i^{\mathcal{S}}_{0,\eta}) = \mathrm{crit}(i^{\mathcal{T}}_{0,\theta}).$$

Call this ordinal α and let

$$\alpha^* = \min(i^{\mathcal{S}}_{0,\eta}(\alpha), i^{\mathcal{T}}_{0,\theta}(\alpha)).$$

As $\alpha < \beta$, $\mathcal{Q}$ has the hull property at α, so

$$\wp(\alpha) \cap \mathcal{P} = \wp(\alpha) \cap \mathcal{Q}.$$

Next we use the fact that

$$\Phi = \{\xi < \Omega \mid i^{\mathcal{S}}_{0,\eta}(\xi) = \xi = i^{\mathcal{T}}_{0,\theta}(\xi)\}$$

is thick in both $\mathcal{P}$ and $\mathcal{Q}$ to show that if $X \subseteq \alpha$ with $X \in \mathcal{P}$, then

$$i^{\mathcal{S}}_{0,\eta}(X) \cap \alpha^* = i^{\mathcal{T}}_{0,\theta}(X) \cap \alpha^*.$$

First note that $\alpha \subseteq \Phi$. Then, given $X \subseteq \alpha$ with $X \in \mathcal{P}$, choose a Skolem term τ and $c \in \Phi^{<\omega}$ such that

$$X = \tau^{\mathcal{P}}[c] \cap \alpha.$$

Let

$$Y = \tau^{\mathcal{Q}}[c] \cap \alpha.$$

Then

$$\begin{aligned}
i^{\mathcal{S}}_{0,\eta}(X) \cap \alpha^* &= i^{\mathcal{S}}_{0,\eta}(\tau^{\mathcal{P}}[c] \cap \alpha) \cap \alpha^* \\
&= \tau^{\mathcal{M}^{\mathcal{S}}_{\eta}}[c] \cap \alpha^* \\
&= \tau^{\mathcal{M}^{\mathcal{T}}_{\theta}}[c] \cap \alpha^* \\
&= i^{\mathcal{T}}_{0,\theta}(\tau^{\mathcal{Q}}[c] \cap \alpha) \cap \alpha^* \\
&= i^{\mathcal{T}}_{0,\theta}(Y) \cap \alpha^*.
\end{aligned}$$

Also

$$X = i^{\mathcal{S}}_{0,\eta}(X) \cap \alpha = i^{\mathcal{T}}_{0,\theta}(Y) \cap \alpha = Y.$$

We have seen that the first extenders used along $[0,\eta]_S$ and $[0,\theta]_T$ are comparable, which is impossible in a coiteration. (E.g., see the subclaim in the proof of Theorem 3.11 of [41].)

The same contradiction is obtained similarly by assuming that

$$\mathrm{crit}(i^{\mathcal{T}}_{0,\theta}) < \beta.$$

$\dashv$

2.18 Definition. Let $\mathcal{P}$ be a mouse of height $< \Omega$. Then $\mathcal{P}$ is A_0-*sound* iff there exists a thick weasel $\mathcal{P}^*$ such that $\mathcal{P} \triangleleft \mathcal{P}^*$ and $\mathcal{P}^*$ has the definability property at all $\alpha \in \mathrm{On} \cap \mathcal{P}$.

The point of isolating A_0-sound mice is that they line up as the next theorem shows.

2.19 Theorem. *Let $\mathcal{P}$ and $\mathcal{Q}$ be A_0-sound mice. Then $\mathcal{P} \trianglelefteq \mathcal{Q}$ or $\mathcal{P} \trianglerighteq \mathcal{Q}$.*

Sketch. Let $\mathcal{P}^*$ and $\mathcal{Q}^*$ be A_0-soundness witnesses for $\mathcal{P}$ and $\mathcal{Q}$ respectively. Let $(\mathcal{S},\mathcal{T})$ be the coiteration of $(\mathcal{P}^*,\mathcal{Q}^*)$. Then

$$\mathcal{M}^{\mathcal{S}}_{\eta} = \mathcal{M}^{\mathcal{T}}_{\theta}$$

where $\eta + 1 = \mathrm{lh}(\mathcal{S})$ and $\theta + 1 = \mathrm{lh}(\mathcal{T})$, and there is no dropping along $[0,\eta]_S$ and $[0,\theta]_T$. It is enough to see that

$$\mathrm{crit}(i^{\mathcal{S}}_{0,\eta}), \mathrm{crit}(i^{\mathcal{T}}_{0,\theta}) \geq \min(\mathrm{On} \cap \mathcal{P}, \mathrm{On} \cap \mathcal{Q}).$$

This is done by contradiction exactly as in the proof of Theorem 2.17 using the hull property and definability property of $\mathcal{P}^*$ and $\mathcal{Q}^*$ at all

$$\alpha < \min(\mathrm{On} \cap \mathcal{P}, \mathrm{On} \cap \mathcal{Q}).$$

$\dashv$

2.20 Definition. K is the union of all the A_0-sound mice.

By Theorem 2.19, K is a premouse. But it is not immediate that K has height Ω.

2.21 Definition. Let $\mathcal{Q}$ be a thick weasel. Then

$$\mathrm{Def}(\mathcal{Q}) = \bigcap\{\mathrm{Hull}^{\mathcal{Q}}(\Gamma) \mid \Gamma \text{ is thick in } \mathcal{Q}\}$$

The plan for proving that K is a weasel is as follows. First we show that K is the Mostowski collapse of $\mathrm{Def}(K^c)$. Then we establish that K^c has the hull and definability properties at U-almost all $\alpha < \Omega$. The last step is to show that $\mathrm{Def}(K^c)$ is unbounded in Ω. The realization of this plan stretches over several theorems.

2.22 Theorem. *Let $\mathcal{P}$ and $\mathcal{Q}$ be thick weasels. Then* $\mathrm{Def}(\mathcal{P}) \simeq \mathrm{Def}(\mathcal{Q})$.

Sketch. Let $(\mathcal{S}, \mathcal{T})$ be the coiteration of $(\mathcal{P}, \mathcal{Q})$. Then

$$\mathcal{M}^{\mathcal{S}}_{\eta} = \mathcal{M}^{\mathcal{T}}_{\theta}$$

where $\eta + 1 = \mathrm{lh}(\mathcal{S})$ and $\theta + 1 = \mathrm{lh}(\mathcal{T})$, and there is no dropping along $[0, \eta]_S$ and $[0, \theta]_T$. It is enough to see that

$$i^{\mathcal{S}}_{0,\eta}``\mathrm{Def}(\mathcal{P}) = \mathrm{Def}(\mathcal{M}^{\mathcal{S}}_{0,\eta})$$

and

$$i^{\mathcal{T}}_{0,\theta}``\mathrm{Def}(\mathcal{Q}) = \mathrm{Def}(\mathcal{M}^{\mathcal{T}}_{0,\theta}).$$

This is an easy exercise using the basic properties of thick sets. $\dashv$

2.23 Theorem. $K \simeq \mathrm{Def}(K^c)$.

Sketch. Let

$$\pi : K' \simeq \mathrm{Def}(K^c)$$

be the inverse of the Mostowski collapse. We must show that $K' = K$.

First let $\mathcal{P} \triangleleft K$ and $\mathcal{P}^*$ be a witness that $\mathcal{P}$ is A_0-sound. Since $\mathcal{P}^*$ has the definability property at all $\alpha < \mathrm{On} \cap \mathcal{P}$,

$$\mathcal{P} \subseteq \mathrm{Def}(\mathcal{P}^*).$$

But $\mathrm{Def}(K^c) \simeq \mathrm{Def}(\mathcal{P}^*) \simeq K'$ by Theorem 2.22. Therefore $\mathcal{P} \triangleleft K'$.

Now let $\mathcal{P} \triangleleft K'$. Let $\theta = \sup(\pi``(\mathrm{On} \cap \mathcal{P}))$. For each $\alpha \in \theta - \mathrm{Def}(K^c)$, pick an A_0-thick set Γ_α such that

$$\alpha \notin \mathrm{Hull}^{K^c}(\Gamma_\alpha).$$

Let

$$\Delta = \bigcap\{\Gamma_\alpha \mid \alpha \in \theta - \mathrm{Def}(K^c)\}$$

and $\mathcal{Q}$ be the Mostowski collapse of $\mathrm{Hull}^{K^c}(\Delta)$. It is an easy exercise to see that $\mathcal{Q}$ witnesses that $\mathcal{P}$ is A_0-sound. Therefore $\mathcal{P} \triangleleft K$. $\dashv$

By Theorems 2.22 and 2.23, $K \simeq \mathrm{Def}(\mathcal{P})$ whenever $\mathcal{P}$ is a thick weasel.

2.24 Theorem. *Let $\mathcal{Q}$ be a thick weasel. Then there exists a C club in Ω such that $\mathcal{Q}$ has the hull property at α for all inaccessible $\alpha \in C$. In particular,*

$$\{\alpha < \Omega \mid \mathcal{Q} \text{ has the hull property at } \alpha\} \in U.$$

Sketch. By recursion, define a continuous decreasing sequence

$$\langle X_\alpha \mid \alpha < \Omega \rangle$$

of thick elementary substructures of $\mathcal{Q}$ and an increasing sequence

$$\langle \lambda_\alpha \mid \alpha < \Omega \rangle$$

of cardinals of $\mathcal{Q}$. For all $\alpha < \Omega$, let $\pi_\alpha : \mathcal{P}_\alpha \simeq X_\alpha$ be the inverse of the Mostowski collapse and $\pi_\alpha(\kappa_\alpha) = \lambda_\alpha$. Arrange the construction so that $\langle \kappa_\alpha \mid \alpha \leq \beta \rangle$ is an initial segment of the infinite cardinals of $\mathcal{P}_\beta$ for all $\beta < \Omega$. Also arrange that for all $\alpha < \beta < \Omega$,

$$\pi_\alpha \restriction (\kappa_\alpha + 1) = \pi_\beta \restriction (\kappa_\alpha + 1)$$

and $\mathcal{P}_\beta$ has the hull property at all $\kappa \leq \kappa_\alpha$.

Start the construction with $\kappa_0 = \lambda_0 = \omega$, $X_0 = \mathcal{Q}$ and $\pi_0 = \mathrm{id} \restriction \mathcal{Q}$. If β is a limit ordinal, then $X_\beta = \bigcap_{\alpha<\beta} X_\alpha$ and this determines $\mathcal{P}_\beta$, π_β, κ_β and λ_β by what we said above. The successor step is more complicated. If $A \in \wp(\kappa_\alpha) \cap \mathcal{P}_\alpha$ and there exists a Γ thick in $\mathcal{P}_\alpha$ such that

$$A \notin \text{Mostowski collapse of } \mathrm{Hull}^{\mathcal{P}_\alpha}(\kappa_\alpha \cup \Gamma),$$

then pick such a Γ and call it Γ_A. Then let

$$\Gamma_\alpha = \bigcap(\{\mathcal{P}_\alpha\} \cup \{\Gamma_A \mid A \in \wp(\kappa_\alpha) \cap \mathcal{P}_\alpha \text{ and } \Gamma_A \text{ is defined}\})$$

and

$$X_{\alpha+1} = \mathrm{Hull}^{\mathcal{P}_\alpha}((\kappa_\alpha + 1) \cup \Gamma_\alpha).$$

This determines $\mathcal{P}_{\alpha+1}$, $\pi_{\alpha+1}$, $\kappa_{\alpha+1}$ and $\lambda_{\alpha+1}$ by what we said at the start.

2.25 Lemma. *If γ is a limit ordinal, then $\mathcal{P}_\gamma = \mathcal{P}_{\gamma+1}$.*

Sketch. Suppose not. Then Γ_A is defined for some $A \in \wp(\kappa_\gamma) \cap \mathcal{P}_\gamma$. Let $\mathcal{P}_A$ be the Mostowski collapse of

$$\mathrm{Hull}^{\mathcal{P}_\gamma}(\kappa_\gamma \cup \Gamma_A).$$

and $(\mathcal{S}, \mathcal{T})$ be the coiteration of $(\mathcal{P}_A, \mathcal{P}_\gamma)$. Then $\mathcal{M}^{\mathcal{S}}_\eta = \mathcal{M}^{\mathcal{T}}_\theta$ where $\eta + 1 = \mathrm{lh}(\mathcal{S})$ and $\theta + 1 = \mathrm{lh}(\mathcal{T})$, and there is no dropping along $[0, \eta]_S$ and $[0, \theta]_T$.

Suppose that $\mathrm{crit}(i^{\mathcal{T}}_{0,\theta}) \geq \kappa_\gamma$. Then

$$A \in \wp(\kappa_\gamma) \cap \mathcal{P}_\gamma = \wp(\kappa_\gamma) \cap \mathcal{M}^{\mathcal{T}}_\theta = \wp(\kappa_\gamma) \cap \mathcal{M}^{\mathcal{S}}_\eta \subseteq \wp(\kappa_\gamma) \cap \mathcal{P}_A$$

since all the extenders used on $\mathcal{S}$ have length at least κ_γ. But $A \notin \mathcal{P}_A$, contradiction!

Therefore, $\mathrm{crit}(i^{\mathcal{T}}_{0,\theta}) < \kappa_\gamma$. Let $\beta < \gamma$ be such that

$$\kappa_\beta = \mathrm{crit}(i^{\mathcal{T}}_{0,\theta}).$$

Then β is equal to the least ordinal $\alpha < \gamma$ such that $\mathcal{M}^{\mathcal{T}}_\theta$ does not have the hull property at $\kappa_{\alpha+1}$. This is not precisely what Theorem 2.16 says about $\mathcal{T}$ but the proof shows it. Applying a similar modification of Theorem 2.16 to $\mathcal{S}$ shows that $\kappa_\beta = \mathrm{crit}(i^{\mathcal{S}}_{0,\eta})$. Finally, use the hull property at κ_β in both $\mathcal{P}_A$ and $\mathcal{P}_\gamma$ to see that the first extenders used on $[0,\eta]_S$ and $[0,\theta]_T$ are compatible. This leads to a standard contradiction. ⊣

2.26 Lemma. *Let $X = \bigcap\{X_\alpha \mid \alpha < \Omega\}$. Then X is thick in $\mathcal{Q}$.*

Sketch. For each $\alpha < \Omega$, pick C_α club in Ω witnessing that X_α is thick in $\mathcal{Q}$. Let C be the diagonal intersection of $\langle C_\alpha \mid \alpha < \Omega\rangle$. We show that C witnesses that X is thick in $\mathcal{Q}$. Let $\beta \in A_0 \cap C$. Clearly $(\beta^+)^{\mathcal{Q}} = \beta^+$ and β is not the critical point of a total-on-$\mathcal{Q}$ extender on the $\mathcal{Q}$ sequence. For each $\alpha < \beta$, there exists a β-club $D_\alpha \subseteq X_\alpha \cap \beta^+$. Let $D = \bigcap\{D_\alpha \mid \alpha < \beta\}$. Then D is a β-club subset of

$$\textstyle\bigcap_{\alpha<\beta} X_\alpha \cap \beta^+ = X_\beta \cap \beta^+ = X_{\beta+1} \cap \beta^+ = X \cap \beta^+.$$

The first equation holds by the definition of X_β. The second holds by Lemma 2.25. The third holds because $\beta \le \lambda_\beta$, $\beta^+ \le \lambda_{\beta+1}$ and

$$X_{\beta+1} \cap (\lambda_{\beta+1} + 1) = X \cap (\lambda_{\beta+1} + 1).$$

In fact, by taking β closed under $\alpha \mapsto \lambda_\alpha$ we get that $\beta = \kappa_\beta = \lambda_\beta$ and $\beta^+ = \kappa_{\beta+1} = \lambda_{\beta+1}$. ⊣

2.27 Lemma. *Let $\mathcal{P}$ be the Mostowski collapse of X. Then $\mathcal{P}$ has the hull property at all $\alpha < \Omega$.*

Sketch. Lemma 2.26 implies that $\mathcal{P}$ is a thick weasel. By construction, $\langle \kappa_\alpha \mid \alpha < \Omega\rangle$ lists the infinite cardinals of $\mathcal{P}$ in increasing order and $\mathcal{P}$ has the hull property at κ_α for all $\alpha < \Omega$. ⊣

Let $(\mathcal{S}, \mathcal{T})$ be the coiteration of $(\mathcal{P}, \mathcal{Q})$. Consider the case in which $\mathcal{S}$ and $\mathcal{T}$ both have length $\Omega + 1$, the other cases being similar. Then $\mathcal{M}^{\mathcal{S}}_\Omega = \mathcal{M}^{\mathcal{T}}_\Omega$ and there is no dropping along $[0,\Omega]_S$ and $[0,\Omega]_T$. Let C be the set of limit ordinals

$$\theta \in [0,\Omega]_S \cap [0,\Omega]_T$$

such that θ is the supremum of

$$\{\mathrm{lh}(E^{\mathcal{S}}_\eta) \mid \eta < \theta\} \cup \{\mathrm{lh}(E^{\mathcal{T}}_\eta) \mid \eta < \theta\}.$$

Then C is club in Ω. Consider an arbitrary $\theta \in C$. Then $\mathcal{M}^{\mathcal{S}}_{\theta}$ has the hull property at θ and, since

$$\operatorname{crit}(i^{\mathcal{S}}_{\theta,\Omega}) \geq \theta,$$

$\mathcal{M}^{\mathcal{S}}_{\Omega}$ has the hull property at θ. The fact that $\operatorname{crit}(i^{\mathcal{T}}_{\theta,\Omega}) \geq \theta$ can be used to see that $\mathcal{M}^{\mathcal{T}}_{\theta}$ has the hull property at θ. Now assume that θ is inaccessible. Then $i^{\mathcal{T}}_{0,\theta}(\theta) = \theta$. To finish the proof of the theorem, we show that $\mathcal{Q}$ has the hull property at θ. Suppose $A \in \wp(\theta) \cap \mathcal{Q}$ and Γ is thick in $\mathcal{Q}$. Let $B = i^{\mathcal{T}}_{0,\theta}(A)$. Then $B \in \wp(\theta) \cap \mathcal{M}^{\mathcal{T}}_{\theta}$ so there is a Skolem term τ and parameters $c \in \theta^{<\omega}$ and $d \in \Gamma^{<\omega}$ such that $d = i^{\mathcal{T}}_{0,\theta}(d)$ and

$$B = \tau^{\mathcal{M}^{\mathcal{T}}_{\theta}}[c, d] \cap \theta.$$

By minimizing c in this equation we find $b \in \theta^{<\omega}$ such that $c = i^{\mathcal{T}}_{0,\theta}(b)$. Thus

$$A = \tau^{\mathcal{Q}}[b, d] \cap \theta.$$

$\dashv$

We have used the Technical Hypothesis that Ω is measurable twice already. First, to see that the set of α such that $(\alpha^{+})^{K^c} = \alpha^{+}$ is stationary in Ω. Second, to show that K^c is $(\omega, \Omega+1)$ iterable starting from the fact that if $\mathcal{P}$ is countable and elementarily embeds into K^c, then $\mathcal{P}$ is (ω, ω_1+1) iterable. The third and final use of the Technical Hypothesis comes in the proof of the following theorem.

2.28 Theorem. $\{\alpha < \Omega \mid K^c$ *has the definability property at* $\alpha\} \in U$.

Sketch. Suppose not. Let

$$D = \{\alpha < \Omega \mid K^c \text{ does not have the definability property at } \alpha\}.$$

Then $D \in U$. For each $\alpha \in D$, pick a thick Γ_α such that

$$\alpha \notin \operatorname{Hull}^{K^c}(\alpha \cup \Gamma_\alpha).$$

We may assume $\Gamma_\beta \subseteq \Gamma_\alpha$ whenever $\alpha < \beta$ are elements of D. We write $\Gamma = \langle \Gamma_\alpha \mid \alpha \in D\rangle$. Form the iteration

$$V \xrightarrow[j]{} V' \xrightarrow[k]{} V''$$

with $V' = \operatorname{Ult}(V, U)$, $U' = j(U)$ and $V'' = \operatorname{Ult}(V', U')$. We will use the general fact that

$$j \circ j = k \circ j.$$

This equation holds because

$$j([\alpha \mapsto x]^V_U) = [\alpha \mapsto j(x)]^{V'}_{U'}.$$

Let $W = K^c$, $W' = j(W)$ and $W'' = k(W')$. By what we just said, $W'' = j(W')$. Consider the inverse of the Mostowski collapse

$$\pi : \mathcal{P} \simeq \mathrm{Hull}^{W'}(\Omega \cup \Gamma'_\Omega)$$

where $\Gamma'_\alpha = j(\Gamma)_\alpha$. Also let $\Gamma''_\alpha = k(\Gamma')_\alpha$. Then $\Gamma''_\alpha = j(\Gamma')_\alpha$. Since W' does not have the definability property at Ω, $\mathrm{crit}(\pi) = \Omega$. By Theorem 2.24,

$$(W' \text{ has the hull property at } \Omega)^{V'},$$

so

$$\wp(\Omega) \cap \mathcal{P} = \wp(\Omega) \cap W'.$$

Let $\Omega' = j(\Omega)$. Note that $\pi(\Omega) < \Omega'$ because Γ'_Ω is unbounded in Ω'. Let F be the extender of length $\pi(\Omega)$ derived from π. We claim that

$$\pi(A) = j(A) \cap \pi(\Omega)$$

for all $A \in \wp(\Omega) \cap W'$. From the claim, it follows that F is countably certified in V', which can be used to show that F witnesses that Ω is a superstrong cardinal in W'. To prove the claim, pick a Skolem term τ and parameters $c \in \Omega^{<\omega}$ and $d \in (\Gamma'_\Omega)^{<\omega}$ such that $A = \tau^{W'}[c, d] \cap \Omega$. Then

$$j(A) = \tau^{W''}[c, j(d)] \cap \Omega'$$

and

$$j(d) \in (\Gamma''_{\Omega'})^{<\omega} \subseteq (\Gamma''_\Omega)^{<\omega}$$

because Γ'' is a descending sequence and $\Omega' > \Omega$. In particular,

$$\tau^{W''}[c, j(d)] \in \mathrm{Hull}^{W''}(\Omega \cup \Gamma''_\Omega)$$

and

$$A = \tau^{W''}[c, j(d)] \cap \Omega.$$

By elementarity,

$$k(\pi) : k(\mathcal{P}) \simeq \mathrm{Hull}^{W''}(\Omega \cup \Gamma''_\Omega).$$

Finally, since $\mathrm{crit}(k) = \Omega' > \pi(\Omega)$ and $A \subseteq \Omega$,

$$\begin{aligned}
\pi(A) &= k(\pi(A)) = k(\pi)(k(A)) = k(\pi)(A) \\
&= k(\pi)(\tau^{W''}[c, j(d)] \cap \Omega) \\
&= \tau^{W''}[c, j(d)] \cap k(\pi(\Omega)) \\
&= j(A) \cap \pi(\Omega).
\end{aligned}$$

⊣

2.29 Theorem. *K is a weasel.*

Proof. Consider the following recursive construction. Let $\Gamma_0 = \Omega$. Assuming that Γ_α has been defined, if

$$\mathrm{Hull}^{K^c}(\Gamma_\alpha) = \mathrm{Def}(K^c),$$

then stop the construction. Otherwise, let

$$\gamma_\alpha = \min(\mathrm{Hull}^{K^c}(\Gamma_\alpha) - \mathrm{Def}(K^c))$$

and pick $\Gamma_{\alpha+1} \subseteq \Gamma_\alpha$ so that

$$\gamma_\alpha \notin \mathrm{Hull}^{K^c}(\Gamma_{\alpha+1}).$$

If β is a limit ordinal, then let

$$\Gamma_\beta = \bigcap\{\Gamma_\alpha \mid \alpha < \beta\}.$$

Suppose for contradiction that $\mathrm{Def}(K^c)$ is bounded in Ω. Then γ_α and Γ_α are defined for all $\alpha < \Omega$. And there exists an $\alpha < \Omega$ such that

$$\mathrm{Def}(K^c) \cap \Omega \subseteq \gamma_\alpha.$$

By Theorem 2.28, there exists a $\delta \in (\gamma_\alpha, \Omega)$ such that

$$\delta = \sup(\{\gamma_\beta \mid \beta < \delta\}) \leq \gamma_\delta$$

and K^c has the definability property at δ. This implies that there exist an ordinal $\beta \in (\alpha, \delta)$, parameters $c \in (\gamma_\beta)^{<\omega}$ and $d \in (\Gamma_{\delta+1})^{<\omega}$, and a Skolem term τ such that $\delta = \tau^{K^c}[c, d]$. Then c is a witness to the sentence:

There exists a $b \in (\gamma_\beta)^{<\omega}$ such that $\gamma_\beta < \tau^{K^c}[b, d] < \gamma_{\delta+1}$.

Since γ_β and $\gamma_{\delta+1}$ are elements of $\mathrm{Hull}^{K^c}(\Gamma_\beta)$ we may pick a witness b to this sentence with

$$b \in \mathrm{Hull}^{K^c}(\Gamma_\beta).$$

By the minimality of γ_β and the fact that $b \in (\gamma_\beta)^{<\omega}$,

$$b \in \mathrm{Def}(K^c).$$

Hence

$$\tau^{K^c}[b, d] \in \mathrm{Hull}^{K^c}(\Gamma_{\delta+1}).$$

By the choice of γ_α and the fact that $\gamma_\alpha < \gamma_\beta < \tau^{K^c}[b, d]$,

$$\tau^{K^c}[b, d] \notin \mathrm{Def}(K^c).$$

By the minimality of $\gamma_{\delta+1}$,

$$\tau^{K^c}[b, d] \geq \gamma_{\delta+1}.$$

But

$$\tau^{K^c}[b, d] < \gamma_{\delta+1},$$

which is a contradiction. $\dashv$

At the corresponding point in [42], Steel goes on to prove that

$$\{\alpha < \Omega \mid (\alpha^+)^K = \alpha^+\} \in U.$$

(Cf., Theorem 3.1 below.) The calculations involve combinatorics similar to the proof of Theorem 2.29 but we omit them here. From this and Theorem 2.8, it follows that K is universal. Also at this point, Steel shows that K is absolute under forcing in $H(\Omega)$. (Cf., Theorem 3.4 below.) The proof involves abstracting the properties of A_0 in the arguments we have given so far.

2.2. First-Order Definition of K

Now we head in a slightly different direction. Notice that the definition of K we have given is second-order over $H(\Omega)$. Moreover, there is no obvious sense in which the definition works locally. For example, it is not immediate from what we have said so far that $K \cap \mathrm{HC}$ is less complex than K.[7] Our next goal is to find an equivalent first-order definition of K that gives meaningful local bounds on complexity. For example, $K \cap \mathrm{HC}$ turns out to be Σ_1 definable over $L_{\omega_1}(\mathbb{R})$. (Cf., Theorem 3.5.) By results of Woodin, this is the best possible upper bound on the complexity of $K \cap \mathrm{HC}$. The ideas that go into the first-order definition of K are central to the proof of the weak covering theorem in Sect. 4.

Before launching into the details, let us motivate what is to come. It is not hard to see that all universal weasels have the same subsets of ω, namely those in

$$\mathcal{J}^K_{(\omega_1)^K} = \bigcup\{\mathcal{Q} \mid \mathcal{Q} \text{ is a sound mouse and } \rho^{\mathcal{Q}}_\omega = 1\}.$$

Nor is it hard to see that all universal weasels have the same subsets of $(\omega_1)^K$, namely those in

$$\mathcal{J}^K_{(\omega_2)^K} = \bigcup\{\mathcal{Q} \mid \mathcal{Q} \text{ is a sound mouse with } \rho^{\mathcal{Q}}_\omega = (\omega_1)^K \text{ and } \mathcal{J}^K_{(\omega_1)^K} \triangleleft \mathcal{Q}\}.$$

This points to a simultaneous definition of what it means for α to be a cardinal of K on one hand, and $\mathcal{J}^K_{(\alpha^+)^K}$ on the other, by induction on $\alpha < \Omega$. However, the general pattern is more complicated than we have indicated; it has to be by Woodin's result on the complexity of $K \cap \mathrm{HC}$. Instead, Steel wove together three definitions,

- α is a cardinal of K,

[7] By definition, $\mathrm{HC} = H(\aleph_1)$. The reader should be attentive here to the difference between

$$J^K_{(\omega_1)^K} = \mathrm{HC}^K$$

and

$$J^K_{(\omega_1)^V} = K \cap \mathrm{HC}.$$

- $\mathcal{Q}$ is an α-strong mouse, and
- $\mathcal{J}^K_{(\alpha^+)^K}$

by induction on $\alpha < \Omega$, where *α-strong* is a natural strengthening of iterable. In the end, if α is a cardinal of K, then

$$\mathcal{J}^K_{(\alpha^+)^K} = \bigcup\{\mathcal{Q} \mid \mathcal{Q} \text{ is a sound } \alpha\text{-strong mouse with } \omega\rho^{\mathcal{Q}}_\omega = \alpha \text{ and } \mathcal{J}^K_\alpha \lhd \mathcal{Q}\}.$$

The simpler pattern that leaves out α-strong holds for α less than the least measurable cardinal of K, as the reader familiar with the core model theory of Dodd and Jensen would expect. A remarkable fact due to Ralf Schindler is that the simpler pattern holds again if $\alpha \geq \aleph_2$. See Theorem 3.6.

Let us make the convention that if $\mathcal{P}$ is a mouse and $\mathcal{T}$ is an iteration tree on $\mathcal{P}$, then we have equipped $\mathcal{P}$ with an $(\omega, \Omega+1)$ iteration strategy $\Sigma^{\mathcal{P}}$ and $\mathcal{T}$ is consistent with $\Sigma^{\mathcal{P}}$. Unless, of course, we specify otherwise. This will save us some writing and make the main points clearer.

2.30 Definition. Suppose that $\mathcal{Q}$ is a premouse and $\alpha \leq \mathrm{On} \cap \mathcal{Q} \leq \Omega$. Let $\mathcal{P} = \mathcal{J}^{\mathcal{Q}}_\alpha$. Then $\mathcal{Q}$ is *α-strong* iff

1. $\mathcal{P}$ is A_0-sound (i.e., $\mathcal{P} \lhd K$) and
2. for each witness $\mathcal{P}^*$ that $\mathcal{P}$ is A_0-sound, there exist
   (a) an iteration tree $\mathcal{T}$ on $\mathcal{P}^*$ of successor length $\theta + 1 \leq \Omega + 1$ such that $\nu(E^{\mathcal{T}}_\eta) \geq \alpha$ for all $\eta < \theta$,
   (b) $\mathcal{R} \trianglelefteq \mathcal{M}^{\mathcal{T}}_\theta$ and
   (c) an elementary embedding $\pi : \mathcal{Q} \to \mathcal{R}$ with $\pi \restriction \alpha = \mathrm{id} \restriction \alpha$.

Definition 2.30 does not have the features advertised before in that it is not first-order over $H(\Omega)$ and it is not a natural strengthening of iterability. But there is a satisfactory equivalent formulation that we get to somewhat later. However, the following connection between K and α-strong tells us that we are on the right track.

2.31 Theorem. *Let α be a cardinal of K and $\mathcal{Q}$ be a sound premouse that agrees with K below α. Assume that $\rho^{\mathcal{Q}}_\omega = \alpha$. Then*

$$\mathcal{Q} \lhd K \quad \Longleftrightarrow \quad \mathcal{Q} \textit{ is } \alpha\textit{-strong.}$$

The proof of this and the following closely related basic result are left as reasonable exercises for the reader.

2.32 Theorem. *Let α be a cardinal of K and $\mathcal{P} = \mathcal{J}^K_\alpha$. Suppose that $\mathcal{P}^*$ is a witness that $\mathcal{P}$ is A_0-sound. Let $\beta = (\alpha^+)^K$. Then*

(1) $\beta = (\alpha^+)^{\mathcal{P}^*}$,

(2) $\mathcal{P}^*$ and K agree below β and

(3) $\mathcal{P}^*$ is α-strong.

Theorem 2.31 tells us how to formulate a recursive definition of K in terms of α-strong mice. But the definition of α-strong involves quantification over weasels that witness A_0-soundness, hence over subsets of $H(\Omega)$, so we are no better off than we started in terms of complexity. The first-order formulation we have in mind involves a generalization of the notion of an iteration tree on a mouse to an iteration tree on a phalanx, which is defined below. Such iteration trees also generalize the *double-rooted* iteration trees that appear in the proofs of condensation, Theorem 5.1 of [41], and solidity, Theorem 5.3 of [41], the difference being that we allow an arbitrary number of roots. (These condensation and solidity theorems originally appeared in [20] where double-rooted iteration trees are called *pseudo-iteration trees*.)

2.33 Definition. Suppose that $\vec{\lambda} = \langle \lambda_\alpha \mid \alpha < \gamma \rangle$ is an increasing sequence of ordinals, and $\vec{\mathcal{Q}} = \langle \mathcal{Q}_\alpha \mid \alpha \leq \gamma \rangle$ is a sequence of mice. Then $(\vec{\mathcal{Q}}, \vec{\lambda})$ is a *phalanx of length* $\gamma + 1$ iff $\mathcal{Q}_\alpha$ and $\mathcal{Q}_\beta$ agree below λ_α whenever $\alpha < \beta \leq \gamma$.

As an example, observe that if $\mathcal{S}$ is an iteration tree of successor length, then

$$(\langle \mathcal{M}^{\mathcal{S}}_\alpha \mid \alpha < \mathrm{lh}(\mathcal{S}) \rangle, \langle \mathrm{lh}(E^{\mathcal{S}}_\alpha) \mid \alpha < \mathrm{lh}(\mathcal{S}) - 1 \rangle)$$

is a phalanx of length $\mathrm{lh}(\mathcal{S})$. Notice that in passing from $\mathcal{S}$ to this phalanx we retain the models and record the relevant amount of agreement between the models but we lose all information about how the models were created and the tree order. Of course, not every phalanx comes from an iteration tree in this way.

2.34 Definition. Let $(\vec{\mathcal{Q}}, \vec{\lambda})$ be a phalanx of length $\gamma + 1$ and $\theta \geq \gamma + 1$. An *iteration tree $\mathcal{T}$ of length θ* on $(\vec{\mathcal{Q}}, \vec{\lambda})$ consists of

- a tree structure $<_T$ on θ for which each ordinal $\leq \gamma$ is a root,
- the corresponding root operation $\mathrm{root}^T : \theta \to \gamma + 1$,
- the corresponding predecessor operation pred^T that maps successor ordinals in the interval $[\gamma + 1, \theta)$ to ordinals $\leq \theta$,
- premice $\mathcal{M}^{\mathcal{T}}_\eta$ for $\eta < \theta$,
- extenders $E^{\mathcal{T}}_\eta$ whenever $\gamma < \eta + 1 < \theta$,
- a set of successor ordinals $D^{\mathcal{T}} \subseteq [\gamma + 1, \theta)$,
- a commutative system of embeddings

$$i^{\mathcal{T}}_{\zeta,\eta} : \mathcal{M}^{\mathcal{T}}_\zeta \to \mathcal{M}^{\mathcal{T}}_\eta$$

indexed by $\zeta <_T \eta$ for which

$$(\zeta, \eta]_T \cap D^{\mathcal{T}} = \emptyset$$

and

- an operation $\deg^{\mathcal{T}} : [\gamma + 1, \theta) \to \omega + 1$

with the following properties.

- If $\alpha \leq \gamma$, then $\mathcal{M}_\alpha^{\mathcal{T}} = \mathcal{Q}_\alpha$ and $\lambda_\alpha^{\mathcal{T}} = \lambda_\alpha$.
- If $\gamma < \eta + 1 < \theta$, then $E_\eta^{\mathcal{T}}$ is an extender from the $\mathcal{M}_\eta^{\mathcal{T}}$ sequence, $\mathrm{pred}^T(\eta + 1)$ is the least $\zeta \leq \eta$ such that

  $$\mathrm{crit}(E_\eta^{\mathcal{T}}) < \lambda_\zeta^{\mathcal{T}},$$

  and

  $$\mathcal{M}_{\eta+1}^{\mathcal{T}} = \mathrm{Ult}(\mathcal{N}, E_\eta^{\mathcal{T}})$$

  where $\mathcal{N}$ is the greatest initial segment of $\mathcal{M}_{\mathrm{pred}^T(\eta+1)}^{\mathcal{T}}$ such that $E_\eta^{\mathcal{T}}$ is an extender over $\mathcal{N}$. And

  $$\eta + 1 \in D^{\mathcal{T}} \quad \Longleftrightarrow \quad \mathcal{N} \neq \mathcal{M}_{\mathrm{pred}^T(\eta+1)}^{\mathcal{T}}.$$

  The degree of this ultrapower is $\deg^{\mathcal{T}}(\eta + 1)$, and this degree equals the largest $n \leq \omega$ such that

  $$\rho_n^{\mathcal{N}} > \mathrm{crit}(E_\eta^{\mathcal{T}})$$

  If $\eta + 1 \notin D^{\mathcal{T}}$, then

  $$i_{\mathrm{pred}^T(\eta+1), \eta+1}^{\mathcal{T}} : \mathcal{M}_{\mathrm{pred}^T(\eta+1)}^{\mathcal{T}} \to \mathcal{M}_{\eta+1}^{\mathcal{T}}$$

  is the ultrapower embedding. And

  $$\lambda_\eta^{\mathcal{T}} = \mathrm{lh}(E_\eta^{\mathcal{T}}).$$

- If $\gamma < \eta < \theta$ and η is a limit ordinal, then

  $$[\mathrm{root}^T(\eta), \eta)_T$$

  is a cofinal branch of $T \restriction \eta$. Moreover,

  $$D^{\mathcal{T}} \cap [\mathrm{root}^T(\eta), \eta)_T$$

  is finite and $\mathcal{M}_\eta^{\mathcal{T}}$ is the direct limit of the models $\mathcal{M}_\zeta^{\mathcal{T}}$ under the embeddings

  $$i_{\iota,\zeta}^{\mathcal{T}} : \mathcal{M}_\iota^{\mathcal{T}} \to \mathcal{M}_\zeta^{\mathcal{T}}$$

  for $\iota, \zeta \in [\mathrm{root}^T(\eta), \eta)_T - \max(D^{\mathcal{T}})$ with $\iota <_T \zeta$. In addition,

  $$\deg^{\mathcal{T}}(\eta) = \liminf_{\zeta <_T \eta} \deg^{\mathcal{T}}(\zeta).$$

Just like with iteration trees on a single mouse, in the literature one sees the ultrapower embedding $\mathcal{N} \to \mathcal{M}^{\mathcal{T}}_{\eta+1}$ above denoted

$$i^*_{\eta+1} : \mathcal{M}^*_{\eta+1} \to \mathcal{M}_{\eta+1}.$$

Adding a superscript $\mathcal{T}$ leads to admittedly unattractive notation but we do not break with tradition.

We remark that in most cases of interest, the degree is non-increasing between drops in model so the lim inf ends up being the eventual value. The phrase *drop in degree* has the obvious meaning.

The notion of an iteration strategy generalizes in the obvious way to phalanxes. An iteration strategy picks cofinal branches at limit stages and is responsible for wellfoundedness in both successor and limit stages. When we speak of an iteration tree on an iterable phalanx, the reader should assume that the iteration tree is compatible with a fixed iteration strategy on the phalanx.

The following theorem is the key step towards a recursive definition of α-strong. We write $<\beta$-strong to mean α-strong for all $\alpha < \beta$.

2.35 Theorem. *Suppose that α is a cardinal of K and $\mathcal{Q}$ is a premouse of height $\leq \Omega$ that agrees with K below α. Then the following are equivalent.*

(1) $\mathcal{Q}$ is α-strong.

(2) For all $<\alpha$-strong premice $\mathcal{P}$,

$$(\langle \mathcal{P}, \mathcal{Q} \rangle, \langle \alpha \rangle)$$

is an $\Omega + 1$ iterable phalanx.

Proof. That (2) implies (1) is an immediate consequence of Theorem 2.32(3) and the following result.

2.36 Lemma. *Suppose that α is a cardinal of K and $\mathcal{P} = \mathcal{J}^K_\alpha$. Let $\mathcal{P}^*$ be a witness that $\mathcal{P}$ is A_0-sound and $\mathcal{Q}$ be a premouse of height $\leq \Omega$. Suppose that $(\langle \mathcal{P}^*, \mathcal{Q} \rangle, \langle \alpha \rangle)$ is an $\Omega + 1$ iterable phalanx. Then clause 2 of Definition 2.30 holds for $\mathcal{Q}$ and $\mathcal{P}^*$.*

Sketch. Let $(\mathcal{S}, \mathcal{T})$ be the coiteration of the pair

$$((\langle \mathcal{P}^*, \mathcal{Q} \rangle, \langle \alpha \rangle), \mathcal{P}^*).$$

We have not discussed this sort of coiteration before but it is defined in the natural way, using comparison of extender sequences to decide which extenders to apply at successor stages. The proof of the comparison, Theorem 3.11 of [41], generalizes to show that this coiteration is successful, which means that either $\mathcal{M}^{\mathcal{S}}_{1+\eta} \trianglelefteq \mathcal{M}^{\mathcal{T}}_\theta$ or vice-versa where $1 + \eta + 1 = \mathrm{lh}(\mathcal{S})$ and $\theta + 1 = \mathrm{lh}(\mathcal{T})$. And that $1 + \eta$, $\theta \leq \Omega$.

2.37 Claim. $\mathrm{root}^{\mathcal{S}}(1+\eta) = 1$.

Sketch. For contradiction, suppose that $\mathrm{root}^{\mathcal{S}}(1+\eta) = 0$. As in the proof of universality Theorem 2.8, the fact that $\mathcal{P}^*$ computes κ^+ correctly for stationary many $\kappa < \Omega$ can be used to see that

$$\mathcal{M}^{\mathcal{S}}_{1+\eta} = \mathcal{M}^{\mathcal{T}}_{\theta}$$

and there is no dropping along $[0, 1+\eta]_S$ and $[0,\theta]_T$. We have the embeddings

$$i^{\mathcal{S}}_{0,1+\eta} : \mathcal{P}^* \to \mathcal{M}^{\mathcal{S}}_{1+\eta}$$

and

$$i^{\mathcal{T}}_{0,\theta} : \mathcal{P}^* \to \mathcal{M}^{\mathcal{T}}_{1+\eta}$$

with

$$\mathrm{crit}(i^{\mathcal{S}}_{0,1+\eta}) < \alpha.$$

Theorems 2.13 and 2.16 generalize to iteration trees on phalanxes. Thus using the fact that $\mathcal{P}^*$ has the definability and hull properties at all ordinals $< \alpha$, we see that $i^{\mathcal{S}}_{0,1+\eta}$ and $i^{\mathcal{T}}_{0,\theta}$ have the same critical point and move subsets of their critical point the same way. In other words, the first extenders used along $[0, 1+\eta]_S$ and $[0,\theta]_T$ agree, which leads to a contradiction as in the proof of comparison, Theorem 3.11 of [41]. ⊣

Again as in the proof of Theorem 2.8,

$$\mathcal{M}^{\mathcal{S}}_{1+\eta} \trianglelefteq \mathcal{M}^{\mathcal{T}}_{\theta}$$

and there is no dropping along $[1, 1+\eta]_S$. So we have the embedding

$$i^{\mathcal{S}}_{1,1+\eta} : \mathcal{Q} \to \mathcal{M}^{\mathcal{S}}_{1+\eta}$$

with $\mathrm{crit}(i^{\mathcal{S}}_{1,1+\eta}) \geq \alpha$. Since $\mathcal{Q}$ and $\mathcal{P}^*$ agree below α, $\mathrm{lh}(E^{\mathcal{T}}_{\zeta}) \geq \alpha$ for all $\zeta < \theta$. Since α is a cardinal of K, it is a cardinal of $\mathcal{P}^*$. This can be used to see that $\nu(E^{\mathcal{T}}_{\zeta}) \geq \alpha$ for all $\zeta < \theta$. Thus $i^{\mathcal{S}}_{1,1+\eta}$ and $\mathcal{T}$ witness that $\mathcal{Q}$ is α-strong relative to $\mathcal{P}^*$ as desired. ⊣

We have seen that (2) implies (1). Let β be a cardinal of K. We show that (1) for β implies (2) for β. Suppose that $\mathcal{Q}$ is a β-strong premouse and $\mathcal{P}$ is a $<\beta$-strong premouse. We must show that $(\langle \mathcal{P}, \mathcal{Q}\rangle, \langle \beta \rangle)$ is $\Omega + 1$ iterable. By the proof of Theorem 2.29, there exist a witness W that $\mathcal{J}^K_\beta$ is A_0-sound and an elementary embedding

$$\sigma : W \to K^c.$$

We do not have a lower bound on the critical point of σ, nor is it relevant. By Definition 2.30, for each $\alpha \leq \beta$, we have an iteration tree $\mathcal{T}_\alpha$ of length $\theta_\alpha + 1 \leq \Omega + 1$ on W such that $\nu(F^{\mathcal{T}_\alpha}_\eta) \geq \alpha$ for all $\eta < \theta_\alpha$,

$$\mathcal{R}_\alpha \trianglelefteq \mathcal{M}^{\mathcal{T}_\alpha}_{\theta_\alpha}$$

and an elementary embedding π_α with $\pi_\alpha \restriction \alpha = \mathrm{id} \restriction \alpha$. If $\alpha < \beta$, then

$$\pi_\alpha : \mathcal{P} \to \mathcal{R}_\alpha$$

whereas

$$\pi_\beta : \mathcal{Q} \to \mathcal{R}_\beta.$$

Use σ to copy each $\mathcal{T}_\alpha$ to an iteration tree $\sigma\mathcal{T}_\alpha$ on K^c and let

$$\tau_\alpha : \mathcal{R}_\alpha \to \mathcal{S}_\alpha$$

be the restriction of the final copying map to $\mathcal{R}_\alpha$. Then

$$(\tau_\alpha \circ \pi_\alpha) \restriction \alpha = \tau_\alpha \restriction \alpha = \sigma \restriction \alpha$$

for all $\alpha \leq \beta$.

We wish to construe

$$(\langle \mathcal{S}_\alpha \mid \alpha \leq \beta \rangle, \langle \sigma(\alpha) \mid \alpha < \beta \rangle)$$

as a phalanx. Formally, for this we let $\langle \alpha_\eta \mid \eta \leq \theta \rangle$ enumerate the cardinals of K up to and including β and set

$$\mathfrak{F} = (\langle \mathcal{S}_{\alpha_\eta} \mid \eta \leq \theta \rangle, \langle \sigma(\alpha_\eta) \mid \eta < \theta \rangle).$$

Then $\mathfrak{F}$ is a phalanx. There are two basic elements to the remainder of the proof. Notice that all the models of $\mathfrak{F}$ are obtained by iterating K^c. We call such phalanxes K^c *based*. Steel proved that all K^c based phalanxes are $\Omega + 1$ iterable. The reader is referred to [42, §6] for the proof, which builds on Steel's proof that K^c is $(\omega, \Omega + 1)$ iterable. The second idea is that the sequence of embeddings

$$\psi_\eta = \tau_{\alpha_\eta} \circ \pi_{\alpha_\eta}$$

for $\eta \leq \theta$ can be used to pull back an iteration strategy on $\mathfrak{F}$ to an iteration strategy on $(\langle \mathcal{P}, \mathcal{Q} \rangle, \langle \beta \rangle)$. For this we use a generalization of the copying construction in Sect. 4.1 of [41]. The generalization is routine except for a few technical details. The main wrinkle comes in the case $\beta = (\alpha^+)^K$ when we apply the shift lemma to an ultrapower of $\mathcal{P}$ by an extender with critical point α. The difficulty is that $\psi_{\theta-1} = \tau_\alpha \circ \pi_\alpha$ and $\psi_\theta = \tau_\beta \circ \pi_\beta$ agree to α in this case whereas agreement to β would be needed to quote Lemma 4.2 of [41]. Nevertheless, a version of the shift lemma still goes through. We refer the reader to [42, pp. 49–50] for the details. This type of copying construction is used repeatedly in the proof of the weak covering property in Sect. 4. $\dashv$

We are about to arrive at the much promised definition of K that is first-order over $H(\Omega)$. Clause b of Theorem 2.35 quantifies over weasels so there is still something to do.

2.38 Definition. If $\mathcal{T}$ is an iteration tree of length θ, then $\mathcal{T}$ is called *bad* if it is a losing position for player II in the iteration game. In other words,

1. if $\theta = \eta + 1$, then there is an extender F on the $\mathcal{M}_\eta^\mathcal{T}$ sequence such that $\mathrm{lh}(F) > \mathrm{lh}(E_\zeta^\mathcal{T})$ for all $\zeta < \eta$ but if $\zeta \leq \eta$ is least such that $\mathrm{crit}(F) \geq \nu(E_\zeta^\mathcal{T})$ and $\mathcal{N}$ is the greatest initial segment of $\mathcal{M}_\zeta^\mathcal{T}$ over which F is an extender, then $\mathrm{Ult}(\mathcal{N}, F)$ is illfounded where the degree of the ultrapower is as large as possible, and

2. if θ is a limit ordinal, then all cofinal branches of $\mathcal{T}$ have infinitely many drops in model or are illfounded.

Because of our Technical Hypothesis, $\Omega + 1$ iterability is equivalent to Ω iterability. In light of our Anti-Large Cardinal Hypothesis, there are many cases in which $\Omega + 1$ iterability reduces further to the non-existence of a countable bad tree. For example, the proof of Theorem 2.3 can be extended to show that if a premouse $\mathcal{P}$ of height Ω is not $\Omega + 1$ iterable, then there is a countable bad tree on $\mathcal{P}$. We give another useful example.

2.39 Definition. A premouse $\mathcal{P}$ is defined to be *properly small* iff $\mathcal{P}$ has no Woodin cardinals and $\mathcal{P}$ has a largest cardinal.

Notice that if $\mathcal{P}$ is a weasel and $\mu < \Omega$, then $\mathcal{J}^\mathcal{P}_{(\mu^+)^\mathcal{P}}$ is properly small. It is also easy to see that the properly small levels of K that project to α are unbounded in $(\alpha^+)^K$. If each premouse of a phalanx is properly small, then the $\Omega + 1$ iterability of the phalanx reduces to the non-existence of a countable bad tree on the phalanx. Arguing along these lines we obtain the following characterization.

2.40 Theorem. *Suppose that α is a cardinal of K and $\mathcal{Q}$ is a properly small premouse of height $< \Omega$ that agrees with K below α. Then the following are equivalent.*

(1) $\mathcal{Q}$ is not α-strong.

(2) There is a properly small $<\alpha$-strong premouse $\mathcal{P}$ with the same cardinality as $\mathcal{Q}$ and a countable bad iteration tree on the phalanx

$$(\langle \mathcal{P}, \mathcal{Q} \rangle, \langle \alpha \rangle).$$

Sketch. Suppose that $\mathcal{Q}$ is not α-strong. Then there exist a weasel $\mathcal{P}^*$ that witnesses $\mathcal{J}^K_\alpha$ is A_0-sound and a bad iteration tree on

$$(\langle \mathcal{P}^*, \mathcal{Q} \rangle, \langle \alpha \rangle).$$

The same bad iteration tree can be construed as a bad iteration tree, call it $\mathcal{U}$, on

$$(\langle \mathcal{P}^{**}, \mathcal{Q} \rangle, \langle \alpha \rangle)$$

for some properly small $\mathcal{P}^{**} \lhd \mathcal{P}^*$. Let $Y \prec H(\Omega)$ with $\mathcal{U} \in Y$ such that Y has the same cardinality as $\mathcal{Q}$. Let $\tau : N \simeq Y$ with N transitive. Then

$\tau^{-1}(\mathcal{Q}) = \mathcal{Q}$. Let $\mathcal{P} = \tau^{-1}(\mathcal{P}^{**})$. Then $\mathcal{P}$ is $<\alpha$-strong, properly small and has the same cardinality as $\mathcal{Q}$. Let $X \prec N$ with X countable and $\tau^{-1}(\mathcal{U}) \in X$. Let $\sigma : M \simeq X$ with M transitive. Let $\mathcal{S} = (\tau \circ \sigma)^{-1}(\mathcal{U})$. An absoluteness argument like that used in the proof of Theorem 2.3 shows that $\mathcal{S}$ is bad. (Here is where the hypothesis that $\mathcal{Q}$ is properly small is used.) Let $\mathcal{T} = \sigma\mathcal{S}$. Then $\mathcal{T}$ is a countable bad iteration tree on $(\langle\mathcal{P}, \mathcal{Q}\rangle, \langle\alpha\rangle)$. ⊣

Finally, we reach Steel's recursive definition of K.

2.41 Theorem. *Let $\mathcal{M}$ be a premouse of height $< \Omega$. Then $\mathcal{M} \lhd K$ iff there exist $\theta < \Omega$, an increasing continuous sequence of ordinals*

$$\langle \alpha_\eta \mid \eta \leq \theta + 1\rangle$$

starting with $\alpha_0 = \omega$, an $\lhd$ increasing continuous sequence of premice

$$\langle \mathcal{R}_\eta \mid \eta \leq \theta + 1\rangle$$

with $\mathcal{M} \lhd \mathcal{R}_{\theta+1}$ and a double-indexed sequence of sets

$$\langle \mathcal{F}_{\zeta,\eta} \mid \zeta \leq \eta \leq \theta\rangle$$

that satisfy the following conditions.

(1) For all $\zeta \leq \eta \leq \theta$ and $\mathcal{Q}$,

$$\mathcal{Q} \in \mathcal{F}_{\zeta,\eta}$$

iff $\mathcal{Q}$ is a properly small premouse of cardinality $|\alpha_\eta|$ such that

$$\mathcal{R}_\zeta \lhd \mathcal{Q}$$

and, if

$$\mathcal{P} \in \bigcap\{\mathcal{F}_{\iota,\eta} \mid \iota < \zeta\},$$

then

$$(\langle\mathcal{P}, \mathcal{Q}\rangle, \langle\alpha_\zeta\rangle)$$

is a phalanx on which there is no countable bad iteration tree.

(2) For all $\eta \leq \theta$,

$$\{\mathcal{Q} \in \mathcal{F}_{\eta,\eta} \mid \mathcal{Q} \textit{ is sound and } \omega\rho_\omega^{\mathcal{Q}} = \alpha_\eta\}$$

is a family of premice that are pairwise comparable under $\trianglelefteq$. Moreover, the union of this family is $\mathcal{R}_{\eta+1}$, which is a premouse of height $\alpha_{\eta+1}$.

Sketch. The idea is that, for all $\zeta \leq \eta < \Omega$,

$$\alpha_\eta = (\aleph_\eta)^K$$

$$\mathcal{R}_\eta = \mathcal{J}^K_{(\aleph_\eta)^K}$$

and $\mathcal{F}_{\zeta,\eta}$ is the set of properly small $(\aleph_\zeta)^K$-strong premice of size $|(\aleph_\eta)^K|$. And θ is large enough so that

$$\mathcal{M} \lhd \mathcal{J}^K_{(\aleph_{\theta+1})^K}.$$

⊣

3. Core Model Tools

Throughout this section, we continue to assume the Anti-Large Cardinal Hypothesis,

there is no proper class model with a Woodin cardinal

and the Technical Hypothesis,

U is a normal measure over Ω.

Under these hypotheses, in the previous section, a certain transitive model of ZFC of ordinal height Ω is defined and named K. Here, we list properties of K that are useful in applications. For the most part, it is not necessary to read the previous section to make sense of these properties.

3.1. Covering Properties

Jensen showed that if $0^{\#}$ does not exist and A is an uncountable set of ordinals, then there exists a set $B \in L$ such that $A \subseteq B$ and $|A| = |B|$. Dodd and Jensen proved the same theorem for K under the hypothesis that there is no inner model with a measurable cardinal. If there is a measurable cardinal, then the Jensen covering property for K fails in any Prikry forcing extension. Mitchell proved that if there is no inner model satisfying $\exists\kappa(o(\kappa) = \kappa^{++})$, then K still satisfies several consequences of the Jensen covering property and that these weak covering properties are still useful in applications. Mitchell's work in this regard and the history behind it is the subject of the Handbook chapter [18].

The first result we list in this subsection, which is due to Steel, says that K computes the successor of almost every cardinal correctly.

3.1 Theorem.

$$\{\kappa < \Omega \mid (\kappa^+)^K = \kappa^+\} \in U.$$

The reader should cite Theorem 5.18(2) of [42] when applying Theorem 3.1. We mentioned this result in Sect. 2 just after the proof of Theorem 2.29.

Many people would identify the following result, which is due to Mitchell and the author, as the weak covering theorem for K. It implies that K computes successors of singular cardinals correctly but contains other applicable information.

3.2 Theorem. *Let κ be a cardinal of K such that*

$$\omega_2 \leq \kappa < \Omega.$$

and

$$\lambda = (\kappa^+)^K.$$

Then

$$\mathrm{cf}(\lambda) \geq |\kappa|.$$

Thus either $\lambda = |\kappa|^+$ or $\mathrm{cf}(\lambda) = |\kappa|$.

The reader should cite Theorem 0.1 of [19] when applying Theorem 3.2. The proof builds on that of Theorem 1.1 [21], which is the special case in which $|\kappa|$ is a countably closed cardinal. We outline the proof under this and further simplifying assumptions in Sect. 4.

The next result, which is due to Steel and the author, says that K computes successors of weakly compact cardinals correctly. The corresponding fact for L under the assumption that $0^{\#}$ does not exist was observed by Kunen in the 1970s.

3.3 Theorem. *Let κ be a weakly compact cardinal such that $\kappa < \Omega$. Then*

$$(\kappa^+)^K = \kappa^+.$$

The reader should cite Theorem 3.1 of [30] when applying Theorem 3.3.

3.2. Absoluteness, Complexity and Correctness

Steel proved the following theorem, which says that K is forcing absolute.

3.4 Theorem. *Let $\mathbb{P} \in H(\Omega)$ be a poset. Then*

$$\Vdash_{\mathbb{P}} K = K^V.$$

The reader should cite Theorem 5.18(3) of [42] when applying Theorem 3.4. We mentioned this result in Sect. 2 just after the proof of Theorem 2.29.

Using his first-order definition of K, Steel carried out the first part of the following computation of $K \cap \mathrm{HC}$. Think of this as the set of reals that code the countable levels of K, countable in V that is. The second part, a computation done by Schindler, shows that the complexity drops if only finitely many countable ordinals are strong cardinals in K.

3.5 Theorem. *There is a Σ_1 formula $\varphi(x)$ such that for all $a \in \mathrm{HC}$,*

$$a \in K \iff L_{\omega_1}(\mathbb{R}) \models \varphi[a].$$

Moreover, if $K \cap \mathrm{HC}$ has at most finitely many strong cardinals, then there is a formula $\psi(x)$ such that for all $a \in \mathrm{HC}$,

$$a \in K \iff \mathrm{HC} \models \psi[a].$$

The reader should cite Theorem 6.15 of [42] when applying the first part of Theorem 3.5. We mentioned this result in Sect. 2; it is a corollary to Theorem 2.41. The reader should cite Theorems 3.4 and 3.6 of [11] when applying the *moreover* part of Theorem 3.5.

Steel defined the levels of K by recursion on their ordinal height $< \Omega$. It turns out that iterability alone is not enough to guarantee that a mouse with all the right first-order properties to be a level of K is actually a level of K. So, simultaneous with his recursive definition of the levels of K, Steel defined increasingly strong forms of iterability. This is explained in detail in Sect. 2.2. The following theorem of Schindler shows that there is a tremendous simplification in the recursive definition for levels of K of height $\geq \aleph_2$.

3.6 Theorem. *Let κ be a cardinal of K such that $\aleph_2 \leq \kappa < \Omega$. Suppose that $\mathcal{M}$ is a mouse such that*

(1) $\mathcal{M}$ and K agree below κ,

(2) $\rho_\omega^{\mathcal{M}} \leq \kappa$ and

(3) $\mathcal{M}$ is sound above κ.

Then $\mathcal{M}$ is an initial segment of K.

One says that above $\aleph_2$, K is obtained by stacking mice. The reader should cite Lemma 3.5 of [10] when using Theorem 3.6 and should consult Lemma 2.2 of [34] as well. The proof of Theorem 3.6 builds on the proof of Theorem 3.2.

By definition, a class M is Σ^1_n correct iff $M \prec_{\Sigma^1_n} V$. In other words, for each Σ^1_n formula $\psi(x)$ and $a \in \mathbb{R} \cap M$,

$$\psi[a]^M \iff \psi[a].$$

Jensen proved that if $x^\#$ exists for all $x \subseteq \omega$ but there is no inner model with a measurable cardinal, then K is Σ^1_3 correct. The following result is due to Steel.

3.7 Theorem. *Suppose that there exists a measurable cardinal $< \Omega$. Then K is Σ^1_3 correct.*

The reader should cite Theorem 7.9 of [42] when applying Theorem 3.7. It is not known if the existence of a measurable cardinal $< \Omega$ is needed. There is also an attractive conjecture regarding Σ^1_4 correctness that has been open for about a decade.[8]

3.3. Embeddings of K

The first result in this subsection, which is due to Steel, says that K is rigid.

3.8 Theorem. *If $j : K \to K$ is an elementary embedding, then j is the identity.*

The reader should cite Theorem 8.8 of [42] when applying Theorem 3.8.

Steel proved the following result, which says that K is universal.

3.9 Theorem. *K is the unique universal weasel that elementarily embeds into all other universal weasels.*

The reader should cite Theorem 8.10 of [42] when applying Theorem 3.9. Universal weasels were defined in Sect. 2. See Definitions 2.1 and 2.7.

Now we turn to external embeddings and their actions on K. The question is whether the restriction to K of an embedding from an iteration of V is the embedding from an iteration of K.

[8] Assume that $M_1(x)$ exists for all sets x but that there is no model with two Woodin cardinals. Show that K is Σ^1_4 correct.

3.10 Theorem. *Suppose that $\mathcal{T}$ is an iteration tree on V with final model N and branch embedding*

$$\pi : V \to N.$$

Assume that

(1) $\mathcal{T}$ is finite and ${}^{\omega}N \subseteq N$, or

(2) $\mathcal{T}$ is countable and ρ-maximal in the sense of Neeman [23].

Then there is an iteration tree on K whose last model is K^N and whose branch embedding is $\pi \restriction K$.

Keep in mind that even if the external iteration tree $\mathcal{T}$ consists of a single ultrapower by a normal measure, the corresponding iteration tree on K may be infinite and quite complicated. Schindler proved Theorem 3.10 under assumption (1). The author observed that Schindler's proof goes through with assumption (2). The reader should cite Corollary 3.1 of [36] in case (1) and Corollary 3.2 [36] in case (2) when applying Theorem 3.10.

3.4. Maximality

Steel proved that K is maximal in the following sense.

3.11 Theorem. *Let F be an extender that coheres with the extender sequence of K. Suppose that (K, F) is countably certified. Then F is on the extender sequence of K.*

The reader should cite Theorem 8.6 of [42] when applying Theorem 3.11. This can be used to see that certain large cardinals reflect to K. For example, if $\kappa < \Omega$ and κ is a λ-strong cardinal for all $\lambda < \Omega$, then κ has the same property in K. The proof of a theorem slightly more general than Theorem 8.6 of [42], applications of maximality and other results along these lines by Steel and the author can be found in [30]. For example, Theorem 3.4 of [30] says that if κ is a cardinal such that $\aleph_2 \leq \kappa < \Omega$, then $H(\kappa) \cap K$ is universal for mice in $H(\kappa)$.

3.5. Combinatorial Principles

Jensen's results with the fine structure of L generalize to models of the form $L[E]$.

3.12 Theorem. *Let $\mathcal{Q}$ be a weasel. Then $\mathcal{Q}$ satisfies the following statements.*

(1) If κ is a cardinal, then $\diamondsuit^+_{\kappa^+}$ holds.

(2) If κ is an inaccessible cardinal, then

$$\diamondsuit^+_{\kappa} \text{ holds} \iff \kappa \text{ is not ineffable.}$$

(3) If κ is a cardinal, then

$$\square_\kappa \text{ holds} \iff \kappa \text{ is not subcompact.}$$

(4) If κ is a regular cardinal, then there is a κ^+ morass.

When applying Theorem 3.12, the reader should cite Theorem 1.2 of [27] for the clauses on diamond, which are due to the author. The reader should cite Theorem 2 of [31] for the existence of a $\square_\kappa$-sequence. (It is a theorem of ZFC due to Burke [4] that if κ is a subcompact cardinal, then $\square_\kappa$ fails.) Zeman and the author [32] proved the clause on morass.

Even though $\mathcal{Q} = K$ is its most interesting instance, Theorem 3.12 holds in situations in which we do not know how to define K. Neither the Anti-Large Cardinal Hypothesis nor the Technical Hypothesis is used in the proof of Theorem 3.12. This explains why we bothered to mention subcompact cardinals in the clause on square since subcompact cardinals are themselves Woodin cardinals, which do not exist under our Anti-Large Cardinal Hypothesis. We should add that only a weak form of iterability is needed for the proof of Theorem 3.12, much less than is assumed in the definition of weasel.

The next result gives conditions under which the $\square_\kappa$ sequence in K cannot be threaded in V. It is a result of the author.

3.13 Theorem. *Let κ be a cardinal such that*

$$\aleph_2 \leq \kappa < \Omega.$$

Suppose that κ is a limit cardinal of K. Let $\lambda = (\kappa^+)^K$. Then there exists a

$$\langle C_\alpha \mid \alpha < \lambda \rangle \in K$$

such that $\langle C_\alpha \mid \alpha < \lambda \rangle$ is a $\square_\kappa$ sequence in K and $\langle C_\alpha \mid \alpha < \lambda \rangle$ has no thread. That is, there is no club D in λ such that

$$D \cap \alpha = C_\alpha$$

for all $\alpha \in \lim(D)$.

The reader should cite [29] when applying Theorem 3.13.

3.6. On the Technical Hypothesis

Schindler proved that below "zero hand grenade", the Technical Hypothesis can be avoided:

3.14 Theorem. *If there is no proper class model with a proper class of strong cardinals, then the Technical Hypothesis is not needed for the results in this chapter.*

The reader should consult [33] before applying Theorem 3.14. Not only is Theorem 3.14 loosely worded, it does not make sense, at least not literally, since there are results in this paper that explicitly refer to the normal measure U over Ω. For these, Ω should be replaced by On and statements about sets in U should be read as statements about stationary classes of ordinals.

Without going to a more restrictive anti-large cardinal hypothesis, it is not known how to get away without a technical hypothesis. But technical hypotheses weaker than a measurable cardinal are known to suffice. For example, Steel showed that the existence of $X^{\#}$ for all $X \in H(\Omega)$ is enough. Also, Steel and the author showed in Theorem 5.1 of [42] that an ω-Erdős cardinal is enough.

4. Proof of Weak Covering

In this section, we discuss elements of the proof of Theorem 3.2 under some simplifying assumptions. Earlier versions of this theorem due to Jensen, Dodd and Jensen, and Mitchell had no technical hypothesis and much stronger anti-large cardinal hypotheses. In particular, their proofs involved linear iterations at most whereas we deal with iteration trees and even some generalizations of iteration trees. To make our task manageable we assume that the reader is familiar with at least one of these earlier proofs, such as any proof in the Handbook chapter [18] or just the proof for L as presented in [28] or in the Handbook chapter [37]. Our emphasis here is on the new complications and how to overcome them, really just a segue into [21] for the reader.

4.1 Definition. A cardinal κ is *countably closed* iff $\mu^{\aleph_0} < \kappa$ for all cardinals $\mu < \kappa$.

For example, if $2^{\aleph_0} < \aleph_\omega$ then $\aleph_\omega$ is countably closed. The following special case of Theorem 3.2 was proved in [21]. We continue to assume the same anti-large cardinal hypothesis and technical hypothesis as in all earlier sections, so that K exists.

4.2 Theorem. *Let κ be a cardinal of K such that $|\kappa|$ is countably closed and $\lambda = (\kappa^+)^K$. Then*

$$\mathrm{cf}(\lambda) \geq |\kappa|.$$

Thus either $\lambda = |\kappa|^+$ or $\mathrm{cf}(\lambda) = |\kappa|$.

For example, if $2^{\aleph_0} < \aleph_\omega$ and $\kappa = \aleph_\omega$, then $(\kappa^+)^K = \aleph_{\omega+1}$.

Outline. The proof begins pretty much as do earlier proofs of weak covering under stronger anti-large cardinal hypotheses. Let $\lambda = (\kappa^+)^K$ and assume for contradiction that

$$\mathrm{cf}(\lambda) < |\kappa|.$$

By taking the union of an elementary chain of length ω_1, we find

$$X \prec (V_{\Omega+1}, \in, U)$$

with

$$\sup(X \cap \lambda) = \lambda$$

and

$$^{\omega}X \subseteq X$$

such that

$$|X| < \mathrm{cf}(\lambda)^{\aleph_0} < |\kappa|.$$

Let $\pi : N \simeq X$ with N transitive and $\delta = \mathrm{crit}(\pi)$. Note that $\pi(\delta) \leq \kappa$. Let

$$\overline{\kappa} = \pi^{-1}(\kappa)$$

$$\overline{\lambda} = \pi^{-1}(\lambda)$$

and

$$\overline{\Omega} = \pi^{-1}(\Omega).$$

Consider an arbitrary $\mu \leq \Omega$. Let $E_\pi \restriction \mu$ be the extender of length μ derived from π. This means the following. For each $a \in [\mu]^{<\omega}$, let

$$\delta_a = \min(\{\gamma \in \overline{\Omega} \cap N \mid a \in [\pi(\gamma)]^{<\omega}\}).$$

Then let

$$(E_\pi)_a = \{X \subseteq [\delta_a]^{|a|} \mid a \in \pi(X)\}.$$

Notice that $(E_\pi)_a$ is an ultrafilter over

$$\wp([\delta_a]^{|a|}) \cap N.$$

And

$$E_\pi \restriction \mu = \{(a, X) \mid a \in [\mu]^{<\omega} \text{ and } X \in (E_\pi)_a\}.$$

The point of this extender is that if M is a transitive model and

$$\wp(\delta_a) \cap M \subseteq N$$

for all $a \in [\mu]^{<\omega}$, then it makes sense to talk about the ultrapower map

$$i_E^M : M \to \mathrm{Ult}(M, F)$$

where

$$F = E_\pi \cap ([\mu]^{<\omega} \times M).$$

Put another way, we may apply F to M iff

$$\wp(\gamma) \cap M \subseteq N$$

for all γ such that $\pi(\gamma) \geq \mu$. Define

$$\mathrm{Ult}(M, \pi, \mu) = \mathrm{Ult}(M, E_\pi \restriction \mu).$$

Here are a few more general remarks. If $a \in [\delta]^{<\omega}$, then $(E_\pi)_a$ is principal and therefore $E_\pi \restriction \delta$ is trivial in the sense that it gives rise to the identity embedding. Observe that $(E_\pi)_{\{\delta\}}$ is equivalent to the normal measure derived from π,

$$\{X \subseteq \delta \mid \delta \in \pi(X)\},$$

in the sense that they determine the same ultrapower. We call

$$E_\pi \restriction \pi(\delta)$$

the superstrong extender derived from π. And we call $E_\pi \restriction \mu$ a *long extender* whenever $\pi(\delta) < \mu$ or, equivalently, whenever $\delta_a > \delta$ for some $a \in [\mu]^{<\omega}$. Long extenders come up in the covering theorem for L in exactly the same way although the terminology had not been established when Jensen discovered the proof. The reader may refer to [28] for an account of Jensen's proof in these terms.

Instead of K we work with an A_0-soundness witness for a large enough initial segment of K. Large enough for us means height Ω_0 where

$$\Omega > \Omega_0 \geq |\lambda|^+ = |\kappa|^+.$$

But for convenience we assume that Ω_0 is an inaccessible cardinal. Let W be the witness that $\mathcal{J}^K_{\Omega_0}$ is A_0-sound that comes out of the proof of Theorem 2.24. There is an elementary embedding $\sigma : W \to K^c$ that is relevant later in the current proof. Let

$$\overline{W} = \pi^{-1}(W)$$

and $(\overline{\mathcal{T}}, \mathcal{T})$ be the coiteration of $(\overline{W}, W)$. Say

$$\theta + 1 = \mathrm{lh}(\mathcal{T})$$

and

$$\overline{\theta} + 1 = \mathrm{lh}(\overline{\mathcal{T}}).$$

Simplify the notation by setting

$$W_\eta = \mathcal{M}^{\mathcal{T}}_\eta$$

for $\eta \leq \theta$ and

$$\overline{W}_\eta = \mathcal{M}^{\overline{\mathcal{T}}}_\eta$$

for $\eta \leq \overline{\theta}$. Because W is universal,

$$D^{\overline{\mathcal{T}}} \cap [0, \overline{\theta}]_{\overline{\mathcal{T}}} = \emptyset$$

and

$$\overline{W}_{\overline{\theta}} \trianglelefteq W_\theta.$$

Nothing we have said so far differs significantly from earlier proofs of weak covering under stronger anti-large cardinal hypotheses except possibly that we are using W instead of K. Before continuing, let us review the main points of the earlier proofs and compare and contrast them with the current proof. In the earlier proofs, it is shown that $\overline{K} = \pi^{-1}(K)$ does not move in its coiteration with K. The current proof shows this too but in an indirect way.[9] Now let $\eta \leq \theta$ be least such that

$$\nu(E^{\mathcal{T}}_{\eta}) > \overline{\kappa}$$

if there is such an η; otherwise let $\eta = 0$. In the earlier proofs, it is shown that there exist $\mathcal{P} \trianglelefteq W_\eta$ and $n < \omega$ such that

$$\rho^{\mathcal{P}}_n \geq \overline{\lambda} = (\overline{\kappa}^+)^{\mathcal{P}}$$

and

$$\mathcal{P} = \mathrm{Hull}^{\mathcal{P}}_{n+1}(\overline{\kappa} \cup p^{\mathcal{P}}_{n+1}).$$

People refer to $\mathcal{P}$ as the *least mouse missing from N at $\overline{\kappa}$*. The current proof is different in that W_η might be a weasel and

$$(\overline{\kappa}^+)^{W_\eta} = \overline{\lambda}.$$

In this case, we set $\mathcal{P} = W_\eta$. Then $\mathcal{P}$ is a thick weasel. Moreover, because $\nu(E^{\mathcal{T}}_{\zeta}) \leq \overline{\kappa}$ for all $\zeta < \eta$, we conclude that $\mathcal{P}$ has the hull and definability properties at μ whenever $\overline{\kappa} \leq \mu < \Omega_0$. This collection of facts about $\mathcal{P}$ turns out to be an adequate substitute if $\mathcal{P}$ happens to be a weasel instead of a premouse of height $< \Omega$. Moving on with our discussion, in the earlier proofs, $E_\pi \restriction \lambda$ is an extender over $\mathcal{P}$ and one sets

$$\mathcal{R} = \mathrm{Ult}(\mathcal{P}, \pi, \lambda).$$

People refer to $\mathcal{R}$ as the *lift up of $\mathcal{P}$*. In the current proof, because iteration trees need not be linear, something along the lines of $\overline{W}$ not moving is needed just to make sense of the definition of $\mathcal{R}$. In the earlier proofs, a standard argument using the fact that ${}^\omega X \subseteq X$ shows that $\mathcal{R}$ is an iterable premouse. The current proof is different on this point. For although $\mathcal{R}$ is wellfounded, it can fail to be a premouse! This happens exactly when $\rho_1(\mathcal{P}) \leq \overline{\kappa}$ (that is, $n = 0$), $\mathcal{P}$ has a top extender with critical point $\mu < \overline{\kappa}$ and π is discontinuous at $(\mu^+)^{\mathcal{P}}$. For then the top extender of $\mathcal{R}$ is not total on $\mathcal{R}$ since its critical point is $\pi(\mu)$ but it only measures sets in

$$J^{\mathcal{R}}_{\sup(\pi``(\mu^+)^{\mathcal{P}})} \triangleleft J^{\mathcal{R}}_{(\pi(\mu)^+)^{\mathcal{R}}}.$$

We call $\mathcal{R}$ a *protomouse* and its top predicate $F^{\mathcal{R}}$ an *extender fragment.* Vaguely put, our answer to the possibility that $\mathcal{R}$ is not a premouse is to find an actual premouse that corresponds to $\mathcal{R}$. But let us set aside this

[9] The current proof is a complicated induction that shows no extender of length $< \overline{\Omega}_0$ is used on $\overline{\mathcal{T}}$.

complication until later and assume that $\mathcal{R}$ is a premouse. In the discussion so far, we have implicitly used some basic facts about the ultrapower embedding $\widetilde{\pi}:\mathcal{P}\to\mathcal{R}$, mainly that
$$\widetilde{\pi}\restriction\overline{\lambda}=\pi\restriction\overline{\lambda}.$$
It is also easy to see that
$$\mathcal{R}=\mathrm{Ult}_n(\mathcal{P},\pi,\kappa).$$
And that, if $\mathcal{P}$ is not a weasel, then
$$\mathcal{R}=\mathrm{Hull}^{\mathcal{R}}_{n+1}(\kappa\cup\widetilde{\pi}(p^{\mathcal{P}}_{n+1}))=\mathrm{Hull}^{\mathcal{R}}_{n+1}(\kappa\cup p^{\mathcal{R}}_{n+1}),$$
whereas if $\mathcal{P}$ is a weasel, then $\mathcal{R}$ is a thick weasel with the hull and definability properties at μ whenever $\kappa\le\mu<\Omega_0$. The last step in the earlier proofs is to analyze the coiteration of $\mathcal{R}$ versus W to obtain the contradiction
$$\lambda=(\kappa^+)^K=(\kappa^+)^W>(\kappa^+)^{\mathcal{R}}=\sup(\widetilde{\pi}``\overline{\lambda})=\sup(\pi``\overline{\lambda})=\lambda.$$
At the analogous step in the current proof, we coiterate $(\langle W,\mathcal{R}\rangle,\langle\kappa\rangle)$ versus W. For this we need that the phalanx is iterable. Basically, we need to know that $\mathcal{R}$ is κ-strong whereas in the earlier proofs, iterability was enough. Our solution, which we make precise soon, is to work up to this phalanx by an induction that involves other phalanxes. In summary, the new complications are:

- how to show that $\overline{W}$ does not move,
- $\mathcal{P}$ and $\mathcal{R}$ could be weasels,
- $\mathcal{R}$ might be a protomouse but not a premouse and
- how to show that $\mathcal{R}$ is κ-strong.

We need more definitions to explain our strategy for dealing with these new complications. Let $\vec{\kappa}$ enumerate the infinite cardinals of $\overline{W}_{\overline{\theta}}$ up to $\overline{\Omega}_0=\pi^{-1}(\Omega_0)$. Thus
$$\kappa_\alpha=(\aleph_\alpha)^{\overline{W}_{\overline{\theta}}}$$
for all $\alpha<\overline{\Omega}_0$. Also let $\vec{\lambda}$ enumerate the infinite successor cardinals of $\overline{W}_{\overline{\theta}}$. Thus $\lambda_\alpha=\kappa_{\alpha+1}$ for all $\alpha<\overline{\Omega}_0$. The main idea for dealing with the first and last new complications involves an induction on $\gamma<\overline{\Omega}_0$ with six induction hypotheses. As they are introduced, we assume $(1)_\alpha$ through $(6)_\alpha$ for all $\alpha<\gamma$. Our obligation is to prove $(1)_\gamma$ through $(6)_\gamma$. The first induction hypothesis tells us that $\overline{W}$ has not moved yet. We use the notation $\overline{E}_\eta=E^{\mathcal{T}}_\eta$.

(1)$_\alpha$ *For all $\eta\le\overline{\theta}$, if $\overline{E}_\eta\neq\emptyset$, then* $\mathrm{lh}(\overline{E}_\eta)>\lambda_\alpha$.

The next step is to derive a phalanx from $\mathcal{T}$. Let $\eta(\alpha)$ be the least $\eta \leq \theta$ such that

$$\nu(E^{\mathcal{T}}_{\eta}) > \kappa_\alpha$$

if there is such an η; otherwise, let $\eta(\alpha) = 0$. Then let $\mathcal{P}_\alpha$ be the unique $\mathcal{P} \trianglelefteq W_{\eta(\alpha)}$ such that for some $n < \omega$

$$\rho^{\mathcal{P}}_n \geq \lambda_\alpha = (\kappa^+_\alpha)^{\mathcal{P}}$$

and $\rho^{\mathcal{P}}_{n+1} \leq \kappa_\alpha$ if it exists. In this case,

$$\mathcal{P} = \mathrm{Hull}^{\mathcal{P}}_{n+1}(\kappa_\alpha \cup p^{\mathcal{P}}_{n+1}).$$

Otherwise, let $\mathcal{P}_\alpha = W_{\eta(\alpha)}$. In this case, $\mathcal{P}_\alpha$ is a thick weasel with the hull and definability properties at μ whenever $\kappa_\alpha \leq \mu < \Omega_0$.

4.3 Lemma. *The phalanx* $(\vec{\mathcal{P}}\restriction(\gamma+1), \vec{\lambda}\restriction\gamma)$ *is iterable.*

Idea. We may construe an iteration tree on this phalanx as an iteration tree extending $\mathcal{T}\restriction(\eta(\gamma)+1)$. But W is iterable. ⊣

By our induction hypothesis $(1)_\alpha$, $E_\pi\restriction\pi(\kappa_\alpha)$ is an extender over $\mathcal{P}_\alpha$ for each $\alpha < \gamma$.[10] This allows us to define

$$\mathcal{R}_\alpha = \mathrm{Ult}(\mathcal{P}_\alpha, \pi, \pi(\kappa_\alpha))$$

and

$$\Lambda_\alpha = \sup(\pi``\lambda_\alpha) = (\pi(\kappa_\alpha)^+)^{\mathcal{R}_\alpha}.$$

A standard application of the fact that ${}^\omega X \subseteq X$ shows that $\mathcal{R}_\alpha$ is a transitive structure. Let $\pi_\alpha : \mathcal{P}_\alpha \to \mathcal{R}_\alpha$ be the ultrapower map. More standard calculations show that

$$\pi_\alpha\restriction\lambda_\alpha = \pi\restriction\lambda_\alpha$$

and

$$\pi_\alpha(\lambda_\alpha) = \Lambda_\alpha \leq \pi(\lambda_\alpha).$$

Also that

$$\mathcal{R}_\alpha = \mathrm{Ult}(\mathcal{P}_\alpha, \pi, \Lambda_\alpha).$$

And, if $\mathcal{P}_\alpha$ is not a weasel, then

$$\mathcal{R}_\alpha = \mathrm{Hull}^{\mathcal{R}_\alpha}_{n+1}(\pi(\kappa_\alpha) \cup \pi_\alpha(p^{\mathcal{P}_\alpha}_{n+1})) = \mathrm{Hull}^{\mathcal{R}_\alpha}_{n+1}(\pi(\kappa_\alpha) \cup p^{\mathcal{R}_\alpha}_{n+1})$$

for some $n < \omega$, whereas if $\mathcal{P}_\alpha$ is a weasel, then $\mathcal{R}_\alpha$ is a thick weasel with the hull and definability properties at μ whenever $\pi(\kappa_\alpha) \leq \mu < \Omega_0$. But notice

10 Models on a non-linear iteration tree are not necessarily contained in the starting model. In order to form $\mathrm{Ult}(\mathcal{P}_\alpha, \pi, \pi(\kappa_\alpha))$ we must know that $E_\pi\restriction\pi(\kappa_\alpha)$ measures all sets in $\mathcal{P}_\alpha$. The proof presented in [21] overlooks this detail but can be straightened out easily using the approach shown here.

that if $\rho_1(\mathcal{P}_\alpha) \leq \kappa_\alpha$, $\mathcal{P}_\alpha$ is an active premouse and π is discontinuous at the cardinal successor of $\mathrm{crit}(F^{\mathcal{P}_\alpha})$ in $\mathcal{P}_\alpha$, then $\mathcal{R}_\alpha$ is not a premouse.

Observe that

$$(\vec{\mathcal{R}}\restriction(\gamma+1), \vec{\Lambda}\restriction\gamma)$$

satisfies the agreement condition for being a phalanx. We call it a *phalanx of protomice*. Let us examine the situation in which $\beta \leq \gamma$ and $\mathcal{R}_\beta$ is not a premouse. Equivalently, there exist $\alpha < \beta$ with

$$\mathrm{crit}(F^{\mathcal{P}_\beta}) = \kappa_\alpha$$

and

$$\Lambda_\alpha < \pi(\lambda_\alpha).$$

In this case,

$$\mathrm{crit}(F^{\mathcal{R}_\beta}) = \pi(\kappa_\alpha).$$

And, although $F^{\mathcal{R}_\beta}$ is an extender fragment but not an extender over $\mathcal{R}_\beta$, it is an extender over $\mathcal{R}_\alpha$. More generally, if $\mathcal{U}$ is what would naturally be called an iteration tree on

$$(\vec{\mathcal{R}}\restriction(\gamma+1), \vec{\Lambda}\restriction\gamma)$$

and $\gamma < \beta' < \mathrm{lh}(\mathcal{U})$ with

$$\mathrm{root}^U(\beta') = \beta$$

and

$$D^{\mathcal{U}} \cap (\beta, \beta']_U = \emptyset,$$

then

$$\mathrm{crit}(F^{\mathcal{M}^{\mathcal{U}}_{\beta'}}) = \pi(\kappa_\alpha) = \mathrm{crit}(F^{\mathcal{R}_\beta})$$

and the two extender fragments are total over $\mathcal{R}_\alpha$. Thus $F^{\mathcal{M}^{\mathcal{U}}_{\beta'}}$ could legitimately be applied to $\mathcal{R}_\alpha$ to form an extension of $\mathcal{U}$. While the following result is not used in the current proof, others like it are.

4.4 Lemma. *The phalanx of protomice*

$$(\vec{\mathcal{R}}\restriction(\gamma+1), \vec{\Lambda}\restriction\gamma)$$

is iterable.

Idea. In the standard way, use the fact that ${}^\omega X \subseteq X$ to reduce the iterability of the above phalanx to that of

$$(\vec{\mathcal{P}}\restriction(\gamma+1), \vec{\lambda}\restriction\gamma).$$

The latter phalanx is iterable by Lemma 4.3. $\dashv$

Based on our discussion of earlier proofs of weak covering, we would expect to want to iterate

$$(\langle W, \mathcal{R}_\gamma\rangle, \langle\pi(\kappa_\gamma)\rangle).$$

We can make sense of what we mean by this even if $\mathcal{R}_\gamma$ is not a premouse, but iterating this phalanx of protomice does not seem to accomplish much in this case. Our solution to this problem is complicated. For each $\alpha \leq \gamma$, if $\mathcal{R}_\alpha$ is not a premouse, then we define a certain premouse $\mathcal{S}_\alpha$ that agrees with $\mathcal{R}_\alpha$ below Λ_α. We also find a premouse $\mathcal{Q}_\alpha$ that agrees with $\mathcal{P}_\alpha$ below λ_α such that

$$\mathcal{S}_\alpha = \mathrm{Ult}(\mathcal{Q}_\alpha, \pi, \pi(\kappa_\alpha)).$$

Only near the end of the current proof will we say exactly what $\mathcal{Q}_\alpha$ and $\mathcal{S}_\alpha$ are in this case. On the other hand, if $\mathcal{R}_\alpha$ is a premouse, then $\mathcal{Q}_\alpha = \mathcal{P}_\alpha$ and $\mathcal{S}_\alpha = \mathcal{R}_\alpha$. The reader is asked to consider this case only for the moment.

As we just indicated, the main thing we want to know besides $(1)_\gamma$ is that $\mathcal{S}_\gamma$ is $\pi(\kappa_\gamma)$-strong, so we make it an induction hypothesis in the following way.

(2)$_\alpha$ $(\langle W, \mathcal{S}_\alpha\rangle, \langle\pi(\kappa_\alpha)\rangle)$ *is an iterable phalanx.*

(3)$_\alpha$ $(\langle \overline{W}, \mathcal{Q}_\alpha\rangle, \langle\kappa_\alpha\rangle)$ *is an iterable phalanx.*

4.5 Lemma. $(3)_\gamma$ *implies* $(2)_\gamma$.

Idea. The proof uses the fact that $\mathcal{S}_\gamma = \mathrm{Ult}(\mathcal{Q}_\gamma, \pi, \lambda_\gamma)$ together with countable closure ${}^\omega X \subseteq X$. It is not as routine as Lemma 4.4 though. ⊣

The next hypothesis is the key to showing that $\overline{W}$ does not move. It also represents an interesting switch in that $\overline{W}$ appears as the starting model instead of the back-up model.

(4)$_\alpha$ $((\vec{\mathcal{P}}\restriction\alpha)^\frown\langle\overline{W}\rangle, \vec{\lambda}\restriction\alpha)$ *is an iterable phalanx.*

4.6 Lemma. $(4)_\gamma$ *implies* $(1)_\gamma$.

Idea. Let $(\mathcal{U}, \mathcal{V})$ be the coiteration of the phalanxes

$$((\vec{\mathcal{P}}\restriction\gamma)^\frown\langle\overline{W}\rangle, \vec{\lambda}\restriction\gamma)$$

and

$$((\vec{\mathcal{P}}\restriction\gamma)^\frown\langle\mathcal{P}_\gamma\rangle, \vec{\lambda}\restriction\gamma).$$

The former phalanx is iterable by $(4)_\gamma$. The latter phalanx is iterable by Lemma 4.3. In particular, $\mathcal{V}$ can be construed as an extension of $\mathcal{T}\restriction\eta(\gamma) + 1$. Let $\zeta + 1 = \mathrm{lh}(\mathcal{U})$. Standard arguments can be used to see that

$$\gamma = \mathrm{root}^U(\zeta)$$

and

$$D^{\mathcal{U}} \cap (\gamma, \zeta]_U = \emptyset.$$

These arguments use the hull and definability properties at κ_α when $\mathcal{P}_\alpha$ is a thick weasel and soundness at κ_α otherwise. Suppose for contradiction that $(1)_\gamma$ fails. Since $(1)_\alpha$ holds for all $\alpha < \gamma$,

$$\mathrm{lh}(\overline{E}_0) = \lambda_\gamma.$$

Consequently, the first extenders used on $\mathcal{U}$ and $\overline{\mathcal{T}}$ are the same, i.e.,

$$E^{\mathcal{U}}_\gamma = \overline{E}_0.$$

Hence

$$\mathrm{lh}(E^{\mathcal{U}}_\gamma) = \lambda_\gamma < ((\kappa_\gamma)^+)^{\overline{W}}.$$

This can be used to see that if

$$\gamma = \mathrm{pred}^U(\iota + 1)$$

then

$$\kappa_\gamma \leq \mathrm{crit}(E^{\mathcal{U}}_\iota)$$

so

$$\iota + 1 \in D^{\mathcal{U}},$$

which is a contradiction. $\dashv$

Here is a fact whose proof is like that of Lemma 4.6. Hypothesis $(4)_\alpha$ implies that there is an iteration tree $\mathcal{V}_\alpha$ on W that extends $\mathcal{T}\restriction(\eta(\alpha)+1)$, an initial segment $\mathcal{N}_\alpha$ of the last model of $\mathcal{V}_\alpha$ with

$$\wp(\kappa_\alpha) \cap \overline{W} = \wp(\kappa_\alpha) \cap \mathcal{N}_\alpha$$

and an elementary embedding $k_\alpha : \overline{W} \to \mathcal{N}_\alpha$ with $k_\alpha\restriction\kappa_\alpha = \mathrm{id}\restriction\kappa_\alpha$. This fact and the notation just established comes up again when we prove $(3)_\gamma$.

$(5)_\alpha$ $((\vec{\mathcal{R}}\restriction\alpha)^\frown\langle W\rangle, \vec{\Lambda}\restriction\alpha)$ *is an iterable phalanx of protomice.*

It makes sense to iterate this phalanx of protomice for reasons like those we gave before Lemma 4.4. The difference is that W is the starting model instead of $\mathcal{R}_\gamma$.

4.7 Lemma. $(5)_\gamma$ *implies* $(4)_\gamma$*.*

Idea. Consider the sequence of embeddings

$$\langle \pi_\alpha \mid \alpha < \gamma\rangle^\frown\langle\pi\rangle.$$

Since $\pi_\alpha\restriction\lambda_\alpha = \pi\restriction\lambda_\alpha$ for all $\alpha < \gamma$, this sequence can be used to reduce the iterability of

$$((\vec{\mathcal{P}}\restriction\gamma)^\frown\langle\overline{W}\rangle, \vec{\lambda}\restriction\gamma)$$

to that of

$$((\vec{\mathcal{R}}\restriction\gamma)^\frown\langle W\rangle, \vec{\Lambda}\restriction\gamma).$$

The latter phalanx is iterable by $(5)_\gamma$. $\dashv$

It is worth noticing that the iteration trees on $((\vec{\mathcal{R}}\restriction\gamma)^\frown\langle W\rangle, \vec{\Lambda}\restriction\gamma)$ that are relevant to the proof of Lemma 4.7 have a special form: whenever $\alpha < \gamma$ and an extender is applied to $\mathcal{R}_\alpha$, the critical point of the extender is exactly $\pi(\kappa_\alpha)$. Similarly, only special iteration trees are relevant to the proof of Lemma 4.4.

(6)$_\alpha$ *$((\vec{\mathcal{S}}\restriction\alpha)^\frown\langle W\rangle, \vec{\Lambda}\restriction\alpha)$ is an iterable phalanx.*

4.8 Lemma. $(6)_\gamma$ *implies* $(5)_\gamma$.

Since we have not defined $\vec{S}\restriction\gamma$ it would be meaningless to sketch the proof of Lemma 4.8, which is not easy. It is interesting, though, that the proof involves a variant of the usual copying constructions in which the tree structure changes. And an ultrapower by an extender fragment in an iteration tree on $((\vec{\mathcal{R}}\restriction\gamma)^\frown\langle W\rangle, \vec{\Lambda}\restriction\gamma)$ corresponds to something like padding in the copied iteration tree on $((\vec{\mathcal{S}}\restriction\gamma)^\frown\langle W\rangle, \vec{\Lambda}\restriction\gamma)$.

Having seen that

$$(6)_\gamma \implies (5)_\gamma \implies (4)_\gamma \implies (1)_\gamma$$

and

$$(3)_\gamma \implies (2)_\gamma$$

it remains to prove $(3)_\gamma$ and $(6)_\gamma$, which we do next.

4.9 Lemma. $(3)_\gamma$ *holds.*

Idea. We must see that $(\langle\overline{W}, \mathcal{Q}_\gamma\rangle, \langle\kappa_\gamma\rangle)$ is iterable. Consider the sequence of embeddings

$$\langle k_\alpha \mid \alpha < \gamma\rangle^\frown\langle \mathrm{id}\restriction\mathcal{Q}_\gamma\rangle$$

where $k_\alpha : \overline{W} \to \mathcal{N}_\alpha$ was defined just after the proof of Lemma 4.6. Since $k_\alpha\restriction\kappa_\alpha = \mathrm{id}\restriction\kappa_\alpha$, this sequence of embeddings can be used to reduce the iterability of

$$(\langle\overline{W}, \mathcal{Q}_\gamma\rangle, \langle\kappa_\gamma\rangle)$$

to that of

$$(\langle\mathcal{N}_\alpha \mid \alpha < \gamma\rangle^\frown\langle\mathcal{Q}_\gamma\rangle, \vec{\kappa}\restriction\gamma).$$

There is a subtlety in the copying construction that also came up at the end of the proof of Theorem 2.35 but once again we omit this detail. The phalanx $(\langle\mathcal{N}_\alpha \mid \alpha < \gamma\rangle^\frown\langle\mathcal{Q}_\gamma\rangle, \vec{\kappa}\restriction\gamma)$ is what we call W *based* because each of its models appears on an iteration tree on W. For $\alpha < \gamma$, the iteration tree is $\mathcal{V}_\alpha$. And for $\mathcal{Q}_\gamma$ the iteration tree is $\mathcal{T}\restriction(\eta(\gamma)+1)$ because we are still assuming for simplicity that $\mathcal{Q}_\gamma = \mathcal{P}_\gamma$. (Otherwise a generalized notion of W based is used.) We chose W so that there is an elementary embedding from $\sigma : W \to K^c$. Copy each $\mathcal{V}_\alpha$ to $\sigma\mathcal{V}_\alpha$ and let

$$\sigma^*_\alpha : \mathcal{N}_\alpha \to \mathcal{N}^*_\alpha$$

be the final copy embedding restricted to $\mathcal{N}_\alpha$. Next, copy $\mathcal{T}\restriction(\eta(\gamma)+1)$ to $\sigma\mathcal{T}\restriction(\eta(\gamma)+1)$ and let

$$\sigma^*_\gamma : \mathcal{Q}_\gamma \to \mathcal{Q}^*_\gamma$$

be the final copy embedding restricted to $\mathcal{Q}_\gamma$. The sequence of embeddings

$$\langle \sigma^*_\alpha \mid \alpha \leq \gamma \rangle$$

can be used to reduce the iterability of $(\langle \mathcal{N}_\alpha \mid \alpha < \gamma \rangle ^\frown \langle \mathcal{Q}_\gamma \rangle, \vec{\kappa}\restriction\gamma)$ to that of

$$(\langle \mathcal{N}^*_\alpha \mid \alpha < \gamma \rangle ^\frown \langle \mathcal{Q}^*_\gamma \rangle, \langle \sigma(\kappa_\alpha) \mid \alpha < \gamma \rangle).$$

The latter phalanx is K^c based and hence iterable by §9 of [42]. ⊣

The following lemma is the last step in our induction.

4.10 Lemma. $(6)_\gamma$ *holds.*

Idea. Consider an arbitrary $\alpha < \gamma$. Freeing up earlier notation, let $(\mathcal{U}, \mathcal{V})$ be the coiteration of W versus $(\langle W, \mathcal{S}_\alpha \rangle, \langle \pi(\kappa_\alpha) \rangle)$. The latter phalanx is iterable by $(2)_\alpha$. Say $\mathrm{lh}(\mathcal{U}) = \zeta + 1$ and $\mathrm{lh}(\mathcal{V}) = \eta + 1$. Standard arguments as in Sect. 2 show that

$$\mathcal{M}^{\mathcal{U}}_\zeta \trianglerighteq \mathcal{M}^{\mathcal{V}}_\eta,$$

$1 = \mathrm{root}^V(\eta)$ and $D^{\mathcal{V}} \cap (1, \eta]_V = \emptyset$. Since $\mathcal{S}_\alpha$ and W agree below Λ_α, the extenders used on $\mathcal{U}$ and $\mathcal{V}$ all have length $\geq \Lambda_\alpha$. In the remainder of this proof, we refer to

$$j_\alpha = i^{\mathcal{V}}_{1,\eta}$$

and

$$\mathcal{M}_\alpha = \mathcal{M}^{\mathcal{V}}_\eta.$$

Note that $j_\alpha : \mathcal{S}_\alpha \to \mathcal{M}_\alpha$ is an elementary embedding and

$$j_\alpha\restriction\pi(\kappa_\alpha) = \mathrm{id}\restriction\pi(\kappa_\alpha).$$

To show that $(6)_\gamma$ holds we must see that the phalanx

$$((\vec{\mathcal{S}}\restriction\gamma)^\frown \langle W \rangle, \vec{\Lambda}\restriction\gamma)$$

is iterable. Using the sequence of embeddings

$$\langle j_\alpha \mid \alpha < \gamma \rangle ^\frown \langle \mathrm{id}\restriction W \rangle$$

this reduces to seeing that the phalanx

$$(\langle \mathcal{M}_\alpha \mid \alpha < \gamma \rangle ^\frown \langle W \rangle, \vec{\Lambda}\restriction\gamma)$$

is iterable. But the latter phalanx is W based. Since W embeds into K^c and all K^c based phalanxes are iterable, all W based phalanxes are iterable. ⊣

This concludes the proof by induction that $(1)_\alpha$ through $(6)_\alpha$ hold for all $\alpha < \overline{\Omega}_0$. Now fix $\overline{\alpha}$ so that $\kappa_{\overline{\alpha}} = \overline{\kappa}$. Then $\lambda_{\overline{\alpha}} = \overline{\lambda}$ and $\Lambda_{\overline{\alpha}} = \lambda$. Write $\mathcal{P} = \mathcal{P}_{\overline{\alpha}}$, $\mathcal{R} = \mathcal{R}_{\overline{\alpha}}$, $\mathcal{Q} = \mathcal{Q}_{\overline{\alpha}}$ and $\mathcal{S} = \mathcal{S}_{\overline{\alpha}}$. Also let $\widetilde{\pi} : \mathcal{Q} \to \mathcal{S}$ be the ultrapower embedding.

4.11 Lemma. *It is not the case that $\mathcal{S} \neq \mathcal{R}$ and $\mathcal{S}$ is not a weasel.*

Idea. Assume otherwise. We build on the facts from the proof of Lemma 4.10 about the coiteration $(\mathcal{U}, \mathcal{V})$ of W versus $(\langle W, \mathcal{S}\rangle, \langle\kappa\rangle)$. We have that

$$\mathcal{S} = \mathrm{Hull}^{\mathcal{S}}_{n+1}(\kappa \cup p^{\mathcal{S}}_{n+1}).$$

Standard arguments show that either

$$\mathcal{S} \triangleleft \mathcal{M}^{\mathcal{V}}_0 = W$$

or

$$E^{\mathcal{U}}_0 = E^W_\lambda$$

and

$$\mathcal{S} = \mathcal{M}^{\mathcal{V}}_1 = \mathrm{Ult}((\mathcal{M}^*_1)^{\mathcal{V}}, E^{\mathcal{V}}_0).$$

Either way, we get the contradiction

$$\lambda = (\kappa^+)^{\mathcal{S}} < (\kappa^+)^W = (\kappa^+)^K.$$

⊣

4.12 Lemma. *It is not the case that $\mathcal{S} \neq \mathcal{R}$ and $\mathcal{S}$ is a weasel.*

Idea. Assume otherwise. We build on facts about the coiteration $(\mathcal{U}, \mathcal{V})$ of W versus $(\langle W, \mathcal{S}\rangle, \langle\kappa\rangle)$ from the proof of Lemma 4.10. We have that $\mathcal{S}$ is a thick weasel with the hull and definability properties at μ whenever $\kappa \leq \mu < \Omega_0$. By universality,

$$\mathcal{M}^{\mathcal{U}}_\zeta = \mathcal{M}^{\mathcal{V}}_\eta.$$

$\mathcal{M}^{\mathcal{V}}_\eta$ has the hull property at κ because $\mathrm{crit}(i^{\mathcal{V}}_{1,\eta}) \geq \kappa$. On the other hand, since $\mathcal{M}^{\mathcal{V}}_\eta$ also results from the iteration

$$W \xrightarrow[i^{\mathcal{T}}_{0,\eta(\overline{\alpha})}]{} \mathcal{Q} \xrightarrow[\widetilde{\pi}]{} \mathcal{S} \xrightarrow[i^{\mathcal{V}}_{1,\eta}]{} \mathcal{M}^{\mathcal{V}}_\eta$$

and $\mathrm{crit}(\widetilde{\pi}) = \mathrm{crit}(\pi) = \delta$, we conclude that $\mathcal{M}^{\mathcal{V}}_\eta$ does not have the definability property at δ. Here we are using that $W_{\eta(\overline{\alpha})} = \mathcal{P} = \mathcal{Q}$. This implies that $\mathcal{U}$ is not trivial. Let $E^{\mathcal{U}}_\iota$ be the first extender used along $[0, \zeta]_U$. That is,

$$0 = \mathrm{pred}^U(\iota + 1) \leq_U \zeta.$$

Since $\mathcal{M}^{\mathcal{U}}_\zeta$ does not have the definability property at δ,

$$\mathrm{crit}(E^{\mathcal{U}}_\iota) \leq \delta.$$

Recall that $\mathcal{S}$ and W agree below λ. But λ is a cardinal in both hence not the index of an extender on the sequence of either. Thus,

$$\mathrm{lh}(E_\iota^{\mathcal{U}}) > \lambda.$$

This implies that the generators of $E_\iota^{\mathcal{U}}$ are unbounded in λ. But then $\mathcal{M}_\zeta^{\mathcal{U}}$ does not have the hull property at κ. This is a contradiction. ⊣

To wrap things up for this section we give the definitions of $\mathcal{Q}_\beta$ and $\mathcal{S}_\beta$ and discuss how they fit with the outline of the proof of Theorem 4.2 given so far. Recall that if $\mathcal{R}_\beta$ is a premouse, then we already defined $\mathcal{Q}_\beta = \mathcal{P}_\beta$ and $\mathcal{S}_\beta = \mathcal{R}_\beta$. Suppose that $\mathcal{R}_\beta$ is not a premouse. Say $\alpha < \beta$ and $\mathrm{crit}(F_\beta^{\mathcal{R}}) = \pi(\kappa_\alpha)$. Recall that $F_\beta^{\mathcal{R}}$ is an extender over $\mathcal{R}_\alpha$. Suppose for the moment that $\mathcal{R}_\alpha$ is a premouse. Then what we would do is set

$$\mathcal{S}_\beta = \mathrm{Ult}(\mathcal{R}_\alpha, F^{\mathcal{R}_\beta}) = \mathrm{Ult}(\mathcal{S}_\alpha, F^{\mathcal{R}_\beta})$$

and

$$\mathcal{Q}_\beta = \mathrm{Ult}(\mathcal{P}_\alpha, F^{\mathcal{P}_\beta}) = \mathrm{Ult}(\mathcal{Q}_\alpha, F^{\mathcal{P}_\beta}).$$

It is easy to see that, in this case, $\mathcal{S}_\beta$ is a premouse and

$$\begin{aligned} \mathcal{S}_\beta \text{ is a weasel} \quad &\iff \quad \mathcal{R}_\alpha \text{ is a weasel}\\ &\iff \quad \mathcal{P}_\alpha \text{ is a weasel}\\ &\iff \quad \mathcal{Q}_\beta \text{ is a weasel.}\end{aligned}$$

Of course, $\mathcal{R}_\beta$ is not a weasel. With a little more work, one sees that

$$\mathcal{S}_\beta = \mathrm{Ult}(\mathcal{Q}_\beta, \pi, \pi(\kappa_\alpha)) = \mathrm{Ult}(\mathcal{Q}_\beta, \pi, \Lambda_\alpha).$$

As for $\mathcal{Q}_\alpha$, it is a model on a finite extension of $\mathcal{T}\restriction(\eta(\alpha)+1)$ in this case but not so literally in others.

The general definition of $\mathcal{S}_\beta$ and $\mathcal{Q}_\beta$ is by induction. We set

$$\mathcal{S}_\beta = \mathrm{Ult}(\mathcal{S}_\alpha, F^{\mathcal{R}_\beta})$$

and

$$\mathcal{Q}_\beta = \mathrm{Ult}(\mathcal{Q}_\alpha, F^{\mathcal{P}_\beta})$$

whenever $\alpha < \beta$,

$$\mathrm{crit}(F_\beta^{\mathcal{R}}) = \pi(\kappa_\alpha)$$

and $\mathcal{R}_\beta$ is not a premouse. For example, we could have $\alpha < \beta < \gamma$,

$$\begin{aligned}\mathcal{S}_\alpha &= \mathcal{R}_\alpha\\ \mathcal{S}_\beta &= \mathrm{Ult}(\mathcal{S}_\alpha, F^{\mathcal{R}_\beta})\\ \mathcal{S}_\gamma &= \mathrm{Ult}(\mathcal{S}_\beta, F^{\mathcal{R}_\gamma})\end{aligned}$$

and the analogous equations for $\mathcal{Q}_\alpha$, $\mathcal{Q}_\beta$ and $\mathcal{Q}_\gamma$. Note that $\mathcal{Q}_\gamma$ is a model on a finite extension of $\mathcal{T}\restriction(\eta(\alpha)+1)$ but not in the conventional sense. What we mean by W based phalanxes and the theorems about them can be generalized accordingly though. This is needed to complete the proof of Lemma 4.9.

Beyond this, we do not attempt to explain how to incorporate this definition of $\mathcal{S}$ and $\mathcal{Q}$ into the proof by induction of $(1)_\alpha$ through $(6)_\alpha$. In particular, the proof of Lemma 4.8 is beyond the scope of this exposition. Instead, we finish this section by showing that it is still possible to obtain a contradiction assuming $(1)_\alpha$ through $(6)_\alpha$ hold for all $\alpha < \overline{\Omega}_0$ without assuming that $\mathcal{S} = \mathcal{R}$. The argument uses two additional concepts: the Dodd decomposition of an extender and fine structure for thick weasels. The simplest case in which $\mathcal{S} \neq \mathcal{R}$ already illustrates the main new ideas. First we look at the non-weasel subcase.

4.13 Lemma. *Let $\alpha < \beta$ and $F = F^{\mathcal{P}_\beta}$. Suppose that*

$$\rho_{n+1}^{\mathcal{P}_\alpha} \leq \kappa_\alpha < \lambda_\alpha \leq \rho_n^{\mathcal{P}_\alpha}$$

and $\mathcal{Q}_\beta = \mathrm{Ult}(\mathcal{P}_\alpha, F)$. Then

$$\mathcal{Q}_\beta = \mathrm{Hull}_{n+1}^{\mathcal{Q}_\beta}(\kappa_\beta \cup p_{n+1}^{\mathcal{Q}_\beta}).$$

Idea. For simplicity, assume $n = 0$. (Otherwise, use the Σ_n mastercode structure for $\mathcal{P}_\alpha$.) Let $i : \mathcal{P}_\alpha \to \mathcal{Q}_\beta$ be the ultrapower map. The lemma is relatively easy to see if $\nu(F) = \kappa_\beta$ because then

$$p_1^{\mathcal{Q}_\beta} = i(p_1^{\mathcal{P}_\alpha}).$$

More generally, we show that

$$p_1^{\mathcal{Q}_\beta} - \kappa_\beta = i(p_1^{\mathcal{P}_\alpha}) \cup (s - \kappa_\beta)$$

for a certain $s \in [\mathrm{lh}(F)]^{<\omega}$ whose identity we are about to reveal.

The *Dodd projectum of* $\mathcal{P}_\beta$, written $\tau^{\mathcal{P}_\beta}$, is the least ordinal τ such that

$$\lambda_\alpha = (\mathrm{crit}(F)^+)^{\mathcal{P}_\beta} \leq \tau \leq \nu(F)$$

and there exists an $s \in [\nu(F)]^{<\omega}$ such that F and $F\restriction(\tau \cup s)$ have the same ultrapower. The *Dodd parameter of* $\mathcal{P}_\beta$, written $s^{\mathcal{P}_\beta}$, is the least parameter $s \in [\nu(F)]^{<\omega}$ such that F and $F\restriction(\tau^{\mathcal{P}_\beta} \cup s)$ have the same ultrapower.[11] In fact, $\tau = \max(\rho_1^{\mathcal{P}_\beta}, \lambda_\alpha)$. There is a relationship between the $s^{\mathcal{P}_\beta}$ and $p_1^{\mathcal{P}_\beta}$ that is slightly more complicated but not needed here. By a result of Steel in [38], if $\mathcal{P}_\beta$ is 1-sound, then for all $i < |s^{\mathcal{P}_\beta}|$,

$$F\restriction(s_i^{\mathcal{P}_\beta} \cup (s^{\mathcal{P}_\beta}\restriction i)) \in \mathcal{P}_\beta$$

[11] Recall that parameters, i.e., finite sets of ordinals, are often identified with descending sequences of ordinals, and that the ordering on parameters is lexicographic.

and for all $\xi < \tau^{\mathcal{P}_\beta}$,

$$F\restriction(\xi \cup s^{\mathcal{P}_\beta}) \in \mathcal{P}_\beta.$$

These properties are known as *Dodd solidity* and *Dodd amenability* respectively. Counterexamples for mice that are not 1-sound can be found in [27].

If $\mathcal{P}_\beta \lhd W_{\eta(\beta)}$, then certainly $\mathcal{P}_\beta$ is 1-sound and therefore Dodd solid and Dodd amenable. The fact that F and $F\restriction(\kappa_\beta \cup s^{\mathcal{P}_\beta})$ have the same ultrapower translates into

$$\mathcal{Q}_\beta = \mathrm{Hull}_1^{\mathcal{Q}_\beta}(\kappa_\beta \cup i(p_1^{\mathcal{P}_\alpha}) \cup s^{\mathcal{P}_\beta}).$$

The fact that

$$F\restriction(s_i^{\mathcal{P}_\beta} \cup (s^{\mathcal{P}_\beta}\restriction i)) \in \mathcal{P}_\beta$$

for all $i < |s^{\mathcal{P}_\beta} - \kappa_\beta|$ translates into

$$p_1^{\mathcal{Q}_\beta} - \kappa_\beta = i(p_1^{\mathcal{P}_\alpha}) \cup (s^{\mathcal{P}_\beta} - \kappa_\beta).$$

Suppose instead that $\mathcal{P}_\beta = W_{\eta(\beta)}$. Then $\mathcal{P}_\beta$ is not 1-sound. Let $\iota + 1$ be the last drop in model or degree along $[0, \eta(\beta)]_T$ and let

$$W^*_{\iota+1} \trianglelefteq W_{\mathrm{pred}^T(\iota+1)}$$

be the level to which we drop. Also let

$$i^*_{\iota+1} : W^*_{\iota+1} \to W_{\iota+1} = \mathrm{Ult}(W^*_{\iota+1}, F^{\mathcal{T}}_\iota)$$

be the ultrapower embedding. Since $W^*_{\iota+1}$ is 1-sound, it is Dodd solid and Dodd amenable by [38]. Now by induction on ζ such that

$$\iota + 1 \leq_T \zeta \leq_T \eta(\beta)$$

it is possible to show that if

$$s = i^{\mathcal{T}}_{\iota+1,\zeta}(i^*_{\iota+1}(s^{W^*_{\iota+1}})),$$

then F^{W_ζ} and $F^{W_\zeta}\restriction(\nu^{\mathcal{T}}_\zeta \cup s)$ have the same ultrapower,

$$F^{W_\zeta}\restriction(s_i \cup (s\restriction i)) \in W_\zeta$$

for all $i < |s - \nu^{\mathcal{T}}_\zeta|$ and

$$s - \nu^{\mathcal{T}}_\zeta = s^{W_\zeta} - \nu^{\mathcal{T}}_\zeta.$$

By definition, $\kappa_\beta \geq \nu^{\mathcal{T}}_{\eta(\beta)}$. So at the end of this induction we see that if $s = s^{\mathcal{P}_\beta}$, then F and $F\restriction(\kappa_\beta \cup s)$ have the same ultrapower and

$$F\restriction(s_i \cup (s\restriction i)) \in \mathcal{P}_\beta$$

for all $i < |s - \kappa_\beta|$. As before, these facts translate into the desired result. $\dashv$

The facts about Dodd solidity in the proof of Lemma 4.13 can be used to avoid a convoluted argument in [21].[12]

4.14 Lemma. *It is not the case that $\mathcal{S} \neq \mathcal{R}$ and $\mathcal{S}$ is not a weasel.*

Idea. In the simplest case, which is the only one we discuss here, $\overline{\kappa} = \kappa_\beta$ satisfies the hypothesis of Lemma 4.13. Then

$$\mathcal{S} = \mathrm{Hull}_{n+1}^{\mathcal{S}}(\kappa \cup p_{n+1}^{\mathcal{S}}).$$

Now repeat the proof of Lemma 4.11 to obtain a contradiction. ⊣

4.15 Lemma. *It is not the case that $\mathcal{S} \neq \mathcal{R}$ and $\mathcal{S}$ is a weasel.*

Idea. There is an analog of Lemma 4.13 that is valid when $\mathcal{Q}_\beta$ is a weasel. With this analog, the proof of Lemma 4.12 can be adapted to give the proof of Lemma 4.15. The basic idea behind this analog is as follows.

Once again, we look only at the simplest instance of $\mathcal{Q}_\beta \neq \mathcal{P}_\beta$. That is, $\alpha < \beta$ and $F = F^{\mathcal{P}_\beta}$ and $\mathcal{Q}_\beta = \mathrm{Ult}(\mathcal{P}_\alpha, F)$. But this time suppose that $\mathcal{P}_\alpha = W_{\eta(\alpha)}$ is a thick weasel with the hull and definability properties at μ whenever $\kappa_\alpha \leq \mu < \Omega_0$. Then $\mathcal{Q}_\beta$ is also a thick weasel. If $\nu(F) = \kappa_\beta$, then we can show that $\mathcal{Q}_\beta$ has the hull and definability properties at μ whenever $\kappa_\beta \leq \mu < \Omega_0$, which is just what is needed to run the proof of Lemma 4.12 when $\kappa_\beta = \overline{\kappa}$. More generally, consider again the fact that F and its Dodd decomposition $F \restriction (\tau^{\mathcal{P}_\beta} \cup s^{\mathcal{P}_\beta})$ have the same ultrapower and $\tau^{\mathcal{P}_\beta} \leq \kappa_\beta$. There is a natural sense in which $\mathcal{Q}_\beta$ has the $s^{\mathcal{P}_\beta}$ definability property at μ whenever $\kappa_\beta \leq \mu < \Omega_0$. This fact motivates defining $\kappa^{\mathcal{Q}_\beta}$ to be the least ordinal μ_0 such that there exists a $c \in [\Omega_0]^{<\omega}$ such that $\mathcal{Q}_\beta$ has the c definability property at μ whenever $\mu_0 \leq \mu < \Omega_0$. This is the *class projectum*. We have that

$$\kappa^{\mathcal{Q}_\beta} \leq \kappa_\beta$$

as witnessed by $s^{\mathcal{P}_\beta}$. We also define $c^{\mathcal{Q}_\beta}$ to be the least parameter $c \in [\Omega_0]^{<\omega}$ such that $\mathcal{Q}_\beta$ has the c definability property at μ whenever $\kappa^{\mathcal{Q}_\beta} \leq \mu < \Omega_0$. This is the *class parameter*. The proof of Lemma 4.13 shows that F is Dodd solid above κ_β. This fact translates into

$$c^{\mathcal{Q}_\beta} - \kappa_\beta = s^{\mathcal{P}_\beta}.$$

The two displayed facts above are our version of Lemma 4.13 when $\mathcal{Q}_\beta$ is a weasel. They translate into

$$\kappa^{\mathcal{S}} \leq \kappa$$

and

$$c^{\mathcal{S}} - \kappa = s^{\mathcal{R}}$$

when $\kappa_\beta = \overline{\kappa}$. With some additional work we can adapt the proof of Lemma 4.12 to finish the proof of Lemma 4.15. ⊣

This concludes our outline of the proof of Theorem 4.2. ⊣

[12] Avoid Lemma 2.1.2 and Corollaries 2.1.3 and 2.1.6 of [21].

5. Applications of Core Models

In this section, we list some results whose proofs use core model theory at a level that involves iteration trees. These are stated in a way that minimizes core model prerequisites. We have also tried to avoid overly technical hypotheses. For example, in some theorems, the hypothesis that Ω is a measurable cardinal can be reduced to the existence of sharps for elements of $H(\Omega)$ or even less.

5.1. Determinacy

Some of the results in Sect. 5 are stated in terms of determinacy instead of large cardinals. Often it is easier to phrase things one way or the other but there are reasons to think that there is more to it than that. We begin this subsection by recalling some of the known equiconsistencies between large cardinals and determinacy.

5.1 Theorem. *The following are equiconsistent.*

(1) There exists a Woodin cardinal.

(2) Δ^1_2-determinacy.

5.2 Theorem. *The following are equiconsistent.*

(1) There exist infinitely many Woodin cardinals.

(2) $L(\mathbb{R})$-determinacy.

Theorems 5.1 and 5.2 are due to Woodin. A proof that (2) is consistent relative to (1) in Theorem 5.2 is given in the Handbook chapter [22]. The consistency of (1) relative to (2) in the two theorems is given in the Handbook chapter [14]. It would be reasonable for the reader to suspect that these parts of the proofs use core model theory. However, Woodin obtained these results in the 1980's before Steel developed the theory of K at the level of one Woodin cardinal. Woodin used HOD instead of K. In the proof of Theorem 5.1, Woodin showed that if Δ^1_2-determinacy holds, then there exists a real x such that $\omega_2^{L[y]}$ is a Woodin cardinal in $\mathrm{HOD}^{L[y]}$ whenever $x \in L[y]$. And his proof of Theorem 5.2 built on that of Theorem 5.1. More recently, Steel discovered alternate proofs that use core models.

Theorems 5.1 and 5.2 are equiconsistencies between determinacy and the existence of large cardinals. This is a good place to recall some of the known equivalences between determinacy and the existence of mice. For this, we must recall the definition of $M_n^\#(x)$, which can also be found in [41, §7].

The theory of mice generalizes to a theory of mice built over a real. If $n \leq \omega$ and $x \subseteq \omega$, then there is at most one structure

$$\mathcal{M} = \langle J_\beta^{E,x}, \in, E, F\rangle$$

such that $\mathcal{M}$ is a $\omega_1 + 1$ iterable sound premouse built over x,

$$J^{E,x}_{\mathrm{crit}(F)} \models \text{the number of Woodin cardinals} = n$$

and for all $\alpha < \beta$, if $E_\alpha \neq \emptyset$, then

$$J^{E,x}_{\mathrm{crit}(E_\alpha)} \models \text{the number of Woodin cardinals} < n.$$

If it exists, then this unique mouse built over x is called $M_n^\#(x)$. For $n = 0$, we have that $M_0^\#(x)$ is Turing equivalent to $x^\#$.

Let us point out some features of $M_n^\#$. Recall that the empty extender codes the identity embedding. The next weakest possibility is that the critical point of an extender is the only generator of the extender, in which case the extender codes the embedding from a normal measure. It follows from the definition that $F^{M_n^\#(x)}$ is a measure in this sense and that if δ is the supremum of the Woodin cardinals of $M_n^\#(x)$, then

$$\delta < \mathrm{crit}(F^{M_n^\#(x)})$$

and

$$E_\alpha^{M_n^\#(x)} = \emptyset$$

whenever $\delta \leq \alpha < \mathrm{crit}(F^{M_n^\#(x)})$. Regarding the projectum and standard parameter, it is easy to see that

$$\rho_1^{M_n^\#(x)} = 1$$

and

$$p_1^{M_n^\#(x)} = \emptyset.$$

In particular, $M_n^\#(x)$ is countable. We have enough iterability to guarantee that all (not just the first ω_1 many) iterates of $M_n^\#(x)$ by images of its top extender are wellfounded. By iterating away the top extender of $M_n^\#(x)$ in this way we obtain a proper class model that goes by the name $M_n(x)$. For $n = 0$ we have that $M_0(x) = L[x]$. Observe that $M_n(x)$ has the same Woodin cardinals as $M_n^\#(x)$ and that $M_n(x)$ is $\omega_1 + 1$ iterable. Moreover, the critical points of extenders used on this linear iteration form a club class of $M_n(x)$ indiscernibles. In the case $n = 0$, these are the $L[x]$ indiscernibles.

Let us call a structure that satisfies the first-order properties in the definition of $M_n^\#(x)$ but is λ iterable instead of $\omega_1 + 1$ iterable a λ *iterable* $M_n^\#(x)$.

5.3 Theorem. *Let $n < \omega$ and assume $\mathbf{\Pi^1_n}$-determinacy. Then the following are equivalent.*

(1) $\mathbf{\Pi^1_{n+1}}$-determinacy.

(2) For every $x \in \mathbb{R}$, there is an ω_1 iterable $M_n^\#(x)$.

(3) For every $x \in \mathbb{R}$, there is a unique ω_1 iterable $M_n^\#(x)$.

The case $n = 0$ boils down to the fact that

$$\boldsymbol{\Pi}^1_1\text{-determinacy} \iff \forall x \in \mathbb{R}\ (x^\# \text{ exists})$$

where the forward implication is due to Martin and the reverse is due to Harrington. The proof that (1) implies (3) is due to Woodin and uses core models. Parts of the proof can be found in the Handbook chapter [14] and Theorem 7.7 of [42]. The proof that (2) implies (1) is due to Woodin for odd n and Neeman for even n. See the Handbook chapter [22].

5.4 Corollary. *The following are equivalent.*

(1) Projective Determinacy.

(2) For all $n < \omega$ and $x \subseteq \omega$, there is an ω_1 iterable $M^\#_n(x)$.

(3) For all $n < \omega$ and $x \subseteq \omega$, there is a unique ω_1 iterable $M^\#_n(x)$.

(4) For all $n < \omega$ and $x \subseteq \omega$, there exists a Σ^1_n correct model M with n Woodin cardinals and $x \in M$.

This equivalence combines results of Martin, Steel and Woodin.

Woodin proved that if $M^\#_\omega(x)$ exists for all $x \subseteq \omega$, then $L(\mathbb{R})$-determinacy holds. See the Handbook chapter [22] for a proof due to Neeman. Steel and Woodin obtained the following optimal result.

5.5 Theorem. *The following are equivalent.*

(1) $L(\mathbb{R})$-determinacy.

(2) For all $x \subseteq \omega$ and every Σ_1 formula φ, if $\varphi[x, \mathbb{R}]$ holds in $L(\mathbb{R})$, then there is a countable, ω_1 iterable model M satisfying ZF$^-$ *plus there are ω Woodin cardinals such that $x \in M$, and $\varphi[x, \mathbb{R}^*]$ holds in the derived model of M.*

Next we state several theorems which show that some well-known consequences of determinacy are equivalent to determinacy.

5.6 Theorem. *Assume that for all $x \subseteq \omega$, $x^\#$ exists and the $\Sigma^1_3(x)$ separation property holds for subsets of ω. Then $\boldsymbol{\Delta}^1_2$-determinacy holds.*

Steel proved Theorem 5.6 by combining the Σ^1_3 correctness of K, Theorem 3.7, with ideas due to Alexander Kechris. See [42, Corollary 7.14].

Recall that if $A, B \subseteq {}^\omega\omega$, then $A \leq_w B$ iff there is a continuous function $f : {}^\omega\omega \to {}^\omega\omega$ such that $A = f^{-1}[B]$. This is Wadge reducibility, which can also be expressed in terms of games and winning strategies. By Γ Wadge determinacy we mean that for all $A, B \in \Gamma$, either $A \leq_w B$ or $B \leq_w {}^\omega\omega - A$. Under mild assumptions, Γ determinacy implies Γ Wadge determinacy. In the other direction, Harrington showed that $\Pi^1_1(x)$ Wadge determinacy implies $x^\#$ exists, hence $\Pi^1_1(x)$-determinacy by the result due to Martin mentioned earlier. One level up, Greg Hjorth proved the following.

5.7 Theorem. $\mathbf{\Pi^1_2}$ *Wadge determinacy implies* $\mathbf{\Pi^1_2}$*-determinacy.*

Theorem 5.7 is Theorem 3.15 of [12]. The proof uses the Σ^1_3 correctness of K, Theorem 3.7.

Projective Determinacy has the following well-known consequences: every projective subset of $\mathbb{R}$ is Lebesgue measurable and has the property of Baire, and every projective binary relation on $\mathbb{R}$ has a projective uniformization. Woodin once conjectured that the conjunction of these three consequences of PD implies PD, and he proved several theorems that provided evidence in favor of his conjecture. Eventually, Steel disproved Woodin's conjecture by showing that these three consequences of PD hold in $V^{\mathrm{Col}(\omega,\kappa)}$ if V is the minimal extender model with a cardinal λ such that the set of $\kappa < \lambda$ that are $<\lambda$-strong is unbounded in λ. This large cardinal axiom is weaker than the existence of a Woodin cardinal, hence weaker than the consistency strength of PD by Theorem 5.1. The reader is referred to Hauser and Schindler [11] where the history is reviewed more completely than here and Steel's theorem is reversed. While these consequences of determinacy do not match up with determinacy at the projective level, it turns out that they do match up at other levels. For example, Woodin proved the following theorem using his core model induction technique.

5.8 Theorem. *The following statements are equivalent.*

(1) $L(\mathbb{R})$*-determinacy.*

(2) For every $A \in L(\mathbb{R})$ *such that* $A \subseteq \mathbb{R} \times \mathbb{R}$ *and* A *is* Δ^2_1 *definable in* $L(\mathbb{R})$ *from real parameters,*

  (a) A *is Lebesgue measurable,*

  (b) A *has the property of Baire and*

  (c) A *can be uniformized by a function* $f \in L(\mathbb{R})$*. (By reflection,* f *can be chosen to be* Δ^2_1 *definable in* $L(\mathbb{R})$ *from real parameters.)*

(3) Same as (2) except instead of (c) we have

  (c′) *A can be uniformized by a function f such that every $B \subseteq \mathbb{R}$, if B is projective in f, then B is are Lebesgue measurable and has the property of Baire. (Note that f is not required to be in $L(\mathbb{R})$.)*

5.2. Tree Representations and Absoluteness

Shoenfield showed that all transitive proper class models of ZFC are Σ^1_2 correct. The proof involves a canonical recursive tree T that projects to a complete $\mathbf{\Sigma^1_1}$ subset of ${}^\omega\omega$ and a tree T^* on $\omega \times \mathrm{On}$ such that

$$\mathrm{proj}([T^*]) = {}^\omega\omega - \mathrm{proj}([T^*])$$

holds in every uncountable transitive model of ZFC. Forcing and Shoenfield absoluteness can be used to reprove the classical theorem that $\mathbf{\Sigma^1_1}$ sets are Lebesgue measurable; the argument is due to Solovay.

Suppose that κ be a measurable cardinal. Martin showed that all $\mathbf{\Pi^1_1}$ sets are κ-homogeneous and all κ-homogeneous sets are determined.[13] The projection of a κ-homogeneous set is called κ-weakly homogeneous and there is a corresponding notion of a κ-weakly homogeneous tree. Martin and Solovay showed that if T is a κ-weakly homogeneous tree, then there is a tree T^* on $\omega \times \mathrm{On}$ such that

$$\mathrm{proj}([T^*]) = {}^{\omega}\omega - \mathrm{proj}([T^*])$$

in $V^{\mathbb{P}}$ whenever $\mathbb{P} \in V_\kappa$. We say that T and T^* are $<\kappa$ absolutely complemented and that their projections are $<\kappa$ absolutely Suslin. (This property of the projections is also called $<\kappa$ universally Baire.) Martin and Solovay used this to show that $V^{\mathbb{P}}$ is Σ^1_3 correct in $V^{\mathbb{P}*\mathbb{Q}}$ for all $\mathbb{P}*\mathbb{Q} \in V_\kappa$. Forcing and Martin-Solovay absoluteness can be used to see that $\mathbf{\Sigma^1_2}$ sets are Lebesgue measurable.

The main theorem of Martin and Steel [16] is that if δ is a Woodin cardinal and $A \subseteq {}^{\omega}\omega \times {}^{\omega}\omega$ is δ^+ homogeneous, then ${}^{\omega}\omega - \mathrm{proj}(A)$ is $<\delta$ homogeneous. This has many important corollaries. For example, suppose that $\delta < \kappa$ where δ is a Woodin cardinal and κ is a measurable cardinal. Then $\mathbf{\Pi^1_2}$ sets are $<\delta$ homogeneous and $\mathbf{\Sigma^1_3}$ sets are $<\delta$ weakly homogeneous. (The latter was proved by Woodin before Martin and Steel obtained their result.) By Martin, $\mathbf{\Pi^1_2}$ sets are determined. By Martin-Solovay, $\mathbf{\Sigma^1_3}$ sets are $<\delta$ absolutely Suslin and $V^{\mathbb{P}}$ is Σ^1_4 correct in $V^{\mathbb{P}*\mathbb{Q}}$ whenever $\mathbb{P}*\mathbb{Q} \in V_\delta$. Forcing and Σ^1_4 absoluteness can be used to see that $\mathbf{\Sigma^1_3}$ sets are Lebesgue measurable.

Martin and Steel also combined their main theorem with an earlier theorem of Woodin to see that if there are $\delta < \kappa$ such that δ is a limit of Woodin cardinals and κ is a measurable cardinal, then all sets of reals in $L(\mathbb{R})$ are $<\delta$ homogeneous and hence determined. (Note that we are no longer assuming that δ is a Woodin cardinal.) From this it follows that all sets of reals in $L(\mathbb{R})$ are $< \delta$ weakly homogeneous, that the theory of $L(\mathbb{R})$ cannot be changed by forcing and that all sets of reals in $L(\mathbb{R})$ are Lebesgue measurable. (These last three consequences were proved before Martin and Steel obtained their result; see Woodin-Shelah [40] and Woodin [50].)

Now we turn to lower bounds on the large cardinal consistency strength of the properties discussed above.

5.9 Theorem. *Let Ω be a measurable cardinal. Suppose that for all posets $\mathbb{P} \in H(\Omega)$,*

$$(L_{\omega_1}(\mathbb{R}))^{V^{\mathbb{P}}} \equiv (L_{\omega_1}(\mathbb{R}))^V.$$

Then

$$K^c \models \textit{there is a Woodin cardinal.}$$

[13] For these and other notions discussed below, we refer to the Handbook chapter [22].

Theorem 5.9 is due to Woodin and appears as Theorem 7.4 of [42]. The proof uses Theorem 3.5, that $K \cap \mathrm{HC}$ is Σ_1 definable over $L_{\omega_1}(\mathbb{R})$. It also uses almost everywhere weak covering, Theorem 3.1, which allows us to use forcing to change the truth value of the statement that ω_1 of the universe is a successor cardinal of K.

5.10 Theorem. *Let Ω be a measurable cardinal. Then the following are equivalent.*

(1) For all posets $\mathbb{P} \in V_\Omega$,

$$(L(\mathbb{R}))^{V^{\mathbb{P}}} \equiv (L(\mathbb{R}))^V.$$

(2) For all posets $\mathbb{P} \in V_\Omega$,

$$(L(\mathbb{R})\text{-}\mathit{determinacy})^{V^{\mathbb{P}}}.$$

(3) For all posets $\mathbb{P} \in V_\Omega$,

$$(L(\mathbb{R}) \text{ } \mathit{Lebesgue\ measurability})^{V^{\mathbb{P}}}.$$

(4) For all posets $\mathbb{P} \in V_\Omega$,

$$(\mathit{there\ is\ no}\ \omega_1\ \mathit{sequence\ of\ distinct\ reals\ in}\ L(\mathbb{R}))^{V^{\mathbb{P}}}.$$

(5) There exists an $\Omega + 1$ iterable model of height Ω with infinitely many Woodin cardinals.

Theorem 5.10 is due independently to Steel and Woodin and appears as Theorem 3.1 in [43]. The proof that the failure of (5) implies the failure of (4) uses core model theory. Instead of K^c and K, an "excellent" premouse $\mathcal{P}$ is found so that the maximal countably complete construction above $\mathcal{P}$ yields a relativized weasel $K^c(\mathcal{P})$ such that all the Woodin cardinals of $K^c(\mathcal{P})$ are in $\mathcal{P}$ and $K^c(\mathcal{P})$ is $\Omega + 1$ iterable above $\mathcal{P}$. The relativized core model $K(\mathcal{P})$ is extracted from $K^c(\mathcal{P})$ as in Sect. 2. One of the main tools is a version of the recursive definition of K, Theorem 3.5, that shows $K(\mathcal{P}) \cap \mathrm{HC} \in L(\mathbb{R})$ in this more general context.

5.3. Ideals and Generic Embeddings

Let κ be an uncountable cardinal and let I be a κ-complete ideal on $\mathcal{P}(\kappa)$. Assume that I is κ^+-saturated. In other words, $\mathcal{P}(\kappa)/I$ has the κ^+-chain condition. Suppose that G is V generic over $\mathcal{P}(\kappa)/I$. Let

$$j : V \to M = \mathrm{Ult}(V, G)$$

be the ultrapower map computed in $V[G]$. Then M is transitive, $\mathrm{crit}(j) = \kappa$ and

$$^{<j(\kappa)}M \subseteq M.$$

Such a j is called a *generic almost huge embedding*. The story of saturated ideals from the forcing side is far too rich to tell here but we do mention a couple of results. Shelah showed that if δ is a Woodin cardinal, then there is a semiproper poset $\mathbb{P}$ with the δ chain condition such that the nonstationary ideal over ω_1 is $\aleph_2$ saturated in $V^{\mathbb{P}}$. The following result in this subsection comes close to showing that one Woodin cardinal is the exact consistency strength.

5.11 Theorem. *Assume that Ω is a measurable cardinal and $\kappa < \Omega$. Let $\mathbb{P} \in V_\Omega$ be a poset. Suppose that forcing with $\mathbb{P}$ produces a generic almost huge embedding. Then there is a model of height Ω that satisfies "there is a Woodin cardinal".*

Theorem 5.11 is due to Steel and appears as Theorem 7.1 of [42]. The proof uses core model theory. In particular, it uses forcing absoluteness, Theorem 3.4 and the recursive definition of K, Theorem 3.5.

If I is a countably complete non-trivial ideal on $\mathcal{P}(\omega_1)$, then I is $\aleph_1$-dense iff $\mathcal{P}(\omega_1)/I$ has a dense subset of cardinality $\aleph_1$. This implies that forcing with $\mathcal{P}(\omega_1)/I$ is equivalent to forcing with $\mathrm{Col}(\omega, \omega_1)$, which in turn implies that I is $\aleph_2$ saturated. It also implies that $\mathcal{P}(\omega_1)/I$ is weakly homogeneous in the sense of forcing; we just say that I is homogeneous in this case. Woodin showed that the existence of an $\aleph_1$-dense ideal is consistent relative to $L(\mathbb{R})$-determinacy in [49]. Using core models, Steel proved that if there is a homogeneous ideal on ω_1 and CH holds, then PD holds. Building on this, Woodin showed his hypothesis was optimal.

5.12 Theorem. *The following are equiconsistent over* ZFC*.*

(1) There is an $\aleph_1$-dense ideal over ω_1.

(2) $L(\mathbb{R})$-determinacy.

The passage from (1) to (2) uses core models. In particular, it uses K and a method due to Woodin known as the *core model induction*. Woodin proves that if $A \subseteq \mathbb{R}$ and $A \in L(\mathbb{R})$, then A is determined. One could say that his proof is by induction on the least $(\alpha, n) \in \mathrm{On} \times \omega$ such that $A \in \Sigma_{n+1}(J_\alpha(\mathbb{R}))$. Steel uses a version of the core model induction in [44].

5.4. Square and Aronszajn Trees

This section is actually on the failure of square and the non-existence of Aronszajn trees, i.e., the tree property.

If λ is an ordinal and $C = \langle C_\alpha \mid \alpha < \lambda \rangle$, then C is a *coherent sequence* iff for all limit $\beta < \lambda$,

- C_β is club in β and
- if $\alpha \in \lim(C_\beta)$, then $C_\alpha = \alpha \cap C_\beta$.

If C is a coherent sequence, then D is a *thread* of C iff D is club in λ and $C_\alpha = \alpha \cap D$ for all $\alpha \in \lim(D)$. The principle $\square(\lambda)$ says that there is a coherent sequence of length λ with no thread. The principle $\square_\kappa$ says that there is a coherent sequence C of length κ^+ such that $\mathrm{type}(C_\alpha) \leq \kappa$ for all limit $\alpha < \lambda$. Coherent sequences are the topic of the Handbook chapter [46]. In this and the next section, it is convenient to set $\mathfrak{c} = 2^{\aleph_0}$.

5.13 Theorem. *Let $\kappa \geq \max(\aleph_2, \mathfrak{c})$. Suppose that both $\square_\kappa$ and $\square(\kappa)$ fail. Then $L(\mathbb{R})$-determinacy holds.*

See [29], which explains credit for Theorem 5.13 and related results, and has a proper introduction. Two basic elements of the proof are generalizations of Theorems 3.2 and 3.13. Theorem 3.6 is also used. The author derived PD from the hypothesis of Theorem 5.13. In fact, he showed that $M_n(X)$ exists for all $n < \omega$ and bounded $X \subseteq \kappa^+$. Steel observed that the author's proof meshed with techniques from [44] to give the result as stated.

Todorcevic proved that if $\square(\kappa)$ holds then there is an Aronszajn tree on κ. See [46]. From this and Theorem 5.13, one may conclude, for example, that if $\mathfrak{c} \leq \aleph_2$ and the tree property holds at $\aleph_2$ and $\aleph_3$, then $L(\mathbb{R})$-determinacy holds. Related theorems about the tree property were proved earlier without going through square; see [6] and its bibliography.

5.14 Theorem. *Suppose that κ is a singular strong limit cardinal and $\square_\kappa$ fails. Then $L(\mathbb{R})$-determinacy holds.*

Theorem 5.14 is Theorem 0.1 of [44], which includes an explanation of credit and related results. The proof uses Theorem 3.12, a generalization of Theorem 3.2 and a version of Woodin's core model induction due to Steel.

5.15 Theorem. *Suppose that κ is a weakly compact cardinal and $\square_\kappa$ fails. Then $L(\mathbb{R})$-determinacy holds.*

Theorem 5.15 is Corollary 8 of [31], which includes an explanation of credit. Two basic elements of the proof are generalizations of Theorems 3.3 and 3.12.

5.16 Theorem. *Suppose that κ is a measurable cardinal and $\square_\kappa$ fails. Then there is a model of height κ that satisfies "there is a proper class of strong cardinals" and "there is a proper class of Woodin cardinals".*

See [2], which includes an explanation of credit. The proof uses a generalization of Theorem 3.12 for K^c and nothing about K. The hypothesis of Theorem 5.16 holds if κ is strongly compact by a well-known theorem of Solovay. Woodin has shown that the conclusion of Theorem 5.16 implies the consistency of $\mathrm{ZF} + \mathrm{AD}_\mathbb{R}$ where $\mathrm{AD}_\mathbb{R}$ asserts that all real games of length ω are determined.

The following is a very recent theorem due to Jensen, Schimmerling, Schindler and Steel [13].

5.17 Theorem. *Let $\kappa \geq \aleph_3$ be regular and countably closed. Suppose that both $\square_\kappa$ and $\square(\kappa)$ fail. Then there is a proper class model that satisfies "there is a proper class of strong cardinals" and "there is a proper class of Woodin cardinals".*

5.5. Forcing Axioms

If $\mathcal{C}$ is a class of posets, then $\mathrm{FA}(\mathcal{C})$ says that for all $\mathbb{P} \in \mathcal{C}$ and $\mathcal{D}$ with $|\mathcal{D}| = \aleph_1$, there exists a $\mathcal{D}$-generic filter on $\mathbb{P}$. By definition,

$$\mathrm{PFA} \equiv \mathrm{FA}(\{\mathbb{P} \mid \mathbb{P} \text{ is proper}\}).$$

This is the Proper Forcing Axiom. For any cardinal λ, we set

$$\mathrm{PFA}(\lambda) = \mathrm{FA}(\{\mathbb{P} \mid \mathbb{P} \text{ is proper and } |\mathbb{P}| = \lambda\}).$$

Todorcevic and Velickovic showed that $\mathrm{PFA}(\mathfrak{c})$ implies that $\mathfrak{c} = \aleph_2$. See [48, Theorem 1.8] and [3, Theorem 3.16]. Todorcevic [47] showed that if λ is an ordinal such that $\mathrm{cf}(\lambda) \geq \aleph_2$, then $\mathrm{PFA}(\lambda^{\aleph_0})$ implies the failure of $\square(\lambda)$. Therefore $\mathrm{PFA}(\mathfrak{c}^+)$ implies the hypothesis of Theorem 5.13.

5.18 Corollary. $\mathrm{PFA}(\mathfrak{c}^+)$ *implies $L(\mathbb{R})$-determinacy.*

Note too that $\mathrm{PFA}(\mathfrak{c}^{++})$ implies the hypothesis of Theorem 5.17.

5.19 Corollary. $\mathrm{PFA}(\mathfrak{c}^{++})$ *implies that there is a proper class model that satisfies "there is a proper class of strong cardinals" and "there is a proper class of Woodin cardinals".*

Baumgartner and Shelah showed that PFA is consistent relative to the existence of a supercompact cardinal. The levels of the PFA hierarchy described above do not require a supercompact cardinal. For example, Neeman and Schimmerling [25] showed that the consistency strength of $\mathrm{PFA}(\mathfrak{c}^+)$ is strictly less than the existence of a cardinal κ that is κ^+-supercompact. More about this shortly.

By definition,

$$\mathrm{SPFA} \equiv \mathrm{FA}(\{\mathbb{P} \mid \mathbb{P} \text{ is semi-proper}\})$$

and

$$\mathrm{MM} \equiv \mathrm{FA}(\{\mathbb{P} \mid \mathbb{P} \text{ preserves stationary subsets of } \omega_1\}).$$

These are the Semi-proper Forcing Axiom and Martin's Maximum respectively. It is straightforward to see that MM implies SPFA, which in turn implies PFA. Foreman, Magidor and Shelah showed that MM is consistent relative to a supercompact cardinal; see [7, Theorem 5]. Their proof used Shelah's revised countable support iteration. (Donder and Fuchs [5] is a good source for this.) Later, Shelah [39] proved that SPFA and MM are equivalent.

Recall that a poset $\mathbb{P} = (P, <_P)$ is λ-*linked* iff there is a function $\ell : P \to \lambda$ such that for all $p, q \in P$, if $\ell(p) = \ell(q)$, then p and q are compatible in $\mathbb{P}$. Here are two obvious comments. If $|P| = \lambda$, then $\mathbb{P}$ is λ-linked. If $\mathbb{P}$ is λ-linked, then $\mathbb{P}$ has the λ^+-chain condition. For any cardinal λ, we define

$$\mathrm{SPFA}(\lambda\text{-linked}) \equiv \mathrm{FA}(\{\mathbb{P} \mid \mathbb{P} \text{ is semi-proper and } \lambda\text{-linked}\})$$

and

$$\mathrm{MM}(\lambda) \equiv \mathrm{FA}(\{\mathbb{P} \mid \mathbb{P} \text{ preserves stationary subsets of } \omega_1 \text{ and } |P| = \lambda\}).$$

Shelah [39] showed that SPFA implies MM. In [25], this theorem is refined to SPFA($\mathfrak{c}^+$-linked) implies MM($\mathfrak{c}$). This is useful because Neeman and Schimmerling also show in [25] that SPFA($\mathfrak{c}^+$-linked) is consistent relative to the existence of a cardinal λ that is (λ, Σ^2_1)-subcompact. Without reproducing the definition, we remark that a witness that λ is (λ, Σ^2_1)-subcompact is a certain family of elementary embeddings of the form

$$\pi : H(\kappa^+) \to H(\lambda^+)$$

with $\mathrm{crit}(\pi) = \kappa$ and $\pi(\kappa) = \lambda$. Our point here is that each embedding of this sort comes from a superstrong extender. Consequently, (λ, Σ^2_1)-subcompactness is strictly weaker than κ^+-supercompactness in the large cardinal hierarchy. The consistency proof in [25] of SPFA($\mathfrak{c}^+$-linked) uses a revised countable support iteration of semi-proper posets of length λ as did Shelah's consistency proof of SPFA. Not surprisingly, if countable supports and proper posets are used instead, then one obtains a model of PFA($\mathfrak{c}^+$-linked) starting from the same large cardinal in the ground model. The theory of extender models can accommodate (λ, Σ^2_1)-subcompactness but core model techniques are not sufficiently developed to measure the consistency strength of PFA($\mathfrak{c}^+$-linked). However, there is evidence towards an equiconsistency: Neeman [24] showed that in order to force PFA($\mathfrak{c}^+$-linked) by proper forcing over an extender model, if λ is $\aleph_2$ of the generic extension, then λ is (λ, Σ^2_1)-subcompact in the ground model.

Taking a fundamentally different approach, Woodin [51] established that MM($\mathfrak{c}$) is consistent relative to the theory

$$\mathrm{ZF} + \mathrm{AD}_{\mathbb{R}} + \Theta \text{ is regular}$$

where

$$\Theta = \sup(\{\alpha \in \mathrm{On} \mid \text{ there is a surjection } f : \mathbb{R} \to \alpha\}).$$

The proof uses Woodin's $\mathbb{P}_{\max}$ theory; see the Handbook chapter [15] for an introduction to this technique.

Todorcevic showed that MM($\mathfrak{c}$) implies the Stationary Reflection Principle SRP(ω_2), which says that for every stationary $S \subseteq \mathcal{P}_{\omega_1}(\omega_2)$, if for all stationary $T \subseteq \omega_1$, $\{X \in S \mid X \cap \omega_1 \in T\}$ is stationary in $\mathcal{P}_{\omega_1}(\omega_2)$, then there exists an α such that $\omega_1 < \alpha < \omega_2$ and $S \cap \mathcal{P}_{\omega_1}(\alpha)$ contains a club in

$\mathcal{P}_{\omega_1}(\alpha)$. This version comes from Definition 9.74(3) and Lemma 9.75(1) of Woodin [51]. The reason we bring this up here is the following core model result of Steel and Zoble [45].

5.20 Theorem. SRP(ω_2) *implies* $L(\mathbb{R})$*-determinacy.*

The proof builds on that of Corollary 9.86 of Woodin [51], which says that SRP(ω_2) implies PD.

Another well-known variant of MM is Bounded Martin's Maximum or BMM, which says that if $\mathbb{P}$ preserves stationary subsets of ω_1, then

$$(H(\omega_2))^V \prec_{\Sigma_1} (H(\omega_2))^{V^{\mathbb{P}}}.$$

Woodin has shown that BMM is consistent relative to the existence of $\omega + 1$ many Woodin cardinals; see [51, Theorem 10.99]. The following lower bound by Schindler [35] uses core models.

5.21 Theorem. BMM *implies that for every set* X *there is a model with a strong cardinal containing* X*.*

5.6. The Failure of UBH

The theory of iteration trees was initiated by Martin and Steel in the context of inner models in [17] and determinacy in [16]. Three Hypotheses are isolated in Sect. 5 of the former paper: UBH (Unique Branches), CBH (Cofinal Branches), and SBH (Strategic Branches). These hypotheses have to do with iteration trees on V but their motivation is the construction of inner models with large cardinals. Results, both positive and negative, about the three hypotheses and their variants give useful information towards a solution to the inner model problem.

Woodin showed that UBH and CBH are false assuming sufficient large cardinals. This lead to the question of consistency strength and the following core model result of Steel [43].

5.22 Theorem. *Suppose that there is a non-overlapping iteration tree* $\mathcal{T}$ *on* V *with cofinal wellfounded branches* $b \neq c$*. Then there is an inner model with infinitely many Woodin cardinals. If, in addition,*

$$\delta(\mathcal{T}) \in \mathrm{ran}(i^{\mathcal{T}}_{0,b}) \cap \mathrm{ran}(i^{\mathcal{T}}_{0,c}),$$

then there is an inner model with a strong cardinal that is a limit of Woodin cardinals.

Woodin eventually reduced the large cardinal assumption in his refutations of UBH and CBH to a supercompact cardinal. Motivated by this, Neeman and Steel [26] constructed counterexamples starting from much less in the way of large cardinals. For example, under a large cardinal assumption slightly stronger than the one mentioned in Theorem 5.22, they constructed an iteration tree on V with distinct cofinal wellfounded branches. See [26] for a discussion on additional results on UBH and CBH and their failure.

5.7. Cardinality and Cofinality

Shelah famously showed that if $\aleph_\omega$ is a strong limit cardinal, then $(\aleph_\omega)^{\aleph_0} < \aleph_{\omega_4}$. See the Handbook chapter [1]. An important conjecture is that the actual bound is $\aleph_{\omega_1}$. The following theorem appears as Theorem 1.1 of [10]. It provides valuable information about what it would take to obtain a counterexample to the conjecture.

5.23 Theorem. *Let α be a limit ordinal. Suppose that $2^{|\alpha|} < \aleph_\alpha$ and $2^{|\alpha|^+} < \aleph_{|\alpha|^+}$ but $(\aleph_\alpha)^{|\alpha|} > \aleph_{|\alpha|^+}$. Then $M_n(X)$ exists for all $n < \omega$ and bounded $X \subseteq \aleph_{|\alpha|^+}$.*

The following theorem appears as Theorem 1.4 of [10]. Recently, Gitik showed that its hypothesis is consistent relative to the existence of a supercompact cardinal. See [8].

5.24 Theorem. *Let λ be a cardinal such that $\omega < \mathrm{cf}(\lambda) < \lambda$. Suppose that $\{\kappa < \lambda \mid 2^\kappa = \kappa^+\}$ is stationary and co-stationary in λ. Then $M_n^\#(X)$ exists for all $X \subseteq \lambda$.*

In [9], Gitik showed that if there is a proper class of strongly compact cardinals, then there is a model of ZF in which all uncountable cardinals are singular. Towards measuring the consistency strength of this statement, Daniel Busche showed the following, which will appear in his PhD thesis.

5.25 Theorem. *Suppose that all uncountable cardinals are singular. Then* AD *holds in $L(\mathbb{R})^{\mathrm{HOD}^{\mathbb{P}}}$ for some $\mathbb{P} \in \mathrm{HOD}$.*

1. Introduction

In this chapter we survey recent advances in descriptive set theory, starting (roughly) from where Moschovakis' book [31] ends. Our survey is not intended to be complete, but focuses mainly on the structural consequences of determinacy for the model $L(\mathbb{R})$, including the important case of the projective sets. By "structural" we are referring to the combinatorial theory of the pointclasses (for example, the scale property which in some sense describes the structure of the set) as well as the cardinal structure up to the natural ordinal associated with these pointclasses. This might include determining their cofinalities, partition properties, and so forth.

The Axiom of Determinacy (AD), is the assertion that every two-player integer game is determined; we review the basic concepts below. The axiom was introduced by Mycielski and Steinhaus in the 1960s, and it soon became apparent that AD was a powerful tool for unlocking the combinatorial structure of sets of reals, and a program for doing this was begun. One of the central achievements during this period was the extension, assuming Projective Determinacy, to the general projective sets of the basic structural theory of the $\boldsymbol{\Pi}^1_1$, $\boldsymbol{\Sigma}^1_1$ sets developed by the "classical" descriptive set theorists from the 1920s through the 1940s. References [31] and [18] provide detailed accounts of the history of these developments. The results we discuss here can thus be viewed as extensions and refinements of the basic determinacy theory developed by the descriptive set theorists of the 1960s and 1970s as described in [31, 18].

We note that more recent work of Martin, Steel, and Woodin [28, 41] (described in a little more detail below) has pinpointed the connection between large cardinal axioms and various levels of determinacy, including $\mathrm{AD}^{L(\mathbb{R})}$.

We work throughout this chapter in the base theory $\mathrm{ZF} + \mathrm{DC}$ (except at a few points where we mention the use of DC). However, we will be dealing almost entirely in this chapter with the consequences of AD. In particular we assume AD throughout Sects. 3–5. In Sect. 2 we mention explicitly the hypotheses as needed. The reader should recall that AD contradicts the Axiom of Choice as well as many of its consequences. In particular, successor cardinals need not be regular and measurable cardinals need not be limit cardinals.

There were two ways in which the earlier theory was inadequate. First, the theory of the projective sets was described largely in terms of the so-called projective ordinals, the $\boldsymbol{\delta}^1_n$. The first four of these were computed, and several general results were proved (a good reference here is [16]). Kunen initiated a program for computing the $\boldsymbol{\delta}^1_n$. The idea of a homogeneous tree, which plays a central part in the program, arose independently in the work of Kunen and Martin. Kechris and Martin independently (see [17]) then formulated the general notion of a homogeneous tree. Despite this important progress, however, the values of $\boldsymbol{\delta}^1_n$ for $n \geq 5$, and the combinatorial structure of the intervening cardinals were left open. Secondly, the projective sets represent only the sets of reals occurring in the first level of the $L(\mathbb{R})$ hierarchy. It is generally believed, however, that AD should suffice to develop the structural theory (in some reasonable sense) of the entire model $L(\mathbb{R})$. Thus, two central goals emerge: first, to refine the arguments from the projective sets to permit a detailed analysis of the cardinal structure within the projective ordinals, and secondly, to extend this analysis as far as possible.

In the early 1980s, Martin and Steel [27] showed that $(\boldsymbol{\Sigma}^2_1)^{L(\mathbb{R})}$ was the largest pointclass in $L(\mathbb{R})$ having the scale property. Extending their methods, Steel [37] developed an analysis of the scale property in $L(\mathbb{R})$. This important work can be thought of as extending both the scale analysis of the projective sets and also the "fine structure" theory of L (developed by Jensen), and uses methods of both. This fine structure theory of $L(\mathbb{R})$, like the earlier theory of the projective sets, is not detailed enough to analyze the fine combinatorial structure of the cardinals, nor to answer many questions about the model $L(\mathbb{R})$ (though it suffices to answer many "scale type" questions, e.g., showing which pointclasses are the κ-Suslin sets for some κ, or showing every reliable cardinal is a Suslin cardinal; see [37]).

In the early 1980s, Martin [23] obtained a result on the ultrapowers of $\boldsymbol{\delta}^1_3$ by the normal measures on $\boldsymbol{\delta}^1_3$. Building on this and some joint work with Martin, the author computed $\boldsymbol{\delta}^1_5$. In the mid-1980s, this was extended to compute all the $\boldsymbol{\delta}^1_n$, and to develop the combinatorics of the cardinal structure of the cardinals up to that point. The analysis, naturally, proceeded by induction. The complete "first-step" of the induction appears in [11]. The analysis revealed a rich combinatorial structure to these cardinals. Indeed, even the answer $\boldsymbol{\delta}^1_5 = \aleph_{\omega^{\omega^\omega}+1}$ hints at such a structure (in general $\boldsymbol{\delta}^1_{2n+1} = \aleph_{\omega(2n-1)+1}$, where $\omega(0) = 1$ and $\omega(n+1) = \omega^{\omega(n)}$). A goal, then, is to extend some version of this "very-fine" structure theory to the entire model $L(\mathbb{R})$. In the late 1980s the author extended the analysis further, up to the least inaccessible cardinal in $L(\mathbb{R})$, although this lengthy analysis has never been written up. It was clear, however, that new, serious problems were being encountered shortly past the least inaccessible. In [10], for example, results were given that show that the theory fell far short of $\kappa^{\mathbb{R}}$, the ordinal of the inductive sets (the Wadge ordinal of the least non-selfdual pointclass closed under real quantification).

More recently, attempts have been made to isolate some of the "global" obstructions to extending the detailed $L(\mathbb{R})$ analysis. Some combinatorial principles were thus formulated which seem to be necessary for extending the theory sufficiently high in $L(\mathbb{R})$ and which seem not to be provable by an inductive "from below" argument. The most important principle along these lines is called the weak square property, $\boxminus_{\kappa,\lambda}$, for κ a Suslin cardinal and λ an ordinal $< \Theta$ (the supremum of the lengths of prewellorderings of the reals). Recently, the author has established this choice-like principle (to be defined in Sect. 6). This has a number of consequences. For example, it follows that every regular κ which is either a Suslin cardinal or the successor of a Suslin cardinal is $\boldsymbol{\delta}^2_1$-supercompact in $L(\mathbb{R})$. This and other global choice-like principles will be discussed in Sect. 6.

At the time of this writing, then, we may summarize the current situation as follows. A detailed structural analysis for an initial segment of $L(\mathbb{R})$ including the projective sets is known. Certain choice-like principles which seem to be important for further extensions have been established globally (that is, below Θ). What remains is to identify the further global principles required, and integrate them with the inductive analysis.

In the present chapter we will survey both approaches mentioned above. We will adopt a somewhat informal style at times in order to keep this chapter reasonably self-contained, still give proofs, and keep the discussion to a reasonable length. In Sect. 2 we will collect together and review various results from descriptive set theory and determinacy theory we will need. We will present proofs for some of these results of particular significance for us, and reference the others. In Sect. 3 we develop the AD theory of the Suslin cardinals, culminating in a classification theorem. In Sect. 4 we will develop a theory of "trivial" descriptions. This is not actually necessary, and in fact was omitted from [11]. Descriptions are the combinatorial ingredients that "describe" how to generate equivalence classes of functions with respect to certain measures. At the level of ω_1 (here the measures are simply the n-fold products of the normal measure), descriptions are trivial enough objects that they need not be introduced explicitly, but rather absorbed into the notation. Nevertheless, by introducing them explicitly the reader can see the general flavor of the arguments while the combinatorics is still trivial. Using this approach, we will show in this section the strong partition relation on ω_1, the weak partition relation on $\boldsymbol{\delta}^1_3$, and give a new proof of the Kechris-Martin Theorem for $\boldsymbol{\Pi}^1_3$. In all cases, our proofs will use only the theory of the trivial descriptions and techniques that will generalize to higher levels (in particular, no use is made of the theory of indiscernibles for L). In Sect. 5 we will introduce the (non-trivial) notion of a description of level 1. This corresponds to the analysis for computing $\boldsymbol{\delta}^1_5$ and proving the strong partition relation on $\boldsymbol{\delta}^1_3$, etc. Although we state complete definitions and theorems, we will illustrate proofs here frequently by considering examples which show the reader the ideas involved without getting lost in details. In Sect. 6 we introduce $\boxminus_{\kappa,\lambda}$ and other global choice-like principles. Some of the results presented here are of interest in their own right, and several are new.

We hope Sects. 4, 5 will provide a good introduction to, and an overview of, the modern theory of the projective sets (that is, the developments since [31]), and Sect. 6 will give some insight into the problems being faced in extending the theory and their possible solutions.

Although the focus of this chapter is on the consequences of AD, we mention briefly some connections with other hypotheses. Martin (see [25] and [26]) showed Borel Determinacy is a theorem of ZFC, although H. Friedman [4] showed that $\aleph_1$ iterations of the power set axiom applied to the reals is needed to prove it. Martin also showed $\boldsymbol{\Pi}^1_1$-determinacy followed from the existence of $x^\#$ for every $x \in \omega^\omega$, and Harrington proved the converse. Martin also showed the curious result that $\boldsymbol{\Delta}^1_{2n}$-determinacy implies $\boldsymbol{\Sigma}^1_{2n}$-

determinacy (see [19] for another proof). More recently, Martin and Steel [28] showed that the existence of n Woodin cardinals (see [28] for the definition) plus a larger measurable implies $\mathbf{\Delta}^1_{n+1}$-determinacy. Woodin showed that the existence of ω many Woodin cardinals plus a larger measurable implies $\mathrm{AD}^{L(\mathbb{R})}$. In fact, $\mathbf{\Delta}^1_{n+1}$-determinacy is equiconsistent with the existence of n Woodin cardinals, and AD is equiconsistent with the existence of ω many Woodin cardinals. Thus, the AD hypothesis now has the added measure of respect that $\mathrm{AD}^{L(\mathbb{R})}$ follows from more "conventional" large cardinal hypotheses. It should be noted, however, that the program of using AD to explore the structural theory of the projective sets and beyond was begun in the 1960s, well before this connection was known.

We review now some notation and terminology that we will use throughout the chapter. We generally work in the Polish space (complete, separable, metric space) ω^ω, the space of functions from ω to ω topologized with the product of the discrete topologies on ω. As a topological space this is homeomorphic to the space of irrationals, but any two uncountable Polish spaces are Borel isomorphic (in fact, isomorphic by a $\mathbf{\Delta}^0_3$-measurable function). We follow the usual convention of referring to the elements of ω^ω as "reals". By a *perfect product space* we mean a space of the form $X = X_1 \times \cdots \times X_n$, where each $X_i = \omega$ or ω^ω (ω always with the discrete topology), and at least one factor is ω^ω. All perfect product spaces are recursively homeomorphic to ω^ω by recursive coding and decoding maps, whose notation we now standardize.

For each $n \geq 2$, fix a recursive bijection

$$(m_0, \dots, m_{n-1}) \to \langle m_0, \dots, m_{n-1} \rangle_n$$

from ω^n to ω which is increasing in each argument, and let

$$m \to ((m)_0, \dots, (m)_{n-1})$$

denote the recursive inverse map. Let $(x_0, x_1, \dots) \to \langle x_0, x_1, \dots \rangle$ also denote the induced recursive bijection from $(\omega^\omega)^\omega$ to ω^ω defined by

$$\langle x_0, x_1, \dots \rangle(m) = x_{m_0}(m_1),$$

where (m_0, m_1) refers to the inverse of the coding map $\langle\ \rangle_2$. Similarly, for any perfect product space $X = X_1 \times \cdots \times X_{n-1}$, there is a recursive bijection between X and ω^ω, we will use the same notation $(x_0, \dots, x_{n-1}) \to \langle x_0, \dots, x_{n-1} \rangle_n$, and $x \to ((x)_0, \dots, (x)_{n-1})$, for the coding and decoding maps. Since the precise meaning is generally clear from the context, we will usually drop the subscripts and extra parentheses from the notation.

For X a perfect product space and $A \subseteq X$, we write A^c for $X - A$ (it will always be clear which X we are referring to). If $R \subseteq X \times Y$, the domain of R is defined by $\mathrm{dom}(R) = \{x : \exists y\ (x, y) \in R\}$. For any $x \in X$, we let R_x denote the section of R at x, that is, $R_x = \{y : (x, y) \in R\}$.

A (boldface) *pointclass* $\mathbf{\Gamma}$ is a collection of subsets of perfect product spaces X which is closed under continuous inverse image. That is, if $f : X \to Y$ is continuous and $A \subseteq Y$ is in $\mathbf{\Gamma}$, then $B = f^{-1}(A)$ is in $\mathbf{\Gamma}$. We also say A is *Wadge reducible* to B, written $A \leq_w B$. As is customary in descriptive set theory, we frequently use logical notation in describing sets, and thus we write $A(x)$ for $x \in A$. Thus we may rewrite the above as $B(x) \longleftrightarrow A(f(x))$, and for this reason pointclasses are referred to as being closed under continuous substitution (or Wadge reduction). Likewise $\neg A(x)$ means $x \notin A$. For $\mathbf{\Gamma}$ a pointclass, $\check{\mathbf{\Gamma}}$ denotes the *dual* pointclass, that is, $A \in \check{\mathbf{\Gamma}}$ iff $A^c \in \mathbf{\Gamma}$. We say $\mathbf{\Gamma}$ is *non-selfdual* if $\mathbf{\Gamma} \neq \check{\mathbf{\Gamma}}$, and otherwise say $\mathbf{\Gamma}$ is *selfdual.* We let $\exists^\omega$ and $\exists^{\omega^\omega}$ denote existential quantification over ω and ω^ω respectively, and likewise for $\forall^\omega$ and $\forall^{\omega^\omega}$. We apply this notation also to pointclasses. For example, $\exists^{\omega^\omega}\mathbf{\Gamma}$ denotes the $A \subseteq X$ for which there is a $B \subseteq X \times \omega^\omega$ such that $\forall x\ (A(x) \longleftrightarrow \exists y \in \omega^\omega\ B(x,y))$. For $\mathbf{\Gamma}$ a (usually non-selfdual) pointclass we let $\mathbf{\Delta}(\mathbf{\Gamma}) = \mathbf{\Gamma} \cap \check{\mathbf{\Gamma}}$. When $\mathbf{\Gamma}$ is understood we frequently just write $\mathbf{\Delta}$.

Let X, Y be perfect product spaces, and $A \subseteq X$, $B \subseteq Y$. Assuming AD, Wadge's Lemma asserts that either $A \leq_w B$ or $B \leq_w A^c$. In fact, the proof shows something stronger. For example, suppose $X = Y = \omega^\omega$, and let $A, B \subseteq \omega^\omega$. Consider the integer game where I plays integers $a(i)$, and II plays $b(i)$, thereby producing reals $a, b \in \omega^\omega$, and II wins the run iff $(a \in A \longleftrightarrow b \in B)$. If II has a winning strategy τ, then τ defines a *Lipschitz continuous function* (which we also call τ) from ω^ω to ω^ω. By this we mean $\tau(a){\restriction}n$ depends only on $a{\restriction}n$. Also, $a \in A \longleftrightarrow \tau(a) \in B$. If I has a winning strategy σ, we likewise get a Lipschitz continuous function σ such that $b \in B \longleftrightarrow \sigma(b) \in A^c$. If we let $\leq_l$ denote reduction by a Lipschitz continuous function, we therefore have either $A \leq_l B$ or $B \leq_l A^c$.

For X a Polish space, we let $\mathbf{\Sigma}^0_1$ (respectively $\mathbf{\Pi}^0_1$) denote the collection of open (respectively closed) subsets of X. For $\alpha < \omega_1$, we recursively define $\mathbf{\Sigma}^0_\alpha$ to be the sets $A \subseteq X$ which are countable unions of sets A_n, each of which lies in $\mathbf{\Pi}^0_\beta$ for some $\beta < \alpha$. Also, $\mathbf{\Pi}^0_\alpha = \check{\mathbf{\Sigma}}^0_\alpha$, and $\mathbf{\Delta}^0_\alpha = \mathbf{\Sigma}^0_\alpha \cap \mathbf{\Pi}^0_\alpha$. The sets which are $\mathbf{\Sigma}^0_\alpha$ for some $\alpha < \omega_1$ (equivalently $\mathbf{\Pi}^0_\alpha$ for some $\alpha < \omega_1$) are the *Borel* sets. The *projective hierarchy* is defined as follows. The $\mathbf{\Sigma}^1_1$ (or *analytic*) sets are the sets which are continuous images of closed sets in Polish spaces. An equivalent definition is $\mathbf{\Sigma}^1_1 = \exists^{\omega^\omega}\mathbf{\Pi}^0_1$. Also, we define $\mathbf{\Pi}^1_1 = \check{\mathbf{\Sigma}}^1_1$, and $\mathbf{\Delta}^1_1 = \mathbf{\Sigma}^1_1 \cap \mathbf{\Pi}^1_1$. Suslin's theorem says that the $\mathbf{\Delta}^1_1$ sets are exactly the Borel sets. In general, we define $\mathbf{\Sigma}^1_n = \exists^{\omega^\omega}\mathbf{\Pi}^1_{n-1}$, $\mathbf{\Pi}^1_n = \check{\mathbf{\Sigma}}^1_n$, and $\mathbf{\Delta}^1_n = \mathbf{\Sigma}^1_n \cap \mathbf{\Pi}^1_n$. The *lightface* projective classes, Σ^1_n, Π^1_n, Δ^1_n are defined an analogous manner, except at the bottom we take Σ^0_1 to be the collection of sets of the form $\bigcup_{n \in \omega} V_{f(n)}$, where $f \colon \omega \to \omega$ is recursive, and $\{V_n\}_{n \in \omega}$ is a recursive presentation for the space X. See [31] for further details (we will always have X a perfect product space, in which case any reasonable enumeration of the usual basis for X will be a recursive presentation).

For s a finite sequence (i.e., a function with domain some $n \in \omega$), we let $\mathrm{lh}(s) = n$ denote the length of s. Thus, $s{\restriction}m$, for $m \leq n$, is the initial subsequence of s of length m.

By a tree on a set X we mean a set $T \subseteq X^{<\omega}$ closed under subsequence. Given sets X and Y, we frequently identify a tree T on the set $X \times Y$ with a set $T \subseteq \{(s,t) \in (X \times Y)^{<\omega} : \mathrm{lh}(s) = \mathrm{lh}(t)\}$ closed under initial segment, that is, if $(s,t) \in T$, then $(s\restriction m, t\restriction m) \in T$ for any $m < \mathrm{lh}(s)$. Similarly, we identify trees on $X_1 \times \cdots \times X_n$ with subsets of $X_1^{<\omega} \times \cdots \times X_n^{<\omega}$. $[T]$ denotes the set of paths or branches through T. We say a tree is *well-founded* iff it is well-founded under the extension relation, and otherwise say it is ill-founded. Thus, T is ill-founded iff $[T] \neq \emptyset$. If T is ill-founded, and X is equipped with a wellorder $<_X$, then T has a *left-most* branch $f \in [T]$. That is, for all $g \in [T]$, if $f \neq g$, then for the least n such that $f(n) \neq g(n)$ we have $f(n) <_X g(n)$. For T a tree on $X \times Y$, and $x \in X^\omega$, we let $T_x = \{s \in Y^{<\omega} : (x\restriction \mathrm{lh}(s), s) \in T\}$ denote the section of the tree T at x. For T a tree on $X \times Y$, we let $p[T]$ denote the projection of $[T]$, that is,

$$p[T] = \{x \in X^\omega : \exists y \in Y^\omega\ \forall n\ (x\restriction n, y\restriction n) \in T\}.$$

If T is a tree on $\lambda_1 \times \cdots \times \lambda_n$ and $\beta \in \mathrm{On}$, then we let

$$T\restriction\beta = \{(s_1, \ldots, s_n) \in T : \forall m < \mathrm{lh}(s_1)\ (s_1(m), \ldots, s_n(m) < \beta)\}.$$

If $(X, <_X)$ is a wellordered set, then for any $n \in \omega$ the set X^n is wellordered by the induced lexicographic ordering defined by:

$$s <_{\mathrm{lex}} t \longleftrightarrow \exists k(s(k) <_X t(k) \wedge \forall l < k\ s(l) = t(l)).$$

We let $|s|_{\mathrm{lex}}$ denote the rank of $s \in X^n$ in the lexicographic ordering. If T is a tree on X, then the wellorder $<_X$ also induces a linear order on T, known as the Kleene-Brouwer order, defined by:

$$\begin{aligned} s <_{\mathrm{KB}} t \longleftrightarrow{} & (s \text{ extends } t) \text{ or } \exists k < \min\{\mathrm{lh}(s), \mathrm{lh}(t)\} \\ & (s(k) <_X t(k) \wedge \forall l < k\ s(l) = t(l)). \end{aligned}$$

The Kleene-Brouwer order on T is a wellordering iff T is well-founded, that is, $[T] = \emptyset$. If T is a tree on X and $s \in T$, we let $T(s)$ denote $\{t \in T : t \text{ extends } s\}$. If T is a well-founded tree, we let $|T|$ denote the rank of T. In this case, we let $|T|_{\mathrm{KB}}$ denote the rank of T in the Kleene-Brouwer order (this also implicitly depends on the wellorder of X). We always have $|T| \leq |T|_{\mathrm{KB}}$. Note that $|T(s)|$ is the rank of s in T, and we also denote this by $|s|_T$. Also, $|(T\restriction\alpha)(s)|$ denotes the rank of s in the tree $T\restriction\alpha$, and likewise for $|(T\restriction\alpha)(s)|_{\mathrm{KB}}$. More generally, if $\prec$ is any well-founded relation on $\delta \in \mathrm{On}$, we let $\prec\restriction\alpha$ denote $\prec \cap \{(\beta,\gamma) : \beta, \gamma < \alpha\}$. Likewise, $\prec(\alpha) = \prec \cap \{(\beta,\gamma) : \beta, \gamma \prec \alpha\}$. We let $|\prec|$ denote the rank of $\prec$. Similarly, $|\prec(\alpha)| = |\alpha|_\prec$ both denote the rank of α in the well-founded relation $\prec$.

By a game on a set X we mean a two player game where players I and II alternate playing $x_0, x_1, \ldots \in X$ building $\vec{x} \in X^\omega$, and I wins the run iff $\vec{x} \in A$, where $A \subseteq X^\omega$ is the *payoff* set. Although the game is officially identified with its payoff set $A \subseteq X^\omega$, we sometimes write G_A to denote this game for conceptual clarity. A strategy for I (II) in a game on X is a function from the sequences from X of even (odd) length into X. The strategy is winning for I (II) if every run of the game where I (II) follows the strategy is a win for I (II). A game A is *determined* if one of the players has a winning strategy. AD is the assertion that every game on ω is determined. A *quasi-strategy* for I (II) is a relation $R \subseteq X^{<\omega} \times X$ such that $\forall s \in X^{<\omega}\ \exists x \in X\ R(s,x)$, and $\forall s \in X^{<\omega}$ of odd (even) length, $\forall x \in X\ R(s,x)$. We think of a quasi-strategy as a multi-valued strategy. A quasi-strategy is winning for I (II) if every run $\vec{x} \in X^\omega$ of the game such that $\forall n\ R(\vec{x}\restriction n, x(n))$ is a win for I (II). A game G_A is *quasi-determined* if one of the two players has a winning quasi-strategy. If X can be wellordered (e.g., $X = \omega$), then from a winning quasi-strategy for one of the players we easily get a winning strategy for the same player. If X is a perfect product space, Y is a set, and $A \subseteq X \times Y^\omega$, then $\Game^Y A$ is the set $B \subseteq X$ defined by $x \in B$ iff I has a winning strategy in the game $G_A(x)$ where I and II alternate playing $y_0, y_1, y_2, \ldots \in Y$ producing $\vec{y} \in Y^\omega$, and I wins the run if $(x, \vec{y}) \in A$. We abbreviate this by writing $x \in B \longleftrightarrow \exists y_0\ \forall y_1\ \exists y_2\ \forall y_3 \cdots (x, \vec{y}) \in A$.

By a *measure* on a set X we mean a countably additive ultrafilter on X. Recall that assuming AD, every ultrafilter on a set X is countably additive, that is, a measure. If ν is a measure on X, and f is a function with domain X, we let $[f]_\nu$ denote the equivalence class of f in the ultrapower, that is, $f \sim g \longleftrightarrow \nu(\{x \in X : f(x) = g(x)\}) = 1$. When considering ultrapowers by measures, we also let $[f]_\nu$ denote the image of $[f]_\nu$ in the transitive collapse of the ultrapower. We often say "A has measure one" in place of $\nu(A) = 1$. We also write $\forall^*_\nu x \in X$ to abbreviate "for ν measure one many $x \in X$".

We introduce a useful notational convention. Let $\nu_1, \ldots, \nu_n$ be measures. If $P \subseteq \mathrm{On}$ and $\delta \in \mathrm{On}$, we let $\forall^*_{\nu_1}\alpha_1\ \forall^*_{\nu_2}\alpha_2 \cdots \forall^*_{\nu_n}\alpha_n\ P(\delta(\alpha_1, \ldots, \alpha_n))$ abbreviate the statement: if $[f_1]_{\nu_1} = \delta$ then for ν_1 almost all α_1, if $[f_2]_{\nu_2} = f_1(\alpha_1)$, then for ν_2 almost all α_2, if $[f_3]_{\nu_3} = f_2(\alpha_2), \ldots,$ for ν_n almost all α_n, $P(f_n(\alpha_n))$. It is easily checked that this statement is well-defined. We also extend this convention to properties of pairs of ordinals, etc. For example, given measures $\nu_1, \ldots, \nu_n$ and ordinals δ, ϵ, we might write $\forall^*_{\nu_1}\alpha_1 \cdots \forall^*_{\nu_n}\alpha_n\ \mathrm{cf}(\delta(\alpha_1, \ldots, \alpha_n)) \leq \epsilon(\alpha_1, \ldots, \alpha_n)$. If the measures are understood, we simply write $\forall^*\alpha_1, \ldots, \alpha_n\ P(\delta(\alpha_1, \ldots, \alpha_n))$, etc.

If $f : X \to \mathrm{On}$ is a function and $\alpha \in \mathrm{On}$, we write $N_f(\alpha)$ for the least ordinal in the range of f greater than α. Likewise, if $A \subseteq \mathrm{On}$, we write $N_A(\alpha)$ for the least ordinal greater than α in A.

2. Survey of Basic Notions

Throughout Sect. 2 we work in the base theory ZF + DC, stating other hypotheses explicitly as needed.

2.1. Prewellordering, Scales, and Periodicity

We begin with a review of the basic concepts of scale and prewellordering. The definition of a scale was introduced by Moschovakis, and represents a distillation of the key ideas in the Novikov-Kondo proof of uniformization for $\mathbf{\Pi}^1_1$ sets.

Recall the basic notions of pointclass, Wadge reduction, etc., that were defined in the introduction. If $\mathbf{\Gamma}$ is a pointclass, we say $U \subseteq \omega^\omega \times X$ in $\mathbf{\Gamma}$ is *universal* for $\mathbf{\Gamma}\restriction X$ (where $X = X_0 \times \cdots \times X_n$ is a perfect product space) if for every $B \subseteq X$ in $\mathbf{\Gamma}$, there is a $y \in \omega^\omega$ such that $B = U_y = \{x : (y, x) \in U\}$. Assuming AD, Wadge's Lemma implies that every non-selfdual pointclass $\mathbf{\Gamma}$ has universal sets. For suppose $A \in \mathbf{\Gamma} - \check{\mathbf{\Gamma}}$. For every product space $X = X_0 \times \cdots \times X_n$, define $U_X \subseteq \omega^\omega \times X$ by $U_X(y, x_0, \ldots, x_n) \longleftrightarrow f_y(\langle x_0, \ldots, x_n\rangle) \in A$ where we view every $y \in \omega^\omega$ as coding a Lipschitz continuous function $f_y : \omega^\omega \to \omega^\omega$ (say by $f_y(a_0, \ldots, a_n) = (y(\langle a_0\rangle), \ldots, y(\langle a_0, \ldots, a_n\rangle))$. Clearly $U_X \in \mathbf{\Gamma}$. If $B \subseteq X$ is in $\mathbf{\Gamma}$, then by Wadge $B \leq_l A$, so for some y we have $B = (U_X)_y$.

The usual diagonal argument shows that a universal $\mathbf{\Gamma}$ set $U \subseteq \omega^\omega \times \omega^\omega$ cannot lie in $\check{\mathbf{\Gamma}}$, and thus if $\mathbf{\Gamma}$ has a universal set, it is non-selfdual. Also, the *s-m-n* and Recursion Theorems go through at this level of generality. Specifically, we have:

2.1 Theorem. *Let $\mathbf{\Gamma}$ be a pointclass with a universal set. Then there are universal sets $U_X \subseteq \omega^\omega \times X$ for all product spaces X with the following properties:*

(1) (s-m-n Theorem) For every $X = X_1 \times \cdots \times X_n$, $Y = X_1 \times \cdots \times X_n \times \cdots \times X_m$ where $m > n$, there is a continuous $s_{Y,X} : \omega^\omega \times X \to \omega^\omega$ such that

$$U_Y(y, x_1, \ldots, x_n, \ldots, x_m) \longleftrightarrow U_{X'}(s_{Y,X}(y, x_1, \ldots, x_n), x_{n+1}, \ldots, x_m)$$

where $X' = X_{n+1} \times \cdots \times X_m$.

(2) (Recursion Theorem) For every product space $X = X_1 \times \cdots \times X_n$ and $\mathbf{\Gamma}$ set $A \subseteq \omega^\omega \times X$, there is a $y^* \in \omega^\omega$ such that for all $x \in X$, $U_X(y^*, x) \longleftrightarrow A(y^*, x)$.

Proof. Let $U \subseteq \omega^\omega \times \omega^\omega$ in $\mathbf{\Gamma}$ be universal for $\mathbf{\Gamma}$ subsets of ω^ω. For $X = X_1 \times \cdots \times X_n$ define $U_X(y, (x_1, \ldots, x_n)) \longleftrightarrow U(y_0, \langle y_1, x_1, \ldots, x_n\rangle)$, where here $y \to (y_0, y_1)$ denotes our recursive bijection from ω^ω to $\omega^\omega \times \omega^\omega$. Suppose $Y = X_1 \times \cdots \times X_n \times \cdots \times X_m$. Then

$$U_Y(y, (x_1, \ldots, x_n, \ldots, x_m)) \longleftrightarrow U(y_0, \langle y_1, x_1, \ldots, x_n, \ldots, x_m\rangle)$$

and

$$U_{X'}(s, (x_{n+1}, \ldots, x_m)) \longleftrightarrow U(s_0, \langle s_1, x_{n+1}, \ldots, x_m\rangle).$$

Thus, it suffices to take $s_{Y,X}(y, x_1, \ldots, x_n) = \langle \epsilon, \langle y, x_1, \ldots, x_n\rangle\rangle$ where ϵ is such that $U(\epsilon, \langle\langle y, x_1, \ldots, x_n\rangle, x_{n+1}, \ldots, x_m\rangle) \longleftrightarrow U(y_0, \langle y_1, x_1, \ldots, x_m\rangle)$ for all $y, x_1, \ldots, x_m$. That is, choose ϵ so that for all z

$$U(\epsilon, z) \longleftrightarrow U(z_{0,0,0}, \langle z_{0,0,1}, z_{0,1}, \ldots, z_{0,n}, z_1, \ldots, z_{m-n}\rangle)$$

which is possible as U is universal (here $z_{0,0,0}$ abbreviates $(((z)_0)_0)_0$, etc., and these decoding functions refer to the obvious product spaces).

As for the Recursion Theorem, fix $X = X_1 \times \cdots \times X_n$, and let $A \subseteq \omega^\omega \times X$ be in $\mathbf{\Gamma}$. Let $\epsilon \in \omega^\omega$ be such that $U(\epsilon, y, x) \longleftrightarrow A(s(y,y), x)$, where s is the s-m-n function from $(\omega^\omega)^2$ to ω^ω corresponding to the spaces ω^ω and $\omega^\omega \times X$. Thus, $U(s(\epsilon, y), x) \longleftrightarrow U(\epsilon, y, x) \longleftrightarrow A(s(y,y), x)$ for all y, x, where we have dropped the cumbersome subscripts on the U. Let then $y = \epsilon$, and thus $y^* = s(\epsilon, \epsilon)$. ⊣

Following Moschovakis, we call sets U_X satisfying Theorem 2.1 *good* universal sets. We shall frequently implicitly assume (without loss of generality) that our universal sets are good. Note that the construction of the U_X is uniform in the universal sets A.

We review now some of the general theory of prewellorderings and scales.

2.2 Definition. A *(regular) norm* on a set $A \subseteq \omega^\omega$ is a map ϕ from A into (onto) some ordinal. A norm $\phi : A \to \mathrm{On}$ is said to be a $\mathbf{\Gamma}$-*norm* if there are $\mathbf{\Gamma}, \check{\mathbf{\Gamma}}$ binary relations $\leq_\phi^{\mathbf{\Gamma}}$, $\leq_\phi^{\check{\mathbf{\Gamma}}}$ on ω^ω such that for all $y \in A$, $\forall x\ [(x \in A \wedge \phi(x) \leq \phi(y)) \longleftrightarrow x \leq_\phi^{\mathbf{\Gamma}} y \longleftrightarrow x \leq_\phi^{\check{\mathbf{\Gamma}}} y]$. A pointclass $\mathbf{\Gamma}$ has the *prewellordering property*, written $\mathrm{pwo}(\mathbf{\Gamma})$, if every $A \in \mathbf{\Gamma}$ admits a $\mathbf{\Gamma}$-norm.

Norms can be identified with *prewellorderings* of A (that is, transitive, reflexive, connected binary relations $\preceq$ on A). We let $\prec$ denote the strict part of a prewellordering $\preceq$ and vice versa (i.e., $x \prec y \longleftrightarrow x \preceq y \wedge \neg y \preceq x$).

The above definition generalizes immediately to any perfect product space X as well. A standard and straightforward lemma (Theorem 4B.1 of [31]) says that if $\mathbf{\Gamma}$ is closed under $\wedge, \vee$, then $\phi : A \to \mathrm{On}$ is a $\mathbf{\Gamma}$-norm on $A \in \mathbf{\Gamma}$ iff the following relations are in $\mathbf{\Gamma}$:

$$x \leq_\phi^* y \longleftrightarrow x \in A \wedge (y \notin A \vee \phi(x) \leq \phi(y)),$$
$$x <_\phi^* y \longleftrightarrow x \in A \wedge (y \notin A \vee \phi(x) < \phi(y)).$$

In fact, to show that the existence of the starred relations implies the prewellordering property requires no closure assumptions on $\mathbf{\Gamma}$.

If $\mathbf{\Gamma}$ has the prewellordering property and is closed under $\vee$, $\wedge$, then any two $\mathbf{\Gamma}$ sets A, B have comparable $\mathbf{\Gamma}$-norms. That is, there are $\mathbf{\Gamma}$-norms ϕ, ψ on A, B respectively and $\mathbf{\Gamma}$ relations $\leq_{\psi,\phi}^{\mathbf{\Gamma}}$, $\leq_{\phi,\psi}^{\mathbf{\Gamma}}$ and $\check{\mathbf{\Gamma}}$ relations $\leq_{\psi,\phi}^{\check{\mathbf{\Gamma}}}$, $\leq_{\phi,\psi}^{\check{\mathbf{\Gamma}}}$ such that $\forall y \in A\ \forall x\ [(x \in B \wedge \psi(x) \leq \phi(y)) \longleftrightarrow x \leq_{\psi,\phi}^{\mathbf{\Gamma}} y \longleftrightarrow x \leq_{\psi,\phi}^{\check{\mathbf{\Gamma}}} y]$, and likewise $\forall y \in B\ \forall x\ [(x \in A \wedge \phi(x) \leq \psi(y)) \longleftrightarrow x \leq_{\phi,\psi}^{\mathbf{\Gamma}} y \longleftrightarrow x \leq_{\phi,\psi}^{\check{\mathbf{\Gamma}}} y]$. To see this, let $E = \{\langle i, z\rangle : (i = 0 \wedge z \in A) \vee (i = 1 \wedge z \in B)\}$. Let ρ be a $\mathbf{\Gamma}$-norm on E, and let $\phi(x) = \rho(\langle 0, x\rangle)$ for $x \in A$, and $\psi(x) = \rho(\langle 1, x\rangle)$ for $x \in B$. We can take, for example $x \leq_{\phi,\psi}^{\mathbf{\Gamma}} y$ iff $\langle 0, x\rangle \leq_\rho^{\mathbf{\Gamma}} \langle 1, y\rangle$. Note, however, that these norms are not regular.

2.3 Definition. A set $A \subseteq \omega^\omega$ is κ-*Suslin* if there is a tree T on $\omega \times \kappa$ such that $A = p[T]$. Let $S(\kappa)$ denote the pointclass of κ-Suslin sets. A cardinal κ is a *Suslin cardinal* if $S(\kappa) - \bigcup_{\kappa' < \kappa} S(\kappa') \neq \emptyset$.

A closely related concept (see Lemma 2.5) is that of a scale.

2.4 Definition. A *semi-scale* $\{\phi_n\}_{n\in\omega}$ on a set $A \subseteq X$ (X a perfect product space) is a collection of norms ϕ_n on A such that if $\{x_m\}_{m\in\omega} \subseteq A$ is a sequence of points in A converging to x, and for all n, $\phi_n(x_m)$ is eventually constant, then $x \in A$. We say $\{\phi_n\}$ is an α *semi-scale* if all norms map into α. We say $\{\phi_n\}$ is a *scale* if it in addition satisfies the lower semi-continuity property: $\forall n\ \phi_n(x) \leq \lambda_n \doteq \lim_{m\to\infty} \phi_n(x_m)$. Likewise we define α-scale.

A (semi)-scale $\{\phi_n\}$ on A is a *good* (semi)-scale if whenever $x_m \in A$ and for all n, $\phi_n(x_m)$ is eventually constant, then $x = \lim_{m\to\infty} x_m$ exists (and thus $x \in A$).

A (semi)-scale is called *very good* if it is good and whenever $x, y \in A$ and $\phi_n(x) \leq \phi_n(y)$, then $\phi_i(x) \leq \phi_i(y)$ for all $i < n$.

A (semi)-scale is called *excellent* if it is very good and whenever $x, y \in A$ and $\phi_n(x) = \phi_n(y)$ then $x\restriction n = y\restriction n$ (assuming now $X = \omega^\omega$).

The notions of good α-scale, etc., are defined in the same manner, requiring the norms to map into α.

The next lemma shows the essential equivalence of these concepts.

2.5 Lemma. *For every $A \subseteq \omega^\omega$ and every $\alpha \in \mathrm{On}$, A is α-Suslin iff A has an α-semiscale iff A has an α-scale iff A has an excellent α-scale.*

Proof. Clearly excellent scale $\to$ very good scale $\to$ good scale $\to$ scale $\to$ semi-scale, for any α. If $\{\phi_n\}$ is a semi-scale on A into α, define the tree of the semi-scale as follows:

$$\begin{aligned}&((a_0,\dots,a_{n-1}),(\beta_0,\dots,\beta_{n-1})) \in T_\phi\\ &\quad\longleftrightarrow \exists x \in A\ \big[x\restriction n = (a_0,\dots,a_{n-1}) \wedge \phi_0(x) = \beta_0,\dots,\phi_{n-1}(x) = \beta_{n-1}\big].\end{aligned}$$

Clearly $A \subseteq p[T]$. If $(x, f) \in [T]$, then $\exists x_m \in A$ such that $x_m \to x$ and $\phi_n(x_m) \to f(n)$ for all n. Thus, $x \in A$ by definition of a semi-scale. Hence, $A = p[T]$.

Thus, it suffices to show that A is α-Suslin implies A admits an excellent α-scale. First note that A is α-Suslin iff A is κ-Suslin, where $\kappa = |\alpha|$. Thus we may assume $\alpha = \kappa$ is a cardinal. Fix a tree T on $\omega \times \kappa$ such that $A = p[T]$. We consider two cases.

First assume $\mathrm{cf}(\kappa) > \omega$. Then $\forall x \in A\ \exists \beta < \kappa\ (x \in p[T\restriction\beta])$. Define a tree S by:

$$\begin{aligned}&((a_0,\dots,a_{n-1}),(\beta_0,\dots,\beta_{n-1})) \in S\\ &\quad\longleftrightarrow \beta_0 > \beta_1,\dots,\beta_{n-1} \wedge ((a_0,\dots,a_{n-2}),(\beta_1,\dots,\beta_{n-1})) \in T.\end{aligned}$$

Thus, $A = p[S]$ as well. For $x \in A$, define

$$\phi_n(x) = |(f(0), x(0),\dots, f(n-1), x(n-1)|^*_{\mathrm{lex}},$$

where $f : \omega \to \kappa$ is the leftmost branch through S_x, and $|\vec{s}|^*_{\text{lex}}$ denotes the rank of $\vec{s}$ in the lexicographic ordering restricted to $\vec{t} \in \kappa^{2n}$ such that $t(0) > t(1), \dots, t(2n-1)$. Thus, $\phi_n : A \to \kappa$. Suppose $\{x_m\} \subseteq A$ and $\phi_n(x_m) \to \lambda_n$ for all n. Let $\vec{s}_n$ be such that $|\vec{s}_n|^*_{\text{lex}} = \lambda_n$. Then $\vec{s}_{n+1}$ extends $\vec{s}_n$ for all n, so $x_m \to x \in \omega^\omega$ and the $\vec{s}_n$ define an $f : \omega \to \kappa$ for which $(x, f) \in [T]$. This shows $\{\phi_n\}$ is a semi-scale, and the lower semi-continuity and excellence are easily verified.

Suppose next that $\text{cf}(\kappa) = \omega$. Let $\kappa_i < \kappa$ with $\sup_{i\in\omega} \kappa_i = \kappa$. We may assume T is a tree on $\omega \times (\kappa - \omega)$. Define a tree S on $\omega \times \kappa$ by "padding" T as follows. An element of S will be of the form

$$((a_0, \dots, a_{n-1}), (k_0, 0, \dots, 0, \beta_0, \dots, k_i, 0, \dots, 0, \beta_i, \dots))$$

such that:

(1) Each $k_l \in \omega$, and after k_l occur k_l 0's. Also, $\beta_l < \kappa_{k_l}$.

(2) $((a_0, \dots, a_j), (\beta_0, \dots, \beta_j)) \in T$, where j is maximal so that $(k_0 + 2) + \dots + (k_j + 2) \leq n$.

Note that if $(\vec{a}, \vec{s}) \in S$, then $\forall i\ \vec{s}(i) < \kappa_i$. Easily, $A = p[S]$ as well. We now define ϕ_n as in the previous case (using lexicographic ordering on $(\kappa_n)^{2n}$). It is easily checked that $\{\phi_n\}$ is an excellent α-scale. $\dashv$

One standard consequence of scales is the Kunen-Martin Theorem (cf. [31, Theorem 2G.2]) which we now state.

2.6 Theorem (Kunen, Martin). *Every κ-Suslin well-founded relation on ω^ω has length less than κ^+.*

We next recall the fundamental notion of a $\mathbf{\Gamma}$-scale, a notion introduced by Moschovakis.

2.7 Definition. A scale $\{\phi_n\}$ on a set A is a $\mathbf{\Gamma}$-*scale* if all of the norms ϕ_n are $\mathbf{\Gamma}$-norms. We say $\mathbf{\Gamma}$ has *the scale property*, scale($\mathbf{\Gamma}$), if every $A \in \mathbf{\Gamma}$ admits a $\mathbf{\Gamma}$-scale.

The prewellordering and scale properties are the basic structural ingredients in descriptive set theory, and have numerous applications there (this theory is developed in [31]). For example, if pwo($\mathbf{\Gamma}$) and $\mathbf{\Gamma}$ is closed under $\forall^\omega$ and $\wedge$, $\vee$, then $\mathbf{\Gamma}$ has the number uniformization property, that is, every $A \subseteq \omega^\omega \times \omega$ in $\mathbf{\Gamma}$ can be uniformized by a $\mathbf{\Gamma}$ relation $B \subseteq A$. Namely, set

$$B(x, n) \longleftrightarrow (\forall m\ (x, n) \leq^* (x, m)) \wedge (\forall m < n\ (x, n) <^* (x, m)),$$

where $\leq^*, <^*$ correspond to a $\mathbf{\Gamma}$-norm on A. [The number uniformization property can also be shown directly for pointclasses of the form $\exists^\omega\mathbf{\Gamma}$ where $\mathbf{\Gamma}$ is closed under $\forall^\omega$ but not $\exists^\omega$.] Likewise, if $\mathbf{\Gamma}$ has the scale property and is closed under $\forall^{\omega^\omega}$ and $\wedge, \vee$, then every $\mathbf{\Gamma}$ relation $A \subseteq \omega^\omega \times \omega^\omega$ has a $\mathbf{\Gamma}$

uniformization. To see this, note that if $\{\phi_n\}$ is a $\boldsymbol{\Gamma}$ scale on $A \subseteq \omega^\omega \times \omega^\omega$, and we define

$$\psi_n(x,y) = \big|(\phi_0(x,y), x(0), y(0), \ldots, \phi_{n-1}(x,y), x(n-1), y(n-1)\big|_{\text{lex}},$$

then $\{\psi_n\}$ is a very good $\boldsymbol{\Gamma}$-scale on A. For $x \in \text{dom}(A)$, $n \in \omega$, let $s_n = (\alpha_0, x(0), y(0), \ldots, \alpha_{n-1}, x(n-1), y(n-1))$ be lexicographically least such that for some $(x, y_n) \in A$, $\psi_n(x, y_n) = |s_n|_{\text{lex}}$. Note that s_{n+1} extends s_n. By the scale property, there is a $(x,y) \in A$ with $\psi_n(x,y) = |s_n|_{\text{lex}}$ for all n, and by very goodness this y is unique. Thus if we define $B(x,y) \longleftrightarrow \forall z \forall n\ (x,y) \leq^*_{\psi_n} (x,z)$, then B uniformizes A.

It is a relatively straightforward ZF result that the prewellordering and scale properties propagate from a pointclass $\boldsymbol{\Gamma}$ closed under $\forall^{\omega^\omega}$ to $\exists^{\omega^\omega}\boldsymbol{\Gamma}$. The important periodicity theorems assert that, granted sufficient determinacy, they also propagate from a pointclass $\boldsymbol{\Gamma}$ closed under $\exists^{\omega^\omega}$ to $\forall^{\omega^\omega}\boldsymbol{\Gamma}$. We state without proof the first two of the three periodicity theorems (proofs may be found in [31]). These theorems are due to Martin-Moschovakis, Moschovakis, and Moschovakis respectively. We note that DC is not required for the following two theorems.

2.8 Theorem (First Periodicity). *Let $\boldsymbol{\Gamma}$ be a pointclass closed under $\exists^{\omega^\omega}$ with* pwo($\boldsymbol{\Gamma}$). *If $\boldsymbol{\Delta}$-determinacy holds, then* pwo($\forall^{\omega^\omega}\boldsymbol{\Gamma}$).

2.9 Theorem (Second Periodicity). *Let $\boldsymbol{\Gamma}$ be a pointclass closed under $\exists^{\omega^\omega}$ and $\wedge, \vee$ with the scale property. If $\boldsymbol{\Delta}$-determinacy holds, then $\forall^{\omega^\omega}\boldsymbol{\Gamma}$ has the scale property.*

2.10 Remark. The proof of the Second Periodicity Theorem also shows that if $A \subseteq \lambda^\omega \times \omega^\omega$ admits a scale (that is, is Suslin), then so does $B \subseteq \lambda^\omega$, where $B(\vec{\alpha}) \longleftrightarrow \forall x \in \omega^\omega\ A(\vec{\alpha}, x)$.

Thus, assuming Projective Determinacy the pointclasses amongst the $\boldsymbol{\Sigma}^1_n$, $\boldsymbol{\Pi}^1_n$ having the scale property are $\boldsymbol{\Pi}^1_1$, $\boldsymbol{\Sigma}^1_2$, $\boldsymbol{\Pi}^1_3$, $\boldsymbol{\Sigma}^1_4, \ldots$, exhibiting a periodicity of order two.

We also recall a version of the Third Periodicity Theorem, due also to Moschovakis. Because we will have specific need for this result later, we give the proof. For the version we state, we require DC.

Let X be a set, and $A \subseteq X^\omega$. Recall G_A is the game where I, II alternate playing $x_0, x_1, \ldots \in X$, and I wins iff $(x_0, x_1, \ldots) \in A$. Assume I has a winning quasi-strategy in the game G_A, and A admits a very good semi-scale $\{\phi_n\}$ (defined in an obvious way using X^ω in place of ω^ω, where X is given the discrete topology). We define (assuming sufficient determinacy) a canonical winning quasi-strategy τ for I in G_A as follows. Suppose $s, t \in X^{<\omega}$ are winning positions for I in G_A of the same odd length (i.e., II's turn to move). For $n \in \omega$, consider the game $G^n_{s,t}$ played as follows:

s	F $a(0)$			S $a(1)$	F $a(2)$			S $a(3)$
t		S $b(0)$	F $b(1)$			S $b(2)$	F $b(3)$	

$$
\begin{array}{c|ccccc}
\vdots & \vdots & \vdots & \vdots & \vdots & \\
s_3 & \mathrm{F}\, a_3(0) & a_3(1) & \mathrm{F}\, a_3(2) & a_3(3) & \cdots \\
\hline
s_3 & a_3(0) & \mathrm{F}\, a_3(1) & a_3(2) & \mathrm{F}\, a_3(3) & \cdots \\
 & & & & & \\
s_2 & \mathrm{F}\, a_2(0) & a_2(1) & \mathrm{F}\, a_2(2) & a_2(3) & \cdots \\
\hline
s_2 & a_2(0) & \mathrm{F}\, a_2(1) & a_2(2) & \mathrm{F}\, a_2(3) & \cdots \\
 & & & & & \\
s_1 & \mathrm{F}\, a_1(0) & a_1(1) & \mathrm{F}\, a_1(2) & a_1(3) & \cdots \\
\hline
s_1 & a_1(0) & \mathrm{F}\, a_1(1) & a_1(2) & \mathrm{F}\, a_1(3) & \cdots \\
 & & & & & \\
s_0 & \mathrm{F}\, a_0(0) & \mathrm{I}\ a_0(1) & \mathrm{F}\, a_0(2) & \mathrm{I}\ a_0(3) & \cdots
\end{array}
$$

Figure 21.1

The game consists of two players F and S (first and second), making moves from X as shown. Let $a, b \in X^\omega$ be the sequences they produce. We say S wins the run of the game iff $s^\frown a \leq^*_{\phi_n} t^\frown b$. Let W_m, for odd m, be the set of winning positions for I in G_A of length m (i.e., I has a winning quasi-strategy starting from that position). For $s, t \in W_m$ set $s \leq^m_n t$ iff S has a winning quasi-strategy in $G^n_{s,t}$. We assume here that the games $G^n_{s,t}$ are quasi-determined. We claim that each $\leq^m_n$ is a prewellordering on each W_m. First note that there cannot be an infinite sequence $s_0, s_1, \ldots \in W_m$ such that $\forall i\ s_i \not\leq^m_n s_{i+1}$. For if so, fix winning quasi-strategies for F in all of the games $G^n_{s_i,s_{i+1}}$, and fill in the sequence of games as shown in Fig. 21.1, using DC.

Here F follows the fixed winning quasi-strategies on all of the boards (moves made by following one of F's winning quasi-strategies are marked with an F), S's moves in the various boards are obtained by copying as shown, except in the bottom run where S follows a fixed winning quasi-strategy for the game G_A starting from s_0 (these moves are marked with a I). Let a_0, a_1, a_1, a_2, $a_2, \ldots,$ be the sequences they produce. Thus $s_0{}^\frown a_0 \in A$ and $\phi_n(s_0{}^\frown a_0) > \phi_n(s_1{}^\frown a_1) > \cdots$, a contradiction. It follows that $\leq^m_n$ is wellfounded, reflexive, and connected on each W_m. Transitivity of $\leq^m_n$ also easily follows, since if $s \leq^m_n t$, $t \leq^m_n u$, but $\neg(s \leq^m_n u)$, we could play quasi-strategies for S in the first two games against one for F in the third game to get a contradiction. Thus, each $\leq^m_n$ is a prewellordering on each W_m.

Define the quasi-strategy τ as follows. If $s = (s(0), \ldots, s(2n-1))$ is a winning position for I in G_A of even length, $s^\frown a \in \tau$ iff $s^\frown a$ is a winning position for I and $s^\frown a \leq^{2n+1}_n s^\frown b$ for all $b \in X$ such that $s^\frown b$ is a winning position for I.

To see this is a winning quasi-strategy, suppose $a = (a(0), a(1), \ldots)$ is a run following τ. Consider then the play of the games as shown in Fig. 21.2.

$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\vdots$	
$a(0)$	$a(1)$	$a(2)$	$a(3)$	$a(4)$	$a(5)$	S $a_3(6)$	$\cdots$
$a(0)$	$a(1)$	$a(2)$	$a(3)$	$a_2(4)$	S $a_2(5)$	$a_2(6)$	$\cdots$
$a(0)$	$a(1)$	$a(2)$	$a(3)$	S $a_2(4)$	$a_2(5)$	S $a_2(6)$	$\cdots$
$a(0)$	$a(1)$	$a_1(2)$	S $a_1(3)$	$a_1(4)$	S $a_1(5)$	$a_1(6)$	$\cdots$
$a(0)$	$a(1)$	S $a_1(2)$	$a_1(3)$	S $a_1(4)$	$a_1(5)$	S $a_1(6)$	$\cdots$
I $a_0(0)$	S $a_0(1)$	I $a_0(2)$	S $a_0(3)$	I $a_0(4)$	S $a_0(5)$	I $a_0(6)$	$\cdots$

Figure 21.2

Here I is following a fixed winning quasi-strategy for G_A on the bottom run (these moves are marked with a I), and S is following winning quasi-strategies for the $G^n_{s,t}$, $s = (a(0), \ldots, a(2n))$, $t = (a(0), \ldots, a(2n-1), a_n(2n))$, on all the boards (these moves are marked with an S). If we let $a_n = (a(0), \ldots, a(2n-1), a_n(2n), a_n(2n+1), \ldots)$, then $a_n \in A$ and $\phi_n(a_n) \leq \phi_n(a_{n-1})$. Since $\{\phi_n\}$ is a very good scale, it follows that all the $\phi_n(a_m)$ are eventually constant and thus $a \in A$.

We state now our version of the Third Periodicity Theorem.

2.11 Theorem (Third Periodicity). *Let X be a set, $A \subseteq X^\omega$, and $\{\phi_n\}$ a very good semi-scale on A. Assume I has a winning quasi-strategy in G_A, and all of the games $G^n_{s,t}$ defined above are quasi-determined. Then the canonical quasi-strategy τ defined above is winning for I. If each of the games $G^n_{s,t}$ is determined, that is one of the players has a winning strategy, then each of the relations $\leq^{m*}_n, <^{m*}_n$ corresponding to the prewellordering $\leq^m_n$ on W_m is in $\Game^X \phi_n$. Specifically,*

$$s \leq^{m*}_n t \longleftrightarrow \forall a(0)\exists b(0)\forall b(1)\exists a(1)\cdots\ s^\frown a \leq^*_{\phi_n} t^\frown b,$$
$$s <^{m*}_n t \longleftrightarrow \exists b(0)\forall a(0)\exists a(1)\forall b(1)\cdots\ s^\frown a <^*_{\phi_n} t^\frown b.$$

Proof. Assuming all the games $G^n_{s,t}$ are quasi-determined, we have defined the quasi-strategy τ for I, and shown that it is winning for I. Assume now that all of the games $G^n_{s,t}$ are actually determined. For odd m, let $\leq^{m*}_n$, $<^{m*}_n$ be the starred relations corresponding to the prewellordering $\leq^m_n$ defined above; we must verify the equivalences stated in the theorem. Let $s, t \in X^m$, and suppose first that $s \leq^{m*}_n t$. In particular, $s \in W_m$. If $t \in W_m$ as well, so $s \leq^m_n t$, then the right hand side of the first equivalence holds, since it just asserts II has a winning strategy in the game $G^n_{s,t}$, which is the definition of $s \leq^m_n t$ in this case. If $t \notin W_m$, II easily wins $G^n_{s,t}$ by playing so the a, b produced in the run of $G^n_{s,t}$ satisfy $s^\frown a \in A$ and $t^\frown b \notin A$. Assume now the right-hand side of the first equivalence, that is, II wins $G^n_{s,t}$. We must

$$
\begin{array}{c|lllll}
\vdots & \vdots & \vdots & \vdots & \vdots & \\
s & \mathrm{S}\, a_3(0) & a_3(1) & \mathrm{S}\, a_3(2) & a_3(3) & \cdots \\
\hline
s & a_3(0) & \mathrm{F}\, a_3(1) & a_3(2) & \mathrm{F}\, a_3(3) & \cdots \\
 & & & & & \\
t & \mathrm{F}\, a_2(0) & a_2(1) & \mathrm{F}\, a_2(2) & a_2(3) & \cdots \\
\hline
t & a_2(0) & \mathrm{S}\, a_2(1) & a_2(2) & \mathrm{S}\, a_2(3) & \cdots \\
 & & & & & \\
s & \mathrm{S}\, a_1(0) & a_1(1) & \mathrm{S}\, a_1(2) & a_1(3) & \cdots \\
\hline
s & a_1(0) & \mathrm{F}\, a_1(1) & a_1(2) & \mathrm{F}\, a_1(3) & \cdots \\
 & & & & & \\
t & \mathrm{F}\, a_0(0) & \mathrm{I}\ a_0(1) & \mathrm{F}\, a_0(2) & \mathrm{I}\ a_0(3) & \cdots
\end{array}
$$

Figure 21.3

have $s \in W_m$, as otherwise I could easily win this game by playing to ensure $s^\frown a \notin A$. If $t \notin W_m$, $s \leq_n^{m*} t$ holds by definition, and if $t \in W_m$ then again by definition $s \leq_n^m t$ and so $s \leq_n^{m*} t$.

For the second equivalence, note first that the right-hand side is asserting that F has a winning strategy in the game $H_{s,t}^n$:

$$
\begin{array}{llllllll}
s & & \mathrm{S}\ a(0) & \mathrm{F}\ a(1) & & & \mathrm{S}\ a(2) & \mathrm{F}\ a(3) \\
t & \mathrm{F}\ b(0) & & & \mathrm{S}\ b(1) & \mathrm{F}\ b(2) & &
\end{array}
$$

where F wins the run iff $s^\frown a <_{\phi_n}^* t^\frown b$.

Assume first now that $s, t \in X^m$ and $s <_n^{m*} t$. In particular $s \in W_m$. If $t \notin W_m$, then easily F has a winning strategy in $H_{s,t}^n$ by playing to ensure that $s^\frown a \in A$ and $s^\frown b \notin A$. So, assume $t \in W_m$. Suppose, toward a contradiction, that S has a winning strategy ρ in $H_{s,t}^n$. Since $\neg(t \leq_n^m s)$, we may fix also a winning strategy σ for F in $G_{t,s}^n$. Using DC, fill in the runs of the games as in Fig. 21.3.

In the bottom run, the moves marked with a I are those following a winning quasi-strategy to produce a_0 with $t^\frown a_0 \in A$. In the boards with moves marked by F, those moves are made in accordance with σ. In the boards with moves marked by S, those moves are made in accordance with ρ. The other moves are made by copying as shown. Thus $t^\frown a_0 \in A$, and from the definitions of ρ, σ we have:

$$\phi_n(t^\frown a_0) > \phi_n(s^\frown a_1) \geq \phi_n(t^\frown a_2) > \phi_n(s^\frown a_3) \ldots,$$

a contradiction. Assume finally the right-hand side of the second equivalence, that is, F has a winning strategy in $H_{s,t}^n$. Easily this implies $s \in W_m$. If $t \notin W_m$, then the left-hand side is true by definition, so assume $t \in W_m$ as well. If $\neg(s <_n^{m*} t)$, then we would have $t \leq_n^m s$, and so S would have a winning strategy in $G^n_{t,s}$. These two strategies may be directly played against each other to get a contradiction. $\dashv$

A case of particular importance is when $X = \omega$, and $A \subseteq \omega^\omega$ is $\boldsymbol{\Sigma}^1_{2n}$. Assuming $\boldsymbol{\Delta}^1_{2n}$-determinacy ($\longleftrightarrow$ $\boldsymbol{\Sigma}^1_{2n}$-determinacy), Theorem 2.11 shows that if I wins G_A, then I has a $\boldsymbol{\Delta}^1_{2n+1}$ winning strategy. For we may define a canonical winning strategy τ for I in G_A by:

$$\tau(s) = k \longleftrightarrow \forall m\ (s^\frown k) \leq_l^{2l+1*} (s^\frown m) \wedge \forall m < k\ (s^\frown k) <_l^{2l+1*} (s^\frown m),$$

where $\mathrm{lh}(s) = 2l$. Thus the relation $\tau(s) = k$ is $\boldsymbol{\Pi}^1_{2n+1}$ from Theorem 2.11 since $\boldsymbol{\Sigma}^1_{2n}$ has the scale property and $\boldsymbol{\Pi}^1_{2n+1} = \Game^{\omega^\omega} \boldsymbol{\Sigma}^1_{2n}$. Since this relation does define a strategy, it follows that the relation is $\boldsymbol{\Delta}^1_{2n+1}$. Similarly, if I wins a $\boldsymbol{\Pi}^1_{2n+1}$ game, then, assuming $\boldsymbol{\Pi}^1_{2n+1}$-determinacy, I has a $\boldsymbol{\Delta}^1_{2n+2}$ winning strategy.

2.2. Projective Ordinals, Sets, and the Coding Lemma

The Moschovakis Coding Lemma is a basic tool in determinacy theory. We present the result in a general form.

2.12 Theorem (AD + DC; Coding Lemma). *Let $\boldsymbol{\Gamma}$ be a non-selfdual pointclass closed under $\exists^{\omega^\omega}$ and $\wedge$, and $\prec$ a $\boldsymbol{\Gamma}$ well-founded relation on ω^ω of rank $\theta \in \mathrm{On}$. Let $R \subseteq \mathrm{dom}(\prec) \times \omega^\omega$ be such that $\forall x \in \mathrm{dom}(\prec)\ \exists y\ R(x, y)$. Then there is a $\boldsymbol{\Gamma}$ set $A \subseteq \mathrm{dom}(\prec) \times \omega^\omega$ which is a choice set for R, that is:*

(1) $\forall \alpha < \theta\ \exists x \in \mathrm{dom}(\prec)\ \exists y\ [|x|_\prec = \alpha \wedge A(x, y)]$.

(2) $\forall x \forall y\ A(x, y) \to [x \in \mathrm{dom}(\prec) \wedge R(x, y)]$.

Proof. We may assume θ is minimal so that the theorem fails, and fix $\prec$, R, and a good universal set $U \subseteq (\omega^\omega)^3$ for the $\boldsymbol{\Gamma}$ subsets of $(\omega^\omega)^2$. Easily, θ is a limit ordinal. For $\delta < \theta$, say $u \in \omega^\omega$ codes a δ-choice set provided (1) holds for $\alpha \leq \delta$ using $A = U_u$, and (2) holds for $A = U_u$ where we replace $x \in \mathrm{dom}(\prec)$ with $x \in \mathrm{dom}(\prec) \wedge |x|_\prec \leq \delta$. By minimality of θ, for all $\delta < \theta$ there are δ-choice sets. Play the game where I, II play out $u, v \in \omega^\omega$, and II wins provided that if u codes a δ_1-choice set for some $\delta_1 < \theta$, then v codes a δ_2-choice set for some $\delta_2 > \delta_1$. If I has a winning strategy, we get a $\boldsymbol{\Sigma}^1_1$ set B of reals coding δ-choice sets for arbitrarily large $\delta < \theta$. Define then $A(x, y) \longleftrightarrow \exists w \in B\ U(w, x, y)$, which easily works.

Suppose now that τ is a winning strategy for II. From the *s-m-n* Theorem, let $s : (\omega^\omega)^2 \to \omega^\omega$ be continuous such that for all ϵ, x, t, w, $U(s(\epsilon, x), t, w) \longleftrightarrow \exists y\ \exists z\ [y \prec x \wedge U(\epsilon, y, z) \wedge U(z, t, w)]$. By the Recursion Theorem, let ϵ_0 be such that $U(\epsilon_0, x, z) \longleftrightarrow z = \tau(s(\epsilon_0, x))$. A straightforward induction on $|x|_\prec$ for $x \in \mathrm{dom}(\prec)$ shows that $\forall x \in \mathrm{dom}(\prec)\ \exists! z\ U(\epsilon_0, x, z)$, and $\forall x \in \mathrm{dom}(\prec)$ $\forall z\ [U(\epsilon_0, x, z) \to z$ codes a $\geq |x|_\prec$-choice set$]$. Let $A(x, y) \longleftrightarrow \exists z \in \mathrm{dom}(\prec)$ $\exists w\ [U(\epsilon_0, z, w) \wedge U(w, x, y)]$. $\dashv$

The Coding Lemma is frequently used where $\prec$ is the strict part of a prewellordering $\preceq$ which is also in $\mathbf{\Gamma}$ ($\mathbf{\Gamma}$ as in Theorem 2.12), and where the set R is invariant, that is, there is an $R' \subseteq \theta \times \omega^\omega$ such that $R(x,y) \longleftrightarrow R'(|x|_\prec, y)$. In this case, the relation A may be taken to have domain $\mathrm{dom}(\preceq)$. For we may define $A(x,y) \longleftrightarrow \exists x' \, [x' \preceq x \wedge x \preceq x' \wedge A'(x',y)]$, where A' is the $\mathbf{\Gamma}$ choice set from Theorem 2.12. A useful consequence of this is that if there is a $\mathbf{\Gamma}$ prewellordering $\preceq$ of length α whose strict part $\prec$ is also in $\mathbf{\Gamma}$, then every $S \subseteq \alpha$ is $\mathbf{\Delta}$ in the codes provided by $\prec$. That is, there are $\mathbf{\Gamma}, \check{\mathbf{\Gamma}}$ sets C, D such that for all $x \in \mathrm{dom}(\preceq)$, $S(|x|_\prec) \longleftrightarrow C(x) \longleftrightarrow D(x)$. To see this, apply the Coding Lemma to the relation $R(x,a) \longleftrightarrow (|x|_\prec \in S \wedge a = 1) \vee (|x|_\prec \notin S \wedge a = 0)$ (identifying $0, 1$ with two reals). Let A be an invariant choice set for R in $\mathbf{\Gamma}$, and set $C(x) \longleftrightarrow (x,1) \in A$, $D(x) \longleftrightarrow (x,0) \notin A$.

Finally, if $\mathbf{\Gamma}$ is a non-selfdual pointclass closed under $\forall^{\omega^\omega}$, $\vee$, and $\mathrm{pwo}(\mathbf{\Gamma})$, then we may improve the definability estimate. Namely, suppose $P \in \mathbf{\Gamma} - \check{\mathbf{\Gamma}}$ and ϕ is a $\mathbf{\Gamma}$ norm on P mapping onto α. Then every $S \subseteq \alpha$ is $\mathbf{\Delta} = \mathbf{\Gamma} \cap \check{\mathbf{\Gamma}}$ in the codes provided by ϕ (rather than $\mathbf{\Delta}(\exists^{\omega^\omega}\mathbf{\Gamma})$). To see this, let U be universal for $\check{\mathbf{\Gamma}} \restriction \omega^\omega \times \omega$. For $\beta < \alpha$ (we may assume α is a limit ordinal), say y codes $S \restriction \beta$ if for all (x,a),

$$\begin{aligned} U_y(x,a) \longleftrightarrow & (x \in P \wedge \phi(x) < \beta \wedge x \in S \wedge a = 1) \\ & \vee (x \in P \wedge \phi(x) < \beta \wedge x \notin S \wedge a = 0). \end{aligned}$$

From the Coding Lemma, for all $\beta < \alpha$ there is a y coding $S \restriction \beta$. Play the integer game where I plays x, II plays y, and II wins iff $[x \in P \rightarrow \exists \beta > \phi(x) \, (y \text{ codes } S \restriction \beta)]$. II wins by boundedness (a winning strategy for I would give a $\mathbf{\Sigma}^1_1$ set $S \subseteq P$ coding cofinally in α many ordinals, from which we would compute $P \in \check{\mathbf{\Gamma}}$ by $x \in P \longleftrightarrow \exists y \in S \; x \leq_{\check{\mathbf{\Gamma}}} y$), and if τ is winning for II, define $D(x) \longleftrightarrow U_{\tau(x)}(x,1)$ and $C(x) \longleftrightarrow \neg U_{\tau(x)}(x,0)$.

There is also a "uniform" version of the Coding Lemma. Roughly speaking, this asserts that A may be chosen so that $A \cap \{(x,w) : |x|_\preceq \leq \delta\}$ is $\mathbf{\Sigma}_1(\preceq_\delta)$, where $\preceq_\delta$ denotes the prewellordering restricted to reals of rank $\leq \delta$. We refer the reader to [22] for a precise statement. This is particularly useful for long prewellorderings, where the initial segments may be much simpler than the overall prewellordering (this also provides another proof of the result of the previous paragraph).

The following lemma, due to Moschovakis, is of frequent use. It can be proved using the Coding Lemma, or by a direct argument using the Recursion Theorem (cf. [31, 4C.14]). To illustrate the Coding Lemma and Recursion Theorem, we give both arguments.

2.13 Lemma (AD + DC). *Let $\mathbf{\Gamma}$ be non-selfdual and closed under $\forall^{\omega^\omega}$, $\wedge$, $\vee$, and assume* $\mathrm{pwo}(\mathbf{\Gamma})$. *Then any $\check{\mathbf{\Gamma}}$ well-founded relation has length less than $\delta(\mathbf{\Gamma}) \doteq$ the supremum of the lengths of the $\mathbf{\Delta}$ prewellorderings (where $\mathbf{\Delta} = \mathbf{\Gamma} \cap \check{\mathbf{\Gamma}}$).*

Proof. First we give the argument using the Coding Lemma. Let P be a $\mathbf{\Gamma}$-complete set, and ϕ a regular $\mathbf{\Gamma}$-norm on P. By definition of $\delta(\mathbf{\Gamma})$, ϕ maps into $\delta(\mathbf{\Gamma})$. Suppose that $\prec$ is a $\check{\mathbf{\Gamma}}$ well-founded relation of length $\geq |\phi|$ (the length of the norm ϕ). We may assume that $|\prec|$ is equal to $|\phi|$. Apply the Coding Lemma to the relation $R \subseteq \mathrm{dom}(\prec) \times \omega^\omega$ given by $R(x, y) \longleftrightarrow (y \in P \wedge \phi(y) = |x|_\prec)$, where $|x|_\prec$ denotes the rank of x in the relation $\prec$. The Coding Lemma gives a $\check{\mathbf{\Gamma}}$ choice set $A \subseteq \mathrm{dom}(\prec) \times \omega^\omega$ as in Theorem 2.12. Let $B(y) \longleftrightarrow \exists x\ A(x, y)$. Then $B \subseteq P$ is in $\check{\mathbf{\Gamma}}$, and for every $\alpha < |\phi|$ there is a $y \in B$ with $\phi(y) = \alpha$. This contradicts boundedness, namely, we could now compute $P \in \check{\mathbf{\Gamma}}$ by $P(z) \longleftrightarrow \exists y\ (B(y) \wedge z \leq_{\check{\mathbf{\Gamma}}} y)$, where $\leq_{\check{\mathbf{\Gamma}}}$ is the $\check{\mathbf{\Gamma}}$ relation corresponding to the norm ϕ.

Now we give the proof using the Recursion Theorem. Let now $U \subseteq \omega^\omega \times \omega^\omega$ be (good) universal for $\mathbf{\Gamma}$ (see Theorem 2.1), and let ϕ be a regular $\mathbf{\Gamma}$-norm on U. Again, $|\phi| \leq \delta(\mathbf{\Gamma})$. Let $\prec$ be a $\check{\mathbf{\Gamma}}$ well-founded relation, and we again show that $|\prec| < |\phi|$. It is enough to show that $|\prec| \leq |\phi|$, as it is easy, given any $\check{\mathbf{\Gamma}}$ relation $\prec$, to define a $\check{\mathbf{\Gamma}}$ relation $\prec'$ having length $|\prec|\ +1$. From the Recursion Theorem, let $x \in \omega^\omega$ be such that

$$U(x, y) \longleftrightarrow \forall z\ (z \prec y \rightarrow (x, z) <^*_\phi (x, y)),$$

holds for all y, where $<^*_\phi$ is the norm relation corresponding to ϕ. For every $y \in \mathrm{dom}(\prec)$, a straightforward induction on $|y|_\prec$ shows that $U(x, y)$ and $\phi(x, y) \geq |y|_\prec$. To see this, first prove by induction on $|y|_\prec$ that $U(x, y)$ holds. For if $|y|_\prec$ were a least violation, then for all $z \prec y$ we would have $U(x, z)$, and thus $(x, z) <^*_\phi (x, y)$ from the definition of $<^*_\phi$. But then $U(x, y)$ holds from the above equation defining U_x. So, for any $y \in \mathrm{dom}(\prec)$, $U(x, y)$ holds. From the definition of U_x it now follows that if $z \prec y$ then $\phi(x, z) < \phi(x, y)$. Thus, $|\phi| \geq |\prec|$. $\dashv$

2.14 Remark. The second proof given above has the advantage that it works in ZF provided $\mathbf{\Gamma}$ has a universal set.

The next lemma, due to Martin, is also frequently useful. It has the same hypotheses as the previous lemma.

2.15 Lemma (AD+DC). *Let $\mathbf{\Gamma}$ be non-selfdual and closed under $\forall^{\omega^\omega}$, $\wedge$, $\vee$, and assume* pwo$(\mathbf{\Gamma})$. *Then $\mathbf{\Delta} = \mathbf{\Gamma} \cap \check{\mathbf{\Gamma}}$ is closed under $<\!\delta(\mathbf{\Gamma})$ length unions and intersections.*

Proof. It is enough to show $\mathbf{\Delta}$ is closed under $<\!\delta(\mathbf{\Gamma})$ unions. Suppose not, and let $\rho < \delta(\mathbf{\Gamma})$ be least such that $\mathbf{\Delta}$ is not closed under ρ-unions. Let $\{A_\alpha\}_{\alpha<\rho}$ be a sequence of $\mathbf{\Delta}$ sets with $A \doteq \bigcup_{\alpha<\rho} A_\alpha$ not in $\mathbf{\Delta}$. By minimality of ρ we may assume that the A_α form an increasing sequence. From the Coding Lemma and the fact that there is a $\mathbf{\Delta}$ prewellordering $\prec$ of length ρ it follows that $A \in \check{\mathbf{\Gamma}}$. [Apply the Coding Lemma to $R \subseteq \mathrm{dom}(\prec) \times \omega^\omega$ given by $R(x, y) \longleftrightarrow (U_y = A_{|x|_\prec})$, where $U \subseteq \omega^\omega \times \omega^\omega$ is universal for $\check{\mathbf{\Gamma}}$. Let $S \in \check{\mathbf{\Gamma}}$ be the set produced by the Coding Lemma. Then $z \in A \longleftrightarrow \exists x\ \exists y\ (S(x, y) \wedge U(y, z))$.] So, A is $\check{\mathbf{\Gamma}}$-complete. Let ϕ be the norm on A corresponding to the union $A = \bigcup_{\alpha<\rho} A_\alpha$, that is, $\phi(x) =$ the least α such that $x \in A_\alpha$. Then ϕ

is a $\check{\boldsymbol{\Gamma}}$-norm on A. For example $x <^*_\phi y \longleftrightarrow \exists \alpha < \rho\ (x \in A_\alpha \wedge y \notin A_\alpha)$, which writes $<^*_\phi$ as a ρ-union of $\boldsymbol{\Delta}$ sets and thus shows $<^*_\phi \in \check{\boldsymbol{\Gamma}}$. This shows $\mathrm{pwo}(\check{\boldsymbol{\Gamma}})$. This, however, contradicts the ZF fact that for $\boldsymbol{\Gamma}$ having a universal set, $\boldsymbol{\Gamma}$ and $\check{\boldsymbol{\Gamma}}$ cannot both have the prewellordering property. [We mention results along this line in Sect. 2.3, however we can also directly argue this last fact as follows. Let $U \subseteq \omega^\omega \times \omega^\omega$ be a universal $\boldsymbol{\Gamma}$ set, and ϕ a $\boldsymbol{\Gamma}$ norm on A. Define $B(x,y) \longleftrightarrow (x_0,y) <^*_\phi (x_1,y)$, and $C(x,y) \longleftrightarrow (x_1,y) <^*_\phi (x_0,y)$, so $B, C \in \boldsymbol{\Gamma}$, and $B \cap C = \emptyset$ (here $x \mapsto (x_0,x_1)$ is our recursive bijection between ω^ω and $\omega^\omega \times \omega^\omega$). Assume toward a contradiction that $\mathrm{pwo}(\check{\boldsymbol{\Gamma}})$ also holds. Let ψ_1, ψ_2 be comparable $\check{\boldsymbol{\Gamma}}$-norms on B^c, C^c (see the discussion after Definition 2.2). Define $E(x,z) \longleftrightarrow (x,z) <^*_{\psi_1,\psi_2} (x,z)$. Note also $E(x,z) \longleftrightarrow \neg(x,z) \leq^*_{\psi_2,\psi_1} (x,z)$, since $B^c \cup C^c = \omega^\omega \times \omega^\omega$. So $E \in \boldsymbol{\Delta}$. However, E is also universal for $\boldsymbol{\Delta}$. For if $D \subseteq \omega^\omega$ is $\boldsymbol{\Delta}$, let x be such that $D^c = U_{x_0}$, $D = U_{x_1}$, and hence $D^c = B_x$, $D = C_x$. Then $E_x = D$. Being selfdual, however, the pointclass $\boldsymbol{\Delta}$ cannot have a universal set by the usual diagonal argument (the set $S(x) \longleftrightarrow \neg E(x,x)$ cannot be in $\boldsymbol{\Delta}$).] $\dashv$

We mention one more result of a general nature.

2.16 Lemma. *Let $\boldsymbol{\Gamma}$ be non-selfdual and closed under $\exists^{\omega^\omega}$, $\wedge$. Then the supremum of the lengths of the $\boldsymbol{\Gamma}$ well-founded relations is a regular cardinal.*

Proof. Let κ be the supremum of the lengths of the $\boldsymbol{\Gamma}$ well-founded relations. Clearly κ is a limit ordinal. Suppose $\rho \doteq \mathrm{cf}(\kappa) < \kappa$, and let $f : \rho \to \kappa$ be cofinal. Let $\prec$ be a $\boldsymbol{\Gamma}$ well-founded relation of length ρ. Let $U \subseteq \omega^\omega \times \omega^\omega$ be universal for $\boldsymbol{\Gamma}$. Apply the Coding Lemma to $R \subseteq \mathrm{dom}(\prec) \times \omega^\omega$ given by $R(x,y) \longleftrightarrow (x \in \mathrm{dom}(\prec) \wedge U_y$ is well-founded of length $\geq f(|x|_\prec))$. Let $A \subseteq \mathrm{dom}(\prec) \times \omega^\omega$ be as in the Coding Lemma, so $A \in \boldsymbol{\Gamma}$. Define then $(x,y,z) \ll (x',y',z') \longleftrightarrow ((x,y) \in A \wedge (x,y) = (x',y') \wedge U_y(z,z'))$. Then $\ll$ is a $\boldsymbol{\Gamma}$ well-founded relation of length κ, a contradiction. $\dashv$

Recall from the introduction the definitions of the projective pointclasses $\boldsymbol{\Sigma}^1_n$, $\boldsymbol{\Pi}^1_n$, $\boldsymbol{\Delta}^1_n$. Also, assuming Projective Determinacy, $\boldsymbol{\Pi}^1_{2n+1}$ and $\boldsymbol{\Sigma}^1_{2n+2}$ have the scale property for all n. We now define the projective ordinals and establish their basic properties.

2.17 Definition. $\boldsymbol{\delta}^1_n$ = the supremum of the lengths of the $\boldsymbol{\Delta}^1_n$ prewellorderings of the reals.

2.18 Theorem (AD + DC). *For all n, $\boldsymbol{\delta}^1_n$ is the supremum of the lengths of the $\boldsymbol{\Sigma}^1_n$ well-founded relations. Each $\boldsymbol{\delta}^1_n$ is a regular cardinal, $\boldsymbol{\delta}^1_{2n+2} = (\boldsymbol{\delta}^1_{2n+1})^+$, and $\boldsymbol{\delta}^1_{2n+1} = \lambda^+_{2n+1}$ for some Suslin cardinal λ_{2n+1} of cofinality ω. $\boldsymbol{\Sigma}^1_{2n+2} = \boldsymbol{\delta}^1_{2n+1}$-Suslin and $\boldsymbol{\Sigma}^1_{2n+1} = \lambda_{2n+1}$-Suslin. The Suslin cardinals within the projective ordinals are exactly the λ_{2n+1} and the $\boldsymbol{\delta}^1_{2n+1}$.*

Proof. If $\phi : A \to \delta$ is a regular $\boldsymbol{\Pi}^1_{2n+1}$ norm on a $\boldsymbol{\Pi}^1_{2n+1}$ set A, then by definition $\delta \leq \boldsymbol{\delta}^1_{2n+1}$ (as all initial segments of the prewellordering are in

$\boldsymbol{\Delta}^1_{2n+1}$). Thus, from the scale property for $\boldsymbol{\Pi}^1_{2n+1}$, every $\boldsymbol{\Pi}^1_{2n+1}$, and hence also every $\boldsymbol{\Sigma}^1_{2n+2}$, set is $\boldsymbol{\delta}^1_{2n+1}$-Suslin. From the Coding Lemma it also follows that every $\boldsymbol{\delta}^1_{2n+1}$-Suslin set is $\boldsymbol{\Sigma}^1_{2n+2}$, so $S(\boldsymbol{\delta}^1_{2n+1}) = \boldsymbol{\Sigma}^1_{2n+2}$. If A is universal for $\boldsymbol{\Pi}^1_{2n+1}$, then from Lemma 2.13, $\delta = \boldsymbol{\delta}^1_{2n+1}$ and every $\boldsymbol{\Sigma}^1_{2n+1}$ well-founded relation has length less than δ (this also follows from the Kunen-Martin Theorem mentioned below, but the argument above does not need scales). So, $\boldsymbol{\delta}^1_{2n+1}$ is the supremum of the lengths of the $\boldsymbol{\Sigma}^1_{2n+1}$ well-founded relations. From Lemma 2.16, $\boldsymbol{\delta}^1_{2n+1}$ is regular.

From the Kunen-Martin Theorem 2.6, $\boldsymbol{\delta}^1_{2n+2} \leq$ the supremum of the lengths of the $\boldsymbol{\Sigma}^1_{2n+2}$ well-founded relations $\leq (\boldsymbol{\delta}^1_{2n+1})^+$. Conversely, let $\prec$ be a wellordering of $\boldsymbol{\delta}^1_{2n+1}$. The Coding Lemma implies that $\prec$ is $\boldsymbol{\Delta}^1_{2n+2}$ in the codes relative to a norm ϕ on a $\boldsymbol{\Pi}^1_{2n+1}$ universal set A, that is, the relation $(x, y \in A \wedge \phi(x) \prec \phi(y))$ is $\boldsymbol{\Delta}^1_{2n+2}$. Thus, $\boldsymbol{\delta}^1_{2n+2} = (\boldsymbol{\delta}^1_{2n+1})^+$, and $\boldsymbol{\delta}^1_{2n+2} =$ the supremum of the $\boldsymbol{\Sigma}^1_{2n+2}$ well-founded relations. From Lemma 2.16, $\boldsymbol{\delta}^1_{2n+2}$ is also regular.

Note that $\boldsymbol{\delta}^1_n < \boldsymbol{\delta}^1_{n+1}$ as the $\boldsymbol{\Sigma}^1_n$ well-founded relations can be "put together" into a single $\boldsymbol{\Sigma}^1_n \wedge \boldsymbol{\Pi}^1_n$ well-founded relation via a universal $\boldsymbol{\Sigma}^1_n$ set.

Suppose A is a universal $\boldsymbol{\Sigma}^1_{2n+1}$ set, and write $A(x) \longleftrightarrow \exists y\, B(x, y)$ where $B \in \boldsymbol{\Pi}^1_{2n}$. Clearly if B is κ-Suslin, then so is A. Now B admits a $\boldsymbol{\Delta}^1_{2n+1}$ scale (using scale($\boldsymbol{\Pi}^1_{2n+1}$)), and thus A is λ-Suslin for some $\lambda < \boldsymbol{\delta}^1_{2n+1}$. Let λ_{2n+1} be the least such λ. It follows that every $\boldsymbol{\Sigma}^1_{2n+1}$ set is λ_{2n+1}-Suslin. From the Kunen-Martin Theorem and the definition of $\boldsymbol{\delta}^1_{2n+1}$, it follows that $\boldsymbol{\delta}^1_{2n+1} = \lambda^+_{2n+1}$. We claim that $\mathrm{cf}(\lambda_{2n+1}) = \omega$. For if not, then A could be written as a λ_{2n+1} union of sets A_α, each of which is $<\lambda_{2n+1}$-Suslin. Each A_α must be $\boldsymbol{\Sigma}^1_{2n}$, as otherwise by Wadge, some $\boldsymbol{\Pi}^1_{2n}$-complete set, and hence every $\boldsymbol{\Sigma}^1_{2n+1}$ set, would be $<\lambda_{2n+1}$-Suslin. By Lemma 2.15, $A \in \boldsymbol{\Delta}^1_{2n+1}$, a contradiction. So, $\mathrm{cf}(\lambda_{2n+1}) = \omega$. We noted above $\boldsymbol{\Sigma}^1_{2n+1} \subseteq S(\lambda_{2n+1})$. The reverse inclusion follows from the Coding Lemma. Thus, $S(\lambda_{2n+1}) = \boldsymbol{\Sigma}^1_{2n+1}$.

For any κ the pointclass of κ-Suslin sets is closed under $\exists^{\omega^\omega}$ (as well as $\wedge, \vee$). From Wadge's Lemma, the only pointclasses within the projective hierarchy that are closed under $\exists^{\omega^\omega}$ (and contain the closed sets) are the $\boldsymbol{\Sigma}^1_n$, and thus we have determined all the Suslin classes and cardinals within the projective hierarchy. ⊣

It follows also from our discussion above that $\boldsymbol{\delta}^1_1 = \omega_1$ and $\boldsymbol{\delta}^1_2 = \omega_2$. Martin and Solovay also computed $\boldsymbol{\delta}^1_3 = \omega_{\omega+1}$, and $\boldsymbol{\delta}^1_4 = \omega_{\omega+2}$ (see also the next section). In Sect. 2.6 we will show (assuming AD) that each $\boldsymbol{\delta}^1_n$ is measurable, and in fact has the countable exponent partition property $\boldsymbol{\delta}^1_n \to (\boldsymbol{\delta}^1_n)^\lambda$ for all $\lambda < \omega_1$ (defined in Sect. 2.6).

2.3. Wadge Degrees and Abstract Pointclasses

We now recall some of the abstract theory of pointclasses. Additional background may be found in [35, 36], and [39]. We assume AD + DC throughout this section, though the determinacy required is "local", e.g., only Projective Determinacy is required within the projective sets, etc.

If $\mathbf{\Gamma}$ is a pointclass and κ a cardinal, let $\bigcup_\kappa \mathbf{\Gamma}$ denote those $A \subseteq \omega^\omega$ which can be written as $A = \bigcup_{\alpha<\kappa} A_a$ where each $A_\alpha \in \mathbf{\Gamma}$. We similarly define $\bigcap_\kappa \mathbf{\Gamma}$.

We note the simple observation that if $\mathbf{\Gamma}$ is a non-selfdual pointclass, then the closure of $\mathbf{\Gamma}$ under $\exists^\omega$ implies the closure of $\mathbf{\Gamma}$ under countable unions, and likewise the closure under $\forall^\omega$ implies the closure under countable intersections. For suppose $A \in \mathbf{\Gamma} - \check{\mathbf{\Gamma}}$, and $A_n \in \mathbf{\Gamma}$ for $n \in \omega$. Thus, $A_n \leq_w A$ for all n, and it follows easily that $B \leq_w A$ as well, where $B(x) \longleftrightarrow \bar{x} \in A_{x(0)}$ and $\bar{x}(i) = x(i+1)$. Then $x \in \bigcup_n A_n \longleftrightarrow \exists i\ B(i^\frown x)$. Another simple but useful observation is that if $\mathbf{\Gamma}$ is non-selfdual and closed under countable intersections (respectively unions), then $\exists^{\omega^\omega}\mathbf{\Gamma}$ (respectively $\forall^{\omega^\omega}\mathbf{\Gamma}$) is closed under countable unions and intersections. As we already noted, $\exists^{\omega^\omega}\mathbf{\Gamma}$ is closed under countable unions (since $\mathbf{\Gamma}$ has a universal set, so does $\exists^{\omega^\omega}\mathbf{\Gamma}$, and hence it also is non-selfdual). To check countable intersections, let $A_n \in \exists^{\omega^\omega}\mathbf{\Gamma}$, say $A_n(x) \longleftrightarrow \exists y\ B_n(x,y)$ with $B_n \in \mathbf{\Gamma}$. Then $x \in \bigcap_n A_n \longleftrightarrow \exists y\ B(x,y)$, where $B = \bigcap_n B_n$ and $B_n(x,y) \longleftrightarrow A_n(x,(y)_n)$. Thus, $\bigcap_n A_n \in \exists^{\omega^\omega}\mathbf{\Gamma}$.

Recall the definitions of Lipschitz reduction $\leq_l$ and Wadge reduction $\leq_w$ from the introduction. We say a set $A \subseteq \omega^\omega$ is *selfdual* if $A \leq_l A^c$. A theorem of Steel [39] says that $A \leq_l A^c$ iff $A \leq_w A^c$. Thus, A is selfdual iff the pointclass generated by A, namely $\mathbf{\Gamma}_A = \{B : B \leq_w A\}$, is selfdual (i.e., closed under complements).

Consider now pairs of the form (A, A^c) (if A is selfdual, we may equivalently take just A in what follows). We extend $\leq_l$ to such pairs by setting $(A, A^c) \leq_l (B, B^c)$ iff one of A, A^c is $\leq_l$ to one of B, B^c. This is easily seen to be transitive, reflexive, and by Wadge's Lemma, connected. A Lipschitz degree, or l-degree, denotes an equivalence class of a pair under the relation $(A, A^c) \equiv_l (B, B^c)$ iff $(A, A^c) \leq_l (B, B^c)$ and $(B, B^c) \leq_l (A, A^c)$. An important basic result of Martin (cf. [39]) asserts that the strict part of $\leq_l$ is well-founded.

The Wadge degrees, or w-degrees, are defined analogously, using $\leq_w$ in place of $\leq_l$. Of course, a Wadge degree is an amalgamation of l-degrees, and it is immediate that the Wadge degrees are also wellordered. From the result of Steel mentioned above, it follows that only selfdual l-degrees are amalgamated in forming a w-degree. It is shown in [39] that for α a limit ordinal of cofinality ω, an l-degree of rank α must be selfdual, and for $\mathrm{cf}(\alpha) > \omega$ the pair is non-selfdual. Furthermore, following any non-selfdual l-degree (A, A^c), the next ω_1 l-degrees are all selfdual and of the same w-degree (that of the join of A and A^c, that is, $\{n^\frown x : (n \text{ is even } \wedge x \in A) \vee (n \text{ is odd } \wedge x \notin A)\}$). This gives a general picture of the w-degrees: the selfdual and non-selfdual w degrees alternate, and at limit ordinals α, a pair of Wadge degree α is selfdual iff $\mathrm{cf}(\alpha) = \omega$. For $A \subseteq \omega^\omega$, we let $o(A)$ denote the rank of (A, A^c) in $\leq_w$.

In [36, 35] some additional structural results for general pointclasses were obtained. Recall $\mathbf{\Gamma}$ has the reduction property, $\mathrm{red}(\mathbf{\Gamma})$, if for all $A, B \in \mathbf{\Gamma}$

$\exists A', B' \in \mathbf{\Gamma}$ such that $A' \subseteq A$, $B' \subseteq B$, $A' \cap B' = \emptyset$ and $A' \cup B' = A \cup B$. $\mathbf{\Gamma}$ has the separation property, $\mathrm{sep}(\mathbf{\Gamma})$, if for all $A, B \in \mathbf{\Gamma}$ with $A \cap B = \emptyset$, $\exists C \in \mathbf{\Delta}$ $(A \subseteq C \subseteq B^c)$. A standard result in descriptive theory (see [31]) is that $\mathrm{pwo}(\mathbf{\Gamma}) \rightarrow \mathrm{red}(\mathbf{\Gamma})$ for $\mathbf{\Gamma}$ closed under $\wedge$, $\vee$, and $\mathrm{red}(\mathbf{\Gamma}) \rightarrow \mathrm{sep}(\check{\mathbf{\Gamma}})$. Reference [36] shows that for any non-selfdual pointclass $\mathbf{\Gamma}$, either $\mathrm{sep}(\mathbf{\Gamma})$ or $\mathrm{sep}(\check{\mathbf{\Gamma}})$, and from [39], both sides cannot have the separation property. Also, if $\mathbf{\Gamma}$ is closed under $\wedge, \vee$ then $\mathrm{red}(\mathbf{\Gamma})$ or $\mathrm{red}(\check{\mathbf{\Gamma}})$. More generally, Steel [35] shows that if $\mathbf{\Gamma}$ is closed under $\wedge$ and $\neg\,\mathrm{sep}(\mathbf{\Gamma})$, then $\mathrm{red}(\mathbf{\Gamma})$. Finally, [35] shows that if $\mathbf{\Gamma}$ is a *Levy* class, that is closed under $\exists^{\omega^\omega}$ or $\forall^{\omega^\omega}$, and if we make the technical assumption that $\mathbf{\Delta} = \mathbf{\Gamma} \cap \check{\mathbf{\Gamma}}$ is not closed under wellordered unions (this is true in $L(\mathbb{R})$, for example, for all selfdual $\mathbf{\Delta} \neq \mathcal{P}(\omega^\omega)$) then either $\mathrm{pwo}(\mathbf{\Gamma})$ or $\mathrm{pwo}(\check{\mathbf{\Gamma}})$. It is also shown there that if $\mathbf{\Delta}$ is closed under real quantifiers, and $\mathrm{sep}(\mathbf{\Gamma})$, then $\mathbf{\Gamma}$ is closed under $\exists^{\omega^\omega}$ (and thus $\check{\mathbf{\Gamma}}$ is closed under $\forall^{\omega^\omega}$).

2.19 Definition. Let $\mathbf{\Gamma}$ be a (possibly selfdual) pointclass. We let $o(\mathbf{\Gamma}) = \sup\{o(A) : A \in \mathbf{\Gamma}\}$. We let $\delta(\mathbf{\Gamma})$ = the supremum of the lengths of the $\mathbf{\Delta}$ prewellorderings of ω^ω (where $\mathbf{\Delta} = \mathbf{\Gamma} \cap \check{\mathbf{\Gamma}}$).

In [21] it is shown that for $\mathbf{\Delta}$ closed under real quantification, $\wedge$ and $\vee$, $o(\mathbf{\Delta}) = \delta(\mathbf{\Delta})$ = the supremum of the $\mathbf{\Delta}$ well-founded relations on ω^ω. We note that for $\mathbf{\Delta}$ closed under real quantification, closure under $\wedge$ and $\vee$ is almost automatic; it is needed only to rule out the case of a largest Wadge degree in $\mathbf{\Delta}$, which occurs only when $\mathbf{\Delta} = \mathbf{\Gamma} \cap \check{\mathbf{\Gamma}}$ for some non-selfdual $\mathbf{\Gamma}$ closed under real quantification (by the hierarchy analysis below).

If $\mathbf{\Delta}$ is selfdual and closed under real quantifiers, $o(\mathbf{\Delta})$ has uncountable cofinality, and we again make the technical assumption that $\mathbf{\Delta}$ is not closed under wellordered unions, then Steel [35] shows there is a non-selfdual pointclass $\mathbf{\Gamma}$ closed under $\forall^{\omega^\omega}$ with $\mathrm{pwo}(\mathbf{\Gamma})$ such that $\mathbf{\Delta} = \mathbf{\Gamma} \cap \check{\mathbf{\Gamma}}$. Steel establishes this by getting a useful representation for the $\mathbf{\Gamma}$ sets. Namely, if δ is the least ordinal such that $\mathbf{\Delta}$ is not closed under δ unions, then $\mathbf{\Gamma}$ is the collection of $\mathbf{\Sigma}^1_1$-bounded δ unions of $\mathbf{\Delta}$ sets. A union $A = \bigcup_{\alpha<\delta} A_\alpha$ is $\mathbf{\Sigma}^1_1$-*bounded* if for every $\mathbf{\Sigma}^1_1$ set $B \subseteq A$, $\exists \delta' < \delta$ $(B \subseteq \bigcup_{\alpha<\delta'} A_\alpha)$.

Steel shows in [35] (generalizing results of [21]) that these results suffice to place the prewellordering property within the Levy classes, as well as to classify the Levy classes within projective-like hierarchies. We summarize the conclusions. Suppose $\mathbf{\Gamma}$ is non-selfdual and closed under $\exists^{\omega^\omega}$ or $\forall^{\omega^\omega}$. Let α be the supremum of the limit ordinals β such that $\mathbf{\Delta}_\beta \doteq \{A : o(A) < \beta\}$ is closed under real quantifiers and $\mathbf{\Delta}_\beta \subseteq \mathbf{\Gamma}$. We have the following cases:

Type I Hierarchy $\mathrm{cf}(\alpha) = \omega$. The pointclass $\mathbf{\Lambda}$ of Wadge degree α is selfdual, consisting of ω-joins of sets of smaller degree. Let $\mathbf{\Gamma}_0$ be the class of countable unions of sets, each of degree $< \alpha$. Then $\mathbf{\Gamma}_0$ is the smallest class closed under $\exists^\omega$ containing $\mathbf{\Lambda}$, and we have $\mathrm{pwo}(\mathbf{\Gamma}_0)$. If we let $\mathbf{\Gamma}_1 = \forall^{\omega^\omega}\mathbf{\Gamma}_0$, $\mathbf{\Gamma}_2 = \exists^{\omega^\omega}\mathbf{\Gamma}_1$, etc., then $\mathrm{pwo}(\mathbf{\Gamma}_n)$ for all n by first periodicity. $\mathbf{\Gamma}_0$ is closed under countable unions and finite intersections, and $\mathbf{\Gamma}_n$ for $n \geq 1$ is closed under countable unions and intersections. Also, $\mathbf{\Gamma} = \mathbf{\Gamma}_i$ or $\check{\mathbf{\Gamma}}_i$ for some i.

Type II, III Hierarchies $\mathrm{cf}(\alpha) > \omega$, so there is a non-selfdual pointclass $\mathbf{\Gamma}_0$ of degree α closed under $\forall^{\omega^\omega}$ and with $\mathrm{pwo}(\mathbf{\Gamma}_0)$. We assume in these cases that $\mathbf{\Gamma}_0$ is not closed under $\exists^{\omega^\omega}$. If we let $\mathbf{\Gamma}_1 = \exists^{\omega^\omega}\mathbf{\Gamma}_0$, $\mathbf{\Gamma}_2 = \forall^{\omega^\omega}\mathbf{\Gamma}_1$, etc., then $\mathrm{pwo}(\mathbf{\Gamma}_n)$ for all n. For $n \geq 1$, $\mathbf{\Gamma}_n$ is closed under countable unions and intersections. If $\mathbf{\Gamma}_0$ is as well (by [35, Theorem 2.2] this is equivalent to $\mathbf{\Gamma}_0$ being closed under finite unions), this is referred to as a type III hierarchy, otherwise a type II hierarchy. Clearly, $\mathbf{\Gamma} = \mathbf{\Gamma}_i$ or $= \check{\mathbf{\Gamma}}_i$ for some i.

Type IV Hierarchy $\mathrm{cf}(\alpha) > \omega$, and for $\mathbf{\Gamma}_0$ as in the previous case, $\mathbf{\Gamma}_0$ is closed under real quantifiers. Let $\mathbf{\Gamma}_1 = \{A \cap B : A \in \mathbf{\Gamma}_0 \wedge B \in \check{\mathbf{\Gamma}}_0\}$. Let $\mathbf{\Gamma}_2 = \exists^{\omega^\omega}\mathbf{\Gamma}_1$, $\mathbf{\Gamma}_3 = \forall^{\omega^\omega}\mathbf{\Gamma}_2$, etc. Then $\mathrm{pwo}(\mathbf{\Gamma}_n)$ for all n, and for $n \geq 2$ (or $n = 0$) $\mathbf{\Gamma}_n$ is closed under countable unions and intersections. Clearly, $\mathbf{\Gamma} = \mathbf{\Gamma}_i$ or $= \check{\mathbf{\Gamma}}_i$ for some i.

2.20 Remark. We refer to the pointclasses $\mathbf{\Gamma}_0$ as in the type II, III hierarchies above as *Steel pointclasses*.

We present one more result in the abstract theory of pointclasses which we will need later, and which illustrates the usefulness of the hierarchy classification.

2.21 Lemma. *If $\mathbf{\Gamma}$ is a non-selfdual pointclass closed under $\exists^{\omega^\omega}$ and $\mathrm{pwo}(\mathbf{\Gamma})$, then $\mathbf{\Gamma}$ is closed under wellordered unions.*

Proof. If $\mathbf{\Gamma}$ is closed under $\forall^{\omega^\omega}$ as well, this is [14, Theorem 1.1], so assume $\forall^{\omega^\omega}\mathbf{\Gamma} \neq \mathbf{\Gamma}$. If $\mathbf{\Gamma}$ is closed under countable unions and intersections, the result follows from [21, Lemma 2.4.1]. Suppose now that $\mathbf{\Gamma}$ is not closed under countable intersections. The hierarchy analysis above shows that $\mathbf{\Gamma}$ is the base of a type I hierarchy, that is, $\mathbf{\Gamma} = \bigcup_\omega \mathbf{\Delta}$, and $\mathbf{\Delta}$ is closed under real quantifiers. Note that $\mathbf{\Gamma}$ is closed under $\wedge$. Towards a contradiction, let κ be the least cardinal so that $\bigcup_\kappa \mathbf{\Gamma} \nsubseteq \mathbf{\Gamma}$. Thus, κ is regular. Let $\mathbf{\Gamma}_1 = \exists^{\omega^\omega}\check{\mathbf{\Gamma}}$. By Wadge's Lemma, $\check{\mathbf{\Gamma}} \subseteq \bigcup_\kappa \mathbf{\Gamma}$, and thus $\mathbf{\Gamma}_1 \subseteq \bigcup_\kappa \mathbf{\Gamma}$. Using the regularity of κ, let $\langle A_\alpha \mid \alpha < \kappa\rangle$ be a strictly increasing κ sequence of sets in $\mathbf{\Gamma}$ whose union A is in $\check{\mathbf{\Gamma}} - \mathbf{\Gamma}$. Let $B = \{x : S_x \subseteq A\}$, where $S \subseteq (\omega^\omega)^2$ is universal $\mathbf{\Sigma}^1_1$. $B \in \check{\mathbf{\Gamma}}$ as $\check{\mathbf{\Gamma}}$ is closed under $\forall^{\omega^\omega}$ and $\vee$. Let $B = \bigcup_{\alpha<\kappa} B_\alpha$, where $B_\alpha \in \mathbf{\Gamma}$. If we replace A_α by $\{y : \exists x \in B_\alpha\ (y \in S_x)\}$, then the A_α form a $\mathbf{\Sigma}^1_1$-bounded sequence of $\mathbf{\Gamma}$ sets with union A. Let $U \subseteq (\omega^\omega)^2$ be a universal $\mathbf{\Gamma}$ set. Play the game where I plays x, II plays y, z, and II wins iff $x \in A \to \exists \alpha > |x|\ (U_y = A_\alpha \wedge z \in A_\alpha - \bigcup_{\beta<\alpha} A_\beta)$, where $|x|$ is the least $\alpha < \kappa$ such that $x \in A_\alpha$. By $\mathbf{\Sigma}^1_1$-boundedness, II wins, say by τ. Define $x \prec y$ iff $x, y \in A \wedge \tau(y)_1 \notin U_{\tau(x)_0}$. Thus, $\prec$ is a $\check{\mathbf{\Gamma}}$ prewellordering of length κ. By the Coding Lemma, then, $\bigcup_\kappa \mathbf{\Gamma} \subseteq \mathbf{\Gamma}_1$, and hence $\bigcup_\kappa \mathbf{\Gamma} = \mathbf{\Gamma}_1$. Now, $\mathbf{\Delta}_1 = \mathbf{\Gamma}_1 \cap \check{\mathbf{\Gamma}}_1$ is clearly also not closed under κ unions, and any κ union of sets in $\mathbf{\Delta}_1$ is in $\mathbf{\Gamma}_1$. Thus, $\mathbf{\Gamma}_1 = \bigcup_{\kappa'} \mathbf{\Delta}_1$, where $\kappa' \leq \kappa$ is least such that $\mathbf{\Delta}_1$ is not closed under κ' unions. This, however, shows $\mathrm{pwo}(\mathbf{\Gamma}_1)$, a contradiction (this last part is Martin's argument from Theorem 2.15 again). ⊣

In the case of a type II, III, or IV hierarchy, the following observations are occasionally useful.

2.22 Lemma. *Let $\mathbf{\Gamma}$ be non-selfdual, closed under $\forall^{\omega^\omega}$, with $\mathrm{pwo}(\mathbf{\Gamma})$, and assume $\mathbf{\Delta}$ is closed under real quantification. Let $\kappa = o(\mathbf{\Delta})$. Then $\mathrm{cf}(\kappa)$ is the least ordinal ρ such that $\mathbf{\Delta}$ is not closed under ρ-length unions. Furthermore, there is a κ strictly increasing sequence of sets in $\mathbf{\Delta}$.*

Proof. From $\mathrm{pwo}(\mathbf{\Gamma})$ we have that $\mathbf{\Delta}$ is not closed under $\delta(\mathbf{\Delta}) = \delta(\mathbf{\Delta}) = \kappa$ length unions. Let ρ be least so that $\mathbf{\Delta}$ is not closed under ρ-length unions. Clearly $\rho \leq \kappa$ is a regular cardinal. Suppose $\rho > \mathrm{cf}(\kappa)$. Let $\{A_\alpha\}_{\alpha<\rho}$ be an increasing sequence of $\mathbf{\Delta}$ sets whose union A is not in $\mathbf{\Delta}$. Since $\rho > \mathrm{cf}(\kappa)$ is regular, there is a $\beta < \kappa$ such that for cofinally in ρ many α we have $o(A_\alpha) \leq \beta$. By Lemma 2.21 we may find a non-selfdual $\mathbf{\Gamma}_0 \subseteq \mathbf{\Delta}$ which is closed under wellordered unions and with $o(\mathbf{\Gamma}_0) > \beta$. Then $A \in \mathbf{\Gamma}_0$, a contradiction. Suppose $\rho < \mathrm{cf}(\kappa)$ and again consider a sequence $\{A_\alpha\}_{\alpha<\rho}$ as above. Since $\rho < \mathrm{cf}(\kappa)$, there is a $\beta < \kappa$ such that for all $\alpha < \rho$, $o(A_\alpha) \leq \beta$, and we reach the same contradiction as before. So, $\rho = \mathrm{cf}(\kappa)$.

Fix now a sequence $\{A_\alpha\}_{\alpha<\mathrm{cf}(\kappa)}$ of sets in $\mathbf{\Delta}$ whose union A is not in $\mathbf{\Delta}$. Let $h(\alpha) = o(A_\alpha)$, so h is cofinal in κ. Without loss of generality we may assume that h is strictly increasing. Furthermore, we may assume that there is a prewellordering of length $h(\alpha)$ of Wadge degree less than $A_{\alpha+1}$. Let $\preceq$ be a $\mathbf{\Delta}$ prewellordering of length $\mathrm{cf}(\kappa)$ (we may assume $\mathrm{cf}(\kappa) < \kappa$ as otherwise there is nothing to show in the second claim). View every real y as coding a Lipschitz continuous function $f_y : \omega^\omega \to \omega^\omega$. By the Coding Lemma there is a $\mathbf{\Delta}$ relation $R \subseteq (\omega^\omega)^2$ with $\mathrm{dom}(R) = \mathrm{dom}(\preceq)$ and such that for all $(x, y) \in R$, $f_y^{-1}(A_{|x|+1})$ is a prewellordering of length $h(|x|)$, where $|x|$ denotes the rank of x in $\preceq$. For $\beta < \kappa$ define E_β by:

$$\begin{aligned}(x, y, z) \in E_\beta \longleftrightarrow{} & x \in \mathrm{dom}(\preceq) \wedge (\forall \gamma < |x|\ h(\gamma) \leq \beta) \\ & \wedge R(x, y) \wedge |z|_{f_y^{-1}(A_{|x|+1})} \leq \beta.\end{aligned}$$

Clearly the E_β form a κ-length strictly increasing sequence. To see that $E_\beta \in \mathbf{\Delta}$, let $\alpha_0 < \mathrm{cf}(\kappa)$ be least such that $h(\alpha_0) > \beta$. Then $E_\beta = \bigcup_{\alpha \leq \alpha_0} E_{\alpha,\beta}$ where:

$$(x, y, z) \in E_{\alpha,\beta} \longleftrightarrow x \in \mathrm{dom}(\preceq) \wedge (|x| = \alpha) \wedge R(x, y) \wedge |z|_{f_y^{-1}(A_{\alpha+1})} \leq \beta.$$

Since $\mathbf{\Delta}$ is closed under $<\mathrm{cf}(\kappa)$ unions, it is enough to show each $E_{\alpha,\beta} \in \mathbf{\Delta}$. The first three conjuncts are clearly in $\mathbf{\Delta}$. For the last, note that $P_y \doteq f_y^{-1}(A_{\alpha+1})$ is a $\mathbf{\Delta}$ prewellordering computed uniformly from y, that is, $(u, v) \in P_y \longleftrightarrow f_y(\langle u, v\rangle) \in A_{\alpha+1}$. From the Coding Lemma it is straightforward to compute that $\{(y, z) : |z|_{P_y} \leq \beta\}$ is projective in any pointclass of Wadge degree at least $o(A_{\alpha+1})$. ⊣

2.4. The Scale Theory of $L(\mathbb{R})$

The pointclass results of Sect. 2.3 can be considered to be a generalization of the "Spector" theory of the projective sets, that is, the theory which uses only the prewellordering property for the $\boldsymbol{\Pi}^1_{2n+1}$, $\boldsymbol{\Sigma}^1_{2n+2}$ sets. There is likewise a generalization of the scale theory of the projective sets to the sets of reals in $L(\mathbb{R})$. This theory is developed in [37]. We survey without proof the main results of this theory. We assume AD + $V = L(\mathbb{R})$. Recall that Θ is the supremum of the lengths of the prewellorderings of the reals.

Recall that the $J_\alpha(\mathbb{R})$ hierarchy building up $L(\mathbb{R})$ is defined similarly to the J_α hierarchy for L, except that we start with $J_1(\mathbb{R}) = V_{\omega+1}$. Thus, for limit α, $J_\alpha(\mathbb{R}) = \bigcup_{\alpha'<\alpha} J_{\alpha'}(\mathbb{R})$, and $J_{\alpha+1}(\mathbb{R})$ is the closure of $J_\alpha(\mathbb{R}) \cup \{J_\alpha(\mathbb{R})\}$ under suitable rudimentary functions. $\boldsymbol{\Sigma}_n(J_\alpha(\mathbb{R}))$ denotes the subsets of $J_\alpha(\mathbb{R})$ which are $\boldsymbol{\Sigma}_n$-definable over $J_\alpha(\mathbb{R})$ using parameters from $J_\alpha(\mathbb{R})$. We also let $\boldsymbol{\Sigma}_n(J_\alpha(\mathbb{R}))$ denote the pointclass $\boldsymbol{\Sigma}_n(J_\alpha(\mathbb{R})) \cap \mathcal{P}(\mathbb{R})$. Note that $\boldsymbol{\Sigma}^1_n = \boldsymbol{\Sigma}_n(J_1(\mathbb{R}))$, so the $\boldsymbol{\Sigma}_n(J_\alpha(\mathbb{R}))$ hierarchy provides an extension of the projective hierarchy to all the pointclasses in $L(\mathbb{R})$. Recall that for $X = \omega^\omega$ or $X = \mathcal{P}(\omega^\omega)$, a relation $R \subseteq X$ is $\boldsymbol{\Sigma}^2_1$ if it can be written in the form $R(x) \longleftrightarrow \exists B \subseteq \omega^\omega \; P(x, B)$, where P is projective. That is, $P(x, B) \longleftrightarrow \exists z_1 \in \omega^\omega \; \forall z_2 \in \omega^\omega \cdots \exists(\forall) z_n \in \omega^\omega \; Q(x, B, z_1, \ldots, z_n)$, where Q is in the smallest collection containing any Borel relation on the real coordinates, the relations $z_i \in B$, $z_i \in x$ (if $X = \mathcal{P}(\omega^\omega)$), and closed under countable unions, intersections, and complements. Let ${\boldsymbol{\delta}^2_1}^{L(\mathbb{R})}$ be the supremum of the lengths of the $(\boldsymbol{\Delta}^2_1)^{L(\mathbb{R})}$ prewellorderings. We will henceforth just write $\boldsymbol{\delta}^2_1$ in place of ${\boldsymbol{\delta}^2_1}^{L(\mathbb{R})}$ (we will never consider $\boldsymbol{\delta}^2_1$ in a context outside of $L(\mathbb{R})$). $\boldsymbol{\delta}^2_1$ is the least ordinal δ such that $J_\delta(\mathbb{R}) \prec^{\mathbb{R}}_1 L(\mathbb{R})$, that is elementary for $\boldsymbol{\Sigma}_1$ formulas with real parameters. Also, $(\boldsymbol{\Sigma}^2_1)^{L(\mathbb{R})} = \boldsymbol{\Sigma}_1(J_{\boldsymbol{\delta}^2_1}(\mathbb{R})) \cap \mathcal{P}(\mathbb{R})$ and $(\boldsymbol{\Delta}^2_1)^{L(\mathbb{R})} = J_{\boldsymbol{\delta}^2_1}(\mathbb{R}) \cap \mathcal{P}(\mathbb{R})$.

Martin and Steel [27] (using an idea of Moschovakis) show that $(\boldsymbol{\Sigma}^2_1)^{L(\mathbb{R})}$ has the scale property, and is the largest scaled pointclass in $L(\mathbb{R})$. Steel [37] refines this analysis as follows. Following Steel, call $[\alpha, \beta]$, where $\alpha \leq \beta$, a $\boldsymbol{\Sigma}_1$-*gap* if $J_\alpha(\mathbb{R}) \prec^{\mathbb{R}}_1 J_\beta(\mathbb{R})$ and the interval $[\alpha, \beta]$ is maximal with this property. The gaps thus partition the ordinals in $[1, \Theta]$. $[\boldsymbol{\delta}^2_1, \Theta]$ is the last gap, and for the first non-trivial gap, that is where $\beta > \alpha$, $\boldsymbol{\Sigma}_1(J_\alpha(\mathbb{R}))$ already contains all the inductive sets (the smallest non-selfdual pointclass closed under real quantification). For α beginning a gap $[\alpha, \beta]$, $\boldsymbol{\Sigma}_1(J_\alpha(\mathbb{R}))$ has the scale property, and $\boldsymbol{\Sigma}_1(J_\alpha(\mathbb{R})) = \boldsymbol{\Sigma}_1(J_\alpha(\mathbb{R}); \mathbb{R})$, that is, every $\boldsymbol{\Sigma}_1(J_\alpha(\mathbb{R}))$ set is $\boldsymbol{\Sigma}_1$-definable over $J_\alpha(\mathbb{R})$ using only parameters from $\mathbb{R}$. If $\boldsymbol{\Sigma}_1(J_\alpha(\mathbb{R}))$ is not closed under real quantifiers, then periodicity propagates the scale property to $\boldsymbol{\Pi}_{2n}(J_\alpha(\mathbb{R}))$, $\boldsymbol{\Sigma}_{2n+1}(J_\alpha(\mathbb{R}))$. Otherwise (by a result of Martin), none of the $\boldsymbol{\Sigma}_n(J_\alpha(\mathbb{R}))$, $\boldsymbol{\Pi}_n(J_\alpha(\mathbb{R}))$ have the scale property for $n \geq 2$. If $\beta > \alpha$, then none of the classes $\boldsymbol{\Sigma}_n(J_\gamma(\mathbb{R}))$, $\boldsymbol{\Pi}_n(J_\gamma(\mathbb{R}))$ for $\alpha < \gamma < \beta$ have the scale property. The existence of scales at the end of a gap hinges on whether the gap satisfies a certain reflection property (a "strong" gap in the terminology of [37]). If so, there are no new scaled classes at the end of the gap. If not (a "weak" gap), then $\boldsymbol{\Sigma}_n(J_\beta(\mathbb{R}))$ has the scale property, where n is least such that $\boldsymbol{\Sigma}_n(J_\beta(\mathbb{R}))\cap\mathcal{P}(\mathbb{R}) \nsubseteq J_\beta(\mathbb{R})$. A periodicity argument then propagates the scale property to the $\boldsymbol{\Sigma}_{n+2k}(J_\beta(\mathbb{R}))$, $\boldsymbol{\Pi}_{n+2k+1}(J_\beta(\mathbb{R}))$. These results place exactly the scale property among the classes $\boldsymbol{\Sigma}_n(J_\alpha(\mathbb{R}))$, $\boldsymbol{\Pi}_n(J_\alpha(\mathbb{R}))$. With a little extra argument, this suffices to place exactly the scale property among the Levy classes in $L(\mathbb{R})$ (the only additional classes with the scale property are the Steel classes $\boldsymbol{\Gamma}_0$ such that $\exists^{\omega^\omega}\boldsymbol{\Gamma}_0 = \boldsymbol{\Sigma}_1(J_\alpha(\mathbb{R}))$ for some α beginning a gap).

The analysis also shows that for α beginning a gap, a universal $\boldsymbol{\Sigma}_1(J_\alpha(\mathbb{R}))$ set U_α and a $\boldsymbol{\Sigma}_1(J_\alpha(\mathbb{R}))$ scale $\{\phi_n^\alpha\}$ on U_α can be constructed uniformly in α. This uniformity, however, fails for the Steel pointclasses having the scale property; this presents an obstacle in some arguments.

2.5. Determinacy and Coding Results

We begin by recalling a useful ordinal determinacy result. If $\lambda_1, \dots, \lambda_n \in$ On and $A \subseteq \lambda_1^\omega \times \cdots \times \lambda_n^\omega$, we say A is *Suslin* if there is a tree T on $\lambda_1 \times \cdots \times \lambda_n \times \lambda_{n+1}$ for some $\lambda_{n+1} \in$ On such that $(\vec{\alpha}_1, \dots, \vec{\alpha}_n) \in A$ iff $\exists \vec{\alpha}_{n+1} \in \lambda_{n+1}^\omega\ (\vec{\alpha}_1, \dots, \vec{\alpha}_{n+1}) \in [T]$. The collection of Suslin sets contains the open and closed sets (${\lambda_i}^\omega$ endowed with the product of the discrete topology on λ_i), is closed under $\exists^{\omega^\omega}$, countable unions and intersections, continuous preimages, and assuming AD, $\forall^{\omega^\omega}$ (the only non-trivial part is closure under $\forall^{\omega^\omega}$ which follows from the proof of the Second Periodicity Theorem). We say A is *co-Suslin* if $(\lambda_1^\omega \times \cdots \times \lambda_n^\omega) - A$ is Suslin.

The following theorem is the basis for many ordinal determinacy results.

2.23 Theorem (AD). *Let $\lambda < \Theta$, and $A \subseteq \lambda^\omega$ be Suslin and co-Suslin. Then the ordinal game G_A is determined.*

The theorem is due originally to Moschovakis, and appears as Theorem 2.2 of [32] (though in a weaker form). The proof there is similar to that of the Third Periodicity Theorem, using also the Harrington-Kechris Theorem to ensure the determinacy of certain real games. A second proof appears in [22, Theorem 2.5], and is a more direct combinatorial proof.

An important tool in the theory of $L(\mathbb{R})$ is the Solovay Basis Theorem. This, along with Theorem 2.23, will provide the determinacy of some of the games we will consider later.

2.24 Theorem (ZF; Solovay Basis Theorem). *Let $P(A)$ be a $\boldsymbol{\Sigma}_1^2$ relation on sets $A \subseteq \omega^\omega$. If $L(\mathbb{R}) \models \exists A\ P(A)$ then $L(\mathbb{R}) \models \exists A \in \boldsymbol{\Delta}_1^2\ P(A)$.*

Proof. Write $P(A) \longleftrightarrow \exists B \subseteq \omega^\omega\ Q(A, B)$ where Q is projective. Work inside $L(\mathbb{R})$. Since every set in $L(\mathbb{R})$ is ordinal definable from a real, we may fix reals x_0, y_0 and formulas ϕ_1, ϕ_2 such that for some $\alpha, \beta \in$ On we have

$$L(\mathbb{R}) \models \exists! A\ \exists! B\ [\phi_1(x_0, \alpha, A) \wedge \phi_2(y_0, \beta, B) \wedge Q(A, B)].$$

Let $\psi(x_0, \alpha, y_0, \beta)$ denote the right-hand side and $\psi'(x_0, \alpha, y_0, \beta, A, B)$ denote the part inside the square brackets. Let $N \in \omega$ be large enough so that a transitive set model of $\mathrm{ZF}_N + V = L(\mathbb{R})$ containing the reals must be of the form $J_\delta(\mathbb{R})$. Let $(\delta_0, \alpha_0, \beta_0)$, where $\delta_0 > \alpha_0, \beta_0$, be the lexicographically least triple such that

$$J_{\delta_0}(\mathbb{R}) \models \mathrm{ZF}_N + \exists! A\ \exists! B[\phi_1(x_0, \alpha_0, A) \wedge \phi_2(y_0, \beta_0, B) \wedge Q(A, B)].$$

A hull argument shows that δ_0 exists, and there is a map from the reals onto $J_{\delta_0}(\mathbb{R})$, and thus $J_{\delta_0}(\mathbb{R})$ may be coded by a set of reals (that is, there is a structure $(\mathbb{R}, E)$ isomorphic to $J_{\delta_0}(\mathbb{R})$). Let A, B be the unique sets of reals in $J_{\delta_0}(\mathbb{R})$ such that $\phi_1(x_0, \alpha_0, A)$, $\phi_2(y_0, \beta_0, B)$, and $Q(A, B)$ hold in $J_{\delta_0}(\mathbb{R})$. Since Q is projective, $Q(A, B)$ holds in $L(\mathbb{R})$, and thus $P(A)$. We have:
$x \in A \longleftrightarrow \exists E \subseteq \omega^\omega \times \omega^\omega\ \exists x', x_0', y_0' \in \mathbb{R}$ satisfying the following:

(1) $(\mathbb{R}, E)$ is well-founded, $(\mathbb{R}, E) \models \mathrm{ZF}_N + V = L(\mathbb{R})$, and $\mathbb{R} \subseteq \pi(\mathbb{R}, E)$, where π is the transitive collapse map.

(2) $\pi(x') = x$, $\pi(x_0') = x_0$, $\pi(y_0') = y_0$.

(3) $(\mathbb{R}, E) \models \exists \alpha', \beta'\ [\psi(x_0', \alpha', y_0', \beta') \ \wedge\ \forall(\alpha'', \beta'') <_{\mathrm{lex}} (\alpha', \beta')\ \neg\psi(x_0', \alpha'', y_0', \beta'') \wedge \exists A' \exists B'\ \psi'(x_0', \alpha', y_0', \beta', A', B') \wedge x' \in A']$.

(4) $(\mathbb{R}, E) \models \forall \delta' \in \mathrm{On}\ J_{\delta'}(\mathbb{R}) \not\models \exists \alpha', \beta'\ \psi(x_0', \alpha', y_0', \beta')$.

Since (1)–(4) are projective statements about E, this shows that $A \in \boldsymbol{\Sigma}^2_1$, and a similar computation shows $A^c \in \boldsymbol{\Sigma}^2_1$. ⊣

From this, we get a useful determinacy result.

2.25 Theorem $(\mathrm{AD} + V = L(\mathbb{R}))$. *Let $\lambda < \Theta$ and $F : \lambda^\omega \times (\omega^\omega)^n \to \omega^\omega$ be continuous, and $A \subseteq \omega^\omega$. Consider the game $G_{\lambda,F,A}$ on λ where I, II play $\alpha_0, \alpha_1, \dots$ producing $\vec{\alpha} \in \lambda^\omega$, and I wins iff*

$$\exists x_1 \forall x_2 \cdots \exists(\forall) x_n\ F(\vec{\alpha}, x_1, x_2, \dots, x_n) \in A.$$

Then $G_{\lambda,F,A}$ is determined.

Proof. Suppose the theorem fails. By a hull argument, there is an $E \subseteq \omega^\omega \times \omega^\omega$ such that $(\mathbb{R}, E)$ is well-founded, $\mathbb{R} \subseteq \pi(M, E)$, where π denotes the transitive collapse map, and there are $\lambda', F', A' \in \mathbb{R}$ such that $(\mathbb{R}, E) \models \mathrm{ZF}_N +$ "(λ', F', A') witnesses the theorem fails". From Theorem 2.24, we may fix such an E which is $\boldsymbol{\Delta}^2_1$. Let $J_\delta(\mathbb{R}) = \pi(\mathbb{R}, E)$. Let $\lambda'' = \pi(\lambda')$, $A'' = \pi(A')$, $F'' = \pi(F')$. So, $J_\delta(\mathbb{R}) \models$ "(λ'', A'', F'') witness the theorem fails". Since $E \in \boldsymbol{\Delta}^2_1$, easily $A'' \in \boldsymbol{\Delta}^2_1$. Hence A'' is Suslin, co-Suslin in $L(\mathbb{R})$, and thus so is

$$\{(\vec{\alpha}, x_1, \dots, x_n) \in \lambda''^\omega \times (\omega^\omega)^n : F''(\vec{\alpha}, x_1, \dots, x_n,) \in A''\}.$$

By periodicity, $G_{\lambda'',A'',F''}$ is Suslin, co-Suslin in $L(\mathbb{R})$ and therefore determined. However, a winning strategy for this game can be identified with a subset of $\lambda'' < \Theta^{J_\delta(\mathbb{R})}$. By the Coding Lemma, the strategy must then lie in $J_\delta(\mathbb{R})$, a contradiction. ⊣

2.26 Corollary ($\mathrm{AD} + V = L(\mathbb{R})$). *Let $\lambda < \Theta$, $F : \lambda^\omega \to \omega^\omega$ be continuous, $A \subseteq \omega^\omega$, and G the game on λ with payoff $F^{-1}(A)$. Then G is determined.*

If $\mathbf{\Gamma}$ is a pointclass closed under $\forall^{\omega^\omega}, \vee$, and $\mathrm{pwo}(\mathbf{\Gamma})$, and if $\phi : A \xrightarrow{onto} \kappa$ is a $\mathbf{\Gamma}$ norm on the $\mathbf{\Gamma}$-complete set A, then the usual boundedness principle applies: every $B \subseteq A$ in $\check{\mathbf{\Gamma}}$ is bounded below κ with respect to ϕ. In this case, κ is the supremum of the lengths of the $\mathbf{\Delta}$ prewellorderings, and κ is regular. There is a useful generalization of this principle, due to Steel, which applies to all ordinals $\alpha < \Theta$. First, we recall one of the main results of [35]:

2.27 Theorem (AD; Steel). *Let $\mathbf{\Gamma}$ be non-selfdual, and $\exists^{\omega^\omega} \mathbf{\Delta} \subseteq \mathbf{\Delta}$. Then $\mathbf{\Gamma}$ is closed under intersections with κ-Suslin sets for $\kappa < \mathrm{cf}(o(\mathbf{\Delta}))$.*

The non-trivial case of Theorem 2.27 is when $\mathrm{sep}(\mathbf{\Gamma})$ holds, for if $\mathrm{sep}(\check{\mathbf{\Gamma}})$ then $\mathbf{\Gamma}$ is closed under $\wedge$ by [35].

Using Theorem 2.27 we now have the following general boundedness principle. We follow the proof in [12]. We say a norm $\phi : A \xrightarrow{onto} \alpha$ is *κ-Suslin bounded* if for every $B \subseteq A$ which is κ-Suslin we have $\sup\{\phi(x) : x \in B\} < \alpha$.

2.28 Theorem (AD; Steel). *Let $\alpha < \Theta$ be a limit ordinal. Then there is an $A \subseteq \omega^\omega$ and a norm $\phi : A \xrightarrow{onto} \alpha$ which is κ-Suslin bounded for all $\kappa < \mathrm{cf}(\alpha)$.*

Proof. First note that we may assume α is regular, since a norm of length $\mathrm{cf}(\alpha)$ which is κ-Suslin bounded for all $\kappa < \mathrm{cf}(\alpha)$ produces one of length α. For example, let $\delta = \mathrm{cf}(\alpha)$, $h : \delta \to \alpha$ be cofinal and increasing, and $\psi : B \to \delta$ a norm which is κ-Suslin bounded for all $\kappa < \delta$. Let $\rho : C \xrightarrow{onto} \alpha$ be a norm. Define for $\beta < \alpha$,

$$A_\beta(x) \longleftrightarrow [x_0 \in C \ \wedge \ \rho(x_0) = \beta \ \wedge x_1 \in B \ \wedge \ \beta < h(\psi(x_1))] \,.$$

Let $A = \bigcup_{\beta<\alpha} A_\beta$, and $\phi(x) = \rho(x_0)$ for $x \in A$. Suppose $S \subseteq A$ is κ-Suslin for some $\kappa < \delta$. Let $S_1 = \{x_1 : x \in S\}$. Then S_1 is κ-Suslin and $S_1 \subseteq B$, and so $\eta \doteq \sup\{\psi(x_1) : x \in S\} < \delta$. But clearly then $\sup\{\phi(x) : x \in S\} \leq h(\eta)$. So assume α is regular.

Similarly, it suffices to produce a norm $\psi : A \xrightarrow{onto} \rho$ which is κ-Suslin bounded for all $\kappa < \alpha$, for some ρ of cofinality α. For suppose $\psi : A \xrightarrow{onto} \rho$ is such a norm, and $\mathrm{cf}(\rho) = \alpha$. Let $h : \alpha \to \rho$ be cofinal. Define $\phi : A \xrightarrow{onto} \alpha$ by $\phi(x) =$ the least $\beta < \alpha$ such that $h(\beta) > \psi(x)$. Then easily ϕ is κ-Suslin bounded for all $\kappa < \alpha$.

Let $\rho > \alpha$ be a limit cardinal of cofinality α such that the collection $\mathbf{\Delta}$ of sets of Wadge degree $< \rho$ is closed under $\exists^{\omega^\omega}$. We produce an A and a norm $\phi : A \xrightarrow{onto} \rho$ which is κ-Suslin bounded for all $\kappa < \alpha$. Let $\mathbf{\Gamma}$ be the non-selfdual pointclass closed under $\forall^{\omega^\omega}$ with $\mathbf{\Delta} = \mathbf{\Gamma} \cap \check{\mathbf{\Gamma}}$ (see [35], we assume $\alpha > \omega$ as otherwise the result is trivial). Let B be a $\mathbf{\Gamma}$ universal set. Define A by: $x \in A$ iff x_0, x_1 code continuous functions f_{x_0}, f_{x_1} with $f_{x_0}^{-1}(B) = \omega^\omega - f_{x_1}^{-1}(B)$. For $x \in A$, let $\phi(x)$ be the Wadge degree of the $\mathbf{\Delta}$ set $f_{x_0}^{-1}$. Clearly $\phi : A \xrightarrow{onto} \rho$. Suppose $S \subseteq A$ is κ-Suslin for some $\kappa < \alpha$, and assume towards a contradiction that $\sup\{\phi(x) : x \in S\} = \rho$. Define

$$C(x,y) \overset{\text{def}}{\longleftrightarrow} (x \in S \wedge f_{x_0}(y) \in B) \longleftrightarrow (x \in S \wedge f_{x_1}(y) \notin B)\,.$$

Thus, $C \in \mathbf{\Delta}$ by Theorem 2.27. This is a contradiction, since any $\mathbf{\Delta}$ set is Wadge reducible to C. For let $D \in \mathbf{\Delta}$, and take $x \in S$ so that $f_{x_0}^{-1}(B) = \omega^\omega - f_{x_1}^{-1}(B) = D' \geq_w D$. Then $y \in D' \longleftrightarrow (x,y) \in C$. ⊣

2.6. Partition Relations

We recall some facts and terminology associated with partition relations that we will be using frequently. We give the definitions working in our base theory ZF + DC, although to obtain non-trivial results we will have to assume AD.

If $f : \alpha \to \mathrm{On}$, we say f has *uniform cofinality* ω if there is a $f' : \alpha \times \omega \to \mathrm{On}$ such that $\forall \beta < \alpha\ f(\beta) = \sup\{f'(\beta,n) : n \in \omega\}$ and f' is increasing in the second argument, that is, $\forall \beta\ \forall n,m\ [n < m \to f'(\beta,n) < f'(\beta,m)]$.

2.29 Definition. We say $f : \alpha \to \mathrm{On}$ *is of the correct type* if f is increasing, everywhere discontinuous (i.e., for all $\beta < \alpha$, $f(\beta) > \sup\{f(\beta') : \beta' < \beta\}$), and of uniform cofinality ω.

Generalizing this, we define:

2.30 Definition. Let $f, S : \alpha \to \mathrm{On}$. We say f has *uniform cofinality* S if there is a function $l : \{(\beta,\gamma) : \beta < \alpha \wedge \gamma < S(\beta)\} \to \mathrm{On}$ which is increasing in the second argument and $\forall \beta < \alpha\ f(\beta) = \sup\{l(\beta,\gamma) : \gamma < S(\beta)\}$. We frequently just say $f(\beta)$ has uniform cofinality $S(\beta)$.

If μ is a measure (i.e., a countably additive ultrafilter) on α, we say f has *uniform cofinality* S *almost everywhere*, for S as above, if $\forall^*_\mu \beta < \alpha\ f(\beta) = f(\beta) = \sup\{l(\beta,\gamma) : \gamma < S(\beta)\}$. We usually just say $f(\beta)$ has uniform cofinality $S(\beta)$ almost everywhere with respect to μ.

Note that the statement "f has uniform cofinality S almost everywhere with respect to μ" depends only on $[f]_\mu$, $[S]_\mu$.

For κ a cardinal and $\lambda \leq \kappa$, we let $(\kappa)^\lambda$ denote the set of increasing functions from λ to κ. We write $\kappa \to (\kappa)^\lambda$ to mean: for every partition $\mathcal{P} : (\kappa)^\lambda \to \{0,1\}$ of the increasing functions from λ to κ into two pieces, there is a homogeneous $H \subseteq \kappa$ of size κ. That is, there is an $i \in \{0,1\}$ such that for all $f \in (H)^\lambda$ we have $\mathcal{P}(f) = i$. We define a variation on this as follows. We say $\kappa \xrightarrow{\text{c.u.b.}} (\kappa)^\lambda$ if for all partitions $\mathcal{P} : (\kappa)^\lambda \to \{0,1\}$ of the increasing functions from λ to κ into two pieces, there is a closed unbounded $C \subseteq \kappa$ such that for some $i \in \{0,1\}$ and all $f : \lambda \to C$ of the correct type, $\mathcal{P}(f) = i$.

The following well-known fact connects these two variations. The proof is straightforward, and left to the reader.

2.31 Fact. For all cardinals κ and ordinals $\lambda \leq \kappa$:

1. $\kappa \overset{\text{c.u.b.}}{\longrightarrow} (\kappa)^\lambda \implies \kappa \to (\kappa)^\lambda$.

2. $\kappa \to (\kappa)^{\omega \cdot \lambda} \implies \kappa \overset{\text{c.u.b.}}{\longrightarrow} (\kappa)^\lambda$.

The instances of the partition property of particular importance to us are expressed in the following definition.

2.32 Definition. We say a cardinal κ has the *strong partition property* if $\kappa \to (\kappa)^\kappa$. We say κ has the *weak partition property* if $\kappa \to (\kappa)^\lambda$ for all $\lambda < \kappa$.

From Fact 2.31 it follows that the notions of strong and weak partition property of κ do not depend on which of the two variations of the definition are used. In all of the determinacy arguments, it is the "c.u.b." version of the partition relation which is relevant. Since we will never need the other variation, we therefore adopt the convention that henceforth, $\kappa \to (\kappa)^\lambda$ means $\kappa \overset{\text{c.u.b.}}{\longrightarrow} (\kappa)^\lambda$.

There are two slight generalizations of the strong partition property of κ which we will employ frequently. First, if $\prec$ is a wellordering of some set $\mathrm{dom}(\prec)$ of order-type κ, we have the strong partition property for partitions of functions $f : \mathrm{dom}(\prec) \to \kappa$ of the correct type (defined in the obvious manner). Second, instead of considering functions $f : \kappa \to \kappa$ or $f : \mathrm{dom}(\prec) \to \kappa$ of the correct type, we may consider f which are increasing, everywhere discontinuous, and of uniform cofinality S, for any fixed $S : \kappa \to \kappa$. Alternatively, we may consider partitions of functions f which are increasing, continuous at limit ordinals (or points of limit rank in $\prec$), and such that $f(\alpha)$ has uniform cofinality $S(\alpha)$ at points of successor rank. In either case, the generalized version of the strong partition property follows easily from the usual strong partition relation.

We present now an abstract form of Martin's proof of the strong partition relation on ω_1. We state it in the most general form for which we are able to prove it.

2.33 Definition. Let κ be a regular cardinal, $\lambda \in \mathrm{On}$, $\lambda \leq \kappa$. We say κ is λ-*reasonable* there is a non-selfdual pointclass $\boldsymbol{\Gamma}$ closed under $\exists^{\omega^\omega}$, and a map ϕ with domain ω^ω satisfying (where $\boldsymbol{\Delta} = \boldsymbol{\Gamma} \cap \check{\boldsymbol{\Gamma}}$):

(1) $\forall x\ \phi(x) \subseteq \lambda \times \kappa$.

(2) $\forall F : \lambda \to \kappa\ \exists x\ (\phi(x) = F)$.

(3) $\forall\beta<\lambda\ \forall\gamma<\kappa\ R_{\beta,\gamma}\in\mathbf{\Delta}$, where

$$x\in R_{\beta,\gamma}\longleftrightarrow\phi(x)(\beta,\gamma)\wedge\forall\gamma'<\kappa\ (\phi(x)(\beta,\gamma')\to\gamma'=\gamma).$$

(4) Suppose $\beta<\lambda$, $A\in\exists^{\omega^\omega}\mathbf{\Delta}$, and $A\subseteq R_\beta\doteq\{x:\exists\gamma<\kappa\ R_{\beta,\gamma}(x)\}$. Then $\exists\gamma_0<\kappa\ \forall x\in A\ \exists\gamma<\gamma_0\ R_{\beta,\gamma}(x)$.

We say κ is *reasonable* if it is κ-reasonable. If $\exists!\gamma\ \phi(x)(\beta,\gamma)$, then we write $\phi(x)(\beta)$ for this unique γ. Note that the pointclass hypotheses of the theorem are really just that $\mathbf{\Delta}=\mathbf{\Gamma}\cap\check{\mathbf{\Gamma}}$ for some Levy class $\mathbf{\Gamma}$ (i.e., $\mathbf{\Gamma}$ is non-selfdual and closed under $\exists^{\omega^\omega}$ or $\forall^{\omega^\omega}$) as the hypotheses are symmetric between $\mathbf{\Gamma}$ and $\check{\mathbf{\Gamma}}$. Recall that from AD we have either pwo($\mathbf{\Gamma}$) or pwo($\check{\mathbf{\Gamma}}$).

2.34 Theorem (AD; Martin). *If κ is $\omega\cdot\lambda$-reasonable, then $\kappa\to(\kappa)^\lambda$.*

Proof. We will show below that $\mathbf{\Delta}$ is in fact closed under $<\kappa$ unions and intersections; we assume this for now. We refer below to the sets R_β, $R_{\beta,\gamma}$ of Definition 2.33.

Fix a partition $\mathcal{P}:(\kappa)^\lambda\to\{0,1\}$. Play the integer game where I plays out $x\in\omega^\omega$, II plays out $y\in\omega^\omega$. If there is a least ordinal $\beta<\omega\cdot\lambda$ such that $x\notin R_\beta$ or $y\notin R_\beta$, then II wins provided $x\notin R_\beta$. Otherwise, let f_x, $f_y:\omega\cdot\lambda\to\kappa$ be the functions they determine (e.g., $f_x(\beta)=\phi(x)(\beta)$). Define in this case $f_{x,y}:\lambda\to\kappa$ by

$$f_{x,y}(\beta)=\sup\{\max(f_x(\beta'),f_y(\beta')):\beta'<\omega\cdot(\beta+1)\}\,.$$

II then wins iff $\mathcal{P}(f_{x,y})=1$.

Assume without loss of generality that II has a winning strategy τ. For $\beta<\omega\cdot\lambda$ and $\gamma<\kappa$, define $x\in S_{\beta,\gamma}\longleftrightarrow\forall\beta'\le\beta\ \exists\gamma'\le\gamma\ x\in R_{\beta',\gamma'}$. Thus, $S_{\beta,\gamma}\in\mathbf{\Delta}$. Hence, for all $\beta<\omega\cdot\lambda$ and $\gamma<\kappa$, $\tau[S_{\beta,\gamma}]\in\exists^{\omega^\omega}\mathbf{\Delta}$ (note that for any Levy class $\mathbf{\Gamma}$ that $\exists^{\omega^\omega}\mathbf{\Delta}$ is closed under $\wedge$, $\vee$; an easy consequence of the hierarchy analysis of Sect. 2.3). Now, $\tau[S_{\beta,\gamma}]\subseteq R_\beta$. Thus, $\theta(\beta,\gamma)\doteq\sup\{\phi(x)(\beta):x\in\tau[S_{\beta,\gamma}]\}<\kappa$, from (4) of Definition 2.33. Let $C\subseteq\kappa$ be the set of points closed under θ, and $C'\subseteq C$ the set of limit points of C.

Suppose $F:\lambda\to C'$ is of the correct type; we show that $\mathcal{P}(F)=1$. Let x be such that $\phi(x)$ determines a function $f_x:\omega\cdot\lambda\to C$ such that $F(\beta)=\sup\{f_x(\beta'):\beta'<\omega\cdot(\beta+1)\}$. We may assume $f_x(\beta)\ge\beta$ for all β. Let $y=\tau(x)$. From the definition of C it follows that $\phi(y)$ determines a function $f_y:\omega\cdot\lambda\to\kappa$ such that $f_y(\beta)\le f_x(\beta+1)$ for all β. Thus, $F=f_{x,y}$, so $\mathcal{P}(F)=1$.

We show now that $\mathbf{\Delta}$ is closed under $<\kappa$ unions. Suppose not, and let $\delta<\kappa$ be least such that some union $A=\bigcup_{\alpha<\delta}A_\alpha$ is not in $\mathbf{\Delta}$. Note that $R_0=\bigcup_{\gamma<\kappa}R_{0,\gamma}$ is a κ union of $\mathbf{\Delta}$ sets, and $R_0\notin\exists^{\omega^\omega}\mathbf{\Delta}$. Suppose first pwo($\mathbf{\Gamma}$). Then $\mathbf{\Gamma}$ is closed under wellordered unions by Lemma 2.21. Thus $A\in\mathbf{\Gamma}$, and by Wadge's Lemma, $R_0=\bigcup_{\alpha<\delta}S_\alpha$ for some $S_\alpha\in\mathbf{\Delta}$. Since κ is regular, one of the $S_\alpha\subseteq R_0$ must be "unbounded" in κ, a contradiction to $\omega \cdot \lambda$-reasonableness. So assume pwo($\check{\boldsymbol{\Gamma}}$), and thus pwo($\boldsymbol{\Gamma}_1$), where $\boldsymbol{\Gamma}_1 = \exists^{\omega^\omega} \check{\boldsymbol{\Gamma}}$. Thus, $\boldsymbol{\Gamma}_1$ is closed under wellordered unions, and so $R_0 \in \boldsymbol{\Gamma}_1$. We cannot have $\bigcup_\delta \boldsymbol{\Delta} = \boldsymbol{\Gamma}$, as otherwise Martin's argument (Theorem 2.15) shows pwo($\boldsymbol{\Gamma}$). It follows that $\bigcup_\delta \boldsymbol{\Delta} \supseteq \check{\boldsymbol{\Gamma}}$, and so $\bigcup_\delta \exists^{\omega^\omega} \boldsymbol{\Delta} \supseteq \boldsymbol{\Gamma}_1$ (and hence actually $\boldsymbol{\Gamma}_1 = \bigcup_\delta \exists^{\omega^\omega} \boldsymbol{\Delta}$). Thus, $R_0 = \bigcup_{\alpha<\delta} S_\alpha$, with each $S_\alpha \in \exists^{\omega^\omega} \boldsymbol{\Delta}$. As before, this contradicts reasonableness. ⊣

2.35 Remark. The proof shows that if $\boldsymbol{\Gamma}$,ϕ witness the λ-reasonableness of κ, then $\boldsymbol{\Delta}$ is closed under $<\kappa$ unions. With a little extra work one can show $\boldsymbol{\Gamma}$ is closed under countable unions, intersections, and pwo($\check{\boldsymbol{\Gamma}}$).

The next lemma shows that all the $\boldsymbol{\delta}^1_{2n+1}$, and in particular ω_1, have the countable exponent partition relation. We will take this as the start of our analysis in the next section.

2.36 Theorem (AD). *Let $\boldsymbol{\Gamma}$ be a non-selfdual pointclass closed under $\forall^{\omega^\omega}$, $\wedge, \vee$ and assume* pwo($\boldsymbol{\Gamma}$). *Let $\delta = \delta(\boldsymbol{\Gamma})$ = the supremum of the lengths of the $\boldsymbol{\Delta} = \boldsymbol{\Gamma} \cap \check{\boldsymbol{\Gamma}}$ prewellorderings. Then $\delta \to (\delta)^\lambda$ for all $\lambda < \omega_1$.*

Proof. Fix λ, and a bijection $\pi : \omega \to \lambda$. Fix also a $\boldsymbol{\Gamma}$ universal set P and a $\boldsymbol{\Gamma}$ norm ψ on P. We may assume ψ is onto an ordinal, in which case that ordinal is δ. We define the map ϕ so that $\check{\boldsymbol{\Gamma}}, \phi$ witness the λ-reasonableness of δ. Define $\phi(x)(\beta, \gamma)$ iff $x_n \in P \wedge \psi(x_n) = \gamma$, where $\pi(n) = \beta$. Items (1)–(3) are immediate, and (4) follows since a $\check{\boldsymbol{\Gamma}}$ subset of P is bounded. ⊣

Note that if we know directly that $\boldsymbol{\Gamma}$ is closed under countable unions and intersections, then the pointclass arguments in Theorem 2.34 are not necessary for the application to Theorem 2.36, as the sets $S(\alpha, \gamma)$ as defined there are in $\boldsymbol{\Delta}$ directly.

3. Suslin Cardinals

In this section we develop the basic theory of Suslin cardinals and scales assuming AD. The results presented here completely classify the Suslin cardinals κ and the corresponding Suslin classes $S(\kappa)$. They also suffice to completely determine the scaled pointclasses with one exception: if $\boldsymbol{\Gamma}$ is scaled and closed under quantifiers, then if λ denotes the next Suslin cardinal, we do not get the scale property at $\boldsymbol{\Sigma}_0$ or $\boldsymbol{\Pi}_1$ where $\boldsymbol{\Sigma}_0$ is the class of countable unions of sets of Wadge degree less than λ. We do, however, get the scale property at $\boldsymbol{\Sigma}_2$ (and by periodicity for the appropriate classes in the remainder of this projective-like hierarchy). As we show in this case, λ^+ is the next Suslin cardinal after λ, and $\boldsymbol{\Sigma}_2 = S(\lambda^+)$. Steel's analysis of scales in $L(\mathbb{R})$ (which we over-viewed in Sect. 2.4) provides a more detailed description if one assumes in addition $V = L(\mathbb{R})$. Namely, this analysis gives also the scale property at $\boldsymbol{\Sigma}_0$, $\boldsymbol{\Pi}_1$.

The main result is Theorem 3.28. We assume AD throughout this section. The arguments of this section are mainly due to Martin and appear in [24], which we follow.

We assume in this section a basic knowledge of homogeneous and weakly homogeneous trees, though we only need here (aside from Theorem 3.2 below) the basic definitions and general properties of the homogeneous tree construction. The reader could skip ahead to Definition 5.1 and its following paragraphs for a discussion.

Throughout this section, ν will denote the Martin measure on the Turing degrees $\mathcal{D}$. Recall that $A \subseteq \mathcal{D}$ has ν measure one iff it contains a cone, that is, there is a degree d such that for all $d' \geq_T d$, $d' \in A$ (here $\leq_T$ denotes Turing reducibility). From AD, ν is a measure (i.e., a countably additive ultrafilter) on $\mathcal{D}$. Thus we will write "$\forall^*_\nu\, d$" to mean "for ν almost all degrees $d \in \mathcal{D}$". When we are clearly talking about degrees, we will frequently just write $x \leq d$ instead of $x \leq_T d$.

Recall that $S(\kappa)$ denotes the pointclass of κ-Suslin sets. Recall also the definitions of $o(\boldsymbol{\Gamma})$, $\delta(\boldsymbol{\Gamma})$ from Definition 2.19. We will use frequently the fact mentioned previously (from [21]) that for $\boldsymbol{\Delta}$ closed under real quantification, $\wedge$ and $\vee$, we have $o(\boldsymbol{\Delta}) = \delta(\boldsymbol{\Delta})$.

We state two theorems we will need for this analysis. The first, due to Steel and Woodin, is the following.

3.1 Theorem (Steel, Woodin). *The set of Suslin cardinals is closed below their supremum.*

Thus, assuming AD, the set of Suslin cardinals is closed below Θ except that the supremum of the Suslin cardinals, if less than Θ, may perhaps not be a Suslin cardinal. Woodin [42] has isolated a strengthening of AD called AD^+ which implies that the Suslin cardinals are closed below Θ. It is apparently unknown whether AD implies AD^+. We refer the reader to [42] for further discussion of AD^+.

We will also need the following theorem of Martin and Woodin on weak homogeneity. We refer the reader to [30] for a proof.

3.2 Theorem (Martin, Woodin). *Let κ be less than the supremum of the Suslin cardinals. Then every tree on $\omega \times \kappa$ is weakly homogeneous.*

3.1. Pointclass Arguments

We recall the following fact about the homogeneously Suslin sets.

3.3 Lemma. *Let κ be a cardinal. Let $\boldsymbol{\Gamma}$ be the collection of $A \subseteq \omega^\omega$ which can be written in the form $A = p[T]$ where T is a homogeneous tree on $\omega \times \kappa$. Then $\boldsymbol{\Gamma}$ is a pointclass and is closed under $\forall^{\omega^\omega}$.*

Proof. It is straightforward to check that $\boldsymbol{\Gamma}$ is a pointclass. We first show that $\forall^{\omega^\omega} \boldsymbol{\Gamma} \subseteq S(\kappa)$. Suppose $A(x) \longleftrightarrow \forall y\, B(x, y)$ where $B \in \boldsymbol{\Gamma}$, say $B = p[T]$

where T is a homogeneous tree on $\omega \times \omega \times \kappa$. Let $\{s_i\}_{i\in\omega}$ enumerate $\omega^{<\omega}$ in a reasonable manner. Define a tree U on $\omega \times \kappa$ by:

$$(t, \vec{\alpha}) \in U \longleftrightarrow \forall i < \mathrm{lh}(t)\ (t{\restriction}\,\mathrm{lh}(s_i), s_i, \vec{\beta}) \in T,$$

where $\vec{\beta} = (\alpha_{j(0)}, \alpha_{j(1)}, \ldots, \alpha_{j(\mathrm{lh}(s_i)-1)})$, and $j(a)$ is the integer such that $s_{j(a)} = s_i{\restriction}a$. Clearly $p[U] \subseteq A$. The inclusion $A \subseteq p[U]$ follows also if we have that for every $x \in A$ there is a Lipschitz continuous $f : \omega^\omega \to \kappa^\omega$ such that for all $y \in \omega^\omega$, $(x, y, f(y)) \in [T]$ (for this f will produce a branch through U_x). The existence of f follows from the homogeneity of T: play the (closed for II) game where I plays integers $y(i)$, II plays ordinals $\alpha(i) < \kappa$, and II wins the run iff for all n, $(x{\restriction}n, y{\restriction}n, \vec{\alpha}{\restriction}n) \in T$. Since T is homogeneous, II has a winning strategy in this game, and this gives the desired function f. So, $\forall^{\omega^\omega}\boldsymbol{\Gamma} \subseteq S(\kappa)$.

If $\boldsymbol{\Gamma} = S(\kappa)$, then this shows $\forall^{\omega^\omega}\boldsymbol{\Gamma} = \boldsymbol{\Gamma}$ (and $\boldsymbol{\Gamma}$ is closed under $\exists^{\omega^\omega}$ as well). Suppose $\boldsymbol{\Gamma} \subsetneq S(\kappa)$. If κ is not the largest Suslin cardinal, then from Theorem 3.2 we have $S(\kappa) = \exists^{\omega^\omega}\boldsymbol{\Gamma}$. If $\forall^{\omega^\omega}\boldsymbol{\Gamma} \neq \boldsymbol{\Gamma}$, then by Wadge's Lemma $\forall^{\omega^\omega}\boldsymbol{\Gamma} \supseteq \forall^{\omega^\omega}\check{\boldsymbol{\Gamma}} = \check{S}(\kappa)$, a contradiction. If κ is the largest Suslin cardinal, then $S(\kappa)$ is closed under $\forall^{\omega^\omega}$ (as well as $\exists^{\omega^\omega}$) as otherwise periodicity would give a larger Suslin class. So, $\boldsymbol{\Delta}(S(\kappa))$ is closed under real quantification. Also, any $A \in S(\kappa) - \check{S}(\kappa)$ cannot be in $\boldsymbol{\Gamma}$ (or even be the projection of a weakly homogeneous tree), as otherwise $\omega^\omega - A$ would be Suslin from the homogeneous tree construction. Thus, in this case $\boldsymbol{\Gamma} \subseteq \boldsymbol{\Delta}(S(\kappa))$. We borrow one fact from the upcoming Lemma 3.6, namely that $\mathrm{cf}(\kappa) > \omega$. Thus, every $S(\kappa)$ set is an increasing union of sets in $\bigcup_{\lambda<\kappa} S(\lambda)$. If $\bigcup_{\lambda<\kappa} S(\lambda)$ were properly contained in $\boldsymbol{\Delta}(S(\kappa))$, then we could find a pointclass $\boldsymbol{\Gamma}_0$ properly contained in $\boldsymbol{\Delta}(S(\kappa))$ which is closed under $\exists^{\omega^\omega}$, $\mathrm{pwo}(\boldsymbol{\Gamma}_0)$, and $\bigcup_{\lambda<\kappa} S(\lambda) \subseteq \boldsymbol{\Gamma}_0$. From Lemma 2.21 it follows that $S(\kappa) \subseteq \boldsymbol{\Gamma}_0$, a contradiction. So, every $\boldsymbol{\Delta}(S(\kappa))$ set is λ-Suslin for some $\lambda < \kappa$. From Theorem 3.2 it follows that every set in $\boldsymbol{\Delta}(S(\kappa))$ is the existential quantification of a set in $\boldsymbol{\Gamma}$, and so $\boldsymbol{\Gamma} = \boldsymbol{\Delta}(S(\kappa))$. Hence, $\boldsymbol{\Gamma}$ is closed under $\forall^{\omega^\omega}$. $\dashv$

We need the following simple lemma.

3.4 Lemma. *Let κ be a Suslin cardinal. Then there is a κ-length strictly increasing sequence of sets in $S(\kappa)$. If $\mathrm{cf}(\kappa) > \omega$, then there is a κ-length strictly increasing sequence of sets each of which is $<\kappa$-Suslin.*

Proof. The proof that every Suslin cardinal is reliable (cf. [37, Lemma 4.6] and Sect. 6.1) shows that for any Suslin cardinal κ there is an $A \in S(\kappa) - \check{S}(\kappa)$ and a scale $\{\phi_i\}$ on A with norms into κ and with ϕ_0 onto κ. We recall the argument. Let $B \in S(\kappa) - \check{S}(\kappa)$, and $\{\psi_i\}$ a regular scale on B with norms into κ. Let $A = \{x : x' \in B\}$, where $x'(n) = x(n + 1)$. Define for $x \in A$, $\phi_0(x) = \psi_{x(0)}(x')$, and $\phi_{i+1}(x) = \psi_i(x')$. Then ϕ_0 is onto κ as otherwise $A \in S(\lambda)$ for some $\lambda < \kappa$. For $\alpha < \kappa$ let $A_\alpha = \{x \in A : \phi_0(x) \leq \alpha\}$. Each A_α is in $S(\kappa)$. Moreover, the A_α form a strictly increasing sequence of $S(\kappa)$ sets of length κ.

Suppose now that $\mathrm{cf}(\kappa) > \omega$. We now use the argument of [14, Lemma 2.1]. Recall ϕ_0 maps onto κ. For $\alpha < \beta < \kappa$ define

$$A_{\alpha,\beta} = \{x : \forall i\ \phi_i(x) < \beta\} \cup \{x : \forall i\ \phi_i(x) \leq \beta \wedge \phi_0(x) \leq \alpha\}.$$

Each $A_{\alpha,\beta}$ is $<\kappa$-Suslin. If we view the increasing pairs (α, β) as ordered first by the second coordinate and then the first, clearly the $A_{\alpha,\beta}$ form a (not necessarily strictly) increasing sequence of order type κ. For each $\alpha < \kappa$, there is an x with $\phi_0(x) = \alpha$ and for this x there is a least $\beta > \alpha$ such that $\forall i\ \phi_i(x) \leq \beta$. It follows that for these α, β that $A_{\alpha,\beta} - \bigcup_{\alpha',\beta'} A_{\alpha',\beta'} \neq \emptyset$ where the union ranges over (α', β') less than (α, β) in the ordering described. Thus there is a κ length subsequence of the $A_{\alpha,\beta}$ which is strictly increasing. $\dashv$

We will need the following result, due to Chuang, in the theory of pointclasses. The methods used in the proof are similar to those of [14].

3.5 Theorem (Chuang). *Let* $\boldsymbol{\Gamma}$ *be non-selfdual and closed under* $\forall^{\omega^\omega}$, $\vee$, *and assume* $\mathrm{pwo}(\boldsymbol{\Gamma})$. *Then there is no strictly increasing or decreasing sequence of* $\boldsymbol{\Gamma}$ *sets of length* $(\delta(\boldsymbol{\Gamma}))^+$.

Proof. Let $\boldsymbol{\Delta} = \boldsymbol{\Gamma} \cap \check{\boldsymbol{\Gamma}}$ as usual. Note that $\boldsymbol{\Gamma}$ is closed under countable intersections and $\exists^{\omega^\omega}\boldsymbol{\Gamma}$ (which may be $\boldsymbol{\Gamma}$) is closed under countable unions and intersections. We fix a universal $\boldsymbol{\Gamma}$ set $U \subseteq \omega^\omega \times \omega^\omega$, so every real x codes a $\boldsymbol{\Gamma}$ set $U_x \subseteq \omega^\omega$. Let δ_0 be the supremum of those limit β such that $\{A : o(A) < \beta\}$ is closed under real quantification and is contained within $\boldsymbol{\Delta}$. Let $\boldsymbol{\Delta}_0 = \{A : o(A) < \delta_0\}$. Let $\delta = \delta(\boldsymbol{\Gamma}) =$ the supremum of the lengths of the $\boldsymbol{\Delta}$ prewellorderings. Suppose $\{A_\alpha\}_{\alpha<\delta^+}$ is a strictly increasing sequence of $\boldsymbol{\Gamma}$ sets. By thinning the sequence we may assume that for all $\alpha < \delta^+$ that $\bigcup_{\beta<\alpha} A_\beta \subsetneq A_\alpha$. Let $A = \bigcup_\alpha A_\alpha$. For $x \in A$ let $\phi(x) < \delta^+$ be the least ordinal α such that $x \in A_\alpha$. Let $\prec$ be the strict prewellordering defined by

$$x \prec y \longleftrightarrow x, y \in A \wedge \phi(x) < \phi(y).$$

Thus, $\prec$ has length δ^+.

We consider two cases, though the argument in each case is similar.

Case I. $\boldsymbol{\Gamma}$ is not closed under $\exists^{\omega^\omega}$.

By periodicity $\mathrm{pwo}(\exists^{\omega^\omega}\boldsymbol{\Gamma})$, and so by Lemma 2.21 $\exists^{\omega^\omega}\boldsymbol{\Gamma}$ is closed under wellordered unions. It follows that $\prec\, \in \exists^{\omega^\omega}\boldsymbol{\Gamma}$ since $x \prec y$ iff $\exists \alpha < \beta < \delta^+\ (x \in A_\alpha \wedge y \in A_\beta \wedge y \notin A_\alpha)$. We use here the fact that $\check{\boldsymbol{\Gamma}} \subseteq \exists^{\omega^\omega}\boldsymbol{\Gamma}$ as $\boldsymbol{\Gamma}$ is not closed under $\exists^{\omega^\omega}$. Let $C \subseteq (\omega^\omega)^3$ be defined by:

$$(x, y, z) \in C \longleftrightarrow \exists \alpha < \delta^+\ (U_x = A_\alpha \wedge y, z \in A \wedge \phi(y) = \alpha \wedge \phi(z) = \alpha + 1).$$

Applying the Coding Lemma to the $\exists^{\omega^\omega}\boldsymbol{\Gamma}$ relation $\prec$ gives an $\exists^{\omega^\omega}\boldsymbol{\Gamma}$ set $S \subseteq C$ such that for all $\alpha < \delta^+$ there is an $(x, y, z) \in S$ with $\phi(y) = \alpha$. From $\mathrm{pwo}(\boldsymbol{\Gamma})$ and the closure of $\boldsymbol{\Gamma}$ under $\vee$ the usual boundedness argument shows that if ψ is a regular $\boldsymbol{\Gamma}$ norm on a $\boldsymbol{\Gamma}$ complete set B, then ψ maps onto δ and every $\check{\boldsymbol{\Gamma}}$ subset of B is bounded in the norm. In particular, every $\check{\boldsymbol{\Gamma}}$ well-founded relation has length less than δ (otherwise the Coding Lemma gives an unbounded $\check{\boldsymbol{\Gamma}}$ subset of B). Also from $\mathrm{pwo}(\boldsymbol{\Gamma})$, every $\boldsymbol{\Gamma}$ set is a δ union of $\boldsymbol{\Delta}$ sets. It follows that every $\exists^{\omega^\omega}\boldsymbol{\Gamma}$ set is a δ union of $\exists^{\omega^\omega}\boldsymbol{\Delta} \subseteq \check{\boldsymbol{\Gamma}}$ sets. So write $S = \bigcup_{\beta<\delta} S_\beta$, where each $S_\beta \in \check{\boldsymbol{\Gamma}}$. For $\beta < \delta$ let $\leq_\beta$ be the prewellordering on S_β defined by

$$\begin{aligned}
&(x_1, y_1, z_1) \leq_\beta (x_2, y_2, z_2)\\
&\quad\longleftrightarrow (x_1, y_1, z_1), (x_2, y_2, z_2) \in S_\beta \wedge \phi(y_1) \leq \phi(y_2)\\
&\quad\longleftrightarrow (x_1, y_1, z_1), (x_2, y_2, z_2) \in S_\beta \wedge y_1 \in U_{x_2}\\
&\quad\longleftrightarrow (x_1, y_1, z_1), (x_2, y_2, z_2) \in S_\beta \wedge z_2 \notin U_{x_1}.
\end{aligned}$$

Thus, $\leq_\beta$ can be written as the intersection of $S_\beta \times S_\beta$ with a $\boldsymbol{\Gamma}$ set or with a $\check{\boldsymbol{\Gamma}}$ set. In particular, $\leq_\beta \in \check{\boldsymbol{\Gamma}}$, and has length less than δ. A similar computation shows the strict part $<_\beta$ of the prewellordering to be in $\check{\boldsymbol{\Gamma}}$ as well.

This however gives a one-to-one map of δ^+ into $\delta \times \delta$, a contradiction. Namely, given $\alpha < \delta^+$ let $\pi_0(\alpha)$ be the least ordinal $\beta < \delta$ such that there is an $(x, y, z) \in S_\beta$ with $\phi(y) = \alpha$. Let $\pi_1(\alpha)$ be the rank of any $(x, y, z) \in S_\beta$ with $\phi(y) = \alpha$ in the prewellordering $\leq_\beta$. It is easy to check that this is well-defined and that $\alpha \mapsto (\pi_0(\alpha), \pi_1(\alpha))$ is one-to-one.

Case II. $\boldsymbol{\Gamma}$ is closed under $\exists^{\omega^\omega}$.

In this case $\boldsymbol{\Gamma}$ is closed under real quantification, countable unions and intersections. Define C as in case I. If there is a $\boldsymbol{\Gamma}$ well-founded relation of length δ^+, then using the coding as in case I gives a $\boldsymbol{\Gamma}$ set S as in that case. We still have that every $\check{\boldsymbol{\Gamma}}$ well-founded relation has length less than δ, and we thus get a contradiction exactly as in case I. So suppose every $\boldsymbol{\Gamma}$ well-founded relation has length less than δ^+. From the Coding Lemma there are $\boldsymbol{\Gamma}$ well-founded relations of any length less than δ^+, so δ^+ is the supremum of the lengths of the $\boldsymbol{\Gamma}$ well-founded relations. From this, the Coding Lemma easily implies that δ^+ is regular. Consider the integer game where I plays out $w \in \omega^\omega$ and II plays out $(x, y, z) \in (\omega^\omega)^3$. II wins the run iff (where U' is universal for $\boldsymbol{\Gamma}$ subsets of $(\omega^\omega)^2$):

$$U'_w \text{ is well-founded } \longrightarrow ((x, y, z) \in C \wedge \phi(y) > |U'_w|),$$

where $|U'_w|$ denotes the rank of the relation U'_w. I cannot have a winning strategy, as this would give a $\boldsymbol{\Sigma}^1_1$ set of codes of $\boldsymbol{\Gamma}$ well-founded relations whose lengths were unbounded in δ^+, and from this we would get a $\boldsymbol{\Gamma}$ well-founded relation of length δ^+ (in fact there can be no $\boldsymbol{\Gamma}$ set of codes of $\boldsymbol{\Gamma}$ well-founded relations having lengths unbounded in δ^+). Let τ be a winning strategy for II. Define the relation

$$w_1 \ll w_2 \longleftrightarrow (U'_{w_1}, U'_{w_2} \text{ are well-founded}) \wedge y_2 \notin U_{x_1},$$

where $\tau(w_1) = (x_1, y_1, z_1)$ and $\tau(w_2) = (x_2, y_2, z_2)$. From the closure of $\boldsymbol{\Gamma}$ under quantifiers it follows easily that $\ll \in \check{\boldsymbol{\Gamma}}$, and from the regularity of δ^+ an easy argument shows that $\ll$ has length δ^+ [For $\alpha < \delta^+$ let $f(\alpha) < \delta^+$ be least such that for some w with U'_w well-founded and $|U'_w| = \alpha$ we have $f(\alpha) = \phi(y)$ where $\tau(w) = (x, y, z)$. Let $C \subseteq \delta^+$ be closed unbounded and closed under f. By a straightforward induction check that for $\alpha \in C$ and w with $|U'_w| = \alpha$, we have $|w|_{\ll} \geq \gamma$, where α is the γth element of C.] Thus we have produced a $\check{\boldsymbol{\Gamma}}$ well-founded relation of length δ^+, a contradiction.

We have shown that there is no strictly increasing sequence of $\boldsymbol{\Gamma}$ sets of length $\delta(\boldsymbol{\Gamma})^+$. The argument for decreasing sequences is similar in each case (we use now for C the set of all (x, y, z) such that x codes some A_α, $y \in A_\alpha - A_{\alpha+1}$, and z codes $A_{\alpha+1}$). ⊣

By a *limit Suslin cardinal* we mean a Suslin cardinal which is the supremum of the smaller Suslin cardinals. A limit Suslin cardinal is necessarily a limit cardinal. By a *successor Suslin cardinal* we mean a Suslin cardinal κ which is the least Suslin cardinal greater than some Suslin cardinal λ. κ may or may not be a successor cardinal in this case. From Theorem 3.1 it follows that every Suslin cardinal is either a limit Suslin cardinal or a successor Suslin cardinal.

3.6 Lemma. *Let κ be a Suslin cardinal and assume $S(\kappa)$ is closed under $\forall^{\omega^\omega}$. Then κ is a regular limit of Suslin cardinals and* scale$(S(\kappa))$.

Proof. In this case $S(\kappa)$ is closed under real quantification and thus also countable unions and intersections. So $\boldsymbol{\Delta} = \boldsymbol{\Delta}(S(\kappa))$ is closed under real quantification, countable unions and intersections. Thus, $S(\kappa)$ is at the base of a type IV hierarchy. Let $\delta = o(\boldsymbol{\Delta})$. Since $S(\kappa)$ is closed under $\wedge$, $\vee$, an argument using the Coding Lemma shows that δ is regular. [If δ were singular, then the Coding Lemma would give an $S \in \boldsymbol{\Delta}$ consisting of pairs (x, y) coding Lipschitz continuous function f_x, f_y with $f_x^{-1}(A) = f_y^{-1}(B)$, where A is a $S(\kappa)$ complete set and B is $\check{S}(\kappa)$ complete. So, (x, y) codes a $\boldsymbol{\Delta}$ set of some Wadge rank $|(x, y)| < \delta$. Also, $\{|(x, y)| : (x, y) \in S\}$ will be cofinal in δ. Let

$$\begin{aligned} D &= \{(x, y, z) : (x, y) \in S \wedge f_x(z) \in A\} \\ &= \{(x, y, z) : (x, y) \in S \wedge f_y(z) \in B\}. \end{aligned}$$

But then $D \in \boldsymbol{\Delta}$ yet every set in $\boldsymbol{\Delta}$ is Wadge reducible to D, a contradiction.]

We cannot have $\delta > \kappa$ as then there would be a $\boldsymbol{\Delta}$ prewellordering of length κ, and by the Coding Lemma every subset of κ could be coded in $\boldsymbol{\Delta}$, and so $S(\kappa)$ would be contained in $\boldsymbol{\Delta}$. So, $\delta \leq \kappa$. On the other hand, from Lemma 3.4 there is a κ strictly increasing sequence of $S(\kappa)$ sets. Note that $\boldsymbol{\Delta}$ is not closed under wellordered unions, since if it were the standard tree computation would show that $S(\kappa)$ is contained in $\boldsymbol{\Delta}$. Thus (cf. the discussion before Definition 2.19) either pwo$(S(\kappa))$ or pwo$(\check{S}(\kappa))$. From Theorem 3.5

(applied to either $S(\kappa)$ or $\check{S}(\kappa)$, whichever has the prewellordering property) we have $\kappa < \delta^+$, so $\kappa \leq \delta$. Thus, $\kappa = \delta$. In particular, κ is regular.

Let λ be the supremum of the Suslin cardinals which are less than κ. We show that $\lambda = \kappa$. Suppose $\lambda < \kappa$. From Lemma 3.4 there is a κ strictly increasing sequence of sets in $S(\lambda)$. [Note: λ is actually a Suslin cardinal by Theorem 3.1, but we do not need this here. Note that $S(\lambda)$ is properly contained in $\boldsymbol{\Delta}$ from the regularity of δ, even if λ is not a Suslin cardinal.] Within the projective hierarchy over $S(\lambda)$ we may find a non-selfdual $\boldsymbol{\Gamma}_0$ closed under $\exists^{\omega^\omega}$ and $\mathrm{pwo}(\boldsymbol{\Gamma}_0)$, and so by Lemma 2.21, $\boldsymbol{\Gamma}_0$ is closed under wellordered unions. Then $S(\kappa) \subseteq \boldsymbol{\Gamma}_0$, a contradiction (as $\boldsymbol{\Gamma}_0 \subseteq \boldsymbol{\Delta}$). Thus, κ is a limit Suslin cardinal.

We cannot have $\mathrm{pwo}(\check{S}(\kappa))$ as then $\check{S}(\kappa)$ would be closed under wellordered unions and then $S(\kappa) \subseteq \check{S}(\kappa)$, a contradiction. So, $\mathrm{pwo}(S(\kappa))$. Thus, $S(\kappa)$ is closed under wellordered unions. Hence, $S(\kappa) = \bigcup_\kappa \boldsymbol{\Delta}$. To see now $\mathrm{scale}(S(\kappa))$, let $A \in S(\kappa) - \check{S}(\kappa)$ and let T be a tree on $\omega \times \kappa$ with $A = p[T]$. For $x \in A$, let $\phi_0(x)$ be the least $\alpha < \kappa$ such that $x \in p[T \restriction \alpha]$. For $i > 0$ let

$$\phi_i(x) = \langle \phi_0(x), \ell_0^{\phi_0(x)}, \ldots, \ell_i^{\phi_0(x)}(x) \rangle,$$

where $\ell_i^\beta(x)$ is the ith coordinate of the left-most branch of $(T\restriction\beta)_x$. Here $\langle \beta, \alpha_0, \ldots, \alpha_i \rangle$ denotes the rank of the tuple $(\beta, \alpha_0, \ldots, \alpha_i)$ in lexicographic ordering on those tuples satisfying $\beta \geq \max\{\alpha_0, \ldots, \alpha_i\}$. It is easy to check that $\{\phi_i\}$ is a scale on A with all norms into κ. Moreover, each of the norms ϕ_i is an $S(\kappa)$-norm as the norm relations $\leq_i^*$, $<_i^*$ are easily expressible as κ unions of $\boldsymbol{\Delta}$ sets. ⊣

We consider first Suslin cardinals of uncountable cofinality. First we consider the successor Suslin cardinals.

3.7 Lemma. *Let κ be a successor Suslin cardinal with* $\mathrm{cf}(\kappa) > \omega$. *Let λ be the largest Suslin cardinal less than κ. Then $\kappa = \lambda^+$ and* $\mathrm{cf}(\lambda) = \omega$. *Furthermore, $S(\kappa)$ has the scale property and $S(\kappa) = \exists^{\omega^\omega} \check{S}(\lambda)$. Also, κ is regular.*

Proof. Let $A \in S(\kappa) - \check{S}(\kappa)$, and let $\{\phi_i\}$ be a regular scale on A with norms into κ. From Lemma 3.4, there is a κ strictly increasing sequence of λ-Suslin sets. We cannot have $\mathrm{pwo}(S(\lambda))$ as then $S(\lambda)$ would be closed under wellordered unions by Lemma 2.21, and so A would be in $S(\lambda)$. So, $\mathrm{pwo}(\check{S}(\lambda))$. From Theorem 3.5 applied to $\check{S}(\lambda)$ it follows that $\kappa < \delta(\check{S}(\lambda))^+$, and thus $\kappa \leq \delta(\check{S}(\lambda))$. Every $\boldsymbol{\Delta}(\check{S}(\lambda))$ prewellordering is in $S(\lambda)$ and so by the Kunen-Martin Theorem has length $< \lambda^+$. So, $\kappa \leq \lambda^+$ and thus $\kappa = \lambda^+$.

Since $\kappa \leq \delta(\check{S}(\lambda))$, there is an $S(\lambda)$ well-founded relation of length λ. From the Coding Lemma it follows that $S(\lambda)$ is closed under λ unions. Suppose that $\mathrm{cf}(\lambda) > \omega$. Then every $S(\lambda)$ set is a λ union of $\boldsymbol{\Delta}(S(\lambda))$ sets. Thus $S(\lambda) = \bigcup_\lambda \boldsymbol{\Delta}(S(\lambda))$. By Martin's argument (cf. Lemma 2.15) this gives $\mathrm{pwo}(S(\lambda))$, a contradiction. So, $\mathrm{cf}(\lambda) = \omega$. Since $\mathrm{pwo}(\check{S}(\lambda))$ we also have

$\mathrm{pwo}(\exists^{\omega^\omega}\check{S}(\lambda))$ and so from Lemma 2.21, $\exists^{\omega^\omega}\check{S}(\lambda)$ is closed under wellordered unions. Note that $S(\lambda)$ is not closed under $\forall^{\omega^\omega}$ as otherwise by Lemma 3.6 λ would be regular. It follows that $S(\lambda) \subseteq \exists^{\omega^\omega}\check{S}(\lambda)$. Every $S(\kappa)$ set is a wellordered union of $S(\lambda)$ sets, and thus $S(\kappa) \subseteq \exists^{\omega^\omega}\check{S}(\lambda)$. To show the other inclusion it suffices to show that $\check{S}(\lambda) \subseteq S(\kappa)$, and this is immediate by Wadge's Lemma. So, $S(\kappa) = \exists^{\omega^\omega}\check{S}(\lambda)$.

Since $\mathrm{pwo}(\check{S}(\lambda))$ and $S(\kappa) = \exists^{\omega^\omega}\check{S}(\lambda)$ we have $\mathrm{pwo}(S(\kappa))$. Thus, $S(\kappa)$ is closed under wellordered unions by Lemma 2.21. It follows that $S(\kappa) = \bigcup_\kappa \mathbf{\Delta}(S(\kappa))$. Since $\mathrm{cf}(\kappa) > \omega$, the argument at the end of Lemma 3.6 shows that every $S(\kappa)$ set admits a scale all of whose norm relations can be written as κ unions of $\mathbf{\Delta}(S(\kappa))$ sets. Thus, $\mathrm{scale}(S(\kappa))$.

Finally, from $\kappa = \delta(S(\lambda))$ and the Kunen-Martin Theorem it follows that κ is the supremum of the lengths of the $S(\lambda)$ well-founded relations. From Lemma 2.16 it follows that κ is regular. ⊣

Next we consider the limit Suslin cardinals of uncountable cofinality.

3.8 Lemma. *Suppose that κ is a limit Suslin cardinal with $\mathrm{cf}(\kappa) > \omega$. Then $\mathrm{scale}(S(\kappa))$. Furthermore, if $\mathbf{\Delta} = \bigcup_{\lambda<\kappa} S(\lambda)$ and $\mathbf{\Gamma}$ is the corresponding Steel pointclass, then $S(\kappa) = \exists^{\omega^\omega}\mathbf{\Gamma}$. Also, $\mathrm{scale}(\mathbf{\Gamma})$.*

Proof. Let $\mathbf{\Delta} = \bigcup_{\lambda<\kappa} S(\lambda)$. Thus $\mathbf{\Delta}$ is selfdual and closed under real quantification, countable unions and intersections (for countable unions and intersections we use $\mathrm{cf}(\kappa) > \omega$). Let $\delta = \delta(\mathbf{\Delta}) = o(\mathbf{\Delta})$. Let $\mathbf{\Gamma}$ be the corresponding Steel pointclass, that is, $\mathbf{\Delta} = \mathbf{\Delta}(\mathbf{\Gamma})$ and $\mathbf{\Gamma}$ is closed under $\forall^{\omega^\omega}$. Similar to an earlier argument, we cannot have $\kappa < \delta$ as then the Coding Lemma would compute $S(\kappa) \subseteq \mathbf{\Delta}$. So, $\delta \leq \kappa$. Suppose $\delta < \kappa$. From Lemma 3.4 there is a strictly increasing sequence $\{A_\alpha\}_{\alpha<\kappa}$ of $\mathbf{\Delta}$ sets of length κ. For each $\beta < \delta$ let $S_\beta \subseteq \kappa$ consist of those α such that $o(A_\alpha) = \beta$. If all the S_β had size $< \delta$, then since $\kappa = \bigcup_{\beta<\delta} S_\beta$, we would have a map from $\delta \times \delta$ onto κ, a contradiction. Fix β so that $|S_\beta| \geq \delta$. Thus we have a δ-length strictly increasing sequence of sets $\{B_\gamma\}_{\gamma<\delta}$ of Wadge degree $\leq \beta$. Within $\mathbf{\Delta}$ we can find a non-selfdual pointclass $\mathbf{\Gamma}_0$ closed under $\wedge$, $\vee$ and closed under wellordered unions and properly containing the sets of Wadge degree $\leq \beta$ (from Lemma 2.21). The prewellordering associated to the B_γ (i.e., $x \prec y \longleftrightarrow \exists \eta_1 < \eta_2\ (x \in B_{\eta_1} \wedge y \in B_{\eta_2} \wedge y \notin B_{\eta_1})$) is a $\mathbf{\Gamma}_0$ prewellordering of length δ, a contradiction (recall δ is the supremum of the $\mathbf{\Delta}$ well-founded relations). So, $\kappa = \delta$.

Recall also $\mathrm{pwo}(\mathbf{\Gamma})$ (cf. [37]). Thus $\mathrm{pwo}(\exists^{\omega^\omega}\mathbf{\Gamma})$, and by Lemma 2.21 $\exists^{\omega^\omega}\mathbf{\Gamma}$ is closed under wellordered unions. Since $\mathrm{cf}(\kappa) > \omega$, every $S(\kappa)$ set is a union of $\mathbf{\Delta}$ sets, and so $S(\kappa) \subseteq \exists^{\omega^\omega}\mathbf{\Gamma}$. Since $S(\kappa)$ is closed under $\exists^{\omega^\omega}$, it follows from Wadge's Lemma that either $S(\kappa) = \exists^{\omega^\omega}\mathbf{\Gamma}$ or $S(\kappa) = \check{\mathbf{\Gamma}}$. We claim the first possibility holds. To see this, let $A \in S(\kappa) - \check{S}(\kappa)$, and let $A = p[T]$ with T a tree on $\omega \times \kappa$. From Theorem 3.2, T is weakly homogeneous. Thus, there is a homogeneous tree T' on $\omega \times \kappa$ such that $x \in A \longleftrightarrow \exists y\ \langle x, y\rangle \in p[T']$ (here $x, y \mapsto \langle x, y\rangle$ denotes our coding function). Let $\mathbf{\Gamma}'$ denote the pointclass of sets which are projections of homogeneous trees on $\omega \times \kappa$. Thus, $S(\kappa) = \exists^{\omega^\omega}\mathbf{\Gamma}'$. From Lemma 3.3, $\mathbf{\Gamma}'$ is closed under $\forall^{\omega^\omega}$. If $\mathbf{\Gamma}$ is not closed under $\exists^{\omega^\omega}$, then the facts that $S(\kappa) \subseteq \exists^{\omega^\omega}\mathbf{\Gamma}$ and $S(\kappa) = \exists^{\omega^\omega}\mathbf{\Gamma}'$ where $\mathbf{\Gamma}'$ is closed under $\forall^{\omega^\omega}$ imply that $\mathbf{\Gamma} = \mathbf{\Gamma}'$ and $S(\kappa) = \exists^{\omega^\omega}\mathbf{\Gamma}$. If $\mathbf{\Gamma}$ is closed under real quantification, then $S(\kappa) \subseteq \exists^{\omega^\omega}\mathbf{\Gamma} = \mathbf{\Gamma}$ (and also $\mathbf{\Gamma} = \mathbf{\Gamma}'$) Thus in all cases $S(\kappa) = \exists^{\omega^\omega}\mathbf{\Gamma}$.

Since $\operatorname{pwo}(\mathbf{\Gamma})$ we also have $\operatorname{pwo}(S(\kappa))$, and so $S(\kappa)$ is closed under wellordered unions. Since $\operatorname{cf}(\kappa) > \omega$, the argument at the end of Lemma 3.6 shows that every $S(\kappa)$ sets admits a scale all of whose norm relations can be written as κ unions of $\mathbf{\Delta}$ sets, and thus are $S(\kappa)$ relations. Thus, $\operatorname{scale}(S(\kappa))$.

It remains to show $\operatorname{scale}(\mathbf{\Gamma})$. We use an argument similar to one of [35]. Let $A \in \mathbf{\Gamma}$. Let $U \subseteq (\omega^\omega)^2$ be universal $\mathbf{\Sigma}^1_1$. Define $B = \{y : U_y \subseteq A\}$. As $\check{\mathbf{\Gamma}}$ is closed under intersections with $\mathbf{\Sigma}^1_1$ sets (from [35, Theorem 2.1]), $B \in \mathbf{\Gamma}$. Let $B = p[T]$ where T is a tree on $\omega \times \kappa$. Let S be a tree on $(\omega)^3$ with $p[S] = \{(x, y) : U(y, x)\}$. Let V be the tree on $(\omega)^3 \times \kappa$ defined by:

$$(s, t, u, \vec{\alpha}) \in V \longleftrightarrow (s, t, u) \in S \wedge (t, \vec{\alpha}) \in T.$$

Clearly $A = p[V]$. We identify V with a tree V' on $\omega \times \kappa$ by ordering the triples $(a, b, \alpha) \in \omega \times \omega \times \kappa$ by reverse lexicographic order (i.e., order by α first). Let V'' be the slight modification of V' (using $\operatorname{cf}(\kappa) > \omega$) so that for $(s, \vec{\alpha}) \in V''$, $\alpha_0 \geq \max\{\alpha_1, \dots, \alpha_{\operatorname{lh}(s)}\}$. Let $\{\phi_i\}$ be the very good scale derived from V'', so each ϕ_i maps into κ. To show that $\leq^*_{\phi_i} \in \mathbf{\Gamma}$ (and similarly for $<^*_{\phi_i}$) it suffices to show that $\leq^*_{\phi_i}$ can be written as a $\mathbf{\Sigma}^1_1$-bounded κ-length union of $\mathbf{\Delta}$ sets (see the discussion after Definition 2.19). For $\alpha < \kappa$ let

$$C_\alpha = \{(x, y) : x \in A \wedge \phi_i(x) = \alpha \wedge \neg(y \in A \wedge \phi_i(y) < \alpha)\}.$$

Clearly $C_\alpha \in \mathbf{\Delta}$ (it is a Boolean combination of α-Suslin sets). Suppose $S \subseteq \omega^\omega \times \omega^\omega$ is $\mathbf{\Sigma}^1_1$ and for all $(x, y) \in S$, $x \leq^*_{\phi_i} y$. In particular, $x \in A$. Let $S' = \{x : \exists y\ (x, y) \in S\}$. Let y be such that $U_y = S'$. Then $y \in B$. Fix $\vec{\alpha} \in \kappa^\omega$ so that $(y, \vec{\alpha}) \in p[T]$. Let $\alpha' \geq \max\{\vec{\alpha}_i\}$. Then $S' \subseteq p[V' \restriction (\omega)^3 \times \alpha']$. So for some $\alpha'' < \kappa$, $S' \subseteq \{x : \phi_i(x) \leq \alpha''\}$. It follows that $S \subseteq C_{\alpha''}$. Thus, $\{\phi_i\}$ is a $\mathbf{\Gamma}$-scale on A. $\dashv$

3.2. The Next Suslin Cardinal

The results presented so far suffice to give the theory of the Suslin cardinals up to the least κ so that $S(\kappa)$ is closed under real quantification, that is, at the base of a type IV hierarchy (we will give the details below). However, at the base of a type IV hierarchy a new method is needed since we cannot propagate the scale property upwards by periodicity. Martin [24] developed a method for analyzing the next Suslin cardinal which works not just in this case, but in general. Although we only need this construction in the case where we are at the base of a type IV hierarchy, we present Martin's method in general. The idea is to describe the pointclass where the next scale gets constructed as those sets which are "Wadge reducible to a measure on κ". We will make this statement precise later.

3.9 Definition (Martin). Let $\mathcal{A} = \{A_\alpha\}_{\alpha<\kappa}$ be a sequence of sets $A_\alpha \subseteq \omega^\omega$, for some $\kappa \in \mathrm{On}$. Then $\bar{\mathcal{A}}$ is the collection of $A \subseteq \omega^\omega$ such that for all countable $S \subseteq \omega^\omega$ there is an $\alpha < \kappa$ such that $S \cap A = S \cap A_\alpha$.

For $\boldsymbol{\Gamma}$ a pointclass and $\kappa \in \mathrm{On}$ we let

$$\Lambda(\boldsymbol{\Gamma}, \kappa) = \bigcup\{\bar{\mathcal{A}} : \mathcal{A} \subseteq \boldsymbol{\Gamma} \wedge \|\mathcal{A}\| \leq \kappa\},$$

where $\|\mathcal{A}\|$ denotes the cardinality of $\mathcal{A}$.

Note that $\bar{\mathcal{A}}$ is the closure of $\{A_\alpha : \alpha < \kappa\}$ under the topology on $\mathcal{P}(\omega^\omega)$ with basic open sets of the form $N_f = \{A : \forall x \in \mathrm{dom}(f)\ (x \in A \longleftrightarrow f(x) = 1)\}$, where $f : S \to \{0,1\}$ and $S \subseteq \omega^\omega$ is countable.

Following [24] we next prove a few basic facts about Λ.

3.10 Lemma. *Let $\boldsymbol{\Gamma}$ be non-selfdual and closed under $\forall^{\omega^\omega}$ and assume* $\mathrm{pwo}(\boldsymbol{\Gamma})$. *If $\boldsymbol{\Delta}$ is not closed under real quantification, then assume also that $\exists^{\omega^\omega}\boldsymbol{\Gamma}$ has the scale property with norms into $\kappa \doteq \delta(\boldsymbol{\Gamma})$. Then there is an $\mathcal{A} = \{A_\alpha\}_{\alpha<\kappa}$ with each $A_\alpha \in \boldsymbol{\Delta}$ such that for every $A \in \Lambda(\boldsymbol{\Gamma}, \kappa)$ there is a $B \in \bar{\mathcal{A}}$ with $A \leq_w B$.*

Proof. First consider the case where $\boldsymbol{\Gamma}$ is closed under $\exists^{\omega^\omega}$ (so $\boldsymbol{\Gamma}$ is at the base of a type IV hierarchy), and so also countable unions and intersections. First we show in this case that for every $\mathcal{A} = \{A_\alpha\}_{\alpha<\kappa}$ with each $A_\alpha \in \boldsymbol{\Gamma}$ there is an $\mathcal{A}' = \{A'_\alpha\}_{\alpha<\kappa}$ with each $A_\alpha \in \boldsymbol{\Delta}$ such that $\bar{\mathcal{A}} \subseteq \bar{\mathcal{A}}'$. Let W be a $\boldsymbol{\Gamma}$ complete set and ϕ a $\boldsymbol{\Gamma}$ norm on W. Let $C = \{(x,y) : x \in W \wedge y \in A_{\phi(x)}\}$. By the Coding Lemma $C \in \boldsymbol{\Gamma}$. Let $C = \bigcup_{\beta<\kappa} C_\beta$ where $C_\beta \in \boldsymbol{\Delta}$. For $\alpha, \beta < \kappa$ let $A'_{\alpha,\beta} = \{y : \exists x\ (x \in W \wedge \phi(x) = \alpha \wedge (x,y) \in C_\beta)\}$. Then $A'_{\alpha,\beta} \in \boldsymbol{\Delta}$ and easily $\bar{\mathcal{A}} \subseteq \bar{\mathcal{A}}'$. Next we show that there is a "universal" $\mathcal{A} = \{A_\alpha\}_{\alpha<\kappa}$ with all $A_\alpha \in \boldsymbol{\Gamma}$. That is, for all $A' \in \Lambda(\boldsymbol{\Gamma}, \kappa)$, $A' \leq_w A$ for some $A \in \bar{\mathcal{A}}$. Let $U_1 \subseteq (\omega^\omega)^2$, $U_2 \subseteq (\omega^\omega)^3$ in $\boldsymbol{\Gamma}$ be universal for $\boldsymbol{\Gamma}\restriction\omega^\omega$, $\boldsymbol{\Gamma}\restriction(\omega^\omega)^2$ respectively. For $\alpha < \kappa$ let $A_\alpha \subseteq \omega^\omega \times \omega^\omega$ be defined by

$$(x,y) \in A_\alpha \longleftrightarrow \exists z, u\ [z \in W \wedge \phi(z) = \alpha \wedge U_2(x,z,u) \wedge U_1(u,y)].$$

Each A_α lies in $\boldsymbol{\Gamma}$. Given $\mathcal{A}' = \{A'_\alpha\}_{\alpha<\kappa}$ with each $A'_\alpha \in \boldsymbol{\Gamma}$, by the Coding Lemma there is an x_0 such that for all $\alpha < \kappa$, $A'_\alpha = (A_\alpha)_{x_0}$. Suppose $A' \in \bar{\mathcal{A}}'$. For each Turing degree d, let $\beta(d)$ be the least $\beta < \kappa$ so that A' and A'_β agree on all $x \in d$ (i.e., $A' \cap d = A'_\beta \cap d$). Define $A \subseteq \omega^\omega \times \omega^\omega$ by:

$$(x,y) \in A \longleftrightarrow \forall^*_\nu\, d\ [(x,y) \in A_{\beta(d)}].$$

Clearly $A' = A_{x_0}$. Also, we easily have $A \in \bar{\mathcal{A}}$. [If $S \subseteq \omega^\omega \times \omega^\omega$ is countable, then for every $(x,y) \in S$ let $d_{x,y}$ be a large enough degree so that for all $d \geq_T d_{x,y}$ we have $(x,y) \in A_{\beta(d)}$ iff $(x,y) \in A$. Then for any d above all the $d_{x,y}$ for $(x,y)\in S$ we have that A and $A_{\beta(d)}$ agree on all $(x,y)\in S$.] So $A'=A_{x_0}\leq_w A\in\bar{\mathcal{A}}$.

Suppose now that we are in the case where $\boldsymbol{\Delta}$ is closed under real quantification, but $\boldsymbol{\Gamma}$ is not closed under $\exists^{\omega^\omega}$ (so $\boldsymbol{\Gamma}$ is at the base of a type II or III hierarchy). Again in this case $\kappa=o(\boldsymbol{\Delta})$. Suppose $\mathcal{A}=\{A_\alpha\}_{\alpha<\kappa}$ with each $A_\alpha\in\exists^{\omega^\omega}\boldsymbol{\Gamma}$. From Lemma 2.22 there is an $\exists^{\omega^\omega}\boldsymbol{\Gamma}$ set W and an $\exists^{\omega^\omega}\boldsymbol{\Gamma}$ prewellordering of W of length κ with corresponding norm ϕ say, such that for each $\alpha<\kappa$, $W_\alpha=\{x\in W:\phi(x)=\alpha\}\in\boldsymbol{\Delta}$. Let C be defined as in the first case. Then $C\in\exists^{\omega^\omega}\boldsymbol{\Gamma}$. We can write $C=\bigcup_{\beta<\rho}C_\beta$ where each $C_\beta\in\boldsymbol{\Delta}$ and $\rho\leq\kappa$ (in fact $\rho=\mathrm{cf}(\kappa)$ from Lemma 2.22). For $\alpha<\kappa$, $\beta<\rho$ let as in the first case $A'_{\alpha,\beta}=\{y:\exists x\ (x\in W\wedge\phi(x)=\alpha\wedge(x,y)\in C_\beta)\}$. Then $A'_{\alpha,\beta}\in\boldsymbol{\Delta}$ and $\bar{\mathcal{A}}\subseteq\bar{\mathcal{A}}'$. It suffices then to construct a universal $\mathcal{A}=\{A_\alpha\}_{\alpha<\kappa}$ with all $A_\alpha\in\exists^{\omega^\omega}\boldsymbol{\Gamma}$. This is done as in the first case, using the W, ϕ just mentioned, universal sets U_1, U_2 for $\exists^{\omega^\omega}\boldsymbol{\Gamma}$, and the Coding Lemma with respect to the pointclass $\exists^{\omega^\omega}\boldsymbol{\Gamma}$.

Suppose finally that $\boldsymbol{\Delta}$ is not closed under real quantification. Inspecting the hierarchy analysis shows that $\boldsymbol{\Gamma}$ is not at the base of a projective hierarchy. [It cannot be at the base of a type I hierarchy because in that case the prewellordering property falls on the side closed under $\exists^{\omega^\omega}$, and it cannot be at the base of a type II, III, or IV hierarchy since then $\boldsymbol{\Delta}$ is closed under quantifiers.] It follows that $\boldsymbol{\Gamma}$ is closed under countable unions and intersections. From Lemma 2.13, a $\boldsymbol{\Gamma}$-norm on a $\boldsymbol{\Gamma}$-complete set has length κ, and every $\check{\boldsymbol{\Gamma}}$ well-founded relation has length less than κ. So, κ is the supremum of the lengths of the $\check{\boldsymbol{\Gamma}}$ well-founded relations, and from Lemma 2.16 it follows that κ is regular. We are assuming in this case that $\exists^{\omega^\omega}\boldsymbol{\Gamma}\subseteq S(\kappa)$. The reverse inclusion follows by the Coding Lemma, so $S(\kappa)=\exists^{\omega^\omega}\boldsymbol{\Gamma}$. The same argument as in the previous case also shows here that there is a single $\mathcal{A}=\{A_\alpha\}_{\alpha<\kappa}$ with all $A_\alpha\in\exists^{\omega^\omega}\boldsymbol{\Gamma}$ which is universal for all such sequences. It remains to show that for such a $\mathcal{A}$ we can find a $\mathcal{A}'=\{A'_\alpha\}_{\alpha<\kappa}$ with $A'_\alpha\in\boldsymbol{\Delta}$ such that $\bar{\mathcal{A}}\subseteq\bar{\mathcal{A}}'$. Let $\{\phi_n\}$ be a regular $\exists^{\omega^\omega}\boldsymbol{\Gamma}$-scale on a $\exists^{\omega^\omega}\boldsymbol{\Gamma}$-universal set U. Let $T\subseteq(\omega\times\kappa)^{<\omega}$ be the tree of the scale $\{\phi_n\}$. From the Coding Lemma there is an $\exists^{\omega^\omega}\boldsymbol{\Gamma}$ relation $R\subseteq\omega^\omega\times\omega^\omega$ with $\mathrm{dom}(R)=W$ (a $\boldsymbol{\Gamma}$-complete set with a $\boldsymbol{\Gamma}$-norm ϕ onto κ) and such that $R(x,y)$ implies $U_y=A_{\phi(x)}$. For $\alpha<\kappa$ let $\beta(\alpha)$ be the least reliable ordinal $>\alpha$ with respect to $\{\phi_n\}$ ($\beta(\alpha)<\kappa$ since κ is regular). As in the Becker-Kechris Theorem (see [3]), there is an ordinal game $G_\alpha(z)$ (defined uniformly from α and $z\in\omega^\omega$) in which I plays ordinals $<\beta(\alpha)$, II plays ordinals $<\kappa$, and the game is closed for II satisfying: for all $z\in\omega^\omega$, $z\in A_\alpha$ iff II has a winning strategy in $G_\alpha(z)$. For $\gamma<\kappa$, let $G_{\alpha,\gamma}(z)$ be the game played as $G_\alpha(z)$ except now II's ordinal moves are restricted to be $<\gamma$. Let $A_{\alpha,\gamma}$ be the set of z such that II has a winning strategy in $G_{\alpha,\gamma}(z)$. Thus, $A_\alpha=\bigcup_\gamma A_{\alpha,\gamma}$. Finally, for $\delta<\kappa$ let $A_{\alpha,\gamma,\delta}$ be the set of z such that I does not win the open game $G_{\alpha,\gamma}(z)$ with ordinal $<\delta$ (that is, it is not the case that the empty node has rank $<\delta$ in the rank analysis of the open game). Clearly for any countable $S\subseteq\omega^\omega$ and any α, there are γ, $\delta<\kappa$ such that $A_\alpha\cap S=A_{\alpha,\gamma,\delta}\cap S$. Also, each $A_{\alpha,\gamma,\delta}\in\boldsymbol{\Delta}$ since $\boldsymbol{\Delta}$ is closed under $<\kappa$ unions and intersections by Martin's argument (cf. the proof of Theorem 2.15). We use here the fact that the games $G_\alpha(z)$ are "uniformly" closed for II, that is, the set of all $(\vec{\eta}, z)$ such that $\vec{\eta}$ is a winning run for II in $G_\alpha(z)$ is closed in $\kappa^\omega \times \omega^\omega$. If we let the A'_α enumerate the $A_{\alpha,\gamma,\delta}$ then $\bar{\mathcal{A}} \subseteq \bar{\mathcal{A}}'$. ⊣

Note that if $\boldsymbol{\Delta}$ is any selfdual class closed under $\wedge$, and κ is any cardinal, then $\Lambda(\boldsymbol{\Delta}, \kappa)$ is closed under $\wedge$, $\vee$, and $\neg$. For example, to see closure under $\wedge$, given $\mathcal{A} = \{A_\alpha\}_{\alpha<\kappa}$, and $\mathcal{B} = \{B_\alpha\}_{\alpha<\kappa}$ and $A \in \bar{\mathcal{A}}$, $B \in \bar{\mathcal{B}}$, consider the sequence $\mathcal{C} = \{A_\alpha \cap B_\beta : \alpha, \beta < \kappa\}$. Easily $A \cap B \in \bar{\mathcal{C}}$. In particular, for any Levy class $\boldsymbol{\Gamma}$ and any κ, $\Lambda(\boldsymbol{\Delta}(\boldsymbol{\Gamma}), \kappa)$ is closed under $\wedge$, $\vee$, $\neg$. Thus as an immediate corollary to Lemma 3.10 we have the following.

3.11 Corollary. *Under the hypotheses of Lemma 3.10,* $\Lambda(\boldsymbol{\Gamma}, \kappa)$ *is closed under* $\wedge$, $\vee$, *and* $\neg$.

The next lemma shows that if $\boldsymbol{\Gamma}$ is closed under real quantification, then so will be Λ.

3.12 Lemma. *Let* $\boldsymbol{\Gamma}$ *be non-selfdual and closed under* $\forall^{\omega^\omega}$, $\exists^{\omega^\omega}$, *and assume* pwo$(\boldsymbol{\Gamma})$. *Let* $\kappa = \delta(\boldsymbol{\Delta}) = o(\boldsymbol{\Delta})$. *Then* $\Lambda(\boldsymbol{\Gamma}, \kappa)$ *is closed under* $\forall^{\omega^\omega}$, $\exists^{\omega^\omega}$.

Proof. Let $A \subseteq \omega^\omega \times \omega^\omega$ be in $\Lambda = \Lambda(\boldsymbol{\Gamma}, \kappa)$. Fix $\mathcal{A} = \{A_\alpha\}_{\alpha<\kappa}$ with each $A_\alpha \in \boldsymbol{\Delta}$ and with $A \in \bar{\mathcal{A}}$ (here each $A_\alpha \subseteq \omega^\omega \times \omega^\omega$). Define $x \in B \longleftrightarrow \exists y\ (x, y) \in A$. View every real z as coding a countable $s_z \subseteq \omega^\omega$ and a $f_z : s_z \to \{0, 1\}$. For d a Turing degree, let $\alpha_z(d)$ be the least ordinal $<\kappa$, if one exists, such that $\forall x \in s_z\ (f_z(x) = 1 \longleftrightarrow \exists y \leq d\ (x, y) \in A_\alpha)$. Let $C = \{z : \forall^*_\nu d\ \alpha_z(d) \text{ is defined}\}$. A straightforward computation using the closure of $\boldsymbol{\Gamma}$ shows that $C \in \boldsymbol{\Gamma}$. Let ϕ be the norm on C corresponding to the prewellordering $z_1 \preceq z_2 \longleftrightarrow \forall^*_\nu d\ (\alpha_{z_1}(d) \leq \alpha_{z_2}(d))$. A straightforward computation shows that the norm relation $\leq^*_\phi$, $<^*_\phi$ are in $\boldsymbol{\Gamma}$, so ϕ is a $\boldsymbol{\Gamma}$-norm on C. For example,

$$\begin{aligned} z_1 \leq^*_\phi z_2 \longleftrightarrow \forall^*_\nu d\ \exists \alpha < \kappa\ \forall \beta < \alpha & \\ & \big[\forall x \in s_{z_1} (f_{z_1}(x) = 1 \longleftrightarrow \exists y \leq d\ (x, y) \in A_\alpha) \\ & \wedge \neg \forall x \in s_{z_2} (f_{z_2}(x) = 1 \longleftrightarrow \exists y \leq d\ (x, y) \in A_\beta)\big]. \end{aligned}$$

This is in $\boldsymbol{\Gamma}$ using the closure of $\boldsymbol{\Delta}$ under $<\kappa$ intersections. Thus ϕ has length κ.

For $z \in C$, define $B_{\phi(z)}$ by:

$$x \in B_{\phi(z)} \longleftrightarrow \forall^*_\nu d\ \exists y \leq d\ (x, y) \in A_{\alpha_z(d)}.$$

A straightforward computation as above shows $B_{\phi(z)} \in \boldsymbol{\Delta}$. It suffices to show that $B \in \bar{\mathcal{B}}$ where $\mathcal{B} = \{B_{\phi(z)} : z \in C\}$. Let $s \subseteq \omega^\omega$ be countable. Define $f : s \to \{0, 1\}$ by $f(x) = 1$ iff $x \in B$. Let z code s, f. Since $A \in \bar{\mathcal{A}}$ it follows that $z \in C$, so $\phi(z)$ is defined. Let d_0 be a large enough degree so that for all $x \in s$ we have $x \in B$ iff $\exists y \leq d_0\ (x, y) \in A$. For any $d \geq d_0$ and $x \in s$ we then have:

$$\begin{aligned} x \in B &\longleftrightarrow \exists y \leq d\ (x, y) \in A \\ &\longleftrightarrow \exists y \leq d\ (x, y) \in A_{\alpha_z(d)}, \end{aligned}$$

which shows that for $x \in s$, $x \in B$ iff $x \in B_{\phi(z)}$. $\dashv$

We next make precise the statement that $\Lambda(\mathbf{\Gamma}, \kappa)$ is the pointclass of sets "Wadge reducible to a measure on κ". Let $\mathbf{\Gamma}$, κ be as in Lemma 3.10. From the Coding Lemma, every subset of κ may be coded within the pointclass $\exists^{\omega^\omega}\mathbf{\Gamma}$. To make this precise, let $U \subseteq \omega^\omega \times \omega^\omega$ be universal for $\exists^{\omega^\omega}\mathbf{\Gamma}$. Let ψ be an $\exists^{\omega^\omega}\mathbf{\Gamma}$-norm on a $\exists^{\omega^\omega}\mathbf{\Gamma}$ set W of length κ (the existence of ψ follows from Lemmas 2.21 and 2.22). For $z \in \omega^\omega$, define $B_z \subseteq \kappa$ by $\alpha \in B_z$ iff $\exists x \in W\ (\psi(x) = \alpha \wedge U(z, x))$. By the Coding Lemma, every subset of κ is of the form B_z for some z. We now define the code set C_μ of a measure μ on κ.

3.13 Definition. Let $\mathbf{\Gamma}$, κ be as in Lemma 3.10. For μ a measure on κ define $C_\mu = \{z : \mu(B_z) = 1\}$.

3.14 Lemma. *Let $\mathbf{\Gamma}$, κ be as in Lemma 3.10. Then $A \in \Lambda(\mathbf{\Gamma}, \kappa)$ iff there is a measure μ on κ such that $A \leq_w C_\mu$.*

Proof. First suppose μ is a measure on κ and we show $C_\mu \in \Lambda(\mathbf{\Gamma}, \kappa)$. For $\alpha < \kappa$ define $A_\alpha = \{z : \alpha \in B_z\}$. Clearly $A_\alpha \in \exists^{\omega^\omega}\mathbf{\Gamma}$. It suffices to observe that $C_\mu \in \bar{\mathcal{A}}$, where $\mathcal{A} = \{A_\alpha\}_{\alpha<\kappa}$ (using the fact that $\Lambda(\exists^{\omega^\omega}\mathbf{\Gamma}, \kappa) = \Lambda(\mathbf{\Gamma}, \kappa)$ from the proof of Lemma 3.10). Let $s \subseteq \omega^\omega$ be countable. Let $\alpha(s)$ be the least element of $\bigcap_{z\in s} B'_z$, where $B'_z = B_z$ if $z \in C_\mu$ and otherwise $B'_z = \kappa - B_z$. Then for all $z \in s$ we have $z \in C_\mu$ iff $z \in A_{\alpha(s)}$. So, $C_\mu \in \Lambda(\mathbf{\Gamma}, \kappa)$.

Suppose next that $A \in \Lambda(\mathbf{\Gamma}, \kappa)$. Fix $\mathcal{A} = \{A_\alpha\}_{\alpha<\kappa}$ with $A \in \bar{\mathcal{A}}$. For d a Turing degree let $f(d)$ be the least ordinal less than κ such that for all $z \in d$, $z \in A$ iff $z \in A_{f(d)}$. Define $\mu = f(\nu)$ where again ν is the Martin measure on the Turing degrees. Consider the relation $R(y, x) \longleftrightarrow (x \in W \wedge y \in A_{\psi(x)})$, where W, ψ are defined just before Definition 3.13. From the Coding Lemma, $R \in \exists^{\omega^\omega}\mathbf{\Gamma}$. From the *s-m-n* Theorem there is a continuous function $h : \omega^\omega \to \omega^\omega$ such that $U_{h(y)} = \{x \in W : y \in A_{\psi(x)}\}$, and thus $B_{h(y)} = \{\alpha : y \in A_\alpha\}$. We then have that for all $y \in \omega^\omega$, $y \in A$ iff $\forall^*_\nu d\ (y \in A_{f(d)})$ iff $\forall^*_\mu \alpha\ (y \in A_\alpha)$ iff $h(y) \in C_\mu$. So, $A \leq_w C_\mu$. $\dashv$

We next show that the pointclass $\Lambda(\mathbf{\Gamma}, \kappa)$ is where the next semi-scale is constructed. We first show the upper bound.

3.15 Lemma. *Let $\mathbf{\Gamma}$ be non-selfdual and closed under $\forall^{\omega^\omega}$, and assume* $\mathrm{pwo}(\mathbf{\Gamma})$. *Assume also $\exists^{\omega^\omega}\mathbf{\Gamma}$ has the scale property with norms into $\kappa \doteq \delta(\mathbf{\Gamma})$. Assume also that there is a Suslin cardinal greater than κ. Then every set in $\forall^{\omega^\omega}\check{\mathbf{\Gamma}}$ admits a semi-scale with each norm a $\Lambda(\mathbf{\Gamma}, \kappa)$-norm.*

Proof. In all cases we have $\mathrm{cf}(\kappa) > \omega$. [$\mathbf{\Gamma}$ cannot be at the base of a type I hierarchy as then prewellordering falls on the side closed under $\exists^{\omega^\omega}$. If $\mathbf{\Gamma}$ is at the base of a type II, III, or IV hierarchy, then $\mathrm{cf}(\kappa) = \mathrm{cf}(o(\mathbf{\Delta})) > \omega$. If $\mathbf{\Gamma}$ is not at the base of a hierarchy, then $\mathbf{\Gamma}$ is closed under countable unions and intersections, and it follows that $\delta(\mathbf{\Gamma})$ has uncountable cofinality.] If $A \in \exists^{\omega^\omega}\mathbf{\Gamma}$ then there is a tree T on $\omega \times \kappa$ with $A = p[T]$ by hypothesis. Since $\mathrm{cf}(\kappa) > \omega$ we may assume T has the property that if $(s, \vec{\alpha}) \in T$ with $\vec{\alpha} = (\alpha_0, \dots, \alpha_{n-1})$, then $\alpha_0 > \max\{\alpha_1, \dots, \alpha_{n-1}\}$. From Theorem 3.2, T is weakly homogeneous. The homogeneous tree construction then produces a tree T' with $p[T'] = \omega^\omega - A \doteq B$. Let $\{\phi_n\}$ be the norms on B this construction gives. For $x \in B$, $\phi_n(x)$ is of the form $[f_x]_\mu$ where f_x is the rank function on T_x and μ is a measure on κ^j for some j. Our property of T gives that $f_x(\vec{\alpha}) < \kappa$ for every $\vec{\alpha} \in T_x$. The usual homogeneous tree argument shows that $\{\phi_n\}$ is a semi-scale on B [if $\{x_m\} \to x$ and for each n the norms $\phi_n(x_m)$ converge, then we get a sequence of measure one sets (with respect to the homogeneity measures μ_s for T) A_s, for $s \in \omega^{<\omega}$, and an order-preserving map from $T_x \restriction \{A_s\}$ to the ordinals. From the weak homogeneity of T this gives that T_x is well-founded.] It suffices to show that the norm relations $\leq^*_{\phi_n}$, $<^*_{\phi_n}$ are in $\Lambda = \Lambda(\mathbf{\Gamma}, \kappa)$. We consider the case $\phi = \phi_0$ which is of the form $\phi(x) = [\alpha \mapsto f_x(\alpha)]_\mu$ (that is, $j = 1$). The general case is similar. For α, $\beta < \kappa$, let

$$A_{\alpha,\beta} = \{(x, y) : \exists \gamma \leq \beta\ (|\alpha|_{T_x} \leq \gamma \wedge \neg(|\alpha|_{T_y} \leq \gamma))\},$$

where $|\alpha|_{T_x} \leq \gamma$ means α is in the well-founded part of T_x and has rank $\leq \gamma$. We claim that each $A_{\alpha,\beta}$ is in $\mathbf{\Delta} = \mathbf{\Delta}(\mathbf{\Gamma})$. If $\mathbf{\Gamma}$ is closed under real quantification or $\mathbf{\Delta}$ is not closed under real quantification, then this follows from the fact that $\mathbf{\Delta}$ is closed under $<\kappa$ unions and intersections. The remaining case is when $\mathbf{\Gamma}$ is at the base of a type II or III hierarchy. Since $\mathbf{\Delta}$ is closed under real quantification, we may apply the Coding Lemma to a suitable non-selfdual pointclass $\mathbf{\Gamma}_0 \subseteq \mathbf{\Delta}$ closed under $\exists^{\omega^\omega}$ to code functions $h : (\alpha + 1)^{<\omega} \to \beta$. From this and the closure of $\mathbf{\Delta}$ under quantifiers we easily compute $A_{\alpha,\beta} \in \mathbf{\Delta}$.

Suppose $s = \{(x_n, y_n) : n \in \omega\}$ is a countable set of pairs. For each n such that $x_n \leq^*_\phi y$, let B_n be a μ measure one set such that for all $\alpha \in B_n$, $f_x(\alpha) \leq f_y(\alpha)$ (we allow here the possibility that $\vec{\alpha}$ is in the illfounded part of f_y). For other n, let B_n be such that for all $\vec{\alpha} \in B_n$ we have either α is in the illfounded part of T_x or else $f_y(\alpha) < f_x(\alpha)$. Fix $\alpha \in \bigcap_n B_n$. Let β be large enough so that for all n, if $f_{x_n}(\alpha)$ is defined, then $f_{x_n}(\alpha) < \beta$. Then for all n we have $x_n \leq^*_\phi y_n$ iff $(x_n, y_n) \in A_{\alpha,\beta}$. This shows $\leq^*_\phi \in \bar{\mathcal{A}}$ where $\mathcal{A} = \{A_{\alpha,\beta}\}$. A similar argument works for $<^*_\phi$. ⊣

3.16 Remark. The $\{\phi_n\}$ produced in the above argument is only a semi-scale, not necessarily a scale. We could get a scale by using the left-most branch of the tree T', but then we seem to loose the definability estimate $\leq^*_{\phi_n} \in \Lambda$. This was an oversight in the original arguments, and was pointed out by Grigor Sargsyan. We also thank John Steel for some helpful correspondences.

We next get the lower bound.

3.17 Lemma. *Let* $\mathbf{\Gamma}$, κ *be as in Lemma 3.15. Let* A *be* $\forall^{\omega^\omega}\check{\mathbf{\Gamma}}$*-complete. Then* A *does not admit a scale all of whose norm relations are Wadge reducible to some* $B \in \Lambda(\mathbf{\Gamma}, \kappa)$*.*

Proof. Fix $\mathcal{A} = \{A_\alpha\}_{\alpha<\kappa}$ with each $A_\alpha \in \mathbf{\Delta}$ and which is universal for $\Lambda = \Lambda(\mathbf{\Gamma}, \kappa)$ (i.e., every $A \in \Lambda$ is Wadge reducible to some $B \in \bar{\mathcal{A}}$). This is possible from Lemma 3.10. View every real r as coding a continuous function $r : (\omega)^2 \times (\omega^\omega)^3 \to \omega^\omega$, and every real z as coding a Lipschitz continuous function $w \mapsto z(w)$. Define $D \subseteq \omega^\omega \times \omega^\omega$ by:

$$\begin{aligned} D(x,y) \longleftrightarrow & \exists r \leq_T x \; \forall^*_\nu d \; \exists \alpha < \kappa \; \forall n, m \in \omega \\ & (y(n) = m \longleftrightarrow \exists z \leq_T d \; \forall w \leq_T d \; r(n,m,x,z(w),w) \in A_\alpha). \end{aligned}$$

From the closure of $\exists^{\omega^\omega}\mathbf{\Gamma}$ under wellordered unions it follows easily that $D \in \forall^{\omega^\omega}\exists^{\omega^\omega}\mathbf{\Gamma}$. Also, each section D_x of D is countable since it can be wellordered (for fixed $r \leq_T x$, the wellordering is induced by the map $y \to [f]_\nu$ where ν is the Martin measure on the degrees and $f(d)$ is the least $\alpha < \kappa$ satisfying the definition above). Consider $D^c \in \exists^{\omega^\omega}\forall^{\omega^\omega}\check{\mathbf{\Gamma}}$. Since we are assuming every $\forall^{\omega^\omega}\check{\mathbf{\Gamma}}$ set has a scale all of whose norms are reducible to some $B \in \Lambda$, a standard argument shows that D^c has a uniformizing function $f : \omega^\omega \to \omega^\omega$ such that the relation $R(n,m,x) \longleftrightarrow f(x)(n) = m$ is in $\Game\Lambda$. To see this, write $\neg D(x,y) \longleftrightarrow \exists u \; E(x,y,u)$ with $E \in \forall^{\omega^\omega}\check{\mathbf{\Gamma}}$. Let $\{\phi_n\}$ be an excellent scale on E with all norm relations $\leq^*_{\phi_n}$ Wadge reducible to $B \in \Lambda$ (in particular $\phi_n(x,y,u)$ determines $x\restriction(n+1)$, $y\restriction(n+1)$, $z\restriction(n+1)$). This is possible since Λ is closed under $\wedge$, $\vee$. Let f be the canonical uniformizing function for D^c from this scale (that is, for some u, $(x, f(x), u)$ has minimal ϕ_n norm for all n). Then $f(x)(n) = m$ iff I wins the game $G^{n,m}_x$ where I and II play out $z = \langle y, u\rangle$, $w = \langle y', u'\rangle$ respectively and I wins the run iff $y(n) = m$ and $(x,y,u) \leq^*_{\phi_n} (x,y',u')$. Fix now a $B \in \Lambda$ and a real r coding a continuous function so that for all n, m, x, z, w,

$$\begin{aligned} f(x)(n) = m & \longleftrightarrow \text{I wins the game } G^{n,m}_x \\ & \longleftrightarrow \Game\langle z, w\rangle \; r(n,m,x,z,w) \in B \\ & \longleftrightarrow \forall^*_\nu d \; \exists z \leq_T d \; \forall w \leq_T d \; r(n,m,x,z(w),w) \in B. \end{aligned}$$

Fix now $x \geq_T r$ and let $y = f(x)$, so $\neg D(x,y)$. On the other hand, for d a Turing degree let $\alpha(d) < \kappa$ be least such that B and $A_{\alpha(d)}$ agree on reals in d. Then for any n, m we have

$$y(n) = m \;\longleftrightarrow\; \forall^* d \; \exists z \leq_T d \; \forall w \leq_T d \; r(n,m,x,z(w),w) \in A_{\alpha(d)}.$$

Intersecting countably many cones gives that

$$\forall^*_\nu d \; \forall n, m \; (y(n) = m \longleftrightarrow \exists z \leq_T d \; \forall w \leq_T d \; r(n,m,x,z(w),w) \in A_{\alpha(d)}).$$

Since $r \leq_T x$, this shows that $D(x,y)$, a contradiction. $\dashv$

Lemmas 3.15 and 3.17 show that $\Lambda(\mathbf{\Gamma}, \kappa)$ is precisely where the norms relations for the next semi-scale are constructed. We record this in the following theorem.

3.18 Theorem (Martin). *Let $\mathbf{\Gamma}$ be non-selfdual and closed under $\forall^{\omega^\omega}$, and assume* $\mathrm{pwo}(\mathbf{\Gamma})$. *Assume also $\exists^{\omega^\omega}\mathbf{\Gamma}$ has the scale property with norms into $\kappa \doteq \delta(\mathbf{\Gamma})$. Assume also that there is a Suslin cardinal greater than κ. Then every $\forall^{\omega^\omega}\check{\mathbf{\Gamma}}$ set admits a semi-scale all of whose norm relations lie in the pointclass $\Lambda = \Lambda(\mathbf{\Gamma}, \kappa)$. Furthermore, there is no scale on a $\forall^{\omega^\omega}\check{\mathbf{\Gamma}}$ complete set all of whose norm relations are Wadge reducible to some $B \in \Lambda$.*

In the case where $\mathbf{\Gamma}$ is closed under quantifiers, and hence so is Λ, the last sentence of the previous theorem is equivalent to saying that there is no semi-scale on a $\check{\mathbf{\Gamma}}$ complete set all of whose norm relations are Wadge reducible to some $B \in \Lambda$ (since a semi-scale can be converted to a scale within the next projective hierarchy). It follows that $\mathrm{cf}(o(\Lambda)) = \omega$. In fact, we can say a bit more in this case.

3.19 Lemma. *Let $\mathbf{\Gamma}$ be non-selfdual, closed under real quantification, and* $\mathrm{scale}(\mathbf{\Gamma})$. *Assume there is a Suslin cardinal greater than $\kappa = o(\mathbf{\Gamma})$. Then $\lambda \doteq o(\Lambda)$ (where $\Lambda = \Lambda(\mathbf{\Gamma}, \kappa)$) is the least Suslin cardinal greater than κ. Furthermore, every set in Λ is λ-Suslin.*

Proof. Recall in this case that Λ is a selfdual class closed under real quantification. If $A \in \check{\mathbf{\Gamma}}$ and $\{\phi_n\}$ is the semi-scale on A as in Lemma 3.15 (i.e., from the homogeneous tree construction) then each norm relation $\leq_n^*$ is in Λ and so has length less than $\delta(\Lambda) = o(\Lambda)$. Thus, A is λ-Suslin. On the other hand, if A were λ'-Suslin where $\lambda' < \lambda$, then from the Coding Lemma and the closure of Λ under real quantifiers a straightforward computation shows that for some $B \in \Lambda$, the scale corresponding to the λ' tree has norm relations $\leq_n^*$ Wadge reducible to B for all n. This contradicts Lemma 3.17. [Since $\delta(\mathbf{\Delta}) = o(\mathbf{\Delta})$ we can find a non-selfdual $\mathbf{\Gamma}_0 \subseteq \mathbf{\Delta}$ closed under $\exists^{\omega^\omega}$, $\wedge$, $\vee$, with $\mathrm{pwo}(\mathbf{\Gamma}_0)$ and such that there is a $\mathbf{\Gamma}_0$ prewellordering of length λ'. Then each $\leq_n^*$ is in $\Sigma_2(\mathbf{\Gamma}_0)$.] Thus, λ is the next Suslin cardinal after κ.

Suppose now that $B \in \Lambda$. Let $A \in \check{\mathbf{\Gamma}} - \mathbf{\Gamma}$, and let T be the tree of the semi-scale $\{\phi_n\}$ from Lemma 3.15. Let $\{\psi_n\}$ be the scale on A corresponding to T (we do not know that the norm relations $\leq_{\psi_n}^*$ are in Λ). Let $\mathbf{\Gamma}_0 \subseteq \Lambda$ be a non-selfdual pointclass containing B and $\omega^\omega - B$. Let $\mathbf{\Gamma}_1 \subseteq \Lambda$ be non-selfdual, closed under $\exists^{\omega^\omega}$, $\mathrm{pwo}(\mathbf{\Gamma}_1)$, and $\mathbf{\Gamma}_1$ properly contains $\mathbf{\Gamma}_0$. Let $\lambda_1 < \lambda$ be greater than the supremum of the lengths of the $\mathbf{\Gamma}_1$ prewellorders. Fix n so that ψ_n has length $> \lambda_1$ (by the previous paragraph). For α less than the length of ψ_n, let $A_\alpha = \{x \in A : \psi_n(x) \leq \alpha\}$. If all the A_α are in $\mathbf{\Gamma}_0$, then from Lemma 2.21 we would have a $\mathbf{\Gamma}_1$ prewellordering of length $\geq \lambda_1$, a contradiction. Fix α so that $A_\alpha \notin \mathbf{\Gamma}_0$. Then $B \leq_w A_\alpha$. The scale $\{\psi_n\}$ restricted to A_α is a scale on A_α with all the norm mapping into λ. So, A_α is λ-Suslin. Since $B \leq_w A_\alpha$, B also admits such a λ-scale. $\dashv$

3.3. More on Λ in the Type IV Case

In the case where $\boldsymbol{\Gamma}$ is closed under real quantification (the type IV case) we can say more about Λ. We will need these extra facts for the scale analysis to follow. However, these results are also of independent interest. These results were obtained after the oversight mentioned in Remark 3.16, and allow us to recover the full scale analysis except for the scaled pointclasses immediately after a type IV pointclass $\boldsymbol{\Gamma}$ (we state these results explicitly in the next section). We again thank Steel for some helpful correspondences.

Throughout this section $\boldsymbol{\Gamma}$ will denote a Suslin class $S(\kappa)$ which is closed under real quantification. We assume κ is not the largest Suslin cardinal. We let $\Lambda = \Lambda(\boldsymbol{\Gamma}, \kappa)$ be the corresponding Martin class. We let $\lambda = o(\Lambda) = \delta(\Lambda)$. We showed in Lemma 3.19 that λ is the next Suslin cardinal after κ. Also from that Lemma, $\Lambda \subseteq S(\lambda)$.

We let $\boldsymbol{\Sigma}_0 = \bigcup_\omega \Lambda$ denote the pointclass of countable unions of sets from Λ. Let $\boldsymbol{\Pi}_0$ denote the dual class to $\boldsymbol{\Sigma}_0$, and define $\boldsymbol{\Sigma}_1 = \exists^{\omega^\omega} \boldsymbol{\Pi}_0$, etc., as usual.

3.20 Lemma. $S(\lambda) = \boldsymbol{\Sigma}_1$.

Proof. Since $S(\lambda)$ contains Λ and is closed under countable unions, intersections, and $\exists^{\omega^\omega}$, it follows that $\boldsymbol{\Sigma}_1 \subseteq S(\lambda)$. Since there are clearly $\boldsymbol{\Sigma}_1$ prewellorderings of length λ, it follows from the Coding Lemma that every tree on $\omega \times \lambda$ can be coded in the pointclass $\boldsymbol{\Sigma}_1$. It follows easily that $S(\lambda) \subseteq \boldsymbol{\Sigma}_1$. ⊣

3.21 Lemma. pwo$(\boldsymbol{\Sigma}_0)$, pwo$(\boldsymbol{\Pi}_1)$, *and* $\delta_1 \doteq \delta(\boldsymbol{\Pi}_1) = \lambda^+$. *Also,* λ^+ *is regular.*

Proof. pwo$(\boldsymbol{\Sigma}_0)$ follows easily from $\boldsymbol{\Sigma}_0 = \bigcup_\omega \Lambda$ [if $A \in \boldsymbol{\Sigma}_0$, say $A = \bigcup_n A_n$ where $A_n \in \Lambda$, the norm on A given by $\phi(x) = \mu n\ (x \in A_n)$ is a $\boldsymbol{\Sigma}_0$-norm]. By periodicity we also have pwo$(\boldsymbol{\Pi}_1)$. Also, $\boldsymbol{\Pi}_1$ is closed under countable unions, intersections, and $\forall^{\omega^\omega}$. From Lemma 2.13 we have that δ_1 is the supremum of the lengths of the $\boldsymbol{\Sigma}_1$ wellfounded relations, and from the Coding Lemma it then follows that δ_1 is regular. Every $\boldsymbol{\Sigma}_1$ wellfounded relation has length $< \lambda^+$ by the Kunen-Martin Theorem. Since there are clearly $\boldsymbol{\Sigma}_1$ wellfounded relations of length greater than λ, we have $\delta_1 = \lambda^+$. ⊣

The next says, roughly, that the Martin class of the Martin class is still the Martin class.

3.22 Lemma. *Let* $B \in \Lambda$, $\rho < \lambda$, *and let* $\mathcal{A} = \{A_\alpha\}_{\alpha<\rho}$ *be a sequence where each* $A_\alpha \leq_w B$. *Then* $\bar{\mathcal{A}} \subseteq \Lambda$.

Proof. More generally, for ρ_0, $\rho_1 < \lambda$, let Λ_{ρ_0,ρ_1} be the pointclass of all sets in some $\bar{\mathcal{A}}$ where $\mathcal{A} = \{A_\alpha\}_{\alpha<\rho_0}$ and for each α we have $|A_\alpha|_w < \rho_1$. If the lemma fails, then for some ρ_0, $\rho_1 < \lambda$ we have $\boldsymbol{\Sigma}_0 \subseteq \Lambda_{\rho_0,\rho_1}$. We first show by following the proof of Lemma 3.12 that if $\boldsymbol{\Pi}_n \subseteq \Lambda_{\rho_0,\rho_1}$, then by increasing ρ_0, ρ_1 to ρ_0', $\rho_1' < \lambda$ we have $\boldsymbol{\Sigma}_{n+1} \subseteq \Lambda_{\rho_0',\rho_1'}$. Suppose $A(x) \longleftrightarrow \exists y\ B(x, y)$, where $B \in \mathbf{\Pi}_n \subseteq \Lambda_{\rho_0,\rho_1}$. Let $\mathcal{B} = \{B_\alpha\}_{\alpha<\rho_0}$ be such that $B \in \bar{\mathcal{B}}$, where each $|B_\alpha|_w < \rho_1$. View every real z as coding a countable set $s_z \subseteq \omega^\omega$ and a function $f_z : s_z \to \{0,1\}$. Define

$$z \in C \longleftrightarrow \forall^* d\ \exists \alpha < \rho_0\ \forall x \in s_z\ (f_z(x) = 1 \longleftrightarrow \exists y \leq_T d\ B_\alpha(x,y)).$$

Let $\alpha_z(d)$ be the least ordinal $\alpha < \rho_0$ in the above definition, if one exists. From the closure properties of Λ and the Coding Lemma it follows easily that $C \in \Lambda$. Define the prewellordering $\prec$ on C by:

$$z_1 \prec z_2 \longleftrightarrow \forall^* d\ (\alpha_{z_1}(d) < \alpha_{z_2}(d)).$$

Easily, $\prec$ is also in Λ. Let $\rho_0' = |\prec|$. For $\alpha < \rho_0'$, say $\alpha = |z|_\prec$ with $z \in C$, define:

$$x \in A'_\alpha \longleftrightarrow \forall^* d\ \exists y \leq_T d\ B_{\alpha_z(d)}(x,y)\,.$$

There is a bound ρ_1' on the Wadge degrees of the A'_α (all the A'_α lie in the projective hierarchy over a code set for the sequence of B_α). As in Lemma 3.12 we have that $A \in \bar{\mathcal{A}}'$, where $\mathcal{A} = \{A'_\alpha\}_{\alpha<\rho_0'}$.

So, by increasing ρ_0, ρ_1 we may assume that $\mathbf{\Sigma}_2 \subseteq \Lambda_{\rho_0,\rho_1}$. Fix $\mathcal{A} = \{A_\alpha\}_{\alpha<\rho_0}$ such that $\bar{\mathcal{A}}$ contains a complete $\mathbf{\Sigma}_2$ set. We now proceed as in Lemma 3.17. Define $D \subseteq \omega^\omega \times \omega^\omega$ by:

$$\begin{aligned} D(x,y) \longleftrightarrow\ & \exists \tau \leq_T x\ \forall^* d\ \exists \alpha < \rho_0\ \forall m,n \in \omega \\ & (y(m) = n \longleftrightarrow \exists z \leq_T d\ \tau(x,z,n,m) \in A_\alpha), \end{aligned}$$

where we regard each real τ as coding a continuous function from $(\omega^\omega)^2 \times (\omega)^2 \to \omega^\omega$. Clearly $D \in \Lambda$ and all sections of D are countable. So, $\neg D$ is λ-Suslin and has a (total) uniformizing function f. Since the tree on $\omega \times \lambda$ projecting to $\neg D$ can be coded in the pointclass $\mathbf{\Sigma}_0$ (from the Coding Lemma), an easy computation shows the graph of f to be $\mathbf{\Sigma}_2$. Thus, there is a continuous function τ such that for all x we have:

$$f(x)(n) = m \longleftrightarrow \exists z\ \tau(x,z,n,m) \in A,$$

where $A \in \bar{\mathcal{A}}$. Let $x \geq_T \tau$. Then $D(x, f(x))$, a contradiction. $\dashv$

We say an ordinal δ is *closed under ultrapowers* if for every $\rho < \delta$ and measure μ on some $\eta < \delta$ we have $j_\mu(\rho) < \delta$. If $\mathrm{cf}(\delta) = \omega$, this is equivalent to saying that $j_\mu(\delta) = \delta$ for all measures μ on δ.

3.23 Lemma. *λ is closed under ultrapowers.*

Proof. Let μ be a measure on $\alpha < \lambda$, and let $\beta < \lambda$. Let $\prec$ be a prewellordering of length $\gamma > \max\{\alpha,\beta\}$ with $\prec$ in a pointclass $\mathbf{\Gamma}_0 \subseteq \Lambda$ which is non-selfdual, and closed under $\wedge$, $\vee$, $\exists^{\omega^\omega}$. Fix a universal set U for $\mathbf{\Gamma}_0$, and use U via the Coding Lemma to code subsets of γ. Define $\mathcal{A} = \{A_\alpha\}_{\alpha<\gamma}$ by:

$$x \in A_\alpha \longleftrightarrow \exists y\ (|y|_\prec = \alpha \wedge U(x,y)).$$

As in Lemma 3.14, the code set C_μ of the measure μ in $\bar{\mathcal{A}}$, and hence in Λ from the previous lemma. From this and the Coding Lemma it follows that the prewellordering corresponding to $j_\mu(\beta)$ lies in Λ, and so has length $<\lambda$. $\dashv$

3.24 Lemma. *δ_1 is closed under ultrapowers.*

Proof. This follows immediately from the previous lemma and the fact that $\delta_1 = \lambda^+$. That is, any measure μ on $\alpha < \delta_1$ is equivalent to a measure μ' on λ, and any $\beta < \delta_1$ is in bijection with λ. So, $j_\mu(\beta)$ has the same cardinality as $j_{\mu'}(\lambda) = \lambda$. $\dashv$

3.25 Lemma. *δ_1 is a Suslin cardinal and $S(\delta_1) = \boldsymbol{\Sigma}_2$.*

Proof. Let A be a complete $\boldsymbol{\Sigma}_1$ set, and write $A = p[T]$ where T is a tree on $\omega \times \lambda$. T is weakly homogeneous, and the homogeneous tree construction gives a tree T' with $p[T'] = B \doteq \omega^\omega - A$. Also. the ordinals in T' are bounded by an ordinal of the form $j_\mu(\beta)$ where $\beta < \lambda^+$ and μ is one of the homogeneity measures on λ. From Lemma 3.24 we have that T' is a tree on $\omega \times \delta_1$.

Hence, δ_1 is a Suslin cardinal and $\boldsymbol{\Pi}_1 \subseteq S(\delta_1)$. Since $S(\delta_1)$ is closed under $\exists^{\omega^\omega}$, we also have $\boldsymbol{\Sigma}_2 \subseteq S(\delta_1)$. From the Coding Lemma and $\mathrm{pwo}(\boldsymbol{\Pi}_1)$ (which gives $\boldsymbol{\Pi}_1$ prewellorderings of length δ_1) it follows that $S(\delta_1) \subseteq \boldsymbol{\Sigma}_2$. $\dashv$

3.26 Lemma. $\mathrm{scale}(\boldsymbol{\Sigma}_2)$ *with norms into δ_1.*

Proof. This follows from Lemma 3.7 since δ_1 is a regular successor Suslin cardinal. $\dashv$

We show one more result concerning measures on λ (which we do not need for the main result).

3.27 Lemma. *$\boldsymbol{\Delta}_1$, $\boldsymbol{\Sigma}_1$, $\boldsymbol{\Pi}_1$ are closed under measure quantification for measures on λ. That is, if μ is a measure on λ and $\{A_\alpha\}_{\alpha<\lambda}$ is a sequence of sets in $\boldsymbol{\Delta}_1$ (or $\boldsymbol{\Sigma}_1$,* etc.*), then $A \in \boldsymbol{\Delta}_1$ where $A(x) \longleftrightarrow \forall^*_\mu \alpha\ (x \in A_\alpha)$.*

Proof. Consider first the case of $\boldsymbol{\Delta}_1$, Since $\mathrm{cf}(\lambda) = \omega$, we may assume μ is a measure on $\rho < \lambda$, and $\{A_\alpha\}_{\alpha<\rho}$ is a $<\lambda$ sequence of $\boldsymbol{\Delta}_1$ sets. Let $A(x) \longleftrightarrow \forall^*_\mu \alpha\ (x \in A_\alpha)$. It suffices to show that $A \in \boldsymbol{\Sigma}_1$. Let $\prec$ be a prewellordering in Λ of length greater than ρ. Let $\boldsymbol{\Gamma}_0 \subseteq \Lambda$ be non-selfdual, closed under $\wedge$, $\vee$, $\exists^{\omega^\omega}$, and such that $C_\mu \in \boldsymbol{\Delta}(\boldsymbol{\Gamma}_0)$, where C_μ denotes the code set of μ with respect to the prewellordering $\prec$. Recall this means the following. Let $U \subseteq \omega^\omega \times \omega^\omega$ be universal for $\boldsymbol{\Gamma}_0$. We view every real x as coding a subset B_x of ρ by $\alpha \in B_x \longleftrightarrow \exists y\ (|y|_\prec = \alpha \wedge U(x, y))$. Then there is a $C \in \boldsymbol{\Delta}(\boldsymbol{\Gamma}_0)$ such that $C(z) \longleftrightarrow \mu(B_z) = 1$.

We have:

$$A(x) \longleftrightarrow \exists z\ (C(z) \wedge \forall \alpha \in B_z\ (x \in A_\alpha)).$$

It suffices to show that $D \in \boldsymbol{\Sigma}_1$ where $D(x, z) \longleftrightarrow \forall \alpha \in B_z\ (x \in A_\alpha)$. From Lemma 2.15, $\boldsymbol{\Delta}_1$ is closed under $<\delta_1$ length unions and intersections. So, it suffice to fix $\alpha < \rho$ and show that $D_\alpha \in \boldsymbol{\Delta}_1$, where:

$$D_\alpha(x, z) \longleftrightarrow (\alpha \notin B_z \vee x \in A_\alpha).$$

But, $\{z : \alpha \in B_z\} \in \boldsymbol{\Gamma}_0$ and $A_\alpha \in \boldsymbol{\Delta}_1$, so clearly $D_\alpha \in \boldsymbol{\Delta}_1$.

For the case of $\boldsymbol{\Sigma}_1$, the argument is similar, but we now need the fact that $\boldsymbol{\Sigma}_1$ is closed under $<\lambda$ intersections. This follows from the fact that $\boldsymbol{\Sigma}_1 = \exists^{\omega^\omega} \boldsymbol{\Pi}_0$ and the Coding Lemma. Briefly, let $\prec$ and $\boldsymbol{\Gamma}_0$ be as before. From the Coding Lemma there is a $\boldsymbol{\Gamma}_0$ relation $R \subseteq \omega^\omega \times \omega^\omega$ with $\mathrm{dom}(R) = \mathrm{dom}(\prec)$ and such that for all $(x, y) \in \mathrm{dom}(R)$, y is a $\boldsymbol{\Pi}_0$ code for a set B_y in $\omega^\omega \times \omega^\omega$ projecting to $A_{|x|_\prec}$. Let $\prec'$ be the relation on R given by $(x_1, y_1) \prec' (x_2, y_2)$ iff $(x_1 \prec x_2)$. If $w \in \bigcap_{\alpha<\rho} A_\alpha$, then by the Coding Lemma applied to $\prec'$, there is a $S \subseteq (\omega^\omega)^3$ in $\boldsymbol{\Gamma}_0$ such that (1) $(x, y, z) \in S \to (x, y) \in R$, (2) for every $\alpha < \rho$ there is an (x, y, z) in S with $|x|_\prec = \alpha$, and (3) for all (x, y, z) in S we have $B_y(w, z)$. It follows that

$$\begin{aligned} w \in \textstyle\bigcap_{\alpha<\rho} A_\alpha \longleftrightarrow\ & \exists S \in \boldsymbol{\Gamma}_0\ (S \text{ satisfies (1) and (2)} \\ & \wedge \forall (x, y, z) \in S \to B_y(w, z)) \end{aligned}$$

which shows that $\bigcap_{\alpha<\rho} A_\alpha$ is $\boldsymbol{\Sigma}_1$. ⊣

3.4. The Classification of the Suslin Cardinals

We are now ready to classify the Suslin cardinals and scale property assuming AD. This is the content of the next theorem. The reader should recall the definition of the Steel pointclass from Remark 2.20.

3.28 Theorem. *Let κ be a limit of Suslin cardinals, and suppose there is a Suslin cardinal greater than κ. Then κ is a Suslin cardinal and one of the following cases applies.*

Case I. $\mathrm{cf}(\kappa) = \omega$.

Let $\boldsymbol{\Sigma}_0 = \bigcup_\omega S_{<\kappa}$, where $S_{<\kappa} = \bigcup_{\rho<\kappa} S(\rho)$. Define $\boldsymbol{\Pi}_0 = \check{\boldsymbol{\Sigma}}_0$, and for $i > 0$, define as usual $\boldsymbol{\Sigma}_i = \exists^{\omega^\omega} \boldsymbol{\Pi}_{i-1}$ and $\boldsymbol{\Pi}_i = \forall^{\omega^\omega} \boldsymbol{\Sigma}_{i-1}$. Then $\boldsymbol{\Sigma}_0$ has the scale property with norms into κ. Also, $S(\kappa) = \boldsymbol{\Sigma}_1$. Let $\delta_{2i+1} = \delta(\boldsymbol{\Pi}_{2i+1})$. Then for all i, $\mathrm{scale}(\boldsymbol{\Pi}_{2i+1})$ and $\mathrm{scale}(\boldsymbol{\Sigma}_{2i+2})$ with scales into δ_{2i+1}. δ_{2i+1} is a Suslin cardinal and $S(\delta_{2i+1}) = \boldsymbol{\Sigma}_{2i+2}$. Also, $\delta_{2i+1} = (\lambda_{2i+1})^+$, where λ_{2i+1} is a Suslin cardinal of cofinality ω, and $\lambda_1 = \kappa$. $S(\lambda_{2i+1}) = \boldsymbol{\Sigma}_{2i+1}$. The sequence δ_1, λ_3, $\delta_3, \dots$ enumerates the first ω Suslin cardinals greater than κ.

Case II. $\mathrm{cf}(\kappa) > \omega$ *and the Steel pointclass $\boldsymbol{\Gamma}_0$ is not closed under $\exists^{\omega^\omega}$.*

Let $\boldsymbol{\Sigma}_0 = \exists^{\omega^\omega} \boldsymbol{\Gamma}_0$, $\boldsymbol{\Pi}_0 = \check{\boldsymbol{\Sigma}}_0$, and for $i > 0$ define the $\boldsymbol{\Sigma}_i$, $\boldsymbol{\Pi}_i$ as usual. Then $\mathrm{scale}(\boldsymbol{\Gamma}_0)$ and $\mathrm{scale}(\boldsymbol{\Sigma}_0)$ with norms into κ. Let $\delta_{2i+1} = \delta(\boldsymbol{\Pi}_{2i+1})$. Then for *all i,* $\mathrm{scale}(\boldsymbol{\Pi}_{2i+1})$ *and* $\mathrm{scale}(\boldsymbol{\Sigma}_{2i+2})$ *with scales into* δ_{2i+1}*.* δ_{2i+1} *is a Suslin cardinal and* $S(\delta_{2i+1}) = \boldsymbol{\Sigma}_{2i+2}$*. Also,* $\delta_{2i+1} = (\lambda_{2i+1})^+$*, where* λ_{2i+1} *is a Suslin cardinal of cofinality* ω*.* $S(\lambda_{2i+1}) = \boldsymbol{\Sigma}_{2i+1}$*. The sequence* λ_1*,* δ_1*,* λ_3*,* $\delta_3, \ldots$ *enumerates the first* ω *Suslin cardinals greater than* κ*.*

Case III. $\mathrm{cf}(\kappa) > \omega$ *and the Steel pointclass* $\boldsymbol{\Gamma}_0$ *is closed under* $\exists^{\omega^\omega}$*.*

$\boldsymbol{\Gamma}_0$ *has the scale property with norms into* κ*. Let* $\Lambda = \Lambda(\boldsymbol{\Gamma}_0, \kappa)$*. Let* $\boldsymbol{\Sigma}_0 = \bigcup_\omega \Lambda$*,* $\boldsymbol{\Pi}_0 = \check{\boldsymbol{\Sigma}}_0$*, and for* $i > 0$ *define* $\boldsymbol{\Sigma}_i$*,* $\boldsymbol{\Pi}_i$ *as usual. Let* $\delta_{2i+1} = \delta(\boldsymbol{\Pi}_{2i+1})$*. Then* $\mathrm{scale}(\boldsymbol{\Sigma}_2)$ *with norms into* $\delta_1 = \lambda_1^+$*, where* $\lambda_1 = o(\Lambda)$*. For all* $i > 0$*,* $\mathrm{scale}(\boldsymbol{\Pi}_{2i+1})$ *and* $\mathrm{scale}(\boldsymbol{\Sigma}_{2i+2})$ *with norms into* δ_{2i+1}*. For all* i*,* δ_{2i+1} *is a Suslin cardinal and* $S(\delta_{2i+1}) = \boldsymbol{\Sigma}_{2i+2}$*. Also,* $\delta_{2i+1} = (\lambda_{2i+1})^+$*, where* λ_{2i+1} *is a Suslin cardinal of cofinality* ω*.* $S(\lambda_{2i+1}) = \boldsymbol{\Sigma}_{2i+1}$*. The sequence* λ_1*,* δ_1*,* λ_3*,* $\delta_3, \ldots$ *enumerates the first* ω *Suslin cardinals greater than* κ*.*

Proof. Consider first case I, that is, $\mathrm{cf}(\kappa) = \omega$. Let $A \in \boldsymbol{\Sigma}_0$, and write $A = \bigcup_i A_i$ with $A_i \in S_{<\kappa}$. Let $\{\phi^i_n\}_{n\in\omega}$ be a scale on A_i of length $\gamma_i < \kappa$. From the Coding Lemma, all of the norm relations $\leq^*_{\phi^i_n}$, $<^*_{\phi^i_n}$ are in $S_{<\kappa}$. Define the norms ψ_n on A as follows. $\psi_0(x) = \mu i\ (x \in A_i)$, $\psi_{k+1}(x) = \langle \psi_0(x), \phi_k^{\psi_0(x)}(x)\rangle$, where $\langle \alpha, \beta\rangle$ denotes the rank of (α, β) in the lexicographic ordering on $(\gamma_i)^2$. This is easily checked to be a scale on A with norms into κ, and is clearly a $\boldsymbol{\Sigma}_0$-scale. Thus, $\mathrm{scale}(\boldsymbol{\Sigma}_0)$. From the Coding Lemma an easy computation show $S(\kappa) \subseteq \boldsymbol{\Sigma}_1$. Also, $\boldsymbol{\Sigma}_1 \subseteq S(\kappa)$ as $S(\kappa)$ is closed under $\exists^{\omega^\omega}$ and countable intersections. Thus, $S(\kappa) = \boldsymbol{\Sigma}_1$. By periodicity, $\mathrm{scale}(\boldsymbol{\Pi}_{2i+1})$, $\mathrm{scale}(\boldsymbol{\Sigma}_{2i})$. By definition of δ_{2i+1}, every regular $\boldsymbol{\Pi}_{2i+1}$ scale has length $\leq \delta_{2i+1}$. In particular, every $\boldsymbol{\Pi}_{2i+1}$, and hence every $\boldsymbol{\Sigma}_{2i+2}$ set is δ_{2i+1}-Suslin. A straightforward computation from the Coding Lemma shows $S(\delta_{2i+1}) \subseteq \boldsymbol{\Sigma}_{2i+2}$, so $S(\delta_{2i+1}) = \boldsymbol{\Sigma}_{2i+2}$. Every $\boldsymbol{\Pi}_{2i+1}$ set admits a $\boldsymbol{\Pi}_{2i+1}$-scale with norms into δ_{2i+1}, and the standard argument transferring the scale property to $\exists^{\omega^\omega}\boldsymbol{\Pi}_{2i+1}$ shows that every $\boldsymbol{\Sigma}_{2i+2}$ set admits a $\boldsymbol{\Sigma}_{2i+2}$-scale with norms into δ_{2i+1} (that is, the lengths of the norms do not increase with this transfer). Since $\boldsymbol{\Pi}_{2i+1}$ is closed under $\forall^{\omega^\omega}$, $\wedge$, $\vee$ and $\mathrm{pwo}(\boldsymbol{\Pi}_{2i+1})$, another standard argument (cf. the proof of Theorem 2.18) shows that δ_{2i+1} is the supremum of the lengths of the $\boldsymbol{\Sigma}_{2i+1}$ well-founded relations, and from the Coding Lemma this must be a regular cardinal. So, δ_{2i+1} is regular. From the Kunen-Martin Theorem $\delta_1 \leq \kappa^+$, and so $\delta_1 = \kappa^+$. Clearly δ_{2i+1} cannot be a limit Suslin cardinal (there are only finitely many Levy classes between $\boldsymbol{\Sigma}_o$ and $\boldsymbol{\Sigma}_{2i+1}$). From Lemma 3.7, $\delta_{2i+1} = \lambda^+_{2i+1}$ for some Suslin cardinal λ_{2i+1} with $\mathrm{cf}(\lambda_{2i+1}) = \omega$. Also from that lemma, $\boldsymbol{\Sigma}_{2i+2} = \exists^{\omega^\omega}\check{S}(\lambda_{2i+1})$, and thus $S(\lambda_{2i+1}) = \boldsymbol{\Sigma}_{2i+1}$ (this also follows from the fact there is only one Levy class closed under $\exists^{\omega^\omega}$ between $\boldsymbol{\Sigma}_{2i}$ and $\boldsymbol{\Sigma}_{2i+2}$). As we have now accounted for all the Levy classes closed under $\exists^{\omega^\omega}$, we must have that δ_1, λ_3, $\delta_3, \ldots$ enumerates the next ω Suslin cardinals after κ.

Consider next case II. From Lemma 3.8 we have $\mathrm{scale}(\boldsymbol{\Sigma}_0)$ with norms into κ. Since $\boldsymbol{\Sigma}_0$ is not closed under $\forall^{\omega^\omega}$ (as $\boldsymbol{\Pi}_0 \subseteq \forall^{\omega^\omega}\boldsymbol{\Sigma}_0$) we may propagate the scale property by periodicity to $\boldsymbol{\Pi}_{2i+1}$, $\boldsymbol{\Sigma}_{2i+2}$. As in the previous case, δ_{2i+1} is a Suslin cardinal, $S(\delta_{2i+1}) = \boldsymbol{\Sigma}_{2i+2}$, and $\delta_{2i+1} = \lambda^+_{2i+1}$, where λ_{2i+1}

is a Suslin cardinal of cofinality ω. In this case, since $\mathrm{cf}(\kappa) > \omega$, we have $\lambda_1 > \kappa$. From Lemma 3.7 again we have that $S(\lambda_{2i+1}) = \boldsymbol{\Sigma}_{2i+1}$. As we have again accounted for all the Levy classes closed under $\exists^{\omega^\omega}$, the sequence $\lambda_1, \delta_1, \lambda_3, \delta_3, \dots$ enumerates the next ω Suslin cardinals after κ. scale($\boldsymbol{\Gamma}_0$) follows from Lemma 3.8.

Consider now case III. From Lemma 3.8, $\boldsymbol{\Gamma}_0$ has the scale property with norms into κ, and also $S(\kappa) = \boldsymbol{\Gamma}_0$. Recall in this case that Λ is selfdual and closed under real quantification, and $\mathrm{cf}(\lambda) = \omega$, where $\lambda = o(\Lambda)$. From Lemma 3.19, λ is the next Suslin cardinal after κ, and $S(\lambda) = \boldsymbol{\Sigma}_1$ ($\boldsymbol{\Sigma}_1 \subseteq S(\lambda)$ follows from the closure of $S(\lambda)$ under $\exists^{\omega^\omega}$ and countable intersections, and $S(\lambda) \subseteq \boldsymbol{\Sigma}_1$ follows by a straightforward computation using the Coding Lemma and the closure of $\boldsymbol{\Sigma}_1$ under countable unions and intersections). From Lemma 3.26, $\boldsymbol{\Sigma}_2$ has the scale property with norms into $\delta_1 = \lambda^+$. In particular, $\lambda_1 = \lambda$. The remaining arguments are exactly as in the previous cases. $\dashv$

4. Trivial Descriptions: A Theory of $\boldsymbol{\omega_1}$

We assume AD + DC throughout Sect. 4.

Our goal in this section is to present a "theory of ω_1", using only techniques that will generalize to higher levels. Starting from the weak partition relation on ω_1 (proved in the last section), we prove the strong partition relation on ω_1, calculate $\boldsymbol{\delta}^1_3$, and prove the weak partition relation on $\boldsymbol{\delta}^1_3$. This represents the first step in the inductive analysis of the projective ordinals. We also use these techniques to present a proof of the Kechris-Martin Theorem on $\boldsymbol{\Pi}^1_3$. These results are not new (cf. [9, 33]), but our proofs do not rely on the theory of indiscernibles for L (as did the original proofs) but rather on a direct analysis on the measures on ω_1 (and the ω_n). The idea of using an analysis of measures to provide a good coding for sets was first used by Kunen (see [33]) in the original proof of the weak partition relation on $\boldsymbol{\delta}^1_3$.

As we mentioned in the introduction, one of our motivations in this section is to introduce and use the terminology of "descriptions", even though the concept at this level is rather trivial and could be dispensed with. This way, the arguments at the higher levels will have the same general form, though the concept of description will become non-trivial. This will free us, in the next section, to concentrate on this point.

Our first job is to analyze the measures on ω_1, from which the strong partition relation on ω_1 will follow.

Recall that if $T \subseteq \rho^{<\omega}$ is a tree on ρ and $\alpha < \rho$, then $T\restriction\alpha = T \cap \alpha^{<\omega}$ denotes the tree restricted to α, and if β is in the well-founded part of $T\restriction\alpha$, then $|(T\restriction\alpha)(\beta)|$ denotes the rank of β in $T\restriction\alpha$. Also, if T is a tree on $\alpha \times \rho$, then $T_x = \{\vec{s} \in \rho^{<\omega} : (x\restriction \mathrm{lh}(\vec{s}), \vec{s}) \in T\}$ is the section of the tree at x.

Let $\mathrm{WO} \subseteq \omega^\omega$ be the standard set of codes for wellorderings, that is $x \in \mathrm{WO}$ iff $\prec_x \doteq \{(n,m) : x(\langle n,m\rangle) = 1\}$ is a wellordering of ω. Let $\mathrm{WF} \supseteq \mathrm{WO}$ be the set of codes of well-founded, transitive relations on ω. That is, $x \in \mathrm{WF}$

iff $\prec_x$ is a well-founded and transitive relation. Both WO, WF are in $\Pi^1_1 - \boldsymbol{\Sigma}^1_1$. For $x \in \mathrm{WF}$, let $|x| = |\prec_x| = \sup\{|n|_{\prec_x} + 1 : n \in \mathrm{dom}(\prec_x)\}$.

The finite exponent partition relation on ω_1 easily implies that the closed unbounded filter on ω_1 is a normal measure, and is the unique normal measure on ω_1. We let W_1^m denote the m-fold product of this normal measure. Equivalently, $A \subseteq (\omega_1)^m$ has measure one with respect to W_1^m iff there is a closed unbounded $C \subseteq \omega_1$ such that $(C)^m \subseteq A$. Note that we regard W_1^m as a measure on the set of tuples $(\alpha_0, \dots, \alpha_{m-1})$ for which $\alpha_0 < \dots < \alpha_{m-1}$. With this convention, we may safely write the ordinals in the tuple in any order (which will be notationally convenient later).

Recall the construction of the Kunen tree on ω_1:

4.1 Lemma (Kunen). *There is a tree T on $\omega \times \omega_1$ such that for all $f : \omega_1 \to \omega_1$, there is an $x \in \omega^\omega$ such that T_x is well-founded and for all $\omega \leq \alpha < \omega_1$ we have $f(\alpha) \leq |T_x \restriction \alpha|$.*

Proof. Let S be a recursive tree on $\omega \times \omega$ with $p[S]$ a $\boldsymbol{\Sigma}^1_1$-complete set. Define the tree U on $\omega \times \omega_1$ by:

$$\begin{aligned} &((a_0, \dots, a_{n-1}), (\alpha_0, \dots, \alpha_{n-1})) \in U \\ &\quad \longleftrightarrow \forall i, j < n \ (a_{\langle i,j \rangle} = 1 \to \alpha_i < \alpha_j) \\ &\qquad\quad \wedge \forall i, j, k < n \ (a_{\langle i,j \rangle} = 1 \wedge a_{\langle j,k \rangle} = 1 \to a_{\langle i,k \rangle} = 1). \end{aligned}$$

Clearly, $p[U] = \mathrm{WF}$. Let V be the tree on $\omega \times \omega \times \omega_1 \times \omega \times \omega$ defined by:

$$\begin{aligned} (\vec{s}, \vec{a}, \vec{\alpha}, \vec{b}, \vec{c}) \in V \longleftrightarrow &(\vec{a}, \vec{\alpha}) \in U \wedge (\vec{b}, \vec{c}) \in S \\ &\wedge \exists \sigma \text{ extending } \vec{s} \ (\sigma(\vec{a}) = \vec{b}), \end{aligned}$$

where we view every real σ as coding a strategy for II in some reasonable manner. Suppose $f : \omega_1 \to \omega_1$. Consider the game where I, II play out x, y, and II wins iff $[x \in \mathrm{WF} \to S_y$ is well-founded $\wedge\, |S_y| > \sup\{f(\beta) : \beta \leq |x|\}]$. II easily wins by boundedness, noting that

$$\sup\{|S_y| : S_y \text{ is well-founded}\} = \omega_1,$$

as otherwise $p[S]$ would be Borel. Let σ be winning for II. Note that for all $\alpha < \omega_1$, if $x \in \mathrm{WF}$ and $|x| = \alpha$, then $U_x \restriction \alpha$ is ill-founded. It follows that V_σ is well-founded and for all $\alpha \geq \omega$, we have $|V_\sigma \restriction \alpha| > f(\alpha)$. It is now easy to code the 2nd, 3rd, 4th, and 5th coordinates of V into the second coordinate of a tree T (say by weaving the values of the four components; this does not decrease rank, that is, $|T_\sigma \restriction \alpha| \geq |V_\sigma \restriction \alpha|$ for all σ, α). ⊣

We note that the Kunen tree T is Δ^1_1 in the codes. By this we mean that there are Σ^1_1, Π^1_1 relations $S(n, a, x)$, $R(n, a, x)$ such that for all x with $x_0, \dots, x_{n-1} \in \mathrm{WO}$, we have

$$\begin{aligned} S(n, a, x) &\longleftrightarrow R(n, a, x) \\ &\longleftrightarrow ((a_0, \dots, a_{n-1}), (|x_0|, \dots, |x_{n-1}|)) \in T. \end{aligned}$$

This follows immediately from the definition of T (see Lemma 4.1).

Although the difference is not large, it is sometimes to more convenient to deal with linear orderings rather than trees. The following theorem shows that we may modify the Kunen tree so as to make this possible. Recall that if $s \in \omega^n$, then $T_s = \{\vec{\alpha} \in \omega_1^n : (s, \vec{\alpha}) \in T\}$.

4.2 Theorem. *There is a function $s \to T(s)$ which assigns to each $s \in \omega^{<\omega}$ a wellordering of a subset of ω_1 with the following properties. If t extends s, then $T(t) \supseteq T(s)$. For $x \in \omega^\omega$, let $T(x) = \bigcup_n T(x \restriction n)$, so $T(x)$ is a linear order. Then for any $f : \omega_1 \to \omega_1$, there is an $x \in \omega^\omega$ such that $T(x)$ is a wellordering and for all $\alpha \geq \omega$, $f(\alpha) < |T(x) \restriction \alpha|$. Furthermore, the map $s \to T(s)$ is Δ^1_1 in the codes. That is, there are Σ^1_1, Π^1_1 relations $S(n, a, x, y)$, $R(n, a, x, y)$ such that for all $x, y \in \mathrm{WO}$, we have*

$$S(n, a, x, y) \longleftrightarrow R(n, a, x, y) \longleftrightarrow [(|x|, |y|) \in T(a_0, \ldots, a_{n-1})].$$

Proof. We modify the Kunen tree T as follows. Fix a bijection $\pi : (\omega_1)^{<\omega} \to \omega_1$ such that for all $\alpha_0, \ldots, \alpha_{n-1} < \omega$, we have $\pi(\alpha_0, \ldots, \alpha_{n-1}) < \omega$. For $s \in \omega^{<\omega}$, let $T(s)$ be the wellordering defined by

$$\alpha \ T(s) \ \beta \longleftrightarrow \pi^{-1}(\alpha), \pi^{-1}(\beta) \in T_s \wedge (\pi^{-1}(\alpha) <^{\mathrm{KB}}_{T_s} \pi^{-1}(\beta)),$$

where $<^{\mathrm{KB}}_{T_s}$ denotes the Kleene-Brouwer ordering on T_s. For $x \in \omega^\omega$, let $T(x) = \bigcup_n T(x \restriction n)$. Clearly $T(x)$ is a linear ordering, and is a wellordering iff T_x is well-founded. Suppose now that $f : \omega_1 \to \omega_1$. Let $C \subseteq \omega_1$ be the closed unbounded set of ordinals closed under π. Note that $\omega \in C$. For $\alpha \geq \omega$, let $l(\alpha)$ be the greatest element of C which is less than or equal to α. Define

$$f'(\alpha) = \sup\{f(\beta) : l(\beta) = l(\alpha)\}.$$

Let $x \in \omega^\omega$ be such that T_x is well-founded and for all $\alpha \geq \omega$, $|T_x \restriction \alpha| > f'(\alpha)$. We claim that for all $\alpha \geq \omega$, $|T(x) \restriction \alpha| > f(\alpha)$. Note that π^{-1} applied to $T(x) \restriction \alpha$ contains the entire tree $T_x \restriction l(\alpha)$. Thus, $|T(x) \restriction \alpha| \geq |T_x \restriction l(\alpha)| > f'(l(\alpha)) \geq f(\alpha)$. We may also choose the bijection π so that π is Δ^1_1 in the codes, and it is then straightforward to check that $s \to T(s)$ is Δ^1_1 in the codes. $\dashv$

In the future, we will use the notation T_s for the Kunen "tree", regardless of whether we are using the tree T_s or the linear ordering $T(s)$. The meaning will be clear from the context.

For the rest of Sect. 4, T will denote the Kunen tree of Lemma 4.1.

Note that for every $f : \omega_1 \to \omega_1$, the equivalence class $[f]_{W^1_1}$ may be coded by a pair (x, β) where $x \in \omega^\omega$, $\beta < \omega_1$. By this we mean $\forall^*_{W^1_1} \alpha \ f(\alpha) = |(T_x \restriction \alpha)(\beta)|$. To see that x and β exist, use normality and the fact that $\forall^* \alpha \ \exists \beta < \alpha \ f(\alpha) = |(T_x \restriction \alpha)(\beta)|$.

4.3 Definition. A level -1, or *trivial description*, d is simply a positive natural number $d \in \omega$. We let $\mathcal{D}^{-1} = \omega - \{0\}$ be the set of trivial descriptions. The interpretation function h assigns to each $d \in \mathcal{D}^{-1}$ an ordinal by: $h(d) = d$. We say a trivial description d is *well-defined*, or *satisfies condition D*, with respect to a measure W_1^m iff $d \leq m$. If d is well-defined with respect to W_1^m and $\beta_1 < \cdots < \beta_m < \omega_1$, we define $h(\beta_1, \ldots, \beta_m; d) = \beta_d$. If $g : \omega_1 \to \omega_1$, and d is well-defined with respect to W_1^m, we define an ordinal $(g; W_1^m; d)$. This is represented with respect to W_1^m by the function which assigns to $\beta_1, \ldots, \beta_m$ the ordinal $(g; \beta_1, \ldots, \beta_m; d) \doteq g(h(\beta_1, \ldots, \beta_m; d)) = g(\beta_d)$.

Clearly, $(g; W_1^m; d)$ only depends on $[g]_{W_1^1}$. In this way, the trivial descriptions, together with the equivalence classes of functions with respect to the normal measure on ω_1, generate equivalence classes with respect to the family of measures W_1^m. Note that for $g = \mathrm{id}$, the identity function on ω_1, we have $(\mathrm{id}; \vec{\beta}; d) = \beta_d$. We introduce a "lowering operator" $\mathcal{L}$ on $\mathcal{D}^{-1}$.

4.4 Definition. We define $\mathcal{L}(d) = d - 1$ for $d > 1$. If $d = 1$, we do not define $\mathcal{L}(d)$, and say $d = 1$ is *minimal* with respect to $\mathcal{L}$.

By definition, there is a unique $d \in \mathcal{D}^{-1}$ which is minimal with respect to $\mathcal{L}$.

As a warm-up, we use this terminology to recast one familiar proof of the computation $\boldsymbol{\delta}_3^1 = \omega_{\omega+1}$. In this context, our "main technical lemma" is the following (the reader will note that the lemma corresponds to a well-known property of indiscernibles for L).

4.5 Lemma. *Let $f : (\omega_1)^m \to \omega_1$, d be well-defined with respect to W_1^m, and assume $[f]_{W_1^m} < (\mathrm{id}; W_1^m; d)$. If d is non-minimal with respect to $\mathcal{L}$, then there is a $g : \omega_1 \to \omega_1$ such that $[f]_{W_1^m} < (g; W_1^m; \mathcal{L}(d))$. If d is minimal with respect to $\mathcal{L}$, then $\exists \alpha < \omega_1\ [f]_{W_1^m} < \alpha$.*

Proof. We have $\forall^*_{W_1^m} \beta_1, \ldots, \beta_m\ f(\vec{\beta}) < (\mathrm{id}; \beta_1, \ldots, \beta_m; d) = \beta_d$. Consider the case d non-minimal with respect to $\mathcal{L}$. Consider the partition $\mathcal{P}$, where we partition ordinals $\beta_1 < \cdots < \beta_m < \omega_1$ with the extra ordinal $\beta_{d-1} < \gamma < \beta_d$ according to whether $\gamma > f(\beta_1, \ldots, \beta_m)$. Clearly, on the homogeneous side the stated property holds. Let $C \subseteq \omega_1$ be closed unbounded and homogeneous for $\mathcal{P}$. Let $g(\alpha) =$ the least element of C greater than α. Then $\forall^*_{W_1^m} \beta_1, \ldots, \beta_m\ f(\vec{\beta}) < g(\beta_{d-1}) = (g; \beta_1, \ldots, \beta_m; \mathcal{L}(d))$, thus $[f]_{W_1^m} < (g; W_1^m; \mathcal{L}(d))$. The case where d is minimal with respect to $\mathcal{L}$ is similar. ⊣

We let $<$ be the transitive relation on $\mathcal{D}^{-1}$ generated by the relation $\mathcal{L}(d) < d$. Of course, $<$ is just the usual ordering on the positive integers. We let $|d|$ denote the rank of d in this ordering, so $|d| = d - 1$.

Lemma 4.5 and the analysis of functions $f : \omega_1 \to \omega_1$ with respect to the normal measure W_1^1 on ω_1 (i.e., the Kunen tree construction) suffice to compute upper bound for $j_{W_1^m}(\omega_1)$, where $j_{W_1^m}$ denotes the ultrapower embedding corresponding to the measure W_1^m. This is made explicit in the following theorem.

4.6 Theorem. *Let d be defined with respect to W_1^m. Then* $(\mathrm{id}; W_1^m; d) \leq \omega_{|d|+1}$.

Proof. By induction on $|d|$. If $|d| = 0$ (i.e., $d = 1$), then $(\mathrm{id}; W_1^m; d) \leq \omega_1$ from Lemma 4.5. Otherwise, let $\alpha < (\mathrm{id}; W_1^m; d)$. From Lemma 4.5, $\exists g : \omega_1 \to \omega_1$ such that $\alpha < (g; W_1^m; \mathcal{L}(d))$. Recall that T is the Kunen tree of Lemma 4.1. Let $x \in \omega^\omega$ be such that T_x is well-founded and $\forall^*_{W_1^m} \beta\, g(\beta) < |T_x \restriction \beta|$. Let $|T_x|$ also denote the function $\beta \to |T_x \restriction \beta|$. Thus, $\alpha < (|T_x|; W_1^m; \mathcal{L}(d))$. T_x also induces a bijection π between $(\mathrm{id}; W_1^m; \mathcal{L}(d))$ and $(|T_x|; W_1^m; \mathcal{L}(d))$. Namely, if $\delta < (\mathrm{id}; W_1^m; \mathcal{L}(d))$, then $\pi(\delta) < (|T_x|; W_1^m; \mathcal{L}(d))$ is defined by

$$\forall^*_{W_1^m} \beta_1, \ldots, \beta_m\ [\pi(\delta)(\vec{\beta}) = |(T_x \restriction (\mathrm{id}; \vec{\beta}; \mathcal{L}(d)))(\delta(\vec{\beta}))|].$$

Thus, $(g; W_1^m; d) < (\mathrm{id}; W_1^m; \mathcal{L}(d))^+$, and so $(\mathrm{id}; W_1^m; d) \leq (\mathrm{id}; W_1^m; \mathcal{L}(d))^+$. By induction, $(\mathrm{id}; W_1^m; \mathcal{L}(d)) \leq \omega_{|\mathcal{L}(d)|+1} = \omega_{|d|}$, so $(\mathrm{id}; W_1^m; d) \leq \omega_{|d|+1}$. ⊣

As a corollary, we have an upper bound for $\boldsymbol{\delta}^1_3$.

4.7 Corollary. $\boldsymbol{\delta}^1_3 \leq \omega_{\omega+1}$.

Proof. The homogeneous tree analysis, which we will not reproduce here, shows that every $\boldsymbol{\Pi}^1_2$ set is λ_3-Suslin, where $\lambda_3 \leq \sup j_\nu(\omega_1)$, the supremum ranging over measures ν occurring in the homogeneous tree on a $\boldsymbol{\Pi}^1_1$-complete set; that is, the measures W_1^m. [The homogeneous tree construction is described in detail in [17]. The definition of a homogeneous tree is given in Sect. 5, and more general arguments are presented there as well. In particular, the arguments immediately after Definition 5.1 suffice to prove the above claim.] From the Kunen-Martin Theorem, it follows that $\boldsymbol{\delta}^1_3 \leq [\sup_m j_{W_1^m}(\omega_1)]^+$. Now, a small variation in the proof of Lemma 4.5 shows that $j_{W_1^m}(\omega_1) \leq (\mathrm{id}; W_1^m; \tilde{d})^+$, where $\tilde{d} \doteq m$ is the *maximal* description defined with respect to W_1^m. Thus, $j_{W_1^m}(\omega_1) \leq \omega_{m+1}$, and so $\lambda_3 \leq \omega_\omega$. ⊣

We will get the lower bound for $\boldsymbol{\delta}^1_3$ as a consequence of a general result of Martin. However, we first need the strong partition relation on ω_1.

4.1. Analysis of Measures on $\boldsymbol{\delta}^1_1$

The next theorem is our analysis of an arbitrary measure ν on ω_1. The key idea is to exploit a pressing down argument with respect to ν.

4.8 Theorem. *Let ν be a measure on ω_1. Then there are finitely many reals $x_0, \ldots, x_n$ with T_{x_i} well-founded for $0 \leq i \leq n$, and an ordinal $\alpha < \omega_1$ such that for all $A \subseteq \omega_1$:*

$$\nu(A) = 1 \longleftrightarrow \forall^*_{W_1^{n+1}} \beta_0, \ldots, \beta_n\ (h^\alpha_{x_0,\ldots,x_n}(\beta_0, \ldots, \beta_n) \in A),$$

where for $0 \leq i \leq n$, $\delta_i \doteq h^\alpha_{x_0,\ldots,x_i}(\beta_0, \ldots, \beta_i)$ is defined inductively by: $\delta_i = |(T_{x_i} \restriction \beta_i)(\delta_{i-1})|$, and $\delta_{-1} = \alpha$. In particular, ν is equivalent to W_1^{n+1} for some $n \in \omega$.

Proof. We may assume that ν is non-principal. Let $g_0 : \omega_1 \to \omega_1$ satisfy:

(1) There is a ν measure one set A such that $g_0 \restriction A$ is monotonically increasing (i.e., if $\alpha < \beta$ are in A, then $g_0(\alpha) \leq g_0(\beta)$).

(2) There does not exist a ν measure one set A such that $g_0 \restriction A$ is constant.

(3) If $[g]_\nu < [g_0]_\nu$, then g does not satisfy (1) and (2).

g_0 exists, since the identity function satisfies (1) and (2). Consider the measure $g_0(\nu)$ (that is, $g_0(\nu)(A) = 1$ iff $\nu(g_0^{-1}(A)) = 1$). If $C \subseteq \omega_1$ is closed unbounded, then $g_0(\nu)(C) = 1$, as otherwise $p \circ g_0$ violates the minimality of g_0, where $p(\alpha) =$ the largest element of C less than or equal to α. Thus, $g_0(\nu) = W_1^1$. Fix A of ν measure one such that $g_0 \restriction A$ is monotonically increasing. Define $h(\alpha) = \sup\{\beta \in A : g_0(\beta) \leq \alpha\}$. Clearly $h : \omega_1 \to \omega_1$. Let x_0 be such that T_{x_0} is well-founded and $\forall^*_{W_1^1}\beta\ h(\beta) < |T_{x_0} \restriction \beta|$. Thus, $\forall^*_\nu \alpha\ \alpha < h(g_0(\alpha)) \leq |T_{x_0} \restriction g_0(\alpha)|$. Let $r_0 : \omega_1 \to \omega_1$ be such that $\forall^*_\nu \alpha\ r_0(\alpha) < g_0(\alpha)$ and $\forall^*_\nu \alpha\ [\alpha = |(T_{x_0} \restriction g_0(\alpha))(r_0(\alpha))|]$. Let $d_0 = d_1 = 1$, which are defined with respect to W_1^1. For α in the ν measure one set such that $r_0(\alpha) < g_0(\alpha)$ is defined, we define

$$\begin{aligned} h(g_0(\alpha); (W_1^1; x_0; d_0, d_1); r_0(\alpha)) &= |(T_{x_0} \restriction h(g_0(\alpha); d_0))(r_0(\alpha))| \\ &= |(T_{x_0} \restriction g_0(\alpha))(r_0(\alpha))|. \end{aligned}$$

We have thus produced a tuple $(\langle W_1^1; x_0; d_0, d_1 \rangle, g_0, r_0)$ satisfying the following:

(1) d_0, d_1 are defined with respect to W_1^1 and T_{x_0} is well-founded.

(2) $g_0(\nu) = W_1^1$.

(3) $\forall^*_\nu \alpha\ r_0(\alpha) < h(g_0(\alpha); d_1)$.

(4) $\forall^*_\nu \alpha\ [\alpha = h(g_0(\alpha); (W_1^1; x_0; d_0, d_1); r_0(\alpha))]$.

With this first step as motivation, we make the following definitions.

4.9 Definition. A *level*-1 *complex* is a tuple of the form

$$\mathcal{C} = \langle W_1^m; x_0, \ldots, x_{n-1}; d_0, \ldots, d_n \rangle$$

where $m \geq 1$, $n \in \omega$ (if $n = 0$, then no x_i appear). If $n \geq 1$, then each d_i is defined with respect to W_1^m for $0 \leq i \leq n$, $d_0 > d_1 > \cdots > d_{n-1} \geq d_n$, and each T_{x_i} is well-founded for $0 \leq i \leq n-1$.

If $\mathcal{C}$ as above is a complex with $n \geq 1$, $\gamma < \omega_1$, and $\beta_1 < \cdots < \beta_m < \omega_1$, define

$$h(\beta_1, \ldots, \beta_m; \mathcal{C}; \gamma) = |(T_{x_0} \restriction h(\vec{\beta}; d_0))(\alpha_1)|,$$

where $\alpha_1 = |(T_{x_1} \restriction h(\vec{\beta}; d_1))(\alpha_2)|, \ldots, \alpha_{n-1} = |(T_{x_{n-1}} \restriction h(\vec{\beta}; d_{n-1}))(\alpha_n)|$, and $\alpha_n = \gamma$. If $n = 0$, then we define $h(\vec{\beta}; \mathcal{C}; \gamma) = \gamma$.

Written out directly, the equation for h is:

$$h(\beta_1, \dots, \beta_m; \mathcal{C}; \gamma) = |T_{x_0} \restriction \beta_{d_0}(|T_{x_1} \restriction \beta_{d_1}(\dots |T_{x_{n-1}} \restriction \beta_{d_{n-1}}(\gamma)| \dots)).$$

The definition of $h(\vec{\beta}; \mathcal{C}; \gamma)$ is actually only on the W_1^m measure one set of $\vec{\beta}$ such that $h(\vec{\beta}; d_0) > \alpha_1$, etc. Off this measure one set, we leave $h(\vec{\beta}; \mathcal{C}; \gamma)$ undefined. Note that the last description d_n is not used in the definition of $h(\vec{\beta}; \mathcal{C}; \gamma)$; its role is to provide a bound for the r function in the following definition (the r stands for "remainder"—it represents, roughly speaking, the part of the measure that has not yet been analyzed).

We abstract the general step of the analysis into the following definition.

4.10 Definition. A *situation* for ν is a triple $(\mathcal{C}, g, r)$ satisfying the following:

(1) $\mathcal{C} = \langle W_1^m; x_0, \dots, x_{n-1}; d_0, \dots, d_n \rangle$ is a complex (defined immediately above).

(2) $g : \omega_1 \to (\omega_1)^m$, and $g(\nu) = W_1^m$.

(3) $r : \omega_1 \to \omega_1$, and $\forall^*_\nu \alpha \; r(\alpha) < h(g(\alpha); d_n)$.

(4) $\forall^*_\nu \alpha \; [\alpha = h(g(\alpha); \mathcal{C}; r(\alpha))]$.

Among all situations for ν, we now choose one with the minimal value for $[\alpha \to h(g(\alpha); d_n)]_\nu$ (i.e., minimizing the bound for the function r). We denote this situation by $(\mathcal{C}; g; r)$, where $\mathcal{C} = \langle W_1^m; x_0, \dots, x_{n-1}; d_0, \dots, d_n \rangle$.

We claim that r is constant ν almost everywhere, that is, $\exists \gamma < \omega_1 \; \forall^*_\nu \alpha \; r(\alpha) = \gamma$. Granting this, it follows from (2) and (4) that $\nu(A) = 1$ iff $\exists$ c.u.b. $C \subseteq \omega_1 \; \forall \beta_1, \dots, \beta_m \in C \; h(\vec{\beta}; \mathcal{C}; \gamma) \in A$. This gives the theorem via a minor cosmetic change: if $m > n$ we replace W_1^m by W_1^n, and replace $d_0, \dots, d_{n-1}$ by $n, n-1, \dots, 1$, which gives the same measure (we eliminate the coordinates of W_1^m not used in the definition of $h(\vec{\beta}; \mathcal{C}; \gamma)$).

We consider the case where d_n is minimal, that is, $d_n = 1$, the other case being similar (in fact, as we remarked above, there is no loss of generality in assuming $m = n$ and $d_0, \dots, d_{n-1} = n, \dots, 1$, in which case $d_n = 1$). We consider two cases.

First assume that there is a ν measure one set A such that for $\alpha \in A$ there is a $\delta < h(g(\alpha); d_n)$ (that is, $\delta < \beta_1$, where $g(\alpha) = \beta_1, \dots, \beta_m$) such that for all $\alpha' \in A$ with $g(\alpha') = g(\alpha)$ we have $r(\alpha') < \delta$. Fix such a measure one set A, and by (3) we may assume $\forall \alpha \in A \; r(\alpha) < h(g(\alpha); d_n)$. By (2), let C be closed unbounded such that for all $\beta_1 < \dots < \beta_m \in C \; \exists \alpha \in A \; g(\alpha) = (\beta_1, \dots, \beta_m)$. Thus,

$$\forall \beta_1 < \dots < \beta_m \in C \; \exists \delta < \beta_1 \; \sup\{r(\alpha) : \alpha \in A \wedge g(\alpha) = (\beta_1, \dots, \beta_m)\} < \delta.$$

By normality, δ is constant on a W_1^m measure one set, and by countable additivity of ν, r is constant on a ν measure one set.

Suppose now that such a measure one set does not exist. It follows that for any A of ν measure one that $\forall^*_\nu \alpha \in A\ \forall \delta < \beta_1\ \exists \alpha' \in A\ [g(\alpha') = g(\alpha) \wedge r(\alpha') > \delta]$, where $g(\alpha) = (\beta_1, \ldots, \beta_m)$. Let $g' : \omega_1 \to \omega_1$ satisfy the following:

(1) $\forall^*_\nu \alpha\ g'(\alpha) < h(g(\alpha); d_n)$. In other words, $g'(\alpha) < \beta_1$, where $g(\alpha) = (\beta_1, \ldots, \beta_m)$.

(2) There is a ν measure one set A such that if $\alpha_1, \alpha_2 \in A$, $g(\alpha_1) = g(\alpha_2)$, and $r(\alpha_1) \leq r(\alpha_2)$, then $g'(\alpha_1) \leq g'(\alpha_2)$.

(3) For any A of ν measure one we have $\forall^*_\nu \alpha \in A\ \forall \delta < \beta_1\ \exists \alpha' \in A\ [g(\alpha') = g(\alpha) \wedge g'(\alpha') > \delta]$, where $g(\alpha) = (\beta_1, \ldots, \beta_m)$.

(4) If $[g'']_\nu < [g']_\nu$, then g'' does not satisfy (1)–(3).

g' exists, since r satisfies (1)–(3). Also, $g'(\nu) = W_1^1$, since if there were a closed unbounded C such that $\forall^*_\nu \alpha\ g'(\alpha) \notin C$, then $p \circ g'$ would violate the minimality of g', where $p(\alpha) =$ the largest element of C less than or equal to α. Let $\tilde{g}(\alpha) = g'(\alpha)^\frown g(\alpha)$, so $\tilde{g}(\nu) = W_1^{m+1}$. Fix a ν measure one set A witnessing (1) and (2) for g'. Consider the partition $\mathcal{P}$: we partition $\beta_0 < \delta < \beta_1 < \beta_2 < \cdots < \beta_m$ according to whether

$$\sup\{r(\alpha) : \alpha \in A \wedge g(\alpha) = (\beta_1, \ldots, \beta_m) \wedge g'(\alpha) \leq \beta_0\} < \delta.$$

Using (2) and (3) it follows that on the homogeneous side the stated property holds. Let $C \subseteq \omega_1$ be closed unbounded and homogeneous for $\mathcal{P}$, and let $N_C(\alpha) =$ the least element of C greater than α. Thus, $\forall^*_\nu \alpha\ r(\alpha) < N_C(g'(\alpha))$. Let x_n be such that T_{x_n} is well-founded and $\forall^*_{W_1^1} \beta\ N_C(\beta) < |T_{x_n} \restriction \beta|$. Define $r' : \omega_1 \to \omega_1$ so that $\forall^*_\nu \alpha\ r'(\alpha) < g'(\alpha)$ and $\forall^*_\nu \alpha\ [r(\alpha) = |(T_{x_n} \restriction g'(\alpha))(r'(\alpha))|$. Let $d'_0 = d_0 + 1, \ldots, d'_{n-1} = d_{n-1} + 1$ (to maintain the correspondence between the appropriate coordinates of W_1^m and W_1^{m+1}), and let $d'_n = d'_{n+1} = 1$. Let $\mathcal{C}' = \langle W_1^{m+1}; x_0, \ldots, x_n; d'_0, \ldots, d'_n, d'_{n+1}\rangle$. Note then that $\forall^*_\nu \alpha\ [\alpha = h(\tilde{g}(\alpha); \mathcal{C}'; r'(\alpha)]$. Since $\forall^*_\nu \alpha\ h(\tilde{g}(\alpha); d'_n) < h(g(\alpha); d_n)$, it follows that $(\mathcal{C}'; \tilde{g}; r')$ violates the minimality of $(\mathcal{C}; g; r)$, a contradiction. ⊣

4.2. The Strong Partition Relation on ω_1

We now convert this analysis of measures to a coding of the subsets of ω_1. As we mentioned before, this idea is due to Kunen. Throughout Sect. 4.2, T continues to denote the Kunen tree of Lemma 4.1.

First we code (enough) closed unbounded sets. If $\sigma \in \omega^\omega$, let

$$C_\sigma = \{\alpha < \omega_1 : \alpha > \omega \wedge \forall \beta < \alpha\ (T_\sigma \restriction \beta \text{ is well-founded } \wedge |T_\sigma \restriction \beta| < \alpha)\}.$$

For any σ, C_σ is a closed subset of ω_1, and if T_σ is well-founded then C_σ is also unbounded. Also, for all closed unbounded $C \subseteq \omega_1$, there is a $\sigma \in \omega^\omega$ such that T_σ is well-founded and $C_\sigma \subseteq C$. For we may choose σ so that for all infinite $\beta < \omega_1$, $|T_\sigma \restriction \beta| > N_C(\beta)$.

4.11 Definition. Suppose $\mathcal{C} = \langle W_1^m; x_0, \dots, x_{n-1}; d_0, \dots, d_n \rangle$ is a complex, T_σ is well-founded, and $\gamma < \omega_1$. If $n \geq 1$, we define (with h as in Definition 4.9)

$$S_{\sigma,\mathcal{C},\gamma} = \{h(\beta_1, \dots, \beta_m; \mathcal{C}; \gamma) : \vec{\beta} \in (C_\sigma)^m \wedge \gamma < \beta_1 \wedge h(\vec{\beta}; \mathcal{C}; \gamma) \geq \beta_m\}.$$

For $n = 0$ we define $S_{\sigma,\mathcal{C},\gamma} = \{\gamma\}$. We say $S \subseteq \omega_1$ is *simple* if it is of the form $S_{\sigma,\mathcal{C},\gamma}$ for some $\sigma, \mathcal{C}, \gamma$.

4.12 Theorem. *Every $A \subseteq \omega_1$ is a countable union of simple sets.*

Proof. Let $A \subseteq \omega_1$, and suppose the theorem fails for A. Let $\mathcal{I} \subseteq \mathcal{P}(A)$ denote the countably additive ideal of $I \subseteq A$ such that $I = \bigcup_i S_i$ is a countable union of simple sets $S_i \subseteq A$. Thus, $A \notin \mathcal{I}$. Also, $\mathcal{I}$ contains all singletons as every $\{\gamma\}$ is simple. By AD, every countably additive filter (dual to an ideal $\mathcal{I}$) on an ordinal $< \Theta$ (identified here with A) can be extended to a measure. [One way to see this: by the Coding Lemma, let $\pi : \omega^\omega \to \mathcal{I}$ be onto. For d a Turing degree, let $f(d) =$ least element of $A - \bigcup_{x \in d} \pi(x)$. If μ is the Martin measure on the degrees, then $f(\mu)$ is a measure on A with $f(\mu)(I) = 0$ for all $I \in \mathcal{I}$.]

Let ν be a measure on A extending the filter dual to $\mathcal{I}$. Since $\nu(A) = 1$, by Theorem 4.8 we have some simple set $S \subseteq A$ with $\nu(S) = 1$. This contradicts $S \in \mathcal{I}$. ⊣

We view each real z as coding countably many reals z_n, each of which codes reals σ_n, w_n, and a sequence $\mathcal{C}_n = \langle W_1^m; x_0, \dots, x_{t-1}; d_0, \dots, d_t \rangle$ which satisfies the definition of a complex except that we do not require the T_{x_i} to be well-founded (we call this a *partial complex*). To each z_n we associate a set A_{z_n} defined as follows. If $w_n \notin \mathrm{WO}$ (the set of codes for wellorderings of ω), we set $A_{z_n} = \emptyset$. Otherwise, set

$$\begin{aligned} \alpha \in A_{z_n} \longleftrightarrow\ & \exists \beta_1 < \cdots < \beta_m \leq \alpha \\ & [\beta_1 > |w_n| \wedge \{\forall i\ \beta_i \in C_{\sigma_n} \wedge\ \alpha = h(\vec{\beta}; \mathcal{C}_n; |w_n|)\}]. \end{aligned}$$

We define here $h(\vec{\beta}; \mathcal{C}_n; \gamma)$ for the partial complex $\mathcal{C}_n$ similarly to Definition 4.9: $h(\vec{\beta}; \mathcal{C}_n; \gamma) = |T_{x_0} \restriction h(\vec{\beta}; d_0)(\alpha_1)|$, where $\alpha_1 = |T_{x_1} \restriction h(\vec{\beta}; d_1)(\alpha_2)|$, etc., provided α_1 is in the well-founded part of $T_{x_0} \restriction h(\vec{\beta}; d_0)$, α_2 is in the well-founded part of $T_{x_1} \restriction h(\vec{\beta}; d_1)$, etc. If some α_{i+1} is not in the well-founded part of $T_{x_i} \restriction h(\vec{\beta}; d_i)$, we leave $h(\vec{\beta}; \mathcal{C}_n; \gamma)$ undefined. Thus, for all $z \in \omega^\omega$, the sets $A_{z_n} \subseteq \omega_1$ are defined. We set $A_z = \bigcup_{n \in \omega} A_{z_n}$.

The following theorem says that this coding is reasonable.

4.13 Theorem. *The coding $z \to A_z$ satisfies the following:*

(1) $\forall A \subseteq \omega_1\ \exists z\ A = A_z$.

(2) $\forall \alpha < \omega_1\ \{z : \alpha \in A_z\} \in \boldsymbol{\Delta}^1_1$.

Proof. (1) follows immediately from Theorem 4.12. (2) is a straightforward computation using the facts that $\forall \beta < \omega_1 \ \{\sigma : \beta \in C_\sigma\} \in \boldsymbol{\Delta}^1_1$, and $\forall \beta, \gamma, \delta < \omega_1 \ \{z : |(T_z \restriction \beta)(\gamma)| \leq \delta\} \in \boldsymbol{\Delta}^1_1$. ⊣

If we view functions $F : \omega_1 \to \omega_1$ as subsets of $(\omega_1)^2$, and use our coding above (identifying $(\omega_1)^2$ with ω_1), it is not quite good enough to witness that ω_1 is ω_1-reasonable. To get this, we must make a small modification to our coding, essentially modifying only the first step of the proof of Theorem 4.8. We sketch the changes that need to be made.

We code binary relations $F \subseteq \omega_1 \times \omega_1$ as follows. Every real z codes countably many reals z_n, each of which codes reals σ_n, w^1_n, w^2_n, and a partial complex $\mathcal{C}_n = \langle W^m_1; x_0, \dots, x_{t-1}; d_0, \dots, d_t \rangle$. Set

$$\begin{aligned}(\alpha, \beta) \in F_z \longleftrightarrow \exists n \ \big[& w^1_n, w^2_n \in \mathrm{WO} \wedge |w^1_n| < \alpha \wedge |w^2_n| < \alpha \\ & \wedge \exists \beta_1 < \cdots < \beta_m \leq \alpha \ \big[\beta_1 > \max\{|w^1_n|, |w^2_n\} \wedge \forall i \ \beta_i \in C_{\sigma_n} \\ & \wedge \alpha = h(\vec{\beta}; \mathcal{C}; |w^1_n|) \wedge \beta = h(\vec{\beta}; \mathcal{C}; |w^2_n|)\big]\big] \\ & \wedge \forall n' \in \omega \ \big[\{w^1_{n'}, w^2_{n'} \in \mathrm{WO} \wedge |w^1_{n'}| < \alpha \wedge |w^2_{n'}| < \alpha \wedge \\ & \exists \beta'_1 < \cdots < \beta'_m \leq \alpha \ \big[\beta'_1 > \max\{w^1_{n'}, w^2_{n'}\} \wedge \forall i \ \beta'_i \in C_{\sigma_{n'}} \\ & \wedge \alpha = h(\vec{\beta}'; \mathcal{C}; |w^1_{n'}|)\big]\big\} \to h(\vec{\beta}'; \mathcal{C}; |w^2_{n'}|) = \beta\big].\end{aligned}$$

The main difference now is that the β_i are required to be $\leq \alpha$ (rather than $\leq \max\{\alpha, \beta\}$). Note also that if $F_z(\alpha, \beta)$ and $F_z(\alpha, \beta')$, then $\beta = \beta'$.

The analog of Theorem 4.12 becomes:

4.14 Theorem. *For every function $F : \omega_1 \to \omega_1$, $F = F_z$ for some z.*

Proof. Fix $F : \omega_1 \to \omega_1$. Let $X = \{(\alpha, \beta) : \beta = F(\alpha)\}$. Let $\mathcal{I}$ be the countably additive ideal on X consisting of countable unions of sets I such that $I \subseteq S \subseteq F$ for some *simple* S, that is, $S = S_{\sigma, \mathcal{C}, \gamma_1, \gamma_2}$ for some complex $\mathcal{C}$, well-founded T_σ, and $\gamma_1, \gamma_2 < \omega_1$, where

$$\begin{aligned}&(\alpha, \beta) \in S_{\sigma, \mathcal{C}, \gamma_1, \gamma_2} \\ &\quad \longleftrightarrow \ \exists \beta_1 < \cdots < \beta_m \leq \alpha \ \big[\beta_1 > \max\{\gamma_1, \gamma_2\} \\ &\qquad \wedge \forall i (\beta_i \in C_{\sigma_n}) \wedge \alpha = h(\vec{\beta}; \mathcal{C}; \gamma_1) \wedge \beta = h(\vec{\beta}; \mathcal{C}; \gamma_2)\big].\end{aligned}$$

We finish as in Theorem 4.12 provided we show that every measure ν on X is generated by simple sets. To do this, we need only modify the first step in the proof of Theorem 4.8.

Let $\pi(\alpha, \beta) = \alpha$ be the projection onto the first coordinate. Let $\nu' = \pi(\nu)$. Define g_0 exactly as in Theorem 4.8, using ν'. Let A be a ν' measure one set on which g_0 is monotonically increasing, and define $h(\alpha) = \sup\{\max(\beta, \gamma) : \beta \in A \wedge \gamma = F(\beta) \wedge g_0(\beta) \leq \alpha\}$. Let T_{x_0} be well-founded and $\forall^*_{W^1_1} \gamma \ h(\gamma) < |T_{x_0} \restriction \gamma|$. Thus, $\forall^*_\nu (\alpha, \beta) \ \max(\alpha, \beta) < |T_{x_0} \restriction g_0(\alpha)|$. Let $r_0, s_0 : \omega_1 \to \omega_1$ be such that $\forall^*_\nu (\alpha, \beta) \ r_0(\alpha), s_0(\alpha) < g_0(\alpha)$ and

$$\forall^*_\nu (\alpha, \beta) \ [\alpha = |(T_{x_0} \restriction g_0(\alpha))(r_0(\alpha))| \wedge \beta = |(T_{x_0} \restriction g_0(\alpha))(s_0(\alpha))|].$$

The argument then proceeds as in Theorem 4.8. ⊣

This coding suffices for the strong partition relation on ω_1.

4.15 Theorem. *The coding $z \to F_z$ witnesses that ω_1 is reasonable relative to the pointclass $\mathbf{\Sigma}^1_1$.*

Proof. (1) and (2) in Definition 2.33 are immediate, and (3) is a straightforward computation using the definition of F_z. (4) follows from the fact that if $A \in \mathbf{\Sigma}^1_1$, $\alpha < \omega_1$ and $\forall z \in A\ \exists \beta\ F_z(\alpha, \beta)$, then there is a $\mathbf{\Sigma}^1_1$ relation $\prec$ such that for all $z_1, z_2 \in A$, $F_{z_1}(\alpha) < F_{z_2}(\alpha) \longleftrightarrow z_1 \prec z_2$. ⊣

4.16 Corollary. $\omega_1 \to (\omega_1)^{\omega_1}$.

We now obtain the lower bound for $\boldsymbol{\delta}^1_3$, again, using only techniques that will generalize. We use the following general theorem of Martin.

4.17 Theorem (Martin). *Assume $\kappa \to (\kappa)^\kappa$. Then for any measure ν on κ, the ultrapower $j_\nu(\kappa)$ is a cardinal.*

Proof. Toward a contradiction, fix ν such that $j_\nu(\kappa)$ is not a cardinal, and let $F : j_\nu(\kappa) \to \lambda$ be a bijection, where $\lambda < j_\nu(\kappa)$. Consider the partition $\mathcal{P}$: we partition $f, g : \kappa \to \kappa$ of the correct type with $f(\alpha) < g(\alpha) < f(\alpha + 1)$ according to whether $F([f]_\nu) < F([g]_\nu)$. It is clear by wellfoundedness that we cannot have a closed unbounded set homogeneous for the contrary side of the partition. Let $C \subseteq \kappa$ be closed unbounded and homogeneous for $\mathcal{P}$. Fix an ordinal θ with $\lambda < \theta < j_\nu(\kappa)$, and let $[h]_\nu = \theta$. Define $h' : \kappa \to C$ inductively by: $h'(\alpha) =$ the $\omega \cdot (h(\alpha) + 1)$st element in C greater than $\sup_{\beta<\alpha} h'(\beta)$. Since κ is regular, this is well defined. We then produce an order preserving map H from θ into λ, a contradiction. Namely, if $\delta < \theta$, let $[f_\delta]_\nu = \delta$, with $f_\delta < h$ everywhere. Define $f'_\delta : \kappa \to C$ by: $f'_\delta(\alpha) =$ the $\omega \cdot (f_\delta(\alpha) + 1)$st element of C greater than $\sup_{\beta<\alpha} h'(\beta)$. Then set $H(\delta) = F([f'_\delta]_\nu)$. It is easy to see that this is well-defined and order-preserving from θ into λ. ⊣

4.18 Corollary. $\boldsymbol{\delta}^1_3 = \omega_{\omega+1}$.

Proof. Define $\pi : j_{W_1^m}(\omega_1) \to j_{W_1^{m+1}}(\omega_1)$ by: $\pi([f]_{W_1^m}) = [f']_{W_1^{m+1}}$ where $f'(\alpha_1, \ldots, \alpha_{m+1}) = f(\alpha_1, \ldots, \alpha_m)$. This gives an embedding from $j_{W_1^m}(\omega_1)$ into $[\mathrm{id}_{m+1}]_{W_1^{m+1}}$, where $\mathrm{id}_{m+1}(\alpha_1, \ldots, \alpha_{m+1}) = \alpha_{m+1}$. Thus, $j_{W_1^m}(\omega_1) < j_{W_1^{m+1}}(\omega_1)$. From Theorem 4.17 and the previous upper bound, it follows that $j_{W_1^n}(\omega_1) = \omega_{n+1}$. Using the Coding Lemma to code functions $f : (\omega_1)^m \to \omega_1$, and also our coding of closed unbounded sets, it is easy to compute the prewellordering corresponding to the ultrapower $j_{W_1^m}(\omega_1)$ as $\mathbf{\Delta}^1_3$ (in fact, a more careful computation shows that the prewellordering lies in the pointclass $\Game\, \omega \cdot m\text{–}\mathbf{\Pi}^1_1$). Thus, $\boldsymbol{\delta}^1_3 \geq \sup_m j_{W_1^m}(\omega_1) = \omega_\omega$. Since $\boldsymbol{\delta}^1_3$ is regular, $\boldsymbol{\delta}^1_3 \geq \omega_{\omega+1}$. ⊣

4.3. The Weak Partition Relation on $\boldsymbol{\delta}^1_3$

Starting from the weak partition relation on $\boldsymbol{\delta}^1_1 = \omega_1$, we have computed $\boldsymbol{\delta}^1_3$ and proved the strong partition relation on $\boldsymbol{\delta}^1_1$. To complete the cycle, we establish now the weak partition relation on $\boldsymbol{\delta}^1_3$. As we mentioned before, this is a result of Kunen (see [33]). Again, we wish to use only methods and terminology that will generalize. Nevertheless, the proof closely parallels Kunen's. An important concept which is introduced here is that of a *tree of uniform cofinalities*; this plays a central role in the general inductive analysis as well.

First, we analyze possible uniform cofinalities with respect to the measures W^m_1. This analysis is well known, but we emphasize that we use only the weak partition relation on ω_1 and the Kunen tree analysis.

4.19 Lemma. *Let $f : (\omega_1)^m \to \omega_1$, and assume $\forall^*_{W^m_1} \alpha_1, \ldots, \alpha_m\ f(\vec{\alpha})$ is a limit ordinal. Then either f has uniform cofinality ω almost everywhere with respect to W^m_1, or there is an i, $1 \leq i \leq m$, such that $f(\vec{\alpha})$ has uniform cofinality α_i almost everywhere. Also, each of these uniform cofinalities is distinct, that is, these cases are mutually exclusive.*

4.20 Remark. The uniform cofinalities other than ω are thus described by the descriptions d defined with respect to W^m_1. The lemma also holds for any $f : (\omega_1)^m \to \Theta$ assuming $\mathrm{AD} + V = L(\mathbb{R})$ (see Sect. 6).

Proof. Fix $f : (\omega_1)^m \to \omega_1$, and call a pair (S, l) a *liftup* to f provided $S : (\omega_1)^m \to \omega_1$, $l : \{(\alpha_1, \ldots, \alpha_m, \beta) : \beta < S(\vec{\alpha})\} \to \omega_1$ and $\forall^*_{W^m_1} \vec{\alpha}\ f(\vec{\alpha}) = \sup\{l(\vec{\alpha}, \beta) : \beta < S(\vec{\alpha})\}$. Fix a liftup (S, l) for which $[S]_{W^m_1}$ is minimal. If S is constant almost everywhere, then easily f has uniform cofinality ω. Let $1 \leq d \leq m$ be minimal so that $\forall^*_{W^m_1} \vec{\alpha}\ S(\vec{\alpha}) \leq h(\vec{\alpha}; d) = \alpha_d$. If equality holds almost everywhere we are done, as then $f(\vec{\alpha})$ has uniform cofinality α_d almost everywhere. Otherwise, there is an x with T_x well-founded such that $\forall^*_{W^m_1} \vec{\alpha}\ S(\vec{\alpha}) < |T_x \restriction \alpha_{d-1}|$ ($d > 1$ now). For almost all $\vec{\alpha}$, set $S'(\vec{\alpha}) = \alpha_{d-1}$, and for $\beta < \alpha_{d-1}$ define $l'(\vec{\alpha}, \beta) = \sup\{l(\vec{\alpha}, \gamma) : \gamma < |(T_x \restriction \alpha_{d-1})(\beta)|\}$ if $|(T_x \restriction \alpha_{d-1})(\beta)| < S(\vec{\alpha})$, and $= 0$ otherwise. Then (S', l') is a liftup to f with $[S']_{W^m_1} < [S]_{W^m_1}$, a contradiction. We leave the uniqueness proof to the reader. ⊣

We introduce some useful notation.

4.21 Definition. Suppose $\pi = (n, i_2, \ldots, i_n)$ is a permutation of $\{1, \ldots, n\}$ beginning with n. $<^\pi$ is the wellordering of $(\omega_1)^n$ defined by: $(\alpha_1, \ldots, \alpha_n)$ $<^\pi$ $(\beta_1, \ldots, \beta_n)$ iff $(\alpha_n, \alpha_{i_2}, \ldots, \alpha_{i_n}) <_{\mathrm{lex}} (\beta_n, \beta_{i_2}, \ldots, \beta_{i_n})$. We say an n-tuple of ordinals $(\gamma_1, \ldots, \gamma_n)$ has *type* π if it is order-isomorphic to π. By a *partial permutation* of n we mean a $\pi = (n, i_2, \ldots, i_m)$, $m \leq n$, which can be extended to a permutation. We likewise define the ordering $<^\pi$ on $(\omega_1)^n$ in this case by: $(\alpha_1, \ldots, \alpha_n) <^\pi (\beta_1, \ldots, \beta_n)$ iff $(\alpha_n, \alpha_{i_2}, \ldots, \alpha_{i_m}) <_{\mathrm{lex}}$ $(\beta_n, \beta_{i_2}, \ldots, \beta_{i_m})$. We identify $\vec{\alpha}, \vec{\beta} \in \mathrm{dom}(<^\pi)$ if $\alpha_n = \beta_n, \ldots, \alpha_{i_m} = \beta_{i_m}$.

Note that if $\pi = (n, i_2, \dots, i_m)$ is a partial permutation and $m < n$, then if $f : \mathrm{dom}(<^\pi) \to \omega_1$ is order-preserving, $f(\alpha_1, \dots, \alpha_n)$ depends only on $\alpha_n, \alpha_{i_2}, \dots, \alpha_{i_m}$.

If $\pi = (n, i_2, \dots, i_k)$, $\pi' = (m, j_2, \dots, j_l)$ are partial permutations, we say π' *extends* π provided $m \geq n$, $l > k$, and $(m, j_2, \dots, j_k)$ is order-isomorphic to π. If, in addition, $l = k + 1$, we say π' is an *immediate extension* of π.

4.22 Definition. If $\pi = (n, i_2, \dots, i_n)$ is a permutation and $f : <^\pi \to \omega_1$ is order-preserving, we define the "mth invariant" $f(m) : (\omega_1)^m \to \omega_1$, for $m \leq n$ by:

$$f(m)(\alpha_n, \alpha_{i_2}, \dots, \alpha_{i_m}) \\ = \sup\{f(\alpha_n, \alpha_{i_2}, \dots, \alpha_{i_m}, \beta_{i_{m+1}}, \dots, \beta_{i_n}) : (\alpha_n, \dots, \beta_{i_n}) \text{ has type } \pi\}.$$

For example, if $\pi = (3, 1, 2)$, and $f : \mathrm{dom}(<_\pi) \to \omega_1$ is order-preserving, then $f(2)(\alpha_1, \alpha_3) = \sup\{f(\alpha_1, \alpha_2, \alpha_3) : \alpha_1 < \alpha_2 < \alpha_3\}$. Recall our convention that for $g : (\omega_1)^2 \to \omega_1$ and $\alpha_1 < \alpha_3$, we write $g(\alpha_1, \alpha_3)$ interchangeably with $g(\alpha_3, \alpha_1)$, etc.

4.23 Lemma. *Let $f : (\omega_1)^n \to \omega_1$ with $\omega_n < [f]_{W_1^n}$. Then there is an $m \leq n$ and a partial permutation $\pi = (n, i_2, \dots, i_m)$ such that for some closed unbounded $C \subseteq \omega_1$ and any $\vec{\alpha}, \vec{\beta} \in (C)^n$, $f(\vec{\alpha}) < f(\vec{\beta})$ iff $(\alpha_n, \alpha_{i_2}, \dots, \alpha_{i_m}) <_{\mathrm{lex}} (\beta_n, \beta_{i_2}, \dots, \beta_{i_m})$.*

Proof. Suppose $(n, i_2, \dots, i_k)$ have been defined so that there is a closed unbounded $C \subseteq \omega_1$ satisfying

$$\forall \vec{\alpha}, \vec{\beta} \in (C)^n \ (\alpha_n, \alpha_{i_2}, \dots, \alpha_{i_k}) <_{\mathrm{lex}} (\beta_n, \beta_{i_2}, \dots, \beta_{i_k}) \to f(\vec{\alpha}) < f(\vec{\beta}).$$

For each $i \in \{1, \dots, n\} - \{n, i_1, \dots, i_k\}$, consider the partition $\mathcal{P}_i$: we partition ordinals $\alpha_1 < \cdots < \alpha_n$ and $\beta_1 < \cdots < \beta_n$ with $\alpha_n = \beta_n, \dots, \alpha_{i_k} = \beta_{i_k}$, $\alpha_i < \beta_i < \alpha_{i+1}$, and $\alpha_{j-1} < \beta_j < \alpha_j$ for all other j. We partition according to whether $f(\vec{\alpha}) < f(\vec{\beta})$.

If all the partitions $\mathcal{P}_i$ are homogeneous for the contrary side, it is easy to see that on a closed unbounded set, if $(\alpha_n, \dots, \alpha_{i_k}) = (\beta_n, \dots, \beta_{i_k})$, then $f(\vec{\alpha}) = f(\vec{\beta})$, and we are done.

Otherwise, it is easy to see that there is a unique i such that $\mathcal{P}_i$ is homogeneous for the stated side. We may then extend $(n, i_2, \dots, i_k)$ to $(n, i_2, \dots, i_k, i_{k+1})$, setting $i_{k+1} = i$. Continuing, we establish the theorem. ⊣

Lemmas 4.19 and 4.23 completely analyze the "type" of a function $f : (\omega_1)^n \to \omega_1$. If $\pi = (n, i_2, \dots, i_m)$ is a partial permutation of n, we say $f : (\omega_1)^n \to \omega_1$ is of type π if f is order-preserving from $<^\pi$ to ω_1, of uniform cofinality ω, and is everywhere discontinuous, that is, for $\vec{\alpha} \in (\omega_1)^n$, $f(\vec{\alpha}) > \sup\{f(\vec{\beta}) : \vec{\beta} <^\pi \vec{\alpha}\}$. We say that f is of type (π, s) if f is order-preserving from $<^\pi$ and for $\vec{\alpha} \in (\omega_1)^n$ of limit rank in $<^\pi$, $f(\vec{\alpha}) = \sup\{f(\vec{\beta}) :$

$\vec{\beta} <^{\pi} \vec{\alpha}\}$ (and for $\vec{\alpha}$ of successor rank, $f(\vec{\alpha})$ has uniform cofinality ω). Finally, if $\pi' = (n+1, j_2, \ldots, j_{m+1})$ is a partial permutation extending π, we say that f is of type (π, π') if f is order-preserving with respect to $<^{\pi}$, everywhere discontinuous, and $f(\alpha_{n+1}, \alpha_{j_2}, \ldots, \alpha_{j_m})$ has uniform cofinality $\{\beta : (\alpha_{n+1}, \alpha_{j_2}, \ldots, \alpha_{j_m}, \beta)$ has type $\pi'\}$ if this set has limit order-type (and otherwise has uniform cofinality ω). We say that f has type π, (π, s) or (π, π') almost everywhere if there is a closed unbounded C such that $f\restriction(C)^n$ is order-preserving with respect to $<^{\pi}$, and $f\restriction(C)^n$ has the appropriate uniform cofinality and continuity properties.

Lemmas 4.19 and 4.23 consequently say that if $f : (\omega_1)^n \to \omega_1$, $[f] > \omega_n$, and $\forall^*_{W_1^n} \vec{\alpha}\ f(\vec{\alpha})$ is a limit ordinal, then f has type π, (π, s), or (π, π') almost everywhere, for some partial permutation(s) π, π'.

The next lemma is simple but important. It says we may change the values of functions on measure zero sets so that they are everywhere ordered correctly.

4.24 Lemma (Sliding Lemma). *Suppose $f : (\omega_1)^m \to \omega_1$, $g : (\omega_1)^n \to \omega_1$ have types $\pi_1 = (m, i_2, \ldots, i_k)$, $\pi_2 = (n, j_2, \ldots, j_l)$ almost everywhere respectively. Suppose $r \leq \min(k, l)$ is such that $[f(r-1)] = [g(r-1)]$, but $[f(r)] < [g(r)]$. Then there are f', g' of types π_1, π_2 with $[f'] = [f]$, $[g'] = [g]$, $\mathrm{ran}(f') \subseteq \mathrm{ran}(f)$, $\mathrm{ran}(g') \subseteq \mathrm{ran}(g)$, and such that for all $\vec{\alpha} \in (\omega_1)^m$, $\vec{\beta} \in (\omega_1)^n$, $g(\vec{\beta}) > f(\vec{\alpha})$ iff $(\beta_n, \beta_{j_2}, \ldots, \beta_{j_r}) \geq_{\mathrm{lex}} (\alpha_m, \alpha_{i_2}, \ldots, \alpha_{i_r})$.*

Proof. Note that $(m, i_2, \ldots, i_r)$, $(n, j_2, \ldots, j_r)$ are order-isomorphic, say to the permutation $\pi = (r, k_2, \ldots, k_r)$, by uniqueness of the uniform cofinality and the fact that $[f(r-1)] = [g(r-1)]$. Let $C_1 \subseteq \omega_1$ be closed unbounded such that $f\restriction(C_1)^m$ is order-preserving with respect to $<^{\pi_1}$ and of uniform cofinality ω, and similarly for g. Let $l : \omega_1 \to \omega_1$, and $C \subseteq C_1$ be closed unbounded and closed under l such that

$$\begin{aligned}\forall \vec{\alpha} \in (C)^r\ f(r)(\alpha_r, \alpha_{k_2}, \ldots, \alpha_{k_r}) &< g(r)(\alpha_r, \alpha_{k_2}, \ldots, \alpha_{k_r}) \\ &< f(r)(\alpha_r, \alpha_{k_2}, \ldots, l(\alpha_{k_r})).\end{aligned}$$

Let $p(\alpha) =$ the $\omega \cdot \alpha$th element of C. Define

$$f'(\alpha_1, \ldots, \alpha_m) = f(p(\alpha_1), \ldots, p(\alpha_m)),$$

and similarly

$$g'(\alpha_1, \ldots, \alpha_n) = g(p(\alpha_1), \ldots, p(\alpha_n)).$$

It is easy to check that f', g' have the desired properties. ⊣

A useful special case of the lemma is that if $f : (\omega_1)^n \to \omega_1$ has type π almost everywhere, then there is an f' of type π with $[f'] = [f]$ and $\mathrm{ran}(f') \subseteq \mathrm{ran}(f)$. A small variation of the argument shows this is also true for functions f of type (π, s) or (π, π') almost everywhere.

We now define the notion of a tree of uniform cofinalities, which plays an important role in the projective hierarchy analysis. The concept is similar to that of a homogeneous tree. Roughly speaking, for each node in this tree we allow as extensions all possible uniform cofinalities with respect to the measure which is associated to that node (these uniform cofinalities in turn define new measures).

In the following definition, we let $(s), (\omega)$ be two formal symbols (the first stands for "sup", and the second for "uniform cofinality ω").

4.25 Definition. A *type-1* tree of uniform cofinalities (of depth n) is a function $\mathcal{R}$ satisfying the following:

(1) $\langle p_1, i_1\rangle \in \mathrm{dom}(\mathcal{R})$ for $0 \le i_1 \le a$ for some integer a, and $p_1 =$ the unique permutation of length 1, namely $p_1 = (1)$. For $i_1 = 0$, $\mathcal{R}(\langle p_1, i_1\rangle) = (s)$, and for $i_1 > 0$, $\mathcal{R}(\langle p_1, i_1\rangle)$ is either (ω), or a permutation p_2 of length 2 (hence $p_2 = (2, 1)$). Also, $\langle p_1, i_1\rangle$ is maximal in $\mathrm{dom}(\mathcal{R})$ iff $\mathcal{R}(\langle p_1, i_1\rangle) = (s)$ or (ω).

(2) In general, $\mathrm{dom}(\mathcal{R})$ consists of tuples $\langle p_1, i_1, \dots, i_{m-1}, p_m, i_m\rangle$, $m \le n$, and such a tuple is maximal in $\mathrm{dom}(\mathcal{R})$ iff $\mathcal{R}(\langle p_1, i_1, \dots, p_m, i_m\rangle) = (s)$ or (ω) (these are the only values permitted, therefore, if $m = n$). $\mathcal{R}(\langle p_1, i_1, \dots, p_m, i_m\rangle) = (s)$ iff $i_m = 0$. If $\mathcal{R}(\langle p_1, i_1, \dots, p_m, i_m\rangle) \ne (s)$ or (ω), then $\mathcal{R}(\langle p_1, i_1, \dots, p_m, i_m\rangle)$ is a permutation p_{m+1} immediately extending p_m. In this case, $(\langle p_1, i_1, \dots, p_m, i_m, p_{m+1}, i_{m+1}\rangle) \in \mathrm{dom}(\mathcal{R})$ for some integers $0 \le i_{m+1} \le a$ ($a \ge 0$ and depends on $\langle p_1, i_1, \dots, p_m, i_m, p_{m+1}\rangle$).

For $\mathcal{R}$ a type-1 tree of uniform cofinalities, we define $<^{\mathcal{R}}$ to be the lexicographic ordering on sequences $\langle \alpha_1, i_1, \dots, i_{m-1}, \alpha_m, i_m\rangle$, $m \le n$, satisfying:

(1) $\alpha_1, \dots, \alpha_m < \omega_1$.

(2) $(\alpha_1, \dots, \alpha_m)$ is of type p_m, where $(p_1, \dots, p_m)$ is the unique sequence such that $\langle p_1, i_1, \dots, p_m, i_m\rangle \in \mathrm{dom}(\mathcal{R})$.

We say a sequence $\langle \alpha_1, i_1, \dots, \alpha_m, i_m\rangle$ with $(\alpha_1, \dots, \alpha_m)$ as in (2) is of type $\langle p_1, i_1, \dots, p_m, i_m\rangle$.

To each tree of uniform cofinalities $\mathcal{R}$ we associate a measure $M^{\mathcal{R}}$. First, say a function $f : \mathrm{dom}(<^{\mathcal{R}}) \to \omega_1$ is of *type* $\mathcal{R}$ if it is order-preserving, $f(\langle \alpha_1, i_1, \dots, \alpha_m, i_m\rangle)$ has uniform cofinality ω if $\mathcal{R}(\langle p_1, i_1, \dots, p_m, i_m\rangle) = (\omega)$ or $\langle \alpha_1, i_1, \dots, \alpha_m, i_m\rangle$ has successor rank in $<^{\mathcal{R}}$ (for $\langle \alpha_1, i_1, \dots, \alpha_m, i_m\rangle$ having type $\langle p_1, i_1, \dots, p_m, i_m\rangle$), and otherwise

$$f(\langle \alpha_1, i_1, \dots, \alpha_m, i_m\rangle) = \sup\{f(\vec{s}) : \vec{s} <^{\mathcal{R}} \langle \alpha_1, i_1, \dots, \alpha_m, i_m\rangle\}.$$

Define A to have measure one with respect to $M^{\mathcal{R}}$ iff $\exists$ c.u.b. $C \subseteq \omega_1$ $\forall f : \mathrm{dom}(<^{\mathcal{R}}) \to C$ of type $\mathcal{R}$ $(\dots, \alpha^{\langle p_1, i_1, \dots, p_m, i_m\rangle}, \dots) \in A$, where $\alpha^{\langle p_1, i_1, \dots, p_m, i_m\rangle}$ is represented with respect to W_1^m by:

$$f^{\langle p_1, i_1, \dots, p_m, i_m\rangle}(\alpha_1, \dots, \alpha_m) = f(\langle \alpha_1, i_1, \dots, \alpha_m, i_m\rangle).$$

(Recall our notational convention; the $\alpha_1, \dots, \alpha_m$ here are not written in increasing order).

Thus, each $M^{\mathcal{R}}$ is a measure on $(\omega_\omega)^{<\omega}$, and these measures generalize somewhat the measures occurring in the homogeneous tree construction on a $\boldsymbol{\Pi}^1_2$-complete set. We note that the requirement that $\langle p_1, i_1, \dots, p_m, i_m\rangle$ be non-maximal in $\mathrm{dom}(\mathcal{R})$ if $\mathcal{R}(\langle p_1, i_1, \dots, p_m, i_m\rangle) \neq (s)$ or (ω) causes no essential loss of generality as far as specifying functions of type $\mathcal{R}$ is concerned. For suppose $\mathcal{R}(\langle p_1, i_1, \dots, p_m, i_m\rangle) = p_{m+1}$, where p_{m+1} is the permutation $(m+1, j_2, \dots, j_m, j_{m+1})$. Thus, p_m is order-isomorphic to $(m+1, j_2, \dots, j_m)$. Suppose $f : \mathrm{dom}(<^{p_m}) \to \omega_1$ is order-preserving, f is discontinuous, that is, for $(\alpha_1, \dots, \alpha_m)$ of type p_m we have

$$f(\alpha_1, \dots, \alpha_m) > \sup\{f(\vec{\beta}) : \vec{\beta} <^{\pi} \vec{\alpha}\},$$

and for W^m_1 almost $(\alpha_1, \dots, \alpha_m)$ of type p_m we have $f(\vec{\alpha})$ has uniform cofinality $\{\beta : (\alpha_1, \dots, \alpha_m, \beta) \text{ has type } p_{m+1}\}$. By definition, there is an

$$f' : \{(\alpha_1, \dots, \alpha_m, \beta) : (\alpha_1, \dots, \alpha_m, \beta) \text{ has type } p_{m+1}\} \to \omega_1$$

order-preserving with respect to $<^{p_{m+1}}$, so that $f'(\vec{\alpha}, \beta) = \sup_{\beta' < \beta} f'(\vec{\alpha}, \beta')$ for limit β and f' induces f in that $f(\vec{\alpha}) = \sup_\beta f'(\vec{\alpha}, \beta)$ almost everywhere. Furthermore, it is not difficult to see that $[f']_{W_1^{m+1}}$ is uniquely determined from $[f]_{W_1^m}$. This shows that adding $\langle p_1, i_1, \dots, p_m, i_m, p_{m+1}, 0\rangle$ to $\mathrm{dom}(\mathcal{R})$ does no harm.

If $\mathcal{R}$ is a type-1 tree of uniform cofinalities, and $f_1, f_2 : \mathrm{dom}(<^{\mathcal{R}}) \to \omega_1$ are of type $\mathcal{R}$, we write $[f_1] = [f_2]$ to mean that for all $\langle p_1, i_1, \dots, p_k, i_k\rangle \in \mathrm{dom}(\mathcal{R})$ we have $[f_1^{\langle p_1, i_1, \dots, p_k, i_k\rangle}]_{W_1^k} = [f_2^{\langle p_1, i_1, \dots, p_k, i_k\rangle}]_{W_1^k}$.

We say the type-1 tree of uniform cofinalities $\mathcal{R}'$ *extends* $\mathcal{R}$ if there is a length preserving injection $\rho : \mathrm{dom}(\mathcal{R}) \to \mathrm{dom}(\mathcal{R}')$ such that $\mathcal{R}(\vec{s}) = \mathcal{R}'(\rho(\vec{s}))$ for all $\vec{s} \in \mathrm{dom}(\mathcal{R})$. We usually just say $\vec{s} \in \mathrm{dom}(\mathcal{R})$ is "identified" with $\rho(\vec{s}) \in \mathrm{dom}(\mathcal{R}')$. We say $\mathcal{R}'$ is an *immediate extension* of $\mathcal{R}$ is there is exactly one sequence $\vec{s}$ not ending in 0 in $\mathrm{dom}(\mathcal{R}') - \mathrm{dom}(\mathcal{R})$.

We say $\mathcal{R}'$ is a *partial extension* of $\mathcal{R}$ if $\mathcal{R}'$ has a unique extra sequence $\vec{s} = \langle q_1, j_1, \dots, q_l, j^*_l\rangle$ in $\mathrm{dom}(\mathcal{R}')$, and $j^*_l \neq 0$. More precisely, this means that $\langle q_1, j_1, \dots, q_l, j_l\rangle \in \mathrm{dom}(\mathcal{R})$ for $0 \le j_l \le a$ and we have $\langle q_1, j_1, \dots, q_l, j_l\rangle \in \mathrm{dom}(\mathcal{R}')$ for $0 \le j_l \le a+1$. For $j_l < j^*_l$, we identify $\langle q_1, j_1, \dots, q_l, j_l\rangle \in \mathrm{dom}(<^{\mathcal{R}})$ with $\langle q_1, j_1, \dots, q_l, j_l\rangle \in \mathrm{dom}(<^{\mathcal{R}'})$, and for $j_l \ge j^*_l$, we identify $\langle q_1, j_1, \dots, q_l, j_l\rangle \in \mathrm{dom}(<^{\mathcal{R}})$ with $\langle q_1, j_1, \dots, q_l, j_l + 1\rangle \in \mathrm{dom}(<^{\mathcal{R}'})$. We leave $\mathcal{R}'(\vec{s})$ undefined (more formally, in order to still have $\vec{s} \in \mathrm{dom}(\mathcal{R}')$, we require $\mathcal{R}'(\vec{s})$ to be a formal symbol (u) for "undefined"). We define $<^{\mathcal{R}'}$ as for immediate extensions. Thus, after identifying $\mathrm{dom}(<^{\mathcal{R}})$ with a subset of $\mathrm{dom}(<^{\mathcal{R}'})$ we have

$$\mathrm{dom}(<^{\mathcal{R}'}) = \mathrm{dom}(<^{\mathcal{R}}) \cup \{\langle \alpha_1, j_1, \dots, \alpha_l, j^*_l\rangle : (\alpha_1, \dots, \alpha_l) \text{ has type } q_l\}.$$

Finally, we say that $g' : \mathrm{dom}(<^{\mathcal{R}'}) \to \omega_1$ is of *semi-type* $\mathcal{R}'$ if g' is order-preserving with respect to $<^{\mathcal{R}'}$, and the function $g : \mathrm{dom}(<^{\mathcal{R}}) \to \omega_1$ it induces by restriction is of type $\mathcal{R}$. Note that g' being of semi-type $\mathcal{R}'$ imposes no restriction on the uniform cofinality of the component function $g'^{\langle q_1, j_1, \dots, q_l, j_l^* \rangle}$.

Lemma 4.24 generalizes to level-1 trees of uniform cofinalities as follows.

4.26 Lemma. *Let $\mathcal{R}$ be a level-1 tree of uniform cofinalities, and suppose $f : \mathrm{dom}(<^{\mathcal{R}}) \to \omega_1$ is of type $\mathcal{R}$. Suppose $\vec{s} = \langle p_1, i_1, \dots, p_k, i_k \rangle$ is non-maximal in $\mathrm{dom}(\mathcal{R})$, and $\mathcal{R}(\vec{s}) = p_{k+1}$. Suppose $\delta \in \mathrm{On}$ and for W_1^{k+1} almost all $(\alpha_1, \dots, \alpha_{k+1})$ of type p_{k+1} we have $\delta(\vec{\alpha}) < f(\langle \alpha_1, i_1, \dots, \alpha_k, i_k \rangle)$. Let i_{k+1}^* be maximal such that $\langle p_1, i_1, \dots, p_{k+1}, i_{k+1}^* \rangle \in \mathrm{dom}(\mathcal{R})$. Let $\mathcal{R}'$ be the partial extension of $\mathcal{R}$ with extra sequence $\langle p_1, i_1, \dots, p_{k+1}, i_{k+1}^* + 1 \rangle$ in its domain. Then there is an f' of semi-type $\mathcal{R}'$ such that:*

(1) $[f' \restriction \mathrm{dom}(<^{\mathcal{R}})] = [f]$. *That is, for each $\langle q_1, j_1, \dots, q_l, j_l \rangle \in \mathrm{dom}(\mathcal{R})$, $\forall^*_{W_1^l}(\alpha_1, \dots, \alpha_l)\ f'(\langle \alpha_1, q_1, \dots, \alpha_l, q_l \rangle) = f(\langle \alpha_1, q_1, \dots, \alpha_l, q_l \rangle)$.*

(2) $\mathrm{ran}(f') \subseteq \mathrm{ran}(f) \cup (\mathrm{ran}(f))'$.

(3) $\forall^*_{W_1^{k+1}}(\alpha_1, \dots, \alpha_{k+1})\ \delta(\vec{\alpha}) < f'(\langle \alpha_1, i_1 \dots, \alpha_{k+1}, i_{k+1}^* \rangle)$.

Proof. Fix a representing function $\vec{\alpha} \to \delta(\vec{\alpha})$ for δ, and fix $b : \omega_1 \to \omega_1$ and a closed unbounded $C \subseteq \omega_1$ closed under b such that for all $(\alpha_1, \dots, \alpha_{k+1})$ of type p_{k+1} in C, $\delta(\vec{\alpha}) < f(\langle \alpha_1, i_1, \dots, \alpha_k, i_k, b(\alpha_{k+1}), 0 \rangle)$. Let D be the set of closure points of C, and define $l(\alpha) = \alpha$th element of D. For $\langle \alpha_1, j_1, \dots, \alpha_l, j_l \rangle \in \mathrm{dom}(<^{\mathcal{R}})$, define

$$f'(\langle \alpha_1, j_1, \dots, \alpha_l, j_l \rangle) = f(\langle l(\alpha_1), j_1, \dots, l(\alpha_l), j_l \rangle).$$

Define also

$$f'(\langle \alpha_1, i_1, \dots, i_k, \alpha_{k+1}, i_{k+1}^* \rangle) = f(\langle l(\alpha_1), i_1, \dots, l(\alpha_k), i_k, \beta, 0 \rangle),$$

where β is the ωth element of C greater than $l(\alpha_{k+1})$. It is easy to check that f' satisfies (1)–(3) above, and also satisfies all of the requirements for being of type $\mathcal{R}$ except for the requirement that $f'(\vec{s})$ have uniform cofinality ω for $\vec{s}$ in certain measure zero sets. It is easy, however, to redefine $f'(\vec{s})$ at these points to guarantee this last requirement. ⊣

4.27 Definition. A *generalized trivial* (or *type-1*) *description* defined relative to a measure W_1^m and a type-1 tree of uniform cofinalities $\mathcal{R}$ is a sequence $d = \langle d_1, i_1, \dots, d_k, i_k \rangle$ where each d_i is a trivial description defined relative to W_1^m (i.e., $1 \leq d_i \leq m$), and for some (uniquely determined) $\langle p_1, i_1, \dots, p_k, i_k \rangle \in \mathrm{dom}(\mathcal{R})$ we have p_k is order-isomorphic to $(d_1, d_2, \dots, d_k)$. We order the generalized descriptions lexicographically.

We extend the interpretation function h to generalized descriptions. If $d = \langle d_1, i_1, \dots, d_k, i_k \rangle$ is defined relative to W_1^m and $\mathcal{R}$, $f : \mathrm{dom}(<^{\mathcal{R}}) \to \omega_1$ is of type $\mathcal{R}$, and $\beta_1 < \dots < \beta_m$, then we define

$$h(f; \vec{\beta}; d) = f(\langle h(\vec{\beta}; d_1), i_1, \dots, h(\vec{\beta}; d_k), i_k \rangle).$$

We extend also the lowering operation $\mathcal{L}$ to generalized descriptions as follows.

4.28 Definition. Suppose $d = \langle d_1, i_1, \ldots, d_k, i_k \rangle$ is defined relative to W_1^m and $\mathcal{R}$. Let $\langle p_1, i_1, \ldots, p_k, i_k \rangle \in \mathrm{dom}(\mathcal{R})$, where p_k is order-isomorphic to $(d_1, \ldots, d_k)$. We define $\mathcal{L}(d)$ through the following cases:

(1) If $\mathcal{R}(\langle p_1, i_1, \ldots, p_k, i_k \rangle) = (\omega)$, $\mathcal{L}(d) = \langle d_1, i_1, \ldots, d_k, i_k - 1 \rangle$ (note here that $i_k > 0$).

(2) If $i_k = 0$, then $\mathcal{L}(d) = \langle d_1, i_1, \ldots, \mathcal{L}(d_k), i_k^* \rangle$ provided $\mathcal{L}(d_k)$ is defined (i.e., $d_k > 1$) and $(d_1, \ldots, \mathcal{L}(d_k))$ is order-isomorphic to p_k. Here i_k^* is maximal such that $\langle p_1, i_1, \ldots, p_k, i_k^* \rangle \in \mathrm{dom}(\mathcal{R})$. Otherwise, set $\mathcal{L}(d) = \langle d_1, i_1, \ldots, d_{k-1}, i_{k-1} - 1 \rangle$ (note that $i_{k-1} > 0$) provided $k > 1$. For $k = 1$ in this case (and thus $d = \langle d_1, 0 \rangle$, with $d_1 = 1$), we declare d to be $\mathcal{L}$-minimal, and do not define $\mathcal{L}(d)$.

(3) Suppose now that $i_k > 0$ and $\mathcal{R}(\langle p_1, i_1, \ldots, p_k, i_k \rangle) = p_{k+1}$. Let $1 \leq j \leq k$ be such that if $\alpha_{d_j - 1} < \beta < \alpha_{d_j}$, then $(\alpha_{d_1}, \ldots, \alpha_{d_k}, \beta)$ is order-isomorphic to p_{k+1}. If $d_{k+1}^* \doteq d_j - 1 \notin \{d_1, \ldots, d_k\}$, set $\mathcal{L}(d) = \langle d_1, i_1, \ldots, d_k, i_k, d_{k+1}^*, i_{k+1}^* \rangle$, where i_{k+1}^* is maximal such that

$$\langle p_1, i_1, \ldots, p_k, i_k, p_{k+1}, i_{k+1}^* \rangle \in \mathrm{dom}(\mathcal{R}).$$

If $d_j - 1 = 0$ or $d_j - 1 \in \{d_1, \ldots, d_k\}$, set $\mathcal{L}(d) = \langle d_1, i_1, \ldots, d_k, i_k - 1 \rangle$.

The significance of this definition is embodied in the following lemma.

4.29 Lemma. *Suppose $d = \langle d_1, i_1, \ldots, d_k, i_k \rangle$ is defined relative to $W_1^m, \mathcal{R}$, and $f : \mathrm{dom}(<^{\mathcal{R}}) \to \omega_1$ has type $\mathcal{R}$. Let $\delta \in \mathrm{On}$ be such that $\forall^*_{W_1^m} \vec{\beta}\ \delta(\vec{\beta}) < h(f; \vec{\beta}; d)$. Suppose d is non-minimal with respect to $\mathcal{L}$. Then there is an $f' : \mathrm{dom}(<^{\mathcal{R}}) \to \omega_1$ of type $\mathcal{R}$ such that $[f'] = [f]$ and $\forall^*_{W_1^m} \vec{\beta}\ \delta(\vec{\beta}) < N_{f'}(h(f'; \vec{\beta}; \mathcal{L}(d)))$.*

Proof. The result follows easily from Lemma 4.26 in all cases. For example, suppose $d = \langle d_1, i_1, \ldots, d_k, i_k \rangle$, and $\mathcal{L}(d) = \langle d_1, i_1, \ldots, d_k, i_k, d_{k+1}^*, i_{k+1}^* \rangle$, where $d_{k+1}^* = d_j - 1$. Thus,

$$\forall^*_{W_1^m} \vec{\alpha}\ \exists \beta < \alpha_{d_j}\ \ \delta(\vec{\alpha}) < f(\langle h(\vec{\alpha}; d_1), i_1, \ldots, h(\vec{\alpha}; d_k), i_k, \beta, 0 \rangle).$$

Thus, there is an $l : \omega_1 \to \omega_1$ such that

$$\forall^*_{W_1^m} \vec{\alpha}\ \delta(\vec{\alpha}) < f(\langle h(\vec{\alpha}; d_1), i_1, \ldots, h(\vec{\alpha}; d_k), i_k, l(\alpha_{d_j - 1}), 0 \rangle).$$

From Lemma 4.26 there is an f' of type $\mathcal{R}$ with $[f'] = [f]$ (and in fact with $\mathrm{ran}(f') \subseteq \mathrm{ran}(f) \cup \mathrm{ran}(f)'$), and

$$\begin{aligned} \forall^* \vec{\alpha}\ & N_{f'}(\langle h(\vec{\alpha}; d_1), i_1, \ldots, h(\vec{\alpha}; d_k), i_k, \alpha_{d_j j - 1}, i_{k+1}^* \rangle) \\ & > f(\langle h(\vec{\alpha}; d_1), i_1, \ldots, h(\vec{\alpha}; d_k), i_k, l(\alpha_{d_j - 1}), 0 \rangle). \end{aligned}$$

f' is as desired. ⊣

4.30 Definition. A *level-2 complex* $\mathcal{C} = \langle \mathcal{R}; W_1^m; x_0, \dots, x_{n-1}; d_0, \dots, d_n \rangle$ is a sequence where $\mathcal{R}$ is a type-1 tree of uniform cofinalities, $T_{x_0}, \dots, T_{x_{n-1}}$ are well-founded, and $d_0, \dots, d_n$ are generalized trivial descriptions defined relative to W_1^m.

For $\mathcal{C}$ a complex as above, $f : \mathrm{dom}(<^{\mathcal{R}}) \to \omega_1$ of type $\mathcal{R}$, $\vec{\beta} \in (\omega_1)^m$, and $\gamma < \omega_1$, we define $h(f; \vec{\beta}; \mathcal{C}; \gamma) = |T_{x_0} \restriction h(f; \vec{\beta}; d_0)(\alpha_1)|$, where $\alpha_1 = |T_{x_1} \restriction h(f; \vec{\beta}; d_1)(\alpha_2)|, \dots, \alpha_{n-1} = |T_{x_{n-1}} \restriction h(f; \vec{\beta}; d_{n-1})(\alpha_n)|$, and $\alpha_n = \gamma$. For f of type $\mathcal{R}$, we let $h(f; W_1^m; \mathcal{C}; \gamma) < \omega_{m+1}$ be the ordinal represented with respect to W_1^m by the function $\vec{\beta} \to h(f; \vec{\beta}; \mathcal{C}; \gamma)$. Note that d_n is not used in the definition of $h(f; \vec{\beta}; \mathcal{C}; \gamma)$ (it plays a role in the definition of a situation below).

The following theorem analyzes the measures on ω_ω.

4.31 Theorem. *Let ν be a measure on ω_ω. Then there is a measure μ on ω_1 and a complex $\mathcal{C} = \langle \mathcal{R}; W_1^m; x_0, \dots, x_{n-1}; d_0, \dots, d_n \rangle$ such that for all $A \subseteq \omega_\omega$:*

$$\begin{aligned} \nu(A) = 1 \longleftrightarrow {} & \forall^*_\mu \gamma \; \exists \text{ c.u.b. } C \subseteq \omega_1 \\ & \forall f : \mathrm{dom}(<^{\mathcal{R}}) \to C \text{ of type } \mathcal{R} \; [h(f; W_1^m; \mathcal{C}; \gamma) \in A]. \end{aligned}$$

Proof. The proof is similar to that of Theorem 4.8. Fix the measure ν, and let m be least such that $\nu(\omega_{m+1}) = 1$. We may assume $m \geq 1$.

4.32 Definition. A *situation* for ν is a triple $(\mathcal{C}, g, r)$ consisting of a complex $\mathcal{C} = \langle \mathcal{R}; W_1^m; x_0, \dots, x_{n-1}; d_0, \dots, d_n \rangle$ (same m as above), and functions g, r with domain ω_{m+1} satisfying:

(1) $g : \omega_{m+1} \to \omega_{m+1}^{<\omega}$ and $g(\nu) = M^{\mathcal{R}}$, the measure associated with $\mathcal{R}$.

(2) $r : \omega_{m+1} \to \omega_{m+1}$ and $\forall^*_\nu \alpha \; r(\alpha) < h(g(\alpha); W_1^m; d_n)$.

(3) $\forall^*_\nu \alpha \; [\alpha = h(g(\alpha); W_1^m; \mathcal{C}; r(\alpha))]$.

Note that in (2) and (3), when we write $h(g(\alpha); W_1^m; d_n)$, for example, we mean $h(g; W_1^m; d_n)$ where $g : \mathrm{dom}(<^{\mathcal{R}}) \to \omega_1$ of type $\mathcal{R}$ represents $g(\alpha)$.

We fix now a situation $(\mathcal{C}; g; r)$ for ν with minimal value for

$$[\alpha \to h(g(\alpha); W_1^m; d_n)]_\nu,$$

where $\mathcal{C} = \langle \mathcal{R}; W_1^m; x_0, \dots, x_{n-1}; d_0, \dots, d_n \rangle$.

We claim that $\forall^*_\nu \alpha \; r(\alpha) < \omega_1$. Granting this, let $\mu = r(\nu)$. Let ν' be the measure defined by:

$$\begin{aligned} \nu'(A) = 1 \longleftrightarrow {} & \forall^*_\mu \gamma \; \exists \text{ c.u.b. } C \subseteq \omega_1 \\ & \forall f : \mathrm{dom}(<^{\mathcal{R}}) \to C \text{ of type } \mathcal{R} \; [h(f; W_1^m; \mathcal{C}; \gamma) \in A]. \end{aligned}$$

We show that $\nu' = \nu$. Suppose not, and let $\nu'(A) = 1$, $\nu(A^c) = 1$. By the ω_2-additivity of $M^{\mathcal{R}}$ (which follows from an easy partition argument) fix a μ measure one set $D \subseteq \omega_1$, and a closed unbounded $C \subseteq \omega_1$ such that if $\gamma \in D$ and $f : \text{dom}(<^{\mathcal{R}}) \to C$ is of type $\mathcal{R}$, then $h(f; W_1^m; \mathcal{C}; \gamma) \in A$. Since $g(\nu) = M^{\mathcal{R}}$ and $r(\nu) = \mu$, there is an $\alpha \in A^c$ such that $r(\alpha) \in D$ and $g(\alpha)$ is representable by $f : \text{dom}(<^{\mathcal{R}}) \to C$ of type $\mathcal{R}$, and such that $\alpha = h(f; W_1^m; \mathcal{C}; r(\alpha))$. However, $h(f; W_1^m; \mathcal{C}; r(\alpha)) \in A$, a contradiction.

To fix notation, say $d_n = \langle d_1^n, i_1, \ldots, d_k^n, i_k\rangle$. We may assume d_n is non-minimal with respect to $\mathcal{L}$, since otherwise $\forall^*_\nu \alpha\, r(\alpha) < h(g(\alpha); W_1^m; d_n) = \omega_1$. We proceed to violate the minimality of $(\mathcal{C}; g; r)$. From Lemma 4.29 we have that $\forall^*_\nu \alpha\ \exists f : \text{dom}(<^{\mathcal{R}}) \to \omega_1$ of type $\mathcal{R}$ such that $[f] = g(\alpha)$ and $\forall^*_{W_1^m} \vec{\beta}\ r(\alpha)(\vec{\beta}) < N_f(h(f; \vec{\beta}; \mathcal{L}(d_n))$.

Define a partial extension $\mathcal{R}'$ of $\mathcal{R}$ as follows. If

$$\mathcal{L}(d_n) = \langle d_1^n, i_1, \ldots, d_k^n, i_k - 1\rangle,$$

then $\mathcal{R}'$ has the extra sequence $\langle d_1^n, i_1, \ldots, d_k^n, i_k\rangle$ in its domain. We identify $\langle d_1^n, \ldots, i\rangle \in \text{dom}(\mathcal{R})$ with $\langle d_1^n, \ldots, i\rangle \in \text{dom}(\mathcal{R}')$ for $i < i_k$, and with $\langle d_1^n, \ldots, i+1\rangle \in \text{dom}(\mathcal{R}')$ for $i \geq i_k$. If $i_k = 0$ and

$$\mathcal{L}(d_n) = \langle d_1^n, i_1, \ldots, \mathcal{L}(d_k^n), i_k^*\rangle,$$

then $\mathcal{R}'$ has the extra sequence $\langle d_1^n, i_1, \ldots, \mathcal{L}(d_k^n), i_k^* + 1\rangle$ in its domain. If $i_k = 0$ and

$$\mathcal{L}(d_n) = \langle d_1^n, i_1, \ldots, d_{k-1}^n, i_{k-1} - 1\rangle,$$

then $\mathcal{R}'$ has the extra sequence $\langle d_1^n, i_1, \ldots, d_{k-1}^n, i_{k-1}\rangle$ in its domain. Finally, if

$$\mathcal{L}(d_n) = \langle d_1^n, i_1, \ldots, d_k^n, i_k, d_{k+1}^*, i_{k+1}^*\rangle,$$

then $\mathcal{R}'$ has the extra sequence $\langle d_1^n, i_1, \ldots, d_k^n, i_k, d_{k+1}^*, i_{k+1}^*+1\rangle$ in its domain. Thus, in all cases the extra sequence is inserted according to Lemma 4.29. In all cases, let d_n^* be the generalized description corresponding to the extra sequence in the partial complex $\mathcal{R}'$. For example, if

$$\mathcal{L}(d_n) = \langle d_1^n, i_1, \ldots, d_k^n, i_k - 1\rangle,$$

then $d_n^* = d_n = \langle d_1^n, i_1, \ldots, d_k^n, i_k\rangle$, and if

$$\mathcal{L}(d_n) = \langle d_1^n, i_1, \ldots, d_k^n, i_k, d_{k+1}^*, i_{k+1}^*\rangle,$$

then $d_n^* = \langle d_1^n, i_1, \ldots, d_{k+1}^*, i_{k+1}^* + 1\rangle$.

To unify notation, let $\vec{s} = \langle q_1, j_1, \ldots, q_l, j_l\rangle$ be the extra sequence in $\text{dom}(\mathcal{R}') - \text{dom}(\mathcal{R})$. We therefore have: $\forall^*_\nu \alpha\ \exists f' : \text{dom}(\mathcal{R}') \to \omega_1$ of semi-type $\mathcal{R}'$ inducing f of type $\mathcal{R}$ such that $[f] = g(\alpha)$ and $\forall^*_{W_1^m} \vec{\beta}\ r(\alpha)(\vec{\beta}) < N_{f'}(h(f; \vec{\beta}; \mathcal{L}(d_n)))$. As in Theorem 4.8 we consider two cases.

First suppose there is a ν measure one A such that for all $\alpha \in A$ there is a $f' : \mathrm{dom}(<^{\mathcal{R}'}) \to \omega_1$ of semi-type $\mathcal{R}'$ inducing (by restriction) the function $f : \mathrm{dom}(<^{\mathcal{R}}) \to \omega_1$ of type $\mathcal{R}$ such that $[f] = g(\alpha)$ and

$$\forall \alpha' \in A \ \big[(g(\alpha') = g(\alpha)) \to \forall^*_{W_1^m} \vec{\beta} \ r(\alpha')(\vec{\beta}) \leq N_{f'}(h(f; \vec{\beta}; \mathcal{L}(d_n)))\big].$$

Consider the partition $\mathcal{P}$ where we partition f' of semi-type $\mathcal{R}'$ inducing f of type $\mathcal{R}$, and where $f'(\langle \alpha_1, j_1, \ldots, \alpha_l, j_l \rangle)$ has uniform cofinality ω, according to whether

$$\forall \alpha' \in A \ \big[(g(\alpha') = [f]) \to \forall^*_{W_1^m} \vec{\beta} \ r(\alpha')(\vec{\beta}) \leq N_{f'}(h(f; \vec{\beta}; \mathcal{L}(d_n)))\big].$$

We easily have, using Lemma 4.24, that on the homogeneous side the stated property holds. Fix $C \subseteq \omega_1$ homogeneous for $\mathcal{P}$. Let T_{x_n} be well-founded and $\forall^*_{W_1^m} \beta \ |T_{x_n} \restriction \beta| > N_C(\beta)$. Then $\forall^*_\nu \alpha \ \exists f$ of type $\mathcal{R}$ with $[f] = g(\alpha)$ and $\forall^*_{W_1^m} \vec{\beta} \ r(\alpha)(\vec{\beta}) < |T_{x_n} \restriction h(f; \vec{\beta}; \mathcal{L}(d_n))|$. Define r' by: $\forall^*_\nu \alpha$ if $[f] = g(\alpha)$, then

$$\forall^*_{W_1^m} \vec{\beta} \ r(\alpha)(\vec{\beta}) = |(T_{x_n} \restriction h(f; \vec{\beta}; \mathcal{L}(d_n)))(r'(\alpha)(\vec{\beta}))|.$$

Let $\mathcal{C}' = \langle \mathcal{R}; W_1^m; x_0, \ldots, x_{n-1}, x_n; d_0, \ldots, d_{n-1}, \mathcal{L}(d_n), \mathcal{L}(d_n) \rangle$. It follows that $(\mathcal{C}'; g; r')$ violates the minimality of the original situation.

Suppose next that such a measure one set does not exist. Let g' satisfy the following:

(1) $\forall^*_\nu \alpha \ g'(\alpha)$ is represented by an $f' : \mathrm{dom}(<^{\mathcal{R}'}) \to \omega_1$ of semi-type $\mathcal{R}'$ inducing f of type $\mathcal{R}$ representing $g(\alpha)$.

(2) There is a ν measure one set A such that if $\alpha_1, \alpha_2 \in A$, $g(\alpha_1) = g(\alpha_2)$, and $r(\alpha_1) \leq r(\alpha_2)$, then $[f_1'^{\langle q_1, j_1, \ldots, q_l, j_l \rangle}]_{W_1^l} \leq [f_2'^{\langle q_1, j_1, \ldots, q_l, j_l \rangle}]_{W_1^l}$. Here f_1', f_2' represent $g'(\alpha_1)$, $g'(\alpha_2)$.

(3) There does not exist a ν measure one set A such that $\forall \alpha \in A \ \exists f'$ of semi-type $\mathcal{R}'$ inducing f of type $\mathcal{R}$ representing $g(\alpha)$ and

$$\forall \alpha' \in A \ [(g(\alpha') = g(\alpha)) \to [f_1'^{\langle q_1, j_1, \ldots, q_l, j_l \rangle}]_{W_1^l} \leq [f'^{\langle q_1, j_1, \ldots, q_l, j_l \rangle}]_{W_1^l}.$$

Here f_1' represents $g'(\alpha)$.

(4) For all $[g'']_\nu < [g']_\nu$, g'' does not satisfy (1)–(3).

Easily g' is well-defined [to satisfy (1)–(3), let $g'(\alpha)$ be least such that it is representable by an f' of semi-type $\mathcal{R}$ inducing f representing $g(\alpha)$ and such that $\forall^*_{W_1^m} \vec{\beta} \ r(\alpha)(\vec{\beta}) \leq N_{f'}(h(f; \vec{\beta}; \mathcal{L}(d_n)))$]. From (4) it follows by a pressing down argument that for any closed unbounded $C \subseteq \omega_1$, $\forall^*_\nu \alpha \ g'(\alpha)$ is represented by some $f' : \mathrm{dom}(<^{\mathcal{R}'}) \to C$ of semi-type $\mathcal{R}'$. By countable additivity of ν, there is an immediate extension $\mathcal{R}''$ of $\mathcal{R}$ extending $\mathcal{R}'$ (that is, $\mathcal{R}''(\vec{s})$ is now defined) such that $\forall^*_\nu \alpha \ g'(\alpha)$ is representable by f'

of type $\mathcal{R}''$. Fix a ν measure one set A on which (1) and (2) above hold. Consider the partition $\mathcal{P}$: we partition f' of type $\mathcal{R}''$ with the "extra values" $h(\langle \alpha_1, j_1, \dots, \alpha_l, j_l\rangle)$, for $(\alpha_1, \dots, \alpha_l)$ of type q_l, of uniform cofinality ω inserted between $f'(\langle \alpha_1, j_1, \dots, \alpha_l, j_l\rangle)$ and $N_{f'}(f'(\langle \alpha_1, j_1, \dots, \alpha_l, j_l\rangle))$ according to whether

$$\forall \alpha' \in A\ [(g'(\alpha') = [f']) \to \forall^*_{W_1^m} \vec{\beta}\ r(\alpha')(\vec{\beta}) \leq N_{f'}(f'; \vec{\beta}; d^*_n)].$$

From (2), (3) and the definition of A it follows that on the homogeneous side the stated property holds. Fix $C \subseteq \omega_1$ homogeneous for $\mathcal{P}$, and x_n with T_{x_n} well-founded such that $\forall^*_{W_1^m} \beta\ |T_{x_n} \restriction \beta| > N_C(\beta)$. Define r' so that

$$\forall^*_\nu \alpha\ r'(\alpha) < h(f'; W_1^m; d^*_n)$$

and

$$\forall^*_\nu \alpha\ \forall^*_{W_1^m} \vec{\beta}\ r(\alpha)(\vec{\beta}) = |(T_{x_n} \restriction h(f'; \vec{\beta}; d^*_n))(r'(\alpha)(\vec{\beta}))|,$$

where $[f'] = g'(\alpha)$. Let

$$\mathcal{C}' = \langle \mathcal{R}''; W_1^m; x_0, \dots, x_n; \pi(d_1), \dots, \pi(d_{n-1}), d^*_n, d^*_n \rangle\,,$$

where $\pi(d_i)$ is the generalized description defined relative to $\mathcal{R}''$ corresponding to d_i defined relative to $\mathcal{R}$. Then $(\mathcal{C}'; g'; r')$ violates the minimality of the original situation. $\dashv$

From Theorem 4.31, a suitable coding for the subsets of ω_ω follows, and thus the weak partition relation on $\boldsymbol{\delta}^1_3$. Since the details are now almost identical to those of Theorem 4.12, we merely sketch the results.

If $\mathcal{C} = \langle \mathcal{R}; W_1^m; x_0, \dots, x_{n-1}; d_0, \dots, d_n\rangle$ is a level-2 complex, $B \subseteq \omega_1$, and $\sigma \in \omega^\omega$ codes the closed unbounded set $C_\sigma \subseteq \omega_1$, let $S_{\sigma,\mathcal{C},B} \subseteq \omega_{m+1}$ be the corresponding *simple* set defined by:

$$\alpha \in S_{\sigma,\mathcal{C},B} \longleftrightarrow \exists \gamma \in B\ \exists f : \mathrm{dom}(<^{\mathcal{R}}) \to C_\sigma \text{ of type } \mathcal{R}\ [\alpha = h(f; W_1^m; \mathcal{C}; \gamma)].$$

Theorem 4.31 then shows that every $A \subseteq \omega_{m+1}$ is a countable union of simple sets.

We define our coding $z \to A_z \subseteq \omega_\omega$ as follows. Every real z codes countably many reals z_n, each of which codes a real σ_n, a set $B_n \subseteq \omega_1$, and a sequence $\mathcal{C}_n = \langle \mathcal{R}_n; W_1^m; x_0, \dots, x_{t-1}; d_0, \dots, d_t\rangle$ (here m, t depend on n) satisfying the definition of a complex, except we do not require the T_{x_i} to be well-founded (the exact manner in which B_n is coded is not important; we could use the coding of Theorem 4.13, or simply use the Coding Lemma). For each $n \in \omega$, define $A_{z_n} \subseteq \omega_{m(n)+1}$ as follows. If σ_n does not code a closed unbounded set, or one of the T_{x_i} is ill-founded, set $A_{z_n} = \emptyset$. Otherwise, $A_{z_n} = S_{\sigma_n, \mathcal{C}_n, B_n}$. Then set $A_z = \bigcup_{n \in \omega} A_{z_n}$.

4.33 Theorem. *The coding $z \to A_z \subseteq \omega_\omega$ satisfies the following:*

(1) $\forall A \subseteq \omega_\omega\ \exists z\ A = A_z$.

(2) $\forall \alpha < \omega_\omega\ \{z : \alpha \in A_z\} \in \boldsymbol{\Delta}^1_3$.

Proof. The computation in (2) is straightforward using the closure of $\mathbf{\Delta}^1_3$ under $<\boldsymbol{\delta}^1_3$ unions and intersections, and the fact that if $A_{\beta_1,\dots,\beta_k}$ are $\mathbf{\Delta}^1_3$ sets for all $\vec{\beta} \in (\omega_1)^k$, then $\{x : \forall^*_{W_1^k} \vec{\beta}\ x \in A_{\vec{\beta}}\} \in \mathbf{\Delta}^1_3$ (this last fact is an easy computation using our coding of closed unbounded sets). ⊣

As a corollary we obtain the following result, due originally to Kunen.

4.34 Theorem. *For all* $\lambda < \boldsymbol{\delta}^1_3$, $\boldsymbol{\delta}^1_3 \to (\boldsymbol{\delta}^1_3)^\lambda$.

Proof. Fix $\lambda < \boldsymbol{\delta}^1_3$, and a bijection $\pi : \omega_\omega \to \lambda$. Fix the coding $z \to A_z \subseteq (\omega_\omega)^3$ satisfying (1), (2) above (identifying $(\omega_\omega)^3$ and ω_ω). Define $z \to R_z \subseteq \lambda \times \boldsymbol{\delta}^1_3$ as follows. If $\pi(\alpha) = \delta$, set $R_z(\delta, \epsilon) \longleftrightarrow \{(\beta,\gamma) : A_z(\alpha,\beta,\gamma)\}$ is a wellordering of length ϵ. From the closure of $\mathbf{\Delta}^1_3$ under $<\boldsymbol{\delta}^1_3$ unions and intersections, it is easy to see that the coding $z \to R_z$ satisfies (3) in the definition of reasonable, Definition 2.33. Theorem 4.33 also implies that there is a $\mathbf{\Delta}^1_3$ coding of the ordinals (i.e., singleton sets) less than ω_ω. That is, there is a map $x \to |x| < \omega_\omega$ from ω^ω onto ω_ω such that for all $\alpha < \omega_\omega$, $\{x : |x| = \alpha\} \in \mathbf{\Delta}^1_3$. [In Definition 4.36 below we define a better $\mathbf{\Delta}^1_3$ coding of ω_ω via code sets WO_m for the ordinals less than ω_m.] From the closure of $\mathbf{\Delta}^1_3$ under $<\boldsymbol{\delta}^1_3$ unions it follows that $\{(x,z) : |x| \in A_z\} \in \mathbf{\Delta}^1_3$. From this, it follows that (4) in the definition of reasonable is satisfied, since if $S \subseteq \{z : R_z$ is well-founded$\}$ is $\mathbf{\Sigma}^1_3$, then we get a $\mathbf{\Sigma}^1_3$ well-founded relation on ω^ω of length $\geq \sup\{|R_z| : z \in S\}$. ⊣

As another consequence of the analysis of measures we obtain the following result, also due originally to Kunen.

4.35 Theorem. *Let* $\alpha, \beta < \boldsymbol{\delta}^1_3$, *and* μ *a measure on* μ. *Then* $j_\mu(\beta) < \boldsymbol{\delta}^1_3$.

Proof (Sketch). We may assume $\alpha = \beta = \omega_\omega$. We use the coding of subsets of $\omega_\omega \times \omega_\omega$ given by Theorem 4.33. It is enough to show that the prewellordering $\preceq$ corresponding to the ultrapower relation, that is,

$$\begin{aligned} x \preceq y \longleftrightarrow\ & (x, y \text{ code functions } f_x, f_y : \omega_\omega \to \omega_\omega) \\ & \wedge\ \forall^*_\mu \alpha\ \exists \beta_1, \beta_2 < \omega_\omega\ (f_x(\alpha) = \beta_1 \wedge f_y(\alpha) = \beta_2 \wedge (\beta_1 \leq \beta_2)) \end{aligned}$$

is $\mathbf{\Delta}^1_3$. Using the closure of $\mathbf{\Delta}^1_3$ under $<\boldsymbol{\delta}^1_3$ length unions and intersections, we see that it suffices to show that if $\{B_\alpha\}_{\alpha < \boldsymbol{\delta}^1_3}$ is a sequence of $\mathbf{\Delta}^1_3$ sets, then $B \doteq \{x : \forall^*_\mu \alpha\ (x \in B_\alpha)\}$ is also $\mathbf{\Delta}^1_3$. It clearly suffices to show that B_μ is $\mathbf{\Sigma}^1_3$. Let

$$\mathcal{C} = \langle \mathcal{R}; W_1^m; x_0, \dots, x_{n-1}; d_0, \dots, d_n \rangle$$

be a level-2 complex, and μ_1 a measure on ω_1, which generate μ, as in Theorem 4.31. Let $y_0, \dots, y_n$ be reals with T_{y_j} well-founded for all j, and $\epsilon < \omega_1$ which generate μ_1 as in Theorem 4.8 (ϵ playing the role of α there). T is again the Kunen tree. Recall our coding of closed unbounded subsets of ω_1 from Sect. 4.2. We then have

$$\begin{aligned} x \in B \longleftrightarrow \exists \sigma_1, \sigma_2\ (&T_{\sigma_1}, T_{\sigma_2} \text{ are well-founded} \\ &\wedge \forall \gamma_1 < \cdots < \gamma_n \in C_{\sigma_1}\ \forall \vec{\delta} \in (\omega_\omega)^{<\omega}\ \forall \eta < \omega_\omega \text{ [If } \vec{\delta} \text{ is} \\ &\text{representable by an } f : \mathrm{dom}(<_{\mathcal{R}}) \to \omega_1 \text{ of the correct type,} \\ &\text{each } f^{\langle p_1, i_1, \ldots, p_k, i_k \rangle} \text{ has range in } C_{\sigma_2} \text{ almost everywhere,} \\ &\text{and } h(f; W_1^m; \mathcal{C}; \gamma') = \eta, \text{ then } x \in B_\eta]) \end{aligned}$$

where h is as in Theorem 4.31, and $\gamma' = h^{\epsilon}_{y_0,\ldots,y_n}(\gamma_1, \ldots, \gamma_n)$ as in Theorem 4.8. Note that $h(f; W_1^m; \mathcal{C}; \gamma')$ depends only on $\vec{\delta}$. From the closure properties of $\boldsymbol{\Delta}^1_3$ again, it is enough to show that if $C_{\alpha_1,\ldots,\alpha_l} \in \boldsymbol{\Delta}^1_3$ for all $\vec{\alpha} \in (\omega_1)^l$, then C defined by

$$z \in C \longleftrightarrow \forall^*_{W_1^l} \vec{\alpha}\ (z \in C_{\vec{\alpha}})$$

is also $\boldsymbol{\Delta}^1_3$. This special case now follows easily by the same type of computation, using just level-1 complexes. ⊣

Starting from the weak partition relation on $\boldsymbol{\delta}^1_1 = \omega_1$, we have obtained the strong partition relation on $\boldsymbol{\delta}^1_1$, calculated $\boldsymbol{\delta}^1_3$, and obtained the weak partition relation on $\boldsymbol{\delta}^1_3$. This completes the first step in the inductive projective hierarchy analysis. We have used only techniques that will generalize (when combined with a suitable notion of description at the higher levels). We will sketch how this generalization takes place in Sect. 5.

4.4. The Kechris-Martin Theorem Revisited

We finish this section by using our theory of "trivial descriptions" to give a proof of the Kechris-Martin Theorem for $\boldsymbol{\Pi}^1_3$ sets. This is an important result in descriptive set theory, although it and its higher level analogs are not needed for the inductive analysis of the projective sets. The proof we give follows closely the proof of Kechris and Martin, recast into the theory of trivial descriptions (their original proof appealed to the theory of indiscernibles for L). We assume AD throughout this section. We caution the reader that we will be using lightface notions in this section.

To state the theorem, we first introduce our coding for the ordinals $< \omega_\omega$. T continues to denote the Kunen tree from Lemma 4.1 (or Theorem 4.2).

4.36 Definition. $\mathrm{WO}_1 = \mathrm{WO} =$ the standard set of codes of wellorderings of ω. For $m \geq 1$,

$$\mathrm{WO}_{m+1} = \{\langle a, x_1, \ldots, x_m \rangle : a \in \mathrm{WO}_1 \wedge \forall i \leq m\ T_{x_i} \text{ is well-founded}\}.$$

For $y = \langle a, x_1, \dots, x_m\rangle \in \mathrm{WO}_{m+1}$, let $|y| = [f_y]_{W_1^m}$, where $f_y : (\omega_1)^m \to \omega_1$ is defined by:

$$\begin{aligned} f_y(\beta_1, \dots, \beta_m) &= |(T_{x_m} \restriction \beta_m)(\delta_{m-1})|, \\ &\text{where } \delta_{m-1} = |(T_{x_{m-1}} \restriction \beta_{m-1})(\delta_{m-2})|, \quad \dots, \\ &\delta_1 = |(T_{x_1} \restriction \beta_1)(\delta_0)|, \quad \text{and} \quad \delta_0 = |a|. \end{aligned}$$

Let $\mathrm{WO}_\omega = \bigcup_m \mathrm{WO}_m$.

Easily, $\mathrm{WO}_{m+1} \in \boldsymbol{\Pi}^1_2$ for all $m \geq 1$, and for all $\alpha < \omega_{m+1}$ there is a $y \in \mathrm{WO}_{m+1}$ with $|y| = \alpha$.

4.37 Definition. We say a relation $R \subseteq \omega^\omega \times \mathrm{WO}_{m+1}$, $m \geq 0$, is *invariant in the codes* if

$$\forall x, w_1, w_2\ [w_1, w_2 \in \mathrm{WO}_{m+1} \wedge |w_1| = |w_2| \wedge R(x, w_1) \to R(x, w_2)].$$

In this case, we write $R(x, \alpha)$, for $\alpha < \omega_{m+1}$, to denote $\exists w \in \mathrm{WO}_{m+1}\ [|w| = \alpha \wedge R(x, w)]$. We similarly define R being invariant in the codes for $R \subseteq \mathrm{WO}_m$, or $R \subseteq \omega^\omega \times \mathrm{WO}_m \times \mathrm{WO}_n$, etc.

4.38 Theorem (Kechris-Martin). *Let $R \subseteq \omega^\omega \times \mathrm{WO}_{m+1}$, $m \geq 0$ be Π^1_3 and invariant in the codes. Then $P(x) \longleftrightarrow \exists w \in \mathrm{WO}_{m+1}\ R(x, w)$ is also Π^1_3.*

For the sake of completeness we include first the $m = 0$ case, though the proof is unchanged here (cf. [15]). So, let $R \subseteq \omega^\omega \times \mathrm{WO}$ be Π^1_3 and invariant in the codes. We show that $P(x) \longleftrightarrow \exists w\ R(x, w) \longleftrightarrow \exists w \in \Delta^1_3(x)\ R(x, w)$, which suffices (cf. [31, Theorem 4D.3]). So fix x such that $P(x)$. Let $S(w) \longleftrightarrow w \in \mathrm{WO} \wedge \forall w' \in \Delta^1_3(w)\ [|w'| \leq |w| \to \neg R(x, w')]$. By "bounded quantification" [31, Theorem 4D.3] $S \in \Sigma^1_3(x)$. Clearly S is invariant in the codes and codes a proper initial segment of ω_1. Relativizing to x, it suffices to show the following claim.

4.39 Claim. *If $S \subseteq \mathrm{WO}$ is Σ^1_3, invariant in the codes, and* $\sup\{|w| : w \in S\} = \alpha_0 < \omega_1$, *then $\exists w^* \in \Delta^1_3 \cap \mathrm{WO}\ (|w^*| > \alpha_0)$.*

Proof. Let $S(w) \longleftrightarrow \exists z\ B(w, z)$, where $B \in \Pi^1_2$. Consider the integer game where I plays out w_1, z, and II plays out w_2. II wins iff $w_2 \in \mathrm{WO} \wedge [B(w_1, z) \to |w_2| > |w_1|]$. This is a Σ^1_2 game for II, and II clearly wins, so by third periodicity II has a Δ^1_3 winning strategy τ. Then $A \doteq \tau(\omega^\omega) \subseteq \mathrm{WO}$ is $\Sigma^1_1(\tau)$, so there is a $\Delta^1_1(\tau)$ real $w^* \in \mathrm{WO}$ with $|w^*| > \sup\{|w| : w \in A\} \geq \sup\{|w| : w \in S\}$. Since $\tau \in \Delta^1_3$, $w^* \in \Delta^1_3$. ⊣

A useful consequence of the $m = 0$ case which we shall need is the following lemma.

4.40 Lemma. *Let $R \subseteq \omega^\omega \times \mathrm{WO}$ be Σ^1_3 (Π^1_3, Δ^1_3) and invariant in the codes. Then $P(x) \longleftrightarrow \forall^*_{W^1_1} \alpha\ R(x, \alpha)$ is Σ^1_3 (Π^1_3, Δ^1_3).*

Proof. Suppose, for example, $R \in \Sigma^1_3$. We use a variation of our previous coding of closed unbounded subsets of ω_1. For any closed unbounded $C \subseteq \omega_1$, there is a strategy σ for II such that $\forall z \in \mathrm{WO}\ \sigma(z) \in \mathrm{WO}$ and $C(\sigma) \doteq \{\alpha < \omega_1 : \forall z \in \mathrm{WO}\ (|z| < \alpha \to |\sigma(z)| < \alpha)\}$ is a closed unbounded subset of C. This follows by playing a simple Solovay game (I plays x, II plays y, and II wins iff $(x \in \mathrm{WO} \to y \in \mathrm{WO}\ \wedge\ |y| > N_C(|x|))$.

Then

$$\begin{aligned} P(x) \longleftrightarrow \exists\sigma\ \big[&\forall w \in \mathrm{WO}\ (\sigma(w) \in \mathrm{WO}) \\ &\wedge \forall w \in \mathrm{WO}\ (\forall z(z \in \mathrm{WO} \wedge |z| < |w| \\ &\to |\sigma(z)| < |w|) \to R(x,w))\big]. \end{aligned}$$

From the $m = 0$ case, $P \in \Sigma^1_3$. From this, the result for Π^1_3, Δ^1_3 follows immediately. ⊣

We recall our coding $z \to F_z \subseteq (\omega_1)^2$ of Theorem 4.15, which we will need for the proof. Recall each real z codes countably many z_n, each of which codes reals σ_n, w^1_n, w^2_n, and a partial (level-1) complex

$$\mathcal{C}_n = \langle W^m_1; x_0, \ldots, x_{t-1}; d_0, \ldots, d_t \rangle.$$

As we noted previously, each F_z is a partial function.

The next lemma summarizes the properties of this coding we will need.

4.41 Lemma. *Consider the relations defined by:*

$$\begin{aligned} R_0(z) &\longleftrightarrow \forall\beta\ \exists\gamma\ F_z(\beta,\gamma) \\ R_1(z,y) &\longleftrightarrow y \in \mathrm{WO} \wedge \exists\gamma\ F_z(|y|,\gamma) \\ R_2(z,y) &\longleftrightarrow y \in \mathrm{WO} \wedge \forall\beta \le |y|\ \exists\gamma\ F_z(\beta,\gamma) \\ R_3(z,x,y) &\longleftrightarrow x,y \in \mathrm{WO} \wedge \forall\beta \le |x|\ \exists\gamma \le |y|\ F_z(\beta,\gamma). \end{aligned}$$

Then $R_0 \in \Pi^1_2$, and $R_1, R_2 \in \Pi^1_1$. Also, R_3 is Δ^1_1 in the codes for x, y, that is, there are Σ^1_1, Π^1_1 relations C, D such that for all z and $x, y \in \mathrm{WO}$, $R_3(z,x,y) \longleftrightarrow C(z,x,y) \longleftrightarrow D(z,x,y)$.

Proof. The computations are all straightforward, as in the proof of the strong partition relation. For example, (in this equation, t, x_i refer to $\mathcal{C}_n$, and t', x'_i refer to $\mathcal{C}_{n'}$)

$$\begin{aligned} R_1(z,y) \longleftrightarrow\ & y \in \mathrm{WO} \wedge \exists n\ \big\{w^1_n, w^2_n \in \mathrm{WO} \wedge |w^1_n|, |w^2_n| < |y| \\ & \wedge \exists\beta_{t-1} < \cdots < \beta_0 \le |y|\ \exists\gamma_{t-1}, \ldots, \gamma_1 < |y|\ \exists\delta_{t-1}, \ldots, \delta_1 < |y| \\ & \big[\beta_{t-1} > \max(|w^1_n|, |w^2_n|) \wedge \forall i\ \beta_i \in C_{\sigma_n} \\ & |(T_{x_{t-1}} \restriction \beta_{t-1})(|w^1_n|)| = \gamma_{t-1} \wedge |(T_{x_{t-2}} \restriction \beta_{t-2})(\gamma_{t-1})| = \gamma_{t-2} \\ & \wedge \cdots \wedge |(T_{x_0} \restriction \beta_0)(\gamma_1)| = |y| \wedge |(T_{x_{t-1}} \restriction \beta_{t-1})(|w^2_n|)| = \delta_{t-1} \end{aligned}$$

$$\begin{aligned}
&\wedge |(T_{x_{t-2}} \restriction \beta_{t-2})(\delta_{t-1})| = \delta_{t-2} \wedge \cdots \\
&\wedge \delta_1 \text{ is in the well-founded part of } (T_{x_0} \restriction \beta_0) \\
&\wedge \forall n' \in \omega \big[\big\{ w^1_{n'}, w^2_{n'} \in \mathrm{WO} \wedge |w^1_{n'}|, |w^2_{n'}| < |y| \\
&\wedge \exists \beta'_{t'-1} < \cdots < \beta'_0 \leq |y| \ \exists \gamma'_{t'-1}, \ldots, \gamma'_1 < |y| \\
&\exists \delta'_{t'-1}, \ldots, \delta'_1 < |y| (\forall i \ \beta'_i \in C_{\sigma_{n'}} \\
&|(T_{x'_{t'-1}} \restriction \beta'_{t'-1})(|w^1_{n'}|)| = \gamma'_{t'-1} \\
&\wedge |(T_{x'_{t'-2}} \restriction \beta'_{t'-2})(\gamma'_{t'-1})| = \gamma'_{t'-2} \wedge \cdots \wedge |(T_{x'_0} \restriction \beta'_0)(\gamma'_1)| = |y| \\
&\wedge |(T_{x'_{t'-1}} \restriction \beta'_{t'-1})(|w^2_{n'}|)| = \delta'_{t'-1} \\
&\wedge |(T_{x'_{t'-2}} \restriction \beta'_{t'-2})(\delta'_{t'-1})| = \delta'_{t'-2} \\
&\wedge \cdots \wedge |(T_{x'_1} \restriction \beta'_1)(\delta'_2)| = \delta'_1) \big\} \\
&\rightarrow |(T_{x'_0} \restriction \beta'_0)(\delta'_1)| = |(T_{x_0} \restriction \beta_0)(\delta_1)| \big] \big] \big\}.
\end{aligned}$$

In the last line of this formula, "$|(T_{x'_0} \restriction \beta'_0)(\delta'_1)| = |(T_{x_0} \restriction \beta_0)(\delta_1)|$" abbreviates "$\delta'_1$ is in the well-founded part of $T_{x'_0} \restriction \beta'_0$ and $|(T_{x'_0} \restriction \beta'_0)(\delta'_1)| = |(T_{x_0} \restriction \beta_0)(\delta_1)|$". It is straightforward to check that all clauses in this formula define Δ^1_1 relations except the clauses "$y \in \mathrm{WO}$" and "δ_1 is in the well-founded part of $T_{x_0} \restriction \beta_0$", which are Π^1_1. ⊣

We will write "F_z is a function" in place of $R_0(z)$, "$F_z(|y|)$ is defined" in place of $R_1(z, y)$.

4.42 Lemma. *The relation* $Q(x, z) \longleftrightarrow [x \in \mathrm{WO}_2 \wedge (F_z$ *is a function*$) \wedge |x| = [F_z]_{W^1_1}]$ *is* Δ^1_3.

Proof. $Q(x, z) \longleftrightarrow \exists \sigma \ [T_\sigma$ is well-founded $\wedge \forall w \in \mathrm{WO}(|w| \in C_\sigma \rightarrow \exists v \in \mathrm{WO} \ (f_x(|w|) = |v| \wedge F_z(|w|, |v|)))]$. The $m = 0$ case shows $Q \in \Sigma^1_3$. A similar computation shows that $Q^c \in \Sigma^1_3$. ⊣

If V is a tree on $\omega \times \omega_1$ and $x \in \omega^\omega$, let $\prec_x$ denote the Kleene-Brouwer ordering on V_x. Thus, $\prec_x$ is a linear ordering, and is a wellorder iff V_x is well-founded. We say $\alpha < \omega_1$ is *represented in the well-founded part of* $V_x \restriction \beta$ if there is an $s \in V_x \restriction \beta$ such that the initial segment determined by s in the Kleene-Brouwer ordering on $V_x \restriction \beta$ is order-isomorphic to α. For the trees used below this will be equivalent to saying that the initial segment of $\prec_x$ determined by s is order-isomorphic to α.

4.43 Lemma. *Let* $R \subseteq \omega^\omega \times \omega^\omega$ *be* Π^1_2. *Then there is a tree* V *on* $\omega \times \omega_1$ *such that:*

(1) V *is* Δ^1_1 *in the codes.*

(2) $\forall x, y \in \omega^\omega$ *[*$R(x, y) \longleftrightarrow V_{\langle x,y \rangle}$ *is well-founded* $\longleftrightarrow \forall \alpha < \omega_1$ *(*α *is represented in the well-founded part of* $V_{\langle x,y \rangle} \restriction \alpha$*)].*

(3) *The relation* $S(x,y,w) \longleftrightarrow [w \in \mathrm{WO} \wedge |w|$ *is represented in the well-founded part of* $V_{\langle x,y\rangle}\restriction|w|]$ *is* Δ^1_1 *in the codes for* w.

Proof. Let V' be the standard Shoenfield tree on $\omega \times \omega_1$ for R^c. Thus, V' is Δ^1_1 in the codes and $\forall x, y\ [R(x,y) \longleftrightarrow V'_{\langle x,y\rangle}$ is well-founded]. Let V be a minor modification of V' such that

$$\forall x\, \forall \alpha < \omega_1\ (V_x\restriction\alpha \text{ is well-founded } \rightarrow |V_x\restriction\alpha| > \alpha).$$

[For example, code into V_x all finite decreasing chains $\beta_0 > \beta_1 > \cdots > \beta_n$.] We may assume that if $((a_0,\ldots,a_n),(\alpha_0,\ldots,\alpha_n)) \in V$, then $\alpha_0 \geq \alpha_1,\ldots,\alpha_n$. Clearly V is Δ^1_1 in the codes.

If $R(x,y)$, then $V_{\langle x,y\rangle}$ is well-founded, and by construction $\forall\alpha\ |V_{\langle x,y\rangle}\restriction\alpha| > \alpha$, hence α is represented in the well-founded part of $V_{\langle x,y\rangle}\restriction\alpha$. If $(x,y) \notin R$, then $V_{\langle x,y\rangle}$ is ill-founded, say $(\langle x,y\rangle,(\beta_0,\beta_1,\ldots)) \in [V]$. If the initial segment $I^{\vec{\alpha}}_{x,y}$ of $\prec_{\langle x,y\rangle}$ determined by $\vec{\alpha} = (\alpha_0,\ldots,\alpha_{n-1}) \in V_{\langle x,y\rangle}$ is well-founded, we must have $\alpha_0,\ldots,\alpha_n \leq \beta_0$. Thus,

$$\gamma \doteq \sup\{|\vec{\alpha}|_{\prec_{\langle x,y\rangle}} : I^{\vec{\alpha}}_{x,y} \text{ is well-founded}\} < \omega_1.$$

For $\delta > \max\{\beta_0,\gamma\}$, δ is not represented in the well-founded part of $V_{\langle x,y\rangle}\restriction\delta$.

Finally, (3) is a standard computation using (1). ⊣

4.44 Lemma. *Let* $W \subseteq \mathrm{WO}_2$ *be* Σ^1_3, *invariant in the codes, and code a bounded initial segment of* ω_2. *Then there is a* Δ^1_3 *relation* $F \subseteq \mathrm{WO} \times \mathrm{WO}$ *which is invariant in the codes, and defines a total function* $F : \omega_1 \to \omega_1$ *(i.e.,* $\forall\alpha < \omega_1 \exists!\beta < \omega_1\ F(\alpha,\beta)$*) such that* $[F]_{W^1_1} > |x|$ *for all* $x \in W$.

Proof. Define $W'(w) \longleftrightarrow \exists x \in \mathrm{WO}_2\ [W(x) \wedge (w$ codes a function $F_w : \omega_1 \to \omega_1) \wedge (|x| = [F_w]_{W^1_1})]$. From Lemma 4.42, $W' \in \Sigma^1_3$. W' is also invariant in the sense that if w, w' code functions $F_w, F_{w'}$, $[F_w]_{W^1_1} = [F_{w'}]_{W^1_1}$, and $W'(w)$, then $W'(w')$. Let $W'(w) \longleftrightarrow \exists y\ R(w,y)$, where $R \in \Pi^1_2$. Let V be a tree on $\omega \times \omega_1$ as in Lemma 4.43, in particular $R(w,y) \longleftrightarrow V_{\langle w,y\rangle}$ is well-founded.

Say a real w is *α-good* if $F_w(\alpha)$ is defined, and say w is $\leq\alpha$-good if it is α' good for all $\alpha' \leq \alpha$. Say a pair (w,y) is *α-good* if w is α-good and α is represented in the well-founded part of $V_{\langle w,y\rangle}\restriction\alpha$.

Consider the integer game G where I plays out reals w_1, y, and II plays out w_2, and II wins the run iff there exists an $\eta_0 < \omega_1$ such that either:

(1) $\forall\eta < \eta_0\ (w_1,y), w_2$ are η-good, (w_1,y) is not η_0-good, and w_2 is η_0-good, or

(2) $\forall\eta \leq \eta_0\ (w_1,y), w_2$ are η-good, and $F_{w_1}(\eta_0) < F_{w_2}(\eta_0)$.

Using Lemmas 4.41 and 4.43, G is a Σ^1_2 game for II. II easily wins the game, by playing any w^* coding a function $F_{w^*} : \omega_1 \to \omega_1$ such that $[F_{w^*}]_{W^1_1} > \sup\{|x| : x \in W\}$. Thus, by third periodicity, II has a Δ^1_3 winning strategy τ.

Define $b : \omega_1 \to \omega_1$ inductively as follows. Let $b(\eta_0)$ be the maximum of $(\sup_{\eta<\eta_0} b(\eta)) + 1$ and

$$\sup\{F_{\tau(w_1,y)}(\eta_0) : \forall \eta < \eta_0 \ [(w_1, y) \text{ is } \eta\text{-good } \wedge F_{w_1}(\eta) = b(\eta)]\}.$$

We show by induction on η_0 that:

4.45 Claim.

(a) $b(\eta_0)$ is well-defined, that is, $b(\eta_0) < \omega_1$.

(b) If (w_1, y) is $\leq\eta_0$-good and $\forall \eta \leq \eta_0$ $F_{w_1}(\eta) = b(\eta)$, then $\forall \eta \leq \eta_0$ $F_{w_2}(\eta) \leq F_{w_1}(\eta)$, where $w_2 = \tau(w_1, y)$.

Proof. Suppose the claim holds for all $\eta < \eta_0$. Note that if (w_1, y) is η-good for all $\eta < \eta_0$ and $\forall \eta < \eta_0$ $F_{w_1}(\eta) = b(\eta)$, then by (b) and induction, $F_{w_2}(\eta_0)$ is defined, where $w_2 = \tau(w_1, y)$, as otherwise II would lose this run of the game. Now, $B_{\eta_0} \doteq \{(w_1, y) : \forall \eta < \eta_0 \ [(w_1, y) \text{ is } \eta\text{-good } \wedge F_{w_1}(\eta) = b(\eta)]\}$ is $\boldsymbol{\Delta}^1_1$, as it is Δ^1_1 in any real coding η_0 and $b\restriction\eta_0$. The reasonableness of the coding $z \to F_z$ now gives (a) (cf. (4) in Definition 2.33). (b) at η_0 is now immediate from the definition of $b(\eta_0)$. ⊣

Next we claim that $[b]_{W^1_1} > |x|$ for all $x \in W$. If not, then by the invariance and initial segment properties of W', there is a w_1 in W' with $F_{w_1} = b$. Let y be such that $R(w_1, y)$, and have I play (w_1, y) against τ, producing $w_2 = \tau(w_1, y)$. Since $\forall \eta_0 < \omega_1$ (w_1, y) is η_0-good, a straightforward induction using (b) shows that $\forall \eta_0 < \omega_1$ $F_{w_2}(\eta_0)$ is defined and $F_{w_2}(\eta_0) \leq F_{w_1}(\eta_0)$, a contradiction to II winning the game.

Finally, we show that the relation $F(z_1, z_2) \longleftrightarrow z_1, z_2 \in \mathrm{WO} \wedge b(|z_1|) = |z_2|$ is Δ^1_3. We have $F(z_1, z_2)$ iff the following hold:

(1) $z_1, z_2 \in \mathrm{WO}$.

(2) There is a $y \in \omega^\omega$ and a $z \in \mathrm{WO}$ with $|z| = |z_1| + 1$ and $|0|_{\prec_z} = |z_1|$ satisfying:

  (a) $\forall n \ y_n \in \mathrm{WO}$.

  (b) The map $n \to |y_n|$ defines an order-preserving map from $\prec_z$ to ω_1.

  (c) For any $n \in \mathrm{dom}(\prec_z)$, $|y_n|$ is the maximum of $(\sup\{|y_m| : m \prec_z n\}) + 1$ and

$$\sup\{F_{\tau(w_1,y)}(|n|_z) : \forall m \prec_z n \ ((w_1, y) \text{ is } |m|_{\prec_z}\text{-good} \wedge F_{w_1}(|m|_{\prec_z}) = |y_m|)\}.$$

  (d) $|y_0| = |z_2|$.

It follows easily that $F \in \Sigma^1_2(\tau)$, so $F \in \Delta^1_3$. ⊣

We prove now the $m = 1$ case of the Kechris-Martin Theorem. Let $R(x,w) \subseteq \omega^\omega \times \mathrm{WO}_2$ be Π^1_3 and invariant in the codes. Define $R'(x,w) \longleftrightarrow w \in \mathrm{WO}_2 \wedge \exists w' \in \mathrm{WO}_2\ [|w'| \leq |w| \wedge R(x,w')]$. Clearly R' is invariant in the codes, and we claim that $R' \in \Pi^1_3$. To see this, note that

$$R'(x,w) \longleftrightarrow w = \langle a,v\rangle \in \mathrm{WO}_2 \wedge \exists b \in \mathrm{WO}\ \big[\forall^* \beta < \omega_1\ |(T_v{\restriction}\beta)(|b|)| \\ \leq |(T_v{\restriction}\beta)(|a|)| \wedge \forall z \in \mathrm{WO}_2(|z| = |\langle b,v\rangle| \to R(x,z))\big].$$

From Lemma 4.40 and the $m = 0$ case of the theorem it follows that $R' \in \Pi^1_3$. Replacing now R with R', we may assume that $R(x,w)$ is also closed upwards in the codes w.

We employ a standard coding for the $\Delta^1_3(x)$ subsets of $\omega^\omega \times \omega^\omega$, uniformly in x. Thus, let $Q \subseteq (\omega^\omega)^3$ be Π^1_3 and such that for every $\Pi^1_3(x)$ set $A \subseteq (\omega^\omega)^2$, there is a real y recursive in x such that $A = Q_x$. Let $Q'_0(x,y,z) \longleftrightarrow Q(x_0,y,z)$, and $Q'_1(x,y,z) \longleftrightarrow Q(x_1,y,z)$. Let Q_0, Q_1 in Π^1_3 reduce Q'_0, Q'_1. We then say *x codes a Δ^1_3 set* if $\forall y,z\ [Q_0(x,y,z) \vee Q_1(x,y,z)]$, in which case x codes the $\Delta^1_3(x)$ set $D_x = \{(y,z) : Q_0(x,y,z)\}$.

Returning to the proof, let $P(x) \longleftrightarrow \exists w \in \mathrm{WO}_2\ R(x,w)$, where $R \in \Pi^1_3$ is invariant and closed upwards in the codes. From Lemma 4.44 we have:

$$\begin{aligned} P(x) \longleftrightarrow \exists y \in \Delta^1_3(x)\ \big[&(y \text{ codes a } \Delta^1_3 \text{ relation } D_y \subseteq (\omega^\omega)^2) \\ &\wedge (D_y \subseteq \mathrm{WO} \times \mathrm{WO} \wedge D_y \text{ is invariant in the codes}) \\ &\wedge (D_y \text{ defines a total function from } \omega_1 \text{ to } \omega_1) \\ &\wedge \forall w \in \mathrm{WO}_2\ \big[(\forall^*_{W^1_1} \alpha < \omega_1\ (\alpha, f_w(\alpha)) \in D_y) \to R(x,w)\big]\big]. \end{aligned}$$

For "D_y defines a total function from ω_1 to ω_1" we use:

$$\forall x, z_1, z_2 \in \mathrm{WO}\ [D_y(x,z_1) \wedge D_y(x,z_2) \to |z_1| = |z_2|] \\ \wedge \forall x \in \mathrm{WO}\ \exists z \in \mathrm{WO}\ [\forall z' \in \mathrm{WO}\ (|z'| = |z| \to D_y(x,z'))].$$

By the $m = 0$ case of the theorem, this expression defines a Π^1_3 set, so $P \in \Pi^1_3$, using Lemma 4.40. This completes the $m = 1$ case of the theorem.

We prove now the general case $m > 1$ of the theorem. So let $P(x) \longleftrightarrow \exists w \in \mathrm{WO}_{m+1}\ R(x,w)$, where $R \in \Pi^1_3$ is invariant in the codes w. Recall that for $w \in \mathrm{WO}_{m+1}$, f_w is the corresponding function from ω_1^m to ω_1 (defined W^m_1 almost everywhere) representing $|w|$. For any such f_w, there is a function $g : \omega_1 \to \omega_1$ such that $\forall^*_{W^m_1}(\alpha_1,\ldots,\alpha_m)\ f_w(\vec{\alpha}) < g(\alpha_m)$. We may take $g = f_y$ for some $y = \langle a,u\rangle \in \mathrm{WO}_2$. Thus we have:

$$\begin{aligned} P(x) \longleftrightarrow \exists y = \langle a,u\rangle \in \mathrm{WO}_2\ \exists z \in \mathrm{WO}_m \\ \big[&\forall^*_{W^{m-1}_1} \alpha_1,\ldots,\alpha_{m-1}\ f_z(\vec{\alpha}) \prec_{T_u} |a| \\ &\wedge \forall w \in \mathrm{WO}_{m+1}\ \big[(\forall^*_{W^m_1} \alpha_1,\ldots,\alpha_m\ f_w(\alpha_1,\ldots,\alpha_m) \\ &= |(T_u{\restriction}\alpha_m)(f_z(\alpha_1,\ldots,\alpha_{m-1}))|) \to R(x,w)\big]\big]. \end{aligned}$$

Note that the expression beginning with $\exists z \in \mathrm{WO}_m$ is invariant in the codes for y; it is equivalent to $\exists f : (\omega_1)^m \to \omega_1\ \forall^*_{W_1^m} \alpha_1, \dots, \alpha_m\ f(\alpha_1, \dots, \alpha_m) < f_y(\alpha_m)$ and $R(x, [f]_{W_1^m})$. By the $m = 1$ and $m - 1$ cases of the theorem, $P \in \Pi^1_3$. This completes the proof of Theorem 4.38. $\dashv$

5. Higher Descriptions

We assume AD throughout Sect. 5. We sketch in this section how the theory of Sect. 4 can be extended to higher levels. Indeed, the arguments here should extend to the general case of a successor Suslin cardinal in the hierarchy of $L(\mathbb{R})$. We will concentrate here, however, on the projective hierarchy, and in fact largely on the theory of $\boldsymbol{\delta}^1_5$, since all of the new ideas occur here. As we said in the introduction, our style here will be somewhat informal. We will concentrate on presenting the new ideas without getting lost in details; we will sometimes illustrate proofs by considering a representative example. The reader wishing to see the complete details for the next level of the analysis (the strong partition relation on $\boldsymbol{\delta}^1_3$, the computation of $\boldsymbol{\delta}^1_5$, and the weak partition relation on $\boldsymbol{\delta}^1_5$) can consult [11]. In Sect. 6 we will consider topics related to extending this theory further.

Reflecting on the arguments of the previous section, we see that there were two fundamental ingredients. First was the Kunen analysis, Lemma 4.1, which provided an analysis of the equivalence classes of function $f : \omega_1 \to \omega_1$ with respect to the normal measure W^1_1 on ω_1. Second was the analysis, embodied in Lemma 4.5, which showed how equivalence classes of functions with respect to the more general measures W^m_1 are generated from the normal measure analysis. The combinatorics of the process was described by the descriptions. Admittedly, the concept there was rather trivial (descriptions being just integers), and there was really no interesting combinatorics taking place. The situation changes as we move to the higher levels, though, and the concept of the description becomes a central point. Indeed, armed with the correct notion of description and proper generalization of the Kunen tree analysis (due to Martin, see below), the general step in the projective hierarchy analysis is quite similar to that of Sect. 4. Thus, we concentrate in this section on showing how these two key ingredients generalize.

5.1. Martin's Theorem on Normal Measures

From the weak partition relation on $\boldsymbol{\delta}^1_3$, Theorem 4.34, it follows that there are precisely three normal measures on $\boldsymbol{\delta}^1_3$, corresponding to the three regular cardinals $\omega, \omega_1, \omega_2$ below $\boldsymbol{\delta}^1_3$. [The weak partition relation shows that the closed unbounded filter restricted to points of one of these cofinalities is a normal measure. Conversely, any normal measure on $\boldsymbol{\delta}^1_3$ must give every closed unbounded set measure one, and by countable additivity must concentrate on one these cofinalities. Thus, it must coincide with one of these three normal measures.]

The ω-cofinal normal measure on $\boldsymbol{\delta}^1_3$ behaves just as the normal measure on ω_1; indeed, the Kunen tree analysis is quite general and holds for all the $\boldsymbol{\delta}^1_{2n+1}$. Thus, there is a tree T on $\omega \times \boldsymbol{\delta}^1_{2n+1}$ such that for all $f : \boldsymbol{\delta}^1_{2n+1} \to \boldsymbol{\delta}^1_{2n+1}$, there is an $x \in \omega^\omega$ with T_x well-founded such that $\forall^* \alpha < \boldsymbol{\delta}^1_{2n+1}\ f(\alpha) < |T_x \restriction \alpha|$ (where $\forall^*$ refers to the ω-cofinal normal measure). The proof is a small variation of Lemma 4.1. Instead of WF, one uses the set W defined by $W(x) \longleftrightarrow \forall n\ P(x_n)$, where P is a $\boldsymbol{\Pi}^1_{2n+1}$-complete set. Let $\{\phi_n\}$ be a $\boldsymbol{\Pi}^1_3$ scale on P. Using $\{\phi_n\}$, define a tree U on $\omega \times \boldsymbol{\delta}^1_3$ with $p[U] = W$ (a branch $\vec{\alpha}$ through U_x gives subsequences $\vec{\alpha}_1$, $\vec{\alpha}_2$, etc., such that for all m, $(x_m, \vec{\alpha}_m)$ is a branch through the tree of the scale $\{\phi_n\}$). We think of $x \in W$ as coding the ordinal $|x| \doteq \sup_n \phi_0(x_n)$. Note that for almost all $\alpha < \boldsymbol{\delta}^1_3$ with respect to the ω-cofinal normal measure, there is an $x \in W$ with $|x| = \alpha$ and $U_x \restriction \alpha$ is ill-founded. Let S be a complete $\boldsymbol{\Sigma}^1_{2n+1}$ set, which is $(\boldsymbol{\delta}^1_3)^-$-Suslin by Theorem 2.18. Say $S = p[V]$, V a tree on $\omega \times (\boldsymbol{\delta}^1_3)^-$. Since $S \notin \boldsymbol{\Delta}^1_3$, it follows from Theorem 2.15 that $\sup\{|V_x| : V_x \text{ is well-founded}\} = \boldsymbol{\delta}^1_3$. The Kunen tree T is then constructed as in Lemma 4.1.

For the other normal measures, however, the situation is different. To discuss this, we need to recall some facts from the homogeneous tree construction. A detailed account of this may be found in [17]; we summarize the main points.

Recall that if T is a tree on $\omega \times \kappa$, and $s \in \omega^n$, then $T_s = \{\vec{\alpha} \in \kappa^n : (s, \vec{\alpha}) \in T\}$. If t extends s, let $\pi_{s,t}$ denote the natural map from T_t to T_s defined by $\pi_{s,t}(\vec{\alpha}) = \vec{\alpha} \restriction \mathrm{lh}(s)$. If μ is a measure on T_t, then $\pi_{s,t}(\mu)$ is a measure on T_s (recall $\pi_{s,t}(\mu)(A) = \mu(\pi^{-1}_{s,t}(A))$).

5.1 Definition. A tree T on $\omega \times \kappa$ is *homogeneous* if there are measures μ_s, for $s \in \omega^{<\omega}$, with $\mu_s(T_s) = 1$ such that if t extends s then $\pi_{s,t}(\mu_t) = \mu_s$, and having the following homogeneity property: for all $x \in \omega^\omega$, if T_x is ill-founded and for each n a set $A_n \subseteq T_{x\restriction n}$ is given with $\mu_{x \restriction n}(A_n) = 1$, then there is a sequence $\vec{\alpha} \in \kappa^\omega$ such that for all n, $\alpha \restriction n \in A_n$.

The homogeneity property for T_x is equivalent to saying that the direct limit of the ultrapowers (of On) by the measures $\mu_{x\restriction n}$ is well-founded.

We extend the definition in the obvious way to trees T on $\omega \times \omega \times \kappa$, etc. (in this case, the measures $\mu_{s,t}$ are indexed by pairs of sequences of the same length). We say T is a homogeneous tree for $P \subseteq \omega^\omega$ if T is homogeneous and $p[T] = P$.

If $P \subseteq 2^\omega$ is $\boldsymbol{\Pi}^1_1$, the standard Shoenfield construction gives a tree T_1 on $2 \times \omega_1$ with $P = p[T_1]$. T_1 may be defined so that for each $s \in 2^\omega$, there is a permutation π_s of $\{1, \dots, n\}$, $n = \mathrm{lh}(s)$, with n occurring first, such that $(s, \vec{\alpha}) \in T_1$ iff $\vec{\alpha}$ is order-isomorphic to π_s. For π a permutation of $\{1, \dots, n\}$, let W^π_1 be the natural measure on n-tuples $\vec{\alpha}$ which are order-isomorphic to π (i.e., W^π_1 is equivalent to W^n_1 under the map which re-arranges $\vec{\alpha}$ into increasing order). Thus, the measures $W^{\pi_s}_1$ witness that T_1 is homogeneous.

If $S \subseteq 2^\omega$ is $\boldsymbol{\Sigma}^1_2$, then $S(x) \longleftrightarrow \exists y\ P(x, y)$, where $P \in \boldsymbol{\Pi}^1_1$, so $P = p[T_1]$ for some homogeneous tree T_1 on $2 \times 2 \times \omega_1$ (if we identify T_1 with a tree

T_1' on $2 \times \omega_1$ by identifying the second and third coordinates of T_1 with the second coordinate of T_1', then T_1' is said to be *weakly homogeneous*). For $s, t \in 2^{<\omega}$ of the same length, let $\pi_{s,t}$ and $W_1^{\pi_{s,t}}$ be the permutation and measure associated to s, t, and T_1. We may assume without loss of generality that for $s, t \in 2^{<\omega}$ of the same length, that $\pi_{s,t}$ depends only on $s \restriction (\mathrm{lh}(s) - 1)$, $t \restriction (\mathrm{lh}(t) - 1)$. For convenience we also assume (without loss of generality) that for any s, t of the same length, $(T_1)_{s,t} \neq \emptyset$. If $Q = S^c$, then the homogeneous tree construction shows how, using the strong partition relation on ω_1, to get a homogeneous tree T_2 for Q. One way of doing this is as follows. For $s \in 2^{<\omega}$, let $\prec_s$ be the Kleene-Brouwer ordering on $(T_1)_s \subseteq (2 \times \omega_1)^{\leq \mathrm{lh}(s)}$. In specifying the Kleene-Brouwer ordering, we order pairs $(n, \alpha) \in 2 \times \omega_1$ first by α. It is convenient here to adopt a minor variation of the definition of $\mathcal{R}$ being a type-1 tree of uniform cofinalities, Definition 4.25. First, we drop all sequences $\vec{p} = \langle p_1, i_1, \dots, p_m, i_m \rangle$ where $i_m = 0$ from the domain of $\mathcal{R}$. Thus, for any $\vec{p}$, $\mathcal{R}(\vec{p})$ is now either (ω) or a permutation p_{m+1} extending p_m. Second, we now allow either possibility for $\mathcal{R}(\vec{p})$ when $\vec{p}$ is maximal in $\mathrm{dom}(\mathcal{R})$. We define $<^{\mathcal{R}}$ exactly as before, and define $f : \mathrm{dom}(<^{\mathcal{R}}) \to \omega_1$ being of type $\mathcal{R}$ in the obvious way (for $\vec{p}$ maximal in $\mathrm{dom}(\mathcal{R})$ with $\mathcal{R}(\vec{p}) = p_{m+1}$, we require $f^{\vec{p}}(\alpha_1, \dots, \alpha_m)$ to almost everywhere have uniform cofinality $\{\beta : (\alpha_1, \dots, \alpha_m, \beta)$ is order-isomorphic to $p_{m+1}\}$). It is now easy to check that $\prec_s$ is of the form $<^{\mathcal{R}_s}$ for some type-1 tree of uniform cofinalities $\mathcal{R}_s$. In fact, we can define $\mathcal{R}_s$ as follows. Let $\vec{p} = \langle p_1, i_1, \dots, p_m, i_m \rangle \in \mathrm{dom}(\mathcal{R}_s)$ iff $m \leq \mathrm{lh}(s)$, each $i_k = 1$ or 2, and $p_m = \pi_{s \restriction m, t}$, where $t = (i_1 - 1, \dots, i_m - 1)$. We set $\mathcal{R}_s(\vec{p}) = \pi_{s', t'}$, where s', t' are any immediate extensions of s, t (by our assumption, this only depends on s and t).

We define $(s, \vec{\beta}) \in T_2$ iff there is an $f : \mathrm{dom}(<^{\mathcal{R}_s}) \to \omega_1$ of type $\mathcal{R}_s$ with $\vec{\beta} = [f] \restriction \mathrm{lh}(s)$. To say $\vec{\beta} = [f] \restriction \mathrm{lh}(s)$ means that for all $i < \mathrm{lh}(s)$, $\beta_i = [f^{\langle p_1, i_1, \dots, p_k, i_k \rangle}]_{W_1^k}$, where $(i_1, \dots, i_k)$ is the ith element of $2^{<\omega}$ in some reasonable enumeration, and $p_j = \pi_{(s \restriction j, (i_1, \dots, i_j))}$. From the strong partition relation on ω_1 it is not difficult to see that T_2 is homogeneous for Q, with measures $M^{\mathcal{R}_s}$. [For example, to show homogeneity, suppose $(T_2)_x$ is ill-founded, and each A_n has measure one with respect to $M^{\mathcal{R}_{x \restriction n}}$. Let C_n be a closed unbounded subset of ω_1 defining a $M^{\mathcal{R}_{x \restriction n}}$ measure one set contained in A_n. Let $C = \bigcap_n C_n$. Since $x \in Q = P^c$, $(T_1)_x$ is well-founded. Let f be order-preserving from the Kleene-Brouwer ordering on $(T_1)_x$ to C such that for all n, $f \restriction \mathrm{dom}(\prec_{x \restriction n})$ is of type $\mathcal{R}_{x \restriction n}$. Let $\beta_i = [f^{\langle p_1, i_1, \dots, p_k, i_k \rangle}]_{W_1^k}$, where again $(i_1, \dots, i_k)$ is the ith element of $2^{<\omega}$ in our enumeration. Then $(\beta_0, \dots, \beta_n) \in A_n$ for all n.]

Recall WO_2 is the $\mathbf{\Pi}^1_2$ set of codes for ordinals $< \omega_2$ (Definition 4.36), and for $x \in \mathrm{WO}_2$, $|x| = [f_x]_{W_1^1} < \omega_2$ is the ordinal coded by x. The next lemma shows that we may get a homogeneous tree for WO_2 with an additional property.

5.2 Lemma. *There is a homogeneous tree U on $\omega \times \omega_\omega$ with* $\mathrm{WO}_2 = p[U]$ *and with the following property:*

($\star$) *If* $\{\psi_n\}$ *is the scale on* WO_2 *corresponding to* U *(using left-most branches), then* $\forall x \in \mathrm{WO}_2 |x| \leq \psi_0(x)$.

Proof. Let T be the Kunen tree of Sect. 4, where we use the linear-order version of Theorem 4.2. Recall $x \in \mathrm{WO}_2$ if $x = \langle a, y\rangle$ where $a \in \mathrm{WO}$ and T_y is a wellordering. Since T is Δ^1_1 in the codes, there is a $\boldsymbol{\Sigma}^1_1$ relation E such that for all $b \in \mathrm{WO}$:

$$E(y, b, x_1, x_2) \longleftrightarrow \big[x_1, x_2 \in \mathrm{WO} \wedge |x_1|, |x_2| < |b| \wedge |x_2|\ T_y\ |x_1|\big].$$

Let W_1 be a tree on ω^5 projecting to E. Let W_2 be a homogeneous tree on $\omega \times \omega_1$ for WO. We may assume that for all $(s, (\alpha_0, \dots, \alpha_{n-1})) \in W_2$ that $\alpha_0 > \max\{\alpha_1, \dots, \alpha_{n-1}\}$. Define the tree V on $\omega^2 \times \omega_1 \times \omega^2$ as follows. Let $(p, s, \vec{\alpha}, v, w) \in V$ iff $(s, \vec{\alpha}) \in W_2$ and (p, s, v, w) satisfies: for all $i < \mathrm{lh}(p) - 1$, if j is maximal so that $\langle i, j\rangle$, $\langle i+1, j\rangle < \mathrm{lh}(p)$, then

$$\big(p{\restriction}j, s{\restriction}j, \big(v_i(0), \dots, v_i(j)\big), \big(v_{i+1}(0), \dots, v_{i+1}(j)\big), (w_i(0), \dots, w_i(j))\big) \in W_1,$$

where $v_i(k) = v(\langle i, k\rangle)$, and similarly for w. This last requirement is just building the Kunen-Martin tree for the relation E. In particular, V_y is well-founded iff for all $a \in \mathrm{WO}$, $T_y{\restriction}|a|$ is a wellorder, that is, iff T_y is a wellorder. Also, if T_y is well-founded, then for all $\beta < \omega_1$ the rank of $T_y{\restriction}\beta$ is less than or equal to the rank of $V_y^\beta \doteq$ those $(p, s, \vec{\alpha}, v, w) \in V_y$ with $\alpha_0 \leq \beta$ (as in the proof of the Kunen-Martin Theorem).

Let W_3 be the homogeneous tree on $\omega \times \omega_\omega$ constructed from V, so $p[W_3] = \{y : T_y \text{ is well-founded}\}$. For each $p \in \omega^n$, the homogeneity measure μ_p will be of the form $M^{\mathcal{R}_p}$ for some type-1 tree of uniform cofinalities $\mathcal{R}_p$. Thus, $(p, \vec{\beta}) \in W_3$ iff there is an f of type $\mathcal{R}_p$ such that for all $j < n$, $\beta_j = [f^{\langle p_1, i_1, \dots, p_k, i_k\rangle}]_{W_1^k}$, where $\langle p_1, i_1, \dots, p_k, i_k\rangle$ is the jth element of $\mathrm{dom}(\mathcal{R}_p)$ in some enumeration. We may assume that $\beta_0 = [f^{\langle p_1, i_1\rangle}]_{W_1^1}$, where i_1 is maximal so that $\langle p_1, i_1\rangle \in \mathrm{dom}(\mathcal{R}_p)$.

Finally, define U to be the tree which is the "conjunction" of W_2 and W_3:

$$\begin{aligned}&\big((y(0), a(0), \dots, y(n-1), a(n-1)), (\beta_0, \alpha_0, \dots, \beta_{n-1}, \alpha_{n-1})\big) \in U \\ &\quad\longleftrightarrow (a{\restriction}n, (\alpha_0, \dots, \alpha_{n-1})) \in W_2 \wedge (y{\restriction}n, (\beta_0, \dots, \beta_{n-1})) \in W_3.\end{aligned}$$

It is easy to see that U is homogeneous with measures of the form $W_1^\pi \times M^{\mathcal{R}}$. Clearly $p[U] = \mathrm{WO}_2$. To verify ($\star$), suppose that

$$x = \langle a, y\rangle = (y(0), a(0), y(1), a(1), \dots) \in \mathrm{WO}_2\,.$$

By definition $|x| \leq |T_y|$. It is enough to show that if $(y, \vec{\beta}) \in [W_3]$, then $\beta_0 \geq |T_y|$. For each n, let f_n be of type $\mathcal{R}_{y{\restriction}n}$ with $[f_n] = (\beta_0, \dots, \beta_{n-1})$. For $C \subseteq \omega_1$, let $V_y{\restriction}C$ denote those $(s, \vec{\alpha}, v, w) \in V_y$ with all $\alpha_j \in C$. From the f_n we get a function f and a closed unbounded $C \subseteq \omega_1$ such that:

(1) f is order-preserving from the Kleene-Brouwer ordering on $V_y \restriction C$ to On.

(2) For each n, f induces by restriction a function f'_n of type $\mathcal{R}_{y\restriction n}$ with $[f'_n] = [f_n] = (\beta_0, \dots, \beta_{n-1})$.

Thus, for all $\alpha \in C$ we have $f'_0(\alpha) \geq |V_y^\alpha \restriction C|$. However, for α a closure point of C (i.e., α is the α^{th} element of C), we easily have $|V_y^\alpha \restriction C| = |V_y^\alpha|$. Hence, $\beta_0 = [f'_0]_{W_1^1} \geq [\alpha \to |V_y^\alpha|]_{W_1^1} \geq [\alpha \to |T_y \restriction \alpha|]_{W_1^1} = |T_y|$. ⊣

The above homogeneous tree construction, without the ($\star$) argument, also shows that every $\boldsymbol{\Pi}^1_2$ set is the projection of a homogeneous tree on $\omega \times \omega_\omega$. This also shows that every $\boldsymbol{\Sigma}^1_3$ set is weakly homogeneous. Using the weak partition on $\boldsymbol{\delta}^1_3$ and the homogeneous tree construction again, one can then show that every $\boldsymbol{\Pi}^1_3$ set admits a homogeneous tree T on $\omega \times \boldsymbol{\delta}^1_3$. We wish, however, to modify this construction to obtain a homogeneous tree on a $\boldsymbol{\Pi}^1_3$-complete set with some additional properties. Our argument is really just Martin's analysis of functions with respect to the normal measures. The form we present it here may be of use elsewhere. We sketch another version in Theorem 5.6.

5.3 Theorem. *There is a $\boldsymbol{\Pi}^1_3$ complete set P, a $\boldsymbol{\Pi}^1_3$-norm $z \to |z| < \boldsymbol{\delta}^1_3$ from P onto $\boldsymbol{\delta}^1_3$, and a homogeneous tree S on $\omega \times \boldsymbol{\delta}^1_3$ for P satisfying the following. There is a closed unbounded $C \subseteq \boldsymbol{\delta}^1_3$ such that for all $\alpha \in C$ there is a $z \in P$ with $|z| = \alpha$ and with $S_z \restriction (\sup_\nu j_\nu(\alpha))$ ill-founded, the supremum ranging over measures $\nu = M^{\mathcal{R}_s}$ occurring in the homogeneous tree U of Lemma 5.2. Furthermore, for any z and $\vec{\beta} = (\beta_0, \beta_1, \dots)$, if $(z, \vec{\beta}) \in [S]$, then $|z| \leq \beta_0$.*

Proof. Recall according to Theorem 4.33 our $\boldsymbol{\Delta}^1_3$ coding $z \to A_z$ of subsets of ω_ω (or $(\omega_\omega)^2$, etc.). We assume for this proof that for all z, $A_z \subseteq \omega_2 \times \omega_\omega \times \omega_\omega$. If $\alpha < \omega_2$, let $A_z^\alpha = \{(\beta, \gamma) : (\alpha, \beta, \gamma) \in A_z\}$. Define

$$P(z) \longleftrightarrow \forall \alpha < \omega_2 \; A_z^\alpha \text{ is well-founded.}$$

Note that the relation

$$C(z, x_1, x_2, x_3) \longleftrightarrow x_1 \in \mathrm{WO}_2 \wedge x_2, x_3 \in \mathrm{WO}_\omega \wedge (|x_1|, |x_2|, |x_3|) \in A_z$$

is $\boldsymbol{\Delta}^1_3$ by the closure of $\boldsymbol{\Delta}^1_3$ under $<\boldsymbol{\delta}^1_3$ unions (in fact, it is straightforward to show that C is Δ^1_3). Thus, $P \in \boldsymbol{\Pi}^1_3$. For $z \in P$, let $|z| = \sup\{|A_z^\alpha| : \alpha < \omega_2\}$. Using the closure of $\boldsymbol{\Delta}^1_3$ under $<\boldsymbol{\delta}^1_3$ unions and intersections, it is straightforward to check that this defines a $\boldsymbol{\Pi}^1_3$-norm onto $\boldsymbol{\delta}^1_3$.

Let $C^* \subseteq (\omega^\omega)^5$ be $\boldsymbol{\Pi}^1_2$ projecting to C. Let T_2^* be a homogeneous tree on $\omega^5 \times \omega_\omega$ for C^*. Let U be a homogeneous tree on $\omega \times \omega_\omega$ for WO_2 satisfying ($\star$). Define a tree V on $\omega^2 \times \omega_\omega \times \omega \times \omega_\omega$ as follows. Set $(p, s, \vec{\alpha}, u, \vec{\beta}) \in V$ iff $(s, \vec{\alpha}) \in U$ and if $u = (u(0), \dots, u(n-1))$, then the $u(i)$ code more and more of reals $u_0, u_1, \dots$ and reals $w_0, w_1, \dots$. Each $u(j+1)$ extends the array coded by $u(j)$ by adding one extra pair $(u_i(k), u_{i+1}(k))$ for some i, k, and one extra value $w_i(k)$. For each i,k, if the pairs $(u_i(0),u_{i+1}(0)),\dots,(u_i(k-1),u_{i+1}(k-1))$ are added at stages $q_0,\dots,q_{k-1}<n$, then we require that

$$(p{\restriction}k, s{\restriction}k, u_i{\restriction}k, u_{i+1}{\restriction}k, w_i{\restriction}k, (\beta_{q_0},\dots,\beta_{q_{k-1}}))\in T_2^*.$$

Again, V embodies the Kunen-Martin construction for the relation C. The tree V is also homogeneous, witnessed by measures $M_{p,s,u}=\nu_s\times\mu_{p,s,u}$ where ν_s are the homogeneity measures for U and $\mu_{p,s,u}$ are measures of the form $M^{\mathcal{R}_{p,s,u}}$ for some type-1 trees of uniform cofinalities $\mathcal{R}_{p,s,u}$ which are simply obtained from the type-1 trees giving the measures for T_2^*. (Note that for any two type-1 trees $\mathcal{R}_1$ and $\mathcal{R}_2$, there is a type-1 tree $\mathcal{R}$ whose measure $M^{\mathcal{R}}$ projects naturally to both $M^{\mathcal{R}_1}$ and $M^{\mathcal{R}_2}$.)

We now apply the homogeneous tree construction to V to produce a tree S on $\omega\times\boldsymbol{\delta}^1_3$ such that for all z, S_z is ill-founded iff V_z is well-founded. For any $p\in\omega^{<\omega}$, let $\prec_{V_p}$ denote the Kleene-Brouwer ordering on V_p. In specifying the Kleene-Brouwer order, we must say how the tuples $(s(n),\alpha_n,u(n),\beta_n)$ are ordered. In comparing two such tuples, it is important (at least for $n=0$) that we order first by α_n (the remaining order is unimportant). We define $(p,\vec{\gamma})\in S$ iff there exists an f which is order-preserving and of the correct type from V_p with the Kleene-Brouwer order to $\boldsymbol{\delta}^1_3$, and f represents $\vec{\gamma}$ in the following sense. First, we require $\gamma_0=\sup(f)$. Let (s_i,u_i), $i\geq 1$, enumerate the pairs of finite sequences of the same length, with $\mathrm{lh}(s_i)\leq i$. Then γ_i, for $i\geq 1$, is represented with respect to $M_{p\restriction \mathrm{lh}(s_i),s_i,u_i}$ by the function $f^{s_i,u_i}(\vec{\alpha},\vec{\beta})=f(s_i,\vec{\alpha},u_i,\vec{\beta})$. The weak partition relation on $\boldsymbol{\delta}^1_3$ shows that S is homogeneous (though we do not need this for the proof).

If $z\in P$, and hence V_z is well-founded, then easily S_z is ill-founded and in fact there is a $\vec{\gamma}$ with $(z,\vec{\gamma})\in[S]$ such that $\gamma_0\leq\omega\cdot|\prec_{V_z}|$, where $\prec_{V_z}$ is the Kleene-Brouwer ordering on V_z. That S_z being ill-founded implies $z\in P$ will be shown below.

We now define the closed unbounded set $C\subseteq\boldsymbol{\delta}^1_3$ as required. Fix for the moment $\alpha<\omega_2$, $\beta<\boldsymbol{\delta}^1_3$. Let

$$P_{\alpha,\beta}=\{z:\forall\alpha'\leq\alpha\ A_z^{\alpha'}\text{ is well-founded of rank }\leq\beta\}.$$

A standard computation, using the closure of $\boldsymbol{\Delta}^1_3$ under $<\boldsymbol{\delta}^1_3$ unions and intersections shows $P_{\alpha,\beta}\in\boldsymbol{\Delta}^1_3$. Note that if $z\in P_{\alpha,\beta}$ then V_z restricted to tuples $(s,\vec{\alpha},u,\vec{\beta})$ such that $\alpha_0\leq\alpha$ is well-founded; this uses property $(\star)$ of the tree U. Since $P_{\alpha,\beta}\in\boldsymbol{\Sigma}^1_3$ and is thus ω_ω-Suslin, an easy tree argument shows that $b(\alpha,\beta)\doteq\sup\{|\alpha|_{V_z}:z\in P_{\alpha,\beta}\}<\boldsymbol{\delta}^1_3$, where by $|\alpha|_{V_z}$ we mean the supremum of the ranks of $(s(0),\alpha,u(0),\gamma_0)$ in the Kleene-Brouwer ordering of V_z. This defines the function $b:\omega_2\times\boldsymbol{\delta}^1_3\to\boldsymbol{\delta}^1_3$. Let then $C\subseteq\boldsymbol{\delta}^1_3$ be a closed unbounded set consisting of limit ordinals and closed under b.

Suppose now that $\delta\in C$ and $\mathrm{cf}(\delta)=\omega_2$. Let $h:\omega_2\to\delta$ be increasing and cofinal. Let $z\in\omega^\omega$ be such that $\forall\alpha<\omega_2\ A_z^\alpha$ is well-founded of rank $h(\alpha)$. Thus $P(z)$, and for all $\alpha<\omega_2$, $z\in P_{\alpha,h(\alpha)}$. For all $\alpha<\omega_2$ we have $|\alpha|_{V_z}\leq b(\alpha,h(\alpha))<\delta$. Hence there is an order-preserving map f from the

Kleene-Brouwer ordering of V_z to δ. If f represents $\vec{\gamma}$, then $\gamma_0 \leq \delta$ and for all n, $\gamma_n \leq \sup_{p,s,u} j_{M_{p,s,u}}(\delta)$.

Suppose now that $(z, (\beta_0, \beta_1, \ldots)) \in [S]$. We show that $z \in P$, and if we let $h(\alpha) = |A_z^\alpha|$ for $\alpha < \omega_2$, then $\sup(h) \leq \beta_0$. For each j, let $f_j : V_{z\restriction j} \to \boldsymbol{\delta}^1_3$ be order-preserving representing $(\beta_1, \ldots, \beta_j)$, and with $\beta_0 = \sup(f_j)$. Recall that for $i \leq j$ and $i > 0$, β_i is represented with respect to $M_{z\restriction \mathrm{lh}(s_i), s_i, u_i} = \nu_{s_i} \times \mu_{z\restriction \mathrm{lh}(s_i), s_i, u_i}$ by the function $f_j^{s_i, u_i}$. For each $i > 0$, let E_i be a $M_{z\restriction \mathrm{lh}(s_i), s_i, u_i}$ measure one set such that for all $j_1, j_2 \geq i$ and all $(\vec{\alpha}, \vec{\beta}) \in E_i$ we have $f_{j_1}^{s_i,u_i}(\vec{\alpha}, \vec{\beta}) = f_{j_2}^{s_i,u_i}(\vec{\alpha}, \vec{\beta})$. For $(\vec{\alpha}, \vec{\beta}) \in E_i$, let $f^{s_i,u_i}(\vec{\alpha}, \vec{\beta})$ denote the common value of $f_j^{s_i,u_i}(\vec{\alpha}, \vec{\beta})$ for $j \geq i$. Let A_i be a ν_{s_i} measure one set such that for all $\vec{\alpha} \in A_i$ we have that for $\mu_{z\restriction \mathrm{lh}(s_i), s_i, u_i}$ almost all $\vec{\beta}$ that $(\vec{\alpha}, \vec{\beta}) \in E_i$. Consider now $\alpha < \omega_2$, and fix $x \in \mathrm{WO}_2$ with $|x| = \alpha$. By homogeneity of U, fix $\vec{\alpha} = (\alpha_0, \alpha_1, \ldots)$ such that $(x, \vec{\alpha}) \in [U]$ and for all k, $\vec{\alpha}\restriction k \in \bigcap_i A_i$, where the intersection runs over the i such that $s_i = x\restriction k$.

Consider the tree

$$\begin{aligned} V_{z,x,\vec{\alpha}} \cap \vec{B} = &\big\{(u, \vec{\beta}) : (z\restriction \mathrm{lh}(u), x\restriction \mathrm{lh}(u), \vec{\alpha}\restriction \mathrm{lh}(u), u, \vec{\beta}) \in V \\ &\wedge\ \vec{\beta} \in B_{z\restriction \mathrm{lh}(u), x\restriction \mathrm{lh}(u), u}\big\} \end{aligned}$$

where $B_{z\restriction \mathrm{lh}(u), x\restriction \mathrm{lh}(u), u}$ is a $\mu_{z\restriction \mathrm{lh}(u), x\restriction \mathrm{lh}(u), u}$ measure-one set satisfying $\{\vec{\alpha}\restriction \mathrm{lh}(u)\} \times B_{z\restriction \mathrm{lh}(u), x\restriction \mathrm{lh}(u), u} \subseteq E_i$, for that i with $(s_i, u_i) = (x\restriction \mathrm{lh}(u), u)$. The map $(u, \vec{\beta}) \to f^{x\restriction \mathrm{lh}(u), u}(\vec{\alpha}\restriction \mathrm{lh}(u), \vec{\beta})$ is order-preserving from the Kleene-Brouwer ordering of $V_{z,x,\vec{\alpha}} \cap \vec{B}$ to β_0. In particular, the tree $V_{z,x,\vec{\alpha}} \cap \vec{B}$ has rank at most β_0. On the other hand, the proof of the Kunen-Martin Theorem shows that the tree of finite sequences $(y_0, \ldots, y_n)$ of reals such that for all $i < n$, $C(z, x, y_{i+1}, y_i)$, embeds into $V_{z,x,\vec{\alpha}} \cap \vec{B}$ (we use here the homogeneity of T_2^*, which allows the "witness sequences" from the Kunen-Martin proof to be chosen in the B sets). Thus, A_z^α is well-founded of rank at most $|V_{z,x,\vec{\alpha}} \cap \vec{B}| \leq \beta_0$. Since $\alpha < \omega_2$ was arbitrary, we have $\sup(h) \leq \beta_0$.

We have proved the theorem for points of cofinality ω_2. A similar (but slightly easier) construction works for points of cofinality ω_1, using WO in place of WO_2. The cofinality ω case, we already observed, is the Kunen result. ⊣

5.4 Remark. If $\{\phi_n\}_{n\in\omega}$ is the semi-scale on P corresponding to S (using left-most branches), then one can show that $\{\phi_n\}$ is a (not necessarily regular) $\boldsymbol{\Pi}^1_3$-scale.

From Theorem 5.3, Martin's Theorem now follows quickly.

5.5 Theorem (Martin). *There is a tree T on $\omega \times \boldsymbol{\delta}^1_3$ such that for all $f : \boldsymbol{\delta}^1_3 \to \boldsymbol{\delta}^1_3$ there is a $z \in \omega^\omega$ with T_z well-founded, and a closed unbounded $C \subseteq \boldsymbol{\delta}^1_3$ such that for all $\alpha \in C$, $f(\alpha) < |T_z \restriction \sup_\nu j_\nu(\alpha)|$, the supremum ranging over measures ν occurring in the homogeneous trees on $\boldsymbol{\Pi}^1_1$, $\boldsymbol{\Pi}^1_2$-complete sets.*

Proof. The argument is now almost identical to the Kunen case. Fix P, S as in Theorem 5.3. Let W be a tree on $\omega \times \omega_\omega$ such that $p[W]$ is $\mathbf{\Sigma}^1_3$-complete, and thus $\sup\{|W_w| : W_w \text{ is well-founded}\} = \boldsymbol{\delta}^1_3$. Let U be the tree on $\omega^2 \times \boldsymbol{\delta}^1_3 \times \omega \times \omega_\omega$ defined by:

$$\begin{aligned}&(p, s, \vec{\alpha}, u, \vec{\beta}) \in U\\ &\qquad \longleftrightarrow (s, \vec{\alpha}) \in S \wedge (u, \vec{\beta}) \in W \wedge\ \exists \sigma(\sigma \text{ extends } p \wedge \sigma(s) = u).\end{aligned}$$

If $f : \boldsymbol{\delta}^1_3 \to \boldsymbol{\delta}^1_3$, then play the game where I plays out z, II plays out y, and II wins iff $(z \in P) \to (W_y \text{ is well-founded and } |W_y| > f(|z|))$. II wins by boundedness (a $\mathbf{\Sigma}^1_1$ subset of P codes a bounded below $\boldsymbol{\delta}^1_3$ set of ordinals). If σ is a winning strategy for II, and C is as in Theorem 5.3, then for all $\alpha \in C$, $|U_\sigma \restriction \sup_\nu j_\nu(\alpha)| > f(\alpha)$. Weaving the second, third, fourth, and fifth coordinates of U into a single coordinate produces a tree T as desired. ⊣

We refer to the tree T of Theorem 5.5 as the *Martin tree.*

In [11] a version of Martin's Theorem is presented which does not get the extra information about the homogeneous scale, but which refines slightly the inequality. Actually, the refined inequality can also be obtained by examining the proof of Theorem 5.3. Nevertheless, this second variation of the proof has, we feel, enough advantages to warrant presenting. Specifically, we will use this second variation of the proof in Theorem 5.7.

5.6 Theorem (Martin). *There is a tree T on $\omega \times \boldsymbol{\delta}^1_3$ such that for all $f : \boldsymbol{\delta}^1_3 \to \boldsymbol{\delta}^1_3$, there is a z with T_z well-founded and a closed unbounded $C \subseteq \boldsymbol{\delta}^1_3$ such that for all $\alpha \in C$, $f(\alpha) < |T_z \restriction \sup_\nu j_\nu(\alpha)|$, where if $\mathrm{cf}(\alpha) = \omega_1$ the supremum ranges over the measures W^m_1 occurring in the homogeneous tree on a $\mathbf{\Pi}^1_1$-complete set, and if $\mathrm{cf}(\alpha) = \omega_2$, the supremum ranges over the measures occurring in the homogeneous tree on a $\mathbf{\Pi}^1_2$-complete set (if $\mathrm{cf}(\alpha) = \omega$, we use $|T_z \restriction \alpha|$).*

Proof. The proof of this version is similar to that of the version presented above, so we give a sketch. Let P, U be as in Theorem 5.3, and let ν_s be the homogeneity measures for U. Define (where A^α_z is as in the proof of Theorem 5.3)

$$P'(z, x) \longleftrightarrow x \in \mathrm{WO}_2\ \wedge\ A^{|x|}_z \text{ is well-founded.}$$

Thus $P' \in \mathbf{\Pi}^1_3$ and $P(z) \longleftrightarrow \forall x\ [x \in \mathrm{WO}_2 \to P'(z, x)]$. Let V be a homogeneous tree on $\omega \times \omega \times \boldsymbol{\delta}^1_3$ for P' with $\boldsymbol{\delta}^1_3$-complete measures $\mu_{s,t}$ (which the usual homogeneous tree construction gives). Now define the tree W on $\omega \times \boldsymbol{\delta}^1_3$ as follows. Let $\{s_n\}_{n \in \omega}$ be an enumeration of $\omega^{<\omega}$ with any sequence preceding its extensions. Define $((z(0), \ldots, z(n-1)), (\beta_0, \ldots, \beta_{n-1})) \in W$ iff for all $j < n$, if $s_j = (s(0), \ldots, s(k-1))$ and $q_0 < q_1 < \cdots < q_{k-1} = j$ are such that $s_{q_l} = (s(0), \ldots, s(l))$, and $f_0, \ldots, f_{k-1}$ represent $\beta_{q_0}, \ldots, \beta_{q_{k-1}}$ with respect to $\nu_{s(0)}, \ldots, \nu_{(s(0), \ldots, s(k-1))}$, then

$$\forall^*_{\nu_{s_j}} \gamma_0, \ldots, \gamma_{k-1}\ (z \restriction k, s_j, (f_0(\gamma_0), \ldots, f_{k-1}(\gamma_0, \ldots, \gamma_{k-1}))) \in V.$$

We claim first that $P = p[W]$. $p[W] \subseteq P$ is easily checked, and uses only the homogeneity of U. If $z \in P$, consider the ordinal game G_z where I plays out $x \in \omega^\omega$, $\vec{\alpha} = (\alpha_0, \alpha_1, \dots) \in (\omega_\omega)^\omega$ with $\alpha_0 < \omega_2$, II plays out $\vec{\delta} \in (\boldsymbol{\delta}^1_3)^\omega$, and II wins iff $\forall n\ [(x \restriction n, \vec{\alpha} \restriction n) \in U \to (z \restriction n, x \restriction n, \vec{\delta} \restriction n) \in V]$. The game is closed for II, hence determined, and the usual homogeneity argument, using the $\boldsymbol{\delta}^1_3$ completeness of the measures for V, shows that I cannot have a winning strategy [otherwise, by $\boldsymbol{\delta}^1_3$-completeness of the measures $\mu_{s,t}$, we could stabilize I's moves on measure one sets, and then by the homogeneity of those measures, get a play for II which wins]. A winning strategy τ for II then gives functions f_s, and thus ordinals β_i, such that $(z, \vec{\beta}) \in [W]$. Namely, if $\mathrm{lh}(s_i) = k$, then β_i is represented with respect to ν_{s_i} by the function $f_{s_i}(\gamma_0, \dots, \gamma_{k-1}) = \tau(s_i, (\gamma_0, \dots, \gamma_{k-1}))$.

Fix for the moment $\alpha < \omega_2$, $\beta < \boldsymbol{\delta}^1_3$. Let $G_{z,\alpha}$ be the game defined just as G_z, except I's first ordinal move α_0 satisfies $\alpha_0 \le \alpha$. Let $P_{\alpha,\beta}$ be as in Theorem 5.3. For $z \in P_{\alpha,\beta}$, let $b(z,\alpha) < \boldsymbol{\delta}^1_3$ be least so that II has a winning strategy in $G_{z,\alpha}$ playing ordinals $< b(z,\alpha)$ (this exists since $\boldsymbol{\delta}^1_3$ is regular). We claim that $b(\alpha,\beta) \doteq \sup\{b(z,\alpha) : z \in P_{\alpha,\beta}\} < \boldsymbol{\delta}^1_3$. This follows from the fact that $P_{\alpha,\beta}$ is ω_ω-Suslin. To see this, consider the auxiliary game where I plays out $z, x \in \omega^\omega$, $\vec{\gamma} \in (\omega_\omega)^\omega$, $\vec{\alpha} \in (\omega_\omega)^\omega$ with $\alpha_0 \le \alpha$, and II plays out $\vec{\delta} \in (\boldsymbol{\delta}^1_3)^\omega$, and II wins iff

$$\forall n\ [((z \restriction n, \vec{\gamma} \restriction n) \in U_2 \wedge (x \restriction n, \vec{\alpha} \restriction n) \in U) \to (z \restriction n, x \restriction n, \vec{\delta} \restriction n) \in V],$$

where U_2 is a tree on $\omega \times \omega_\omega$ with $p[U_2] = P_{\alpha,\beta}$. II again wins, and $b(\alpha,\beta) \le$ any ordinal η large enough so that II can win this auxiliary game playing ordinals $< \eta$.

Let now $C \subseteq \boldsymbol{\delta}^1_3$ be a closed unbounded set consisting of limit ordinals and closed under b. Let $\delta \in C$ with $\mathrm{cf}(\delta) = \omega_2$. Let $h : \omega_2 \to \delta$ be increasing and cofinal, and $z \in P$ be such that $\forall \alpha < \omega_2\ |A^z_\alpha| = h(\alpha)$. Then we claim that $z \in p[W \restriction \sup_\nu j_\nu(\delta)]$, the supremum ranging over the measures ν_s for U. We must show that II can win G_z playing only ordinals $< \delta$. If I first moves $(x(0), \alpha_0)$, II picks the least ordinal $\eta \le b(\alpha_0, h(\alpha_0)) < \delta$ such that II can win $G_{z,\alpha}$ starting from that position playing only ordinals $< \eta$. II then follows the canonical winning strategy for the closed game $G_{z,\alpha} \restriction \eta$.

Thus, we have produced a tree W and a closed unbounded C such that $P = p[W]$ and for all $\alpha \in C$ of cofinality ω_2 there is a $z \in p[W \restriction \sup_\nu j_{\nu_s}(\alpha)]$ such that $|z| = \alpha$, that is, $\alpha = \sup\{|A^\beta_z| : \beta < \omega_2\}$. Again, the argument for cofinality ω_1 points is similar, using WO instead of WO_2. The argument now finishes exactly as before (i.e., Theorem 5.5). $\dashv$

Theorems 5.5 and 5.6 are the correct extension of the Kunen analysis on ω_1 to $\boldsymbol{\delta}^1_3$. The fact that the identity function of the Kunen analysis is replaced by $\alpha \to \sup_\nu j_\nu(\alpha)$ is, at bottom, the source of the combinatorial complications at the higher levels.

The proofs of Theorems 5.3, 5.5, and 5.6 are quite general. For example, the proof of Theorem 5.6 generalizes to the following (the proof is identical to that of Theorem 5.6 so we omit it).

5.7 Theorem. *Let $\lambda < \kappa$ be regular cardinals, and $\mathbf{\Gamma}$ a non-selfdual pointclass closed under $\forall^{\omega^\omega}, \wedge, \vee$. Assume:*

(1) There is a $\mathbf{\Delta}$ coding of the ordinals less than λ. That is, there is a $\mathbf{\Delta}$ set $C \subseteq \omega^\omega$ and a map $x \to |x|_C < \lambda$ for $x \in C$ such that the relations $(x_1, x_2 \in C \wedge |x_1|_C \leq |x_2|_C)$ and $(x_1, x_2 \in C \wedge |x_1|_C < |x_2|_C)$ are both in $\mathbf{\Delta}$.

(2) There is a homogeneous tree U on C such that for all $x \in C$, $|x| \leq \psi_0(x) < \lambda$, where $\{\psi_n\}$ is the semi-scale corresponding to U.

(3) There is a map $z \to A_z \subseteq \lambda \times \kappa$, for $z \in \omega^\omega$, satisfying:

(a) $\forall f : \lambda \to \kappa\ \exists z\ A_z = f$.

(b) The relation $P'(z, x) \longleftrightarrow [x \in C \wedge \exists! \beta\ A_z(|x|_C, \beta)]$ is in $\mathbf{\Gamma}$.

(c) For all $\alpha < \lambda$, $\beta < \kappa$, $P_{\alpha,\beta} \doteq \{z : \forall \alpha' \leq \alpha\ \exists \beta' \leq \beta\ [A_z(\alpha', \beta') \wedge \forall \beta''(A_z(\alpha', \beta'') \to \beta' = \beta'')]\}$ is in $\mathbf{\Delta}$.

(4) Every $\mathbf{\Gamma}$ set admits a homogeneous tree on κ with κ-complete measures.

(5) Every $\mathbf{\Delta}$ set is α-Suslin for some $\alpha < \kappa$. Also, if $A \subseteq P \doteq \{z : \forall x \in C\ P'(z, x)\}$ is in $\exists^{\omega^\omega} \mathbf{\Delta}$, then $\sup\{|z| : z \in A\} < \kappa$, *where for $z \in P$, $|z|$ is the supremum of the range of the function $A_z : \lambda \to \kappa$.*

Then there is a tree W on $\omega \times \kappa$ with $p[W] = P$ and a closed unbounded $D \subseteq \kappa$ such that for all $\alpha \in D$ with $\mathrm{cf}(\alpha) = \lambda$, *there is a $z \in P$ with $|z| = \alpha$ and $W_z \restriction (\sup_\nu j_\nu(\alpha))$ is ill-founded, the supremum ranging over the measures ν for the homogeneous tree U.*

5.8 Remark. The hypotheses imply that the prewellordering property falls on the $\mathbf{\Gamma}$ side. For if not, then $\check{\mathbf{\Gamma}}$ is closed under wellordered unions. From (3c) it follows that there is a κ increasing sequence of $\mathbf{\Delta}$ sets. Thus, there is a $\check{\mathbf{\Gamma}}$ prewellordering of length κ. If $\mathbf{\Delta}$ is not closed under $\exists^{\omega^\omega}$, then by (5.7) this prewellordering is α-Suslin for some $\alpha < \kappa$, a contradiction. If $\mathbf{\Delta}$ is closed under real quantification, then $\kappa = o(\mathbf{\Delta})$, and $\mathbf{\Delta}$ is closed under $<\kappa$ unions. Then P is a union of $\mathbf{\Delta}$ sets, so is in $\check{\mathbf{\Gamma}}$, and hence in $\mathbf{\Delta}$. This contradicts (5.7). Thus, pwo($\mathbf{\Gamma}$). Similarly, it can be shown that $\mathbf{\Delta}$ is closed under $<\kappa$ length unions and intersections.

This general form of Martin's Theorem is particularly useful when combined with another result of Martin and Steel (cf. [29]) which provides the existence of homogeneous trees in a general setting. We recall this theorem. Let $\{s_i\}_{i \in \omega}$ be an enumeration of $\omega^{<\omega}$ with each sequence preceding its proper extensions, and such that if $s_i = t^\frown a$, $s_j = t^\frown b$, then $a < b \to i < j$. View each real σ as a strategy for II via $\sigma(s_{i+1}) = \sigma(i)$ (note $s_0 = \emptyset$).

Let $\mathbf{\Gamma}$ be a Steel pointclass (i.e., $\mathbf{\Gamma}$ is non-selfdual, closed under $\forall^{\omega^\omega}$, pwo($\mathbf{\Gamma}$), and $\mathbf{\Delta}$ is closed under real quantification). By red($\mathbf{\Gamma}$), let $U, V \subseteq (\omega^\omega)^3$ be disjoint $\mathbf{\Gamma}$ sets such that for every disjoint $\mathbf{\Gamma}$ sets $A, B \subseteq (\omega^\omega)^2$ there is an $x \in \omega^\omega$ with $A = U_x$, $B = V_x$. We say $\mathbf{\Delta}$ is uniformly closed under $\exists^{\omega^\omega}$ if the relations

$$R(x,z) \longleftrightarrow \forall z, w\ [U_x(z,w) \vee V_x(z,w)] \wedge \exists w\ U_x(z,w),$$
$$S(x,z) \longleftrightarrow \forall z, w\ [U_x(z,w) \vee V_x(z,w)] \wedge \forall w\ U_x(z,w)$$

are in $\mathbf{\Gamma}$.

5.9 Theorem (AD; Martin, Steel). *Let $\mathbf{\Gamma}$ be a non-selfdual pointclass, $A \in \mathbf{\Gamma} - \check{\mathbf{\Gamma}}$, and assume A and A^c are both Suslin. Let $B = \{\sigma : \forall y\ \sigma(y) \in A\}$. Then B is $\forall^{\omega^\omega}\mathbf{\Gamma}$-complete and B admits a scale $\{\psi_n\}$ whose corresponding tree T_ψ is homogeneous. If $\{\phi_n\}$ is a $\mathbf{\Gamma}$ very good scale on A and either $\mathbf{\Gamma}$ is closed under $\exists^{\omega^\omega}$ or $\mathbf{\Delta}$ is uniformly closed under $\exists^{\omega^\omega}$, then $\{\psi_n\}$ is a $\forall^{\omega^\omega}\mathbf{\Gamma}$ scale. If $\mathbf{\Gamma}$ is closed under $\forall^\omega$, countable unions and intersections, then the measures in T_ψ will be κ-complete, where $\kappa =$ the supremum of the lengths of the $\mathbf{\Delta} = \mathbf{\Gamma} \cap \check{\mathbf{\Gamma}}$ prewellorderings of the reals.*

Combining this with Theorem 5.7 we have the following.

5.10 Theorem (AD + $V = L(\mathbb{R})$). *Let $\kappa < \boldsymbol{\delta}^2_1$ be a regular limit Suslin cardinal, and $\lambda < \kappa$ be regular. Let $\mathbf{\Gamma}$ be the pointclass closed under $\forall^{\omega^\omega}$ such that $S(\kappa) = \exists^{\omega^\omega}\mathbf{\Gamma}$. Assume there is a $\mathbf{\Delta}$ coding of λ with homogeneous tree U as in (1) and (2) of Theorem 5.7. Then there is a tree W on $\omega \times \kappa$ with $p[W] = P$, a $\mathbf{\Gamma}$-complete set, and a map $z \to |z| < \kappa$ for $z \in P$ satisfying:*

(1) If $S \subseteq P$ is in $\mathbf{\Delta}$, then $\sup\{|z| : z \in S\} < \kappa$.

(2) There is a closed unbounded $C \subseteq \kappa$ such that for all $\alpha \in C$ of cofinality λ, there is a $z \in P$ such that $|z| = \alpha$ and $W_z \restriction \sup_\nu j_\nu(\alpha)$ is ill-founded, the supremum ranging over the homogeneity measures ν for U.

Proof (Sketch). $\mathbf{\Gamma}$ is closed under countable unions and intersections from [35], and also from [37] $\mathbf{\Gamma}$ has the scale property. The proof of Theorem 3.3 of [35] also shows that $\mathbf{\Delta}$ is uniformly closed under $\exists^{\omega^\omega}$. Note also that κ is the supremum of the lengths of the $\mathbf{\Delta}$ prewellorderings, and $\mathbf{\Delta}$ is closed under $<\kappa$ unions and intersections. By Theorem 5.9, some $\mathbf{\Gamma}$-complete set admits a homogeneous tree with κ-complete measures, and thus so does every $\mathbf{\Gamma}$ set. The coding $z \to A_z \subseteq \lambda \times \kappa$ is given simply from the Coding Lemma (relative to some $\mathbf{\Delta}$ prewellordering of length λ and some $\mathbf{\Gamma}$-norm on a $\mathbf{\Gamma}$-complete set). We define P, W as in Theorem 5.6, using a homogeneous tree V with κ-complete measures for P'. Items (1)–(5) of Theorem 5.7 are easily checked. ⊣

We note that if λ is a regular Suslin cardinal, the hypotheses of the previous theorem are automatically satisfied. For there is a non-selfdual pointclass $\mathbf{\Lambda}$

closed under $\forall^{\omega^\omega}$ with the scale property such that λ is the supremum of the lengths of the $\boldsymbol{\Delta} = \boldsymbol{\Delta}(\boldsymbol{\Lambda})$ prewellorderings. If λ is inaccessible, $\boldsymbol{\Delta}$ is uniformly closed under $\exists^{\omega^\omega}$. If λ is a successor Suslin, then from Theorem 4.3 of [37], $\boldsymbol{\Lambda} = \forall^{\omega^\omega}\boldsymbol{\Lambda}^-$ with $\boldsymbol{\Lambda}^-$ closed under $\exists^{\omega^\omega}$ with scale($\boldsymbol{\Lambda}^-$). In either case, by Theorem 5.9, there is a $\boldsymbol{\Lambda}$-scale $\{\psi_n\}$ on a $\boldsymbol{\Lambda}$-complete set C whose tree U is homogeneous. We must have ψ_0 onto λ in this case (assuming without loss of generality that the scale is regular, i.e., all norms map onto an initial segment on the ordinals). Letting our coding of λ be given by $|x| = \psi_0(x)$ for $x \in C$, this verifies (1) and (2) of Theorem 5.7.

We make some comments on the possible significance of Theorem 5.10 to extending the inductive analysis of the projective sets to higher levels of $L(\mathbb{R})$. In analyzing the measures on κ, the first step of the proof of Theorem 4.8 shows it is necessary to have at hand an analysis of the functions on κ with respect to the semi-normal measures (the measures that give every closed unbounded set measure one). At successor Suslin cardinals, Theorem 5.7 and the analysis below κ should give the analog of Theorem 5.6. If κ is singular, there should be no analog of Martin's Theorem required, though other methods become necessary (we will discuss some of these in the next section). For κ inaccessible Suslin, Theorem 5.10 is a step towards providing the necessary result, but is not complete as it handles only the normal measures on κ corresponding to fixed cofinalities $\lambda < \kappa$.

5.2. Some Canonical Measures

For the remainder of this section we return to the projective hierarchy, and discuss the other main ingredient; the theory of descriptions. As we said in the introduction, our purpose here is not to present complete details, but rather to exposit the main ideas. We will frequently illustrate a proof by considering a case which shows the central idea.

According to Theorem 5.6, in analyzing functions $f : \boldsymbol{\delta}^1_3 \to \boldsymbol{\delta}^1_3$ with respect to the ω_1 cofinal normal measure, we need to consider ultrapowers by the measures W^m_1. There is nothing more to say in this case. With respect to the ω_2-cofinal normal measure, we need consider ultrapowers by the measures $M^{\mathcal{R}}$ occurring in the homogeneous tree on a $\boldsymbol{\Pi}^1_2$ set. One suspects that there is a combinatorially simpler family which "dominates" these measures. Indeed, it simplifies considerably the resulting theory to have such a family at hand.

Let $<_m$ be the ordering on $(\omega_1)^m$ corresponding to the permutation $\pi = (m, 1, 2, \ldots, m-1)$. Thus,

$$\begin{aligned}&(\alpha_1, \ldots, \alpha_m) <_m (\beta_1, \ldots, \beta_m)\\ &\quad\longleftrightarrow (\alpha_m, \alpha_1, \ldots, \alpha_{m-1}) <_{\text{lex}} (\beta_m, \beta_1, \ldots, \beta_{m-1}).\end{aligned}$$

Recall that a function f from the domain of a wellordering $\prec$ to the ordinals is of the correct type if it order-preserving with respect to $\prec$, of uniform cofinality ω, and everywhere discontinuous.

5.11 Definition. S_1^m is the measure on ω_{m+1} induced by the strong partition relation on ω_1 and functions $h : \mathrm{dom}(<_m) \to \omega_1$ of the correct type. That is, A has measure one if there is a closed unbounded $C \subseteq \omega_1$ such that $[f]_{W_1^m} \in A$ for all $f : \mathrm{dom}(<_m) \to C$ of the correct type.

Thus, S_1^1 is the ω cofinal normal measure on ω_2. We let W_1 denote the collection of measures W_1^m, and S_1 the collection S_1^m.

According to the next theorem, we need only consider ultrapowers by the measures S_1^m in Theorem 5.6.

5.12 Theorem. *There is a closed unbounded $C \subseteq \boldsymbol{\delta}_3^1$ such that for all $\theta \in C$ of cofinality ω_2, $\sup_\nu j_\nu(\theta) = \sup_m j_{S_1^m}(\theta)$, the first supremum ranging over measures ν of the form $M^{\mathcal{R}}$ for some type-1 tree of uniform cofinalities $\mathcal{R}$.*

We let C be the set of θ closed under the embeddings j_ν, for $\nu = M^{\mathcal{R}}$ (recall Theorem 4.35). The theorem follows easily from the following lemma:

5.13 Lemma. *Let $\nu = M^{\mathcal{R}}$. There is an $m \in \omega$, a measure μ on ω_ω, and a function $h : \omega_{m+1} \to (\omega_\omega)^{<\omega}$ satisfying the following:*

(1) $\forall^*_{S_1^m}\alpha\ \exists\vec{\gamma} \in \mathrm{dom}(\nu)\ \forall^*_\mu\beta\ h(\alpha)(\beta) < \vec{\gamma}$. By $h(\alpha)(\beta) < \vec{\gamma}$ we mean that if $\vec{\gamma}$ is represented by $f : \mathrm{dom}(<^{\mathcal{R}}) \to \omega_1$ of type $\mathcal{R}$, and $h(\alpha)(\beta)$ by $g : \mathrm{dom}(<^{\mathcal{R}}) \to \omega_1$ of type $\mathcal{R}$, then $[g^{\langle p_1,i_1\rangle}]_{W_1^1} < [f^{\langle p_1,i_1\rangle}]_{W_1^1}$ for all $\langle p_1, i_1\rangle \in \mathrm{dom}\,\mathcal{R}$.

(2) If $A \subseteq \mathrm{dom}(\nu)$ has ν measure one, then $\forall^*_{S_1^m}\alpha\ \forall^*_\mu\beta\ h(\alpha)(\beta) \in A$.

To see this proves the theorem, fix $\delta = [F]_\nu < j_\nu(\theta)$, where $\theta \in C$. Define ϵ by: $\forall^*_{S_1^m}\alpha\ \forall^*_\mu\beta\ \epsilon(\alpha)(\beta) = F(h(\alpha)(\beta))$. From (5.13) this depends only on $[F]_\nu$, and from (5.13) it follows easily that $\epsilon < j_{S_1^m}(\theta)$. [We use here the fact that if $F : \mathrm{dom}(\nu) \to \mathrm{On}$, then there is a ν measure one set A such that if $f, g : \mathrm{dom}(<^{\mathcal{R}}) \to \omega_1$ of type $\mathcal{R}$ represent $[f], [g] \in A$ and $[g^{\langle p_1,i_1\rangle}] < [f^{\langle p_1,i_1\rangle}]$ for all $\langle p_1, i_1\rangle \in \mathrm{dom}(\mathcal{R})$, then $F([g]) \le F([f])$. This follows by an easy partition argument.] From (5.13), the map $\pi(\delta) = \epsilon$ is an embedding of $j_\nu(\theta)$ into $j_{S_1^m}(\theta)$.

The lemma is proved by a direct construction of the measure μ. We illustrate with a case. Suppose that $<^{\mathcal{R}}$ is the lexicographic ordering on tuples $\langle \gamma_1, i_1, \gamma_2, \gamma_3\rangle$ where $\gamma_3 < \gamma_2 < \gamma_1 < \omega_1$, and $i_1 \in \{0, 1\}$ (we have removed irrelevant indices from our notation now). Also, ν is induced by functions $f : \mathrm{dom}(<^{\mathcal{R}}) \to \omega_1$ of the correct type (ν is actually the two-fold product of the measure on ω_4 corresponding to the permutation $(3, 2, 1)$). In this case, take $m = 4$ and $\mu = W_1^2 \times S_1^2$. We define the function h as required. Let $\alpha < \omega_5$ be represented by $f_\alpha : \mathrm{dom}(<_4) \to \omega_1$ of the correct type. Define $h(\alpha)$ so that for almost all $\vec{\beta} = (\beta_1, \beta_2, \beta_3) \in \mathrm{dom}\,\mu$, so $\beta_1 < \beta_2 < \omega_1$ and $\beta_3 < \omega_3$ is represented by $f_{\beta_3} : \mathrm{dom}(<_2) \to \omega_1$ of the correct type, $h(\alpha)(\vec{\beta}) \in \mathrm{dom}(\nu)$ is represented by $h(\alpha)(\vec{\beta})(\langle \gamma_1, i_1, \gamma_2, \gamma_3\rangle) = f_\alpha(\beta_{i_1}, \gamma_2, f_{\beta_3}(\gamma_3, \gamma_2), \gamma_1)$. It is easy to check that this is well-defined and satisfies (1) and (2). $\dashv$

We state one more embedding theorem which helps to simplify the analysis. By Theorem 2.18, $\boldsymbol{\delta}^1_5 = \lambda_5^+$, where λ_5 is least such that every $\boldsymbol{\Pi}^1_4$ set is λ_5-Suslin. The weak partition relation on $\boldsymbol{\delta}^1_3$ and the homogeneous tree construction shows every $\boldsymbol{\Pi}^1_3$ set admits a homogeneous tree with measures ν_s on $\boldsymbol{\delta}^1_3$. Thus, every $\boldsymbol{\Sigma}^1_4$ set is weakly homogeneous with the same family of measures. The homogeneous tree construction again shows every $\boldsymbol{\Pi}^1_4$ set is λ-Suslin, where $\lambda = \sup_\nu j_\nu(\boldsymbol{\delta}^1_3)$, ν ranging over the measures in a homogeneous tree on a $\boldsymbol{\Pi}^1_3$-complete set (granting the strong partition relation on $\boldsymbol{\delta}^1_3$, the resulting tree on $\omega \times \lambda$ is also homogeneous). Thus, $\lambda_5 \leq \lambda$. Computing the upper bound for $\boldsymbol{\delta}^1_5$ is thus reduced to bounding the ultrapowers $j_\nu(\boldsymbol{\delta}^1_3)$.

Again, one suspects that a simpler family of measures will suffice here.

5.14 Definition. W^m_3 is the measure on $\boldsymbol{\delta}^1_3$ induced by the weak partition relation on $\boldsymbol{\delta}^1_3$, functions $f : \omega_{m+1} \to \boldsymbol{\delta}^1_3$ of the correct type, and the measure S^m_1 on ω_{m+1}. That is, $W^m_3(A) = 1$ iff there is a closed unbounded $C \subseteq \boldsymbol{\delta}^1_3$ such that for all $f : \omega_{m+1} \to C$ of the correct type, $[f]_{S^m_1} \in A$.

5.15 Theorem. *Let ν be a measure on $\boldsymbol{\delta}^1_3$ occurring in the homogeneous tree on a $\boldsymbol{\Pi}^1_3$-complete set. Then for some $m \in \omega$, $j_\nu(\boldsymbol{\delta}^1_3) \leq j_{W^m_3}(\boldsymbol{\delta}^1_3)$.*

5.16 Remark. The theorem actually holds for any measure ν on $\boldsymbol{\delta}^1_3$, although this requires the analysis of measures on $\boldsymbol{\delta}^1_3$ to show. The proof of Theorem 5.15 is similar to that of Theorem 5.12. The reader can find the details in [11].

5.3. The Higher Descriptions

In view of Theorem 5.15, the basic problem in computing the upper bound for $\boldsymbol{\delta}^1_5$ is to analyze equivalence classes of functions $F : \boldsymbol{\delta}^1_3 \to \boldsymbol{\delta}^1_3$ with respect to the measures W^m_3. This leads us to the notion of a level 1 description. It is helpful to consider some examples first.

Let us construct first an equivalence class of a function $F : \boldsymbol{\delta}^1_3 \to \boldsymbol{\delta}^1_3$ with respect to W^1_3. We must define $F([f]_{S^1_1})$ for $f : \omega_2 \to \boldsymbol{\delta}^1_3$ of the correct type. We will define $F(f)$ for any such f, and note that our definition only depends on $[f]_{S^1_1}$. $F(f)$ is defined to be the ordinal represented with respect to $K_1 = S^1_1$ by the function which assigns to $[h_1]_{W^1_1}$ (here $h_1 : \omega_1 \to \omega_1$ is of the correct type) the value $F(f, [h_1])$. We will define $F(f, h_1)$ for any such h_1, and note that this depends only on $[h_1]_{W^1_1}$, so we set $F(f, [h_1]) = F(f, h_1)$. Finally, $F(f, h_1)$ is the ordinal represented with respect to $K_2 = S^1_1$ by the function which assigns to $[h_2]_{W^1_1}$ the value $F(f, h_1, h_2) \doteq f([h_1 \circ h_2]_{W^1_1})$. Extending our earlier notational convention, we abbreviate this definition by saying $\forall^* f\ \forall^* h_1\ \forall^* h_2\ F(f, h_1, h_2) = f([h_1 \circ h_2])$. We could also write $\forall^* f\ \forall^* h_1\ \forall^* h_2\ F(f, h_1, h_2) = f([h])$, where $\forall^*_{W^1_1} \alpha\ h(\alpha) = h_1(h_2(\alpha))$.

It is easy to see that this definition is well-defined. Note, however, the map $(h_1, h_2) \to f([h_1 \circ h_2]_{W^1_1})$ is not well-defined with respect to $S^1_1 \times S^1_1$, that is, it does not just depend on $[h_1]_{W^1_1}, [h_2]_{W^1_1}$. Note also that it is important that we compose the functions h_1, h_2 in the order shown; the other way does not lead to a well-defined definition.

This simple example shows that the basic operation of composition leads to well-defined definitions of equivalence classes of functions $F : \boldsymbol{\delta}^1_3 \to \boldsymbol{\delta}^1_3$. In the general definition of a level 1 description, we generalize by allowing finitely many functions $h_1, \dots, h_t$, where each h_i is either a function $h_i : \mathrm{dom}\,(<_m) \to \omega_1$ of the correct type, or a finite tuple of ordinals $\beta_1 < \cdots < \beta_m < \omega_1$. That is, instead of S^1_1 in the example above, we allow measures S^m_1, W^m_1.

We first consider one more example. We now define the equivalence class of three functions F_1, F_2, F_3 with respect to the measure W^2_3. Thus, we must define $F_i([f]_{S^2_1}) = F_i(f)$ where $f : \omega_3 \to \boldsymbol{\delta}^1_3$ is of the correct type. In all three case we will use the sequence of measures $K_1 = K_2 = S^2_1$, $K_3 = W^2_1$. We define F_1 by:

$$\forall^* f\ \forall^* h_1\ \forall^* h_2 \forall^* h_3 = (\beta_1, \beta_2)\ F_1(f, h_1, h_2, h_3) = \sup\{f(\delta) : \delta < [h]_{W^2_1}\},$$

where $\forall^*_{W^2_1} \alpha_1, \alpha_2\ h(\alpha_1, \alpha_2) = h_1(1)(\alpha_2)$ (recall that $h_1(1)(\alpha_2) = \sup\{h_1(\gamma, \alpha_2) : \gamma < \alpha_2\}$). We define $F_2(f, h_1, h_2, h_3) = f([h])$, where

$$h(\alpha_1, \alpha_2) = h_1(h_2(1)(\alpha_1), \alpha_2).$$

We define $F_3(f, h_1, h_2, h_3) = f([h])$, where

$$h(\alpha_1, \alpha_2) = h_1(h_2(\beta_2, \alpha_1), \alpha_2).$$

It is easy to check that all three functions are well-defined, and that $\forall^*_{W^2_3}[f]$ $F_3(f) < F_2(f) < F_1(f)$. We will return to this example in a moment.

In general, a description d will be a finitary object defined relative to a sequence $K_1, \dots, K_t$ of measures, each of the form W^r_1 or S^r_1. It will describe how, given the functions $h_1, \dots, h_t$, to generate the function h as in the above examples. In the first example, $h : \omega_1 \to \omega_1$, and in the second example, we had $h : (\omega_1)^2 \to \omega_1$ in all three cases. In general we will have $h : (\omega_1)^m \to \omega_1$ for some $m \in \omega$. The set $\mathcal{D}$ of descriptions will be partitioned accordingly as $\mathcal{D} = \bigcup_m \mathcal{D}_m$. The $d \in \mathcal{D}_m$, which we call the m-descriptions, will thus generate $h : (\omega_1)^m \to \omega_1$ given the functions $h_1, \dots, h_t$. We write also $\mathcal{D}_m(K_1, \dots, K_t)$ to denote those m-descriptions defined relative to $K_1, \dots, K_t$.

Thus, in the first example the underlying description (which we haven't defined yet) lies in $\mathcal{D}_1(S^1_1, S^1_1)$, and in the second, the descriptions lie in $\mathcal{D}_2(S^2_1, S^2_1, W^2_1)$.

Given a description $d \in \mathcal{D}_m(K_1, \dots, K_t)$, we will write $h(d; h_1, \dots, h_t)$ to denote the function $h : (\omega_1)^m \to \omega_1$ generated according to d from the $\vec{h}$.

Fix now $m \in \omega$ and the sequence $K_1, \dots, K_t$. The primitive descriptions in $\mathcal{D}_m(K_1, \dots, K_t)$ are those which do not involve composing functions. We refer to these as the *basic* descriptions, and the others as non-basic. As we define the descriptions, we simultaneously define $k(d) \in \{1, \dots, t\} \cup \{\infty\}$ for each description which gives the least k so that the function h_k is involved in the definition of $h(d;\vec{h})$. As we define the descriptions, we also define how to interpret them, i.e. we define $h(d;\vec{h})(\alpha_1,\dots,\alpha_m)$. For $h_k : \mathrm{dom}(<_r) \to \omega_1$ order-preserving, and $l \le r$, recall the definition of $h_k(l) : (\omega_1)^l \to \omega_1$ from Definition 4.22. In this case it reduces to (for $l = r$, $h_k(l) = h_k$):

$$\begin{aligned} &h_k(l)(\alpha_1,\dots,\alpha_l)\\ &\quad = \sup\{h_k(\alpha_1,\dots,\alpha_{l-1},\beta_1,\dots,\beta_{r-l},\alpha_l) : \alpha_{l-1} < \beta_1 < \cdots < \beta_{r-l} < \alpha_l\}. \end{aligned}$$

5.17 Definition (Descriptions).

(1) (Basic) We allow:

(a) $d = (p)$ where p is an integer $1 \le p \le m$ (which we put in parentheses to distinguish from a level-1 description). We define $h(d;\vec{h})(\alpha_1,\dots,\alpha_m) = \alpha_p$. We set $k(d) = \infty$.

(b) $d = (k;p)$ where $1 \le k \le t$, K_k is of the form $K_k = W_1^r$, and $1 \le p \le r$. In this case, we define $h(d;\vec{h})(\alpha_1,\dots,\alpha_m) = \beta_p$, where $h_k = (\beta_1,\dots,\beta_r)$. We set $k(d) = k$.

(2) (Non-Basic) Suppose $1 \le k \le t$ and $K_k = S_1^r$. We allow:

(a) $d = (k; d_r, d_1,\dots,d_l)$, where $d_1,\dots,d_l,d_r \in \mathcal{D}_m(K_1,\dots,K_t)$, $l < r$, and $k(d_1),\dots,k(d_l),k(d_r) > k$. We set $k(d) = k$ and define:

$$h(d;\vec{h})(\vec{\alpha}) = h_k(l+1)(h(d_1;\vec{h})(\vec{\alpha}),\dots,h(d_l;\vec{h})(\vec{\alpha}),h(d_r;\vec{h})(\vec{\alpha}))$$

(b) $d = (k; d_r, d_1,\dots,d_l)^s$, where $d_1,\dots,d_l,d_r \in \mathcal{D}_m(K_1,\dots,K_t)$, $l < r$, $k(d_1),\dots,k(d_l),k(d_r) > k$, and s is a formal symbol (which stands for "sup"). We require in this case that $r \ge 2$, $l \ge 1$. We set $k(d) = k$ and define:

$$\begin{aligned} h(d;\vec{h})(\vec{\alpha}) = &\sup\bigl\{h_k(l+1)(h(d_1;\vec{h})(\vec{\alpha}),\dots,h(d_{l-1};\vec{h}),\beta,\\ &h(d_r;\vec{h})(\vec{\alpha})) : \beta < h(d_l;\vec{h})\bigr\}. \end{aligned}$$

We write $(k; d_r, d_1,\dots,d_l)^{(s)}$ to indicate the symbol s may or may not appear.

This completes the definition of $\mathcal{D}$ and the "interpretation function" h. We will write d^m when we wish to emphasize $d \in \mathcal{D}_m$. In the first example above, the description is given by $d^1 = (1;(2;(1)))$. In the second example, the three descriptions are given by $d_a^2 = (1;(2))$, $d_b^2 = (1;(2);(2;(1)))$, and $d_c^2 = (1;(2);(2;(1),(3;2)))$.

If $d_1, d_2 \in \mathcal{D}_m(K_1, \ldots, K_t)$, define $d_1 < d_2$ iff $\forall^* h_1 \cdots \forall^* h_t\ h(d_1; \vec{h}) < h(d_2; \vec{h})$ almost everywhere. Here $\forall^*$ refers to the measure on functions of the correct type induced by the strong partition relation. Note that in a non-basic description $d = (k; d_r, d_1, \ldots, d_l)$ the component descriptions are listed in their order of significance in determining $h(d; \vec{h})$. It is not difficult to reformulate the $<$ relation on $\mathcal{D}_m(K_1, \ldots, K_t)$ in a purely "syntactical" manner, we leave this to the reader.

The requirement that $k(d_r), k(d_1), \ldots, k(d_l) > k = k(d)$ for non-basic descriptions d is one of two necessary to ensure the equivalence class of $h(d; \vec{h})$ is well-defined with respect to the measures $K_1, \ldots, K_t$. This guarantees that for almost all $h_{k+1}, \ldots, h_t$, the values $h(d_r; \vec{h})(\vec{\alpha})$, etc. that we are putting into h_k will lie in a closed unbounded set on which two functions h_k, h'_k (with $[h_k] = [h'_k]$) agree. The other requirement is that these values be in the correct order. We can now state this requirement, which is referred to as "condition C".

5.18 Definition (Definition of C). We say $d \in \mathcal{D}$ *satisfies condition* C if either d is basic or else d is non-basic, say of the form $d = (k; d_r, d_1, \ldots, d_l)^{(s)}$, all $d_r, d_1, \ldots, d_l$ satisfy C, and $d_1 < d_2 < \cdots < d_l < d_r$.

It is now easy to check that if d satisfies this condition, then the equivalence class of $h(d; \vec{h})$ is well-defined in the following precise sense:

5.19 Lemma. *Suppose $d \in \mathcal{D}_m(K_1, \ldots, K_t)$ satisfies condition* C. *Then for almost all h_1, if $[h'_1] = [h_1]$, then for almost all h_2, if $[h'_2] = [h_2], \ldots$ for almost all h_t if $[h'_t] = [h_t]$, then $[h(d; h_1, \ldots, h_t)]_{W_1^m} = [h(d; h'_1, \ldots, h'_t)]_{W_1^m}$.*

All of the descriptions in the examples above satisfy C.

From now on, we officially let $h(d; \vec{h})$ be the ordinal $< \omega_{m+1}$ (where $d \in \mathcal{D}_m$) represented by the function h.

We expand a little our notational convention mentioned at the end of the introduction. Suppose that $K_1, \ldots, K_t$ is a sequence of measures, $d \in \mathcal{D}(K_1, \ldots, K_t)$ satisfies C, and $P \subseteq \mathrm{On}$. When we write

$$\forall^* h_1, \ldots, h_t\ P(h(d; h_1, \ldots, h_t)),$$

we mean: $\forall^*_{K_1} \eta_1$ if $[h_1] = \eta_1$, then $\forall^*_{K_2} \eta_2$ if $[h_2] = \eta_2, \ldots, \forall^*_{K_t} \eta_t$ if $[h_t] = \eta_t$, then $P(h(d; h_1, \ldots, h_t))$. If $\theta \in \mathrm{On}$, we write

$$\forall^* h_1, \ldots, h_t\ P(\theta(h_1, \ldots, h_t))$$

to mean: if we fix a representing function $\eta_1 \to \theta(\eta_1)$ for θ with respect to K_1 then $\forall^*_{K_1} \eta_1$ if $[h_1] = \eta_1$, then if we fix a representing function $\eta_2 \to \theta([h_1], \eta_2)$ for $\theta([h_1])$ with respect to K_2, then $\forall^*_{K_2} \eta_2$ if $[h_2] = \eta_2$, $\ldots$, if we fix a representing function $\eta_t \to \theta([h_1], \ldots, [h_{t-1}], \eta_t)$ for $\theta([h_1], \ldots, [h_{t-1}])$ with respect to K_t, then $\forall^*_{K_t} \eta_t$ if $[h_t] = \eta_t$, then $P(\theta([h_1], \ldots, [h_t]))$.

We can use these conventions simultaneously. For example, for d satisfying C we may write

$$\forall^* h_1, \dots, h_t \;\; \mathrm{cf}(h(d; h_1, \dots, h_t)) < \theta(h_1, \dots, h_t).$$

This abbreviates: $\forall^*_{K_1} \eta_1$ if $[h_1] = \eta_1$, then $\forall^*_{K_2} \eta_2$ if $[h_2] = \eta_2, \dots, \forall^*_{K_t} \eta_t$ if $[h_t] = \eta_t$, then $\mathrm{cf}(h(d; h_1, \dots, h_t)) < \theta([h_1], \dots, [h_t])$. Written out in full, this becomes: if $\eta_1 \to \theta(\eta_1)$ represents θ with respect to K_1, then $\forall^*_{K_1} \eta_1$, if $[h_1] = \eta_1$ and $\eta_2 \to \theta([h_1], \eta_2)$ represents $\theta([h_1])$ with respect to K_2, then $\forall^*_{K_2} \eta_2$, if $[h_2] = \eta_2$ and $\eta_3 \to \theta([h_1], [h_2], \eta_3)$ represents $\theta([h_1], [h_2])$ with respect to $K_3, \dots, \forall^*_{K_t} \eta_t$, if $[h_t] = \eta_t$, then $\mathrm{cf}(h(d; h_1, \dots, h_t)) < \theta([h_1], \dots, [h_t])$. Such a statement is well-defined by Lemma 5.19.

Recall the purpose of a description $d \in \mathcal{D}_m$ is to generate an ordinal $\alpha < \omega_{m+1}$ which we can plug into a function $f : \omega_{m+1} \to \boldsymbol{\delta}^1_3$ in our attempt to generate an equivalence class $[F]_{W^m_3}$. By "plug in" we mean either take $f(\alpha)$ or $\sup\{f(\alpha') : \alpha' < \alpha\}$. Condition C guarantees the ordinal α is well-defined in an appropriate sense. However, it does not guarantee α will be representable by a function $h : \mathrm{dom}(<_m) \to \omega_1$ of the correct type, or that it is a limit of such ordinals. Thus we introduce another condition, condition D, below.

First we extend slightly the notion of a description. Let $\bar{\mathcal{D}}_m$ be the set of objects ("extended descriptions") of the form (d) or $(d)^s$ where $d \in \mathcal{D}_m$ satisfies C, together with one new object $()^s$. We write $(d)^{(s)}$ to denote either (d) or $(d)^s$.

5.20 Definition (Definition of D). Suppose $d \in \bar{\mathcal{D}}_m(K_1, \dots, K_t)$. Then:

1. (d) *satisfies condition* D if $\forall^* h_1, \dots, h_t \; h(d; \vec{h}) : (\omega_1)^m \to \omega_1$ is of the correct type almost everywhere (i.e. restricted to a measure one set with respect to W^m_1).

2. $(d)^s$ *satisfies condition* D if $\forall h_1, \dots, h_t \; h(d; \vec{h})$ is the supremum of ordinals representable by functions $h : (\omega_1)^m \to \omega_1$ of the correct type almost everywhere. We also define $()^s$ to satisfy D.

We can now describe our generation of equivalence classes.

5.21 Definition. Let $m \in \omega$, $K_1, \dots, K_t \in W_1 \cup S_1$, let $(d)^{(s)} \in \bar{\mathcal{D}}_m(K_1, \dots, K_t)$ satisfy condition D, and let $g : \boldsymbol{\delta}^1_3 \to \boldsymbol{\delta}^1_3$. We define an ordinal which we denote by $(g; (d)^{(s)}; K_1, \dots, K_t)$. We represent this ordinal with respect to W^m_3 by the function which assigns to $[f]_{S^m_1}$ the ordinal $(g; f; (d)^{(s)}; K_1, \dots, K_t)$, for $f : \omega_{m+1} \to \boldsymbol{\delta}^1_3$ of the correct type. We represent $(g; f; (d)^{(s)}; K_1, \dots, K_t)$ with respect to K_1 by the function which assigns to $[h_1]$ the ordinal $(g; f; (d)^{(s)}; h_1, K_2, \dots, K_t)$, and in general, represent $(g; f; (d)^{(s)}; h_1, \dots, h_{i-1}\ K_i, \dots, K_t)$ with respect to K_i by the function which assigns to $[h_i]$ the ordinal $(g; f; (d)^{(s)}; h_1, \dots,\ h_i,\ K_{i+1}, \dots, K_t)$. Finally, we define $(g; f; (d)^{(s)}, h_1, \dots, h_t)$ by cases as follows:

(1) If s does not appear, then $(g; f; (d); h_1, \dots, h_t) = g(f(h(d; \bar{h})))$.

(2) If s appears, then $(g; f; (d)^s; h_1, \dots, h_t) = g(\sup\{f(\beta) : \beta < h(d; \vec{h})\})$.

(3) For the object $()^s$, $(g; f; ()^s; h_1, \dots, h_t) = g(\sup\{f(\beta) : \beta < \omega_{m+1}\})$.

Of particular importance is the case $g = \mathrm{id}$, the identity function. In the first example considered previously, the equivalence class $[F]_{W_3^1}$ constructed was $(\mathrm{id}; (d); K_1, K_2)$, where $d = (1; (2; (1)))$, and $K_1 = K_2 = S_1^1$. The three functions of the second example represent the ordinals $(\mathrm{id}; (d_a)^s; K_1, K_2, K_3)$, $(\mathrm{id}; (d_b); K_1, K_2, K_3)$, and $(\mathrm{id}; (d_c); K_1, K_2, K_3)$ respectively.

It turns out, though we will not prove this fully here, that the cardinals $\boldsymbol{\delta}_3^1 < \kappa < (\boldsymbol{\delta}_5^1)^-$ are precisely the ordinals of the form $(\mathrm{id}; (d)^{(s)}; K_1, \dots, K_t)$.

We have thus seen how descriptions generate equivalence classes of functions $F : \boldsymbol{\delta}_3^1 \to \boldsymbol{\delta}_3^1$ with respect to the measures W_3^m, just as the trivial descriptions did for functions $F : \omega_1 \to \omega_1$ with respect to the measures W_1^m, Definition 4.3. The main task remaining is to formulate and prove a result analogous to Lemma 4.5, the "main lemma" in the theory of trivial descriptions. To do that we need the correct analog of the lowering operator $\mathcal{L}$ (which we will still call $\mathcal{L}$).

If we fix $m \in \omega$ and measures $K_1, \dots, K_t \in W_1 \cup S_1$, then the relation $<$ on $\mathcal{D}_m(K_1, \dots, K_t)$ is a linear ordering. For $d \in \mathcal{D}_m(K_1, \dots, K_t)$, $\mathcal{L}(d)$ will again give the description preceding d in this ordering, except for a unique minimal description. For the sake of completeness we will give the complete definition of $\mathcal{L}$, though will be content to illustrate the proof of the main lemma through one of our examples. The $\mathcal{L}$ operation is defined by defining a series of approximations $\mathcal{L}^k$ to it. $\mathcal{L}^k(d)$ will only be defined for d with $k(d) \geq k$. Roughly speaking, $\mathcal{L}^k$ is the result of holding $h_1, \dots, h_{k-1}$ constant and lowering with respect to $h_k, \dots, h_t$ only. We will thus take $\mathcal{L}(d) = \mathcal{L}^1(d)$. Following [11], we define $\mathcal{L}^k$ as follows.

5.22 Definition (Definition of $\mathcal{L}^k$). Let $m \in \omega$ and $K_1, \dots, K_t \in W_1 \cup S_1$. Let $k \in \{1, \dots, t\} \cup \{\infty\}$, and assume $d \in \mathcal{D}_m(K_1, \dots, K_t)$ with $k(d) \geq k$. Then $\mathcal{L}^k(d)$ is defined by reverse induction on k through the following cases:

I $k = \infty$. So, $d = (i)$ where $1 \leq i \leq m$. If $i > 1$, then $\mathcal{L}^\infty(d) = (i-1)$. For $i = 1$, d is minimal with respect to $\mathcal{L}^\infty$.

II $1 \leq k \leq t$.

(1) $k = k(d)$.

(a) $d = (k; p)$ is basic. For $p > 1$, we set $\mathcal{L}^k(d) = (k; p-1)$, and for $p = 1$ we define d to be minimal.

(b) $d = (k; d_r, d_1, \dots, d_l)$, where $K_k = S_1^r$ and $l = r - 1$. We set $\mathcal{L}^k(d) = (k; d_r, d_1, \dots, d_l)^s$ if $l \geq 1$, and if $r = 1$ and $d = (k; d_r)$, we set $\mathcal{L}^k(d) = d_r$.

(c) $d = (k; d_r, d_1, \ldots, d_l)$, where $K_k = S_1^r$ and $l < r - 1$. First assume $l \geq 1$. If $\mathcal{L}^{k+1}(d_r)$ is defined and $> d_l$, we set $\mathcal{L}^k(d) = (k; d_r, d_1, \ldots, d_l, \mathcal{L}^{k+1}(d_r))$. If $\mathcal{L}^{k+1}(d_r)$ is not defined or is $\leq d_l$, we set $\mathcal{L}^k(d) = (k; d_r, d_1, \ldots, d_l)^s$. If $l = 0$ (so $d = (k; d_r)$), we set $\mathcal{L}^k(d) = (d_r; \mathcal{L}^{k+1}(d_r))$ if $\mathcal{L}^{k+1}(d_r)$ is defined, and otherwise $\mathcal{L}^k(d) = d_r$.

(d) $d = (k; d_r, d_1, \ldots, d_l)^s$, where $K_k = S_1^r$ (so $l \geq 1$). We set $\mathcal{L}^k(d) = (k; d_r, d_1, \ldots, d_{l-1}, \mathcal{L}^{k+1}(d_l))$ if $\mathcal{L}^{k+1}(d_l)$ is defined and if $l \geq 2$ also satisfies $\mathcal{L}^{k+1}(d_l) > d_{l-1}$. Otherwise, we set $\mathcal{L}^k(d) = (k; d_r, d_1, \ldots, d_{l-1})^s$ if $l \geq 2$ and for $l = 1$, $\mathcal{L}^k(d) = d_r$.

(2) $k < k(d)$, $K_k = W_1^r$.

(a) d not minimal with respect to $\mathcal{L}^{k+1}$. We then set $\mathcal{L}^k(d) = \mathcal{L}^{k+1}(d)$.

(b) d is minimal with respect to $\mathcal{L}^{k+1}(d)$. We then set $\mathcal{L}^k(d) = (k; r)$.

(3) $k < k(d)$, $K_k = S_1^r$.

(a) d not minimal with respect to $\mathcal{L}^{k+1}$. We then set $\mathcal{L}^k(d) = (k; \mathcal{L}^{k+1}(d))$.

(b) d minimal with respect to $\mathcal{L}^{k+1}$. Then d is minimal with respect to $\mathcal{L}^k$.

Recall our previous example where $m = 2$, $K_1 = K_2 = S_1^2$, $K_3 = W_1^2$, and we had the three descriptions $d_a = (1; (2))$, $d_b = (1; (2); (2; (1)))$, and $d_c = (1; (2); (2; (1), (3; 2)))$. The reader can check now that $\mathcal{L}(d_a) = d_b$, $\mathcal{L}(d_b) = (1; (2); (2; (1)))^s$, and $\mathcal{L}((1; (2); (2; (1)))^s) = d_c$.

We also extend the $\mathcal{L}$ operation to $\bar{\mathcal{D}}_m(K_1, \ldots, K_t)$ as follows. We set $\mathcal{L}((d)) = ((d)^s)$, and $\mathcal{L}((d)^s) = (\mathcal{L}^{(p)}(d))$, where $\mathcal{L}^{(p)}(d)$ denotes the pth iterate of $\mathcal{L}$, and p is least so that $\mathcal{L}^{(p)}(d)$ satisfies condition D. If such a p does not exist, we say $(d)^s$ is minimal with respect to $\mathcal{L}$. Finally, for the distinguished object $()^s$, we define $\mathcal{L}(()^s) = (\tilde{d})^{(s)}$, where $\tilde{d}$ is the maximal description in $\mathcal{D}_m(K_1, \ldots, K_t)$ such that $(\tilde{d})$ or $(\tilde{d})^s$ satisfies D (in the first case, s does not appear, and in the second it does). If there are no descriptions satisfying D, then $()^s$ is declared minimal.

To illustrate, let $m = 2$, and consider the sequence of measures K_1, K_2, K_3 where $K_1 = K_2 = S_1^2$, and $K_3 = W_1^2$. Applying the $\mathcal{L}$ operation repeatedly to $()^s \in \bar{\mathcal{D}}_2(K_1, K_2, K_3)$ results in a sequence whose first few terms are: $(d_0)^s$, (d_1), $(d_1)^s$, (d_2), $(d_2)^s$, (d_3), $(d_3)^s$, $(d_4)^s$, (d_5), $(d_5)^s$, (d_6), $(d_6)^s$, (d_7), $(d_7)^s$,

(d_8), $(d_8)^s$, (d_9), where:

$$\begin{aligned}
d_0 &= (1;(2;(2))) \\
d_1 &= (1;(2;(2));(2;(2);(1))) \\
d_2 &= (1;(2;(2));(2;(2);(1)))^s \\
d_3 &= (1;(2;(2));(2;(2);(1))^s) \\
d_4 &= (1;(2;(2));(2;(2);(1))^s)^s \\
d_5 &= (1;(2;(2));(2;(2);(3;2))) \\
d_6 &= (1;(2;(2));(2;(2);(3;2)))^s \\
d_7 &= (1;(2;(2));(2;(2);(3;2))^s) \\
d_8 &= (1;(2;(2));(2;(2);(3;2))^s)^s \\
d_9 &= (1;(2;(2));(2;(2);(3;1)))
\end{aligned}$$

Note that (d_0), and (d_4) do not satisfy Condition D.

We now state our "main lemma", the analog of Lemma 4.5.

5.23 Theorem (Main Lemma). *Let $(d)^{(s)} \in \bar{\mathcal{D}}(K_1,\dots,K_t)$ satisfy Condition* D. *Suppose $\theta < (\mathrm{id};(d)^{(s)};K_1,\dots,K_t)$. Then:*

(1) If $(d)^{(s)}$ is not minimal with respect to $\bar{\mathcal{L}}$, then there is a $g : \boldsymbol{\delta}^1_3 \to \boldsymbol{\delta}^1_3$ such that $\theta < (g;\mathcal{L}((d)^{(s)});\ K_1,\dots,K_t)$.

(2) If $(d)^{(s)}$ is minimal with respect to $\mathcal{L}$, then $\theta < \boldsymbol{\delta}^1_3$.

We will illustrate the proof of the main lemma by considering the example $(d_a)^s$ above, where $d_a = (1;(2))$. So, fix $\theta < (\mathrm{id};(d_a)^s;K_1,K_2,K_3)$. Thus,

$$\forall^*_{W^2_3} f\ \forall^* h_1,h_2,h_3\ [\theta(f,\vec{h}) < (\mathrm{id};f;(d_a)^s;\vec{h}) = \sup\{f(\gamma) : \gamma < h(d_a;\vec{h})\}].$$

Hence,

$$\forall^* f\ \exists\delta\ \forall^* h_1,h_2,h_3\ [\delta(\vec{h}) < h(d_a;\vec{h}) \wedge \theta(f,\vec{h}) < f(\delta(\vec{h}))].$$

Suppose now $\delta \in \mathrm{On}$ is such that $\forall^* h_1,h_2,h_3\ \delta(\vec{h}) < h(d_a;\vec{h})$. In other words,

$$\forall^* h_1,h_2,h_3\ \forall^*_{W^2_1} \alpha_1,\alpha_2\ \delta(\vec{h})(\alpha_1,\alpha_2) < h(d_a;\vec{h})(\alpha_1,\alpha_2).$$

Recall that $h(d_a;\vec{h})(\alpha_1,\alpha_2) = h_1(1)(\alpha_2) = \sup\{h_1(\eta,\alpha_2) : \eta < \alpha_2\}$. Thus,

$$\forall^* h_1,h_2,h_3\ \forall^* \alpha_1,\alpha_2\ \exists\eta < \alpha_2\ [\delta(\vec{h})(\alpha_1,\alpha_2) < h_1(\eta,\alpha_2)].$$

It follows that

$$\forall^* h_1,h_2,h_3\ \exists g : \omega_1 \to \omega_1\ \forall^* \alpha_1,\alpha_2\ [\delta(\vec{h})(\alpha_1,\alpha_2) < h_1(g(\alpha_1),\alpha_2)].$$

In this expression, only the equivalence class of g with respect to W^1_1 matters, and we may assume the g is of the correct type. Using the ω_2-additivity of the measure S^1_1, it follows that

$$\forall^* h_1, h_2\ \exists g : \omega_1 \to \omega_1\ \forall^* h_3\ \forall^* \alpha_1, \alpha_2\ [\delta(\vec{h})(\alpha_1, \alpha_2) < h_1(g(\alpha_1), \alpha_2)].$$

For fixed h_1 of the correct type, and fixed $\delta(h_1) \in \mathrm{On}$ such that

$$\forall^* h_2\ \exists g : \omega_1 \to \omega_1\ \forall^* h_3\ \forall^* \alpha_1, \alpha_2\ [\delta(h_1)(h_2, h_3)(\alpha_1, \alpha_2) < h_1(g(\alpha_1), \alpha_2)],$$

we consider the partition $\mathcal{P}$: we partition $h_2 : \mathrm{dom}(<_2) \to \omega_1$ of the correct type with the extra value $g(\alpha)$ inserted between $h_2(1)(\alpha)$ and $N_{h_2}(h_2(1)(\alpha))$ (with $g(\alpha)$ of uniform cofinality ω) according to whether

$$\forall^* h_3\ \forall^* \alpha_1, \alpha_2\ [\delta(h_1)(h_2, h_3)(\alpha_1, \alpha_2) < \ h_1(g(\alpha_1), \alpha_2)].$$

From Lemma 4.24 (with $m = 2$, $n = 1$, $r = 1$) it follows that a closed unbounded set cannot be homogeneous for the contrary side of the partition. Let C be homogeneous for $\mathcal{P}$, and $g(\alpha) =$ the ωth element of C greater that α. We then have that for any $h_2 : \mathrm{dom}(<_2) \to C'$ of the correct type

$$\forall^* h_3\ \forall^* \alpha_1, \alpha_2\ [\delta(h_1)(h_2, h_3)(\alpha_1, \alpha_2) < h_1(g(h_2(1)(\alpha_1)), \alpha_2)].$$

Since for almost all h_1, $\delta(h_1)$ satisfies the hypothesis of the partition, we have:

$$\begin{aligned}&\forall^* h_1\ \exists g : \omega_1 \to \omega_1\ \forall^* h_2, h_3\ \forall^* \alpha_1, \alpha_2\\ &\quad [\delta(h_1, h_2, h_3)(\alpha_1, \alpha_2) < h_1(g(h_2(1)(\alpha_1)), \alpha_2)].\end{aligned}$$

Fix a representing function $h_1 \to \delta(h_1)$ for δ, and consider the partition $\mathcal{P}$: we partition $h_1 : \mathrm{dom}(<_2) \to \omega_1$ of the correct type with the extra values $g(\gamma_1, \gamma_1)$ (of uniform cofinality ω) inserted between $h_1(\gamma_1, \gamma_2)$ and $N_{h_1}(h_1(\gamma_1, \gamma_2))$ according to whether

$$\begin{aligned}&\forall^* h_2, h_3\ \forall^* \alpha_1, \alpha_2\\ &\quad [\delta(h_1, h_2, h_3)(\alpha_1, \alpha_2) < N_g(h_1(h_2(1)(\alpha_1), \alpha_2)) = g(h_2(1)(\alpha_1), \alpha_2)].\end{aligned}$$

It follows from Lemma 4.24 that we cannot have a closed unbounded set C homogeneous for the contrary side of the partition. For if so, fix a representing function $h_1 \to \delta(h_1)$ for δ, and fix then a $h_1 : \mathrm{dom}(<_2) \to C$ of the correct type such that for some $\bar{g} : \omega_1 \to \omega_1$ of the correct type, which we fix, we have:

$$\forall^* h_2, h_3\ \forall^* \alpha_1, \alpha_2\ [\delta(\vec{h})(\alpha_1, \alpha_2) < h_1(\bar{g}(h_2(1)(\alpha_1)), \alpha_2)].$$

Define $\tilde{g}(\gamma_1, \gamma_2) = h_1(\bar{g}(\gamma_1), \gamma_2)$. Apply then Lemma 4.24 to $f = h_1$ and $\tilde{g}$ (and $r = 2$). This produces h_1', g' which are ordered as in $\mathcal{P}$, have range in C, and for which the property stated in $\mathcal{P}$ holds, a contradiction. If we fix now a closed unbounded C homogeneous for $\mathcal{P}$, and define $g(\alpha)=$ the ωth element of C greater than α, then we have:

$$\forall^* h_1, h_2, h_3\ \forall^* \alpha_1, \alpha_2\ [\delta(\vec{h})(\alpha_1, \alpha_2) < g(h_1(h_2(1)(\alpha_1), \alpha_2))].$$

We now have that for almost all $f : \omega_3 \to \boldsymbol{\delta}^1_3$ of the correct type, there is a $g : \omega_1 \to \omega_1$ such that

$$\forall^* h_1, h_2, h_3\ \theta(f, \vec{h}) < f(\gamma) \tag{21.1}$$

where:

$$\forall^* \alpha_1, \alpha_2\ \gamma(\alpha_1, \alpha_2) = g(h_1(h_2(1)(\alpha_1), \alpha_2)) = g(h(d_b; \vec{h})(\alpha_1, \alpha_2)), \tag{21.2}$$

and $d_b = (1; (2); (2; (1)))$ as before.

Fix a representing function $f \to \theta(f)$ for θ with respect to W^2_3, and consider the partition $\mathcal{P}$: we partition $f : \omega_3 \to \boldsymbol{\delta}^1_3$ of the correct type with the extra values $f_2(\alpha)$ of uniform cofinality ω inserted between $f(\alpha)$ and $f(\alpha+1)$ according to whether $\forall^* h_1, h_2, h_3\ \theta(f)(\vec{h}) < f_2(\gamma)$, where $\gamma = h(d_b; \vec{h})$. There cannot be a closed unbounded $C \subseteq \boldsymbol{\delta}^1_3$ homogeneous for the contrary side, for if so, fix $f : \omega_3 \to C$ of the correct type such that there is a $g : \omega_1 \to \omega_1$ as in (21.1), (21.2), and fix such a g. Define $f_2 : \omega_3 \to C$ by: $f_2(\gamma) = f(\delta)$, where $\forall^* \alpha_1, \alpha_2\ \delta(\alpha_1, \alpha_2) = g(\gamma(\alpha_1, \alpha_2))$. A variation of Lemma 4.24 shows that there are $f', f'_2 : \omega_3 \to C$ of the correct type and ordered as in $\mathcal{P}$ such that $[f']_{S^2_1} = [f]_{S^2_1}$, $[f'_2]_{S^2_1} = [f_2]_{S^2_1}$. This contradicts the homogeneity of C for the contrary side. Let $C \subseteq \boldsymbol{\delta}^1_3$ now be a closed unbounded set homogeneous for $\mathcal{P}$. Define $g : \boldsymbol{\delta}^1_3 \to \boldsymbol{\delta}^1_3$ by $g(\alpha) =$ the ω^{th} element of C greater than α. We then have that $\forall^* f\ \forall^* h_1, h_2, h_3\ \theta(f, \vec{h}) < g(f(\gamma))$, where $\gamma = h(d_b; \vec{h})$. In other words, $\theta < (g; (d_b); K_1, K_2, K_3)$. ⊣

From Lemma 5.23 and Theorem 5.5 our main result analyzing equivalence classes with respect to the measures W^m_3 on $\boldsymbol{\delta}^1_3$ now follows.

5.24 Theorem. *Suppose $(d)^{(s)} \in \bar{\mathcal{D}}_m(K_1, \dots, K_t)$ satisfies Condition* D. *If $(d)^{(s)}$ is not minimal with respect to $\mathcal{L}$ then*

$$(\mathrm{id}; (d)^{(s)}; K_1, \dots, K_t) \le \Big[\sup_{K_{t+1} \in W_1 \cup S_1} (\mathrm{id}; \mathcal{L}((d)^{(s)}); K_1, \dots, K_t, K_{t+1}) \Big]^+.$$

Here $\mathcal{L}((d)^{(s)})$ is computed relative to the sequence $K_1, \dots, K_t$. If $(d)^{(s)}$ is minimal with respect to $\mathcal{L}$, then $(\mathrm{id}; (d)^{(s)}; K_1, \dots, K_t) = \boldsymbol{\delta}^1_3$.

Proof. We consider the first case, and suppose $\theta < (\mathrm{id}; (d)^{(s)}; K_1, \dots, K_t)$. By Lemma 5.23, there is a $g : \boldsymbol{\delta}^1_3 \to \boldsymbol{\delta}^1_3$ such that

$$\theta < (g; \mathcal{L}((d)^{(s)}); K_1, \dots, K_t).$$

Let T be as in Theorem 5.5, and fix a real x and a closed unbounded $C \subseteq \boldsymbol{\delta}^1_3$ such that for all $\alpha \in C$, $g(\alpha) < |T_x \restriction \sup_{K_{t+1}} j_{K_{t+1}}(\alpha)|$, the supremum ranging over measures $K_{t+1} \in W_1 \cup S_1$. For $\alpha < \boldsymbol{\delta}^1_3$, let

$$l(\alpha) = \sup_{K_{t+1}} j_{K_{t+1}}(\alpha) \quad \text{and} \quad l'(\alpha) = |T_x \restriction l(\alpha)|.$$

We define a well-founded relation $\prec$ on $\lambda \doteq (l; \mathcal{L}((d)^{(s)}); K_1, \ldots, K_t)$ by: $\rho_1 \prec \rho_2$ iff

$$\forall^*_{W_3^m} f \ \forall^* h_1, \ldots, h_t \ |T_x \restriction \lambda(f, \vec{h})(\rho_1(f, \vec{h}))| < |T_x \restriction \lambda(f, \vec{h})(\rho_2(f, \vec{h}))|.$$

Easily, $|\prec| \geq (l'; \mathcal{L}((d)^{(s)}); K_1, \ldots, K_t) \geq \theta$. It follows that

$$(\mathrm{id}; (d)^{(s)}; K_1, \ldots, K_t) \leq \Big[\Big(\sup_{K_{t+1}} j_{K_{t+1}}; \mathcal{L}((d)^{(s)}); K_1, \ldots, K_t\Big)\Big]^+.$$

By countable additivity of the measures $W_3^m, K_1, \ldots, K_t$, we have that if $\alpha < (\sup_{K_{t+1}} j_{K_{t+1}};\ \mathcal{L}((d)^{(s)}); K_1, \ldots, K_t)$ then there is a K_{t+1} such that $\alpha < (j_{K_{t+1}};\mathcal{L}((d)^{(s)}); K_1, \ldots, K_t)$. Also, from the definitions of these ordinals it is immediate that

$$(j_{K_{t+1}}; \mathcal{L}((d)^{(s)}); K_1, \ldots, K_t) = (\mathrm{id}; \mathcal{L}((d)^{(s)}); K_1, \ldots, K_t, K_{t+1}).$$

The result now follows. ⊣

To compute the upper bound for $\boldsymbol{\delta}^1_5$, it suffices to compute the rank of the $\mathcal{L}$ operation, in a suitable sense. Namely, fix m and consider the set of all tuples $((d)^{(s)}; K_1, \ldots, K_t)$ where $(d)^{(s)} \in \bar{\mathcal{D}}_m(K_1, \ldots, K_t)$ satisfies Condition D relative to $K_1, \ldots, K_t$. Let $\prec_m$ be the transitive relation on this set generated by the relation $((d)^{(s)}; K_1, \ldots, K_t) \prec_m (\mathcal{L}((d)^{(s)}); K_1, \ldots, K_t, K_{t+1})$ for all K_{t+1}, where $\mathcal{L}((d)^{(s)})$ is again computed relative to the sequence $K_1, \ldots, K_t$. The relation $\prec_m$ is easily well-founded. Let $|\vec{s}\rceil_m$ denote the rank of the tuple $\vec{s}$, computed in the slightly non-standard manner by: $|\vec{s}\rceil_m = (\sup\{|\vec{t}\rceil_m : \vec{t} \prec_m \vec{s}\}) + 1$; by convention if $\vec{s}$ is minimal, then $|\vec{s}\rceil = 0$ (thus, at limit ranks, this is one more than the usual rank).

An immediate induction on the $\prec_m$ rank using Theorem 5.24 then shows:

5.25 Theorem. *For all $m \in \omega$, $(d)^{(s)} \in \bar{\mathcal{D}}_m(K_1, \ldots, K_t)$ satisfying Condition* D*, we have* $(\mathrm{id}; (d)^{(s)}; K_1, \ldots, K_t) \leq \aleph_{\omega+1+|((d)^{(s)}; K_1, \ldots, K_t)|_m}$. ⊣

Let θ_m be the supremum of the $|\ |_m$ ranks of the tuples $((d)^{(s)}; K_1, \ldots, K_t)$ where $(d)^{(s)} \in \bar{\mathcal{D}}_m(K_1, \ldots, K_t)$. From Theorem 5.25 and the homogeneous tree analysis (cf. two paragraphs before Definition 5.14) we thus have $\boldsymbol{\delta}^1_5 \leq [\aleph_{\sup_m \theta_m}]^+$.

The computation of the θ_m is a purely combinatorial problem, and is relatively straightforward. We omit the proof, and simply state the result that $\theta_m = \omega^{\omega^m}$ (ordinal exponentiation). As an immediate corollary we have:

5.26 Corollary (Jackson). $\boldsymbol{\delta}^1_5 \le \aleph_{\omega^{\omega^\omega}+1}$.

At this point we have extended the basic ingredients in the theory, Martin's theorem and the description analysis, from the $\boldsymbol{\delta}^1_1$ level to the $\boldsymbol{\delta}^1_3$ level, and we have used this to do one step in the next level of the inductive analysis, namely the upper bound for $\boldsymbol{\delta}^1_5$. To finish the next level analysis, it remains to prove the strong partition relation on $\boldsymbol{\delta}^1_3$, the lower bound for $\boldsymbol{\delta}^1_5$, and the weak partition relation for $\boldsymbol{\delta}^1_5$. The proofs in all cases follow in outline those of Sect. 4, using the description analysis, Theorem 5.24. Since we have now illustrated all of the ideas which go into these arguments, we will content ourselves with this. The complete details of these arguments can be found in [11]. We mention only that the analysis of measures on $\boldsymbol{\delta}^1_3$ and on λ_5 require the notions of type-2 and type-3 trees of uniform cofinalities respectively (roughly corresponding to the measures occurring in homogeneous trees on $\boldsymbol{\Pi}^1_3, \boldsymbol{\Pi}^1_4$-complete sets).

5.4. Some Further Results

We close this section with some remarks on generalizations and refinements of the results discussed. All the ordinals $(\mathrm{id}; (d)^{(s)}; K_1, \dots, K_t)$, it can be shown, are actually cardinals (Theorem 5.24 shows that all cardinals between $\boldsymbol{\delta}^1_3$ and λ_5 must be of this form). This is proved in [13]. It is also not difficult to show that if μ is a semi-normal measure on a cardinal κ having the strong partition relation, then $j_\mu(\kappa)$ is a regular cardinal. For the three normal measures μ_ω, μ_{ω_1}, μ_{ω_2} on $\boldsymbol{\delta}^1_3$, these ultrapowers are computed to be $\boldsymbol{\delta}^1_4 = \aleph_{\omega+2}$, $\aleph_{\omega\cdot 2+1}$, and $\aleph_{\omega^\omega+1}$ respectively. These three regular cardinals κ all satisfy $\kappa \to (\kappa)^\lambda$ for all $\lambda < \boldsymbol{\delta}^1_4$, but $\kappa \not\to (\kappa)^{\boldsymbol{\delta}^1_4}$. One can also compute the cofinalities of all successor cardinals between $\boldsymbol{\delta}^1_4$ and λ_5. The result, from [13] is:

5.27 Theorem. *Suppose $\boldsymbol{\delta}^1_3 = \aleph_{\omega+1} < \aleph_{\alpha+1} < \aleph_{\omega^{\omega^\omega}+1} = \boldsymbol{\delta}^1_5$. Let $\alpha = \omega^{\beta_1} + \cdots + \omega^{\beta_n}$, where $\omega^\omega > \beta_1 \ge \cdots \ge \beta_n$ be the normal form for α. Then:*

(1) If $\beta_n = 0$, then $\mathrm{cf}(\kappa) = \boldsymbol{\delta}^1_4 = \aleph_{\omega+2}$.

(2) If $\beta_n > 0$, and is a successor ordinal, then $\mathrm{cf}(\kappa) = \aleph_{\omega\cdot 2+1}$.

(3) If $\beta_n > 0$ and is a limit ordinal, then $\mathrm{cf}(\kappa) = \aleph_{\omega^\omega+1}$.

Finally, one can extend the results of this section to all levels of the projective hierarchy. One first defines the measures W^m_{2n+1}, $S^{l,m}_{2n+1}$, for $m \in \omega$, $1 \le l \le 2^{n+1} - 1$, assuming the weak and strong partition relations on $\boldsymbol{\delta}^1_{2n+1}$ respectively (for $n = 0$, we set $S^m_1 = S^{1,m}_1$ to agree with our previous notation). Order these (to be defined) families of measures as: W^m_1, $S^{1,m}_1$, W^m_3, $S^{1,m}_3$, $S^{2,m}_3$, $S^{3,m}_3$, W^m_5, etc. W^m_{2n+1} is defined to be the measure on $\boldsymbol{\delta}^1_{2n+1}$ induced from the weak partition relation on $\boldsymbol{\delta}^1_{2n+1}$, functions $f : \mathrm{dom}(S^{l_0,m}_{2n-1}) \to \boldsymbol{\delta}^1_{2n+1}$, where $l_0 = 2^n - 1$, and the measure $S^{l_0,m}_{2n-1}$ on $\mathrm{dom}(S^{l_0,m}_{2n-1}) < \lambda_{2n+1}$. $S^{1,m}_{2n+1}$ is the measure on $(\boldsymbol{\delta}^1_{2n+1})^{+m}$ defined just as

S_1^m was, using $\boldsymbol{\delta}^1_{2n+1}$ in place of ω_1. For $l > 1$, $S^{l,m}_{2n+1}$ is the measure on $\mathrm{dom}(S^{l,m}_{2n+1}) < \lambda_{2n+3}$ induced by the strong partition relation on $\boldsymbol{\delta}^1_{2n+1}$, functions $f : \boldsymbol{\delta}^1_{2n+1} \to \boldsymbol{\delta}^1_{2n+1}$ of the correct type, and the measure ν on $\boldsymbol{\delta}^1_{2n+1}$. Here ν is the measure on $\boldsymbol{\delta}^1_{2n+1}$ induced by the weak partition relation on $\boldsymbol{\delta}^1_{2n+1}$, functions $h : \mathrm{dom}(\mu) \to \boldsymbol{\delta}^1_{2n+1}$, and the measure μ, where μ is the mth measure in the $(l-1)$st family. In [8] it is shown that these measures dominate the general measures in the homogeneous trees on $\boldsymbol{\Pi}^1_{2n+1}, \boldsymbol{\Pi}^1_{2n+2}$-complete sets, in the sense of Theorems 5.12, 5.15. The notion of a level n description is introduced there, and the analog of the main theorem, Theorem 5.24, is proved (with a suitable generalization of the $\mathcal{L}$ operator). The ranks of these generalized $\mathcal{L}$ operations are also computed, giving the upper bounds for the $\boldsymbol{\delta}^1_{2n+1}$. As mentioned in the introduction, the result is $\boldsymbol{\delta}^1_{2n+1} \leq \aleph_{\omega(2n-1)+1}$, where $\omega(0) = 0$ and $\omega(n+1) = \omega^{\omega(n)}$. With the main theorem, the inductive step is then similar to that of Sect. 4 or [11] (see the forthcoming [7]). In particular, $\sup_n \boldsymbol{\delta}^1_n = \aleph_{\epsilon(0)}$, where $\epsilon(0) = \sup_m \omega(m)$. Also, the regular cardinals between $\boldsymbol{\delta}^1_{2n+1}$ and $\boldsymbol{\delta}^1_{2n+3}$ are given by the ultrapowers of $\boldsymbol{\delta}^1_{2n+1}$ by the normal measures on $\boldsymbol{\delta}^1_{2n+1}$, corresponding to the regular cardinals below $\boldsymbol{\delta}^1_{2n+1}$. Thus, there are $2^{n+1} - 1$ regular cardinals between $\boldsymbol{\delta}^1_{2n+1}$ and $\boldsymbol{\delta}^1_{2n+3}$.

In fact, these arguments extend with little modification up to $\boldsymbol{\delta}^1_{\omega_1} = \aleph_{\omega_1}$. Here $\boldsymbol{\delta}^1_\alpha$ is the supremum of the lengths of the $\boldsymbol{\Delta}^1_\alpha$ prewellorderings, where $\boldsymbol{\Sigma}^1_\alpha$ is the αth pointclass closed under $\exists^{\omega^\omega}$ (so $\boldsymbol{\Sigma}^1_0 = \boldsymbol{\Sigma}^0_1$, and for limit α, $\boldsymbol{\delta}^1_\alpha = \sup_{\beta<\alpha} \boldsymbol{\delta}^1_\beta$). For there are no new measures on $\boldsymbol{\delta}^1_\alpha$ for α limit $< \omega_1$, and a coding of $\mathcal{P}(\boldsymbol{\delta}^1_\alpha)$ may be constructed trivially from codings of $\mathcal{P}(\boldsymbol{\delta}^1_\beta)$, $\beta < \alpha$. Also, the only normal measures on the $\boldsymbol{\delta}^1_{\alpha+2n+1}$ for limit α correspond to the fixed cofinalities below $\boldsymbol{\delta}^1_{\alpha+2n+1}$ (since there will be only countably many regular cardinals below $\boldsymbol{\delta}^1_{\alpha+2n+1}$). Again, the ultrapowers of the $\boldsymbol{\delta}^1_{\alpha+2n+1}$ by these normal measures, together with the $\boldsymbol{\delta}^1_{\alpha+2n+1}$ precisely constitute the regular cardinals below $\boldsymbol{\delta}^1_{\omega_1}$.

At $\aleph_{\omega_1}$, or at any limit Suslin cardinal δ of cofinality $> \omega$, the situation changes as there are, of course, new measures on δ. One can show directly here that the next Suslin cardinal after $\boldsymbol{\delta}^1_{\omega_1}$ has cardinality the supremum of the ultrapowers of $\boldsymbol{\delta}^1_{\omega_1}$ by the measures on $\boldsymbol{\delta}^1_{\omega_1}$. Actually, Martin has proved a general result which shows the same fact for any limit Suslin cardinal of cofinality $> \omega$ (or any successor Suslin cardinal as well). In unpublished work, the author has analyzed these measures and shown that the supremum of their ultrapowers is $\aleph_{\aleph_\omega}$. We will consider some of the problems associated with further extending the theory in the next section.

6. Global Results

We consider in this section some results and problems of a "global" nature, that is, related to the attempt to push the structural theory of $L(\mathbb{R})$ up through Θ. The problems we consider here (and in some cases solve) seem to be necessary for further extensions of the theory, but are almost certainly not sufficient. Identifying the remaining obstructions remains a central goal of this subject. Nevertheless, some of the results we mention in this section are of independent interest. We will not require any of the results of Sects. 4, 5 for this section. We assume AD throughout this section, occasionally assuming $V = L(\mathbb{R})$ as well.

6.1. Generic Codes

Kechris and Woodin [20] have developed a theory of generic codes for uncountable ordinals which we will use in several of the arguments of this section. We will only need, however, the most basic lemma of their theory, the one asserting the existence of a generic coding function. For the sake of completeness, we give their proof of this result.

We say an ordinal α is *reliable* if there is a $P \subseteq \omega^\omega$ and a scale $\{\phi_n\}_{n\in\omega}$ with $\phi_n : P \to \alpha$ with ϕ_0 onto α. Every Suslin cardinal is easily reliable (cf. [37, Lemma 4.6]), and in [37] it is shown from $\mathrm{AD} + V = L(\mathbb{R})$ that every reliable cardinal is a Suslin cardinal. Actually, using some additional arguments this can be shown to follow from just AD. There are, however, many reliable ordinals which are not cardinals, as, for example, the set of reliable ordinals is closed unbounded in every $\boldsymbol{\delta}^1_{2n+1}$. For the purposes of generic codes, it is convenient to slightly strengthen the definition of reliable to include the requirement that the scale relations $\leq^*_n$, $<^*_n$ are both Suslin and co-Suslin. This only has the effect of removing the largest Suslin cardinal, if there is one, from consideration. We henceforth officially adopt this stronger form of the definition.

If α is reliable, $S \in \mathcal{P}_{\omega_1}(\alpha)$, and $\beta \in S$, we say S is β-*honest* if there is an $x \in P$ with $\phi_0(x) = \beta$ and $\forall n\ \phi_n(x) \in S$ (this notion is defined relative to the choice of P and $\{\phi_n\}$). We say S is *honest* if it is β-honest for all $\beta \in S$. For $x \in P$ we frequently write $|x|$ for $\phi_0(x)$. If S is a countable set of ordinals, then S^ω (S having the discrete topology) is homeomorphic to ω^ω and so carries a natural notion of category. When we speak of meager or comeager, we are always referring to this topology. If $p \in S^{<\omega}$, we write $\forall^*_p s \in S^\omega$ to mean for comeager many s in the neighborhood $N_p = \{s \in S^\omega : s{\restriction}\mathrm{lh}(p) = p\}$. We just write $\forall^* s \in S^\omega$ to mean for comeager many s in the space S^ω. Recall from Definition 2.3 that $S(\kappa)$ denotes the pointclass of κ-Suslin sets.

Recall that from AD, every set $A \subseteq S^\omega$ has the Baire property. In particular, A is either meager or else comeager on some neighborhood N_p. Also from AD, a wellordered union of meager sets is meager ("additivity of category").

6.1 Theorem (Kechris-Woodin). *Let α be reliable, as witnessed by P, $\{\phi_n\}$. Then there is Lipschitz continuous function $G : \alpha^\omega \to \omega^\omega$ satisfying:*

(1) $\forall \vec{s} = (\alpha_0, \alpha_1, \dots) \in \alpha^\omega\ \forall n \in \omega\ [G(\vec{s})_n \in P \wedge \phi_0(G(\vec{s})_n) \leq \alpha_n]$.

(2) If $\vec{s} = (\alpha_0, \alpha_1, \dots) \in \alpha^\omega$ enumerates an honest set S, then for all $n \in \omega$, $\phi_0(G(\vec{s})_n) = \alpha_n$.

Proof. Let T be the tree of the scale $\{\phi_n\}$, so T is a tree on $\omega \times \alpha$. For $\gamma < \alpha$, let

$$T_\gamma = \{(s, \vec{\alpha}) \in T : \alpha_0 = \gamma\}.$$

Consider the following ordinal game:

I	α_0		α_1		α_2		α_3		$\dots$	
II		β_0		β_1		β_2		β_3		$\dots$
		$x(0)$		$x(1)$		$x(2)$		$x(3)$		$\dots$

Here $\alpha_i, \beta_i < \alpha$, $x(i) \in \omega$, so I plays out $\vec{\alpha} \in \alpha^\omega$, and II plays out $\vec{\beta} \in \alpha^\omega$ and $x \in \omega^\omega$. Let $S = \{\alpha_i : i \in \omega\}$. x codes reals x_i and $\vec{\beta}$ codes sequences $(\vec{\beta})_i \in \alpha^\omega$ in the usual manner, so $x_i(j) = x(\langle i, j\rangle)$, and $(\vec{\beta})_i(j) = \beta_{\langle i,j\rangle}$ (we assume $\langle i, j\rangle \geq i$ for all j, so II does not have to play any of the $x_i(j)$ or $(\vec{\beta})_i(j)$ until I has played α_i). II wins the run of the game iff

$$\forall i\ (x_i, \alpha_i{}^\frown(\vec{\beta})_i) \in [T] \wedge \forall i\, \forall y\ [y \in p[T_{\alpha_i}\restriction S] \to \phi_0(y) \leq \phi_0(x_i)].$$

Now I cannot have a winning strategy, for as soon as I plays α_i, II can pick some $x_i \in P$ with $\phi_0(x_i) = \alpha_i$, and pick $(\vec{\beta})_i$ with $(x_i, \alpha_i{}^\frown(\vec{\beta})_i) \in [T]$ and proceed to play these to defeat I's strategy. Thus, if the game is determined, then II has a winning strategy τ. Ignoring the ordinal moves of τ gives the function G as desired.

To show the game is determined, it is enough to observe that it is Suslin, co-Suslin by Theorem 2.23. The first conjunct in the payoff definition trivially defines a Suslin, co-Suslin set (in fact, a closed set). For the second conjunct, note that

$$y \in p[T_{\alpha_i}\restriction S] \longleftrightarrow \exists \pi \in \omega^\omega\ \forall n\ (y\restriction n, (\alpha_i, \alpha_{\pi(1)}, \dots, \alpha_{\pi(n-1)})) \in T.$$

From the closure of the Suslin sets under $\vee^\omega, \wedge^\omega, \exists^{\omega^\omega}$, and $\forall^{\omega^\omega}$ (the latter by the Second Periodicity Theorem; see Remark 2.10), it follows that this relation, and thus the second conjunct, is Suslin, co-Suslin. ⊣

If there is a largest Suslin cardinal Ξ, then Theorem 6.1 does not immediately give a generic coding function $G : \Xi^\omega \to \omega^\omega$ at Ξ. In this case $\boldsymbol{\Gamma} = S(\Xi)$ will be a non-selfdual pointclass closed under real quantification, $\wedge$, $\vee$, and scale($\boldsymbol{\Gamma}$). The scale relations $\leq_n^*$, $<_n^*$ will not be co-Suslin, however. Nevertheless, we can argue that a generic coding function G still exists. To see this, fix a $\boldsymbol{\Gamma}$-scale $\{\phi_n\}_{n\in\omega}$ on a $\boldsymbol{\Gamma}$-complete set A. Without loss of generality, all of the norms ϕ_n are onto Ξ. Recall that Ξ is regular and a limit of Suslin cardinals. Also, the Suslin cardinals are closed unbounded in Ξ. By boundedness, there is a closed unbounded $C \subseteq \Xi$ such that for all $\alpha \in C$ and

$\beta < \alpha$, if $B^i_\beta = \{x \in A : \phi_i(x) < \beta\}$, then $\sup\{\phi_j(x) : j \in \omega \wedge x \in B^i_\beta\} < \alpha$. Note that every Suslin cardinal in C is reliable with respect $\{\phi_n\}$. For every Suslin cardinal $\alpha \in C$, there is a generic coding function at α with respect to $A_\alpha = \{x \in A : \forall i\ \phi_i(x) < \alpha\}$ and the norms $\phi_i \restriction A_\alpha$ (from Theorem 6.1). It suffices to show that we can get a function which to each such α assigns a generic coding function G_α with respect to A_α and the $\phi_i \restriction A_\alpha$. For then we can define $G : \Xi^\omega \to \omega^\omega$ by: $G(\alpha_0, \alpha_1, \dots) = z$ where for all j we have $(z)_j = (G_{\alpha'_j}(\beta_0, \beta_1, \dots))_j$ where α'_j is the least Suslin cardinal in C greater than α_j and $\beta_k = \alpha_k$ if $\alpha_k < \alpha'_j$ and otherwise $\beta_k = \alpha_j$. Using the definition of C it is not hard to check that G is a generic coding function (the point is that if S is α_j-honest then $S \cap \alpha'_j$ is α_j-honest). It remains to show that we can uniformly define the G_α for $\alpha \in C$ a Suslin cardinal. Let $\mathcal{G}_\alpha$ denote the generic coding game as in Theorem 6.1 using A_α and the $\phi_i \restriction A_\alpha$. The payoff set for II is Suslin and co-Suslin, and is uniformly Suslin (but not uniformly co-Suslin). For all Suslin cardinals α in C, II has a winning strategy in $\mathcal{G}_\alpha$. From a Suslin representation for II's payoff set and the fact that II has a winning strategy, we can uniformly in α get a winning strategy for II in $\mathcal{G}_\alpha$, which then gives us the generic coding function G_α. In fact, either of the two proofs that Suslin, co-Suslin ordinal games are determined shows this (cf. [32, Theorem 2.2] or [22, Theorem 2.5], also [27, Theorem 2]).

We are frequently only concerned with getting a real which codes the ordinal α_0. Thus, let $G_0 : \alpha^\omega \to \omega^\omega$ be a Lipschitz continuous function so that $\forall \vec{s} \in \alpha^\omega\ G_0(\vec{s}) = G(\vec{s})_0$. The functions G_0, G are referred to as generic coding functions, and we fix them for the remainder of this section. Of course, these functions depend on the choice of the set P and the scale $\{\phi_n\}$, but we suppress writing this. Frequently, α will be a Suslin cardinal.

Recall Theorem 2.25, according to which any game on α whose payoff depends only on $G(\vec{s})$ is determined (where $\vec{s}$ is the sequence I and II build, assuming now $V = L(\mathbb{R})$). Thus, for any game on α with payoff set $R \subseteq \alpha^\omega$, there is a determined game $R' \subseteq \alpha^\omega$ approximating R. Namely, define $R'(\vec{s}) \longleftrightarrow R(|G(\vec{s})_0|, |G(\vec{s})_1|, \dots)$. R' is always determined, and if $\vec{s}$ enumerates an honest set, then $R'(\vec{s}) \longleftrightarrow R(\vec{s})$.

The generic coding functions are particularly useful when combined with the existence of supercompactness measures. Recall that from $\mathrm{AD} + V = L(\mathbb{R})$ there is a supercompactness measure (i.e., a fine, normal, countably additive ultrafilter) ν on $\mathcal{P}_{\omega_1}(\boldsymbol{\delta}^2_1)$, which in turn induces one on $\mathcal{P}_{\omega_1}(\delta)$ for any $\delta \leq \boldsymbol{\delta}^2_1$. Woodin has shown [40] that the supercompactness measure ν on $\mathcal{P}_{\omega_1}(\delta)$, for any $\delta \leq \boldsymbol{\delta}^2_1$ is unique. Woodin has also shown that there is a supercompactness measure on $\mathcal{P}_{\omega_1}(\lambda)$ for any $\lambda < \Theta$ assuming $\mathrm{AD} + V = L(\mathbb{R})$.

In fact, the existence of generic coding functions can be used to give a quick proof of the existence of the supercompactness measure on $\mathcal{P}_{\omega_1}(\boldsymbol{\delta}^2_1)$, assuming $\mathrm{AD} + V = L(\mathbb{R})$. Recall $\boldsymbol{\delta}^2_1$ is a Suslin cardinal, and $S(\boldsymbol{\delta}^2_1) = \boldsymbol{\Sigma}^2_1$ has the scale property. Let $G : (\boldsymbol{\delta}^2_1)^\omega \to \omega^\omega$ be a generic coding function at $\boldsymbol{\delta}^2_1$ (see the remarks after the proof of Theorem 6.1). If $A \subseteq \mathcal{P}_{\omega_1}(\boldsymbol{\delta}^2_1)$, define $\nu(A) = 1$

iff II has a winning strategy in the game G_A: I and II alternate playing $\alpha_0, \alpha_1, \ldots$ building $\vec{s} \in (\boldsymbol{\delta}^2_1)^\omega$, and II wins iff $S = \{|G(\vec{s})_0|, |G(\vec{s})_1|, \ldots\} \in A$. It is not hard to check that this defines a fine, normal measure on $\mathcal{P}_{\omega_1}(\boldsymbol{\delta}^2_1)$, using standard dovetailing arguments and the fact that either player can play to ensure S is honest. Alternatively, one can argue just using Theorem 6.1 as follows. Let μ be a normal measure on $\boldsymbol{\delta}^2_1$ (the proof that the $\boldsymbol{\delta}^1_{2n+1}$ are measurable works for $\boldsymbol{\delta}^2_1$). For every reliable $\lambda < \boldsymbol{\delta}^2_1$ there is a generic coding function $G : \lambda^\omega \to \omega^\omega$ from Theorem 6.1, and this gives a supercompactness measure on $\mathcal{P}_{\omega_1}(\lambda)$ as above. By Woodin's theorem, this supercompactness measure on $\mathcal{P}_{\omega_1}(\lambda)$ is unique, call it ν_λ. A supercompactness measure on $\mathcal{P}_{\omega_1}(\boldsymbol{\delta}^2_1)$ can then be defined by $\nu(A) = 1$ iff $\forall^*_\mu \lambda\ \forall^*_{\nu_\lambda} S \in \mathcal{P}_{\omega_1}(\lambda)\ S \in A$.

As an example of using generic coding arguments, we prove, following [12], the following theorem.

6.2 Theorem. *Let κ be a regular Suslin cardinal less than the supremum of the Suslin cardinals. Let $\lambda < \Theta$ be a cardinal with $j_{\nu_\alpha}(\lambda) = \lambda$ for all $\alpha < \kappa$, where ν_α is the supercompactness measure on $\mathcal{P}_{\omega_1}(\alpha)$. Then* $\mathrm{cf}(\lambda^+) > \kappa$.

6.3 Corollary. *If $\omega_1 < \lambda^+ < \Theta$, then* $\mathrm{cf}(\lambda^+) > \omega_1$.

Proof. Fix κ, λ as above, and assume $f : \kappa \to \lambda^+$ is cofinal. For $\alpha < \kappa$, let $\alpha' < \kappa$ denote the least reliable ordinal $> \alpha$ relative to the scale used in constructing the generic coding function G_0 for κ (it is not hard to see that $\alpha' < \kappa$ using the regularity of κ). Consider the game where I, II play $\alpha_0, \alpha_1, \ldots$ building $\vec{s}$, and II plays also $x(0), x(1), \ldots \in \omega$ building $x \in \omega^\omega$. II wins iff x codes a wellordering of λ of length $\geq f(\phi_0(G_0(\vec{s})))$. Here we code subsets of λ by reals in some manner which is not important, say by the Coding Lemma. I cannot have a winning strategy, for as soon as I plays α_0, II can enumerate an honest set containing α_0 and closed under I's winning strategy, and play some x coding a wellordering of λ of length $\geq f(\alpha_0)$.

A winning strategy τ for II gives (ignoring II's ordinal moves) a Lipschitz continuous $\mathcal{F} : \kappa^\omega \to \omega^\omega$ such that

(1) For all $\vec{s} \in \kappa^\omega$, $\mathcal{F}(\vec{s})$ codes a wellordering of λ.

(2) For all $\alpha < \kappa$ and all $\vec{s}$ enumerating an honest S containing α, $\mathcal{F}(\alpha{}^\frown\vec{s})$ codes a wellordering of λ of length $\geq f(\alpha)$.

Let $|\beta|_x$ denote the rank of β in the wellordering coded by x.

Fix for the moment $\alpha < \kappa$ and an honest set $S \in \mathcal{P}_{\omega_1}(\alpha')$ containing α. Define a tree T on $S^{<\omega} \times \lambda$ as follows. Put $((p_0, \beta_0), \ldots, (p_n, \beta_n))$ in T iff

(1) For all $i < n$, p_{i+1} extends p_i.

(2) $\forall^*_{p_{i+1}} \vec{s} \in S^\omega\ |\beta_{i+1}|_{\mathcal{F}(\alpha{}^\frown\vec{s})} < |\beta_i|_{\mathcal{F}(\alpha{}^\frown\vec{s})}$.

(3) $\forall i \leq n\ \exists \eta_i \in \mathrm{On}\ \forall^*_{p_i} \vec{s} \in S^\omega\ |\beta_i|_{\mathcal{F}(\alpha{}^\frown\vec{s})} = \eta_i$.

The last clause guarantees that T is well-founded, as the η_i are decreasing along any branch. We define an order-preserving map π from the tree of the ϵ relation on $f(\alpha)$ into T. Suppose

$$\pi(\gamma_0, \gamma_1, \ldots, \gamma_n) = ((p_0, \beta_0), \ldots, (p_n, \beta_n))$$

has been defined, and assume inductively that

$$\forall^*_{p_n} \vec{s} \in S^\omega \ |\beta_n|_{\mathcal{F}(\alpha^\frown \vec{s})} = \eta_n \geq \gamma_n.$$

If $\gamma_{n+1} < \gamma_n$, then let $\pi(\gamma_0, \ldots, \gamma_{n+1})$ be the least sequence

$$((p_0, \beta_0), \ldots, (p_{n+1}, \beta_{n+1}))$$

extending $((p_0, \beta_0), \ldots, (p_n, \beta_n))$ such that

$$\forall^*_{p_{n+1}} \vec{s} \in S^\omega \ |\beta_{n+1}|_{\mathcal{F}(\alpha^\frown \vec{s})} = \eta_{n+1} \geq \gamma_{n+1} \text{ and } \eta_{n+1} < \eta_n.$$

The additivity of category shows that $p_{n+1}, \beta_{n+1}, \eta_{n+1}$ exist.

The definition of the tree $T = T^\alpha_S$ is uniform in α, S. Let now $F(\alpha) = [S \to T^\alpha_S]_{\nu_{\alpha'}}$. $F(\alpha)$ may be viewed as a wellordering of $j_{\nu_{\alpha'}}(\lambda) = \lambda$, and clearly $|F(\alpha)| \geq f(\alpha)$. This gives a wellordering of λ of length λ^+, a contradiction. $\dashv$

The analog of Corollary 6.3 with $\kappa = \boldsymbol{\delta}^1_{2n+1}$ replacing ω_1 was shown by Kechris and Woodin to hold for λ below the supremum of the projective ordinals, i.e., $\lambda < \aleph_{\epsilon(0)}$ (this also follows from the projective hierarchy analysis, cf. Theorem 5.27). Along with Corollary 6.3, this suggests the following conjecture:

6.4 Conjecture. If κ is a regular Suslin cardinal and $\kappa < \lambda^+ < \Theta$, then $\mathrm{cf}(\lambda^+) > \kappa$.

6.2. Weak Square and Uniform Cofinalities

One of the important ingredients in the projective hierarchy analysis is the analysis of uniform cofinalities. In the general step, one has the notion of a type-n tree of uniform cofinalities $\mathcal{R}$ with associated measure $M^{\mathcal{R}}$, and it is necessary to analyze the possible uniform cofinalities with respect to these measures. Consider then the general question: given a measure ν on κ, what are the possible uniform cofinalities of a function $f : \kappa \to \lambda \in \mathrm{On}$ with respect to ν? One possibility is that for some function g from κ to the regular cardinals we have $\forall^*_\nu \alpha \ f(\alpha)$ has uniform cofinality $g(\alpha)$. We call these the trivial uniform cofinalities. What are the possible non-trivial uniform cofinalities? Suppose, for example, $\kappa = \omega_2$, $\nu = S^1_1$, and $\lambda \in \mathrm{On}$. Are the possible non-trivial uniform cofinalities for $f : \omega_2 \to \lambda$ the same as for $f : \omega_2 \to \boldsymbol{\delta}^1_3$? Intuitively, it seems as though the possible non-trivial uniform cofinalities should depend only on κ (and ν), and not on λ (a phenomenon reminiscent of the Coding Lemma). For small λ, one can extend the projective hierarchy arguments directly to answer this question, but for large λ, such an inductive approach does not seem to help.

From these considerations the author formulated a combinatorial principle called $\boxminus_{\kappa,\lambda}$. In fact, this principle also arose independently from attempts to extend some joint work with Becker [2, 6]. The statement of the principle follows.

6.5 Definition. Let κ, $\lambda < \Theta$. $\boxminus_{\kappa,\lambda}$ is the assertion that for all $f : \kappa \to \lambda$ such that $\mathrm{cf}(f(\alpha)) \leq \kappa$ for all $\alpha < \kappa$, there is an $A \subseteq \lambda$ of size $\leq \kappa$ such that for all $\alpha < \kappa$, $A \cap f(\alpha)$ is cofinal in $f(\alpha)$.

Thus, $\boxminus_{\kappa,\lambda}$ can be viewed as a choice principle. The principle can be stated for any cardinal κ, but for non-Suslin κ can fail. For example, it is not difficult to see that $\boxminus_{\omega_2,\omega_3}$ fails (using just that $\mathrm{cf}(\omega_3) = \omega_2$). In [12], the following theorem is proved.

6.6 Theorem ($\mathrm{AD} + V = L(\mathbb{R})$). *$\boxminus_{\kappa,\lambda}$ holds for any Suslin cardinal κ and any $\lambda < \Theta$.*

This theorem provides a positive answer to the question on uniform cofinalities asked above. Specifically, we have the following.

6.7 Theorem ($\mathrm{AD} + V = L(\mathbb{R})$). *Let κ be a Suslin cardinal, μ a measure on κ, $\lambda < \Theta$, and $f : \kappa \to \lambda$. Then one of the following holds.*

(1) $\forall^*_\mu \alpha\ \mathrm{cf}(f(\alpha)) \leq \kappa$. Then the uniform cofinality of f with respect to μ is realized by a function $f' : \kappa \to \kappa$.

(2) $\forall^*_\mu \alpha\ \mathrm{cf}(f(\alpha)) > \kappa$. Let $g(\alpha) = \mathrm{cf}(f(\alpha))$. Then there is an h with domain $\{(\alpha, \beta) : \alpha < \kappa \wedge \beta < g(\alpha)\}$ such that $h(\alpha, \beta) < f(\alpha)$ and $\forall^*_\mu \alpha\ f(\alpha) = \sup\{h(\alpha, \beta) : \beta < g(\alpha)\}$.

We require a preliminary lemma. Throughout, ν denotes the supercompactness measure on $\mathcal{P}_{\omega_1}(\kappa)$.

6.8 Lemma. *Let κ be a Suslin cardinal and $\lambda \in \mathrm{On}$ with $\mathrm{cf}(\lambda) > \kappa$. Suppose $F : \mathcal{P}_{\omega_1}(\kappa) \to \lambda$. Then $\exists \delta < \lambda\ \forall^*_\nu S\ F(S) < \delta$.*

Proof. Fix an $S(\kappa)$-bounded prewellordering (C, ψ) of length λ according to Theorem 2.28. Play the game where I plays $\alpha_0, \alpha_2, \ldots$, II plays $\alpha_1, \alpha_3, \ldots$ and $x(0), x(1), \ldots \in \omega$, and II wins iff $x \in C$ and $\psi(x) \geq F(S)$, where $S = \{|G(\vec{s})_0|, |G(\vec{s})_1|, \ldots\}$ and $\vec{s} = (\alpha_0, \alpha_1, \ldots)$. The game is determined and easily I cannot win. A winning strategy for II gives a Lipschitz continuous function $\mathcal{F} : \kappa^\omega \to \kappa^\omega \times \omega^\omega$ such that $\forall \vec{s} \in \kappa^\omega\ \mathcal{F}(\vec{s}) \in C$ (ignoring II's ordinal moves in computing $\mathcal{F}(\vec{s})$), and for all $\vec{s}$ enumerating an honest set S closed under $\mathcal{F}$, $\psi(\mathcal{F}(\vec{s})) \geq F(S)$. Let $w \in B \longleftrightarrow \exists \vec{s} \in \kappa^\omega\ w = \mathcal{F}(\vec{s})$. $B \subseteq C$ and is κ-Suslin, so $\delta = \sup\{\phi(w) : w \in B\} < \lambda$ (to see B is κ-Suslin, note that the Lipschitz continuous $\mathcal{F}$ can be coded by the Coding Lemma with the pointclass $S(\kappa)$). Thus, $\forall^*_\nu S\ F(S) < \delta$. ⊣

Proof of Theorem 6.7. Assume first $\forall^*_\mu\alpha\ \mathrm{cf}(f(\alpha)) \leq \kappa$. By $\boxminus_{\kappa,\lambda}$, let $A \subseteq \lambda$ have size κ such that $\forall^*_\mu\alpha\ (A \cap f(\alpha)$ is cofinal in $f(\alpha))$. Taking the transitive collapse of A, we may assume that $\lambda < \kappa^+$. Let $\prec$ be a wellordering of κ of length $> \lambda$. For $\alpha < \kappa$, let $R(\alpha) \leq \kappa$ be least such that $\sup\{|\beta|_\prec : \beta < R(\alpha) \wedge |\beta|_\prec < f(\alpha)\} = f(\alpha)$. For $\beta < R(\alpha)$, let $l(\alpha, \beta) = |\beta|_\prec$ if $|\beta|_\prec < f(\alpha)$, and 0 otherwise. R, l provide a liftup to f, as in the proof of Lemma 4.19. The uniform cofinality of f with respect to μ is the same as that of R.

Assume now $\forall^*_\mu\alpha\ \mathrm{cf}(f(\alpha)) > \kappa$. Let $g(\alpha) = \mathrm{cf}(f(\alpha))$. The game argument above produces a Lipschitz continuous $\mathcal{F} : \kappa^\omega \to \kappa^\omega \times \omega^\omega$ such that for all $\alpha < \kappa$, and all $\vec{s} \in \kappa^\omega$ enumerating an honest set containing α and closed under $\mathcal{F}$, $\mathcal{F}(\alpha^\frown s)$ codes (ignoring II's ordinal moves) an increasing $g(\alpha)$ sequence cofinal in $f(\alpha)$. The exact manner in which reals code $g(\alpha)$ sequences below λ is not important, say by the Coding Lemma with respect to a suitably large pointclass.

Fix for the moment $\alpha < \kappa$ and an honest S containing α and closed under $\mathcal{F}$. For $p \in S^{<\omega}$ and $\beta < g(\alpha)$ define $h(\alpha, \beta, S, p)$ to be the least $\gamma < f(\alpha)$ such that $\forall^*_p s \in S^\omega\ \mathcal{F}(\alpha^\frown s)(\beta) < \gamma$ if one exists, and 0 otherwise. Define $h(\alpha, \beta, S) = \sup\{h(\alpha, \beta, S, p) : p \in S^{<\omega}\}$. Clearly $h(\alpha, \beta, S) < f(\alpha)$. If $\gamma < f(\alpha)$, then by additivity of category there is a $p \in S^{<\omega}$, a $\beta < g(\alpha)$, and a $\eta < f(\alpha)$ such that $\eta > \gamma$ and

$$\forall^*_p s \in S^\omega\ \mathcal{F}(\alpha^\frown s)(\beta) = \eta.$$

Thus, $h(\alpha, \beta, S, p) > \gamma$. Hence, $f(\alpha) = \sup\{h(\alpha, \beta, S) : \beta < g(\alpha)\}$. Also, an easy argument shows that $h(\alpha, \beta, S)$ is monotonically increasing in β. Define

$$h(\alpha, \beta) = \text{ the least } \delta < f(\alpha) \text{ such that } \forall^*_\nu S \in \mathcal{P}_{\omega_1}(\kappa)\ h(\alpha, \beta, S) < \delta.$$

By Lemma 6.8, this is well-defined. Fix now $\alpha < \kappa$, and suppose towards a contradiction that $\rho \doteq \sup\{h(\alpha, \beta) : \beta < g(\alpha)\} < f(\alpha)$. We have

$$\forall^*_\nu S\ \exists \beta < g(\alpha)\ [h(\alpha, \beta, S) > \rho].$$

By Lemma 6.8 and monotonicity, $\exists \beta_0 < g(\alpha)\ \forall^*_\nu S\ [h(\alpha, \beta_0, S) > \rho]$. However, $\forall^*_\nu S\ h(\alpha, \beta_0, S) \leq h(\alpha, \beta_0) \leq \rho$. ⊣

Theorem 6.6 has other applications as well. For example, in [12] it is used to show the following.

6.9 Theorem ($\mathrm{AD} + V = L(\mathbb{R})$). *Let κ be a regular cardinal which is either a Suslin cardinal or the successor of a Suslin cardinal. Then κ is $\boldsymbol{\delta}^2_1$-supercompact.*

6.10 Corollary ($\mathrm{AD} + V = L(\mathbb{R})$). *All the projective ordinals $\boldsymbol{\delta}^1_n$ are $\boldsymbol{\delta}^2_1$-supercompact.*

Solovay [34] first showed, assuming $\mathrm{AD}^{\mathbb{R}}$, that $\boldsymbol{\delta}^1_1 = \omega_1$ is λ-supercompact for all $\lambda < \Theta$. The work of Martin-Steel [27] and Harrington-Kechris [5] showed that $\boldsymbol{\delta}^1_1$ is $(\boldsymbol{\delta}^2_1)^{L(\mathbb{R})}$-supercompact from just AD. Woodin later showed from AD that ω_1 is λ-supercompact for all $\lambda < \Theta$. The $\kappa = \boldsymbol{\delta}^1_2$ case of Corollary 6.10 is due to Becker [1].

One of the main ideas in the proof of Theorem 6.6 involves combining certain category methods with the generic coding arguments. We will not prove Theorem 6.6 in detail here. Rather, we present a result whose proof uses the same idea.

We fix some notation for the remainder of this section. We assume AD + $V = L(\mathbb{R})$. κ will henceforth denote a Suslin cardinal, and ν the supercompactness measure on $\mathcal{P}_{\omega_1}(\kappa)$. From the scale analysis in $L(\mathbb{R})$ (see [37]) there is a κ-Suslin set P and a κ-Suslin scale $\{\phi_n\}$ on P with ϕ_0 onto κ (for κ below the supremum of the projective ordinals, that is, $\kappa = \boldsymbol{\delta}^1_{2n+1}$ or $\kappa = (\boldsymbol{\delta}^1_{2n+1})^-$, this is immediate). We write $|x|$ for $\phi_0(x)$, for $x \in P$. The generic coding functions G_0, G are defined relative to $P, \{\phi_n\}$, and are henceforth fixed. The pointclass $S(\kappa)$ of κ-Suslin sets is closed under $\exists^{\omega^\omega}$, so by the Coding Lemma we may code subsets of κ within the pointclass $S(\kappa)$. In particular, strategies (Lipschitz continuous functions) may be coded within $S(\kappa)$. If $\tau \in \omega^\omega$ codes a strategy, we also write τ for the strategy it codes. Thus, if τ codes a strategy $\tau : \kappa^\omega \to \kappa^\omega \times \omega^\omega$, the relation $\tau(\alpha_1, \dots, \alpha_n) = ((\beta_0, \dots, \beta_n), (a_0, \dots, a_n))$ is κ-Suslin in the codes (with respect to ϕ_0). For any other object we need to code by reals, the exact manner in which we do so is not important, say by using the Coding Lemma with respect to some sufficiently large pointclass.

Suppose $\tau : \kappa^\omega \to \kappa^\omega \times \omega^\omega$ is a strategy, and $\vec{s} = (\alpha_0, \alpha_2, \dots) \in \kappa^\omega$. Let $(\alpha_1, \alpha_3, \dots)$ be the ordinal part of τ's response, and $x = (x(0), x(1), \dots)$ the integer part. Let $S = \{\alpha_0, \alpha_1, \dots\} \in \mathcal{P}_{\omega_1}(\kappa)$. We say x codes a comeager set $A \subseteq S^\omega$ and a continuous function $f : A \to \omega^\omega$ provided x_0 codes the comeager set A, and x_1 the continuous function f as follows. x_0 codes A by having each $(x_0)_n$ code a dense open $D_n \subseteq S^\omega$ such that $A = \bigcap_n D_n$. To say y codes the dense open set $D \subseteq S^\omega$ means each $y(k)$ codes a sequence $u_k \in \omega^{<\omega}$, and $D = \bigcup_k N_{u_k^*}$, where if $u_k = (a_0, \dots, a_l)$, then $N_{u_k^*}$ is the basic open set in S^ω determined by the sequence $u_k^* = (\alpha_{a_0}, \dots, \alpha_{a_l})$. Likewise, x_1 codes f by coding a sequence of tuples of integers $(a_0, \dots, a_l, b_0, \dots, b_m)$, where for $u = (a_0, \dots, a_l)$ coding a basic open set in D_k we have $m \geq k$ and for $s \in A \cap N_{u^*}$, $f(s)$ extends $(b_0, \dots, b_m)$. It is easy to see that for a fixed enumeration $\alpha_0, \alpha_1, \dots$ of a set S, the set of x coding a comeager set and a continuous function on S^ω is $\boldsymbol{\Pi}^0_2$.

If $\tau : \kappa^\omega \to \kappa^\omega \times \omega^\omega$ is a strategy and $\vec{s} \in \kappa^\omega$, we usually write $\tau(\vec{s})$ to denote the real obtained as the integer moves of τ against $\vec{s}$.

6.11 Theorem (AD + $V = L(\mathbb{R})$). *Let κ be a Suslin cardinal, and ν the supercompactness measure on $\mathcal{P}_{\omega_1}(\kappa)$. Suppose $F : \mathcal{P}_{\omega_1}(\kappa) \to \lambda < \Theta$. Then* $\mathrm{cf}([F]_\nu) > \kappa$ *iff* $\forall^*_\nu S \in \mathcal{P}_{\omega_1}(\kappa)$ $[\mathrm{cf}(F(S)) > \omega]$.

The full proof of this theorem can be found in [12]. We will prove here a somewhat weaker version which still suffices to illustrate the main idea used in the proof of Theorem 6.6. Specifically, we show here that

(1) If $\forall^*_\nu S$ $[\mathrm{cf}(F(S)) \leq \omega]$ then $\mathrm{cf}([F]_\nu) \leq \kappa$.

(2) If $\forall^*_\nu S$ $[\mathrm{cf}(F(S)) > \kappa]$, then $\mathrm{cf}([F]_\nu) > \kappa$.

The proof of the full Theorem in [12] uses these ideas plus also the Becker-Kechris method used in proving the invariance of $L[T_{2n+1}]$ (see [3]).

Proof. Suppose first that $\forall^*_\nu S$ $\mathrm{cf}(F(S)) \leq \omega$. Play the game where I plays $\alpha_0, \alpha_2, \ldots$, II plays $\alpha_1, \alpha_3, \ldots$ and $x(0), x(1), \in \omega$, and II wins iff x codes an ω sequence of ordinals cofinal in $F(S')$, where $S' = \{|G(\vec{s})_0|, |G(\vec{s})_1|, \ldots\}$, and $\vec{s} = (\alpha_0, \alpha_1, \ldots)$. II has a winning strategy, since II can defeat any strategy for I by enumerating an honest set S closed under I's strategy, and playing an x coding an ω sequence cofinal in $F(S)$. A winning strategy for II gives a Lipschitz continuous function $\mathcal{F} : \kappa^\omega \to \omega^\omega$ (ignoring the ordinal moves) such that for all $\vec{s} \in \kappa^\omega$ $\mathcal{F}(\vec{s})$ codes an ω sequence of ordinals $|\mathcal{F}(\vec{s})_0|, |\mathcal{F}(\vec{s})_1|, \ldots$, and for all $\vec{s}$ enumerating an honest set S closed under $\mathcal{F}$, $\sup_i |\mathcal{F}(\vec{s})_i| = F(S)$.

For $S \in \mathcal{P}_{\omega_1}(\kappa)$ honest and closed under $\mathcal{F}$, define $G(S) \subseteq F(S)$ by: $G(S) = \{G_{n,p}(S) : n \in \omega, p \in S^{<\omega}\}$, where $G_{n,p}(S) \doteq$ the least ordinal $\beta < F(S)$ such that $\forall^*_p \vec{s} \in S^\omega$ $|\mathcal{F}(\vec{s})_n| = \beta$ if such an ordinal exists, and $G_{n,p}(S) = 0$ otherwise. The additivity of category shows that $G(S)$ is cofinal in $F(S)$. Thus, $[G]_\nu$ is cofinal in $[F]$, and by normality, $[G]_\nu$ is a set of size $\leq \kappa$. This shows the first claim.

Suppose now that $\forall^*_\nu S$ $\mathrm{cf}(F(S)) > \kappa$. Suppose towards a contradiction that $\mathrm{cf}([F]_\nu) \leq \kappa$, and let $B \subseteq [F]_\nu$ be cofinal with $|B| \leq \kappa$. By the usual game argument as above and Theorem 2.28, there is a Lipschitz continuous $\mathcal{F} : \kappa^\omega \to \kappa^\omega \times \omega^\omega$ such that for all $\vec{s} \in \kappa^\omega$, $u \doteq \mathcal{F}(\vec{s})$ codes a $S(\kappa)$-bounded prewellordering (C_u, ψ_u) of some limit length which we denote by $|u|$, and for all $\vec{s}$ enumerating an honest set S closed under $\mathcal{F}$, $|u| = F(S)$.

If $\beta < [F]_\nu$, we say a real z is *β-good* if:

(1) z codes a Lipschitz continuous function $z : \kappa^\omega \to \kappa^\omega \times \omega^\omega$ such that if $s_0 \in \kappa^\omega$ enumerates an honest set S closed under z and $\mathcal{F}$, then $z(s_0)$ codes a comeager set $A_{z(s_0)} \subseteq S^\omega$, and a continuous function $z(s_0, -) : A_{z(s_0)} \to \omega^\omega$ such that for all $s_1 \in A_{z(s_0)}$, $w \doteq z(s_0, s_1)$ is in the $S(\kappa)$-bounded union (C_u, ψ_u) coded by $u \doteq \mathcal{F}(s_1)$.

(2) $\forall^*_\nu S \in \mathcal{P}_{\omega_1}(\kappa)$ $\forall^* s_0$ $\forall^* s_1 \in S^\omega$ the rank of $w = z(s_0, s_1)$ in the $S(\kappa)$-bounded union coded by $u = \mathcal{F}(s_1)$ is greater than $\beta(S)$. (Recall $S \to \beta(S)$ represents β.)

We first claim that for all $\beta < [F]_\nu$ there is a $z \in \omega^\omega$ such that z is β-good. To see this, fix a function $S \to \beta(S)$ representing β with respect to ν, and play the game where I plays $\alpha_0, \alpha_2, \ldots$, II plays $\alpha_1, \alpha_3, \ldots$, and $x(0), x(1), \ldots$, and II wins iff x codes a comeager set $A_x \subseteq S^\omega$, where $S = \{|G(\vec{s})_0|, |G(\vec{s})_1|, \ldots\}$, $\vec{s} = (\alpha_0, \alpha_1, \ldots)$, and a continuous function $x(-) : A_x \to \omega^\omega$ such that for all $s_1 \in A_x$, $x(s_1) = \overline{0}$ if $\mathcal{F}(s_1) = u$ does not code $F(S)$, and otherwise the rank of $x(s_1)$ in the $S(\kappa)$-bounded union coded by u is $> \beta(S)$. This game is again determined. Suppose I won by σ. Let S be an honest set closed under σ and $\mathcal{F}$, and such that $\mathrm{cf}(F(S)) > \kappa$, and $F(S) > \beta(S)$. II will enumerate S in the $\alpha_1, \alpha_3, \ldots$. Let $R \subseteq S^\omega \times \omega^\omega$ be defined by: $R(s_1, w) \longleftrightarrow [s_1$ enumerates $S \wedge w \in C_u$ where $u = \mathcal{F}(s_1) \wedge \psi_u(w) \geq \beta(S)]$. From AD, we may uniformize R by R' on a comeager set. Also, every function defined on a comeager subset of S^ω is continuous restricted to a comeager set. Let $x \in \omega^\omega$ code such a comeager set $A_x \subseteq S^\omega$ (coding neighborhoods using only the $\alpha_1, \alpha_3, \ldots$) and continuous function $x(-) : A_x \to \omega^\omega$. If II plays this x, then II defeats I. A winning strategy τ for II then gives a β-good real.

By the Coding Lemma, there is an $S(\kappa)$ set $C \subseteq \omega^\omega$ such that $\forall \tau \in C$ $\exists \beta < [F]_\nu$ τ is β-good, and $\forall \beta \in B$ $\exists \tau \in C$ τ is β-good. We now define $G : \mathcal{P}_{\omega_1}(\kappa) \to \mathrm{On}$ such that $[G]_\nu < [F]_\nu$ but $\forall \beta \in B$ $\forall^*_\nu S$ $G(S) > \beta(S)$, a contradiction.

Let S be honest and closed under $\mathcal{F}$. Let $G(S)$ be the least $\alpha \in \mathrm{On}$ such that $\forall^* s_1 \in S^\omega$ $G(S, s_1) < \alpha$, where $G(S, s_1)$ is defined as follows. Let $u = \mathcal{F}(s_1)$, so (C_u, ψ_u) is a $S(\kappa)$-bounded prewellordering of length $F(S)$. Set $G(S, s_1) = \sup\{\psi_u(w) : w \in B_{s_1}\}$, where

$$w \in B_{s_1} \longleftrightarrow \exists s_0 \text{ enumerating } S \; \exists \tau \in C \; \big[(S \text{ is closed under } \tau) \wedge (s_1 \in A_{\tau(s_0)}) \wedge (w = \tau(s_0, s_1))\big].$$

Easily, $B_{s_1} \in S(\kappa)$. Also, $B_{s_1} \subseteq C_u$, and so by boundedness, $G(S, s_1) < F(S)$ for all $s_1 \in S^\omega$. By additivity of category, $G(S) < F(S)$. Thus, $[G]_\nu < [F]_\nu$.

Fix now $\beta \in B$ and a function $S \to \beta(S)$ representing β, and let $\tau \in C$ be β-good. Let S be honest, closed under $\mathcal{F}$ and τ, and such that (6.2) in the definition of β-good above holds for S for this τ. We show that $G(S) > \beta(S)$, a contradiction. It is enough to show that $\forall^* s_1 \in S^\omega$ $G(S, s_1) > \beta(S)$. Fix s_0 enumerating S so that the remaining clause in (6.2) of β-good is satisfied. If $s_1 \in A_{\tau(s_0)}$ and $w = \tau(s_0, s_1)$, then $w \in B_{s_1}$ (using τ and s_0 as witnesses) and so $G(S, s_1) \geq \psi_u(w)$, where $u = \mathcal{F}(s_1)$. On the other hand, from the choice of S, s_0 and (6.2) of β-good we have $\forall^* s_1$ $\psi_u(w) > \beta(S)$. Thus, $\forall^* s_1$ $G(S, s_1) > \beta(S)$. ⊣

6.3. Some Final Remarks

We close this chapter with some final (somewhat tentative) thoughts on extending the structural theory throughout $L(\mathbb{R})$. The analysis, of course, is inductive, and proceeds by induction on the Suslin cardinals. As we remarked earlier, the arguments of Sects. 4, 5 should provide the necessary ingredients at successor Suslin cardinals. At singular Suslin cardinals δ, Theorems 6.6, 6.7, and similar results should provide a basis for the analysis. Aside from providing an analysis of the uniform cofinalities (Theorem 6.7), these techniques should provide a method for “gluing together” the description analyses at the lower Suslin cardinals to obtain one at δ (Theorem 6.7 may be viewed as a simple case of this; it shows how to glue together the pointwise cofinalities below δ to obtain a uniform cofinality).

At inaccessible Suslin cardinals δ, one gets some facts for "free", such as the strong partition relation on δ (see [22]). However, it still seems necessary to analyze the measures on δ to permit analysis at the next Suslin cardinal. One of the main problems here, as we mentioned earlier, is analyzing the semi-normal measures on δ (which is where the first step in the "pressing down" analysis of the measures leaves one; see the proof of Theorem 4.8). The normal measures on δ corresponding to fixed cofinalities $\kappa < \delta$ seem well-behaved (for example, we get Theorem 5.10), but there are, in general, many more semi-normal measures on δ.

Let $S \subseteq \delta$ be a "thin" stationary set. By thin we mean for all $\alpha \in S$, $S \cap \alpha$ is not stationary in α. Then the closed unbounded filter restricted to S defines a normal measure μ_S on δ. We refer to this as the *atomic normal measure* corresponding to S. This is shown using the strong partition relation on δ. For example, to see this defines an ultrafilter, for $A \subseteq \delta$ consider the partition of $f : \delta \to \delta$ of the correct type according to whether $\alpha(f, S) \in A$, where $\alpha(f, S) =$ the least limit point of $\mathrm{ran}(f)$ in S.

Given thin stationary sets S_1, S_2, define $S_1 \prec S_2$ iff there is a closed unbounded $C \subseteq \delta$ such that for all $f : \delta \to C$ of the correct type, $\alpha(f, S_1) < \alpha(f, S_2)$. The strong partition relation on δ shows that $\prec$ is a wellordering on equivalence classes $[S]$, where $S \sim T$ iff there is a closed unbounded $C \subseteq \delta$ such that $S \cap C = T \cap C$. Equivalently, $S_1 \prec S_2$ iff there is a closed unbounded $C \subseteq \delta$ such that for all $\alpha \in C \cap S_2$, S_1 is stationary in α. Let $o(\delta)$ denote the rank of this prewellordering, and $o(S)$ the rank of S in $\prec$ (this forms a generalized notion of Mahlo rank; δ is inaccessible if $o(\delta) \geq \delta$, Mahlo if $o(\delta) \geq \delta + 1$, etc.). Note that the atomic normal measure corresponding to S depends only on $[S]$. For $\beta < o(\delta)$, let $[S_\beta]$ denote the βth equivalence class in the stationary set ordering.

If $o(\delta)$ is fairly small compared with δ, we can transfer a semi-normal measure μ on δ onto a smaller ordinal, and thereby begin to analyze μ. Suppose, for example, $o(\delta) = \delta + \omega_1$, and μ concentrates on inaccessible cardinals. A generic coding argument, which we omit, shows that we may pick thin stationary sets S_α for $\alpha < \omega_1$ which are pairwise disjoint and $o(S_\alpha) = \delta + \alpha$. For μ almost all $\alpha < \delta$, let $\alpha \in S_{f(\alpha)}$. Then $\nu = f(\mu)$ is a measure on ω_1. Let μ' be the measure obtained by integrating the μ_S with respect to ν, that is, $\mu'(A) = 1$ iff $\forall^*_\nu \alpha < \omega_1\ \forall^*_{\mu_{S_\alpha}} \beta\ (\beta \in A)$. It is then not hard to see that $\mu = \mu'$. Thus we have analyzed the semi-normal measures on δ.

One can attempt to extend these arguments to larger values of $o(\delta)$. Suppose, for example, that $o(\delta) = j_{\nu_\omega}(\delta)$, where ν_ω denotes the ω-cofinal normal measure on δ. Using the strong partition relation on δ, ν_ω induces a measure $\mathcal{V}$ on $j_{\nu_\omega}(\delta)$ (using functions of the correct type, say). Integrating the $\nu_{[S_\alpha]}$ using $\mathcal{V}$ produces a semi-normal measure ν on δ (there is a problem now in trying to pick representatives S_α for the equivalence classes; the measure $\nu_{[S_\alpha]}$, however, is still well-defined). In fact, if $o(\delta)$ is large enough we may lift an arbitrary measure μ on δ to a new measure ν on δ in this manner (using μ in place of ν_ω). It seems reasonable (but not clear) that one might reverse the above process, and thus reduce the semi-normal measure ν on δ to a "smaller" measure μ on δ and proceed inductively. The measure is smaller in the following sense.

6.12 Lemma. *Let μ be a measure on δ, where δ is an inaccessible Suslin cardinal (and so has the strong partition property). Let $\mathcal{V}$ be the measure on $j_\mu(\delta)$ induced by the strong partition property, functions $F : \delta \to \delta$ of the correct type, and the measure μ on δ. Assume $o(\delta) \geq j_\mu(\delta)$, and let ν be the measure on δ defined by: $\nu(A) = 1$ iff $\forall^*_{\mathcal{V}} \beta < j_\mu(\delta)\ \forall^*_{[S_\beta]} \alpha < \delta\ \alpha \in A$. Then $j_\mu(\delta) < j_\nu(\delta)$.*

The proof of the lemma is not difficult, we omit it (the basic fact is that if $S_1 \prec S_2$ then $j_{S_1}(\delta)$ embeds into $[f]_{S_2}$, where $f(\alpha) =$ the next Suslin cardinal after α).

Unfortunately, the main definite result along these lines at the moment is a negative one; it asserts that for Suslin cardinals δ where $S(\delta)$ is closed under real quantification, $o(\delta)$ is closed under the above ultrapower operation in the following precise sense (cf. [10]).

6.13 Theorem. *Let δ be a Suslin cardinal with $S(\delta)$ closed under $\exists^{\omega^\omega}$, $\forall^{\omega^\omega}$. Let $\beta < o(\delta)$, and ν_β the corresponding atomic normal measure. Then $j_{\nu_\beta}(\delta) < o(\delta)$. Furthermore, $\mathrm{cf}(o(\delta)) > \delta$, and $\mathrm{cf}(o(\delta)) \neq j_{\nu_\beta}(\delta)$ for all $\beta < o(\kappa)$.*

It is conjectured in [10] that $o(\delta)$ is regular for such δ; Theorem 6.13 seems a step towards showing that. A recent theorem of Steel [38] shows that in $L(\mathbb{R})$ every regular cardinal below Θ is measurable (using techniques of inner model theory). Thus, granting the above conjecture, new (normal) measures appear on δ which seem not to be approachable "from below" in the previous sense. Undoubtedly, new techniques will be necessary.

\end{array}$$

Diagram 22.1: The game $G_\omega(C)$

Given a set $C \subseteq \omega^\omega$ define $G_\omega(C)$, the length ω game with payoff set C, to be played as follows: Players I and II collaborate to produce an infinite sequence $x = \langle x(i) \mid i < \omega \rangle$ of natural numbers. They take turns as in Diagram 22.1, I picking $x(i)$ for even i and II picking $x(i)$ for odd i. If at the end the sequence x they produce belongs to C then player I wins; and otherwise player II wins. $G_\omega(C)$, or any other game for that matter, is *determined* if one of the two players has a *winning strategy*, namely a strategy for the game that wins against all possible plays by the opponent. The set C is said to be determined if the corresponding game $G_\omega(C)$ is determined. Determinacy is said to hold for a pointclass $\mathbf{\Gamma}$ if all sets of reals in $\mathbf{\Gamma}$ are determined. (Following standard abuse of notation we identify $\mathbb{R}$ with ω^ω.)

Perhaps surprisingly, determinacy has turned out to have a crucial and central role in the study of definable sets of reals. This role resulted from two lines of discoveries. On the one hand it was seen that determinacy for definable sets of reals, taken as an axiom, can be used to prove many desirable results about these sets, and indeed to obtain a rich and powerful structure theory. On the other hand it was seen that determinacy can be proved for definable sets of reals, from large cardinal axioms.

The earliest work on consequences of determinacy, by Banach, Mazur, and Ulam [23] at the famous Scottish Café in the 1930's, Oxtoby [35], Davis [3], and Mycielski-Swierczkowski [27], established that determinacy for a pointclass Γ implies that all sets of reals in Γ have the Baire property, have the perfect set property, and are Lebesgue measurable. Later on Blackwell [2] used the determinacy of open sets to prove Kuratowski's reduction theorem. (In modern terminology this theorem states that for any $\mathbf{\Pi}^1_1$ sets A, B, there are $A^* \subseteq A$ and $B^* \subseteq B$ so that $A^* \cup B^* = A \cup B$ and $A^* \cap B^* = \emptyset$.) Inspired by his methods, Martin [15] and Addison-Moschovakis [1] used determinacy for projective sets to prove reduction for each of the pointclasses $\mathbf{\Pi}^1_n$, $n > 1$ odd, and indeed prove for these pointclasses some of the structural properties that hold for $\mathbf{\Pi}^1_1$. Their results initiated a wider study of consequences of the Axiom of Determinacy (AD), the assertion that all sets of reals are determined, proposed initially by Mycielski-Steinhaus [26]. Over time this line of research, which the reader may find in Moschovakis [25], Jackson [7], and of course the Cabal volumes [9–12], established determinacy axioms as natural assumptions in the study of definable sets of reals.

It should be emphasized that AD was not studied as an assumption about V. (It contradicts the axiom of choice.) Rather, it was studied as an assumption about more restrictive models, models which contain all the reals but have only definable sets of reals. A prime example was the model $L(\mathbb{R})$, consisting of all sets which are constructible from $\{\mathbb{R}\} \cup \mathbb{R}$. It was known by work of Solovay [37] that this model need not satisfy the axiom of choice, and that in fact it is consistent that all sets of reals in this model are Lebesgue measurable. The extra assumption of AD allowed for a very careful analysis of $L(\mathbb{R})$, in terms that combined descriptive set theory, fine structure, and infinitary combinatorics. It seemed plausible that if there were a model of AD, $L(\mathbb{R})$ would be it.

Research into the consequences of determinacy was to some extent done on faith. The established hierarchy of strength in set theory involved large cardinals axioms, axioms asserting the existence of elementary embeddings from the universe of sets into transitive subclasses, not determinacy axioms. A great deal of work has been done in set theory on large cardinal axioms, with Kanamori [8] a good reference, and large cardinals have come to be regarded as the backbone of the universe of sets, providing a hierarchy of consistency strengths against which all other statements are measured. From $\mathsf{AD}^{L(\mathbb{R})}$ one could obtain objects in $L(\mathbb{R})$ which are very strongly reminiscent of large cardinal axioms in V, suggesting a connection between the two. Perhaps the most well-known of the early results in this direction is Solovay's proof that ω_1 is measurable under AD. Further justification for the use of $\mathsf{AD}^{L(\mathbb{R})}$ was provided by proofs of determinacy for simply definable sets: for open sets in Gale-Stewart [6], for Borel sets in Martin [18, 17], and for $\mathbf{\Pi}^1_1$ sets from a measurable cardinal in Martin [16], to name the most well-known. Additional results, inspired by Solovay's proof that ω_1 is measurable under AD and Martin's proof of $\mathbf{\Pi}^1_1$ determinacy from a measurable cardinal, identified detailed and systematic correspondences of strength, relating models for many measurable cardinals to determinacy for pointclasses just above $\mathbf{\Pi}^1_1$. These levels are well below the pointclass of all sets in $L(\mathbb{R})$, but still the accumulated evidence of the results suggested that there should be a proof of $\mathsf{AD}^{L(\mathbb{R})}$ from large cardinals, and conversely a construction of inner models with these large cardinals from $\mathsf{AD}^{L(\mathbb{R})}$. In 1985 the faith in this connection was fully vindicated. A sequence of results of Foreman, Magidor, Martin, Shelah, Steel, and Woodin (see [5, 36, 21, 22, 43] for the papers involved and the introduction in [30] for an overview) brought the identification of a new class of large cardinals, known now as Woodin cardinals, new structures of iterated ultrapowers, known now as iteration trees, and new proofs of determinacy, including a proof of $\mathsf{AD}^{L(\mathbb{R})}$. Additional results later on produced Woodin cardinals from determinacy axioms, and indeed established a deep and intricate connection between the descriptive set theory of $L(\mathbb{R})$ under AD, and inner models for Woodin cardinals.

In this chapter we prove $\mathsf{AD}^{L(\mathbb{R})}$ from Woodin cardinals. Our exposition is complete and self-contained: the necessary large cardinals are introduced in Sect. 1, and every result about them which is needed in the course of proving $\mathsf{AD}^{L(\mathbb{R})}$ is included in the chapter, mostly in Sects. 2 and 3. The climb to $\mathsf{AD}^{L(\mathbb{R})}$ is carried out progressively in the remaining sections. In Sect. 4 we introduce homogeneously Suslin sets and present a proof of determinacy for $\mathbf{\Pi}^1_1$ sets from a measurable cardinal. In Sect. 5 we move up and present a proof of projective determinacy from Woodin cardinals. The proof in essence converts the quantifiers over reals appearing in the definition of a projective set to quantifiers over iteration trees and branches through the trees, and these quantifiers in turn are tamed by the iterability results in Sect. 2. In Sect. 6 we improve on the results in Sect. 5 by reducing the large cardinal assumption needed for the determinacy of universally Baire sets. The section also lays the ground for Sect. 7, where we show that models with Woodin cardinals can be iterated to absorb an arbitrary given real into a generic extension. Finally, in Sect. 8 we derive $\mathsf{AD}^{L(\mathbb{R})}$.

There is much more to be said about proofs of determinacy that cannot be fitted within the scope of this chapter. Martin [18, 19] and Neeman [32] for example prove weaker forms of determinacy (from weaker assumptions) using completely different methods, which handle increments of payoff complexity corresponding to countable unions, rather than real quantifiers. Perhaps more importantly there are strengthenings of $\mathsf{AD}^{L(\mathbb{R})}$ in two directions, one involving stronger payoff sets, and the other involving longer games. In the former direction the reader should consult Steel [39], which contains a proof of Woodin's derived model theorem, a fundamental theorem connecting models of AD to symmetric extensions of models of choice with Woodin cardinals, and uses this theorem to establish AD in models substantially stronger than $L(\mathbb{R})$. In the latter direction the reader should consult Neeman [30, 33], which contain proofs of determinacy for games of fixed countable lengths, variable countable lengths, and length ω_1.

Historical Remarks. With some exceptions, noted individually inside the various sections, the following remarks summarize credits for the material in the chapter. Extenders were introduced by Mitchell [24], then simplified to their present forms by Jensen. The related material on ultrapowers in Sect. 1 is by now folklore within set theory. Its history can be found in Kanamori [8]. The material on iteration trees in Sect. 1 is due to Martin-Steel [22] and so is all the material in Sect. 2. The material in Sect. 3 is due to Martin-Steel [21], and follows the exposition of Neeman [30]. The material in Sect. 4 is due to Martin. The material in Sect. 5 is due to Martin-Steel [21]. (The exposition here is specifically geared to easing the transition to the next section.) The material in Sects. 6 and 7 is due to Neeman. $\mathsf{AD}^{L(\mathbb{R})}$ from infinitely many Woodin cardinals and a measurable cardinal above them is due to Woodin, proved using the methods of stationary tower forcing (see Larson [14]) and an appeal to the main theorem, Theorem 5.11, in Martin-Steel [21]. A proof using Woodin's genericity iterations [38, 4.3] and fine structure instead of stationary tower forcing is due to Steel, and the proof reached in this chapter (using a second form of genericity iterations and no fine structure) is due to Neeman.

1. Extenders and Iteration Trees

Throughout this chapter we shall deal with elementary embeddings of the universe into transitive classes. Here we develop tools for the study of such embeddings. Most basic among them is the ultrapower construction, which allows the creation of an embedding $\pi : V \to M$ from the restriction of such an embedding to a set. We begin by characterizing the restrictions.

1.1 Remark. By embedding we always mean elementary embedding, even when this is not said explicitly. As a matter of convention when we say a wellfounded model of set theory we mean a *transitive* model equipped with the standard membership relation $\in$. More generally we always take the wellfounded parts of our models to be transitive.

Let $(*, *)$ denote the Gödel pairing operation on ordinals. Given sets of ordinals A and B define $A \times B$ to be $\{(\alpha, \beta) \mid \alpha \in A \wedge \beta \in B\}$. Note that $A \times B$ is then a set of ordinals too. We refer to it as the *product* of A and B. In general define finite products of sets of ordinals as follows: For $n = 0$ set $\prod_{i \leq n} A_i$ equal to A_0; for $n > 0$ set $\prod_{i \leq n} A_i$ equal to $(\prod_{i \leq n-1} A_i) \times A_n$. Define finite sequences of ordinals similarly by setting the empty sequence equal to 0, setting (α) equal to α, and setting $(\alpha_0, \ldots, \alpha_n)$ equal to $((\alpha_0, \ldots, \alpha_{n-1}), \alpha_n)$ for $n > 0$.

If A is a set of ordinal sequences of length n, and $\sigma : n \to n$ is a permutation of n, then define σA by setting

$$(\alpha_0, \ldots, \alpha_{n-1}) \in \sigma A \iff (\alpha_{\sigma^{-1}(0)}, \ldots, \alpha_{\sigma^{-1}(n-1)}) \in A.$$

If A is a set of ordinal sequences of length $n + 1$, then define $\mathrm{bp}(A)$ to be the set $\{(\alpha_0, \ldots, \alpha_{n-1}) \mid (\exists \xi \in \alpha_0)(\alpha_0, \ldots, \alpha_{n-1}, \xi) \in A\}$. $\mathrm{bp}(A)$ is the *bounded projection* of A.

By a *fiber* of sets $\langle A_i \mid i < \omega \rangle$ we mean a sequence $\langle \alpha_i \mid i < \omega \rangle$ so that $(\alpha_0, \ldots, \alpha_{i-1}) \in A_i$ for every $i < \omega$.

1.2 Definition. A (*short*) *extender* is a function E that satisfies the following conditions:

(1) The domain of E is equal to $\mathcal{P}(\kappa)$ for an ordinal κ closed under Gödel pairing.

(2) E sends ordinals to ordinals and sets of ordinals to sets of ordinals.

(3) $E(\alpha) = \alpha$ for $\alpha < \kappa$, and $E(\kappa) \neq \kappa$.

(4) E respects products, intersections, set differences, membership, the predicates of equality and membership, permutations, and bounded projections. More precisely this means that for all $A, B \in \mathrm{dom}(E)$, all ordinals $\alpha \in \mathrm{dom}(E)$, and all permutations σ of the appropriate format:

(a) $E(A \times B) = E(A) \times E(B)$, $E(A \cap B) = E(A) \cap E(B)$, and $E(A - B) = E(A) - E(B)$.

(b) $\alpha \in A \Longrightarrow E(\alpha) \in E(A)$.

(c) $E(\{(\alpha, \beta) \in A \times A \mid \alpha = \beta\})$ is equal to $\{(\alpha, \beta) \in E(A) \times E(A) \mid \alpha = \beta\}$, and similarly with $\alpha \in \beta$ replacing $\alpha = \beta$.

(d) $E(\sigma A) = \sigma E(A)$.

(e) $E(\mathrm{bp}(A)) = \mathrm{bp}(E(A))$.

(5) E is *countably complete*. Precisely, this means that for any sequence $\langle A_i \mid i < \omega \rangle$ of sets which are each in the domain of E, if there exists a fiber through $\langle E(A_i) \mid i < \omega \rangle$ then there exists also a fiber through $\langle A_i \mid i < \omega \rangle$.

The first ordinal moved by E is called the *critical point* of E, denoted $\mathrm{crit}(E)$. By condition (3), this critical point is precisely equal to the ordinal κ of condition (1). The set $\bigcup_{A \in \mathrm{dom}(E)} E(A)$ is called the *support* of E, denoted $\mathrm{spt}(E)$. Using condition (2) it is easy to see that the support of E is an ordinal.

1.3 Remark. Condition (3) limits our definition to extenders with domains consisting of just the subsets of the extenders' critical points. It is this condition that makes our extenders "short". We shall see later that it has the effect of limiting the strength of embeddings generated by our (short) extenders to a level known as superstrong. This level is more than adequate for our needs. We shall therefore deal exclusively with short extenders in this chapter, and refer to them simply as extenders. For a more general definition see Neeman [31].

1.4 Definition. A (two-valued) *measure* over a set U is a function μ from $\mathcal{P}(U)$ into $\{0, 1\}$ with the properties that $\mu(\emptyset) = 0$, $\mu(U) = 1$, and $\mu(X \cup Y) = \mu(X) + \mu(Y)$ for any disjoint $X, Y \subseteq U$.

1.5 Remark. Given $a \in \mathrm{spt}(E)$ define $E_a : \mathcal{P}(\kappa) \to \{0, 1\}$ to be the function given by $E_a(X) = 1$ if $a \in E(X)$, and 0 otherwise. E_a is then a measure over κ. It has been customary to define extenders by specifying properties of the sequence $\langle E_a \mid a \in \mathrm{spt}(E) \rangle$ equivalent to the properties of E specified in Definition 1.2. For a definition of extender through properties of $\langle E_a \mid a \in \mathrm{spt}(E) \rangle$ see Martin-Steel [21, §1A] (short extenders) and Kanamori [8, §26] (the general case).

By a *pre-extender* over a model Q we mean an object E that satisfies conditions (1)–(4) in Definition 1.2, with $\mathcal{P}(\kappa)$ in condition (1) replaced by $\mathcal{P}^Q(\kappa)$, but not necessarily condition (5). The point of this distinction is that condition (5) involves second-order quantification over E, whereas conditions (1)–(4) involve only E, the power set of κ, and bounded quantifiers over the transitive closure of E. By removing condition (5) we obtain a notion that is absolute in the sense given by Claim 1.7:

1.6 Definition. Two models Q and N *agree to* an ordinal ρ if (ρ is contained in the wellfounded part of both models, and) $\mathcal{P}^Q(\xi) = \mathcal{P}^N(\xi)$ for each $\xi < \rho$. Q and N *agree past* an ordinal κ if they agree to $\kappa + 1$.

1.7 Claim. *Let Q and N be models of set theory. Suppose that E is an extender in N, and let $\kappa = \mathrm{crit}(E)$. Suppose that Q and N agree past κ. Then E is a pre-extender over Q.*

Extenders are naturally induced by elementary embeddings. Let $\pi : V \to M$ be a non-trivial elementary embedding of V into some wellfounded class model M. Let κ be the critical point of π, namely the first ordinal moved by π. Let $\lambda \leq \pi(\kappa)$ be an ordinal closed under Gödel pairing. Define the λ-*restriction* of π to be the map E given by:

(R1) $\mathrm{dom}(E) = \mathcal{P}(\kappa)$.

(R2) $E(X) = \pi(X) \cap \lambda$ for each $X \in \mathrm{dom}(E)$.

It is then easy to check that E is an extender. The items in condition (4) of Definition 1.2 follow directly from the elementarity of π and, in the case of condition (4e), the absoluteness between M and V of formulae with only bounded quantifiers. Condition (5) follows from the elementarity of π and the *wellfoundedness* of M. If a fiber through $\langle E(A_i) \mid i < \omega\rangle$ exists in V then using the wellfoundedness of M such a fiber must also exist in M. Its existence can then be pulled back via π to yield a fiber through $\langle A_i \mid i < \omega\rangle$.

1.8 Remark. The λ-restriction makes sense also in the case of an embedding into an illfounded model M, so long as the wellfounded part of M contains λ. But countable completeness may fail in this case, and the λ-restriction need only be a pre-extender.

The description above shows how extenders are induced by elementary embeddings into wellfounded models. Extenders also give rise to such elementary embeddings, through the ultrapower construction, which we describe next.

Let ZFC^- consist of the standard axioms of ZFC excluding the Power Set Axiom. Fix a model Q of ZFC^- and a pre-extender E over Q. Let $\kappa = \mathrm{crit}(E)$. Let $\mathcal{F}$ be the class of functions $f \in Q$ so that $\mathrm{dom}(f) \subseteq \kappa$. Let $\mathcal{D} = \{\langle f, a\rangle \mid f \in \mathcal{F} \wedge a \in E(\mathrm{dom}(f))\}$.

For two functions $f, g \in \mathcal{F}$ set $Z^{=}_{f,g} = \{(\alpha, \beta) \mid f(\alpha) = g(\beta)\}$ and $Z^{\in}_{f,g} = \{(\alpha, \beta) \mid f(\alpha) \in g(\beta)\}$. Both $Z^{=}_{f,g}$ and $Z^{\in}_{f,g}$ are then subsets of κ in Q, and therefore elements of the domain of E.

Define a relation $\sim$ on $\mathcal{D}$ by setting $\langle f, a\rangle \sim \langle g, b\rangle$ iff $(a, b) \in E(Z^{=}_{f,g})$. One can check using condition (4) in Definition 1.2 that $\sim$ is an equivalence relation. Let $[f, a]$ denote the equivalence class of $\langle f, a\rangle$. Let $\mathcal{D}^*$ denote $\mathcal{D}/{\sim}$. Define a relation R on $\mathcal{D}^*$ by setting $[f, a]\ R\ [g, b]$ iff $(a, b) \in E(Z^{\in}_{f,g})$. Again using condition (4) in Definition 1.2 one can check that R is well defined.

The following property, known as Łoś's Theorem, can be proved from the various definitions, by induction on the complexity of φ:

1.9 Theorem (Łoś). *Let $[f_1, a_1], \ldots, [f_n, a_n]$ be elements of $\mathcal{D}^*$. Let $\varphi = \varphi(v_1, \ldots, v_n)$ be a formula. Let Z be the set*

$$\{(\alpha_1, \ldots, \alpha_n) \mid Q \models \varphi[f_1(\alpha_1), \ldots, f_n(\alpha_n)]\}.$$

Then $(\mathcal{D}^*, R) \models \varphi[[f_1, a_1], \ldots, [f_n, a_n]]$ iff $(a_1, \ldots, a_n)$ belongs to $E(Z)$.

For each set x let c_x be the function with domain $\{0\}$ and value $c_x(0) = x$. From Łoś's Theorem it follows that the map $x \mapsto [c_x, 0]$ is elementary, from Q into $(\mathcal{D}^*, R)$. (In particular, $(\mathcal{D}^*, R)$ satisfies ZFC^-.)

1.10 Definition. The *ultrapower* of Q by E, denoted $\mathrm{Ult}(Q, E)$, is the structure $(\mathcal{D}^*; R)$. The *ultrapower embedding* is the map $j : Q \to \mathrm{Ult}(Q, E)$ defined by $j(x) = [c_x, 0]$.

In general $\mathrm{Ult}(Q, E)$ need not be wellfounded. (If it is then we of course identify it with its transitive collapse, and identify R with $\in$.) But notice that wellfoundedness is a consequence of countable completeness: if $\langle [f_i, a_i] \mid i < \omega \rangle$ is an infinite descending sequence in R, then the sequence of sets $A_i = \{(\alpha_0, \ldots, \alpha_{i-1}) \mid f_0(\alpha_0) \ni f_1(\alpha_1) \ni \cdots \ni f_{i-1}(\alpha_{i-1})\}$ violates countable completeness. Ultrapowers by extenders, as opposed to mere pre-extenders, are therefore wellfounded.

Let $\lambda = \mathrm{spt}(E)$. Using the various definitions one can prove the following two properties of the ultrapower. The first relates the ultrapower embedding back to the extender E, and the second describes a certain minimality of the ultrapower:

(U1) The λ-restriction of j is precisely equal to E.

(U2) Every element of $\mathrm{Ult}(Q, E)$ has the form $j(f)(a)$ for some function $f \in \mathcal{F}$ and some $a \in \lambda$.

These properties determine the ultrapower and the embedding completely.

The following lemma relates an embedding $\pi : V \to M$ to the ultrapower embedding by the extender over V derived from π. It shows that the ultrapower by the λ-restriction of π captures π up to λ.

1.11 Lemma. *Let $\pi : V \to M$ be an elementary embedding of V into a wellfounded model M, and let $\kappa = \mathrm{crit}(\pi)$. Let $\lambda \leq \pi(\kappa)$ be an ordinal closed under Gödel pairing. Let E be the λ-restriction of π. Let $N = \mathrm{Ult}(V, E)$ and let $j : V \to N$ be the ultrapower embedding.*

Then there is an elementary embedding $k : N \to M$ with $\pi = k \circ j$ (see Diagram 22.2) and $\mathrm{crit}(k) \geq \lambda$.

1.12 Exercise. Let μ be a two-valued measure over a cardinal κ. Let $\mathcal{F}$ be the class of functions from κ into V. For $f, g \in \mathcal{F}$ set $f \sim g$ iff $\{\xi < \kappa \mid f(\xi) = g(\xi)\}$ has measure one. Show that $\sim$ is an equivalence relation. Let $\mathcal{F}^* = \mathcal{F}/{\sim}$. For $f \in \mathcal{F}$ let $[f]$ denote the equivalence class of f. Define

$$\begin{tikzcd} & M \\ V \arrow[ur, "\pi"] \arrow[r, "j"'] & N = \mathrm{Ult}(V, E) \arrow[u, "k"'] \end{tikzcd}$$

Diagram 22.2: The original map π and the ultrapower map j

a relation R on $\mathcal{F}^*$ by $[f]\ R\ [g]$ iff $\{\xi < \kappa \mid f(\xi) \in g(\xi)\}$ has measure one. Show that R is well defined.

Define $\mathrm{Ult}(V, \mu)$, the *ultrapower* of V by μ, to be the structure $(\mathcal{F}^*; R)$, and define the *ultrapower embedding* $j : V \to \mathrm{Ult}(V, \mu)$ by $j(x) = [c_x]$ where $c_x : \kappa \to V$ is the constant function which takes the value x.

Show that ultrapower embedding is elementary. Show that if μ is countably complete, meaning that $\mu(\bigcap_{n<\omega} X_n) = 1$ whenever $\langle X_n \mid n < \omega\rangle$ is a sequence of sets of measure one, then the ultrapower is wellfounded.

1.13 Exercise. The *seed* of a measure μ is the element [id] of the ultrapower, where $\mathrm{id} : \kappa \to V$ is the identity function. Let s be the seed of μ. Prove that every element of $\mathrm{Ult}(V, \mu)$ has the form $j(f)(s)$, where $j : V \to \mathrm{Ult}(V, \mu)$ is the ultrapower embedding.

1.14 Exercise. A (two-valued) measure μ over a set U is called *non-principal* just in case that $\mu(\{\xi\}) = 0$ for each singleton $\{\xi\}$. μ is *κ-complete* if $\mu(\bigcap_{\alpha<\tau} X_\alpha) = 1$ whenever $\tau < \kappa$ and $X_\alpha \subseteq U$ $(\alpha < \tau)$ are all sets of measure one. A cardinal κ is called *measurable* if there is a two-valued, non-principal, κ-complete measure over κ. Let κ be measurable, let μ witness this, and let $j : V \to \mathrm{Ult}(V, \mu)$ be the ultrapower embedding. Show that $\mathrm{crit}(j) = \kappa$.

1.15 Exercise. Let κ be measurable and let μ witness this. Let $M = \mathrm{Ult}(V, \mu)$. Prove that $\mathcal{P}(\kappa) \subseteq M$, and that $\mathcal{P}(\mathcal{P}(\kappa)) \not\subseteq M$.

Hint. To see that $\mathcal{P}(\kappa) \subseteq M$, note that $j(X) \cap \kappa = X$ for each $X \subseteq \kappa$ (where $j : V \to M$ is the ultrapower embedding).

To see that $\mathcal{P}(\mathcal{P}(\kappa)) \not\subseteq M$, prove that $\mu \notin M$: Suppose for contradiction that $\mu \in \mathrm{Ult}(V, \mu)$. Without loss of generality you may assume that κ is the smallest cardinal carrying a measure μ with $\mu \in \mathrm{Ult}(V, \mu)$. Derive a contradiction to the analogous minimality of $j(\kappa)$ in M by showing that $\mu \in \mathrm{Ult}(M, \mu)$. $\dashv$

1.16 Definition. An embedding $\pi : V \to M$ is *α-strong* just in case that $\mathcal{P}(\xi) \subseteq M$ for all $\xi < \alpha$. An extender E is *α-strong* just in case that $\mathcal{P}(\xi) \subseteq \mathrm{Ult}(V, E)$ for all $\xi < \alpha$. The *strength* of $\pi : V \to M$ is defined to be the largest α so that π is α-strong. The strength of an extender E is defined similarly, using the ultrapower, and is denoted $\mathrm{Strength}(E)$. (Notice that the strength of an embedding is always a cardinal.) An embedding π with critical point κ is *superstrong* if it is $\pi(\kappa)$-strong. A cardinal κ is *α-strong* if it is the critical point of an α-strong embedding, and *superstrong* if it is the critical point of a superstrong embedding.

Measurable cardinals lie at the low end of the hierarchy of strength: assuming GCH, an ultrapower embedding by a measure on κ is κ^+-strong and no more. Superstrong embeddings lie much higher in the hierarchy. These embedding are the most we can hope to capture using (short) extenders:

1.17 Lemma. *Let E be a (short) extender with critical point κ. Let j be the ultrapower embedding by E. Then E is at most $j(\kappa)$-strong.*

Proof. Using the ultrapower construction and the elementarity of j, one can see that every element x of $j(\kappa^+)$ has the form $j(f)(a)$ for a function $f : \kappa \to \kappa^+$ and an $a \in \mathrm{dom}(j(f)) = j(\kappa)$. (The fact that f can be taken to have domain κ traces back to the fact that the domain of E consists precisely of the subsets of its critical point, in other words to the fact that E is a *short* extender.) It follows that $j(\kappa^+)$ has cardinality at most $\theta = (\kappa^+)^\kappa \cdot j(\kappa)$. If j is $j(\kappa)$-strong then $j(\kappa)$ is a strong limit cardinal in V, and a quick calculation shows that $\theta = j(\kappa)$. Thus $j(\kappa^+) = (j(\kappa)^+)^{\mathrm{Ult}(V,E)}$ has cardinality $j(\kappa)$ in V, and from this it follows that $\mathrm{Ult}(V, E)$ must be missing some subsets of $j(\kappa)$. So E is not $j(\kappa) + 1$-strong. $\dashv$

1.18 Lemma. *Let $\pi : V \to M$ with critical point κ. Suppose that π is α-strong where $\alpha \leq \pi(\kappa)$. Let $\lambda \leq \pi(\kappa)$ be an ordinal closed under Gödel pairing and such that $\lambda \geq (2^{<\alpha})^M$. Then the λ-restriction of π is an α-strong extender.*

Proof. Immediate from Lemma 1.11. $\dashv$

Lemma 1.18 shows that (short) extenders are adequate means for capturing the strength of embeddings at or below the level of superstrong. On the other hand Lemma 1.17 shows that (short) extenders cannot capture embeddings beyond superstrong. Such stronger embeddings can be captured using the general extenders mentioned in Remark 1.3, but for our purpose in this chapter the greater generality is not necessary.

1.19 Definition. We write $Q\|\alpha$ to denote V^Q_α. We say that Q and N *agree well beyond* κ if the first inaccessible above κ is the same in both Q and N, and, letting $\alpha > \kappa$ be this inaccessible, $Q\|\alpha = N\|\alpha$. Given further embeddings $i : Q \to Q^*$ and $j : N \to N^*$ we say that i and j *agree well beyond* κ if $i{\restriction}(Q\|\alpha \cup \{Q\|\alpha\}) = j{\restriction}(N\|\alpha \cup \{N\|\alpha\})$.

We shall use the notion of Definition 1.19 as an all-purpose security blanket, giving us (more than) enough room in several arguments below.

$$\begin{tikzcd}
Q^* \arrow[rr, bend left, "i^*"] & E^* \in N^* & \mathrm{Ult}(Q^*, E^*) \\
Q \arrow[u, "\pi"] \arrow[rr, bend right, "i"'] & E \in N \arrow[u, "\sigma"] & \mathrm{Ult}(Q, E) \arrow[u, "\tau"]
\end{tikzcd}$$

Diagram 22.3: Copying the ultrapower of Q by E to an ultrapower of Q^* by E^*

1.20 Claim. *Let Q and N be models of set theory. Suppose that E is an extender in N, and let $\kappa = \mathrm{crit}(E)$. Suppose that Q and N agree well beyond κ, so that (in particular) E is a pre-extender over Q. Let i be the ultrapower embedding of Q by E, and let j be the ultrapower embedding of N by E. Then i and j agree well beyond κ, and $\mathrm{Ult}(Q, E)$ and $\mathrm{Ult}(N, E)$ agree well beyond $i(\kappa) = j(\kappa)$.*

Let Q and N be models of set theory. Suppose that E is an extender in N, and let $\kappa = \mathrm{crit}(E)$. Suppose that Q and N agree well beyond κ, so that in particular E is a pre-extender over Q.

Let $\pi : Q \to Q^*$ and $\sigma : N \to N^*$ be elementary. Let $E^* = \sigma(E)$. Suppose that π and σ agree well beyond κ. Hence in particular Q^* and N^* agree well beyond $\pi(\kappa) = \sigma(\kappa)$, and E^* is therefore a pre-extender over Q^*. The models and embeddings are presented in Diagram 22.3.

For an element $x = [f, a]$ of $\mathrm{Ult}(Q, E)$ define $\tau(x)$ to be the element $[\pi(f), \sigma(a)]$ of $\mathrm{Ult}(Q^*, E^*)$.

Then τ is a well defined (meaning invariant under the choice of representatives for $x \in \mathrm{Ult}(Q, E)$) elementary embedding from $\mathrm{Ult}(Q, E)$ into $\mathrm{Ult}(Q^*, E^*)$; $\tau \restriction \mathrm{spt}(E) = \sigma \restriction \mathrm{spt}(E)$; and τ makes Diagram 22.3, with i and i^* being the relevant ultrapower embeddings, commute.

The ultrapower of Q^* by E^* is called the *copy*, via the pair $\langle \pi, \sigma \rangle$, of the ultrapower of Q by E. τ is called the *copy embedding*. Note that the definition of τ involves both π and σ, and the agreement between these two embeddings is important for the proof that τ is well defined.

1.21 Remark. Recall that every element of $\mathrm{Ult}(Q, E)$ has the form $i(f)(a)$ for a function $f \in Q$ and an ordinal $a \in \mathrm{spt}(E)$. The copy embedding τ is characterized completely by the condition $\tau(i(f)(a)) = (i^* \circ \pi)(f)(\sigma(a))$ for all f and a.

Next we describe how to repeatedly form ultrapowers by extenders, to obtain a chain, or a tree, of models. For the record let us start by defining direct limits.

1.22 Definition. Let $\langle M_\xi, j_{\zeta,\xi} \mid \zeta < \xi < \alpha\rangle$ be a system of models M_ξ and elementary embeddings $j_{\zeta,\xi} : M_\zeta \to M_\xi$, commuting in the natural way. Let $\mathcal{D} = \{\langle \xi, x\rangle \mid \xi < \alpha \wedge x \in M_\xi\}$.

Define an equivalence relation $\sim$ on $\mathcal{D}$ by setting $\langle \xi, x\rangle \sim \langle \xi', x'\rangle$ iff $j_{\xi,\nu}(x) = j_{\xi',\nu}(x)$ where $\nu = \max\{\xi, \xi'\}$. Let $\mathcal{D}^* = \mathcal{D}/{\sim}$.

Define a relation R on $\mathcal{D}^*$ by setting $[\xi, x]\ R\ [\xi', x']$ iff $j_{\xi,\nu}(x) \in j_{\xi',\nu}(x)$ where again $\nu = \max\{\xi, \xi'\}$. It is easy to check that R is well defined.

The structure $M^* = (\mathcal{D}^*; R)$ is called the *direct limit* of the system $\langle M_\xi, j_{\zeta,\xi} \mid \zeta < \xi < \alpha\rangle$. The embeddings $j_{\xi,*} : M_\xi \to M^*$ determined by $j_\xi(x) = [\xi, x]$ are called the *direct limit embeddings*. It is easy to check that these embeddings commute with the embeddings $j_{\zeta,\xi}$ in the natural way.

1.23 Remark. If $(\mathcal{D}^*; R)$ is wellfounded then we identify it with its transitive collapse, and identify R with $\in$.

We pass now to the matter of iterated ultrapowers.

1.24 Definition. A *tree order* is an order T on an ordinal α so that:

(1) T is a suborder of $<\restriction(\alpha \times \alpha)$.

(2) For each $\eta < \alpha$, the set $\{\xi \mid \xi\ T\ \eta\}$ is linearly ordered by T.

(3) For each ξ so that $\xi + 1 < \alpha$, the ordinal $\xi + 1$ is a successor in T.

(4) For each limit ordinal $\gamma < \alpha$, the set $\{\xi \mid \xi\ T\ \gamma\}$ is cofinal in γ.

1.25 Definition. An *iteration tree* $\mathcal{T}$ of length α on a model M consists of a tree order T on α and a sequence $\langle E_\xi \mid \xi + 1 < \alpha\rangle$, so that the following conditions hold with an additional sequence $\langle M_\xi, j_{\zeta,\xi} \mid \zeta\ T\ \xi < \alpha\rangle$ which is determined completely by the conditions:

(1) $M_0 = M$.

(2) For each ξ so that $\xi + 1 < \alpha$, E_ξ is an extender of M_ξ, or $E_\xi =$ "pad".

(3) (a) If $E_\xi =$ "pad" then $M_{\xi+1} = M_\xi$, the T-predecessor of $\xi + 1$ is ξ, and $j_{\xi,\xi+1}$ is the identity.
(b) If $E_\xi \neq$ "pad" then $M_{\xi+1} = \mathrm{Ult}(M_\zeta, E_\xi)$ and $j_{\zeta,\xi+1} : M_\zeta \to M_{\xi+1}$ is the ultrapower embedding, where ζ is the T-predecessor of $\xi + 1$. It is implicit in this condition that M_ζ must agree with M_ξ past $\mathrm{crit}(E_\xi)$, so that E_ξ is a pre-extender over M_ζ by Claim 1.7.

(4) For limit $\lambda < \alpha$, M_λ is the direct limit of the system $\langle M_\zeta, j_{\zeta,\xi} \mid \zeta\ T\ \xi\ T\ \lambda\rangle$, and $j_{\zeta,\lambda} : M_\zeta \to M_\lambda$ for $\zeta\ T\ \lambda$ are the direct limit embeddings.

(5) The remaining embeddings $j_{\zeta,\xi}$ for $\zeta\ T\ \xi < \alpha$ are obtained through composition.

M_ξ and $j_{\zeta,\xi}$ for $\zeta\ T\ \xi < \alpha$ are the *models* and *embeddings of* $\mathcal{T}$. We view them as part of $\mathcal{T}$, though formally they are not.

$$\begin{tikzcd} M_{n+1} & \\ & E_n \in M_n \\ M_k \arrow[uu, "j_{k,n+1}"] & \end{tikzcd}$$

Diagram 22.4: Forming M_{n+1}

1.26 Remark. The inclusion of pads in iteration tree is convenient for purposes of indexing in various constructions, and we shall use it later on. But for much of the discussion below we make the implicit assumption that the iteration tree considered has no pads. This assumption poses no loss of generality.

We shall only need iteration trees of length ω in this chapter. We shall construct these trees recursively. In stage n of the construction we shall have the models $M_0, \ldots, M_n$. During the stage we shall pick an extender E_n in M_n, and pick further some $k \leq n$ so that M_k and M_n agree past $\mathrm{crit}(E_n)$. We shall then set k to be the T-predecessor of $n+1$ and set $M_{n+1} = \mathrm{Ult}(M_k, E_n)$. This is illustrated in Diagram 22.4. After ω stages of a construction of this kind we obtain an iteration tree of length ω.

A *branch* through an iteration tree $\mathcal{T}$ is a set b which is linearly ordered by T. The branch is *cofinal* if $\sup(b) = \mathrm{lh}(\mathcal{T})$. By the *direct limit* along b, denoted $M_b^{\mathcal{T}}$ or simply M_b, we mean the direct limit of the system $\langle M_\xi, j_{\zeta,\xi} \mid \zeta \; T \; \xi \in b\rangle$. We use $j_{\zeta,b}^{\mathcal{T}}$, or simply $j_{\zeta,b}$, to denote the direct limit embeddings of this system. The branch b is called *wellfounded* just in case that the model M_b is wellfounded.

2. Iterability

The existence of wellfounded cofinal branches through certain iteration trees is crucial to proofs of determinacy. This existence is part of the general topic of iterability. In this section we briefly describe the topic, point out its most important open problem, and sketch a proof of the specific iterability necessary for the determinacy results in this chapter.

Let M be a model of ZFC^-. In the (*full*) *iteration game* on M players "good" and "bad" collaborate to construct an iteration tree $\mathcal{T}$ of length ω_1^V+1 on M. "bad" plays all the extenders, and determines the T-predecessor of $\xi+1$ for each ξ. "good" plays the branches $\{\zeta \mid \zeta \; T \; \lambda\}$ for limit λ, thereby determining the T-predecessors of λ and the direct limit model M_λ. Note that "good" is also responsible for the final move, which determines $M_{\omega_1^V}$.

If ever a model along the tree is reached which is illfounded then "bad" wins. Otherwise "good" wins. M is (*fully*) *iterable* if "good" has a winning strategy in this game. An *iteration strategy* for M is a strategy for the good player in the iteration game on M. The *Strategic Branches Hypothesis* (SBH) asserts that every countable model which embeds into a rank initial segment of V is iterable.

As stated the hypothesis is more general than necessary. The iteration trees that come up in applications follow a specific format, and only the restriction of SBH to trees of such format is needed.

Call an iteration tree $\mathcal{T}$ on M *nice* if:

(1) The extenders used in $\mathcal{T}$ have increasing strengths. More precisely, $\langle \mathrm{Strength}^{M_\xi}(E_\xi) \mid \xi + 1 < \mathrm{lh}(\mathcal{T})\rangle$ is strictly increasing.

(2) For each ξ, $\mathrm{Strength}^{M_\xi}(E_\xi)$ is inaccessible in M_ξ.

(3) For each ξ, $\mathrm{spt}(E_\xi) = \mathrm{Strength}^{M_\xi}(E_\xi)$.

2.1 Remark. Throughout this chapter, whenever a result claims the existence of an iteration tree, the iteration tree is nice. In the later sections we often neglect to mention this explicitly.

A model N is λ-*closed* if every subset of N of size λ in V belongs to N.

2.2 Exercise. Let $\mathcal{T}$ be a nice, finite iteration tree on V. Prove that each of the models in $\mathcal{T}$ is countably closed, and conclude from this that each of the models in $\mathcal{T}$ is wellfounded. Prove further that each of the models in $\mathcal{T}$ is $2^{\aleph_0}$-closed.

Hint. Prove the general fact that if $Q \models$"E is an extender with inaccessible support", N agrees with Q past the critical point of E, and both N and Q are countably (respectively $2^{\aleph_0}$) closed, then $\mathrm{Ult}(N, E)$ is countably (respectively $2^{\aleph_0}$) closed. Wellfoundedness follows from countable closure, since by elementarity each of the models in $\mathcal{T}$ satisfies internally that "there are no infinite descending sequences of ordinals". $\dashv$

Call M *iterable for nice trees* if "good" has a winning strategy in the iteration game on M when "bad" is restricted to extenders which give rise to nice trees. Let nSBH be the assertion that every countable model which embeds elementarily into a rank initial segment of V is iterable for nice trees. nSBH is a technical weakening of SBH, sufficient for all known applications. A proof of nSBH would constitute a substantial breakthrough in the study of large cardinals, particularly in inner model theory.

For the sake of the determinacy proofs in this chapter we need only a weak form of iterability, involving linear compositions of trees of length ω. This iterability was proved by Martin-Steel [22]. We now proceed to state the iterability precisely, and give its proof.

A *weak iteration* of M of length α consists of objects M_ξ, $\mathcal{T}_\xi$, b_ξ for $\xi < \alpha$ and embeddings $j_{\zeta,\xi} : M_\zeta \to M_\xi$ for $\zeta < \xi < \alpha$, so that:

$$\begin{tikzcd} M \arrow[r, "\mathcal{T}_0"', "b_0"] & M_1 \arrow[r, dotted] & M_\xi \arrow[r, "\mathcal{T}_\xi"', "b_\xi"] & M_{\xi+1} \arrow[r, dotted] & {} \end{tikzcd}$$

Diagram 22.5: A weak iteration of M

$$\begin{tikzcd} V\|\theta & \\ M \arrow[u, "\pi"] \arrow[r, "\mathcal{T}"', "j_b"] & M_b \arrow[ul, "\sigma"'] \end{tikzcd}$$

Diagram 22.6: Theorem 2.3

(1) $M_0 = M$.

(2) For each $\xi < \alpha$, $\mathcal{T}_\xi$ is a nice iteration tree of length ω on M_ξ; b_ξ is a cofinal branch through $\mathcal{T}_\xi$; $M_{\xi+1}$ is the direct limit along b_ξ; and $j_{\xi,\xi+1} : M_\xi \to M_{\xi+1}$ is the direct limit embedding along b_ξ.

(3) For limit $\lambda < \alpha$, M_λ is the direct limit of the system $\langle M_\xi, j_{\zeta,\xi} \mid \zeta < \xi < \lambda\rangle$ and $j_{\zeta,\lambda} : M_\zeta \to M_\lambda$ are the direct limit embeddings.

(4) The remaining embeddings $j_{\zeta,\xi}$ are obtained by composition.

A weak iteration is thus a linear composition of length ω iteration trees.

In the *weak iteration game* on M players "good" and "bad" collaborate to produce a weak iteration of M, of length ω_1^V. "Bad" plays the iteration trees $\mathcal{T}_\xi$ and "good" plays the branches b_ξ. (These moves determine the iteration completely.) If ever a model M_ξ, $\xi < \omega_1$, is reached which is illfounded, then "bad" wins. Otherwise "good" wins. M is *weakly iterable* if "good" has a winning strategy in the weak iteration game on M.

2.3 Theorem. *Let $\pi : M \to V\|\theta$ be elementary with M countable. Let $\mathcal{T}$ be a nice iteration tree of length ω on M. Then there is a cofinal branch b through $\mathcal{T}$, and an embedding $\sigma : M_b \to V\|\theta$, so that $\sigma \circ j_b = \pi$. (Note that b is then a wellfounded branch, since M_b embeds into $V\|\theta$.)*

2.4 Corollary. *Let $\pi : M \to V\|\theta$ be elementary with M countable. Then "good" has a winning strategy in the weak iteration game on M.*

Proof. Immediate through iterated applications of Theorem 2.3. "Good" should simply keep choosing branches given by the theorem, successively embedding each $M_{\xi+1}$ into $V\|\theta$, and preserving commutativity which is needed for the limits.

The idea of proving iterability by embedding back into V, simple only in retrospect, was first used by Jensen in the context of linear iterations. ⊣

Theorem 2.3 and Corollary 2.4 provide the iterability necessary for the determinacy proofs in this chapter. In the remainder of this section we give the proof of the theorem.

2.5 Definition. Let $\mathcal{T}$ be a nice iteration tree of length ω on a model M, giving rise to models and embeddings $\langle M_m, j_{m,n} \mid m \; T \; n < \omega\rangle$. $\mathcal{T}$ is *continuously illfounded* if there exists a sequence of ordinals $\alpha_n \in M_n$ $(n < \omega)$ so that $j_{m,n}(\alpha_m) > \alpha_n$ whenever $m \; T \; n$.

Note that a continuously illfounded iteration tree has *no* wellfounded cofinal branches. Indeed, for any cofinal branch b, the sequence $j_{n,b}(\alpha_n)$ for $n \in b$ witnesses that M_b is illfounded. Continuously illfounded iteration trees, on countable models M which embed into rank initial segments of V, thus contradict Theorem 2.3 in a very strong way. We begin by showing that in fact any counterexample to Theorem 2.3 gives rise to a continuously illfounded iteration tree.

2.6 Lemma. *Let $\pi : M \to V\|\theta$ be elementary with M countable. Let $\mathcal{T}$ be a nice iteration tree of length ω on M, and suppose that the conclusion of Theorem 2.3 fails for $\mathcal{T}$. Then there is a continuously illfounded nice iteration tree on V.*

Proof. Let E_n, M_n, and $j_{m,n}$ $(m \; T \; n < \omega)$ denote the extenders, models, and embeddings of $\mathcal{T}$. Working recursively define a length ω iteration tree $\mathcal{T}^*$ on V, and embeddings $\pi_n : M_n \to M_n^*$ through the conditions:

- $M_0^* = V$ and $\pi_0 = \pi$.
- $E_n^* = \pi_n(E_n)$.
- The T^*-predecessor of $n+1$ is the same as the T-predecessor of $n+1$.
- $M_{n+1}^* = \mathrm{Ult}(M_k^*, E_n^*)$ where k is the T-predecessor of $n+1$, and π_{n+1} is the copy embedding via the pair $\langle \pi_k, \pi_n\rangle$.

It is easy to check that this definition goes through, giving rise to a nice iteration tree $\mathcal{T}^*$ and the commuting diagram presented in Diagram 22.7. We will show that $\mathcal{T}^*$ is continuously illfounded.

2.7 Definition. The tree $\mathcal{T}^*$ defined through the conditions above is the *copy* of $\mathcal{T}$ via $\pi : M \to V$. It is denoted $\pi\mathcal{T}$.

From the fact that M is countable it follows that each M_n is countable. Let $\vec{e}^n = \langle e_l^n \mid l < \omega\rangle$ enumerate M_n. Given an embedding σ with domain M_n, we use $\sigma \restriction l$ to denote the restriction of σ to $\{e_0^n, \dots, e_{l-1}^n\}$, and we write $M_n \restriction l$ to denote $\{e_0^n, \dots, e_{l-1}^n\}$.

Working in V let R be the tree of attempts to create a cofinal branch b through $\mathcal{T}$ and a commuting system of embeddings realizing the models along b into V. More precisely, a node in R consists of a finite branch a through T, and of partial embeddings $\sigma_i : M_i \to V$, $i \in a$, satisfying the following conditions (where l is the length of a):

$$\begin{tikzcd}
\mathcal{T}^* & V \arrow[r, dotted, dash] & M_k^* \arrow[rr, bend left, "j^*_{k,n_1}"] & M_n^* & M_{n+1}^* \arrow[r, dotted, dash] & {} \\
\mathcal{T} & M_0 \arrow[u, "\pi"'] \arrow[r, dotted, dash] & M_k \arrow[u, "\pi_k"'] \arrow[rr, bend right, "j_{k,n+1}"'] & M_n \arrow[u, "\pi_n"'] & M_{n+1} \arrow[u, "\pi_{n+1}"'] \arrow[r, dotted, dash] & {}
\end{tikzcd}$$

Diagram 22.7: $\mathcal{T}$ and $\mathcal{T}^*$

- For each i the domain of σ_i is precisely $M_i{\restriction}l$.
- (Commutativity) If $i \ T \ i' \in a$, $x \in M_i{\restriction}l$, $x' \in M_{i'}{\restriction}l$, and $x' = j_{i,i'}(x)$, then $\sigma_{i'}(x') = \sigma_i(x)$.
- σ_0 is equal to $\pi{\restriction}l$.

The tree R consists of these nodes, ordered naturally by extension for each component.

An infinite branch through R gives rise to a corresponding infinite branch $b = \{n_0, n_1, \ldots\}$ through T and an embedding σ_∞ of the direct limit along b into V, with the commutativity $\sigma_\infty \circ j_b = \pi$. Thus, an infinite branch through R produces precisely the objects b and σ necessary for the conclusion of Theorem 2.3.

The assumption of the current lemma is that $\mathcal{T}$ witnesses the failure of Theorem 2.3. The tree R must therefore have *no* infinite branches. Let $\varphi : R \to \mathrm{On}$ be a rank function, that is a function assigning to each node in R an ordinal, in such a way that if a node s' extends a node s then $\varphi(s') < \varphi(s)$. The existence of such a function follows from the fact that R has no infinite branches.

For each finite branch $a = \langle 0 = n_0 \ T \ n_1 \ldots T \ n_{l-1} \rangle$ through T, let s_a consist of a itself and the embeddings $(\pi_{n_{l-1}} \circ j_{n_i, n_{l-1}}){\restriction}l$ for each $i < l$. Using the commutativity of Diagram 22.7 it is easy to check that s_a is a node in $j^*_{0,n_{l-1}}(R)$.

For $k < \omega$ let s_k be the node s_a where a is the branch of T ending at k. s_k is then a node in $j^*_{0,k}(R)$. For $k \ T \ k'$ it is easy to check, again using the commutativity of Diagram 22.7, that $s_{k'}$ extends $j^*_{k,k'}(s_k)$.

Let $\alpha_k = j^*_{0,k}(\varphi)(s_k)$. This is the rank of the node s_k of $j^*_{0,k}(R)$ given by the shift of the rank function φ to M_k^*. From the fact that $s_{k'}$ extends $j^*_{k,k'}(s_k)$ for $k \ T \ k'$ it follows that $\alpha_{k'} < j_{k,k'}(\alpha_k)$. The ordinals $\langle \alpha_k \mid k < \omega \rangle$ therefore witness that $\mathcal{T}^*$ is continuously illfounded. ⊣

2.8 Lemma. *Let $\mathcal{U}$ be a nice length ω iteration tree on V. Then $\mathcal{U}$ is* not *continuously illfounded.*

Proof. Suppose for contradiction that $\mathcal{U}$ is a nice, length ω, continuously illfounded iteration tree on V, and let $\langle \beta_n \mid n < \omega \rangle$ witness this. Let η be large enough that $\mathcal{U}$ belongs to $V \| \eta$. By replacing each β_n with the β_nth regular cardinal of $M_n^{\mathcal{U}}$ above $j_{0,n}^{\mathcal{U}}(\eta)$ we may assume that β_n is regular in $M_n^{\mathcal{U}}$ for each n, and larger than $j_{0,n}^{\mathcal{U}}(\eta)$.

Let θ be large enough that both $\mathcal{U}$ and $\langle \beta_n \mid n < \omega \rangle$ belong to $V \| \theta$. Let H be a countable Skolem hull of $V \| \theta$ with $\mathcal{U}$ and $\langle \beta_n \mid n < \omega \rangle$ elements of H. Let M be the transitive collapse of H and let $\pi : M \to V \| \theta$ be the anticollapse embedding. Let $\mathcal{T} = \pi^{-1}(\mathcal{U})$ and let $\langle \alpha_n \mid n < \omega \rangle = \pi^{-1}(\langle \beta_n \mid n < \omega \rangle)$. Then $\mathcal{T}$ is a nice, length ω, continuously illfounded iteration tree on M; $\langle \alpha_n \mid n < \omega \rangle$ witnesses this; for each n, α_n is regular in $M_n = M_n^{\mathcal{T}}$; and, for each n, $E_n = E_n^{\mathcal{T}}$ belongs to $M_n \| \alpha_n$. (The last clause follows from the fact that β_n is greater than $j_{0,n}^{\mathcal{U}}(\eta)$, obtained in the previous paragraph, and the fact that η was chosen large enough that $E_n^{\mathcal{U}} \in V \| j_{0,n}^{\mathcal{U}}(\eta)$.)

Let M_n, E_n, and $j_{m,n}$ ($m \; T \; n < \omega$) be the models and embeddings of $\mathcal{T}$. Let ρ_n be the strength of E_n in M_n. The sequence $\langle \rho_n \mid n < \omega \rangle$ is increasing, and for each $n < n^*$, M_n and M_{n^*} agree to ρ_n.

Let $P_0 = V \| \beta_0$ and let $\sigma_0 = \pi \restriction (M \| \alpha_0)$. We work by recursion to produce models P_n and embeddings σ_n satisfying the following conditions:

(1) σ_n is elementary from $M_n \| \alpha_n$ into P_n.

(2) σ_n belongs to P_n and is countable in P_n.

(3) For $\bar{n} < n$, $\sigma_{\bar{n}}$ and σ_n agree on $M_{\bar{n}} \| \rho_{\bar{n}}$.

We shall construct so that:

(i) For each n, $P_{n+1} \in P_n$.

At the end of the construction we shall thus have an infinite $\in$-decreasing sequence, a contradiction.

We already have conditions (1) and (2) for $n = 0$, and condition (3) is vacuous for $n = 0$. Suppose inductively that we have conditions (1)–(3) for n. We describe how to construct P_{n+1} and σ_{n+1}.

Let k be the T-predecessor of $n+1$, so that M_{n+1} is the ultrapower of M_k by E_n. We wish to copy this ultrapower to an ultrapower of P_k via the pair $\langle \sigma_k, \sigma_n \rangle$. We cannot quite manage this, since the domain of σ_k is $M_k \restriction \alpha_k$ rather than M_k. We adjust our wishes as follows: Let $\gamma = j_{k,n+1}(\alpha_k)$. $M_{n+1} \| \gamma$ is then the ultrapower of $M_k \| \alpha_k$ by E_n. Now let P_n^* be the copy of this ultrapower via the pair $\langle \sigma_k, \sigma_n \rangle$, and let $\sigma_n^* : M_{n+1} \| \gamma \to P_n^*$ be the copy embedding.

We would have liked to simply set $P_{n+1} = P_n^*$ and σ_{n+1} equal to the restriction of σ_n^* to $M_{n+1} \| \alpha_{n+1}$. There are two problems with this. First, P_n^* does not belong to P_n, so we lose condition (i), the crucial condition in our scheme for a contradiction. Second, σ_n^* does not belong to P_n^*, so we lose condition (2). We handle the second problem first.

2.9 Claim. *Let τ denote the restriction of σ_n^* to $M_{n+1}\|\rho_n$. Then τ belongs to P_n^*.*

Proof. Let φ_n denote $\sigma_n(\rho_n)$. Let F_n denote $\sigma_n(E_n)$.

P_n^* is the ultrapower of P_k by F_n. F_n is φ_n-strong in P_n. It follows that P_n^* and P_n agree to φ_n.

The definition of copy embedding requires that σ_n^* and σ_n agree on the support of E_n. This support must contain ρ_n, since otherwise E_n could not be ρ_n-strong. σ_n^* and σ_n thus agree on ρ_n. By condition (2) and the inaccessibility of φ_n in P_n, $\sigma_n\restriction\rho_n$ belongs to $P_n\restriction\varphi_n$. Since P_n and P_n^* agree to φ_n, $\sigma_n\restriction\rho_n$ belongs to P_n^*. Now σ_n^* is the same as σ_n up to ρ_n, so $\sigma_n^*\restriction\rho_n$ belongs to P_n^*. From this, using the inaccessibility of ρ_n in M_{n+1}, one can argue that $\sigma_n^*\restriction(M_{n+1}\|\rho_n)$ belongs to P_n^*. $\dashv$

Let $\alpha_n^* = \sigma_n^*(\alpha_{n+1})$. Notice that the definition makes sense, as α_{n+1} is smaller than $\gamma = j_{k,n+1}(\alpha_k)$, and therefore belongs to the domain of σ_n^*.

2.10 Claim. *There is an elementary embedding $\sigma_n^{**} : M_{n+1}\|\alpha_{n+1} \to P_n^*\|\alpha_n^*$ so that:*

- *The restriction of σ_n^{**} to $M_{n+1}\|\rho_n$ is equal to τ.*
- *$\sigma_n^{**}(\rho_n) = \varphi_n$.*
- *σ_n^{**} belongs to P_n^* and is countable in P_n^*.*

Notice that σ_n^*, restricted to $M_{n+1}\|\alpha_{n+1}$, already satisfies the first two demands of the claim. Replacing it by an embedding σ_n^{**} that also satisfies the third demand solves our "second problem" mentioned above.

Proof of Claim 2.10. This is a simple matter of absoluteness. Using the fact that τ belongs to P_n^* we can put together, inside P_n^*, the tree of attempts to construct an embedding σ_n^{**} satisfying the demands of the claim. This tree of attempts has an infinite branch in V, given by the restriction of σ_n^* to $M_{n+1}\|\alpha_{n+1}$. By absoluteness then it has an infinite branch inside P_n^*. $\dashv$

Let $P_n^{**} = P_n^*\|\alpha_n^*$. Note that P_n^{**} is then a *strict* rank initial segment of P_n^*, ultimately because $\alpha_{n+1} < j_{k,n+1}(\alpha_n)$.

Taking $P_{n+1} = P_n^{**}$ and $\sigma_{n+1} = \sigma_n^{**}$ would satisfy conditions (1)–(3). But we need one more adjustment to obtain condition (i), the crucial condition in our scheme for a contradiction. This final adjustment hinges on the fact that P_n^{**} is a strict initial segment of P_n^*, and therefore an element of P_n^*. Let H be the Skolem hull of $P_n^{**}\|\varphi_n \cup \{\varphi_n, \sigma_n^{**}\}$ inside P_n^{**}. Let P_{n+1} be the transitive collapse of H, and let $j : P_{n+1} \to H$ be the anticollapse embedding. Let $\sigma_{n+1} = j^{-1} \circ \sigma_n^{**}$. It is easy to check that conditions (1)–(3) hold with these assignments.

Since P_n^{**} and σ_n^{**} belong to P_n^*, the Skolem hull H taken above has cardinality φ_n *inside* P_n^*. It follows that P_{n+1} can be coded by a subset of φ_n

inside P_n^*. Now P_n^* is equal to $\mathrm{Ult}(P_k, F_n)$. Since P_k and P_n agree well beyond the critical point of F_n, the ultrapowers $\mathrm{Ult}(P_k, F_n)$ and $\mathrm{Ult}(P_n, F_n)$ agree well beyond the image of this critical point (Claim 1.20). This image in turn is at least φ_n, that is the strength of F_n, since F_n is a short extender. (See Lemma 1.17.) It follows that all subsets of φ_n in $P_n^* = \mathrm{Ult}(P_k, F_n)$ belong also to $\mathrm{Ult}(P_n, F_n)$. Now $\mathrm{Ult}(P_n, F_n)$ can be computed over P_n (as $F_n \in P_n$). So all subsets of φ_n in P_n^* belong to P_n. We noted at the start of this paragraph that P_{n+1} can be coded by such a subset. So P_{n+1} belongs to P_n, and we have condition (i), as required. ⊣

Lemmas 2.6 and 2.8 combine to prove Theorem 2.3.

2.11 Remark. The contradiction in Lemma 2.8 is obtained through the very last adjustment in the proof, replacing P_n^{**} by a Skolem hull which belongs to P_n. It is crucial for that final adjustment that P_n^{**} is a strict rank initial segment of P_n^*, and this is where the continuous illfoundedness of $\mathcal{T}$ is used. The ordinals witnessing the continuous illfoundedness provide the necessary drops in rank.

2.12 Lemma. *Let $\mathcal{T}$ be a nice iteration tree of length ω on V. Then $\mathcal{T}$ has a cofinal branch leading to a wellfounded direct limit.*

Proof. Suppose not. For each cofinal branch b through $\mathcal{T}$ fix a sequence $\langle \alpha_n^b \mid n \in b\rangle$ witnessing that the direct limit along b is illfounded, more precisely satisfying $j_{m,n}(\alpha_m^b) > \alpha_n^b$ for all $m < n$ both in b. Let θ be large enough that all the ordinals α_n^b are smaller than θ.

For each $n < \omega$ let B_n be the set of cofinal branches b through $\mathcal{T}$ with $n \in b$. Let F_n be the set of functions from B_n into θ. Let $\prec$ be the following relation: $\langle n, f\rangle \prec \langle m, g\rangle$ iff $f \in F_n$, $g \in F_m$, $m\ T\ n$, and $f(b) < g(b)$ for every $b \in F_n$. The relation $\prec$ is wellfounded: if $\langle\langle n_i, f_i\rangle \mid i < \omega\rangle$ were an infinite descending chain in $\prec$, then $\langle f_i(b) \mid i < \omega\rangle$, where b is the cofinal branch through $\mathcal{T}$ generated by $\{n_i \mid i < \omega\}$, would be an infinite descending sequence of ordinals.

For each $n < \omega$ let φ_n be the function $b \mapsto \alpha_n^b$, defined on $b \in B_n$, that is on branches b so that $n \in b$. By Exercise 2.2, each of the models M_n of $\mathcal{T}$ is $2^{\aleph_0}$-closed, and it follows that for each $n < \omega$, φ_n belongs to M_n. Let $\prec_n$ denote the relation $j_{0,n}(\prec)$. Using the fact that $j_{m,n}(\alpha_m^b) > \alpha_n^b$ for all b and all $m < n$ both in b, it is easy to check that $\langle n, \varphi_n\rangle \prec_n \langle m, j_{m,n}(\varphi_m)\rangle$ whenever $m\ T\ n$. Letting γ_n be the rank of φ_n in $\prec_n$ it follows that $\gamma_n < j_{m,n}(\gamma_m)$ whenever $m\ T\ n$. But then the sequence $\langle \gamma_n \mid n < \omega\rangle$ is a witness that $\mathcal{T}$ is continuously illfounded, contradicting Lemma 2.8. ⊣

3. Creating Iteration Trees

The creation of iteration trees with non-linear tree orders is not a simple matter. Recall that the model M_{n+1} in an iteration tree $\mathcal{T}$ is created by picking an extender $E_n \in M_n$, picking $k \leq n$ so that M_k and M_n agree past $\text{crit}(E_n)$, and setting $M_{n+1} = \text{Ult}(M_k, E_n)$. The agreement between M_k and M_n is necessary for the ultrapower to make sense. The agreement can be obtained trivially by taking $k = n$. But doing this repeatedly would generate a linear iteration, that is an iteration with the simple tree order $0\ T\ 1\ T\ 2 \ldots$. For the creation of iteration trees with more complicated orders we need a way of ensuring that M_n has extenders with critical points within the level of agreement between M_n and previous models in the tree.

This section introduces the large cardinals and machinery that will allow us to create iteration trees with as complicated a tree order as we wish. The results here are due to Martin-Steel [21]. The terminology follows Neeman [30, §1A(1)].

3.1 Definition. u is called a *(κ, n)-type*, where κ is a limit ordinal and $n < \omega$, if u is a set of formulae involving n free variables $v_0, \ldots, v_{n-1}$, a constant $\widetilde{\delta}$, and additional constants $\widetilde{c}$ for each $c \in V\|\kappa \cup \{\kappa\}$.

A (κ, n)-type can be coded by a subset of $(V\|\kappa)^{<\omega}$. Since κ is assumed to be a limit ordinal, $(V\|\kappa)^{<\omega} \subseteq V\|\kappa$. We may therefore view (κ, n)-types as subsets of $V\|\kappa$.

We refer to κ as the *domain* of u, denoted $\text{dom}(u)$. For $\tau \leq \kappa$ and $m \leq n$, we let

$$\begin{aligned}\text{proj}^m_\tau(u) = \big\{&\phi(\widetilde{\delta}, \widetilde{c}_0, \ldots, \widetilde{c}_k, v_0, \ldots, v_{m-1}) \mid k \in \mathbb{N},\ c_0, \ldots, c_k \in V\|\tau \cup \{\tau\},\\ &\phi(\widetilde{\delta}, \widetilde{c}_0, \ldots, \widetilde{c}_k, v_0, \ldots, v_{n-1}) \in u,\ \text{and } \phi \text{ makes no mention of}\\ &v_m, \ldots, v_{n-1}\big\}.\end{aligned}$$

We use $\text{proj}_\tau(u)$ to denote $\text{proj}^n_\tau(u)$, and $\text{proj}^m(u)$ to denote $\text{proj}^m_\kappa(u)$.

3.2 Definition. We say that a (κ, n)-type u is *realized* (*relative to* δ) *by* $x_0, \ldots, x_{n-1}$ *in* $V\|\eta$ just in case that:

- $x_0, \ldots, x_{n-1}$ and δ are elements of $V\|\eta$.
- For any $k < \omega$, any $c_0, \ldots, c_k \in V\|\kappa \cup \{\kappa\}$, and any formula $\phi(\widetilde{\delta}, \widetilde{c}_0, \ldots, \widetilde{c}_k, v_0, \ldots, v_{n-1})$, $\phi(\widetilde{\delta}, \widetilde{c}_0, \ldots, \widetilde{c}_k, v_0, \ldots, v_{n-1}) \in u$ if and only if $V\|\eta \models \phi[\delta, c_0, \ldots, c_k, x_0, \ldots, x_{n-1}]$. (Implicitly we must have $\eta > \kappa$ and $\eta > \delta$.)

We call u the *κ-type of* $x_0, \ldots, x_{n-1}$ *in* $V\|\eta$ (relative to δ) if u is the unique (κ, n)-type which is realized by $x_0, \ldots, x_{n-1}$ in $V\|\eta$. A (κ, n)-type u is *realizable* (relative to δ) if it is realized by some $x_0, \ldots, x_{n-1}$ in some $V\|\eta$.

We often neglect to mention the set δ involved in the realization. In applications δ is usually fixed, and clear from the context.

3.3 Note. If u is realized by $x_0, \ldots, x_{n-1}$ in $V\|\eta$, then $\text{proj}^m_\tau(u)$ is realized by $x_0, \ldots, x_{m-1}$ in $V\|\eta$.

3.4 Definition. If the formula "there exists a largest ordinal" and the formula "$\widetilde{\kappa}, \widetilde{\delta}, v_0, \ldots, v_{n-1} \in V\|\nu$, where ν is the largest ordinal" are both elements of the (κ, n)-type u we define

$$\begin{aligned} u^- = \bigl\{\phi(\widetilde{\delta}, \widetilde{c}_0, \ldots, \widetilde{c}_k, v_0, \ldots, v_{n-1}) \mid\, & k \in \mathbb{N},\ c_0, \ldots, c_k \in V\|\kappa \cup \{\kappa\}, \\ & \text{and the formula "}V\|\nu \models \phi[\widetilde{\delta}, \widetilde{c}_0, \ldots, \widetilde{c}_k, v_0, \ldots, v_{n-1}] \\ & \text{where } \nu \text{ is the largest ordinal" is an element of } u\bigr\}. \end{aligned}$$

3.5 Note. If $\kappa, \delta, x_0, \ldots, x_{n-1} \in V\|\eta$ and u is realized by $x_0, \ldots, x_{n-1}$ in $V\|\eta + 1$ then u^- is defined and is realized by the same $x_0, \ldots, x_{n-1}$ in $V\|\eta$.

3.6 Definition. Let u be a (κ, n)-type, and let w be a (τ, m)-type. We say that w is a *subtype* of u (and write $w < u$) if:

- $\tau < \kappa$.
- $m \geq n$.
- The formula "there is an ordinal ν and $v_n, \ldots, v_{m-1} \in V\|\nu$ such that $\widetilde{w}$ is realized by some permutation of $v_0, \ldots, v_{m-1}$ in $V\|\nu$" is an element of the type u.

3.7 Note. Let u be the κ-type of $x_0, \ldots, x_{n-1}$ in $V\|\eta$. Then w is a subtype of u iff there are $\tau < \kappa$, $\nu < \eta$, $m \geq n$, and sets $x_n, \ldots, x_{m-1}$ so that w is the τ-type of some permutation of $x_0, \ldots, x_{m-1}$ in $V\|\nu$.

3.8 Remark. Definition 3.6 makes no mention of realizability but only stipulates that one particular formula belongs to u. It is immediate then that the property $w < u$ is absolute for any two models of set theory which have w and u as elements.

3.9 Definition. We say that a (τ, m)-type w *exceeds* the (κ, n)-type u, if:

- $\tau > \kappa$.
- $m \geq n$.
- There exist ordinals ν, η, and sets $x_0, \ldots, x_{m-1} \in V\|\nu$ such that
  - u is realized by $x_0, \ldots, x_{n-1}$ in $V\|\eta$,
  - w is realized by some permutation of $x_0, \ldots, x_{m-1}$ in $V\|\nu$, and
  - $\nu + 1 < \eta$.

ν, η, and $x_0, \ldots, x_{m-1}$ are said to witness the fact that w exceeds u.

3.10 Remark. The definition here is slightly more liberal than the corresponding definition in Neeman [30], where it is required that w be realized by $x_0, \ldots, x_{m-1}$ in their original order, not by a permutation of $x_0, \ldots, x_{m-1}$. A similar comment applies to Definition 3.6.

3.11 Note. Let u be the κ-type of $x_0, \dots, x_{n-1}$ in $V\|\eta$. Suppose there are $\tau > \kappa$, ν with $\nu + 1 < \eta$, $m \geq n$, and $x_n, \dots, x_{m-1}$ so that w is the τ-type of a permutation of $x_0, \dots, x_{m-1}$ in $V\|\nu$. Then w exceeds u. This should be compared with Note 3.7. There τ is smaller than κ, and here τ must be larger than κ.

3.12 Definition. Let $\kappa < \lambda$, E a λ-strong extender with $\operatorname{crit}(E) = \kappa$, and u a type with $\operatorname{dom}(u) = \kappa$. Let $i_E : V \to \operatorname{Ult}(V, E)$ be the ultrapower embedding. We define $\operatorname{Stretch}^E_\lambda(u)$ to be equal to $\operatorname{proj}_\lambda(i_E(u))$.

$i_E(u)$ in Definition 3.12 is a type in $\operatorname{Ult}(V, E)$ with domain $i_E(\kappa)$. $i_E(\kappa)$ is at least as large as λ by Lemma 1.17, since E is λ-strong. So the projection to λ in Definition 3.12 makes sense.

3.13 Definition. A (κ, n)-type u is called *elastic* just in case that u^- is defined and u contains the following formulae:

- "$\widetilde{\delta}$ is an inaccessible cardinal."
- "Let ν be the largest ordinal. Then for all $\lambda < \widetilde{\delta}$ there exists an extender $E \in V\|\widetilde{\delta}$ such that
  - $\operatorname{crit}(E) = \widetilde{\kappa}$, $\operatorname{spt}(E) = \operatorname{Strength}(E)$, $\operatorname{Strength}(E)$ is an inaccessible cardinal greater than λ, and
  - $\operatorname{Stretch}^E_\lambda(u^-)$ is realized (relative to $\widetilde{\delta}$) by $v_0, \dots, v_{n-1}$ in $V\|\nu$."

Formally the last clause should begin with "$\operatorname{Stretch}^E_\lambda(w)$, where w is the type of $v_0, \dots, v_{n-1}$ in $V\|\nu$" instead of $\operatorname{Stretch}^E_\lambda(u^-)$, as u^- is not a parameter in formulae in u.

3.14 Remark. The requirements on support and of inaccessible strength in Definition 3.13 are not part of the definition in Neeman [30]. They are added in this chapter so as to make sure, later on, that our iteration trees are nice.

3.15 Remark. Definition 3.13 makes no mention of realizability but only stipulates that certain formulae belong to u. It is immediate then that the property of being elastic is absolute between models of set theory.

Ordinarily if u is realized by $x_0, \dots, x_{n-1}$ in $V\|\nu + 1$ then $\operatorname{Stretch}^E_\lambda(u^-)$ is realized by $i_E(x_0), \dots, i_E(x_{n-1})$ in $\operatorname{Ult}(V, E)\|i_E(\nu)$, and relative to $i_E(\delta)$. The demand in Definition 3.13 that it must also be realized by $x_0, \dots, x_{n-1}$ in $V\|\nu$, and relative to δ, places a requirement of certain strength on the extender E. The existence of realizable elastic types is dependent on the existence of enough extenders with such strength.

3.16 Definition. Let H be a set. Let E be an extender and let $\kappa = \operatorname{crit}(E)$. Let j be the ultrapower embedding by E. Let $\alpha \leq j(\kappa)$. E is said to be *α-strong with respect to H* if (a) it is α-strong; and (b) $j(H \cap \kappa)$ and H agree to α, i.e., $j(H \cap \kappa) \cap \alpha = H \cap \alpha$.

A cardinal κ is said to be *α-strong with respect to H* if it is the critical point of an extender which is α-strong with respect to H.

A cardinal κ is said to be *$<\alpha$-strong with respect to H* if it is β-strong with respect to H for each $\beta < \alpha$.

3.17 Lemma. *Let τ be the critical point of a superstrong extender. Let $H \subseteq \tau$. Then there is a $\kappa < \tau$ which is $<\tau$-strong with respect to H.*

Proof. Let E be a superstrong extender with critical point τ, let $M = \mathrm{Ult}(V, E)$, and let $\pi : V \to M$ be the ultrapower embedding. Let $\tau^* = \pi(\tau)$. For each $\alpha < \tau^*$ let F_α be the λ-restriction of π, where $\lambda < \tau^*$ is the least ordinal satisfying the requirements in Lemma 1.18 relative to α. Notice that F_α is then an element of $V \| \tau^*$, and therefore, through of the agreement between V and M, an element of M. Notice further that, by Lemma 1.18, F_α is α-strong. Let j_α be the ultrapower embedding by F_α, and notice finally that $j_\alpha(H)$ and $\pi(H)$ agree up to λ, meaning that $j_\alpha(H) \cap \lambda = \pi(H) \cap \lambda$. Since $H = \pi(H) \cap \kappa$ it follows that F_α is α-strong with respect to $\pi(H)$.

The extenders F_α, $\alpha < \tau^*$, thus witness that τ is $<\tau^*$-strong in M with respect to $\pi(H)$. So M is a model of the statement "there is a $\kappa < \tau^*$ which is $<\tau^*$-strong with respect to $\pi(H)$." Using the elementarity of π to pull this statement back to V it follows that there is a $\kappa < \tau$ which is $<\tau$-strong with respect to H. $\dashv$

3.18 Definition. A cardinal δ is called a *Woodin cardinal* if for every $H \subseteq \delta$, there exists a $\kappa < \delta$ which is $<\delta$-strong with respect to H.

Lemma 3.17 shows that the critical point of a superstrong extender is Woodin. The next exercise shows that there are Woodin cardinals below the critical point. In fact Woodin cardinals sit *well* below such critical points in the large cardinal hierarchy, and there are many large cardinal axioms strictly between the existence of Woodin cardinals and the existence of superstrong extenders.

3.19 Exercise. Let E be a superstrong extender. Show that there are Woodin cardinals below the critical point of E. In fact, show that the critical point of E is a limit of Woodin cardinals.

3.20 Exercise. Let δ be a Woodin cardinal. Show that δ is a limit of (strongly) inaccessible cardinals, and that it is (strongly) inaccessible itself.

3.21 Exercise. Let δ be a Woodin cardinal. Let $H \subseteq \delta$ and let κ be $<\delta$-strong with respect to H. Let $\alpha < \delta$ be given. Prove that there is an extender E with critical point κ so that E is α-strong with respect to H, and so that $\mathrm{spt}(E) = \mathrm{Strength}(E)$ and $\mathrm{Strength}(E)$ is an inaccessible cardinal greater than α.

Hint. Let $\lambda < \delta$ be the first inaccessible cardinal above α. Using the fact that κ is $<\delta$-strong with respect to H, get an extender F with critical point

κ so that F is λ-strong with respect to H. In particular then F is α-strong with respect to H, and $\mathrm{Strength}(F) \geq \lambda$. Let π be the ultrapower embedding by F, and let E be the λ-restriction of π. Show that the strength of E is precisely λ, and that E is α-strong with respect to H. ⊣

3.22 Lemma. *Let δ be a Woodin cardinal. Let $\eta > \delta$, and let $x_0, \ldots, x_{n-1}$ be elements of $V\|\eta$. Then there exist unboundedly many $\kappa < \delta$ such that the κ-type of $x_0, \ldots, x_{n-1}$ in $V\|\eta + 1$ relative to δ is elastic.*

Proof. For each (strongly) inaccessible $\gamma < \delta$, let A_γ be the γ-type of $x_0, \ldots, x_{n-1}$ in $V\|\eta$ relative to δ, viewed as a subset of γ. Let $H = \{(\xi, \gamma) \mid \xi \in A_\gamma\}$, where $(*, *)$ is the Gödel pairing.

Let κ be $<\delta$-strong with respect to H. Let u be the κ-type of $x_0, \ldots, x_{n-1}$ in $V\|\eta + 1$.

It is easy to check that if λ^* is closed under Gödel pairing and E is λ^*-strong with respect to H, then for every $\lambda < \lambda^*$, $\mathrm{Stretch}^E_\lambda(u^-)$ is realized by $x_0, \ldots, x_{n-1}$ in $V\|\eta$. Using Exercise 3.21 it follows that the formula in the second clause of Definition 3.13 holds for $x_0, \ldots, x_{n-1}$ in $V\|\eta + 1$, and is therefore an element of u. By Exercise 3.20, δ is inaccessible, and so the formula in the first clause of Definition 3.13 belongs to u. This shows that u is elastic.

We have so far obtained one cardinal $\kappa < \delta$ such that the κ-type of $x_0, \ldots, x_{n-1}$ in $V\|\eta$ is elastic. We leave it to the reader to show that there are unboundedly many. ⊣

We now know that Woodin cardinals provide the strength necessary for the existence of many elastic types. The usefulness of elastic types appears through the following lemma. The lemma essentially says that an elastic type u which is exceeded by a type w can be stretched to a supertype of w.

3.23 Lemma (One-Step Lemma). *Assume that u is an elastic type, and that w exceeds u (with all realizations relative to δ). Let $\tau = \mathrm{dom}(w)$ and let $\kappa = \mathrm{dom}(u)$. Suppose that $\tau < \delta$. Then there exists an extender $E \in V\|\delta$ so that*

- $\mathrm{crit}(E) = \kappa$, $\mathrm{spt}(E) = \mathrm{Strength}(E)$, *the strength of E is an inaccessible cardinal greater than τ, and*
- $w < \mathrm{Stretch}^E_{\tau+\omega}(u)$.

Proof. Let $\nu, \eta, x_0, \ldots, x_{m-1}$ witness that w exceeds u. Since u^- exists, η is a successor ordinal. Say $\eta = \bar{\eta} + 1$. Pick $E \in V\|\delta$ so that $\mathrm{crit}(E) = \kappa$, E has inaccessible strength greater than τ, and $\mathrm{Stretch}^E_{\tau+\omega}(u^-)$ is realized by $x_0, \ldots, x_{n-1}$ in $V\|\bar{\eta}$ relative to δ. This is possible since u is elastic.

Then w is a subtype of $\mathrm{Stretch}^E_{\tau+\omega}(u^-)$, as it is realized by a permutation of $x_0, \ldots, x_{n-1}, x_n, \ldots, x_m$ in $V\|\nu$ and $\nu < \bar{\eta}$. Simple properties of realizable types now imply that w is a subtype of $\mathrm{Stretch}^E_{\tau+\omega}(u)$. ⊣

We now have the tools necessary for the creation of iteration trees. We work for the rest of the section under the assumption that δ is a Woodin cardinal.

3.24 Lemma. *Let $M_0 = V$. There is an iteration tree with the structure of models presented in the following diagram:*

$$\begin{tikzcd} M_0 \arrow[rrr, bend left] & = & M_1 \arrow[rr, bend right] & M_2 & M_3 \end{tikzcd}$$

Proof. Let η be an ordinal greater than δ. Let $\kappa_0 < \delta$ be such that the κ_0-type of η in $V\|\eta + 5$ is elastic. Let u_0 be this type.

Let $\kappa_1 > \kappa_0$ be such that the κ_1-type of η in $V\|\eta + 3$ is elastic. Let u_1 be this type.

Notice that u_1 exceeds u_0. Using the One-Step Lemma pick a $\kappa_1 + 1$-strong extender $E_1 \in M_1\|\delta$ so that $\mathrm{crit}(E_1) = \kappa_0$, and u_1 is a subtype of $\mathrm{Stretch}^{E_1}_{\kappa_1+\omega}(u_0)$.

Set $M_2 = \mathrm{Ult}(M_0, E_1)$, and let $j_{0,2} : M_0 \to M_2$ be the ultrapower embedding. Then u_1 is a subtype of $j_{0,2}(u_0)$. By the elementarity of $j_{0,2}$, $j_{0,2}(u_0)$ is realized by $j_{0,2}(\eta)$ in $M_2\|j_{0,2}(\eta) + 5$. It follows from this and from the fact that u_1 is a subtype of $j_{0,2}(u_0)$, that u_1 is also realized in M_2, specifically it must be realized by $j_{0,2}(\eta)$ in $M_2\|j_{0,2}(\eta) + 3$. The level $j_{0,2}(\eta) + 3$ is reached by observing that u_1 contains the formula "$v_0 + 2$ is the largest ordinal".

Working now in M_2, let $\kappa_2 > \kappa_1$ be such that the κ_2-type of $j_{0,2}(\eta)$ in $M_2\|j_{0,2}(\eta) + 1$ is elastic. Let u_2 be this type. Notice that u_2 then exceeds u_1, inside M_2. This uses the realization of u_1 in M_2, reached in the previous paragraph. Applying the One-Step Lemma pick an extender $E_2 \in M_2$ which stretches u_1 to a supertype of u_2. E_2 has critical point κ_1, and κ_1 is within the level of agreement between M_2 and M_1. E_2 can therefore be applied to M_1. Set $M_3 = \mathrm{Ult}(M_1, E_2)$. ⊣

3.25 Exercise. Construct an iteration tree with the structure presented in the following diagram:

$$\begin{tikzcd} M_0 \arrow[rrr, bend left] & = & M_1 \arrow[rr, bend right] & M_2 \arrow[rr, bend left] & M_3 & M_4 \end{tikzcd}$$

3.26 Exercise. Construct a length ω iteration tree with the tree order presented in the following diagram:

$$\begin{tikzcd} M_0 \arrow[rrr, bend left] & = & M_1 \arrow[rr, bend right] & M_2 \arrow[rr, bend left] & M_3 \arrow[rr, bend right] & M_4 & M_5 & \cdots \end{tikzcd}$$

Hint. The following definition is useful:

3.27 Definition. Let $\nu_{\mathrm{L}} < \nu_{\mathrm{H}}$ be ordinals greater than δ. We say that $\langle \nu_{\mathrm{L}}, \nu_{\mathrm{H}} \rangle$ is a pair of *local indiscernibles* relative to δ just in case that:

$$(V\|\nu_{\mathrm{L}} + \omega) \models \phi[\nu_{\mathrm{L}}, c_0, \ldots, c_{k-1}] \quad \Longleftrightarrow \quad (V\|\nu_{\mathrm{H}} + \omega) \models \phi[\nu_{\mathrm{H}}, c_0, \ldots, c_{k-1}]$$

for any $k < \omega$, any formula ϕ with $k+1$ free variables, and any $c_0, \ldots, c_{k-1} \in V\|\delta + \omega$.

Given local indiscernibles $\nu_{\mathrm{L}} < \nu_{\mathrm{H}}$, note that a type u is realized by ν_{L} in $V\|\nu_{\mathrm{L}} + 1$ iff it is realized by ν_{H} in $V\|\nu_{\mathrm{H}} + 1$. Notice further that if u is realized by ν_{H} in $V\|\nu_{\mathrm{H}} + 1$, then any type of larger domain, which is realized by ν_{L} in $V\|\nu_{\mathrm{L}} + 3$, exceeds $\mathrm{proj}^0(u)$, because $\nu_{\mathrm{L}} + 3 < \nu_{\mathrm{H}} + 1$. (It should be pointed out that the use of the projection is necessary here, to pass to a type which does not involve ν_{H} as a parameter.) In sum then you have:

3.28 Claim. *Let u be κ-type realized by ν_{L} in $V\|\nu_{\mathrm{L}} + 1$. Let $\tau > \kappa$ and let w be a τ-type realized by ν_{L} in $V\|\nu_{\mathrm{L}} + 3$. Then w exceeds* $\mathrm{proj}^0(u)$.

You have also the following claim, directly from the definitions:

3.29 Claim. *Let α be an ordinal greater than δ. Let u be a κ-type realized by α in $V\|\alpha + 3$. Let $\tau > \kappa$ and let w be a τ-type realized by α in $V\|\alpha + 1$. Then w exceeds u.*

Use the two claims alternately, to construct the iteration tree required for the exercise, types $u_n \in M_n$, and ordinals α_n for $n < \omega$ odd, with $\alpha_1 = \nu_{\mathrm{L}}$, so that:

(1) For even $n < \omega$, u_n is realized by $j_{0,n}(\nu_{\mathrm{L}})$ in $M_n\|j_{0,n}(\nu_{\mathrm{L}}) + 3$.

(2) For odd $n < \omega$, u_{n-1} is realized by α_n in $M_n\|\alpha_n + 3$, and u_n is realized by α_n in $M_n\|\alpha_n + 1$.

The construction is similar to that of the previous exercise, except that the use of the projection introduces some changes. The ordinals α_n for $n > 1$ odd are chosen using the third clause of Definition 3.6, applied to the fact that u_{n-1} is a subtype of $j_{n-2,n}(\mathrm{proj}^0(u_{n-2}))$. If you get $\alpha_n < j_{n-2,n}(\alpha_{n-2})$ for $n > 1$ odd, then you are on the right track. $\dashv$

3.30 Exercise. Go back to the last exercise, and make sure that the tree you construct is nice.

4. Homogeneously Suslin Sets

By a *tree* on a set X we mean a set $T \subseteq X^{<\omega}$, closed under initial segments. We use $[T]$ to denote the set of infinite branches through T, that is the set $\{x \in X^\omega \mid (\forall n) x \restriction n \in T\}$. Given a tree T on $X \times Y$ we often think of T as a subset of $X^{<\omega} \times Y^{<\omega}$ rather than $(X \times Y)^{<\omega}$, and similarly we think of $[T]$ as a subset of $X^\omega \times Y^\omega$. For T a tree on $X \times Y$ we use $p[T]$ to denote the *projection* of $[T]$ to X^ω, namely the set $\{x \in X^\omega \mid (\exists y)\langle x, y\rangle \in [T]\}$. We use T_s (for $s \in X^{<\omega}$) to denote the set $\{t \in Y^{<\omega} \mid \langle s, t\rangle \in T\}$, and use T_x (for $x \in X^\omega$) to denote the tree $\bigcup_{n<\omega} T_{x\restriction n}$. x is an element of $p[T]$ iff $[T_x]$ is non-empty. We sometimes apply similar terminology in the case that T is a tree on a product of more than two sets, for example $p[T] = \{x \mid (\exists y)(\exists z)\langle x, y, z\rangle \in [T]\}$ in the case that T is a tree on $X \times Y \times Z$.

Recall that a set $A \subseteq X^\omega$ is $\mathbf{\Sigma}^1_1$ iff there is a tree R on $X \times \omega$ so that $A = p[R]$. A set is $\mathbf{\Pi}^1_n$ if its complement is $\mathbf{\Sigma}^1_n$; and a set $A \subseteq X^\omega$ is $\mathbf{\Sigma}^1_{n+1}$ (for $n \geq 1$) if there is a $\mathbf{\Pi}^1_n$ set $B \subseteq X^\omega \times \omega^\omega$ so that $x \in A \iff (\exists y)\langle x, y\rangle \in B$. A set is *projective* if it is $\mathbf{\Pi}^1_n$ for some $n < \omega$. The projective sets are thus obtained from closed sets using complementations and projections along the real line.

The sets of reals in the very first level $L_1(\mathbb{R})$ (Definition 8.3) are precisely the projective sets, and our climb to $\mathsf{AD}^{L(\mathbb{R})}$ begins at the low end of the projective hierarchy. We prove determinacy for $\mathbf{\Pi}^1_1$ sets assuming measurable cardinals. The proof, due to Martin [16], can with hindsight be divided into two parts: a proof, using a measurable cardinal κ, that all $\mathbf{\Pi}^1_1$ sets are κ-homogeneously Suslin (see below for the definition); and a proof that all homogeneously Suslin sets are determined.

Let γ be an ordinal and let $m < n < \omega$. For $Z \subseteq \gamma^m$ let $Z^* = \{f \in \gamma^n \mid f\restriction m \in Z\}$. A measure ν over γ^n is an *extension* of a measure μ over γ^m just in case that for every $Z \subseteq \gamma^m$, $\mu(Z) = 1 \rightarrow \nu(Z^*) = 1$.

A *tower of measures* over γ is a sequence $\langle \mu_n \mid n < \omega\rangle$ so that:

(i) μ_n is a measure over γ^n for each n.

(ii) μ_n is an extension of μ_m for all $m < n < \omega$.

The tower is *countably complete* just in case that:

(iii) If $\mu_n(Z_n) = 1$ for each n then there is a fiber through $\langle Z_n \mid n < \omega\rangle$, namely a sequence $\langle \alpha_i \mid i < \omega\rangle$ so that $\langle \alpha_0, \ldots, \alpha_{n-1}\rangle \in Z_n$ for each n.

For sequences s and t we write $s \leq t$ to mean that s is an initial segment of t, and $s < t$ to mean that s is a proper initial segment of t.

4.1 Definition. A tree T on $X \times \gamma$ is *homogeneous* if there is a sequence of measures $\langle \mu_s \mid s \in X^{<\omega}\rangle$ so that:

(1) For each $s \in X^{<\omega}$, μ_s is a measure over T_s (equivalently, over $\gamma^{\mathrm{lh}(s)}$ with $\mu_s(T_s) = 1$), and μ_s is $\mathrm{card}(X)^+$-complete.

(2) If $s \leq t$ then μ_t is an extension of μ_s.

It follows from condition (2) that for every $x \in X^\omega$, the sequence $\langle \mu_{x\restriction n} \mid n < \omega\rangle$ is a tower.

(3) If $x \in p[T]$ then the tower $\langle \mu_{x\restriction n} \mid n < \omega\rangle$ is countably complete.

T is *κ-homogeneous* if in addition each of the measures μ_s is κ-complete.

4.2 Exercise. Let T be a homogeneous tree on $X \times \gamma$. Prove that there is a system $\langle M_s, f_s, j_{s,t} \mid s \le t \in X^{<\omega}\rangle$ of (wellfounded) models M_s, nodes f_s, and embeddings $j_{s,t}$ satisfying the following conditions:

(1) $j_{s,t} : M_s \to M_t$ for each $s \le t$, $\mathrm{crit}(j_{s,t})$ is larger than $\mathrm{card}(X)$, $M_\emptyset = V$, and the system $\langle M_s, j_{s,t} \mid s \le t \in X^{<\omega}\rangle$ commutes in the natural way.

(2) $f_s \in j_{\emptyset,s}(T_s)$ for each $s \in X^{<\omega}$, and the nodes $\langle f_s \mid s \in X^{<\omega}\rangle$ cohere in the natural way, meaning that $s < t \Longrightarrow j_{s,t}(f_s) < f_t$.

(3) If $x \in p[T]$ then the system $\langle M_s, j_{s,t} \mid s \le t < x\rangle$ has a wellfounded direct limit.

Hint. Let $M_s = \mathrm{Ult}(V, \mu_s)$ and let $j_s : V \to M_s$ be the ultrapower embedding. Let f_s be the seed of the measure μ_s. Notice that f_s is an element of $j_s(T_s)$.

Recall that each element of M_s has the form $j_s(g)(f_s)$ for some function $g : \gamma^{\mathrm{lh}(s)} \to V$. For $s \le t \in X^{<\omega}$ define an embedding $j_{s,t} : M_s \to M_t$ by letting $j_{s,t}$ send $j_s(g)(f_s)$ to $j_t(g)(f_t \restriction \mathrm{lh}(f_s))$.

Prove that the resulting system satisfies conditions (1)–(3). $\dashv$

4.3 Exercise. Let T be a tree on $X \times \gamma$ and suppose that there is a system $\langle M_s, f_s, j_{s,t} \mid s \le t \in X^{<\omega}\rangle$ satisfying the conditions in Exercise 4.2. Prove that T is homogeneous.

Suppose in addition that the embeddings $j_{s,t}$ all have critical points at least κ. Show that T is κ-homogeneous.

Hint. Set $\mu_s(Z) = 1$ iff $f_s \in j_{\emptyset,s}(Z)$. Prove that the resulting system of measures $\langle \mu_s \mid s \in X^{<\omega}\rangle$ satisfies the conditions in Definition 4.1. $\dashv$

The existence of a system satisfying the conditions in Definition 4.1 is thus equivalent to the existence of a system satisfying the conditions in Exercise 4.2. We use the two systems alternately, and refer to both of them as *homogeneity systems* for the tree T.

4.4 Exercise. Show that the converse of condition (3) in Exercise 4.2 follows from conditions (1) and (2) in the exercise. Condition (3) can therefore be strengthened to an equivalence, and so can condition (3) in Definition 4.1.

Hint. Fix x. Let M_x be the direct limit of the system $\langle M_s, j_{s,t} \mid s \le t < x\rangle$, and let $j_{s,x} : M_s \to M_x$ for $s < x$ be the direct limit embeddings. Let $f_x = \bigcup_{s<x} j_{s,x}(f_s)$, and notice that using condition (2), f_x is an infinite branch through $j_{\emptyset,x}(T_x)$. Use the wellfoundedness of M_x to find some infinite branch f through $j_{\emptyset,x}(T_x)$ with $f \in M_x$, and then using the elementarity of $j_{\emptyset,x}$ argue that $x \in p[T]$. $\dashv$

A set $A \subseteq X^\omega$ is *Suslin* if there is an ordinal γ and a tree T on $X \times \gamma$ so that $p[T] = A$. $A \subseteq X^\omega$ is *homogeneously Suslin* if in addition T can be taken to be homogeneous, and κ*-homogeneously Suslin* if T can be taken to be κ-homogeneous. These definitions are due independently to Kechris and Martin. In the context of the axiom of choice, which we employ throughout the chapter, every $A \subseteq X^\omega$ is Suslin. But of course not every set is homogeneously Suslin.

Let κ be a measurable cardinal. Fix a set $X \in V \| \kappa$ and a $\mathbf{\Pi}^1_1$ set $A \subseteq X^\omega$. We aim to show that A is κ-homogeneously Suslin.

4.5 Exercise. Let $R \subseteq \omega^{<\omega}$ be a tree. The *Kleene-Brouwer order* on R is the strict order $\prec$ defined by the condition: $s \prec t$ iff s extends t or $s(n) < t(n)$ where n is least so that $s(n) \neq t(n)$. Prove that $\prec$ is illfounded iff R has an infinite branch.

4.6 Exercise. Show that there is a map $s \mapsto \prec_s$, defined on $s \in X^{<\omega}$, so that:

- $\prec_s$ is a linear order on $\mathrm{lh}(s)$.
- If $s \leq t$ then $\prec_s \subseteq \prec_t$.
- $x \in A$ iff $\prec_x$ is wellfounded, where $\prec_x = \bigcup_{n<\omega} \prec_{x \restriction n}$.

The last condition is the most important one. The first two conditions are needed to make sense of $\prec_x$.

Hint to Exercise 4.6. Let $R \subseteq (X \times \omega)^{<\omega}$ be a tree so that $p[R]$ is precisely equal to the complement of A. Define the map $s \mapsto \prec_s$ in such a way that for each $x \in X^\omega$, $\prec_x$ is isomorphic to the Kleene-Brouwer order on R_x. $\dashv$

Let $T \subseteq X \times \kappa$ be the tree consisting of nodes $\langle s, f \rangle$ so that f has the form $\langle \alpha_0, \ldots, \alpha_{\mathrm{lh}(s)-1} \rangle$ with $\alpha_i < \kappa$ for each i, and $\alpha_i < \alpha_j$ iff $i \prec_s j$.

4.7 Exercise. Show that $p[T] = A$.

Since κ is measurable, there is an elementary embedding $j : V \to M$ with $\mathrm{crit}(j) = \kappa$. Let μ be the measure over κ defined by $\mu(Z) = 1$ iff $\kappa \in j(Z)$.

4.8 Exercise. Prove that μ is a κ-complete, non-principal measure on κ.

4.9 Exercise. A function $f : \kappa \to \kappa$ is *pressing down* if $f(\alpha) < \alpha$ for all $\alpha < \kappa$. A measure over κ is called *normal* if every pressing down function on κ is constant on a set of measure one. Prove that the measure μ defined above is normal.

4.10 Exercise. The *diagonal intersection* of the sets Z_α $(\alpha < \kappa)$ is defined to be the set $\{\xi \in \kappa \mid (\forall \alpha < \xi) \xi \in Z_\alpha\}$. Prove, for the measure μ defined above, that the diagonal intersection of sets of measure one has measure one.

For each $s \in X^{<\omega}$ and each $C \subseteq \kappa$ define C^s to be the set of tuples $\langle \alpha_0, \dots, \alpha_{\mathrm{lh}(s)-1} \rangle$ with $\alpha_i \in C$ for each i, and $\alpha_i < \alpha_j$ iff $i \prec_s j$. Define a filter $\mathcal{F}_s$ over $\kappa^{\mathrm{lh}(s)}$ by setting $Z \in \mathcal{F}_s$ iff there exists a set $C \subseteq \kappa$ so that $Z \supseteq C^s$ and $\mu(C) = 1$.

4.11 Exercise. Prove that $\mathcal{F}_s$ is an ultrafilter over $\kappa^{\mathrm{lh}(s)}$, meaning that for every $Z \subseteq \kappa^{\mathrm{lh}(s)}$, either $Z \in \mathcal{F}_s$ or else $\kappa^s - Z \in \mathcal{F}_s$.

Hint. Work by induction on the length of s. The inductive step makes several uses of Exercises 4.9 and 4.10. $\dashv$

Define a two-valued measure μ_s on κ^s by setting $\mu_s(Z) = 1$ iff $Z \in \mathcal{F}_s$.

4.12 Exercise. Prove that μ_s is κ-complete.

4.13 Exercise. Let $s \leq t \in X^{<\omega}$. Prove that μ_t extends μ_s.

4.14 Exercise. Let $x \in X^\omega$, and suppose that x belongs to A, so that $\prec_x$ is wellfounded. Prove that the tower $\langle \mu_{x \restriction n} \mid n < \omega \rangle$ is countably complete.

Hint. Suppose that $\mu_{x \restriction n}(Z_n) = 1$ for each $n < \omega$. Fix C_n so that $\mu(C_n) = 1$ and $C_n^s \subseteq Z_n$. Let $C = \bigcap_{n<\omega} C_n$. Then $C^s \subseteq Z_n$ for each n, and $\mu(C) = 1$ by countable completeness. Since $x \in A$, $\prec_x$ is wellfounded. The order $\prec_x$ can therefore be embedded into the ordinals, and in fact into C since C is uncountable. Pick then a sequence $\langle \alpha_i \mid i < \omega \rangle$ of ordinals in C so that $i \prec_x j$ iff $\alpha_i < \alpha_j$. The sequence $\langle \alpha_i \mid i < \omega \rangle$ is a fiber through $\langle Z_n \mid n < \omega \rangle$. $\dashv$

4.15 Theorem. *Let κ be a measurable cardinal. Let X belong to $V \| \kappa$ and let $A \subseteq X^\omega$ be $\mathbf{\Pi}^1_1$. Then A is κ-homogeneously Suslin.*

Proof. Let $T \subseteq (X \times \kappa)^{<\omega}$ be the tree defined above and let μ_s be the measures defined above. Exercises 4.12 through 4.14 establish that $\langle \mu_s \mid s \in X^{<\omega} \rangle$ is a κ-homogeneity system for T. $\dashv$

Next we prove that homogeneously Suslin sets are determined. We work for the rest of the section with some set X and a homogeneously Suslin set $A \subseteq X^\omega$. Let T and $\langle \mu_s \mid s \in X^{<\omega} \rangle$ witness that A is homogeneously Suslin.

Define G^* to be the game played according to Diagram 22.8 and the following rules:

- $x_n \in X$ for each $n < \omega$.
- $\langle x_0, \alpha_0, \dots, x_{n-1}, \alpha_{n-1} \rangle \in T$ for each $n < \omega$.

The first rule is a requirement on player I if n is even, and on player II if n is odd. The second rule is a requirement on player I. A player who violates a rule loses. Infinite runs of G^* are won by player I.

4.16 Exercise. Prove that G^* is determined.

$$\begin{array}{c|ccccccccc}
\text{I} & x_0 & \alpha_0 & & \alpha_1 & x_2 & \alpha_2 & & \alpha_3 & \dots & \\
\hline
\text{II} & & & x_1 & & & & x_3 & & & \dots
\end{array}$$

Diagram 22.8: The game G^*

Hint. You are asked to prove the famous theorem of Gale-Stewart [6] that infinite games with closed payoff are determined. Let S be the set of positions in G^* from which player II has a winning strategy. If the initial position belongs to S, then player II has a winning strategy in G^*. Suppose that the initial position does not belong to S, and prove that there is a strategy for player I which stays on positions outside S, and that this strategy is winning. $\dashv$

4.17 Exercise. Suppose that player I has a winning strategy in G^*. Prove that player I has a winning strategy in $G_\omega(A)$.

Hint. Let σ^* be a winning strategy for I in G^*. Say that a position $p = \langle x_0, \dots, x_{n-1}\rangle$ in $G_\omega(A)$ is nice if it can be expanded to a position $p^* = \langle x_0, \alpha_0, \dots, x_{n-1}, \alpha_{n-1}\rangle$ in G^* so that p^* is according to σ^*. Note that if such an expansion exists, then it is unique. Define a strategy σ for I in $G_\omega(A)$ by setting $\sigma(p) = \sigma^*(p^*)$. Show that every infinite run according to σ belongs to $p[T]$, and is therefore won by player I in $G_\omega(A)$. $\dashv$

4.18 Lemma. *Suppose that player* II *has a winning strategy in* G^*. *Then player* II *has a winning strategy in* $G_\omega(A)$.

Proof. Let σ^* be a winning strategy for II in G^*.

Let $s = \langle x_0, \dots, x_{i-1}\rangle$ be a position of odd length in $G_\omega(A)$. For each $\varphi = \langle \alpha_0, \dots, \alpha_{i-1}\rangle \in T_s$, let $h_s(\varphi)$ be σ^*'s move following the position $\langle x_0, \alpha_0, \dots, x_{i-1}, \alpha_{i-1}\rangle$ in G^*. h_s is then a function from T_s into X. By the completeness of μ_s there is a specific move x_i so that:

($*$) $\{\varphi \mid h_s(\varphi) = x_i\}$ has μ_s-measure one.

Define $\sigma(s)$ to be equal to this x_i.

Suppose now that $x = \langle x_i \mid i < \omega\rangle$ is an infinite run of $G_\omega(A)$, played according to σ. We have to show that x is won by player II.

Using condition ($*$) fix for each odd $n < \omega$ a set $Z_n \subseteq T_{x\restriction n}$ so that $h_{x\restriction n}(\varphi) = x_n$ for every $\varphi \in Z_n$ and $\mu_{x\restriction n}(Z_n) = 1$. For even $n < \omega$ let $Z_n = T_{x\restriction n}$.

Suppose for contradiction that $x \in A$. Then $\langle \mu_{x\restriction n} \mid n < \omega\rangle$ is countably complete and so there is a fiber $\langle \alpha_i \mid i < \omega\rangle$ for the sequence $\langle Z_n \mid n < \omega\rangle$. In other words there is a sequence $\langle \alpha_i \mid i < \omega\rangle$ in $[T_x]$ so that $h_{x\restriction n}(\langle \alpha_0, \dots, \alpha_{n-1}\rangle) = x_n$ for each odd $n < \omega$. But then $\langle x_i, \alpha_i \mid i < \omega\rangle$ is a run of G^* and is consistent with σ^*. This is a contradiction, since σ^* is a winning strategy for player II, and infinite runs of G^* are won by player I. $\dashv$

4.19 Corollary. *Let $A \subseteq X^\omega$ be homogeneously Suslin. Then $G_\omega(A)$ is determined.*

Proof. By Exercise 4.16, G^* is determined. By Exercise 4.17 and Lemma 4.18, the player who has a winning strategy in G^* has a winning strategy in $G_\omega(A)$. ⊣

Theorem 4.15 and Corollary 4.19 establish the determinacy of $\mathbf{\Pi}^1_1$ subsets of ω^ω, assuming the existence of a measurable cardinal. In the next section we deal with $\mathbf{\Pi}^1_2$ sets.

5. Projections and Complementations

Martin and Steel [21] use Woodin cardinals to propagate the property of being homogeneously Suslin under complementation and existential real quantification, proving in this manner that all projective sets are determined. In this section we present their results. We begin by proving that if δ is a Woodin cardinal, and $A \subseteq X^\omega \times \omega^\omega$ is δ^+-homogeneously Suslin, then the set $B = \{x \in X^\omega \mid (\forall y)\langle x, y\rangle \notin A\}$ is determined. We then go on to show that B is κ-homogeneously Suslin for all $\kappa < \delta$. Together with the results in Sect. 4 this shows that all $\mathbf{\Pi}^1_{n+1}$ sets are determined, assuming that there are n Woodin cardinals and a measurable cardinal above them.

Let δ be a Woodin cardinal. Let X be a set in $V \| \delta$, and let $A \subseteq X^\omega \times \omega^\omega$. Let $B = \{x \in X^\omega \mid (\forall y)\langle x, y\rangle \notin A\}$. Suppose that A is δ^+-homogeneously Suslin, and let $S \subseteq (X \times \omega \times \gamma)^{<\omega}$ (for some ordinal γ) and $\langle \mu_{s,t} \mid \langle s, t\rangle \in (X \times \omega)^{<\omega}\rangle$ witness this.

5.1 Remark. The objects in the homogeneity system are given for pairs $\langle s, t\rangle \in X^{<\omega} \times \omega^{<\omega}$ with $\mathrm{lh}(s) = \mathrm{lh}(t)$. We sometimes write $\mu_{s,t}$ or $S_{s,t}$ also when s and t are of different length. We mean $\mu_{s\restriction n, t\restriction n}$ where $n = \min\{\mathrm{lh}(s), \mathrm{lh}(t)\}$, and similarly with $S_{s,t}$. We also write $\mu_{x,t}$ for $x \in X^\omega$ to mean $\mu_{x\restriction n,t}$ where $n = \mathrm{lh}(t)$, and similarly with $S_{x,t}$.

5.2 Exercise (Martin-Solovay [20]). Let t_i ($i < \omega$) enumerate $\omega^{<\omega}$. The *Martin-Solovay tree* for the complement of $p[A]$, where $A \subseteq X^\omega \times \omega^\omega$ is the projection of a tree S with homogeneity system $\langle \mu_{s,t} \mid \langle s, t\rangle \in (X \times \omega)^{<\omega}\rangle$, is the tree of attempts to create $x \in X^\omega$ and a sequence $\langle \rho_i \mid i < \omega\rangle$ so that:

(i) ρ_i is a partial function from $S_{x\restriction \mathrm{lh}(t_i), t_i}$ into $|S|^+$, and the domain of ρ_i has $\mu_{x\restriction \mathrm{lh}(t_i), t_i}$-measure one.

(ii) If $t_i < t_j$ then $\rho_i(f \restriction \mathrm{lh}(t_i)) > \rho_j(f)$ for every $f \in \mathrm{dom}(\rho_j)$.

Prove that this tree projects to $X^\omega - p[A]$.

Definitions 5.3 and 5.6 below essentially code a subset of the Martin-Solovay tree for B by a relation on types. We will use this coding to prove that

$G_\omega(B)$ is determined, and that in fact B is homogeneously Suslin. Martin-Steel [21] proved that the Martin-Solovay tree itself is homogeneous. We work with types, rather than the Martin-Solovay tree of functions, in preparation for Sect. 6.

The constructions below use the definitions of Sect. 3. By type here we always mean a type with domain less than δ and greater than $\mathrm{rank}(X)$. All realizations in V are relative to the fixed Woodin cardinal δ. The variable v_0 in each type will always be realized by S. (Realizations in iterates M of V are made relative to the appropriate image of δ, and with the first variable realized by the image of S.)

5.3 Definition. Let $\langle s,t\rangle \in X^{<\omega}\times\omega^{<\omega}$, with $\mathrm{lh}(s)=\mathrm{lh}(t)=k$ say. Let w be a $(k+2)$-type. Define $Z_{s,t}$ to be the set of $f \in S_{s,t}$ for which $(\exists\eta\in\mathrm{On})(\exists\alpha > \max\{\delta,\mathrm{rank}(S)\})$ so that w is realized by S, $\langle 0,f(0)\rangle$, ..., $\langle k-1,f(k-1)\rangle$, and α in $V\|\eta$. Define $\rho_{s,t} : Z_{s,t} \to \mathrm{On}$ by setting $\rho_{s,t}(f)$ equal to the least η witnessing the existential statement above.

5.4 Remark. Both $Z_{s,t}$ and $\rho_{s,t}$ depend on w. When we wish to emphasize the dependence we write $Z_{s,t}(w)$ and $\rho_{s,t}(w)$.

Definition 5.3 lets us view types as defining partial functions $\rho_{s,t}$ from $S_{s,t}$ into the ordinals. The domain of the partial function $\rho_{s,t}$ is $Z_{s,t}$. Connecting the definition to the homogeneity system, let us say that w is $\langle s,t\rangle$-*nice* if $Z_{s,t}$ has $\mu_{s,t}$-measure one.

5.5 Claim. *Let w be a $(k+2)$-type and suppose that w is $\langle s,t\rangle$-nice. Then w contains the formula "$\{v_1,\dots,v_k\}$ is a node in the tree $(v_0)_{\widetilde{s},\widetilde{t}}$".*

Note that both s and t belong to the domain of w, since they are elements of $X^{<\omega}$, and the domain of w is greater than $\mathrm{rank}(X)$ (see the comment following Remark 5.1). The reference to $\widetilde{s}$ and $\widetilde{t}$ in a formula which may potentially belong to w therefore makes sense. $(v_0)_{\widetilde{s},\widetilde{t}}$ in the formula stands for the tree of nodes g so that $\langle s,t,g\rangle$ belongs to the interpretation of v_0.

Proof of Claim 5.5. Let f be any element of $Z_{s,t}(w)$. ($Z_{s,t}$ has $\mu_{s,t}$-measure one, and so certainly it is not empty.) Then

(1) w is realized by S, $\langle 0,f(0)\rangle$, ..., $\langle k-1,f(k-1)\rangle$, α in $V\|\eta$ for some α and η.

(2) $\langle s,t,f\rangle$ belongs to S, meaning that f, which is formally equal to the set $\{\langle 0,f(0)\rangle,\dots,\langle k-1,f(k-1)\rangle\}$, belongs to $S_{s,t}$.

It follows that the formula in the claim belongs to w. ⊣

5.6 Definition. Let s' and t' extend s and t (perhaps not strictly), with $\mathrm{lh}(s') = \mathrm{lh}(t') = k'$. Let w be $\langle s,t\rangle$-nice and let w' be $\langle s',t'\rangle$-nice. We write $w' \prec w$ to mean that the set $\{f' \in S_{s',t'} \mid \rho_{s',t'}(w')(f') < \rho_{s,t}(w)(f'{\restriction}k)\}$ has $\mu_{s',t'}$-measure one.

5.7 Claim. *The relation $\prec$ is transitive.*

5.8 Definition. Given a $k{+}2$-type w we use $\mathrm{dcp}(w)$ (pronounced "decap w") to denote $\mathrm{proj}^{k+1}(w)$. If w is realized by S, $\langle 0, f(0)\rangle$, $\dots$, $\langle k-1, f(k-1)\rangle$, and α, then $\mathrm{dcp}(w)$ is realized by S, $\langle 0, f(0)\rangle$, $\dots$, and $\langle k-1, f(k-1)\rangle$.

5.9 Claim. *Let w be $\langle s,t\rangle$-nice, and suppose that w contains the formula "$\mathrm{v}_{k+1}+2$ exists" (where $k = \mathrm{lh}(s) = \mathrm{lh}(t)$, and w is a $(k+2)$-type). Let s' and t' extend s and t, with $\mathrm{lh}(s') = \mathrm{lh}(t') = k'$. Then there is a $(k'+2)$-type u so that:*

(1) u is $\langle s', t'\rangle$-nice.

(2) u contains the formula "$\mathrm{v}_{k'+1}$ is the largest ordinal".

(3) $\mathrm{dcp}(u)$ is elastic.

(4) u exceeds w.

(5) $u \prec w$.

Proof. Fix for a moment some $f' \in S_{s',t'}$, and suppose that $f'{\restriction}k \in Z_{s,t}(w)$. Let $\eta = \rho_{s,t}(f'{\restriction}k)$, so that w is realized by S, $\langle 0, f'(0)\rangle, \dots, \langle k-1, f'(k-1)\rangle$, and some $\alpha > \max\{\delta, \mathrm{rank}(S)\}$ in $V\|\eta$. Since w contains the formula "$v_{k+1}+2$ exists", it must be that $\eta > \alpha+2$.

Let $\tau < \delta$ be such that the τ-type of S, $\langle 0, f'(0)\rangle, \dots,$ and $\langle k'-1, f'(k'-1)\rangle$ in $V\|\alpha+1$ is elastic, and such that $\tau > \mathrm{dom}(w)$. Such a τ exists by Lemma 3.22. Let u be the τ-type of S, $\langle 0, f'(0)\rangle$, $\dots$, $\langle k'-1, f'(k'-1)\rangle$, and α in $V\|\alpha+1$. Then u contains the formula "$v_{k'+1}$ is the largest ordinal", u exceeds w, and $\mathrm{dcp}(u)$ is elastic.

The type u defined above depends on the node $f' \in S_{s',t'}$ used. To emphasize the dependence let us from now on write $u(f')$ to denote this type. Let us similarly write $\alpha(f')$ and $\eta(f')$ to emphasize the dependence of α and η on f'.

The function $f' \mapsto u(f')$ maps $\{f' \in S_{s',t'} \mid f'{\restriction}k \in Z_{s,t}\}$ into $V\|\delta$. Using the fact that $Z_{s,t}$ has $\mu_{s,t}$-measure one it is easy to check that the domain of this function has $\mu_{s',t'}$-measure one. From this and the δ^+-completeness of the measures it follows that the function is fixed on a set of $\mu_{s',t'}$-measure one. Thus, there exists a particular type u, and a set $Z \subseteq S_{s',t'}$, so that $u(f') = u$ for each $f' \in Z$, and Z has $\mu_{s',t'}$-measure one.

Clearly $Z_{s',t'}(u) \supseteq Z$, and it follows from this that u is $\langle s',t'\rangle$-nice. It is also clear that $\rho_{s',t'}(u)(f') \le \alpha(f')+1 < \eta(f')$ for each $f' \in Z$, and it follows from this that $u \prec w$. $\dashv$

5.10 Claim. *Let u be $\langle s,t\rangle$-nice, where $\mathrm{lh}(s) = \mathrm{lh}(t) = k$. Let w be a $(k+2)$-type, containing the formula "$\mathrm{v}_{k+1} > \max\{\widetilde{\delta}, \mathrm{rank}(\mathrm{v}_0)\}$". Suppose that w is a subtype of $\mathrm{dcp}(u)$. Then w is $\langle s,t\rangle$-nice, and $w \prec u$.*

Proof. Fix for a moment some $f \in Z_{s,t}(u)$. Let $\eta = \rho_{s,t}(u)(f)$, so that u is realized by S, $\langle 0, f(0)\rangle, \ldots, \langle k-1, f(k-1)\rangle$, and some α in $V\|\eta$.

Since w is a subtype of $\text{dcp}(u)$, there must be some β and some ν so that w is realized by S, $\langle 0, f(0)\rangle, \ldots, \langle k-1, f(k-1)\rangle$, and β in $V\|\nu$, and so that $\nu < \eta$. Since w contains the formula "$v_{k+1} > \max\{\widetilde{\delta}, \text{rank}(v_0)\}$", β is greater than $\max\{\delta, \text{rank}(S)\}$.

It follows from the argument of the previous paragraph that, for each $f \in Z_{s,t}(u)$, there exist ν and $\beta > \max\{\delta, \text{rank}(S)\}$ so that w is realized by S, $\langle 0, f(0)\rangle, \ldots, \langle k-1, f(k-1)\rangle$, and β in $V\|\nu$, and that the least ν witnessing this is smaller than $\rho_{s,t}(u)(f)$. In other words $f \in Z_{s,t}(w)$ and $\rho_{s,t}(w)(f) < \rho_{s,t}(u)(f)$, for each $f \in Z_{s,t}(u)$. Since $Z_{s,t}(u)$ has $\mu_{s,t}$-measure one this implies that w is $\langle s,t\rangle$-nice and that $w \prec u$. ⊣

5.11 Claim. *Let $x \in X^\omega$. Suppose that there are types $\langle w_t \mid t \in \omega^{<\omega}\rangle$ so that:*

(1) Each w_t is $\langle x,t\rangle$-nice.

(2) For each $t < t^* \in \omega^{<\omega}$, $w_{t^*} \prec w_t$.

Then $x \in B$.

Proof. We have to show that $(\forall y \in \omega^\omega)\langle x,y\rangle \notin A$. Fix $y \in \omega^\omega$. For each $n < \omega$ let μ_n denote $\mu_{x\restriction n, y\restriction n}$. Let ρ_n denote $\rho_{x,y\restriction n}(w_{y\restriction n})$. ρ_n is a partial function with domain a μ_n-measure one subset of $S_{x\restriction n, y\restriction n}$.

Set $Z_0 = S_{\emptyset,\emptyset}$ and for each $n < \omega$ set $Z_{n+1} = \{f \in S_{x\restriction n+1, y\restriction n+1} \mid \rho_{n+1}(f) < \rho_n(f\restriction n)\}$. By assumption $w_{y\restriction n+1} \prec w_{y\restriction n}$ so Z_{n+1} has μ_{n+1}-measure one.

Suppose for contradiction that $\langle x,y\rangle \in A$. The tower $\langle \mu_n \mid n < \omega\rangle$ is then countably complete by Definition 4.1, so the sequence $\langle Z_n \mid n < \omega\rangle$ has a fiber, $f = \langle \alpha_i \mid i < \omega\rangle$ say. Then $f\restriction n+1 \in Z_{n+1}$ for each $n < \omega$, meaning that $\rho_{n+1}(f\restriction n+1) < \rho_n(f\restriction n)$, so that $\langle \rho_n(f\restriction n) \mid n < \omega\rangle$ is an infinite descending sequence of ordinals, contradiction. ⊣

Let $\langle \nu_{\text{L}}, \nu_{\text{H}}\rangle$ be the lexicographically least pair of local indiscernibles (Definition 3.27) of V relative to $\max\{\delta, \text{rank}(S)\}$, minimizing first over the second coordinate.

5.12 Claim. *For each $\kappa < \delta$, the κ-type of S and ν_{L} in $V\|\nu_{\text{L}} + 1$ is $\langle\emptyset,\emptyset\rangle$-nice.*

For $t \in \omega^{<\omega}$ let $\text{pred}(t)$ denote $t\restriction(\text{lh}(t) - 1)$.

5.13 Definition. Define G^*, illustrated in Diagram 22.9, to be played according to the following rules:

(1) $x_n \in X$.

(2) $t_n \in \omega^{<\omega}$.

I		w_0	x_0		w_1			w_2	x_2	$\ldots$
II	l_0, t_0, u_0			l_1, t_1, u_1		x_1	l_2, t_2, u_2			$\ldots$

Diagram 22.9: The game G^*

(3) u_n is a (k_n+2)-type, $\mathrm{dcp}(u_n)$ is elastic, and u_n contains the formula "$\{v_1, \ldots, v_{k_n}\}$ is a node in the tree $(v_0)_{\tilde{s}_n, \tilde{t}_n}$", where $k_n = \mathrm{lh}(t_n)$ and $s_n = x \restriction k_n$.

(4) If $n > 0$ then $\mathrm{dom}(u_n) > \mathrm{dom}(u_{n-1})$. (And $\mathrm{dom}(u_0) > \mathrm{rank}(X)$, see the comment following Remark 5.1.)

(5) If $t_n = \emptyset$ then u_n is realized by S and ν_{L} in $V \| \nu_{\mathrm{L}} + 1$.

(6) If $t_n \neq \emptyset$ then $l_n < n$ is such that $t_{l_n} = \mathrm{pred}(t_n)$, and u_n exceeds w_{l_n}.

(7) w_n too is a (k_n+2)-type, w_n is a subtype of $\mathrm{dcp}(u_n)$, and w_n contains the formulae "$v_{k_n+1} > \max\{\widetilde{\delta}, \mathrm{rank}(v_0)\}$" and "$v_{k_n+1}+2$ exists and is the largest ordinal".

The first player to violate any of the rules loses. Infinite runs where all rules have been followed are won by player I.

5.14 Lemma. *Suppose that player* I *has a winning strategy in G^*. Then player* I *has a winning strategy in $G_\omega(B)$.*

Proof. Let σ^* be a winning strategy for player I in G^*. Let $\langle t^*_n \mid n < \omega \rangle$ enumerate $\omega^{<\omega}$ in such a way that $(\forall t \in \omega^{<\omega})$ $\mathrm{pred}(t)$ is enumerated before t. In particular $t^*_0 = \emptyset$. For $n > 0$ let $l^*_n < n$ be such that $\mathrm{pred}(t^*_n) = t^*_{l^*_n}$. Let $l^*_0 = 0$.

Fix an opponent willing to play for II in $G_\omega(B)$. We describe how to play against the opponent, and win. Our description takes the form of a construction of a run of G^*. σ^* supplies moves for I. The opponent supplies the moves $x_1, x_3, x_5, \ldots$ for II. It is up to us to come up with the remaining moves, l_n, t_n, u_n for $n < \omega$. We make sure as we play that:

(1) $t_n = t^*_n$ and $l_n = l^*_n$.

(2) u_n contains the formula "v_{k_n+1} is the largest ordinal" where $k_n = \mathrm{lh}(t_n)$.

(3) u_n is $\langle x, t_n \rangle$-nice.

(We write $\langle x, t_n \rangle$-nice, but notice that only $x \restriction \mathrm{lh}(t_n)$ is relevant to the condition.)

w_n, by the rules of G^*, is a (k_n+2)-type, is a subtype of $\mathrm{dcp}(u_n)$, and contains the formula "$v_{k_n+1} > \max\{\widetilde{\delta}, \mathrm{rank}(v_0)\}$". It follows by Claim 5.10 that:

(i) w_n is $\langle x, t_n\rangle$-nice.

(ii) $w_n \prec u_n$.

Let us now describe how to play l_n, t_n, and u_n. We begin with the case $n = 0$. Set $t_0 = \emptyset$ and $l_0 = 0$. Using Lemma 3.22 let $\kappa_0 < \delta$ be such that the κ_0-type of S in $V\|\nu_{\text{L}} + 1$ is elastic. Set u_0 to be the κ_0-type of S and ν_{L} in $V\|\nu_{\text{L}} + 1$. These assignments determine the moves l_0, t_0, and u_0. It is easy to check that they satisfy the relevant rules of G^*, and conditions (1)–(3) above for $n = 0$.

Suppose next that rounds 0 through $n-1$ have been played, subject to the relevant rules and to conditions (1)–(3) above. Set $t_n = t_n^*$ and $l_n = l_n^*$. Note that by condition (i), w_{l_n} is $\langle x, t_{l_n}\rangle$-nice. Let $k_n = \text{lh}(t_n)$. Using Claim 5.9, set u_n to be a (k_n+2)-type so that: u_n is $\langle x, t_n\rangle$-nice; u_n contains the formula "v_{k_n+1} is the largest ordinal"; $\text{dcp}(u_n)$ is elastic; u_n exceeds w_{l_n}; and $u_n \prec w_{l_n}$. These assignments determine the moves l_n, t_n, and u_n. It is again easy to check that they satisfy the relevant rules of G^*, and conditions (1)–(3) above. For the record let us note that we have also the following condition:

(iii) $u_n \prec w_{l_n}$.

The assignments made above, together with moves supplied by σ^* and by the opponent, determine an infinite run $\langle l_n, t_n, w_n, u_n, x_n \mid n < \omega\rangle$ of G^*. It remains to check that the real $x = \langle x_n \mid n < \omega\rangle$ constructed as part of this run is won by player I in $G_\omega(B)$.

By conditions (ii) and (iii), $w_n \prec w_{l_n}$ for each $n > 0$. It follows from this that $w_n \prec w_m$ whenever $t_n > t_m$. By Claim 5.11, $x \in B$. So x is won by player I in $G_\omega(B)$, as required. ⊣

5.15 Lemma. *Suppose that player* II *has a winning strategy in G^*. Then player* II *has a winning strategy in $G_\omega(B)$.*

Proof. Let σ^* be a winning strategy for player II in G^*. Fix an opponent willing to play for I in $G_\omega(B)$. We describe how to play against the opponent, and win. Again our description takes the form of a construction. But this time we do not construct a run of G^*. Rather we construct an iteration tree $\mathcal{T}$ with an even branch consisting of $\{0, 2, 4, \ldots\}$, and a run of $j_{\text{even}}(G^*)$, played according to $j_{\text{even}}(\sigma^*)$.

Precisely, we construct:

(A) l_n, t_n, u_n, w_n, and x_n for $n < \omega$.

(B) An iteration tree $\mathcal{T}$ giving rise to models M_k for $k < \omega$ and embeddings $j_{l,k}$ for $l\ T\ k < \omega$.

(C) Nodes $g_n \in j_{0,2n+1}(S)_{x,t_n}$ for $n < \omega$.

x in the last condition is the sequence $\langle x_n \mid n < \omega\rangle$, although of course only $x\restriction \mathrm{lh}(t_n)$ is relevant to the condition.

We construct so that:

- $0\, T\, 2\, T\, 4 \dots$.
- If $t_n \neq \emptyset$ then the T-predecessor of $2n+1$ is $2l_n+1$.
- If $t_n = \emptyset$ then the T-predecessor of $2n+1$ is $2n$.

Note that these conditions determine the tree order T completely.

Let $p_0 = \emptyset$ and recursively define

$$p_{n+1} = j_{2n,2n+2}(p_n)^\frown\langle l_n, t_n, j_{2n,2n+2}(u_n), w_n, x_n\rangle.$$

We construct so that p_n is a position in $j_{0,2n}(G^*)$, played according to $j_{0,2n}(\sigma^*)$. This amounts to maintaining the following conditions:

(1) l_n, t_n, and u_n are the moves played by $j_{0,2n}(\sigma^*)$ following the position p_n.

(2) w_n is a legal move for player I following the position $j_{2n,2n+2}(p_n)^\frown\langle l_n, t_n, j_{2n,2n+2}(u_n)\rangle$.

(3) If n is odd then x_n is the move played by $j_{0,2n+2}(\sigma^*)$ following the position $j_{2n,2n+2}(p_n)^\frown\langle l_n, t_n, j_{2n,2n+2}(u_n), w_n\rangle$.

Notice that conditions (1) and (3) determine l_n, t_n, and u_n for each n, and x_n for odd n.

Let k_n denote $\mathrm{lh}(t_n)$. Condition (C) above already places some restriction on the nature of g_n. It must be a sequence of length k_n, and $\langle x\restriction k_n, t_n, g_n\rangle$ must belong to $j_{0,2n+1}(S)$. We maintain the following additional condition during the construction:

(4) w_n is realized by $j_{0,2n+1}(S)$, $\langle 0, g_n(0)\rangle$, $\dots$, $\langle k_n-1, g_n(k_n-1)\rangle$ and $j_{0,2n+1}(\nu_{\mathrm{L}})$ in $M_{2n+1}\|j_{0,2n+1}(\nu_{\mathrm{L}})+3$.

Notice that from this it automatically follows that w_n is a (k_n+2)-type and that it contains the formulae "$v_{k_n+1} > \max\{\widetilde{\delta}, \mathrm{rank}(v_0)\}$" and "$v_{k_n+1}+2$ exists and is the largest ordinal" as demanded by rule (7) of G^*.

Finally, we maintain the conditions:

(5) w_n is elastic.

(6) M_{2n+1} agrees with all later models of $\mathcal{T}$, that is all models M_i for $i > 2n+1$, past $\mathrm{dom}(w_n)$. w_n belongs to M_i for each $i > 2n+1$.

(7) All the extenders used in $\mathcal{T}$ have critical points above $\mathrm{rank}(X)$. For each $m > n$, the critical point of $j_{2n+2,2m+2}$ is greater than the domain of w_n. In particular $j_{2n+2,2m+2}(w_n) = w_n$ for each $m \geq n$.

5.16 Remark. It follows directly from the last condition that p_n has the form $\langle l_i, t_i, j_{2i,2n}(u_i), w_i, x_i \mid i < n\rangle$.

Let us now describe the construction in round n, assuming inductively that we have already constructed the objects corresponding to rounds 0 through $n-1$, and that we maintained conditions (1)–(7) for these rounds.

Set l_n, t_n, and u_n to be the moves played by $j_{0,2n}(\sigma^*)$ following the position p_n, in line with condition (1). The construction continues subject to one of the following cases:

Case 1. $t_n = \emptyset$. The rules of G^* are such that u_n is realized by $j_{0,2n}(S)$ and $j_{0,2n}(\nu_{\mathrm{L}})$ in $M_{2n}\|j_{0,2n}(\nu_{\mathrm{L}})+1$. From the local indiscernibility of ν_{L} and ν_{H} it follows that u_n is realized by $j_{0,2n}(S)$ and $j_{0,2n}(\nu_{\mathrm{H}})$ in $M_{2n}\|j_{0,2n}(\nu_{\mathrm{H}})+1$. Working in M_{2n} using Lemma 3.22, let $\tau < j_{0,2n}(\delta)$ be such that $\tau > \mathrm{dom}(u_n)$ and such that the τ-type of $j_{0,2n}(S)$ and $j_{0,2n}(\nu_{\mathrm{L}})$ in $j_{0,2n}(\nu_{\mathrm{L}})+3$ is elastic. Let w_n be this type. It is easy to check that w_n exceeds $\mathrm{dcp}(u_n)$ in M_{2n}.

Set E_{2n} = "pad" so that $M_{2n+1} = M_{2n}$ and $j_{2n,2n+1}$ is the identity. Using the One-Step Lemma 3.23, find an extender $E_{2n+1} \in M_{2n+1}$ so that w_n is a subtype of $\mathrm{Stretch}^{E_{2n+1}}_{\tau+\omega}(\mathrm{dcp}(u_n))$. Set $M_{2n+2} = \mathrm{Ult}(M_{2n}, E_{2n+1})$, and set $j_{2n,2n+2}$ to be the ultrapower embedding. Note that these settings are such that w_n is a subtype of $j_{2n,2n+2}(\mathrm{dcp}(u_n))$. It is easy now to check that w_n satisfies the conditions of rule (7) of G^*, shifted to M_{2n+2}, following the position $j_{2n,2n+2}(p_n{}^\frown\langle l_n, t_n, u_n\rangle)$.

Finally, set x_n to be the move played by $j_{0,2n+2}(\sigma^*)$ following the position $j_{2n,2n+2}(p_n){}^\frown\langle l_n, t_n, j_{2n,2n+2}(u_n), w_n\rangle$ if n is odd, and the move played by the opponent in $G_\omega(B)$ following $\langle x_0, \dots, x_{n-1}\rangle$ if n is even. This completes the round. ⊣ (Case 1)

Case 2. $t_n \neq \emptyset$. The rules of $j_{0,2n}(G^*)$ following the position p_n are such that u_n exceeds w_{l_n} in M_{2n}. (We are making an implicit use of Remark 5.16 here.) Let κ denote the domain of u_n. Using the One-Step Lemma in M_{2n} find an extender E_{2n} with critical point $\mathrm{dom}(w_{l_n})$, so that u_n is a subtype of $\mathrm{Stretch}^{E_{2n}}_{\kappa+\omega}(w_{l_n})$. Set $M_{2n+1} = \mathrm{Ult}(M_{2l_n+1}, E_{2n})$, and set $j_{2l_n+1,2n+1}$ to be the ultrapower embedding, so that u_n is a subtype of $j_{2l_n+1,2n+1}(w_{l_n})$.

5.17 Exercise. Complete the precise details of this construction, verifying that there is enough agreement between the various models to make sense of the ultrapower taken.

Let k denote $\mathrm{lh}(t_n)$. Note that $t_{l_n} = \mathrm{pred}(t_n)$, so $\mathrm{lh}(t_{l_n}) = k-1$. Let $\bar{k}$ denote $k-1$. Let $\bar{g}$ denote g_{l_n}, and let $\bar{g}' = j_{2l_n+1,2n+1}(\bar{g})$.

Now w_{l_n} is realized by $j_{0,2l_n+1}(S)$, $\langle 0, \bar{g}(0)\rangle$, $\dots$, $\langle \bar{k}-1, \bar{g}(\bar{k}-1)\rangle$ and $j_{0,2l_n+1}(\nu_{\mathrm{L}})$ in $M_{2l_n+1}\|j_{0,2l_n+1}(\nu_{\mathrm{L}})+3$. Using the elementarity of the embedding $j_{2l_n+1,2n+1}$ it follows that $j_{2l_n+1,2n+1}(w_{l_n})$ is realized by $j_{0,2n+1}(S)$, $\langle 0, \bar{g}'(0)\rangle$, $\dots$, $\langle \bar{k}-1, \bar{g}'(\bar{k}-1)\rangle$ and $j_{0,2n+1}(\nu_{\mathrm{L}})$ in $M_{2n+1}\|j_{0,2n+1}(\nu_{\mathrm{L}})+3$. Since u_n is a subtype of $j_{2ln+1,2n+1}(w_{l_n})$ it must be realized, by the same objects and one more object, at a lower rank. Combining this with the fact that u_n is a $(k{+}2)$-type which contains the formula in rule (3) of the definition of G^* (Definition 5.13), we see that there must exist some set z so that u_n is realized by $j_{0,2n+1}(S)$, $\langle 0, \bar{g}'(0)\rangle$, ..., $\langle \bar{k}-1, \bar{g}'(\bar{k}-1)\rangle$, $\langle \bar{k}, z\rangle$ and $j_{0,2n+1}(\nu_{\mathrm{L}})$ in $M_{2n+1}\|j_{0,2n+1}(\nu_{\mathrm{L}}){+}1$, and that moreover the function $g = \bar{g}' \cup \{\langle \bar{k}, z\rangle\}$ is a node in $j_{0,2n+1}(S)_{x,t_n}$. Set g_n equal to this function g, securing the demands of condition (C) above. For the record let us note that:

(i) g_n extends $j_{2l_n+1,2n+1}(g_{l_n})$.

We now continue very much as we did in case 1. Using the local indiscernibility of ν_{L} and ν_{H}, we see that u_n is realized by $j_{0,2n+1}(S)$, $\langle 0, g_n(0)\rangle$, ..., $\langle k-1, g_n(k-1)\rangle$, and $j_{0,2n+1}(\nu_{\mathrm{H}})$ in $M_{2n+1}\|j_{0,2n+1}(\nu_{\mathrm{H}})+1$. Working in M_{2n+1} using Lemma 3.22, let $\tau < j_{0,2n+1}(\delta)$ be such that $\tau > \mathrm{dom}(u_n)$ and such that the τ-type of $j_{0,2n+1}(S)$, $\langle 0, g_n(0)\rangle$, ..., $\langle k-1, g_n(k-1)\rangle$, $j_{0,2n+1}(\nu_{\mathrm{L}})$ in $M_{2n+1}\|j_{0,2n+1}(\nu_{\mathrm{L}})+3$ is elastic. Let w_n be this type. w_n then exceeds $\mathrm{dcp}(u_n)$ in M_{2n+1}.

Using the One-Step Lemma in M_{2n+1}, find an extender $E_{2n+1} \in M_{2n+1}$, with critical point equal to the domain of u_n, so that w_n is a subtype of $\mathrm{Stretch}^{E_{2n+1}}_{\tau+\omega}(\mathrm{dcp}(u_n))$. Set $M_{2n+2} = \mathrm{Ult}(M_{2n}, E_{2n+1})$, and set $j_{2n,2n+2}$ to be the ultrapower embedding. Note that these settings are such that w_n is a subtype of $j_{2n,2n+2}(\mathrm{dcp}(u_n))$, and this secures the main requirement on w_n posed by rule (7) of G^*, shifted to M_{2n+2}, following the position $j_{2n,2n+2}(p_n{}^\frown\langle l_n, t_n, u_n\rangle)$.

Finally, as in case 1, set x_n to be the move played by $j_{0,2n+2}(\sigma^*)$ following the position $j_{2n,2n+2}(p_n)^\frown\langle l_n, t_n, j_{2n,2n+2}(u_n), w_n\rangle$ if n is odd, and the move played by the opponent in $G_\omega(B)$ following $\langle x_0, \dots, x_{n-1}\rangle$ if n is even. This completes the round. $\dashv$ (Case 2)

5.18 Exercise. Verify that the construction described above maintains conditions (1)–(7).

It remains now to check that every sequence $x = \langle x_n \mid n < \omega\rangle \in X^\omega$ that can be obtained by following the construction described above (with moves x_n for even n supplied by the opponent) is won by player II in $G_\omega(B)$.

Let x, $\mathcal{T}$, $\langle l_n, t_n, u_n, w_n \mid n < \omega\rangle$, and $\langle g_n \mid n < \omega\rangle$ be obtained through the construction above. We work through a series of claims to show that $x \notin B$.

5.19 Claim. *The even branch of $\mathcal{T}$ has an illfounded direct limit.*

Proof. Suppose for contradiction that M_{even} is wellfounded. Let R be the tree of attempts to construct an infinite run of G^*, played according to σ^*. Note that $j_{\mathrm{even}}(R)$ has an infinite branch, consisting of $\bigcup_{n<\omega} j_{2n,\mathrm{even}}(p_n)$. Since M_{even} is wellfounded, the existence of an infinite branch through $j_{\mathrm{even}}(R)$ reflects to M_{even}. Thus, $M_{\mathrm{even}} \models$ "there is an infinite run of $j_{\mathrm{even}}(G^*)$, played according to $j_{\mathrm{even}}(\sigma^*)$". Using the elementarity of j_{even} it follows that $V \models$ "there is an infinite run of G^* played according to σ^*". But this contradicts the fact that σ^* is a winning strategy for player II, the player who loses infinite runs. $\dashv$

Let θ be a regular cardinal, large enough that all the objects involved in the construction belong to $V\|\theta$. Let H be a countable elementary substructure of $V\|\theta$, with x, $\mathcal{T}$, $\langle l_n, t_n, u_n, w_n \mid n < \omega\rangle$ and $\langle g_n \mid n < \omega\rangle$ in H. Let P be the transitive collapse of H, and let $\pi : P \to H$ be the anti-collapse embedding. Let $\mathcal{U} = \pi^{-1}(\mathcal{T})$ and let $h_n = \pi^{-1}(g_n)$. Let P_i and $\bar{j}_{i,i'}$ denote the models and embeddings of $\mathcal{U}$. Let $\bar{S}$ denote $\pi^{-1}(S)$. Let $\bar{x}_i = \pi^{-1}(x_i)$ and let $\bar{x} = \langle \bar{x}_i \mid i < \omega\rangle$.

Using Theorem 2.3 find an infinite branch b through $\mathcal{U}$ so that there is an embedding $\sigma : \bar{P}_b \to V\|\theta$ with $\sigma \circ \bar{j}_b = \pi$.

5.20 Claim. *b is not the even branch.*

Proof. The fact that $\bar{P}_b$ embeds into $V\|\theta$ implies that it is wellfounded. $\bar{P}_{\text{even}}$ is not wellfounded, by Claim 5.19. ⊣

Let $m_0, m_1, \dots$ be such that $2m_0 + 1, 2m_1 + 1, 2m_2 + 2, \dots$ lists, in increasing order, all the odd models in b. The tree structure of $\mathcal{T}$, and hence of $\mathcal{U}$, is such that:

- $t_{m_0} = \emptyset$.
- $\text{pred}(t_{m_{i+1}}) = t_{m_i}$.

From the last condition and from condition (i) of the construction it follows that:

- $h_{m_{i+1}}$ extends $\bar{j}_{2m_i+1,2m_{i+1}+1}(h_{m_i})$.

Letting $h^*_i = \bar{j}_{2m_i+1,b}(h_{m_i})$ it follows that:

- h^*_{i+1} extends h^*_i for each i.

Let $y = \bigcup_{i<\omega} t_{m_i}$ and let $h^* = \bigcup_{i<\omega} h^*_i$. Condition (C) of the construction implies that $\langle \bar{x}\restriction i, y\restriction i, h^*\restriction i\rangle$ is a node in $\bar{j}_b(\bar{S})$. Applying the embedding $\sigma : P_b \to V\|\theta$ to this statement, and using the fact that $\sigma \circ \bar{j}_b = \pi$, it follows that $\langle x\restriction i, y\restriction i, \sigma(h^*\restriction i)\rangle$ is a node in $\pi(\bar{S}) = S$. This is true for each i, and hence:

5.21 Claim. *$\langle x, y\rangle \in p[S]$.*

Proof. Let $h^{**} = \bigcup_{i<\omega} \sigma(h^*\restriction i)$. The argument of the previous paragraph shows that $\langle x, y, h^{**}\rangle$ is an infinite branch through S. ⊣

Recall that $A = p[S]$ and that $B = \{x \in X^\omega \mid (\forall y)\langle x, y\rangle \notin A\}$. From the last claim it follows that $x \notin B$, and therefore x is won by player II in $G_\omega(B)$, as required. ⊣

5.22 Definition. Let M be a model of ZFC^-. Let X belong to M and let $S \in M$ be a tree on $X \times U$ for some set $U \in M$. Define $\text{gp}(S)$, the *generalized projection* of S, by setting $x \in \text{gp}(S)$ iff there exists a length ω iteration tree $\mathcal{T}$

on M, using only extenders with critical points above $\text{rank}(X)$, so that for every wellfounded cofinal branch b of $\mathcal{T}$, $x \in p[j_b^{\mathcal{T}}(S)]$. An iteration tree $\mathcal{T}$ witnessing that $x \in \text{gp}(S)$ is said to put x in a *shifted projection* of S. Notice that the tree must be such that $x \in p[j_b^{\mathcal{T}}(S)]$ for *all* wellfounded cofinal branches of $\mathcal{T}$.

5.23 Exercise. Let M be a model of ZFC and let δ be a Woodin cardinal of M. Let X belong to $M\|\delta$ and let $S \in M$ be a tree on $X \times \omega \times \gamma$ for some ordinal γ. Let G^* be the game of Definition 5.13 but relativized to M. Suppose $M \models$ "player II has a winning strategy in G^*". Prove that there is a strategy σ for player II in the game on X so that, in V, every infinite play according to σ belongs to $\text{gp}(S)$.

Hint. Let $\sigma^* \in M$ be a winning strategy for player II in G^*. Imitate the construction in the proof of Lemma 5.15 to define a strategy σ for II in the game on X. Show that if $x \in X^\omega$ and $\mathcal{T}$ are produced by the construction in the proof of Lemma 5.15, then $\mathcal{T}$ witnesses that x belongs to a shifted projection of S: Claim 5.19 shows that the even branch of $\mathcal{T}$ is illfounded, and the argument following Claim 5.20 can be modified to produce, for each cofinal branch b other than the even branch, some y and f so that $\langle x, y, f\rangle \in [j_b(S)]$. ⊣

Lemmas 5.14 and 5.15 combine to show that $G_\omega(B)$ is determined: G^* is determined since it is a closed game, and by Lemmas 5.14 and 5.15 the player who has a winning strategy in G^* has a winning strategy in $G_\omega(B)$. We thus obtained the following theorem:

5.24 Theorem. *Let δ be a Woodin cardinal. Let X belong to $V\|\delta$ and let $A \subseteq (X \times \omega)^\omega$. Let $B = \{x \in X^\omega \mid (\forall y)\langle x, y\rangle \notin A\}$. Suppose that A is δ^+-homogeneously Suslin. Then B is determined.*

In the next section we weaken the assumption, from homogeneously Suslin to universally Baire. But first we continue toward a proof that B is homogeneously Suslin.

Let Γ be the map that assigns to each position $q^* = \langle l_i, t_i, u_i, w_i, x_i \mid i < n\rangle$ in the game G^* the move $\langle l_n, t_n, u_n\rangle$ described in the proof of Lemma 5.14. By this we mean the move that the construction there would produce for round n, assuming that the moves of the previous rounds were $\langle l_i, t_i, u_i, w_i, x_i \mid i < n\rangle$. (The construction appears between conditions (ii) and (iii) in the proof of Lemma 5.14. Notice that this part does not depend on the strategy σ^*.) If the moves in $\langle l_i, t_i, u_i, w_i, x_i \mid i < n\rangle$ do not satisfy the inductive conditions in the proof of Lemma 5.14, then leave $\Gamma(q^*)$ undefined.

Given a sequence $q = \langle x_i, w_i \mid i < n\rangle$ define q^* to be the sequence $\langle l_i, t_i, u_i, w_i, x_i \mid i < n\rangle$ where for each $m < n$, $\langle l_m, t_m, u_m\rangle$ is equal to $\Gamma(q^* \restriction m)$. If for some $m < n$, $q^* \restriction m$ is not a legal position in G^* or $\Gamma(q^* \restriction m)$ is undefined, then leave q^* undefined.

Let $R \subseteq (X \times V\|\delta)^{<\omega}$ be the tree of sequences $q = \langle x_i, w_i \mid i < n\rangle$ so that q^* is defined.

5.25 Exercise. Suppose that $x \in p[R]$. Prove that $x \in B$.

Hint. Let $\langle w_i \mid i < \omega \rangle$ be such that $\langle x_i, w_i \mid i < n \rangle \in R$ for each $n < \omega$. Let q_n denote $\langle x_i, w_i \mid i < n \rangle$. Note that for each $n < \omega$, q_n^* is defined. Let $q^* = \bigcup_{n<\omega} q_n^*$. Check that q^* is an infinite run of G^*, satisfying all the conditions in the proof of Lemma 5.14. Use the final argument in that proof to conclude that $x \in B$. $\dashv$

Given $z \in X^\omega$ let $\langle l_n^z, t_n^z, u_n^z, w_n^z, x_n^z \mid n < \omega \rangle$, $\mathcal{T}^z$, and $\langle g_n^z \mid n < \omega \rangle$ be the objects obtained by constructing subject to the conditions in the proof of Lemma 5.15, with condition (1) replaced by the condition "$\langle l_n, t_n, u_n \rangle = j_{0,2n}(\Gamma)(p_n)$", and condition (3) replaced by the condition "$x_n = z_n$ for all n". These two replacements remove the use of the opponent and of σ^* in the construction. The use of σ^* is replaced by a use of Γ and of the odd half of z. The use of the opponent is replaced by a use of the even half of z.

Notice that the dependence of the construction on z is continuous, in the sense that knowledge of $z \restriction n$ suffices to determine the construction in rounds 0 through $n-1$. These rounds construct, among other things, $\mathcal{T}^z \restriction 2n+1$, and $\langle w_0, \ldots, w_{n-1} \rangle$. We have therefore maps $s \mapsto \mathcal{T}^s$, $s \mapsto \langle l_i^s, t_i^s, u_i^s, w_i^s, x_i^s \mid i < \mathrm{lh}(s) \rangle$, and $s \mapsto \langle g_i^s \mid i < \mathrm{lh}(s) \rangle$, defined on $s \in X^{<\omega}$, with the properties:

- $\mathcal{T}^s$ is an iteration tree of length $2\,\mathrm{lh}(s) + 1$, leading to a final model indexed $2\,\mathrm{lh}(s)$.
- $\mathcal{T}^z = \bigcup_{n<\omega} \mathcal{T}^{z \restriction n}$.
- $l_i^z = l_i^s$ whenever z extends s and $i < \mathrm{lh}(s)$, and similarly with t_i^z, u_i^z, w_i^z, x_i^z, and g_i^z.

Let M_i^s, for $i \leq 2\,\mathrm{lh}(s)$, be the models of the tree $\mathcal{T}^s$. Let $j_{i,i'}^s$ be the embeddings of the tree.

5.26 Exercise. Show that $\langle x_i^s, w_i^s \mid i < \mathrm{lh}(s) \rangle$ belongs to $j_{0,2\,\mathrm{lh}(s)}^s(R)$.

Hint. Let $q = \langle x_i^s, w_i^s \mid i < \mathrm{lh}(s) \rangle$. Let $p = \langle l_i^s, t_i^s, j_{2i,2\,\mathrm{lh}(s)}^s(u_i^s), w_i^s, x_i^s \mid i < \mathrm{lh}(s) \rangle$. Use the fact that $\langle l_i^s, t_i^s, u_i^s \rangle = j_{0,2i}(\Gamma)(p \restriction i)$ to show that q^* (in the sense of $M_{2\,\mathrm{lh}(s)}^s$) is equal to p. $\dashv$

Define M_s to be the last model of the tree $\mathcal{T}^s$, namely the model $M_{2\,\mathrm{lh}(s)}^s$. Define $j_{s,s^*} : M_s \to M_{s^*}$ to be the embedding $j_{2\,\mathrm{lh}(s),2\,\mathrm{lh}(s^*)}^{s^*}$. Define φ_s to be the sequence $\langle w_i^s \mid i < \mathrm{lh}(s) \rangle$.

5.27 Exercise. Prove that R is homogeneous by showing that the system $\langle M_s, \varphi_s, j_{s,s^*} \mid s < s^* \in X^{<\omega} \rangle$ satisfies the conditions in Exercise 4.2. Conclude that B is homogeneously Suslin.

Hint. Condition (2) of Exercise 4.2 follows from the previous exercise. For condition (3): The direct limit of $\langle M_s, j_{s,s^*} \mid s < s^* < x \rangle$ is simply the direct limit along the even branch of $\mathcal{T}^x$. You can use its illfoundedness as a replacement for Claim 5.19, and proceed from there as in the proof of Lemma 5.15, to show that $x \notin B$, and hence by Exercise 5.25, $x \notin p[R]$. To conclude that B is homogeneously Suslin you now only need the converse to Exercise 5.25. To prove it use the fact that illfoundedness of the direct limit of $\langle M_s, j_{s,s^*} \mid s < s^* < x \rangle$ implies not only $x \notin p[R]$, but $x \notin B$. $\dashv$

5.28 Exercise. Prove that the Martin-Solovay tree for B (see Exercise 5.2) is homogeneous.

Hint. Embed R into the Martin-Solovay tree for B, and use the embedding to transfer the homogeneity measures on R to the Martin-Solovay tree. $\dashv$

The exercises above establish that B is homogeneously Suslin. With a small additional adjustment we obtain the following:

5.29 Exercise. Let δ be a Woodin cardinal. Let X belong to $V \| \delta$ and let $A \subseteq (X \times \omega)^\omega$. Let $B = \{x \in X^\omega \mid (\forall y)\langle x, y\rangle \notin A\}$. Suppose that A is δ^+-homogeneously Suslin. Then B is κ-homogeneously Suslin for each $\kappa < \delta$.

Hint. Fix $\kappa < \delta$. Revise the construction in the proof of Lemma 5.14 to make sure that $\mathrm{dom}(u_0) > \kappa$. Show that if Γ is defined using this revised construction, then the embeddings j_{s,s^*} obtained above all have critical points above κ. $\dashv$

5.30 Corollary. *Suppose that there are n Woodin cardinals and a measurable cardinal above them. Let $A \subseteq \omega^\omega$ be $\mathbf{\Pi}^1_{n+1}$. Then A is homogeneously Suslin.*

Proof. Let $\delta_1 < \cdots < \delta_n$ be the Woodin cardinals, and let $\kappa > \delta_n$ be the measurable cardinal. Let $\delta_0 = \aleph_0$.

Let $A_k \subseteq (\omega^\omega)^k$ be such that A_{n+1} is $\mathbf{\Pi}^1_1$, $A_k = \{\langle x, y_1, \ldots, y_{k-1}\rangle \mid (\forall y_k)\langle x, y_1, \ldots, y_k\rangle \notin A_{k+1}\}$ for each $k \leq n$, and $A_1 = A$.

By Theorem 4.15, A_{n+1} is $(\delta_n)^+$-homogeneously Suslin. Successive applications of Exercise 5.29, starting from $k = n$ and working down to $k = 1$, show that A_k is $(\delta_{k-1})^+$-homogeneously Suslin. Finally then $A = A_1$ is homogeneously Suslin. $\dashv$

5.31 Corollary. *Suppose that there are n Woodin cardinals and a measurable cardinal above them. Let $A \subseteq \omega^\omega$ be $\mathbf{\Pi}^1_{n+1}$. Then $G_\omega(A)$ is determined.*

6. Universally Baire Sets

Let δ be a Woodin cardinal. Let X belong to $V \| \delta$. Let S be a tree on $X \times \omega \times \gamma$ for some ordinal γ, let $A = p[S] \subseteq X^\omega \times \omega^\omega$, and let $B = \{x \in X^\omega \mid (\forall y)\langle x, y\rangle \notin A\}$. In the previous section we showed that if S is δ^+-homogeneous then $G_\omega(B)$ is determined. Here we work without the assumption of homogeneity, and try to salvage as much determinacy as we can. We cannot hope for actual determinacy since every set is Suslin under the axiom of choice, but not every set is determined. The approximation for determinacy that we salvage is the following lemma. Recalling a standard notation, $\mathrm{Col}(\omega, \delta)$ is the poset that adjoins a map from ω onto δ using finite partial maps as conditions.

6.1 Lemma. *Let g be $\mathrm{Col}(\omega, \delta)$-generic over V. In $V[g]$ define B^* to be the set $\{x \in X^\omega \mid (\forall y)\langle x, y\rangle \notin p[S]\}$, where X^ω, the quantifier $(\forall y)$, and the projection $p[S]$ are all computed in $V[g]$. Then at least one of the following cases hold:*

(1) In V, player II *has a winning strategy in the game $G_\omega(B)$.*

(2) In $V[g]$, player I *has a winning strategy in $G_\omega(B^*)$.*

With a sufficiently absolute set B the lemma can be used to obtain actual determinacy, as we shall see later on.

Proof of Lemma 6.1. Let G^* be the game defined in the previous section, specifically in Definition 5.13. Notice that the game is defined with no reference to the homogeneity system of the previous section, and so we may use it in the current context. Notice further that Lemma 5.15 is proved without use of the homogeneity system. It too applies in the current context, showing that if player II has a winning strategy in G^* then player II has a winning strategy in $G_\omega(B)$. To complete the proof of Lemma 6.1 it thus suffices to show that if player I has a winning strategy in G^*, then condition (2) of Lemma 6.1 holds true.

Let σ^* be a winning strategy for player I in G^*. Let $\rho : \delta \to V\|\delta$ be a bijection. To be precise we emphasize that both σ^* and ρ are taken in V. Working now in $V[g]$, notice that $\rho \circ g$ is a bijection of ω and $V\|\delta$.

In Lemma 5.14 we used the homogeneity measures for S to ascribe auxiliary moves for player II in G^* while playing against σ^*. We cannot do the same here since T is not assumed to be homogeneous. Instead, we plan to ascribe to player II the $\rho \circ g$-first legal move in each round.

6.2 Claim. *Let $p^* = \langle l_i, t_i, u_i, w_i, x_i \mid i < n\rangle$ be a legal position in G^*. Then there is a move $\langle l_n, t_n, u_n\rangle$ which is legal for player* II *in G^* following p^*.*

Proof. Let $\zeta < \delta$ be large enough that all the moves made in p belong to $V\|\zeta$. Using Lemma 3.22 let $\kappa < \delta$ be such that the κ-type of S in $V\|\nu_{\mathrm{L}} + 1$ is elastic, and such that $\kappa > \zeta$. Set u to be the κ-type of S and ν_{L} in $V\|\nu_{\mathrm{L}} + 1$. (ν_{L} here is taken from the lexicographically least pair of local indiscernibles relative to $\max\{\delta, \mathrm{rank}(S)\}$.) It is easy to check that the triple $\langle 0, \emptyset, u\rangle$ is legal for II in G^* following p^*. It falls under the case of rule (5) in Definition 5.13. $\dashv$

Call a number $e < \omega$ *valid* at a position $p^* = \langle l_i, t_i, u_i, w_i, x_i \mid i < n\rangle$ in G^* just in case that $(\rho \circ g)(e)$ is a legal move for player II in G^* following p^*.

By this we mean that $(\rho \circ g)(e)$ is equal to a tuple $\langle l_n, t_n, u_n\rangle \in V\|\delta$ that satisfies the relevant rules in Definition 5.13. By the last claim there is always a number which is valid at p^*.

6.3 Definition. A position $\langle x_0, \dots, x_{n-1}\rangle$ in $G_\omega(B^*)$ is *nice* if it can be expanded to a position $p^* = \langle l_i, t_i, u_i, w_i, x_i \mid i < n\rangle^\frown\langle l_n, t_n, u_n, w_n\rangle$ in G^* so that:

(1) p^* is according to σ^*.

(2) For each $m \le n$, $\langle l_m, t_m, u_m\rangle$ is equal to $(\rho\circ g)(e)$ for the *least* number e which is valid at $p^*\restriction m$.

Notice that if p is nice then the expansion p^* is unique: condition (1) uniquely determines w_m for each $m \le n$, and condition (2) uniquely determines l_m, t_m, and u_m for each $m \le n$. Define a strategy σ for player I in $G_\omega(B^*)$ by setting $\sigma(p) = \sigma(p^*)$ in the case that p is a nice position of even length. (It is easy to check that all finite plays by σ lead to nice positions. So there is no need to define σ on positions which are not nice.)

The generic g comes in to the definition of σ through condition (2) in Definition 6.3. σ is thus not an element of V, but of $V[g]$. We now aim to show that, in $V[g]$, σ is winning for I in $G_\omega(B^*)$.

Let $x \in V[g]$ be an infinite run, played according to σ. Suppose for contradiction that $x \notin B$, and let $y \in V[g]$ and $f \in V[g]$ be such that $\langle x, y, f\rangle$ is an infinite branch through S.

For each $n < \omega$ let p^*_n be the unique expansion of $x\restriction n$ that satisfies the conditions of Definition 6.3. Let $p^* = \bigcup_{n<\omega} p^*_n$. Let l_i, t_i, u_i, and w_i be such that $p^* = \langle l_i, t_i, u_i, w_i, x_i \mid i < \omega\rangle$. Let e_n be the least number valid at $p^*\restriction n$, so that $\langle l_i, t_i, u_i\rangle = (\rho \circ g)(e_i)$.

We work recursively to construct sequences $n_0 < n_1 < \cdots$ and $\alpha_0, \alpha_1, \dots$ so that for each i:

(1) $t_{n_i} = y\restriction i$.

(2) u_{n_i} is realized by S, $\langle 0, f(0)\rangle$, …, $\langle i-1, f(i-1)\rangle$, and α_i in $V\|\alpha_i + 1$.

Set to begin with $n_0 = 0$ and $\alpha_0 = \nu_{\mathrm{L}}$. The rules of G^* are such that $t_0 = \emptyset$ and u_0 is the type of S and ν_{L} in $V\|\nu_{\mathrm{L}} + 1$. Conditions (1) and (2) for $i = 0$ therefore hold with these settings.

Suppose now that n_i and α_i have been defined and that conditions (1) and (2) hold for i. The rules of G^* are such that w_{n_i} is a subtype of $\mathrm{dcp}(u_{n_i})$, and must therefore be realized at a lower level. In fact, using the realization of u_{n_i} given by condition (2) above, the specific requirements in rule (7) in Definition 5.13 are such that there must exist some ordinal $\beta < \alpha_i$ so that w_{n_i} is realized by S, $\langle 0, f(0)\rangle$, …, $\langle i-1, f(i-1)\rangle$, and β in $V\|\beta + 3$, and so that $\beta > \max\{\delta, \mathrm{rank}(S)\}$.

Let α_{i+1} be this ordinal β. For the record we note that:

(i) $\alpha_{i+1} < \alpha_i$.

(ii) w_{n_i} is realized by S, $\langle 0, f(0)\rangle$, …, $\langle i-1, f(i-1)\rangle$, and α_{i+1} in $V\|\alpha_{i+1}+3$.

It remains to define n_{i+1} in such a way that conditions (1) and (2) hold for $i+1$.

6.4 Claim. *Let $E = \max\{e_0, \ldots, e_{n_i}\}$. Then there exist $e < \omega$ and $\kappa < \delta$ so that:*

(a) $(\rho \circ g)(e)$ has the form $\langle l, t, u\rangle$ with $l = n_i$, $t = y{\restriction}i+1$, and u equal to the κ-type of S, $\langle 0, f(0)\rangle$, …, $\langle i, f(i)\rangle$, and α_{i+1} in $V\|\alpha_{i+1}+1$.

(b) $\mathrm{dcp}(u)$ is elastic.

(c) $e > E$.

(d) κ is large enough that $(\rho\circ g)(0)$, …, $(\rho\circ g)(e-1)$ all belong to $V\|\kappa$.

Proof. Let $D \subseteq \mathrm{Col}(\omega, \delta)$ be the set of conditions q so that conditions (a)–(d) hold for some $e < \mathrm{dom}(q)$ and $\kappa < \delta$, with $(\rho\circ g)$ replaced by $(\rho \circ q)$ in conditions (a) and (d). Notice that D is defined in V: it only makes reference to $f{\restriction}i+1$ and $y{\restriction}i+1$. Using Lemma 3.22 it is easy to check that D is dense. Thus $g \cap D$ is non-empty and the claim follows. ⊣

Let e be given by the last claim. Let $\langle l, t, u\rangle = (\rho\circ g)(e)$, and let $\kappa = \mathrm{dom}(u)$.

6.5 Claim. *$\langle l, t, u\rangle$ is a legal move for player II in G^* following $p^*{\restriction}n$, for every n such that:*

(1) $n > n_i$.

(2) $\mathrm{dom}(u_{n-1}) < \kappa$.

Proof. This is easy to verify, using conditions (1), (ii), (a), and (b) above, and the fact that $\langle x{\restriction}i+1, y{\restriction}i+1, f{\restriction}i+1\rangle$ is a node in S. ⊣

6.6 Claim. *There exists an $n < \omega$ so that $e_n = e$.*

Proof. Let n be least so that $e_n \geq e$. Since $e > E = \max\{e_0, \ldots, e_{n_i}\}$, certainly $n > n_i$. Note that $e_{n-1} < e$ and so from condition (d) it follows that $(\rho\circ g)(e_{n-1})$ belongs to $V\|\kappa$. In particular then u_{n-1} belongs to $V\|\kappa$, so certainly $\mathrm{dom}(u_{n-1}) < \kappa$. Applying Claim 6.5 it follows that $\langle l, t, u\rangle$ is legal for II in G^* following $p^*{\restriction}n$, and hence e is valid at $p^*{\restriction}n$. Since e_n is the least number which is valid at $p^*{\restriction}n$, it must be that $e_n \leq e$. We have $e_n \geq e$ by the initial choice of n. Thus $e_n = e$. ⊣

Set n_{i+1} equal to the number n given by the last claim. By condition (a) of Claim 6.4 then, $l_{n_{i+1}}$, $t_{n_{i+1}}$, and $u_{n_{i+1}}$ are such that $l_{n_{i+1}} = n_i$, $t_{n_{i+1}} = y{\restriction}i+1$, and $u_{n_{i+1}}$ is equal to the κ-type of $S, \langle 0, f(0)\rangle, \ldots, \langle i, f(i)\rangle$, and α_{i+1} in $V\|\alpha_{i+1}+1$. In particular conditions (1) and (2) hold for $i+1$.

Working by recursion we completed the construction of the sequences $\langle n_i \mid i < \omega\rangle$ and $\langle \alpha_i \mid i < \omega\rangle$. By condition (i) above the sequence $\langle \alpha_i \mid i < \omega\rangle$ is descending. The construction of this infinite descending sequence was based on the assumption that $\langle x, y, f\rangle$ is an infinite branch through S. (This assumption was used in the proof of Claim 6.5.) The assumption must therefore be false, and this shows that x, an arbitrary play according to σ^* in $V[g]$, must belong to B^*. This completes the proof of Lemma 6.1. ⊣

6.7 Corollary. *Let δ be a Woodin cardinal. Let X belong to $V\|\delta$. Let T be a tree on $X \times \gamma$ for some ordinal γ. Let g be* $\mathrm{Col}(\omega, \delta)$*-generic over V. Then at least one of the following holds:*

(1) $V \models$ "player II *has a winning strategy in the game $G_\omega(\neg p[T])$".*

(2) $V[g] \models$ "player I *has a winning strategy in the game $G_\omega(\neg p[T])$".*

($\neg p[T]$ here is the complement of the projection of T. Notice that $\neg p[T]$ need not be the same in $V[g]$ and in V.)

Proof. Immediate from Lemma 6.1 by introducing a vacuous coordinate, more precisely by using the tree $S = \{\langle s, t, f\rangle \in (X \times \omega \times \gamma)^{<\omega} \mid \langle s, f\rangle \in T\}$. ⊣

6.8 Exercise. It may seem that we are losing ground in passing from the lemma to the corollary, but in fact we are not. Prove that Lemma 6.1 is a consequence of Corollary 6.7.

Hint. Let $S \subseteq (X \times \omega \times \gamma)^{<\omega}$ be given. Let $\varphi : \omega \times \gamma \to \gamma'$ be a bijection of $\omega \times \gamma$ onto an ordinal γ'. Define a tree T on $X \times \gamma'$ in such a way that $\langle x, y, f\rangle \in [S]$ iff $\langle x, g\rangle \in [T]$ where $g(n) = \varphi(\langle y_n, f(n)\rangle)$. Use Corollary 6.7 with T. ⊣

6.9 Exercise. Let M be a model of ZFC. Let δ be a Woodin cardinal of M. Let X belong to $M\|\delta$. Let $T \in M$ be a tree on $X \times \gamma$ for some ordinal γ. Let g be $\mathrm{Col}(\omega, \delta)$-generic over M. Prove that at least one of the following holds:

(1) There is a strategy σ for player II in the game on X so that, in V, every infinite play according to σ belongs to $\mathrm{gp}(T)$.

(2) There is a strategy $\sigma \in M[g]$ for player I in the game on X so that, in $M[g]$, every infinite play according to σ avoids $p[T]$.

Hint. Relativize the proof of Corollary 6.7 to M, but replace the use of Lemma 5.15, which ultimately leads to the case of condition (1) in Corollary 6.7, with a use of Exercise 5.23. ⊣

6.10 Corollary. *Let δ be a Woodin cardinal. Let X belong to $V\|\delta$. Let T be a tree on $X \times \gamma$ for some ordinal γ. Let g be $\mathrm{Col}(\omega, \delta)$-generic over V. Then at least one of the following holds:*

(1) $V \models$ "player I *has a winning strategy in the game $G_\omega(p[T])$".*

(2) $V[g] \models$ "player II *has a winning strategy in the game $G_\omega(p[T])$".*

(Notice that $p[T]$ need not be the same in $V[g]$ and in V.)

Proof. Immediate from Corollary 6.7, using continuous substitution to reverse the roles of the players. Let us just point out that both here and in Corollary 6.7, the player who has a winning strategy in V is the player who wants to get into $p[T]$, and the player who has a winning strategy in $V[g]$ is the player who wants to avoid $p[T]$. ⊣

We can use various forms of absoluteness to obtain actual determinacy, either in V or in $V[g]$, from Corollary 6.10:

6.11 Lemma. *Let δ be a Woodin cardinal. Let X belong to $V\|\delta$. Let T be a tree on $X \times \gamma$ for some ordinal γ. Let g be $\mathrm{Col}(\omega, \delta)$-generic over V. Suppose that there is a tree S in V so that $V[g] \models$ "$p[S] = \neg p[T]$". Then $V[g] \models$ "$G_\omega(p[T])$ is determined".*

Proof. It is enough to show that if case 1 of Corollary 6.10 holds, then player I wins $G_\omega(p[T])$ also in $V[g]$.

Suppose then that player I wins $G_\omega(p[T])$ in V, and let σ witness this. Let R be the tree of attempts to construct a pair $\langle x, f\rangle$ so that $x \in X^\omega$ is a play according to σ, and $\langle x, f\rangle \in [S]$.

The tree R belongs to V. An infinite branch in V through R would produce an x which belongs to both $p[T]$ and $p[S]$. But then the same x, taken in $V[g]$, would exhibit a contradiction to the assumption of the lemma that $(p[S])^{V[g]}$ and $(p[T])^{V[g]}$ are complementary.

Thus R has no infinite branches in V. By absoluteness R has no infinite branches in $V[g]$ either. It follows that all plays according to σ in $V[g]$ belong to the complement of $(p[S])^{V[g]}$, which by assumption is $(p[T])^{V[g]}$. So σ witnesses that player I wins $G_\omega(p[T])$ in $V[g]$. ⊣

6.12 Corollary (Woodin). *Let δ be a Woodin cardinal and g a $\mathrm{Col}(\omega, \delta)$-generic filter over V. Then $V[g]$ is a model of Δ^1_2 (lightface) determinacy.*

Let X be hereditarily countable. A set $C \subseteq X^\omega$ is λ*-universally Baire* if all its continuous preimages, to topological spaces with regular open bases of cardinality $\leq \lambda$, have the property of Baire. C is ∞-universally Baire if it is λ-universally Baire for all cardinals λ. Feng-Magidor-Woodin [4] provides the following convenient characterization of universally Baire sets, and the basic results in Exercises 6.15 and 6.16:

6.13 Definition. A pair of trees T and T^* on $X \times \gamma$ and $X \times \gamma^*$ respectively is *exhaustive* for a poset $\mathbb{P}$ if the statement "$p[T] \cup p[T^*] = X^\omega$" is forced to hold in all generic extensions of V by $\mathbb{P}$.

6.14 Fact (Feng-Magidor-Woodin [4]). Let X be hereditarily countable, let $C \subseteq X^\omega$, and let λ be an infinite cardinal. C is λ-universally Baire iff there are trees T and T^* so that:

(1) $p[T] = C$ and $p[T^*] = X^\omega - C$.

(2) The pair $\langle T, T^* \rangle$ is exhaustive for all posets of size $\leq \lambda$.

6.15 Exercise. Suppose T and T^* are trees so that:

(1) $p[T] \cap p[T^*]$ is empty.

(2) $\langle T, T^* \rangle$ is exhaustive for $\mathrm{Col}(\omega, \lambda)$.

Prove that $p[T^*] = \mathbb{R} - p[T]$, and that $p[T]$ is λ-universally Baire.

Hint. Use condition (2) and simple absoluteness to argue that $p[T] \cup p[T^*] = \mathbb{R}$. This establishes that $p[T^*] = \mathbb{R} - p[T]$. Basic forcing arguments show that condition (2) here is equivalent to the corresponding condition in Fact 6.14. $\dashv$

6.16 Exercise (Feng-Magidor-Woodin [4]). A set $C \subseteq X^\omega$ is *weakly homogeneously Suslin* (respectively, *weakly λ-homogeneously Suslin*) if it is the projection to X^ω of a homogeneously Suslin (respectively, λ-homogeneously Suslin) subset of $X^\omega \times \omega^\omega$. Prove that if C is weakly λ^+-homogeneously Suslin then it is λ-universally Baire.

Hint. Let $A \subseteq X^\omega \times \omega^\omega$ be λ^+-homogeneously Suslin with $p[A] = C$. Let $S \subseteq (X \times \omega \times \gamma)^{<\omega}$ be a λ^+-homogeneous tree projecting to A, and let $\langle \mu_{s,t} \mid \langle s, t \rangle \in (X \times \omega)^{<\omega} \rangle$ be a λ^+-homogeneity system for S.

Let T be equal to S, viewed as a tree on $X \times (\omega \times \gamma)$, so that T projects to $p[A] = C$. Let T^* be the Martin-Solovay tree for the complement of $p[A]$, defined in Exercise 5.2. Prove that $\langle T, T^* \rangle$ is exhaustive for every poset $\mathbb{P}$ of size $\leq \lambda$. You will need the following claim, which follows from the completeness of the measures $\mu_{s,t}$: Let $\dot{\rho} \in V^{\mathbb{P}}$ be a function from $S_{s,t}$ into the ordinals. Then there is a $\mu_{s,t}$-measure one set Z so that $\dot{\rho} \restriction \check{Z}$ is forced to belong to V. $\dashv$

Using the characterization in Fact 6.14 we can prove, from a Woodin cardinal δ, that δ-universally Baire sets are determined. In light of Exercise 6.16 this is a strengthening of Theorem 5.24:

6.17 Theorem. *Suppose that C is δ-universally Baire and δ is a Woodin cardinal. Then $G_\omega(C)$ is determined.*

Proof. Let T and T^* witness that C is δ-universally Baire. Apply Corollary 6.10 with T and Corollary 6.7 with T^*.

If case 1 of Corollary 6.10 with T holds, then player I wins $G_\omega(C)$ in V. If case 1 of Corollary 6.7 with T^* holds, then player II wins $G_\omega(C)$ in V. Thus it suffices to show that it cannot be that case 2 holds in both applications.

Suppose for contradiction that case 2 holds in both applications. Then in $V[g]$ player II wins $G_\omega(p[T])$ and player I wins $G_\omega(\neg p[T^*])$. Pitting I's winning strategy against II's winning strategy we obtain a real $x \in V[g]$ which does not belong to $(p[T])^{V[g]}$ and does belong to $(\neg p[T^*])^{V[g]}$. In other words x belongs to neither $(p[T])^{V[g]}$ nor $(p[T^*])^{V[g]}$. But this contradicts the fact that $\langle T, T^*\rangle$ is exhaustive for $\mathrm{Col}(\omega, \delta)$. $\dashv$

Our plan for the future is to prove $\mathsf{AD}^{L(\mathbb{R})}$ by proving, from large cardinals, that the least non-determined set in $L(\mathbb{R})$, if it exists, is universally Baire, and then appealing to Theorem 6.17 to conclude that in fact the set is determined.

7. Genericity Iterations

Given a tree S on $X \times U_1 \times U_2$, define $\mathrm{dp}(S)$, the *demanding projection* of S, by putting $x \in \mathrm{dp}(S)$ iff there exist $f_1 : \omega \to U_1$ and $f_2 : \omega \to U_2$ so that $\langle x, f_1, f_2\rangle \in [S]$ and so that f_1 is onto U_1. It is the final clause, that f_1 must be onto U_1, that makes the demanding projection more demanding than the standard projection $p[S]$.

Let M be a model of ZFC and let δ be a Woodin cardinal of M. Let X belong to $M\|\delta$ and let $S \in M$ be a tree on $X \times U_1 \times U_2$ for some sets $U_1, U_2 \in M$. For convenience suppose that $U_1 \cap U_2 = \emptyset$. For further convenience suppose that U_1 and U_2 are the smallest (meaning $\subseteq$-minimal) sets so that S is a tree on $X \times U_1 \times U_2$. U_1 and U_2 are then definable from S.

Define $\mathrm{gdp}(S)$, the *generalized demanding projection* of S, by setting $x \in \mathrm{gdp}(S)$ iff there exists a length ω iteration tree $\mathcal{T}$ on M, using only extenders with critical points above $\mathrm{rank}(X)$, so that for every wellfounded cofinal branch b of $\mathcal{T}$, $x \in \mathrm{dp}(j_b^{\mathcal{T}}(S))$.

An iteration tree $\mathcal{T}$ witnessing that $x \in \mathrm{gdp}(S)$ is said to put x in a *shifted demanding projection* of S. Note that the tree must be such that $x \in \mathrm{dp}(j_b^{\mathcal{T}}(S))$ for *every* cofinal wellfounded branch of $\mathcal{T}$.

The generalized projection here is similar to the one in Definition 5.22, only using the demanding projection instead of the standard projection. We work next to obtain some parallel to the result in Exercise 6.9, for the generalized demanding projection. We work with the objects M, X, δ, and S fixed. We assume throughout that U_1 and $\mathcal{P}^M(\delta)$ are countable in V, so that in V there are surjections onto U_1, and there are $\mathrm{Col}(\omega, \delta)$ filters which are generic over M.

7.1 Definition. Working inside M, define G^* to be played according to Diagram 22.10 and the following rules:

I		w_0	x_0		w_1			w_2	x_2	$\dots$
II	l_0, u_0			l_1, u_1		x_1	l_2, u_2			$\dots$

Diagram 22.10: The game G^*

I	$f_1(0)$		$f_1(1)$		$\dots$	
II		$f_2(0)$		$f_2(1)$		$\dots$

Diagram 22.11: The game $G(\neg S_x)$

(1) $x_n \in X$.

(2) u_n is a $(2k_n + 2)$-type for some number k_n, $\text{dcp}(u_n)$ is elastic, and, setting $s_n = x{\restriction}k_n$, u_n contains the formula "$\langle \widetilde{s}_n, a, b\rangle$ is a node in v_0 where $a = \{v_1, v_3, \dots, v_{2k_n-1}\}$ and $b = \{v_2, v_4, \dots, v_{2k_n}\}$".

(3) If $n > 0$ then $\text{dom}(u_n) > \text{dom}(u_{n-1})$. $\text{dom}(u_0) > \text{rank}(X)$.

(4) If $k_n = 0$ then u_n is realized by S and ν_{L} in $V\|\nu_{\text{L}} + 1$.

(5) If $k_n \neq 0$ then $l_n < n$ is such that $k_{l_n} = k_n - 1$, and u_n exceeds w_{l_n}.

(6) w_n is a $2k_n + 3$-type, w_n is a subtype of $\text{dcp}(u_n)$, and w_n contains the formulae "$v_{2k_n+2} > \max\{\widetilde{\delta}, \text{rank}(v_0)\}$", "$v_{2k_n+2} + 2$ exists and is the largest ordinal", and "v_{2k_n+1} has the form $\langle k_n, z\rangle$ with $z \in A_1$, where A_1, A_2 are the smallest sets so that v_0 is a tree on $\widetilde{X} \times A_1 \times A_2$".

The first player to violate any of the rules loses. Infinite runs where all rules have been followed are won by player I.

7.2 Remark. The key difference between the definition here and that in Sect. 5 is the addition of variables to the types. The use of these variables is governed by rules (2) and (6). Rule (2) is such that the sets realizing $v_1, \dots, v_{2k}$ must form a node $\langle a, b\rangle$ of S_x. Rule (6) is such that v_{2k+1} must be realized by a pair $\langle k, z\rangle$ with $z \in U_1$.

A smaller difference is the elimination here of the moves t_n of Sect. 5. These moves correspond to the vacuous coordinate in the derivation of Corollary 6.7 from Lemma 6.1, and are not needed in a direct proof.

For $x \in X^\omega$ define $G(\neg S_x)$ to be the following game: players I and II alternate moves as in Diagram 22.11 to construct sequences $f_1 = \langle f_1(n) \mid n < \omega\rangle \in (U_1)^\omega$ and $f_2 = \langle f_2(n) \mid n < \omega\rangle \in (U_2)^\omega$. If at any point $\langle x{\restriction}n, f_1{\restriction}n, f_2{\restriction}n\rangle \notin S$ then player I wins. Otherwise player II wins.

Define $\Game(\neg S)$ by setting $x \in \Game(\neg S)$ iff I has a winning strategy in $G(\neg S_x)$.

7.3 Exercise. Suppose $x \notin \text{dp}(S)$. Prove that $x \in \Game(\neg S)$.

7.4 Lemma. *Let g be* $\mathrm{Col}(\omega,\delta)$*-generic over M, and let $B = \Game(\neg S)$ in the sense of $M[g]$. Suppose that $M \models$ "player* I *has a winning strategy in G^*". Then $M[g] \models$ "player* I *has a winning strategy in $G_\omega(B)$".*

Proof. We adapt the construction in the proof of Lemma 6.1.

Let $\sigma \in M$ be a winning strategy for player I in G^*. Let $\rho \in M$ be a bijection of δ onto $V\|\delta$. Call a number $e < \omega$ *valid* at a position $p^* = \langle l_i, u_i, w_i, x_i \mid i < n\rangle$ in G^* just in case that $(\rho \circ g)(e)$ is a legal move for player II in G^* following p^*. Adapting the proof of Claim 6.2, it is easy to see that player II always has a legal move in G^*, so that there is always a number which is valid at p^*.

7.5 Definition. Call a position $\langle x_0, \ldots, x_{n-1}\rangle$ in $G_\omega(B)$ *nice* if it can be expanded to a position $p^* = \langle l_i, u_i, w_i, x_i \mid i < n\rangle^\frown\langle l_n, u_n, w_n\rangle$ in G^* so that:

(1) p^* is according to σ^*.

(2) For each $m \leq n$, $\langle l_m, u_m\rangle$ is equal to $(\rho \circ g)(e)$ for the *least* number e which is valid at $p^* \restriction m$.

Notice that if p is nice then the expansion p^* is unique. Define a strategy σ for player I in $G_\omega(B)$ by setting $\sigma(p) = \sigma(p^*)$ in the case that p is a nice position of even length. (All finite plays by σ lead to nice positions, so there is no need to define σ on positions which are not nice.)

We now aim to show that, in $M[g]$, σ is winning for I in $G_\omega(B)$. Again we adapt the argument in the proof of Lemma 6.1.

Let $x \in M[g]$ be an infinite run of $G_\omega(B)$, played according to σ. Suppose for contradiction that $x \notin B$. This implies that there is a strategy $\tau \in M[g]$ which is winning for II in $G(\neg S_x)$. We intend to use τ and the nature of rule (6) in Definition 7.1 as replacements for the infinite branch through S_x used in the proof of Lemma 6.1.

For each $n < \omega$ let p_n^* be the unique expansion of $x \restriction n$ that satisfies the conditions of Definition 7.5. Let $p^* = \bigcup_{n<\omega} p_n^*$. Let l_i, u_i, and w_i be such that $p^* = \langle l_i, u_i, w_i, x_i \mid i < \omega\rangle$. Let e_i be the least number valid at $p^* \restriction n$, so that $\langle l_i, u_i\rangle = (\rho \circ g)(e_i)$.

We work recursively to construct $f_1 \in (U_1)^\omega$, $f_2 \in (U_2)^\omega$, and sequences $n_0 < n_1 < \cdots$ and $\alpha_0, \alpha_1, \ldots$ so that for each i:

(1) $k_{n_i} = i$ (see Definition 7.1 for the definition of k_n).

(2) $\langle x \restriction i, f_1 \restriction i, f_2 \restriction i\rangle \in S$.

(3) $\langle f_1 \restriction i, f_2 \restriction i\rangle$, viewed as a position in $G(\neg S_x)$, is according to τ.

(4) u_{n_i} is realized by S, $\langle 0, f_1(0)\rangle$, $\langle 0, f_2(0)\rangle$, $\ldots$, $\langle i-1, f_1(i-1)\rangle$, $\langle i-1, f_2(i-1)\rangle$ and α_i in $V\|\alpha_i + 1$.

As in the proof of Lemma 6.1, we shall have $\alpha_{i+1} < \alpha_i$, leading to a contradiction.

Set to begin with $n_0 = 0$, $\alpha_0 = \nu_{\text{L}}$, $f_1\restriction 0 = \emptyset$, and $f_2\restriction 0 = \emptyset$. It is easy to check that these assignments satisfy conditions (1)–(4). In the case of condition (4) note that condition (5) in Definition 7.1 implies that $k_0 = 0$, whence by condition (4) of the definition, u_0 is realized by S and ν_{L} in $V\|\nu_{\text{L}} + 1$.

Suppose now that n_i, α_i, $f_1\restriction i$, and $f_2\restriction i$ have been defined and that conditions (1)–(4) hold for i. The rules of G^* are such that w_{n_i} is a subtype of u_{n_i}. Using the realization of u_{n_i} given by condition (4) and the conditions placed on w_{n_i} by rule (6) in Definition 7.1, it follows that there are $\beta < \alpha_i$ and $z \in U_1$ so that w_{n_i} is realized by S, $\langle 0, f_1(0)\rangle$, $\langle 0, f_2(0)\rangle$, $\dots$, $\langle i-1, f_1(i-1)\rangle$, $\langle i-1, f_2(i-1)\rangle$, $\langle i, z\rangle$, and β, in $V\|\beta + 3$, and so that $\beta > \max\{\delta, \text{rank}(S)\}$.

Let $\alpha_{i+1} = \beta$ and let $f_1(i) = z$. Let $f_2(i)$ be τ's reply to the move $f_1(i) = z$ following the position $\langle f_1\restriction i, f_2\restriction i\rangle$ in $G(\neg S_x)$. Since τ is a winning strategy for II in $G(\neg S_x)$, $\langle x\restriction i+1, f_1\restriction i+1, f_2\restriction i+1\rangle$ is a node in S.

7.6 Remark. The use of rule (6) in Definition 7.1 to obtain $f_1(i)$, and the use of τ to obtain $f_2(i)$, together replace the use of the infinite branch through S in the proof of Lemma 6.1.

We have so far determined α_{i+1}, $f_1\restriction i+1$, and $f_2\restriction i+1$. It remains to determine n_{i+1}.

7.7 Claim. *Let $E = \max\{e_0, \dots, e_{n_i}\}$. Then there exist $e < \omega$ and $\kappa < \delta$ so that:*

(a) $(\rho \circ g)(e)$ has the form $\langle l, u\rangle$ with $l = n_i$, and u equal to the κ-type of S, $\langle 0, f_1(0)\rangle$, $\langle 0, f_2(0)\rangle$, $\dots$, $\langle i, f_1(i)\rangle$, $\langle i, f_2(i)\rangle$, and α_{i+1} in $V\|\alpha_{i+1} + 1$.

(b) $\text{dcp}(u)$ is elastic, $e > E$, and κ is large enough that $(\rho \circ q)(0)$, $\dots$, $(\rho \circ q)(e-1)$ all belong to $V\|\kappa$.

Proof. Similar to the proof of Claim 6.4. ⊣

Let e be given by the last claim. Let $\langle l, u\rangle = (\rho \circ g)(e)$, and let $\kappa = \text{dom}(u)$. An argument similar to that in the proof of Claim 6.5, using the fact that $\langle x\restriction i+1, f_1\restriction i+1, f_2\restriction i+1\rangle$ is a node in S, shows that $\langle l, u\rangle$ is a legal move for player I following $p^*\restriction n$. An argument similar to that in the proof of Claim 6.6 produces $n < \omega$ so that $e_n = e$. Set n_{i+1} equal to this n. By condition (a) then, $l_{n_{i+1}} = n_i$ and $u_{n_{i+1}}$ is equal to the κ-type of S, $\langle 0, f_1(0)\rangle$, $\langle 0, f_2(0)\rangle$, $\dots$, $\langle i, f_1(i)\rangle$, $\langle i, f_2(i)\rangle$, and α_{i+1} in $V\|\alpha_{i+1} + 1$. It is easy now to check that conditions (1)–(4) hold for $i + 1$.

The recursive construction above is such that $\alpha_{i+1} < \alpha_i$ for each $i < \omega$. This contradiction, similar to the one obtained in the proof of Lemma 6.1, completes the proof of Lemma 7.4. ⊣

7.8 Lemma. *Suppose that player* II *has a winning strategy in G^*. Then there is a strategy σ for player* II *in the game on X so that, in V, every infinite play according to σ belongs to* $\text{gdp}(S)$.

Proof. We adapt the solution for Exercise 5.23 to the current setting.

Let $\sigma \in M$ be a winning strategy for player II in G^*. Fix an opponent, willing to play for I in the game on X. We describe how to play against the opponent, making sure that each infinite play according to our description ends up in $\mathrm{gdp}(S)$. As usual our description takes the form of a construction. Precisely, we construct:

(A) l_n, u_n, w_n, and x_n for $n < \omega$.

(B) An iteration tree $\mathcal{T}$ on M giving rise to models M_k for $k < \omega$ and embeddings $j_{l,k}$ for $l\ T\ k < \omega$.

(C) Nodes $\langle a_n, b_n \rangle \in j_{0,2n+1}(S)_x$ for $n < \omega$.

(D) $z_n \in j_{0,2n+1}(U_1)$ for $n < \omega$.

This list of objects is similar to the one in the proof of Lemma 5.15, and our construction too will be similar to the one in that proof.

As in Lemma 5.15 we construct so that: $0\ T\ 2\ T\ 4\ldots$; if $k_n \neq 0$ then the T-predecessor of $2n+1$ is $2l_n+1$; and if $k_n = 0$ then the T-predecessor of $2n+1$ is $2n$. k_n here is such that u_n is a $(2k_n+2)$-type, see Definition 7.1.

Let $p_0 = \emptyset$ and recursively define

$$p_{n+1} = j_{2n,2n+2}(p_n)^\frown \langle l_n, j_{2n,2n+2}(u_n), w_n, x_n \rangle.$$

We construct so that p_n is a position in $j_{0,2n}(G^*)$, played according to $j_{0,2n}(\sigma^*)$. In addition we maintain the conditions:

(1) w_n is realized by the objects $j_{0,2n+1}(S)$, $\langle 0, a_n(0) \rangle$, $\langle 0, b_n(0) \rangle, \ldots, \langle k_n - 1, a_n(k_n-1) \rangle$, $\langle k_n - 1, b_n(k_n-1) \rangle$, $\langle k_n, z_n \rangle$, and $j_{0,2n+1}(\nu_{\mathrm{L}})$ in $M_{2n+1} \| j_{0,2n+1}(\nu_{\mathrm{L}}) + 3$.

(2) w_n is elastic.

(3) M_{2n+1} agrees with all later models of $\mathcal{T}$, that is all models M_i for $i > 2n+1$, past $\mathrm{dom}(w_n)$. w_n belongs to M_i for each $i > 2n+1$.

(4) All the extenders used in $\mathcal{T}$ have critical points above $\mathrm{rank}(X)$. For each $m > n$, the critical point of $j_{2n+2,2m+2}$ is greater than the domain of w_n. In particular $j_{2n+2,2m+2}(w_n) = w_n$ for each $m \geq n$.

Notice that from condition (1) and the fact that $z_n \in j_{0,2n+1}(U_1)$ it automatically follows that w_n is a $(2k_n+3)$-type and that it contains the formulae required by rule (6) of G^*.

To begin round n of the construction set l_n, and u_n to be the moves played by $j_{0,2n}(\sigma^*)$ following the position p_n. Let k_n be such that u_n is a $(2k_n+2)$-type. The construction in round n continues subject to one of the following cases:

Case 1. $k_n = 0$. The rules of G^* are such that u_n is realized by $j_{0,2n}(S)$ and $j_{0,2n}(\nu_{\mathrm{L}})$ in $M_{2n} \| j_{0,2n}(\nu_{\mathrm{L}}) + 1$. From the local indiscernibility of ν_{L} and ν_{H} it follows that u_n is realized by $j_{0,2n}(S)$ and $j_{0,2n}(\nu_{\mathrm{H}})$ in $M_{2n} \| j_{0,2n}(\nu_{\mathrm{H}}) + 1$. Pick a set $z_n \in j_{0,2n}(U_1)$. We shall say more on how this set should be picked, later on. Working in M_{2n} using Lemma 3.22, let $\tau < j_{0,2n}(\delta)$ be such that $\tau > \mathrm{dom}(u_n)$ and such that the τ-type of $j_{0,2n}(S)$, $\langle 0, z_n\rangle$, and $j_{0,2n}(\nu_{\mathrm{L}})$ in $j_{0,2n}(\nu_{\mathrm{L}}) + 3$ is elastic. Let w_n be this type. It is easy to check that w_n exceeds $\mathrm{dcp}(u_n)$ in M_{2n}.

Set E_{2n} = "pad" so that $M_{2n+1} = M_{2n}$ and $j_{2n,2n+1}$ is the identity. Applying the One-Step Lemma 3.23 in M_{2n+1}, find an extender $E_{2n+1} \in M_{2n+1}$ so that w_n is a subtype of $\mathrm{Stretch}^{E_{2n+1}}_{\tau+\omega}(\mathrm{dcp}(u_n))$. Set $M_{2n+2} = \mathrm{Ult}(M_{2n}, E_{2n+1})$, and set $j_{2n,2n+2}$ to be the ultrapower embedding. Note that these settings are such that w_n is a subtype of $j_{2n,2n+2}(\mathrm{dcp}(u_n))$. It is easy now to check that w_n satisfies the conditions of rule (6) of G^*, shifted to M_{2n+2}, following the position $j_{2n,2n+2}(p_n{}^\frown\langle l_n, u_n\rangle)$.

Finally, set x_n to be the move played $j_{0,2n+2}(\sigma^*)$ following the position $j_{2n,2n+2}(p_n)^\frown\langle l_n, j_{2n,2n+2}(u_n), w_n\rangle$ if n is odd, and the move played by the opponent in the game on X following $\langle x_0, \ldots, x_{n-1}\rangle$ if n is even. This completes the round. ⊣ (Case 1)

Case 2. $k_n \neq 0$. The rules of $j_{0,2n}(G^*)$ following the position p_n are such that u_n exceeds w_{l_n} in M_{2n}. Let κ denote the domain of u_n. Using the One-Step Lemma in M_{2n} find an extender E_{2n} with critical point $\mathrm{dom}(w_{l_n})$, so that u_n is a subtype of $\mathrm{Stretch}^{E_{2n}}_{\kappa+\omega}(w_{l_n})$. Set $M_{2n+1} = \mathrm{Ult}(M_{2l_n+1}, E_{2n})$, and set $j_{2l_n+1,2n+1}$ to be the ultrapower embedding, so that u_n is a subtype of $j_{2l_n+1,2n+1}(w_{l_n})$.

Let $k = k_n$ be such that u_n is a $(2k_n + 2)$-type. Let $\bar{k}$ denote $k - 1$. The rules of G^* are such that w_{l_n} is a $(2\bar{k} + 3)$-type. Let $\bar{a}$, $\bar{b}$, and $\bar{z}$ denote a_{l_n}, b_{l_n}, and z_{l_n}. Let $a = j_{2l_n+1,2n+1}(\bar{a})$ and similarly with b and z.

Our construction is such that w_{l_n} is realized by $j_{0,2l_n+1}(S)$, $\langle 0, \bar{a}(0)\rangle$, $\langle 0, \bar{b}(0)\rangle$, $\ldots$, $\langle \bar{k} - 1, \bar{a}(\bar{k} - 1)\rangle$, $\langle \bar{k} - 1, \bar{b}(\bar{k} - 1)\rangle$, $\langle \bar{k}, z\rangle$, and $j_{0,2l_n+1}(\nu_{\mathrm{L}})$ in $M_{2l_n+1} \| j_{0,2l_n+1}(\nu_{\mathrm{L}}) + 3$. Using the elementarity of $j_{2l_n+1,2n+1}$, the fact that u_n is a subtype of $j_{2l_n+1,2n+1}$, and the conditions placed on u_n by rule (2) of Definition 7.1, it follows that there must exist some set z' so that u_n is realized by $j_{0,2n+1}(S)$, $\langle 0, a(0)\rangle$, $\langle 0, b(0)\rangle$, $\ldots$, $\langle \bar{k} - 1, a(\bar{k} - 1)\rangle$, $\langle \bar{k} - 1, b(\bar{k} - 1)\rangle$, $\langle \bar{k}, z\rangle$, $\langle \bar{k}, z'\rangle$, and $j_{0,2n+1}(\nu_{\mathrm{L}})$ in $M_{2n+1} \| j_{0,2n+1}(\nu_{\mathrm{L}}) + 1$, and that moreover $\langle a^\frown\langle z\rangle, b^\frown\langle z'\rangle\rangle$ is a node in $j_{0,2n+1}(S)_x$. Set $a_n = a^\frown\langle z\rangle$ and set $b_n = b^\frown\langle z'\rangle$. Then $\langle a_n, b_n\rangle$ is a node in $j_{0,2n+1}(S)$, and u_n is realized by $j_{0,2n+1}(S)$, $\langle 0, a_n(0)\rangle$, $\langle 0, b_n(0)\rangle$, $\ldots$, $\langle k - 1, a_n(k - 1)\rangle$, $\langle k - 1, b_n(k - 1)\rangle$, and $j_{0,2n+1}(\nu_{\mathrm{L}})$ in $M_{2n+1} \| j_{0,2n+1}(\nu_{\mathrm{L}}) + 1$. For the record we note that:

(i) a_n extends $j_{2l_n+1,2n+1}(a_{l_n})$, and similarly with b_n.

(ii) $j_{2l_n+1,2n+1}(z_{l_n})$ belongs to the range of a_n.

From here we continue as in case 1.

By the local indiscernibility of ν_{L} and ν_{H}, u_n is realized by $j_{0,2n+1}(S)$, $\langle 0, a_n(0)\rangle$, $\langle 0, b_n(0)\rangle$, ..., $\langle k-1, a_n(k-1)\rangle$, $\langle k-1, b_n(k-1)\rangle$, and $j_{0,2n+1}(\nu_{\text{H}})$ in $M_{2n+1} \| j_{0,2n+1}(\nu_{\text{H}}) + 1$.

Pick some set $z_n \in j_{0,2n+1}(U_1)$. We shall say more on how this set should be picked, later on. Working in M_{2n+1} using Lemma 3.22, let $\tau < j_{0,2n+1}(\delta)$ be such that $\tau > \text{dom}(u_n)$ and such that the τ-type of $j_{0,2n+1}(S)$, $\langle 0, a_n(0)\rangle$, $\langle 0, b_n(0)\rangle$, ..., $\langle k-1, a_n(k-1)\rangle$, $\langle k-1, b_n(k-1)\rangle$, $\langle k, z_n\rangle$, and $j_{0,2n+1}(\nu_{\text{L}})$ in $M_{2n+1} \| j_{0,2n+1}(\nu_{\text{L}}) + 3$ is elastic. Let w_n be this type. It is easy to check that w_n exceeds $\text{dcp}(u_n)$ in M_{2n+1}.

Using the One-Step Lemma 3.23, in M_{2n+1}, find an extender $E_{2n+1} \in M_{2n+1}$ so that w_n is a subtype of $\text{Stretch}^{E_{2n+1}}_{\tau+\omega}(\text{dcp}(u_n))$. Set $M_{2n+2} = \text{Ult}(M_{2n}, E_{2n+1})$, and set $j_{2n,2n+2}$ to be the ultrapower embedding. As in case 1, w_n satisfies the conditions of rule (6) of G^*, shifted to M_{2n+2}, following the position $j_{2n,2n+2}(p_n {}^\frown \langle l_n, u_n\rangle)$.

Finally, set x_n to be the move played by $j_{0,2n+2}(\sigma^*)$ following the position $j_{2n,2n+2}(p_n)^\frown\langle l_n, j_{2n,2n+2}(u_n), w_n\rangle$ if n is odd, and the move played by the opponent in the game on X following $\langle x_0, \ldots, x_{n-1}\rangle$ if n is even. This completes the round. ⊣ (Case 2)

The description above completes the construction, except that we have yet to specify how the sets z_n are picked. Note that the structure of the iteration tree $\mathcal{T}$ is such that cofinal branches other than the even branch have the form $0, 2, \ldots, 2m_0, 2m_0+1, 2m_1+1, \ldots$ for some increasing sequence $\{m_i\}$. The sets z_n should be picked during the construction in such a way that:

(iii) For every cofinal branch b other than the even branch, for every odd node $2m+1 \in b$, and for every set $y \in j_{0,2m+1}(U_1)$, there exists a node $2m^*+1 \in b$, with $m^* > m$, so that z_{m^*} is equal to $j_{2m+1,2m^*+1}(y)$.

Securing this through some condition on the way z_n is chosen is a simple matter of book-keeping, using the fact that U_1 is countable in V. Let us just note that this book-keeping cannot in general be phrased inside M, since U_1 is only assumed to be countable in V. Thus the strategy σ which our construction describes need not be an element of M.

With the construction complete, it remains to check that every sequence $x = \langle x_n \mid n < \omega\rangle \in X^\omega$ that can be obtained by following the construction, with moves x_n for even n supplied by the opponent, belongs to $\text{gdp}(S)$.

Let x, $\mathcal{T}$, $\langle l_n, u_n, w_n \mid n < \omega\rangle$, $\langle a_n \mid n < \omega\rangle$, $\langle b_n \mid n < \omega\rangle$ and $\langle z_n \mid n < \omega\rangle$ be obtained through the construction above. We work through a series of claims to show that x belongs to $\text{gdp}(S)$.

7.9 Claim. *The even branch of $\mathcal{T}$ has an illfounded direct limit.*

Proof. Identical to the proof of Claim 5.19. ⊣

7.10 Claim. *Let b be a branch of $\mathcal{T}$ other than the even branch. Let $\{m_i\}$ be such that $b = \{0, 2, \ldots, 2m_0, 2m_0+1, \ldots, 2m_i+1, \ldots\}$. Let $a^*_i = j_{2m_i+1,b}(a_i)$ and let $b^*_i = j_{2m_i+1,b}(b_i)$. Let $a^* = \bigcup_{i<\omega} a^*_i$ and let $b^* = \bigcup_{i<\omega} b^*_i$. Then:*

(1) $\langle x, a^*, b^* \rangle \in [j_{0,b}(S)]$.

(2) a^* *is onto* $j_{0,b}(U_1)$.

Proof. Note first that by condition (i), $\bigcup_{i<\omega} a_i^*$ and $\bigcup_{i<\omega} b_i^*$ are both increasing unions giving rise to infinite sequences. By condition (C), below Lemma 7.8, $\langle x \restriction i, a_i^*, b_i^* \rangle$ is a node in $j_{0,b}(S)$ for each i. Thus $\langle x, a^*, b^* \rangle$ is an infinite branch through $j_{0,b}(S)$.

By conditions (ii), $j_{2m_i+1,b}(z_{m_i})$ belongs to the range of a^* for each i. From this and condition (iii) it follows that a^* is onto $j_{0,b}(U_1)$. ⊣

Claims 7.9 and 7.10 together combine to show that $x \in \mathrm{dp}(j_{0,b}(S))$ for every wellfounded cofinal branch b of $\mathcal{T}$. $\mathcal{T}$ therefore witnesses that $x \in \mathrm{gdp}(S)$. ⊣

7.11 Corollary. *Let M be a model of* ZFC*. Let δ be a Woodin cardinal of M. Let X belong to $M\|\delta$.*

Let $S \in M$ be a tree. Suppose that both S and $\mathcal{P}^M(\delta)$ are countable in V. Let g be $\mathrm{Col}(\omega, \delta)$*-generic over M.*

Then at least one of the following conditions holds:

(1) There is a strategy σ for player II *in the game on X so that, in V, every infinite run according to σ belongs to* $\mathrm{gdp}(S)$.

(2) There is a strategy $\sigma \in M[g]$ for player I *in the game on X so that, in $M[g]$, every infinite run according to σ belongs to $\supset(\neg S)$.*

Proof. Immediate from Lemma 7.4, Lemma 7.8, and the fact that the game G^* is closed and therefore determined in M. ⊣

Sometimes we want to restrict players on X to some specific subtree of $X^{<\omega}$. The next exercise is useful in such circumstances.

7.12 Exercise. Work in the setting of Corollary 7.11, and in addition to the objects there let $R \in M$ be a tree on X with no terminal nodes. Show that at least one of the cases in the corollary holds, with “game on X” replaced by “game on R” in both cases.

Hint. Define $\pi : X^{<\omega} \to R$ so that $\mathrm{lh}(\pi(s)) = \mathrm{lh}(s)$ for each $s \in X^{<\omega}$, $s < t \Longrightarrow \pi(s) < \pi(t)$ for all $s, t \in X^{<\omega}$, and so that π is onto R. Let $\hat{S} = \{\langle s, u_1, u_2 \rangle \mid \langle \pi(s), u_1, u_2 \rangle \in S\}$. Use Corollary 7.11 on $\hat{S}$. ⊣

One can use Corollary 7.11 to directly obtain determinacy results. Here instead we use the corollary to obtain a genericity result, and then use the genericity result in conjunction with Theorem 6.17 to obtain determinacy.

7.13 Definition. Let $\mathbb{P} \in M$ be a poset. An iteration tree $\mathcal{T}$ on M is said to *absorb* x to an extension by an image of $\mathbb{P}$ just in case that for every wellfounded cofinal branch b through $\mathcal{T}$, there is a generic extension $M_b^{\mathcal{T}}[g]$ of $M_b^{\mathcal{T}}$ by the poset $j_{0,b}^{\mathcal{T}}(\mathbb{P})$, so that $x \in M_b^{\mathcal{T}}[g]$.

7.14 Exercise. Let M be a model of ZFC. Let δ be a Woodin cardinal of M. Let X belong to $M\|\delta$. Suppose that $\mathcal{P}^M(\delta)$ is countable in V.

Let U_1 be the set of dense sets in $\mathrm{Col}(\omega,\delta)$. Let A be the set of canonical names in M for functions from ω into X. Let U_2 be the union of A with the set of conditions in $\mathrm{Col}(\omega,\delta)$. Working in M let $S \subseteq (X \times U_1 \times U_2)^{<\omega}$ be the tree of attempts to construct sequences $x = \langle x_0, x_1, \dots\rangle \in X^\omega$, $\langle D_0, D_1, \dots\rangle \in (U_1)^\omega$, and $\langle \dot{x}, p_1, p_2, \dots\rangle \in (U_2)^\omega$ so that:

(1) $\dot{x} \in A$ and $p_n \in \mathrm{Col}(\omega,\delta)$ for each n.

(2) $p_{n+1} < p_n$ and $p_{n+1} \in D_n$ for each n.

(3) $p_n \Vdash$"$\dot{x}(\check{n}) = \check{x}_n$" for each n.

Prove that $x \in \mathrm{dp}(S)$ iff there is a g which is $\mathrm{Col}(\omega,\delta)$-generic over M with $x \in M[g]$.

7.15 Exercise. Continuing to work with the tree of the previous exercise, prove that $x \in \eth(\neg S)$ iff there is *no* g which is $\mathrm{Col}(\omega,\delta)$-generic over M with $x \in M[g]$.

7.16 Theorem. *Let M be a model of* ZFC*. Let δ be a Woodin cardinal of M. Let X belong to $M\|\delta$. Suppose that $\mathcal{P}^M(\delta)$ is countable in V.*

Then for every $x \in X^\omega$ there is a length ω iteration tree $\mathcal{T}$ on M which absorbs x into an extension by an image of $\mathrm{Col}(\omega,\delta)$.

Note that in particular any real number in V can be absorbed into a generic extension of an iterate of M.

Proof of Theorem 7.16. Let g be $\mathrm{Col}(\omega,\delta)$-generic over M, and apply Corollary 7.11 to the tree S of Exercise 7.14. Notice that condition (2) of the corollary cannot hold: the strategy σ in that condition belongs to $M[g]$, and certainly then there are plays $x \in X^\omega$ which are according to σ, and which belong to $M[g]$. But from Exercise 7.15 and the fact that x belongs to $M[g]$ it follows that $x \notin \eth(\neg S)$, while from condition (2) of the corollary and the fact that x is according to σ it follows that $x \in \eth(\neg S)$.

Thus condition (1) of the corollary must hold, and this immediately implies that for every sequence $\langle x_0, x_2, \dots\rangle \in X^\omega$, there is a sequence $\langle x_1, x_3, \dots\rangle \in X^\omega$ and a length ω iteration tree $\mathcal{T}$ on M, so that the combined sequence $x = \langle x_0, x_1, \dots\rangle$ belongs to $\mathrm{dp}(j_{0,b})(S)$ for every cofinal wellfounded branch b of $\mathcal{T}$. By Exercise 7.14 then, x belongs to a generic extension of $M_b^{\mathcal{T}}$ by $j_{0,b}(\mathrm{Col}(\omega,\delta))$. So $\mathcal{T}$ absorbs x, and therefore certainly $\langle x_0, x_2, \dots\rangle$, into an extension by an image of $\mathrm{Col}(\omega,\delta)$. ⊣

Theorem 7.16 was proved in Neeman [28, 29]. It is the second of two genericity results. The first is due to Woodin [42]. Woodin's theorem uses a forcing notion which has the δ chain condition, and it does not require any assumption on the size of δ or its power set in V. These properties often make it more useful than Theorem 7.16, see for example Neeman-Zapletal [34]. On the other hand Woodin's theorem requires full iterability for trees of lengths up to ω_1, and in our setting this is a disadvantage.

7.17 Definition. Let M be a model of ZFC, let δ be a cardinal of M, let $X \in M\|\delta$, and let $\dot{A} \in M$ be a $\mathrm{Col}(\omega, \delta)$-name for a subset of X^ω.

$x \in X^\omega$ belongs to the *generalized interpretation* of $\dot{A}$ if there exists a length ω iteration tree $\mathcal{T}$ on M using only extenders with critical points above $\mathrm{rank}(X)$, and a map $h : \omega \to \mathrm{On}^{<\omega}$, so that for every wellfounded cofinal branch b of $\mathcal{T}$:

(1) $h_b = \bigcup_{n \in b} h(n)$ is $\mathrm{Col}(\omega, j_b^{\mathcal{T}}(\delta))$-generic over $M_b^{\mathcal{T}}$.

(2) x belongs to $j_b^{\mathcal{T}}(\dot{A})[h_b]$.

7.18 Exercise. Let M be a model of ZFC. Let δ be a Woodin cardinal of M. Let X belong to $M\|\delta$. Suppose that $\mathcal{P}^M(\delta)$ is countable in V. Let g be $\mathrm{Col}(\omega, \delta)$-generic over M.

Let $\dot{A} \in M$ be a $\mathrm{Col}(\omega, \delta)$-name for a subset of X^ω. Prove that at least one of the following conditions holds:

(1) In V, player I has a winning strategy in $G_\omega(A^*)$, where A^* is the generalized interpretation of $\dot{A}$.

(2) In $M[g]$, player II has a winning strategy in $G_\omega(\dot{A}[g])$.

Hint. First note that by changing the roles of the players (and modifying the name $\dot{A}$ accordingly) the exercise can be reduced to proving that at least one of the following conditions holds:

(1) There is a strategy σ for player II so that, in V, every play according to σ belongs to the generalized interpretation of $\dot{A}$.

(2) There is a strategy $\sigma \in M[g]$ for player I so that, in $M[g]$, every play according to σ belongs to the complement of $\dot{A}[g]$.

Were it not for the need for continuity of the map $b \mapsto h_b$ in Definition 7.17, this could be derived from Corollary 7.11, using a tree S similar to the one defined in Exercise 7.14, but replacing the set A used in that exercise with the set of names forced to belong to $\dot{A}$. The continuity of the map $b \mapsto h_b$ is a consequence of the proof of Corollary 7.11, tracing back to the way b^* is constructed in Claim 7.10. $\dashv$

Exercise 7.18 appeared in Neeman [28]. When applied with an iterable model M and a name $\dot{A}$ for a set defined by an absolute condition, the exercise leads to determinacy, and Neeman [28] uses it to prove projective determinacy and indeed $\mathsf{AD}^{L(\mathbb{R})}$.

Tracing through the construction leading to the exercise, the reader can check that in condition (1), the tree $\mathcal{T}$ and the function h witnessing that x

belongs to the generalized interpretation of $\dot{A}$ depend on x continuously. This element of continuity is expressed more explicitly in Lemma 1.7 of Neeman [28]. It is crucial for proofs of determinacy of long games, but we shall not get into this here. The interested reader may find more in Neeman [30].

7.19 Exercise (Windßus [41], see [13, Lemma 4.5, Theorem 5.2]). Let $\pi : P \to V\|\theta$ be elementary, with P countable. Let $\bar{\kappa} \in P$. Let A be the set of sequences $\langle u_i \mid i < \omega\rangle \in P^\omega$ so that:

(i) u_i is a (nice) finite iteration tree on P. If $i < j$ then u_j extends u_i, so that $\mathcal{U} = \bigcup_{i<\omega} u_i$ is a (nice) iteration tree of length ω. The trees use only extenders with critical points above $\bar{\kappa}$.

(ii) Let $n_i + 1 = \mathrm{lh}(u_i)$. Then $b = \{n_i \mid i < \omega\}$ is a branch through U.

(iii) The direct limit of the models of $\pi\mathcal{U}$ along b is wellfounded. (Recall that $\pi\mathcal{U}$ is the copy of $\mathcal{U}$ via π, see Definition 2.7. It is an iteration tree on V.)

Prove that A is $\pi(\bar{\kappa})$-homogeneously Suslin.

Proof. The proof builds on that of Lemma 2.12. Let B be the set of sequences $\langle u_i \mid i < \omega\rangle$ satisfying conditions (i) and (ii), but such that the direct limit of $\pi\mathcal{U}$ along b is illfounded. For each $x = \langle u_i \mid i < \omega\rangle$ in B fix a sequence $\langle \alpha_i^x \mid i < \omega\rangle$ witnessing the illfoundedness, more precisely a sequence so that:

(1) for all $i < \omega$, $j^{\pi u_{i+1}}_{n_i,n_{i+1}}(\alpha_i^x) > \alpha_{i+1}^x$.

Let θ be larger than all the ordinals α_i^x.

For $s = \langle u_0, \dots, u_{i-1}\rangle$ let B_s be the set of $x \in B$ which extend s. Let T be the tree of attempts to construct sequences $x = \langle u_i \mid i < \omega\rangle$ and $\langle \sigma_i \mid i < \omega\rangle$ so that:

(2) x satisfies conditions (i) and (ii).

(3) $\sigma_i : B_{\langle u_0,\dots,u_i\rangle} \to \theta$.

(4) For all i and all $y \in B_{\langle u_0,\dots,u_{i+1}\rangle}$, $\sigma_i(y) > \sigma_{i+1}(y)$.

Prove that $x \in B \implies x \notin p[T]$, and hence $p[T] \subseteq A$. You will prove that $A \subseteq p[T]$ later on.

Let $M_\emptyset = V$. For $s = \langle u_0, \dots, u_i\rangle$ let M_s be the final model $M^{\pi u_i}_{n_i}$ of the copied tree πu_i. Let φ_s be the function $x \mapsto \alpha_i^x$, defined for $x \in B_s$, where α_i^x are the ordinals witnessing condition (1) above. The models of πu_i are $2^{\aleph_0}$-closed by Exercise 2.2, and hence $\varphi_s \in M_s$.

For $t = \langle u_0, \dots, u_{i^*}\rangle$ extending $s = \langle u_0, \dots, u_i\rangle$ let $j_{s,t} : M_s \to M_t$ be the embedding $j^{\pi u_{i^*}}_{n_i,n_{i^*}}$. Let $j_{\emptyset,t} : V \to M_t$ be the embedding $j^{\pi u_{i^*}}_{0,i^*}$. Notice that all these embeddings have critical points above $\pi(\bar{\kappa})$.

Show using condition (1) that $f_s = \langle j_{s\restriction 1,s}(\varphi_{s\restriction 1}), j_{s\restriction 2,s}(\varphi_{s\restriction 2}), \ldots, \varphi_s\rangle$ is a node in $j_{\emptyset,s}(T_s)$, and use the models M_s, embeddings $j_{s,t}$, and nodes f_s to assemble a homogeneity system for T along the conditions of Exercise 4.2. Finally use the converse of condition (3) of Exercise 4.2, given by Exercise 4.4, to show that $A \subseteq p[T]$. ⊣

7.20 Exercise (Woodin, see [14, Theorem 3.3.8]). Let δ be Woodin in V and let $A \subseteq \omega^\omega$ be δ-universally Baire. Prove that A is weakly κ-homogeneously Suslin for each $\kappa < \delta$.

Hint. Fix κ. Let $\langle T, T^*\rangle$ witness that A is δ-universally Baire. Let θ be large enough that δ, T, and T^* belong to $V\|\theta$. Let $\pi : P \to V\|\theta$ be elementary, with P countable and κ, δ, T, and T^* in the range of π. Let $\bar{\kappa}$ be such that $\pi(\bar{\kappa}) = \kappa$, and similarly with $\bar{\delta}$, $\bar{T}$, and $\bar{T}^*$.

Let B be the set of tuples $\langle x, \mathcal{U}, b, n, \dot{x}, g\rangle$ so that: $x \in \omega^\omega$; $\mathcal{U}$ is a (nice) length ω iteration tree on P using only extenders with critical points above $\bar{\kappa}$; b is a cofinal branch through U, leading to a wellfounded direct limit in the copy tree $\pi\mathcal{U}$ on V; $n \in b$; $\dot{x} \in P_n$ is a name in $\mathrm{Col}(\omega, j_{0,n}(\bar{\delta}))$, forced by the empty condition to be a real belonging to $p[j_{0,n}(\bar{T})]$; g is $\mathrm{Col}(\omega, j_b(\bar{\delta}))$-generic over P_b; and $j_{n,b}(\dot{x})[g] = x$.

Show using Exercise 7.19 that B is κ-homogeneously Suslin. Then show using Theorem 7.16 and Lemma 2.12 that $x \in A$ iff $(\exists\mathcal{U})(\exists b)(\exists n)(\exists\dot{x})(\exists g)$ $\langle x, \mathcal{U}, b, n, \dot{x}, g\rangle \in B$. The quantifiers all involve elements of P and P^ω, which are isomorphic to ω and ω^ω. Use this to present A as the projection of a κ-homogeneously Suslin subset of $\omega^\omega \times \omega^\omega$. ⊣

7.21 Remark. If κ is a limit of Woodin cardinals, then for any $A \subseteq \omega^\omega$, Exercises 5.29, 6.16, and 7.20 together imply that A is $<\kappa$-universally Baire iff A is $<\kappa$-homogeneously Suslin iff A is weakly $<\kappa$-homogeneously Suslin.

7.22 Exercise. Let $j : M \to N$ be elementary. Let h be $\mathrm{Col}(\omega, \kappa)$-generic over M. Suppose that $\mathrm{crit}(j) > \kappa$. Prove that j can be extended to an embedding $j^* : M[h] \to N[h]$.

Hint. Define j^* by setting $j^*(\dot{a}[h]) = (j(\dot{a}))[h]$. Show that j^* is well defined and elementary. ⊣

7.23 Exercise. Let M be a model of ZFC. Let δ be a Woodin cardinal of M. Let X belong to $M\|\delta$. Suppose that $\mathcal{P}^M(\delta)$ is countable in V.

Let $\kappa < \delta$. Let h be $\mathrm{Col}(\omega, \kappa)$-generic over M.

Let $x \in X^\omega$. Then there is a length ω iteration tree $\mathcal{T}$ on M so that:

(1) All the extenders used in $\mathcal{T}$ have critical points above κ. (In particular then the embeddings along branches of $\mathcal{T}$ extend to act on $M[h]$.)

(2) For every cofinal wellfounded branch b of $\mathcal{T}$, there is a g $\mathrm{Col}(\omega, j_b(\delta))$-generic over $M_b[h]$ so that x belongs to $M_b[h][g]$.

Note that in particular any real in V can be absorbed into a generic extension of $M_b[h]$ for an iterate M_b of M.

Hint to Exercise 7.23. Let $\widehat{X} = M \| \kappa + \omega$. Let $R \subseteq \widehat{X}^{<\omega}$ be the tree of attempts to construct a sequence $\langle\langle x_0, q_0\rangle, E_0, \langle x_1, q_1\rangle, E_1, \dots\rangle$ so that:

(1) $x_n \in X$ for each n, and q_n is a condition in $\mathrm{Col}(\omega, \kappa)$.

(2) E_n is a dense subset of $\mathrm{Col}(\omega, \kappa)$ for each n.

(3) $q_{n+1} < q_n$ and $q_{n+1} \in E_n$ for each n.

For clarity let us point out that in games on R, player I plays the objects $\langle x_n, q_n\rangle$, and player II plays the objects E_n.

Working in M let U_1 be the set of $\mathrm{Col}(\omega, \kappa)$-names for dense subsets of $\mathrm{Col}(\omega, \delta)$, let A be the set of canonical $\mathrm{Col}(\omega, \kappa) \times \mathrm{Col}(\omega, \delta)$-names for functions from ω into X, and let U_2 be the union of A with the set of conditions in $\mathrm{Col}(\omega, \delta)$.

Let $S \subseteq (\widehat{X} \times U_1 \times U_2)^{<\omega}$ be the tree of attempts to construct a sequence $\langle\langle x_0, q_0\rangle, E_0, \langle x_1, q_1\rangle, E_1, \dots\rangle \in [R]$, a sequence $\langle \dot{D}_0, \dot{D}_1, \dots\rangle \in (U_1)^\omega$, and a sequence $\langle \dot{x}, p_1, p_2, \dots\rangle \in (U_2)^\omega$ so that:

(1) $\dot{x} \in A$ and $p_n \in \mathrm{Col}(\omega, \delta)$ for each n.

(2) For each n and each $i \leq n$, $p_{n+1} < p_n$ and $q_{n+1} \not\Vdash^{\mathrm{Col}(\omega,\kappa)}$ "$\check{p}_{i+1} \notin \dot{D}_i$."

(3) For each n and each $i \leq n$, $\langle q_n, p_n\rangle \not\Vdash^{\mathrm{Col}(\omega,\kappa)\times\mathrm{Col}(\omega,\delta)}$ "$\dot{x}(\check{i}) \neq \check{x}_i$."

Apply Exercise 7.12 to $\widehat{X}$, R, and S as defined above. Argue first that case (2) cannot hold. (For this you will need the following forcing claim: Let g be $\mathrm{Col}(\omega, \delta)$-generic over M. Let h^* belong to $M[g]$ and suppose that h^* is $\mathrm{Col}(\omega, \kappa)$-generic over M. Then there exists a g^* which is $\mathrm{Col}(\omega, \delta)$-generic over $M[h^*]$ and so that $M[h^*][g^*] = M[g]$.) Then use case (1) of Exercise 7.12 to reach the conclusion of the current exercise. ⊣

7.24 Remark. Let $\kappa_1 < \kappa_2 < \cdots < \kappa_i = \kappa$. $\mathrm{Col}(\omega, \kappa)$ is then isomorphic to $\mathrm{Col}(\omega, \kappa_1) \times \cdots \times \mathrm{Col}(\omega, \kappa_i)$. Exercise 7.23 can therefore be rephrased to replace h by a generic $h_1 \times \cdots \times h_i$ for $\mathrm{Col}(\omega, \kappa_1) \times \cdots \times \mathrm{Col}(\omega, \kappa_i)$. This sets the stage for an iterated use of the exercise, assuming an increasing sequence of Woodin cardinals. We shall make such a use in the next section.

8. Determinacy in $L(\mathbb{R})$

Let M be a model of ZFC and let $\delta_0 < \delta_1 < \cdots$ be ω Woodin cardinals in M. Let $\delta_\infty = \sup_{n<\omega} \delta_n$. Suppose that $\mathcal{P}^M(\delta_\infty)$ is countable in V.

Let $\mathbb{P}$ be the finite support product $\mathrm{Col}(\omega, \delta_0) \times \mathrm{Col}(\omega, \delta_1) \times \cdots$.

Given a filter $G = \langle g_i \mid i < \omega\rangle$ which is $\mathbb{P}$-generic over M define $R^*[G]$ to be $\bigcup_{n<\omega} \mathbb{R}^{M[G\restriction n]}$. We refer to $R^*[G]$ as the reals in the *symmetric collapse* of M induced by G. We refer to $L_{M\cap\mathrm{On}}(R^*[G])$ as the *derived model* of M induced by G. (This is $L(R^*[G])$ if M is a class model.)

8.1 Remark. Suppose that $v_1, \dots, v_k \in M[G\restriction n]$. Let $\mathbb{P}_{\mathrm{L}} = \mathrm{Col}(\omega, \delta_0) \times \cdots \times \mathrm{Col}(\omega, \delta_{n-1})$, so that $G\restriction n$ is $\mathbb{P}_{\mathrm{L}}$-generic over M, and let $\mathbb{P}_{\mathrm{H}} = \mathrm{Col}(\omega, \delta_n) \times \cdots$. Because of the symmetry of $\mathbb{P}_{\mathrm{H}}$, any statement $\varphi[v_1, \dots, v_k]$ which holds in $M(R^*[G])$ must be forced to hold in $M(R^*[G])$ by the *empty condition* in $\mathbb{P}_{\mathrm{H}}$ over $M[G\restriction n]$.

8.2 Exercise. Let R^* denote the reals of the symmetric collapse of M induced by G, and let W denote the derived model of M induced by G. Prove that $\mathbb{R}^W = R^*$.

Hint. The inclusion $\mathbb{R}^W \supseteq R^*$ is clear. For the reverse inclusion: let $b \in \mathbb{R}^W$. b is definable in W from some parameters in $R^* \cup (\mathrm{On} \cap M)$. Thus there is some $n < \omega$ so that the parameters defining b belong to $M[G\restriction n]$. Use this and the symmetry given by Remark 8.1 to argue that b belongs to $M[G\restriction n]$, and therefore $b \in R^*$. $\dashv$

Exercise 8.2 makes no use of the assumption that δ_∞ is a limit of Woodin cardinals in M. But without this assumption the derived model need not even satisfy the axiom of dependent choice for reals, and in such circumstances the conclusion of the exercise is less meaningful than it appears.

8.3 Definition. By a $\Sigma_1(\mathbb{R})$ *statement over* $L(\mathbb{R})$, $\Sigma_1(\mathbb{R})$ for short, we mean a statement of the form $(\exists Q \supseteq \mathbb{R})\, Q \models \psi[x_1, \dots, x_n]$, where $x_1, \dots, x_n \in \mathbb{R}$.

We say that $L_\alpha(R)$ is an *initial segment* of $L_\beta(R)$ if: (1) $\alpha \le \beta$; and (2) $\mathbb{R}^{L_\alpha(R)} = \mathbb{R}^{L_\beta(R)} = R$.

8.4 Claim. *Suppose that $L_\alpha(R)$ is an initial segment of $L_\beta(R)$. Then any $\Sigma_1(R)$ statement true in $L_\alpha(R)$ is also true in $L_\beta(R)$.*

The failure of $\mathsf{AD}^{L(\mathbb{R})}$ is $\Sigma_1(\mathbb{R})$, and so is the failure of dependent choice for reals in $L(\mathbb{R})$.

8.5 Lemma. *Let $\varphi[x_1, \dots, x_k]$ be $\Sigma_1(\mathbb{R})$ over $L(\mathbb{R})$. Suppose that $x_1, \dots, x_k$ belong to the symmetric collapse of M induced by G. Suppose that M is countable and embeds into a rank initial segment of V. Then if $\varphi[x_1, \dots, x_k]$ holds in the derived model of M induced by G, it must hold also in (the true) $L(\mathbb{R})$.*

Proof. Let Σ be the weak iteration strategy for M given by Corollary 2.4. Let θ be a cardinal large enough that M, Σ, G, and $\mathbb{R}$ all belong to $V\|\theta$, and so that $V\|\theta$ satisfies enough of ZFC for the argument below. Let X be a countable elementary substructure of $V\|\theta$ containing these objects. Let P be the transitive collapse of X and let $\tau : P \to V\|\theta$ be the anti-collapse embedding. Notice that M, being countable, is not moved by the collapse. So $\tau(M) = M$. Notice further that $\tau^{-1}(\Sigma)$ is simply equal to $\Sigma \cap P$. This is because the iteration trees which come up in weak iteration games on M are countable, and not moved by τ.

Let $\langle a_i \mid n \leq i < \omega\rangle$ be an enumeration of the reals of P, which is $\mathrm{Col}(\omega, \mathbb{R}^P)$-generic over P. Let $M_0 = M_1 = \cdots = M_n = M$ and let $j_{i,i'}$ for $i \leq i' \leq n$ be the identity. For $i < n$ let $h_i = g_i$. Below let h^i denote $h_0 \times h_1 \times \cdots \times h_{i-1}$. Using repeated applications of Exercise 7.23 and Remark 7.24 construct $\mathcal{T}_i$, b_i, M_i, and h_i for $i \geq n$, and a commuting system of embeddings $j_{i,i'} : M_i \to M_{i'}$ for $i \leq i' < \omega$ so that:

(1) $\mathcal{T}_i$ is a length ω iteration tree on M_i, using only extenders with critical points above $j_{0,i}(\delta_{i-1})$.

(2) b_i is the cofinal branch through $\mathcal{T}_i$ given by Σ (equivalently by $\bar{\Sigma}$).

(3) M_{i+1} is the direct limit of the models of $\mathcal{T}_i$ along b_i. $j_{i,i+1} : M_i \to M_{i+1}$ is the direct limit embedding.

(4) h_i is $\mathrm{Col}(\omega, j_{0,i+1}(\delta_i))$-generic over $M_{i+1}[h^i]$.

(5) a_i belongs to $M_{i+1}[h^i \times h_i]$.

The key point in the construction is the last condition, condition (5). It is obtained through an application of Exercise 7.23, inside P, on the model $M_i[h^i]$, to absorb the real a_i into a generic extension of an iterate. $\mathcal{T}_i$ is the iteration tree given by the exercise.

The construction is dependent on the sequence $\langle a_i \mid n \leq i < \omega\rangle$ which does not belong to P. Thus the sequence $\langle M_i, \mathcal{T}_i, b_i, h_i \mid i < \omega\rangle$ does not belong to P. But notice that every stage of the construction is done inside P. Each of the individual objects in the sequence is therefore an element of P (and countable in P, since M is countable in P). Using this and some book-keeping it is easy to arrange that:

(i) For every $i < \omega$, and every $D \in M_i$ which is dense in $j_{0,i}(\mathbb{P})$, there exists some $i^* > i$ so that the filter $h_0 \times \cdots \times h_{i^*-1}$ meets $j_{i,i^*}(D)$.

The book-keeping requires an enumeration of $\bigcup_{i<\omega} M_i$. Notice that there are such enumerations in $P[a_i \mid n \leq i < \omega]$ since each M_i is countable in P, and therefore coded by a real.

Let M_∞ be the direct limit of the system $\langle M_i, j_{i,i'} \mid i \leq i' < \omega\rangle$, and let $j_{i,\infty}$ be the direct limit maps. M_∞ is wellfounded since it is obtained in a play of the weak iteration game according to Σ.

From condition (1) it follows that $\mathrm{crit}(j_{i^*,\infty}) \geq j_{0,i^*}(\delta_{i-1})$ for every $i^* < \omega$. Conditions in h^{i^*} are therefore not moved by $j_{i^*,\infty}$. From this and condition (i) it follows that $H = \langle h_i \mid i < \omega\rangle$ is $j_{0,\infty}(\mathbb{P})$-generic over M_∞.

8.6 Claim. *$\varphi[x_1, \ldots, x_k]$ holds in the derived model of M_∞ induced by H.*

Proof. We know that $\varphi[x_1,\dots,x_k]$ holds in the derived model of M induced by G. By Remark 8.1 this statement, let us denote it $(*)$, is forced, over $M[g_0\times\cdots\times g_{n-1}] = M[h_0\times\cdots\times h_{n-1}]$ by the empty condition in $\mathbb{P}_{\text{H}}$. $j_{0,\infty}$ has critical point above δ_{n-1} and therefore extends to an elementary embedding of $M[h_0 \times\cdots\times h_{n-1}]$ into $M_\infty[h_0\times\cdots\times h_{n-1}]$. $x_1,\dots,x_k$, being reals, are not moved by the embedding. From this and elementarity if follows that the statement $(*)$ is forced to hold also over $M_\infty[h_0\times\cdots\times h_{n-1}]$. It follows that $\varphi[x_1,\dots,x_k]$ holds in the derived model of M_∞ induced by H. ⊣

8.7 Claim. $R^*(H) = \mathbb{R}^P$.

Proof. From the restriction on the critical points in condition (1) it follows that $\mathbb{R}\cap M_\infty[H{\restriction}i] = \mathbb{R}\cap M_i[H{\restriction}i]$. Since M_i and $H{\restriction}i$ belong to P it follows that $\mathbb{R}\cap M_\infty[H{\restriction}i]\subseteq P$, and hence $R^*(H)\subseteq\mathbb{R}^P$.

Conversely, every real in P belongs to $\{a_i \mid n\le i<\omega\}$, and is, by construction, an element of $M_{i+1}[h^i][h_i] = M_{i+1}[H{\restriction}i+1]$ for some i. Using the restriction on the critical points in condition (1), $\mathbb{R}\cap M_{i+1}[H{\restriction}i+1] = \mathbb{R}\cap M_\infty[H{\restriction}i+1]$. So $\mathbb{R}^P\subseteq R^*(H)$. ⊣

8.8 Claim. *$\varphi[x_1,\dots,x_k]$ holds in $(L(\mathbb{R}))^P$.*

Proof. Notice that the ordinals of M_∞ are contained in the ordinals of P. (This is because M_∞ belongs to $P[a_i \mid n\le i<\omega]$.) From this and the last claim it follows that the derived model of M_∞ induced by H is an initial segment of the model $(L(\mathbb{R}))^P$. By Claim 8.6, $\varphi[x_1,\dots,x_k]$ holds in the former model. From this and the fact that φ is $\Sigma_1(\mathbb{R})$ it follows that $\varphi[x_1,\dots,x_k]$ holds also in the latter. ⊣

We showed so far that $\varphi[x_1,\dots,x_k]$ holds in $(L(\mathbb{R}))^P$, where P is the transitive collapse of a Skolem hull of a rank initial segment of V. Using the elementarity of the anti-collapse embedding it follows that $\varphi[x_1,\dots,x_k]$ holds in $(L(\mathbb{R}))^{V\|\theta}$, and since $\varphi[x_1,\dots,x_k]$ is $\Sigma_1(\mathbb{R})$ this implies that it holds in $(L(\mathbb{R}))^V$. ⊣

8.9 Lemma. *Suppose that $\langle\eta_i \mid i<\omega\rangle$ is an increasing sequence of Woodin cardinals of V. Let $\mathbb{Q}$ be the finite support product $\mathrm{Col}(\omega,\eta_1)\times\mathrm{Col}(\omega,\eta_2)\times\cdots$. Let $H=\langle h_i \mid i<\omega\rangle$ be $\mathbb{Q}$-generic over V.*

Then the derived model of V induced by H satisfies the axiom of dependent choice for reals (and hence the full axiom of dependent choice).

Proof. Suppose not. Let θ be a cardinal large enough that $\mathbb{Q}\in V\|\theta$ and so that $V\|\theta$ satisfies the fragment of ZFC that must be assumed in a model M for Lemma 8.5 to hold for the model. Let $\pi: M\to V\|\theta$ be elementary, with M countable and $\mathbb{Q}\in\mathrm{range}(\pi)$. By elementarity, dependent choice for reals fails in the derived models of M. The failure of dependent choice for reals is $\Sigma_1(\mathbb{R})$. Thus by Lemma 8.5 dependent choice for reals must fail also in the true $L(\mathbb{R})$. But this is a contradiction. Dependent choice for reals in the true $L(\mathbb{R})$ follows from the axiom of choice in V and the fact that countable sequences of reals can be coded by reals. $\dashv$

8.10 Theorem. *Suppose that $\langle \eta_i \mid i < \omega \rangle$ is an increasing sequence of Woodin cardinals of V. Let $\mathbb{Q}$ be the finite support product* $\mathrm{Col}(\omega, \eta_1) \times \mathrm{Col}(\omega, \eta_2) \times \cdots$. *Let $H = \langle h_i \mid i < \omega \rangle$ be $\mathbb{Q}$-generic over V.*

Then the derived model of V induced by H satisfies AD.

Proof. Let R^* denote $R^*[H]$, and suppose for contradiction that there is a set $A \in L(R^*)$ so that $A \subseteq R^*$ and $G_\omega(A)$ is not determined in $L(R^*)$.

Since every set in $L(R^*)$ is definable from real and ordinal parameters in a level of $L(R^*)$, there must be a parameter $a \in R^*$, a formula φ, and ordinals γ, ζ so that

$$x \in A \iff L_\gamma(R^*) \models \varphi[x, a, \zeta].$$

Without loss of generality we may assume that $a \in \mathbb{R}^V$. Otherwise we may simply replace V by $V[h_0 \times \cdots \times h_i]$ for i large enough that $a \in \mathbb{R}^{V[h_0 \times \cdots \times h_i]}$.

Again without loss of generality we may assume that $\langle \gamma, \zeta \rangle$ is the lexicographically least pair of ordinals for which the set $\{x \mid L_\gamma(R^*) \models \varphi[x, a, \zeta]\}$ is not determined. By the symmetry of the collapse, this minimality of $\langle \gamma, \zeta \rangle$ is forced by the empty condition in $\mathbb{Q}$ over V.

8.11 Remark. We refer to A as the *least* non-determined set definable from a and ordinal parameters in $L(R^*)$.

Let θ be a cardinal larger than $\sup_{i<\omega} \eta_i$, larger than γ, and so that $V\|\theta$ satisfies the fragment of ZFC that must be assumed in a model M for Lemma 8.5 to hold for the model. Let $\dot{R}^* \in V$ be the canonical name for $R^*[H]$.

8.12 Definition. Working in V let $T_{\text{in}} \subseteq \omega \times V\|\theta$ be the tree of attempts to construct a real x, and a sequence $\langle \langle e_i, f_i \rangle \mid i < \omega \rangle \in (V\|\theta)^\omega$ so that:

(1) $\{e_i \mid i < \omega\}$ is an elementary substructure of $V\|\theta$.

Let M be the transitive collapse of $\{e_i \mid i < \omega\}$, and let $\pi : M \to V\|\theta$ be the anticollapse embedding.

(2) $e_0 = a$, e_1 is equal to $\langle \eta_i \mid i < \omega \rangle$, $e_2 = \mathbb{Q}$, $e_3 = \dot{R}^*$, $e_4 = \gamma$, $e_5 = \zeta$, and e_6 is a name for a real in the symmetric collapse of V by $\mathbb{Q}$.

(3) It is forced by the empty condition in $\mathbb{Q}$ that $L_{\check{\gamma}}(\dot{R}^*) \models \varphi[e_6, \check{a}, \check{\zeta}]$.

Let $\dot{x}$ denote $\pi^{-1}(e_6)$. Let $\mathbb{P}$ denote $\pi^{-1}(\mathbb{Q})$.

(4) The set $G = \{\pi^{-1}(e_{f_i}) \mid i < \omega\}$ forms a $\mathbb{P}$-generic filter over M.

(5) $\dot{x}[G]$ is equal to x.

Let $T_{\text{out}} \in V$ be defined similarly, only changing "$\models$" in condition (3) to "$\not\models$".

8.13 Remark. We emphasize that both T_{in} and T_{out} are defined in V, that is with no reference to H.

8.14 Remark. Let $x \in p[T_{\text{in}}]$ and let $\langle\langle e_i, f_i\rangle \mid i < \omega\rangle$ witness this. Let M, π, and G be as in Definition 8.12. Note in this case that the derived model of M induced by G satisfies the statement "there is a non-determined set definable from a and ordinal parameters, and x belongs to the least such set". This follows from the minimality of $\langle\gamma, \zeta\rangle$, the elementarity of π, condition (3) of Definition 8.12, and condition (5) of the definition.

Similarly, if $x \in p[T_{\text{out}}]$, then the derived model of M induced by G satisfies the statement "there is a non-determined set definable from a and ordinal parameters, and x belongs to the *complement* of the least such set."

8.15 Claim. *The pair* $\langle T_{\text{in}}, T_{\text{out}}\rangle$ *is exhaustive for* $\mathrm{Col}(\omega, \eta_0)$.

Proof. Let x be a real in $V[h_0]$. Recall that $A = \{x \mid L_\gamma(R^*) \models \varphi[x, a, \zeta]\}$. If $x \in A$ then a Skolem hull argument in $V[H]$ easily shows that $x \in (p[T_{\text{in}}])^{V[H]}$, and from this by absoluteness it follows that $x \in (p[T_{\text{in}}])^{V[h_0]}$. If $x \notin A$ then a similar argument shows that $x \in (p[T_{\text{out}}])^{V[h_0]}$. ⊣

8.16 Claim. *Let x be a real in V. Suppose that $x \in p[T_{\text{in}}]$. Then, in $L(\mathbb{R})$, there is a non-determined set definable from a and ordinal parameters, and x belongs to the least such set.*

Proof. Let $\langle\langle e_i, f_i\rangle \mid i < \omega\rangle$ witness that $x \in p[T_{\text{in}}]$. Let M, π, $\dot{x}$, and G be as in Definition 8.12. By Remark 8.14, the derived model of M induced by G satisfies the statement "there is a non-determined set definable from a and ordinals parameters, and x belongs to the least such set". This statement is $\Sigma_1(\mathbb{R})$. By Lemma 8.5 the statement must hold of x and a in the true $L(\mathbb{R})$. ⊣

8.17 Claim. *Let x be a real in V. Suppose that $x \in p[T_{\text{out}}]$. Then, in $L(\mathbb{R})$, there is a non-determined set definable from a and ordinal parameters, and x belongs to the* complement *of the least such set.*

Proof. Similar to the proof of the previous claim. ⊣

8.18 Claim. $V \models$ *"$p[T_{\text{in}}] \cap p[T_{\text{out}}] = \emptyset$".*

Proof. This follows immediately from the last two claims: x cannot belong to both the least non-determined set and its complement. ⊣

From Claims 8.15 and 8.18, and Exercise 6.15, it follows that, in V, $p[T_{\text{out}}]$ is precisely equal to the complement of $p[T_{\text{in}}]$. In particular this means that, in the true $L(\mathbb{R})$, there is a non-determined set definable from a and ordinal parameter, for otherwise both $p[T_{\text{in}}]$ and $p[T_{\text{out}}]$ would be empty by Claims 8.16 and 8.17. $p[T_{\text{in}}]$ is equal to the least such set.

Again from Exercise 6.15, $p[T_{\text{in}}]$ is η_0-universally Baire. By Theorem 6.17, $G_\omega(p[T_{\text{in}}])$ must be determined. But this is a contradiction since $p[T_{\text{in}}]$ is the least *non*-determined set. The contradiction completes the proof of Theorem 8.10. $\dashv$

8.19 Definition. Let $A \subseteq \mathbb{R}$ in V be $<\eta$-universally Baire, i.e. κ-universally Baire for each $\kappa < \eta$. Let H be $\mathrm{Col}(\omega, <\eta)$-generic over V and let $\mathbb{R}^* = R^*[H] = \bigcup_{\alpha<\eta} \mathbb{R}^{V[H\restriction\alpha]}$. The set A has a *canonical extension* to a set $A^* \subseteq \mathbb{R}^*$, defined as follows: $x \in \mathbb{R}^{V[H\restriction\alpha]}$ belongs to A^* iff $x \in p[T]$ for some, and equivalently any, pair $\langle T, T^* \rangle \in V$ witnessing that A is α-universally Baire. (The equivalence is easy to prove using the conditions in Fact 6.14, and makes the canonical extension useful.)

8.20 Exercise. Let η be a limit of Woodin cardinals and H a $\mathrm{Col}(\omega, <\eta)$-generic filter over V. Let $A \subseteq \mathbb{R}$ in V be $<\eta$-universally Baire (equivalently, by Remark 7.21, $<\eta$-homogeneously Suslin, or weakly $<\eta$-homogeneously Suslin). Let A^* be the canonical extension of A to a subset of $\mathbb{R}^* = R^*[H]$. Prove that $L(\mathbb{R}^*, A^*)$ satisfies AD.

Exercise 8.20 is a first step towards Woodin's derived model theorem, which the reader can find in Steel [40]. Assuming enough large cardinals, it can be shown that there are universally Baire sets which do not belong to $L(\mathbb{R})$, and in that case Exercise 8.20 is a proper strengthening of Theorem 8.10, taking determinacy to sets outside $L(\mathbb{R}^*)$.

Hint to Exercise 8.20. Adapt the proof of Theorem 8.10, replacing $L(\mathbb{R})$ by $L(\mathbb{R}, A)$ and, for countable N and $\sigma : N \to V\|\theta$, replacing derived models of N by models of the form $L_{N\cap\mathrm{On}}(\bar{\mathbb{R}}^*, \bar{A}^*)$ where $\bar{\mathbb{R}}^*$ is the set of reals of the derived model and $\bar{A}^*$ is the canonical extension of $\bar{A} = \sigma^{-1}(A)$ to a subset of $\bar{\mathbb{R}}^*$. (Notice that all the countable models which come up during the proof of Theorem 8.10 embed into rank initial segments of V, either directly by construction or because they are obtained through uses of Theorem 2.3.) You will need the following observation, which is easily verified, to connect $L(\bar{\mathbb{R}}^*, \bar{A}^*)$ with $L(\mathbb{R}, A)$: Let $\sigma : N \to V\|\theta$ be elementary, with N countable and $\sigma(\bar{A}) = A$, $\sigma(\bar{\eta}) = \eta$. Let $\bar{H} \in V$ be $\mathrm{Col}(\omega, \bar{\eta})$-generic over N. Let $\bar{\mathbb{R}}^* = \bigcup_{\alpha<\bar{\eta}} \mathbb{R}^{N[\bar{H}\restriction\alpha]}$ and let $\bar{A}^*$ be the canonical extension of $\bar{A}$ to a subset of $\bar{\mathbb{R}}^*$, as defined inside $N[\bar{H}]$. Then for every $x \in \bar{\mathbb{R}}^*$, $x \in \bar{A}^* \iff x \in A$. $\dashv$

8.21 Theorem. *Suppose that there is a model M of* ZFC *so that:*

- *M has ω Woodin cardinals and a measurable cardinal above them.*
- *M is countable in V.*
- *M is weakly iterable.*

Then the true $L(\mathbb{R})$ satisfies AD.

Proof. Let Σ be a weak iteration strategy for M. Let θ be a cardinal large enough that $\Sigma \in V\|\theta$, and so that $V\|\theta$ satisfies enough of ZFC for the argument below. Let X be a countable elementary substructure of $V\|\theta$ with $M, \Sigma \in X$. Let P be the transitive collapse of X and let $\tau : P \to V\|\theta$ be the anti-collapse embedding. We intend to show that $(L(\mathbb{R}))^P$ satisfies AD, and then use the elementarity of τ.

Let $\langle \delta_i \mid i < \omega \rangle \in M$ be an increasing sequence of Woodin cardinals of M, and let ρ be a measurable cardinal of M above these Woodin cardinals. Let $\mathbb{P}$ denote the finite support product $\mathrm{Col}(\omega, \delta_0) \times \mathrm{Col}(\omega, \delta_1) \times \cdots$.

Using iterated applications of Exercise 7.23 construct a weak iteration $\langle M_i, j_{i,i'} \mid i \leq i' \leq \omega \rangle$ of $M_0 = M$, and a filter H, so that: the iteration is according to Σ, H is $j_{0,\omega}(\mathbb{P})$-generic over M_ω, and $R^*[H]$ is precisely equal to $\mathbb{R} \cap P$. The construction is similar to the main construction in the proof of Lemma 8.5.

By Theorem 8.10, the derived model of M_ω induced by H satisfies AD. This model is an initial segment of $(L(\mathbb{R}))^P$: it has the reals that P has, but it does not have all the ordinals P has. We now add ordinals by passing from M_ω to an iterate of M_ω obtained through ultrapowers by a measure on ρ and its images.

Let μ witness that ρ is measurable in M. Extend the iteration $\langle M_i, j_{i,i'} \mid i \leq i' \leq \omega \rangle$ of M to a weak iteration of length ω_1 by setting $M_{\xi+1} = \mathrm{Ult}(M_\xi, j_{0,\xi}(\mu))$ for each $\xi \geq \omega$ and setting $j_{\xi,\xi+1}$ to be the ultrapower embedding. This completely determines the iteration.

Let η_α denote the ordinal height of M_α, that is $\mathrm{On} \cap M_\alpha$.

8.22 Exercise. Show that $\eta_\alpha \geq \alpha$.

Hint. The map $\xi \mapsto j_{0,\xi}(\rho)$ embeds $\alpha - \omega$ into the ordinals of M_α. ⊣

Note that, for $\alpha \geq \omega$, $j_{\omega,\alpha}$ has critical point $j_{0,\omega}(\rho)$, and this is larger than $j_{0,\omega}(\sup_{i<\omega} \delta_i)$. It follows that H is generic also over M_α, and that the reals of the symmetric collapse induced by H over M_α are the same as the reals of the symmetric collapse induced by H over M_ω, which in turn are the same as the reals of P. Thus, for each $\alpha \geq \omega$:

(i) The derived model of M_α induced by H is equal to $L_{\eta_\alpha}(\mathbb{R}^P)$.

From this and Theorem 8.10 it follows that:

(ii) $L_{\eta_\alpha}(\mathbb{R}^P)$ satisfies AD.

Using (i) and Exercise 8.2:

(iii) $\mathbb{R}^{L_{\eta_\alpha}(\mathbb{R}^P)}$ is equal to $\mathbb{R}^P$.

Using Exercise 8.22 fix some $\alpha < \omega_1$ so that $\eta_\alpha > \mathrm{On} \cap P$. By condition (iii) then, $(L(\mathbb{R}))^P$ is an initial segment of $L_{\eta_\alpha}(\mathbb{R}^P)$. From this and condition (ii) it follows that $(L(\mathbb{R}))^P$ satisfies AD. Using the elementarity of τ it follows that $(L(\mathbb{R}))^{V\|\theta} = L_\theta(\mathbb{R})$ satisfies AD. Since θ could be chosen arbitrarily large, it follows finally that $L(\mathbb{R})$ satisfies AD. ⊣

8.23 Remark. Readers familiar with sharps can verify, by adapting the proof given above, that the assumption in Theorem 8.21 can be weakened, from demanding that M has ω Woodin cardinals and a measurable cardinal above them, to demanding that M is a sharp for ω Woodin cardinals.

8.24 Theorem. *Suppose that in V there are ω Woodin cardinals and a measurable cardinal above them. Then $L(\mathbb{R})$ satisfies* AD.

Proof. Let θ be a cardinal large enough that $V\|\theta \models$ "there are ω Woodin cardinals and a measurable cardinal above them", and so that $V\|\theta$ satisfies the fragment of ZFC necessary in a model M for Theorem 8.21 to hold for the model. Let X be a countable elementary substructure of $V\|\theta$ and let M be the transitive collapse of X. Then $M \models$ "there are ω Woodin cardinals and a measurable cardinal above them", M is countable in V, and, by Corollary 2.4, M is weakly iterable. Applying Theorem 8.21 it follows that $L(\mathbb{R})$ satisfies AD. $\dashv$

1. Introduction

In this chapter we give an account of Woodin's technique for deriving large cardinal strength from determinacy hypotheses. These results appear here for the first time and for this reason we have gone into somewhat more detail than is customary in a handbook. All unattributed results that follow are either folklore or due to Woodin.

1.1. Determinacy and Large Cardinals

In the era of set theory following the discovery of independence a major concern has been the discovery of new axioms that settle the statements left undecided by the standard axioms (ZFC). One interesting feature that has emerged is that there are often deep connections between axioms that spring from entirely different sources. In this chapter we will be concerned with one instance of this phenomenon, namely, the connection between axioms of definable determinacy and large cardinal axioms.

In this introduction we will give a brief overview of axioms of definable determinacy and large cardinal axioms (in Sects. A and B), discuss their interconnections (in Sects. C and D), and give an overview of the chapter (in Sect. E). At some points we will draw on notation and basic notions that are explained in fuller detail in Sects. 1.2 and 2.1.

A. Determinacy

For a set of reals $A \subseteq \omega^\omega$ consider the game where two players take turns playing natural numbers:

$$\begin{array}{lccccccc} \mathrm{I} & x(0) & & x(2) & & x(4) & & \ldots \\ \mathrm{II} & & x(1) & & x(3) & & \ldots & \end{array}$$

At the end of a round of this game the two players will have produced a real x, obtained through "interleaving" their plays. We say that Player I wins the round if $x \in A$; otherwise Player II wins the round. The set A is said to be *determined* if one of the players has a "winning strategy" in the associated game, that is, a strategy which ensures that the player wins a round regardless of how the other player plays. The *Axiom of Determinacy* (AD) is the statement that *every* set of reals is determined.

It is straightforward to see that very simple sets are determined. For example, if A is the set of all reals then clearly I has a winning strategy; if A is empty then clearly II has a winning strategy; and if A is countable then II has a winning strategy (by "diagonalizing"). A more substantive result is that if A is closed then one player must have a winning strategy. This might lead one to expect that *all* sets of reals are determined. However, it is straightforward to use the Axiom of Choice (AC) to construct a non-determined set (by listing all winning strategies and "diagonalizing" across them). For this reason AD was never really considered as a serious candidate for a new axiom. However, there is an interesting class of related axioms that are consistent with AC, namely, the axioms of *definable determinacy*. These axioms extend the above pattern by asserting that all sets of reals at a given level of complexity are determined, notable examples being, $\utilde{\Delta}^1_1$-determinacy (all Borel sets of reals are determined), PD (all projective sets of reals are determined) and $\mathrm{AD}^{L(\mathbb{R})}$ (all sets of reals in $L(\mathbb{R})$ are determined).

One issue is whether these are really new axioms or whether they follow from ZFC. In the early development of the subject the result on the determinacy of closed sets was extended to higher levels of definability. These developments culminated in Martin's proof of $\utilde{\Delta}^1_1$-determinacy in ZFC. It turns out that this result is close to optimal—as one climbs the hierarchy of definability, shortly after $\utilde{\Delta}^1_1$ one arrives at axioms that fall outside the provenance of ZFC. For example, this is true of PD and $\mathrm{AD}^{L(\mathbb{R})}$. Thus, we have here a hierarchy of axioms (including PD and $\mathrm{AD}^{L(\mathbb{R})}$) which are genuine candidates for new axioms.

There are actually two hierarchies of axioms of definable determinacy, one involving *lightface* notions of definability (by which we mean notions (such as Δ^1_2) that do not involve real numbers as parameters) and the other involving *boldface* notions of definability (by which we mean notions (such as $\utilde{\Delta}^1_2$) that do involve real numbers as parameters). (See Jackson's chapter in this Handbook for details concerning the various grades of definability and the relevant notation.) Each hierarchy is, of course, ordered in terms of increasing complexity. Moreover, each hierarchy has a natural limit: the natural limit of the lightface hierarchy is OD-determinacy (all OD sets of reals are determined) and the natural limit of the boldface hierarchy is $\mathrm{OD}(\mathbb{R})$-determinacy (all $\mathrm{OD}(\mathbb{R})$ sets of reals are determined). The reason these are natural limits is that the notions of lightface and boldface ordinal definability are candidates for the richest lightface and boldface notions of definability. To see this (for the lightface case) notice first that any notion of definability which does not render all of the ordinals definable can be transcended (as can be seen by considering the least ordinal which is not definable according to the notion) and second that the notion of ordinal definability cannot be so transcended (since by reflection OD is ordinal definable). It is for this reason that Gödel proposed the notion of ordinal definability as a candidate for an "absolute" notion of definability. Our limiting cases may thus be regarded as two forms of absolute definable determinacy.

So we have two hierarchies of increasingly strong candidates for new axioms and each has a natural limit. There are two fundamental questions concerning such new axioms. First, are they *consistent*? Second, are they *true*? In the most straightforward sense these questions are asked in an *absolute* sense and not relative to a particular theory such as ZFC. But since we are dealing with new axioms, the traditional means of answering such questions—namely, by establishing their consistency or provability relative to the standard axioms (ZFC)—is not available. Nevertheless, one can hope to establish results—such as relative consistency and logical connections with respect to other plausible axioms—that collectively shed light on the original, absolute question. Indeed, there are a number of results that one can bring to bear in favour of PD and $\mathrm{AD}^{L(\mathbb{R})}$. For example, these axioms lift the structure theory that can be established in ZFC to their respective domains, namely, second-order arithmetic and $L(\mathbb{R})$. Moreover, they do so in a fashion which settles a remarkable number of statements that are independent of ZFC. In fact, there is no "natural" statement concerning their respective domains that is known to be independent of these axioms. (For more on the structure theory provided by determinacy and the traditional considerations in their favour see [9] and for more recent work see Jackson's chapter in this Handbook.) The results of this chapter figure in the case for PD and $\mathrm{AD}^{L(\mathbb{R})}$. However, our concern will be with the question of relative consistency; more precisely, we wish to calibrate the consistency strength of axioms of definable determinacy—in particular, the ultimate axioms of lightface and boldface determinacy—in terms of the large cardinal hierarchy.

There are some reductions that we can state at the outset. In terms of consistency strength the two hierarchies collapse at a certain stage: Kechris and Solovay showed that $\mathrm{ZF}+\mathrm{DC}$ implies that in the context of $L[x]$ for $x \in \omega^\omega$, OD-determinacy and Δ^1_2-determinacy are equivalent (see Theorem 6.6). And it is a folklore result that $\mathrm{ZFC}+\mathrm{OD}(\mathbb{R})$-determinacy and $\mathrm{ZFC}+\mathrm{AD}^{L(\mathbb{R})}$ are equiconsistent. Thus, in terms of consistency strength, the lightface hierarchy collapses at Δ^1_2-determinacy and the boldface hierarchy collapses at $\mathrm{AD}^{L(\mathbb{R})}$. So if one wishes to gauge the consistency strength of lightface and boldface determinacy it suffices to concentrate on Δ^1_2-determinacy and $\mathrm{AD}^{L(\mathbb{R})}$.

Now, it is straightforward to see that if Δ^1_2-determinacy holds then it holds in $L[x]$ for some real x and likewise if $\mathrm{AD}^{L(\mathbb{R})}$ (or AD) holds then it holds in $L(\mathbb{R})$. Thus, the natural place to study the consistency strength of lightface definable determinacy is $L[x]$ for some real x and the natural place to study the consistency strength of boldface definable determinacy (or full determinacy) is $L(\mathbb{R})$. For this reason these two models will be central in what follows.

To summarize: We shall be investigating the consistency strength of lightface and boldface determinacy. This reduces to Δ^1_2-determinacy and $\mathrm{AD}^{L(\mathbb{R})}$. The settings $L[x]$ and $L(\mathbb{R})$ will play a central role. Consistency strength will be measured in terms of the large cardinal hierarchy. Before turning to a discussion of the large cardinal hierarchy let us first briefly discuss stronger forms of determinacy.

Our concern in this chapter is with axioms of determinacy of the above form, where the games have length ω and the moves are natural numbers. However, it is worthwhile to note that there are two directions in which one can generalize these axioms.

First, one can consider games of length greater than ω (where the moves are still natural numbers). A simple argument shows that one cannot have the determinacy of all games of length ω_1 but there is a great deal of room below this upper bound and much work has been done in this area. For more on this subject see [10].

Second, one can consider games where the moves are more complex than natural numbers (and where the length of the game is still ω). One alternative is to consider games where the moves are real numbers. The axiom $\mathrm{AD}_{\mathbb{R}}$ states that all such games are determined. One might try to continue in this direction and consider the axiom $\mathrm{AD}_{\mathscr{P}(\mathbb{R})}$ asserting the determinacy of all games where the moves are sets of real numbers. It is straightforward to see that this axiom is inconsistent. In fact, even the definable version asserting that all OD subsets of $\mathscr{P}(\mathbb{R})^\omega$ is inconsistent. Another alternative is to consider games where the moves are ordinal numbers. Again, a simple argument shows that one cannot have the determinacy of all subsets of ${\omega_1}^\omega$. However, a result of Harrington and Kechris shows that in this case if one adds a definability constraint then one can have determinacy at this level. In fact, OD-determinacy implies that every OD set $A \subseteq {\omega_1}^\omega$ is determined. It is natural then to extend this to large ordinals. The ultimate axiom in this direction would simply assert that every OD set $A \subseteq \mathrm{On}^\omega$ is determined. Perhaps surprisingly, at this stage a certain tension arises since recent work in inner model theory provides evidence that this axiom is in fact inconsistent. See [12] for more on this subject.

B. Large Cardinals

Our aim is to calibrate the consistency strength of lightface and boldface determinacy in terms of the large cardinal hierarchy. The importance of the large cardinal hierarchy in this connection is that it provides a canonical means of climbing the hierarchy of consistency strength. To show, for a given hypothesis φ and a given large cardinal axiom L, that the theories $\mathrm{ZFC} + \varphi$ and $\mathrm{ZFC} + L$ are equiconsistent one typically uses the dual methods of *inner model theory* and *outer model theory* (also known as *forcing*). Very roughly, given a model of $\mathrm{ZFC} + L$ one forces to obtain a model of $\mathrm{ZFC} + \varphi$ and given a model of $\mathrm{ZFC} + \varphi$ one uses the method of inner model theory to construct a model of $\mathrm{ZFC} + L$. The large cardinal hierarchy is (for the most part) naturally well-ordered and it is a remarkable phenomenon that given any two "natural" theories extending ZFC one can compare them in terms of consistency strength (equivalently, interpretability) by lining them up with the large cardinal hierarchy.

In a very rough sense large cardinal axioms assert that there are "large" levels of the universe. A template for formulating a broad class of large cardinal axioms is in terms of elementary embeddings. The basic format of the template is as follows: There is a transitive class M and a non-trivial elementary

$$j : V \to M.$$

To say that the embedding is non-trivial is simply to say that it is not the identity, in which case one can show that there is a least ordinal moved. This ordinal is denoted $\mathrm{crit}(j)$ and called the *critical point* of j. A cardinal is said to be a *measurable cardinal* if and only if it is the critical point of such an embedding.

It is easy to see that for any such elementary embedding there is necessarily a certain degree of agreement between V and M. In particular, it follows that $V_{\kappa+1} \subseteq M$, where $\kappa = \mathrm{crit}(j)$. This degree of agreement in conjunction with the elementarity of j can be used to show that κ has strong reflection properties, in particular, κ is strongly inaccessible, Mahlo, weakly compact, etc.

One way to strengthen a large cardinal axiom of the above form is to demand greater agreement between M and V. For example, if one demands that $V_{\kappa+2} \subseteq M$ then the fact that κ is measurable is recognized within M and hence it follows that M satisfies that there is a measurable cardinal below $j(\kappa)$, namely, κ. Thus, by the elementarity of the embedding, V satisfies that there is a measurable cardinal below κ. The same argument shows that there are arbitrarily large measurable cardinals below κ.

This leads to a natural progression of increasingly strong large cardinal axioms. It will be useful to discuss some of the major axioms in this hierarchy: If κ is a cardinal and $\eta > \kappa$ is an ordinal then κ is *η-strong* if there is a transitive class M and a non-trivial elementary embedding $j : V \to M$ such that $\mathrm{crit}(j) = \kappa$, $j(\kappa) > \eta$ and $V_\eta \subseteq M$. A cardinal κ is *strong* iff it is η-strong for all η. As we saw above if κ is $(\kappa+2)$-strong then κ is measurable and there are arbitrarily large measurable cardinals below κ. Next, one can demand that the embedding preserve certain classes: If A is a class, κ is a cardinal, and $\eta > \kappa$ is an ordinal then κ is *η-A-strong* if there exists a $j : V \to M$ which witnesses that κ is η-strong and which has the additional feature that $j(A \cap V_\kappa) \cap V_\eta = A \cap V_\eta$. The following large cardinal notion will play a central role in this chapter.

1.1 Definition. A cardinal κ is a *Woodin cardinal* if κ is strongly inaccessible and for all $A \subseteq V_\kappa$ there is a cardinal $\kappa_A < \kappa$ such that

$$\kappa_A \text{ is } \eta\text{-}A\text{-strong},$$

for each η such that $\kappa_A < \eta < \kappa$.

It should be noted that in contrast to measurable and strong cardinals, Woodin cardinals are not characterized as the critical point of an embedding or collection of embeddings. In fact, a Woodin cardinal need not be measurable. However, if κ is a Woodin cardinal, then V_κ is a model of ZFC and from the point of view of V_κ there is a proper class of strong cardinals.

Going further, a cardinal κ is *superstrong* if there is a transitive class M and a non-trivial elementary embedding $j : V \to M$ such that $\mathrm{crit}(j) = \kappa$ and $V_{j(\kappa)} \subseteq M$. If κ is superstrong then κ is a Woodin cardinal and there are arbitrarily large Woodin cardinals below κ.

One can continue in this vein, demanding greater agreement between M and V. The ultimate axiom in this direction would, of course, demand that $M = V$. This axiom was proposed by Reinhardt. But shortly after its introduction Kunen showed that it is inconsistent with ZFC. In fact, Kunen showed that assuming ZFC, there can be no non-trivial elementary embedding $j : V_{\lambda+2} \to V_{\lambda+2}$. (An interesting open question is whether these axioms are inconsistent with ZF or whether there is a hierarchy of "choiceless" large cardinal axioms that climb the hierarchy of consistency strength far beyond what can be reached with ZFC.)

There is a lot of room below the above upper bound. For example, a very strong axiom is the statement that there is a non-trivial elementary embedding $j : V_{\lambda+1} \to V_{\lambda+1}$. The strongest large cardinal axiom in the current literature is the axiom asserting that there is a non-trivial elementary embedding $j : L(V_{\lambda+1}) \to L(V_{\lambda+1})$ such that $\mathrm{crit}(j) < \lambda$. Surprisingly, this axiom yields a structure theory of $L(V_{\lambda+1})$ which is closely analogous to the structure theory of $L(\mathbb{R})$ under the axiom $\mathrm{AD}^{L(\mathbb{R})}$. This parallel between axioms of determinacy and large cardinal axioms suggests seeking stronger large cardinal axioms by following the guide of the strong axioms of determinacy discussed at the close of the previous section. In fact, there is evidence that the parallel extends. For example, there is a new large cardinal axiom that is the analogue of $\mathrm{AD}_{\mathbb{R}}$. See [12] for more on these recent developments.

C. Determinacy from Large Cardinals

Let us return to the questions of the truth and the consistency of axioms of definable determinacy, granting that of large cardinal axioms. In the late 1960s Solovay conjectured that $\mathrm{AD}^{L(\mathbb{R})}$ is provable from large cardinal axioms (and hence that ZF+AD is consistent relative to large cardinal axioms). This conjecture was realized in stages.

In 1970 Martin showed that if there is a measurable cardinal then all $\undertilde{\Sigma}^1_1$ sets of reals are determined. Later, in 1978, he showed that under the much stronger assumption of a non-trivial iterable elementary embedding $j : V_\lambda \to V_\lambda$ all $\undertilde{\Sigma}^1_2$ sets of reals are determined. It appeared that there would be a long march up the hierarchy of axioms of definable determinacy. However, in 1984 Woodin showed that if there is a non-trivial elementary embedding $j : L(V_{\lambda+1}) \to L(V_{\lambda+1})$ with $\mathrm{crit}(j) < \lambda$, then $\mathrm{AD}^{L(\mathbb{R})}$ holds.

The next major advances concerned reducing the large cardinal hypothesis used to obtain $\mathrm{AD}^{L(\mathbb{R})}$. The first step in this direction was made shortly after, in 1985, when Martin and Steel proved the following remarkable result, using a completely different technique:

1.2 Theorem (Martin and Steel). *Assume* ZFC. *Suppose that there are n Woodin cardinals with a measurable cardinal above them all. Then $\undertilde{\Sigma}^1_{n+1}$-determinacy holds.*

It follows that if there is a Woodin cardinal with a measurable cardinal above, then Δ^1_2-determinacy holds and if there are infinitely many Woodin cardinals then PD holds. Finally, the combination of Martin and Steel's work and Woodin's work on the stationary tower (see [8]) led to a significant reduction in the hypothesis required to obtain $\mathrm{AD}^{L(\mathbb{R})}$.

1.3 Theorem. *Assume* ZFC. *Suppose there are infinitely many Woodin cardinals with a measurable cardinal above them all. Then* $\mathrm{AD}^{L(\mathbb{R})}$.

A more recent development is that, in addition to being implied by large cardinal axioms, $\mathrm{AD}^{L(\mathbb{R})}$ is implied by a broad array of other strong axioms, which have nothing to do with one another—in fact, there is reason to believe that $\mathrm{AD}^{L(\mathbb{R})}$ is implied by *all* sufficiently strong "natural" theories. For further discussion of this subject and other more recent results that contribute to the case for certain axioms of definable determinacy see [7, 11, 13].

Each of the above results concerns the *truth* of axioms of definable determinacy, granting large cardinal axioms. A closely related question concerns the *consistency* of axioms of definable determinacy, granting that of large cardinal axioms. For this one can get by with slightly weaker large cardinal assumptions.

1.4 Theorem. *Assume* ZFC. *Suppose δ is a Woodin cardinal. Suppose $G \subseteq \mathrm{Col}(\omega, \delta)$ is V-generic. Then $V[G] \models \Delta^1_2$-determinacy.*

1.5 Theorem. *Assume* ZFC. *Suppose that λ is a limit of Woodin cardinals. Suppose $G \subseteq \mathrm{Col}(\omega, {<}\lambda)$ is V-generic and let $\mathbb{R}^* = \bigcup\{\mathbb{R}^{V[G\restriction\alpha]} \mid \alpha < \lambda\}$. Then $L(\mathbb{R}^*) \models \mathrm{AD}$.*

For more on the topic of this section see Neeman's chapter in this Handbook.

D. Large Cardinals from Determinacy

The above results lead to the question of whether the large cardinal assumptions are "necessary". Of course, large cardinal assumptions (in the traditional sense of the term) cannot be necessary in the strict sense since axioms of definable determinacy (which concern sets of reals) do not outright imply the existence of large cardinals (which are much larger objects). The issue is whether they are necessary in the sense that one cannot prove the axioms of definable determinacy with weaker large cardinal assumptions. To establish this one must show that the consistency of the axioms of definable determinacy implies that of the large cardinal axioms and one way to do this is to show that axioms of definable determinacy imply that there are *inner models* of the large cardinal axioms.

There are two approaches to inner model theory, each originating in the work of Gödel. These approaches have complementary advantages and disadvantages. The first approach is based on L, the universe of constructible sets. The advantage of this approach is that L is very well understood; in fact, it is fair to say that within ZFC one can carry out a "full analysis" of this model. As a consequence of this one can show, for example, that under ZF + AD, ω_1^V is inaccessible in L. The disadvantage is that L is of limited applicability since it cannot accommodate strong large cardinal axioms such as the statement that there is a measurable cardinal. So if the large cardinal assumptions in Theorems 1.4 and 1.5 are close to optimal then L is of no use in establishing this.

The second approach is based on HOD, the universe of hereditarily ordinal definable sets. This inner model can accommodate virtually all large cardinal axioms that have been investigated. But it has a complementary defect in that one cannot carry out a full analysis of this structure within ZFC.

A major program in set theory—*the inner model program*—aims to combine the advantages of the two approaches by building inner models that resemble L in having a highly ordered inner structure but which resemble HOD in that they can accommodate strong large cardinal axioms.

"L-like" inner models at the level of Woodin cardinals were developed in stages beginning with work of Martin and Steel, and continuing with work of Mitchell and Steel. The Mitchell-Steel inner models are true analogs of L. Martin and Steel used their models to show that the large cardinal hypotheses in their proofs of determinacy were essentially optimal. For example, they showed that if there is a Woodin cardinal then there is a canonical inner model M that contains a Woodin cardinal and has a Δ^1_3 well-ordering of the reals. It follows that one cannot prove $\underset{\sim}{\Sigma}^1_2$-determinacy from the assumption of a Woodin cardinal alone.

However, this still left open a number of questions. First, does the consistency of ZFC + "There is a Woodin cardinal" follow from that of ZFC + Δ^1_2-determinacy? Second, can one build an inner model of a Woodin cardinal directly from ZFC + Δ^1_2-determinacy? Third, what is the strength of ZFC + $\mathrm{AD}^{L(\mathbb{R})}$? To approach these questions it would seem that one would need *fine-structural* inner model theory. However, at the time when the central results of this chapter were proved, fine-structural inner model theory had not yet reached the level of Woodin cardinals. One option was to proceed with HOD.

In contrast to L the structure of HOD is closely tied to the universe in which it is constructed. In the general setting, where one works in ZF and constructs HOD in V, the structure theory of HOD is almost as intractable as that of V. Surprisingly if one strengthens the background theory then the structure theory of HOD becomes tractable. For example, Solovay showed that under ZF + AD, HOD satisfies that ω_1^V is a measurable cardinal. It turns out that both lightface and boldface definable determinacy are able to illuminate the structure of HOD (when constructed in the natural inner models of these axioms—$L[x]$ and $L(\mathbb{R})$) to the point where one can recover the large cardinals that are necessary to establish their consistency.

In the case of lightface definable determinacy the result is the following:

1.6 Theorem. *Assume* $\mathrm{ZF}+\mathrm{DC}+\Delta^1_2$*-determinacy. Then for a Turing cone of* x*,*

$$\mathrm{HOD}^{L[x]} \models \mathrm{ZFC} + \omega_2^{L[x]} \textit{ is a Woodin cardinal.}$$

Thus, the consistency strength of ZFC + OD-determinacy is precisely that of ZFC + "There is a Woodin cardinal". For the case of boldface determinacy let us first state a preliminary result of which the above result is a localization. First we need a definition. Let

$$\Theta = \sup\{\alpha \mid \text{there is a surjection } \pi : \omega^\omega \to \alpha\}.$$

1.7 Theorem. *Assume* ZF + AD*. Then*

$$\mathrm{HOD}^{L(\mathbb{R})} \models \Theta^{L(\mathbb{R})} \textit{ is a Woodin cardinal.}$$

In fact, both of these results are special instances of a general theorem on the generation of Woodin cardinals—the Generation Theorem. In addition to giving the above results, the Generation Theorem will also be used to establish the optimal large cardinal lower bound for boldface determinacy:

1.8 Theorem. *Assume* ZF + AD*. Suppose* Y *is a set. There is a generalized Prikry forcing* $\mathbb{P}_Y$ *through the* Y*-degrees such that if* $G \subseteq \mathbb{P}_Y$ *is* V*-generic and* $\langle [x_i]_Y \mid i<\omega\rangle$ *is the associated sequence, then*

$$\mathrm{HOD}^{V[G]}_{Y,\langle [x_i]_Y \mid i<\omega\rangle,V} \models \mathrm{ZFC} + \textit{There are } \omega\textit{-many Woodin cardinals,}$$

where $[x]_Y = \{z \in \omega^\omega \mid \mathrm{HOD}_{Y,z} = \mathrm{HOD}_{Y,x}\}$ *is the* Y*-degree of* x*.*

Thus, the consistency strength of ZFC + OD($\mathbb{R}$)-determinacy and of ZF + AD is precisely that of ZFC + "There are ω-many Woodin cardinals".

The main results of this chapter have applications beyond equiconsistency; in particular, the theorems play an important role in the structure theory of AD^+ (a potential strengthening of AD that we will define and discuss in Sect. 8). For example, Steel showed that under AD, in $L(\mathbb{R})$ every uncountable regular cardinal below Θ is a measurable cardinal. (See Steel's chapter in this Handbook for a proof.) This theorem generalizes to a theorem of AD^+ and the theorems of this chapter are an important part of the proof. We will discuss some other applications in the final section of this chapter.

E. Overview

The results on the strength of lightface and boldface determinacy were established in the late 1980s. However, the current presentation and many of the results that follow are quite recent. One of the key new ingredients is the following abstract theorem on the generation of Woodin cardinals, which lies at the heart of this chapter:

1.9 Theorem (Generation Theorem). *Assume* ZF. *Suppose*

$$M = L_{\Theta_M}(\mathbb{R})[T, A, B]$$

is such that

(1) $M \models \mathrm{T}_0$,

(2) Θ_M *is a regular cardinal,*

(3) $T \subseteq \Theta_M$,

(4) $A = \langle A_\alpha \mid \alpha < \Theta_M \rangle$ *is such that* A_α *is a prewellordering of the reals of length greater than or equal to* α,

(5) $B \subseteq \omega^\omega$ *is nonempty, and*

(6) $M \models$ *Strategic determinacy with respect to* B.

Then

$$\mathrm{HOD}^M_{T,A,B} \models \mathrm{ZFC} + \textit{There is a } T\textit{-strong cardinal.}$$

Here T_0 is the theory $\mathrm{ZF} + \mathrm{AC}_\omega(\mathbb{R}) - \text{Power Set} + \text{“}\mathscr{P}(\omega)\text{exists”}$ and the notion of “strategic determinacy” is a technical notion that we will state precisely later.

The Generation Theorem provides a template for generating models containing Woodin cardinals. One simply has to show that in a particular setting the various conditions can be met, though this is often a non-trivial task. The theorem is also quite flexible in that it is a result of ZF that does not presuppose DC and has applications in both lightface and boldface settings. It will play a central role in the calibration of the strength of both lightface and boldface determinacy.

We shall approach the proof of the Generation Theorem by proving a series of increasingly complex approximations.

In Sect. 2 we take the initial step by proving Solovay's theorem that under $\mathrm{ZF} + \mathrm{AD}$, ω_1^V is a measurable cardinal in HOD and we show that the associated measure is normal. The proof that we give is slightly more complicated than the standard proof but has the virtue of illustrating in a simple setting some of the key components that appear in the more complex variations. We illustrate this at the end of the section by showing that the proof of Solovay's theorem generalizes to show that under $\mathrm{ZF} + \mathrm{AD}$, the ordinal $(\underset{\sim}{\delta}^2_1)^{L(\mathbb{R})}$ is a measurable cardinal in $\mathrm{HOD}^{L(\mathbb{R})}$. Our main aim in this section is to illustrate the manner in which "boundedness" and "coding" combine to yield normal ultrafilters. In subsequent sections stronger forms of boundedness (more precisely, "reflection") and stronger forms of coding will be used to establish stronger forms of normality.

In Sect. 3 we prove the strong forms of coding that will be central throughout.

In Sect. 4, as a precursor to the proof of the Generation Theorem, we prove the following theorem:

1.10 Theorem. *Assume* $\mathrm{ZF} + \mathrm{DC} + \mathrm{AD}$. *Then*

$$\mathrm{HOD}^{L(\mathbb{R})} \models \mathrm{ZFC} + \Theta^{L(\mathbb{R})} \textit{ is a Woodin cardinal.}$$

The assumption of DC is merely provisional—it will ultimately be eliminated when we prove the Generation Theorem. Toward the proof of the above theorem, we begin in Sect. 4.1 by establishing the reflection phenomenon that will play the role played by boundedness in Sect. 2. We will then use this reflection phenomenon in $L(\mathbb{R})$ to define for cofinally many $\lambda < \Theta$, an ultrafilter μ_λ on $\underset{\sim}{\delta}^2_1$ that is intended to witness that $\underset{\sim}{\delta}^2_1$ is λ-strong. In Sect. 4.2 we shall introduce and motivate the notion of *strong normality* by showing that the strong normality of μ_λ ensures that $\underset{\sim}{\delta}^2_1$ is λ-strong. We will then show how reflection and uniform coding combine to secure strong normality. In Sect. 4.3 we will prove the above theorem by relativizing the construction of Sect. 4.2 to subsets of $\Theta^{L(\mathbb{R})}$.

In Sect. 5 we extract the essential components of the above construction and prove two abstract theorems on Woodin cardinals in a general setting, one that involves DC and one that does not. The first theorem is proved in Sect. 5.1. The importance of this theorem is that it can be used to show that in certain strong determinacy settings HOD can contain many Woodin cardinals. The second theorem is the Generation Theorem, the proof of which will occupy the remainder of the section. The aim of the Generation Theorem is to show that the construction of Sect. 4 can be driven by lightface determinacy alone. The difficulty is that the construction of Sect. 4 involves games that are defined in terms of real parameters. To handle this we introduce the notion of "strategic determinacy", a notion that resembles boldface determinacy in that it involves real parameters but which can nonetheless hold in settings where one has AC. To motivate the notion of "strategic determinacy" we shall begin in Sect. 5.2 by examining one such setting, namely, $L[S, x]$ where S is a class of ordinals and x is a real. Once we show that "strategic determinacy" can hold in this setting we shall return in Sect. 5.3 to the general setting and prove the Generation Theorem. In the final subsection, we prove a number of special cases, many of which are new. Although some of these applications involve lightface settings, they all either involve assuming full AD or explicitly involve "strategic determinacy".

In Sect. 6 we use two of the special cases of the Generation Theorem to calibrate the consistency strength of lightface and boldface definable determinacy in terms of the large cardinal hierarchy. In the case of the first result the main task is to show that Δ^1_2-determinacy suffices to establish that "strategic determinacy" can hold. In the case of the second result the main task is to show that the Generation Theorem can be iteratively applied to generate ω-many Woodin cardinals.

In Sect. 7 we show that the Generation Theorem can itself be localized in two respects. In the first localization we show that Δ^1_2-determinacy implies that for a Turing cone of x, $\omega_1^{L[x]}$ is a Woodin cardinal in an inner model of $L[x]$. In the second localization we show that the proof can in fact be carried out in second-order arithmetic.

In Sect. 8 we survey some further results. First, we discuss results concerning the actual equivalence of axioms of definable determinacy and axioms asserting the existence of inner models with Woodin cardinals. Second, we revisit the analysis of $\mathrm{HOD}^{L(\mathbb{R})}$ and $\mathrm{HOD}^{L[x][g]}$, for certain generic extensions $L[x][g]$, in light of the advances that have been made in fine-structural inner model theory. Remarkably, it turns out that not only are these models well-behaved in the context of definable determinacy—they are actually fine-structural inner models, but of a kind that falls outside of the traditional hierarchy.

We have tried to keep the account self-contained, presupposing only acquaintance with the constructible universe, the basics of forcing, and the basics of large cardinal theory. In particular, we have tried to minimize appeal to fine structure and descriptive set theory. Fine structure enters only in Sect. 8 where we survey more recent developments, but even there one should be able to get a sense of the lay of the land without following the details. For the relevant background and historical development of the subject see [1, 2, 9].

Acknowledgments

We would like to thank Scott Cramer, Moti Gitik, Aki Kanamori, Richard Ketchersid, Paul Larson, and Nam Trang for sending us helpful comments at various stages. We are especially grateful to Andrés Caicedo and an anonymous referee for sending us extensive comments on an earlier draft of this chapter. The first author would like to acknowledge the support of the Clarke/Cooke fund and the second author would like to acknowledge the support of the National Science Foundation under grants DMS-9970255 and DMS-0355334.

1.2. Notation

For the most part our notational conventions are standard. Nevertheless, some comments are in order.

(1) We use $\mu\alpha\,\varphi(\alpha)$ to indicate the least ordinal α such that $\varphi(\alpha)$.

(2) In writing OD_X and HOD_X we always mean that X itself (as opposed to its elements) is allowed as a parameter. The notation $\mathrm{OD}_{\{X\}}$ is

sometimes used for this, for example, in contexts where one would like to speak of both $\mathrm{OD}_{\{X\}}$ and OD_X. However, in this chapter we will have no occasion to speak of the latter and so we have dropped the curly brackets on the ground that they would only serve to clutter the text. We also use OD_X as both a name (for the class of sets which are ordinal definable from X) and as an adjective (for example when we say that a particular class is OD_X.) We use $<_{\mathrm{OD}_X}$ for a fixed canonical OD_X-well-ordering of OD_X sets. The notation $\mathrm{OD}(\mathbb{R})$ is used in analogy with $L(\mathbb{R})$.

(3) A *strategy* for Player I is a function $\sigma : \bigcup_{i<\omega} \omega^{2i} \to \omega$. Letting $\sigma * y$ be the real produced when Player I follows σ and Player II plays y, we say that σ is a *winning strategy* for Player I in the game with payoff $A \subseteq \omega^\omega$ if for all $y \in \omega^\omega$, $\sigma * y \in A$. The corresponding notions for Player II are defined similarly. We typically reserve σ for strategies for Player I and τ for strategies for Player II. The play that results from having II play y against σ is denoted $\sigma * y$ and likewise the play that results from having I play x against τ is denoted $x * \tau$. We write $x * y$ for the real that results from having Player I play x and Player II play y and in this case we let $(x * y)_I = x$ and $(x * y)_{II} = y$. For example, $(\sigma * y)_I$ is the real that Player I plays when following the strategy σ against II's play of y. If σ is a strategy for Player I and τ is a strategy for Player II we write $\sigma * \tau$ for the real produced by playing the strategies against one another. Occasionally, when $z = x * y$ we write z_{even} to indicate x and z_{odd} to indicate y.

(4) If X is a subset of the plane $\omega^\omega \times \omega^\omega$ we use $\mathrm{proj}_1(X)$ for the "projection to the first coordinate" and $\mathrm{proj}_2(X)$ for the "projection to the second coordinate".

(5) For $n_0, \ldots, n_{k-1} \in \omega$, we use $\langle n_0, \ldots, n_{k-1} \rangle$ to denote the natural number encoding $(n_0, \ldots, n_{k-1})$ via a recursive bijection between ω^k and ω (which we fix throughout) and we let $(n)_i$ be the associated projection functions. For $x \in \omega^\omega$ and $i \in \omega$ we also use $(x)_i$ for the projection function associated to a recursive bijection between $(\omega^\omega)^\omega$ and ω^ω. See [9, Chap. 3] for further details on such recursive coding and decoding functions.

There is a slight conflict in notation in that angle brackets are also traditionally used for sequences and n-tuples. We have lapsed into this usage at points but the context resolves the ambiguity; for example, when we write $\langle x_\alpha \mid \alpha < \lambda \rangle$ it is clear that we are referring to a sequence.

(6) In this chapter by the "reals" we mean ω^ω, which, under the standard topology, is homeomorphic to the irrationals as normally construed. However, we continue to use the symbol '$\mathbb{R}$' in contexts where it is traditional, for example, in $L(\mathbb{R})$.

(7) We use $\mathrm{tc}(x)$ for the transitive closure of x.

(8) A base theory that will play a central role throughout is

$$\mathrm{T}_0 = \mathrm{ZF} + \mathrm{AC}_\omega(\mathbb{R}) - \text{Power Set} + \text{“}\mathscr{P}(\omega) \text{ exists”}.$$

2. Basic Results

The central result of this section is Solovay's theorem to the effect that under ZF + AD, ω_1 is a measurable cardinal. The proof that we will give is slightly more involved than the standard proof but it has the advantage of illustrating some of the key components in the more general theorems to be proved in later sections. One thing we would like to illustrate is the manner in which "boundedness" and "coding" combine to yield normal ultrafilters. In subsequent sections stronger forms of boundedness (more precisely, "reflection") and stronger forms of coding will be used to establish stronger forms of normality. This will culminate in the production of Woodin cardinals.

In Sect. 2.1 we review some basic consequences of ZF + AD. In Sect. 2.2 we prove $\utilde{\Sigma}^1_1$-boundedness and use it to prove the Basic Coding Lemma, a simple case of the more general coding lemmas to be proved in Sect. 3. In Sect. 2.3 we use $\utilde{\Sigma}^1_1$-boundedness to show that the club filter on ω_1 witnesses that ω_1 is a measurable cardinal and we use $\utilde{\Sigma}^1_1$-boundedness and the Basic Coding Lemma to show that this ultrafilter is normal. In Sect. 2.4 we introduce $\utilde{\delta}^2_1$ and establish its basic properties. Finally, in Sect. 2.5 we draw on the Coding Lemma of Sect. 3 to show that the proof of Solovay's theorem generalizes to show that assuming ZF + DC + AD then in the restricted setting of $L(\mathbb{R})$ the ordinal $(\utilde{\delta}^2_1)^{L(\mathbb{R})}$ is a measurable cardinal. Later, in Sect. 4, we will dispense with DC and reprove this theorem in ZF + AD.

2.1. Preliminaries

In order to keep this account self-contained, in this subsection we shall collect together some of the basic features of the theory of determinacy. These concern (1) the connection between determinacy and choice, (2) the implications of determinacy for regularity properties, and (3) the implications of determinacy for the Turing degrees. See [2, 9], and Jackson's chapter in this Handbook for further details and references.

Let us begin with the axiom of choice. A straightforward diagonalization argument shows that AD contradicts the full axiom of choice, AC. However, certain fragments of AC are consistent with AD and, in fact, certain fragments of AC follow from AD.

2.1 Definition. The *Countable Axiom of Choice*, AC_ω, is the statement that every countable set consisting of non-empty sets has a choice function.

The *Countable Axiom of Choice for Sets of Reals*, $\mathrm{AC}_\omega(\mathbb{R})$, is the statement that every countable set consisting of non-empty sets of reals has a choice function.

2.2 Theorem. *Assume* ZF + AD. *Then* $\mathrm{AC}_\omega(\mathbb{R})$.

Proof. Let $\{X_n \mid n < \omega\}$ be a countable collection of non-empty sets of reals. Consider the game

$$\begin{array}{lccccccc} \mathrm{I} & x(0) & & x(1) & & x(2) & & \dots \\ \mathrm{II} & & y(0) & & y(1) & & \dots & \end{array}$$

where I wins if and only if $y \notin X_{x(0)}$. (Notice that we are leaving the definition of the payoff set of reals A implicit. In this case the payoff set is $\{x \in \omega^\omega \mid x_{\text{odd}} \notin X_{x(0)}\}$. In the sequel we shall leave such routine transformations to the reader.) Thus, Player I is to be thought of as playing an element X_n of the countable collection and Player II must play a real which is not in this element. Of course, Player I cannot win. So there must be a winning strategy τ for Player II. The function

$$\begin{aligned} f : \omega &\to \omega^\omega \\ n &\mapsto (\langle n, 0, 0, \dots \rangle * \tau)_{II} \end{aligned}$$

is a choice function for $\{X_n \mid n < \omega\}$. $\dashv$

2.3 Corollary. *Assume* ZF + AD. *Then* ω_1 *is regular.*

2.4 Definition. The *Principle of Dependent Choices*, DC, is the statement that for every non-empty set X and for every relation $R \subseteq X \times X$ such that for all $x \in X$ there is a $y \in X$ such that $(x, y) \in R$, there is a function $f : \omega \to X$ such that for all $n < \omega$, $(f(n), f(n+1)) \in R$. The *Principle of Dependent Choices for Sets of Reals*, $\mathrm{DC}_\mathbb{R}$, is simply the restricted version of DC where X is $\mathbb{R}$.

It is straightforward to show that DC implies AC_ω and Jensen showed that this implication cannot be reversed. Solovay showed that $\mathrm{Con}(\mathrm{ZF} + \mathrm{AD}_\mathbb{R})$ implies $\mathrm{Con}(\mathrm{AD} + \neg\mathrm{DC})$ and this was improved by Woodin.

2.5 Theorem. *Assume* $\mathrm{ZF} + \mathrm{AD} + V = L(\mathbb{R})$. *Then in a forcing extension there is an inner model of* $\mathrm{AD} + \neg\mathrm{AC}_\omega$.

2.6 Theorem (Kechris). *Assume* ZF + AD. *Then* $L(\mathbb{R}) \models \mathrm{DC}$.

1 Open Question. Does AD imply $\mathrm{DC}_\mathbb{R}$?

Thus, of the above fragments of AC, $\mathrm{AC}_\omega(\mathbb{R})$ is known to be within the reach of AD, $\mathrm{DC}_\mathbb{R}$ could be within the reach of AD, and the stronger principles AC_ω and DC are known to be consistent with but independent of AD (assuming consistency of course). For this reason, to minimize our assumptions, in what follows we shall work with $\mathrm{AC}_\omega(\mathbb{R})$ as far as this is possible. There are two places where we invoke DC, namely, in Kunen's theorem (Theorem 3.11) and in Lemma 4.8 concerning the well-foundedness of certain ultrapowers. However, in our applications, DC will reduce to $\mathrm{DC}_\mathbb{R}$ and so if the above open question has a positive answer then these appeals to DC can also be avoided.

We now turn to regularity properties. The axiom of determinacy has profound consequences for the structure theory of sets of real numbers. See [9] and Jackson's chapter in this Handbook for more on this. Here we mention only one central consequence that we shall need below.

2.7 Theorem (Mycielski-Swierczkowski; Mazur, Banach; Davis). *Assume* $\mathrm{ZF}+\mathrm{AD}$*. Then all sets are Lebesgue measurable, have the property of Baire, and have the perfect set property.*

Proof. See [2, Sect. 27]. ⊣

Another important consequence we shall need is the following:

2.8 Theorem. *Assume* $\mathrm{ZF}+\mathrm{AD}$*. Then every ultrafilter is* ω_1*-complete.*

Proof. Suppose $\mathscr{U} \subseteq \mathscr{P}(X)$ is an ultrafilter. If $\mathscr{U}$ is not ω_1-complete then there exists $\{X_i \mid i<\omega\}$ such that

(1) for all $i<\omega$, $X_i \in \mathscr{U}$ and

(2) $\bigcap_{i<\omega} X_i \notin \mathscr{U}$.

Without loss of generality we can suppose that $\bigcap_{i<\omega} X_i = \varnothing$. So this gives a partition $\{Y_i \mid i<\omega\}$ of X into disjoint non-empty sets each of which is not in $\mathscr{U}$. Define $\mathscr{U}^* \subseteq \mathscr{P}(\omega)$ as follows:

$$\sigma \in \mathscr{U}^* \quad \text{iff} \quad \bigcup\{Y_i \mid i \in \sigma\} \in \mathscr{U}.$$

This is an ultrafilter on ω which is not principal since by assumption $Y_i \notin \mathscr{U}$ for each $i<\omega$. However, as Sierpiński showed, a non-principal ultrafilter over ω (construed as a set of reals) is not Lebesgue measurable. ⊣

Finally, we turn to the implications of determinacy for the Turing degrees. For $x, y \in \omega^\omega$, we say that x is *Turing reducible* to y, $x \leqslant_T y$, if x is recursive in y and we say that x is *Turing equivalent* to y, $x \equiv_T y$, if $x \leqslant_T y$ and $y \leqslant_T x$. The *Turing degrees* are the corresponding equivalence classes $[x]_T = \{y \in \omega^\omega \mid y \equiv_T x\}$. Letting

$$\mathscr{D}_T = \{[x]_T \mid x \in \omega^\omega\}$$

the relation $\leqslant_T$ lifts to a partial ordering on $\mathscr{D}_T$. A *cone of Turing degrees* is a set of the form

$$\{[y]_T \mid y \geqslant_T x_0\}$$

for some $x_0 \in \omega^\omega$. A *Turing cone of reals* is a set of the form

$$\{y \in \omega^\omega \mid y \geqslant_T x_0\}$$

for some $x_0 \in \omega^\omega$. In each case x_0 is said to be the *base* of the cone. In later sections we will discuss different degree notions. However, when we speak of a "cone of x" without qualification we always mean a "Turing cone of x". The *cone filter on* $\mathscr{D}_T$ is the filter consisting of sets of Turing degrees that contain a cone of Turing degrees.

2.9 Theorem (Cone Theorem; Martin). *Assume* ZF + AD. *The cone filter on* $\mathscr{D}_T$ *is an ultrafilter.*

Proof. For $A \subseteq \mathscr{D}_T$ consider the game

$$\begin{array}{lccccccc} \mathrm{I} & x(0) & & x(1) & & x(2) & & \ldots \\ \mathrm{II} & & y(0) & & y(1) & & \ldots & \end{array}$$

where I wins iff $[x * y]_T \in A$. If I has a winning strategy σ_0 then σ_0 witnesses that A is in the cone filter since for $y \geqslant_T \sigma_0$, $[y]_T = [\sigma_0 * y]_T \in A$. If II has a winning strategy τ_0 then τ_0 witnesses that $\mathscr{D}_T \smallsetminus A$ is in the cone filter since for $x \geqslant_T \tau_0$, $[x]_T = [x * \tau_0]_T \in \mathscr{D}_T \smallsetminus A$. $\dashv$

It follows that under ZF + AD each statement $\varphi(x)$ either holds for a Turing cone or reals x or fails for a Turing cone of reals x.

The proof of the Cone Theorem easily relativizes to fragments of definable determinacy. For example, assuming Σ^1_2-determinacy every Σ^1_2 set which is invariant under Turing equivalence either contains or is disjoint from a Turing cone of reals.

It is of interest to note that when Martin proved the Cone Theorem he thought that he would be able to refute AD by finding a property that "toggles". He started with Borel sets and, when no counterexample arose, moved on to more complicated sets. We now know (assuming there are infinitely many Woodin cardinals with a measurable above) that no counterexamples are to be found in $L(\mathbb{R})$. Moreover, the statement that there are no counterexamples in $L(\mathbb{R})$ (i.e. the statement that *Turing determinacy* holds in $L(\mathbb{R})$) actually implies $\mathrm{AD}^{L(\mathbb{R})}$ (over ZF + DC). Thus, the basic intuition that the Cone Theorem is strong is correct—it is just not as strong as $0 = 1$.

2.2. Boundedness and Basic Coding

We begin with some definitions. For $x \in \omega^\omega$, let E_x be the binary relation on ω such that mE_xn iff $x(\langle m, n\rangle) = 0$, where recall that $\langle \cdot, \cdot \rangle : \omega \times \omega \to \omega$ is a recursive bijection. The real x is said to *code* the relation E_x. Let $\mathrm{WO} = \{x \in \omega^\omega \mid E_x$ is a well-ordering$\}$. For $x \in \mathrm{WO}$, let α_x be the ordertype of E_x and, for $\alpha < \beta < \omega_1$ let $\mathrm{WO}_\alpha = \{x \in \mathrm{WO} \mid \alpha_x = \alpha\}$, $\mathrm{WO}_{<\alpha} = \{x \in$

$\mathrm{WO} \mid \alpha_x < \alpha\}$, $\mathrm{WO}_{(\alpha,\beta]} = \{x \in \mathrm{WO} \mid \alpha < \alpha_x \leqslant \beta\}$ and likewise for other intervals of countable ordinals. For $x \in \mathrm{WO}$, let $\mathrm{WO}_x = \mathrm{WO}_{\alpha_x}$. It is straightforward to see that these sets are Borel and that WO is a complete $\underset{\sim}{\Pi}^1_1$ set. (See [1, Chap. 25] for details.)

In addition to the topological and recursion-theoretic characterizations of $\underset{\sim}{\Sigma}^1_1$ there is a model-theoretic characterization which is helpful in simplifying complexity calculations. A model (M, E) satisfying T_0 (or some sufficiently strong fragment of ZF) is an *ω-model* if $(\omega^M, E{\restriction}\omega^M) \cong (\omega, \in{\restriction}\omega)$, where recall that T_0 is the theory $\mathrm{ZF} + \mathrm{AC}_\omega(\mathbb{R}) - \text{Power Set} + \text{“}\mathscr{P}(\omega)\text{ exists”}$. Notice that ω-models are correct about arithmetical statements and hence Π^1_1 statements are downward absolute to ω-models. Moreover, the statement “There exists a real coding an ω-model of T_0” is Σ^1_1, in contrast to the statement “There exists a real coding a well-founded model of T_0”, which is Σ^1_2. Thus we have the following characterization of the pointclass $\underset{\sim}{\Sigma}^1_1$: $A \subseteq \omega^\omega$ is $\underset{\sim}{\Sigma}^1_1$ iff there is a formula φ and there exists a $z \in \omega^\omega$ such that

$$\begin{aligned} A = \{y \in \omega^\omega \mid{} & \text{there is a real coding an } \omega\text{-model } M \text{ with } z \in M \\ & \text{such that } y \in M \text{ and } M \models \mathrm{T}_0 + \varphi[y, z]\}. \end{aligned}$$

The lightface version Σ^1_1 is defined similarly by omitting the parameter z, as are the Σ^1_1 subsets of $(\omega^\omega)^n$ and the Σ^1_1 statements, etc. Theories much weaker than T_0 yield an equivalent definition. For example, one can use the finite theory ZF_N of the first N axioms of ZF for some sufficiently large N.

As an illustration of the utility of this model-theoretic characterization of $\underset{\sim}{\Sigma}^1_1$ we shall use it to show that for each $x \in \mathrm{WO}$, $\mathrm{WO}_{<x}$ is $\underset{\sim}{\Delta}^1_1$: Notice that ω-models of T_0 correctly compute “$x, y \in \mathrm{WO}$ and $\alpha_y < \alpha_x$” in the following sense: If $x, y \in \mathrm{WO}$ and $\alpha_y < \alpha_x$ and M is an ω-model of T_0 which contains x and y, then $M \models$ “$x, y \in \mathrm{WO}$ and $\alpha_y < \alpha_x$”. (By downward absoluteness M satisfies that $x, y \in \mathrm{WO}$ and hence that α_y and α_x are defined. Furthermore, since M is an ω-model it correctly computes the ordering of α_x and α_y.) If $x \in \mathrm{WO}$ and M is an ω-model of T_0 which satisfies “$x, y \in \mathrm{WO}$ and $\alpha_y < \alpha_x$” then $y \in \mathrm{WO}$ and $\alpha_y < \alpha_x$. (The point is that M satisfies that there is an order-preserving map $f : E_y \to E_x$ and, since ω-models are correct about such maps and since E_x is truly well-founded, it follows that $y \in \mathrm{WO}$ and $\alpha_y < \alpha_x$). So, for $x \in \mathrm{WO}$,

$$\begin{aligned} \mathrm{WO}_{<x} = \{y \in \omega^\omega \mid{} & \text{there is a real coding an } \omega\text{-model } M \text{ such that} \\ & x, y \in M \text{ and } M \models \mathrm{T}_0 + \text{“}x, y \in \mathrm{WO} \text{ and } \alpha_y < \alpha_x\text{”}\} \\ = \{y \in \omega^\omega \mid{} & \text{for all reals coding } \omega\text{-models } M \text{ if } x, y \in M \\ & \text{and } M \models \mathrm{T}_0 \text{ then } M \models \text{“}x, y \in \mathrm{WO} \text{ and } \alpha_y < \alpha_x\text{”}\}. \end{aligned}$$

Thus, for $x \in \mathrm{WO}$, $\mathrm{WO}_{<x}$ is $\underset{\sim}{\Delta}^1_1$ and hence Borel.

2.10 Lemma ($\underset{\sim}{\Sigma}^1_1$-Boundedness; Luzin-Sierpiński). *Assume* $\mathrm{ZF} + \mathrm{AC}_\omega(\mathbb{R})$. *Suppose* $X \subseteq \mathrm{WO}$ *and* X *is* $\underset{\sim}{\Sigma}^1_1$. *Then there exists an* $\alpha < \omega_1$ *such that* $X \subseteq \mathrm{WO}_{<\alpha}$.

Proof. Assume toward a contradiction that X is unbounded. Then

$$y \in \mathrm{WO} \quad \text{iff} \quad \text{there is a } x \in X \text{ such that } \alpha_y < \alpha_x$$

since for $x \in X \subseteq \mathrm{WO}$, ω-models of T_0 correctly compute $\alpha_y < \alpha_x$. By the above remark, we can rewrite this as

$$\begin{aligned} y \in \mathrm{WO} \quad \text{iff} \quad & \text{there is an } x \in X \text{ and there is an } \omega\text{-model } M \text{ such that} \\ & x, y \in M \text{ and } M \models \mathrm{T}_0 + \text{“}x, y \in \mathrm{WO} \text{ and } \alpha_y < \alpha_x\text{”}. \end{aligned}$$

Thus, WO is $\underset{\sim}{\Sigma}^1_1$, which contradicts the fact that WO is a complete $\underset{\sim}{\Pi}^1_1$ set. (Without appealing to the fact that WO is a complete $\underset{\sim}{\Pi}^1_1$ set we can arrive at a contradiction (making free use of AC) as follows: Let $z \in \omega^\omega$ be such that both X and WO are $\Sigma^1_1(z)$. Let α be such that $V_\alpha \models \mathrm{T}_0$ and choose $Y \prec V_\alpha$ such that Y is countable and $z \in Y$. Let N be the transitive collapse of Y. By correctness, $X \cap N = X^N$. Choose a uniform ultrafilter $U \subseteq \mathscr{P}(\omega_1)^N$ such that if

$$j : N \to \mathrm{Ult}(N, U)$$

is the associated embedding then $\mathrm{crit}(j) = \omega_1^N$ and $j(\omega_1^N)$ is not well-founded. (To obtain such an ultrafilter build a generic for $(\mathscr{P}(\omega_1)/\text{countable})^N$. See Lemma 22.20 of [1].) Since $\mathrm{Ult}(N, U)$ is an ω-model of T_0 it correctly computes WO. It follows that $(\mathrm{WO})^{\mathrm{Ult}(N,U)} \subseteq \mathrm{WO}$, which in turn contradicts the fact that $\omega_1^{\mathrm{Ult}(N,U)}$ is not well-founded.) ⊣

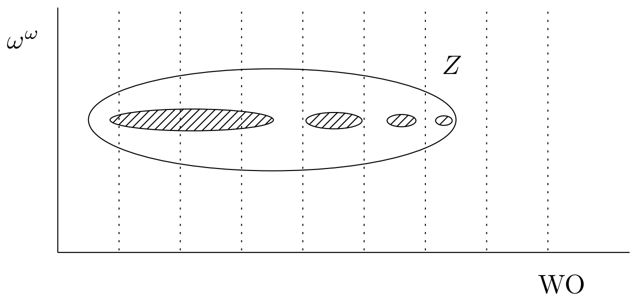
2.11 Lemma (Basic Coding; Solovay). *Assume* ZF + AD. *Suppose* $Z \subseteq \mathrm{WO} \times \omega^\omega$. *Then there exists a* $\underset{\sim}{\Sigma}^1_2$ *set* Z^* *such that*

(1) $Z^* \subseteq Z$ *and*

(2) for all $\alpha < \omega_1$, $Z^* \cap (\mathrm{WO}_\alpha \times \omega^\omega) \neq \varnothing$ *iff* $Z \cap (\mathrm{WO}_\alpha \times \omega^\omega) \neq \varnothing$.

Moreover, there is such a Z^* *which is of the form* $X \cap (\mathrm{WO} \times \omega^\omega)$ *where* $X \subseteq \omega^\omega \times \omega^\omega$ *is* $\underset{\sim}{\Sigma}^1_1$.

Proof. Here is the picture:



The space $\mathrm{WO} \times \omega^\omega$ is sliced into sections $\mathrm{WO}_\alpha \times \omega^\omega$ for $\alpha < \omega_1$. Z is represented by the unshaded ellipse and Z^* is represented by the shaded region. Basic Coding says that whenever Z meets one of the sections so does Z^*. In such a situation we say that Z^* is a *selector* for Z.

To see that Z^* exists, consider the game

$$\begin{array}{cccccccc} \mathrm{I} & x(0) & & x(1) & & x(2) & & \dots \\ \mathrm{II} & & y(0) & & y(1) & & \dots & \end{array}$$

where II wins iff whenever $x \in \mathrm{WO}$ then y codes a countable set Y such that

(1) $Y \subseteq Z$ and

(2) for all $\alpha \leqslant \alpha_x$, $Y \cap (\mathrm{WO}_\alpha \times \omega^\omega) \neq \varnothing$ iff $Z \cap (\mathrm{WO}_\alpha \times \omega^\omega) \neq \varnothing$.

The idea is that Player I challenges by playing a countable ordinal α_x and Player II meets this challenge provided he can play (a code for a) a selector Y for $Z \cap (\mathrm{WO}_{\leqslant \alpha_x} \times \omega^\omega)$.

Claim. *There can be no winning strategy for Player I in this game.*

Proof. Suppose σ is a winning strategy for I. As the play unfolds, Player I can attempt to increase α_x as Player II's play is revealed. However, Player II can anticipate all such attempts as follows: The set

$$X = \{(\sigma * y)_I \mid y \in \omega^\omega\}$$

is $\Sigma^1_1(\sigma)$ and, since σ is winning for I, $X \subseteq \mathrm{WO}$. So, by $\underset{\sim}{\Sigma}^1_1$-boundedness, there is a $\beta < \omega_1$ such that $X \subseteq \mathrm{WO}_{<\beta}$. Since we have $\mathrm{AC}_\omega(\mathbb{R})$ (by Theorem 2.2), we can choose a countable set $Y \subseteq Z$ such that for all $\alpha < \beta$, $Y \cap (\mathrm{WO}_\alpha \times \omega^\omega) \neq \varnothing$ iff $Z \cap (\mathrm{WO}_\alpha \times \omega^\omega) \neq \varnothing$. Let y code Y and play y against σ. The resulting play $\sigma * y$ is a win for II, which is a contradiction. ⊣

Thus II has a winning strategy τ. For $x \in \mathrm{WO}$, let Y^x be the countable subset of Z coded by $(x * \tau)_{II}$. Then

$$Z^* = \bigcup \{Y^x \mid x \in \mathrm{WO}\}$$

is $\Sigma^1_2(\tau)$ and such that

(1) $Z^* \subseteq Z$,

(2) for all $\alpha < \omega_1$, $Z^* \cap (\mathrm{WO}_\alpha \times \omega^\omega) \neq \varnothing$ iff $Z \cap (\mathrm{WO}_\alpha \times \omega^\omega) \neq \varnothing$.

Hence Z^* is as desired.

To see that we can choose Z^* to be of the form $X \cap (\mathrm{WO} \times \omega^\omega)$ where $X \subseteq \omega^\omega \times \omega^\omega$ is $\underset{\sim}{\Sigma}^1_1$, let

$$\begin{aligned} X = \{(a, b) \mid {} & \text{there is an } \omega\text{-model } M \\ & \text{such that } a, b, \tau \in M \text{ and } M \models \mathrm{T}_0 + (a, b) \in Z^{**}\} \end{aligned}$$

where

$$Z^{**} = \bigcup \{Y^x \cap (\mathrm{WO}_{\alpha_x} \times \omega^\omega) \mid x \in \mathrm{WO}\}.$$

This set is $\Sigma^1_1(\tau)$. The trouble is that although for $a \in \mathrm{WO}$ such models M are correct about $(a, b) \in Z^{**}$, M might think $a \in \mathrm{WO}$ when $a \notin \mathrm{WO}$. To overcome this difficulty we pare down, letting $Z^* = X \cap (\mathrm{WO} \times \omega^\omega)$. ⊣

2.3. Measurability

2.12 Theorem (Solovay). *Assume* ZF + AD. *Then the club filter is an ω_1-complete ultrafilter on ω_1.*

Proof. The ultrafilter on ω_1 will be extracted from a game. As motivation, for the moment work in ZFC. For $S \subseteq \omega_1$, consider the game

$$\begin{array}{lccccccc} \mathrm{I} & \alpha_0 & & \alpha_1 & & \alpha_2 & & \dots \\ \mathrm{II} & & \beta_0 & & \beta_1 & & \dots & \end{array}$$

where we demand that $\alpha_0 < \beta_0 < \alpha_1 < \cdots < \omega_1$ and where the first player that fails to meet this demand loses and if both players meet the demand then I wins provided $\sup_{i<\omega} \alpha_i \in S$.

We claim that I wins this game for S if and only if S contains a club in ω_1. Suppose first that S contains a club C. Let σ be a strategy for I which chooses an element of C larger than the last ordinal played by II. This is a winning strategy for I. For if II meets the first condition then the ordinals played form an increasing sequence. The even elements of this sequence are in C and hence the supremum of the sequence is in C (since C is club) and hence in S. Thus σ is a winning strategy for I. Suppose next that I have a winning strategy σ. Let C be the set of limit ordinals $\gamma < \omega_1$ with the feature that for every $i < \omega$ and for every increasing sequence $\xi_0, \dots, \xi_{2i}$ of ordinals less than γ, the response $\sigma(\langle \xi_0, \dots, \xi_{2i} \rangle)$ is also less than γ. Let C' be the limit points of C. Since ω_1 is regular it follows that C and C' are club in ω_1. Now suppose $\gamma \in C'$. Let $\langle \gamma_i \mid i < \omega \rangle$ be an increasing sequence of ordinals in C which is cofinal in γ and such that γ_0 is greater than I's first move via σ. The key point is that this sequence is a legal play for II. Player II has "taken control" of the game. Now, since σ is a winning strategy for I it follows that the supremum, γ, is in S. Thus, S contains the club C'. So, if we had determinacy (which of course is impossible in ZFC) we would have an ultrafilter on ω_1.

Now return to ZF + AD. We want to mimic the above game via a game where each player plays natural numbers. This can be done since in an integer game each player ultimately plays a real x that can be regarded as coding ω-many reals $(x)_i$ each of which (potentially) codes a countable ordinal. More precisely, for $S \subseteq \omega_1$, let $G(S)$ be the game

$$\begin{array}{lccccccc} \mathrm{I} & x(0) & & x(1) & & x(2) & & \dots \\ \mathrm{II} & & y(0) & & y(1) & & \dots & \end{array}$$

with the following rules: Rule 1: For all $i < \omega$, $(x)_i, (y)_i \in \mathrm{WO}$. If Rule 1 is violated then, letting i be least such that either $(x)_i \notin \mathrm{WO}$ or $(y)_i \notin \mathrm{WO}$, I wins if $(x)_i \in \mathrm{WO}$; otherwise II wins. Now suppose Rule 1 is satisfied. Rule 2: $\alpha_{(x)_0} < \alpha_{(y)_0} < \alpha_{(x)_1} < \alpha_{(y)_1} < \cdots$. The first failure defines who wins as above. If both rules are satisfied then I wins if and only if $\sup_{i<\omega} \alpha_{(x)_i} \in S$.

Now let

$$\mu = \{S \subseteq \omega_1 \mid \mathrm{I} \text{ wins } G(S)\}.$$

We claim that if I has a winning strategy in $G(S)$ then S contains a club: Let σ be a winning strategy for I. For $\alpha < \omega_1$, let

$$X_\alpha = \big\{((\sigma * y)_I)_n \mid n < \omega,\ y \in \omega^\omega,\ \text{and} \\ \forall i < n \big((y)_i \in \mathrm{WO} \text{ and } \alpha_{(y)_i} < \alpha\big)\big\}.$$

Notice that each $X_\alpha \subseteq \mathrm{WO}$ (since X_α is $\underset{\sim}{\Sigma}^1_1$ (in σ and the code for α) and σ is a winning strategy) and so by $\underset{\sim}{\Sigma}^1_1$-boundedness, there exists an α' such that $X_\alpha \subseteq \mathrm{WO}_{<\alpha'}$. Let $f : \omega_1 \to \omega_1$ be the function which given α chooses the least α' such that $X_\alpha \subseteq \mathrm{WO}_{<\alpha'}$. As before let C be the set of limit ordinals $\gamma < \omega_1$ with the feature that for every $\xi < \gamma$, $f(\xi) < \gamma$. Let C' be the limit points of C. Since ω_1 is regular (by Corollary 2.3) it follows that C and C' are club in ω_1. Now suppose $\gamma \in C'$. Let $\langle \gamma_i \mid i < \omega\rangle$ be an increasing sequences of ordinals in C which is cofinal in γ. Let $y \in \omega^\omega$ be such that for all $i < \omega$, $\alpha_{(y)_i} = \gamma_i$. We claim that playing y against σ witnesses that $\gamma \in S$. It suffices to show that y is legal with respect to the two rules. For then the supremum, γ, must be in S since σ is a winning strategy for I. Now the first rule is trivially satisfied since we chose y such that for all $i < \omega$, $(y)_i \in \mathrm{WO}$. To see that the second rule is satisfied we need to see that for each $i < \omega$, $\alpha_{((\sigma * y)_I)_i} < \gamma_i$. This follows from the fact that $X_{\gamma_i} \subseteq \mathrm{WO}_{<\gamma_i}$. Again, Player II has "taken control" of the game.

A similar argument shows that if II has a winning strategy in $G(S)$ then $\omega_1 \smallsetminus S$ contains a club. Thus the club filter on ω_1 is an ultrafilter and so μ is that ultrafilter. Finally, the fact that μ is ω_1-complete follows from Theorem 2.8. ⊣

We now wish to show that under AD the club filter is normal. This was proved by Solovay, using DC. We shall give a proof that avoids appeal to DC and generalizes to larger ordinals.

2.13 Theorem. *Assume* ZF + AD. *Then the club filter is an ω_1-complete normal ultrafilter on ω_1.*

Proof. For $S \subseteq \omega_1$ let $G(S)$ be the game from the previous proof and let μ be as defined there. We know that μ is the club filter. To motivate the proof of normality we give a proof of ω_1-completeness that will generalize to produce normal ultrafilters on ordinals larger than ω_1. This is merely for illustration—the proof uses DC but this will be eliminated in Claim 2.

Claim 1. *μ is ω_1-complete.*

Proof. Suppose $S_j \in \mu$ for $j < \omega$. We have to show that $S = \bigcap_{j<\omega} S_j \in \mu$. Let σ_j be a winning strategy for I in $G(S_j)$. Assume toward a contradiction that $S \notin \mu$—that is, that I does not win $G(S)$—and let σ be a winning strategy for I in $G(\omega_1 \smallsetminus S)$. Our strategy is to build a play y that is legal for II against each σ_j and against σ. This will give us our contradiction by implying that $\sup_{i<\omega} \alpha_{(y)_i}$ is in each S_j but not in S.

We build $z_n = (y)_n$ by recursion on n using the foresight provided by $\underset{\sim}{\Sigma}^1_1$-boundedness. For the initial step we use $\underset{\sim}{\Sigma}^1_1$-boundedness to get $\beta_0 < \omega_1$ such that for all $j < \omega$ and for all $y \in \omega^\omega$

$$\alpha_{((\sigma_j * y)_I)_0} < \beta_0 \quad \text{and} \quad \alpha_{((\sigma * y)_I)_0} < \beta_0.$$

Choose $z_0 \in \mathrm{WO}_{\beta_0}$. For the $(n+1)$st step we use $\underset{\sim}{\Sigma}^1_1$-boundedness to get $\beta_{n+1} < \omega_1$ such that $\beta_n < \beta_{n+1}$ and for all $j < \omega$ and for all $y \in \omega^\omega$, if $(y)_i = z_i$ for all $i \leqslant n$, then

$$\alpha_{((\sigma_j * y)_I)_{n+1}} < \beta_{n+1} \quad \text{and} \quad \alpha_{((\sigma * y)_I)_{n+1}} < \beta_{n+1}.$$

Choose $z_{n+1} \in \mathrm{WO}_{\beta_{n+1}}$. Finally, let y be such that for all $n < \omega$, $(y)_n = z_n$. The play y is legal for II against each σ_j and σ, which is a contradiction. $\dashv$

Claim 2. *μ is normal.*

Proof. Assume toward a contradiction that $f : \omega_1 \to \omega_1$ is regressive and that there is no $\alpha < \omega_1$ such that $\{\xi < \omega_1 \mid f(\xi) = \alpha\} \in \mu$ or, equivalently (by AD), that for all $\alpha < \omega_1$,

$$S_\alpha = \{\xi < \omega_1 \mid f(\xi) \neq \alpha\} \in \mu.$$

Our strategy is to recursively define

(1.1) an increasing sequence $\langle \eta_i \mid i < \omega \rangle$ of countable ordinals with supremum η,

(1.2) a sequence of collections of strategies $\langle X_i \mid i < \omega \rangle$ where X_i contains winning strategies for I in games $G(S_\alpha)$ for $\alpha \in [\eta_{i-1}, \eta_i)$, where $\eta_{-1} = 0$, and

(1.3) a sequence $\langle y_i \mid i < \omega \rangle$ of plays such that y_i is legal for II against any $\sigma \in X_i$ and $\sup_{j<\omega} \alpha_{(y_i)_j} = \eta$.

Since each $\sigma \in X_i$ is a winning strategy for I, y_i will witness that $\eta \in S_\alpha$ for each $\alpha \in [\eta_{i-1}, \eta_i)$, i.e. y_i will witness that $f(\eta) \neq \alpha$ for each $\alpha \in [\eta_{i-1}, \eta_i)$. Thus collectively the y_i will guarantee that $f(\eta) \neq \alpha$ for any $\alpha < \eta$, which contradicts our assumption that $f(\eta) < \eta$.

We begin by letting

$$Z = \{(x, \sigma) \mid x \in \mathrm{WO} \text{ and } \sigma \text{ is a winning strategy for I in } G(S_{\alpha_x})\}.$$

By the Basic Coding Lemma, there is a $Z^* \subseteq Z$ such that

(2.1) for all $\alpha < \omega_1$, $Z^* \cap (\mathrm{WO}_\alpha \times \omega^\omega) \neq \varnothing$ iff $Z \cap (\mathrm{WO}_\alpha \times \omega^\omega) \neq \varnothing$,

(2.2) $Z^* = X \cap (\mathrm{WO} \times \omega^\omega)$ where X is $\underset{\sim}{\Sigma}^1_1$.

The key point is that for each $\alpha < \omega_1$,

$$X \cap (\mathrm{WO}_{\leqslant\alpha} \times \omega^\omega)$$

is $\underset{\sim}{\Sigma}^1_1$ since $\mathrm{WO}_{\leqslant\alpha}$ is Borel. Thus, we can apply $\underset{\sim}{\Sigma}^1_1$-boundedness to these sets.

The difficulty is that to construct the sequence $\langle y_i \mid i < \omega\rangle$ we shall need DC. For this reason we drop down to a context where we have DC and run the argument there.

Let t be a real such that X is $\Sigma^1_1(t)$. By absoluteness, for each $\alpha < \omega_1^{L[t,f]}$, there exists an $(x,\sigma) \in Z^* \cap L[t,f]$ such that $\alpha = \alpha_x$ and σ is a winning strategy for Player I in $G(S_\alpha^{L[t,f]})$ where

$$S_\alpha^{L[t,f]} = \{\eta < \omega_1^{L[t,f]} \mid f(\eta) \neq \alpha\}.$$

For the remainder of the proof we work in $L[t,f]$ and interpret S_α and X via their definitions, simply writing S_α and X.

For the first step let

$$\begin{aligned}
\eta_0 &= \text{some ordinal } \eta \text{ such that } \eta < \omega_1\\
X_0 &= \mathrm{proj}_2\left(X \cap (\mathrm{WO}_{[0,\eta_0)} \times \omega^\omega)\right)\\
Y_0 &= \left\{((\sigma * y)_I)_0 \mid \sigma \in X_0 \wedge y \in \omega^\omega\right\}\\
z_0 &= \text{some real } z \text{ such that } Y_0 \subseteq \mathrm{WO}_{<\alpha_z}.
\end{aligned}$$

So X_0 is a collection of strategies for games $G(S_\alpha)$ where $\alpha < \eta_0$. Since these strategies are winning for I the set Y_0 is contained in WO. Furthermore, Y_0 is $\underset{\sim}{\Sigma}^1_1$ and hence has a bound α_{z_0}. For the next step let

$$\begin{aligned}
\eta_1 &= \text{some ordinal } \eta \text{ such that } \eta_0, \alpha_{z_0} < \eta < \omega_1\\
X_1 &= \mathrm{proj}_2\left(X \cap (\mathrm{WO}_{[\eta_0,\eta_1)} \times \omega^\omega)\right)\\
Y_1 &= \left\{((\sigma * y)_I)_1 \mid \sigma \in X_0,\ y \in \omega^\omega \text{ such that } (y)_0 = z_0\right\}\\
&\quad \cup \left\{((\sigma * y)_I)_0 \mid \sigma \in X_1,\ y \in \omega^\omega\right\}\\
z_1 &= \text{some real } z \text{ such that } Y_1 \subseteq \mathrm{WO}_{<\alpha_z}.
\end{aligned}$$

For the $(n+1)$st step let

$$\begin{aligned}
\eta_{n+1} &= \text{some ordinal } \eta \text{ such that } \eta_n, \alpha_{z_n} < \eta < \omega_1\\
X_{n+1} &= \mathrm{proj}_2\left(X \cap (\mathrm{WO}_{[\eta_n,\eta_{n+1})} \times \omega^\omega)\right)\\
Y_{n+1} &= \left\{((\sigma * y)_I)_{n+1} \mid \sigma \in X_0,\ y \in \omega^\omega \text{ such that } \forall i \leqslant n\ (y)_i = z_i\right\}\\
&\quad \cup \left\{((\sigma * y)_I)_n \mid \sigma \in X_1,\ y \in \omega^\omega \text{ such that } \forall i \leqslant n-1\ (y)_i = z_{i+1}\right\}\\
&\quad\quad \vdots\\
&\quad \cup \left\{((\sigma * y)_I)_0 \mid \sigma \in X_{n+1},\ y \in \omega^\omega\right\}\\
z_{n+1} &= \text{some real } z \text{ such that } Y_{n+1} \subseteq \mathrm{WO}_{<\alpha_z}.
\end{aligned}$$

Finally, for each $k < \omega$, let y_k be such that $(y_k)_i = z_{i+k}$ for all $i < \omega$. Since each of these reals contains a tail of the z_i's, if $\eta = \sup_{n<\omega} \eta_n$, then

$$\sup_{i<\omega}(\alpha_{(y_k)_i}) = \eta$$

for all $k < \omega$. Furthermore, y_k is a legal play for II against any $\sigma \in X_k$, as witnessed by the $(k+1)$st components of Y_n for $n \geqslant k$. Since each $\sigma \in X_k$ is a winning strategy for I, y_k witnesses that $\eta \in S_\alpha$ for $\alpha \in [\eta_{k-1}, \eta_k)$, i.e. that $f(\eta) \neq \alpha$ for any $\alpha \in [\eta_{k-1}, \eta_k)$. Thus, collectively the y_k guarantee that $f(\eta) \neq \alpha$ for any $\alpha < \eta$, which contradicts the fact that $f(\eta) < \eta$. ⊣

This completes the proof of the theorem. ⊣

It should be noted that using DC normality can be proved without using Basic Coding since in place of the sequence $\langle X_i \mid i \in \omega \rangle$ one can use DC to construct a sequence $\langle \sigma_\alpha \mid \alpha < \eta \rangle$ of strategies. This, however, relies on the fact that η is countable. Our reason for giving the proof in terms of Basic Coding is that it illustrates in miniature how we will obtain normal ultrafilters on ordinals much larger than ω_1.

2.14 Corollary (Solovay). *Assume* ZF + AD*. Then*

$$\text{HOD} \models \omega_1^V \textit{ is a measurable cardinal.}$$

Proof. We have that

$$\text{HOD} \models \mu \cap \text{HOD is a normal ultrafilter on } \omega_1^V,$$

since $\mu \cap \text{HOD} \in \text{HOD}$ (as μ is OD and OD is OD). ⊣

Thus, if ZF + AD is consistent, then ZFC + "There is a measurable cardinal" is consistent.

There is also an *effective* version of Solovay's theorem, which we shall need.

2.15 Theorem. *Assume* ZFC + OD*-determinacy. Then*

$$\text{HOD} \models \omega_1^V \textit{ is a measurable cardinal.}$$

Proof. If S is OD then the game $G(S)$ is OD and hence determined. It follows (by the above proof) that if I has a winning strategy in $G(S)$ then S contains a club and if II has a winning strategy in $G(S)$ then $\omega_1 \setminus S$ contains a club. Thus,

$$V \models \mu \cap \text{HOD is an ultrafilter on HOD}$$

and so

$$\text{HOD} \models \mu \cap \text{HOD is an ultrafilter.}$$

Similarly the proof of Claim 1 in Theorem 2.13 shows that

$$V \models \mu \cap \text{HOD is } \omega_1\text{-complete}$$

and so

$$\text{HOD} \models \mu \cap \text{HOD is } \omega_1\text{-complete},$$

which completes the proof. ⊣

2.4. The Least Stable

We now take the next step in generalizing the above result. For this purpose it is useful to think of ω_1 in slightly different terms: Recall the following definition:

$$\underset{\sim}{\delta}{}^1_1 = \sup\{\alpha \mid \text{there is a } \underset{\sim}{\Delta}{}^1_1\text{-surjection } \pi : \omega^\omega \to \alpha\}.$$

It is a classical result that $\omega_1 = \underset{\sim}{\delta}{}^1_1$. Now consider the following higher-order analogue of $\underset{\sim}{\delta}{}^1_1$:

$$\underset{\sim}{\delta}{}^2_1 = \sup\{\alpha \mid \text{there is a } \underset{\sim}{\Delta}{}^2_1\text{-surjection } \pi : \omega^\omega \to \alpha\}.$$

In this section we will work without determinacy and establish the basic features of this ordinal in the context of $L(\mathbb{R})$. In the next section we will solve for U in the equation

$$\frac{\underset{\sim}{\delta}{}^1_1}{\mathrm{WO}} = \frac{\underset{\sim}{\delta}{}^2_1}{U}$$

in such a way that U is accompanied by the appropriate boundedness and coding theorems required to generalize Solovay's proof to show that $\mathrm{ZF} + \mathrm{DC} + \mathrm{AD}^{L(\mathbb{R})}$ implies that $(\underset{\sim}{\delta}{}^2_1)^{L(\mathbb{R})}$ is a measurable cardinal in $\mathrm{HOD}^{L(\mathbb{R})}$.

The following model-theoretic characterization of the pointclass $\underset{\sim}{\Sigma}{}^2_1$ will be useful in complexity calculations: $A \subseteq \omega^\omega$ is $\underset{\sim}{\Sigma}{}^2_1$ iff for some formula φ and some real $z \in \omega^\omega$,

$$\begin{aligned} A = \{y \in \omega^\omega \mid \ & \text{there is a transitive set } M \text{ such that} \\ & \text{(a) } \omega^\omega \subseteq M, \\ & \text{(b) there is a surjection } \pi : \omega^\omega \to M, \text{ and} \\ & \text{(c) } M \models \mathrm{T}_0 + \varphi[y, z]\}. \end{aligned}$$

As before, theories much weaker than T_0 yield an equivalent definition and our choice of T_0 is simply one of convenience. The lightface version Σ^2_1 is defined similarly by omitting the parameter z.

We wish to study $\underset{\sim}{\delta}{}^2_1$ in the context of $L(\mathbb{R})$. In the interest of keeping our account self-contained and free of fine structure we will give a brief introduction to the basic features of $L(\mathbb{R})$ under the stratification $L_\alpha(\mathbb{R})$ for $\alpha \in \mathrm{On}$. For credits and references see [2].

Definability issues will be central. Officially our language is the language of set theory with an additional constant $\dot{\mathbb{R}}$ which is always to be interpreted as $\mathbb{R}$. For a set M such that $X \cup \{\mathbb{R}\} \subseteq M$, let $\Sigma_n(M, X)$ be the collection of sets definable over M via a Σ_n formula with parameters in $X \cup \{\mathbb{R}\}$. For example, x is $\Sigma_1(L(\mathbb{R}), X)$ iff x is Σ_1-definable over $L(\mathbb{R})$ with parameters from $X \cup \{\mathbb{R}\}$. It is important to note that the parameter $\mathbb{R}$ is always allowed in our definability calculations. To emphasize this we will usually make it explicit.

The basic features of L carry over to $L(\mathbb{R})$, one minor difference being that $\mathbb{R}$ is allowed as a parameter in all definability calculations. For example, for each limit ordinal λ, the sequence $\langle L_\alpha(\mathbb{R}) \mid \alpha < \lambda\rangle$ is $\Sigma_1(L_\lambda(\mathbb{R}), \{\mathbb{R}\})$.

For $X \cup \{\mathbb{R}\} \subseteq M \subseteq N$, let $M \prec_n^X N$ mean that for all parameter sequences $\vec{a} \in (X \cup \{\mathbb{R}\})^{<\omega}$ and for all Σ_n formulas φ, $M \models \varphi[\vec{a}]$ iff $N \models \varphi[\vec{a}]$. Let $M \prec_n N$ be short for $M \prec_n^M N$.

2.16 Definition. The *least stable in* $L(\mathbb{R})$, $\delta_{\mathbb{R}}$, is the least ordinal δ such that

$$L_\delta(\mathbb{R}) \prec_1^{\mathbb{R}\cup\{\mathbb{R}\}} L(\mathbb{R}).$$

A related ordinal of particular importance is δ_F, the least ordinal δ such that

$$L_\delta(\mathbb{R}) \prec_1 L(\mathbb{R}).$$

We aim to show that $(\underset{\sim}{\delta}{}^2_1)^{L(\mathbb{R})} = \delta_{\mathbb{R}} = \delta_F$. For notational convenience we write $\underset{\sim}{\delta}{}^2_1$ for $(\underset{\sim}{\delta}{}^2_1)^{L(\mathbb{R})}$ and Θ for $\Theta^{L(\mathbb{R})}$.

The definability notions involved in the previous definition also have useful model-theoretic characterizations, which we will routinely employ. For example, $A \subseteq \omega^\omega$ is Σ_1-definable over $L(\mathbb{R})$ with parameters from $\mathbb{R} \cup \{\mathbb{R}\}$ iff there is a formula φ and a $z \in \omega^\omega$,

$$\begin{aligned} A = \{y \in \omega^\omega \mid \exists\alpha \in \mathrm{On} \text{ such that } & \\ &\text{(a) } L_\alpha(\mathbb{R}) \models \mathrm{T}_0 \text{ and} \\ &\text{(b) } L_\alpha(\mathbb{R}) \models \varphi[y, z, \mathbb{R}]\}. \end{aligned}$$

Again, theories weaker than T_0 (such as ZF_N for sufficiently large N) suffice. The existence of arbitrarily large levels $L_\alpha(\mathbb{R})$ satisfying T_0 will be proved below in Lemma 2.22.

2.17 Lemma. *Assume* $\mathrm{ZF} + \mathrm{AC}_\omega(\mathbb{R}) + V = L(\mathbb{R})$. *Suppose*

$$\begin{aligned} X = \big\{x \in L_\lambda(\mathbb{R}) \mid x \textit{ is definable over } L_\lambda(\mathbb{R}) & \\ \textit{from parameters in } \mathbb{R} \cup \{\mathbb{R}\}\big\}&, \end{aligned}$$

where λ is a limit ordinal. Then $X \prec L_\lambda(\mathbb{R})$.

Proof. It suffices (by the Tarski-Vaught criterion) to show that if A is a non-empty set which is definable over $L_\lambda(\mathbb{R})$ from parameters in $\mathbb{R} \cup \{\mathbb{R}\}$, then $A \cap X \neq \varnothing$. Let A be such a non-empty set and choose $x_0 \in A$. Since every set in $L_\lambda(\mathbb{R})$ is definable over $L_\lambda(\mathbb{R})$ from a real and an ordinal parameter,

$$\{x_0\} = \{x \in L_\lambda(\mathbb{R}) \mid L_\lambda(\mathbb{R}) \models \varphi_0[x, c_0, \alpha_0, \mathbb{R}]\}$$

for some formula φ_0, and parameters $c_0 \in \omega^\omega$ and $\alpha_0 \in \mathrm{On}$. Let α_1 be least such that there is exactly one element x such that $L_\lambda(\mathbb{R}) \models \varphi_0[x, c_0, \alpha_1, \mathbb{R}]$ and $x \in A$. Notice that α_1 is definable in $L_\lambda(\mathbb{R})$ from c_0 and the real parameter used in the definition of A. Thus, letting x_1 be the unique element such that $L_\lambda(\mathbb{R}) \models \varphi_0[x_1, c_0, \alpha_1, \mathbb{R}]$ we have a set which is in A (by the definition of x_1) and in X (since it is definable in $L_\lambda(\mathbb{R})$ from c_0 and the real parameter used in the definition of A.) $\dashv$

2.18 Lemma. *Assume* $\mathrm{ZF} + \mathrm{AC}_\omega(\mathbb{R}) + V = L(\mathbb{R})$*. For each* $\alpha < \Theta$*, there is an* OD *surjection* $\pi : \omega^\omega \to \alpha$*.*

Proof. Fix $\alpha < \Theta$. Since every set in $L(\mathbb{R})$ is OD_x for some $x \in \omega^\omega$ there is an OD_x surjection $\pi : \omega^\omega \to \alpha$. For each $x \in \omega^\omega$, let π_x be the $<_{\mathrm{OD}_x}$-least such surjection if one exists and let it be undefined otherwise. We can now "average over the reals" to eliminate the dependence on real parameters, letting

$$\begin{aligned} \pi : \omega^\omega &\to \alpha \\ x &\mapsto \begin{cases} \pi_{(x)_0}((x)_1) & \text{if } \pi_{(x)_0} \text{ is defined} \\ 0 & \text{otherwise.} \end{cases} \end{aligned}$$

This is an OD surjection. ⊣

2.19 Lemma (Solovay). *Assume* $\mathrm{ZF} + \mathrm{AC}_\omega(\mathbb{R}) + V = L(\mathbb{R})$*. Then* Θ *is regular in* $L(\mathbb{R})$*.*

Proof. By the proof of the previous lemma, there is an OD sequence

$$\langle \pi_\alpha \mid \alpha < \Theta \rangle$$

such that each $\pi_\alpha : \omega^\omega \to \alpha$ is an OD surjection. Assume for contradiction that Θ is singular. Let

$$f : \alpha \to \Theta$$

be a cofinal map witnessing the singularity of Θ. Let $g : \omega^\omega \to \alpha$ be a surjection. It follows that the map

$$\begin{aligned} \pi : \omega^\omega &\to \Theta \\ x &\mapsto \pi_{f \circ g((x)_0)}((x)_1) \end{aligned}$$

is a surjection, which contradicts the definition of Θ. ⊣

2.20 Lemma. *Assume* $\mathrm{ZF} + \mathrm{AC}_\omega(\mathbb{R}) + V = L(\mathbb{R})$*. Then*

$$L_\Theta(\mathbb{R}) = \{x \in L(\mathbb{R}) \mid \textit{there is a surjection } \pi : \omega^\omega \to \mathrm{tc}(x)\}.$$

Thus, $\mathscr{P}(\mathbb{R}) \subseteq L_\Theta(\mathbb{R})$*.*

Proof. For the first direction suppose $x \in L_\Theta(\mathbb{R})$. Let $\lambda < \Theta$ be a limit ordinal such that $x \in L_\lambda(\mathbb{R})$. Thus $\mathrm{tc}(x) \subseteq L_\lambda(\mathbb{R})$. Moreover, there is a surjection $\pi : \omega^\omega \to L_\lambda(\mathbb{R})$, since every element of $L_\lambda(\mathbb{R})$ is definable from an ordinal and real parameters.

For the second direction suppose $x \in L(\mathbb{R})$ and that there is a surjection $\pi : \omega^\omega \to \mathrm{tc}(x)$. We wish to show that $x \in L_\Theta(\mathbb{R})$. Let λ be a limit ordinal such that $x \in L_\lambda(\mathbb{R})$. Thus $\mathrm{tc}(x) \subseteq L_\lambda(\mathbb{R})$. Let

$$\begin{aligned} X = \big\{ y \in L_\lambda(\mathbb{R}) \mid y &\text{ is definable over } L_\lambda(\mathbb{R}) \\ &\text{from parameters in } \mathrm{tc}(x) \cup \mathbb{R} \cup \{\mathbb{R}\} \big\}, \end{aligned}$$

By the proof of Lemma 2.17, $X \prec L_\lambda(\mathbb{R})$ and $\mathrm{tc}(x) \subseteq X$. By Condensation, the transitive collapse of X is $L_{\bar\lambda}(\mathbb{R})$ for some $\bar\lambda$. Since there is a surjection $\pi : \omega^\omega \to \mathrm{tc}(x)$ and since all members of $L_{\bar\lambda}(\mathbb{R})$ are definable from parameters in $\mathrm{tc}(x) \cup \mathbb{R} \cup \{\mathbb{R}\}$, there is a surjection $\rho : \omega^\omega \to L_{\bar\lambda}(\mathbb{R})$. So $\bar\lambda < \Theta$ and since $x \in L_{\bar\lambda}(\mathbb{R})$ this completes the proof. ⊣

2.21 Lemma. *Assume* $\mathrm{ZF} + \mathrm{AC}_\omega(\mathbb{R}) + V = L(\mathbb{R})$. *Then*

$$L_\Theta(\mathbb{R}) \models \mathrm{T}_0.$$

Proof. It is straightforward to see that $L_\Theta(\mathbb{R})$ satisfies T_0 − Separation − Replacement.

To see that $L_\Theta(\mathbb{R}) \models$ Separation note that if $S \subseteq x \in L_\Theta(\mathbb{R})$ then $S \in L_\Theta(\mathbb{R})$, by Lemma 2.20. To see that $L_\Theta(\mathbb{R}) \models$ Replacement we verify Collection, which is equivalent to Replacement, over the other axioms. Suppose

$$L_\Theta(\mathbb{R}) \models \forall x \in a\, \exists y\, \varphi(x, y),$$

where $a \in L_\Theta(\mathbb{R})$. Let

$$\begin{aligned} f &: a \mapsto \Theta \\ &\quad x \to \mu\alpha\,(\exists y \in L_\alpha(\mathbb{R}) \text{ such that } L_\Theta(\mathbb{R}) \models \varphi(x, y)). \end{aligned}$$

The ordertype of $\mathrm{ran}(f)$ is less that Θ since otherwise there would be a surjection $\pi : \omega^\omega \to \Theta$ (since there is a surjection $\pi : \omega^\omega \to a$). Moreover, since Θ is regular, it follows that $\mathrm{ran}(f)$ is bounded by some $\lambda < \Theta$. Thus,

$$L_\Theta(\mathbb{R}) \models \forall x \in a\, \exists y \in L_\lambda(\mathbb{R})\, \varphi(x, y),$$

which completes the proof. ⊣

2.22 Lemma. *Assume* $\mathrm{ZF} + \mathrm{AC}_\omega(\mathbb{R}) + V = L(\mathbb{R})$. *There are arbitrarily large α such that $L_\alpha(\mathbb{R}) \models \mathrm{T}_0$.*

Proof. The proof is similar to the previous proof. Let us say that α is an $\mathbb{R}$-*cardinal* if for every $\gamma < \alpha$ there does not exist a surjection $\pi : \mathbb{R} \times \gamma \to \alpha$. For each limit ordinal $\gamma \in \mathrm{On}$, letting

$$\Theta(\gamma) = \sup\{\alpha \mid \text{there is a surjection } \pi : \mathbb{R} \times \gamma \to \alpha\}$$

we have that $\Theta(\gamma)$ is an $\mathbb{R}$-cardinal. For each γ which is closed under the Gödel pairing function, the argument of Lemma 2.19 shows that $\Theta(\gamma)$ is regular. The proof of the previous lemma generalizes to show that for every regular $\Theta(\gamma)$, $L_{\Theta(\gamma)}(\mathbb{R}) \models \mathrm{T}_0$. ⊣

2.23 Lemma (Solovay). *Assume* $\mathrm{ZF} + \mathrm{AC}_\omega(\mathbb{R}) + V = L(\mathbb{R})$. $L_\Theta(\mathbb{R}) \prec_1 L(\mathbb{R})$.

Proof. Suppose
$$L(\mathbb{R}) \models \varphi[a],$$
where $a \in L_\Theta(\mathbb{R})$ and φ is Σ_1. By Reflection, let λ be a limit ordinal such that
$$L_\lambda(\mathbb{R}) \models \varphi[a].$$
Let
$$X = \big\{y \in L_\lambda(\mathbb{R}) \mid y \text{ is definable over } L_\lambda(\mathbb{R}) \\ \text{from parameters in } \mathrm{tc}(a) \cup \mathbb{R} \cup \{\mathbb{R}\}\big\},$$
By Condensation and Lemma 2.20, the transitive collapse of X is $L_{\bar\lambda}(\mathbb{R})$ for some $\bar\lambda < \Theta$. Thus, by upward absoluteness,
$$L_\Theta(\mathbb{R}) \models \varphi[a].$$
⊣

2.24 Lemma. *Assume* ZF + $\mathrm{AC}_\omega(\mathbb{R})$ + $V = L(\mathbb{R})$. *There are arbitrarily large* $\alpha < \delta_F$ *such that* $L_\alpha(\mathbb{R}) \models \mathrm{T}_0$

Proof. Suppose $\xi < \delta_F$. Since $L_\Theta(\mathbb{R}) \models \mathrm{T}_0$,
$$L(\mathbb{R}) \models \exists \alpha > \xi\, (L_\alpha(\mathbb{R}) \models \mathrm{T}_0).$$
The formula is readily seen to be Σ_1 with parameters in $\{\mathbb{R}, \xi\}$ by our model-theoretic characterization. Thus, by the definition of δ_F,
$$L_{\delta_F}(\mathbb{R}) \models \exists \alpha > \xi\, (L_\alpha(\mathbb{R}) \models \mathrm{T}_0),$$
which completes the proof. ⊣

2.25 Lemma. *Assume* ZF + $\mathrm{AC}_\omega(\mathbb{R}) + V = L(\mathbb{R})$. *Suppose* φ *is a formula and* $a \in \omega^\omega$. *Suppose* λ *is least such that* $L_\lambda(\mathbb{R}) \models \mathrm{T}_0 + \varphi[a]$. *Let*
$$X = \big\{x \in L_\lambda(\mathbb{R}) \mid y \textit{ is definable over } L_\lambda(\mathbb{R}) \\ \textit{from parameters in } \mathbb{R} \cup \{\mathbb{R}\}\big\}.$$
Then $X = L_\lambda(\mathbb{R})$. *Moreover, there is a surjection* $\pi : \omega^\omega \to L_\lambda(\mathbb{R})$ *such that* π *is definable over* $L_{\lambda+1}(\mathbb{R})$ *from* $\mathbb{R}$ *and* a.

Proof. By Lemma 2.17 we have that $X \prec L_\lambda(\mathbb{R})$. By condensation the transitive collapse of X is some $L_{\bar\lambda}(\mathbb{R})$. So $L_{\bar\lambda}(\mathbb{R}) \models \mathrm{T}_0 + \varphi[a]$ and thus by the minimality of λ we have $\bar\lambda = \lambda$. Since every $x \in X$ is definable from a real parameter and since $L_\lambda(\mathbb{R}) \cong X$, we have that every $x \in L_\lambda(\mathbb{R})$ is definable from a real parameter, in other words, $X = L_\lambda(\mathbb{R})$. The desired map $\pi : \omega^\omega \to L_\lambda(\mathbb{R})$ is the map which takes a real coding the Gödel number of φ and a real parameter a to the set $\{x \in L_\lambda(\mathbb{R}) \mid L_\lambda(\mathbb{R}) \models \varphi[x, a]\}$. This map is definable over $L_{\lambda+1}(\mathbb{R})$. ⊣

2.26 Lemma. *Assume* $\mathrm{ZF} + \mathrm{AC}_\omega(\mathbb{R}) + V = L(\mathbb{R})$. *Suppose* $0 < \alpha < \delta_{\mathbb{R}}$. *Then there is a surjection* $\pi : \omega^\omega \to L_\alpha(\mathbb{R})$ *such that* $\{(x, y) \mid \pi(x) \in \pi(y)\}$ *is* $\underset{\sim}{\Delta}{}^2_1$. *Thus,* $\delta_{\mathbb{R}} \leqslant \underset{\sim}{\delta}{}^2_1$.

Proof. Fix α such that $0 < \alpha < \delta_{\mathbb{R}}$. By the minimality of $\delta_{\mathbb{R}}$,

$$L_\alpha(\mathbb{R}) \not\prec_1^{\mathbb{R}\cup\{\mathbb{R}\}} L(\mathbb{R}).$$

So there is an $a \in \omega^\omega$ and a Σ_1 formula φ such that if β is the least ordinal such that $L_\beta(\mathbb{R}) \models \varphi[a]$ then $\beta > \alpha$. Let γ be least such that $\gamma > \beta > \alpha$ and $L_\gamma(\mathbb{R}) \models \mathrm{T}_0$ (which exists by Lemma 2.22). So γ is least such that $L_\gamma(\mathbb{R}) \models \mathrm{T}_0 + \varphi[a]$ and, by Lemma 2.25, there is a surjection $\pi : \omega^\omega \to L_\gamma(\mathbb{R})$ which is definable over $L_{\gamma+1}(\mathbb{R})$ with the parameters $\mathbb{R}$ and a. Let $A = \{(x, y) \mid \pi(x) \in \pi(y)\}$. Let ψ_1 and ψ_2 be the formulas defining A and $(\omega^\omega)^2 \smallsetminus A$ over $L_{\gamma+1}(\mathbb{R})$, respectively. By absoluteness,

$$\begin{array}{lll} (x,y) \in A & \text{iff} & \text{there is a transitive set } M \text{ such that} \\ & & \omega^\omega \subseteq M, \\ & & \text{there is a surjection } \pi : \omega^\omega \to M, \text{ and} \\ & & M \models \mathrm{T}_0 + \exists\gamma\,(L_\gamma(\mathbb{R}) \models \mathrm{T}_0 + \varphi[a] \text{ and} \\ & & L_{\gamma+1}(\mathbb{R}) \models \psi_1[x,y]). \end{array}$$

This shows, by our model-theoretic characterization of $\underset{\sim}{\Sigma}{}^2_1$ that A is $\underset{\sim}{\Sigma}{}^2_1$. A similar argument shows that $(\omega^\omega)^2 \smallsetminus A$ is $\underset{\sim}{\Sigma}{}^2_1$. Finally, the desired map can be extracted from π. ⊣

We now use a universal $\underset{\sim}{\Sigma}{}^2_1$ set to knit together all of these "$\underset{\sim}{\Delta}{}^2_1$ projection maps".

2.27 Lemma. *Assume* $\mathrm{ZF} + \mathrm{AC}_\omega(\mathbb{R}) + V = L(\mathbb{R})$. *Then there is a partial surjection* $\rho : \omega^\omega \to L_{\delta_{\mathbb{R}}}(\mathbb{R})$ *such that* $\mathrm{dom}(\rho)$ *and* ρ *are both* Σ_1*-definable over* $L_{\delta_{\mathbb{R}}}(\mathbb{R})$ *with the parameter* $\mathbb{R}$. *Thus,* $L_{\delta_{\mathbb{R}}}(\mathbb{R}) \prec_1 L(\mathbb{R})$ *and hence* $\delta_F \leqslant \delta_R$.

Proof. Let U be a Σ^2_1 subset of $\omega^\omega \times \omega^\omega \times \omega^\omega$ that is universal for $\underset{\sim}{\Sigma}{}^2_1$ subsets of $\omega^\omega \times \omega^\omega$, that is, such that for each $\underset{\sim}{\Sigma}{}^2_1$ subset $A \subseteq \omega^\omega \times \omega^\omega$ there is an $x \in \omega^\omega$ such that $A = U_x$ where by definition

$$U_x = \{(y, z) \in \omega^\omega \times \omega^\omega \mid (x, y, z) \in U\}.$$

We define ρ using U. For the domain of ρ we take

$$\begin{aligned} \mathrm{dom}(\rho) = \{x \in \omega^\omega \mid \exists\alpha \in \mathrm{On}\,(&L_\alpha(\mathbb{R}) \models \mathrm{T}_0 \text{ and} \\ &L_\alpha(\mathbb{R}) \models U_{(x)_0} = (\omega^\omega \times \omega^\omega) \smallsetminus U_{(x)_1})\}. \end{aligned}$$

Notice that $\mathrm{dom}(\rho)$ is $\Sigma_1(L(\mathbb{R}), \{\mathbb{R}\})$ and hence $\Sigma_1(L_{\delta_{\mathbb{R}}}(\mathbb{R}), \{\mathbb{R}\})$. Notice also that in general if $L_\alpha(\mathbb{R}) \models \mathrm{T}_0$ then

$$(U_{(x)_0})^{L_\alpha(\mathbb{R})} \subseteq U_{(x)_0}$$

and thus, if in addition,

$$(U_{(x)_0})^{L_\alpha(\mathbb{R})} = (\omega^\omega \times \omega^\omega) \smallsetminus (U_{(x)_1})^{L_\alpha(\mathbb{R})},$$

then,

$$(U_{(x)_0})^{L_\alpha(\mathbb{R})} = U_{(x)_0}.$$

We can now define ρ as follows: Suppose $x \in \mathrm{dom}(\rho)$. Let $\alpha(x)$ be the least α as in the definition of $\mathrm{dom}(\rho)$. If there is an ordinal η and a surjection $\pi : \omega^\omega \to L_\eta(\mathbb{R})$ such that

$$\{(t_1, t_2) \mid \pi(t_1) \in \pi(t_2)\} = (U_{(x)_0})^{L_{\alpha(x)}(\mathbb{R})}$$

then let $\rho(x) = \pi((x)_2)$; otherwise let $\rho(x) = \varnothing$. Notice that the map ρ is $\Sigma_1(L(\mathbb{R}), \{\mathbb{R}\})$ and hence $\Sigma_1(L_{\delta_\mathbb{R}}(\mathbb{R}), \{\mathbb{R}\})$. By Lemma 2.26, $\rho : \mathrm{dom}(\rho) \to L_{\delta_\mathbb{R}}(\mathbb{R})$ is a surjection.

For the last part of the proof recall that by definition $L_{\delta_\mathbb{R}}(\mathbb{R}) \prec_1^{\mathbb{R}\cup\{\mathbb{R}\}} L(\mathbb{R})$. The partial surjection $\rho : \omega^\omega \to L_{\delta_\mathbb{R}}(\mathbb{R})$ allows us to reduce arbitrary parameters in $L_{\delta_\mathbb{R}}(\mathbb{R})$ to parameters in ω^ω. ⊣

2.28 Theorem. *Assume* $\mathrm{ZF} + \mathrm{AC}_\omega(\mathbb{R}) + V = L(\mathbb{R})$. $\underset{\sim}{\delta}^2_1 = \delta_\mathbb{R} = \delta_F$.

Proof. We have $\delta_\mathbb{R} \leqslant \underset{\sim}{\delta}^2_1$ (by Lemma 2.26), $\delta_\mathbb{R} \leqslant \delta_F$ (by definition), and $\delta_F \leqslant \delta_\mathbb{R}$ (by Lemma 2.27). It remains to show $\underset{\sim}{\delta}^2_1 \leqslant \delta_\mathbb{R}$.

Suppose $\gamma < \underset{\sim}{\delta}^2_1$. We wish to show that $\gamma < \delta_\mathbb{R}$. Let $\pi : \omega^\omega \to \alpha$ be a surjection such that $A = \{(x, y) \mid \pi(x) < \pi(y)\}$ is $\underset{\sim}{\Delta}^2_1$. Using the notation from the previous proof let x be such that

$$U_{(x)_0} = A \quad \text{and} \quad U_{(x)_1} = (\omega^\omega \times \omega^\omega) \smallsetminus A.$$

There is an ordinal α such that $L_\alpha(\mathbb{R}) \models \mathrm{T}_0$ and

$$(U_{(x)_0})^{L_\alpha(\mathbb{R})} = (\omega^\omega \times \omega^\omega) \smallsetminus (U_{(x)_1})^{L_\alpha(\mathbb{R})}.$$

Since

$$L_{\delta_\mathbb{R}}(\mathbb{R}) \prec_1^{\mathbb{R}\cup\{\mathbb{R}\}} L(\mathbb{R}),$$

the least such ordinal, $\alpha(x)$, is less than $\delta_\mathbb{R}$. Thus,

$$(U_{(x)_0})^{L_{\alpha(x)}(\mathbb{R})} = A.$$

Finally, since $L_{\alpha(x)}(\mathbb{R}) \models \mathrm{T}_0$, this model can compute the ordertype, γ, of A. Thus, $\gamma < \alpha(x) < \delta_\mathbb{R}$. ⊣

2.29 Remark. Although we will not need these facts it is worthwhile to note that the above proofs show

(1) $(\underset{\sim}{\Sigma}^2_1)^{L(\mathbb{R})} = \underset{\sim}{\Sigma}_1(L_{\underset{\sim}{\delta}^2_1}(\mathbb{R})) \cap \mathscr{P}(\omega^\omega)$,

(2) $(\underset{\sim}{\Delta}^2_1)^{L(\mathbb{R})} = L_{\underset{\sim}{\delta}^2_1}(\mathbb{R}) \cap \mathscr{P}(\omega^\omega)$, and

(3) (Solovay's Basis Theorem) if $L(\mathbb{R}) \models \exists X\, \varphi(X)$ where φ is $\underset{\sim}{\Sigma}^2_1$ then $L(\mathbb{R}) \models \exists X \in \underset{\sim}{\Delta}^2_1\ \varphi(X)$.

2.5. Measurability of the Least Stable

We are now in a position to show that under ZF + DC + AD,

$$\mathrm{HOD}^{L(\mathbb{R})} \models (\underset{\sim}{\delta}^2_1)^{L(\mathbb{R})} \text{ is a measurable cardinal.}$$

This serves as a warm-up to Sect. 4, where we will show that under ZF + DC + AD,

$$\mathrm{HOD}^{L(\mathbb{R})} \models (\underset{\sim}{\delta}^2_1)^{L(\mathbb{R})} \text{ is } \lambda\text{-strong,}$$

for each $\lambda < \Theta^{L(\mathbb{R})}$, and, in fact, that

$$\mathrm{HOD}^{L(\mathbb{R})} \models \Theta^{L(\mathbb{R})} \text{ is a Woodin cardinal.}$$

The proof that we give in Sect. 4 will show that DC can be eliminated from the result of the present section.

First we need an analogue U of WO that enables us to encode (unboundedly many) ordinals below $\underset{\sim}{\delta}^2_1$ and is accompanied by the boundedness and coding theorems required to push the above proof through for $\underset{\sim}{\delta}^2_1$. The following works: Let U be a Σ^2_1 subset of $\omega^\omega \times \omega^\omega$ that is universal for $\underset{\sim}{\Sigma}^2_1$ subsets of ω^ω. For $y \in \omega^\omega$ we let $U_y = \{z \in \omega^\omega \mid (y,z) \in U\}$. For $(y,z) \in U$, let $\Theta_{(y,z)}$ be least such that

$$L_{\Theta_{(y,z)}}(\mathbb{R}) \models \mathrm{T}_0 \quad \text{and} \quad (y,z) \in U^{L_{\Theta_{(y,z)}}(\mathbb{R})}.$$

Let $\delta_{(y,z)} = (\underset{\sim}{\delta}^2_1)^{L_{\Theta_{(y,z)}}(\mathbb{R})}$. These ordinals are the analogues of α_x from the proof that ω_1 is measurable. For notational convenience we will routinely use our recursive bijection from $\omega^\omega \times \omega^\omega$ to ω^ω to identify pairs of reals (y,z) with single reals $x = \langle y,z\rangle$. Thus we will write Θ_x and δ_x instead of $\Theta_{(y,z)}$ and $\delta_{(y,z)}$.

2.30 Lemma. *Assume* ZF + $\mathrm{AC}_\omega(\mathbb{R})$ + $V = L(\mathbb{R})$. $\{\delta_x \mid x \in U\}$ *is unbounded in* $\underset{\sim}{\delta}^2_1$.

Proof. Let $\alpha < \underset{\sim}{\delta}^2_1$. Let A be (the set of reals coding) a $\underset{\sim}{\Delta}^2_1$ prewellordering of length greater than α. Let $y, z \in \omega^\omega$ be such that $U_y = A$ and $U_z = \omega^\omega \smallsetminus A$. So $L(\mathbb{R}) \models$ "$U_y = \omega^\omega \smallsetminus U_z$". Since $\underset{\sim}{\delta}^2_1$ is the least stable, there is a $\beta < \underset{\sim}{\delta}^2_1$ such that $L_\beta(\mathbb{R}) \models$ "$U_y = \omega^\omega \smallsetminus U_z$" and since $(U_y)^{L_\beta(\mathbb{R})} \subseteq A$ and $(U_z)^{L_\beta(\mathbb{R})} \subseteq \omega^\omega \smallsetminus A$ we have that $A = (U_y)^{L_\beta(\mathbb{R})}$. Now, letting $x \in U \smallsetminus U^{L_\beta(\mathbb{R})}$ and $\gamma < \underset{\sim}{\delta}^2_1$ be such that $L_\gamma(\mathbb{R}) \models \mathrm{T}_0$ + "$x \in U$", we have that $\alpha < \delta_x$ since $A \in L_\gamma(\mathbb{R})$ and $L_\gamma(\mathbb{R})$ can compute the ordertype of A. ⊣

In analogy with WO, for $x \in U$ let $U_{\delta_x} = \{y \in U \mid \delta_y = \delta_x\}$, $U_{<\delta_x} = \{y \in U \mid \delta_y < \delta_x\}$ and so on.

2.31 Lemma ($\underset{\sim}{\Delta}^2_1$-Boundedness, Moschovakis). *Assume* ZF + $\mathrm{AC}_\omega(\mathbb{R})$ + $V = L(\mathbb{R})$. *Suppose* $X \subseteq U$ *and* X *is* $\underset{\sim}{\Delta}^2_1$. *Then there exists an* $x \in U$ *such that such that* $X \subseteq U_{<\delta_x}$.

Proof. Let $y, z \in \omega^\omega$ be such that $U_y = X$ and $U_z = \omega^\omega \setminus X$. (Notice that we are identifying X with the set of reals that recursively encodes it.) As above, there is a $\beta_0 < \underset{\sim}{\delta}^2_1$ such that $X = (U_y)^{L_{\beta_0}(\mathbb{R})}$. Choose γ such that $\beta_0 < \gamma < \underset{\sim}{\delta}^2_1$ and $L_\gamma(\mathbb{R})$ satisfies T_0. Then for all $z \in X$, $\delta_z < \gamma$. Now choose $x \in U$ such that $\delta_x > \gamma$. ⊣

2.32 Lemma (Coding; Moschovakis). *Assume* ZF + AD. *Suppose* $Z \subseteq U \times \omega^\omega$. *Then there exists a* $Z^* \subseteq Z$ *such that for all* $x \in U$

(i) $Z^* \cap (U_{\delta_x} \times \omega^\omega) \neq \varnothing$ *iff* $Z \cap (U_{\delta_x} \times \omega^\omega) \neq \varnothing$,

(ii) $Z^* \cap (U_{\leqslant \delta_x} \times \omega^\omega)$ *is* $\underset{\sim}{\Delta}^2_1$.

This lemma will follow from the more general coding lemmas of the next section. See Remark 3.6.

2.33 Theorem (Moschovakis). *Assume* ZF + DC + AD. *Then*

$$L(\mathbb{R}) \models \textit{There is a normal ultrafilter on } \underset{\sim}{\delta}^2_1.$$

Proof. Work in $L(\mathbb{R})$. The proof is virtually a carbon copy of the proof for ω_1. One just replaces $\underset{\sim}{\delta}^1_1$, WO, α_x, and $\underset{\sim}{\Sigma}^1_1$ with $\underset{\sim}{\delta}^2_1$, U, δ_x, and $\underset{\sim}{\Delta}^2_1$, respectively. For completeness we include some of the details, noting the main changes.

For $S \subseteq \underset{\sim}{\delta}^2_1$, let $G(S)$ be the game

I	$x(0)$		$x(1)$		$x(2)$		$\ldots$
II		$y(0)$		$y(1)$		$\ldots$	

with the following rules: Rule 1: For all $i < \omega$, $(x)_i, (y)_i \in U$. If Rule 1 is violated then, letting i be least such that either $(x)_i \notin U$ or $(y)_i \notin U$, I wins if $(x)_i \in U$; otherwise II wins. Now suppose Rule 1 is satisfied. Rule 2: $\delta_{(x)_0} < \delta_{(y)_0} < \delta_{(x)_1} < \delta_{(y)_1} < \cdots$. The first failure defines who wins as above. If both rules are satisfied then I wins iff $\sup_{i \in \omega} \delta_{(x)_i} \in S$.

Now let

$$\mu = \{S \subseteq \underset{\sim}{\delta}^2_1 \mid \text{I wins } G(S)\}.$$

Notice that as before (using $\underset{\sim}{\Delta}^2_1$-boundedness) if I has a winning strategy in $G(S)$ then S contains a set C which is unbounded and closed under ω-sequences. The proof that U is an ultrafilter is exactly as before. To see that it is $\underset{\sim}{\delta}^2_1$-complete and normal one uses the new versions of Boundedness and Coding. We note the minor changes in the proof of normality.

Assume for contradiction that $f : \underset{\sim}{\delta}^2_1 \to \underset{\sim}{\delta}^2_1$ and that there is no $\alpha < \underset{\sim}{\delta}^2_1$ such that $\{\xi \mid f(\xi) = \alpha\} \in \mu$ or, equivalently (by AD) that for all $\alpha < \underset{\sim}{\delta}^2_1$,

$$S_\alpha = \{\xi \mid f(\xi) \neq \alpha\} \in \mu.$$

Let $\langle \delta_\alpha \mid \alpha < \underset{\sim}{\delta}^2_1 \rangle$ enumerate $\langle \delta_x \mid x \in U \rangle$. Here we are appealing to the fact that $\underset{\sim}{\delta}^2_1$ is regular, which can be shown using the Coding Lemma (see [9, p. 433]). In analogy with WO, for $\alpha < \beta < \underset{\sim}{\delta}^2_1$, let $U_\alpha = \{x \in U \mid \delta_x = \delta_\alpha\}$,

$U_{(\alpha,\beta]} = \{x \in U \mid \delta_\alpha < \delta_x \leqslant \delta_\beta\}$ and likewise for other intervals. Let $\leqslant_U$ be the associated prewellordering.

As before, our strategy is to inductively define

(1.1) an increasing sequence $\langle \eta_i \mid i < \omega\rangle$ of ordinals with supremum η,

(1.2) a sequence of collections of strategies $\langle X_i \mid i < \omega\rangle$ where X_i contains winning strategies for I in games $G(S_\alpha)$ for $\alpha \in [\eta_{i-1}, \eta_i)$, where $\eta_{-1} = 0$, and

(1.3) a sequence $\langle y_i \mid i < \omega\rangle$ of plays such that y_i is legal for II against any $\sigma \in X_i$ and $\sup_{j<\omega} \delta_{(y_i)_j} = \eta$.

Thus the y_i will collectively witness that $f(\eta) \neq \alpha$ for any $\alpha < \eta$, which contradicts our assumption that $f(\eta) < \eta$. The key difference is that in our present case we need the Coding Lemma since there are too many games. Let

$$\begin{aligned} Z = \{(x,\sigma) \mid x \in U &\text{ and } \sigma \text{ is a winning strategy for I} \\ &\text{in } G(S_\alpha) \text{ where } \alpha \text{ is such that } \delta_\alpha = \delta_x\} \end{aligned}$$

and, by our new Coding Lemma, let $Z^* \subseteq Z$ be such that for all $\alpha < \utilde{\delta}^2_1$,

(2.1) $Z^* \cap (U_\alpha \times \omega^\omega) \neq \varnothing$ iff $Z \cap (U_\alpha \times \omega^\omega) \neq \varnothing$

(2.2) $Z^* \cap (U_{\leqslant\alpha} \times \omega^\omega)$ is $\utilde{\Delta}^2_1$.

This puts us in a position to apply $\utilde{\Delta}^2_1$-boundedness.

For the first step let

$$\begin{aligned} \eta_0 &= \text{some ordinal } \eta \text{ such that } \eta < \utilde{\delta}^2_1 \\ X_0 &= \operatorname{proj}_2\left(Z^* \cap (U_{[0,\eta_0)} \times \omega^\omega)\right) \\ Y_0 &= \left\{((\sigma * y)_I)_0 \mid \sigma \in X_0 \wedge y \in \omega^\omega\right\} \\ z_0 &= \text{some real } z \text{ such that } Y_0 \subseteq U_{<\delta_z}. \end{aligned}$$

So X_0 is a collection of strategies for games $G(S_\alpha)$ where $\alpha < \eta_0$. Since these strategies are winning for I the set Y_0 is contained in U. Furthermore, Y_0 is $\utilde{\Delta}^2_1$ and hence has a bound δ_{z_0}. For the induction step let

$$\begin{aligned} \eta_{n+1} &= \text{some ordinal } \eta \text{ such that } \eta_n, \delta_{z_n} < \eta < \utilde{\delta}^2_1 \\ X_{n+1} &= \operatorname{proj}_2\left(Z^* \cap (U_{[\eta_n,\eta_{n+1})} \times \omega^\omega)\right) \\ Y_{n+1} &= \left\{((\sigma * y)_I)_{n+1} \mid \sigma \in X_0,\ y \in \omega^\omega \text{ such that } \forall i \leqslant n\ (y)_i = z_i\right\} \\ &\quad \cup \left\{((\sigma * y)_I)_n \mid \sigma \in X_1,\ y \in \omega^\omega \text{ such that } \forall i \leqslant n-1\ (y)_i = z_{i+1}\right\} \\ &\quad\ \ \vdots \\ &\quad \cup \left\{((\sigma * y)_I)_0 \mid \sigma \in X_{n+1},\ y \in \omega^\omega\right\} \\ z_{n+1} &= \text{some real } z \text{ such that } Y_{n+1} \subseteq U_{<\delta_z}. \end{aligned}$$

Finally, for $k < \omega$, let y_k be such that $(y_k)_i = z_{i+k}$ for all $i < \omega$. Since each of these reals contains a tail of the z_i's, if $\eta = \sup_{n<\omega} \eta_n$, then

$$\sup_{i<\omega} \left(\delta_{(y_k)_i}\right) = \eta$$

for all $k < \omega$. Furthermore, y_k is a legal play for II against any $\sigma \in X_k$, as witnessed by the $(k+1)$st components of Y_n with $n \geqslant k$. Since each $\sigma \in X_k$ is a winning strategy for I, y_k witnesses that $\eta \in S_\alpha$ for $\alpha \in [\eta_{k-1}, \eta_k)$, i.e. that $f(\eta) \neq \alpha$ for any $\alpha \in [\eta_{k-1}, \eta_k)$. So collectively the y_k guarantee that $f(\eta) \neq \alpha$ for any $\alpha < \eta$, which contradicts the fact that $f(\eta) < \eta$. ⊣

2.34 Corollary. *Assume* $\mathrm{ZF} + \mathrm{DC} + \mathrm{AD}$. *Then*

$$\mathrm{HOD}^{L(\mathbb{R})} \models (\underset{\sim}{\delta}^2_1)^{L(\mathbb{R})} \textit{ is a measurable cardinal.}$$

The above proof uses DC. However, as we shall see in Sect. 4.1 the theorem can be proved in $\mathrm{ZF} + \mathrm{AD}$. See Lemma 4.7.

The Coding Lemma was used to enable II to "collect together" the relevant strategies and then the $\underset{\sim}{\Delta}^2_1$-boundedness lemma was used to enable II to "take control of the ordinal played" in all such games by devising a play that is legal against all of the relevant strategies and (in each case) has the same fixed ordinal as output. This technique is central in what follows. It is important to note, however, that the above ultrafilter (and, more generally, ultrafilters obtained by such a "sup" game) concentrates on points of cofinality ω. Later we will use a slightly different game, where the role of the $\underset{\sim}{\Delta}^2_1$-boundedness lemma will be played by a certain reflection phenomenon. Before turning to this we prove the coding lemmas we shall need.

3. Coding

In the Basic Coding Lemma we constructed selectors relative to WO; we now do so relative to more general prewellorderings.

3.1. Coding Lemma

We begin by fixing some notation. For $P \subseteq \omega^\omega$, the notion of a $\underset{\sim}{\Sigma}^1_1(P)$ set is defined exactly like that of a $\underset{\sim}{\Sigma}^1_1$ set only now we allow reference to P and to $\omega^\omega \smallsetminus P$. In model-theoretic terms, $X \subseteq \omega^\omega$ is $\underset{\sim}{\Sigma}^1_1(P)$ iff there is a formula φ and a real z such that

$$\begin{aligned} X = \big\{ y \in \omega^\omega \mid {} & \text{there is an } \omega\text{-model } M \text{ such that} \\ & y, z, P \cap M \in M \text{ and } M \models \mathrm{T}_0 + \varphi[y, z, P \cap M] \big\}. \end{aligned}$$

The notion of a $\underset{\sim}{\Sigma}^1_1(P, P')$ set is defined in the same way, only now reference to both P and P' and their complements is allowed. The lightface versions of these notions and the versions involving $P \subseteq (\omega^\omega)^n$ are all defined in the obvious way.

Let $U^{(n)}(P)$ be a $\Sigma^1_1(P)$ subset of $(\omega^\omega)^{n+1}$ that is universal for $\utilde{\Sigma}^1_1(P)$ subsets of $(\omega^\omega)^n$, that is, such that for each $\utilde{\Sigma}^1_1(P)$ set $A \subseteq (\omega^\omega)^n$ there is an $e \in \omega^\omega$ such that $A = U^{(n)}_e(P) = \{y \in (\omega^\omega)^n \mid (e,y) \in U^{(n)}(P)\}$. We do this in such a way that the same formula is used, so that the definition is uniform in P. Likewise, for $U^{(n)}(P,P')$ etc. (The existence of such a universal set $U^{(n)}(P)$ is guaranteed by the fact that the pointclass in question, namely, $\utilde{\Sigma}^1_1(P)$, is ω-parameterized and closed under recursive substitution. See [9], 3E.4 on p. 160 and especially 3H.1 on p. 183. We further assume that the universal sets are "good" in the sense of [9], p. 185 and we are justified in doing so by [9], 3H.1. A particular component of this assumption is that our universal sets satisfy the *s-m-n*-theorem (uniformly in P (or P and P')). See Jackson's chapter in this Handbook for further details.)

3.1 Theorem (Recursion Theorem; Kleene). *Suppose $f : \omega^\omega \to \omega^\omega$ is $\utilde{\Sigma}^1_1(P)$. Then there is an $e \in \omega^\omega$ such that*

$$U^{(2)}_e(P) = U^{(2)}_{f(e)}(P).$$

Proof. For $a \in \omega^\omega$, let

$$T_a = \{(b,c) \mid (a,a,b,c) \in U^{(3)}(P)\}.$$

Let $d : \omega^\omega \to \omega^\omega$ be Σ^1_1 such that $T_a = U^{(2)}_{d(a)}(P)$. (The function d comes from the *s-m-n*-theorem. In fact, $d(a) = s(a,a)$ (in the notation of Jackson's chapter) and d is continuous.) Let

$$Y = \{(a,b,c) \mid (b,c) \in U^{(2)}_{f(d(a))}(P)\}$$

and let a_0 be such that $Y = U^{(3)}_{a_0}(P)$. Notice that Y is $\utilde{\Sigma}^1_1(P)$ using the parameter for Y (as can readily be checked using the model-theoretic characterization of $\utilde{\Sigma}^1_1(P)$). We have

$$\begin{aligned} (b,c) \in U^{(2)}_{d(a_0)}(P) \quad &\text{iff} \quad (a_0,a_0,b,c) \in U^{(3)}(P) \\ &\text{iff} \quad (a_0,b,c) \in U^{(3)}_{a_0}(P) = Y \\ &\text{iff} \quad (b,c) \in U^{(2)}_{f(d(a_0))}(P) \end{aligned}$$

and so $d(a_0)$ is as desired. ⊣

3.2 Theorem (Coding lemma; Moschovakis). *Assume* ZF + AD. *Suppose $X \subseteq \omega^\omega$ and $\pi : X \to$* On. *Suppose $Z \subseteq X \times \omega^\omega$. Then there is an $e \in \omega^\omega$ such that*

(1) $U^{(2)}_e(Q) \subseteq Z$ and

(2) for all $a \in X$, $U^{(2)}_e(Q) \cap (Q_a \times \omega^\omega) \neq \varnothing$ iff $Z \cap (Q_a \times \omega^\omega) \neq \varnothing$,

where $Q = \{\langle a,b\rangle \mid \pi(a) \leqslant \pi(b)\}$.

Proof. Assume toward a contradiction that there is no such e. Consider the set G of reals e for which (1) in the statement of the theorem is satisfied:

$$G = \{e \in \omega^\omega \mid U_e^{(2)}(Q) \subseteq Z\}.$$

So, for each $e \in G$, (2) in the statement of the theorem fails for some $a \in X$. Let α_e be the least α such that (2) fails at the αth-section:

$$\alpha_e = \min\{\alpha \mid \exists a \in X \ (\pi(a) = \alpha \wedge U_e^{(2)}(Q) \cap (Q_a \times \omega^\omega) = \varnothing \\ \wedge Z \cap (Q_a \times \omega^\omega) \neq \varnothing)\}.$$

Now play the game

$$\begin{array}{lccccccc} \mathrm{I} & x(0) & & x(1) & & x(2) & & \ldots \\ \mathrm{II} & & y(0) & & y(1) & & \ldots & \end{array}$$

where I wins if $x \in G$ and either $y \notin G$ or $\alpha_x \geqslant \alpha_y$. Notice that by our assumption that there is no index e as in the statement of the theorem, neither I nor II can win a round of this game by playing a selector. The best they can do is play "partial" selectors. For a play $e \in G$, let us call $U_e^{(2)}(Q) \cap (Q_{<\alpha_e} \times \omega^\omega)$ the *partial* selector played. Using this terminology we can restate the winning conditions by saying that II wins either by ensuring that I does not play a subset of Z or, failing this, by playing a partial selector which is *longer* than that played by I.

We will arrive at a contradiction by showing that neither player can win this game.

Claim 1. *Player I does not have a winning strategy.*

Proof. Suppose toward a contradiction that σ is a winning strategy for I. As in the proof of the Basic Coding Lemma our strategy will be to "bound" all of I's plays and then use this bound to construct a play e^* which defeats σ.

Since σ is a winning strategy,

$$U^{(2)}_{(\sigma * y)_I}(Q) \subseteq Z$$

for all $y \in \omega^\omega$. Let e_σ be such that

$$U^{(2)}_{e_\sigma}(Q) = \bigcup_{y \in \omega^\omega} U^{(2)}_{(\sigma * y)_I}(Q).$$

By assumption, $U^{(2)}_{e_\sigma}(Q)$ is not a selector. So α_{e_σ} exists. Since for all $y \in \omega^\omega$, $\alpha_{e_\sigma} \geqslant \alpha_{(\sigma * y)_I}$, we can take α_{e_σ} as our bound. Choose $a \in X$ such that $\pi(a) = \alpha_{e_\sigma}$. Pick $(x_1, x_2) \in Z \cap (Q_a \times \omega^\omega)$. Let e^* be such that

$$U^{(2)}_{e^*}(Q) = U^{(2)}_{e_\sigma} \cup \{(x_1, x_2)\}.$$

So $e^* \in G$. But $\alpha_{e_\sigma} < \alpha_{e^*}$. In summary, we have that for all $y \in \omega^\omega$, $\alpha_{(\sigma * y)_I} \leqslant \alpha_{e_\sigma} < \alpha_{e^*}$. Thus, by playing e^*, II defeats σ. ⊣

Claim 2. *Player II does not have a winning strategy.*

Proof. Assume toward a contradiction that τ is a winning strategy for II. We shall show that τ yields a selector for Z; in other words, it yields an e^* such that

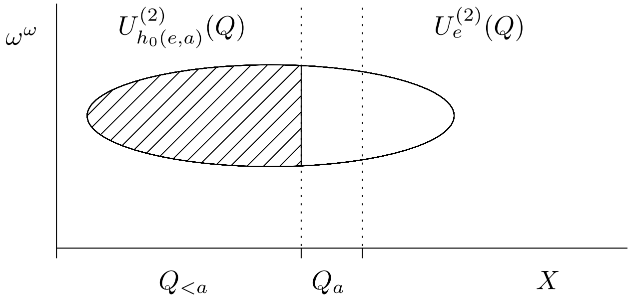
(1) $U^{(2)}_{e^*}(Q) \subseteq Z$ and

(2) for all $a \in X$, $U^{(2)}_{e^*}(Q) \cap (Q_a \times \omega^\omega) \neq \varnothing$ iff $Z \cap (Q_a \times \omega^\omega) \neq \varnothing$.

Choose $h_0 : \omega^\omega \times X \to \omega^\omega$ such that h_0 is $\Sigma^1_1(Q)$ and for all $e, a \in \omega^\omega$,

$$U^{(2)}_{h_0(e,a)}(Q) = U^{(2)}_e(Q) \cap (Q_{<a} \times \omega^\omega).$$

Thus, the set coded by $h_0(e,a)$ is the result of taking the initial segment given by a of the set coded by e.



Choose $h_1 : \omega^\omega \to \omega^\omega$ such that h_1 is $\underset{\sim}{\Sigma}^1_1(Q)$ and for all $e \in \omega^\omega$,

$$U^{(2)}_{h_1(e)}(Q) = \bigcup_{a \in X} \big(U^{(2)}_{(h_0(e,a)*\tau)_{II}}(Q) \cap (Q_a \times \omega^\omega)\big).$$

Thus, the set coded by $h_1(e)$ is the union of all "a-sections" of sets played by II in response to "$<a$-initial segments" of the set coded by e.

By the recursion theorem there is a fixed point for h_1; that is, there is an e^* such that

$$U^{(2)}_{e^*}(Q) = U^{(2)}_{h_1(e^*)}(Q).$$

This set has the following closure property: if I plays an initial segment of it then II responds with a subset of it. We shall see that $e^* \in G$. Moreover, if $U^{(2)}_{e^*}(Q)$ is *not* a selector then having I play the largest initial segment which is a partial selector, II responds with a *larger* selector, which is a contradiction. Thus, e^* codes a selector. Here are the details.

Subclaim 1. $e^* \in G$.

Proof. Suppose for contradiction that $U^{(2)}_{e^*}(Q) \setminus Z \neq \varnothing$. Choose $(x_1, x_2) \in U^{(2)}_{e^*}(Q) \setminus Z$ with $\pi(x_1)$ minimal. So

$$\begin{aligned}(x_1, x_2) \in U^{(2)}_{e^*}(Q) &= U^{(2)}_{h_1(e^*)}(Q) \\ &= \bigcup_{a \in X} \big(U^{(2)}_{(h_0(e^*,a)*\tau)_{II}}(Q) \cap (Q_a \times \omega^\omega)\big).\end{aligned}$$

Fix $a \in X$ such that

$$(x_1, x_2) \in U^{(2)}_{(h_0(e^*,a)*\tau)_{II}}(Q) \cap (Q_a \times \omega^\omega).$$

The key point is that $h_0(e^*, a) \in G$ since we chose (x_1, x_2) with $\pi(x_1) = \pi(a)$ minimal. Thus, since τ is a winning strategy, $(h_0(e^*, a) * \tau)_{II} \in G$, and so $(x_1, x_2) \in Z$, which is a contradiction. ⊣

Subclaim 2. *α_{e^*} does not exist.*

Proof. Suppose for contradiction that α_{e^*} exists. Let $a \in X$ be such that $\pi(a) = \alpha_{e^*}$. Thus $h_0(e^*, a) \in G$ and $\alpha_{h_0(e^*,a)} = \alpha_{e^*}$. Since τ is a winning strategy for II,

$$\alpha_{(h_0(e^*,a)*\tau)_{II}} > \alpha_{h_0(e^*,a)} = \alpha_{e^*},$$

which is impossible since

$$U^{(2)}_{(h_0(e^*,a)*\tau)_{II}}(Q) \subseteq U^{(2)}_{e^*}(Q).$$

Thus α_{e^*} does not exist. ⊣

Hence e^* is the code for a selector. ⊣

This completes the proof of the Coding Lemma. ⊣

3.2. Uniform Coding Lemma

We shall need a uniform version of the above theorem. The version we prove is different than that which appears in the literature [6]. We shall need the following uniform version of the recursion theorem.

3.3 Theorem (Uniform Recursion Theorem; Kleene). *Suppose $f : \omega^\omega \to \omega^\omega$ is $\underset{\sim}{\Sigma}^1_1$. Then there is an $e \in \omega^\omega$ such that for all $P, P' \subseteq \omega^\omega$,*

$$U^{(2)}_e(P, P') = U^{(2)}_{f(e)}(P, P').$$

Proof. The proof is the same as before. The key point is that the definition of the fixed point $d(a_0)$ depends only on f and, of course, d, which is uniform in P, P'. ⊣

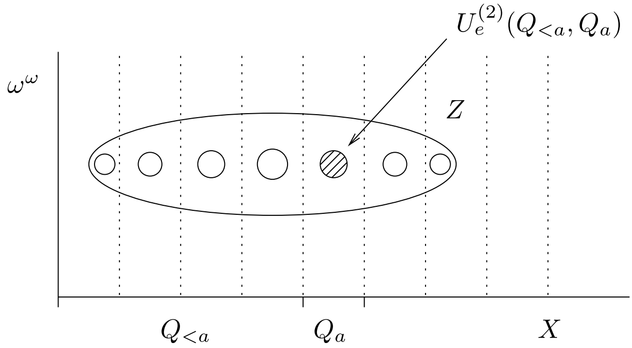
3.4 Theorem (Uniform Coding Lemma). *Assume* ZF + AD. *Suppose $X \subseteq \omega^\omega$ and $\pi : X \to \mathrm{On}$. Suppose $Z \subseteq X \times \omega^\omega$. Then there exists an $e \in \omega^\omega$ such that for all $a \in X$,*

(1) $U^{(2)}_e(Q_{<a}, Q_a) \subseteq Z \cap (Q_a \times \omega^\omega)$ and

(2) $U^{(2)}_e(Q_{<a}, Q_a) \neq \varnothing$ iff $Z \cap (Q_a \times \omega^\omega) \neq \varnothing$,

where $Q_{<a} = \{b \in X \mid \pi(b) < \pi(a)\}$ and $Q_a = \{b \in X \mid \pi(b) = \pi(a)\}$.

Proof. Here is the picture:



Think of e as providing a "rolling selector". The unshaded ellipse, Z, is sliced into sections $Z \cap (Q_a \times \omega^\omega)$. The Uniform Coding Lemma tells us that there is a simple selector $U_e^{(2)}(Q_{<a}, Q_a)$ for each of these sections which is uniform in the parameters $Q_{<a}$, Q_a; that is, there is a fixed e such that $U_e^{(2)}(Q_{<a}, Q_a)$ selects from $Z \cap (Q_a \times \omega^\omega)$, for all parameters $Q_{<a}$, Q_a.

Assume toward a contradiction that there is no such e. Consider the set G of reals e for which (1) in the statement of the theorem is satisfied:

$$G = \left\{e \in \omega^\omega \mid \forall a \in X \ \left(U_e^{(2)}(Q_{<a}, Q_a) \subseteq Z \cap (Q_a \times \omega^\omega)\right)\right\}.$$

So, for each $e \in G$, (2) in the statement of the theorem fails for some $a \in X$. Let α_e be least such that (2) fails at the α_eth-section:

$$\alpha_e = \min\left\{\alpha \mid \exists a \in X \ (\pi(a) = \alpha \wedge U_e^{(2)}(Q_{<a}, Q_a) = \varnothing \\ \wedge Z \cap (Q_a \times \omega^\omega) \neq \varnothing)\right\}.$$

Now play the game

$$\begin{array}{lccccccc} \mathrm{I} & x(0) & & x(1) & & x(2) & & \ldots \\ \mathrm{II} & & y(0) & & y(1) & & \ldots & \end{array}$$

where I wins if $x \in G$ and either $y \notin G$ or $\alpha_x \geqslant \alpha_y$.

Claim 1. *Player I does not have a winning strategy.*

Proof. Suppose toward a contradiction that σ is a winning strategy for I. As before our strategy is to "bound" all of I's plays and then use this bound to construct a play e^* for II which defeats σ.

The proof is as before except that we have to take care to choose a parameter e_σ that works uniformly for all parameters $Q_{<a}$, Q_a: Choose e_σ such that for all $P, P' \subseteq \omega^\omega$,

$$U_{e_\sigma}^{(2)}(P, P') = \bigcup\nolimits_{y \in \omega^\omega} U_{(\sigma * y)_I}^{(2)}(P, P').$$

In particular, e_σ is such that for all $a \in X$,

$$U^{(2)}_{e_\sigma}(Q_{<a}, Q_a) = \bigcup_{y \in \omega^\omega} U^{(2)}_{(\sigma * y)_I}(Q_{<a}, Q_a).$$

Since σ is a winning strategy for I, $(\sigma * y)_I \in G$ for all $y \in \omega^\omega$. Thus,

$$U^{(2)}_{e_\sigma}(Q_{<a}, Q_a) \subseteq Z \cap (Q_a \times \omega^\omega),$$

that is, $e_\sigma \in G$. Notice that for all $y \in \omega^\omega$, $\alpha_{(\sigma * y)_I} \leqslant \alpha_{e_\sigma}$. We have thus "bounded" all of I's plays. It remains to construct a defeating play e^* for II.

Choose $a \in X$ such that $\pi(a) = \alpha_{e_\sigma}$. So

$$U^{(2)}_{e_\sigma}(Q_{<a}, Q_a) = \varnothing$$

and

$$Z \cap (Q_a \times \omega^\omega) \neq \varnothing.$$

Pick $(x_1, x_2) \in Z \cap (Q_a \times \omega^\omega)$. Choose e^* such that for all $P, P' \subseteq \omega^\omega$,

$$U^{(2)}_{e^*}(P, P') = \begin{cases} U^{(2)}_{e_\sigma}(P, P') & \text{if } x_1 \notin P' \\ U^{(2)}_{e_\sigma}(P, P') \cup \{(x_1, x_2)\} & \text{if } x_1 \in P'. \end{cases}$$

In particular, e^* is such that for all $a' \in X$,

$$U^{(2)}_{e^*}(Q_{<a'}, Q_{a'}) = \begin{cases} U^{(2)}_{e_\sigma}(Q_{<a'}, Q_{a'}) & \text{if } x_1 \notin Q_{a'} \\ U^{(2)}_{e_\sigma}(Q_{<a'}, Q_{a'}) \cup \{(x_1, x_2)\} & \text{if } x_1 \in Q_{a'}. \end{cases}$$

So $e^* \in G$. But $\alpha_{e_\sigma} < \alpha_{e^*}$. In summary, we have that for all $y \in \omega^\omega$, $\alpha_{(\sigma * y)_I} \leqslant \alpha_{e_\sigma} < \alpha_{e^*}$. Thus, by playing e^*, II defeats σ. ⊣

Claim 2. *Player II does not have a winning strategy.*

Proof. Assume toward a contradiction that τ is a winning strategy for II. We seek e^* such that

$$\begin{aligned} &U^{(2)}_{e^*}(Q_{<a}, Q_a) \subseteq Z \cap (Q_a \times \omega^\omega) \quad \text{and} \\ &U^{(2)}_{e^*}(Q_{<a}, Q_a) \neq \varnothing \quad \text{iff} \quad Z \cap (Q_a \times \omega^\omega) \neq \varnothing. \end{aligned}$$

Choose $h_0 : \omega^\omega \times \omega^\omega \to \omega^\omega$ such that h_0 is Σ^1_1 and for all $e, z \in \omega^\omega$ and for all $P, P' \subseteq \omega^\omega$,

$$U^{(2)}_{h_0(e,z)}(P, P') = \begin{cases} U^{(2)}_e(P, P') & \text{if } z \notin P \cup P' \\ \varnothing & \text{if } z \in P \cup P'. \end{cases}$$

In particular, for all $a \in X$,

$$U^{(2)}_{h_0(e,z)}(Q_{<a}, Q_a) = \begin{cases} U^{(2)}_e(Q_{<a}, Q_a) & \text{if } z \notin Q_{<a} \cup Q_a \\ \varnothing & \text{if } z \in Q_{<a} \cup Q_a. \end{cases}$$

Notice that for $e \in \omega^\omega$ and $z \in X$, the set $U^{(2)}_{h_0(e,z)}(\cdot,\cdot)$ is such that it agrees with $U^{(2)}_e(\cdot,\cdot)$ for parameters $Q_{<a}, Q_a$ where $\pi(a) < \pi(z)$ and is empty for parameters $Q_{<a}, Q_a$ where $\pi(a) \geqslant \pi(z)$.

Choose $h_1 : \omega^\omega \to \omega^\omega$ such that h_1 is $\Sigma^1_1(\tau)$ and for all $e \in \omega^\omega$ and for all $P, P' \subseteq \omega^\omega$,

$$U^{(2)}_{h_1(e)}(P,P') = \bigcup\nolimits_{z \in P'} U^{(2)}_{(h_0(e,z)*\tau)_{II}}(P,P').$$

In particular, for all $a \in X$,

$$U^{(2)}_{h_1(e)}(Q_{<a},Q_a) = \bigcup\nolimits_{z \in Q_a} U^{(2)}_{(h_0(e,z)*\tau)_{II}}(Q_{<a},Q_a).$$

The idea is roughly this: Fix $e \in \omega^\omega$ and $z \in Q_a$. $U^{(2)}_{h_0(e,z)}(\cdot,\cdot)$ is such that it agrees with $U^{(2)}_e(\cdot,\cdot)$ for parameters $Q_{<\bar a}, Q_{\bar a}$ where $\pi(\bar a) < \pi(a)$ and is empty for parameters $Q_{<\bar a}, Q_{\bar a}$ where $\pi(\bar a) \geqslant \pi(a)$. Think of this as a play for I. In the case of interest, this play will be in G. And since τ is a winning strategy, II's response will be in G and when provided with parameters $Q_{<a}$,Q_a it will select from the a-component. $U_{h_1(e)}(Q_{<a},Q_a)$ is the union of these over $z \in Q_a$.

Let e^* be a fixed point for h_1, by Theorem 3.3.

Subclaim 1. *$e^* \in G$.*

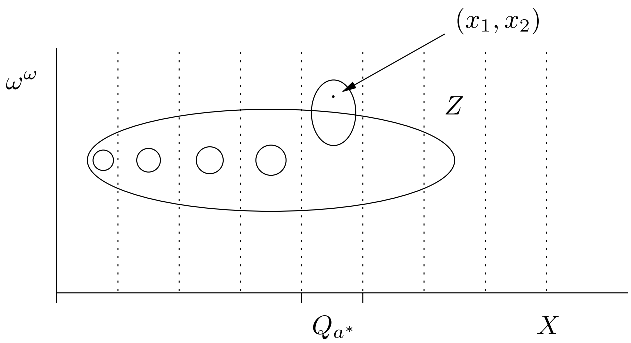
Proof. Suppose for contradiction that for some $a \in X$,

$$U^{(2)}_{e^*}(Q_{<a},Q_a) \smallsetminus (Z \cap (Q_a \times \omega^\omega)) \neq \varnothing.$$

Let a^* be an a where $\pi(a)$ is least such that

$$U^{(2)}_{e^*}(Q_{<a},Q_a) \smallsetminus (Z \cap (Q_a \times \omega^\omega)) \neq \varnothing.$$

Choose $(x_1,x_2) \in U^{(2)}_{e^*}(Q_{<a^*},Q_{a^*}) \smallsetminus (Z \cap (Q_{a^*} \times \omega^\omega))$.



So

$$\begin{aligned}(x_1,x_2) \in U^{(2)}_{e^*}(Q_{<a^*},Q_{a^*}) &= U^{(2)}_{h_1(e^*)}(Q_{<a^*},Q_{a^*}) \\ &= \bigcup\nolimits_{z \in Q_{a^*}} U^{(2)}_{(h_0(e^*,z)*\tau)_{II}}(Q_{<a^*},Q_{a^*}).\end{aligned}$$

Fix $z^* \in Q_{a^*}$ such that

$$(x_1, x_2) \in U^{(2)}_{(h_0(e^*,z^*)*\tau)_{II}}(Q_{<a^*}, Q_{a^*}).$$

The key point is that $h_0(e^*, z^*) \in G$: By the definition of h_0, for all $a \in X$ and for all $z \in \omega^\omega$,

$$U^{(2)}_{h_0(e^*,z)}(Q_{<a}, Q_a) = \begin{cases} U^{(2)}_{e^*}(Q_{<a}, Q_a) & \text{if } z \notin Q_{<a} \cup Q_a \\ \varnothing & \text{if } z \in Q_{<a} \cup Q_a. \end{cases}$$

We have fixed $z^* \in Q_{a^*}$. For this fixed value, allowing a to vary, we have (i) $z^* \notin Q_{<a} \cup Q_a$ iff $\pi(a) < \pi(a^*)$ and (ii) $z^* \in Q_{<a} \cup Q_a$ iff $\pi(a) \geqslant \pi(a^*)$. So

$$U^{(2)}_{h_0(e^*,z^*)}(Q_{<a}, Q_a) = U^{(2)}_{e^*}(Q_{<a}, Q_a),$$

for all a such that $\pi(a) < \pi(a^*)$ and

$$U^{(2)}_{h_0(e^*,z^*)}(Q_{<a}, Q_a) = \varnothing,$$

for all a such that $\pi(a) \geqslant \pi(a^*)$. Thus,

$$U^{(2)}_{h_0(e^*,z^*)}(Q_{<a}, Q_a) \subseteq Z \cap (Q_a \times \omega^\omega),$$

for *all* $a \in X$, i.e. $h_0(e^*, z^*) \in G$.

Now since τ is a winning strategy for II, $(h_0(e^*, z^*) * \tau)_{II} \in G$, which means that $(x_1, x_2) \in Z$, a contradiction. ⊣

Subclaim 2. *α_{e^*} does not exist.*

Proof. Suppose not. Let $a^* \in X$ be such that $\pi(a^*) = \alpha_{e^*}$, and choose $z^* \in Q_{a^*}$. Thus, $h_0(e^*, z^*) \in G$, since $e^* \in G$ by Subclaim 1, and $h_0(e^*, z^*)$ is defined such that for all $a \in X$,

$$U^{(2)}_{h_0(e^*,z^*)}(Q_{<a}, Q_a) = \begin{cases} U^{(2)}_{e^*}(Q_{<a}, Q_a) & \text{if } \pi(a) < \pi(a^*) \\ \varnothing & \text{if } \pi(a) \geqslant \pi(a^*). \end{cases}$$

So, $\alpha_{h_0(e^*,z^*)} = \alpha_{e^*}$. Since τ is a winning strategy for II,

$$\alpha_{(h_0(e^*,z^*)*\tau)_{II}} > \alpha_{h_0(e^*,z^*)} = \alpha_{e^*},$$

which is impossible since

$$U^{(2)}_{(h_0(e^*,z^*)*\tau)_{II}}(Q_{<a}, Q_a) \subseteq U^{(2)}_{e^*}(Q_{<a}, Q_a)$$

for all $a \in X$. ⊣

Thus, e^* is the code for a uniform selector. ⊣

This completes the proof of the Uniform Coding Lemma. ⊣

3.5 Remark. The game in the above proof is definable from X, π, and Z and no choice is required to show that it works. Thus, if these parameters are OD, then ZF + OD-determinacy suffices for the proof.

3.6 Remark. The version of the Coding Lemma stated in Lemma 2.32 follows from the Uniform Coding Lemma: Take $X = U$ and $\pi : U \to \mathrm{On}$ given by $\pi(x) = \delta_x$. Then

$$Z^* = \bigcup_{x \in U} U_e^{(2)}(Q_{<\delta_x}, Q_{\delta_x}).$$

This gives (i). For (ii) note that

$$Z^* \cap (U_{\leqslant \delta_x} \times \omega^\omega) = \bigcup_{y \in U_{\leqslant \delta_x}} U_e^{(2)}(Q_{<\delta_y}, Q_{\delta_y}),$$

which is $\underset{\sim}{\Delta}^2_1$.

2 Open Question (Strong Coding Lemma). Suppose $X \subseteq \omega^\omega$ and $\pi : X \to \mathrm{On}$. Let $\leqslant_X$ be the prewellordering associated with π. Suppose $Z \subseteq X^{<\omega}$ is a tree. Then there exists a subtree $Z^* \subseteq Z$ such that

(1) Z^* is $\Sigma^1_1(\leqslant_X)$ and

(2) for all $\vec{s} \in (Z^*)^{<\omega}$ and for all $a \in X$, if there exists a $t \in Q_a$ such that $\vec{s}^\frown t \in Z$ then there exists a $t \in Q_a$ such that $\vec{s}^\frown t \in Z^*$,

where $Q_a = \{b \in X \mid \pi(b) = \pi(a)\}$.

3.3. Applications

In this section we will bring together some basic results and key applications of the above coding lemmas that will be of use later. It will be useful to do things in a slightly more general fashion than is customary.

For a set X, let

$$\Theta_X = \sup\{\alpha \mid \text{there is an } \mathrm{OD}_X \text{ surjection } \pi : \omega^\omega \to \alpha\}.$$

3.7 Lemma. *Assume* ZF *and suppose X is a set. Then there is an* OD_X *sequence $A = \langle A_\alpha \mid \alpha < \Theta_X\rangle$ such that A_α is a prewellordering of the reals of length α.*

Proof. Let A_α be the $<_{\mathrm{OD}_X}$-least prewellordering of the reals of length α, where $<_{\mathrm{OD}_X}$ is the canonical OD_X well-ordering of the OD_X sets. ⊣

3.8 Lemma. *Assume* ZF *and suppose X is a set. Suppose that every set is* $\mathrm{OD}_{X,y}$ *for some real y. Then $\Theta = \Theta_X$.*

Proof. Fix $\alpha < \Theta$. We have to show that there is an OD_X surjection $\pi : \omega^\omega \to \alpha$. There is certainly an $\mathrm{OD}_{X,y}$ surjection for some y. For each $y \in \omega^\omega$, let π_y be the $<_{\mathrm{OD}_{X,y}}$-least such surjection if one exists and let it be undefined otherwise. We can now "average over the reals" to eliminate the dependence on real parameters, letting

$$\begin{aligned} \pi : \omega^\omega &\to \alpha \\ y &\mapsto \begin{cases} \pi_{(y)_0}((y)_1) & \text{if } \pi_{(y)_0} \text{ is defined} \\ 0 & \text{otherwise.} \end{cases} \end{aligned}$$

This is an OD_X surjection. ⊣

The following theorem is essentially due to Moschovakis. We are just replacing AD with OD_X-determinacy and the changes are straightforward.

3.9 Theorem. *Assume* $\mathrm{ZF} + \mathrm{OD}_X$*-determinacy, where* X *is a set. Then*

$$\mathrm{HOD}_X \models \Theta_X \textit{ is strongly inaccessible.}$$

Proof. First we show that Θ_X is regular in HOD_X. By Lemma 3.7 there is an OD_X sequence

$$\langle \pi_\alpha \mid \alpha < \Theta_X \rangle$$

where each $\pi_\alpha : \omega^\omega \to \alpha$ is a surjection. Assume for contradiction that Θ_X is singular in HOD_X and let

$$f : \eta \to \Theta_X$$

be an OD_X cofinal map. Let g be an OD_X surjection from ω^ω onto η. Then the map

$$\begin{aligned} \pi : \omega^\omega &\to \Theta_X \\ x &\mapsto \pi_{f \circ g((x)_0)}((x)_1) \end{aligned}$$

is an OD_X surjection, which contradicts the definition of Θ_X.

We now show that Θ_X is a strong limit in HOD_X. For each $\eta < \Theta_X$, we have to show that $|\mathscr{P}(\eta)|^{\mathrm{HOD}_X} < \Theta_X$. For this it suffices to show that there is an OD_X surjection

$$\pi : \omega^\omega \to \mathscr{P}(\eta)^{\mathrm{HOD}_X},$$

since if $|\mathscr{P}(\eta)|^{\mathrm{HOD}_X} \geqslant \Theta_X$ then there would be an OD_X surjection $\rho : \mathscr{P}(\eta) \to \Theta_X$ and so $\rho \circ \pi : \omega^\omega \to \Theta_X$ would be an OD_X surjection, which contradicts the definition of Θ_X.

Let $\pi_\eta : \omega^\omega \to \eta$ be an OD_X surjection and, for $\alpha < \eta$, let $Q_{<\alpha}$ and Q_α be the usual objects defined relative to π_η. For $e \in \omega^\omega$, let

$$S_e = \{\beta < \eta \mid U_e^{(2)}(Q_{<\beta}, Q_\beta) \neq \varnothing\}.$$

The key point is that since π_η is OD_X the game for the Uniform Coding Lemma for $Z = \bigcup\{Q_\alpha \times \omega^\omega \mid \alpha \in S\}$ is determined for each $S \in \mathscr{P}(\eta)^{\mathrm{HOD}_X}$.

(See Remark 3.5.) Thus, every $S \in \mathscr{P}(\eta)^{\mathrm{HOD}_X}$ has the form S_e for some $e \in \omega^\omega$ and hence

$$\begin{aligned}\pi : \omega^\omega &\to \mathscr{P}(\eta)^{\mathrm{HOD}_X} \\ e &\mapsto S_e\end{aligned}$$

is a surjection. Moreover, π is OD_X (since π_η is OD_X), which completes the proof. ⊣

The above theorem has the following corollary. The first part also follows from early work of Friedman and Solovay. The second part is a simple application of the Coding Lemma and Solovay's Lemma 2.23.

3.10 Theorem. *Assume* $\mathrm{ZF} + \mathrm{AD} + V = L(\mathbb{R})$. *Then*

(1) $\mathrm{HOD}^{L(\mathbb{R})} \models \Theta$ *is strongly inaccessible and*

(2) $\mathrm{HOD}^{L(\mathbb{R})} \cap V_\Theta = \mathrm{HOD}^{L_\Theta(\mathbb{R})}$.

Proof. (1) This follows immediately from Theorem 3.9 and Lemma 3.8.

(2) Since $\mathrm{HOD}^{L(\mathbb{R})}$ is Σ_1-definable over $L(\mathbb{R})$ (with the parameter $\mathbb{R}$) and since $L_\Theta(\mathbb{R}) \prec_1 L(\mathbb{R})$ (by Lemma 2.23),

$$\mathrm{HOD}^{L_\Theta(\mathbb{R})} = \mathrm{HOD}^{L(\mathbb{R})} \cap L_\Theta(\mathbb{R}).$$

Thus, it suffices to show

$$\mathrm{HOD}^{L(\mathbb{R})} \cap V_\Theta = \mathrm{HOD}^{L(\mathbb{R})} \cap L_\Theta(\mathbb{R}).$$

The right-to-left inclusion is immediate. For the left-to-right inclusion suppose $x \in \mathrm{HOD}^{L(\mathbb{R})} \cap V_\Theta$. We have to show that $x \in L_\Theta(\mathbb{R})$. Since Θ is strongly inaccessible in $\mathrm{HOD}^{L(\mathbb{R})}$, x is coded by a set of ordinals $A \subseteq \alpha$ where $\alpha < \Theta$. However, by the proof of Theorem 3.9, $\mathscr{P}(\alpha) \in L_\Theta(\mathbb{R})$, for each $\alpha < \Theta$. Thus, $x \in L_\Theta(\mathbb{R})$, which completes the proof. ⊣

3 Open Question. Assume $\mathrm{ZF} + \mathrm{DC} + V = L(\mathbb{R})$.

(1) Suppose that for every $\alpha < \Theta$ there is a surjection $\pi : \omega^\omega \to \mathscr{P}(\alpha)$. Must AD hold in $L(\mathbb{R})$?

(2) Suppose Θ is inaccessible. Must AD hold in $L(\mathbb{R})$?

3.11 Theorem (Kunen). *Assume* $\mathrm{ZF} + \mathrm{DC} + \mathrm{AD}$. *Suppose* $\lambda < \Theta$ *and* μ *is an ultrafilter on* λ. *Then* μ *is* OD.

Proof. Let $\leqslant$ be a prewellordering of ω^ω of length λ. Let $\pi : \omega^\omega \to \mathscr{P}(\lambda)$ be the surjection derived from $\leqslant$ as in the above proof. For $x \in \omega^\omega$, let

$$A_x = \bigcap\{\pi(y) \mid \pi(y) \in \mu \wedge y \leqslant_T x\}.$$

Since there are only countably many such y and AD implies that all ultrafilters are countably complete (Theorem 2.8), A_x is non-empty. Let

$$f(x) = \bigcap A_x.$$

Notice that A_x and $f(x)$ depend only on the Turing degree of x. In particular, we can regard f as a function from the Turing degrees $\mathscr{D}_T$ into the ordinals. Notice also that

$$A \in \mu \quad \text{iff} \quad \text{for a cone of } x, f(x) \in A$$

since if $B \in \mu$ then, for any $x \geqslant_T x_0$ we have $f(x) \in B$, where x_0 is such that $\pi(x_0) = B$. We can now "erase" reference to the prewellordering by taking the ultrapower. Let μ_T be the cone ultrafilter on the Turing degrees (see Theorem 2.9) and consider the ultrapower $V^{\mathscr{D}_T}/\mu_T$. By DC the ultrapower is well-founded. So we can let M be the transitive collapse of $V^{\mathscr{D}_T}/\mu_T$ and let

$$j : V \to M$$

be the canonical map. Letting γ be the ordinal represented by f, we have

$$B \in \mu \quad \text{iff} \quad \gamma \in j(B)$$

and so μ is OD. ⊣

4. A Woodin Cardinal in $\mathrm{HOD}^{L(\mathbb{R})}$

Our main aim in this section is to prove the following theorem:

4.1 Theorem. *Assume* $\mathrm{ZF} + \mathrm{DC} + \mathrm{AD}$. *Then*

$$\mathrm{HOD}^{L(\mathbb{R})} \models \mathrm{ZFC} + \Theta^{L(\mathbb{R})} \textit{ is a Woodin cardinal.}$$

This will serve as a warm-up for the proof of the Generation Theorem in the next section. The proof that we give appeals to DC at only one point (Lemma 4.8) and as we shall see in the next section one can avoid this appeal and prove the result in $\mathrm{ZF} + \mathrm{AD}$. See Theorem 5.36.

In Sect. 4.1 we will establish the reflection phenomenon that will play the role played by boundedness in Sect. 2 and we will define for cofinally many $\lambda < \Theta$, an ultrafilter μ_λ on $\underset{\sim}{\delta}^2_1$ that is intended to witness that $\underset{\sim}{\delta}^2_1$ is λ-strong. In Sect. 4.2 we shall introduce and motivate the notion of *strong normality* by showing that the strong normality of μ_λ ensures that $\underset{\sim}{\delta}^2_1$ is λ-strong. We will then show how reflection and uniform coding combine to secure strong normality. In Sect. 4.3 we will prove the main theorem by relativizing the construction to subsets of Θ. Throughout this section we work in $L(\mathbb{R})$ and so when we write $\underset{\sim}{\delta}^2_1$ and Θ we will always be referring to these notions as interpreted in $L(\mathbb{R})$.

4.1. Reflection

We have seen that ZF + AD implies that Θ is strongly inaccessible in $\mathrm{HOD}^{L(\mathbb{R})}$. Our next task is to show that

$$\mathrm{HOD}^{L(\mathbb{R})} \models \underset{\sim}{\delta}^2_1 \text{ is } \lambda\text{-strong},$$

for all $\lambda < \Theta$. The proof will then relativize to subsets of Θ that are in $\mathrm{HOD}^{L(\mathbb{R})}$ and thereby establish the main theorem.

The ultrafilters that witness strength cannot come from the "sup" game of Sect. 2 since the ultrafilters produced by this game concentrate on ω-club sets, whereas to witness strength we will need ultrafilters according to which there are measure-one many measurable cardinals below $\underset{\sim}{\delta}^2_1$. For this reason we will have to use a variant of the "sup" game. In this variant the role of boundedness will be played by a certain reflection phenomenon.

The reflection phenomenon we have in mind does not presuppose any determinacy assumptions. For the time being work in ZF + $\mathrm{AC}_\omega(\mathbb{R})$. The main claim is that there is a function $F : \underset{\sim}{\delta}^2_1 \to L_{\underset{\sim}{\delta}^2_1}(\mathbb{R})$ which is Δ_1-definable over $L_{\underset{\sim}{\delta}^2_1}(\mathbb{R})$ and for which the following *reflection phenomenon* holds:

> For all $X \in L(\mathbb{R}) \cap \mathrm{OD}^{L(\mathbb{R})}$, for all Σ_1 formulas φ, and for all $z \in \omega^\omega$, if
>
> $$L(\mathbb{R}) \models \varphi[z, X, \underset{\sim}{\delta}^2_1, \mathbb{R}]$$
>
> then there exists a $\delta < \underset{\sim}{\delta}^2_1$ such that
>
> $$L(\mathbb{R}) \models \varphi[z, F(\delta), \delta, \mathbb{R}].$$

One should think of F as a sequence that contains "proxies" or "generic witnesses" for each $\mathrm{OD}^{L(\mathbb{R})}$ set X: Given *any* Σ_1 fact (with a real parameter) about *any* $\mathrm{OD}^{L(\mathbb{R})}$ set X there is a "proxy" $F(\delta)$ in our fixed sequence that witnesses the same fact.

The function F is defined (much like $\diamondsuit$) in terms of the least counterexample. To describe this in more detail let us first recall some basic facts from Sect. 2.4 concerning $L(\mathbb{R})$ and the theory T_0: There are arbitrarily large α such that $L_\alpha(\mathbb{R}) \models \mathrm{T}_0$. In particular,

$$L_\Theta(\mathbb{R}) \models \mathrm{T}_0.$$

Moreover, since

$$L_\Theta(\mathbb{R}) \prec_1 L(\mathbb{R}),$$

there are arbitrarily large $\alpha < \Theta$ such that $L_\alpha(\mathbb{R}) \models \mathrm{T}_0$. Similarly, there are arbitrarily large $\alpha < \underset{\sim}{\delta}^2_1$ such that $L_\alpha(\mathbb{R}) \models \mathrm{T}_0$. However, notice that it is *not* the case $L_{\underset{\sim}{\delta}^2_1}(\mathbb{R}) \models \mathrm{T}_0$ (by Lemma 2.27).

Because of the greater maneuvering room provided by levels $L_\alpha(\mathbb{R})$ that satisfy T_0 we will concentrate (for example, in reflection arguments) on such levels. For example, we can use these levels to give a first-order definition of

$\mathrm{OD}^{L(\mathbb{R})}$ and the natural well-ordering $<_{\mathrm{OD}^{L(\mathbb{R})}}$ on the $\mathrm{OD}^{L(\mathbb{R})}$ sets. For the latter, given $X \in \mathrm{OD}^{L(\mathbb{R})}$, let

$$\begin{aligned}\alpha_X = {} & \text{the least } \alpha \text{ such that} \\ & (1)\ L_\alpha(\mathbb{R}) \models \mathrm{T}_0, \\ & (2)\ X \in L_\alpha(\mathbb{R}), \text{and} \\ & (3)\ X \text{ is definable in } L_\alpha(\mathbb{R}) \text{ from ordinal parameters;}\end{aligned}$$

let φ_X be the least formula that defines X from ordinal parameters in $L_\alpha(\mathbb{R})$; and let $\vec{\xi}_X$ be the lexicographically least sequence of ordinal parameters used to define X in $L_\alpha(\mathbb{R})$ via φ_X. Given X and Y in $\mathrm{OD}^{L(\mathbb{R})}$, working in $L(\mathbb{R})$ set

$$\begin{aligned} X <_{\mathrm{OD}} Y \quad \text{iff} \quad & \alpha_X < \alpha_Y \text{ or} \\ & \alpha_X = \alpha_Y \text{ and } \varphi_X < \varphi_Y \text{ or} \\ & \alpha_X = \alpha_Y \text{ and } \varphi_X = \varphi_Y \text{ and } \vec{\xi}_X <_{\mathrm{lex}} \vec{\xi}_Y. \end{aligned}$$

Since the $L_\alpha(\mathbb{R})$ hierarchy is Σ_1-definable in $L(\mathbb{R})$, it follows that $\mathrm{OD}^{L(\mathbb{R})}$ and $(<_{\mathrm{OD}})^{L(\mathbb{R})}$ are Σ_1-definable in $L(\mathbb{R})$. (This is in contrast to the usual definitions of these notions, which are Σ_2 since they involve existential quantification over the V_α hierarchy, which is Π_1.) Notice that if $L_\alpha(\mathbb{R}) \models \mathrm{T}_0$, then

$$(<_{\mathrm{OD}})^{L_\alpha(\mathbb{R})} \trianglelefteq (<_{\mathrm{OD}})^{L(\mathbb{R})}.$$

Furthermore, if $L_\alpha(\mathbb{R}) \prec_1 L(\mathbb{R})$, then

$$\mathrm{OD}^{L_\alpha(\mathbb{R})} = \mathrm{OD}^{L(\mathbb{R})} \cap L_\alpha(\mathbb{R}) \quad \text{and} \quad (<_{\mathrm{OD}})^{L_\alpha(\mathbb{R})} = (<_{\mathrm{OD}})^{L(\mathbb{R})} \restriction L_\alpha(\mathbb{R}).$$

For example,

$$\mathrm{HOD}^{L_\Theta(\mathbb{R})} = \mathrm{HOD}^{L(\mathbb{R})} \cap L_\Theta(\mathbb{R}).$$

(For this it is crucial that we use the Σ_1 definition given above since the Σ_2 definition involves quantification over the V_α hierarchy and yet in $L_{\utilde{\delta}^2_1}(\mathbb{R})$ even the level $V_{\omega+2}$ does not exist.) Our goal can thus be rephrased as that of showing

$$\mathrm{HOD}^{L_\Theta(\mathbb{R})} \models \utilde{\delta}^2_1 \text{ is a strong cardinal.}$$

We are now in a position to define the reflection function F. If the reflection phenomenon fails in $L(\mathbb{R})$ with respect to $F \restriction \utilde{\delta}^2_1$ then (by Replacement) there is some level $L_\alpha(\mathbb{R})$ which satisfies T_0 over which the reflection phenomenon fails with respect to $F \restriction \utilde{\delta}^2_1$. This motivates the following definition:

4.2 Definition. Assume T_0. Suppose that $F \restriction \delta$ is defined. Let $\vartheta(\delta)$ be least such that

$$L_{\vartheta(\delta)}(\mathbb{R}) \models \mathrm{T}_0 \text{ and there is an } X \in L_{\vartheta(\delta)}(\mathbb{R}) \cap \mathrm{OD}^{L_{\vartheta(\delta)}(\mathbb{R})} \text{ such that}$$

($\star$) there is a Σ_1 formula φ and a real z such that

$$L_{\vartheta(\delta)}(\mathbb{R}) \models \varphi[z, X, \delta, \mathbb{R}]$$

and for all $\bar{\delta} < \delta$,

$$L_{\vartheta(\delta)}(\mathbb{R}) \not\models \varphi[z, F(\bar{\delta}), \bar{\delta}, \mathbb{R}]$$

(if such an ordinal exists) and then set $F(\delta) = X$ where X is $(<_{\mathrm{OD}})^{L_{\vartheta(\delta)}}$-least such that ($\star$) holds.

We have to establish two things: First, $F(\delta)$ is defined for all $\delta < \underset{\sim}{\delta}^2_1$. Second, $F(\underset{\sim}{\delta}^2_1)$ is not defined. This implies that the reflection phenomenon holds with respect to F.

4.3 Lemma. *Assume* $\mathrm{ZF} + \mathrm{AC}_\omega(\mathbb{R})$. *Then*

(1) if $L_\alpha(\mathbb{R}) \models \mathrm{T}_0$, *then* $(F)^{L_\alpha(\mathbb{R})} = F \restriction \gamma$ *for some* γ,

(2) $F^{L_{\underset{\sim}{\delta}^2_1}(\mathbb{R})} = F \restriction \underset{\sim}{\delta}^2_1$, *and*

(3) $F(\delta)$ *is defined for all* $\delta < \underset{\sim}{\delta}^2_1$.

Proof. For (1) suppose that $(F \restriction \delta)^{L_\alpha(\mathbb{R})} = F \restriction \delta$ with the aim of showing that $(F(\delta))^{L_\alpha(\mathbb{R})} = (F(\delta))^{L(\mathbb{R})}$. The point is that

$$L_\alpha(\mathbb{R}) \models \vartheta(\delta) \text{ exists}$$

if and only if

$$(\vartheta(\delta))^{L(\mathbb{R})} < \alpha,$$

in which case

$$(\vartheta(\delta))^{L_\alpha(\mathbb{R})} = (\vartheta(\delta))^{L(\mathbb{R})} \quad \text{and} \quad (F(\delta))^{L_\alpha(\mathbb{R})} = (F(\delta))^{L(\mathbb{R})},$$

by the locality of the definition of F and the assumption that $(F \restriction \delta)^{L_\alpha(\mathbb{R})} = F \restriction \delta$.

For (2) first notice that we can make sense of F as defined over levels (such as $L_{\underset{\sim}{\delta}^2_1}(\mathbb{R})$) that do not satisfy T_0 by letting, for an arbitrary ordinal ξ,

$$F^{L_\xi(\mathbb{R})} = \bigcup \{ F^{L_\alpha(\mathbb{R})} \mid \alpha < \xi \text{ and } L_\alpha(\mathbb{R}) \models \mathrm{T}_0 \}.$$

Thus, $F^{L_{\underset{\sim}{\delta}^2_1}(\mathbb{R})} = F \restriction \gamma$ for some γ, by (1). Assume for contradiction that (2) fails, that is, for some $\gamma < \underset{\sim}{\delta}^2_1$, $F(\gamma)$ is defined and yet $F^{L_{\underset{\sim}{\delta}^2_1}(\mathbb{R})}(\gamma)$ is not defined. Since in $L(\mathbb{R})$, $\vartheta(\gamma)$ and $F(\gamma)$ are defined, the following is a true Σ_1 statement about γ:

$$\exists \alpha > \gamma \, (L_\alpha(\mathbb{R}) \models \mathrm{T}_0 + \vartheta(\gamma) \text{ exists.})$$

Since $L_{\underset{\sim}{\delta}^2_1}(\mathbb{R}) \prec_1 L(\mathbb{R})$, this statement holds in $L_{\underset{\sim}{\delta}^2_1}(\mathbb{R})$ and so $F^{L_\alpha(\mathbb{R})}(\gamma)$ is defined and hence $F^{L_{\underset{\sim}{\delta}^2_1}(\mathbb{R})}(\gamma)$ is defined, which is a contradiction.

For (3) assume for contradiction that $\gamma < \underset{\sim}{\delta}^2_1$, where $\gamma = \mathrm{dom}(F)$. By (2) (and the definition of $F^{L_{\underset{\sim}{\delta}^2_1}(\mathbb{R})}$) there is an $\alpha < \underset{\sim}{\delta}^2_1$ such that $L_\alpha(\mathbb{R}) \models \mathrm{T}_0$ and $F^{L_\alpha(\mathbb{R})} = F\restriction\gamma = F$. We claim that this implies that

$$L_\alpha(\mathbb{R}) \prec_1^{\mathbb{R}\cup\{\mathbb{R}\}} L(\mathbb{R}),$$

which is a contradiction (by Theorem 2.28). Suppose

$$L(\mathbb{R}) \models \psi[z, \mathbb{R}]$$

where ψ is a Σ_1 formula and $z \in \omega^\omega$. We have to show that $L_\alpha(\mathbb{R}) \models \psi[z, \mathbb{R}]$. By Replacement there is an ordinal β such that

$$L_\beta(\mathbb{R}) \models \psi[z, \mathbb{R}].$$

Consider the Σ_1 statement $\varphi[z, X, \mathbb{R}]$ expressing "There exists ξ such that $X = L_\xi(\mathbb{R})$ and $X \models \psi[z, \mathbb{R}]$". Letting $\vartheta > \beta$ be such that $L_\vartheta(\mathbb{R}) \models \mathrm{T}_0$ we have: there exists an $X \in L_\vartheta(\mathbb{R}) \cap \mathrm{OD}^{L_\vartheta(\mathbb{R})}$ (namely, $X = L_\beta(\mathbb{R})$) such that

$$L_\vartheta(\mathbb{R}) \models \mathrm{T}_0 + \varphi[z, X, \mathbb{R}].$$

Moreover, since $\vartheta(\gamma)$ does not exist, it follows (by the definition of $\vartheta(\gamma)$) that there exists a $\bar{\delta} < \gamma$ such that

$$L_\vartheta(\mathbb{R}) \models \varphi[z, F(\bar{\delta}), \mathbb{R}].$$

Thus (unpacking $\varphi[z, X, \mathbb{R}]$) there exists a ξ such that $F(\bar{\delta}) = L_\xi(\mathbb{R})$ and $L_\xi(\mathbb{R}) \models \psi[z, \mathbb{R}]$. Since $F \subseteq L_\alpha(\mathbb{R})$, $\xi < \alpha$ and so, by upward absoluteness,

$$L_\alpha(\mathbb{R}) \models \psi[z, \mathbb{R}],$$

which completes the proof. $\dashv$

It follows that $F\restriction\underset{\sim}{\delta}^2_1 : \underset{\sim}{\delta}^2_1 \to L_{\underset{\sim}{\delta}^2_1}(\mathbb{R})$ is total and Δ_1-definable over $L_{\underset{\sim}{\delta}^2_1}(\mathbb{R})$. It remains to see that $F(\underset{\sim}{\delta}^2_1)$ is not defined.

4.4 Theorem. *Assume* $\mathrm{ZF} + \mathrm{AC}_\omega(\mathbb{R})$. *For all* $X \in \mathrm{OD}^{L(\mathbb{R})}$, *for all* Σ_1 *formulas* φ, *and for all* $z \in \omega^\omega$ *if*

$$L(\mathbb{R}) \models \varphi[z, X, \underset{\sim}{\delta}^2_1, \mathbb{R}]$$

then there exists a $\delta < \underset{\sim}{\delta}^2_1$ *such that*

$$L(\mathbb{R}) \models \varphi[z, F(\delta), \delta, \mathbb{R}].$$

Proof. The idea of the proof is straightforward but the details are somewhat involved.

Assume for contradiction that there is an $X \in \mathrm{OD}^{L(\mathbb{R})}$, a Σ_1 formula φ, and $z \in \omega^\omega$ such that

$$L(\mathbb{R}) \models \varphi[z, X, \underset{\sim}{\delta}^2_1, \mathbb{R}]$$

and for all $\delta < \underset{\sim}{\delta}^2_1$,

$$L(\mathbb{R}) \not\models \varphi[z, F(\delta), \delta, \mathbb{R}].$$

Step 1. By Replacement, let $\vartheta_0 > \underset{\sim}{\delta}^2_1$ be least such that

(1.1) $L_{\vartheta_0}(\mathbb{R}) \models \mathrm{T}_0$ and there is an $X \in L_{\vartheta_0}(\mathbb{R}) \cap \mathrm{OD}^{L_{\vartheta_0}(\mathbb{R})}$ and

($\star$) there is a Σ_1 formula φ and a real z such that

$$L_{\vartheta_0}(\mathbb{R}) \models \varphi[z, X, \underset{\sim}{\delta}^2_1, \mathbb{R}]$$

and for all $\delta < \underset{\sim}{\delta}^2_1$

$$L_{\vartheta_0}(\mathbb{R}) \not\models \varphi[z, F(\delta), \delta, \mathbb{R}].$$

Let X_0 be least (in the order of definability) such that (1.1) and for this choice pick φ_0 and z_0 such that ($\star$). (Thus we have let $\vartheta_0 = \vartheta(\underset{\sim}{\delta}^2_1)$, $X_0 = F(\underset{\sim}{\delta}^2_1)$, and we have picked witnesses φ_0 and z_0 to the failure of reflection with respect to $F(\underset{\sim}{\delta}^2_1)$.)

Notice that $L_{\vartheta_0}(\mathbb{R}) \models \underset{\sim}{\delta}^2_1$ exists $+ F(\delta)$ is defined for all $\delta < \underset{\sim}{\delta}^2_1$. Since

$$F^{L_{\vartheta_0}(\mathbb{R})} \restriction \underset{\sim}{\delta}^2_1 = F \restriction \underset{\sim}{\delta}^2_1,$$

by Lemma 4.3, (1.1) is equivalent to the internal statement $L_{\vartheta_0}(\mathbb{R}) \models \mathrm{T}_0 +$ "reflection fails with respect to $F \restriction \underset{\sim}{\delta}^2_1$". It is this internal statement that we will reflect to get a contradiction. We have that for all $\delta < \underset{\sim}{\delta}^2_1$,

(1.2) $L_{\vartheta_0}(\mathbb{R}) \not\models \varphi_0[z_0, F(\delta), \delta, \mathbb{R}]$.

Our strategy is to reflect to get $\bar{\vartheta} < \underset{\sim}{\delta}^2_1$ such that

$$L_{\bar{\vartheta}}(\mathbb{R}) \models \varphi_0[z_0, F((\underset{\sim}{\delta}^2_1)^{L_{\bar{\vartheta}}(\mathbb{R})}), (\underset{\sim}{\delta}^2_1)^{L_{\bar{\vartheta}}(\mathbb{R})}, \mathbb{R}].$$

By upward absoluteness, this will contradict (1.2). To implement this strategy we need the appropriate Σ_1 fact (in a real) to reflect.

Step 2. The following is a true Σ_1 statement about φ_0 and z_0 (as witnessed by taking α to be ϑ_0 from Step 1): There is an α such that

(2.1) $L_\alpha(\mathbb{R}) \models \underset{\sim}{\delta}^2_1$ exists $+$ $F(\delta)$ is defined for all $\delta < \underset{\sim}{\delta}^2_1$,

(2.2) $L_\alpha(\mathbb{R}) \models \mathrm{T}_0$ and there is an $X \in L_\alpha(\mathbb{R}) \cap \mathrm{OD}^{L_\alpha(\mathbb{R})}$ and

($\star$) there is a Σ_1 formula φ and a real z such that

$$L_\alpha(\mathbb{R}) \models \varphi[z, X, (\underset{\sim}{\delta}^2_1)^{L_\alpha(\mathbb{R})}, \mathbb{R}]$$

and for all $\delta < (\underset{\sim}{\delta}^2_1)^{L_\alpha(\mathbb{R})}$

$$L_\alpha(\mathbb{R}) \not\models \varphi[z, F^{L_\alpha(\mathbb{R})}(\delta), \delta, \mathbb{R}],$$

(2.3) if $\beta < \alpha$ then it is not the case that $L_\beta(\mathbb{R}) \models \mathrm{T}_0$ and there is an $X \in L_\beta(\mathbb{R}) \cap \mathrm{OD}^{L_\beta(\mathbb{R})}$ and

($\star$) there is a Σ_1 formula φ and a real z such that

$$L_\beta(\mathbb{R}) \models \varphi[z, X, (\underset{\sim}{\delta}^2_1)^{L_\alpha(\mathbb{R})}, \mathbb{R}]$$

and for all $\delta < (\underset{\sim}{\delta}^2_1)^{L_\alpha(\mathbb{R})}$

$$L_\beta(\mathbb{R}) \not\models \varphi[z, F^{L_\alpha(\mathbb{R})}(\delta), \delta, \mathbb{R}],$$

and

(2.4) if $\bar{X}$ is least (in the order of definability) such that (2.2) then

$$L_\alpha(\mathbb{R}) \models \varphi_0[z_0, \bar{X}, (\underset{\sim}{\delta}^2_1)^{L_\alpha(\mathbb{R})}, \mathbb{R}]$$

and for all $\delta < (\underset{\sim}{\delta}^2_1)^{L_\alpha(\mathbb{R})}$

$$L_\alpha(\mathbb{R}) \not\models \varphi_0[z_0, F^{L_\alpha(\mathbb{R})}(\delta), \delta, \mathbb{R}].$$

(Notice that in (2.3) the ordinal $\underset{\sim}{\delta}^2_1$ and the function F are computed in $L_\alpha(\mathbb{R})$ while the formulas are evaluated in $L_\beta(\mathbb{R})$.) Thus (2.1) ensures (by Lemma 4.3) that $F^{L_\alpha(\mathbb{R})}\restriction(\underset{\sim}{\delta}^2_1)^{L_\alpha(\mathbb{R})} = F\restriction(\underset{\sim}{\delta}^2_1)^{L_\alpha(\mathbb{R})}$, (2.2) says that $L_\alpha(\mathbb{R})$ satisfies "reflection is failing with respect to $F^{L_\alpha(\mathbb{R})}\restriction(\underset{\sim}{\delta}^2_1)^{L_\alpha(\mathbb{R})}$" and, because of (2.1), this ensures that $\vartheta((\underset{\sim}{\delta}^2_1)^{L_\alpha(\mathbb{R})})$ exists, (2.3) ensures in addition that $\alpha = \vartheta((\underset{\sim}{\delta}^2_1)^{L_\alpha(\mathbb{R})})$, and (2.4) says that φ_0 and z_0 (as chosen in Step 1) witness the existence of $\vartheta((\underset{\sim}{\delta}^2_1)^{L_\alpha(\mathbb{R})})$.

Since $L_{\underset{\sim}{\delta}^2_1}(\mathbb{R}) \prec_1^{\mathbb{R}} L(\mathbb{R})$ and φ_0 and z_0 can be coded by a single real, the least ordinal α witnessing the existential of the above statement must be less than $\underset{\sim}{\delta}^2_1$. Let $\bar{\vartheta}$ be this ordinal.

Step 3. We claim that

$$L_{\bar{\vartheta}}(\mathbb{R}) \models \varphi_0[z_0, F((\underset{\sim}{\delta}^2_1)^{L_{\bar{\vartheta}}(\mathbb{R})}), (\underset{\sim}{\delta}^2_1)^{L_{\bar{\vartheta}}(\mathbb{R})}, \mathbb{R}],$$

which finishes the proof since by upward absoluteness this contradicts (1.2).

The ordinal $\bar{\vartheta}$ has the Σ_1-properties listed in (2.1)–(2.4) for α. So we have: (4.1) $L_{\bar{\vartheta}}(\mathbb{R}) \models$ "$\underset{\sim}{\delta}^2_1$ exists" + "$F(\delta)$ is defined for all $\delta < \underset{\sim}{\delta}^2_1$" and so (by Lemma 4.3) $F^{L_{\bar{\vartheta}}(\mathbb{R})}\restriction(\underset{\sim}{\delta}^2_1)^{L_{\bar{\vartheta}}(\mathbb{R})} = F\restriction(\underset{\sim}{\delta}^2_1)^{L_{\bar{\vartheta}}(\mathbb{R})}$, (4.2) $L_{\bar{\vartheta}}(\mathbb{R})$ satisfies "reflection is failing with respect to $F^{L_{\bar{\vartheta}}(\mathbb{R})}\restriction(\underset{\sim}{\delta}^2_1)^{L_{\bar{\vartheta}}(\mathbb{R})}$" and, because of (4.1), this ensures that $\vartheta((\underset{\sim}{\delta}^2_1)^{L_{\bar{\vartheta}}(\mathbb{R})})$ exists, (4.3) $\bar{\vartheta} = \vartheta((\underset{\sim}{\delta}^2_1)^{L_{\bar{\vartheta}}(\mathbb{R})})$, and (4.4) φ_0 and z_0 (as chosen in Step 1) witness the existence of $\vartheta((\underset{\sim}{\delta}^2_1)^{L_{\bar{\vartheta}}(\mathbb{R})})$. Therefore, by the definition of F, (4.4) implies that

$$L_{\bar{\vartheta}}(\mathbb{R}) \models \varphi_0[z_0, F((\underset{\sim}{\delta}^2_1)^{L_{\bar{\vartheta}}(\mathbb{R})}), (\underset{\sim}{\delta}^2_1)^{L_{\bar{\vartheta}}(\mathbb{R})}, \mathbb{R}],$$

which contradicts (1.2). ⊣

We will need a slight strengthening of the above theorem. This involves the notion of the *reflection filter*, which in turn involves various universal sets.

Let U_X be a good universal $\Sigma_1(L(\mathbb{R}), \{X, \underset{\sim}{\delta}^2_1, \mathbb{R}\})$ set of reals. So U_X is a $\Sigma_1(L(\mathbb{R}), \{X, \underset{\sim}{\delta}^2_1, \mathbb{R}\})$ subset of $\omega^\omega \times \omega^\omega$ such that each $\Sigma_1(L(\mathbb{R}), \{X, \underset{\sim}{\delta}^2_1, \mathbb{R} \cup \{\mathbb{R}\}\})$ subset of ω^ω is of the form $(U_X)_t$ for some $t \in \omega^\omega$. For each $\delta < \underset{\sim}{\delta}^2_1$, let U_δ be the universal $\Sigma_1(L(\mathbb{R}), \{F(\delta), \delta, \mathbb{R}\})$ set obtained using the same definition used for U_X except with X and $\underset{\sim}{\delta}^2_1$ replaced by the reflected proxies $F(\delta)$ and δ. As before, we shall identify each of U_X and U_δ with a set of reals using our recursive bijection between $\omega^\omega \times \omega^\omega$ and ω^ω.

For each Σ_1 formula φ and for each real y, there exists a $z_{\varphi,y} \in \omega^\omega$ such that

$$z_{\varphi,y} \in U_X \ \text{ iff } \ L(\mathbb{R}) \models \varphi[y, X, \underset{\sim}{\delta}^2_1, \mathbb{R}].$$

In such a situation we say that $z_{\varphi,y}$ *certifies* the Σ_1 fact φ about y. The key property is, of course, that if $z_{\varphi,y} \in U_\delta$ then $L(\mathbb{R}) \models \varphi[y, F(\delta), \delta, \mathbb{R}]$. Notice that the real $z_{\varphi,y}$ is recursive in y (uniformly).

In what follows we will drop reference to φ and y and simply write $z \in U_X$, it being understood that the formula and parameter are encoded in z. In these terms Theorem 4.4 can be recast as stating that if $z \in U_X$ then there is an ordinal $\delta < \underset{\sim}{\delta}^2_1$ such that $z \in U_\delta$, in other words, $U_X \subseteq \bigcup_{\delta < \underset{\sim}{\delta}^2_1} U_\delta$. But notice that equality fails since different X can have radically different "reflection points".

For $z \in U_X$, let

$$S_z = \{\delta < \underset{\sim}{\delta}^2_1 \mid z \in U_\delta\}$$

and set

$$\mathscr{F}_X = \{S \subseteq \underset{\sim}{\delta}^2_1 \mid \exists z \in U_X\, (S_z \subseteq S)\}.$$

Equivalently, for a Σ_1 formula φ and a real y such that

$$L(\mathbb{R}) \models \varphi[y, X, \underset{\sim}{\delta}^2_1, \mathbb{R}]$$

let

$$S_{\varphi,y} = \{\delta < \underset{\sim}{\delta}^2_1 \mid L(\mathbb{R}) \models \varphi[y, F(\delta), \delta, \mathbb{R}]\}$$

and set

$$\mathscr{F}_X = \{S \subseteq \underset{\sim}{\delta}^2_1 \mid \text{there is a } \Sigma_1 \text{ formula } \varphi \text{ and a } y \in \omega^\omega \text{ such that } L(\mathbb{R}) \models \varphi[y, X, \underset{\sim}{\delta}^2_1, \mathbb{R}] \text{ and } S_{\varphi,y} \subseteq S\}.$$

Notice that we can reflect to points δ where the proxies $F(\delta), \delta$ resemble $X, \underset{\sim}{\delta}^2_1$ as much as we like. For example, suppose

$$L(\mathbb{R}) \models \psi[y, X, \underset{\sim}{\delta}^2_1, \mathbb{R}]$$

and consider the following Σ_1 statement:

There is an α such that

$$\begin{aligned}
&L_\alpha(\mathbb{R}) \models \mathrm{T}_0,\\
&\delta = (\underset{\sim}{\delta}^2_1)^{L_\alpha(\mathbb{R})}, \quad F\restriction\delta = (F)^{L_\alpha(\mathbb{R})}, \quad \text{and} \quad F(\delta) \in \mathrm{OD}^{L_\alpha(\mathbb{R})}, \quad \text{and}\\
&L_\alpha(\mathbb{R}) \models \psi[y, F(\delta), \delta, \mathbb{R}].
\end{aligned}$$

If we replace δ by $\underset{\sim}{\delta}^2_1$ and $F(\delta)$ by X then this statement is true. It follows that the statement holds for $\mathscr{F}_X$-almost all δ. The second clause ensures that each such δ is a "local $\underset{\sim}{\delta}^2_1$" and that the "local computation of F up to δ" coincides with F. By altering ψ and y we can increase the degree to which the proxies $F(\delta), \delta$ resemble $X, \underset{\sim}{\delta}^2_1$.

4.5 Lemma. *Assume* $\mathrm{ZF} + \mathrm{AC}_\omega(\mathbb{R})$. *Then* $L(\mathbb{R}) \models \mathscr{F}_X$ *is a countably complete filter.*

Proof. Upward closure and the non-triviality condition are immediate. It remains to prove countable completeness. Suppose $\{S_n \mid n < \omega\} \subseteq \mathscr{F}_X$. For $n < \omega$, let $z_n \in U_X$ be such that $S_{z_n} \subseteq S_n$. Let $z \in \omega^\omega$ be such that $(z)_n = z_n$ for all $n < \omega$. The following is a true Σ_1 statement about z, X, $\underset{\sim}{\delta}^2_1$, and $\mathbb{R}$:

There is an α such that

(1) $\underset{\sim}{\delta}^2_1 < \alpha$,
(2) $L_\alpha(\mathbb{R}) \models \mathrm{T}_0$,
(3) $X \in \mathrm{OD}^{L_\alpha(\mathbb{R})}$ and
(4) for all $n < \omega, (z)_n \in (U_X)^{L_\alpha(\mathbb{R})}$.

Let $z^* \in U_X$ certify this statement. It follows that for each $\delta < \underset{\sim}{\delta}^2_1$ such that $z^* \in U_\delta$ the following holds:

There is an α such that

(1) $\delta < \alpha$,
(2) $L_\alpha(\mathbb{R}) \models \mathrm{T}_0$,
(3) $F(\delta) \in \mathrm{OD}^{L_\alpha(\mathbb{R})}$ and
(4) for all $n < \omega, (z)_n \in (U_\delta)^{L_\alpha(\mathbb{R})}$.

But then, by upward absoluteness, $\delta \in \bigcap\{S_{z_n} \mid n < \omega\}$ and so $S_{z^*} \subseteq \bigcap\{S_{z_n} \mid n < \omega\} \subseteq \bigcap\{S_n \mid n < \omega\}$. ⊣

We shall call $\mathscr{F}_X$ the *reflection filter* since, by definition, there are $\mathscr{F}_X$-many reflecting points in the Reflection Theorem.

We wish now to extend the Reflection Theorem by allowing various parameters $S \subseteq \underset{\sim}{\delta}^2_1$ and their "reflections" $S \cap \delta$. For this we bring in AD.

4.6 Theorem (Reflection Theorem). *Assume* ZF + AD. *Suppose* $f : \underset{\sim}{\delta}^2_1 \to \underset{\sim}{\delta}^2_1$ *and* $S \subseteq \underset{\sim}{\delta}^2_1$ *are in* $L(\mathbb{R})$. *For all* $X \in \mathrm{OD}^{L(\mathbb{R})}$, *for all* Σ_1 *formulas* φ, *and for all* $z \in \omega^\omega$, *if*

$$L(\mathbb{R}) \models \varphi[z, X, f, S, \underset{\sim}{\delta}^2_1, \mathbb{R}]$$

then for $\mathscr{F}_X$*-many* $\delta < \underset{\sim}{\delta}^2_1$,

$$L(\mathbb{R}) \models \varphi[z, F(\delta), f \restriction \delta, S \cap \delta, \delta, \mathbb{R}],$$

where here f *and* S *occur as predicates.*

Proof. First we show that the theorem holds for $S \subseteq \underset{\sim}{\delta}^2_1$. For each $\delta < \underset{\sim}{\delta}^2_1$, let

$$Q_\delta = U_\delta \setminus \bigcup \{U_\gamma \mid \gamma < \delta\}.$$

The sequence

$$\langle Q_\delta \mid \delta < \underset{\sim}{\delta}^2_1 \rangle$$

gives rise to a prewellordering of length $\underset{\sim}{\delta}^2_1$. By the Uniform Coding Lemma, there is an $e(S) \in \omega^\omega$ such that

$$U^{(2)}_{e(S)}(Q_{<\delta}, Q_\delta) \neq \varnothing \quad \text{iff} \quad \delta \in S.$$

The key point is that for $\mathscr{F}_X$-almost all δ

$$F^{L_{\vartheta(\delta)}(\mathbb{R})} = F \restriction \delta.$$

To see this let $z \in U_X$ be such that if $z \in U_\delta$ then

$$L_{\vartheta(\delta)}(\mathbb{R}) \models \delta = \underset{\sim}{\delta}^2_1 \quad \text{and} \quad F \restriction \delta \text{ is defined.}$$

Thus, if $\delta \in S_z$, then

$$\delta = (\underset{\sim}{\delta}^2_1)^{L_{\vartheta(\delta)}(\mathbb{R})} \quad \text{and} \quad F \restriction \delta = F^{L_{\vartheta(\delta)}(\mathbb{R})},$$

which implies

$$\langle Q_\gamma \mid \gamma < \delta \rangle = \langle Q_\gamma \mid \gamma < \delta \rangle^{L_{\vartheta(\delta)}(\mathbb{R})}.$$

It follows that for $\delta \in S_z$, $e(S)$ codes $S \cap \delta$.

This enables us to associate with each Σ_1 sentence φ involving the predicate S, a Σ_1 sentence φ^* involving instead the real $e(S)$ in such a way that

$$L(\mathbb{R}) \models \varphi[z, X, \underset{\sim}{\delta}^2_1, S, \mathbb{R}]$$

if and only if

$$L(\mathbb{R}) \models \varphi^*[z, X, \underset{\sim}{\delta}^2_1, e(S), \mathbb{R}]$$

and, for $\delta \in S_z \in \mathscr{F}_X$,

$$L(\mathbb{R}) \models \varphi[z, F(\delta), \delta, S \cap \delta, \mathbb{R}]$$

if and only if

$$L(\mathbb{R}) \models \varphi^*[z, F(\delta), \delta, e(S), \mathbb{R}].$$

In this fashion, the predicate S can be eliminated in favour of the real $e(S)$, thereby reducing the present version of the reflection theorem to the original version (Theorem 4.4).

To see that we can also include parameters of the form $f : \underset{\sim}{\delta}^2_1 \to \underset{\sim}{\delta}^2_1$ simply note that $\mathscr{F}_X$-almost all δ are closed under the Gödel pairing function and so we can include functions $f : \underset{\sim}{\delta}^2_1 \to \underset{\sim}{\delta}^2_1$ by coding them as subsets of $\underset{\sim}{\delta}^2_1$. $\dashv$

We are now in a position to define, for cofinally many $\lambda < \Theta$, an ultrafilter μ_λ on $\underset{\sim}{\delta}^2_1$. For the remainder of this section fix an ordinal $\lambda < \Theta$ and (by the results of Sect. 3.3) an OD-prewellordering $\leqslant_\lambda$ of ω^ω of length λ. Our interest is in applying the Reflection Theorem to

$$X = (\leqslant_\lambda, \lambda).$$

For each $S \subseteq \underset{\sim}{\delta}^2_1$, let $G^X(S)$ be the game

$$\begin{array}{lccccccc} \mathrm{I} & x(0) & & x(1) & & x(2) & & \ldots \\ \mathrm{II} & & y(0) & & y(1) & & \ldots & \end{array}$$

with the following winning conditions: Main Rule: For all $i < \omega$, $(x)_i, (y)_i \in U_X$. If the rule is violated then, letting i be the least such that either $(x)_i \notin U_X$ or $(y)_i \notin U_X$, I wins if $(x)_i \in U_X$; otherwise II wins. If the rule is satisfied then, letting δ be least such that for all $i < \omega$, $(x)_i, (y)_i \in U_\delta$, (which exists by reflection since (as in Lemma 4.5) we can regard this as a Σ_1 statement about a single real) I wins iff $\delta \in S$. Thus, I is picking δ by steering into the δth-approximation U_δ. (Note that the winning condition is not Σ_1.)

Now set

$$\mu_X = \{S \subseteq \underset{\sim}{\delta}^2_1 \mid \mathrm{I} \text{ wins } G^X(S)\}.$$

We let $\mu_\lambda = \mu_X$ but shall typically write μ_X to emphasize the dependence on the prewellorder. For $z \in U_X$, Player I can win $G^X(S_z)$ by playing x such that $(x)_i \in U_X$ for all $i < \omega$ and, for some $i < \omega$, $(x)_i = z$. Thus,

$$\mathscr{F}_X \subseteq \mu_X.$$

It is easy to see that μ_X is upward closed and contains either S or $\underset{\sim}{\delta}^2_1 \setminus S$ for each $S \subseteq \underset{\sim}{\delta}^2_1$.

4.7 Lemma. *Assume* ZF+AD. *Then* $L(\mathbb{R}) \models \mu_X$ *is a* $\underset{\sim}{\delta}^2_1$*-complete ultrafilter.*

Proof. The proof is similar to the proof of Theorem 2.33 (which traces back to the proof of Theorem 2.13). Consider $\{S_\alpha \mid \alpha < \gamma\}$ where $S_\alpha \in \mu_X$ and $\gamma < \underset{\sim}{\delta}^2_1$. Let $S = \bigcap_{\alpha<\gamma} S_\alpha$ and assume for contradiction that $S \notin \mu_X$. Let σ' be a winning strategy for I in $G^X(\underset{\sim}{\delta}^2_1 \smallsetminus S)$. Let

$$Z = \{(x,\sigma) \mid \text{for some } \alpha < \gamma,\ x \in Q_\alpha \text{ and } \sigma \text{ is a winning strategy for I in } G^X(S_\alpha)\}$$

where $Q_\alpha = \{x \in \omega^\omega \mid |x|_{\leqslant_U} = \alpha\}$ and $\leqslant_U$ is the prewellordering of length $\underset{\sim}{\delta}^2_1$ from Theorem 2.33. (One can also use the prewellordering from Theorem 4.6.)

By the Uniform Coding Lemma, let $e_0 \in \omega^\omega$ be such that for all $\alpha < \gamma$,

$$U^{(2)}_{e_0}(Q_{<\alpha}, Q_\alpha) \subseteq Z \cap (Q_\alpha \times \omega^\omega) \quad \text{and} \quad U^{(2)}_{e_0}(Q_{<\alpha}, Q_\alpha) \neq \varnothing.$$

Let

$$\Sigma = \mathrm{proj}_2\left(\bigcup\nolimits_{\alpha<\gamma} U^{(2)}_{e_0}(Q_{<\alpha}, Q_\alpha)\right).$$

Notice that Σ is $\underset{\sim}{\Delta}^2_1$ since $\leqslant_U \restriction \gamma$ is $\underset{\sim}{\Delta}^2_1$. The key point is that (as in Lemma 2.27) we can choose a real that ensures that in a reflection argument we reflect to a level that correctly computes $\leqslant_U \restriction \gamma$ and hence Σ. We assume that all reals below have this feature.

Now we can "take control" of the output ordinal δ_0 with respect to σ' and all $\tau \in \Sigma$:

Base Case. We have

(1.1) $\forall y \in \omega^\omega\, ((\sigma' * y)_I)_0 \in U_X$ and

(1.2) $\forall y \in \omega^\omega\, \forall \sigma \in \Sigma\, ((\sigma * y)_I)_0 \in U_X$

since σ' and σ (as in (1.2)) are winning strategies for I. Since Σ is $\underset{\sim}{\Delta}^2_1$ this is a $\Sigma_1(L(\mathbb{R}), \{X, \underset{\sim}{\delta}^2_1, \mathbb{R}\} \cup \mathbb{R})$ fact about σ' and hence certified by a real $z_0 \in U_X$ such that $z_0 \leqslant_T \sigma'$; more precisely, $z_0 \leqslant_T \sigma'$ is such that for all δ if $z_0 \in U_\delta$ then

(1.3) $\forall y \in \omega^\omega\, ((\sigma' * y)_I)_0 \in U_\delta$ and

(1.4) $\forall y \in \omega^\omega\, \forall \sigma \in \Sigma\, ((\sigma * y)_I)_0 \in U_\delta$.

$(n+1)$st *Step.* Assume we have defined $z_0, \ldots, z_n$ in such a way that $z_n \leqslant_T \cdots \leqslant_T z_0$ and

(2.1) $\forall y \in \omega^\omega\, \bigl(\forall i \leqslant n\, (y)_i = z_i \to ((\sigma' * y)_I)_{n+1} \in U_X\bigr)$ and

(2.2) $\forall y \in \omega^\omega\, \forall \sigma \in \Sigma\, \bigl(\forall i \leqslant n\, (y)_i = z_i \to ((\sigma * y)_I)_{n+1} \in U_X\bigr)$.

Let $z_{n+1} \in U_X$ be such that $z_{n+1} \leqslant_T z_n$ and for all δ, if $z_{n+1} \in U_\delta$ then

(2.3) $\forall y \in \omega^\omega\, \bigl(\forall i \leqslant n\, (y)_i = z_i \to ((\sigma' * y)_I)_{n+1} \in U_\delta\bigr)$ and

(2.4) $\forall y \in \omega^\omega\, \forall \sigma \in \Sigma\, \big(\forall i \leqslant n\, (y)_i = z_i \to ((\sigma * y)_I)_{n+1} \in U_\delta\big)$.

Finally, let $z \in \omega^\omega$ be such that $(z)_i = z_i$ for all $i < \omega$ and let δ_0 be least such that $(z)_i \in U_{\delta_0}$ for all $i \in \omega$. Notice that by our choice of z_n DC is not required to define z. Then, for all $i < \omega$,

(3.1) $((\sigma' * z)_I)_i \in U_{\delta_0}$ by (1.3) and (2.3) and

(3.2) $((\sigma * z)_I)_i \in U_{\delta_0}$ for all $\sigma \in \Sigma$ by (1.4) and (2.4).

So

(4.1) δ_0 is the ordinal produced by $\sigma' * z$, i.e. $\delta_0 \in \underset{\sim}{\delta}^2_1 \smallsetminus S$ and

(4.2) δ_0 is the ordinal produced by $\sigma_\alpha * z$ where $\sigma_\alpha \in \Sigma$ is a winning strategy for I in $G^X(S_\alpha)$, i.e. $\delta_0 \in S_\alpha$ for all $\alpha < \gamma$.

This is a contradiction. ⊣

4.2. Strong Normality

Assuming ZF + AD, in $L(\mathbb{R})$ we have defined, for cofinally many $\lambda < \Theta$, an $\mathrm{OD}^{L(\mathbb{R})}$ ultrafilter on $\underset{\sim}{\delta}^2_1$ and shown that these ultrafilters are $\underset{\sim}{\delta}^2_1$-complete. We now wish to take the ultrapower of $\mathrm{HOD}^{L(\mathbb{R})}$ with these ultrafilters and show that collectively they witness that for each $\lambda < \Theta$, $\underset{\sim}{\delta}^2_1$ is λ-strong in $\mathrm{HOD}^{L(\mathbb{R})}$. This will be achieved by showing that reflection and uniform coding combine to show that μ_λ is *strongly normal.*

We begin with the following basic lemma on the ultrapower construction, which we shall prove in greater generality than we need at the moment.

4.8 Lemma. *Assume* ZF+DC*. Suppose μ is a countably complete ultrafilter on δ and that μ is* OD*. Suppose T is a set. Let $(\mathrm{HOD}_T)^\delta$ be the class of all functions $f : \delta \to \mathrm{HOD}_T$. Then the transitive collapse M of $(\mathrm{HOD}_T)^\delta/\mu$ exists, the associated embedding*

$$j : \mathrm{HOD}_T \to M$$

is OD_T*, and*

$$M \subseteq \mathrm{HOD}_T.$$

Proof. For $f, g : \delta \to \mathrm{HOD}_T$, let $f \sim_\mu g$ iff $\{\alpha < \delta \mid f(\alpha) = g(\alpha)\} \in \mu$ and let $[f]_\mu$ be the set consisting of the members of the equivalence class of f which have minimal rank. The structure $(\mathrm{HOD}_T)^\delta/\mu$ is the class consisting of all such equivalence classes. Let E be the associated membership relation. So $[f]_\mu\ E\ [g]_\mu$ if and only if $\{\alpha < \delta \mid f(\alpha) \in g(\alpha)\} \in \mu$. Notice that both $(\mathrm{HOD}_T)^\delta/\mu$ and E are OD_T.

The map

$$\begin{aligned} j_\mu : \mathrm{HOD}_T &\to (\mathrm{HOD}_T)^\delta/\mu \\ a &\mapsto [c_a]_\mu, \end{aligned}$$

where $c_a \in (\mathrm{HOD}_T)^\delta$ is the constant function with value a, is an elementary embedding, since Łoś's theorem holds, as HOD_T can be well-ordered. Notice that j_μ is OD_T.

Claim 1. $((\mathrm{HOD}_T)^\delta/\mu, E)$ *is well-founded.*

Proof. Suppose for contradiction that $((\mathrm{HOD}_T)^\delta/\mu, E)$ is not well-founded. Then, by DC, there is a sequence

$$\langle [f_n]_\mu \mid n < \omega \rangle$$

such that $[f_{n+1}]_\mu \; E \; [f_n]_\mu$ for all $n < \omega$. For each $n < \omega$, let

$$A_n = \{\alpha < \delta \mid f_{n+1}(\alpha) \in f_n(\alpha)\}.$$

For all $n < \omega$, $A_n \in \mu$ and since μ is countable complete,

$$\bigcap \{A_n \mid n < \omega\} \in \mu.$$

This is a contradiction since for each α in this intersection, $f_{n+1}(\alpha) \in f_n(\alpha)$ for all $n < \omega$. ⊣

Claim 2. $((\mathrm{HOD}_T)^\delta/\mu, E)$ *is isomorphic to a transitive class* $(M, \in)$*.*

Proof. We have established well-foundedness and extensionality is immediate. It remains to show that for each $a \in (\mathrm{HOD}_T)^\delta/\mu$,

$$\{b \in (\mathrm{HOD}_T)^\delta/\mu \mid b \; E \; a\}$$

is a set. Fix $a \in (\mathrm{HOD}_T)^\delta/\mu$ and choose $f \in (\mathrm{HOD}_T)^\delta$ such that $a = [f]_\mu$. Let α be such that $f \in V_\alpha$. Then for each $b \in (\mathrm{HOD}_T)^\delta/\mu$ such that bEa, letting $g \in (\mathrm{HOD}_T)^\delta$ be such that $b = [g]_\mu$,

$$\{\beta < \delta \mid g(\beta) \in V_\alpha\} \in \mu.$$

Thus,

$$\{b \in (\mathrm{HOD}_T)^\delta/\mu \mid b \; E \; a\} = \{[g]_\mu \mid [g]_\mu \; E \; [f]_\mu \text{ and } g \in V_\alpha\},$$

which completes the proof. ⊣

Let

$$\pi : ((\mathrm{HOD}_T)^\delta/\mu, E) \to (M, \in)$$

be the transitive collapse map and let

$$j : \mathrm{HOD}_T \to M$$

be the composition map $\pi \circ j_\mu$. Since π and j_μ are OD_T, j and M are OD_T.

It remains to see that $M \subseteq \mathrm{HOD}_T$. For this it suffices to show that for all α, $M \cap V_{j(\alpha)} \subseteq \mathrm{HOD}_T$. We have

$$M \cap V_{j(\alpha)} = j(\mathrm{HOD}_T \cap V_\alpha).$$

Let $A \in \mathrm{HOD}_T \cap \mathscr{P}(\gamma)$ be such that

$$\mathrm{HOD}_T \cap V_\alpha \subseteq L[A]$$

for some γ. We have

$$M \cap V_{j(\alpha)} = j(\mathrm{HOD}_T \cap V_\alpha) \subseteq L[j(A)].$$

But j and A are OD_T. Thus, $j(A) \in \mathrm{HOD}_T$ and hence $L[j(A)] \subseteq \mathrm{HOD}_T$, which completes the proof. $\dashv$

4.9 Remark. The use of DC in this lemma is essential in that assuming mild large cardinal axioms (such as the existence of a strong cardinal) there are models of $\mathrm{ZF} + \mathrm{AC}_\omega$ in which the lemma is false. In these models the club filter on ω_1 is an ultrafilter and the ultrapower of On by the club filter is not well-founded.

The ultrafilter μ_X defined in Sect. 4.1 is $\mathrm{OD}^{L(\mathbb{R})}$. Thus, by Lemma 4.8 (with $T = \varnothing$), letting

$$\pi : (\mathrm{HOD}^{L(\mathbb{R})})^{\utilde{\delta}^2_1}/\mu_X \to M_X$$

be the transitive collapse map and letting

$$j_X : \mathrm{HOD}^{L(\mathbb{R})} \to M_X$$

be the induced elementary embedding we have that $M_X \subseteq \mathrm{HOD}^{L(\mathbb{R})}$ and the fragments of j_X are in $\mathrm{HOD}^{L(\mathbb{R})}$ (in other words, j_X is amenable to $\mathrm{HOD}^{L(\mathbb{R})}$). Moreover, since μ_X is $\utilde{\delta}^2_1$-complete, the critical point of j_X is $\utilde{\delta}^2_1$.

Our next aim is to show that

$$\mathrm{HOD}^{L(\mathbb{R})} \models \utilde{\delta}^2_1 \text{ is } \lambda\text{-strong}$$

and for this it remains to show that

$$j_X(\utilde{\delta}^2_1) > \lambda \quad \text{and} \quad \mathrm{HOD}^{L(\mathbb{R})} \cap V_\lambda \subseteq M_X.$$

From now on we will also assume that λ is such that $L_\lambda(\mathbb{R}) \prec L_\Theta(\mathbb{R})$ and $\utilde{\delta}^2_1 < \lambda$. There are arbitrarily large $\lambda < \Theta$ with this feature (by the proof of Lemma 2.20). Since

$$\mathrm{HOD}^{L(\mathbb{R})} \cap V_\Theta = \mathrm{HOD}^{L_\Theta(\mathbb{R})}$$

(by Theorem 3.10), it follows that

$$\mathrm{HOD}^{L(\mathbb{R})} \cap V_\lambda = \mathrm{HOD}^{L_\lambda(\mathbb{R})}.$$

Thus, letting $A \subseteq \lambda$ be an $\mathrm{OD}^{L(\mathbb{R})}$ set coding $\mathrm{HOD}^{L_\lambda(\mathbb{R})}$, we have

$$\mathrm{HOD}^{L(\mathbb{R})} \cap V_\lambda = L_\lambda[A].$$

Thus, it remains to show that $A \in M_X$. In fact, we will show that

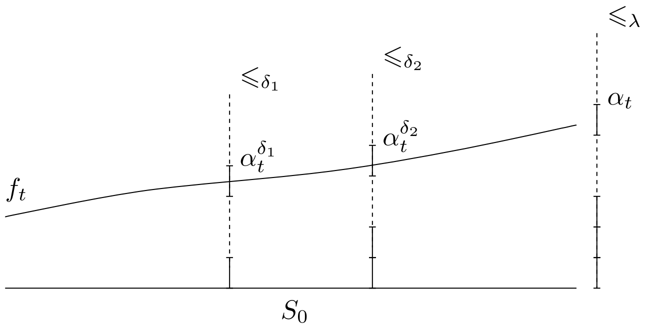
$$\mathscr{P}(\lambda) \cap \mathrm{HOD}^{L(\mathbb{R})} \subseteq M_X.$$

Let

$$S_0 = \{\delta < \underset{\sim}{\delta}^2_1 \mid F(\delta) = (\leqslant_\delta, \lambda_\delta) \text{ where } \leqslant_\delta \text{ is a prewellordering of length } \lambda_\delta \text{ and } L_{\lambda_\delta}(\mathbb{R}) \models \mathrm{T}_0\}.$$

Note that $S_0 \in \mathscr{F}_X$. For $\alpha < \lambda$, let $Q^{\underset{\sim}{\delta}^2_1}_\alpha$ be the αth-component of $\leqslant_\lambda$ and, for $\delta \in S_0$ and $\alpha < \lambda_\delta$, let Q^δ_α be the αth-component of $\leqslant_\delta$. Each $t \in \omega^\omega$ determines a *canonical function* f_t as follows: For $\delta \in S_0$, let α^δ_t be the unique ordinal α such that $t \in Q^\delta_\alpha$ and then set

$$\begin{aligned} f_t : S_0 &\to \underset{\sim}{\delta}^2_1 \\ \delta &\mapsto \alpha^\delta_t. \end{aligned}$$



For $t \in \omega^\omega$, let $\alpha_t = |t|_{\leqslant_\lambda}$ be the rank of t according to $\leqslant_\lambda$, that is, $\alpha_t = |t|_{\leqslant_\lambda} = \mu\alpha\,(t \in Q^{\underset{\sim}{\delta}^2_1}_\alpha)$.

4.10 Lemma. *Assume* $\mathrm{ZF} + \mathrm{AD}$. $j_X(\underset{\sim}{\delta}^2_1) > \lambda$.

Proof. Suppose $t_1, t_2 \in \omega^\omega$ and $|t_1|_{\leqslant_\lambda} = |t_2|_{\leqslant_\lambda}$. This is a true Σ_1 statement in $L(\mathbb{R})$ about t_1, t_2, X and $\mathbb{R}$. Thus, by reflection (Theorem 4.6), it follows that for $\mathscr{F}_X$-almost all $\delta < \underset{\sim}{\delta}^2_1$, $|t_1|_{\leqslant_\delta} = |t_2|_{\leqslant_\delta}$ and so the ordinal $[f_t]_{\mu_X}$ represented by f_t only depends on $|t|_{\leqslant_\lambda}$. Likewise, if $|t_1|_{\leqslant_\lambda} < |t_2|_{\leqslant_\lambda}$ then $[f_{t_1}]_{\mu_X} < [f_{t_2}]_{\mu_X}$. Therefore, the map

$$\begin{aligned} \rho : \lambda &\to \prod \lambda_\delta / \mu_X \\ |t|_{\leqslant_\lambda} &\mapsto [f_t]_{\mu_X} \end{aligned}$$

is well-defined and order-preserving and it follows that $\lambda \leqslant \prod \lambda_\delta / \mu_X < j_X(\underset{\sim}{\delta}^2_1)$. ⊣

We now turn to showing $\mathscr{P}(\lambda) \cap \mathrm{HOD}^{L(\mathbb{R})} \subseteq M_X$. Fix $A \subseteq \lambda$ such that $A \in \mathrm{HOD}^{L(\mathbb{R})}$. By the Uniform Coding Lemma there is an index $e(A) \in \omega^\omega$ such that for all $\alpha < \lambda$,

$$U^{(2)}_{e(A)}(Q^{\underset{\sim}{\delta}^2_1}_{<\alpha}, Q^{\underset{\sim}{\delta}^2_1}_{\alpha}) \neq \varnothing \quad \text{iff} \quad \alpha \in A.$$

For all $\delta \in S_0$, let

$$A^\delta = \{\alpha < \lambda_\delta \mid U^{(2)}_{e(A)}(Q^{\delta}_{<\alpha}, Q^{\delta}_{\alpha}) \neq \varnothing\}$$

be the "reflection of A". Since the statement

$$\{\alpha < \lambda \mid U^{(2)}_{e(A)}(Q^{\underset{\sim}{\delta}^2_1}_{<\alpha}, Q^{\underset{\sim}{\delta}^2_1}_{\alpha}) \neq \varnothing\} \in \mathrm{HOD}^{L(\mathbb{R})}$$

is a true Σ_1 statement about X, $\mathbb{R}$ and $e(A)$, there is a set $S \in \mathscr{F}_X$ such that for all $\delta \in S$, $A^\delta \in \mathrm{HOD}^{L(\mathbb{R})}$.

We wish to show that

$$\begin{aligned} h_A : S &\to \mathrm{HOD}^{L(\mathbb{R})} \\ \delta &\mapsto A^\delta \end{aligned}$$

represents A in the ultrapower. Notice that

$$\begin{aligned} |t|_{\leqslant\lambda} \in A \quad &\text{iff} \quad \{\delta < \underset{\sim}{\delta}^2_1 \mid f_t(\delta) \in A^\delta\} \in \mu_X \\ &\text{iff} \quad [f_t]_{\mu_X} \in [h_A]_{\mu_X}. \end{aligned}$$

The last equivalence holds by definition. For the first equivalence note that if $|t|_{\leqslant\lambda} \in A$ then since this is a true Σ_1 statement about $e(A)$, t and X, for μ_X-almost all δ, $|t|_{\leqslant\delta} \in A^\delta$, that is, $\{\delta < \underset{\sim}{\delta}^2_1 \mid f_t(\delta) \in A^\delta\} \in \mu_X$. Likewise, if $|t|_{\leqslant\lambda} \notin A$ then since this is a true Σ_1 statement about $e(A)$, t and X, for μ_X-almost all δ, $|t|_{\leqslant\delta} \notin A^\delta$.

So it suffices to show that the map

$$\begin{aligned} \rho : \lambda &\to \prod \lambda_\delta/\mu_X \\ |t|_{\leqslant\lambda} &\mapsto [f_t]_{\mu_X} \end{aligned}$$

is an isomorphism since then $\pi([h_A]_{\mu_X}) = A \in M_X$, where recall that $\pi : (\mathrm{HOD}^{L(\mathbb{R})})^{\underset{\sim}{\delta}^2_1}/\mu_X \cong M_X$ is the transitive collapse map. We already know that ρ is well-defined and order-preserving (by Lemma 4.10). It remains to show that ρ is onto, that is, that every function $f \in \prod \lambda_\delta/\mu_X$ is equivalent (modulo μ_X) to a canonical function f_t. To say that this is true is to say that μ_X is *strongly normal*:

4.11 Definition (Strong normality). μ_X is *strongly normal* iff whenever $f : S_0 \to \underset{\sim}{\delta}^2_1$ is such that

$$\{\delta \in S_0 \mid f(\delta) < \lambda_\delta\} \in \mu_X$$

then there exists a $t \in \omega^\omega$ such that

$$\{\delta \in S_0 \mid f(\delta) = f_t(\delta)\} \in \mu_X.$$

Notice that normality is a special case of strong normality since if

$$\{\delta < \underset{\sim}{\delta}^2_1 \mid f(\delta) < \delta\} \in \mu_X$$

then (since for $\mathscr{F}_X$-almost all δ, $\lambda_\delta > \delta$), by strong normality there is a $t \in \omega^\omega$ such that

$$\{\delta < \underset{\sim}{\delta}^2_1 \mid f_t(\delta) = f(\delta)\} \in \mu_X.$$

So if β is such that $t \in Q^{\delta^2_1}_\beta$ then $\beta < \underset{\sim}{\delta}^2_1$, since otherwise by reflection this would contradict the assumption that

$$\{\delta < \underset{\sim}{\delta}^2_1 \mid f(\delta) < \delta\} \in \mu_X.$$

Thus,

$$\{\delta < \underset{\sim}{\delta}^2_1 \mid f(\delta) = \beta\} \in \mu_X.$$

4.12 Theorem. *Assume* ZF + AD. $L(\mathbb{R}) \models \mu_X$ *is strongly normal.*

Proof. Assume toward a contradiction that f is a counterexample to strong normality. So, for each $t \in \omega^\omega$,

$$\{\delta \in S_0 \mid f(\delta) \neq f_t(\delta)\} \in \mu_X.$$

Let

$$\eta = \min\left\{\beta < \lambda \mid \forall t \in Q^{\delta^2_1}_\beta \ \{\delta \in S_0 \mid f(\delta) < f_t(\delta)\} \in \mu_X\right\}$$

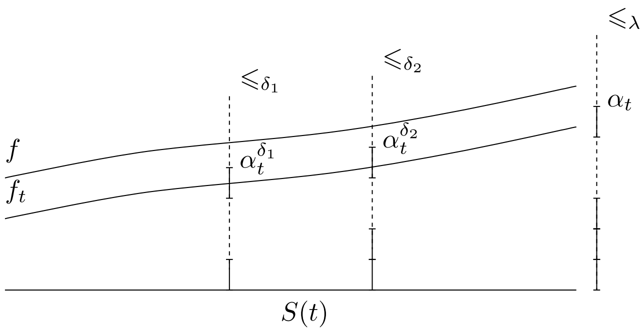
if such β exist; otherwise, let $\eta = \lambda$. Fix $y_\eta \in Q^{\delta^2_1}_\eta$ (unless $\eta = \lambda$, in which case we ignore this parameter) and, for $\delta \in S_0$, let $\eta_\delta = f_{y_\eta}(\delta)$ and for $\delta = \underset{\sim}{\delta}^2_1$, let $\eta_\delta = \eta$. Note that $f_{y_\eta}(\delta) > f(\delta)$ for μ_X-almost all δ. In the proof we will be working on this set and so we modify S_0 by intersecting it with this set if necessary. For convenience let

$$S(t) = \{\delta \in S_0 \mid f_t(\delta) < f(\delta)\}.$$

Notice that by the definition of η and our assumption that f is a counterexample to strong normality, we have that

$$S(t) \in \mu_X$$

for all $t \in Q^{\delta^2_1}_{<\eta}$.



Our aim is to compute f from a real parameter by coding relative to the various prewellorderings. Our computation will give us "$f(\underset{\sim}{\delta}^2_1)$". Then, picking a real $y_f \in Q^{\underset{\sim}{\delta}^2_1}_{\text{“}f(\underset{\sim}{\delta}^2_1)\text{”}}$ we shall have by reflection that for μ_X-almost every δ, $f(\delta) = f_{y_f}(\delta)$, which is a contradiction.

The proof involves a number of parameters which we list here. We will also give a brief description which will not make complete sense at this point but will serve as a useful reference to consult as the proof proceeds.

e_0 is the index of the universal set that selects the Z^δ_α's (represented in the diagrams as ellipses) from Z' (represented in the diagrams as chimneys).

e_1 is the index of the universal set that selects *subsets* of the Z^δ_α's (represented in the diagrams as black dots inside the ellipses).

y_η is the real in $Q^{\underset{\sim}{\delta}^2_1}_\eta$ that determines η_δ for $\delta \in S_0$.

y_f is the real in $Q^{\underset{\sim}{\delta}^2_1}_{\text{“}f(\underset{\sim}{\delta}^2_1)\text{”}}$ that determines $f(\delta)$ for $\delta \in S_3$.

We will successively shrink S_0 to S_1, S_2, and finally S_3. All four of these sets will be members of μ_X. We now proceed with the proof.

Let

$$Z' = \big\{(t, \sigma) \mid t \in Q^{\underset{\sim}{\delta}^2_1}_{<\eta} \text{ and } \sigma \text{ is a winning strategy for I in } G^X(S(t))\big\}.$$

Thus, by our assumption that f is a counterexample to strong normality and by our choice of η we have, for all $\beta < \eta$,

$$Z' \cap (Q^{\underset{\sim}{\delta}^2_1}_\beta \times \omega^\omega) \neq \varnothing,$$

since for all $t \in Q^{\underset{\sim}{\delta}^2_1}_{<\eta}$, I wins $G^X(S(t))$. By the Uniform Coding Lemma, let $e_0 \in \omega^\omega$ be such that for all $\beta < \eta$,

(1.1) $U^{(2)}_{e_0}(Q^{\underset{\sim}{\delta}^2_1}_{<\beta}, Q^{\underset{\sim}{\delta}^2_1}_\beta) \subseteq Z' \cap (Q^{\underset{\sim}{\delta}^2_1}_\beta \times \omega^\omega)$ and

(1.2) $U^{(2)}_{e_0}(Q^{\underset{\sim}{\delta}^2_1}_{<\beta}, Q^{\underset{\sim}{\delta}^2_1}_\beta) \neq \varnothing$.

By reflection, we have that for $\mathscr{F}_X$-almost all δ, for all $\beta < \eta_\delta$,

(2.1) $U^{(2)}_{e_0}(Q^\delta_{<\beta}, Q^\delta_\beta) \subseteq Q^\delta_\beta \times \omega^\omega$ and

(2.2) $U^{(2)}_{e_0}(Q^\delta_{<\beta}, Q^\delta_\beta) \neq \varnothing$.

Notice that in the reflected statement we have had to drop reference to Z' since we cannot reflect Z' as the games involved in its definition are not Σ_1. Let S'_1 be the set of such δ and let $S_1 = S'_1 \cap S_0$. Notice that S_1 is $\Sigma_1(L(\mathbb{R}), \{e_0, y_\eta, f, X, \underset{\sim}{\delta}^2_1, \mathbb{R}\})$.

For $\delta \in S_1 \cup \{\underset{\sim}{\delta}^2_1\}$ and $\beta < \eta_\delta$ let

$$Z^\delta_\beta = U^{(2)}_{e_0}(Q^\delta_{<\beta}, Q^\delta_\beta)$$

and for $\delta \in S_1 \cup \{\underset{\sim}{\delta}^2_1\}$ let

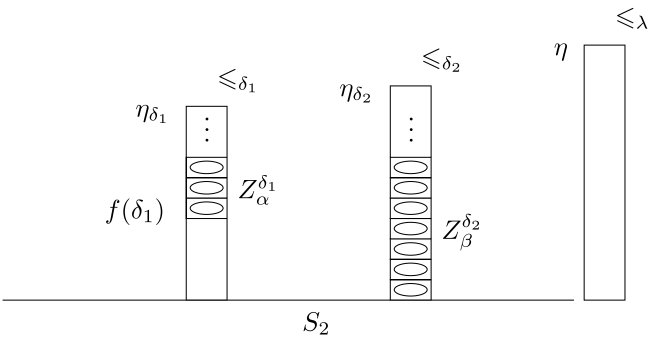
$$Z^\delta = \bigcup_{\beta<\eta_\delta} Z^\delta_\beta.$$

Claim A (Disjointness Property). *There is an $S_2 \subseteq S_1$, $S_2 \in \mu_X$ such that for $\delta_1, \delta_2 \in S_2 \cup \{\underset{\sim}{\delta}^2_1\}$ with $\delta_1 < \delta_2 \leqslant \underset{\sim}{\delta}^2_1$,*

$$Z^{\delta_1}_\alpha \cap Z^{\delta_2}_\beta = \varnothing$$

for all $\alpha \in [f(\delta_1), \eta_{\delta_1})$ and $\beta \in [0, \eta_{\delta_2})$.

Proof. Here is the picture:



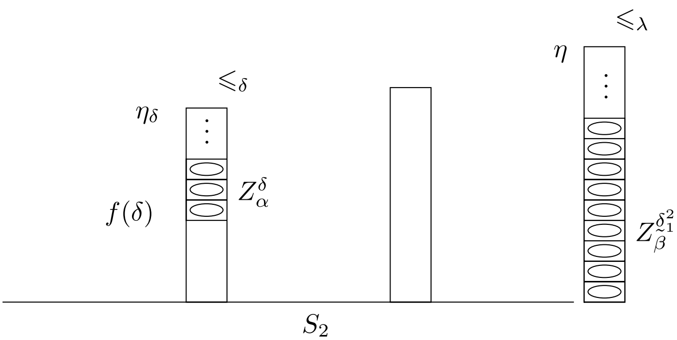
We begin by establishing a special case.

Subclaim. *For μ_X-almost all δ,*

$$Z^\delta_\alpha \cap Z^{\underset{\sim}{\delta}^2_1}_\beta = \varnothing$$

for all $\alpha \in [f(\delta), \eta_\delta)$ and $\beta \in [0, \eta)$.

Proof. The picture is similar:



Let

$$T = \{\delta \in S_1 \mid Z^\delta_\alpha \cap Z^{\underset{\sim}{\delta}^2_1}_\beta = \varnothing \text{ for all } \alpha \in [f(\delta), \eta_\delta) \text{ and } \beta \in [0, \eta)\}$$

and assume, toward a contradiction, that $T \notin \mu_X$. So $(\underset{\sim}{\delta}^2_1 \smallsetminus T) \cap S_1 \in \mu_X$. Let σ' be a winning strategy for I in $G^X((\underset{\sim}{\delta}^2_1 \smallsetminus T) \cap S_1)$.

Let us first motivate the main idea: Suppose z is a legal play for II against σ' (by which we mean a play for II that satisfies the Main Rule) and suppose that the ordinal associated with this play is δ_0. So $\delta_0 \in (\underset{\sim}{\delta}^2_1 \smallsetminus T) \cap S_1$ and (by the definition of T) there exists an $\alpha_0 \in [f(\delta_0), \eta_\delta)$ and $\beta_0 \in [0, \eta)$ such that $Z^{\delta_0}_{\alpha_0} \cap Z^{\underset{\sim}{\delta}^2_1}_{\beta_0} \neq \varnothing$. Pick $(t_0, \sigma_0) \in Z^{\delta_0}_{\alpha_0} \cap Z^{\underset{\sim}{\delta}^2_1}_{\beta_0}$. In virtue of the fact that $(t_0, \sigma_0) \in Z^{\delta_0}_{\alpha_0}$ we have

(3.1) $f_{t_0}(\delta_0) = \alpha_0 \geqslant f(\delta_0)$

and in virtue of the fact that $(t_0, \sigma_0) \in Z^{\underset{\sim}{\delta}^2_1}_{\beta_0}$ we have

(3.2) σ_0 is a winning strategy for I in $G^X(S(t_0))$, where

$$S(t_0) = \{\delta \in S_0 \mid f_{t_0}(\delta) < f(\delta)\}.$$

So we get a contradiction if δ_0 happens to be in $S(t_0)$ (since then $f_{t_0}(\delta_0) < f(\delta_0)$, contradicting (3.1)). Notice that this will occur if we can arrange the play z to be such that in addition to being a legal play against σ' with associated ordinal δ_0 it is *also* a legal play against σ_0 (in the game $G^X(S(t_0))$) with associated ordinal δ_0. We can construct such a play z recursively as in the proof of completeness.

Base Case. We have

(4.1) $\forall y \in \omega^\omega\, ((\sigma' * y)_I)_0 \in U_X$ and

(4.2) $\forall y \in \omega^\omega\, \forall (t, \sigma) \in Z^{\underset{\sim}{\delta}^2_1}\, ((\sigma * y)_I)_0 \in U_X$

since σ' and σ (as in (4.2)) are winning strategies for I. Now all of this is a $\Sigma_1(L(\mathbb{R}), \{X, \underset{\sim}{\delta}^2_1, \mathbb{R}\})$ fact about σ' and e_0 (the index for $Z^{\underset{\sim}{\delta}^2_1}$) and so it is certified by a real $z_0 \in U_X$ such that $z_0 \leqslant_T \langle \sigma', e_0 \rangle$; so z_0 is such that if $z_0 \in U_\delta$ then

(4.3) $\forall y \in \omega^\omega\, ((\sigma' * y)_I)_0 \in U_\delta$ and

(4.4) $\forall y \in \omega^\omega\, \forall (t, \sigma) \in Z^\delta\, ((\sigma * y)_I)_0 \in U_\delta$.

$(n+1)$st *Step.* Assume we have defined $z_0, \dots, z_n$ in such a way that $z_n \leqslant_T \cdots \leqslant_T z_0$ and

(5.1) $\forall y \in \omega^\omega\, \big(\forall i \leqslant n\, (y)_i = z_i \to ((\sigma' * y)_I)_{n+1} \in U_X\big)$ and

(5.2) $\forall y \in \omega^\omega\, \forall (t, \sigma) \in Z^{\underset{\sim}{\delta}^2_1}\, \big(\forall i \leqslant n\, (y)_i = z_i \to ((\sigma * y)_I)_{n+1} \in U_X\big)$.

Again, all of this is a $\Sigma_1(L(\mathbb{R}),\{X,\underset{\sim}{\delta}^2_1,\mathbb{R}\})$ fact about $\sigma', e_0, z_0,\dots,z_n$ and so it is certified by a real $z_{n+1}\in U_X$ such that $z_{n+1}\leqslant_T z_n$; so z_{n+1} is such that if $z_{n+1}\in U_\delta$ then

(5.3) $\forall y\in\omega^\omega\,\big(\forall i\leqslant n\,(y)_i=z_i\rightarrow((\sigma'*y)_I)_{n+1}\in U_\delta\big)$ and

(5.4) $\forall y\in\omega^\omega\,\forall(t,\sigma)\in Z^\delta\,\big(\forall i\leqslant n\,(y)_i=z_i\rightarrow((\sigma*y)_I)_{n+1}\in U_\delta\big)$.

Finally, let $z\in\omega^\omega$ be such that $(z)_i=z_i$ for all $i<\omega$ and let δ_0 be least such that $(z)_i\in U_{\delta_0}$ for all $i\in\omega$. Notice that since we chose z_{n+1} to be recursive in z_n DC is not required to form z. Since $(z)_i\in U_X$ for all $i\in\omega$, z is a legal play for II in any of the games $G^X(S)$ relevant to the argument. Moreover, for all $i\in\omega$,

(6.1) $((\sigma'*z)_I)_i\in U_{\delta_0}$ by (4.3) and (5.3) and

(6.2) $((\sigma*z)_I)_i\in U_{\delta_0}$ for all $\sigma\in\mathrm{proj}_2(Z^{\delta_0})$ by (4.4) and (5.4)

and so

(7.1) δ_0 is the ordinal produced by $\sigma'*z$, i.e. $\delta_0\in(\underset{\sim}{\delta}^2_1\smallsetminus T)\cap S_1$ and

(7.2) δ_0 is the ordinal produced by $\sigma*z$ for any $\sigma\in\mathrm{proj}_2(Z^{\delta_0})$.

Since $\delta_0\in(\underset{\sim}{\delta}^2_1\smallsetminus T)\cap S_1$, by the definition of T there exists an $\alpha_0\in[f(\delta_0),\eta_{\delta_0})$ and $\beta_0\in[0,\eta)$ such that $Z^{\delta_0}_{\alpha_0}\cap Z^{\underset{\sim}{\delta}^2_1}_{\beta_0}\neq\varnothing$. Pick $(t_0,\sigma_0)\in Z^{\delta_0}_{\alpha_0}\cap Z^{\underset{\sim}{\delta}^2_1}_{\beta_0}$. In virtue of the fact that $(t_0,\sigma_0)\in Z^{\delta_0}_{\alpha_0}$ we have

(8.1) $f_{t_0}(\delta_0)=\alpha_0\geqslant f(\delta_0)$

and in virtue of the fact that $(t_0,\sigma_0)\in Z^{\underset{\sim}{\delta}^2_1}_{\beta_0}$ we have

(8.2) σ_0 is a winning strategy for I in $G^X(S(t_0))$, where

$$S(t_0)=\{\delta\in S_0\mid f_{t_0}(\delta)<f(\delta)\}.$$

Combined with (7.2) this implies $\delta_0\in S(t_0)$, in other words, $f_{t_0}(\delta_0)<f(\delta_0)$, which contradicts (8.1). ⊣

Thus, $T\in\mu_X$ and we have

(9.1) $\forall\delta\in T\,\forall\beta\in[0,\eta_{\underset{\sim}{\delta}^2_1})\,\forall\alpha\in[f(\delta),\eta_\delta)\,(Z^\delta_\alpha\cap Z^{\underset{\sim}{\delta}^2_1}_\beta=\varnothing)$.

This is a true Σ_1 statement in $L(\mathbb{R})$ about e_0, y_η, f, X, $\mathbb{R}$, $\underset{\sim}{\delta}^2_1$, and T. Since T is $\Sigma_1(L(\mathbb{R}),\{e_0,y_\eta,f,X,\underset{\sim}{\delta}^2_1,\mathbb{R}\})$, the above statement is $\Sigma_1(L(\mathbb{R}),\{e_0,y_\eta,f,X,\underset{\sim}{\delta}^2_1,\mathbb{R}\})$. Thus by the Reflection Theorem (Theorem 4.6) there exists an $S_2\subseteq S_1$, $S_2\in\mu_X$ such that for all $\delta_2\in S_2$,

(9.2) $\forall\delta_1\in T\cap\delta_2\,\forall\beta\in[0,\eta_{\delta_2})\,\forall\alpha\in[f(\delta_1),\eta_{\delta_1})\,(Z^{\delta_1}_\alpha\cap Z^{\delta_2}_\beta=\varnothing)$.

Notice that S_2 is $\Sigma_1(L(\mathbb{R}), \{X, \underset{\sim}{\delta}^2_1, \mathbb{R}\})$ in e_0, y_η and the parameters for coding. This completes the proof of Claim A. $\dashv$

Claim B (Tail Computation). *There exists an index* $e_1 \in \omega^\omega$ *such that for all* $\delta \in S_2$,

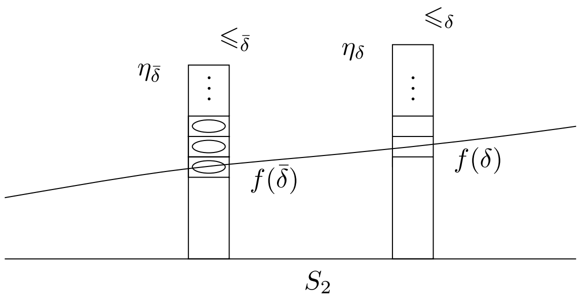
(1) $U^{(2)}_{e_1}(P^\delta, Z^\delta_\beta) \subseteq Z^\delta_\beta$ *for all* $\beta < \eta_\delta$,

(2) $U^{(2)}_{e_1}(P^\delta, Z^\delta_{f(\delta)}) = \varnothing$, *and*

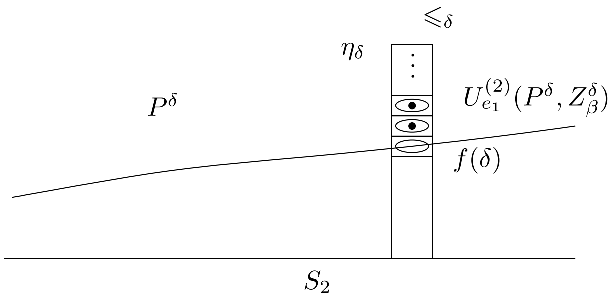
(3) $U^{(2)}_{e_1}(P^\delta, Z^\delta_\beta) \neq \varnothing$ *for* β *such that* $f(\delta) < \beta < \eta_\delta$,

where $P^\delta = \bigcup\{Z^{\bar{\delta}}_\alpha \mid \bar{\delta} \in S_2 \cap \delta$ *and* $\alpha \in [f(\bar{\delta}), \eta_{\bar{\delta}})\}$ *and* S_2 *is from the end of the proof of Claim A.*

Proof. Here is the picture of the "tail parameter" P^δ:



Here is the picture of the statement of Claim B:



Assume toward a contradiction that there is no such e_1. We follow the proof of the Uniform Coding Lemma. To begin with, notice that it suffices to find an $e_1 \in \omega^\omega$ satisfying (2) and

(3′) $U^{(2)}_{e_1}(P^\delta, Z^\delta_\beta) \cap Z^\delta_\beta \neq \varnothing$ for β such that $f(\delta) < \beta < \eta_\delta$

since given the parameter Z^δ_β we can easily ensure (1).

Consider the set of reals such that (2) of the (revised) claim holds, that is,

$$G = \left\{e \in \omega^\omega \mid \forall \delta \in S_2 \left(U^{(2)}_e(P^\delta, Z^\delta_{f(\delta)}) = \varnothing\right)\right\}.$$

So, for each $e \in G$, ($3'$) in the claim fails for some $\delta \in S_2$ and $\beta \in (f(\delta), \eta_\delta)$. For each $e \in G$, let

$$\begin{aligned} \alpha_e = {} & \text{lexicographically least pair } (\delta, \beta) \text{ such that} \\ & (1)\ \delta \in S_2, \\ & (2)\ f(\delta) < \beta < \eta_\delta, \text{ and} \\ & (3)\ U^{(2)}_e(P^\delta, Z^\delta_\beta) \cap Z^\delta_\beta = \varnothing. \end{aligned}$$

Now play the game

$$\begin{array}{lccccccc} \text{I} & x(0) & & x(1) & & x(2) & & \dots \\ \text{II} & & y(0) & & y(1) & & \dots & \end{array}$$

where II wins iff $(x \in G \to (y \in G \wedge \alpha_y >_{\text{lex}} \alpha_x))$

Claim 1. *Player I does not have a winning strategy.*

Proof. Suppose toward a contradiction that σ is a winning strategy for I. As in the proof of the Uniform Coding Lemma, we aim to "bound" all of I's plays and then use this bound to construct a play e^* for II which defeats σ. We will make key use of the Disjointness Property.

Choose $e_\sigma \in \omega^\omega$ such that for all $P, P' \subseteq \omega^\omega$,

$$U^{(2)}_{e_\sigma}(P, P') = \bigcup\nolimits_{y \in \omega^\omega} U^{(2)}_{(\sigma * y)_I}(P, P').$$

In particular, for all $\delta \in S_2$ and $\beta < \eta_\delta$,

$$U^{(2)}_{e_\sigma}(P^\delta, Z^\delta_\beta) = \bigcup\nolimits_{y \in \omega^\omega} U^{(2)}_{(\sigma * y)_I}(P^\delta, Z^\delta_\beta).$$

Note two things: First, since σ is a winning strategy for I, $(\sigma * y)_I \in G$ for all $y \in \omega^\omega$; so $e_\sigma \in G$. Second, for all $y \in \omega^\omega$, $\alpha_{(\sigma * y)_I} \leqslant_{\text{lex}} \alpha_{e_\sigma}$. So e_σ is "at least as good" as any $(\sigma * y)_I$. We have to do "better".

Pick $x_0 \in Z^{\delta_0}_{\beta_0}$ where $(\delta_0, \beta_0) = \alpha_{e_\sigma}$. Choose e^* such that for all $P, P' \subseteq \omega^\omega$,

$$U^{(2)}_{e^*}(P, P') = \begin{cases} U^{(2)}_{e_\sigma}(P, P') & \text{if } x_0 \notin P' \\ U^{(2)}_{e_\sigma}(P, P') \cup \{x_0\} & \text{if } x_0 \in P'. \end{cases}$$

In particular, for all $\delta \in S_2$ and $\beta < \eta_\delta$,

$$U^{(2)}_{e^*}(P^\delta, Z^\delta_\beta) = \begin{cases} U^{(2)}_{e_\sigma}(P^\delta, Z^\delta_\beta) & \text{if } x_0 \notin Z^\delta_\beta \\ U^{(2)}_{e_\sigma}(P^\delta, Z^\delta_\beta) \cup \{x_0\} & \text{if } x_0 \in Z^\delta_\beta. \end{cases}$$

Since we chose $x_0 \in Z^{\delta_0}_{\beta_0}$, by the Disjointness Property (and the fact that for fixed δ, $Z^\delta_\alpha \cap Z^\delta_\beta = \varnothing$ for $\alpha < \beta < \eta_\delta$) we have

(10.1) $x_0 \notin Z^\delta_\beta$ for $\delta \in S_2 \cap [0, \delta_0)$ and $\beta \in [f(\delta), \eta_\delta)$,

(10.2) $x_0 \notin Z^{\delta_0}_\beta$ for $\beta \in [0, \eta_{\delta_0}) \setminus \{\beta_0\}$, and

(10.3) $x_0 \notin Z^\delta_\beta$ for $\delta \in S_2 \cap (\delta_0, \underset{\sim}{\delta}^2_1)$ and $\beta \in [0, \eta_\delta)$.

Thus, by the definition of e^*, we have, by (10.1–3),

$$U^{(2)}_{e^*}(P^\delta, Z^\delta_{f(\delta)}) = U^{(2)}_{e_\sigma}(P^\delta, Z^\delta_{f(\delta)})$$

for all $\delta \in S_2$. Since $e_\sigma \in G$, this means $e^* \in G$. So α_{e^*} exists. Similarly, by the definition of e^*, we have, by (10.1) and (10.2),

$$U^{(2)}_{e^*}(P^\delta, Z^\delta_\beta) = U^{(2)}_{e_\sigma}(P^\delta, Z^\delta_\beta)$$

for all $\delta \in S_2 \cap [0, \delta_0)$ and $\beta \in [f(\delta), \eta_\delta)$ and for $\delta = \delta_0$ and $\beta \in [f(\delta_0), \beta_0)$. So e^* is "at least as good" as e_σ. But since $x_0 \in Z^{\delta_0}_{\beta_0}$, we have that $x_0 \in U^{(2)}_{e^*}(P^{\delta_0}, Z^{\delta_0}_{\beta_0})$, by the definition of e^*; that is, e^* is "better" than e_σ. In other words, $\alpha_{e^*} >_{\text{lex}} \alpha_{e_\sigma} \geqslant_{\text{lex}} \alpha_{(\sigma * y)_I}$ for all $y \in \omega^\omega$ and so, by playing e^*, II defeats σ. ⊣

Claim 2. *Player II does not have a winning strategy.*

Proof. Suppose toward a contradiction that τ is a winning strategy for II. We shall find an e^* such that $e^* \in G$ (Subclaim 1) and α_{e^*} does not exist (Subclaim 2), which is a contradiction.

Choose $h_0 : \omega^\omega \times (\omega^\omega \times \omega^\omega) \to \omega^\omega$ such that h_0 is Σ^1_1 and for all $(e, x) \in \omega^\omega \times (\omega^\omega \times \omega^\omega)$ and for all $P, P' \subseteq \omega^\omega$,

$$U^{(2)}_{h_0(e,x)}(P, P') = \begin{cases} U^{(2)}_e(P, P') & \text{if } x \notin P \cup P' \\ \varnothing & \text{if } x \in P \cup P'. \end{cases}$$

In particular, for $\delta \in S_2$ and $\beta < \eta_\delta$,

$$U^{(2)}_{h_0(e,x)}(P^\delta, Z^\delta_\beta) = \begin{cases} U^{(2)}_e(P^\delta, Z^\delta_\beta) & \text{if } x \notin P^\delta \cup Z^\delta_\beta \\ \varnothing & \text{if } x \in P^\delta \cup Z^\delta_\beta. \end{cases}$$

Choose $h_1 : \omega^\omega \to \omega^\omega$ such that h_1 is Σ^1_1 and for all $P, P' \subseteq \omega^\omega$,

$$U^{(2)}_{h_1(e)}(P, P') = \bigcup\nolimits_{x \in P'} U^{(2)}_{(h_0(e,x) * \tau)_{II}}(P, P').$$

In particular, for $\delta \in S_2$ and $\beta < \eta_\delta$,

$$U^{(2)}_{h_1(e)}(P^\delta, Z^\delta_\beta) = \bigcup\nolimits_{x \in Z^\delta_\beta} U^{(2)}_{(h_0(e,x) * \tau)_{II}}(P^\delta, Z^\delta_\beta).$$

By the Recursion Theorem, there is an $e^* \in \omega^\omega$ such that for all $\delta \in S_2$ and $\beta < \eta_\delta$,

$$U^{(2)}_{e^*}(P^\delta, Z^\delta_\beta) = U^{(2)}_{h_1(e^*)}(P^\delta, Z^\delta_\beta).$$

Subclaim 1. *$e^* \in G$.*

Proof. Suppose for contradiction that $e^* \notin G$. Let $\delta_0 \in S_2$ be least such that

$$U^{(2)}_{e^*}(P^{\delta_0}, Z^{\delta_0}_{f(\delta_0)}) \neq \varnothing.$$

Now

$$\begin{aligned} U^{(2)}_{e^*}(P^{\delta_0}, Z^{\delta_0}_{f(\delta_0)}) &= U^{(2)}_{h_1(e^*)}(P^{\delta_0}, Z^{\delta_0}_{f(\delta_0)}) \\ &= \textstyle\bigcup_{x \in Z^{\delta_0}_{f(\delta_0)}} U^{(2)}_{(h_0(e^*,x)*\tau)_{II}}(P^{\delta_0}, Z^{\delta_0}_{f(\delta_0)}). \end{aligned}$$

So choose $x_0 \in Z^{\delta_0}_{f(\delta_0)}$ such that

$$U^{(2)}_{(h_0(e^*,x_0)*\tau)_{II}}(P^{\delta_0}, Z^{\delta_0}_{f(\delta_0)}) \neq \varnothing.$$

If we can show $h_0(e^*, x_0) \in G$ then we are done since this implies that $(h_0(e^*, x_0) * \tau)_{II} \in G$ (as τ is a winning strategy for II), which contradicts the previous statement.

Subsubclaim. *$h_0(e^*, x_0) \in G$, that is, for all $\delta \in S_2$,*

$$U^{(2)}_{h_0(e^*,x_0)}(P^{\delta}, Z^{\delta}_{f(\delta)}) = \varnothing.$$

Proof. By the definition of h_0, for all $\delta \in S_2$,

$$U^{(2)}_{h_0(e^*,x_0)}(P^{\delta}, Z^{\delta}_{f(\delta)}) = \begin{cases} U^{(2)}_{e^*}(P^{\delta}, Z^{\delta}_{f(\delta)}) & \text{if } x_0 \notin P^{\delta} \cup Z^{\delta}_{f(\delta)} \\ \varnothing & \text{if } x_0 \in P^{\delta} \cup Z^{\delta}_{f(\delta)}. \end{cases}$$

Since $x_0 \in Z^{\delta_0}_{f(\delta_0)}$, by the Disjointness Property, this definition yields the following: For $\delta \in S_2 \cap [0, \delta_0)$ we have $x_0 \notin P^{\delta} \cup Z^{\delta}_{f(\delta)}$ and so,

$$U^{(2)}_{h_0(e^*,x_0)}(P^{\delta}, Z^{\delta}_{f(\delta)}) = U^{(2)}_{e^*}(P^{\delta}, Z^{\delta}_{f(\delta)}) = \varnothing,$$

where the latter holds since we chose δ_0 to be least such that

$$U^{(2)}_{e^*}(P^{\delta_0}, Z^{\delta_0}_{f(\delta_0)}) \neq \varnothing;$$

for $\delta = \delta_0$ we have $x_0 \in Z^{\delta}_{f(\delta)}$ and so

$$U^{(2)}_{h_0(e^*,x_0)}(P^{\delta}, Z^{\delta}_{f(\delta)}) = \varnothing;$$

and for $\delta \in S_2 \cap (\delta_0, \underset{\sim}{\delta}^2_1)$ we have $x_0 \in P^{\delta}$ and so

$$U^{(2)}_{h_0(e^*,x_0)}(P^{\delta}, Z^{\delta}_{f(\delta)}) = \varnothing.$$

Thus, $h_0(e^*, x_0) \in G$. ⊣

This completes the proof of Subclaim 1. ⊣

Subclaim 2. *α_{e^*} does not exist.*

Proof. Suppose for contradiction that α_{e^*} exists. Recall that

$$\begin{aligned}\alpha_{e^*} = {} & \text{lexicographically least pair } (\delta, \beta) \text{ such that} \\ & (1)\ \delta \in S_2, \\ & (2)\ f(\delta) < \beta < \eta_\delta, \text{ and} \\ & (3)\ U^{(2)}_{e^*}(P^\delta, Z^\delta_\beta) \cap Z^\delta_\beta = \varnothing.\end{aligned}$$

Let $(\delta_0, \beta_0) = \alpha_{e^*}$. We shall show $U^{(2)}_{e^*}(P^{\delta_0}, Z^{\delta_0}_{\beta_0}) \cap Z^{\delta_0}_{\beta_0} \neq \varnothing$, which is a contradiction. By the definition of h_1,

$$\begin{aligned}U^{(2)}_{e^*}(P^{\delta_0}, Z^{\delta_0}_{\beta_0}) &= U^{(2)}_{h_1(e^*)}(P^{\delta_0}, Z^{\delta_0}_{\beta_0}) \\ &= \textstyle\bigcup_{x \in Z^{\delta_0}_{\beta_0}} U^{(2)}_{(h_0(e^*, x) * \tau)_{II}}(P^{\delta_0}, Z^{\delta_0}_{\beta_0}).\end{aligned}$$

Fix $x_0 \in Z^{\delta_0}_{\beta_0}$. Since $e^* \in G$, $h_0(e^*, x_0) \in G$, by the Disjointness Property. (This is because for $\delta \in S_2 \cap [0, \delta_0)$ we have $x_0 \notin P^\delta \cup Z^\delta_{f(\delta)}$ and so

$$U^{(2)}_{h_0(e^*, x_0)}(P^\delta, Z^\delta_{f(\delta)}) = U^{(2)}_{e^*}(P^\delta, Z^\delta_{f(\delta)}) = \varnothing,$$

where the latter holds since $e^* \in G$; for $\delta = \delta_0$ we have $x_0 \notin P^\delta \cup Z^\delta_{f(\delta)}$ and since $e^* \in G$ this implies

$$U^{(2)}_{h_0(e^*, x_0)}(P^\delta, Z^\delta_{f(\delta)}) = \varnothing;$$

and for $\delta \in S_2 \cap (\delta_0, \underset{\sim}{\delta}^2_1)$ we have $x_0 \in P^\delta$ and so

$$U^{(2)}_{h_0(e^*, x_0)}(P^\delta, Z^\delta_{f(\delta)}) = \varnothing.)$$

So $\alpha_{h_0(e^*, x_0)}$ exists.

Subsubclaim. $\alpha_{h_0(e^*, x_0)} = \alpha_{e^*}$.

Proof. By the definition of h_0,

$$U^{(2)}_{h_0(e^*, x_0)}(P^\delta, Z^\delta_\beta) = \begin{cases} U^{(2)}_{e^*}(P^\delta, Z^\delta_\beta) & \text{if } x_0 \notin P^\delta \cup Z^\delta_\beta \\ \varnothing & \text{if } x_0 \in P^\delta \cup Z^\delta_\beta \end{cases}$$

for $\delta \in S_2$ and $\beta < \eta_\delta$. So

$$U^{(2)}_{h_0(e^*, x_0)}(P^{\delta_0}, Z^{\delta_0}_{\beta_0}) \cap Z^{\delta_0}_{\beta_0} = \varnothing,$$

since $x_0 \in P^{\delta_0} \cup Z^{\delta_0}_{\beta_0}$. And, when either $\delta = \delta_0$ and $\beta \in (f(\delta_0), \beta_0)$ or $\delta \in S_2 \cap [0, \delta_0)$ and $\beta \in [f(\delta), \eta_\delta)$, we have, by the Disjointness Property, $x_0 \notin P^\delta \cup Z^\delta_\beta$, hence

$$U^{(2)}_{h_0(e^*, x_0)}(P^\delta, Z^\delta_\beta) = U^{(2)}_{e^*}(P^\delta, Z^\delta_\beta).$$

Thus, $\alpha_{h_0(e^*, x_0)} = \alpha_{e^*}$. ⊣

Since τ is winning for II,

$$(h_0(e^*, x_0) * \tau)_{II} \in G$$

and

$$\alpha_{(h_0(e^*,x_0)*\tau)_{II}} >_{\text{lex}} \alpha_{h_0(e^*,x_0)} = \alpha_{e^*}.$$

So

$$U^{(2)}_{(h_0(e^*,x_0)*\tau)_{II}}(P^{\delta_0}, Z^{\delta_0}_{\beta_0}) \cap Z^{\delta_0}_{\beta_0} \neq \varnothing.$$

Since

$$U^{(2)}_{e^*}(P^{\delta_0}, Z^{\delta_0}_{\beta_0}) = \bigcup_{x \in Z^{\delta_0}_{\beta_0}} U^{(2)}_{(h_0(e^*,x)*\tau)_{II}}(P^{\delta_0}, Z^{\delta_0}_{\beta_0})$$

we have

$$U^{(2)}_{e^*}(P^{\delta_0}, Z^{\delta_0}_{\beta_0}) \cap Z^{\delta_0}_{\beta_0} \neq \varnothing,$$

which is a contradiction. ⊣

This completes the proof of Claim 2. ⊣

We have a contradiction and therefore there is an e_1 is as desired. ⊣

Notice that $U^{(2)}_{e_1}(P^\delta, Z^\delta_\alpha)$, for variable α, allows us to pick out $f(\delta)$. Now we can consider the ordinal "$f(\underset{\sim}{\delta}^2_1)$" picked out in this fashion.

Claim C. *There exists a $\beta_0 < \eta$ such that*

(1) $U^{(2)}_{e_1}(P^{\underset{\sim}{\delta}^2_1}, Z^{\underset{\sim}{\delta}^2_1}_{\beta_0}) = \varnothing$ and

(2) $U^{(2)}_{e_1}(P^{\underset{\sim}{\delta}^2_1}, Z^{\underset{\sim}{\delta}^2_1}_{\beta}) \neq \varnothing$ for all $\beta \in (\beta_0, \eta)$, where

$$P^{\underset{\sim}{\delta}^2_1} = \bigcup \{ Z^\delta_\alpha \mid \delta \in S_2 \textit{ and } \alpha \in [f(\delta), \eta_\delta) \}.$$

Proof. Suppose for contradiction that the claim is false. The statement that the claim fails is a true Σ_1 statement about e_0, e_1, y_η, X, $\mathbb{R}$, f and S_2. But then by the Reflection Theorem (Theorem 4.6) this fact reflects to $\mathscr{F}_X$-almost all δ, which contradicts Claim B. ⊣

Pick $y_f \in Q^{\underset{\sim}{\delta}^2_1}_{\beta_0}$. Now the statement that $y_f \in Q^{\underset{\sim}{\delta}^2_1}_{\beta_0}$ where β_0 is such that (1) and (2) of Claim C hold is a true Σ_1 statement about e_0, e_1, y_η, y_f, f, X, $\mathbb{R}$, and $\underset{\sim}{\delta}^2_1$. Thus, by Theorem 4.6, for $\mathscr{F}_X$-almost every $\delta < \underset{\sim}{\delta}^2_1$ this statement reflects. Let $S_3 \subseteq S_2$ be in μ_X and such that the above statement reflects to each point in S_3. Now by Claim B, for $\delta \in S_3$, the least β_0 such that $y_f \in Q^\delta_{\beta_0}$ is $f(\delta)$. Thus,

$$\{\delta \in S_0 \mid f_{y_f}(\delta) = f(\delta)\} \in \mu_X$$

and hence μ_X is strongly normal. ⊣

This completes the proof of the following:

4.13 Theorem. *Assume* $\mathrm{ZF}+\mathrm{DC}+\mathrm{AD}$. *Then, for each* $\lambda<\Theta^{L(\mathbb{R})}$,

$$\mathrm{HOD}^{L(\mathbb{R})}\models \mathrm{ZFC}+(\undertilde{\delta}^2_1)^{L(\mathbb{R})} \textit{ is } \lambda\textit{-strong.}$$

4.14 Remark. For simplicity we proved Lemma 4.7 and Claim A of Theorem 4.12 using a proof by contradiction. This involves an appeal to determinacy. However, one can prove each result more directly, without appealing to determinacy.

Call a real y *suitable* if $(y)_i\in U_X$ for all $i<\omega$. Call a strategy σ a *proto-winning strategy* if σ is a winning strategy for I in $G^X(\undertilde{\delta}^2_1)$. Thus if y is suitable and σ is a proto-winning strategy then

$$\{((\sigma*y)_I)_i,(y)_i\mid i<\omega\}\subseteq U_X$$

and so we can let

$$\delta_{(\sigma,y)}=\text{the least }\delta\text{ such that }\{((\sigma*y)_I)_i\mid i<\omega\}\cup\{(y)_i\mid i<\omega\}\subseteq U_\delta.$$

Let κ be least such that $X\in L_\kappa(\mathbb{R})$ and $L_\kappa(\mathbb{R})\prec_1 L(\mathbb{R})$. This is the "least stable over X". It is easy to see that

$$\mathscr{P}(\mathbb{R})\cap L_\kappa(\mathbb{R})=\Delta_1(L(\mathbb{R}),\mathbb{R}\cup\{X,\undertilde{\delta}^2_1,\mathbb{R}\})$$

and so if $\Sigma\in\mathscr{P}(\mathbb{R})\cap L_\kappa(\mathbb{R})$ then for $\mathscr{F}_X$-almost all δ there is a reflected version Σ_δ of Σ. We can now state the relevant result:

Suppose $\Sigma\in\mathscr{P}(\mathbb{R})\cap L_\kappa(\mathbb{R})$ is a set of proto-winning strategies for I. Then there is a proto-winning strategy σ such that for all suitable reals y, for all $\tau\in\Sigma_{\delta_{(\sigma,y)}}\cap\Sigma$, there is a suitable real y_τ such that

$$\delta_{(\sigma,y)}=\delta_{(\tau,y_\tau)}.$$

The proof of this is a variant of the above proofs and it provides a more direct proof of completeness and strong normality.

4.3. A Woodin Cardinal

We now wish to show that $\Theta^{L(\mathbb{R})}$ is a Woodin cardinal in $\mathrm{HOD}^{L(\mathbb{R})}$. In general, in inner model theory there is a long march up from strong cardinals to Woodin cardinals. However, in our present context, where we have the power of AD and are working with the special inner model $\mathrm{HOD}^{L(\mathbb{R})}$, this next step comes almost for free.

4.15 Theorem. *Assume* $\mathrm{ZF}+\mathrm{DC}+\mathrm{AD}$. *Then*

$$\mathrm{HOD}^{L(\mathbb{R})}\models\Theta^{L(\mathbb{R})} \textit{ is a Woodin cardinal.}$$

Proof. For notational convenience let $\Theta = \Theta^{L(\mathbb{R})}$. To show that

$$\mathrm{HOD}^{L(\mathbb{R})} \models \mathrm{ZFC} + \Theta \text{ is a Woodin cardinal}$$

it suffices to show that for each $T \in \mathscr{P}(\Theta) \cap \mathrm{OD}^{L(\mathbb{R})}$, there is an ordinal δ_T such that

$$\mathrm{HOD}_T^{L_\Theta(\mathbb{R})[T]} \models \mathrm{ZFC} + \delta_T \text{ is } \lambda\text{-}T\text{-strong},$$

for each $\lambda < \Theta$. Since Θ is strongly inaccessible in $\mathrm{HOD}^{L(\mathbb{R})}$, $\mathrm{HOD}^{L(\mathbb{R})}$ satisfies that $V_\Theta^{\mathrm{HOD}^{L(\mathbb{R})}}$ is a model of second-order ZFC. Thus, since $T \in \mathscr{P}(\Theta) \cap \mathrm{HOD}^{L(\mathbb{R})}$ and $V_\Theta^{\mathrm{HOD}^{L(\mathbb{R})}} = \mathrm{HOD}^{L_\Theta(\mathbb{R})}$,

$$\mathrm{HOD}_T^{L_\Theta(\mathbb{R})[T]} \models \mathrm{ZFC}.$$

It remains to establish strength. Since this is almost exactly as before we will just note the basic changes.

The model $L_\Theta(\mathbb{R})[T]$ comes with a natural Σ_1 stratification, namely,

$$\big\langle L_\alpha(\mathbb{R})[T \cap \alpha] \;\big|\; \alpha < \Theta \big\rangle.$$

Since Θ is regular in $L(\mathbb{R})$ and $L_\Theta(\mathbb{R}) \models \mathrm{T}_0$, the set

$$\big\{\alpha < \Theta \mid L_\alpha(\mathbb{R})[T \cap \alpha] \prec L_\Theta(\mathbb{R})[T]\big\}$$

contains a club in Θ. To see this is note that for each $n < \omega$,

$$C_n = \big\{\alpha < \Theta \mid L_\alpha(\mathbb{R})[T \cap \alpha] \prec_n L_\Theta(\mathbb{R})[T]\big\}$$

is club (by Replacement) and, since Θ is regular, $\bigcap\{C_n \mid n < \omega\}$ is club. Thus, there are arbitrarily large $\alpha < \Theta$ such that

$$L_\alpha(\mathbb{R})[T \cap \alpha] \models \mathrm{T}_0.$$

For this reason OD_T, $<_{\mathrm{OD}_T}$ and HOD_T are Σ_1-definable in $L_\Theta(\mathbb{R})[T]$ exactly as before. (Here, as usual, we are working in the language of set theory supplemented with a predicate for T, which is assumed to be allowed in all of our definability calculations.)

Let

$$\delta_T = \text{ the least } \lambda \text{ such that } L_\lambda(\mathbb{R})[T \cap \lambda] \prec_1 L_\Theta(\mathbb{R})[T].$$

As will be evident, the relevant facts concerning $\underset{\sim}{\delta}^2_1$ carry over to the present context. For example, δ_T is the least ordinal λ such that

$$L_\lambda(\mathbb{R})[T \cap \lambda] \prec_1^{\mathbb{R} \cup \{\mathbb{R}\}} L_\Theta(\mathbb{R})[T].$$

The function $F_T : \delta_T \to L_{\delta_T}(\mathbb{R})[T \cap \delta_T]$ is defined as before as follows: Work in T_0. Suppose that $F_T \restriction \delta$ is defined. Let $\vartheta(\delta)$ be least such that

$L_{\vartheta(\delta)}(\mathbb{R})[T \cap \vartheta(\delta)] \models \mathrm{T}_0$ and there is an $X \in L_{\vartheta(\delta)}(\mathbb{R})[T \cap \vartheta(\delta)] \cap \mathrm{OD}_T^{L_{\vartheta(\delta)}(\mathbb{R})[T\cap\vartheta(\delta)]}$ and

($\star$) there is a Σ_1 formula φ and a real z such that

$$L_{\vartheta(\delta)}(\mathbb{R})[T \cap \vartheta(\delta)] \models \varphi[z, X, \delta_T, T \cap \vartheta(\delta), \mathbb{R}]$$

and for all $\bar{\delta} < \delta$,

$$L_{\vartheta(\delta)}(\mathbb{R})[T \cap \vartheta(\delta)] \not\models \varphi[z, F(\bar{\delta}), \bar{\delta}, T \cap \vartheta(\delta), \mathbb{R}]$$

(if such an ordinal exists) and then let $F_T(\delta)$ be the $(<_{\mathrm{OD}_T})^{L_{\vartheta(\delta)(\mathbb{R})}[T\cap\vartheta(\delta)]}$-least X such that ($\star$).

The proof of the Reflection Theorem carries over exactly as before to establish the following: For all $X \in \mathrm{OD}_T^{L_\Theta(\mathbb{R})[T]}$, for all Σ_1 formulas φ, and for all $z \in \omega^\omega$ if

$$L_\Theta(\mathbb{R})[T] \models \varphi[z, X, \delta_T, T, \mathbb{R}]$$

then there exists a $\delta < \delta_T$ such that

$$L_\Theta(\mathbb{R})[T] \models \varphi[z, F_T(\delta), \delta, T \cap \delta, \mathbb{R}].$$

Let U_X^T be a universal $\Sigma_1(L_\Theta(\mathbb{R})[T], \{X, \delta_T, T, \mathbb{R}\})$ set of reals and, for $\delta < \delta_T$, let U_δ^T be the universal $\Sigma_1(L_\Theta(\mathbb{R})[T], \{F_T(\delta), \delta, T\cap\delta, \mathbb{R}\})$ set obtained by using the same definition. For $z \in U_X^T$, let $S_z^T = \{\delta < \delta_T \mid z \in U_\delta^T\}$ and set

$$\mathscr{F}_X^T = \{S \subseteq \delta_T \mid \exists z \in U_X^T\, (S_z^T \subseteq S)\}.$$

As before, $\mathscr{F}_X^T$ is a countably complete filter and in the Reflection Theorem we can reflect to $\mathscr{F}_X^T$-many points $\delta < \delta_T$ and allow parameters $A \subseteq \delta_T$ and $f : \delta_T \to \delta_T$.

Fix an ordinal $\lambda < \Theta$. By the results of Sect. 3.3, there is an $\mathrm{OD}_T^{L_\Theta(\mathbb{R})[T]}$-prewellordering $\leqslant_\lambda$ of ω^ω of length λ. Our interest is in applying the Reflection Theorem to

$$X = (\leqslant_\lambda, \lambda).$$

Working in $L_\Theta(\mathbb{R})[T]$, for each $S \subseteq \delta_T$, let $G_T^X(S)$ be the game

$$\begin{array}{lccccccc} \mathrm{I} & x(0) & & x(1) & & x(2) & & \ldots \\ \mathrm{II} & & y(0) & & y(1) & & \ldots & \end{array}$$

with the following winning conditions: Main Rule: For all $i < \omega$, $(x)_i, (y)_i \in U_X^T$. If the rule is violated then, letting i be the least such that either $(x)_i \notin U_X^T$ or $(y)_i \notin U_X^T$ I wins if $(x)_i \in U_X^T$; otherwise II wins. If the rule is satisfied then, letting δ be least such that for all $i < \omega$, $(x)_i, (y)_i \in U_\delta^T$, I wins iff $\delta \in S$.

Now set

$$\mu_X^T = \{S \subseteq \delta_T \mid \mathrm{I} \text{ wins } G_T^X(S)\}.$$

Notice that $\mu_X^T \in \mathrm{OD}_T^{L_\Theta(\mathbb{R})[T]}$. As before $\mathscr{F}_X^T \subseteq \mu_X^T$ and μ_X^T is a δ_T-complete ultrafilter.

Let

$$S_0 = \{\delta < \delta_T \mid F_T(\delta) = (\leqslant_\delta, \lambda_\delta) \text{ where } \leqslant_\delta \text{ is a prewellordering of length } \lambda_\delta \text{ and } L_{\lambda_\delta}(\mathbb{R})[T \cap \lambda_\delta] \models \mathrm{T}_0\}.$$

By reflection, $S_0 \in \mathscr{F}_X^T$.

As before we say that μ_X^T is *strongly normal* iff whenever $f : S_0 \to \delta_T$ is such that

$$\{\delta \in S_0 \mid f(\delta) < \lambda_\delta\} \in \mu_X^T$$

then there exists a $t \in \omega^\omega$ such that

$$\{\delta \in S_0 \mid f(\delta) = f_t(\delta)\} \in \mu_X^T.$$

The proof that μ_X^T is strongly normal is exactly as before. As in the proof of Lemma 4.8 we can use μ_X^T to take the ultrapower of $\mathrm{HOD}^{L_\Theta(\mathbb{R})[T]}$. In $L_\Theta(\mathbb{R})[T]$ form

$$\left(\mathrm{HOD}_T^{L_\Theta(\mathbb{R})[T]}\right)^{\delta_T} / \mu_X^T.$$

As before we get an elementary embedding

$$j_\lambda : \mathrm{HOD}_T^{L_\Theta(\mathbb{R})[T]} \to M,$$

where M is the transitive collapse of the ultrapower. By completeness, this embedding has critical point δ_T and as in Lemma 4.10 the canonical functions witness that $j_\lambda(\delta_T) > \lambda$. Assuming further that λ is such that

$$L_\lambda(\mathbb{R})[T \cap \lambda] \prec_1 L_\Theta(\mathbb{R})[T]$$

we have that

$$\mathrm{HOD}_T^{L_\Theta(\mathbb{R})[T]} \subseteq M_\lambda.$$

As before, strong normality implies that

$$\begin{aligned} \rho : \lambda &\to \textstyle\prod \lambda_\delta / \mu_X^T \\ |t|_{\leqslant_\lambda} &\mapsto [f_t]_{\mu_X^T} \end{aligned}$$

is an isomorphism. It remains to establish T-strength, that is,

$$|t|_{\leqslant_\lambda} \in T \cap \lambda \quad \text{iff} \quad \{\delta < \delta_T \mid f_t(\delta) \in T \cap \lambda_\delta\} \in \mu_X^T.$$

The point is that both

$$|t|_{\leqslant_\lambda} \in T \cap \lambda$$

and

$$|t|_{\leqslant_\lambda} \notin T \cap \lambda$$

are $\Sigma_1(L_\Theta(\mathbb{R})[T], \{X, \delta_T, T, \mathbb{R}\})$ and so the result follows by the Reflection Theorem (Theorem 4.6) and the fact that $\mathscr{F}^T_X \subseteq \mu^T_X$.

Thus,

$$\mathrm{HOD}_T^{L_\Theta(\mathbb{R})[T]} \models \mathrm{ZFC} + \delta_T \text{ is } \lambda\text{-}T\text{-strong},$$

which completes the proof. ⊣

In the above proof DC was only used in one place—to show that the ultrapowers were well-founded (Lemma 4.8). This was necessary since although the ultrapowers were ultrapowers of HOD and HOD satisfies AC, the ultrapowers were "external" (in that the associated ultrafilters were not in HOD) and so we had to assume DC in V to establish well-foundedness. However, this use of DC can be eliminated by using the extender formulation of being a Woodin cardinal. In this way one obtains strength through a network of "internal" ultrapowers (that is, via ultrafilters that live in HOD) and this enables one to bypass the need to assume DC in V. We will take this route in the next section.

5. Woodin Cardinals in General Settings

Our aim in this section is to abstract the essential ingredients from the previous construction and prove two abstract theorems on Woodin cardinals in general settings, one that requires DC and one that does not.

The first abstract theorem will be the subject of Sect. 5.1:

5.1 Theorem. *Assume* $\mathrm{ZF} + \mathrm{DC} + \mathrm{AD}$*. Suppose X and Y are sets. Let*

$$\Theta_{X,Y} = \sup\{\alpha \mid \textit{there is an } \mathrm{OD}_{X,Y} \textit{ surjection } \pi : \omega^\omega \to \alpha\}.$$

Then

$$\mathrm{HOD}_X \models \mathrm{ZFC} + \Theta_{X,Y} \textit{ is a Woodin cardinal.}$$

There is a variant of this theorem (which we will prove in Sect. 5.4) where one can drop DC and assume less determinacy, the result being that Θ_X is a Woodin cardinal in HOD_X. The importance of the version involving $\Theta_{X,Y}$ is that it enables one to show that in certain settings HOD_X can have many Woodin cardinals. To describe one such key application we introduce the following notion due to Solovay. Assume $\mathrm{ZF} + \mathrm{DC}_\mathbb{R} + \mathrm{AD} + V = L(\mathscr{P}(\mathbb{R}))$ and work in $V = L(\mathscr{P}(\mathbb{R}))$. The sequence $\langle \Theta_\alpha \mid \alpha \leqslant \Omega\rangle$ is defined to be the shortest sequence such that Θ_0 is the supremum of all ordinals γ for which there is an OD surjection of ω^ω onto γ, $\Theta_{\alpha+1}$ is the supremum of all ordinals γ for which there is an OD surjection of $\mathscr{P}(\Theta_\alpha)$ onto γ, $\Theta_\lambda = \sup_{\alpha<\lambda} \Theta_\alpha$ for nonzero limit ordinals $\lambda \leqslant \Omega$, and $\Theta_\Omega = \Theta$.

5.2 Theorem. *Assume* $\mathrm{ZF} + \mathrm{DC}_\mathbb{R} + \mathrm{AD} + V = L(\mathscr{P}(\mathbb{R}))$*. Then for each $\alpha < \Omega$,*

$$\mathrm{HOD} \models \mathrm{ZFC} + \Theta_{\alpha+1} \textit{ is a Woodin cardinal.}$$

The second abstract theorem provides a template that one can use in various contexts to generate inner models containing Woodin cardinals.

5.3 Theorem (Generation Theorem). *Assume* ZF*. Suppose*

$$M = L_{\Theta_M}(\mathbb{R})[T, A, B]$$

is such that

(1) $M \models \mathrm{T}_0$*,*

(2) Θ_M *is a regular cardinal,*

(3) $T \subseteq \Theta_M$*,*

(4) $A = \langle A_\alpha \mid \alpha < \Theta_M \rangle$ *is such that* A_α *is a prewellordering of the reals of length greater than or equal to* α*,*

(5) $B \subseteq \omega^\omega$ *is nonempty, and*

(6) $M \models$ *Strategic determinacy with respect to* B*.*

Then

$$\mathrm{HOD}^M_{T,A,B} \models \mathrm{ZFC} + \textit{There is a } T\textit{-strong cardinal.}$$

The motivation for the statement of the theorem—in particular, the notion of "strategic determinacy"—comes from the attempt to run the construction of Sect. 4.2 using lightface determinacy alone. In doing this one must simulate enough boldface determinacy to handle the real parameters that arise in that construction. To fix ideas we begin in Sect. 5.2 by examining a particular lightface setting, namely, $L[S, x]$ where S is a class of ordinals. Since $(\mathrm{OD}_{S,x})^{L[S,x]} = L[S, x]$ and $L[S, x]$ satisfies AC one cannot have boldface determinacy in $L[S, x]$. However, by assuming full determinacy in the background universe, strong forms of lightface determinacy hold in $L[S, x]$, for an S-cone of x. (The notion of an S-cone will be defined in Sect. 5.2). We will extract stronger and stronger forms of lightface determinacy until ultimately we reach the notion of "strategic determinacy", which is sufficiently rich to simulate boldface determinacy and drive the construction. With this motivation in place we will return to the general setting in Sect. 5.3 and prove the Generation Theorem. Finally, in Sect. 5.4 we will use the Generation Theorem as a template reprove the theorem of the previous section in ZF + AD and to deduce a number of special cases, two of which are worth mentioning here:

5.4 Theorem. *Assume* ZF + AD*. Then for an* S*-cone of* x*,*

$$\mathrm{HOD}_S^{L[S,x]} \models \mathrm{ZFC} + \omega_2^{L[S,x]} \textit{ is a Woodin cardinal.}$$

5.5 Theorem. *Assume* $\mathrm{ZF} + \mathrm{AD}$*. Suppose* Y *is a set and* $a \in H(\omega_1)$*. Then for a* Y*-cone of* x*,*

$$\mathrm{HOD}_{Y,a,[x]_Y} \models \mathrm{ZFC} + \omega_2^{\mathrm{HOD}_{Y,a,x}} \textit{ is a Woodin cardinal,}$$

where $[x]_Y = \{z \in \omega^\omega \mid \mathrm{HOD}_{Y,z} = \mathrm{HOD}_{Y,x}\}$.

(The notion of a Y-cone will be defined in Sect. 5.4.) In Sect. 6 these two results will be used as the basis of a calibration of the consistency strength of lightface and boldface definable determinacy in terms of the large cardinal hierarchy. The second result will also be used to reprove and generalize Kechris' classical result that $\mathrm{ZF} + \mathrm{AD}$ implies that DC holds in $L(\mathbb{R})$. For this reason it is important to note that the theorem does not presuppose DC.

5.1. First Abstraction

5.6 Theorem. *Assume* $\mathrm{ZF} + \mathrm{DC} + \mathrm{AD}$*. Suppose* X *and* Y *are sets. Then*

$$\mathrm{HOD}_X \models \mathrm{ZFC} + \Theta_{X,Y} \textit{ is a Woodin cardinal.}$$

Proof. By Theorem 3.9,

$$\mathrm{HOD}_{X,Y} \models \Theta_{X,Y} \text{ is strongly inaccessible}$$

and so

$$\mathrm{HOD}_X \models \Theta_{X,Y} \text{ is strongly inaccessible.}$$

A direct approach to showing that in addition

$$\mathrm{HOD}_X \models \Theta_{X,Y} \text{ is a Woodin cardinal}$$

would be to follow Sect. 4.3 by showing that for each $T \in \mathscr{P}(\Theta_{X,Y}) \cap \mathrm{OD}_X$ there is an ordinal δ_T such that

$$\mathrm{HOD}_X \cap V_{\Theta_{X,Y}} \models \delta_T \text{ is } \lambda\text{-}T\text{-strong}$$

for each $\lambda < \Theta_{X,Y}$. However, such an approach requires that for each $\lambda < \Theta_{X,Y}$, there is a prewellordering of ω^ω of length λ which is OD in $L_{\Theta_{X,Y}}(\mathbb{R})[T]$ and in our present, more general setting we have no guarantee that this is true. So our strategy is to work with a larger model (where such prewellorderings exist), get the ultrafilters we need, and then pull them back down to $L_{\Theta_{X,Y}}(\mathbb{R})[T]$ by Kunen's theorem (Theorem 3.11).

We will actually first show that

$$\mathrm{HOD}_{X,Y} \models \Theta_{X,Y} \text{ is a Woodin cardinal.}$$

Let T be an element of $\mathscr{P}(\Theta_{X,Y}) \cap \mathrm{OD}_{X,Y}$ and let (by Lemma 3.7)

$$A = \langle A_\alpha \mid \alpha < \Theta_{X,Y} \rangle$$

be an $\mathrm{OD}_{X,Y}$ sequence such that each A_α is a prewellordering of ω^ω of length α. We will work with the structure

$$L_{\Theta_{X,Y}}(\mathbb{R})[T,A]$$

and the natural hierarchy of structures that it provides.

To begin with we note some basic facts. First, notice that

$$\Theta_{X,Y} = (\Theta_{T,A})^{L(\mathbb{R})[T,A]} = \Theta^{L(\mathbb{R})[T][A]}.$$

(For the first equivalence we have

$$(\Theta_{T,A})^{L(\mathbb{R})[T,A]} \geqslant \Theta_{X,Y}$$

because of A and we have

$$(\Theta_{T,A})^{L(\mathbb{R})[T,A]} \leqslant \Theta_{X,Y}$$

because $L(\mathbb{R})[T,A]$ is $\mathrm{OD}_{X,Y}$. The second equivalence holds since every element in $L(\mathbb{R})[T,A]$ is $\mathrm{OD}_{T,A,y}^{L(\mathbb{R})[T][A]}$ for some $y \in \omega^\omega$. So the "averaging over reals" argument of Lemma 3.8 applies.) It follows that our earlier arguments generalize. For example, by the proof of Theorem 3.10,

$$\Theta_{X,Y} \text{ is strongly inaccessible in } \mathrm{HOD}^{L(\mathbb{R})[T,A]}$$

and

$$\Theta_{X,Y} \text{ is regular in } L(\mathbb{R})[T,A].$$

(Note that $\Theta_{X,Y}$ need not be regular in V. For example, assuming $\mathrm{ZF} + \mathrm{DC} + \mathrm{AD}_\mathbb{R}$, Θ_0 has cofinality ω in V.) Moreover, the proof of Lemma 2.21 shows that

$$L_{\Theta_{X,Y}}(\mathbb{R})[T,A] \models \mathrm{T}_0$$

and the proof of Lemma 2.23 shows that

$$L_{\Theta_{X,Y}}(\mathbb{R})[T,A] \prec_1 L(\mathbb{R})[T,A].$$

This implies (in conjunction with the fact that $\Theta_{X,Y}$ is regular in $L(\mathbb{R})[T,A]$) that

$$\{\alpha < \Theta_{X,Y} \mid L_\alpha(\mathbb{R})[T{\restriction}\alpha, A{\restriction}\alpha] \prec L_{\Theta_{X,Y}}(\mathbb{R})[T,A]\}$$

is club in $\Theta_{X,Y}$ and hence that each such level satisfies T_0.

So we are in exactly the situation of Sect. 4.3 except that now the prewellorderings are explicitly part of the structure. The proof of Theorem 4.15 thus shows that: For each $T \in \mathscr{P}(\Theta_{X,Y}) \cap \mathrm{OD}_{X,Y}$ there is an ordinal $\delta_{T,A}$ such that

$$\mathrm{HOD}_{T,A}^{L_{\Theta_{X,Y}}(\mathbb{R})[T,A]} \models \delta_{T,A} \text{ is } \lambda\text{-}T\text{-strong}$$

for each $\lambda < \Theta_{X,Y}$, as witnessed by an ultrafilter μ_λ^T on $\delta_{T,A}$. These ultrafilters are $\mathrm{OD}_{T,A}^{L_{\Theta_{X,Y}}(\mathbb{R})[T,A]}$.

The key point is that all of these ultrafilters μ_λ^T are actually OD by Kunen's theorem (Theorem 3.11). This is where DC is used.

Now we return to the smaller model $L_{\Theta_{X,Y}}(\mathbb{R})[T]$. Since $\Theta_{X,Y}$ is strongly inaccessible in HOD_X there is a set $H \in \mathscr{P}(\Theta_{X,Y})^{L_{\Theta_{X,Y}}(\mathbb{R})[T]}$ such that

$$\mathrm{HOD}_X \cap V_{\Theta_{X,Y}} = L_{\Theta_{X,Y}}[H].$$

We may assume without loss of generality that H is folded into T. Thus

$$\mathrm{HOD}_T^{L_{\Theta_{X,Y}}(\mathbb{R})[T]} = \mathrm{HOD}_X \cap V_{\Theta_{X,Y}}$$

and this structure contains all of the ultrafilters μ_λ^T. These ultrafilters can now be used (as in the proof of Lemma 4.8) to take the ultrapower and so we have

$$\mathrm{HOD}_T^{L_{\Theta_{X,Y}}(\mathbb{R})[T]} \models \delta_{T,A} \text{ is } \lambda\text{-}T\text{-strong},$$

which completes the proof. ⊣

5.2. Strategic Determinacy

Let us now turn to the Generation Theorem. We shall begin by motivating the notion of "strategic determinacy" by examining the special case of $L[S,x]$ where S is a class of ordinals.

For $x \in \omega^\omega$, the *S-degree of x* is $[x]_S = \{y \in \omega^\omega \mid L[S,y] = L[S,x]\}$. The *$S$-degrees* are the sets of the form $[x]_S$ for some $x \in \omega^\omega$. Let $\mathscr{D}_S = \{[x]_S \mid x \in \omega^\omega\}$. Define $x \leqslant_S y$ to hold iff $x \in L[S,y]$ and define the notions $x \equiv_S y$, $x <_S y$, $x \geqslant_S y$, $[x]_S \leqslant_S [y]_S$ in the obvious way. A *cone of S-degrees* is a set of the form $\{[y]_S \mid y \geqslant_S x_0\}$ for some $x_0 \in \omega^\omega$. An *S-cone of reals* is a set of form $\{y \in \omega^\omega \mid y \geqslant_S x_0\}$ for some $x_0 \in \omega^\omega$. The *cone filter on $\mathscr{D}_S$* is the filter consisting of sets of S-degrees that contain a cone of S-degrees. Given a formula $\varphi(x)$ we say that *φ holds for an S-cone of x* if there is a real x_0 such that for all $y \geqslant_S x_0$, $L[S,y] \models \varphi(y)$. The proof of the Cone Theorem (Theorem 2.9) generalizes.

5.7 Theorem (Martin). *Assume* ZF + AD*. The cone filter on $\mathscr{D}_S$ is an ultrafilter.*

Proof. For $A \subseteq \mathscr{D}_S$ consider the game

I	$x(0)$		$x(1)$		$x(2)$		$\ldots$
II		$y(0)$		$y(1)$		$\ldots$	

where I wins iff $[x * y]_S \in A$. If I has a winning strategy σ_0 then σ_0 witnesses that A is in the S-cone filter since for $y \geqslant_S \sigma_0$, $[y]_S = [\sigma_0 * y]_S \in A$. If II has a winning strategy τ_0 then τ_0 witnesses that $\mathscr{D}_S \smallsetminus A$ is in the S-cone filter since for $x \geqslant_S \tau_0$, $[x]_S = [x * \tau_0]_S \in \mathscr{D}_S \smallsetminus A$. ⊣

It follows that each statement φ either holds on an S-cone or fails on an S-cone. In fact, the entire theory stabilizes. However, in order to fully articulate this fact one needs to invoke second-order assumptions (like the existence of a satisfaction relation). Without invoking second-order assumptions one has the following:

5.8 Corollary. *Assume* ZF + AD. *For each $n < \omega$, there is an x_n such that for all $x \geqslant_S x_n$,*

$$L[S,x] \models \varphi \quad \textit{iff} \quad L[S,x_n] \models \varphi,$$

for all Σ^1_n sentences φ.

Proof. Let $\langle \varphi_i \mid i < \omega\rangle$ enumerate the Σ^1_n sentences of the language of set theory and, for each i, let y_i be the base of an S-cone settling φ_i. Now using $\mathrm{AC}_\omega(\mathbb{R})$ (which is provable in ZF + AD) let x_n encode $\langle y_i \mid i < \omega\rangle$. ⊣

A natural question then is: "What is the stable theory?"

5.9 Theorem. *Assume* ZF + AD. *Then for an S-cone of x,*

$$L[S,x] \models \mathrm{CH}.$$

Proof. Suppose for contradiction (by Theorem 5.7) that ¬CH holds for an S-cone of x. Let x_0 be the base of this cone.

We will arrive at a contradiction by producing an $x \geqslant_S x_0$ such that $L[S,x] \models \mathrm{CH}$. This will be done by forcing over $L[S,x_0]$ in two stages, first to get CH and then to get a real coding this generic (while preserving CH). It will be crucial that the generics actually exist.

Claim. *ω_1^V is strongly inaccessible in any inner model M of* AC.

Proof. We first claim that there is no ω_1^V-sequence of distinct reals: Let μ be the club filter on ω_1^V. By Solovay's theorem (Theorem 2.12, which doesn't require DC) μ is a countably complete ultrafilter on ω_1^V. Suppose $\langle a_\alpha \mid \alpha < \omega_1^V\rangle$ is a sequence of characteristic functions for distinct reals. By countable completeness there is a μ-measure one set X_n of elements of this sequence that agree on their nth-coordinate. Thus, $\bigcap_{n<\omega} X_n$ has μ-measure one, which is impossible since it only has one member.

It follows that for each $\gamma < \omega_1^V$, $(2^\gamma)^M < \omega_1^V$ since otherwise (γ being countable) there would be an ω_1^V sequence of distinct reals. Since ω_1^V is clearly regular in M the result follows. ⊣

Step 1. Let G be $L[S,x_0]$-generic for $\mathrm{Col}(\omega_1^{L[S,x_0]}, \mathbb{R}^{L[S,x_0]})$. (By the Claim this generic exists in V). So

$$L[S,x_0][G] \models \mathrm{CH} \quad \text{and} \quad \mathbb{R}^{L[S,x_0][G]} = \mathbb{R}^{L[S,x_0]}.$$

The trouble is that $L[S,x_0][G]$ is not of the form $L[S,x]$ for $x \in \mathbb{R}$. (We could code G via a real by brute force but doing so might destroy CH. A more delicate approach is needed.)

Step 2. Code G using almost disjoint forcing: First, view G as a subset of $\omega_1^{L[S,x_0]}$ by letting $A \subseteq \omega_1^{L[S,x_0]}$ be such that

$$L[S,x_0][G] = L[S,x_0,A].$$

Now let

$$\langle \sigma_\alpha \mid \alpha < \omega_1^{L[S,x_0]} \rangle \in L[S,x_0]$$

be a sequence of infinite almost disjoint subsets of ω (that is, such that if $\alpha \neq \beta$ then $\sigma_\alpha \cap \sigma_\beta$ is finite). By almost disjoint forcing, in $L[S,x_0,A]$ there is a c.c.c. forcing $\mathbb{P}_A$ of size $\omega_1^{L[S,x_0,A]}$ such that if $H \subseteq \mathbb{P}_A$ is $L[S,x_0,A]$-generic then there is a $c(A) \subseteq \omega$ such that

$$\alpha \in A \quad \text{iff} \quad c(A) \cap \sigma_\alpha \text{ is infinite.}$$

(See [1, pp. 267–268] for details concerning this forcing notion.) Also

$$L[S,x_0,A][H] = L[S,x_0,A][c(A)] = L[S,x_0,c(A)].$$

Finally,

$$L[S,x_0,c(A)] \models \mathrm{CH}$$

as $\mathbb{P}_A$ is c.c.c., $|\mathbb{P}_A| = \omega_1^{L[S,x_0,A]}$, and $L[S,x_0,A] \models \mathrm{CH}$, and so there are, up to equivalence, only $\omega_1^{L[S,x_0,A]}$-many names for reals. ⊣

5.10 Corollary. *Assume* $\mathrm{ZF} + \mathrm{AD}$. *For an* S*-cone of* x*,*

$$L[S,x] \models \mathrm{GCH} \textit{ below } \omega_1^V.$$

Proof. Let x_0 be such that for all $x \geqslant_S x_0$,

$$L[S,x] \models \mathrm{CH}.$$

Fix $x \geqslant_S x_0$. We claim that $L[S,x] \models \mathrm{GCH}$ below ω_1^V: Suppose for contradiction that there is a $\lambda < \omega_1^V$ such that $L[S,x] \models 2^\lambda > \lambda^+$. Let $G \subseteq \mathrm{Col}(\omega,\lambda)$ be $L[S,x]$-generic. Thus $L[S,x][G] \models \neg\mathrm{CH}$. But $L[S,x][G] = L[S,y]$ for some real y and so $L[S,x][G] \models \mathrm{CH}$. ⊣

A similar proof shows that $\diamondsuit$ holds for an S-cone of x, the point being that adding a Cohen subset of ω_1 forces $\diamondsuit$ and this forcing is c.c.c. and of size ω_1. See [1], Exercises 15.23 and 15.24.

5.11 Conjecture. Assume $\mathrm{ZF} + \mathrm{AD}$. For an S-cone of x,

$$L[S,x] \cap V_{\omega_1^V}$$

is an "L-like" model in that it satisfies Condensation, $\square$, Morasses, etc.

Corollary 5.10 tells us that for an S-cone of x,

$$\Theta^{L[S,x]} = (\mathfrak{c}^+)^{L[S,x]} = \omega_2^{L[S,x]}.$$

Thus, to prove that for an S-cone of x,

$$L[S,x] \models \omega_2 \text{ is a Woodin cardinal in } \mathrm{HOD}_S,$$

we can apply our previous construction concerning Θ provided we have enough determinacy in $L[S,x]$.

5.12 Theorem (Kechris and Solovay). *Assume* ZF + AD. *For an S-cone of x,*

$$L[S,x] \models \mathrm{OD}_S\textit{-determinacy.}$$

Proof. Play the following game

$$\begin{array}{ll} \mathrm{I} & a, b \\ \mathrm{II} & c, d \end{array}$$

where, letting $p = \langle a,b,c,d\rangle$, I wins if $L[S,p] \not\models \mathrm{OD}_S$-determinacy and $L[S,p] \models$ "$a * d \in A^p$", where A^p is the least (in the canonical ordering) undetermined $\mathrm{OD}_S^{L[S,p]}$ set in $L[S,p]$. In such a game the reals are played so as to be "interleaved" in the pattern $(a(0), c(0), b(0), d(0), \dots)$. Here the two players are to be thought of as cooperating to determine the playing field $L[S,p]$ in which they will simultaneously play (via a and d) an auxiliary round of the game on the least undetermined OD_S set A^p (assuming, of course, that such a set exists, as I is trying to ensure).

Case 1: I has a winning strategy σ_0.

We claim that for all $x \geqslant_S \sigma_0$, $L[S,x] \models \mathrm{OD}_S$-determinacy, which contradicts the assumption that σ_0 is a winning strategy for I. For consider such a real x and suppose for contradiction that $L[S,x] \not\models \mathrm{OD}_S$-determinacy. As above let $A^x \in \mathrm{OD}_S^{L[S,x]}$ be least such that A^x is not determined. We will arrive at a contradiction by deriving a winning strategy σ for I in A^x from the strategy σ_0. Run the game according to σ_0 while having Player II feed in x for c and playing some auxiliary play $d \in L[S,x]$. This ensures that the resulting model $L[S,p]$ that the two players jointly determine is just $L[S,x]$ and so $A^p = A^x$. We can now derive a winning strategy σ for I in A^x from σ_0 as follows: For $d \in L[S,x]$, let σ be the strategy such that $(\sigma * d)_I$ is the a such that $(\sigma_0 * \langle x,d\rangle)_I = \langle a,b\rangle$.

(It is crucial that we have II play $c = x$ and $d \in L[S,x]$ since otherwise we would get $a * d \in A^p$ for varying p. By having II play $c = x$ and $d \in L[S,x]$, II has "steered into the right model", namely $L[S,x]$, and we have "fixed" the set A^x. This issue will become central later on when we refine this proof.)

Case 2: II has a winning strategy τ_0.

We claim that for $x \geqslant_S \tau_0$, $L[S,x] \models \mathrm{OD}_S$-determinacy. This is as above except that now we run the game according to τ_0, having I steer into $L[S,x]$ by playing x for b and some $a \in L[S,x]$. Then, as above, we derive a winning strategy for I in $\omega^\omega \smallsetminus A^x$ and hence a winning strategy τ for II in A^x. ⊣

To drive the construction of a model containing a Woodin cardinal we need more than OD_S-determinacy since some of the games in the construction are definable in a real parameter. Unfortunately, we cannot hope to get

$$L[S,x] \models \mathrm{OD}_{S,y}\text{-determinacy}$$

for each y since $(\mathrm{OD}_{S,x})^{L[S,x]} = L[S,x]$ and $L[S,x]$ is a model of AC. Nevertheless, it is possible to have $\mathrm{OD}_{S,y}$-determinacy in $L[S,x]$ for certain specially chosen reals y. There is therefore hope of approximating a sufficient amount of boldface definable determinacy to drive the construction. To make precise the approximation we need, we introduce the notion of a "prestrategy".

Let A and B be sets of reals. A *prestrategy for* I (*respectively* II) *in* A is a continuous function f such that for all $x \in \omega^\omega$, $f(x)$ is a strategy for I (respectively II) in A. A prestrategy f in A (for either I or II) is *winning with respect to the basis* B if, in addition, for all $x \in B$, $f(x)$ is a winning strategy in A. The *strategic game with respect to the predicates* $P_1, \ldots, P_k$ *and the basis* B is the game $SG^B_{P_0,\ldots,P_k}$

$$\begin{array}{llllll} \mathrm{I} & A_0 & \cdots & A_n & \cdots & \\ \mathrm{II} & & f_0 & \cdots & f_n & \cdots \end{array}$$

where we require

(1) $A_0 \in \mathscr{P}(\omega^\omega) \cap \mathrm{OD}_{P_0,\ldots,P_k}$, $A_{n+1} \in \mathscr{P}(\omega^\omega) \cap \mathrm{OD}_{P_0,\ldots,P_k,f_0,\ldots,f_n}$ and

(2) f_n is a prestrategy for A_n that is winning with respect to B,

and II wins iff II can play all ω rounds. We say that *strategic definable determinacy holds with respect to the predicates* $P_0, \ldots, P_k$ *and the basis* B ($\mathrm{ST}_{P_0,\ldots,P_k}$-*determinacy*) if II wins $SG^B_{P_0,\ldots,P_k}$ and we say that *strategic definable determinacy for* n *moves holds with respect to the predicates* $P_0, \ldots, P_k$ *and the basis* B ($\mathrm{ST}_{P_0,\ldots,P_k}$-*determinacy for* n *moves*) if II can play n rounds of $SG^B_{P_0,\ldots,P_k}$. When these parameters are clear from context we shall often simply refer to SG and ST-determinacy.

In the context of $L[S,x]$ the predicate will be S and the basis B will be the S-degree of x. Thus to say that $L[S,x]$ satisfies ST_S-determinacy (or ST-determinacy for short) is to say that II can play all rounds of the game

$$\begin{array}{llllll} \mathrm{I} & A_0 & \cdots & A_n & \cdots & \\ \mathrm{II} & & f_0 & \cdots & f_n & \cdots \end{array}$$

where we require

(1) $A_0 \in \mathscr{P}(\omega^\omega) \cap \mathrm{OD}_S^{L[S,x]}$, $A_{n+1} \in \mathscr{P}(\omega^\omega) \cap \mathrm{OD}_{S,f_0,\ldots,f_n}^{L[S,x]}$, and

(2) $f_n \in L[S,x]$ is a prestrategy for A_n that is winning with respect to $[x]_S$.

The ability to survive a single round of this game implies that $L[S,x]$ satisfies OD_S-determinacy. So this notion is indeed a generalization of OD_S-determinacy.

Before turning to the main theorems, some remarks are in order. First, notice that the games $\mathrm{ST}_{P_0,\ldots,P_k}$ are closed for Player II, hence determined. The only issue is whether II wins.

Second, notice also that if I wins then I has a *canonical* strategy. This can be seen as follows: Player I can rank partial plays, assigning rank 0 to partial plays in which he wins; Player I can then play by reducing rank. The result is a quasi-strategy that is definable in terms of the tree of partial plays which in turn is ordinal definable. Since I is essentially playing ordinals this quasi-strategy can be converted into a strategy in a definable fashion. We take this to be I's canonical strategy.

Third, notice that each prestrategy can be coded by a real number in a canonical manner. We assume that such a coding has been fixed and, for notational convenience, we will identify a prestrategy with its code.

Fourth, it is important to note that if II is to have a hope of winning then we must allow II to play prestrategies and not strategies. To see this, work in $L[S,x]$ and consider the variant of SG_S^B where we have II play strategies τ_0, τ_1, ... instead of prestrategies. The set $A_0 = \{y \in \omega^\omega \mid L[S, y_{\mathrm{even}}] = L[S,x]\}$ is $\mathrm{OD}_S^{L[S,x]}$ and hence a legitimate first move for I. But then II's response must be a winning strategy for I in A_0 since I can win a play of A_0 by playing x. However, $\mathrm{OD}_{S,\tau_0}^{L[S,x]} = L[S,x]$ and so in the next round I is allowed to play any $A_1 \in L[S,x]$. But then II cannot hope to always respond with a winning strategy since $L[S,x] \not\models \mathrm{AD}$. The upshot is that if II is to have a hope of winning a game of this form then we must allow II to be less committal.

Fifth, although one can use a base B which is slightly larger than $[x]_S$, the previous example motivates the choice of $B = [x]_S$. Let A_0 be as in the previous paragraph and let f_0 be II's response. By the above argument, it follows that for all $z \in B$, $\langle f_0, z\rangle \in [x]_S$ and so in a sense we are "one step away" from showing that one must have $B \subseteq [x]_S$.

Finally, as we shall show in the next section, for every OD basis $B \subseteq \omega^\omega$ there is an OD set $A \subseteq \omega^\omega$ such that there is no OD prestrategy which is winning for A with respect to B (Theorem 6.11). Thus, for each basis B, ST^B-determinacy does not trivially reduce to OD-determinacy.

5.13 Theorem. *Assume* ZF + AD. *Then for an S-cone of x, for each n,*

$$L[S,x] \models \mathrm{ST}_S\text{-}\textit{determinacy for } n \textit{ moves},$$

where $B = [x]_S$.

5.14 Theorem. *Assume* ZF + DC$_{\mathbb{R}}$ + AD. *Then for an S-cone of x,*

$$L[S,x] \models \mathrm{ST}_S\text{-}determinacy,$$

where $B = [x]_S$.

Proofs of Theorems 5.13 and 5.14. Assume toward a contradiction that the statement of Theorem 5.14 is false. By Theorem 5.7, there is a real x_0 such that if $x \geqslant_T x_0$,

$$L[S,x] \models \text{I wins } SG,$$

(where here and below we drop reference to S and B since these are fixed throughout). For $x \geqslant_T x_0$, let σ^x be I's canonical winning strategy in $SG^{L[S,x]}$. Note that the strategy depends only on the model, that is, if $y \equiv_S x$ then $\sigma^y = \sigma^x$.

Our aim is to construct a sequence of games $G_0, G_1, \ldots, G_n, \ldots$ such that the winning strategies (for whichever player wins) enable us to define, for an S-cone of x, prestrategies $f_0^x, f_1^x, \ldots, f_n^x, \ldots$ which constitute a non-losing play against σ^x in $SG^{L[S,x]}$.

Step 0. Consider (in V) the game G_0

$$\begin{array}{ll} \mathrm{I} & a, b \\ \mathrm{II} & c, d \end{array}$$

where, letting $p = \langle a, b, c, d, x_0\rangle$ and $A_0^p = \sigma^p(\varnothing)$, I wins iff $a * d \in A_0^p$. Notice that by including x_0 in p we have ensured that σ^p is defined and hence that the winning condition makes sense. In this game I and II are cooperating to steer into the model $L[S,p]$ and they are simultaneously playing (via a and d) an auxiliary round of the game A_0^p, where A_0^p is I's first move according to the canonical strategy in the strategic game $SG^{L[S,p]}$. I wins a round iff I wins the auxiliary round of this auxiliary game.

Claim 1. *There is a real x_1 such that for all $x \geqslant_S x_1$ there is a prestrategy f_0^x that is a non-losing first move for II against σ^x in $SG^{L[S,x]}$.*

Proof. Case 1: I has a winning strategy σ_0 in G_0.

For $x \geqslant_T \sigma_0$, let f_0^x be the prestrategy derived from σ_0 by extracting the response in the auxiliary game where we have II feed in y for c, that is, for $y \in (\omega^\omega)^{L[S,x]}$ let $f_0^x(y)$ be such that $f_0^x(y) * d = a * d$ where a is such that $(\sigma_0 * \langle y, d\rangle)_I = \langle a, b\rangle$. Note that $f_0^x \in L[S,x]$ as it is definable from σ_0. Let $x_1 = \langle \sigma_0, x_0\rangle$ and for $x \geqslant_S x_1$ let $A_0^x = \sigma^x(\varnothing)$. We claim that for $x \geqslant_S x_1$, f_0^x is a prestrategy for I in A_0^x that is winning with respect to $\{y \in \omega^\omega \mid L[S,y] = L[S,x]\}$, that is, f_0^x is a non-losing first move for II against σ^x in $SG^{L[S,x]}$. To see this fix $x \geqslant_S x_1$ and y such that $L[S,y] = L[S,x]$ and consider $d \in L[S,x]$. The value $f_0^x(y)$ of the prestrategy was defined by running G_0, having II feed in y for c:

$$\begin{array}{ll} \mathrm{I} & a, b \\ \mathrm{II} & y, d \end{array}$$

By our choice of y and d, we have solved the "steering problem", that is, we have $L[S,p] = L[S,x]$ and $A_0^p = A_0^x$ where $p = \langle a, b, y, d, x_0 \rangle$. Now, f_0^x is such that $f_0^x(y) * d = a * d$ where a is such that $(\sigma_0 * \langle y, d \rangle)_I = \langle a, b \rangle$. Since σ_0 is winning for I, we have $f_0^x(y) * d = a * d \in A_0^p = A_0^x$.

Case 2: II has a winning strategy τ_0 in G_0.

Let f_0^x be the prestrategy derived from τ_0 by extracting the response in the auxiliary game where we have I feed in y for b, that is, for $y \in (\omega^\omega)^{L[S,x]}$ let $f_0^x(y)$ be such that $a * f_0^x(y) = a * d$ where d is such that $(\langle a, y \rangle * \tau_0)_{II} = \langle c, d \rangle$. Let $x_1 = \langle \tau_0, x_0 \rangle$ and for $x \geqslant_S x_1$ let $A_0^x = \sigma^x(\varnothing)$. As before, we have that for $x \geqslant_S x_1$, f_0^x is a prestrategy for II in A_0^x that is winning with respect to $\{y \in \omega^\omega \mid L[S,y] = L[S,x]\}$, that is, f_0^x is a non-losing first move for II against σ^x in $SG^{L[S,x]}$.

Let x_1 be as described in whichever case holds. ⊣

Step $n+1$. Assume that we have defined games $G_0, \ldots, G_n$, reals $x_0, \ldots, x_{n+1}$ such that $x_0 \leqslant_S x_1 \leqslant_S \cdots \leqslant_S x_{n+1}$, and prestrategies $f_0^x, \ldots, f_n^x$ which depend only on the degree of x and such that for all $x \geqslant_S x_{n+1}$,

$$f_0^x, \ldots, f_n^x$$

is a non-losing partial play for II against σ^x in $SG^{L[S,x]}$.

Consider (in V) the game G_{n+1}

$$\begin{array}{ll} \mathrm{I} & a, b \\ \mathrm{II} & c, d \end{array}$$

where, letting $p = \langle a, b, c, d, x_{n+1} \rangle$ and A_{n+1}^p be I's response via σ^p to the partial play $f_0^p, \ldots, f_n^p$, I wins iff $a * d \in A_{n+1}^p$. Notice that we have included x_{n+1} in p to ensure that $\sigma^p, f_0^p, \ldots, f_n^p$ are defined and hence that the winning condition makes sense. In this game I and II are cooperating to steer into the model $L[S,p]$ and they are simultaneously playing an auxiliary round (via a and d) on A_{n+1}^p, where A_{n+1}^p is I's response via σ^p to II's non-losing partial play $f_0^p, \ldots, f_n^p$ in the strategic game $SG^{L[S,p]}$. I wins a round iff he wins the auxiliary round of this auxiliary game.

Claim 2. *There is a real x_{n+2} such that for all $x \geqslant_S x_{n+2}$ there is a prestrategy f_{n+1}^x such that $f_0^x, \ldots, f_n^x, f_{n+1}^x$ is a non-losing partial play for II against σ^x in $SG^{L[S,x]}$.*

Proof. Case 1: I has a winning strategy σ_{n+1} in G_{n+1}.

Let f_{n+1}^x be the prestrategy derived from σ_{n+1} by extracting the response in the auxiliary game, that is, for $y \in (\omega^\omega)^{L[S,x]}$ let $f_{n+1}^x(y)$ be such that $f_{n+1}^x(y) * d = a * d$ where a is such that $(\sigma_{n+1} * \langle y, d \rangle)_I = \langle a, b \rangle$. Let $x_{n+2} = \langle \sigma_{n+1}, x_{n+1} \rangle$ and for $x \geqslant_S x_{n+2}$ let $A_{n+1}^x = \sigma^x(\langle f_0^x, \ldots, f_n^x \rangle)$, i.e. A_{n+1}^x is the

$(n+2)$nd move of I in $SG^{L[S,x]}$ following σ^x against II's play of $f_0^x, \ldots, f_n^x$. As in Claim 1, f_{n+1}^x is a prestrategy for I in A_{n+1}^x that is winning with respect to $\{y \in \omega^\omega \mid L[S,y] = L[S,x]\}$, that is, f_{n+1}^x is a non-losing $(n+2)$nd move for II against σ^x in $SG^{L[S,x]}$.

Case 2: II has a winning strategy τ_{n+1} in G_{n+1}.

Let f_{n+1}^x be the prestrategy derived from τ_{n+1} by extracting the response in the auxiliary game, that is, for $y \in (\omega^\omega)^{L[S,x]}$ let $f_{n+1}^x(y)$ be such that $a * f_{n+1}^x(y) = a * d$ where d is such that $(\langle a, y\rangle * \tau_{n+1})_{II} = \langle c, d\rangle$. Let $x_{n+2} = \langle \tau_{n+1}, x_{n+1}\rangle$ and for $x \geqslant_S x_{n+2}$ let $A_{n+1}^x = \sigma^x(\langle f_0^x, \ldots, f_n^x\rangle)$, as above. As before, we have that for $x \geqslant_S x_{n+2}$, f_{n+1}^x is a prestrategy for II in A_{n+1}^x that is winning with respect to $\{y \in \omega^\omega \mid L[S,y] = L[S,x]\}$, that is, f_{n+1}^x is a non-losing $(n+2)$nd move for II against σ^x in $SG^{L[S,x]}$.

Let x_{n+2} be as described in whichever case holds. ⊣

Finally, using $\mathrm{DC}_{\mathbb{R}}$, we get a sequence of reals $x_0, \ldots, x_n, \ldots$ and prestrategies $f_0^x, \ldots, f_n^x, \ldots$ as in each of the steps. Letting $x^\infty \geqslant_S x_n$, for all n, we have that for all $x \geqslant_S x^\infty$, $f_0^x, \ldots, f_n^x, \ldots$ is a non-losing play for II against σ^x in $SG^{L[S,x]}$, which is a contradiction. This completes the proof of Theorem 5.14.

For Theorem 5.13 simply note that $\mathrm{DC}_{\mathbb{R}}$ is not needed to define the finite sequences $x_0, \ldots, x_n, x_{n+1}$ and $f_0^x, \ldots, f_n^x$ for $x \geqslant_S x_{n+1}$ (as these prestrategies are definable from $x_0, \ldots, x_n, x_{n+1}$). ⊣

5.3. Generation Theorem

In the previous section we showed (assuming ZF + AD) that for an S-cone of x,

$$L[S,x] \models \mathrm{OD}_S\text{-determinacy},$$

and (even more) that for each n,

$$L[S,x] \models \mathrm{ST}_S\text{-determinacy for } n \text{ moves},$$

where $B = [x]_S$. It turns out that for a sufficiently large choice of n this degree of determinacy is sufficient to implement the previous arguments and show that

$$L[S,x] \models \omega_2 \text{ is a Woodin cardinal in } \mathrm{HOD}_S.$$

At this stage we could proceed directly to this result but instead, with this motivation behind us, we return to the more general setting. The main theorem to be proved is the Generation Theorem:

5.15 Theorem (Generation Theorem). *Assume* ZF. *Suppose*

$$M = L_{\Theta_M}(\mathbb{R})[T, A, B]$$

is such that

(1) $M \models \mathrm{T}_0$,

(2) Θ_M *is a regular cardinal,*

(3) $T \subseteq \Theta_M$,

(4) $A = \langle A_\alpha \mid \alpha < \Theta_M \rangle$ *is such that* A_α *is a prewellordering of the reals of length greater than or equal to* α,

(5) $B \subseteq \omega^\omega$ *is nonempty, and*

(6) $M \models \mathrm{ST}_{T,A,B}$*-determinacy for four moves.*

Then

$$\mathrm{HOD}^M_{T,A,B} \models \mathrm{ZFC} + \textit{There is a } T\textit{-strong cardinal.}$$

The importance of the restriction to strategic determinacy for four moves is that in a number of applications of this theorem strategic determinacy for n moves (for each n) can be established without any appeal to DC (as for example in Theorem 5.13) in contrast to full strategic determinacy which (just as in Theorem 5.14) uses $\mathrm{DC}_{\mathbb{R}}$.

The external assumption that Θ_M is a regular cardinal is merely for convenience—it ensures that there are cofinally many stages in the stratification of M where T_0 holds. The dedicated reader can verify that this assumption can be dropped by working instead with the theory $\mathrm{ZF}_N + \mathrm{AC}_\omega(\mathbb{R})$ for some sufficiently large N.

The remainder of this section is devoted to a proof of the Generation Theorem.

Proof. Let us start by showing that $\mathrm{HOD}^M_{T,A,B}$ satisfies ZFC. When working with structures of the form $L_{\Theta_M}(\mathbb{R})[T, A, B]$ it is to be understood that we are working in the language of ZFC augmented with constant symbols for T, A, B, and $\mathbb{R}$. The first step is to show that $\mathrm{HOD}^M_{T,A,B}$ is first-order over M. For $\gamma < \Theta_M$, let

$$M_\gamma = L_\gamma(\mathbb{R})[T\restriction\gamma, A\restriction\gamma, B],$$

it being understood that the displayed predicates are part of the structure. Since Θ_M is regular and $M \models \mathrm{T}_0$ there are cofinally many $\gamma < \Theta_M$ such that $M_\gamma \models \mathrm{T}_0$. So a set $x \in M$ is $\mathrm{OD}^M_{T,A,B}$ if and only if there is a $\gamma < \Theta_M$ such that $M_\gamma \models \mathrm{T}_0$ and x is definable in M_γ from ordinal parameters (and the constant symbols for the parameters). It follows that $\mathrm{OD}^M_{T,A,B}$ and $\mathrm{HOD}^M_{T,A,B}$ are Σ_1-definable over M (in the expanded language).

With this first-order characterization of $\mathrm{HOD}^M_{T,A,B}$ all of the standard results carry over to our present setting. For example, since $M \models \mathrm{ZF} -$ Power Set we have that $\mathrm{HOD}^M_{T,A,B} \models \mathrm{ZFC} -$ Power Set. (The proofs that AC holds in $\mathrm{HOD}^M_{T,A,B}$ and that for all $\alpha < \Theta_M$, $V_\alpha \cap \mathrm{HOD}^M_{T,A,B} \in \mathrm{HOD}^M_{T,A,B}$ require that $\mathrm{OD}^M_{T,A,B}$ be ordinal definable.)

5.16 Lemma. $\mathrm{HOD}^M_{T,A,B} \models \mathrm{ZFC}$.

Proof. We have seen that $\mathrm{HOD}^M_{T,A,B} \models \mathrm{ZFC}-\text{Power Set}$. Since $\mathrm{HOD}^M_{T,A,B} \models$ AC it remains to show that for all $\lambda < \Theta_M$,

$$\mathscr{P}(\lambda)^{\mathrm{HOD}^M_{T,A,B}} \in \mathrm{HOD}^M_{T,A,B}.$$

The point is that since $M \models \mathrm{OD}_{T,A,B}$-determinacy, for each $S \in \mathrm{OD}^M_{T,A,B} \cap \mathscr{P}(\lambda)$ the game for coding S relative to the prewellordering A_λ is determined: Without loss of generality, we may assume A_λ has length λ. For $\alpha < \lambda$, let $Q^\kappa_{<\alpha}$ and Q^κ_α be the usual objects defined relative to A_λ. For $e \in \omega^\omega$, let

$$S_e = \{\alpha < \lambda \mid U^{(2)}_e(Q^\kappa_{<\alpha}, Q^\kappa_\alpha) \neq \varnothing\}.$$

Since A_λ is trivially $\mathrm{OD}^M_{T,A,B}$ the game for the Uniform Coding Lemma for $Z = \bigcup\{Q^\kappa_\alpha \times \omega^\omega \mid \alpha \in S\}$ is determined for each $S \in \mathscr{P}(\lambda)^{\mathrm{HOD}^M_{T,A,B}}$. Thus, every $S \in \mathscr{P}(\lambda)^{\mathrm{HOD}^M_{T,A,B}}$ has the form S_e for some $e \in \omega^\omega$ and hence

$$\begin{aligned} \pi : \omega^\omega &\longrightarrow \mathscr{P}(\lambda)^{\mathrm{HOD}^M_{T,A,B}} \\ e &\mapsto S_e \end{aligned}$$

is an $\mathrm{OD}^M_{T,A,B}$ surjection. Thus, $\mathscr{P}(\lambda)^{\mathrm{HOD}^M_{T,A,B}} \in M$ and so, by our first-order characterization, $\mathscr{P}(\lambda)^{\mathrm{HOD}^M_{T,A,B}} \in \mathrm{HOD}^M_{T,A,B}$. $\dashv$

The ordinal κ that we will show to be T-strong in $\mathrm{HOD}^M_{T,A,B}$ is "the least stable in M":

5.17 Definition. Let κ be least such that

$$M_\kappa \prec_1 M.$$

As before the $\Diamond$-like function $F : \kappa \to M_\kappa$ is defined inductively in terms of the least counterexample: Given $F\restriction\delta$ let $\vartheta(\delta)$ be least such that

$$M_{\vartheta(\delta)} \models \mathrm{T}_0 \text{ and there is an } X \in M_{\vartheta(\delta)} \cap \mathrm{OD}^{M_{\vartheta(\delta)}}_{T\restriction\vartheta(\delta),A\restriction\vartheta(\delta),B} \text{ and}$$

($\star$) there is a Σ_1 formula φ and a $t \in \omega^\omega$ such that

$$M_{\vartheta(\delta)} \models \varphi[t, X, \delta, \mathbb{R}]$$

and for all $\bar{\delta} < \delta$

$$M_{\vartheta(\delta)} \not\models \varphi[t, F(\bar{\delta}), \bar{\delta}, \mathbb{R}]$$

(if such an ordinal exists) and then let $F(\delta)$ be the $<^{M_{\vartheta(\delta)}}_{\mathrm{OD}_{T\restriction\vartheta(\delta),A\restriction\vartheta(\delta),B}}$-least X such that ($\star$) holds.

5.18 Theorem. *For all $X \in \mathrm{OD}^M_{T,A,B}$, for all Σ_1 formulas φ, and for all $t \in \omega^\omega$, if*

$$M \models \varphi[t, X, \kappa, \mathbb{R}]$$

then there exists a $\delta < \kappa$ such that

$$M \models \varphi[t, F(\delta), \delta, \mathbb{R}].$$

Proof. Same as the proof of Theorem 4.6. ⊣

Our interest is in applying Theorem 5.18 to

$$X = (\leqslant_\lambda, \lambda)$$

where $\leqslant_\lambda = A_\lambda$ is the prewellordering of length λ, for $\lambda < \Theta_M$. Clearly X is $\mathrm{OD}^M_{T,A,B}$.

Let U_X be a universal $\Sigma_1(M, \{X, \kappa, \mathbb{R}\})$ set of reals and, for $\delta < \kappa$, let U_δ be the reflected version (using the same definition used for U except with $F(\delta)$ and δ in place of X and κ). For $z \in U_X$, let $S_z = \{\delta < \kappa \mid z \in U_\delta\}$ and set

$$\mathscr{F}_X = \{S \subseteq \kappa \mid \exists z \in U_X\,(S_z \subseteq S)\}.$$

As before, $\mathscr{F}_X$ is a countably complete filter and in Theorem 5.18 we can reflect to $\mathscr{F}_X$-many points $\delta < \kappa$. Let

$$S_0 = \{\delta < \kappa \mid F(\delta) = (A_{\lambda_\delta}, \lambda_\delta) \text{ for some } \lambda_\delta > \delta\}.$$

Notice that $S_0 \in \mathscr{F}_X$. For notational conformity let $\leqslant_\delta$ be A_{λ_δ}. For $\alpha < \lambda$, let Q^κ_α be the αth-component of $\leqslant_\lambda$ and, for $\delta \in S_0$ and $\alpha < \lambda_\delta$, let Q^δ_α be the αth-component of $\leqslant_\delta$ (where without loss of generality we may assume that each A_α has length exactly α).

In our previous settings we went on to do two things. First, using the Uniform Coding Lemma we showed that one can allow parameters of the form $A \subseteq \kappa$ and $f : \kappa \to \kappa$ in the Reflection Theorem. Second, for $S \subseteq \kappa$, we defined the games $G^X(S)$ that gave rise to the ultrafilter extending the reflection filter, an ultrafilter that was either explicitly OD in the background universe (as in Sect. 4.3) or shown to be OD by appeal to Kunen's theorem (as in Sect. 5.1). In our present setting (where we have a limited amount of determinacy at our disposal) we will have to manage our resources more carefully. The following notion will play a central role.

5.19 Definition. A set $x \in M$ is *n-good* if and only if II can play n rounds of $(SG^B_{T,A,B,x})^M$. For $y \in M$, a set $x \in M$ is *n-y-good* if and only if (x, y) is n-good.

Notice that if M satisfies $\mathrm{ST}_{T,A,B,y}$-determinacy for $n+1$ moves then II's first move f_0 is n-y-good. Notice also that if x is 1-y-good then every $\mathrm{OD}^M_{T,A,B,x,y}$ set of reals is determined. For example, if $S \subseteq \kappa$ is 1-good then the game for coding S relative to A_κ using the Uniform Coding Lemma is determined. Thus we have the following version of the Reflection Theorem.

5.20 Theorem. *Suppose $f : \kappa \to \kappa$, $G \subseteq \kappa$, $S \subseteq \kappa$ and (f, G, S) is 1-good. For all $X \in M \cap \mathrm{OD}^M_{T,A,B}$, for all Σ_1 formulas φ, and for all $t \in \omega^\omega$, if*

$$M \models \varphi[t, X, \kappa, \mathbb{R}, f, G, S]$$

then for $\mathscr{F}_X$-many $\delta < \kappa$,

$$M \models \varphi[t, F(\delta), \delta, \mathbb{R}, f{\restriction}\delta, G \cap \delta, S \cap \delta].$$

For each $S \subseteq \kappa$, let $G^X(S)$ be the game

$$\begin{array}{lccccccc} \mathrm{I} & x(0) & & x(1) & & x(2) & & \ldots \\ \mathrm{II} & & y(0) & & y(1) & & \ldots & \end{array}$$

with the following winning conditions: Main Rule: For all $i < \omega$, $(x)_i, (y)_i \in U_X$. If the rule is violated, then, letting i be the least such that either $(x)_i \notin U_X$ or $(y)_i \notin U_X$, I wins if $(x)_i \in U_X$; otherwise II wins. If the rule is satisfied, then, letting δ be least such that for all $i < \omega$, $(x)_i, (y)_i \in U_\delta$, I wins iff $\delta \in S$.

As before, if $S \in \mathscr{F}_X$ then I wins $G^X(S)$ by playing any x such that for all $i < \omega$, $(x)_i \in U_X$ and for some $i < \omega$, $(x)_i = z$, where z is such that $S_z \subseteq S$. But we cannot set

$$\mu_X = \{S \subseteq \kappa \mid \mathrm{I} \text{ wins } G^X(S)\}$$

since we have no guarantee that $G^X(S)$ is determined for an arbitrary $S \subseteq \kappa$.

However, if S is 1-good then $G^X(S)$ is determined. In particular, $G^X(S)$ is determined for each $S \in \mathscr{P}(\kappa) \cap \mathrm{HOD}^M_{T,A,B}$. Thus, setting

$$\mu = \{S \in \mathscr{P}(\kappa) \cap \mathrm{HOD}^M_{T,A,B} \mid \mathrm{I} \text{ wins } G^X(S)\}$$

we have directly shown that κ is measurable in $\mathrm{HOD}^M_{T,A,B}$.

It is useful at this point to stand back and contrast the present approach with the two earlier approaches. In both of the earlier approaches (namely, that of Sect. 4.3 and that of Sect. 5.1) the ultrafilters were ultrafilters in V and seen to be complete and normal in V and the ultrafilters were OD^V, the only difference being that in the first case the ultrafilters were *directly* seen to be OD^V, while in the second case they were *indirectly* seen to be OD^V by appeal to Kunen's theorem (Theorem 3.11). Now, in our present setting, there is no hope of getting such ultrafilters in V since we do not have enough determinacy. Instead we will get ultrafilters in $\mathrm{HOD}^M_{T,A,B}$. However, the construction will still be "external" in some sense since we will be defining the ultrafilters in V.

We also have to take care to ensure that the ultrafilters "fit together" in such a way that they witness that κ is T-strong. In short, we will define a (κ, λ)-pre-extender $E_X \in \mathrm{HOD}^M_{T,A,B}$, a notion we now introduce.

For $n \in \omega$ and $z \in [\mathrm{On}]^n$, we write $z = \{z_1, \ldots, z_n\}$, where $z_1 < \cdots < z_n$. Suppose $b \in [\mathrm{On}]^n$ and $a \subseteq b$ is such that $a = \{b_{i_1}, \ldots b_{i_k}\}$, where $i_1 < \cdots < i_k$. For $z \in [\mathrm{On}]^n$, set

$$z_{a,b} = \{z_{i_1}, \ldots, z_{i_k}\}.$$

Thus the elements of $z_{a,b}$ sit in z in the same manner in which the elements of a sit in b. For $\alpha \in \mathrm{On}$ and $X \subseteq [\alpha]^k$, let

$$X^{a,b} = \{z \in [\alpha]^n \mid z_{a,b} \in X\}.$$

For $\alpha \in \mathrm{On}$ and $f : [\alpha]^k \to V$, let $f^{a,b} : [\alpha]^n \to V$ be such that

$$f^{a,b}(z) = f(z_{a,b}).$$

Thus we use 'a, b' as a subscript to indicate that $z_{a,b}$ is the "drop of z from b to a" and we use 'a, b' as a superscript to indicate that $X^{a,b}$ is the "lift of X from a to b".

5.21 Definition. Let κ be an uncountable cardinal and let $\lambda > \kappa$ be an ordinal. The sequence

$$E = \langle E_a \mid a \in [\lambda]^{<\omega} \rangle$$

is a (κ, λ)-*extender* provided:

(1) For each $a \in [\lambda]^{<\omega}$,

$$E_a \text{ is a } \kappa\text{-complete ultrafilter on } [\kappa]^{|a|}$$

that is principal if and only if $a \subseteq \kappa$.

(2) (Coherence) If $a \subseteq b \in [\lambda]^{<\omega}$ and $X \in E_a$, then $X^{a,b} \in E_b$.

(3) (Countable Completeness) If $X_i \in E_{a_i}$ where $a_i \in [\lambda]^{<\omega}$ for each $i < \omega$, then there is an order-preserving map

$$h : \textstyle\bigcup_{i<\omega} a_i \to \kappa$$

such that $h``a_i \in X_i$ for all $i < \omega$.

(4) (Normality) If $a \in [\lambda]^{<\omega}$ and $f : [\kappa]^{|a|} \to \kappa$ is such that

$$\{z \in [\kappa]^{|a|} \mid f(z) < z_i\} \in E_a$$

for some $i \leqslant |a|$, then there is a $\beta < a_i$ such that

$$\{z \in [\kappa]^{|a \cup \{\beta\}|} \mid f(z_{a, a\cup\{\beta\}}) = z_k\} \in E_{a\cup\{\beta\}}$$

where k is such that β is the kth element of $a \cup \{\beta\}$.

If conditions (1) and (2) alone are satisfied then we say that E is a (κ, λ)-*pre-extender*.

We need to ensure that the ultrafilter E_a on $[\kappa]^{|a|}$ depends on a in such a way that guarantees coherence and the other properties. The most natural way to define an ultrafilter E_a on $[\kappa]^{|a|}$ that depends on a is as follows:

(1) For $\mathscr{F}_X$-almost all δ define a “reflected version” $a^\delta \in [\lambda_\delta]^{<\omega}$ of the “generator” a.

(2) For $Y \in \mathscr{P}([\kappa]^{|a|}) \cap \mathrm{HOD}^M_{T,A,B}$, let

$$S(a,Y) = \{\delta < \kappa \mid a^\delta \in Y\}$$

and set

$$E_a = \{Y \in \mathscr{P}([\kappa]^{|a|}) \cap \mathrm{HOD}^M_{T,A,B} \mid \text{I wins } G^X(S(a,Y))\}.$$

In other words, we regard Y as “E_a-large” if and only if it contains the “reflected generators” on a set which is large from the point of view of the game.

The trouble is that we have not guaranteed that $S(a,Y)$ is determined. This set will be determined if it is 1-good but we have not ensured this. So we need to “reflect” a in such a way that $S(a,Y)$ is 1-good. Now the most natural way to reflect $a \in [\lambda]^k$ is as follows: Choose

$$(y_1,\dots,y_k) \in Q^\kappa_{a_1} \times \cdots \times Q^\kappa_{a_k}$$

and, for $\delta \in S_0$, let $a^\delta = \{a^\delta_1, a^\delta_2, \dots, a^\delta_k\}$ be such that

$$(y_1,\dots,y_k) \in Q^\delta_{a^\delta_1} \times \cdots \times Q^\delta_{a^\delta_k}.$$

There is both a minor difficulty and a major difficulty with this approach. The minor difficulty is that we have to ensure that there is no essential dependence on our particular choice of $(y_1,\dots,y_k)$. The major difficulty is that unless $(y_1,\dots,y_k)$ is 1-good we still have no guarantee that $S(a,Y)$ is 1-good. The trouble is that there is in general no way of choosing such 1-good reals. However, assuming that M satisfies $\mathrm{ST}_{T,A,B}$-determinacy for two moves, there *is* a way of generating 1-good prestrategies which (for all $x \in B$) hand us the reals we want. We will prove something slightly more general.

5.22 Lemma. *Assume z is $(n+1)$-good. Then for each $a \in [\lambda]^{<\omega}$ there is a function $f_a : \omega^\omega \to (\omega^\omega)^k$ such that*

(1) f_a is n-z-good and

(2) for all $x \in B$,

$$f_a(x) \in Q^\kappa_{a_1} \times \cdots \times Q^\kappa_{a_k},$$

where $k = |a|$.

Proof. The set

$$A_0 = \{x \in \omega^\omega \mid (x_{\mathrm{even}})_i \in Q^\kappa_{a_{i+1}} \text{ for all } i < k\}$$

is $\mathrm{OD}^M_{T,A,B}$ and clearly I wins A_0. Let A_0 be I's first move in $(SG^B_{T,A,B,z})^M$ and let f_0 be II's response. Notice that f_0 is n-z-good. We have

$$\forall x \in B\, \forall y \in \omega^\omega \,\big(f_0(x) * y \in A_0\big)$$

and hence

$$\forall x \in B\, \forall y \in \omega^\omega \,\big(((f_0(x) * y)_{\mathrm{even}})_i \in Q^\kappa_{a_{i+1}} \text{ for all } i < k\big).$$

Thus the function

$$\begin{aligned} f_a : \omega^\omega &\to (\omega^\omega)^k \\ x &\mapsto \begin{cases} \big(((f_0(x) * 0)_{\mathrm{even}})_0, \ldots, ((f_0(x) * 0)_{\mathrm{even}})_{k-1}\big) & \text{if } x \in B \\ 0 & \text{otherwise} \end{cases} \end{aligned}$$

is n-z-good (since it is definable from the n-z-good object f_0) and has the desired property. ⊣

5.23 Definition. Assume M satisfies $\mathrm{ST}_{T,A,B}$-determinacy for two moves. For $a \in [\lambda]^{<\omega}$, we call a 1-good function $f_a : \omega^\omega \to (\omega^\omega)^{|a|}$ given by Lemma 5.22, a 1-*good code* for a.

The importance of a 1-good code f_a is twofold. First, any game defined in terms of f_a is determined. Second, for $\mathscr{F}_X$-almost all δ a 1-good code f_a selects a reflected version a^δ of a in a manner that is independent of $x \in B$; moreover, we can demand that a^δ inherits any $\Sigma_1(M, \{X, \kappa, \mathbb{R}\})$-property that a has. To see this, consider a statement such as the following: For all $x, x' \in B$, if $\alpha_1, \ldots, \alpha_k$ are such that

$$f_a(x) \in Q^\kappa_{\alpha_1} \times \cdots \times Q^\kappa_{\alpha_k}$$

then

$$f_a(x') \in Q^\kappa_{\alpha_1} \times \cdots \times Q^\kappa_{\alpha_k}$$

and

$$\alpha_1 < \cdots < \alpha_k.$$

This is a true $\Sigma_1(M, \{X, \mathbb{R}, \kappa\})$ statement. Thus, for $\mathscr{F}_X$-almost all δ, the statement reflects.

5.24 Definition. Suppose $a \in [\lambda]^{<\omega}$ and f_a is a 1-good code for a. Let

$$\begin{aligned} S_0(f_a) = \big\{\delta < \kappa \mid \forall x, x' \in B\, \forall \alpha_1, \ldots, \alpha_k\, (f_a(x) \in Q^\delta_{\alpha_1} \times \cdots \times Q^\delta_{\alpha_k} \\ \to f_a(x') \in Q^\delta_{\alpha_1} \times \cdots \times Q^\delta_{\alpha_k} \wedge \alpha_1 < \cdots < \alpha_k)\big\}. \end{aligned}$$

Notice that $S_0(f_a) \in \mathscr{F}_X$ and $S_0(f_a)$ is $\mathrm{OD}^M_{T,A,B,f_a}$.

5.25 Definition. Suppose $a \in [\lambda]^{<\omega}$ and f_a is a 1-good code for a. For $\delta \in S_0(f_a)$ and some (any) $x \in B$, let

$$a^{\delta}_{f_a} = \{|(f_a(x))_1|_{\leqslant\delta}, \ldots, |(f_a(x))_{|a|}|_{\leqslant\delta}\}$$

be the *reflected generator* of a.

5.26 Definition. For $a \in [\lambda]^{<\omega}$, f_a a 1-good code for a, and $Y \in \mathscr{P}([\kappa]^{|a|}) \cap \mathrm{HOD}^M_{T,A,B}$, let

$$S(a, f_a, Y) = \{\delta \in S_0(f_a) \mid a^{\delta}_{f_a} \in Y\}.$$

Since f_a is 1-good and $S(a, f_a, Y)$ is $\mathrm{OD}^M_{T,A,B,f_a}$ it follows that $S(a, f_a, Y)$ is 1-good and hence $G^X(S(a, f_a, Y))$ is determined.

For $a \in [\lambda]^{<\omega}$ and f_a a 1-good code for a, let

$$E_a(f_a) = \{Y \in \mathscr{P}([\kappa]^{|a|}) \cap \mathrm{HOD}^M_{T,A,B} \mid \text{I wins } G^X(S(a, f_a, Y))\}$$

and let

$$\begin{aligned} E_X(f_a) : [\lambda]^{<\omega} &\to \mathrm{HOD}^M_{T,A,B} \\ a &\mapsto E_a(f_a). \end{aligned}$$

The only trouble with this definition is that there is no guarantee that $E_X(f_a)$ is in $\mathrm{HOD}^M_{T,A,B}$ because there is no guarantee that $E_a(f_a)$ is in $\mathrm{HOD}^M_{T,A,B}$. We have to "erase" the dependence on the choice of f_a in the definition of E_a.

5.27 Lemma. *Suppose $a \in [\lambda]^{<\omega}$ and f_a and $\hat{f}_a$ are 1-good codes for a. Suppose $Y \in \mathscr{P}([\kappa]^{|a|}) \cap \mathrm{HOD}^M_{T,A,B}$. Then*

(1) I wins $G^X(\{\delta \in S_0(f_a) \cap S_0(\hat{f}_a) \mid a^{\delta}_{f_a} = a^{\delta}_{\hat{f}_a}\})$.

(2) I wins $G^X(S(a, f_a, Y))$ iff I wins $G^X(S(a, \hat{f}_a, Y))$, and

(3) $E_a(f_a) = E_a(\hat{f}_a)$.

Proof. (1) The statement

$$\forall x \in B\, \forall i \leqslant |a| \left((f_a(x))_i =_\lambda (\hat{f}_a(x))_i\right)$$

is a true $\Sigma_1(M, \{X, \kappa, \mathbb{R}\})$ statement about f_a and $\hat{f}_a$. So, by reflection, the set $\{\delta \in S_0(f_a) \cap S_0(\hat{f}_a) \mid a^{\delta}_{f_a} = a^{\delta}_{\hat{f}_a}\}$ is in $\mathscr{F}_X$ and hence in μ_X.

(2) Assume I wins $G^X(S(a, f_a, Y))$. We have that I wins the game in (1). Let $G^X(S_0(f_a, \hat{f}_a))$ abbreviate this game. So I wins $G^X(S(a, f_a, Y) \cap S_0(f_a, \hat{f}_a))$. But

$$S(a, f_a, Y) \cap S_0(f_a, \hat{f}_a) \subseteq S(a, \hat{f}_a, Y).$$

So I wins $G^X(S(a, \hat{f}_a, Y))$. Likewise if I wins $G^X(S(a, \hat{f}_a, Y))$ then I wins $G^X(S(a, f_a, Y))$.

(3) This follows immediately from (2). $\dashv$

Thus, we may wash out reference to f_a by setting

$$\begin{aligned} E_a &= \bigcap\{E_a(f_a) \mid f_a \text{ is a 1-good code of } a\} \\ &= E_a(f_a) \quad \text{for some (any) 1-good code } f_a \text{ of } a. \end{aligned}$$

Let

$$\begin{gathered} E_X : [\lambda]^{<\omega} \to \mathrm{HOD}^M_{T,A,B} \\ a \mapsto E_a \end{gathered}$$

Note that $E_a \in \mathrm{OD}^M_{T,A,B}$ and $E_a \subseteq \mathrm{HOD}^M_{T,A,B}$. Thus, $E_a \in \mathrm{HOD}^M_{T,A,B}$ and $E_X \in \mathrm{HOD}^M_{T,A,B}$.

Our definition of the extender E_X presupposes that for each $a \in [\lambda]^{<\omega}$ there is a 1-good code f_a of a and the existence of such codes is guaranteed by the assumption that M satisfies $\mathrm{ST}_{T,A,B}$-determinacy for two moves. Thus we have proved the following:

5.28 Lemma. *Assume that M satisfies $\mathrm{ST}_{T,A,B}$-determinacy for two moves. Then E_X is well-defined and $E_X \in \mathrm{HOD}^M_{T,A,B}$.*

It is important to stress that although the extender E_X is in $\mathrm{HOD}^M_{T,A,B}$ it is defined in M. For example, the certification that a certain set Y is in E_a depends on the existence of a winning strategy for a game in M. In general both the strategy and the game will not be in $\mathrm{HOD}^M_{T,A,B}$. So in establishing properties of E_X that hold in $\mathrm{HOD}^M_{T,A,B}$ we nevertheless have to consult the parent universe M.

5.29 Lemma. *Assume that M satisfies $\mathrm{ST}_{T,A,B}$-determinacy for two moves. Then*

$$\mathrm{HOD}^M_{T,A,B} \models E_X \textit{ is a pre-extender},$$

that is, $\mathrm{HOD}^M_{T,A,B}$ satisfies

(1) for each $a \in [\lambda]^{<\omega}$,

(a) E_a is a κ-complete ultrafilter on $[\kappa]^{|a|}$ and

(b) E_a is principal iff $a \subseteq \kappa$, and

(2) if $a \subseteq b \in [\lambda]^{<\omega}$ and $Y \in E_a$ then $Y^{a,b} \in E_b$.

Proof. (1)(a) It is easy to see that E_a is an ultrafilter in $\mathrm{HOD}^M_{T,A,B}$. It remains to see that E_a is κ-complete in $\mathrm{HOD}^M_{T,A,B}$. The proof is similar to that of Lemma 4.7. Let f_a be a 1-good code of a such that $E_a = E_a(f_a)$ and recall that

$$E_a(f_a) = \{Y \in \mathscr{P}([\kappa]^{|a|}) \cap \mathrm{HOD}^M_{T,A,B} \mid \text{I wins } G^X(S(a, f_a, Y))\}.$$

Consider $\{Y_\alpha \mid \alpha < \gamma\} \in \mathrm{HOD}^M_{T,A,B}$ such that $\gamma < \kappa$ and for each $\alpha < \gamma$, $Y_\alpha \in E_\alpha(f_a)$. We have to show that

$$Y = \bigcap\{Y_\alpha \mid \alpha < \gamma\} \in E_a(f_a).$$

The key point is that

$$S(a, f_a, Y) = \bigcap\{S(a, f_a, Y_\alpha) \mid \alpha < \gamma\}$$

and so we are in almost exactly the situation as Lemma 4.7, only now we have to carry along the parameter f_a.

Since $Y \in \mathrm{HOD}^M_{T,A,B}$, $S(a, f_a, Y) \in \mathrm{OD}^M_{T,A,B,f_a}$. Since f_a is 1-good it follows that $G^X(S(a, f_a, Y))$ is determined. Assume for contradiction that I does not win $G^X(S(a, f_a, Y))$ and let σ' be a winning strategy for I in $G^X(\kappa \smallsetminus S(a, f_a, Y))$. We will derive a contradiction by finding a play that is legal against σ' and against winning strategies for I in each game $G^X(S(a, f_a, Y_\alpha))$, for $\alpha < \gamma$.

As in the case of Lemma 4.7, for the purposes of coding the winning strategies (in the games $G^X(S(a, f_a, Y_\alpha))$ for $\alpha < \gamma$) we need a prewellordering of length γ which is such that in a reflection argument we can ensure that it reflects to itself. For this purpose, for $\delta < \kappa$, let

$$Q_\delta = U_\delta \smallsetminus \bigcup\{U_\xi \mid \xi < \delta\}.$$

The sequence

$$\langle Q_\xi \mid \xi < \kappa\rangle$$

gives rise to an $\mathrm{OD}^M_{T,A,B}$ prewellordering with the feature that for $\mathscr{F}_X$-almost all δ,

$$\langle Q_\xi \mid \xi < \delta\rangle = \langle Q_\xi \mid \xi < \delta\rangle^{M_{\vartheta(\delta)}}$$

and, by choosing a real, we can ensure that we always reflect to some such point $\delta > \gamma$.

Now set

$$\begin{aligned} Z = \{(x, \sigma) \mid{} & \text{for some } \alpha < \gamma,\ x \in Q_\alpha \text{ and} \\ & \sigma \text{ is a winning strategy for I in } G^X(S(a, f_a, Y_\alpha))\}. \end{aligned}$$

This set is $\mathrm{OD}^M_{T,A,B,f_a}$, hence determined (as f_a is 1-good). So the game in the Uniform Coding Lemma is determined. The rest of the proof is exactly as before.

(b) By κ-completeness, E_a is principal if and only if there exists $b \in [\kappa]^{|a|}$ such that

$$E_a = \{Y \in \mathscr{P}([\kappa]^{|a|}) \cap \mathrm{HOD}^M_{T,A,B} \mid b \in Y\}.$$

Suppose that $a \in [\kappa]^{|a|}$. We claim that $b = a$ witnesses that E_a is principal. Let f_a be a 1-good code of a. For $\mathscr{F}_X$-almost all δ, $a^\delta_{f_a} = a$. So, for $Y \in$

$\mathscr{P}([\kappa]^{|a|}) \cap \mathrm{HOD}^M_{T,A,B}$,

$$\begin{aligned} Y \in E_a &\leftrightarrow \text{I wins } G^X(S(a, f_a, Y)) \\ &\leftrightarrow \text{I wins } G^X(\{\delta \in S_0(f_a) \mid a^\delta_{f_a} = a \in Y\}) \\ &\leftrightarrow a \in Y. \end{aligned}$$

Suppose that $a \notin [\kappa]^{|a|}$. We claim that no $\beta \in [\kappa]^{|a|}$ witnesses that E_a is principal. Consider $b \in [\kappa]^{|a|}$ and let f_b be a 1-good code for b and let f_a be a 1-good code for a. For $\mathscr{F}_X$-almost all δ, $a^\delta_{f_a} \neq b^\delta_{f_b} = b$. Let S be the set of such δ and let $Y = \{a^\delta_{f_a} \mid \delta \in S\}$. Then $Y \in E_a$ and $b \notin Y$. Hence E_a is not principal.

(2) Suppose $a \subseteq b \in [\lambda]^{<\omega}$ and $Y \in E_a$. So I wins $G^X(S(a, f_a, Y))$ for some (any) 1-good code f_a of a. We must show that I wins $G^X(S(b, f_b, Y^{a,b}))$ for some (any) 1-good code f_b of b. Let f_b be a 1-good code of b and consider the statement describing the manner in which a sits inside b. This is a $\Sigma_1(M, \{X, \mathbb{R}, \kappa\})$ statement about f_a and f_b. So, by reflection, there exists an $S_0(f_a, f_b) \in \mathscr{F}_X$ such that for all $\delta \in S_0(f_a, f_b)$,

$$\langle a^\delta_{f_a}, b^\delta_{f_b}, \in\rangle \cong \langle a, b, \in\rangle.$$

We claim that $S(a, f_a, Y) \cap S_0(f_a, f_b) \subseteq S(b, f_b, Y^{a,b})$. Let δ be an ordinal in $S(a, f_a, Y) \cap S_0(f_a, f_b)$. We have $a^\delta_{f_a} \in Y$ and $\langle a^\delta_{f_a}, b^\delta_{f_b}, \in\rangle \cong \langle a, b, \in\rangle$. Since, by definition,

$$Y^{a,b} = \{z \in [\kappa]^{|b|} \mid z_{a,b} \in Y\},$$

this means that $b^\delta_{f_b} \in Y^{a,b}$ (as $(b^\delta_{f_b})_{a,b} = a^\delta_{f_a}$), that is, $\delta \in S(b, f_b, Y^{a,b})$. Finally, since I wins $G^X\big(S(a, f_a, Y) \cap S_0(f_a, f_b)\big)$, I wins $G^X(S(b, f_b, Y^{a,b}))$. $\dashv$

5.30 Lemma. *Assume that M satisfies $\mathrm{ST}_{T,A,B}$-determinacy for two moves. Then*

$$\mathrm{HOD}^M_{T,A,B} \models E_X \text{ is countably complete.}$$

Proof. Let $\{a_i \mid i < \omega\} \in \mathrm{HOD}^M_{T,A,B}$ and suppose that for each $i < \omega$, $X_i \in E_{a_i}$, that is, I wins $G^X(S(a_i, f_{a_i}, X_i))$ for some (any) 1-good code f_{a_i} of a_i. Let $S = \bigcap_{i<\omega} S(a_i, f_{a_i}, X_i)$. We need to ensure that $G^X(S)$ is determined. The point is that since $\{a_i \mid i < \omega\} \in \mathrm{HOD}^M_{T,A,B}$, a slight modification of the proof of Lemma 5.22 shows that there are f_{a_i} such that $\langle f_{a_i} \mid i < \omega\rangle$ is 1-good. So $G^X(S)$ is determined. As in the proof of the completeness of E_a we have that I wins $G^X(S)$.

As in the proof of coherence there is a set $S_0(f_{a_1}, \ldots, f_{a_n}, \ldots) \in \mathscr{F}_X$ such that for all $\delta \in S_0(f_{a_1}, \ldots, f_{a_n}, \ldots)$,

$$\langle a^\delta_1, \ldots, a^\delta_i, \ldots\rangle \cong \langle a_1, \ldots, a_i, \ldots\rangle.$$

Fix $\delta \in S \cap S_0(f_{a_1}, \dots, f_{a_n}, \dots)$. Set

$$\begin{aligned} h_i : a_i &\to \kappa \\ (a_i)_j &\mapsto ((a_i)^\delta_{f_{a_i}})_j. \end{aligned}$$

Since $\delta \in S_0(f_{a_1}, \dots, f_{a_n}, \dots)$, the function

$$h = \bigcup_{i<\omega} h_i : \bigcup_{i<\omega} a_i \to \kappa$$

is well-defined. Since $\delta \in S(a_i, f_{a_i}, X_i)$, $h``a_i = (a_i)^\delta_{f_{a_i}} \in X_i$. However, h may not belong to $\mathrm{HOD}^M_{T,A,B}$. To see that there is such an h in $\mathrm{HOD}^M_{T,A,B}$ consider the tree $\mathscr{T}$ of attempts to build such a function. (The nth level of T consists of approximations $h^* : \bigcup_{i<n} a_i \to \kappa$ and the order is by inclusion.) Thus $\mathscr{T} \in \mathrm{HOD}^M_{T,A,B}$ and the existence of h in V shows that $\mathscr{T}$ is ill-founded in V. But well-foundedness is absolute, so some such h must belong to $\mathrm{HOD}^M_{T,A,B}$. ⊣

It remains to establish that

$$\mathrm{HOD}^M_{T,A,B} \models E_X \text{ is normal.}$$

This will follow from an analogue of the earlier strong normality theorems.

5.31 Definition. Assume M satisfies $\mathrm{ST}_{T,A,B}$-determinacy for two moves. For $\alpha < \lambda$, let $f_\alpha : \omega^\omega \to \omega^\omega$ be a 1-good code of $\{\alpha\}$ (as in Lemma 5.22) and (as in Definition 5.25), for $\delta \in S_0(f_\alpha)$, let $\alpha^\delta_{f_\alpha}$ be the "reflected version" of α. We call the function

$$\begin{aligned} g_{f_\alpha} : S_0(f_\alpha) &\to \kappa \\ \delta &\mapsto \alpha^\delta_{f_\alpha} \end{aligned}$$

the *canonical function* associated to f_α.

Notice that the manner in which the ordinal $\alpha^\delta_{f_\alpha}$ is determined is different than in Sect. 4. In Sect. 4 we just chose $t \in Q_\alpha$ and let α^δ_t be unique such that $t \in Q^\delta_{\alpha^\delta_t}$. Notice also that g_{f_α} is 1-good since it is $\mathrm{OD}^M_{T,A,B,f_a}$.

The statement and proof of strong normality are similar to before, only now we have to ensure that the objects are sufficiently good to guarantee the determinacy of the games defined in terms of them. The real parameters that arise in the proof of strong normality will now have to be generated using the technique of Lemma 5.22 and every time we use this technique we will sacrifice one degree of goodness. There will be finitely many such sacrifices and so it suffices to assume that M satisfies $\mathrm{ST}_{T,A,B}$-determinacy for n moves for some sufficiently large n. Furthermore, there is no loss in generality in making this assumption since in all of the applications of the Generation Theorem, one will be able to show without DC that M satisfies

$\mathrm{ST}_{T,A,B}$-determinacy for $n < \omega$. As we shall see there will in fact only be two sacrifices of goodness. Thus, since we want our final object to be 1-good (to ensure that the games defined in terms of it are determined) it suffices to start with an object which is 3-good.

5.32 Theorem (Strong Normality). *Suppose $g : \kappa \to \kappa$ is such that*

(1) g is 3-good and

(2) I wins $G^X(\{\delta \in S_0 \mid g(\delta) < \lambda_\delta\})$.

Then there exists an $\alpha < \lambda$ such that

$$I \text{ wins } G^X(\{\delta \in S_0(f_\alpha) \mid g(\delta) = g_{f_\alpha}(\delta)\}),$$

where f_α is any 1-g-good code of α.

Proof. We begin with a few comments. First, note that since g is 3-good, by Lemma 5.22 we have that for each $\alpha < \lambda$ there is a 1-g-good code f_α of α (in fact, there is a 2-g-good code) and hence each game $G^X(\{\delta \in S_0(f_\alpha) \mid g(\delta) = g_{f_\alpha}(\delta)\})$ is determined. The only issue is whether I wins some such game.

Second, notice that α is uniquely specified. For suppose $f_{\hat{\alpha}}$ is a 1-g-good code of $\hat{\alpha}$ such that I wins the corresponding game. If $\alpha < \hat{\alpha}$, then

$$\{\delta \in S_0(f_\alpha) \cap S_0(f_{\hat{\alpha}}) \mid g_{f_\alpha}(\delta) < g_{f_{\hat{\alpha}}}(\delta)\} \in \mathscr{F}_X$$

and I wins $G^X(S)$ where S is this set. But then I cannot win both

$$G^X(\{\delta \in S_0(f_\alpha) \mid g(\delta) = g_{f_\alpha}(\delta)\})$$

and

$$G^X(\{\delta \in S_0(f_{\hat{\alpha}}) \mid g(\delta) = g_{f_{\hat{\alpha}}}(\delta)\}).$$

Third, it will be useful at this point to both list the parameters that will arise in the proof and motivate the need for assuming that g is 3-good. In outline the proof will follow that of Theorem 4.12. The final game in the present proof (the one involving e_1) will be defined in terms of three parameters: g, f_η and e_0, corresponding respectively to f, y_η, and e_0 from Theorem 4.12. To ensure the determinacy of the final game we will need to take steps to ensure that (g, f_η, e_0) is 1-good. Now, the parameter e_0 will be obtained by applying the technique of Lemma 5.22 to the parameter (g, f_η) and so we will need to take steps to ensure that this parameter is 2-good. And the parameter f_η will in turn be obtained by applying the technique of Lemma 5.22 to the parameter g and so we have had to assume from the start that g is 3-good.

We now turn to the proof proper. Suppose $g : \kappa \to \kappa$ is such that

(1.1) g is 3-good and

(1.2) I wins $G^X(\{\delta \in S_0 \mid g(\delta) < \lambda_\delta\})$.

Assume for contradiction that for each $\alpha < \lambda$ and for each 1-g-good code f_α of α,

(2.1) I does not win $G^X(\{\delta \in S_0(f_\alpha) \mid g(\delta) = g_{f_\alpha}(\delta)\})$,

and hence (since each such game is determined, as f_α is 1-g-good)

(2.2) I wins $G^X(\{\delta \in S_0(f_\alpha) \mid g(\delta) \neq g_{f_\alpha}(\delta)\})$.

Step 1. Let

$$\eta = \min\big(\{\beta < \lambda \mid \text{I wins } G^X(\{\delta \in S_0(f_\beta) \mid g(\delta) < g_{f_\beta}(\delta)\}) \text{ for each 1-}g\text{-good code } f_\beta \text{ of } \beta\}\big)$$

if such β exist; otherwise let $\eta = \lambda$. (So if there are such β then η is a limit ordinal.) Notice that

(3.1) whenever $\alpha < \eta$ and f_α is a 1-g-good code of α,

$$\text{I wins } G^X(\{\delta \in S_0(f_\alpha) \mid g(\delta) > g_{f_\alpha}(\delta)\}),$$

which is the desired situation. By Lemma 5.22, let

$$f_\eta \text{ be a 2-}g\text{-good code of } \eta.$$

For notational convenience, for $\delta \in S_0(f_\eta)$, let η_δ be $\eta^\delta_{f_\eta}$. By the definition of η, I wins $G^X(\{\delta \in S_0(f_\eta) \mid g(\delta) < g_{f_\eta}(\delta)\})$. Now update S_0 to be $S_0 \cap \{\delta \in S_0(f_\eta) \mid g(\delta) < g_{f_\eta}(\delta)\}$. We will work on this "large" set. Notice that S_0 is $\mathrm{OD}^M_{T,A,B,g,f_\eta}$. If $\eta = \lambda$ then $\eta_\delta = \delta$ and we may omit mention of f_η in what follows.

For convenience let us write "$S \in \mu_X$" as shorthand for "I wins $G^X(S)$". To summarize:

(4.1) g is 3-good,

(4.2) (g, f_η) is 2-good (First Drop in Goodness),

(4.3) S_0 is $\mathrm{OD}^M_{T,A,B,g,f_\eta}$,

(4.4) $S_0 \in \mu_X$ and for all $\delta \in S_0$, $g(\delta) < g_{f_\eta}(\delta)$, and

(4.5) for all $\alpha < \eta$ and for all 1-g-good codes f_α of α,

$$\{\delta \in S_0(f_\alpha) \mid g(\delta) > g_{f_\alpha}(\delta)\} \in \mu_X.$$

Step 2. We now establish the "disjointness property".

Let

$$Z' = \big\{(x, \langle y, \sigma\rangle) \mid x \in Q^\kappa_\alpha \text{ for some } \alpha < \eta, \\ y \text{ codes a 1-}g\text{-good code } f_\alpha \text{ of } \alpha \\ \text{such that } x \in \operatorname{ran}(f_\alpha \restriction B), \text{ and} \\ \sigma \text{ is a winning strategy for I in} \\ G^X(\{\delta \in S_0(f_\alpha) \mid g(\delta) > g_{f_\alpha}(\delta)\})\big\}.$$

We have

(5.1) Z' is $\mathrm{OD}^M_{T,A,B,g,f_\eta}$ and $Z' \subseteq Q^\kappa_{<\eta} \times \omega^\omega$, and

(5.2) for all $\alpha < \eta$,

$$Z' \cap (Q^\kappa_\alpha \times \omega^\omega) \neq \varnothing,$$

by (3.1).

Since (g, f_η) is 2-good the game in the proof of the Uniform Coding Lemma (Theorem 3.4) is determined. So *there is* an index $e \in \omega^\omega$ such that for all $\alpha < \eta$,

(6.1) $U^{(2)}_e(Q^\kappa_{<\alpha}, Q^\kappa_\alpha) \subseteq Z' \cap (Q^\kappa_\alpha \times \omega^\omega)$ and

(6.2) $U^{(2)}_e(Q^\kappa_{<\alpha}, Q^\kappa_\alpha) \neq \varnothing$.

The trouble is that we have no guarantee that such an index e has any degree of (g, f_η)-goodness; yet this is essential for the present proof since we shall go on to define games in terms of this index and we need some guarantee that these games are determined. As usual, we retreat from the reals we want to the good functions that capture them and this will lead to the second (and final) drop in goodness. Let

$$A_0 = \big\{x \in \omega^\omega \mid x_{\text{even}} \text{ is such that for all } \alpha < \eta \\ (1)\ U^{(2)}_{x_{\text{even}}}(Q^\kappa_{<\alpha}, Q^\kappa_\alpha) \subseteq Z' \cap (Q^\kappa_\alpha \times \omega^\omega) \text{ and} \\ (2)\ U^{(2)}_{x_{\text{even}}}(Q^\kappa_{<\alpha}, Q^\kappa_\alpha) \neq \varnothing\big\}.$$

So $A_0 \in \mathrm{OD}^M_{T,A,B,g,f_\eta}$. Now have I play A_0 in $(SG^B_{T,A,B,g,f_\eta})^M$ and let f_0 be II's response. Since (g, f_η) is 2-good, II's response f_0 is 1-(g, f_η)-good. Furthermore,

(7.1) $\forall x \in B\, \forall y \in \omega^\omega\, (f_0(x) * y \in A_0)$, which is to say,

(7.2) $\forall x \in B\, \forall y \in \omega^\omega\, (f_0(x) * y)_{\text{even}}$ is an index as in (6.1) and (6.2), hence

(7.3) $\forall \alpha < \eta$, $\bigcup_{x \in B} U^{(2)}_{(f_0(x)*0)_{\text{even}}}(Q^\kappa_{<\alpha}, Q^\kappa_\alpha)$ is as in (6.1) and (6.2).

The union in (7.3) is itself $\underset{\sim}{\Sigma}^1_1(B, Q^\kappa_{<\alpha}, Q^\kappa_\alpha)$ and so there is an $e_0 \in \omega^\omega$ which is definable from f_0 (and hence inherits the 1-(g, f_η)-goodness of f_0) such that

(8.1) (g, f_η, e_0) is 1-good (Second Drop in Goodness) and

(8.2) for all $\alpha < \eta$,

(1) $U^{(2)}_{e_0}(B, Q^\kappa_{<\alpha}, Q^\kappa_\alpha) \subseteq Z' \cap (Q^\kappa_\alpha \times \omega^\omega)$ and

(2) $U^{(2)}_{e_0}(B, Q^\kappa_{<\alpha}, Q^\kappa_\alpha) \neq \varnothing$.

Omitting Z', (8.2) is $\Sigma_1(M, \{X, \kappa, \mathbb{R}, f_\eta, e_0\})$. So, for $\mathscr{F}_X$-almost all δ,

(8.3) for all $\alpha < \eta_\delta$,

(1) $U^{(2)}_{e_0}(B, Q^\delta_{<\alpha}, Q^\delta_\alpha) \subseteq (Q^\delta_\alpha \times \omega^\omega)$ and

(2) $U^{(2)}_{e_0}(B, Q^\delta_{<\alpha}, Q^\delta_\alpha) \neq \varnothing$.

The set S_1' of such δ is $\Sigma_1(M, \{X, \kappa, \mathbb{R}, f_\eta, e_0\})$. Let $S_1 = S_1' \cap S_0$. Since $S_1' \in \mu_X$ and $S_0 \in \mu_X$, it follows that $S_1 \in \mu_X$. Notice also that S_1 is $\Sigma_1(M, \{X, \kappa, \mathbb{R}, g, f_\eta, e_0\})$. For $\delta \in S_1 \cup \{\kappa\}$ and $\alpha < \eta_\delta$, let

$$\begin{aligned} Z^\delta_\alpha &= U^{(2)}_{e_0}(B, Q^\delta_{<\alpha}, Q^\delta_\alpha) \quad \text{and} \\ Z^\delta &= \textstyle\bigcup_{\alpha<\eta_\delta} Z^\delta_\alpha. \end{aligned}$$

Claim A (Disjointness Property). *There is an $S_2 \subseteq S_1$ such that $S_2 \in \mu_X$ and for $\delta_1, \delta_2 \in S_2 \cup \{\kappa\}$ with $\delta_1 < \delta_2 \leqslant \kappa$,*

$$Z^{\delta_1}_\alpha \cap Z^{\delta_2}_\beta = \varnothing$$

for all $\alpha \in [g(\delta_1), \eta_{\delta_1})$ and $\beta \in [0, \eta_{\delta_2})$.

Proof. We begin by establishing a special case.

Subclaim. *For μ_X-almost all δ,*

$$Z^\delta_\alpha \cap Z^\kappa_\beta = \varnothing$$

for all $\alpha \in [g(\delta), \eta_\delta)$ and $\beta \in [0, \eta)$.

Proof. Let

$$G = \big\{\delta \in S_1 \mid Z^\delta_\alpha \cap Z^\kappa_\beta = \varnothing \text{ for all } \alpha \in [g(\delta), \eta_\delta) \text{ and } \beta \in [0, \eta)\big\}$$

be the set of "good points". Our aim is to show that $G \in \mu_X$. Note that G is $\mathrm{OD}^M_{T,A,B,g,f_\eta,e_0}$. Since (g, f_η, e_0) is 1-good, $G^X(G)$ is determined. Assume for contradiction that $G \notin \mu_X$. Then, by determinacy, $\kappa \smallsetminus G \in \mu_X$. Since $S_1 \in \mu_X$, we have $(\kappa \smallsetminus G) \cap S_1 \in \mu_X$. Let σ' be a winning strategy for I in $G^X((\kappa \smallsetminus G) \cap S_1)$.

We get a contradiction much as before: We can "take control" of the games to produce a play z and an ordinal δ_0 such that

(9.1) z is a legal play for II against σ' and δ_0 is the associated ordinal and

(9.2) z is a legal play for II against each $\sigma \in (\mathrm{proj}_2(Z^{\delta_0}))_1$ and in each case δ_0 is the associated ordinal.

This will finish the proof: By (9.1) and the definition of G, there is an $\alpha_0 \in [g(\delta_0), \eta_{\delta_0})$ and a $\beta_0 \in [0, \eta)$ such that $Z^{\delta_0}_{\alpha_0} \cap Z^{\kappa}_{\beta_0} \neq \varnothing$. Fix $(x_0, \langle y_0, \sigma_0\rangle) \in Z^{\delta_0}_{\alpha_0} \cap Z^{\kappa}_{\beta_0}$. Since $(x_0, \langle y_0, \sigma_0\rangle) \in Z^{\kappa}_{\beta_0} \subseteq Z' \cap (Q^{\kappa}_{\beta_0} \times \omega^\omega)$ we have, by the definition of Z', $x_0 \in Q^{\kappa}_{\beta_0}$, y_0 codes a 1-g-good code f_{β_0} of β_0, $x_0 \in \mathrm{ran}(f_{\beta_0} \restriction B)$, and σ_0 is a winning strategy for I in $S(\{\delta \in S_0(f_{\beta_0}) \mid g(\delta) > g_{f_{\beta_0}}(\delta)\})$. Since $(x_0, \langle y_0, \sigma_0\rangle) \in Z^{\delta_0}_{\alpha_0}$, $\sigma_0 \in (\mathrm{proj}_2(Z^{\delta_0}))_1$. Now, by (9.2), z is a legal play for II against σ_0 with associated ordinal δ_0, and since σ_0 is a winning strategy for I in $S(\{\delta \in S_0(f_{\beta_0}) \mid g(\delta) > g_{f_{\beta_0}}(\delta)\})$, this implies

(10.1) $\delta_0 \in \{\delta \in S_0(f_{\beta_0}) \mid g(\delta) > g_{f_{\beta_0}}(\delta)\}$,

that is, $g(\delta_0) > g_{f_{\beta_0}}(\delta_0)$. We now argue

(10.2) $g_{f_{\beta_0}}(\delta_0) = \alpha_0$,

which is a contradiction since $\alpha_0 \geqslant g(\delta_0)$. Recall that by definition $g_{f_{\beta_0}}(\delta_0) = |f_{\beta_0}(x)|_{\leqslant_{\delta_0}}$, where x is any element of B. Since we arranged $x_0 \in \mathrm{ran}(f_{\beta_0} \restriction B)$ and since $(x_0, \langle y_0, \sigma_0\rangle) \in Z^{\delta_0}_{\alpha_0}$, this implies that $g_{f_{\beta_0}}(\delta_0) = |f_{\beta_0}(x)|_{\leqslant_{\delta_0}} = \alpha_0$, where x is any element of B. Thus, a play z as in (9.1) and (9.2) will finish the proof.

The play z is constructed as before:

Base Case. We have

(11.1) $\forall y \in \omega^\omega\, ((\sigma' * y)_I)_0 \in U_X$ and

(11.2) $\forall y \in \omega^\omega\, \forall \sigma \in (\mathrm{proj}_2(Z^\kappa))_1\, ((\sigma * y)_I)_0 \in U_X$.

This is a true $\Sigma_1(M, \{X, \kappa, \mathbb{R}, \sigma', e_0, f_\eta\})$ statement. So there is a $z_0 \in U_X$ such that $z_0 \leqslant_T \langle \sigma', e_0, f_\eta\rangle$ and for all δ if $z_0 \in U_\delta$ then

(11.3) $\forall y \in \omega^\omega\, ((\sigma' * y)_I)_0 \in U_\delta$ and

(11.4) $\forall y \in \omega^\omega\, \forall \sigma \in (\mathrm{proj}_2(Z^\delta))_1\, ((\sigma * y)_I)_0 \in U_\delta$.

$(n+1)$st Step. Assume we have defined $z_0, \ldots, z_n$ in such a way that

(12.1) $\forall y \in \omega^\omega\, \big(\forall i \leqslant n\, (y)_i = z_i \rightarrow ((\sigma' * y)_I)_{n+1} \in U_X\big)$ and

(12.2) $\forall y \in \omega^\omega\, \sigma \in (\mathrm{proj}_2(Z^\kappa))_1, \big(\forall i \leqslant n\, (y)_i = z_i \rightarrow ((\sigma * y)_I)_{n+1} \in U_X\big)$.

This is a true $\Sigma_1(M, \{X, \kappa, \mathbb{R}, \sigma', e_0, f_\eta, z_0, \ldots, z_n\})$ statement. So there is a $z_{n+1} \in U_X$ such that $z_{n+1} \leqslant_T z_n$ and for all if $z_{n+1} \in U_\delta$ then

(12.3) $\forall y \in \omega^\omega\, \big(\forall i \leqslant n\, (y)_i = z_i \rightarrow ((\sigma' * y)_I)_{n+1} \in U_\delta\big)$ and

(12.4) $\forall y \in \omega^\omega\, \forall \sigma \in (\mathrm{proj}_2(Z^\delta))_1\, \big(\forall i \leqslant n\, (y)_i = z_i \rightarrow ((\sigma * y)_I)_{n+1} \in U_\delta\big)$.

Finally, let $z \in \omega^\omega$ be such that $(z)_i = z_i$ for all $i \in \omega$ and let δ_0 be least such that $(z)_i \in U_{\delta_0}$ for all $i \in \omega$. Notice that by our choice of z_n, for $n < \omega$, no DC is required to construct z. We have that for all $i \in \omega$,

(13.1) $((\sigma' * z)_I)_i \in U_{\delta_0}$ by (11.3) and (12.3) and

(13.2) $((\sigma * z)_I)_i \in U_{\delta_0}$ for all $\sigma \in (\mathrm{proj}_2(Z^{\delta_0}))_1$ by (11.4) and (12.4).

So we have (9.1) and (9.2), which is a contradiction. ⊣

By the subclaim,

(14.1) $\forall \delta \in G\, \forall \alpha \in [g(\delta), \eta_\delta)\, \forall \beta \in [0, \eta)\, (Z^\delta_\alpha \cap Z^\kappa_\beta = \varnothing)$.

This is a true $\Sigma_1(M, \{X, \kappa, \mathbb{R}, \langle f_\eta, e_0\rangle, g, G\})$ statement φ. Notice that since G is $\mathrm{OD}^M_{T,A,B,g,f_\eta,e_0}$ and (g, f_η, e_0) is 1-good, it follows that (G, g, f_η, e_0) is 1-good. In particular, (G, g) is 1-good, and so Theorem 5.20 applies (taking $\langle f_\eta, e_0\rangle$ for the real t in the statement of that theorem) and we have that

(14.3) for $\mathscr{F}_X$-almost all δ_2,

- (1) $M \models \varphi[\langle f_\eta, e_0\rangle, F(\delta_2), \delta_2, g\restriction\delta_2, G \cap \delta_2]$, that is,
- (2) $\forall \delta_1 \in G \cap \delta_2\, \forall \alpha \in [g(\delta_1), \eta_{\delta_1})\, \forall \beta \in [0, \eta_{\delta_2})\, (Z^{\delta_1}_\alpha \cap Z^{\delta_2}_\beta = \varnothing)$.

Let S'_2 be the set of such δ_2 in (14.3) and let $S_2 = S'_2 \cap G$. Since $S'_2 \in \mathscr{F}_X \subseteq \mu_X$ and $G \in \mu_X$, we have that $S_2 \in \mu_X$. Hence S_2 is as desired in Claim A. Also, S_2 is $\mathrm{OD}^M_{T,A,B,g,f_\eta,e_0}$. ⊣

Notice that two additional parameters have emerged, namely, G and S_2, but these do not lead to a drop in goodness since

(15.1) $\mathrm{OD}^M_{T,A,B,g,f_\eta,e_0,G,S_2} = \mathrm{OD}^M_{T,A,B,g,f_\eta,e_0,G} = \mathrm{OD}^M_{T,A,B,g,f_\eta,e_0}$, and so

(15.2) (g, f_η, e_0, G, S_2) is 1-good.

Step 3. We are now in a position to "compute g".
For $\delta \in S_2$, let

$$P^\delta = \bigcup\{Z^{\bar\delta}_\alpha \mid \bar\delta \in S_2 \cap \delta \wedge \alpha \in [g(\bar\delta), \eta_{\bar\delta})\}.$$

By (15.1), $P^\delta \in \mathrm{OD}^M_{T,A,B,g,f_\eta,e_0}$.

Claim B (Tail Computation). *There exists an index $e_1 \in \omega^\omega$ such that for all $\delta \in S_2$,*

(1) $U^{(2)}_{e_1}(P^\delta, Z^\delta_\alpha) \subseteq Z^\delta_\alpha$ for all $\alpha \in [0, \eta_\delta)$,

(2) $U^{(2)}_{e_1}(P^\delta, Z^\delta_{g(\delta)}) = \varnothing$, and

(3) $U^{(2)}_{e_1}(P^\delta, Z^\delta_\alpha) \neq \varnothing$ for $\alpha \in (g(\delta), \eta_\delta)$.

Proof. As before it suffices to show (2) and (3′) $U^{(2)}_{e_1}(P^\delta, Z^\delta_\alpha) \cap Z^\delta_\alpha \neq \varnothing$ for $\alpha \in (g(\delta), \eta_\delta)$.

Let

$$G = \{e \in \omega^\omega \mid \forall \delta \in S_2\, (U^{(2)}_e(P^\delta, Z^\delta_{g(\delta)}) = \varnothing)\}.$$

Toward a contradiction assume that for each $e \in G$, (3′) in the claim fails for some δ and α. For each $e \in G$, let

$$\begin{aligned} \alpha_e = {} & \text{lexicographically least pair } (\delta, \alpha) \text{ such that} \\ & (1)\ \delta \in S_2, \\ & (2)\ g(\delta) < \alpha < \eta_\delta, \text{ and} \\ & (3)\ U^{(2)}_e(P^\delta, Z^\delta_\alpha) \cap Z^\delta_\alpha = \varnothing. \end{aligned}$$

Now play the game

$$\begin{array}{lccccccc} \text{I} & x(0) & & x(1) & & x(2) & & \ldots \\ \text{II} & & y(0) & & y(1) & & \ldots & \end{array}$$

where II wins iff $(x \in G \to (y \in G \wedge \alpha_y >_{\text{lex}} \alpha_x))$.

The key point is that this payoff condition is $\mathrm{OD}^M_{T,A,B,g,f_\eta,e_0}$, by (15.1), and hence, the game is determined, since (g, f_η, e_0) is 1-good.

The rest of the proof is exactly as before. ⊣

From this point on there are no uses of determinacy that require further "joint goodness".

Claim C. *There exists an $\alpha_0 < \eta$ such that*

(1) $U^{(2)}_{e_1}(P^\kappa, Z^\kappa_{\alpha_0}) = \varnothing$ and

(2) $U^{(2)}_{e_1}(P^\kappa, Z^\kappa_\alpha) \neq \varnothing$ for all $\alpha \in (\alpha_0, \eta)$, where

$$P^\kappa = \bigcup \{Z^\delta_\alpha \mid \delta \in S_2 \wedge \alpha \in [g(\delta), \eta_\delta)\}.$$

Proof. The statement that there is not a largest ordinal α_0 which is "empty" is $\Sigma_1(M, \{X, \kappa, \mathbb{R}, \langle f_\eta, e_0, e_1\rangle, g, G, S_2\})$. Since (g, f_η, e_0) is 1-good and G and S_2 are $\mathrm{OD}^M_{T,A,B,g,f_\eta,e_0}$, it follows that (g, G, S_2) is 1-good. Thus, the Reflection Theorem (Theorem 5.20) applies and we have that for $\mathscr{F}_X$-many δ, the statement reflects, which contradicts Claim B. ⊣

Let α_0 be the unique ordinal as above and let f_{α_0} be a 1-g-good code of α_0 (which exists by Lemma 5.22). The statement

(16.2) $\forall x \in B\, f_{\alpha_0}(x) \in Q^\kappa_\alpha$ where α is such that

(1) $U^{(2)}_{e_1}(P^\kappa, Z^\kappa_\alpha) = \varnothing$ and

(2) $U^{(2)}_{e_1}(P^\kappa, Z^\kappa_\beta) \neq \varnothing$ for $\beta \in (\alpha, \eta_\delta)$.

is $\Sigma_1(M, \{X, \kappa, \mathbb{R}, \langle f_\eta, f_{\alpha_0}, e_0, e_1\rangle, g, G, S_2\})$. Since (g, G, S_2) is 1-good, the Reflection Theorem (Theorem 5.20) applies and hence for $\mathscr{F}_X$-almost all δ the statement reflects. Let $S_3' \in \mathscr{F}_X$ be this set. Let $S_3 = S_3' \cap S_2$. So $S_3 \in \mu_X$. By Claim B and Claim C, for $\delta \in S_3$ the ordinal α in question is $g(\delta)$. So I wins $G^X(\{\delta \in S_0(f_{\alpha_0}) \cap S_3 \mid g(\delta) = g_{f_{\alpha_0}}(\delta)\})$ and hence I wins $G^X(\{\delta \in S_0(f_{\alpha_0}) \mid g(\delta) = g_{f_{\alpha_0}}(\delta)\})$. This game is determined since f_{α_0} is 1-g-good.

To summarize:

(17.1) f_{α_0} is 1-g-good and

(17.2) I wins $G^X(\{\delta \in S_0(f_{\alpha_0}) \mid g(\delta) = g_{f_{\alpha_0}}(\delta)\})$,

which completes the proof of strong normality. ⊣

Since every $g : \kappa \to \kappa$ in $\mathrm{HOD}^M_{T,A,B}$ is 3-good and since in the context of the main theorem we assume that M satisfies $\mathrm{ST}_{T,A,B}$-determinacy for four moves, we have shown:

5.33 Corollary. *Suppose $g : \kappa \to \kappa$ is in $\mathrm{HOD}^M_{T,A,B}$ and such that I wins $G^X(\{\delta \in S_0 \mid g(\delta) < \lambda_\delta\})$. Then there exists an $\alpha < \lambda$ and a 1-g-good code f_α of α such that*

$$I \text{ wins } G^X(\{\delta \in S_0(f_\alpha) \mid g(\delta) = g_{f_\alpha}(\delta)\}).$$

5.34 Lemma (Normality). *In $\mathrm{HOD}^M_{T,A,B}$: If $a \in [\lambda]^{<\omega}$ and $f : [\kappa]^{|a|} \to \kappa$ is such that*

$$\{z \in [\kappa]^{|a|} \mid f(z) < z_i\} \in E_a$$

for some $i \leqslant |a|$, then there is a $\beta < a_i$ such that

$$\{z \in [\kappa]^{|a \cup \{\beta\}|} \mid f(z_{a, a\cup\{\beta\}}) = z_k\} \in E_{a\cup\{\beta\}}$$

where k is such that β is the kth element of $a \cup \{\beta\}$.

Proof. The proof just involves chasing through the definitions: Suppose $f : \kappa^{|a|} \to \kappa$ is a function in $\mathrm{HOD}^M_{T,A,B}$ such that for some $i \leqslant |a|$,

$$\{z \in [\kappa]^{|a|} \mid f(z) < z_i\} \in E_a.$$

Since M satisfies $\mathrm{ST}_{T,A,B}$-determinacy for four moves, f is 4-good. So, by Lemma 5.22, there is a 3-good code f_a of a. Hence

(1.1) I wins $G^X(\{\delta \in S_0(f_a) \mid f(a^\delta_{f_a}) < (a^\delta_{f_a})_i\})$.

Let

$$\begin{aligned} f^* &: \kappa \to \kappa \\ \delta &\mapsto \begin{cases} f(a^\delta_{f_a}) & \text{if } \delta \in S_0(f_a) \\ 0 & \text{otherwise.} \end{cases} \end{aligned}$$

So $f^* \in \mathrm{HOD}^M_{T,A,B,f_a}$ and hence f^* is 3-good. By Theorem 5.32, (1.2) there is an f_β such that

(1) f_β is a 1-f^*-good code of β,
(2) I wins $G^X(\{\delta \in S_0(f_\beta) \mid f^*(\delta) = g_{f_\beta}(\delta)\})$, and
(3) I wins $G^X(\{\delta \in S_0(f_\beta) \cap S_0(f_a) \mid f(a^\delta_{f_a}) = g_{f_\beta}(\delta)\})$.

Note that $\beta < a_i$ since if $\beta \geqslant a_i$ then for $\mathscr{F}_X$-almost all δ, $g_{f_\beta}(\delta) \geqslant (a^\delta_{f_a})_i$ and we get that I wins $G^X(\{\delta \in S_0(f_\beta) \cap S_0(f_a) \mid f(a^\delta_{f_a}) \geqslant (a^\delta_{f_a})_i\})$, which contradicts (1.1).

Let k be such that $\beta = (a \cup \{\beta\})_k$. Let $f_{a\cup\{\beta\}}$ be a 1-good code of $a \cup \{\beta\}$. Note that

(2.1) for $\mathscr{F}_X$-almost all δ,

$$\big((a \cup \{\beta\})^\delta_{f_{a\cup\{\beta\}}}\big)_k = g_{f_\beta}(\delta)$$

and

(2.2) for $\mathscr{F}_X$-almost all δ,

$$\big((a \cup \{\beta\})^\delta_{f_{a\cup\{\beta\}}}\big)_{a,a\cup\{\beta\}} = a^\delta_{f_a}$$

and, moreover, I wins on these sets (since the parameters in the definitions are 1-good). So (1.2)(3) yields

(3.1) I wins $G^X\big(\big\{\delta \in S_0(f_{a\cup\{\beta\}}) \mid f\big(\big((a \cup \{\beta\})^\delta_{f_{a\cup\{\beta\}}}\big)_{a,a\cup\{\beta\}}\big) = \big((a \cup \{\beta\})^\delta_{f_{a\cup\{\beta\}}}\big)_k\big\}\big)$, that is,

(3.2) $\{z \in [\kappa]^{|a\cup\{\beta\}|} \mid f(z_{a,a\cup\{\beta\}}) = z_k\} \in E_{a\cup\{\beta\}}$,

as desired. ⊣

We are now in a position to take the "ultrapower" of $\mathrm{HOD}^M_{T,A,B}$ by E_X. It will be useful to recall this construction and record some basic facts concerning it. For further details see Steel's chapter in this Handbook.

Let

$$D = \{\langle a, f\rangle \in \mathrm{HOD}^M_{T,A,B} \mid a \in [\lambda]^{<\omega} \text{ and } f : [\kappa]^{|a|} \to \mathrm{HOD}^M_{T,A,B}\}.$$

We get an equivalence relation on D by letting

$$\langle a, f\rangle \sim_E \langle b, g\rangle \in D \leftrightarrow \{z \in [\kappa]^{|a\cup b|} \mid f(z_{a,a\cup b}) = g(z_{b,a\cup b})\} \in E_{a\cup b}.$$

Let $[a, f]$ be the elements of minimal rank of the equivalence class of $\langle a, f\rangle$. Let Ult be the structure with domain

$$\{[a, f] \mid \langle a, f\rangle \in D\}$$

and membership relation defined by

$$[a, f] \in_{E_X} [b, g] \leftrightarrow \{z \in [\kappa]^{|a\cup b|} \mid f(z_{a,a\cup b}) \in g(z_{b,a\cup b})\} \in E_{a\cup b}.$$

Since $\mathrm{HOD}^M_{T,A,B}$ satisfies AC, Łoś's theorem holds in the following form: For all formulas $\varphi(x_1, \ldots, x_n)$ and all elements $[a_1, f_1], \ldots, [a_n, f_n] \in \mathrm{Ult}$,

$$\begin{aligned} &\mathrm{Ult} \models \varphi\big[[a_1, f_1], \ldots, [a_n, f_n]\big] \\ &\quad \leftrightarrow \quad \{z \in [\kappa]^{|b|} \mid \mathrm{HOD}^M_{T,A,B} \models \varphi[f_1(z_{a_1,b}), \ldots, f_n(z_{a_n,b})]\} \in E_b, \end{aligned}$$

where $b = \bigcup_{1\leqslant i\leqslant n} a_i$. It follows that

$$\begin{aligned} j'_E : \mathrm{HOD}^M_{T,A,B} &\to \mathrm{Ult} \\ x &\mapsto [\varnothing, c_x], \end{aligned}$$

where c_x is the constant function with value x, is an elementary embedding. The countable completeness of E_X ensures that Ult is well-founded and it is straightforward to see that it is extensional and set-like. So we can take the transitive collapse. Let

$$\pi : \mathrm{Ult} \to M_X$$

be the transitive collapse map and let

$$j_E : \mathrm{HOD}^M_{T,A,B} \to M_X$$

be the elementary embedding obtained by letting $j_E = \pi \circ j'_E$. The κ-completeness of each E_a, for $a \in [\lambda]^{<\omega}$, implies that j_E is the identity on $\mathrm{HOD}^M_{T,A,B} \cap V_\kappa$ and that κ is the critical point of j_E. Normality implies that for each $a \in [\lambda]^{<\omega}$, $\pi([a, z \mapsto z_i]) = a_i$, for each i such that $1 \leqslant i \leqslant |a|$. In particular, if $\alpha < \lambda$ then $\alpha = \pi([\{\alpha\}, z \mapsto \cup z])$. It follows that $\lambda \leqslant j_E(\kappa)$.

5.35 Lemma (T-STRENGTH).

$$\mathrm{HOD}^M_{T,A,B} \models \mathrm{ZFC} + \textit{There is a } T\textit{-strong cardinal.}$$

Proof. We already have that

$$\mathrm{HOD}^M_{T,A,B} \models \mathrm{ZFC},$$

by Lemma 5.16. It follows that there are arbitrarily large $\lambda < \Theta_M$ such that

$$\mathrm{HOD}^M_{T,A,B} \cap V_\lambda^{\mathrm{HOD}^M_{T,A,B}} = L_\lambda[A],$$

where $A \subseteq \lambda$ and $A \in \mathrm{HOD}^M_{T,A,B}$. Let λ be such an ordinal and let κ, j_E, etc. be as above. We have that $j_E(\kappa) \geqslant \lambda$ and it remains to show that

$$V_\lambda^{\mathrm{HOD}^M_{T,A,B}} \subseteq M_X$$

and

$$j_E(T \cap \kappa) \cap \lambda = T \cap \lambda.$$

The proof of each is the same. Let us start with the latter. We have to show that for all $\alpha < \lambda$,

$$\alpha \in j_E(T \cap \kappa) \leftrightarrow \alpha \in T.$$

We have

$$\begin{aligned} \alpha \in j_E(T \cap \kappa) \quad &\leftrightarrow \quad \pi([\{\alpha\}, z \mapsto \cup z]) \in \pi([\varnothing, c_{T \cap \kappa}]) \\ &\leftrightarrow \quad [\{\alpha\}, z \mapsto \cup z] \in_{E_X} [\varnothing, c_{T \cap \kappa}] \\ &\leftrightarrow \quad \{z \in [\kappa]^1 \mid \cup z \in T \cap \kappa\} \in E_{\{\alpha\}}. \end{aligned}$$

So we have to show that

$$\alpha \in T \leftrightarrow \{\{z\} \mid z \in T \cap \kappa\} \in E_{\{\alpha\}}.$$

Let $f_{\{\alpha\}}$ be a 1-good code of $\{\alpha\}$.

Assume $\alpha \in T$. We have to show that

$$\text{I wins } G^X\big(S(\{\alpha\}, f_{\{\alpha\}}, \{\{z\} \mid z \in T \cap \kappa\})\big).$$

The key point is that the statement "for all $x \in B$, $|f_{\{\alpha\}}(x)|_{\leqslant \lambda} \in T$" is a true $\Sigma_1(M, \{X, \kappa, \mathbb{R}, f_{\{\alpha\}}\})$ statement. So the set S of δ to which this statement reflects is in $\mathscr{F}_X$. Since $S \in \mathrm{OD}^M_{T,A,B,f_{\{\alpha\}}}$ and $f_{\{\alpha\}}$ is 1-good, $G^X(S)$ is determined and I wins. But

$$S(\{\alpha\}, f_{\{\alpha\}}, \{\{z\} \mid z \in T \cap \kappa\}) = S_0(f_{\{\alpha\}}) \cap S$$

and so I wins this game as well.

Assume $\alpha \notin T$. We have to show that

$$\text{I does not win } G^X\big(S(\{\alpha\}, f_{\{\alpha\}}, \{\{z\} \mid z \in T \cap \kappa\})\big).$$

Again, the point is that the statement "for all $x \in B$, $|f_{\{\alpha\}}(x)|_{\leqslant \lambda} \notin T$" is a true $\Sigma_1(M, \{X, \kappa, \mathbb{R}, f_{\{\alpha\}}\})$ statement. So this statement reflects to $\mathscr{F}_X$-almost all δ, which implies that I cannot win the above game.

Exactly the same argument with 'A' in place of 'T' shows that

$$j_E(A \cap \kappa) \cap \lambda = A \cap \lambda,$$

and hence that

$$V_\lambda^{\mathrm{HOD}^M_{T,A,B}} = L_\lambda[A] \subseteq M_X,$$

which completes the proof. ⊣

This completes the proof of the Generation Theorem. ⊣

5.4. Special Cases

We now consider a number of special instances of the Generation Theorem. In each case all we have to do is find appropriate values for the parameters Θ_M, T, A, and B. We begin by recovering the main result of Sect. 4.

5.36 Theorem. *Assume* $\mathrm{ZF}+\mathrm{AD}$. *Then*

$$\mathrm{HOD}^{L(\mathbb{R})} \models \Theta^{L(\mathbb{R})} \textit{ is a Woodin cardinal.}$$

Proof. For notational convenience let $\Theta = \Theta^{L(\mathbb{R})}$. Our strategy is to meet the conditions of the Generation Theorem while at the same time arranging that $M = L_\Theta(\mathbb{R})[T, A, B]$ is such that

$$\mathrm{HOD}^M_{T,A,B} = \mathrm{HOD}^{L(\mathbb{R})} \cap V_\Theta.$$

We will do this by taking care to ensure that the ingredients T, A, and B are in $\mathrm{HOD}^{L(\mathbb{R})}$ while at the same time packaging $\mathrm{HOD}^{L(\mathbb{R})} \cap V_\Theta$ as part of T. It will then follow from the Generation Theorem that

$$\mathrm{HOD}^{L(\mathbb{R})} \cap V_\Theta \models \mathrm{ZFC} + \text{There is a } T\text{-strong cardinal},$$

and by varying T the result follows.

To begin with let $\Theta_M = \Theta^{L(\mathbb{R})}$ and, for notational convenience, we continue to abbreviate this as Θ. By Theorem 3.9, Θ is strongly inaccessible in $\mathrm{HOD}^{L(\mathbb{R})}$. Also,

$$\mathrm{HOD}^{L(\mathbb{R})} \cap V_\Theta = \mathrm{HOD}^{L_\Theta(\mathbb{R})},$$

by Theorem 3.10. So we can let $H \in \mathscr{P}(\Theta) \cap \mathrm{HOD}^{L(\mathbb{R})}$ code

$$\mathrm{HOD}^{L(\mathbb{R})} \cap V_\Theta.$$

Fix $T' \in \mathscr{P}(\Theta) \cap \mathrm{HOD}^{L(\mathbb{R})}$ and let $T \in \mathscr{P}(\Theta) \cap \mathrm{HOD}^{L(\mathbb{R})}$ code T' and H. By Lemmas 3.7 and 3.8, there is an $\mathrm{OD}^{L(\mathbb{R})}$ sequence $A = \langle A_\alpha \mid \alpha < \Theta \rangle$ such that each A_α is a prewellordering of reals of length α. Let $B = \mathbb{R}$.

Let

$$M = L_\Theta(\mathbb{R})[T, A, B]$$

where Θ, T, A, and B are as above. Conditions (1)–(5) of the Generation Theorem are clearly met and condition (6) follows since $L(\mathbb{R})$ satisfies AD and M contains all reals. Moreover, since we have arranged that all of the ingredients T, A, and B are in $\mathrm{OD}^{L(\mathbb{R})}$ and also that T codes $\mathrm{HOD}^{L(\mathbb{R})} \cap V_\Theta$, we have

$$\mathrm{HOD}^M_{T,A,B} = \mathrm{HOD}^{L(\mathbb{R})} \cap V_\Theta$$

and, since T' was arbitrary, the result follows as noted above. ⊣

We can also recover the following approximation to Theorem 5.6.

5.37 Theorem. *Assume* $\mathrm{ZF} + \mathrm{AC}_\omega(\mathbb{R})$*. Suppose* ST_X*-determinacy holds, where* X *is a set and* B *is non-empty and* OD_X*. Then*

$$\mathrm{HOD}_X \models \Theta_X \textit{ is a Woodin cardinal.}$$

Proof. Let $\Theta_M = \Theta_X$. Let $A = \langle A_\alpha \mid \alpha < \Theta_X\rangle$ be such that A_α codes the OD_X-least prewellordering of reals of length α. By Theorem 3.9, Θ_X is strongly inaccessible in HOD_X and so there exists an $H \in \mathscr{P}(\Theta_X) \cap \mathrm{HOD}_X$ coding $\mathrm{HOD}_X \cap V_{\Theta_X}$. Let $T \in \mathscr{P}(\Theta_X) \cap \mathrm{HOD}_X$ code H and some arbitrary $T' \in \mathscr{P}(\Theta_X) \cap \mathrm{HOD}_X$.

Let

$$M = L_{\Theta_M}(\mathbb{R})[T, A, B]$$

where Θ_M, T, A, and B are as above. Work in $\mathrm{HOD}_{\{X\}\cup\mathbb{R}}$. Conditions (3)–(5) of the Generation Theorem are clearly met. For condition (2) note that by Lemma 3.7, $\Theta_X = \Theta^{\mathrm{HOD}_{\{X\}\cup\mathbb{R}}}$ and that by the arguments of Lemma 3.8 and Lemma 3.9, $\Theta^{\mathrm{HOD}_{\{X\}\cup\mathbb{R}}}$ is regular in $\mathrm{HOD}_{\{X\}\cup\mathbb{R}}$. Thus, Θ_M is regular in $\mathrm{HOD}_{\{X\}\cup\mathbb{R}}$. Condition (6) follows from the fact that M is OD_X and M contains all of the reals. It remains to see that condition (1) can be met. For this we just have to see that Replacement holds in M. If Replacement failed in M then there would be a cofinal map $\pi : \omega^\omega \to \Theta_X$ that is definable from parameters in M, which in conjunction with A would lead to an OD_X surjection from ω^ω onto Θ_X, which is a contradiction. ⊣

5.38 Remark. Work in ZF+DC. For μ a δ-complete ultrafilter on δ let E_μ be the (δ, λ)-extender derived from μ where $\lambda = j(\delta)$ (or $\lambda = \delta^\delta/\mu$) and j is the ultrapower map. We have the following corollary: Assume $\mathrm{ZF} + \mathrm{AD} + \mathrm{DC}$. Then Θ_X is Woodin in HOD_X and this is witnessed by the collection of $E_\mu \cap \mathrm{HOD}_X$ where μ is a normal ultrafilter on some $\delta < \Theta_X$.

5.39 Remark. Theorem 5.6 cannot be directly recovered from the Generation Theorem and this is why we have singled it out for special treatment. However, it follows from the proof of the Generation Theorem, as can be seen by noting that in the case where one has full boldface determinacy the ultrafilters are actually in HOD_X by Kunen's theorem (Theorem 3.11).

4 Open Question. There are some interesting questions related to Theorem 5.37.

(1) Suppose $\Theta_X = \Theta_0$. Suppose ST_X-determinacy, where B is non-empty and OD_X. Is Θ_0 a Woodin cardinal in HOD?

(2) Suppose ST_X-determinacy, where X is a set and B is non-empty and OD_X. Is Θ_X a Woodin cardinal in HOD?

(3) In the AD^+ setting, every Θ_X is of the form Θ_α and there are constraints on this sequence. For example, each Θ_X must be of the form $\Theta_{\alpha+1}$. Does this constraint apply in the lightface setting?

5.40 Theorem. *Assume* ZF + AD. *Let S be a class of ordinals. Then for an S-cone of x,*

$$\mathrm{HOD}_S^{L[S,x]} \models \omega_2^{L[S,x]} \textit{ is a Woodin cardinal.}$$

Proof. For an S-cone of x,

$$L[S,x] \models \mathrm{ZFC} + \mathrm{GCH} \text{ below } \omega_1^V,$$

by Corollary 5.10, and, for all $n < \omega$,

$$L[S,x] \models \mathrm{ST}_S\text{-determinacy for } n \text{ moves},$$

where $B = [x]_S$, by Theorem 5.13. Let x be in this S-cone.

Let $\Theta_M = \omega_2^{L[S,x]}$. Since $L[S,x]$ satisfies GCH below ω_1^V and $L[S,x] = \mathrm{OD}_{S,x}^{L[S,x]}$, by Lemma 3.8 we have that

$$\omega_2^{L[S,x]} = \sup\{\alpha \mid \text{there is an } \mathrm{OD}_S^{L[S,x]} \text{ prewellordering of length } \alpha\},$$

in other words, $\omega_2^{L[S,x]} = (\Theta_S)^{L[S,x]}$. Let $A = \langle A_\alpha \mid \alpha < \omega_2^{L[S,x]}\rangle$ be such that A_α is the $\mathrm{OD}_S^{L[S,x]}$-least prewellordering of length α. Since $L[S,x] \models \mathrm{OD}_S$-determinacy, it follows (by Theorem 3.9) that $\omega_2^{L[S,x]}$ is strongly inaccessible in $\mathrm{HOD}_S^{L[S,x]}$. So there is a set $H \subseteq \omega_2^{L[S,x]}$ coding $\mathrm{HOD}_S^{L[S,x]} \cap V_{\omega_2^{L[S,x]}}$. Let T' be in $\mathscr{P}(\omega_2^{L[S,x]}) \cap \mathrm{OD}_S^{L[S,x]}$ and let $T \in \mathscr{P}(\omega_2^{L[S,x]}) \cap \mathrm{OD}_S^{L[S,x]}$ code T and H. Let $B = [x]_S$.

Let

$$M = L_{\Theta_M}(\mathbb{R}^{L[S,x]})[T, A, B],$$

where Θ_M, T, A, and B are as above. Conditions (1)–(5) of the Generation Theorem are clearly met and condition (6) follows since $L[S,x]$ satisfies ST_S-determinacy for four moves, M is OD_S in $L[S,x]$ and M contains the reals of $L[S,x]$. Thus,

$$\mathrm{HOD}^M_{T,A,B} \models \mathrm{ZFC} + \text{ There is a } T\text{-strong cardinal.}$$

Since we have arranged that all of the ingredients T, A, and B are in $\mathrm{OD}^{L[S,x]}$ and also that T codes $\mathrm{HOD}^{L[S,x]} \cap V_{\omega_2^{L[S,x]}}$, we have

$$\mathrm{HOD}^M_{T,A,B} = \mathrm{HOD}^{L[S,x]} \cap V_{\omega_2^{L[S,x]}}.$$

Since T' was arbitrary, the result follows. ⊣

5.41 Theorem. *Assume* ZF + AD. *Then for an S-cone of x,*

$$\mathrm{HOD}_{S,\mathrm{HOD}_{S,x}} \models \omega_2^{\mathrm{HOD}_{S,x}} \textit{ is a Woodin cardinal.}$$

Proof. This will follow from the next theorem which is more general. ⊣

The next two theorems require some notation. Suppose Y is a set and $a \in H(\omega_1)$. For $x \in \omega^\omega$, the (Y,a)-*degree* of x is the set

$$[x]_{Y,a} = \{z \in \omega^\omega \mid \mathrm{HOD}_{Y,a,z} = \mathrm{HOD}_{Y,a,x}\}.$$

The (Y,a)-*degrees* are the sets of the form $[x]_{Y,a}$ for some $x \in \omega^\omega$. Define $x \leqslant_{Y,a} y$ to hold iff $x \in \mathrm{HOD}_{Y,a,y}$. A *cone of* (Y,a)-*degrees* is a set of the form $\{[y]_{Y,a} \mid y \geqslant_{Y,a} x_0\}$ for some $x_0 \in \omega^\omega$ and a (Y,a)-*cone of reals* is a set of the form $\{y \in \omega^\omega \mid y \geqslant_{Y,a} x_0\}$ for some $x_0 \in \omega^\omega$. The proof of the Cone Theorem (Theorem 2.9) generalizes to the present context. In the case where $a = \varnothing$ we speak of Y-*degrees*, etc.

5.42 Theorem. *Assume* ZF+AD. *Suppose Y is a set and $a \in H(\omega_1)$. Then for a (Y,a)-cone of x,*

$$\mathrm{HOD}_{Y,a,[x]_{Y,a}} \models \omega_2^{\mathrm{HOD}_{Y,a,x}} \textit{ is a Woodin cardinal,}$$

where $[x]_{Y,a} = \{z \in \omega^\omega \mid \mathrm{HOD}_{Y,a,z} = \mathrm{HOD}_{Y,a,x}\}$.

Proof. By determinacy it suffices to show that the above statement holds for a Turing cone of x, which is what we shall do. The key issues in this case are getting a sufficient amount of GCH and strategic determinacy. To establish the first we need two preliminary claims. Recall that a set $A \subseteq \omega^\omega$ is *comeager* if and only if $\omega^\omega \setminus A$ is meager.

Claim 1. *Assume* ZF + AD. *Suppose that $\langle A_\alpha \mid \alpha < \gamma\rangle$ is a sequence of sets which are comeager in the space ω^ω, where either $\gamma \in \mathrm{On}$ or $\gamma = \mathrm{On}$, in which case the sequence is a definable proper class. Then $\bigcap_{\alpha<\gamma} A_\alpha$ is comeager.*

Proof. Assume for contradiction that the claim fails and let γ be least such that there is a sequence $\langle A_\alpha \mid \alpha < \gamma\rangle$ the intersection of which is not comeager. By AD, $\bigcap_{\alpha<\gamma} A_\alpha$ has the property of Baire and so we may assume without loss of generality that $\bigcap_{\alpha<\gamma} A_\alpha$ is meager. So, every proper initial segment has comeager intersection while the whole sequence has meager intersection. We can now violate the Kuratowski-Ulam Theorem. (This is the analogue for category of Fubini's theorem. See [9, 5A.9].) Define f on the complement of $\bigcap_{\alpha<\gamma} A_\alpha$ as follows:

$$f(x) = \min(\{\alpha < \gamma \mid x \notin A_\alpha\}).$$

So if $y \in \bigcap_{\xi<\alpha} A_\xi$ then $f(y) > \alpha$. Since $\bigcap_{\alpha<\gamma} A_\alpha$ is meager, $\mathrm{dom}(f)$ is comeager. Consider the subset of the plane

$$Z = \{(x,y) \in \mathrm{dom}(f) \times \mathrm{dom}(f) \mid f(x) < f(y)\}.$$

For each $x \in \mathrm{dom}(f)$ the vertical section

$$Z_x = \{y \in \mathrm{dom}(f) \mid f(y) > f(x)\}$$

is comeager since it includes $\bigcap_{\alpha \leqslant f(x)} A_\alpha$ and for each $y \in \mathrm{dom}(f)$ the horizontal section

$$Z^y = \{x \in \mathrm{dom}(f) \mid f(x) < f(y)\}$$

is meager since its complement contains the comeager set $\bigcap_{\alpha < f(y)} A_\alpha$. Since Z has the property of Baire, this contradicts the Kuratowski-Ulam Theorem, the proof of which requires only $\mathrm{AC}_\omega(\mathbb{R})$, which follows from AD (Theorem 2.2). ⊣

Claim 2. *Assume* ZF + AD. *Suppose Y is a set, $a \in H(\omega_1)$ and $\mathbb{P} \in \mathrm{HOD}_{Y,a} \cap H(\omega_1)$ is a partial order. Then for comeager many $\mathrm{HOD}_{Y,a}$-generic $G \subseteq \mathbb{P}$,*

$$\mathrm{HOD}_{Y,a,G} = \mathrm{HOD}_{Y,a}[G].$$

Proof. For each G we clearly have $\mathrm{HOD}_{Y,a}[G] \subseteq \mathrm{HOD}_{Y,a,G}$. We seek a set A that is comeager in the Stone space of $\mathbb{P}$ and such that for all $G \in A$, $\mathrm{HOD}_{Y,a,G} = \mathrm{HOD}_{Y,a}[G]$. We will do this by showing that for each $G \in A$ the latter model can compute the "ordinal theory" of the former model.

For every Σ_2 statement φ and finite sequence of ordinals $\vec{\xi}$ consider the statement $\varphi[\vec{\xi}, Y, a, G]$ about a generic G. Let $B^{\varphi,\vec{\xi},Y,a}$ be the associated collection of filters on $\mathbb{P}$ and let

$$P^{\varphi,\vec{\xi}} = \{p \in \mathbb{P} \mid B^{\varphi,\vec{\xi},Y,a} \text{ is comeager in } O_p\} \quad \text{and}$$
$$N^{\varphi,\vec{\xi}} = \{p \in \mathbb{P} \mid B^{\neg\varphi,\vec{\xi},Y,a} \text{ is comeager in } O_p\},$$

where O_p is the open set of generics containing p. These are the sets of conditions which "positively" and "negatively" decide $\varphi[\vec{\xi}, Y, a, G]$, respectively. So $P^{\varphi,\vec{\xi}} \cup N^{\varphi,\vec{\xi}}$ is predense. Now let

$$\begin{aligned} A_{\varphi,\vec{\xi}} = &\{G \subseteq \mathbb{P} \mid \varphi[\vec{\xi}, Y, a, G] \leftrightarrow G \cap P^{\varphi,\vec{\xi}} \neq \varnothing\} \\ &\cup \{G \subseteq \mathbb{P} \mid \neg\varphi[\vec{\xi}, Y, a, G] \leftrightarrow G \cap N^{\varphi,\vec{\xi}} \neq \varnothing\}. \end{aligned}$$

Each such set is comeager. We thus have a class size well-order of comeager sets and so, by the previous lemma,

$$A = \bigcap\{A_{\varphi,\vec{\xi}} \mid \varphi \text{ is a } \Sigma_2 \text{ formula and } \vec{\xi} \in \mathrm{On}^{<\omega}\}$$

is comeager. But now we have that for all $G \in A$

$$\mathrm{HOD}_{Y,a,G} = \mathrm{HOD}_{Y,a}[G]$$

since the latter can compute all answers to questions involving the former—that is, questions of the form $\varphi[\vec{\xi}, Y, a, G]$ where φ is Σ_2—by checking whether G hits $P^{\varphi,\vec{\xi}}$ or $N^{\varphi,\vec{\xi}}$. (Notice that the restriction to Σ_2 formulas suffices (by reflection) since any statement about an initial segment of $\mathrm{HOD}_{Y,a,G}$ is Σ_2.) ⊣

Claim 3. *Assume* ZF + AD. *Suppose Y is a set and $a \in H(\omega_1)$. Then for a Turing cone of x,*

$$\mathrm{HOD}_{Y,a,x} \models \mathrm{GCH} \textit{ below } \omega_1^V.$$

Proof. It suffices to show that CH holds on a cone since given this the proof that GCH below ω_1^V holds on a cone goes through exactly as before.

Suppose for contradiction (by the Cone Theorem (Theorem 2.9)) that there is a real x_0 such that for all $x \geqslant_T x_0$,

$$\mathrm{HOD}_{Y,a,x} \models \neg\mathrm{CH}.$$

We will arrive at a contradiction by producing an $x \geqslant_T x_0$ with the feature that $\mathrm{HOD}_{Y,a,x} \models \mathrm{CH}$. As before x is obtained by forcing (in two steps) over HOD_{Y,a,x_0}. First, we get a HOD_{Y,a,x_0}-generic

$$G \subseteq \mathrm{Col}(\omega_1^{\mathrm{HOD}_{Y,a,x_0}}, \mathbb{R}^{\mathrm{HOD}_{Y,a,x_0}})$$

and then we use almost disjoint forcing to code G with a real. Viewing the generic g as a real, by the previous claim we have that for comeager many g,

$$\mathrm{HOD}_{Y,a,x_0,g} = \mathrm{HOD}_{Y,a,x_0}[g] \models \mathrm{CH},$$

and hence

$$\mathrm{HOD}_{Y,a,\langle x_0,g\rangle} \models \mathrm{CH},$$

which is a contradiction. ⊣

Claim 4. *Suppose Y is a set and $a \in H(\omega_1)$. Then for a Turing cone of x, for each $n < \omega$, II can play n moves of $SG^B_{Y,a,[x]_{Y,a}}$, where $B = [x]_{Y,a}$, and we demand in addition that II's moves belong to $\mathrm{HOD}_{Y,a,x}$, in other words, II can play n moves of the game*

$$\begin{array}{lccccc} \mathrm{I} & A_0 & & \cdots & A_{n-1} & \\ \mathrm{II} & & f_0 & \cdots & & f_{n-1} \end{array}$$

where we require, for $i+1 < n$,

(1) $A_0 \in \mathscr{P}(\omega^\omega) \cap \mathrm{OD}^V_{Y,a,[x]_{Y,a}}$, $A_{i+1} \in \mathscr{P}(\omega^\omega) \cap \mathrm{OD}^V_{Y,a,[x]_{Y,a},f_0,\ldots,f_i}$ and

(2) f_{i+1} is prestrategy for A_{i+1} that belongs to $\mathrm{HOD}_{Y,a,x}$ and is winning with respect to $[x]_{Y,a}$.

Proof. The proof of Theorem 5.13 actually establishes this stronger result. ⊣

We are now in a position to meet the conditions of the Generation Theorem. For a Turing cone of x,

$$\mathrm{HOD}_{Y,a,x} \models \mathrm{ZFC} + \mathrm{GCH} \text{ below } \omega_1^V,$$

by Claim 3, and for all $n<\omega$,

$$\mathrm{ST}_{Y,a,[x]_{Y,a}}\text{-determinacy for } n \text{ moves}$$

holds in V where $B=[x]_{Y,a}$, by Claim 4. Let x be in this cone.

Let $\Theta_M=\omega_2^{\mathrm{HOD}_{Y,a,x}}$. Since $\mathrm{HOD}_{Y,a,x}\models \mathrm{ZFC}+\mathrm{GCH}$ below ω_1^V,

$$\Theta_M=\Theta.$$

Since every set is $\mathrm{OD}_{Y,a,x}$, and hence $\mathrm{OD}_{Y,a,[x]_Y,x}$,

$$\Theta=\Theta_{Y,a,[x]_Y},$$

by Lemma 3.8. Thus,

$$\omega_2^{\mathrm{HOD}_{Y,a,x}}=\Theta^{\mathrm{HOD}_{Y,a,x}}_{Y,a,[x]_{Y,a}}.$$

Letting $A=\langle A_\alpha\mid\alpha<\omega_2^{\mathrm{HOD}_{Y,a,x}}\rangle$ be such that A_α is the $\mathrm{OD}_{Y,a,[x]_{Y,a}}$-least prewellordering of length α we have that A is $\mathrm{OD}_{Y,a,[x]_{Y,a}}$. We also have that $\omega_2^{\mathrm{HOD}_{Y,a,x}}$ is strongly inaccessible in $\mathrm{HOD}_{Y,a,[x]_{Y,a}}$, by Theorem 3.9. So there is a set $H\subseteq\omega_2^{\mathrm{HOD}_{Y,a,x}}$ coding $\mathrm{HOD}_{Y,a,[x]_{Y,a}}\cap V_{\omega_2^{\mathrm{HOD}_{Y,a,x}}}$. Let T' be in $\mathscr{P}(\omega_2^{\mathrm{HOD}_{Y,a,x}})\cap\mathrm{OD}_{Y,a,[x]_{Y,a}}$ and let $T\in\mathscr{P}(\omega_2^{\mathrm{HOD}_{Y,a,x}})\cap\mathrm{OD}_{Y,a,[x]_{Y,a}}$ code T' and H. Let $B=[x]_{Y,a}$.

Let

$$M=L_{\Theta_M}(\mathbb{R}^{\mathrm{HOD}_{Y,a,x}})[T,A,B],$$

where Θ_M, T, A, and B are as above. Conditions (1)–(5) of the Generation Theorem are clearly met. Condition (6) follows from the fact that M is $\mathrm{OD}_{Y,a,[x]_{Y,a}}$ and we have arranged (in Claim 4) that all of II's moves in $SG^B_{Y,a,[x]_{Y,a}}$ are in M.

Thus,

$$\mathrm{HOD}^M_{T,A,B}\models\mathrm{ZFC}+\text{ There is a } T\text{-strong cardinal},$$

and since we have arranged that

$$\mathrm{HOD}^M_{T,A,B}=\mathrm{HOD}_{Y,a,[x]_{Y,a}}\cap V_{\omega_2^{\mathrm{HOD}_{Y,a,x}}},$$

and T was arbitrary, the result follows. $\dashv$

In the above theorem the degree notion $[x]_{Y,a}$ depends on the initial choice of a. However, later (in Sect. 6.2) we will want to construct models with many Woodin cardinals. A natural approach to doing this is to iteratively apply the previous theorem, starting off with $a=\varnothing$, increasing the degree of x to get that $\omega_2^{\mathrm{HOD}_{Y,x}}$ is a Woodin cardinal in $\mathrm{HOD}_{Y,[x]_Y}$, and then taking $a=[x]_Y$, increasing the degree of x yet again to get that $\omega_2^{\mathrm{HOD}_{Y,[x]_Y,x}}$ is a Woodin cardinal in $\mathrm{HOD}_{Y,[x]_Y,[x]_{Y,[x]_Y}}$, etc. This leads to serious difficulties since the degree notion is changing. We would like to keep the degree notion fixed as we supplement a and for this reason we need the following variant of the previous theorem.

5.43 Theorem. *Assume* ZF + AD. *Suppose Y is a set and $a \in H(\omega_1)$. Then for a Y-cone of x,*

$$\mathrm{HOD}_{Y,a,[x]_Y} \models \omega_2^{\mathrm{HOD}_{Y,a,x}} \textit{ is a Woodin cardinal,}$$

where $[x]_Y = \{z \in \omega^\omega \mid \mathrm{HOD}_{Y,z} = \mathrm{HOD}_{Y,x}\}$.

Proof. The proof is essentially the same as that of the previous theorem. Claims 1 to 3 are exactly as before. The only difference is that now in Claim 4 we have $[x]_Y$ in place of $[x]_{Y,a}$. The proof of this version of the claim is the same, as is that of the rest of the theorem. ⊣

6. Definable Determinacy

We now use the Generation Theorem to derive the optimal amount of large cardinal strength from both lightface and boldface definable determinacy.

The main result concerning lightface definable determinacy is the following:

6.1 Theorem. *Assume* $\mathrm{ZF}+\mathrm{DC}+\Delta^1_2$*-determinacy. Then for a Turing cone of x,*

$$\mathrm{HOD}^{L[x]} \models \mathrm{ZFC} + \omega_2^{L[x]} \textit{ is a Woodin cardinal.}$$

When combined with the results mentioned in the introduction this has the consequence that the theories ZFC + OD-determinacy and ZFC + "There is a Woodin cardinal" are equiconsistent. In order to prove this theorem we will have to get into the situation of the Generation Theorem. The issue here is that Δ^1_2-determinacy does not imply that for a cone of x strategic determinacy holds in $L[x]$ with respect to the constructibility degree of x. Instead we will use a different basis set B, one for which we can establish ST^B-determinacy for four moves, using Δ^1_2-determinacy alone.

The main result concerning boldface definable determinacy is the following:

6.2 Theorem. *Assume* ZF + AD. *Suppose Y is a set. There is a generalized Prikry forcing $\mathbb{P}_Y$ through the Y-degrees such that if $G \subseteq \mathbb{P}_Y$ is V-generic and $\langle [x_i]_Y \mid i < \omega\rangle$ is the associated sequence, then*

$$\mathrm{HOD}^{V[G]}_{Y,\langle [x_i]_Y \mid i<\omega\rangle, V} \models \mathrm{ZFC} + \textit{There are } \omega\textit{-many Woodin cardinals.}$$

When combined with the results mentioned in the introduction this has the consequence that the theories ZFC + OD($\mathbb{R}$)-determinacy and ZFC + "There are ω-many Woodin cardinals" are equiconsistent. As an application we show that when conjoined with the Derived Model Theorem (Theorem 1.5 or, more generally, Theorem 8.12) this result enables one to reprove and generalize Kechris' theorem (Theorem 2.6).

6.1. Lightface Definable Determinacy

In this subsection we will work in the theory $\mathrm{ZF}+\mathrm{DC}+\Delta^1_2$-determinacy and examine the features of the model $L[x]$ for a Turing cone of reals x. Our aim is to show that for a Turing cone of x,

$$\mathrm{HOD}^{L[x]} \models \omega_2^{L[x]} \text{ is a Woodin cardinal.}$$

This will be done by showing that the conditions of the Generation Theorem can be met. We already know that this is true assuming full boldface determinacy in the background universe. But now we are working with a weak form of lightface definable determinacy and this presents new obstacles. The main difficulty is in showing that for a Turing cone of x,

$$L[x] \models \mathrm{ST}^B\text{-determinacy}$$

for an appropriate basis B. In the boldface setting we took our basis B to be the constructibility degree of x. But as we shall see (in Theorem 6.12) in our present setting one cannot secure this version of strategic determinacy. Nevertheless, it turns out that strategic determinacy holds for a different, smaller basis. This leads to the notion of *restricted strategic determinacy.*

We shall successively extract stronger and stronger forms of determinacy until we ultimately reach the version we need. The subsection closes with a series of limitative results, including results that motivate the need for strategic and restricted strategic determinacy.

6.3 Theorem (Martin). *Assume* $\mathrm{ZF}+\mathrm{DC}+\Delta^1_2$*-determinacy. Then* Σ^1_2*-determinacy.*

Proof. Consider $A=\{x\in\omega^\omega \mid \varphi(x)\}$ where φ is Σ^1_2. We have to show that A is determined. Our strategy is to show that if II (the Π^1_2 player) does not have a winning strategy for A then I (the Σ^1_2 player) has a winning strategy for A.

Assume that II does not have a winning strategy for A. First, we have to shift to a "local" setting where we can apply Δ^1_2-determinacy. For each $x\in\omega^\omega$,

$$L[x] \models \text{II does not have a winning strategy in } \{y\in\omega^\omega \mid \varphi(y)\}$$

(since otherwise, by Σ^1_3 upward absoluteness, II would have a winning strategy in V, contradicting our initial assumption) and so, by the Löwenheim-Skolem theorem, there is a countable ordinal λ such that

$$L_\lambda[x] \models \mathrm{T} + \text{II does not have a winning strategy in } \{y\in\omega^\omega \mid \varphi(y)\},$$

where T is some fixed sufficiently strong fragment of ZFC (such as $\mathrm{ZFC_N}$ where N is large or $\mathrm{ZFC}-\mathrm{Replacement}+\Sigma_2$-Replacement). For $x\in\omega^\omega$, let

$$\lambda(x)=\mu\lambda\,(L_\lambda[x]\models \mathrm{T}+\text{II does not have a winning strategy in } \{y\in\omega^\omega \mid \varphi(y)\}).$$

For convenience let $A^x = \{y \in \omega^\omega \mid \varphi(y)\}^{L_{\lambda(x)}[x]}$.

Consider the game G

$$\begin{array}{ll} \mathrm{I} & a, x \\ \mathrm{II} & b \end{array}$$

where I wins iff $a * b \in L_{\lambda(x)}[x]$ and $L_{\lambda(x)}[x] \models \varphi(a * b)$. Here Player I is to be thought of as choosing the playing field $L_{\lambda(x)}[x]$ in which the two players are to play an auxiliary round (via a and b) of the localized game A^x. The key point is that since $\lambda(x)$ is always defined this game is Δ^1_2 and hence determined.

We claim that I has a winning strategy in G (and so I wins each round of the localized games A^x) and, furthermore, that (by ranging over these rounds and applying upward Σ^1_2-absoluteness) this winning strategy yields a winning strategy for I in A.

Assume for contradiction (by Δ^1_2-determinacy) that II has a winning strategy τ_0 in G. For each $x \geqslant_T \tau_0$, in $L_{\lambda(x)}[x]$ we can derive a winning strategy τ^x for II in A^x as follows: For $a \in (\omega^\omega)^{L_{\lambda(x)}[x]}$, let $(a * \tau^x)_{II} = b$ where b is such that $(\langle a, x\rangle * \tau_0)_{II} = b$. Since τ_0 is a winning strategy for II in G and we have arranged that $a * b \in L_{\lambda(x)}[x]$, II must win in virtue of the second clause, which means that $a * b \notin A^x$. Thus, $L_{\lambda(x)}[x] \models$ "τ^x is a winning strategy for II in A^x", which is a contradiction.

Thus I has a winning strategy σ_0 in G. Consider the derived strategy σ such that for $b \in \omega^\omega$, $(\sigma * b)_I = a$ where a is such that $(\sigma_0 * b)_I = \langle a, x\rangle$. Since σ_0 is a winning strategy for I in G, $\sigma * b \in L_{\lambda(x)}[x]$ and $L_{\lambda(x)}[x] \models \varphi(\sigma * b)$ and so, by upward Σ^1_2-absoluteness, $V \models \varphi(\sigma * b)$. Thus, σ is a winning strategy for I in A. ⊣

6.4 Remark.

(1) The above proof relativizes to a real parameter to show that $\Delta^1_2(x)$-determinacy implies $\Sigma^1_2(x)$-determinacy.

(2) A similar but more elaborate argument shows that if Δ^1_2-determinacy holds and for every real x, $x^\#$ exists, then $\mathrm{Th}(L[x])$ is constant for a Turing cone of x. See [4].

6.5 Theorem (Martin). *Assume* ZF + DC + Δ^1_2*-determinacy. If I has a winning strategy in a* Σ^1_2 *game then I has a* Δ^1_3 *strategy.*

Proof. Consider $A = \{x \in \omega^\omega \mid \varphi(x)\}$ where φ is Σ^1_2. Our strategy is to show that if II (the Π^1_2 player) does not win A then I (the Σ^1_2 player) wins A via a Δ^1_3 strategy.

Assume that II does not have a winning strategy in A. For $x \in \omega^\omega$, let $\lambda(x)$, A^x, G, and σ_0 be as in the previous proof. Since σ_0 is a winning strategy for I in G, for $x \geqslant_T \sigma_0$, in $L_{\lambda(x)}[x]$ we can derive a winning strategy σ^x for I in A^x as follows: For $x \geqslant_T \sigma_0$ and $b \in (\omega^\omega)^{L_{\lambda(x)}[x]}$ let $(\sigma * b)_I = a$ where a is such that $(\sigma_0 * b)_I = \langle a, x\rangle$.

Next we show that there is an $x_0 \geqslant_T \sigma_0$ such that for all $x \geqslant_T x_0$, $L_{\lambda(x)}[x] \models \Delta^1_2$-determinacy. Let $\langle \varphi_n, \psi_n \rangle$ enumerate the pairs of Σ^1_2 formulas and let $A_\varphi = \{x \in \omega^\omega \mid \varphi(x)\}$. Using DC let z_n be such that z_n codes a winning strategy for A_{φ_n} if $A_{\varphi_n} = \omega^\omega \smallsetminus A_{\psi_n}$ (i.e. A_{φ_n} is Δ^1_2); otherwise let $z_n = \langle 0, 0, \ldots \rangle$. Finally, let x_0 code $\langle z_n \mid n < \omega \rangle$. Thus, for $x \geqslant_T x_0$,

$$L_{\lambda(x)}[x] \models \text{I has a } \Sigma^1_4 \text{ strategy in } A^x$$

by the Third Periodicity Theorem of Moschovakis.

(For a proof of Third Periodicity see Jackson's chapter in this Handbook. The statement of Third Periodicity typically involves boldface determinacy. However, the proof shows that lightface Δ^1_2 determinacy suffices to get Σ^1_4 winning strategies for Σ^1_2 games that I wins. To see this note that $\text{Scale}(\Sigma^1_2)$ holds in $\text{ZF} + \text{DC}$. Furthermore, we also have the determinacy of the Σ^1_2 games (denoted $G^n_{s,t}$ in Jackson's chapter) that are used to define the prewellorderings and ultimately the definable strategies. It follows that these prewellorderings and strategies are $\Game\Sigma^1_2 \subseteq \Sigma^1_4$. (Notice that if we had $\underset{\sim}{\Delta}^1_2$-determinacy then we could flip the quantifiers and conclude that $\Game\Sigma^1_2 = \Pi^1_3$ and hence get Δ^1_3 strategies. However, in our present lightface setting some more work is required.))

For $x \geqslant_T x_0$, let $\hat{\sigma}^x$ be the Σ^1_4-strategy for I in A^x. For a Turing cone of x the formula $\varphi(y, z)$ defining this strategy is constant. We can now "freeze out" the value of $\hat{\sigma}^x$ on a Turing cone of x. The key point is that the function $x \mapsto L_{\lambda(x)}[x]$ is Δ^1_2. So, for each $s \in \omega^{2n}$ and $m \in \omega$ the statement

$$L_{\lambda(x)}[x] \models \varphi(s, m)$$

is Δ^1_2. Thus, for each $s \in \omega^{2n}$, the m such that $L_{\lambda(x)}[x] \models \varphi(s, m)$ is fixed for a Turing cone of x. Since there are only countably many $s \in \omega^{2n}$ this means that the value of $\hat{\sigma}^x$ is fixed on a Turing cone of x. Finally, letting

$$\begin{aligned} \sigma(s) = m &\leftrightarrow \exists x_0 \forall x \geqslant_T x_0 \, (L_{\lambda(x)}[x] \models \varphi(s, m)) \\ &\leftrightarrow \forall x_0 \exists x \geqslant_T x_0 \, (L_{\lambda(x)}[x] \models \varphi(s, m)) \end{aligned}$$

(where we have used Δ^1_2-determinacy to flip the quantifiers) we have that σ is a Δ^1_3 winning strategy for I in A. $\dashv$

Kechris and Solovay showed (in [3]) that under $\text{ZF} + \text{DC} + \Delta^1_2$-determinacy there is a real x_0 that "enforces" OD-determinacy in the following sense: For all $x \geqslant_T x_0$, $L[x] \models$ OD-determinacy. We will need the following strengthening of this result, which involves a stronger notion of "enforcement". We need the following definition: An ordinal λ is *additively closed* (*a.c.*) iff for all $\alpha, \beta < \lambda$, $\alpha + \beta < \lambda$.

6.6 Theorem. *Assume* $\text{ZF} + \text{DC} + \Delta^1_2$-*determinacy. Then there is a real* x_0 *such that for all additively closed* $\lambda > \omega$, *and for all reals* x, *if* $x_0 \in L_\lambda[x]$, *then* $L_\lambda[x] \models$ OD-*determinacy.*

Proof. Some preliminary remarks are in order. First, for λ additively closed, $L_\lambda[x]$ might satisfy only a very weak fragment of ZFC; so the statement "$L_\lambda[x] \models$ OD-determinacy" is to be taken in the following external sense: For each $\xi < \lambda$ and for each formula φ, $L_\lambda[x] \models$"Either I or II has a winning strategy for $\{z \in \omega^\omega \mid \varphi(z, \xi)\}$". The point is that this statement makes sense even when $\{z \in \omega^\omega \mid \varphi(z, \xi)\}$ is a proper class from the point of view of $L_\lambda[x]$. Second, the key feature of additively closed $\lambda > \omega$, is that if $y \in L_\lambda[x]$ then $L_\lambda[y] \subseteq L_\lambda[x]$. This is true since additively closed ordinals $\lambda > \omega$ are such that $\alpha + \lambda = \lambda$ for all $\alpha < \lambda$ and so if y is constructed at stage α, then $L_\lambda[x]$ still has λ-many remaining stages in which to "catch up" and construct everything in $L_\lambda[y]$. Third, the proof of the theorem is a "localization" of the proof of Theorem 5.12.

Assume for contradiction that for every real x_0 there is an additively closed $\lambda > \omega$ and a real x such that $x_0 \in L_\lambda[x]$ and $L_\lambda[x] \not\models$ OD-determinacy. So, for every real x_0 there is an additively closed $\lambda > \omega$ and a real $x' \geqslant_T x_0$ such that $L_\lambda[x'] \not\models$ OD-determinacy (since we can take $x' = \langle x, x_0\rangle$ where x and x_0 are as in the first statement) and hence, by the Löwenheim-Skolem theorem,

$$\begin{aligned}&\forall x_0 \in \omega^\omega\, \exists x \geqslant_T x_0 \exists\lambda(\lambda \text{ is a.c.} \wedge \omega < \lambda < \omega_1)\\ &\quad \wedge L_\lambda[x] \not\models \text{OD-determinacy},\end{aligned}$$

where 'a.c.' abbreviates 'additively closed'. Since the condition on x in this statement is Σ^1_2 and since we have Σ^1_2-determinacy (by Theorem 6.3)

$$\begin{aligned}&\exists x_0 \in \omega^\omega \forall x \geqslant_T x_0 \exists\lambda(\lambda \text{ is a.c.} \wedge \omega < \lambda < \omega_1)\\ &\quad \wedge L_\lambda[x] \not\models \text{OD-determinacy}\end{aligned}$$

by the Cone Theorem (Theorem 2.9). Let

$$\lambda(x) = \begin{cases} \mu\lambda\,(\omega < \lambda < \omega_1 \wedge \lambda \text{ is a.c.} \wedge L_\lambda[x] \not\models \text{OD-det}) & \text{if such a } \lambda \text{ exists}\\ \text{undefined} & \text{otherwise.}\end{cases}$$

Notice that for a Turing cone of x

$$\lambda(x) \text{ is defined}$$

and that there are x_0 of arbitrarily large Turing degree such that for all $x \geqslant_T x_0$

$$\lambda(x) \geqslant \lambda(x_0).$$

To see this last point it suffices to observe that otherwise (by Σ^1_2-determinacy and the Cone Theorem (Theorem 2.9)) there would be an infinite descending sequence of ordinals. This point will be instrumental below in ensuring that Player II can "steer into the right model".

For each x such that $\lambda(x)$ is defined let (φ_x, ξ_x) be lexicographically least such that

$$L_{\lambda(x)}[x] \models \{z \in \omega^\omega \mid \varphi_x(z, \xi_x)\} \text{ is not determined}$$

and let $A^x = \{z \in \omega^\omega \mid \varphi_x(z, \xi_x)\}$. (However, note that since A^x might be a proper class from the point of view of $L_{\lambda(x)}[x]$, when we write '$L_{\lambda(x)}[x] \models a \in A^x$' we really mean '$L_{\lambda(x)}[x] \models \varphi_x(a, \xi_x)$'.)

Consider the game

$$\begin{array}{ll} \mathrm{I} & a, b \\ \mathrm{II} & c, d \end{array}$$

where, letting $p = \langle a, b, c, d\rangle$, I wins iff $\lambda(p)$ is defined and $L_{\lambda(p)}[p] \models$ "$a * d \in A^p$". This game is Σ^1_2, hence determined.

(Notice that in contrast to the proof of Theorem 5.12 we cannot include x_0 in p since we need our game to be lightface definable. However, in the plays of interest we will have one player fold in x_0. This will ensure that the first clause of the winning condition is satisfied and so the players are to be thought of as cooperating to determine the model $L_{\lambda(p)}[p]$ and simultaneously playing an auxiliary game (via a and d) on the least non-determined OD set of this model, namely, A^x.)

We will arrive at a contradiction by showing that neither player can win.

Case 1: I has a winning strategy σ_0.

Let $x_0 \geqslant_T \sigma_0$ be such that for all $x \geqslant_T x_0$, $\lambda(x)$ is defined and $\lambda(x) \geqslant \lambda(x_0)$. We claim that $L_{\lambda(x_0)}[x_0] \models$ "I has a winning strategy σ in A^{x_0}", which is a contradiction. The strategy σ is the strategy derived by playing the main game according to σ_0 while having II feed in x_0 for c and playing some auxiliary play $d \in L_{\lambda(x_0)}[x_0]$; that is, $(\sigma * d)_I = a$ where a is such that $(\sigma_0 * \langle x_0, d\rangle)_I = \langle a, b\rangle$:

$$\begin{array}{ll} \mathrm{I} & a, b \\ \mathrm{II} & x_0, d. \end{array}$$

Let $p = \langle a, b, x_0, d\rangle$. Since we have ensured that $p \geqslant_T x_0$ we know that $\lambda(p)$ is defined and, since σ_0 is winning for I, I must win in virtue of the first clause and so $L_{\lambda(p)}[p] \models$ "$a * d \in A^p$". It remains to see that II has managed to "steer into the right model", that is, that

$$L_{\lambda(p)}[p] = L_{\lambda(x_0)}[x_0]$$

and hence

$$A^p = A^{x_0}.$$

Since $x_0 \geqslant_T \sigma_0$ and $d \in L_{\lambda(x_0)}[x_0]$ we have that $p \in L_{\lambda(x_0)}[x_0]$ and

$$L_{\lambda(x_0)}[p] = L_{\lambda(x_0)}[x_0]$$

(where for the left to right inclusion we have used that $\lambda(x_0)$ is additively closed). Furthermore, by arrangement, $\lambda(p) \geqslant \lambda(x_0)$ since $p \geqslant_T x_0$. But $\lambda(p)$ is the *least* additively closed λ such that $\omega < \lambda < \omega_1$ and $L_\lambda[p] \not\models$ OD-determinacy. Thus, $\lambda(p) = \lambda(x_0)$ and

$$L_{\lambda(p)}[p] = L_{\lambda(x_0)}[x_0].$$

So $L_{\lambda(x_0)}[x_0] \models$ "$\sigma * d \in A^{x_0}$". Since this is true for any $d \in L_{\lambda(x_0)}[x_0]$, this means that $L_{\lambda(x_0)}[x_0] \models$ "σ is a winning strategy for I in A^{x_0}", which is a contradiction.

Case 2: II has a winning strategy τ_0.

Let $x_0 \geqslant_T \tau_0$ be such that for all $x \geqslant_T x_0$, $\lambda(x)$ is defined and $\lambda(x) \geqslant \lambda(x_0)$. For $a \in L_{\lambda(x_0)}[x_0]$ let $(a * \tau)_{II}$ where d is such that $(\langle a, x_0\rangle * \tau_0)_{II} = \langle c, d\rangle$. Since $p \geqslant_T x_0$, II must win in virtue of the second clause. The rest of the argument is exactly as above. So we have that $L_{\lambda(x_0)}[x_0] \models$ "τ is a winning strategy for II in A^{x_0}", which is a contradiction. ⊣

6.7 Remark. The proof relativizes to a real parameter to show $\mathrm{ZF} + \mathrm{DC} + \Sigma^1_2(x)$-determinacy implies that there is a real enforcing (in the strong sense of Theorem 6.6) OD_x-determinacy.

6.8 Corollary (Kechris and Solovay). *Assume* ZF. *Suppose* $L[x] \models \Delta^1_2$-*determinacy, where* $x \in \omega^\omega$. *Then* $L[x] \models$ OD-*determinacy.*

Proof. This follows by reflection. ⊣

We will now extract an even stronger form of determinacy from Δ^1_2-determinacy. We begin by recalling some definitions. The *strategic game with respect to the basis* B is the game SG^B

$$\begin{array}{lccccccc} \mathrm{I} & A_0 & & \cdots & A_n & & \cdots & \\ \mathrm{II} & & f_0 & & \cdots & f_n & & \cdots \end{array}$$

where we require

(1) $A_0 \in \mathscr{P}(\omega^\omega) \cap \mathrm{OD}$, $A_{n+1} \in \mathscr{P}(\omega^\omega) \cap \mathrm{OD}_{f_0,\ldots,f_n}$ and

(2) f_n is a prestrategy for A_n that is winning with respect to B,

and II wins iff he can play all ω rounds. We say that *strategic determinacy holds with respect to the basis* B (ST^B-*determinacy*) if II wins SG^B.

In the context of $L[S, x]$ we dropped reference to the basis B since it was always understood to be $\{y \in \omega^\omega \mid L[S, y] = L[S, x]\}$. In our present lightface setting we will have to pay more careful attention to B since (as we will see in Theorem 6.12) Δ^1_2-determinacy is insufficient to ensure that for a Turing cone of x, $L[x] \models \mathrm{ST}^B$-determinacy, where $B = \{y \in \omega^\omega \mid L[y] = L[x]\}$. We will now be interpreting strategic determinacy in the local setting of models $L_\lambda[x]$ where $x \in \omega^\omega$ and λ is a countable ordinal and the relevant basis will be of the form $C \cap \{y \in \omega^\omega \mid L_\lambda[y] = L_\lambda[x]\}$ where C is a Π^1_2 set of $L_\lambda[x]$. It is in the attempt to "localize" the proof of Theorem 5.14 that the need for the Π^1_2 set becomes manifest. The issue is one of "steering into the right model" and can be seen to first arise in the proof of Claim 3 below.

Let RST-determinacy abbreviate the statement "There is a Π^1_2 set C such that C contains a Turing cone and ST^B-determinacy holds where $B =$

$C \cap \{y \in \omega^\omega \mid L[y] = V\}$". Here 'R' stands for 'restrictive'. We will be interpreting this notion over models $L_\lambda[x]$ that do not satisfy full Replacement. In such a case it is to be understood that the statement involves the Σ_1 definition of ordinal definability.

6.9 Theorem. *Assume* $\mathrm{ZF}+\mathrm{DC}+\Delta^1_2$*-determinacy. Then for a Turing cone of* x*,*

$$L[x] \models RST\text{-}determinacy.$$

Proof. We will actually prove something stronger: Assume $\mathrm{ZF} + V = L[x] + \Delta^1_2$-determinacy for some $x \in \omega^\omega$. Let T be the theory $\mathrm{ZFC} - \mathrm{Replacement} + \Sigma_2$-Replacement. Then there is a real z_0 such that if $L_\lambda[z]$ is such that $z_0 \in L_\lambda[z]$ and $L_\lambda[z] \models \mathrm{T}$ then $L_\lambda[z] \models$ RST-determinacy. The theorem follows by reflection.

Assume for contradiction that for every real z_0 there is a real $z \geqslant_T z_0$ and an ordinal λ such that $L_\lambda[z] \models \mathrm{T} + \neg$RST-determinacy. The preliminary step is to reduce to a local setting where we can apply Δ^1_2-determinacy. By the Löwenheim-Skolem theorem

$$\forall z_0 \in \omega^\omega\, \exists z \geqslant_T z_0\, \exists \lambda < \omega_1\, (L_\lambda[z] \models \mathrm{T} + \neg\text{RST-determinacy}).$$

Since the condition on z in this statement is Σ^1_2 and since we have OD-determinacy (by Corollary 6.8) it follows (by the Cone Theorem (Theorem 2.9)) that

$$\exists z_0 \in \omega^\omega\, \forall z \geqslant_T z_0\, \exists \lambda < \omega_1\, (L_\lambda[z] \models \mathrm{T} + \neg\text{RST-determinacy}).$$

For $z \in \omega^\omega$, let

$$\lambda(z) = \begin{cases} \mu\lambda\, (L_\lambda[z] \models \mathrm{T} + \neg\text{RST-determinacy}) & \text{if such a } \lambda \text{ exists} \\ \text{undefined} & \text{otherwise.} \end{cases}$$

Thus, if $\lambda(z)$ is defined, then for every $(\Pi^1_2)^{L_{\lambda(z)}[z]}$ set C that contains a Turing cone, I wins the game

$$\begin{array}{lcccccc} \mathrm{I} & A_0 & \cdots & A_n & \cdots & & \\ \mathrm{II} & & f_0 & \cdots & f_n & \cdots \end{array}$$

where we require

(1) $A_0 \in \mathrm{OD}^{L_{\lambda(z)}[z]}$, $A_{n+1} \in \mathrm{OD}^{L_{\lambda(z)}[z]}_{f_0,\ldots,f_n}$, and

(2) f_n is a prestrategy for A_n that is winning with respect to $C \cap \{y \in \omega^\omega \mid L_{\lambda(z)}[y] = L_{\lambda(z)}[z]\}$.

We now need to specify a particular $(\Pi^1_2)^{L_{\lambda(z)}[z]}$ set since (i) we want to get our hands on a canonical winning strategy σ^z for I and (ii) we need to solve the "steering problem". The naïve approach would be to forget about the Π^1_2 sets and just work with $\{y \in \omega^\omega \mid L_{\lambda(z)}[y] = L_{\lambda(z)}[z]\}$. The trouble is that for an element y of this set we might have $\lambda(y) < \lambda(z)$ and yet (when we implement the proof of Theorem 5.13) we will need to ensure that $L_{\lambda(y)}[y] = L_{\lambda(z)}[z]$ and thus $A^y = A^z$ and for this we require that $\lambda(y) = \lambda(z)$. So we will need to intersect with a set C that "holds up the value of $\lambda(y)$". A good candidate is the following: For each z such that $\lambda(z)$ is defined let

$$C_z = \{y \in \omega^\omega \mid \lambda(y) \text{ is undefined}\}^{L_{\lambda(z)}[z]}.$$

This is a $(\Pi^1_2)^{L_{\lambda(z)}[z]}$-set. It contains z (since in $L_{\lambda(z)}[z]$ the ordinal $\lambda(z)$ is certainly undefined). We would like to ensure that it contains the cone above z.

Claim 1. *For a Turing cone of z,*

(1) $\lambda(z)$ is defined,

(2) for all reals $y \in L_{\lambda(z)}[z]$, if $y \geqslant_T z$ then $\lambda(y) = \lambda(z)$.

Proof. We have already proved (1). Assume for contradiction that (2) does not hold on a Turing cone. Then (by OD-determinacy) for every real z there is a real $z' \geqslant_T z$ such that $\lambda(z')$ is defined and in $L_{\lambda(z')}[z']$ there is a real z'' such that $z'' \geqslant_T x'$ and $\lambda(z'') < \lambda(z)$. But then, for each $n < \omega$, we can successively choose $z_{n+1} \geqslant_T z_n$ such that $\lambda(z_{n+1}) < \lambda(z_n)$, which is a contradiction. ⊣

For each z as in Claim 1 we now have that C_z contains the Turing cone above z (since, by (2) of Claim 1, $\lambda(y) = \lambda(z)$ and so $L_{\lambda(y)}[y] = L_{\lambda(z)}[z]$ and again in $L_{\lambda(z)}[z]$ the ordinal $\lambda(y) = \lambda(z)$ is undefined). Letting

$$B_z = \{y \in C_z \mid L_{\lambda(z)}[y] = L_{\lambda(z)}[z]\}$$

we have that

$$\text{I wins } (SG^{B_z})^{L_{\lambda(z)}[z]}.$$

Moreover, since we have arranged that $L_{\lambda(z)}[z] \models \mathrm{T}$, Player I has a canonical strategy $\sigma^z \in \mathrm{HOD}^{L_{\lambda(z)}[z]}$. (This is because, since $L_{\lambda(z)}[z] \models \mathrm{T}$, the $\mathrm{OD}^{L_{\lambda(z)}[z]}$ sets of reals are sets (and not proper classes) in $L_{\lambda(z)}[z]$. So the tree on which $(SG^{B_z})^{L_{\lambda(z)}[z]}$ is played is an element of $\mathrm{HOD}^{L_{\lambda(z)}[z]}$.) Notice also that σ^z depends only on the model $L_{\lambda(z)}[z]$, in the sense that if $L_{\lambda(y)}[y] = L_{\lambda(z)}[z]$ then $\sigma^y = \sigma^z$.

Our aim is to obtain a contradiction by defeating σ^z for some z in the Turing cone of Claim 1. We will do this by constructing a sequence of games $G_0, G_1, \ldots, G_n, \ldots$ such that I must win via $\sigma_0, \sigma_1, \ldots, \sigma_n, \ldots$ and, for a Turing cone of z, the winning strategies give rise to prestrategies $f_0^z, f_1^z, \ldots, f_n^z, \ldots$ that constitute a non-losing play against σ^z in the game $(SG^{B_z})^{L_{\lambda(z)}[z]}$.

Step 0. Consider (in $L[x]$) the game G_0

$$\begin{array}{lll} \mathrm{I} & \epsilon & a, b \\ \mathrm{II} & & c, d \end{array}$$

where ϵ is either 1 or 2 and, letting $p = \langle a, b, c, d\rangle$, I wins iff

(1) p satisfies the condition on z in Claim 1 (so σ^p makes sense) and

(2) $\epsilon = 1$ iff $L_{\lambda(p)}[p] \models$ "$a * d \in A_0^p$", where $A_0^p = \sigma^p(\varnothing)$.

In the plays of interest we will ensure that p is in the cone of Claim 1. So clause (1) of the winning condition will be automatically satisfied and the decisive factor will be whether in $L_{\lambda(p)}[p]$ Player ϵ wins the auxiliary round (via a and d) of A_0^p. This game is Σ_2^1 (for Player I), hence determined.

Claim 2. *I has a winning strategy σ_0 in G_0.*

Proof. Assume for contradiction that I does not have a winning strategy in G_0. Then, by Σ_2^1-determinacy, II has a winning strategy τ_0 in G_0. Let $z_0 \geqslant_T \tau_0$ be such that for all $z \geqslant_T z_0$,

(1) z satisfies the conditions of Claim 1 and

(2) if λ and z are such that $z_0 \in L_\lambda[z]$ and $L_\lambda[z] \models \mathrm{T}$ then $L_\lambda[z] \models$ OD-determinacy (by Theorem 6.6).

Consider $A_0^{z_0} = \sigma^{z_0}(\varnothing)$. Since $L_{\lambda(z_0)}[z_0] \models$ OD-determinacy, $L_{\lambda(z_0)}[z_0] \models$ "$A_0^{z_0}$ is determined". We will use τ_0 to show that neither player can win this game. Suppose for contradiction that $L_{\lambda(z_0)}[z_0] \models$ "σ is a winning strategy for I in $A_0^{z_0}$". Run G_0 according to τ_0, having Player I (falsely) predict that Player I wins the auxiliary game, while steering into $L_{\lambda(z_0)}[z_0]$ by playing $b = z_0$ and using σ to respond to τ_0 on the auxiliary play:

$$\begin{array}{lll} \mathrm{I} & 1 & (\sigma * d)_I, z_0 \\ \mathrm{II} & & c, d \end{array}$$

We have to see that Player I has indeed managed to steer into $L_{\lambda(z_0)}[z_0]$, that is, we have to see that $L_{\lambda(p)}[p] = L_{\lambda(z_0)}[z_0]$, where $p = \langle(\sigma * d)_I, z_0, c, d\rangle$. Since $\sigma, z_0, \tau_0 \in L_{\lambda(z_0)}[z_0]$ and $\lambda(z_0)$ is additively closed, we have $L_{\lambda(z_0)}[p] = L_{\lambda(z_0)}[z_0]$. But $\lambda(p) = \lambda(z_0)$ since z_0 satisfies Claim 1. Thus, $L_{\lambda(p)}[p] = L_{\lambda(z_0)}[z_0]$ and hence $A_0^p = A_0^{z_0}$. Finally, since τ_0 is a winning strategy for II in G_0 and $\epsilon = 1$, we have that $L_{\lambda(p)}[p] \models$ "$\sigma * d \notin A_0^p$", and hence $L_{\lambda(z_0)}[z_0] \models$ "$\sigma * d \notin A_0^{z_0}$", which contradicts the assumption that σ is a winning strategy for I. Similarly, we can use τ_0 to defeat any strategy τ for II in $A_0^{z_0}$. ⊣

Since the game is Σ_2^1 for Player I, Player I has a Δ_3^1-strategy σ_0, by Theorem 6.5.

Claim 3. *For every real $z \geqslant_T \sigma_0$ in the Turing cone of Claim 1, there is a prestrategy f_0^z such that f_0^z is definable in $L_{\lambda(z)}[z]$ from σ_0 and f_0^z is a non-losing first move for II against σ^z in $(SG^{B_z})^{L_{\lambda(z)}[z]}$.*

Proof. Fix $z \geqslant_T \sigma_0$ as in Claim 1. Consider $A_0^z = \sigma^z(\varnothing)$. Let f_0^z be the prestrategy derived from σ_0 in $L_{\lambda(z)}[z]$ by extracting the response in the auxiliary game, that is, for $y \in (\omega^\omega)^{L_{\lambda(z)}[z]}$ let $f_0^z(y)$ be such that for $d \in (\omega^\omega)^{L_{\lambda(z)}[z]}$, $f_0^z(y) * d = a * d$ where a is such that $(\sigma_0 * \langle y, d\rangle)_I = \langle \epsilon, a, b\rangle$. f_0^z is clearly definable in $L_{\lambda(z)}[z]$ from σ_0. We claim that f_0^z is a non-losing first move for II against σ^z in $(SG^{B_z})^{L_{\lambda(z)}[z]}$.

To motivate the need for the Π^1_2 set, let us first see why f_0^z need not be a prestrategy for II in A_0^z that is winning with respect to $\{y \in (\omega^\omega)^{L_{\lambda(z)}[z]} \mid L_{\lambda(z)}[y] = L_{\lambda(z)}[z]\}$. Consider such a real y and an auxiliary play $d \in (\omega^\omega)^{L_{\lambda(z)}[z]}$. By definition $f_0^z(y)$ is such that $f_0^z(y) * d = a * d$ where a is such that $(\sigma_0 * \langle y, d\rangle)_I = \langle \epsilon, a, b\rangle$. Assume first that $\epsilon = 1$. Since σ_0 is a winning strategy for I in G_0, $f_0^z(y) * d = a * d \in A_0^p$ where $p = \langle a, b, y, d\rangle$. What we need, however, is that $f_0^z(y) * d = a * d \in A_0^z$. The trouble is that we may have $L_{\lambda(p)}[p] = L_{\lambda(y)}[y] \subsetneq L_{\lambda(z)}[z]$ because although $L_{\lambda(z)}[y] = L_{\lambda(z)}[z]$ we might have $\lambda(y) < \lambda(z)$. And if this is indeed the case then we cannot conclude that $A_0^p = A_0^z$. If $\epsilon = 0$ then $f_0^z(y) * d = a * d \notin A_0^p$ but again what we need is that $f_0^z(y) * d = a * d \notin A_0^z$ and the same problem arises.

The above problem is solved by demanding in addition that $y \in C_z$, since then $\lambda(y) = \lambda(z)$ and so $\epsilon = 1$ iff $L_{\lambda(z)}[z] \models$ "$f_0^z(y) * d = a * d \in A_0^p = A_0^z$" as desired. Thus f_0^z is a non-losing first move for II against σ_z in $(SG^{B_z})^{L_{\lambda(z)}[z]}$. $\dashv$

Step $n+1$. Assume that we have defined (in $L[x]$) games $G_0, \ldots, G_n$ with winning strategies $\sigma_0, \ldots, \sigma_n \in \mathrm{HOD}$ such that for all $z \geqslant_T \langle \sigma_0, \ldots, \sigma_n\rangle$ in the Turing cone of Claim 1 there are prestrategies $f_0^z, \ldots, f_n^z$ such that f_i^z is definable in $L_{\lambda(z)}[z]$ from $\sigma_0, \ldots, \sigma_i$ (for all $i \leqslant n$) and $f_0^z, \ldots, f_n^z$ is a non-losing partial play for II in $(SG^{B_z})^{L_{\lambda(z)}[z]}$.

Consider (in $L[x]$) the game G_{n+1}

$$\begin{array}{lcc} \mathrm{I} & \epsilon & a, b \\ \mathrm{II} & & c, d \end{array}$$

where ϵ is 1 or 2 and, letting $p = \langle a, b, c, d, \sigma_0, \ldots, \sigma_n\rangle$, I wins iff

(1) p satisfies the condition on z in Claim 1 (so σ^p makes sense) and

(2) $\epsilon = 1$ iff $L_{\lambda(p)}[p] \models$ "$a * d \in A_{n+1}^p$", where A_{n+1}^p is I's response via σ^p to II's partial play $f_0^p, \ldots, f_n^p$.

If p satisfies condition (1) then, since $p \geqslant_T \langle \sigma_0, \ldots, \sigma_n\rangle$, we have, by the induction hypothesis, prestrategies $f_0^p, \ldots, f_n^p$ such that f_i^p is definable in $L_{\lambda(p)}[p]$ from $\sigma_0, \ldots, \sigma_i$ (for all $i \leqslant n$) and $f_0^p, \ldots, f_n^p$ is a non-losing partial play for II in $(SG^{B_p})^{L_{\lambda(p)}[p]}$. Thus, condition (2) in the definition of the game makes sense.

This game is $\Sigma^1_2(\sigma_0, \dots, \sigma_n)$ (for Player I) and hence determined (since $\sigma_0, \dots, \sigma_n \in \mathrm{HOD}$ and we have OD-determinacy, by Theorem 6.6).

Claim 4. *I has a winning strategy σ_{n+1} in G_{n+1}.*

Proof. Assume for contradiction that I does not have a winning strategy. Then, by OD-determinacy, II has a winning strategy τ_{n+1}. Let $z_{n+1} \geqslant_T \langle \tau_{n+1}, \sigma_0, \dots, \sigma_n \rangle$ be such that for all $z \geqslant_T z_{n+1}$,

(1) z satisfies the conditions of Claim 1 and

(2) if λ and z are such that $z_{n+1} \in L_\lambda[z]$ and $L_\lambda[z] \models \mathrm{T}$ then $L_\lambda[z] \models \mathrm{OD}_{\sigma_0,\dots,\sigma_n}$-determinacy (by the relativized version of Theorem 6.6).

It follows that

$$L_{\lambda(z_{n+1})}[z_{n+1}] \models A^{z_{n+1}}_{n+1} \text{ is determined},$$

where $A^{z_{n+1}}_{n+1} = \sigma^{z_{n+1}}(\langle f^{z_{n+1}}_0, \dots, f^{z_{n+1}}_n \rangle)$. This is because $A^{z_{n+1}}_{n+1}$ is an element of $\mathrm{HOD}^{L_{\lambda(z_{n+1})}[z_{n+1}]}(\sigma_0, \dots, \sigma_n)$ (as all of the ingredients $\sigma^{z_{n+1}}$, $f^{z_{n+1}}_0$, $\dots$, $f^{z_{n+1}}_n$ used to define $A^{z_{n+1}}_{n+1}$ are in this model) and we arranged that $L_{\lambda(z_{n+1})}[z_{n+1}]$ satisfies $\mathrm{OD}_{\sigma_0,\dots,\sigma_n}$-determinacy.

[The enforcement of the parameterized version of OD-determinacy in (2) appears to be necessary. The point is that even though, in Step 1 for example, σ_0 is Δ^1_3 and $\sigma_0 \in L_{\lambda(z)}[z]$ we have no guarantee that in $L_{\lambda(z_1)}[z_1]$, σ_0 satisfies this definition. If we did then we would have that A^z_1 is in $\mathrm{HOD}^{L_{\lambda(z_1)}[z_1]}$ and hence just enforce OD-determinacy.]

We will use τ_{n+1} to show that neither player can win this game. The argument is exactly as in Step 0 except with the subscripts '0' replaced by '$n+1$': Suppose for contradiction that $L_{\lambda(z_{n+1})}[z_{n+1}] \models$ "σ is a winning strategy for I in $A^{z_{n+1}}_{n+1}$". Run G_{n+1} according to τ_{n+1}, having Player I (falsely) predict that Player I wins the auxiliary game, while steering into $L_{\lambda(z_{n+1})}[z_{n+1}]$ by playing $b = z_{n+1}$ and using σ to respond to τ_{n+1} on the auxiliary play:

$$\begin{array}{llll} \mathrm{I} & 1 & (\sigma * d)_I, z_{n+1} \\ \mathrm{II} & & c, d \end{array}$$

We have to see that Player I has indeed managed to steer into $L_{\lambda(z_{n+1})}[z_{n+1}]$, that is, we have to see that $L_{\lambda(p)}[p] = L_{\lambda(z_{n+1})}[z_{n+1}]$, where p is the set $\langle (\sigma * d)_I, z_{n+1}, c, d \rangle$. Since $\sigma, z_{n+1}, \tau_{n+1} \in L_{\lambda(z_{n+1})}[z_{n+1}]$ and $\lambda(z_{n+1})$ is additively closed, we have $L_{\lambda(p)}[p] = L_{\lambda(z_{n+1})}[z_{n+1}]$. Since $p \geqslant_T z_{n+1}$ and z_{n+1} satisfies the condition of Claim 1, $\lambda(p) = \lambda(z)$, and so $L_{\lambda(p)}[p] = L_{\lambda(z_{n+1})}[z_{n+1}]$ and hence $A^p_{n+1} = A^{z_{n+1}}_{n+1}$. Finally, since τ_{n+1} is a winning strategy for II in G_{n+1} and $\epsilon = 1$, we have that $L_{\lambda(p)}[p] \models$ "$\sigma * d \notin A^p_{n+1}$", and hence $L_{\lambda(z_{n+1})}[z_{n+1}] \models$ "$\sigma * d \notin A^{z_{n+1}}_{n+1}$", which contradicts the assumption that σ is a winning strategy for I. Similarly, we can use τ_{n+1} to defeat any strategy τ for II in $A^{z_{n+1}}_{n+1}$. ⊣

Since the game is $\Sigma^1_2(\sigma_0, \dots, \sigma_n)$ for Player I, Player I has a $\Delta^1_3(\sigma_0, \dots, \sigma_n)$ strategy σ_{n+1}, by the relativized version of Theorem 6.5.

Claim 5. *For every real $z \geqslant_T \langle \sigma_0, \dots, \sigma_n \rangle$ as in Claim 1, there is a prestrategy f^z_{n+1} that is definable in $L_{\lambda(z)}[z]$ from $\sigma_0, \dots, \sigma_{n+1}$ and such that $f^z_0, \dots, f^z_{n+1}$ is a non-losing first move for II against σ^z in $(SG^{B_z})^{L_{\lambda(z)}[z]}$.*

Proof. The proof is just like the proof of Claim 3. Fix $z \geqslant_T \langle \sigma_0, \dots, \sigma_n \rangle$ as in Claim 1 and consider $A^z_{n+1} = \sigma^z(\langle f^z_0, \dots, f^z_n \rangle)$. Let f^z_{n+1} be the prestrategy derived from σ_{n+1} in $L_{\lambda(z)}[z]$ by extracting the response in the auxiliary game, that is, for $y \in (\omega^\omega)^{L_{\lambda(z)}[z]}$ let $f^z_{n+1}(y)$ be such that for $d \in (\omega^\omega)^{L_{\lambda(z)}[z]}$, $f^z_{n+1}(y) * d = a * d$ where a is such that $(\sigma_{n+1} * \langle y, d \rangle)_I = \langle \epsilon, a, b \rangle$. Clearly, f^z_{n+1} is definable in $L_{\lambda(z)}[z]$ from $\sigma_0, \dots, \sigma_{n+1}$. We claim that f^z_{n+1} is a non-losing first move for II against σ^z in $(SG^{B_z})^{L_{\lambda(z)}[z]}$. Again the point is that for $y \in B_z$, $L_{\lambda(y)}[y] = L_{\lambda(z)}[z]$, hence $A^y_{n+1} = A^z_{n+1}$. Thus, $\epsilon = 1$ iff $L_{\lambda(z)}[z] \models$ "$f^z_{n+1}(y) * d = a * d \in A^p_{n+1} = A^z_{n+1}$" as desired. Hence $\langle f^z_0, \dots, f^z_{n+1} \rangle$ is a non-losing play for II against σ^z in $(SG^{B_z})^{L_{\lambda(z)}[z]}$. ⊣

Finally, letting z^∞ be such that $z^\infty \geqslant_T z_n$ for all n and z^∞ is as in Claim 1, we have that $f^{z^\infty}_0, \dots, f^{z^\infty}_n, \dots$ defeats σ^{z^∞} in $(SG^{B_{z^\infty}})^{L_{\lambda(z^\infty)}[z^\infty]}$, which is a contradiction. ⊣

6.10 Theorem. *Assume* ZF + DC + Δ^1_2*-determinacy. Then for a Turing cone of x,*

$$\mathrm{HOD}^{L[x]} \models \mathrm{ZFC} + \omega_2^{L[x]} \textit{ is a Woodin cardinal.}$$

Proof. For a Turing cone of x, $L[x] \models$ RST-determinacy, by Theorem 6.9. Let x be in this cone. We have to meet the conditions of the Generation Theorem. Let $\Theta_M = \omega_2^{L[x]}$. Since $L[x]$ satisfies GCH and $L[x] = \mathrm{OD}^{L[x]}_x$,

$$\omega_2^{L[x]} = \sup\{\alpha \mid \text{there is an } \mathrm{OD}^{L[x]} \text{ prewellordering of length } \alpha\},$$

in other words, $\omega_2^{L[x]} = (\Theta_0)^{L[x]}$. Let $A = \langle A_\alpha \mid \alpha < \omega_2^{L[x]} \rangle$ be such that A_α is the $\mathrm{OD}^{L[x]}$-least prewellordering of length α. Since $L[x] \models$ OD-determinacy, it follows (by Theorem 3.9) that $\omega_2^{L[x]}$ is strongly inaccessible in $\mathrm{HOD}^{L[x]}$. So there is a set $H \subseteq \omega_2^{L[x]}$ coding $\mathrm{HOD}^{L[x]} \cap V_{\omega_2^{L[x]}}$. Let T' be in $\mathscr{P}(\omega_2^{L[x]}) \cap \mathrm{OD}^{L[x]}$ and let $T \in \mathscr{P}(\omega_2^{L[x]}) \cap \mathrm{OD}^{L[x]}$ code T' and H. Let B be as in the statement of RST-determinacy.

Let

$$M = (L_{\Theta_M}(\mathbb{R})[T, A, B])^{L[x]},$$

where Θ_M, T, A, B are as above. Conditions (1)–(5) of the Generation Theorem are clearly met and condition (6) follows since $L[x]$ satisfies RST-determinacy, M is OD in $L[x]$ and M contains the reals of $L[x]$. Thus,

$$\mathrm{HOD}^M_{T,A,B} \models \mathrm{ZFC} + \text{There is a } T\text{-strong cardinal.}$$

Since, by arrangement, $\mathrm{HOD}^M_{T,A,B} = \mathrm{HOD}^{L[x]} \cap V_{\omega_2^{L[x]}}$, it follows that

$$\mathrm{HOD}^{L[x]} \models \mathrm{ZFC} + \text{There is a } T\text{-strong cardinal.}$$

Since T' was arbitrary, the theorem follows. ⊣

We close with four limitative results. The first result motivates the need for the notion of strategic determinacy by showing that strategic determinacy does not follow trivially from OD-determinacy in the sense that for some OD basis there are OD prestrategies.

6.11 Theorem. *Assume* ZF*. Then for each non-empty* OD *set $B \subseteq \omega^\omega$, there is an* OD *set $A \subseteq \omega^\omega$ such that there is no* OD *prestrategy in A which is winning with respect to the basis B.*

Proof. Assume for contradiction that there is a set $B \subseteq \omega^\omega$ which is OD and such that for all OD sets $A \subseteq \omega^\omega$ there is an OD prestrategy f_A in A which is winning with respect to B. We may assume OD-determinacy since if OD-determinacy fails then the theorem trivially holds (as clearly one cannot have a prestrategy which is winning with respect to a non-empty basis for a non-determined game).

We shall need to establish three claims.

Claim 1. *Assume* ZF*. Then*

$$\bigcap\{A \subseteq \omega^\omega \mid A \in \mathrm{OD},\ A \textit{ is Turing invariant,}\\ \textit{and } A \textit{ contains a Turing cone}\} = \varnothing.$$

Proof. For each $\alpha < \omega_1$, let

$$A_\alpha = \{z \in \omega^\omega \mid \exists x, y \in \omega^\omega \text{ such that}\\ x \equiv_T y \leqslant_T z \text{ and } x \text{ codes } \alpha\}.$$

Notice that A_α is OD, Turing invariant, and contains a Turing cone. But clearly

$$\textstyle\bigcap_{\alpha<\omega_1} A_\alpha = \varnothing$$

since otherwise there would be a real z which recursively encodes all countable ordinals. ⊣

Claim 2. *Assume* $\mathrm{ZF} + \mathrm{OD}$*-determinacy. Then*

$$\mathrm{HOD} \models \textit{There is a countably complete ultrafilter on } \omega_1^V.$$

Proof. Since we are not assuming $\mathrm{AC}_\omega(\mathbb{R})$, the proof of Theorem 2.12 does not directly apply. To see this note that ω_1^V may not be regular in V—in fact, we do not even know whether ω_1^V is regular in HOD. Nevertheless, we will be able to implement some of the previous arguments by dropping into an appropriate model of $\mathrm{AC}_\omega(\mathbb{R})$. In the case of countable completeness an additional change will be required since without $\mathrm{AC}_\omega(\mathbb{R})$ we cannot choose countably many strategies as we did in the earlier proof. Let

$$\mu = \{S \subseteq \omega_1^V \mid S \in \mathrm{HOD} \text{ and I has a winning strategy in } G(S)\},$$

where $G(S)$ is the game from Theorem 2.12.

Subclaim 1. $\mathrm{HOD} \models \mu \cap \mathrm{HOD}$ *is an ultrafilter.*

Proof. It is clear that $\omega_1^V \in \mu$ and $\varnothing \notin \mu$. It is also clear that if $S \in \mu$ and $S' \in \mathrm{HOD} \cap \mathscr{P}(\omega_1^V)$ and $S \subseteq S'$ then $S' \in \mu$.

Suppose that $S \in \mathrm{HOD} \cap \mathscr{P}(\omega_1^V)$ and that II has a winning σ strategy in $G(S)$. We claim that I has a winning strategy in $G(\omega_1^V \smallsetminus S)$. Suppose for contradiction that I does not have a winning strategy. Then, by OD-determinacy, II has a winning strategy σ'. Now work in $L[\sigma, \sigma']$. Using $\underset{\sim}{\Sigma}^1_1$-boundedness, by the usual arguments, one can construct a play x for I which is legal against both σ and σ' and in each case has the same associated ordinal $\alpha < \omega_1^{L[\sigma,\sigma']}$. This is a contradiction.

We now show that if $S_1, S_2 \in \mu$ then $S_1 \cap S_2 \in \mu$. Let σ_1 be a winning strategy for I in $G(S_1)$ and let σ_2 be a winning strategy for I in $G(S_2)$. Suppose for contradiction that $S_1 \cap S_2 \notin \mu$. Since $S_1 \cap S_2$ is OD, $G(S_1 \cap S_2)$ is determined and so II has a winning strategy in $G(S_1 \cap S_2)$, which implies that I has a winning strategy σ in $G(\omega_1^V \smallsetminus (S_1 \cap S_2))$. Work in $L[\sigma_1, \sigma_2, \sigma]$. The strategy σ_1 witnesses (by the usual argument using $\underset{\sim}{\Sigma}^1_1$-boundedness) that $S_1 \cap \omega_1^{L[\sigma_1,\sigma_2,\sigma]}$ contains a club. Likewise, σ_2 witnesses that $S_2 \cap \omega_1^{L[\sigma_1,\sigma_2,\sigma]}$ contains a club and σ witnesses that $(\omega_1^V \smallsetminus (S_1 \cap S_2)) \cap \omega_1^{L[\sigma_1,\sigma_2,\sigma]}$ contains a club. This contradiction completes the proof of Subclaim 1. ⊣

Subclaim 2. $\mathrm{HOD} \models \mu \cap \mathrm{HOD}$ *is countably complete.*

Proof. Suppose for contradiction that the subclaim fails. Let $\langle S_i \mid i < \omega \rangle \in \mathrm{HOD}$ be such that for each $i < \omega$, $S_i \in \mu$ and $\bigcap_{i<\omega} S_i = \varnothing$. Consider the game

$$\begin{array}{lccccccc} \mathrm{I} & i & & y(0) & & y(1) & & \dots \\ \mathrm{II} & & x(0) & & x(1) & & \dots & \end{array}$$

where II wins if and only if $x * y$ is a winning play for I in $G(S_i)$. The idea is that Player I begins by specifying a set S_i in our fixed sequence and then the two players play an auxiliary round of $G(S_i)$, with Player I playing as Player II and Player II playing as Player I.

Notice that this game is OD, hence determined. We claim that II has a winning strategy. Suppose for contradiction that I has a winning strategy σ. In the first move the strategy σ produces a fixed k. Since σ is winning for I, for each $x \in \omega^\omega$, $x * \sigma$ is a win for II in $G(S_k)$. But this is impossible since $S_k \in \mu$ and so I has a winning strategy τ_k in $G(S_k)$; thus, by following τ_k in the auxiliary game, II (playing as I) can defeat σ.

Let τ be a winning strategy for II. Work in $L[\tau]$. We claim that in $L[\tau]$, τ witnesses that for all $i < \omega$, $S_i \cap \omega_1^{L[\tau]}$ contains a club. For our purposes we just need a single $\alpha \in \bigcap_{i<\omega} S_i$. The point is that Player I can play any i as the first move and then use $\underset{\sim}{\Sigma}^1_1$-boundedness to produce a real y such that for all $i < \omega$, $i^\frown y$ is a legal play and in each case the ordinal produced in the auxiliary game is some fixed $\alpha < \omega_1^{L[\tau]}$. This contradiction completes the proof of Subclaim 2. $\dashv$

Thus,

$$\mathrm{HOD} \models \mu \cap \mathrm{HOD} \text{ is a countably complete ultrafilter on } \omega_1^V,$$

which completes the proof. $\dashv$

It follows that ZF + OD-determinacy proves that

$$\mathrm{HOD} \models \exists\kappa \leqslant \omega_1^V \ (\kappa \text{ is a measurable cardinal})$$

(as witnessed by letting κ be the completeness of the ultrafilter), and hence that $\mathbb{R} \cap \mathrm{HOD}$ is countable. Let $\alpha < \omega_1$ be the length of the canonical well-ordering of $\mathbb{R} \cap \mathrm{HOD}$. Let t code α. Then in HOD_t there is a real y^* such that for all $z \in \mathbb{R} \cap \mathrm{HOD}$, $z \leqslant_T y^*$. Let y^* be such a real.

Claim 3. *Suppose $z \in B$. Suppose A is* OD*, A is Turing invariant, and A contains a Turing cone. Then A contains the Turing cone above $\langle y^*, z\rangle$.*

Proof. By our original supposition for contradiction recall that we let f_A be an OD prestrategy which is winning with respect to B. Since A contains a Turing cone f_A must be winning for Player I. This means that for all $z \in B$, for all $y \in \omega^\omega$, $f_A(z) * y \in A$. Now let $y \geqslant_T \langle y^*, z\rangle$. We wish to show that $y \in A$. The point is that

$$y \equiv_T f_A(z) * y \in A$$

and since A is Turing invariant, this implies that $y \in A$. $\dashv$

Claim 3 contradicts Claim 1, which completes the proof. $\dashv$

The second result motivates the need for restricted strategic determinacy by showing that $V = L[x]$ + Δ^1_2-determinacy does not imply ST^B-determinacy, where B is the constructibility degree of x. Thus, in Theorem 6.9 it was necessary to drop down to a restricted form of strategic determinacy. It also follows from the theorem that something close to $\underset{\sim}{\Delta}^1_2$-determinacy is required to establish that ST^B-determinacy holds with respect to the constructibility degree of x since the statement "$\underset{\sim}{\Delta}^1_2$-determinacy" is equivalent to the statement "for every $y \in \omega^\omega$ there is an inner model M such that $y \in M$ and $M \models \mathrm{ZFC} +$ There is a Woodin cardinal".

6.12 Theorem. *Assume* $\mathrm{ZF} + V = L[x]$ *for some* $x \in \omega^\omega$. *Suppose* ST^B-*determinacy, where* $B = \{y \in \omega^\omega \mid L[y] = L[x]\}$. *Suppose there exists an* $\alpha > \omega_1^{L[x]}$ *such that* $L_\alpha[x] \models \mathrm{ZFC}$. *Then for every* $y \in \omega^\omega$ *there is a transitive model* M *such that* $y \in M$ *and* $M \models \mathrm{ZFC} +$ *"There is a Woodin cardinal".*

Proof. Let

$$\begin{aligned} A_0 = \{y \in \omega^\omega \mid \neg\exists M\, (&M \text{ is transitive} \wedge y \in M \\ &\wedge M \models \mathrm{ZFC} + \text{There is a Woodin cardinal})\}. \end{aligned}$$

Suppose for contradiction that $A_0 \neq \varnothing$. Let $t \in A_0$. It follows that A_0 contains a Turing cone of reals. Let Player I play A_0 in SG^B and let f_0 be II's response. Since Player I can win a round of A_0 by playing t, f_0 is winning for I with respect to B, that is, for all $y \in B$, $f_0(y) \in A_0$. We will arrive at a contradiction by constructing a real $y \in B$ such that $f_0(y) \notin A_0$.

We claim that

$$\mathrm{HOD}_{f_0}^{L_\alpha[x]} \models \mathrm{ZFC} + \text{There is a Woodin cardinal.}$$

First note that

$$L[x] \models \mathrm{ST}_{f_0}\text{-determinacy.}$$

Since $L_\alpha[x]$ is ordinal definable in $L[x]$ (as $\alpha > \omega_1^{L[x]}$ and so $L_\alpha[x] = L_\alpha[x']$ for any real x' such that $V = L[x']$) it follows that

$$L_\alpha[x] \models \mathrm{ST}_{f_0}\text{-determinacy.}$$

Thus, by the relativized version of Theorem 6.10,

$$\mathrm{HOD}_{f_0}^{L_\alpha[x]} \models \mathrm{ZFC} + \text{There is a Woodin cardinal.}$$

Therefore $f_0 \notin A_0$.

By $\Sigma_2^1(f_0)$-absoluteness, $L[f_0]$ satisfies that there is a countable transitive model M such that $f_0 \in M$ and

$$M \models \mathrm{ZFC} + \text{There is a Woodin cardinal.}$$

Since $L_\alpha[x] \models$ "$f_0^\#$ exists" (by the effective version of Solovay's Theorem (Theorem 2.15) there is a countable ordinal λ such that $L_\lambda[f_0]$ satisfies ZFC+ "M is countable". In $L_\lambda[f_0]$ let P be a perfect set of reals that are Cohen generic over M. Since P is perfect in $L_\lambda[f_0]$ there is a path $c \in [P]$ which codes x in the sense that $c \geqslant_T x$.

Our desired real y is $\langle f_0, c\rangle$. To see that $\langle f_0, c\rangle \in B$ note that $L_\lambda(\langle f_0, c\rangle)$ can compute x and hence $L_{\omega_1}[\langle f_0, c\rangle] = L_{\omega_1}[x]$. To see that $f_0(\langle f_0, c\rangle) \notin A_0$ note that since c is Cohen generic over M, the model $M[c]$ is a transitive model containing $f_0(\langle f_0, c\rangle)$ satisfying ZFC + "There is a Woodin cardinal". This is a contradiction. ⊣

The third result shows that Martin's "lightface form" of Third Periodicity (Theorem 6.3) does not generalize to higher levels. In fact, the result shows that even ZFC + OD-determinacy (assuming consistency of course) does not imply that for every Σ^1_4 game which Player I wins, Player I has a Δ^1_5 strategy (or even an OD strategy). The reason that the "lightface form" of Third Periodicity holds at the level of Σ^1_2 but not beyond is that in Third Periodicity boldface determinacy is used to get scales but in ZF + DC we get Scale($\utilde{\Sigma}^1_2$) for free.

6.13 Theorem. *Assume* $\mathrm{ZF}+V=L[x]+\mathrm{OD}$*-determinacy for some* $x\in\omega^\omega$*. There is a* Π^1_2 *set of reals which contains a Turing cone but which does not contain a member in* HOD*.*

Proof. Consider the set

$$A=\{y\in\omega^\omega\mid \text{for all additively closed } \lambda<\omega_1,\\ \text{for all } z\geqslant_T y,\ \text{if } x\in\mathrm{OD}^{L_\lambda[z]} \text{ then } x\leqslant_T y\}.$$

This is a Π^1_2 set. Notice that each $y\in A$ witnesses that $\mathbb{R}\cap\mathrm{HOD}^{L[z]}$ is countable for each $z\geqslant_T y$.

Claim 1. *A contains a Turing cone.*

Proof. For $y\in\omega^\omega$ and α such that $\omega<\alpha<\omega_1$, let $R_{\alpha,y}$ be the set of reals which are ordinal definable in $L_\alpha[y]$ and let $<_{\alpha,y}$ the canonical well-ordering of $R_{\alpha,y}$, where we arrange that $<_{\alpha,y}$ is an initial segment of $<_{\alpha',y}$ when $\alpha<\alpha'$. For $y\in\omega^\omega$, let $R_y=\bigcup\{R_{\alpha,y}\mid\omega<\alpha<\omega_1\}$ and let $<_y$ be the induced order on R_y (where we order first by α and then by $<_{\alpha,y}$). Let z^y_α be the αth real in $<_y$ and let ϑ_y be the ordertype of $<_y$. Notice that $R_{\alpha,y}$, R_y, $<_{\alpha,y}$, $<_y$, z^y_α and ϑ_y depend only on the Turing degree of y.

Our strategy is to "freeze out" the values of R_y and $<_y$ on a Turing cone of y. For $\alpha<\omega_1$, the set

$$A_\alpha=\{y\in\omega^\omega\mid\vartheta_y>\alpha\}$$

is OD and hence, by OD-determinacy, either it or its complement contains a Turing cone. Moreover, if A_α contains a Turing cone and $\bar\alpha<\alpha$ then $A_{\bar\alpha}$ contains a Turing cone. Thus,

$$A'=\{\alpha<\omega_1\mid A_\alpha\text{ contains a Turing cone}\}$$

is an initial segment of ω_1. For each $\alpha\in A'$, and for each $y\in\omega^\omega$, the statement "$\vartheta_y>\alpha$ and $z^y_\alpha(n)=m$" is an OD-statement about y. So, by OD-determinacy, the value of z^y_α is fixed for a Turing cone of y. We write z_α for this stable value. It follows that $\langle z_\alpha\mid\alpha\in A'\rangle$ is a definable well-ordering of reals and hence, by OD-determinacy, A' must be countable (by the effective version of Solovay's theorem (Theorem 2.15) and the argument in the Claim in Theorem 5.9). Let $\vartheta = \sup\{\alpha+1 \mid \alpha \in A'\}$. Finally, let $R_\infty = \{z_\alpha \mid \alpha < \vartheta\}$ and $<_\infty = \{(z_\alpha, z_\beta) \mid \alpha < \beta < \vartheta\}$. We claim that for a Turing cone of y, $R_y = R_\infty$. To see this let $y \in L[x]$ be such that $x \leqslant_T y$ (so, in particular $L[x] = L[y]$) and y belongs to all of the (countably many) cones fixing z_α for $\alpha \in A'$. Then $\vartheta_y = \vartheta$ and $R_y = R_\infty$. (In fact, $R_y = \mathbb{R}^{\mathrm{HOD}}$.)

Let z_0 be such that for all $z \geqslant_T z_0$, $R_z = R_{z_0} = R_\infty$. Since R_∞ is countable, we can choose $y_0 \geqslant_T z_0$ such that $R_\infty \leqslant_T y_0$. Then for all $z \geqslant_T y_0$, $R_z = R_\infty \leqslant_T y_0$, that is, $y_0 \in A$. Likewise, if $y \geqslant_T y_0$, then $y \in A$. ⊣

Claim 2. *$A \cap \mathrm{HOD}^{L[x]} = \varnothing$.*

Proof. Suppose for contradiction that $y \in A \cap \mathrm{HOD}^{L[x]}$. Since $y \in A$, y witnesses that R_z is countable for all $z \geqslant_T y$. Let z be such that

$$R_x = R_z.$$

Then since $y \in \mathrm{HOD}^{L[x]}$,

$$\mathrm{HOD}^{L[x]} \models \mathbb{R} \text{ is countable},$$

which is impossible. ⊣

This completes the proof. ⊣

The final result is a refinement of a theorem of Martin [5, Theorem 13.1]. It shows that $\mathrm{ZF} + \mathrm{DC} + \Delta^1_2$-determinacy implies that for a Turing cone of x, $\mathrm{HOD}^{L[x]}$ has a Δ^1_3 well-ordering of reals and hence that for a Turing cone of x, Δ^1_2-determinacy fails in $\mathrm{HOD}^{L[x]}$.

6.14 Theorem. *Assume $\mathrm{ZF} + V = L[x] + \Delta^1_2$-determinacy, for some $x \in \omega^\omega$. Then in HOD there is a Δ^1_3-well-ordering of the reals.*

Proof. For $y \in \omega^\omega$ and α such that $\omega < \alpha < \omega_1$, let $R_{\alpha,y}$, $<_{\alpha,y}$, z^y_α, R_y, $<_y$, and ϑ_y be as in the proof of Theorem 6.13. Let A' and R_∞ be as in the proof of Theorem 6.13. The argument of Claim 1 of Theorem 6.13 shows that $R_\infty = \mathbb{R}^{\mathrm{HOD}}$: To see this let $x' \in L[x]$ be such that $x \leqslant_T x'$ (so, in particular $L[x] = L[x']$) and x' belongs to all of the (countably many) cones fixing z_α for $\alpha \in A'$. Then $\vartheta_{x'} = \vartheta$ and $R_\infty = R_{x'} = \mathbb{R} \cap \mathrm{HOD}^{L[x']} = \mathbb{R}^{\mathrm{HOD}}$.

Notice that

$$\exists y_0 \forall y \geqslant_T y_0 \forall \omega < \alpha < \omega_1 \, (R_{\alpha,y} \subseteq R_\infty \wedge <_{\alpha,y} \trianglelefteq <_\infty),$$

where $\trianglelefteq$ denotes ordering by initial segment; x' as above is such a y_0. Since R_∞ and $<_\infty$ are countable they can be coded by a real. Let y_0 be the base of the above cone and let a be a real coding $\langle y_0, R_\infty, <_\infty \rangle$. The statement "$a$ codes $\langle y_0, R_\infty, <_\infty \rangle$ and for all $y \geqslant_T y_0$, for all $\alpha < \omega_1$, $R_{\alpha,y} \subseteq R_\infty$ and

$<_{\alpha,y} \trianglelefteq <_\infty$" is a Π^1_2 truth about a. Writing $\psi(a)$ for this statement we have the following Π^1_3 definitions (in $L[x]$) of $\omega^\omega \cap \mathrm{HOD}$ and $<_\infty$:

$$z \in R_\infty \leftrightarrow \forall a\,[\,a \text{ codes } (z, R, <) \wedge \psi(a) \rightarrow z \in R\,]$$

and

$$z_0 <_\infty z_1 \leftrightarrow \forall a\,[\,a \text{ codes } (z, R, <) \wedge \psi(a) \rightarrow z_0 < z_1\,].$$

We now look at things from the point of view of HOD. Fix $\xi < \vartheta$. We claim that ξ is countable in HOD. Consider the game

$$\begin{array}{ll} \mathrm{I} & a, b \\ \mathrm{II} & c \end{array}$$

where I wins iff there is an $\alpha < \omega_1$ such that $z_\xi \in R_{\alpha,\langle b,c\rangle}$ and a codes the ordertype of $<_{\alpha,\langle b,c\rangle}\restriction z_\xi$. This game is $\Sigma^1_2(z_\xi)$ (for Player I) and since $z_\xi \in \mathrm{HOD}$ the game is determined. Moreover, I must win (since I can play $b = y_0$ and an a coding ξ). By (the relativized version of) Theorem 6.5, Player I has a winning strategy $\sigma \in \mathrm{HOD}$. It follows that ξ is less than the least admissible relative to σ, which in turn is countable in HOD.

Thus, we can let z be a real in HOD coding $<_\infty\restriction z_\xi$. Consider the game $G(z, z_\xi)$

$$\begin{array}{ll} \mathrm{I} & a \\ \mathrm{II} & b \end{array}$$

where I wins iff there exists an α such that $z_\xi \in R_{\alpha,\langle a,b\rangle}$ and $<_{\alpha,\langle a,b\rangle}\restriction z_\xi = z$. This game is $\Sigma^1_2(\langle z, z_\xi\rangle)$, hence determined. Moreover, I must win. So I has a winning strategy $\sigma_\xi \in \mathrm{HOD}$.

Finally, notice the following: If $y \geqslant_T \sigma_\xi$ then $y \equiv_T \sigma_\xi * y$ and

$$\forall\alpha\,(\omega < \alpha < \omega_1 \wedge z_\xi \in R_{\alpha,y} \rightarrow <_{\alpha,y}\restriction z_\xi = <_\infty\restriction z_\xi).$$

So the following is a Σ^1_3 calculation of $<_\infty$ in HOD:

$$\begin{aligned} x <_\infty y \;\leftrightarrow\; & \exists a \in \omega^\omega \text{ coding } (y_0, <, z) \text{ such that} \\ & < \text{ is a linear ordering of its domain, } \mathrm{dom}(<), \\ & x, y, z \in \mathrm{dom}(<), \\ & x < y \text{ and } y < z, \text{ and} \\ & \forall y' \geqslant_T y_0\, \forall\alpha\,(\omega < \alpha < \alpha_1 \\ & \wedge z \in R_{\alpha,y'} \rightarrow <_{\alpha,y'}\restriction z = <\restriction z). \end{aligned}$$

This completes the proof, since clearly a Σ^1_3 total ordering is also Π^1_3. ⊣

Putting everything together we have that ZF + DC + Δ^1_2-determinacy implies that for a Turing cone of x, $\mathrm{HOD}^{L[x]}$ is an inner model with a Woodin cardinal and a Δ^1_3 well-ordering of reals. It follows that Δ^1_2-determinacy fails in $\mathrm{HOD}^{L[x]}$ for a Turing cone of x.

Some interesting questions remain. For example: Does $\mathrm{HOD}^{L[x]}$ satisfy GCH, for a Turing cone of x? Is $\mathrm{HOD}^{L[x]}$ a fine-structural model, for a Turing cone of x? We will return to this topic in Sect. 8.

6.2. Boldface Definable Determinacy

In this section we will work in ZF + AD. Our aim is to extract the optimal amount of large cardinal strength from boldface determinacy by constructing a model of ZFC that contains ω-many Woodin cardinals.

We shall prove a very general theorem along these lines. Our strategy is to iteratively apply Theorem 5.43. Recall that this theorem states that under ZF + AD, for a Y-cone of x,

$$\mathrm{HOD}_{Y,a,[x]_Y} \models \omega_2^{\mathrm{HOD}_{Y,a,x}} \text{ is a Woodin cardinal,}$$

where

$$[x]_Y = \{z \in \omega^\omega \mid \mathrm{HOD}_{Y,z} = \mathrm{HOD}_{Y,x}\}.$$

We start by taking a to be the empty set. By Theorem 5.43, there exists an x_0 such that for all $x \geqslant_Y x_0$,

$$\mathrm{HOD}_{Y,[x]_Y} \models \omega_2^{\mathrm{HOD}_{Y,x}} \text{ is a Woodin cardinal.}$$

To generate a model with two Woodin cardinals we would like to apply Theorem 5.43 again, this time taking a to be $[x_0]_Y$. This gives us an $x_1 \geqslant_Y x_0$ such that for all $x \geqslant_Y x_1$,

$$\mathrm{HOD}_{Y,[x_0]_Y,[x]_Y} \models \omega_2^{\mathrm{HOD}_{Y,[x_0]_Y,x}} \text{ is a Woodin cardinal}$$

and we would like to argue that

$$\mathrm{HOD}_{Y,[x_0]_Y,[x]_Y} \models \omega_2^{\mathrm{HOD}_{Y,x_0}} < \omega_2^{\mathrm{HOD}_{Y,[x_0]_Y,x}} \text{ are Woodin cardinals.}$$

But there are two difficulties in doing this. First, in the very least, we need to ensure that

$$\omega_2^{\mathrm{HOD}_{Y,x_0}} < \omega_2^{\mathrm{HOD}_{Y,[x_0]_Y,x}}$$

and this is not immediate. Second, in moving to the larger model we need to ensure that we have not collapsed the first Woodin cardinal; a sufficient condition for this is that

$$\mathscr{P}(\omega_2^{\mathrm{HOD}_{Y,x_0}}) \cap \mathrm{HOD}_{Y,[x_0]_Y,[x]_Y} = \mathscr{P}(\omega_2^{\mathrm{HOD}_{Y,x_0}}) \cap \mathrm{HOD}_{Y,[x_0]_Y},$$

but again this is not immediate. It turns out that both difficulties can be overcome by taking x to be of sufficiently high "Y-degree". This will be the content of an elementary observation and a "preservation" lemma. Once these two hurdles are overcome we will be able to generate models with n Woodin cardinals for each $n < \omega$. We shall then have to take extra steps to ensure that we can preserve ω-many Woodin cardinals. This will be achieved by shooting a Prikry sequence through the Y-degrees and proving an associated "generic preservation" lemma.

6.15 Remark. It is important to note that in contrast to Theorem 5.42 here the degree notion in Theorem 5.43 does not depend on a and this is instrumental in iteratively applying the theorem to generate several Woodin cardinals. In contexts such as $L(\mathbb{R})$ where HOD "relativizes" in the sense that $\mathrm{HOD}_a = \mathrm{HOD}[a]$, one could also appeal to Theorem 5.42, since in such a case $\mathrm{HOD}_{Y,a,[x]_{Y,a}} = \mathrm{HOD}_{Y,a,[x]_Y}$. Our reason for not taking this approach is twofold. First, it would take us too far afield to give the argument that $\mathrm{HOD}_a = \mathrm{HOD}[a]$ in, for example, $L(\mathbb{R})$. Second, it is of independent interest to work in a more general setting.

We shall be working with the "Y-degrees"

$$\mathscr{D}_Y = \{[x]_Y \mid x \in \omega^\omega\}.$$

Let μ_Y be the cone filter over $\mathscr{D}_Y$. As noted earlier, the argument of Theorem 2.9 shows that μ_Y is an ultrafilter. Also, by Theorem 2.8 we know that μ_Y is countably complete.

6.16 Lemma (Preservation Lemma). *Assume* $\mathrm{ZF} + \mathrm{AD}$. *Suppose Y is a set, $a \in H(\omega_1)$, and $\alpha < \omega_1$. Then for a Y-cone of x,*

$$\mathscr{P}(\alpha) \cap \mathrm{HOD}_{Y,a,[x]_Y} = \mathscr{P}(\alpha) \cap \mathrm{HOD}_{Y,a}.$$

Proof. The right-to-left direction is immediate. Suppose for contradiction that the left-to-right direction fails. For sufficiently large $[x]_Y$, let

$$f([x]_Y) = \text{ least } Z \in \mathscr{P}(\alpha) \cap \mathrm{HOD}_{Y,a,[x]_Y} \smallsetminus \mathrm{HOD}_{Y,a},$$

where the ordering is the canonical ordering of $\mathrm{OD}_{Y,a,[x]_Y}$. This function is defined for a Y-cone of x and it is $\mathrm{OD}_{Y,a}$. Let $Z_0 \in \mathscr{P}(\alpha)$ be such that

$$\xi \in Z_0 \quad \text{iff} \quad \xi \in f([x]_Y) \text{ for a } Y\text{-cone of } x.$$

Since α is countable and since μ_Y is countably complete $Z_0 = f([x]_Y)$ for sufficiently large x. Thus, $Z_0 \in \mathrm{HOD}_{Y,a}$, which is a contradiction. ⊣

We are now in a position to iteratively apply Theorem 5.43 to generate a model with n Woodin cardinals.

Step 0. By Theorem 5.43, let x_0 be such that for all $x \geqslant_Y x_0$,

$$\mathrm{HOD}_{Y,[x]_Y} \models \omega_2^{\mathrm{HOD}_{Y,x}} \text{ is a Woodin cardinal.}$$

Step 1. Recall that ω_1^V is strongly inaccessible in any inner model of ZFC, by the Claim of Theorem 5.9. It follows that $\omega_2^{\mathrm{HOD}_{Y,x_0}} < \omega_1^V$ and so when we choose $x_1 \geqslant_Y x_0$ we may assume that x_1 codes $\omega_2^{\mathrm{HOD}_{Y,x_0}}$. Thus, there exists an $x_1 \geqslant_Y x_0$ such that for all $x \geqslant_Y x_1$,

$$\omega_2^{\mathrm{HOD}_{Y,x_0}} < \omega_2^{\mathrm{HOD}_{Y,[x_0]_Y,x}},$$

and, by the Preservation Lemma (taking a to be $[x_0]_Y$),

$$\mathscr{P}(\omega_2^{\mathrm{HOD}_{Y,x_0}}) \cap \mathrm{HOD}_{Y,[x_0]_Y,[x]_Y} = \mathscr{P}(\omega_2^{\mathrm{HOD}_{Y,x_0}}) \cap \mathrm{HOD}_{Y,[x_0]_Y},$$

and, by Theorem 5.9 (taking a to be $[x_0]_Y$),

$$\mathrm{HOD}_{Y,[x_0]_Y,[x]_Y} \models \omega_2^{\mathrm{HOD}_{Y,[x_0]_Y,x}} \text{ is a Woodin cardinal.}$$

It follows that

$$\mathrm{HOD}_{Y,[x_0]_Y,[x_1]_Y} \models \omega_2^{\mathrm{HOD}_{Y,x_0}} < \omega_2^{\mathrm{HOD}_{Y,[x_0]_Y,x_1}} \text{ are Woodin cardinals.}$$

Step $n+1$. It is useful at this stage to introduce a piece of notation: For $x_0 \leqslant_Y \cdots \leqslant_Y x_{n+1}$, let

$$\delta_0(x_0) = \omega_2^{\mathrm{HOD}_{Y,x_0}}$$

and

$$\delta_{n+1}(x_0, \ldots, x_{n+1}) = \omega_2^{\mathrm{HOD}_{Y,\langle [x_0]_Y,\ldots,[x_n]_Y\rangle, x_{n+1}}}.$$

Suppose that we have chosen $x_0 \leqslant_Y x_1 \leqslant_Y \cdots \leqslant_Y x_n$ such that

$$\begin{aligned}&\mathrm{HOD}_{Y,\langle [x_0]_Y,\ldots,[x_n]_Y\rangle} \models \delta_0(x_0) < \cdots < \delta_n(x_0, \ldots, x_n)\\ &\quad \text{are Woodin cardinals.}\end{aligned}$$

Again, since ω_1^V is strongly inaccessible in any inner model of ZFC, it follows that each of these ordinals is countable in V and so when we choose $x_{n+1} \geqslant_Y x_n$ we may assume that x_{n+1} collapses these ordinals. Thus, there exists an $x_{n+1} \geqslant_Y x_n$ such that for all $x \geqslant_Y x_{n+1}$,

$$\delta_n(x_0, \ldots, x_n) < \delta_{n+1}(x_0, \ldots, x_n, x)$$

and, by the Preservation Lemma (taking a to be $\langle [x_0]_Y, \ldots, [x_n]_Y\rangle$),

$$\begin{aligned}&\mathscr{P}(\delta_n(x_0, \ldots, x_n)) \cap \mathrm{HOD}_{Y,\langle [x_0]_Y,\ldots,[x_n]_Y\rangle,[x]_Y}\\ &\quad = \mathscr{P}(\delta_n(x_0, \ldots, x_n)) \cap \mathrm{HOD}_{Y,\langle [x_0]_Y,\ldots,[x_n]_Y\rangle}\end{aligned}$$

and, by Theorem 5.43 (taking a to be $\langle [x_0]_Y, \ldots, [x_n]_Y\rangle$),

$$\mathrm{HOD}_{Y,\langle [x_0]_Y,\ldots,[x_n]_Y\rangle,[x]_Y} \models \delta_{n+1}(x_0, \ldots, x_n, x) \text{ is a Woodin cardinal.}$$

It follows that

$$\begin{aligned}&\mathrm{HOD}_{Y,\langle [x_0]_Y,\ldots,[x_n]_Y\rangle,[x]_Y} \models \delta_0(x_0) < \cdots < \delta_{n+1}(x_0, \ldots, x_n, x)\\ &\quad \text{are Woodin cardinals.}\end{aligned}$$

We now need to ensure that when we do the above stacking for ω-many stages, the Woodin cardinals $\delta_n(x_0, \ldots, x_n)$ are preserved in the final model. This is not immediate since, for example, if we are not careful then the reals $x_0, x_1, \ldots$ might code up a real that collapses $\sup_{n<\omega} \delta_n(x_0, \ldots, x_n)$. To circumvent this difficulty we implement the construction relative to a "Prikry sequence" of degrees $[x_0]_Y, [x_1]_Y, \ldots$.

6.17 Definition (The forcing $\mathbb{P}_Y$). Assume ZF + AD. Suppose Y is a set. Let $\mathscr{D}_Y$ and μ_Y be as above. The conditions of $\mathbb{P}_Y$ are of the form $\langle [x_0]_Y, \ldots, [x_n]_Y, F\rangle$ where $F : \mathscr{D}_Y^{<\omega} \to \mu_Y$. The ordering on $\mathbb{P}_Y$ is:

$$\langle [x_0]_Y, \ldots, [x_n]_Y, [x_{n+1}]_Y, \ldots, [x_m]_Y, F^*\rangle \leqslant_{\mathbb{P}_Y} \langle [x_0]_Y, \ldots, [x_n]_Y, F\rangle$$

if and only if

(1) $[x_{i+1}]_Y \in F(\langle [x_0]_Y, \ldots, [x_i]_Y\rangle)$ for all $i \geqslant n$ and

(2) $F^*(p) \subseteq F(p)$ for all $p \in \mathscr{D}_Y^{<\omega}$.

The point of the following lemma is to avoid appeal to DC.

6.18 Lemma. *Assume* ZF + AD. *Suppose φ is a formula in the forcing language and $\langle p, F\rangle \in \mathbb{P}_Y$. Then there is an F^* such that $\langle p, F^*\rangle \leqslant_{\mathbb{P}_Y} \langle p, F\rangle$ and $\langle p, F^*\rangle$ decides φ. Moreover, F^* is uniformly definable from $\langle p, F\rangle$ and φ.*

Proof. Fix φ a formula and $\langle p, F\rangle \in \mathbb{P}_Y$. Let us use '$p$' and '$q$' for "lower parts" of conditions—that is, finite sequences of $\mathscr{D}_Y$—'F' and 'G' for the corresponding "upper parts", and 'a' for elements of $\mathscr{D}_Y$. Write $q \trianglerighteq p$ to indicate that p is an initial segment of q. Set

$$\begin{aligned} Z_0 &= \{\, q \mid q \trianglerighteq p \text{ and } \exists G\ \langle q, G\rangle \leqslant_{\mathbb{P}_Y} \langle p, F\rangle \text{ and } \langle q, G\rangle \Vdash \varphi \,\},\\ Z_{\alpha+1} &= \{\, q \mid \{\, a \mid q^\frown a \in Z_\alpha \,\} \in \mu_Y \,\}, \quad \text{and}\\ Z_\lambda &= \textstyle\bigcup_{\alpha<\lambda} Z_\alpha \quad \text{for } \lambda \text{ a limit.} \end{aligned}$$

Let $D_q^\alpha = \{a \mid q^\frown a \in Z_\alpha\}$. So $Z_{\alpha+1} = \{q \mid D_q^\alpha \in \mu_Y\}$. We claim that for each α,

(1) if $q \in Z_\alpha$, then $D_q^\alpha \in \mu_Y$, and hence

(2) $Z_a \subseteq Z_{\alpha+1}$.

The proof is by induction on α: For $\alpha = 0$ suppose $q \in Z_0$ and let G witness this. So $G(q) \in \mu_Y$. Notice that for each $a \in G(q)$,

$$\langle q^\frown a, G\rangle \leqslant_{\mathbb{P}_Y} \langle q, G\rangle$$

and so $q^\frown a \in Z_0$, i.e. $G(q) \subseteq \{a \mid q^\frown a \in Z_0\} = D_q^0$ and so $D_q^0 \in \mu_Y$ and $Z_0 \subseteq Z_1$. Assume (1) holds for $\alpha + 1$. It follows that $Z_{\alpha+1} \subseteq Z_{\alpha+2}$. Suppose $q \in Z_{\alpha+2}$. Then, by the definition of $Z_{\alpha+2}$, $D_q^{\alpha+1} \in \mu_Y$. However, since $Z_{\alpha+1} \subseteq Z_{\alpha+2}$, it follows that $D_q^{\alpha+1} \subseteq D_q^{\alpha+2}$. So $D_q^{\alpha+2} \in \mu_Y$. For λ a limit ordinal suppose $q \in Z_\lambda$. Then $q \in Z_\alpha$ for some $\alpha < \lambda$. So, by the induction hypothesis, $D_q^\alpha \in \mu_Y$. Since $Z_\alpha \subseteq Z_\lambda$, $D_q^\alpha \subseteq D_q^\lambda$ and so $D_q^\lambda \in \mu_Y$.

Now define a ranking function $\rho : \mathscr{D}_Y^{<\omega} \to \mathrm{On} \cup \{\infty\}$ by

$$\rho(q) = \begin{cases} \text{least } \alpha \text{ such that } q \in Z_\alpha & \text{if there is such an } \alpha\\ \infty & \text{otherwise.} \end{cases}$$

We begin by noting the following three persistence properties which will aid us in shrinking F so as to decide φ. First, if $\rho(q) = \infty$ then set

$$A_q = \{a \mid \rho(q^\frown a) = \infty\}$$

and notice that $A_q \in \mu_Y$ since otherwise we would have $\{a \mid \rho(q^\frown a) \in \mathrm{On}\} \in \mu_Y$ (as μ_Y is an ultrafilter) and letting $\beta = \sup\{\rho(q^\frown a) \mid \rho(q^\frown a) \in \mathrm{On}\}$ we would have $q \in Z_{\beta+1}$, a contradiction. Second, if $\rho(q) \in \mathrm{On} \smallsetminus \{0\}$ then set

$$B_q = \{a \mid \rho(q^\frown a) < \rho(q)\}$$

and notice that $B_q \in \mu_Y$ since $\rho(q)$ is clearly a successor, say $\alpha + 1$, and $q \in Z_\alpha$ and so (by our claim) $D_q^\alpha \in \mu_Y$; but $D_q^\alpha \subseteq B_q$. Third, if $\rho(q) = 0$ then set

$$C_q = \{a \mid \rho(q^\frown a) = 0\}$$

and notice that $C_q \in \mu_Y$ since clearly $q \in Z_0$ and so, by the claim, $D_q^0 \in \mu_Y$; but $D_q^0 \subseteq C_q$.

Now either $\rho(p) = \infty$ or $\rho(p) \in \mathrm{On}$.

Claim 1. *If $\rho(p) = \infty$ then there is an F^* such that $\langle p, F^*\rangle \leqslant_{\mathbb{P}_Y} \langle p, F\rangle$ and $\langle p, F^*\rangle \Vdash \neg\varphi$.*

Proof. Define F^* as follows:

$$F^*(q) = \begin{cases} F(q) \cap A_q & \text{if } \rho(q) = \infty \\ F(q) & \text{otherwise.} \end{cases}$$

Suppose that it is not the case that $\langle p, F^*\rangle \Vdash \neg\varphi$. Then $\exists \langle q, G\rangle \leqslant_{\mathbb{P}_Y} \langle p, F^*\rangle$ such that $\langle q, G\rangle \Vdash \varphi$. But then q is such that $\rho(q) = 0$. However, F^* witnesses that in fact $\rho(q) = \infty$: Suppose $q = p^\frown a_0{}^\frown \cdots {}^\frown a_k$. Since $\rho(p) = \infty$ and $a_0 \in F^*(p)$, we have that $a_0 \in A_p$ and so $\rho(p^\frown a_0) = \infty$. Continuing in this manner, we get that $\rho(q) = \infty$. This is a contradiction. ⊣

Claim 2. *If $\rho(p) \in \mathrm{On}$ then there is an F^* such that $\langle p, F^*\rangle \leqslant_{\mathbb{P}_Y} \langle p, F\rangle$ and $\langle p, F^*\rangle \Vdash \varphi$.*

Proof. Define F^* as follows:

$$F^*(q) = \begin{cases} F(q) \cap B_q & \text{if } \rho(q) \in \mathrm{On} \smallsetminus \{0\} \\ F(q) \cap C_q & \text{if } \rho(q) = 0 \\ F(q) & \text{otherwise.} \end{cases}$$

We claim that $\langle p, F^*\rangle \Vdash \varphi$. Assume not. Then $\exists \langle q, G\rangle \leqslant_{\mathbb{P}_Y} \langle p, F^*\rangle$ such that $\langle q, G\rangle \Vdash \neg\varphi$. Since $\langle q, G\rangle \leqslant_{\mathbb{P}_Y} \langle p, F^*\rangle$ and $\rho(p) \in \mathrm{On}$ we have that $\rho(q) \in \mathrm{On}$ (by an easy induction using the definition of F^*). We may assume that $\langle q, G\rangle$ is chosen so that $\rho(q)$ is as small as possible. But then $\rho(q) = 0$ as otherwise there is an a such $\langle q^\frown a, G\rangle \leqslant_{\mathbb{P}_Y} \langle q, G\rangle$, $\langle q^\frown a, G\rangle \Vdash \neg\varphi$ and $\rho(q^\frown a) < \rho(q)$, contradicting the minimality of $\rho(q)$. Now since $\rho(q) = 0$, $q \in Z_0$ and so $\exists G' \langle q, G'\rangle \Vdash \varphi$. But this is a contradiction since $\langle q, G'\rangle$ is compatible with $\langle q, G\rangle$ and $\langle q, G\rangle \Vdash \neg\varphi$. ⊣

This completes the proof of the lemma. $\dashv$

We can now obtain the following "generic preservation" lemma.

6.19 Lemma (Generic Preservation Lemma). *There exists an F such that if $G \subseteq \mathbb{P}_Y$ is V-generic and $\langle \varnothing, F\rangle \in G$ and $\langle [x_i]_Y \mid i < \omega\rangle$ is the generic sequence associated to G, then, for all $i < \omega$,*

$$\begin{aligned}\mathscr{P}(\delta_i(x_0, \ldots, x_i))^{V[G]} &\cap \mathrm{HOD}^{V[G]}_{Y,\langle [x_j]_Y \mid j<\omega\rangle, V} \\ &= \mathscr{P}(\delta_i(x_0, \ldots, x_i)) \cap \mathrm{HOD}^{V}_{Y,\langle [x_0]_Y, \ldots, [x_i]_Y\rangle}.\end{aligned}$$

Proof. We need the following extension of Lemma 6.18: Suppose $\langle \varphi_\xi \mid \xi < \alpha\rangle$ is a countable sequence of formulas in the forcing language (evaluated in a rank initial segment) and $\langle p, F\rangle \in \mathbb{P}_Y$ is a condition. Then there is an F^* such that $\langle p, F^*\rangle \leqslant_{\mathbb{P}_Y} \langle p, F\rangle$ and $\langle p, F^*\rangle$ decides φ_ξ, for each $\xi < \alpha$, and F^* is uniformly definable from $\langle \varphi_\xi \mid \xi < \alpha\rangle$ and $\langle p, F\rangle$. For each $\xi < \alpha$, let F_ξ be as in Lemma 6.18 (where it is denoted F^*). Letting F^* be the "intersection" of the F_α—i.e., such that $F^*(q) = \bigcap_{\alpha<\beta} F_\alpha(q)$ for each $q \in D^{<\omega}_Y$—we have that $\langle p, F^*\rangle$ decides φ_ξ for each $\xi < \alpha$ and that F^* is uniformly definable from $\langle \varphi_\xi \mid \xi < \alpha\rangle$ and $\langle p, F\rangle$.

Suppose $a \in H(\omega_1)$ and $\alpha < \omega_1$. We claim that we can definably associate with a and α a function $F_{a,\alpha} : \mathscr{D}^{<\omega}_Y \to \mu_Y$ such that $\langle \varnothing, F_{a,\alpha}\rangle$ forces

$$\mathscr{P}(\alpha)^{V[G]} \cap \mathrm{HOD}^{V[G]}_{Y,a,\langle [x_i]_Y \mid i<\omega\rangle, V} = \mathscr{P}(\alpha) \cap \mathrm{HOD}^{V}_{Y,a}.$$

Let φ be the formula in the forcing language that expresses the displayed statement. By Lemma 6.18 there is an $\mathrm{OD}_{Y,a}$ condition $\langle \varnothing, G\rangle$ deciding φ. Suppose for contradiction that this condition forces $\neg\varphi$. Since right-to-left inclusion holds trivially (as we are including V as a parameter) it must be that the left-to-right inclusion fails. Let $A \subseteq \alpha$ be $<\mathrm{OD}^{V[G]}_{Y,a,\langle [x_i]_Y \mid i<\omega\rangle, V}$-least such that

$$A \in \mathrm{HOD}^{V[G]}_{Y,a,\langle [x_i]_Y \mid i<\omega\rangle, V} \smallsetminus \mathrm{HOD}^{V}_{Y,a}.$$

Now, for each $\xi < \alpha$ let φ_ξ be the statement expressing "$\xi \in A$". In an $\mathrm{OD}_{Y,a}$ fashion we can successively shrink $\langle \varnothing, G\rangle$ to decide each φ_ξ. But then A is $\mathrm{OD}_{Y,a}$ and hence in $\mathrm{HOD}^V_{Y,a}$, which is a contradiction.

We now define a "master function" $F : \mathscr{D}^{<\omega}_Y \to \mu_Y$ such that for all $\langle [x_0]_Y, \ldots, [x_n]_Y\rangle \in \mathscr{D}^{<\omega}_Y$,

$$F(\langle [x_0]_Y, \ldots, [x_n]_Y\rangle) = F_{\langle [x_0]_Y\rangle, \delta_0(x_0)} \cap \cdots \cap F_{\langle [x_0]_Y, \ldots, [x_n]_Y\rangle, \delta_n(x_0, \ldots, x_n)}.$$

Suppose $\langle \varnothing, F\rangle \in G$. Suppose $\langle p, H\rangle \in G$ and $p{\restriction} i+1 = \langle [x_0]_Y, \ldots, [x_i]_Y\rangle$. It follows that $\langle p, H \wedge F\rangle \in G$, where, by definition, $H \wedge F$ is such that $(H \wedge F)(q) = H(q) \cap F(q)$ for each q. But

$$\begin{aligned}\langle p, H \wedge F\rangle &\leqslant_{\mathbb{P}_Y} \langle p{\restriction} i+1, H \wedge F\rangle \\ &\leqslant_{\mathbb{P}_Y} \big\langle p{\restriction} i+1, H \wedge F_{p\restriction i+1, \delta_i(x_0, \ldots, x_i)}\big\rangle \\ &\leqslant_{\mathbb{P}_Y} \big\langle \varnothing, F_{p\restriction i+1, \delta_i(x_0, \ldots, x_i)}\big\rangle,\end{aligned}$$

(using the definition of F for the second line) and so $\langle \varnothing, F_{p\restriction i+1,\delta_i(x_0,\ldots,x_i)}\rangle \in G$. Finally, by the definition of $F_{p\restriction i+1,\delta_i(x_0,\ldots,x_i)}$, this condition forces

$$\begin{aligned}\mathscr{P}(\delta_i(x_0,\ldots,x_i))^{V[G]} &\cap \mathrm{HOD}^{V[G]}_{Y,\langle [x_0]_Y,\ldots,[x_i]_Y\rangle,\langle [x_i]_Y \mid i<\omega\rangle,V}\\ &= \mathscr{P}(\delta_i(x_0,\ldots,x_i)) \cap \mathrm{HOD}^{V}_{Y,\langle [x_0]_Y,\ldots,[x_i]_Y\rangle},\end{aligned}$$

which completes the proof. ⊣

6.20 Theorem. *Assume* ZF + AD. *Then there is a condition* $\langle \varnothing, F\rangle \in \mathbb{P}_Y$ *such that if* $G \subseteq \mathbb{P}_Y$ *is* V*-generic and* $\langle \varnothing, F\rangle \in G$*, then*

$$\mathrm{HOD}^{V[G]}_{Y,\langle [x_i]_Y \mid i<\omega\rangle,V} \models \mathrm{ZFC} + \textit{There are } \omega\textit{-many Woodin cardinals,}$$

where $\langle [x_i]_Y \mid i<\omega\rangle$ *is the sequence associated with* G.

Proof. Let $\langle \varnothing, F, \rangle$ be the condition from the Generic Preservation Lemma (Lemma 6.19). We claim that

$$\begin{aligned}\mathrm{HOD}^{V[G]}_{Y,\langle [x_i]_Y \mid i<\omega\rangle,V} &\models \delta_0(x_0) < \cdots < \delta_n(x_0,\ldots,x_n) < \cdots\\ &\text{are Woodin cardinals.}\end{aligned}$$

By the Generic Preservation Lemma it suffices to show that for each $n < \omega$

$$\begin{aligned}\mathrm{HOD}_{Y,\langle [x_0]_Y,\ldots,[x_n]_Y\rangle} &\models \delta_0(x_0) < \cdots < \delta_n(x_0,\ldots,x_n)\\ &\text{are Woodin cardinals,}\end{aligned}$$

which follows by genericity and the argument for the finite case. ⊣

As an interesting application of this theorem in conjunction with the Derived Model Theorem (Theorem 8.12), we obtain Kechris' theorem that under ZF + AD, DC holds in $L(\mathbb{R})$. This alternate proof is of interest since it is entirely free of fine structure and it easily generalizes.

6.21 Theorem (Kechris). *Assume* ZF + AD. *Then* $L(\mathbb{R}) \models \mathrm{DC}$.

Proof Sketch. Work in ZF + AD + $V = L(\mathbb{R})$. Let $Y = \varnothing$ and let $N = \mathrm{HOD}^{V[G]}_{\langle [x_i]_Y \mid i<\omega\rangle,V}$ where G and $[x_i]_Y$ are as in the above theorem. By genericity, the Woodin cardinals δ_i of N have ω_1^V as their supremum. By Vopěnka's theorem (see the proof of Theorem 7.8 below for the statement and a sketch of the proof), each $x \in \mathbb{R}^V$ is N-generic for some $\mathbb{P} \in N \cap V_{\omega_1^V}$. Thus, $N(\mathbb{R}^V)$ is a symmetric extension of N. The derived model of $N(\mathbb{R}^V)$ (see Theorem 8.12 below) satisfies $\mathrm{DC}_{\mathbb{R}}$ and therefore DC since $N \models \mathrm{AC}$. Furthermore $N(\mathbb{R}^V)$ contains $L(\mathbb{R})$ and cannot contain more since then $L(\mathbb{R})$ would have forced its own sharp. (This follows from AD^+ theory: Assume $\mathrm{ZF} + \mathrm{DC}_{\mathbb{R}} + \mathrm{AD} + V = L(\mathscr{P}(\mathbb{R}))$. Suppose $A \subseteq \mathbb{R}$. Then either $V = L(A,\mathbb{R})$ or $A^{\#}$ exists. See Definition 8.10 below.) Thus, $L(\mathbb{R}) \models \mathrm{AD} + \mathrm{DC}$. ⊣

7. Second-Order Arithmetic

The statement that all Δ^1_2 sets are determined is really a statement of second-order arithmetic. So a natural question is whether the construction culminating in Sect. 6.1 can be implemented in this more limited setting. In this section we show that a variant of the construction can be carried out in this context. We break the construction into two steps. First, we show that a variant of the above construction can be carried out with respect to an object smaller than $\omega_2^{L[x]}$, one that is within the reach of second-order arithmetic. Second, we show that this version of the construction can be carried out in the weaker theory of second-order arithmetic.

The need to alter the previous construction is made manifest in the following result:

7.1 Theorem. *Assume* $\mathrm{ZF} + V = L[x] + \Delta^1_2$*-determinacy, for some* $x \in \omega^\omega$*. Suppose* N *is such that*

(1) $\mathrm{On} \subseteq N \subseteq \mathrm{HOD}^{L[x]}$ *and*

(2) $N \models \delta$ *is a Woodin cardinal.*

Then $\delta \geqslant \omega_2^{L[x]}$.

However, it turns out that $\omega_1^{L[x]}$ can be a Woodin cardinal in an inner model that overspills $\mathrm{HOD}^{L[x]}$.

7.2 Theorem. *Assume* $\mathrm{ZF} + V = L[x] + \Delta^1_2$*-determinacy, for some* $x \in \omega^\omega$*. Then there exists an* $N \subseteq L[x]$ *such that*

$$N \models \mathrm{ZFC} + \omega_1^{L[x]} \textit{ is a Woodin cardinal.}$$

Moreover, this result is optimal.

7.3 Theorem. *Assume* $\mathrm{ZF} + \Delta^1_2$*-determinacy. Then there is a real* x *such that*

(1) $L[x] \models \Delta^1_2$*-determinacy, and*

(2) for all $\alpha < \omega_1^{L[x]}$*,* α *is not a Woodin cardinal in any inner model* N *such that* $\mathrm{On} \subseteq N$*.*

In Sect. 7.1 we prove Theorem 7.2. More precisely, we prove the following:

7.4 Theorem. *Assume* $\mathrm{ZF} + \mathrm{DC} + \Delta^1_2$*-determinacy. Then for a Turing cone of* x*,*

$$\mathrm{HOD}^{L[x]}_{[x]_T} \models \mathrm{ZFC} + \omega_1^{L[x]} \textit{ is a Woodin cardinal.}$$

This involves relativizing the previous construction to the Turing degree of x, replacing the notions that concerned reals (for example, winning strategies) with relativized analogues that concern only those reals in the Turing degree of x.

In Sect. 7.2 we show that the relativized construction goes through in the setting of second-order arithmetic.

7.5 Theorem. *Assume that* $\mathrm{PA}_2 + \Delta^1_2$*-determinacy is consistent. Then* $\mathrm{ZFC} +$ *"*On *is Woodin" is consistent.*

Here PA_2 is the standard axiomatization of second-order arithmetic (without AC). The statement that On is Woodin is to be understood schematically. Alternatively, one could work with the conservative extension GBC of ZFC and the analogous conservative extension of PA_2. This would enable one to fuse the schema expressing that On is Woodin into a single statement.

7.1. First Localization

To prove Theorem 7.4 we have to prove an analogue of the Generation Theorem where ω_2 is replaced by ω_1. The two main steps are (1) getting a suitable notion of strategic determinacy and (2) getting definable prewellorderings for all ordinals less than ω_1.

For $x \in \omega^\omega$ we "relativize" our previous notions to the Turing degree of x. The *relativized reals* are $R_x = \{y \in \omega^\omega \mid y \leqslant_T x\}$. Fix $A \subseteq R_x$. A *relativized strategy for I* is a function $\sigma : \bigcup_{n<\omega} \omega^{2n} \to \omega$ such that $\sigma \in R_x$. A relativized strategy σ for I is *winning in A* iff for all $y \in R_x$, $\sigma * y \in A$. The corresponding notions for II are defined similarly. A *relativized prestrategy* is a continuous function f such that (the code for) f is in R_x and for all $y \in R_x$, $f(y)$ is a relativized strategy for either I or II. We say that a relativized prestrategy f is *winning in A for I (II) with respect to $B \subseteq R_x$* if in addition we have that for all $y \in B$, $f(y)$ is a relativized winning strategy for I (II) in A. (In our present setting our basis B will always be $[x]_T$.) We say that a set $A \subseteq R_x$ is *determined in the relativized sense* if either I or II has a relativized winning strategy for A. Let OD-$[x]_T$-determinacy be the statement that for every $\mathrm{OD}_{[x]_T}$ subset of R_x either Player I or Player II has a relativized winning strategy.

The *strategic game relativized to* $[x]_T$ is the game SG-$[x]_T$

$$
\begin{array}{lccccccc}
\mathrm{I} & A_0 & & \cdots & & A_n & & \cdots \\
\mathrm{II} & & f_0 & & \cdots & & f_n & & \cdots
\end{array}
$$

where we require

(1) $A_0 \in \mathscr{P}(R_x) \cap \mathrm{OD}_{[x]_T}$, $A_{n+1} \in \mathscr{P}(R_x) \cap \mathrm{OD}_{[x]_T, f_0, \ldots, f_n}$ and

(2) f_n is a relativized prestrategy that is winning in A_n with respect to $[x]_T$,

and II wins if and only if II can play all ω rounds. We say that *strategic determinacy relativized to* $[x]_T$ *holds* (ST-$[x]_T$-*determinacy*) if II wins SG-$[x]_T$.

We caution the reader that in the context of the relativized notions we are dealing only with *definable* versions of relativized determinacy such as OD-$[x]_T$-determinacy and SG-$[x]_T$-determinacy. In fact, *full* relativized determinacy can never hold. But as we shall see both OD-$[x]_T$-determinacy and SG-$[x]_T$-determinacy can hold.

7.6 Theorem. *Assume* ZF + DC + Δ^1_2*-determinacy. Let* T *be the theory* ZFC − Replacement + Σ_2-Replacement. *There is a real* x_0 *such that for all reals* x *and for all ordinals* λ *if* $x_0 \in L_\lambda[x]$ *and* $L_\lambda[x] \models$ T, *then* $L_\lambda[x] \models$ OD-$[x]_T$*-determinacy.*

Proof. The proof is similar to that of Theorem 6.6. Assume for contradiction that for every real x_0 there is an ordinal λ and a real x such that $x_0 \in L_\lambda[x]$ and $L_\lambda[x] \models \mathrm{T} + \neg$OD-$[x]_T$-determinacy, where T = ZFC − Replacement + Σ_2-Replacement. As before, by the Löwenheim-Skolem theorem and Σ^1_2-determinacy the ordinal

$$\lambda(x) = \begin{cases} \mu\lambda\,(L_\lambda[x] \models \mathrm{T} + \neg\text{OD-}[x]_T\text{-determinacy}) & \text{if such a } \lambda \text{ exists} \\ \text{undefined} & \text{otherwise} \end{cases}$$

is defined for a Turing cone of x. For each x such that $\lambda(x)$ is defined, let $A^x \subseteq R_x$ be the $(\mathrm{OD}_{[x]_T})^{L_{\lambda(x)}[x]}$-least counterexample.

Consider the game

$$\begin{array}{ll} \mathrm{I} & a, b \\ \mathrm{II} & c, d \end{array}$$

where, letting $p = \langle a, b, c, d\rangle$, I wins iff $\lambda(p)$ is defined and $L_{\lambda(p)}[p] \models$ "$a * d \in A^p$", where a and d can be thought of as strategies. This game is Σ^1_2, hence determined.

We arrive at a contradiction by showing that neither player can win.

Case 1: I has a winning strategy σ_0.

Let $x_0 \geqslant_T \sigma_0$ be such that for all $x \geqslant_T x_0$, $\lambda(x)$ is defined. We claim that $L_{\lambda(x_0)}[x_0] \models$ "I has a relativized winning strategy σ in A^{x_0}", which is a contradiction. The relativized strategy σ is derived as follows: Given $d\restriction n \in \omega^n$ have II play $x_0\restriction n, d\restriction n$ in the main game. Let $a\restriction n, b\restriction n$ be σ_0's response along the way and let $a(n)$ be σ_0's next move. Then set $\sigma(d\restriction n) = a(n)$. (Clearly, σ is continuous, and the real $a = \sigma(d)$ it defines is to be thought of as coding a strategy for Player I.) This strategy σ is clearly recursive in σ_0, hence it is a relativized strategy.

It remains to show that for every $d \in R_{x_0}$, $\sigma * d \in A^{x_0}$. The point is that for $d \in R_{x_0}$, $p \equiv_T x_0$, where $p = \langle a, b, x_0, d\rangle$ is the play obtained by letting $\langle a, b\rangle = (\sigma_0 * \langle x_0, d\rangle)_I$. It follows that $\lambda(p) = \lambda(x_0)$ and hence $L_{\lambda(p)}[p] = L_{\lambda(x_0)}[x_0]$ and $A^p = A^{x_0}$. Thus, $L_{\lambda(x_0)}[x_0] \models$ "$\sigma(d) * d \in A^{x_0}$". So $L_{\lambda(x_0)}[x_0] \models$ "σ is a relativized winning strategy for I in A^{x_0}".

Case 2: II has a winning strategy τ_0.

Let $x_0 \geqslant_T \tau_0$ be such that for all $x \geqslant_T x_0$, $\lambda(x)$ is defined and $\lambda(x) \geqslant \lambda(x_0)$. Given $a\restriction(n+1) \in \omega^{n+1}$ have I play $a\restriction(n+1), x_0\restriction(n+1)$ in the main game. Let $c\restriction n, d\restriction n$ be τ_0's response along the way. Then set $\tau(a\restriction n) = d(n)$. This strategy is clearly recursive in τ_0, hence it is a relativized strategy, and, as above, $L_{\lambda(x_0)}[x_0] \models$ "τ is a relativized winning strategy for II in A^{x_0}". $\dashv$

7.7 Theorem. *Assume* ZF + DC + Δ^1_2*-determinacy. Then for a Turing cone of* x*,*

$$L[x] \models \text{ST-}[x]_T\text{-}\textit{determinacy.}$$

Proof. The proof is a straightforward variant of the proof of Theorem 6.9. In fact it is simpler. We note the major changes.

As before we assume that $V = L[x]$ and show that there is a real z_0 with the feature that if $z_0 \in L_\lambda[z]$ and $L_\lambda[z] \models \mathrm{T}$, then $L_\lambda[z] \models \text{ST-}[x]_T$-determinacy.

Assume for contradiction that this fails. For $z \in \omega^\omega$, let

$$\lambda(z) = \begin{cases} \mu\lambda\,(L_\lambda[z] \models \mathrm{T} + \neg\text{ST-}[x]_T\text{-determinacy}) & \text{if such a } \lambda \text{ exists} \\ \text{undefined} & \text{otherwise.} \end{cases}$$

The following is immediate.

Claim 1. *For a Turing cone of* z*,* $\lambda(z)$ *is defined.*

For each z in the cone of Claim 1 Player I has a canonical strategy σ^z that depends only on the Turing degree of z, the point being that if $y \equiv_T z$ then $L_{\lambda(y)}[y] = L_{\lambda(z)}[z]$.

As before our aim is to obtain a contradiction by defeating σ^z for some z in the Turing cone of Claim 1. We do this by constructing a sequence of games $G_0, G_1, \ldots, G_n, \ldots$ such that I must win via $\sigma_0, \sigma_1, \ldots, \sigma_n, \ldots$ and, for a cone of z, the winning strategies give rise to prestrategies $f^z_0, f^z_1, \ldots, f^z_n, \ldots$ that constitute a non-losing play against σ^z in $(SG\text{-}[x]_T)^{L_{\lambda(z)}[z]}$.

Step 0. Consider (in $L[x]$) the game G_0

$$\begin{array}{lll} \mathrm{I} & \epsilon & a, b \\ \mathrm{II} & & c, d \end{array}$$

where ϵ is either 1 or 2 and, letting $p = \langle a, b, c, d\rangle$, I wins iff

(1) p satisfies the condition on z in Claim 1 (so σ^p makes sense) and

(2) $\epsilon = 1$ iff $L_{\lambda(p)}[p] \models$ "$a * d \in A^p_0$", where $A^p_0 = \sigma^p(\varnothing)$.

Claim 2. *I has a winning strategy* σ_0 *in* G_0*.*

Proof. Assume for contradiction that I does not have a winning strategy in G_0. Then, by Σ^1_2-determinacy, II has a winning strategy τ_0 in G_0. Let $z_0 \geqslant_T \tau_0$ be such that for all $z \geqslant_T z_0$,

(1) z satisfies the conditions of Claim 1 and

(2) if λ and z are such that $z_0 \in L_\lambda[z]$ and $L_\lambda[z] \models \mathrm{T}$ then $L_\lambda[z] \models$ OD-$[x]_T$-determinacy (by Theorem 7.6).

Consider $A_0^{z_0} = \sigma^{z_0}(\varnothing)$. Since $L_{\lambda(z_0)}[z_0] \models$ OD-$[x]_T$-determinacy, assume without loss of generality that $L_{\lambda(z_0)}[z_0] \models$ "σ is a relativized winning strategy for I in $A_0^{z_0}$". We use τ_0 to defeat this relativized strategy. Run G_0 according to τ_0, having Player I (falsely) predict that Player I wins the auxiliary game, while steering into $L_{\lambda(z_0)}[z_0]$ by playing $b = z_0$ and using σ to respond to τ_0 on the auxiliary play:

$$\begin{array}{lll} \mathrm{I} & 1 & (\sigma * d)_I, z_0 \\ \mathrm{II} & & c, d \end{array}$$

The point is that $p \equiv_T z_0$ (since $\sigma, \tau_0 \in R_{z_0}$) and so $\lambda(p) = \lambda(z_0)$. Thus the "steering problem" is immediately solved and we have a contradiction as before. ⊣

Since the game is Σ_2^1 for Player I, Player I has a Δ_3^1 strategy σ_0, by Theorem 6.5.

Claim 3. *For every real $z \geqslant_T \sigma_0$ there is a prestrategy f_0^z such that f_0^z is recursive in σ_0 as in Claim 1 and f_0^z is a non-losing first move for II against σ^z in $(SG\text{-}[x]_T)^{L_{\lambda(z)}[z]}$.*

Proof. Fix $z \geqslant_T \sigma_0$ as in Claim 1 and consider $A_0^z = \sigma^z(\varnothing)$. Let f_0^z be the prestrategy derived from σ_0 as follows: Given $y{\upharpoonright}n$ and $d{\upharpoonright}n$ have II play $y{\upharpoonright}n, d{\upharpoonright}n$ in G_0. Let $\epsilon, a{\upharpoonright}n, b{\upharpoonright}n$ be σ_0's response along the way and let $a(n)$ be σ_0's next move. Then let $f_0^z(y{\upharpoonright}n) = a(n)$. We have that f_0^z is recursive in $\sigma_0 \leqslant_T z$ and for $y \in [z]_T$, $f_0^z(y) \in R_z$. It remains to see that for $y \in [z]_T$, $f_0^z(y)$ is a relativized winning strategy for I in A_0^z. The point is that since $y \in [z]_T$, $\lambda(y) = \lambda(z)$ and so $L_{\lambda(y)}[y] = L_{\lambda(z)}[z]$ and $A_0^y = A_0^z$. For $d \in R_z$, by definition $f_0^z(y) * d = a * d$ where a is such that $(\sigma_0 * \langle y, d\rangle)_I = \langle \epsilon, a, b\rangle$. So, letting $p = \langle a, b, y, d\rangle$ we have $p \equiv_T y$. Thus, $\epsilon = 1$ iff $L_{\lambda(z)}[z] \models$ "$f_0^z(y) * d \in A_0^z$". ⊣

Step $n+1$. Assume that we have defined (in $L[x]$) games $G_0, \ldots, G_n$ with winning strategies $\sigma_0, \ldots, \sigma_n \in \mathrm{HOD}$ such that for all $z \geqslant_T \langle \sigma_0, \ldots, \sigma_n\rangle$ as in Claim 1 there are prestrategies $f_0^z, \ldots, f_n^z$ such that f_i^z is recursive in $\langle \sigma_0, \ldots, \sigma_i\rangle$ (for all $i \leqslant n$) and $f_0^z, \ldots f_n^z$ is a non-losing partial play for II in $(SG\text{-}[x]_T)^{L_{\lambda(z)}[z]}$.

Consider (in $L[x]$) the game G_{n+1}

$$\begin{array}{lll} \mathrm{I} & \epsilon & a, b \\ \mathrm{II} & & c, d \end{array}$$

where ϵ is 1 or 2 and, letting $p = \langle a, b, c, d, \sigma_0, \ldots, \sigma_n\rangle$, I wins iff

(1) p satisfies the condition on z in Claim 1 (so σ^p makes sense) and

(2) $\epsilon = 1$ iff $L_{\lambda(p)}[p] \models$ "$a * d \in A^p_{n+1}$", where A^p_{n+1} is I's response via σ^p to II's partial play $f^p_0, \dots, f^p_n$.

This game is $\Sigma^1_2(\sigma_0, \dots, \sigma_n)$ (for Player I) and hence determined (since $\sigma_0, \dots, \sigma_n \in \mathrm{HOD}$ and we have OD-determinacy).

Claim 4. *I has a winning strategy σ_{n+1} in G_{n+1}.*

Proof. The proof is as before, only now we use the relativized version of Theorem 7.6 to enforce $\mathrm{OD}_{\sigma_0,\dots,\sigma_n}$-$[x]_T$-determinacy. ⊣

Since the game is $\Sigma^1_2(\sigma_0, \dots, \sigma_n)$ for Player I, Player I has a $\Delta^1_3(\sigma_0, \dots, \sigma_n)$ strategy σ_{n+1}, by the relativized version of Theorem 6.5.

Claim 5. *For every real $z \geqslant_T \langle \sigma_0, \dots, \sigma_n \rangle$ there is a prestrategy f^z_{n+1} such that f^z_{n+1} is recursive in $\langle \sigma_0, \dots, \sigma_{n+1} \rangle$ and $f^z_0, \dots, f^z_{n+1}$ is a non-losing first move for II against σ^z in $(SG\text{-}[x]_T)^{L_{\lambda(z)}[z]}$.*

Proof. The proof is just like the proof of Claim 3. ⊣

Finally, letting z^∞ as in Claim 1 be such that $z^\infty \geqslant_T z_n$ for all n we have that $f^{z^\infty}_0, \dots, f^{z^\infty}_n, \dots$ defeats σ^{z^∞} in $(SG\text{-}[x]_T)^{L_{\lambda(z^\infty)}[z^\infty]}$, which is a contradiction. ⊣

7.8 Theorem. *Assume* ZF + DC. *Then for every $x \in \omega^\omega$ and for every $\alpha < \omega_1^{L[x]}$ there is an $\mathrm{OD}_{[x]_T}$ surjection $\rho : [x]_T \to \alpha$.*

Proof. First we need to review Vopěnka's theorem. Work in $L[x]$ and let $d = [x]_T$. Let

$$\mathbb{B}'_d = \{A \subseteq d \mid A \in \mathrm{OD}_d\},$$

ordered under $\subseteq$. There is an OD_d isomorphism π between $(\mathbb{B}'_d, \subseteq)$ and a partial ordering $(\mathbb{B}_d, \leqslant)$ in HOD_d.

Claim 1. *$(\mathbb{B}_d, \leq)$ is complete in HOD_d and every real in d is HOD_d-generic for $\mathbb{B}_d$.*

Proof. For completeness consider $S \subseteq \mathbb{B}_d$ in HOD_d. We have to show that $\bigvee S$ exists. Let $S' = \pi^{-1}[S]$. Then $\bigvee S' = \bigcup S' \in \mathbb{B}'_d$ as this set is clearly OD_d. So $\bigvee S = \pi(\bigvee S')$.

Now consider $z \in d$. Let $G'_z = \{A \in \mathbb{B}'_d \mid z \in A\}$ and let $G_z = \pi[G'_z]$. We claim that G_z is HOD_d-generic for $\mathbb{B}_d$. Let $S \subseteq \mathbb{B}_d$ be a maximal antichain. So $\bigvee S = 1$. Let $S' = \pi^{-1}[S]$. Note $\bigvee S' = d$. Thus there exists a $b \in S$ such that $z \in \pi(b)$. So G_z is HOD_d-generic for $\mathbb{B}_d$. Now the map $f : \omega \to \mathbb{B}_d$, defined by $f(n) = \pi(\{x \in d \mid n \in x\})$, is in HOD_d. Moreover, $n \in z$ iff $f(n) \in G_z$. Thus $z \in \mathrm{HOD}_d[G_z]$. ⊣

Notice that $\mathrm{HOD}_d[G] = L[x]$ for every $G = G_z$ that is HOD_d-generic (where $z \in d$) since such a generic adds a real in $[x]_T$. Thus, if $\mathrm{HOD}_d \neq L[x]$ then $\mathbb{B}_d$ is non-trivial. This is a key difference between our present setting and that of Vopěnka's—in general our partial order does not have atoms.

If $L[x] = \mathrm{HOD}_d$ then clearly for each $\alpha < \omega_1^{L[x]}$ there exists a surjection $\rho : d \to \alpha$ such that $\rho \in \mathrm{OD}_d$. So we may assume that $L[x] \neq \mathrm{HOD}_d$. Thus, for every $z \in d$

$$\omega_1^{L[x]} = \omega_1^{\mathrm{HOD}_d[G_z]}.$$

Claim 2. *Assume* ZFC*. Suppose l is an uncountable regular cardinal, $\mathbb{B}$ is a complete Boolean algebra, and $V^{\mathbb{B}} \models \lambda = \omega_1$. Then for every $\alpha < \lambda$ there is an antichain in $\mathbb{B}$ of size $|\alpha|$.*

Proof. If λ is a limit cardinal then since $\mathbb{B}$ collapses all uncountable cardinals below λ it cannot be $\bar{\lambda}$-c.c. for any uncountable cardinal $\bar{\lambda} < \lambda$.

Suppose $\lambda = \bar{\lambda}^+$. We need to show that there is an antichain of size $\bar{\lambda}$. If $\bar{\lambda} > \omega$ then this is immediate since $\mathbb{B}$ collapses $\bar{\lambda}$ and so it cannot be $\bar{\lambda}$-c.c. So assume $\bar{\lambda} = \omega$. There must be an antichain of size ω since not every condition in $\mathbb{B}$ is above an atom. ⊣

Letting $\lambda = \omega_1^{L[x]}$, we are in the situation of the claim. So, for every $\alpha < \lambda$ there is an antichain S_α in $\mathbb{B}$ of size $|\alpha|$. Letting $S'_\alpha = \pi^{-1}[S_\alpha]$ we have that S'_α is an OD_d subset of $\mathbb{B}'_d$ consisting of pairwise disjoint OD_d subsets of d. Picking an element from each set we get an OD_d-surjection $\rho : d \to \alpha$. ⊣

7.9 Theorem. *Assume* $\mathrm{ZF}+\mathrm{DC}+\Delta^1_2$*-determinacy. Then for a Turing cone of x,*

$$\mathrm{HOD}^{L[x]}_{[x]_T} \models \omega_1^{L[x]} \textit{ is a Woodin cardinal.}$$

Proof. For a Turing cone of x, $L[x] \models \mathrm{OD}_{[x]_T}$-determinacy (by the relativized version of Theorem 6.6) and $L[x] \models \mathrm{ST}\text{-}[x]_T$-determinacy (by Theorem 7.7). Let x be in this cone and work in $L[x]$. Let $d = [x]_T$. Since $L[x] \models \mathrm{OD}_{[x]_T}$-determinacy, $\omega_1^{L[x]}$ is strongly inaccessible in HOD_d. Let $H \subseteq \omega_1^{L[x]}$ code $\mathrm{HOD}_d \cap V_{\omega_1^{L[x]}}$. Fix $T \in \mathscr{P}(\omega_1^{L[x]}) \cap \mathrm{OD}_d$ and let $T_0 \subseteq \omega_1^{L[x]}$ code T and H. Let $A = \langle A_\alpha \mid \alpha < \omega_1^{L[x]}\rangle$ be such that A_α is an OD_d prewellordering of length greater than or equal to α (by Theorem 7.8). Let $B = d$. Consider the structure

$$M = \big(L_{\omega_1^{L[x]}}(\mathbb{R})[T_0, A, B]\big)^{L[x]}.$$

We claim that

$$\mathrm{HOD}^M \models \text{There is a } T_0\text{-strong cardinal},$$

which completes the proof as before. The reason is that we are in the situation of the Generation Theorem, except with $\omega_1^{L[x]}$ replacing $\omega_2^{L[x]}$ and $\mathrm{ST}\text{-}[x]_T$-determinacy replacing ST^B-determinacy. The proof of the Generation Theorem goes through unchanged. One just has to check that all of the operations we performed before (which involved definability in various parameters) are in fact recursive in the relevant parameters. ⊣

7.2. Second Localization

We now wish to show that the above construction goes through when we replace ZF + DC with PA_2. Notice that if we had $\utilde{\Delta}^1_2$-determinacy then this would be routine.

7.10 Theorem. *Assume* $\mathrm{PA}_2 + \utilde{\Delta}^1_2$*-determinacy. Then for all reals* x*, there is a model* N *such that* $x \in N$ *and*

$$N \models \mathrm{ZFC} + \textit{There is a Woodin cardinal.}$$

Proof. Working in PA_2 if one has $\utilde{\Delta}^1_2$-determinacy then for every $x \in \omega^\omega$, $x^\#$ exists. It follows that for all $x \in \omega^\omega$, there is an ordinal $\alpha < \omega_1$ such that $L_\alpha[x] \models \mathrm{ZFC}$. Using $\utilde{\Delta}^1_2$-determinacy one can find a real x_0 enforcing OD-determinacy. Thus we have a model $L_{\alpha_0}[x_0]$ satisfying ZFC + $V = L[x_0]$ + OD-determinacy and this puts us in the situation of Theorem 6.10. ⊣

The situation where one only has Δ^1_2-determinacy is bit more involved.

7.11 Theorem. *Assume that* $\mathrm{PA}_2 + \Delta^1_2$*-determinacy is consistent. Then* ZFC + *"*On *is Woodin" is consistent.*

Proof Sketch. First we pass to a theory that more closely resembles the theory used to prove Theorem 7.9. In PA_2 one can simulate the construction of $L_{\omega_1}[x]$. Given a model M of PA_2 and a real $x \in M$, there is a definable set of reals A coding the elements of $L_{\omega_1}[x]$. One can then show that the "inner model" $L_{\omega_1}[x]$ satisfies ZFC−Power Set+$V = L[x]$ (using, for example Comprehension to get Replacement). Thus, ZFC − Power Set + $V = L[x]$ is a conservative extension of PA_2.

Next we need to arrange a sufficient amount of definable determinacy. The most natural way to secure Δ^1_2-determinacy is to let x encode winning strategies for all Δ^1_2 games. However, this approach is unavailable to us since we have not included AC in PA_2 and, in any case, we wish to work with OD-determinacy (understood schematically). For this we simultaneously run (an elaboration of) the proof of Theorem 6.6 while defining $L_{\omega_1}[x]$. In this way, for any model M of PA_2, there is a real x and an associated definable set of reals A which codes a model $L_{\omega_1}[x]$ satisfying ZFC − Power Set + $V = L[x]$ + OD-determinacy.

Working in ZFC − Power Set + $V = L[x]$ + OD-determinacy we wish now to show that

$$\mathrm{HOD}_{[x]_T} \models \mathrm{ZFC} + \mathrm{On\ is\ Woodin}.$$

So we have to localize the construction of the previous section to the structure $\langle L_{\omega_1}[x], [x]_T\rangle$. The first step is to show that

$$\langle L_{\omega_1}[x], [x]_T\rangle \models \text{ST-}[x]_T\text{-determinacy for } n \text{ moves},$$

for each n. Here by ST-$[x]_T$-determinacy we mean what we meant in the previous section. However, there is a slight metamathematical issue that arises when we work without Power Set, namely, at each stage of the game the potential moves for Player I are a proper class from the point of view of $\langle L_{\omega_1}[x], [x]_T\rangle$. So in quantifying over these moves we have to use the first-order definition of OD in $\langle L_{\omega_1}[x], [x]_T\rangle$. The winning condition for the n-move version of the game is first-order over $\langle L_{\omega_1}[x], [x]_T\rangle$ but since the complexity of the definition increases as n increases the full game is not first-order over $\langle L_{\omega_1}[x], [x]_T\rangle$. This is why we have had to restrict to the n-move version.

The proof of this version of the theorem is just like that of Theorem 7.7, only now one has to keep track of definability and verify that there is no essential use of Power Set (for example, in the proof of Third Periodicity). The proof of Theorem 7.8 goes through as before. Finally, as in the proof of Theorem 7.9, the proof of the Generation Theorem gives a structure M such that

$$\mathrm{HOD}^M_{[x]_T} \models \mathrm{ZFC} + \mathrm{On\ is\ } T\text{-strong},$$

for an arbitrary $\mathrm{OD}^{\langle L_{\omega_1}[x],[x]_T\rangle}_{[x]_T}$ class T of ordinals, which implies the final result. ⊣

This raises the following question: Are the theories $\mathrm{PA}_2 + \Delta^1_2$-determinacy and ZFC + "On is Woodin" equiconsistent? We turn to this and other more general issues in the next section.

8. Further Results

In this section we place the above results in a broader setting by discussing some results that draw on techniques that are outside the scope of this chapter. The first topic concerns the intimate connection between axioms of definable determinacy and large cardinal axioms (as mediated through inner models). The second topic concerns the surprising convergence between two very different approaches to inner model theory—the approach based on generalizations of L and the approach based on HOD. In both cases the relevant material on inner model theory can be found in Steel's chapter in this Handbook.

8.1. Large Cardinals and Determinacy

The connection between axioms of definable determinacy and inner models of large cardinals is even more intimate than indicated by the above results. We have seen that certain axioms of definable determinacy imply the existence of inner models of large cardinal axioms. For example, assuming $\mathrm{ZFC} + \utilde{\Delta}^1_2$-determinacy, for each $x \in \omega^\omega$, there is an inner model M such that $x \in M$ and

$$M \models \mathrm{ZFC} + \text{There is a Woodin cardinal.}$$

And, assuming $\mathrm{ZFC} + \mathrm{AD}^{L(\mathbb{R})}$, in $L(\mathbb{R})$ there is an inner model M such that

$$M \models \mathrm{ZFC} + \text{There is a Woodin cardinal.}$$

In many cases these implications can be reversed—axioms of definable determinacy are actually *equivalent* to axioms asserting the existence of inner models of large cardinals. We discuss what is known about this connection, starting with a low level of boldface definable determinacy and proceeding upward. We then turn to lightface determinacy, where the situation is more subtle. It should be emphasized that our concern here is not merely with consistency strength but rather with outright equivalence (over ZFC).

8.1 Theorem. *The following are equivalent:*

(1) $\undertilde{\Delta}^1_2$*-determinacy.*

(2) For all $x \in \omega^\omega$*, there is an inner model* M *such that* $x \in M$ *and* $M \models$ *There is a Woodin cardinal.*

8.2 Theorem. *The following are equivalent:*

(1) PD (*Schematic*).

(2) For every $n < \omega$*, there is a fine-structural, countably iterable inner model* M *such that* $M \models$ *There are* n *Woodin cardinals.*

8.3 Theorem. *The following are equivalent:*

(1) $\mathrm{AD}^{L(\mathbb{R})}$.

(2) In $L(\mathbb{R})$*, for every set* S *of ordinals, there is an inner model* M *and an* $\alpha < \omega_1^{L(\mathbb{R})}$ *such that* $S \in M$ *and* $M \models \alpha$ *is a Woodin cardinal.*

8.4 Theorem. *The following are equivalent:*

(1) $\mathrm{AD}^{L(\mathbb{R})}$ *and* $\mathbb{R}^\#$ *exists.*

(2) $M_\omega^\#$ *exists and is countably iterable.*

8.5 Theorem. *The following are equivalent:*

(1) For all $\mathbb{B}$*,* $V^{\mathbb{B}} \models \mathrm{AD}^{L(\mathbb{R})}$.

(2) $M_\omega^\#$ *exists and is fully iterable.*

The above examples concern *boldface* definable determinacy. The situation with *lightface* definable determinacy is more subtle. For example, assuming $\mathrm{ZFC} + \Delta^1_2$-determinacy, must there exist an $\alpha < \omega_1$ and an inner model M such that α is a Woodin cardinal in M? In light of Theorem 8.1 one would expect that this is indeed the case. However, since Theorem 8.1 also holds in the context of PA_2 one would then expect that the theories $\mathrm{PA}_2 + \Delta^1_2$-determinacy and PA_2 + "There is an $\alpha < \omega_1$ and an inner model M such that $M \models \alpha$ is a Woodin cardinal" are *equivalent*, and yet this expectation is in conflict with the expectation that the theories $\mathrm{PA}_2 + \Delta^1_2$-determinacy and ZFC + "On is Woodin" are *equiconsistent*. In fact, this seems likely, but the details have not been fully checked. We state a version for third-order Peano arithmetic, PA_3, and second-order ZFC. But first we need a definition and some preliminary results.

8.6 Definition. A partial order $\mathbb{P}$ is *δ-productive* if for all δ-c.c. partial orders $\mathbb{Q}$, the product $\mathbb{P} \times \mathbb{Q}$ is δ-c.c.

8.7 Theorem. *In the fully iterable, 1-small, 1-Woodin Mitchell-Steel model the extender algebra built using all extenders on the sequence which are strong to their length is δ-productive.*

This is a warm-up since in the case of interest we do not have iterability. It is unknown if iterability is necessary.

8.8 Theorem. *Suppose δ is a Woodin cardinal. Then there is a proper class inner model $N \subseteq V$ such that*

(1) $N \models \delta$ is a Woodin cardinal and

(2) $N \models$ There is a complete δ-c.c. Boolean algebra $\mathbb{B}$ such that

$$N^{\mathbb{B}} \models \Delta^1_2\text{-}\textit{determinacy.}$$

Let ZFC_2 be second-order ZFC.

8.9 Theorem. *The following are equiconsistent*:

(1) $\mathrm{PA}_3 + \Delta^1_2$*-determinacy.*

(2) $\mathrm{ZFC}_2 + \mathrm{On}$ *is Woodin.*

We now turn from theories to models and discuss the manner in which one can pass back and forth between models of infinitely many Woodin cardinals and models of definable determinacy at the level of $\mathrm{AD}^{L(\mathbb{R})}$ and beyond. We have already dealt in detail with one direction of this—the transfer from models of determinacy to models with Woodin cardinals—and the other direction—the transfer from models with Woodin cardinals to models of determinacy—was briefly discussed in the introduction, but the situation is much more general. To proceed at the appropriate level of generality we need to introduce a potential strengthening of AD.

A set $A \subseteq \omega^\omega$ is *$^\infty$-borel* if there is a set $S \subseteq \mathrm{On}$, an ordinal α, and a formula φ such that

$$A = \{y \in \omega^\omega \mid L_\alpha[S, y] \models \varphi[S, y]\}.$$

It is fairly straightforward to show that to say that A is $^\infty$-borel is equivalent to saying that it has a "transfinite borel code". Notice that under AC every set of reals is $^\infty$-borel.

8.10 Definition. Assume ZF + $\mathrm{DC}_{\mathbb{R}}$. The theory AD^+ consists of the axioms:

(1) Every set $A \subseteq \omega^\omega$ is $^\infty$-borel.

(2) Suppose $\lambda < \Theta$ and $\pi : \lambda^\omega \to \omega^\omega$ is a continuous surjection. Then for each $A \subseteq \omega^\omega$ the set $\pi^{-1}[A]$ is determined.

8.11 Conjecture. AD implies AD^+.

It is known that the failure of this implication has strong consistency strength. For example, $\mathrm{AD} + \neg\mathrm{AD}^+$ proves $\mathrm{Con}(\mathrm{AD}_{\mathbb{R}})$.

The following theorem—the *Derived Model Theorem*—is a generalization of Theorem 1.5, mentioned in the introduction.

8.12 Theorem. *Suppose that δ is a limit of Woodin cardinals. Suppose that $G \subseteq \mathrm{Col}(\omega, <\delta)$ is V-generic and let $\mathbb{R}_G = \cup\{\mathbb{R}^{V[G\restriction\alpha]} \mid \alpha < \delta\}$. Let Γ_G be the set of $A \subseteq \mathbb{R}_G$ such that*

(1) $A \in V(\mathbb{R}_G)$,

(2) $L(A, \mathbb{R}_G) \models \mathrm{AD}^+$.

Then $L(\Gamma_G, \mathbb{R}_G) \models \mathrm{AD}^+$.

There is a "converse" to the Derived Model Theorem, the proof of which is a generalization of the proof of Theorem 6.20.

8.13 Theorem. *Assume AD^+ and $V = L(\mathscr{P}(\mathbb{R}))$. There is a partial order $\mathbb{P}$ such that if H is $\mathbb{P}$-generic over V then there is an inner model $N \subseteq V[H]$ such that*

(1) $N \models \mathrm{ZFC}$,

(2) ω_1^V is a limit of Woodin cardinals in N,

(3) there is a g which is $\mathrm{Col}(\omega, <\omega_1^V)$-generic over N and such that

(a) $\mathbb{R}^V = \mathbb{R}_g$,

(b) $\Gamma_g = \mathscr{P}(\mathbb{R})^V$,

where $\mathbb{R}_g$ and Γ_g are as in the previous theorem with N in the role of V.

Thus, there is an intimate connection between models with infinitely many Woodin cardinals and models of definable determinacy at the level of $\mathrm{AD}^{L(\mathbb{R})}$ and beyond. Moreover, the link is even tighter in the case of fine-structural inner models with Woodin cardinals. For example, if one first applies the Derived Model Theorem to M_ω (the Mitchell-Steel model for ω-many Woodin cardinals) and then applies the "converse" theorem to the resulting derived model $L(\mathbb{R}^*)$ then one recovers the original model M_ω.

8.2. HOD-Analysis

There is also an intimate connection between the two approaches to inner model theory mentioned in the introduction—the approach based on generalizations of L and the approach based on HOD.

As mentioned in the introduction, the two approaches have opposing advantages and disadvantages. The disadvantage of the first approach is that the problem of actually defining the models that can accommodate large cardinals—*the inner model problem*—is quite a difficult problem. However, the advantage is that once the inner model problem is solved at a given level of large cardinals the inner structure of the models is quite transparent and so these models are suitable for extracting the large cardinal content inherent in a given statement. The advantage of the approach based on HOD is that this model is trivial to define and it can accommodate virtually every large cardinal. The disadvantage—*the tractability problem*—is that in general the inner structure of HOD is about as tractable as that of V and so it is not generally suitable for extracting the large cardinal content from a given statement.

Nevertheless, we have taken the approach based on HOD and we have found that $\mathrm{AD}^{L(\mathbb{R})}$ and Δ^1_2-determinacy are able to overcome (to some extent) the tractability problem for their natural models, $L(\mathbb{R})$ and $L[x]$ for a Turing (or constructibility) cone of x. For example, we have seen that under $\mathrm{AD}^{L(\mathbb{R})}$,

$$\mathrm{HOD}^{L(\mathbb{R})} \models \Theta^{L(\mathbb{R})} \text{ is a Woodin cardinal,}$$

and that under Δ^1_2-determinacy, for a Turing cone of reals x,

$$\mathrm{HOD}^{L[x]} \models \omega_2^{L[x]} \text{ is a Woodin cardinal.}$$

Despite this progress, much of the structure of HOD in these contexts is far from clear. For example, it is unclear whether under Δ^1_2-determinacy, for a Turing cone of reals x, $\mathrm{HOD}^{L[x]}$ satisfies GCH, something that would be immediate in the case of "L-like" inner models.

Since the above results were first proved, Mitchell and Steel developed the fine-structural version of the "L-like" inner models at the level of Woodin cardinals. These models have the form $L[\vec{E}]$ where $\vec{E}$ is a sequence of (partial) extenders and (as noted above) their inner structure is very well understood—for example, they satisfy GCH and many of the other combinatorial properties that hold in L. A natural question, then, is whether there is any connection between these radically different approaches, that is, whether HOD as computed in $L(\mathbb{R})$ under $\mathrm{AD}^{L(\mathbb{R})}$ or in $L[x]$, for a Turing cone of x, under Δ^1_2-determinacy, bears any resemblance to the $L[\vec{E}]$ models. The remainder of this section is devoted to this question. We begin with $\mathrm{HOD}^{L(\mathbb{R})}$ and its generalizations (where a good deal is known) and then turn to $\mathrm{HOD}^{L[x]}$ (where the central question is open). Again, the situation with lightface determinacy is more subtle.

The theorems concerning $\mathrm{HOD}^{L(\mathbb{R})}$ only require $\mathrm{AD}^{L(\mathbb{R})}$ but they are simpler to state under the stronger assumption that $\mathrm{AD}^{L(\mathbb{R})}$ holds in all generic extensions of V. By Theorem 8.5, this assumption is equivalent to the statement that $M_\omega^\#$ exists and is fully iterable.

The first hint that $\mathrm{HOD}^{L(\mathbb{R})}$ is a fine-structural model is the remarkable fact that

$$\mathrm{HOD}^{L(\mathbb{R})} \cap \mathbb{R} = M_\omega \cap \mathbb{R}.$$

The agreement between $\mathrm{HOD}^{L(\mathbb{R})}$ and M_ω fails higher up but $\mathrm{HOD}^{L(\mathbb{R})}$ agrees with an iterate of M_ω at slightly higher levels. More precisely, letting N be the result of iterating M_ω by taking the ultrapower ω_1^V-many times using the (unique) normal ultrafilter on the least measurable cardinal, we have that

$$\mathrm{HOD}^{L(\mathbb{R})} \cap \mathscr{P}(\omega_1^V) = N \cap \mathscr{P}(\omega_1^V).$$

Steel improved this dramatically by showing that

$$\mathrm{HOD}^{L(\mathbb{R})} \cap V_{(\underset{\sim}{\delta}{}^2_1)^{L(\mathbb{R})}}$$

is the direct limit of a directed system of iterable fine-structural inner models.

8.14 Theorem (Steel). $\mathrm{HOD}^{L(\mathbb{R})} \cap V_\delta$ *is a Mitchell-Steel model, where* $\delta = (\underset{\sim}{\delta}{}^2_1)^{L(\mathbb{R})}$.

For a proof of this result see Steel's chapter in this Handbook. As a corollary one has that $\mathrm{HOD}^{L(\mathbb{R})}$ satisfies GCH along with the combinatorial principles (such as $\Diamond$ and $\Box$) that are characteristic of fine-structural models.

The above results suggest that all of $\mathrm{HOD}^{L(\mathbb{R})}$ might be a Mitchell-Steel inner model of the form $L[\vec{E}]$. This is not the case.

8.15 Theorem. $\mathrm{HOD}^{L(\mathbb{R})}$ *is not a Mitchell-Steel inner model.*

Nevertheless, $\mathrm{HOD}^{L(\mathbb{R})}$ is a fine-structural inner model, one that belongs to a new, quite different, hierarchy of models. Let

$$\begin{aligned} D = \big\{L[\vec{E}] \;\big|\; & L[\vec{E}] \text{ is an iterate of } M_\omega \text{ by a countable tree} \\ & \text{which is based on the first Woodin cardinal} \\ & \text{and has a non-dropping cofinal branch}\big\}. \end{aligned}$$

Any two structures in D can be compared and the iteration halts in countably many steps (since we have full iterability) with iterates lying in D. So D is a directed system under the elementary embeddings given by iteration maps. By the Dodd-Jensen lemma the embeddings commute and hence there is a direct limit. Let $L[\vec{E}^\infty]$ be the direct limit of D. Let $\langle \delta_i^\infty \mid i < \omega \rangle$ be the Woodin cardinals of $L[\vec{E}^\infty]$.

8.16 Theorem. *Let* $L[\vec{E}^\infty]$ *be as above. Then*

(1) $L[\vec{E}^\infty] \subseteq \mathrm{HOD}^{L(\mathbb{R})}$,

(2) $L[\vec{E}^\infty] \cap V_\delta = \mathrm{HOD}^{L(\mathbb{R})} \cap V_\delta$, *where* $\delta = \delta_0^\infty$,

(3) $\Theta^{L(\mathbb{R})} = \delta_0^\infty$, *and*

(4) $(\underset{\sim}{\delta}{}_1^2)^{L(\mathbb{R})}$ *is the least cardinal in* $L[\vec{E}^\infty]$ *which is* λ*-strong for all* $\lambda < \delta_0^\infty$.

To reach $\mathrm{HOD}^{L(\mathbb{R})}$ we need to supplement $L[\vec{E}^\infty]$ with additional inner-model-theoretic information. A natural candidate is the iteration strategy. It turns out that by folding in the right fragment of the iteration strategy one can capture $\mathrm{HOD}^{L(\mathbb{R})}$. Let

$$\begin{aligned} T^\infty = \big\{T \mid T &\text{ is a maximal iteration tree on } L[\vec{E}^\infty] \text{ based on } \delta_0^\infty, \\ &T \in L[\vec{E}^\infty], \text{ and } \operatorname{length}(T) < \sup\{\delta_n^\infty \mid n < \omega\}\big\} \end{aligned}$$

and

$$P = \big\{\langle b, T\rangle \mid T \in T^\infty \text{ and } b \text{ is the true branch through } T\big\}.$$

8.17 Theorem. *Let* $L[\vec{E}^\infty]$ *and* P *be as above. Then*

$$\mathrm{HOD}^{L(\mathbb{R})} = L[\vec{E}^\infty, P].$$

In fact, there is a single iteration tree $T \in T^\infty$ *such that if* b *is the branch through* T *chosen by* P *then*

$$\mathrm{HOD}^{L(\mathbb{R})} = L[\vec{E}^\infty, b].$$

This analysis has an interesting consequence. Notice that the model $L[\vec{E}^\infty]$ is of the form $L[A]$ for $A \subseteq \delta_0^\infty$. Thus, although the addition of P does not add any new bounded subsets of $\Theta^{L(\mathbb{R})}$ it does a lot of damage to the model above $\Theta^{L(\mathbb{R})}$, for example, it collapses ω-many Woodin cardinals. One might think that this is an artifact of $L[\vec{E}^\infty]$ but in fact the situation is much more general: Suppose $L[\vec{E}]$ is ω-small, fully iterable, and has ω-many Woodin cardinals. Let P be defined as above except using the Woodin cardinals of $L[\vec{E}]$. Then $L[\vec{E}, P] \cap V_\delta = L[\vec{E}] \cap V_\delta$, where δ is the first Woodin cardinal of $L[\vec{E}]$, and $L[\vec{E}] \subsetneq L[\vec{E}, P] \subsetneq L[\vec{E}^\#]$. For example, applying this result to $L[\vec{E}] = M_\omega$, one obtains a canonical inner-model-theoretic object between M_ω and $M_\omega^\#$. In this way, what appeared to be a coarse approach to inner model theory has actually resulted in a hierarchy that supplements and refines the standard fine-structural hierarchy.

The above results generalize. We need a definition.

8.18 Definition (Mouse Capturing). MC is the statement: For all $x, y \in \omega^\omega$, $x \in \mathrm{OD}_y$ iff there is an iterable Mitchell-Steel model M of the form $L[\vec{E}, y]$ such that $x \in M$.

The *Mouse Set Conjecture*, MSC, is the conjecture that it is a theorem of AD^+ that MC holds if there is no iterable model with a superstrong cardinal. There should be a more general version of MC, one that holds for extensions of the Mitchell-Steel models that can accommodate long extenders. And this version of MC should follow from AD^+. However, the details are still being worked out. See [12].

8.19 Theorem. *Assume* $\mathrm{AD}^+ + V = L(\mathscr{P}(\mathbb{R})) + \Theta_0 = \Theta + \mathrm{MSC}$. *Then the inner model* $\mathrm{HOD}^{L(\mathscr{P}(\mathbb{R}))}$ *is of the form* $L[\vec{E}^\infty, P]$, *with the key difference being that* $L[\vec{E}^\infty]$ *need not be* ω*-small.*

8.20 Theorem. *Assume* $\mathrm{AD}^+ + V = L(\mathscr{P}(\mathbb{R})) + \Theta_0 < \Theta + \mathrm{MSC}$. *Then*

(1) Θ_0 *is the least Woodin cardinal in* HOD*,*

(2) $\mathrm{HOD} \cap V_{\Theta_0}$ *is a Mitchell-Steel model,*

(3) $\mathrm{HOD} \cap V_{\Theta_0+1}$ *is not a Mitchell-Steel model, and*

(4) $\mathrm{HOD} \cap V_{\Theta_1}$ *is a model of the form* $L[\vec{E}^\infty, P]$ (*assuming the appropriate form of the Mouse Set Theorem*).

One can move on to stronger hypotheses. For example, assuming AD^+ and $V = L(\mathscr{P}(\mathbb{R}))$, $\mathrm{AD}_\mathbb{R}$ is equivalent to the statement that Ω (defined at the beginning of Sect. 5) is a non-zero limit ordinal. There is a minimal inner model N of $\mathrm{ZF} + \mathrm{AD}_\mathbb{R}$ that contains all of the reals. The model HOD^N has ω-many Woodin cardinals and these are exactly the members of the Θ-sequence. This model belongs to the above hierarchy and has been used to calibrate the consistency strength of $\mathrm{AD}_\mathbb{R}$ in terms of the large cardinal hierarchy. This hierarchy extends and a good deal is known about it.

We now turn to the case of lightface determinacy and the setting $L[x]$ for a Turing cone of x. Here the situation is less clear. In fact, the basic question is open.

5 Open Question. Assume Δ^1_2-determinacy. For a Turing cone of x, what is $\mathrm{HOD}^{L[x]}$ from a fine-structural point of view?

We close with partial results in this direction and with a conjecture. To simplify the discussion we state these results under a stronger assumption than is necessary: Assume Δ^1_2-determinacy and that for all $x \in \omega^\omega$, $x^\#$ exists.

It follows that M_1 and $M_1^\#$ exist. Let $x_0 \in \omega^\omega$ be such that $M_1^\# \in L[x_0]$. Let κ_{x_0} be the least inaccessible of $L[x_0]$ and let $G \subseteq \mathrm{Col}(\omega, < \kappa_{x_0})$ be $L[x_0]$-generic. The Kechris-Solovay result carries over to show that

$$L[x_0][G] \models \text{OD-determinacy}.$$

Furthermore,

$$\mathrm{HOD}^{L[x_0][G]} = \mathrm{HOD}^{L(\mathbb{R})^{L[x_0][G]}} \quad \text{and} \quad \omega_2^{L[x_0][G]} = \Theta^{L(\mathbb{R})^{L[x_0][G]}}.$$

Thus, the model $L(\mathbb{R})^{L[x_0][G]}$ is a "lightface" analogue of $L(\mathbb{R})$. In fact the conditions of the Generation Theorem hold in $L[x_0][G]$ and as a consequence one has that

$$\mathrm{HOD}^{L[x_0][G]} \models \omega_2^{L[x_0][G]} \text{ is a Woodin cardinal.}$$

For a model $L[\vec{E}]$ containing at least one Woodin cardinal let $\delta_0^{\vec{E}}$ be the least Woodin cardinal. Let

$$D = \big\{L[\vec{E}] \subseteq L[x_0][G] \bigm| L[\vec{E}] \text{ is an iterate of } M_1 \text{ and } \delta_0^{\vec{E}} < \omega_1^{L[x_0][G]}\big\}.$$

Let $L[\vec{E}^\infty]$ be the direct limit of D. Let δ^∞ be the least Woodin of $L[\vec{E}^\infty]$ and let κ^∞ be the least inaccessible above δ^∞. Let

$$T^\infty = \big\{T \bigm| T \text{ is a maximal iteration tree on } L[\vec{E}^\infty], \\ T \in L[\vec{E}^\infty], \text{ and } \mathrm{length}(T) < \kappa^\infty\big\}$$

and

$$P = \big\{\langle b, T\rangle \bigm| T \in T^\infty \text{ and } b \text{ is the true branch through } T\big\}.$$

8.21 Theorem. *Let $L[\vec{E}^\infty, P]$ be as above. Then*

(1) $\mathrm{HOD}^{L[x_0][G]} \cap V_{\delta^\infty} = L[\vec{E}^\infty] \cap V_{\delta^\infty}$,

(2) $\mathrm{HOD}^{L[x_0][G]} = L[\vec{E}^\infty, P]$, *and*

(3) $\omega_2^{L[x_0][G]} = \delta^\infty$.

A similar analysis can be carried out for other hypotheses that place one in an "$L(\mathbb{R})$-like" setting. For example, suppose again that x_0 is such that $M_1^\# \in L[x_0]$. One can "generically force" MA as follows: In $L[x_0]$ let $\mathbb{P}$ be the partial order where the conditions $\langle \mathbb{B}_\alpha \mid \alpha < \gamma\rangle$ are such that (i) for each $\alpha < \gamma$, $\mathbb{B}_\alpha$ is c.c.c., (ii) $|\mathbb{B}_\alpha| = \omega_1$, (iii) if $\alpha \leqslant \beta < \gamma$ then $\mathbb{B}_\alpha$ is a complete subalgebra of $\mathbb{B}_\beta$, and (iv) $\gamma < \omega_2$, and the ordering is by extension. The forcing is $<\!\omega_2$-closed. Let $G \subseteq \mathbb{P}$ be $L[x_0]$-generic and let $\mathbb{B}_G$ be the union of the algebras $\mathbb{B}_\alpha$ appearing in the conditions in G. It follows that $\mathbb{B}_G$ is c.c.c in $L[x_0][G]$. Now, letting $H \subseteq \mathbb{B}_G$ be $L[x_0][G]$-generic, we have that $L[x_0][G][H]$ satisfies MA. The result is that

$$\mathrm{HOD}^{L[x_0][G][H]} = L[\vec{E}^\infty, P]$$

for the appropriate $\vec{E}^\infty$ and P. However, in this context

$$\mathrm{HOD}^{L[x_0][G][H]} \models \omega_3^{L[x_0][G][H]} \text{ is a Woodin cardinal.}$$

In the case of $L(\mathbb{R})$ the non-fine-structural analysis showed that $(\underset{\sim}{\delta}{}_1^2)^{L(\mathbb{R})}$ is λ-strong in $\mathrm{HOD}^{L(\mathbb{R})}$ for all $\lambda < \Theta^{L(\mathbb{R})}$ and the HOD-analysis showed that in fact $(\underset{\sim}{\delta}^2_1)^{L(\mathbb{R})}$ is the least ordinal with this feature. In the case of $L[x_0][G]$ the non-fine-structural analysis shows that some ordinal δ is λ-strong in $\mathrm{HOD}^{L[x_0][G]} = \mathrm{HOD}^{L(\mathbb{R})^{L[x_0][G]}}$ for all $\lambda < \omega_2^{L[x_0][G]} = \Theta^{L(\mathbb{R})^{L[x_0][G]}}$. Numerology would suggest that δ is $\underset{\sim}{\delta}^1_2$ as computed in $L[x_0][G]$. It turns out this analogy fails: the least cardinal δ that is λ-strong in $\mathrm{HOD}^{L[x_0][G]}$ for all $\lambda < \omega_2^{L[x_0][G]}$ is in fact strictly less δ^1_2 as computed in $L[x_0][G]$.

But there is another analogy that does hold. First we need some definitions. A set $A \subseteq \omega^\omega$ is *γ-Suslin* if there is an ordinal γ and a tree T on $\omega \times \gamma$ such that $A = p[T] = \{x \in \omega^\omega \mid \exists y \in \gamma^\omega \, \forall n \, (x\restriction n, y\restriction n) \in T\}$. A cardinal κ is a *Suslin cardinal* if there exists a set $A \subseteq \omega^\omega$ such that A is κ-Suslin but not γ-Suslin for any $\gamma < \kappa$. A set $A \subseteq \omega^\omega$ is *effectively γ-Suslin* if there is an ordinal γ and an OD tree $T \subseteq \omega \times \gamma$ such that $A = p[T]$. A cardinal κ is an *effective Suslin cardinal* if there exists a set $A \subseteq \omega^\omega$ such that A is effectively κ-Suslin but not effectively γ-Suslin for any $\gamma < \kappa$.

In $L(\mathbb{R})$, $\underset{\sim}{\delta}^2_1$ is the largest Suslin cardinal. Since $L[x_0][G]$ is a lightface analogue of $L(\mathbb{R})$ one might expect that in $L[x_0][G]$, δ^1_2 is the largest *effective* Suslin cardinal in $L[x_0][G]$. This is indeed the case.

There is one more advance on the HOD-analysis for $L[x]$ that is worth mentioning.

8.22 Theorem. *Assume $\underset{\sim}{\Delta}^1_2$-determinacy. For a Turing cone of x there is a predicate A such that*

(1) $\mathrm{HOD}_A^{L[x]}$ has the form $L[\vec{E}, P]$ where P is a fragment of the iteration strategy,

(2) $\mathrm{HOD}_A^{L[x]} \models \omega_2^{L[x]}$ is a Woodin cardinal,

(3) $\mathrm{HOD}_A^{L[x]}$ is of the form $L[\vec{E}]$ below $\omega_2^{L[x]}$,

(4) $L[x] \models \mathrm{ST}$-determinacy, and

(5) $\mathrm{HOD}^{L[x]} \cap V_\delta = \mathrm{HOD}_A^{L[x]} \cap V_\delta$ where δ is the least cardinal of $\mathrm{HOD}_A^{L[x]}$ that is λ-strong for all $\lambda < \omega_2^{L[x]}$.

Moreover, there exists a definable collection of such A and the collection has size $\omega_1^{L[x]}$.

This provides some evidence that $\mathrm{HOD}^{L[x]}$ is of the form $L[\vec{E}]$ below $\omega_2^{L[x]}$ and that $\mathrm{HOD}^{L[x]}$ is not equal to a model of the form $L[\vec{E}]$.

8.23 Conjecture. $\mathrm{HOD}^{L[x]}$ is of the form $L[\vec{E}, P]$ where P selects branches through all trees in $L[\vec{E}]$ based on the Woodin cardinal and with length less than the successor of the Woodin cardinal.

M. Foreman, A. Kanamori (eds.), *Handbook of Set Theory*,
DOI 10.1007/978-1-4020-5764-9_25,

The *Axiom of Determinacy* (AD) is the statement that all integer games of perfect information of length ω are determined. This statement contradicts the Axiom of Choice, and presents a radically different view of the universe of sets. Nonetheless, determinacy was a subject of intense study by the late 1960s, with an eye towards the possibility that some inner model of set theory satisfies AD (see, for example, the introductory remarks in [32]). Since strategies for these games can be coded by real numbers, the natural inner model to consider is $L(\mathbb{R})$, the smallest model of Zermelo-Fraenkel set theory containing the reals and the ordinals. This approach was validated by the following theorem of Woodin (see [14, 19]), building on work of Martin and Steel [25] and Foreman, Magidor and Shelah [7].

0.1 Theorem. *If there exists a measurable cardinal which is greater than infinitely many Woodin cardinals, then the Axiom of Determinacy holds in* $L(\mathbb{R})$.

This theorem is established in Neeman's chapter in this Handbook.

A companion to Theorem 0.1, also due to Woodin (see [19]) and building on the work of Foreman, Magidor and Shelah [7], shows that the existence of a proper class of Woodin cardinals implies that the theory of $L(\mathbb{R})$ cannot be changed by set forcing. By Theorem 0.1, the Axiom of Determinacy is part of this fixed theory for $L(\mathbb{R})$.

0.2 Theorem. *If δ is a limit of Woodin cardinals and there exists a measurable cardinal greater than δ, then no forcing construction in V_δ can change the theory of* $L(\mathbb{R})$.

Theorem 0.2 has the following corollary. If P is a definable forcing construction in $L(\mathbb{R})$ which is homogeneous (i.e., the theory of the extension can be computed in the ground model), then the theory of the P-extension of $L(\mathbb{R})$ also cannot be changed by forcing (i.e., the P-extensions of $L(\mathbb{R})$ in all forcing extensions of V satisfy the same theory). This suggests that the absoluteness properties of $L(\mathbb{R})$ can be lifted to models of the Axiom of Choice, as Choice can be forced over $L(\mathbb{R})$.

In [35], Steel and Van Wesep made a major step in this direction, forcing over a model of a stronger form of determinacy than AD to produce a model of ZFC satisfying two consequences of AD, that $\underset{\sim}{\delta}^1_2$ (the supremum of the lengths of the $\underset{\sim}{\Delta}^1_2$-definable prewellorderings of the reals) is ω_2 and the nonstationary ideal NS_{ω_1} on ω_1 is saturated. Woodin [38] later improved the hypothesis to $\mathrm{AD}^{L(\mathbb{R})}$.

This theorem is proved in [5, Sect. 5.11].

In the early 1990's, Woodin proved the following theorem, showing for the first time that large cardinals imply the existence of a partial order forcing the existence of a projective set of reals giving a counterexample to the Continuum Hypothesis. The question of whether ZFC is consistent with a projective witness to $\mathfrak{c} \geq \omega_3$ remains open.

0.3 Theorem. *If NS_{ω_1} is saturated and there exists a measurable cardinal, then $\underset{\sim}{\delta}^1_2 = \omega_2$.*

One important point in this proof is the fact that if NS_{ω_1} is saturated then every member of $H(\omega_2)$ (recall that $H(\kappa)$ is the collection of sets of hereditary cardinality less than κ) appears in an iterate (in the sense of the next section) of a countable model of a suitable fragment of ZFC. Since these countable models are elements of $L(\mathbb{R})$, their iterations induce a natural partial order in $L(\mathbb{R})$. With certain technical refinements, this partial order, called $\mathbb{P}_{\max}$, produces an extension of $L(\mathbb{R})$ whose $H(\omega_2)$ is the direct limit of the structures $H(\omega_2)$ of models satisfying every forceable theory (and more). In particular, the structure $H(\omega_2)$ in the $\mathbb{P}_{\max}$ extension of $L(\mathbb{R})$ (assuming $\mathrm{AD}^{L(\mathbb{R})}$) satisfies every Π_2 sentence ϕ (in the language with predicates for NS_{ω_1} and each set of reals in $L(\mathbb{R})$) for $H(\omega_2)$ such that for some integer n the theory ZFC + "There exist n Woodin cardinals" implies that ϕ is forceable. Furthermore, the partial order $\mathbb{P}_{\max}$ can be easily varied to produce other consistency results and canonical models.

The partial order $\mathbb{P}_{\max}$ and some of its variations (and many other related issues) are presented in [39]. The aim of this chapter is to prepare the reader for that book. First, we attempt to give a complete account of the basic analysis of the $\mathbb{P}_{\max}$ extension of $L(\mathbb{R})$, relative to published results. Then we briefly survey some of the issues surrounding $\mathbb{P}_{\max}$, in particular $\mathbb{P}_{\max}$ variations and forcing over larger models of determinacy. We also briefly introduce Woodin's Ω-logic, in order to properly state the maximality properties of the $\mathbb{P}_{\max}$ extension. For the most part, though, our focus is primarily on the $\mathbb{P}_{\max}$ extension of $L(\mathbb{R})$, and secondarily on $\mathbb{P}_{\max}$-style forcing constructions as a means of producing consistency results. For other topics, such as the Ω-conjecture and the relationship between Ω-logic and the Continuum Hypothesis, we refer the reader to [42, 40, 41, 43, 3].

The material in this chapter is due to Woodin, except where noted otherwise. The author would like to thank Howard Becker and John Steel for advising him on parts of the material in Sects. 4 and 9 respectively. He would also like to thank Andrés Caicedo, Neus Castells and Teruyuki Yorioka for making numerous helpful suggestions. The author was supported in part by the Fields Institute, FAPESP (Grant # 02/11551-3, University of São Paulo) and the Centre de Recerca Matemàtica of the Institut d'Estudis Catalans.

1. Iterations

The fundamental construction in the $\mathbb{P}_{\max}$ analysis is the iterated generic elementary embedding. These embeddings can have many forms, but we will concentrate on the following case. Suppose that I is a normal, uniform, proper ideal on ω_1 (so I is a proper subset of $\mathcal{P}(\omega_1)$ containing all the countable subsets, and such that whenever A is an I-positive set (i.e., in $\mathcal{P}(\omega_1) \setminus I$) and $f : A \to \omega_1$ is a regressive function, f is constant on an I-positive set; notationally, we are going to act as though "proper" and "uniform" are contained in the definition of *normal ideal*, and similarly for "measure" and "ultrafilter"). Then forcing with the Boolean algebra $\mathcal{P}(\omega_1)/I$ gives rise to a V-normal ultrafilter U on ω_1^V. By convention, we identify the wellfounded part of the ultrapower $\mathrm{Ult}(V, U)$ with its transitive collapse, and we note that this wellfounded part always contains ω_2^V. The corresponding elementary embedding $j : V \to \mathrm{Ult}(V, U)$ has critical point ω_1^V, and since I is normal, for each $A \in \mathcal{P}(\omega_1)^V$, $A \in U$ if and only if $\omega_1^V \in j(A)$. Under certain circumstances, the corresponding ultrapower of V is wellfounded; if every condition in $\mathcal{P}(\omega_1)/I$ forces this, then I is *precipitous*. See [5] for a general analysis of generic elementary embeddings.

For the most part, we will be concerned only with models of ZFC, but since occasionally we will want to deal with structures whose existence can be proved in ZFC, we define the fragment ZFC$^\circ$ to be the theory ZFC $-$ Power Set $-$ Replacement $+$ "$\mathcal{P}(\mathcal{P}(\omega_1))$ exists" plus the following scheme, which is a strengthening of ω_1-Replacement: every (possibly proper class) tree of height ω_1 definable from set parameters has a maximal branch (i.e., a branch with no proper extensions; in the cases we are concerned with, this just means a branch of length ω_1). By the Axiom of Choice here we mean that every set is the bijective image of an ordinal. We will use ZFC$^\circ$ in place of the theory ZFC* from [39], which asserts closure under the Gödel operations (see [10, p. 178]) plus a scheme similar to the one above. One advantage of using ZFC* is that it holds in $H(\omega_2)$. On the other hand, it raises some technical points that we would rather avoid here. Some of these points appear in Woodin's proof of Theorem 0.3. Our concentration is on $\mathbb{P}_{\max}$, but we hope nonetheless that the reader will have no difficulty in reading the proofs of that theorem in [5, 39] after reading the material in this section.

With either theory, the point is that one needs to be able to prove the version of Łoś's theorem asserting that ultrafilters on ω_1 generate elementary embeddings, which amounts to showing the following fact. The fact follows immediately from the scheme above.

1.1 Fact (ZFC$^\circ$). Let n be an integer. Suppose that ϕ is a formula with $n+1$ many free variables and $f_0, \ldots, f_{n-1}$ are functions with domain ω_1. Then there is a function g with domain ω_1 such that for all $\alpha < \omega_1$,

$$\exists x \phi(x, f_0(\alpha), \ldots, f_{n-1}(\alpha)) \implies \phi(g(\alpha), f_0(\alpha), \ldots, f_{n-1}(\alpha)).$$

If M is a model of ZFC and κ is a cardinal of M of cofinality greater than ω_1^M (in M), then $H(\kappa)^M$ satisfies ZFC$^\circ$ if it has $|\mathcal{P}(\mathcal{P}(\omega_1))|^M$ as a member.

Suppose that M is a model of ZFC$^\circ$, $I \in M$ is a normal ideal on ω_1^M and $\mathcal{P}(\mathcal{P}(\omega_1))^M$ is countable. Then there exist M-generic filters for the partial order $(\mathcal{P}(\omega_1)/I)^M$. Furthermore, if $j : M \to N$ is an ultrapower embedding of this form, then $\mathcal{P}(\mathcal{P}(\omega_1))^N$ is countable, and there exist N-generic filters for $(\mathcal{P}(\omega_1)/j(I))^N$. We can continue choosing generics in this way for up to ω_1 many stages, defining a commuting family of elementary embeddings and using this family to take direct limits at limit stages.

We use the following formal definition.

1.2 Definition. Let M be a model of ZFC$^\circ$ and let I be an ideal on ω_1^M which is normal in M. Let γ be an ordinal less than or equal to ω_1. An *iteration* of (M, I) of length γ consists of models M_α ($\alpha \leq \gamma$), sets G_α ($\alpha < \gamma$) and a commuting family of elementary embeddings $j_{\alpha\beta} : M_\alpha \to M_\beta$ ($\alpha \leq \beta \leq \gamma$) such that

- $M_0 = M$,
- each G_α is an M_α-generic filter for $(\mathcal{P}(\omega_1)/j_{0\alpha}(I))^{M_\alpha}$,
- each $j_{\alpha\alpha}$ is the identity mapping,
- each $j_{\alpha(\alpha+1)}$ is the ultrapower embedding induced by G_α,
- for each limit ordinal $\beta \leq \gamma$, M_β is the direct limit of the system $\{M_\alpha, j_{\alpha\delta} : \alpha \leq \delta < \beta\}$, and for each $\alpha < \beta$, $j_{\alpha\beta}$ is the induced embedding.

If $\langle M_\alpha, G_\beta, j_{\alpha\delta} : \beta < \alpha \leq \delta \leq \omega_1 \rangle$ is an iteration of a pair (M, I) and each $\omega_1^{M_\alpha}$ is wellfounded, then $\{\omega_1^{M_\alpha} : \alpha < \omega_1\}$ is a club subset of ω_1. Note also that if $\langle M_\alpha, G_\beta, j_{\alpha\delta} : \beta < \alpha \leq \delta \leq \gamma \rangle$ is an iteration of a pair (M, I), then $j``\mathrm{On}^{M_0}$ is cofinal in On^{M_γ}.

The models M_α in Definition 1.2 are called *iterates* of (M, I). If M is a model of ZFC$^\circ$ then an iteration of $(M, \mathrm{NS}_{\omega_1}^M)$ is called simply an *iteration of M* and an iterate of $(M, \mathrm{NS}_{\omega_1}^M)$ is called simply an *iterate* of M. When the individual parts of an iteration are not important, we sometimes call the elementary embedding $j_{0\gamma}$ corresponding to an iteration an iteration itself. For instance, if we mention an iteration $j : (M, I) \to (M^*, I^*)$, we mean that j is the embedding $j_{0\gamma}$ corresponding to some iteration

$$\langle M_\alpha, G_\beta, j_{\alpha\delta} : \beta < \alpha \leq \delta \leq \gamma \rangle$$

of (M, I), and that M^* is the final model of this iteration and $I^* = j(I)$.

If M and I are as in Definition 1.2, then the pair (M, I) is *iterable* if every iterate of (M, I) is wellfounded. In this chapter, we are in general interested only in iterable pairs (M, I). When checking for iterability it suffices to consider the countable length iterations, as any iteration of length ω_1 whose final model is illfounded contains an illfounded model at some earlier stage. The following two lemmas show that if

- M is a transitive model of ZFC$^\circ$+ Power Set containing ω_1^V,
- $|\mathcal{P}(\mathcal{P}(\omega_1)/I)|^M$ is countable,
- κ is a cardinal of M greater than $|\mathcal{P}(\mathcal{P}(\omega_1)/I)|^M$ with cofinality greater than ω_1^M in M,
- $I \in M$ is a normal precipitous ideal on ω_1^M,

then the pair $(H(\kappa)^M, I)$ is iterable. In particular, Lemma 1.6 below shows that every such pair (M, I) is iterable, and then Lemma 1.5 shows that $(H(\kappa)^M, I)$ is iterable, as every iterate of $(H(\kappa)^M, I)$ embeds into an iterate of (M, I). This argument is our primary means of finding iterable models.

1.3 Remark. Often in these notes will we use recursive codings of elements of $H(\omega_1)$ by subsets of ω. The following coding is sufficient in all cases: fixing a recursive bijection $\pi : \omega \times \omega \to \omega$, we say that $x \subseteq \omega$ codes $a \in H(\omega_1)$ if

$$\langle \omega, \{(n, m) \mid \pi(n, m) \in x\}\rangle \cong \langle \{a\} \cup \mathrm{tc}(a), \in\rangle,$$

where $\mathrm{tc}(a)$ denotes the transitive closure of a. Under this coding, the relations "$\in$" and "$=$" are both Σ^1_1, since permutations of ω can give rise to different codes for the same set.

1.4 Remark. The statement that a given pair (M, I) is iterable is Π^1_2 in any real x recursively coding the pair. One way to express this (not necessarily the most direct), is: for every countable model N of ZFC$^\circ$ with x as a member and every object $J \in N$ such that $N \models$ "J is an iteration of (M, I)" and every function f from ω to the "ordinals" of the last model of J, either N is illfounded (i.e., there exists an infinite descending sequence of "ordinals" of N) or $f(n+1)$"$\notin$"$f(n)$ for some integer n, where "$\notin$" is the negation of the $\in$-relation of the last model of J. Therefore, whether or not (M, I) is iterable is absolute between models of ZFC$^\circ$ containing the countable ordinals. Furthermore, assuming that $x^\#$ exists and letting γ denote $\omega_1^{L[x^\#]}$, any transitive model N of ZFC$^\circ$ containing $L_\gamma[x^\#]$ is correct about the iterability of (M, I), as $L[x^\#]$ is correct about it, and N thinks that $L_{\omega_1^N}[x^\#]$ is correct about it. Similarly, if γ and δ are countable ordinals coded by reals y and z, then the existence of an iteration of (M, I) of length γ which is illfounded is a Σ^1_1 fact about x and y, and the existence of an iteration of (M, I) of length γ such that the ordinals of the last model of the iteration have height at least (or, exactly) δ is a Σ^1_1 fact about x, y and z.

The first lemma is easily proved by induction. The last part of the lemma uses the assumption that N is closed under ω_1^M-sequences in M (this is the main way in which the lemma differs from the corresponding lemma in [39] (Lemma 3.8)). In our applications, N will often be $H(\kappa)^M$ for some cardinal κ of M such that $M \models \mathrm{cf}(\kappa) > \omega_1^M$, in which case $H(\kappa)^M$ is indeed closed under ω_1^M-sequences in M.

1.5 Lemma. *Suppose that M is a model of* ZFC$^\circ$ *and $I \in M$ is a normal ideal on ω_1^M. Let N be a transitive model of* ZFC$^\circ$ *in M containing $\mathcal{P}(\mathcal{P}(\omega_1)/I)^M$ and closed under ω_1^M-sequences in M. Let $\gamma \leq \omega_1$ be an ordinal and let*

$$\langle N_\alpha, G_\beta, j_{\alpha\delta} : \beta < \alpha \leq \delta \leq \gamma\rangle$$

be an iteration of (N, I). Then there exists a unique iteration

$$\langle M_\alpha, G^*_\beta, j^*_{\alpha\delta} : \beta < \alpha \leq \delta \leq \gamma\rangle$$

of (M, I) such that for all $\beta < \alpha \leq \gamma$, $G_\beta = G^*_\beta$ and

$$\mathcal{P}(\mathcal{P}(\omega_1)/I)^{N_\alpha} = \mathcal{P}(\mathcal{P}(\omega_1)/I)^{M_\alpha}.$$

Furthermore, $N_\alpha = j^*_{0\alpha}(N)$ for all $\alpha \leq \gamma$.

Given ordinals α, β, the partial order $\mathrm{Col}(\alpha, \beta)$ is the set of partial functions from α to β whose domain has cardinality less than that of α, ordered by inclusion. In particular, $\mathrm{Col}(\omega, \beta)$ makes β countable. Given ordinals α and β, $\mathrm{Col}(\alpha, {<}\beta)$ is the partial order consisting of all partial functions $p : \beta \times \alpha \to \beta$ of cardinality less than α, such that for all $(\delta, \gamma) \in \mathrm{dom}(p)$, $p(\delta, \gamma) \in \delta$, ordered by inclusion (we will not use this definition until the next section).

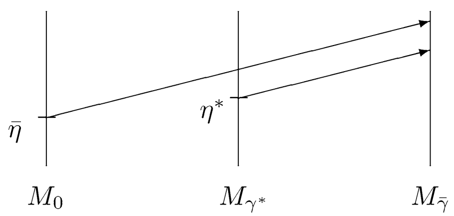
The proof of the following lemma is a modification of standard arguments tracing back to Gaifman and Solovay ([5] contains a variation of the lemma).

1.6 Lemma. *Suppose that M is a transitive model of* ZFC°+ *Power Set + Choice + Σ_1-Replacement and that $I \in M$ is a normal precipitous ideal on ω_1^M. Suppose that $j : (M, I) \to (M^*, I^*)$ is an iteration of (M, I) whose length is in $(\omega_1^V + 1) \cap M$. Then M^* is wellfounded.*

Proof. If j and M^* are as in the statement of the lemma, then M^* is the union of all sets of the form $j(H(\kappa)^M)$, where κ is a regular cardinal in M, and for each such $\kappa > |\mathcal{P}(\mathcal{P}(\omega_1))|^M$, $j{\restriction}H(\kappa)^M$ is an iteration of $(H(\kappa)^M, I)$. If the lemma fails, we may let $(\bar\gamma, \bar\kappa, \bar\eta)$ be the lexicographically least triple (γ, κ, η) such that

- κ is a regular cardinal in M greater than $|\mathcal{P}(\mathcal{P}(\omega_1)/I)|^M$,
- $\eta < \kappa$,
- there is an iteration $\langle N_\alpha, G_\beta, j_{\alpha\delta} : \beta < \alpha \leq \delta \leq \gamma\rangle$ of $(H(\kappa)^M, I)$ such that $j_{0\gamma}(\eta)$ is not wellfounded.

Since I is precipitous in M, $\bar\gamma$ is a limit ordinal, and clearly $\bar\eta$ is a limit ordinal as well. Fix an iteration $\langle N_\alpha, G_\beta, j_{\alpha\delta} : \beta < \alpha \leq \delta \leq \bar\gamma\rangle$ of $(H(\bar\kappa)^M, I)$ such that $j_{0\bar\gamma}(\bar\eta)$ is not wellfounded, and let $\langle M_\alpha, G_\beta, j'_{\alpha\delta} : \beta < \alpha \leq \delta \leq \bar\gamma\rangle$ be the corresponding iteration of M as in Lemma 1.5. By the minimality of $\bar\gamma$ we have that M_α is wellfounded for all $\alpha < \bar\gamma$. Since $N_{\bar\gamma}$ is the direct limit of the iteration leading up to it, we may fix $\gamma^* < \bar\gamma$ and $\eta^* < j_{0\gamma^*}(\bar\eta)$ such that $j_{\gamma^*\bar\gamma}(\eta^*)$ is not wellfounded. By Lemma 1.5, $j'_{\gamma^*,\bar\gamma}(\eta^*) = j_{\gamma^*,\bar\gamma}(\eta^*)$ and $j'_{\gamma^*,\bar\gamma}(\bar\eta) = j'_{\gamma^*,\bar\gamma}(\bar\eta)$.



The key point is that if N is a model of ZFC°, J is a normal ideal on ω_1^N in N, γ is an ordinal and η is an ordinal in N, then the statement positing an iteration of (N, J) of length γ whose last model is illfounded below the image of η is a Σ^1_1 sentence in a real parameter recursively coding N, η and γ, and so this statement is absolute between wellfounded models of ZFC° containing such a real. In particular, if

- N is a transitive model of ZFC° + Power Set,
- J is a normal ideal on ω_1^N in N,
- κ is a regular cardinal in N greater than $|\mathcal{P}(\mathcal{P}(\omega_1))|^N$,
- $\eta < \kappa$ and γ are ordinals in N and $\beta \in N$ is an ordinal greater than or equal to $\max\{(2^\kappa)^N, \gamma\}$,

then if G is N-generic for $\mathrm{Col}(\omega, \beta)$, then $N[G]$ satisfies the correct answer for the assertion that there exists an iteration of $(H(\kappa)^N, J)$ of length γ whose last model is illfounded below the image of η. Let $\phi(\gamma, \kappa, \eta, J)$ be the formula asserting that

- J is a normal ideal on ω_1,
- κ is a regular cardinal greater than $|\mathcal{P}(\mathcal{P}(\omega_1))|$,
- $\eta < \kappa$,
- letting $\beta = \max\{2^\kappa, \gamma\}$, every condition (equivalently, some condition) in $\mathrm{Col}(\omega, \beta)$ forces that there exists an iteration of $(H(\kappa), J)$ of length γ whose last model is illfounded below the image of η.

Then, in M, $(\bar{\gamma}, \bar{\kappa}, \bar{\eta})$ is the lexicographically least triple (γ, κ, η) such that $\phi(\gamma, \kappa, \eta, I)$ holds. Furthermore, since $j'_{0\gamma^*}$ is elementary, in M_{γ^*},

$$(j'_{0\gamma^*}(\bar{\gamma}), j'_{0\gamma^*}(\bar{\kappa}), j'_{0\gamma^*}(\bar{\eta}))$$

is the least triple (γ, κ, η) such that $\phi(\gamma, \kappa, \eta, j'_{0\gamma^*}(I))$ holds. However, the tail of the iteration $\langle N_\alpha, G_\beta, j_{\alpha\delta} : \beta < \alpha \leq \delta \leq \bar{\gamma}\rangle$ starting with N_{γ^*} is an iteration of

$$(H(j_{0\gamma^*}(\bar{\kappa}))^{M_{\gamma^*}}, j_{0\gamma^*}(I))$$

(note that $j'_{0\gamma^*}(H(\bar{\kappa})^M) = j_{0,\gamma^*}(H(\bar{\kappa})^M)$) of length less than or equal to $\bar{\gamma}$ which in turn is less than or equal to $j'_{0\gamma^*}(\bar{\gamma})$. Furthermore, $\eta^* < j'_{0\gamma}(\bar{\eta}) = j_{0\gamma}(\bar{\eta})$, and $j_{\gamma^*\bar{\gamma}}(\eta^*)$ is not wellfounded, which, by the correctness property mentioned above (using the fact that M_{γ^*} is wellfounded) contradicts the minimality of $j'_{0\gamma^*}(\bar{\eta})$. ⊣

1.7 Example. Let M be any countable transitive model of ZFC in which there exists a measurable cardinal κ and a normal measure $\mu \in M$ on κ such that all countable iterates of M by μ are wellfounded. Iterating M by μ ω_1

times, we obtain a model N of ZFC containing ω_1 such that $(V_\kappa)^M = (V_\kappa)^N$. Now suppose that I is a normal precipitous ideal on ω_1^M in M. By Lemmas 1.5 and 1.6, $((V_\kappa)^M, I)$ iterable.

Before moving on, we prove an important fact about iterations of iterable models which will show up later (in Lemmas 3.3, 6.2 and 7.4). This fact is a key step in Woodin's proof of Theorem 0.3.

1.8 Lemma. *Suppose that M is a countable transitive model of* ZFC° *and $I \in M$ is a normal ideal on ω_1^M such that the pair (M, I) is iterable. Let x be a real coding the pair (M, I) under some recursive coding. Let*

$$\mathcal{I} = \langle M_\alpha, G_\beta, j_{\alpha\delta} : \beta < \alpha \leq \delta \leq \omega_1 \rangle$$

be an iteration of (M, I). Then every countable ordinal γ such that $L_\gamma[x]$ satisfies ZFC *is on the critical sequence of $\mathcal{I}$.*

Proof. Fix a countable ordinal γ such that $L_\gamma[x] \models$ ZFC. We want to see that for every $\eta < \gamma$ there is a $\delta < \gamma$ such that the ordinals of the final model of every iteration of (M, I) of length η are contained in δ. To see this, fix η and let $g \subseteq \mathrm{Col}(\omega, \eta)$ be $L_\gamma[x]$-generic. Then $L_\gamma[x][g] \models$ ZFC, and in $L_\gamma[x][g]$, the set of ordertypes of the ordinals of iterates of (M, I) by iterations of length η is a Σ^1_1 set in a real coding (M, I) and g. By the boundedness lemma for $\utilde{\Sigma}^1_1$ sets of wellorderings (see [26]), then, there is a countable (in $L_\gamma[x][g]$) ordinal δ such that all of these ordertypes are less than δ. Furthermore, the nonexistence of an iteration of (M, I) of length η such that δ can be embedded in an order-preserving way into the ordinals of the final model is absolute between $L_\gamma[x][g]$ and V, by $\utilde{\Sigma}^1_1$-absoluteness. ⊣

Lemma 1.8 has the following useful corollary. The case where γ is countable follows immediately from Lemma 1.8. The case where $\gamma = \omega_1$ follows by applying the countable case to a forcing extension where ω_1 is collapsed.

1.9 Corollary. *Suppose that M is a countable transitive model of* ZFC°*, I is normal ideal on ω_1^M in M, (M, I) is iterable and x is a real coding (M, I). Suppose that γ is an x-indiscernible less than or equal to ω_1, and let $j : (M, I) \to (M^*, I^*)$ be an iteration of (M, I) of length γ. Then the ordinals of M^* have height less than the least x-indiscernible above γ.*

We note one more useful fact about sharps. The fact can be proved directly using the remarkable properties of sharps, or by noting that the two functions implicit in the fact necessarily represent the same ordinal in any generic ultrapower.

1.10 Fact. Let x be a real and let γ be the least x-indiscernible above ω_1. Let $\pi : \omega_1 \to \gamma$ be a bijection. Then the set of $\alpha < \omega_1$ such that the ordertype of $\{\pi(\beta) : \beta < \alpha\}$ is the least x-indiscernible above α contains a club.

1.11 Remark. If there exists a precipitous ideal on ω_1, then $A^{\#}$ exists for every $A \subseteq \omega_1$. To see this, note first of all that the existence of a precipitous ideal implies that for each real x there is an nontrivial elementary embedding from $L[x]$ to $L[x]$ in a forcing extension, which means that $x^{\#}$ exists already in the ground model. Furthermore, if I is a precipitous ideal on ω_1 and $j : V \to M$ is the generic embedding derived from a V-generic filter $G \subseteq \mathcal{P}(\omega_1)/I$, then $\mathcal{P}(\omega_1)^V \subseteq H(\omega_1)^M$. Therefore, for every $A \in \mathcal{P}(\omega_1)^V$, $A \in M$ and $M \models$ "$A^{\#}$ exists". Since M and $V[G]$ have the same ordinals, $V[G]$ and V then must also satisfy "$A^{\#}$ exists".

Similarly, if (M, I) is an iterable pair, then M is correct about the sharps of the reals of M, since M is elementarily embedded into a transitive model containing ω_1, and thus M is correct about the sharps of the members of $\mathcal{P}(\omega_1)^M$. In particular, if (M, I) is an iterable pair and A is in $\mathcal{P}(\omega_1)^M$, then $\mathcal{P}(\omega_1)^{L[A]} \subseteq M$, so M correctly computes $\omega_1^{L[A]}$.

2. $\mathbb{P}_{\max}$

We are now ready to define the partial order $\mathbb{P}_{\max}$. We will make one modification of the definition given in [39] and require the conditions to satisfy ZFC° instead of the theory ZFC* defined in [39]. Our $\mathbb{P}_{\max}$ is a dense suborder of the original; furthermore, the basic analysis of the two partial orders is the same, though the proofs of Lemma 7.6 and Theorem 7.7 are less elegant than they might otherwise be.

Recall that $\mathrm{MA}_{\aleph_1}$ is the version of Martin's Axiom for $\aleph_1$-many dense sets, i.e., the statement that whenever P is a c.c.c. partial order and D_α ($\alpha < \omega_1$) are dense subsets of P there is a filter $G \subseteq P$ intersecting each D_α.

2.1 Definition. The partial order $\mathbb{P}_{\max}$ consists of all pairs $\langle (M, I), a\rangle$ such that

1. M is a countable transitive model of ZFC°+ $\mathrm{MA}_{\aleph_1}$,
2. $I \in M$ and in M, I is a normal ideal on ω_1,
3. (M, I) is iterable,
4. $a \in \mathcal{P}(\omega_1)^M$,
5. there exists an $x \in \mathcal{P}(\omega)^M$ such that $\omega_1^M = \omega_1^{L[a,x]}$.

The order on $\mathbb{P}_{\max}$ is as follows: $\langle (M, I), a\rangle < \langle (N, J), b\rangle$ if $N \in H(\omega_1)^M$ and there exists an iteration $j : (N, J) \to (N^*, J^*)$ such that

- $j(b) = a$,
- $j, N^* \in M$,
- $I \cap N^* = J^*$.

We say that a pair (M, I) is a ($\mathbb{P}_{\max}$) *pre-condition* if there exists an a such that $\langle (M, I), a\rangle$ is in $\mathbb{P}_{\max}$.

2.2 Remark. If $\langle (M, I), a\rangle$ is a $\mathbb{P}_{\max}$ condition, then M is closed under sharps for reals (see Remark 1.11), and so a cannot be in $L[x]$ for any real x in M. Therefore, a is unbounded in ω_1^M, and this in turn implies that the iteration witnessing that a given $\mathbb{P}_{\max}$ condition $\langle (M, I), a\rangle$ is stronger than another condition $\langle (N, J), b\rangle$ must have length ω_1^M.

2.3 Remark. To see that the order on $\mathbb{P}_{\max}$ is transitive, let j_0 be an iteration witnessing that $\langle (M_1, I_1), a_1\rangle < \langle (M_0, I_0), a_0\rangle$ and let j_1 be an iteration witnessing that $\langle (M_2, I_2), a_2\rangle < \langle (M_1, I_1), a_1\rangle$. Then j_0 is an element of M_1, and it is not hard to check that $j_1(j_0)$ witnesses that $\langle (M_2, I_2), a_2\rangle < \langle (M_0, I_0), a_0\rangle$.

2.4 Remark. The requirement that the models in $\mathbb{P}_{\max}$ conditions satisfy $\mathrm{MA}_{\aleph_1}$ is used for a particular consequence of $\mathrm{MA}_{\aleph_1}$ known as *almost disjoint coding* [12]. That is, it follows from $\mathrm{MA}_{\aleph_1}$ that if $Z = \{z_\alpha : \alpha < \omega_1\}$ is a collection of infinite subsets of ω whose pairwise intersections are finite (i.e., Z is an *almost disjoint family*), then for each $B \subseteq \omega_1$ there exists a $y \subseteq \omega$ such that for all $\alpha < \omega_1$, $\alpha \in B$ if and only if $y \cap z_\alpha$ is infinite. This will be used to show that if $\langle (M, I), a\rangle$ is a $\mathbb{P}_{\max}$ condition, then any iteration of (M, I) is uniquely determined by the image of a (see Lemma 2.7), so that there is a unique iteration witnessing the order on each pair of comparable conditions. One can vary $\mathbb{P}_{\max}$ by removing condition (5) and the requirement that $\mathrm{MA}_{\aleph_1}$ holds, and replace a with a set of iterations of smaller models into M, as in the definition of the order, satisfying this uniqueness condition. Alternately, one can require that the models satisfy the statement ψ_{AC} (see Definition 6.1 and Remark 6.4), which implies that the image of any stationary, co-stationary subset of ω_1 under an iteration determines the entire iteration.

2.5 Remark. Instead of using ideals on ω_1, we could use the stationary tower $\mathbb{Q}_{<\delta}$ (see [19]) to produce the iterations giving the order on conditions. This gives us another degree of freedom in choosing our models, since in this case a small forcing extension of a condition is also a condition, roughly speaking. The resulting extension is essentially identical.

2.6 Remark. Given a real x, $x^\dagger$ ("x dagger") is a real such that in $L[x^\dagger]$ there exists a transitive model M of ZFC containing $\omega_1^V \cup \{x\}$ in which some ordinal countable in $L[x^\dagger]$ is a measurable cardinal (see [14]; this fact about $x^\dagger$ does not characterize it, but it is its only property that we require in this chapter). By [11], if there exists a measurable cardinal, then there is a partial order forcing that NS_{ω_1} is precipitous. By [22, 13], c.c.c. forcings preserve precipitousness of NS_{ω_1}. Essentially the same arguments show that if κ is a measurable cardinal and P is a c.c.c. forcing in the $\mathrm{Col}(\omega, {<}\kappa)$-extension, then there is a normal precipitous ideal on ω_1 (which is κ) in the $\mathrm{Col}(\omega, {<}\kappa) * P$-extension. By Lemmas 1.5 and 1.6, then, the statement that

$x^\dagger$ exists for each real x implies that every real exists in the model M of some $\mathbb{P}_{\max}$ condition, and, by Lemma 2.8 below, densely many. However, the full strength of $\mathbb{P}_{\max}$ will require the consistency strength of significantly larger cardinals.

We will now prove two facts about iterations which are central to the $\mathbb{P}_{\max}$ analysis.

2.7 Lemma. *Let $\langle(M,I),a\rangle$ be a $\mathbb{P}_{\max}$ condition and let A be a subset of ω_1. Then there is at most one iteration of (M,I) for which A is the image of a. Furthermore, this iteration is in $L[\langle(M,I),a\rangle,A]$, if it exists.*

Proof. Fix a real x in M such that $\omega_1^M=\omega_1^{L[a,x]}$, and let $Z=\langle z_\alpha:\alpha<\omega_1^M\rangle$ be the almost disjoint family defined recursively from the constructibility order in $L[a,x]$ on $\mathcal{P}(\omega)^{L[a,x]}$ by letting z_α be the constructibly (in $L[a,x]$) least infinite $z\subseteq\omega$ almost disjoint from each z_β ($\beta<\alpha$) such that for no finite $a\subseteq\alpha$ does $\bigcup\{z_\beta:\beta\in a\}$ contain the complement of z (modulo finite). Suppose that

$$\mathcal{I}=\langle M_\alpha,G_\beta,j_{\alpha\delta}:\beta<\alpha\le\delta\le\gamma\rangle$$

and

$$\mathcal{I}'=\langle M'_\alpha,G'_\beta,j'_{\alpha\delta}:\beta<\alpha\le\delta\le\gamma'\rangle$$

are two iterations of (M,I) such that $j_{0\gamma}(a)=A=j'_{0\gamma'}(a)$. Then $j_{0\gamma}(Z)=j'_{0\gamma'}(Z)$ (this uses Remark 1.11 to see that the constructibility order on reals in $L[A,x]$ is computed correctly in M_γ and $M'_{\gamma'}$). Let $\langle z_\alpha:\alpha<j_{0\gamma}(\omega_1^M)\rangle$ enumerate $j_{0\gamma}(Z)$.

Without loss of generality, $\gamma\le\gamma'$. We show by induction on $\alpha<\gamma$ that, for each such α, $G_\alpha=G'_\alpha$. This will suffice. Fix α and suppose that

$$\{G_\beta:\beta<\alpha\}=\{G'_\beta:\beta<\alpha\}.$$

Then $M_\alpha=M'_\alpha$. For each $B\in\mathcal{P}(\omega_1)^{M_\alpha}$, $B\in G_\alpha$ if and only if $\omega_1^{M_\alpha}\in j_{\alpha(\alpha+1)}(B)$, and $B\in G'_\alpha$ if and only if $\omega_1^{M_\alpha}\in j'_{\alpha(\alpha+1)}(B)$. Applying almost disjoint coding, fix $x\in\mathcal{P}(\omega)^{M_\alpha}$ such that for all $\eta<\omega_1^{M_\alpha}$, $\eta\in B$ if and only if $x\cap z_\eta$ is infinite. Then $B\in G_\alpha$ if and only if $x\cap z_{\omega_1^M}$ is infinite if and only if $B\in G'_\alpha$.

For the last part of the lemma, note that the argument just given gives a definition for each G_α in terms of A, x and the iteration up to α. ⊣

One consequence of Lemma 2.7 is that, if $G\subseteq\mathbb{P}_{\max}$ is an $L(\mathbb{R})$-generic filter, and $A=\bigcup\{a\mid\langle(M,I),a\rangle\in G\}$, then $L(\mathbb{R})[G]=L(\mathbb{R})[A]$. Therefore, the $\mathbb{P}_{\max}$ extension of $L(\mathbb{R})$ satisfies the sentence "$V=L(\mathcal{P}(\omega_1))$" (see the discussion at the beginning of Sect. 5).

2.8 Lemma (ZFC°). *If (M,I) is a pre-condition in $\mathbb{P}_{\max}$ and J is a normal ideal on ω_1 then there exists an iteration $j:(M,I)\to(M^*,I^*)$ such that $j(\omega_1^M)=\omega_1$ and $I^*=J\cap M^*$.*

Proof. First let us note that if $\langle M_\alpha, G_\beta, j_{\alpha\delta} : \beta < \alpha \leq \delta \leq \omega_1 \rangle$ is any iteration of (M, I), then $j_{0\omega_1}(I) \subseteq J \cap M_{\omega_1}$. To see this, note that if $E \in j_{0\omega_1}(I)$, then $E \in M_{\omega_1}$ and $E = j_{\alpha\omega_1}(E')$ for some $\alpha < \omega_1$ and $E' \in j_{0\alpha}(I)$. Then for all $\beta \in [\alpha, \omega_1)$, $j_{\alpha\beta}(E') \notin G_\beta$, so $\omega_1^{M_\beta} \notin E$. Therefore, E is nonstationary, so $E \in J$ by the normality of J.

Now, noting that J is a normal ideal, let $\{A_{i\alpha} : i < \omega, \alpha < \omega_1\}$ be a collection of pairwise disjoint members of $\mathcal{P}(\omega_1) \setminus J$. We build an iteration $\langle M_\alpha, G_\beta, j_{\alpha\delta} : \beta < \alpha \leq \delta \leq \omega_1 \rangle$ by recursively choosing the G_β's. As we do this, for each $\alpha < \omega_1$ we let the set $\{B_i^\alpha : i < \omega\}$ enumerate $\mathcal{P}(\omega_1)^{M_\alpha} \setminus j_{0\alpha}(I)$. Given

$$\langle M_\alpha, G_\beta, j_{\alpha\delta} : \beta < \alpha \leq \delta \leq \gamma \rangle,$$

then, for some $\gamma \leq \omega_1$, if $\omega_1^{M_\gamma} \in A_{i\alpha}$ for some $i < \omega$ and $\alpha \leq \gamma$, then (noting that there can be at most one such pair (i, α)) we let G_γ be any M_γ-generic filter for $(\mathcal{P}(\omega_1)/j_{0\gamma}(I))^{M_\gamma}$ with $j_{\alpha\gamma}(B_i^\alpha)$ as a member. If $\omega_1^{M_\gamma}$ is not in $A_{i\alpha}$ for any $i < \omega$ and $\alpha \leq \gamma$, then we let G_γ be any M_γ-generic filter.

To see that this construction works, fix $E \in \mathcal{P}(\omega_1)^{M_{\omega_1}} \setminus j_{0\omega_1}(I)$. We need to see that E is not in J. We may fix $i < \omega$ and $\alpha < \omega_1$ such that $E = j_{\alpha\omega_1}(B_i^\alpha)$. Then $F = (A_{i\alpha} \cap \{\omega_1^{M_\beta} : \beta \in [\alpha, \omega_1)\}) \subseteq E$. Since F is the intersection of a club and set not in J, F is not in J, so E is not in J. ⊣

The construction in the proof of Lemma 2.8 appears repeatedly in the analysis of $\mathbb{P}_{\max}$. In order to make our presentation of $\mathbb{P}_{\max}$ more modular (i.e., to avoid having to write out the proof of Lemma 2.8 repeatedly), we give the following strengthening of the lemma in terms of games. We note that the games defined here (and before Lemmas 3.5 and 5.2 and at the end of Sect. 10.2) are not part of Woodin's original presentation of $\mathbb{P}_{\max}$.

Suppose that (M, I) is a pre-condition in $\mathbb{P}_{\max}$, let J be a normal ideal on ω_1 and let B be a subset of ω_1. Let $\mathcal{G}((M, I), J, B)$ be the following game of length ω_1 where Players I and II collaborate to build an iteration

$$\langle M_\alpha, G_\beta, j_{\alpha\delta} : \beta < \alpha \leq \delta \leq \omega_1 \rangle$$

of (M, I) of length ω_1. In each round α, if $\alpha \in B$, then Player I chooses a set A_α in $\mathcal{P}(\omega_1)^{M_\alpha} \setminus j_{0\alpha}(I)$ and then Player II chooses an M_α-generic filter G_α contained in $(\mathcal{P}(\omega_1)/j_{0\alpha}(I))^{M_\alpha}$ with $A_\alpha \in G_\alpha$. If $\alpha \notin B$, then Player II chooses any M_α-generic filter $G_\alpha \subseteq (\mathcal{P}(\omega_1)/j_{0\alpha}(I))^{M_\alpha}$. After all ω_1 many rounds have been played, Player I wins if $j_{0\omega_1}(I) = J \cap M_{\omega_1}$.

The proof of Lemma 2.9 is almost identical to the proof of Lemma 2.8.

2.9 Lemma (ZFC°). *Suppose that (M, I) is a pre-condition in $\mathbb{P}_{\max}$, let J be a normal ideal on ω_1, and let B be a subset of ω_1. Then Player* I *has a winning strategy in $\mathcal{G}((M, I), J, B)$ if and only if $B \notin J$.*

Using Remark 2.6 and Lemmas 2.7 and 2.8, we can show that $\mathbb{P}_{\max}$ is homogeneous and countably closed. By *homogeneity* we mean the following property: for each pair of conditions p_0, p_1 in $\mathbb{P}_{\max}$ there exist conditions q_0, q_1

such that $q_0 \leq p_0$, $q_1 \leq p_1$ and the suborders of $\mathbb{P}_{\max}$ below the conditions q_0 and q_1 are isomorphic. The importance of this property is that it implies that the theory of the $\mathbb{P}_{\max}$ extension can be computed in the ground model.

2.10 Lemma. *If $x^\dagger$ exists for each real x, then $\mathbb{P}_{\max}$ is homogeneous.*

Proof. Let $p_0 = \langle (M_0, I_0), a_0\rangle$ and $p_1 = \langle (M_1, I_1), a_1\rangle$ be conditions in $\mathbb{P}_{\max}$. By Remark 2.6, we can fix a pre-condition (N, J) with $p_0, p_1 \in H(\omega_1)^N$. Applying Lemma 2.8 in N, we may fix iterations $j_0 : (M_0, I_0) \to (M_0^*, I_0^*)$ and $j_1 : (M_1, I_1) \to (M_1^*, I_1^*)$ in N such that $I_0^* = J \cap M_0^*$ and $I_1^* = J \cap M_1^*$. Letting $a_0^* = j_0(a_0)$ and $a_1^* = j_1(a_1)$, then,

$$q_0 = \langle (N, J), a_0^*\rangle$$

and

$$q_1 = \langle (N, J), a_1^*\rangle$$

are conditions in $\mathbb{P}_{\max}$ and j_0 and j_1 witness that $q_0 \leq p_0$ and $q_1 \leq p_1$ respectively.

Now, if $q_0' = \langle (N', J'), a'\rangle$ is a condition below q_0, then there is an iteration $j' : (N, J) \to (N^*, J^*)$ witnessing this. Then $a' = j'(a_0^*)$, and $q_1' = \langle (N', J'), j'(a_1^*)\rangle$ is a condition below q_1. Let π be the map with domain the suborder of $\mathbb{P}_{\max}$ below q_0 which sends each $\langle (N', J'), a'\rangle$ to the corresponding $\langle (N', J'), j'(a_1^*)\rangle$ as above. By Lemma 2.7, this map is an isomorphism between the suborders below q_0 and q_1 respectively. ⊣

In order to show that $\mathbb{P}_{\max}$ is countably closed, we must define a new class of iterations.

3. Sequences of Models and Countable Closure

For each $i < \omega$, let $p_i = \langle (M_i, I_i), a_i\rangle$ be a $\mathbb{P}_{\max}$ condition, and for each such i let $j_{i(i+1)} : (M_i, I_i) \to (M_i^*, I_i^*)$ be an iteration witnessing that $p_{i+1} < p_i$. Let $\{j_{ik} : i \leq k < \omega\}$ be the commuting family of embeddings generated by the $j_{i(i+1)}$'s. Let $a = \bigcup\{a_i : i < \omega\}$. By Lemma 2.7, for each $i < \omega$ there is a unique iteration $j_{i\omega} : (M_i, I_i) \to (N_i, J_i)$ sending a_i to a. Since each (M_i, I_i) is iterable, each N_i is wellfounded, and the structure $(\langle (N_i, J_i) : i < \omega\rangle, a)$ satisfies the following definition.

3.1 Definition. A *limit sequence* is a pair $(\langle (N_i, J_i) : i < \omega\rangle, a)$ such that the following hold for all $i < \omega$:

1. N_i is a countable transitive model of ZFC°,
2. $J_i \in N_i$ and in N_i, J_i is a normal ideal on ω_1,
3. $\omega_1^{N_i} = \omega_1^{N_0}$,
4. for all $k < i$, $N_k \in H(\omega_2)^{N_i}$,

5. for all $k < i$, $J_k = J_i \cap N_k$,

6. $a \in \mathcal{P}(\omega_1)^{N_0}$,

7. there exists an $x \in \mathcal{P}(\omega)^{N_0}$ such that $\omega_1^{N_0} = \omega_1^{L[a,x]}$.

A structure $\langle (N_i, J_i) : i < \omega \rangle$ is a *pre-limit sequence* if there exists a set a such that $(\langle (N_i, J_i) : i < \omega \rangle, a)$ is a limit sequence.

If we write a sequence as $\langle N_k : k < \omega \rangle$ (as we will in Sect. 10.1), the ideals are presumed to be the nonstationary ideal on ω_1.

If p_i $(i < \omega)$ is a descending sequence of $\mathbb{P}_{\max}$ conditions, then the *limit sequence corresponding to* p_i $(i < \omega)$ is the structure

$$(\langle (N_i, J_i) : i < \omega \rangle, a)$$

defined above. In this case each $\langle (N_i, J_i), a \rangle$ is a condition in $\mathbb{P}_{\max}$.

If $\langle (N_i, J_i) : i < \omega \rangle$ is a pre-limit sequence, then a filter

$$G \subseteq \bigcup \{ \mathcal{P}(\omega_1)^{N_i} \setminus J_i : i < \omega \}$$

is a $\bigcup \{ N_i : i < \omega \}$-*normal ultrafilter* for the sequence if for every regressive function f on $\omega_1^{N_0}$ in any N_i, f is constant on some member of G. Given such G and $\langle (N_i, J_i) : i < \omega \rangle$, we form the ultrapower of the sequence by letting N_i^* be the ultrapower of N_i formed from G and *all* functions $f : \omega_1^{N_0} \to N_i$ existing in any N_k (this ensures that the image of each N_i in the ultrapower of each N_k $(k > i)$ is the same as the ultrapower of N_i). As usual, we identify the transitive parts of each N_i^* with their transitive collapses. If (for each $i < \omega$) we let j_i^* be the induced embedding of N_i into N_i^* then for each $i < k < \omega$, $j_i^* = j_k^* \restriction N_i$, so we can let $j^* = \bigcup \{ j_i^* : i < \omega \}$ be the embedding corresponding to the ultrapower of the sequence.

3.2 Definition. Let $\langle (N_i, J_i) : i < \omega \rangle$ be a pre-limit sequence, and let γ be an ordinal less than or equal to ω_1. An *iteration* of $\langle (N_i, J_i) : i < \omega \rangle$ of length γ consists of pre-limit sequences $\langle (N_i^\alpha, J_i^\alpha) : i < \omega \rangle$ $(\alpha \leq \gamma)$, normal ultrafilters G_α $(\alpha < \gamma)$ and a commuting family of embeddings $j_{\alpha\beta}$ $(\alpha \leq \beta \leq \gamma)$ such that

- $\langle (N_i^0, J_i^0) : i < \omega \rangle = \langle (N_i, J_i) : i < \omega \rangle$,
- for all $\alpha < \gamma$, $G_\alpha \subseteq \bigcup \{ \mathcal{P}(\omega_1)^{N_i^\alpha} \setminus J_i^\alpha : i < \omega \}$ is a normal ultrafilter for the sequence $\langle (N_i^\alpha, J_i^\alpha) : i < \omega \rangle$, and $j_{\alpha(\alpha+1)}$ is the corresponding embedding,
- for each limit ordinal $\beta \leq \gamma$, $\langle (N_i^\beta, J_i^\beta) : i < \omega \rangle$ is the direct limit of the system $\{ \langle (N_i^\alpha, J_i^\alpha) : i < \omega \rangle, j_{\alpha\delta} : \alpha \leq \delta < \beta \}$ and for each $\alpha < \beta$ $j_{\alpha\beta}$ is the induced embedding.

As with iterations of single models, we sometimes describe an iteration of a pre-limit sequence by fixing only the initial sequence, the final sequence and the embedding between them. An *iterate* of a pre-limit sequence $\bar{p}$ is a pre-limit sequence appearing in an iteration of $\bar{p}$. If every iterate of a pre-limit sequence is wellfounded, then the sequence is *iterable*.

By Lemma 1.8 and Corollary 1.9, pre-limit sequences derived from descending chains $\{\langle (M_i, I_i), a_i\rangle : i < \omega\}$ in $\mathbb{P}_{\max}$ satisfy the hypotheses of the following lemma, letting x_i be any real in M_{i+1} coding M_i. Yet another way to vary $\mathbb{P}_{\max}$ is to replace the model M in the definition of $\mathbb{P}_{\max}$ conditions with sequences satisfying this hypothesis. This approach is used for the order $\mathbb{Q}^*_{\max}$ defined in Sect. 10.1.

3.3 Lemma. *Suppose that $\bar{p} = \langle (N_i, J_i) : i < \omega\rangle$ is a pre-limit sequence, and suppose that for each $i < \omega$ there is a real $x_i \in N_{i+1}$ such that $x_i^{\#} \in N_{i+1}$ and*

- *the least x_i-indiscernible above $\omega_1^{N_0}$ is greater than the ordinal height of N_i,*
- *every club subset of $\omega_1^{N_0}$ in N_i contains a tail of the x_i-indiscernibles below $\omega_1^{N_0}$.*

Then $\bar{p}$ is iterable.

Proof. First we will show that any iterate of $\bar{p}$ is wellfounded if its version of ω_1 is wellfounded. Then we will show that the ω_1 of each iterate of $\bar{p}$ is wellfounded.

For the first part, if $\langle (N_i^*, J_i^*) : i < \omega\rangle$ is an iterate of $\bar{p}$, then by elementarity the ordinals of each N_i^* embed into the least x_i-indiscernible above $\omega_1^{N_0^*}$. So, if $\omega_1^{N_0^*}$ is actually an ordinal (i.e., is wellfounded), then N_{i+1}^* constructs this next x_i-indiscernible correctly, and so N_i^* is wellfounded.

We prove the second part by induction on the length of the iteration, noting that the limit case follows immediately, and the successor case follows from the case of an iteration of length 1. What we want to see is that if G is a normal ultrafilter for $\bar{p}$ and j is the induced embedding, then $j(\omega_1^{N_0}) = \bigcup\{N_i \cap \mathrm{On} : i < \omega\}$. Notice that for each x_i, if $f_i : \omega_1^{N_0} \to \omega_1^{N_0}$ is defined by letting $f_i(\alpha)$ be the least x_i-indiscernible above α, then $j(f_i)(\omega_1^{N_0})$ is the least indiscernible of x_i above $\omega_1^{N_0}$. Thus

$$j(\omega_1^{N_0}) \geq \sup\{j(f_i)(\omega_1^{N_0}) : i < \omega\} = \bigcup\{N_i \cap \mathrm{On} : i < \omega\}\,.$$

For the other direction, let $h : \omega_1^{N_0} \to \omega_1^{N_0}$ be a function in some N_i. Then the closure points of h contain a tail of the x_i-indiscernibles, which means that $f_i > h$ on a tail of the ordinals below $\omega_1^{N_0}$, so $[f_i]_G > [h]_G$. Thus $j(\omega_1^{N_0}) = \bigcup\{N_i \cap \mathrm{On} : i < \omega\}$. ⊣

The following lemma has essentially the same proof as Lemma 2.8, and shows (given that $x^\dagger$ exists for each real x) that $\mathbb{P}_{\max}$ is countably closed. The point is that if $\langle p_i : i < \omega\rangle$ is a descending sequence of $\mathbb{P}_{\max}$ conditions, letting $\bar{p} = (\langle (N_i, J_i) : i < \omega\rangle, a)$ be the limit sequence corresponding to $\langle p_i : i < \omega\rangle$, if (M, I) is a $\mathbb{P}_{\max}$ pre-condition with $\{p_i : i < \omega\}$, $\bar{p} \in H(\omega_1)^M$, then by letting j^* be an iteration of $\bar{p}$ resulting from applying Lemma 3.4 inside of M, the embedding $j^*(j_{i\omega})$ (where $j_{i\omega}$ is as defined in the first paragraph of this section) witnesses that $\langle (M, I), j^*(a)\rangle$ is below p_i in $\mathbb{P}_{\max}$, for each $i < \omega$.

3.4 Lemma (ZFC°). *Suppose that $\langle (N_i, J_i) : i < \omega\rangle$ is an iterable pre-limit sequence, and let I be a normal ideal on ω_1. Then there is an iteration*

$$j^* : \langle (N_i, J_i) : i < \omega\rangle \to \langle (N_i^*, J_i^*) : i < \omega\rangle$$

such that $j^*(\omega_1^{N_0}) = \omega_1$ and $J_i^* = I \cap N_i^*$ for each $i < \omega$.

Suppose that $\langle (N_i, J_i) : i < \omega\rangle$ is an iterable pre-limit sequence, let I be a normal ideal on ω_1, and let B be a subset of ω_1. Let

$$\mathcal{G}_\omega(\langle (N_i, J_i) : i < \omega\rangle, I, B)$$

be the following game of length ω_1 where Players I and II collaborate to build an iteration of $\langle (N_i, J_i) : i < \omega\rangle$ consisting of pre-limit sequences $\langle (N_i^\alpha, J_i^\alpha) : i < \omega\rangle$ $(\alpha \leq \omega_1)$, normal ultrafilters G_α $(\alpha < \omega_1)$ and a family of embeddings $j_{\alpha\beta}$ $(\alpha \leq \beta \leq \omega_1)$, as follows. In each round α, let

$$X_\alpha = \bigcup\{\mathcal{P}(\omega_1)^{N_i^\alpha} \setminus J_i^\alpha : i < \omega\}\,.$$

If $\alpha \in B$, then Player I chooses a set $A \in X_\alpha$, and then Player II chooses a $\bigcup\{N_i^\alpha : i < \omega\}$-normal filter G_α contained in X_α with $A \in G_\alpha$. If α is not in B, then Player II chooses any $\bigcup\{N_i^\alpha : i < \omega\}$-normal filter G_α contained in X_α. After all ω_1 many rounds have been played, Player I wins if $J_i^{\omega_1} = I \cap N_i^{\omega_1}$ for each $i < \omega$.

Lemma 3.4 can be rephrased in terms of games as follows.

3.5 Lemma (ZFC°). *Suppose that $\langle (N_i, J_i) : i < \omega\rangle$ is an iterable pre-limit sequence, let I be a normal ideal on ω_1 and let B be a subset of ω_1. Then Player* I *has a winning strategy in $\mathcal{G}_\omega(\langle (N_i, J_i) : i < \omega\rangle, I, B)$ if and only if $B \notin I$.*

At this point, we have gone as far with the $\mathbb{P}_{\max}$ analysis as daggers can take us.

4. Generalized Iterability

The following definition gives a generalized iterability property with respect to a given set of reals. In the $\mathbb{P}_{\max}$ analysis, these sets of reals often code $\mathbb{P}_{\max}$-names for sets of reals.

4.1 Definition. Let A be a set of reals. If M is a transitive model of ZFC° and I is an ideal on ω_1^M which is normal and precipitous in M, then the pair (M, I) is A-*iterable* if

- (M, I) is iterable,
- $A \cap M \in M$,
- $j(A \cap M) = A \cap M^*$ whenever $j : (M, I) \to (M^*, I^*)$ is an iteration of (M, I).

4.2 Remark. The definition of A-iterability in [39] is more general than this one, in ways which we will not require.

In order to achieve the full effects of forcing with $\mathbb{P}_{\max}$ over a given model (for now we will deal with $L(\mathbb{R})$) we need to see (and in fact it is enough to see) that for each $A \subseteq \mathbb{R}$ in the model there exists a $\mathbb{P}_{\max}$ pre-condition (M, I) such that

- (M, I) is A-iterable,
- $\langle H(\omega_1)^M, A \cap M\rangle \prec \langle H(\omega_1), A\rangle$.

As it turns out, the existence of such a condition for each $A \subseteq \mathbb{R}$ in $L(\mathbb{R})$ is equivalent to $\mathrm{AD}^{L(\mathbb{R})}$(see [39, pp. 285–290]).

There are two basic approaches to studying the $\mathbb{P}_{\max}$ extension. One can think of V as being a model of some form of determinacy, and use determinacy to analyze the $\mathbb{P}_{\max}$ forcing construction and its corresponding extension. Alternately, one can assume that Choice holds and certain large cardinals exist and use these large cardinals to analyze the $\mathbb{P}_{\max}$ extension of some inner model of ZF satisfying determinacy. Accordingly, the existence of A-iterable conditions (for a given set A) can be derived from determinacy or from large cardinals. We give here an example of each method, quoting some standard facts which we will briefly discuss.

The proof from large cardinals uses weakly homogeneous trees (see [26, 14] for more on the concepts reviewed briefly below). Recall that a *tree on* $\omega^k \times Z$ (for some integer k and some set Z) is a subset of the set of sequences of length $k+1$ whose first k elements are members of ω^n (for some integer n) and whose last element is in Z^n (as usual we require that if $\langle a_1, \ldots, a_k, u\rangle \in T$ and m is less than the length of a_1, then $\langle a_1 \restriction m, \ldots, a_k \restriction m, u \restriction m\rangle \in T$). Given such a tree T, the *projection of* T is the set of $\langle x_1, \ldots, x_k\rangle \in (\omega^\omega)^k$ for which there exists a $z \in Z^\omega$ such that for all integers n,

$$\langle x_1 \restriction n, \ldots, x_k \restriction n, z \restriction n\rangle$$

is in T.

Very briefly, a *countably complete tower* is a sequence of measures $\langle \sigma_i : i < \omega\rangle$ such that each σ_i is a measure on Z^i for some fixed underlying set

Z and for every sequence $\{A_i : i < \omega\}$ of sets such that each $A_i \in \sigma_i$ there exists a function $g \in Z^\omega$ such that $g{\restriction}i \in A_i$ for all $i < \omega$. Given a set Z, an integer k and a cardinal δ, a tree T on $\omega^k \times Z$ is *δ-weakly homogeneous* if there exists a countable family Σ of δ-complete measures on $Z^{<\omega}$ such that for each $\langle x_1, \ldots, x_k\rangle \in (\omega^\omega)^k$, $\langle x_1, \ldots, x_k\rangle \in p[T]$ if and only if there exists a sequence of measures $\{\sigma_i : i < \omega\} \subseteq \Sigma$ such that

- for all $i < \omega$, $\{z \in Z^i \mid \langle x_1{\restriction}i, \ldots, x_k{\restriction}i, z{\restriction}i\rangle \in T\} \in \sigma_i$,
- $\langle \sigma_i : i < \omega\rangle$ forms a countably complete tower.

A set of k-tuples of reals A is *δ-weakly homogeneously Suslin* if there exists a δ-weakly homogeneous tree T whose projection is A, and *weakly homogeneously Suslin* if it is δ-weakly homogeneously Suslin for some uncountable ordinal δ. For each integer k one can naturally code k-tuples of reals by single reals by interleaving coordinates. This induces an association of sets of k-tuples of reals to sets of reals which respects the property of being δ-weakly homogeneously Suslin for a given cardinal δ. This allows us to simplify notion in what follows and talk about weakly homogeneously Suslin sets of reals, knowing that these facts imply the same results for sets of k-sequences of reals.

The following fact is standard.

4.3 Theorem. *Let θ be a regular cardinal, suppose that $T \in H(\theta)$ is a weakly homogeneous tree on $\omega \times Z$ for some set Z. Let $\delta \geq 2^\omega$ be an ordinal such that there exists a countable collection Σ of δ^+-complete measures witnessing the weak homogeneity of T. Then for every elementary submodel Y of $H(\theta)$ of cardinality less than δ with $T, \Sigma \in Y$ there is an elementary submodel X of $H(\theta)$ containing Y such that $X \cap \delta = Y \cap \delta$, and such that, letting S be the image of T under the transitive collapse of X, $p[S] = p[T]$.*

Proof. Fixing θ, T, Σ and δ as in the statement of the theorem, the theorem follows from the following fact. Suppose that Y is an elementary submodel of $H(\theta)$ with $T, \Sigma \in Y$ and $|Y| < \delta$, and fix an $x \in p[T]$. Fix a countably complete tower $\{\sigma_i : i < \omega\} \subseteq \Sigma$ such that for all $i < \omega$, $\{a \in Z^i : (x{\restriction}i, a) \in T\} \in \sigma_i$, and for each $i < \omega$, let $A_i = \bigcap(\sigma_i \cap Y)$. Then since $\{\sigma_i : i < \omega\}$ is countably complete, there exists a $z \in Z^\omega$ such that for all $i < \omega$, $z{\restriction}i \in A_i$. Then the pair (x, z) forms a path through T, and, letting

$$Y[z] = \{f(z{\restriction}i) \mid i < \omega \wedge f : Z^i \to H(\theta) \wedge f \in Y\},$$

$Y[z]$ is an elementary submodel of $H(\theta)$ containing Y and $\{z{\restriction}i : i < \omega\}$, and, since each σ_i is δ^+-complete, $Y \cap \delta = Y[z] \cap \delta$. Repeated application of this fact for each real in the projection of T proves the theorem. ⊣

Proofs of the following facts about weakly homogeneous trees and weakly homogeneously Suslin sets of reals appear in [19]. Some of these facts follow directly from the definitions, and none are due to the author. Theorem 4.6 derives ultimately from [23].

4.4 Fact. For every cardinal δ, the collection of δ-weakly homogeneously Suslin sets of reals is closed under countable unions and continuous images.

4.5 Theorem (Woodin). *If δ is a limit of Woodin cardinals and there exists a measurable cardinal above δ then every set of reals in $L(\mathbb{R})$ is $<\delta$-weakly homogeneously Suslin (i.e., γ-weakly homogeneously Suslin for all $\gamma < \delta$).*

4.6 Theorem. *If δ is a cardinal and T is a δ-weakly homogeneous tree, then there is a tree S such that $p[T] = \omega^\omega \setminus p[S]$ in all forcing extensions by partial orders of cardinality less than δ (including the trivial one).*

4.7 Theorem (Woodin). *If δ is a Woodin cardinal and A is a δ^+-weakly homogeneously Suslin set of reals, then the complement of A is $<\delta$-weakly homogeneously Suslin.*

If S and T are trees whose projections are disjoint, then they remain disjoint in all forcing extensions, as there is a ranking function on the tree of attempts to build a real in both projections (likewise, the projection of a tree being nonempty is absolute to inner models containing the tree). This fact plus Theorem 4.6 gives the following corollary.

4.8 Corollary. *If δ is a cardinal and T_0 and T_1 are δ-weakly homogeneous trees with the same projection, then T_0 and T_1 still have the same projection in all forcing extensions by forcings of cardinality less than δ.*

Given a set of reals A, a set of reals B is *projective in A* if it can be defined by a projective formula (i.e., all unbounded quantifiers ranging over reals) with A as a parameter. Fact 4.4 and Theorem 4.7 together imply that if δ is a limit of Woodin cardinals then the set of $<\delta$-weakly homogeneously Suslin sets of reals is projectively closed. We separate out the following part of the proof of Theorem 4.10.

4.9 Lemma. *Let A be a set of reals, and suppose that M is a transitive model of* ZFC *such that for each set of reals B projective in A there exists a tree $S \in M$ such that $p[S] = B$. Then*

$$\langle H(\omega_1)^M, \in, A \cap M\rangle \prec \langle H(\omega_1), \in, A\rangle.$$

Proof. Let C denote the set of reals which code elements of $H(\omega_1)$ under our fixed coding (this set is Π_1 and hence absolute). Given a real x in C, let $c(x)$ be the element it codes. For each integer n and each formula ϕ in the language with one additional unary predicate with n free variables, the following are equivalent.

1. For all $a_1, \ldots, a_n \in H(\omega_1)^M$, $\langle H(\omega_1), \in, A\rangle \models \phi(a_1, \ldots, a_n)$ if and only if $\langle H(\omega_1)^M, \in, A \cap M\rangle \models \phi(a_1, \ldots, a_n)$.
2. For all $x_1, \ldots, x_n \in (C \cap M)$, $\langle H(\omega_1), \in, A\rangle \models \phi(c(x_1), \ldots, c(x_n))$ if and only if $\langle H(\omega_1)^M, \in, A \cap M\rangle \models \phi(c(x_1), \ldots, c(x_n))$.

3. For all trees $S \in M$ projecting in V to the set

$$\{\langle x_1, \ldots, x_n\rangle \in C^n \mid \langle H(\omega_1), \in, A\rangle \models \phi(c(x_1), \ldots, c(x_n))\},$$

$$p[S] \cap M = \{\langle x_1, \ldots, x_n\rangle \in (C \cap M)^n \mid \\ \langle H(\omega_1)^M, \in, A \cap M\rangle \models \phi(c(x_1), \ldots, c(x_n))\}.$$

We show by induction on the complexity of formulas that these sentences hold for every formula in our language. Let $\dot{A}$ be the additional unary predicate in this language. Then the sentences above clearly hold for the basic formulas $a \in b$, $a = b$ and $\dot{A}(a)$. The induction steps for $\wedge$, $\vee$ and $\neg$ are likewise immediate. For the quantifier $\exists$, suppose that ϕ has the form $\exists \dot{z}_1 \psi(\dot{z}_1, \ldots, \dot{z}_n)$, and let $x_2, \ldots, x_n$ be elements of $C \cap M$ such that $\langle H(\omega_1), \in, A\rangle \models \phi(c(x_2), \ldots, c(x_n))$. Let S be a tree in M projecting in V to the set of $\langle y_1, \ldots, y_n\rangle \in (C \cap M)^n$ such that $\langle H(\omega_1), \in, A\rangle \models \psi(c(y_1), \ldots, c(y_n))$. The existence of a real x_1 such that $\langle x_1, \ldots, x_n\rangle \in p[S]$ is absolute between M and V, which means that there is a real $x_1 \in C \cap M$ witnessing that $\langle H(\omega_1)^M, \in, A \cap M\rangle \models \phi(c(x_2), \ldots, c(x_n))$. ⊣

The following theorem is a generalized existence result which is useful in analyzing variations of $\mathbb{P}_{\max}$.

4.10 Theorem. *Let γ be a strongly inaccessible cardinal, let A be a set of reals, and suppose that θ is a strong limit cardinal of cofinality greater than ω_1 such that every set of reals projective in A is γ^+-weakly homogeneously Suslin as witnessed by a tree and a set of measures in $H(\theta)$. Let X be a countable elementary submodel of $H(\theta)$ with $\gamma, A \in X$, and let M be the transitive collapse of $X \cap H(\gamma)$. Let N be any forcing extension of M in which there exists a normal precipitous ideal I on ω_1^N. Let $j : (N, I) \to (N^*, I^*)$ be any iteration of (N, I). Then*

- *N^* is wellfounded,*
- *$N \cap A \in N$,*
- *$j(N \cap A) = N^* \cap A$,*
- *$\langle H(\omega_1)^{N^*}, A \cap N^*, \in\rangle \prec \langle H(\omega_1), A, \in\rangle$.*

Proof. Let $\{A_i : i < \omega\}$ be a listing in X of the sets of reals projective in A (with $A_0 = A$), and let $\{T_i : i < \omega\}$ and $\{\Sigma_i : i < \omega\}$ be sets in X such that each T_i is a γ^+-weakly homogeneous tree (as witnessed by Σ_i) projecting to A_i. By the proof of Theorem 4.3, there is an elementary submodel Y of $H(\theta)$ containing X such that $X \cap H(\gamma) = Y \cap H(\gamma)$ and such that, letting M^+ be the transitive collapse of Y, and letting, for each $i < \omega$, S_i be the image of T_i under this collapse, $p[S_i] = A_i$. Since there are sets projective in A which are not the projections of countable trees, $\omega_1 \subseteq M^+$. Now, let N be a forcing extension of M with I a normal precipitous ideal on ω_1^N in N, and let N^+ be the corresponding extension of M^+. Let $j : (N, I) \to (N^*, I^*)$ be an iteration of (N, I). By Lemmas 1.5 and 1.6, j extends to an iteration of (N^+, I) (which we will also call j), and N^* is wellfounded. Furthermore, for each $i < \omega$ there is a $j < \omega$ such that S_i and S_j project to complements. Then

- $p[S_i] \subseteq p[j(S_i)]$,
- $p[S_j] \subseteq p[j(S_j)]$,
- $p[j(S_i)] \cap p[j(S_j)] = \emptyset$,

which means that $p[S_i] = p[j(S_i)]$, so $j(N \cap A_i) = N^* \cap A_i$.

The last part of the theorem follows from Lemma 4.9. ⊣

Alternately, we can derive the existence of A-iterable conditions from determinacy. The proof from determinacy requires the following fact: if AD holds and Z is a set of ordinals, then there is an inner model of ZFC containing the ordinals with Z as a member in which some countable ordinal is a measurable cardinal. A tree of finite sequences of ordinals can easily be coded as a set of ordinals (see [27], for instance).

The following theorem of Woodin (see [15, Theorem 5.4]) is more than sufficient, but in the spirit of completeness we will not use it, since its proof is well beyond the scope of this chapter. Given a model M and a set X, HOD^M_X is the class of hereditarily ordinal definable sets (using X as a parameter), as computed in M. It is a standard fact that this model satisfies ZFC.

4.11 Theorem. *Assume* AD. *Suppose that Z is a set of ordinals. Then there exists a real x such that for all reals z with $x \in L[Z, z]$, $\omega_2^{L[Z,z]}$ is a Woodin cardinal in* $\mathrm{HOD}^{L[Z,z]}_{\{Z\}}$.

The following theorem is sufficient for our purposes.

4.12 Theorem. *Assume* AD. *For every subset Z of L, there is an inner model N of* ZFC *containing $\{Z\}$ and the ordinals such that some countable ordinal is measurable in N.*

Proof. For each increasing function $f : \omega \to \omega_1$, let $s(f)$ be the supremum of the range of f, and let $F(f)$ be the filter on $s(f)$ consisting of all subsets of $s(f)$ which contain all but finitely many members of the range of f. For each such f, let $N(f)$ be the inner model $L[Z, F(f)]$. We will find an f such that the restriction of $F(f)$ to $N(f)$ is a countably complete ultrafilter in $N(f)$, i.e., such that

(+) Every function from $s(f)$ to ω in $N(f)$ is constant on a set in $F(f)$.

Note the following facts.

1. If f_0 and f_1 are functions from ω to ω_1 whose ranges are the same modulo a finite set, then $F(f_0) = F(f_1)$ and so not only are the models $N(f_0)$ and $N(f_1)$ the same, but their canonical wellorderings are the same also.

2. Using the canonical wellordering of each $N(f)$, there is a function G choosing for each increasing $f : \omega \to \omega_1$ a function $G(f) : s(f) \to \omega$ failing condition (+) above, if one exists.

The key consequence of AD is the partition property $\omega_1 \to (\omega_1)^{\omega}_{\omega^\omega}$ (see [9] or [14, pp. 391–396]), which says that for every function from the set of increasing ω-sequences from ω_1 to ω^ω (the set of functions from ω to ω) there is an uncountable $E \subseteq \omega_1$ such that the function is constant on the set of increasing ω-sequences from E.

Now, for each increasing $f : \omega \to \omega_1$, let $P(f)$ be the constant function 0 if $F(f)$ satisfies condition (+) in $N(f)$. If f fails condition (+) in $N(f)$, then let $P(f)(0)$ be 1 and let $P(f)(n+1) = G(f)(f(n))$ for all $n \in \omega$. Let E be an uncountable subset of ω_1 such that $P(f)$ is the same for all increasing $f : \omega \to E$. We show that the constant value is the constant function 0. If the constant value corresponds to a failure of (+), then there is an $i : \omega \to \omega$ such that for all increasing $f : \omega \to E$, for all $n \in \omega$, $G(f)(f(n)) = i(n)$. Then i must be constant, since if $n \in \omega$ is such that $i(n) \neq i(0)$, then if f is an increasing function from ω to E and $g : \omega \to E$ is defined by letting $g(m) = f(m+n)$, then $G(f) \neq G(g)$, contradicting the fact that $F(f) = F(g)$. But if i is constant, then for every increasing $f : \omega \to E$, $G(f)$ is constant on a set in $F(f)$, contradicting the failure of (+). $\dashv$

4.13 Theorem. *Assume* $\mathrm{AD}^{L(\mathbb{R})}$*, and let* A *be a set of reals in* $L(\mathbb{R})$*. Then there exists a condition* $\langle (M, I), a\rangle$ *in* $\mathbb{P}_{\max}$ *such that*

- $A \cap M \in M$,
- $\langle H(\omega_1)^M, A \cap M\rangle \prec \langle H(\omega_1), A\rangle$,
- (M, I) *is* A*-iterable.*
- *if* M^+ *is any forcing extension of* M *and* J *is a normal precipitous ideal on* $\omega_1^{M^+}$ *in* M^+ *then* $A \cap M^+ \in M^+$ *and* (M^+, J) *is* A*-iterable, and if* $j : (M^+, J) \to (M^*, J^*)$ *is any iteration of* (M^+, J)*, then*

$$\langle H(\omega_1)^{M^*}, A \cap M^*\rangle \prec \langle H(\omega_1), A\rangle.$$

Proof. Work in $L(\mathbb{R})$. If there is an $A \subseteq \mathbb{R}$ which is a counterexample to the statement of the theorem, then we may assume that there exists such an A which is $\underset{\sim}{\Delta}^2_1$. This follows from the Solovay Basis Theorem (see [9]), which says (in ZF) that every nonempty $\underset{\sim}{\Sigma}^2_1$ collection of sets of reals has a member which is $\underset{\sim}{\Delta}^2_1$. We give a quick sketch of the proof. Note first of all that for any ordinal α the transitive collapse any elementary submodel of $L_\alpha(\mathbb{R})$ containing $\mathbb{R}$ is a set of the form $L_\beta(\mathbb{R})$ for some ordinal $\beta \leq \alpha$. Now, if α is any ordinal, there exist (in $L(\mathbb{R})$) an elementary submodel X of $L_\alpha(\mathbb{R})$ containing $\mathbb{R}$ and a surjection $\pi : \mathbb{R} \to X$, so if α is the least ordinal such that a member of a given $\underset{\sim}{\Sigma}^2_1$ set exists in $L_{\alpha+1}(\mathbb{R})$ then there is a surjection (in $L(\mathbb{R})$) from $\mathbb{R}$ onto $L_{\alpha+1}(\mathbb{R})$, and a formula ϕ and a real x such that some member of the set is defined over $L_\alpha(\mathbb{R})$ by ϕ from x. By the minimality of α, that member has $\underset{\sim}{\Sigma}^2_1$ and $\underset{\sim}{\Pi}^2_1$ definitions using x and incorporating ϕ.

Towards a contradiction, fix a $\underset{\sim}{\Delta}^2_1$ counterexample A. By [24], the pointclass Σ^2_1 has the scale property in $L(\mathbb{R})$, which means that every subset of $\mathbb{R} \times \mathbb{R}$ which is $\underset{\sim}{\Delta}^2_1$ in $L(\mathbb{R})$ is the projection of a tree in $L(\mathbb{R})$ on the product of ω and some ordinal, and can be uniformized by a function which is $\underset{\sim}{\Delta}^2_1$ in $L(\mathbb{R})$. (We refer the reader to [9, 14, 26] for a discussion of scales and their corresponding trees. Briefly, if $B \subseteq \mathbb{R} \times \mathbb{R}$ is the projection of a tree T on $\omega \times \omega \times \gamma$ (for some ordinal γ) then for each real x such that there exists a y with (x, y) in B, we can recursively define functions $f(x) : \omega \to \omega$ and $g(x) : \omega \to \gamma$ as follows: if (m, α) is the lexicographically least pair in $\omega \times \gamma$ such that there exist a real y and a function $a : \omega \to \gamma$ such that

- y extends $f(x){\restriction}n$ and $y(n) = m$,
- a extends $g(x){\restriction}n$ and $a(n) = \alpha$,
- (x, y, a) is a path through T,

then $f(x)(n) = m$ and $g(x)(n) = \alpha$. Then f uniformizes B, and if T is the tree corresponding to a $\underset{\sim}{\Sigma}^2_1$ scale on B, then f is $\underset{\sim}{\Delta}^2_1$.) Now, $\underset{\sim}{\Delta}^2_1$ is closed under complements, projections and countable unions, so there exists a $\underset{\sim}{\Delta}^2_1$ set $B \subseteq \mathbb{R} \times \mathbb{R}$ such that whenever $F : \mathbb{R} \to \mathbb{R}$ is a function uniformizing B and N is a transitive model N of ZF closed under F,

$$\langle H(\omega_1)^N, A \cap N, \in \rangle \prec \langle H(\omega_1), A, \in \rangle.$$

Fix such B and F, both $\underset{\sim}{\Delta}^2_1$. Let S, S^*, T, T^* be trees (on $\omega \times \gamma$, for some ordinal γ) in $L(\mathbb{R})$ projecting to A, the complement of A, F and the complement of F respectively. Note that any transitive model of ZF with T as a member is closed under F.

Now by Theorem 4.12, we may fix a transitive model N of ZFC and a countable ordinal γ such that N contains the ordinals, S, S^*, T and T^* are elements of N and γ is a measurable cardinal in N. Since $N \subseteq L(\mathbb{R})$ and $L(\mathbb{R})$ satisfies AD, ω_1^V is a limit of strongly inaccessible cardinals in N. Let δ be any strongly inaccessible cardinal in N between γ and ω_1^V. Recall (Remark 2.6) that if we choose an N-generic filter G for the forcing consisting of $\mathrm{Col}(\omega, {<}\gamma)$ followed by the standard c.c.c. iteration to make Martin's Axiom hold, as defined in N, then if we let I be the normal ideal generated by an ideal in N dual to a fixed normal measure on γ in N, I is a precipitous ideal in $N[G]$ and

$(N_\delta[G], I)$ is iterable, by Lemmas 1.5 and 1.6. It suffices now to fix a forcing extension M^+ of $N_\delta[G]$ in which there exists a normal precipitous ideal J on $\omega_1^{M^+}$ and to show that the second part of the conclusion of the theorem holds for M^+ and J. Let N^+ be the corresponding forcing extension of $N[G]$. Since $S \in N^+$, $A \cap M^+ \in M^+$. Fix an iteration $j : (M^+, J) \to (M^*, J^*)$. By Lemma 1.6 there is an iteration $j^* : (N^+, J) \to (N^*, J^*)$ such that $j^* \restriction M^+ = j$. Now, $p[S] \subseteq p[j^*(S)]$ and $p[S^*] \subseteq p[j^*(S^*)]$, and further, by absoluteness $p[j^*(S)] \cap p[j^*(S^*)] = \emptyset$, so $p[S] = p[j^*(S)]$. Similarly, $p[T] = p[j^*(T)]$. Then N^* is closed under F, so we have that

$$\langle H(\omega_1)^{M^*}, A \cap M^*, \in\rangle \prec \langle H(\omega_1), A, \in\rangle.$$

Furthermore, $j(A \cap M^+) = p[j^*(S)] \cap M^*$, so $j(A \cap M^+) = A \cap M^*$. This shows that A is not in fact a counterexample to the statement of the theorem. $\dashv$

Suppose that A is a set of reals and x is a real coding a condition p in $\mathbb{P}_{\max}$ by some recursive coding, and let B be the set of reals coding members of $A \times \{x\}$. Then if (M, I) is a B-iterable pair such that

$$\langle H(\omega_1)^M, B \cap M, \in\rangle \prec \langle H(\omega_1), B, \in\rangle,$$

then (M, I) is A-iterable and $p \in H(\omega_1)^M$. Therefore, the existence, for each $A \subseteq \mathbb{R}$ in $L(\mathbb{R})$, of an A-iterable pair (M, I) such that

$$\langle H(\omega_1)^M, A \cap M, \in\rangle \prec \langle H(\omega_1), A, \in\rangle$$

implies that for each $A \subseteq \mathbb{R}$ in $L(\mathbb{R})$ the set of $\langle (M, I), a\rangle$ in $\mathbb{P}_{\max}$ such that (M, I) is A-iterable and $\langle H(\omega_1)^M, A \cap M, \in\rangle \prec \langle H(\omega_1), A, \in\rangle$ is dense.

5. The Basic Analysis

With the existence of A-iterable conditions (for all sets of reals A in $L(\mathbb{R})$) in hand, we can now prove the most important fact about the $\mathbb{P}_{\max}$ extension, that every subset of ω_1 in the extension is the image of a member of the generic filter under the iteration of that member induced by the generic filter.

Formally, if $G \subseteq \mathbb{P}_{\max}$ is a set of pairwise compatible conditions, then since the elementary embedding witnessing the order on a pair of $\mathbb{P}_{\max}$ conditions has critical point the ω_1 of the smaller model, for each $\langle (M, I), a\rangle, \langle (N, J), b\rangle$ in G, $a \cap \gamma = b \cap \gamma$, where $\gamma = \min\{\omega_1^M, \omega_1^N\}$. For any such G, we let

$$A_G = \bigcup\{a \mid \exists (M, I)\ \langle (M, I), a\rangle \in G\}.$$

By Lemma 2.7, for any such G, for any member $\langle (M, I), a\rangle$ of G there is a unique iteration of (M, I) sending a to A_G. Using this fact, we define $\mathcal{P}(\omega_1)_G$ to be the collection of all E such that there exists a condition $\langle (M, I), a\rangle \in G$ and a set $e \in \mathcal{P}(\omega_1)^M$ such that $j(e) = E$, where j is the unique iteration of

(M, I) sending a to A_G. Likewise, we define I_G to be the collection of all E such that there exists a condition $\langle (M, I), a\rangle \in G$ and a set $e \in I$ such that $j(e) = E$, where j is the unique iteration of (M, I) sending a to A_G.

We state the following theorem from the point of view of the ground model (so in particular, the universe V in the statement of the theorem does not satisfy AC). We have seen that large cardinals and determinacy each imply that the hypothesis of the theorem is satisfied in $L(\mathbb{R})$, but as we shall see, it can hold in other models as well.

5.1 Theorem (ZF). *Assume that for every $A \subseteq \mathbb{R}$ there exists a $\mathbb{P}_{\max}$ condition $\langle (M, I), a\rangle$ such that (M, I) is A-iterable and*

$$\langle H(\omega_1)^M, A \cap M, \in\rangle \prec \langle H(\omega_1), A, \in\rangle.$$

Suppose that $G \subseteq \mathbb{P}_{\max}$ is a V-generic filter. Then in $V[G]$ the following hold.

(a) $\mathcal{P}(\omega_1) = \mathcal{P}(\omega_1)_G$.

(b) $\mathrm{NS}_{\omega_1} = I_G$.

(c) $\underset{\sim}{\delta}^1_2 = \omega_2$.

(d) NS_{ω_1} *is saturated.*

Before proving Theorem 5.1, we prove another iteration lemma in terms of games in order to separate out some commonly needed details.

Suppose that p is a $\mathbb{P}_{\max}$ condition, let J be a normal ideal on ω_1 and let B be a subset of ω_1. Let $\mathcal{G}_{\omega_1}(p, J, B)$ be the game where Players I and II collaborate to build a descending ω_1-sequence of $\mathbb{P}_{\max}$ conditions $p_\alpha = \langle (M_\alpha, I_\alpha), a_\alpha\rangle$ below p, where in round $\alpha < \omega_1$, I chooses p_α if $\alpha \notin B$, and II chooses p_α if $\alpha \in B$. At the end of the game, II wins if, letting $A = \bigcup\{a_\alpha : \alpha < \omega_1\}$ and letting $j_\alpha : (M_\alpha, I_\alpha) \to (M^*_\alpha, I^*_\alpha)$ (for each $\alpha < \omega_1$) be the iteration of (M_α, I_α) sending a_α to A, $j_\alpha(I_\alpha) = J \cap M^*_\alpha$ holds for each $\alpha < \omega_1$.

5.2 Lemma (ZFC°). *Suppose that $x^\dagger$ exists for every real x. Let p be a condition in $\mathbb{P}_{\max}$, let J be a normal ideal on ω_1 and let B be a subset of ω_1. Then Player* II *has a winning strategy in $\mathcal{G}_{\omega_1}(p, J, B)$ if and only if $B \notin J$.*

Proof. The interesting direction is showing that II has a winning strategy if $B \notin J$, and for this direction it suffices to consider the case where B consists entirely of limit ordinals (we have no use for the other direction and leave its proof to the reader). The strategy for II uses the usual trick. Partition B into J-positive sets $\{B^\alpha_i : \alpha < \omega_1, i < \omega\}$, and as the p_α are chosen, let $\{E^\alpha_i : i < \omega\}$ enumerate $\mathcal{P}(\omega_1)^{M_\alpha} \setminus I_\alpha$ for each α.

Fix a *ladder system* $\{h_\alpha : \alpha \in B\}$ (so each h_α is an increasing function from ω to α with cofinal range). Having constructed our sequence of p_α's up to some limit stage β in B, let

$$(\langle (N^\beta_i, J^\beta_i) : i < \omega\rangle, a^*_\beta)$$

be the limit sequence corresponding to the descending sequence

$$\langle p_{h_\beta(i)} : i < \omega \rangle,$$

and for each $i < \omega$ let $j'_{i\beta}$ be the unique iteration of $(M_{h_\beta(i)}, I_{h_\beta(i)})$ sending $a_{h_\beta(i)}$ to a^*_β. Since $x^\dagger$ exists for each real x, we may fix a $\mathbb{P}_{\max}$ pre-condition (M_β, I_β) with

$$(\langle (N^\beta_i, J^\beta_i) : i < \omega \rangle, a^*_\beta) \in H(\omega_1)^{M_\beta}.$$

As in Lemma 3.4 (more precisely, using Lemma 3.5), we let j'_β be an iteration of $\langle (N^\beta_i, J^\beta_i) : i < \omega \rangle$ in M_β such that

$$j'_\beta(J^\beta_i) = I_\beta \cap j'_\beta(N^\beta_i)$$

for each $i < \omega$, with the extra stipulation that if

$$\omega_1^{N^\beta_0} \in B^\gamma_k$$

for some $\gamma < \beta$ and $k < \omega$, then, letting i' be the least element i of ω such that $h_\beta(i) \geq \gamma$,

$$j'_{i'\beta}(j_{\gamma h_\beta(i')}(E^\gamma_k))$$

is in the normal filter corresponding to the first step of this iteration of $\langle (N^\beta_i, J^\beta_i) : i < \omega \rangle$ (note that $j'_{i'\beta}(j_{\gamma h_\beta(i')}(E^\gamma_k))$ is $J^\beta_{i'}$-positive by the agreement of ideals imposed by the $\mathbb{P}_{\max}$ order). Then, letting $a_\beta = j'_\beta(a^*_\beta)$, we have that

$$\omega_1^{N^\beta_0} \in j_{\gamma\beta}(E^\gamma_k).$$

Since for each $i < \omega$ and $\alpha < \omega_1$ the set of $\beta \in B^\alpha_i$ such that $\omega_1^{N^\beta_0} = \beta$ is J-positive, by playing in this manner Player II ensures that the image of each E^α_i is J-positive. ⊣

We separate out the following standard argument as well.

5.3 Lemma. *Suppose that $x^\dagger$ exists for every real x, and let $G \subseteq \mathbb{P}_{\max}$ be an $L(\mathbb{R})$-generic filter. Let $p_0 = \langle (M, I), a \rangle$ be a $\mathbb{P}_{\max}$ condition in G, and suppose that $P \in M$ is a set of $\mathbb{P}_{\max}$ conditions such that $p \geq p_0$ for every $p \in P$. Let j be the unique iteration of (M, I) sending a to A_G. Then every member of $j(P)$ is in G.*

Proof. Let $\langle M_\alpha, G_\beta, j^*_{\alpha\delta} : \beta < \alpha \leq \delta \leq \omega_1 \rangle$ be the iteration corresponding to j, and fix $q = \langle (N_0, J_0), b_0 \rangle$ in $j(P)$. Fix $\alpha_0 < \omega_1$ such that $q \in j^*_{0\alpha_0}(P)$, and let j_q (in M_{α_0}) be the iteration of (N_0, J_0) sending b_0 to $j^*_{0\alpha_0}(a)$. By the genericity of G there is a condition $p_1 = \langle (N_1, J_1), b_1 \rangle$ in G such that $p_1 \leq p_0$ and $\alpha_0 < \omega_1^{N_1}$. Then $\langle M_\alpha, G_\beta, j^*_{\alpha\delta} : \beta < \alpha \leq \delta \leq \omega_1^{N_1} \rangle$ is in $M_{\omega_1^{N_1}}$ and is the unique iteration of (M, I) sending a to b_1. Since

$$j_q(J_0) = j^*_{0\alpha_0}(I) \cap j_q(N_0)$$

and

$$j^*_{0\omega_1^{N_1}}(I) = J_1 \cap M_{\omega_1^{N_1}},$$

$j^*_{\alpha_0\omega_1^{N_1}}(j_q)$ witnesses that $q \geq p_1$. $\dashv$

Proof of Theorem 5.1. (a) Let τ be a $\mathbb{P}_{\max}$-name in $L(\mathbb{R})$ for a subset of ω_1, and let A be the set of reals coding (under some fixed recursive coding) the set of triples (p, α, i) such that $p \in \mathbb{P}_{\max}$, $\alpha < \omega_1$, $i \in 2$ and, if $i = 1$ then $p \Vdash \check{\alpha} \in \tau$, otherwise $p \Vdash \check{\alpha} \notin \tau$. Let $p = \langle (N, J), d\rangle$ be any condition in $\mathbb{P}_{\max}$ and let (M, I) be an A-iterable pre-condition such that

- $p \in H(\omega_1)^M$,
- $\langle H(\omega_1)^M, A \cap M, \in\rangle \prec \langle H(\omega_1), A, \in\rangle$.

Applying Lemma 5.2 in M, there exists a descending sequence of $\mathbb{P}_{\max}$ conditions $p_\alpha = \langle (N_\alpha, J_\alpha), d_\alpha\rangle$ ($\alpha < \omega_1^M$) such that

(1) $p_0 = p$,

(2) each $p_{\alpha+1}$ decides the sentence "$\check{\alpha} \in \tau$",

(3) letting $D = \bigcup\{d_\alpha : \alpha < \omega_1^M\}$, for each $\alpha < \omega_1$, $j_\alpha(J_\alpha) = I \cap j_\alpha(N_\alpha)$, where j_α is the unique iteration of (N_α, J_α) sending d_α to D.

Conditions (1) and (2) are easily satisfied, using the fact that $\langle H(\omega_1)^M$, $A \cap M, \in\rangle \prec \langle H(\omega_1), A, \in\rangle$, and we may apply Lemma 5.2 (letting B be the set of countable limit ordinals) inside M to meet Condition (3) since in M, $x^\dagger$ exists for each real x.

Now, letting D be as in Condition (3) above, $\langle (M, I), D\rangle$ is a $\mathbb{P}_{\max}$ condition below each p_α. Let e be the subset of ω_1^M in M such that for each $\alpha < \omega_1$, $\alpha \in e$ if and only if $p_{\alpha+1} \Vdash \check{\alpha} \in \tau$.

Suppose that $p' = \langle (M, I), D\rangle \in G$, and let

$$\langle M_\alpha, G_\beta, j^*_{\alpha\delta} : \beta < \alpha \leq \delta \leq \omega_1\rangle$$

be the unique iteration of (M, I) sending D to A_G. We want to see that $j^*_{0\omega_1}(e) = \tau_G$. Let $\langle q_\alpha : \alpha < \omega_1\rangle = j^*_{0\omega_1}(\langle p_\alpha : \alpha < \omega_1^M\rangle)$. By the elementarity of $j^*_{0\alpha^*}$ and the A-iterability of (M, I), for each $\gamma < \omega_1$, $q_{\gamma+1} \Vdash \check{\gamma} \in \tau$ if $\gamma \in j_{0\alpha^*}(e)$ and $q_{\gamma+1} \Vdash \check{\gamma} \notin \tau$ if $\gamma \notin j_{0\alpha^*}(e)$. By Lemma 5.3, each q_γ is in G, so $j^*(e) = \tau_G$.

(b) The fact that $I_G = \mathrm{NS}_{\omega_1}$ follows almost immediately. If $E \in I_G$, then there is a condition $\langle (M, I), a\rangle$ in G, an $e \in I$ and an iteration j of (M, I) sending e to E. Then E is disjoint from the critical sequence of this iteration and therefore nonstationary. On the other hand, if E is a nonstationary subset of ω_1 in $V[G]$, then there is a club C disjoint from E and a condition $\langle (M, I), a\rangle$ in G, sets $e, c \in \mathcal{P}(\omega_1)^M$ and an iteration j of (M, I) sending e and c to E and C respectively. Then c must be a club subset of ω_1^M in M, so $e \in I$, which means that E is in I_G.

(c) That $\underset{\sim}{\delta}^1_2 = \omega_2$ also follows almost immediately, using Corollary 1.9 and the standard fact that if $x^\#$ exists for every real x, then $\underset{\sim}{\delta}^1_2$ is equivalent to u_2, the second uniform indiscernible (the least ordinal above ω_1 which is an indiscernible of every real) (see [36, 39]). So, showing that $\underset{\sim}{\delta}^1_2 = \omega_2$ then amounts to showing that for every $\gamma < \omega_2$ there is a real x such that the least x-indiscernible above ω_1 is greater than γ. Working in $V[G]$, fix $\gamma \in [\omega_1, \omega_2)$ and a wellordering π of ω_1 of length γ. By the first part of this theorem, we may fix a condition $\langle (M, I), a\rangle \in G$ and an $e \in \mathcal{P}(\omega_1 \times \omega_1)^M$ such that $j(e) = \pi$, where j is the iteration of (M, I) sending a to A_G. Then γ is in $j(M)$, and so is less than the least indiscernible above ω_1 of any real coding (M, I), by Corollary 1.9.

(d) To show that NS_{ω_1} is saturated in $V[G]$, we show that for any set $D \subseteq \mathcal{P}(\omega_1) \setminus \mathrm{NS}_{\omega_1}$ which is dense under the subset order, there is a subset D' of D of cardinality $\aleph_1$ whose diagonal union contains a club. So, following the proof of the first part of this theorem, let τ be a name for such a set D. Let A be the set of reals coding (by a fixed recursive coding) the set of pairs (p, e) such that $p = \langle (M, I), a\rangle$ is a condition in $\mathbb{P}_{\max}$, $e \in \mathcal{P}(\omega_1)^M \setminus I$ and p forces that $j(\check{e}) \in \tau$, where j is the unique iteration of (M, I) sending a to A_G.

Let $p = \langle (N, J), b\rangle$ be any condition in $\mathbb{P}_{\max}$ and let (M, I) be an A-iterable pre-condition such that

- $p \in H(\omega_1)^M$,
- $\langle H(\omega_1)^M, A \cap M, \in\rangle \prec \langle H(\omega_1), A, \in\rangle$.

Fix a partition $\{B^\alpha_i : \alpha < \omega_1, i < \omega\}$ in M of pairwise disjoint I-positive sets whose diagonal union is I-large. Fix also a function $g : \omega_1^M \times \omega \to \omega_1^M$ in M such that $g(\alpha, i) \geq \alpha$ for all $(\alpha, i) \in \mathrm{dom}(g)$.

Working in M, we are going to build a descending sequence of $\mathbb{P}_{\max}$ conditions $p_\alpha = \langle (N_\alpha, J_\alpha), b_\alpha\rangle$ (with the order on conditions witnessed by a commuting family of embeddings $j_{\alpha\beta}$), enumerations $\{e^\alpha_i : i < \omega\}$ in M of each set $\mathcal{P}(\omega_1)^{N_\alpha} \setminus J_\alpha$ and sets d_α ($\alpha \leq \beta \leq \omega_1^M$) such that

(4) $p_0 = p$,

(5) each $d_\alpha \in \mathcal{P}(\omega_1)^{N_{\alpha+1}} \setminus J_{\alpha+1}$ and, if $\alpha = g(\beta, i)$ for some $\beta \leq \alpha$ and $i < \omega$, then $d_\alpha \subseteq j_{\beta(\alpha+1)}(e^\beta_i)$ and $(p_{\alpha+1}, d_\alpha)$ is coded by a real in A,

(6) for each $(\beta, i) \in \mathrm{dom}(g)$, $B^\alpha_i \setminus j_{(g(\beta,i)+1)\omega_1^M}(d_{g(\beta,i)})$ is nonstationary.

Conditions (5) and (6) together imply that our sequence will satisfy Condition (3) from part (a) of this proof. Furthermore, Conditions (4) and (5) here are easily achieved, by the assumptions on τ. In particular, for each $\alpha < \omega_1^M$, by the assumptions on τ there exists a pair (p^*, d^*) such that $p^* \leq p_\alpha$ and Condition (5) holds with p^* in the role of $p_{\alpha+1}$ and d^* in the role of d_α, and we let $(p_{\alpha+1}, d_\alpha)$ be any such pair. Condition (6) implies that the diagonal union of the sets $j_{(g(\beta,i)+1)\omega_1^M}(d_{g(\beta,i)})$ will be I-large.

Condition (6) is achieved in almost exactly the same way as Condition (3) in the first part of the proof (but not exactly the same way; unfortunately we cannot quote Lemma 5.2). Fix a ladder system $\{h_\alpha : \text{limit } \alpha < \omega_1\}$ in M. Having constructed our sequence of p_α's up to some limit stage β, let $(\langle(N_i^\beta, J_i^\beta) : i < \omega\rangle, b^*_\beta)$ be the limit sequence corresponding to the descending sequence $\langle p_{h_\beta(i)} : i < \omega\rangle$, and again for each $i < \omega$ let $j'_{i\beta}$ be the unique iteration of $(N_{h_\beta(i)}, J_{h_\beta(i)})$ sending $b_{h_\beta(i)}$ to b^*_β. Fix a pre-condition (N_β, J_β) in M with

$$(\langle N_i^\beta : i < \omega\rangle, b^*_\beta) \in H(\omega_1)^{N_\beta}.$$

As in Lemma 3.4, we let j'_β be an iteration of $\langle(N_i^\beta, J_i^\beta) : i < \omega\rangle$ in N_β such that

$$j'_\beta(J_i^\beta) = J_\beta \cap j'_\beta(N_i^\beta)$$

for each $i < \omega$, with the extra stipulation that if

$$\omega_1^{N_0^\beta} \in B_k^\gamma$$

for some $\gamma < \beta$ and $k < \omega$ with $g(\gamma, k) < \beta$, then, letting i' be the least $i \in \omega$ such that $h_\beta(i) \geq g(\gamma, k)$,

$$j'_{i'\beta}(j_{(g(\gamma,k)+1)h_\beta(i')}(d_{g(\gamma,k)}))$$

is in the filter corresponding to the first step of this iteration of the sequence $\langle(N_i^\beta, J_i^\beta) : i < \omega\rangle$, ensuring (once we let $b_\beta = j'_\beta(b^*_\beta)$) that

$$\omega_1^{N_0^\beta} \in j_{(g(\gamma,k)+1)\beta}(d_{g(\gamma,k)}).$$

Then since $\{\omega_1^{N_0^\beta} : \text{limit } \beta < \omega_1\}$ is a club subset of ω_1^M, Condition (6) is satisfied.

Now, letting $B = \bigcup\{b_\alpha : \alpha < \omega_1^M\}$, $\langle(M, I), B\rangle$ is a $\mathbb{P}_{\max}$ condition below each p_α. For each $\alpha < \omega_1$ and $i < \omega$, let $d'_{\alpha i} = j_{(g(\alpha,i)+1)\omega_1^M}(d_{g(\alpha,i)})$. Then the diagonal union of

$$\mathcal{A} = \{d'_{\alpha i} : \alpha < \omega_1^M, i < \omega\}$$

contains an I-large subset of ω_1^M in M.

Suppose that $\langle(M, I), B\rangle \in G$, and let $\langle M_\alpha, G_\beta, j^*_{\alpha\delta} : \beta < \alpha \leq \delta \leq \omega_1\rangle$ be the unique iteration of (M, I) sending B to A_G. Then the diagonal union of $j^*_{0\omega_1}(\mathcal{A})$ contains the critical sequence of $j^*_{0\omega_1}$, which is a club. We want to see that $j^*_{0\omega_1}(\mathcal{A}) \subseteq \tau_G$.

Let $\langle q_\alpha : \alpha < \omega_1\rangle = j^*_{0\omega_1}(\langle p_\alpha : \alpha < \omega_1^M\rangle)$. By Lemma 5.3, each q_α is in G. Since (M, I) is A-iterable, each member of $j^*(\mathcal{A})$ is forced to be in τ_G by some q_α, so $j^*(\mathcal{A}) \subseteq \tau_G$. ⊣

5.4 Remark. It is shown in [18] that, under the hypothesis of Theorem 5.1, Todorcevic's Open Coloring Axiom [37] holds in the $\mathbb{P}_{\max}$ extension. The proof in that paper can be greatly simplified by using Lemmas 5.2 and 5.3 to separate out the standard details.

6. ψ_{AC} and the Axiom of Choice

We have not yet shown that the $\mathbb{P}_{\max}$ extension of $L(\mathbb{R})$ satisfies the Axiom of Choice. We shall do this by showing (assuming $\mathrm{AD}^{L(\mathbb{R})}$) that the following axiom holds there.

We let $\mathrm{ot}(X)$ denote the ordertype of a linear order X.

6.1 Definition. ψ_{AC} is the statement that for every pair A, B of stationary, co-stationary subsets of ω_1, there exists a bijection π between ω_1 and some ordinal γ such that the set $\{\alpha < \omega_1 \mid \alpha \in A \iff \mathrm{ot}(\pi[\alpha]) \in B\}$ contains a club.

Using a partition $\{A_\alpha : \alpha < \omega_1\}$ of ω_1 into stationary sets, ψ_{AC} allows us to define an injection from 2^{ω_1} into ω_2. Since the $\mathbb{P}_{\max}$ extension of $L(\mathbb{R})$ satisfies the sentence "$V = L(\mathcal{P}(\omega_1))$", this is enough to see that AC holds there. Let B^* be any stationary, co-stationary subset of ω_1. For each $X \subseteq \omega_1$, let $A_X = \bigcup\{A_\alpha : \alpha \in X\}$, and let γ_X be the ordinal given by ψ_{AC}, where A_X is in the role of A, and B^* is in the role of B. Let X_0 and X_1 be distinct subsets of ω_1, and let E be the (stationary) symmetric difference of A_{X_0} and A_{X_1}. Supposing towards a contradiction that $\gamma_{X_0} = \gamma_{X_1}$, let π_0 and π_1 be bijections and C_0 and C_1 club subsets of ω_1 witnessing ψ_{AC} for the pairs A_{X_0}, B^* and A_{X_1}, B^* respectively. Then there is a club subset D of ω_1 such that $\mathrm{ot}(\pi_0[\alpha]) = \mathrm{ot}(\pi_1[\alpha])$ for all $\alpha \in D$. Then $E \cap C_0 \cap C_1 \cap D$ is nonempty, which gives a contradiction, since $\alpha \in A_{X_0} \iff \mathrm{ot}(\pi_0[\alpha]) \in B \iff \mathrm{ot}(\pi_1[\alpha]) \in B \iff \alpha \in A_{X_1}$ for all $\alpha \in C_0 \cap C_1 \cap D$. Therefore, ψ_{AC} implies that $2^{\omega_1} = \omega_2$. In fact, it also implies that $2^\omega = 2^{\omega_1}$, but we will not take the time to show this (it follows from a result of Shelah proved in [39, Sect. 3.2]); we already know from Theorem 5.1 that the Continuum Hypothesis fails in the $\mathbb{P}_{\max}$ extension (assuming $\mathrm{AD}^{L(\mathbb{R})}$).

That ψ_{AC} holds in the $\mathbb{P}_{\max}$ extension follows from part (a) of Theorem 5.1 and the following lemma.

6.2 Lemma (ZFC°). *Suppose that (M, I) is a pre-condition in $\mathbb{P}_{\max}$, and let $A, B \in M$ be I-positive subsets of ω_1^M whose complements in ω_1^M are also I-positive. Let J be a normal ideal on ω_1. Then there exist an iteration $j : (M, I) \to (M^*, I^*)$ of (M, I) of length ω_1, an ordinal $\gamma < \omega_2$, and a bijection $\pi : \omega_1 \to \gamma$ such that $I^* = J \cap M^*$ and*

$$\{\alpha < \omega_1 \mid \alpha \in j(A) \iff \mathrm{ot}(\pi[\alpha]) \in j(B)\}$$

contains a club.

Proof. Let x be a real coding (M, I). Using Fact 1.10, it suffices to construct an iteration $\langle M_\alpha, G_\beta, j_{\alpha\delta} : \beta < \alpha \leq \delta \leq \omega_1\rangle$ such that for every α which is a limit of countable x-indiscernibles, $j_{0\alpha}(A) \in G_\alpha$ if and only if $j_{0\alpha^*}(B) \in G_{\alpha^*}$, where α^* is the least x-indiscernible above α. By the proof of Lemma 1.8, $\omega_1^{M_\gamma} = \gamma$ for each x-indiscernible γ, so in particular, each such γ is on the critical sequence.

We construct our iteration using the winning strategy for Player I in $\mathcal{G}(\omega_1 \setminus E)$ from Lemma 2.9, where E is the set of countable ordinals of the form α^* as above, where α is a limit of x-indiscernibles. This ensures that $j_{0\omega_1}(I) = J \cap M_{\omega_1}$. To complete the construction, we recursively choose each G_{α^*} ($\alpha^* \in E$) in such a way that $j_{0\alpha^*}(B) \in G_{\alpha^*}$ if and only if $j_{0\alpha}(A) \in G_\alpha$. Fact 1.10 implies that any iteration satisfying these conditions satisfies the conclusion of the lemma. $\dashv$

Stated in the fashion of Theorem 5.1, we have shown the following.

6.3 Theorem (ZF). *Assume that for every $A \subseteq \mathbb{R}$ there exists a $\mathbb{P}_{\max}$ condition $\langle (M, I), a\rangle$ such that (M, I) is A-iterable and*

$$\langle H(\omega_1)^M, A \cap M, \in\rangle \prec \langle H(\omega_1), A, \in\rangle.$$

Suppose that $G \subseteq \mathbb{P}_{\max}$ is a V-generic filter. Then ψ_{AC} holds in $V[G]$.

6.4 Remark. Suppose that A, B are stationary, co-stationary subsets of ω_1, $\pi : \omega_1 \to \gamma$ is a bijection (for some $\gamma < \omega_2$) and the set

$$\{\alpha < \omega \mid \alpha \in A \iff \mathrm{ot}(\pi[\alpha]) \in B\}$$

contains a club subset of ω_1. Then for any normal ideal I on ω_1, A is the Boolean value in the partial order $\mathcal{P}(\omega_1)/I$ that $\gamma \in j(B)$, where j is the induced embedding. It follows that if (M, I) is any iterable pair with M a countable transitive model of ZFC$^\circ$+ ψ_{AC} and B is any stationary, costationary subset of ω_1^M in M, then the image of B under any iteration of (M, I) determines the entire iteration. This in turn implies that one can replace $\mathrm{MA}_{\aleph_1}$ with ψ_{AC} in the definition of $\mathbb{P}_{\max}$ without significantly changing the corresponding analysis; in some cases the analysis is easier with ψ_{AC}.

7. Maximality and Minimality

In this section we will show that if certain large cardinals exist in V then the $\mathbb{P}_{\max}$ extension of the inner model $L(\mathbb{R})$ is maximal, in that all forceable Π_2 sentences for $H(\omega_2)$ hold there, and that it is minimal, in that every subset of ω_1 added by the generic filter for $\mathbb{P}_{\max}$ generates the entire extension. We will also show that a certain form of this maximality characterizes the $\mathbb{P}_{\max}$ extension.

To show that the $\mathbb{P}_{\max}$ extension is Π_2-maximal, we will use the following theorem of Woodin (see [8, 6, 30, 39]; Foreman, Magidor and Shelah originally proved the theorem from the existence of supercompact cardinal [7]). An ideal I on ω_1 is *presaturated* if for any $A \in \mathcal{P}(\omega_1) \setminus I$ and any sequence $\langle \mathcal{A}_i : i < \omega\rangle$ of maximal antichains in $\mathcal{P}(\omega_1) \setminus I$ there exists a $B \in \mathcal{P}(A) \setminus I$ such that there are at most $\aleph_1$ many $X \in \bigcup\{\mathcal{A}_i : i < \omega\}$ such that $X \cap B \notin I$. It is straightforward to check that normal presaturated ideals on ω_1 are precipitous.

7.1 Theorem. *If δ is a Woodin cardinal, then every condition in the partial order* $\mathrm{Col}(\omega_1, {<}\delta)$ *forces that* NS_{ω_1} *is presaturated.*

7.2 Definition. Given a cardinal κ, a set of reals A is *κ-universally Baire* if there exist trees S and T (contained in $\omega \times Z$ for some set Z) such that $p[S] = A$ and S and T project to complements in all extensions by forcing constructions of cardinality less than or equal to κ. The set A is *${<}\kappa$-universally Baire* if it is γ-universally Baire for all $\gamma < \kappa$.

Theorem 4.6 shows that for any cardinal κ, κ^+-weakly homogeneously Suslin sets of reals are κ-universally Baire.

If κ is a cardinal, A is a κ-universally Baire set of reals and $V[G]$ is an extension of V by a forcing construction of cardinality less than or equal to κ, then we let $A(G)$ be the union of all sets of the form $(p[S])^{V[G]}$, where S is a tree in V whose projection in V is contained in A. (The notation A_G is often used here, but we are already using that for something else.) For any pair of trees S and T in V witnessing that A is κ-universally Baire (i.e., such that $p[S] = A$ and S and T project to complements in all extensions by forcing constructions of cardinality less than κ), $(p[S])^{V[G]} = A(G)$.

The following theorem is an immediate consequence of part (a) of Theorem 5.1, and it implies in particular that $\mathrm{MA}_{\aleph_1}$ holds in the $\mathbb{P}_{\max}$ extension.

7.3 Theorem. *Suppose that δ is a limit of Woodin cardinals, and $\kappa > \delta$ is measurable. Let A be a set of reals in $L(\mathbb{R})$. Suppose that ϕ is a Π_2 sentence in the expanded language with two additional unary predicates, and that P is a partial order in V_δ forcing that ϕ holds in the structure $\langle H(\omega_2), \in, A(G)\rangle$. Then ϕ holds in the structure $\langle H(\omega_2), \in A\rangle$ in the $\mathbb{P}_{\max}$ extension of $L(\mathbb{R})$.*

Proof. Suppose that ϕ has the form $\forall X \exists Y \psi(X, Y)$. By part (a) of Theorem 5.1, it suffices to show that for every $\mathbb{P}_{\max}$ condition $\langle (M, I), a\rangle$ and every $x \in H(\omega_2)^M$ there exists a $\mathbb{P}_{\max}$ condition $q = \langle (N, J), b\rangle$ such that

- $q \leq p$,
- (N, J) is A-iterable,
- if $j : (M, I) \to (M^*, I^*)$ is the unique iteration of (M, I) sending a to b, then
$$\langle H(\omega_2)^N, J, A \cap N, \in\rangle \models \exists y\ \psi(j(x), y).$$

Let Z be a countable elementary submodel with $\langle (M, I), a\rangle$, A, P and δ as a members, and let N be the transitive collapse of Z. By Theorem 4.10, any forcing extension of M in which the nonstationary ideal is precipitous will be A-iterable with respect to the nonstationary ideal. Let $N[g_0]$ be a forcing extension of N by P, and let $j : (M, I) \to (M^*, I^*)$ be an iteration of (M, I) in $N[g_0]$ such that $I^* = \mathrm{NS}_{\omega_1}^{N[g_0]} \cap M^*$. Since ϕ holds in the structure $\langle H(\omega_2)^{N[g_0]}, \in, A \cap N[g_0]\rangle$, there is a $y \in H(\omega_2)^{N[g_0]}$ such that $\psi(j(x), y)$ holds there (and in the structure $\langle H(\omega_2)^{N^*}, \in, A \cap N^*\rangle$ of every outer model N^* of

$N[g_0]$ which agrees with $N[g_0]$ about stationarity for subsets of ω_1. In $N[g_0]$ there exists a Woodin cardinal γ, so let $N[g_1]$ be a $\mathrm{Col}(\omega_1, {<}\gamma)$-extension of $N[g_0]$. Finally, let $N[g_2]$ be a c.c.c. forcing extension of $N[g_1]$ in which $\mathrm{MA}_{\aleph_1}$ holds. Then $\langle(N[g_2], \mathrm{NS}_{\omega_1}^{N[g_2]}), j(a)\rangle$ is the desired condition q. ⊣

Theorem 7.8 below is a sort of converse to Theorem 7.3. First we will show that every new subset of ω_1 in the $\mathbb{P}_{\max}$ extension generates the entire generic filter (Theorem 7.7).

The conclusion of the following lemma corresponds to Condition 5 in the definition of $\mathbb{P}_{\max}$.

7.4 Lemma. *Suppose that $x^\dagger$ exists for each real x. Let $\langle(M', I'), a'\rangle$ be a $\mathbb{P}_{\max}$ condition and let e be an element of $\mathcal{P}(\omega_1)^{M'}$. Then there exist a $\mathbb{P}_{\max}$ pre-condition (N, J) with $(M', I') \in H(\omega_1)^N$ and an iteration $j : (M', I') \to (M^*, I^*)$ in N such that*

- $j(\omega_1^{M'}) = \omega_1^N$,
- $I^* = J^* \cap M^*$,

and either

1. *for some $x \in \mathcal{P}(\omega)^N$, $j(e) \in L[x]$, or*
2. *for some $x \in \mathcal{P}(\omega)^N$, $\omega_1^N = \omega_1^{L[j(e),x]}$.*

Proof. Fix a limit sequence $(\langle(M_i, I_i) : i < \omega\rangle, a)$ corresponding to any descending ω-sequence in $\mathbb{P}_{\max}$ starting with $\langle(M', I'), a'\rangle$, and let (N, J) be a $\mathbb{P}_{\max}$ pre-condition with $\{(M', I'), (\langle(M_i, I_i) : i < \omega\rangle, a)\} \in H(\omega_1)^N$. Let j' be the iteration of (M', I') sending a' to a. Now one of two things must hold. Either there exist $i < \omega$, $\gamma < \omega_2^{M_i}$ and a bijection $f : \omega_1^{M_0} \to \gamma$ in M_i such that $\{\alpha < \omega_1^{M_0} : \mathrm{ot}(f``\alpha) \in j'(e)\}$ and $\{\alpha < \omega_1^{M_0} : \mathrm{ot}(f``\alpha) \notin j'(e)\}$ are both I_i-positive subsets of $\omega_1^{M_0}$ in M_i, or there are no such i, γ, f.

If there is no such triple, then the image of $j'(e)$ is the same under every iteration of $\langle(M_i, I_i) : i < \omega\rangle$ of length ω_1^N. Let x be a real in N coding $\langle(M_i, I_i) : i < \omega\rangle$. There exist iterations of $\langle(M_i, I_i) : i < \omega\rangle$ of length ω_1^N in forcing extensions of $L[x]$ by the partial order $\mathrm{Col}(\omega, {<}\omega_1^N)$, and since this partial order is homogeneous, this fixed image of $j'(e)$ exists in $L[x]$. Letting j be any suitable (for example, using a strategy for Player I in $\mathcal{G}(\omega_1)$ as in Theorem 3.5) such iteration in N of length ω_1^N, then, $j(j')$ is an iteration of (M', I') satisfying the first conclusion of the lemma.

If there is such a triple, note that there is a real y in M_{i+1} such that γ is definable in M_{i+1} (absolutely, in fact) from $\omega_1^{M_0}$ and y (for instance, we could let y be the sharp of any real whose least indiscernible above $\omega_1^{M_0}$ is greater than γ). In particular, we may fix a ternary formula ϕ such that γ is the unique ordinal such that $\phi(\gamma, y, \omega_1^{M_0})$ holds in $L[y]$. Let

$$A = \{\alpha < \omega_1^{M_0} : \mathrm{ot}(f``\alpha) \in j'(e)\}.$$

Then A is the Boolean value of the statement that γ is in the image of $j'(e)$. Let x be a real in N coding $(\langle (M_i, I_i) : i < \omega \rangle, a)$. Then just as in the proof of Lemma 1.8, the indiscernibles of x are on the critical sequence of any iteration of $\langle (M_i, I_i) : i < \omega \rangle$. Fix a set $B \subseteq \omega_1^N$ in N such that $\omega_1^N = \omega_1^{L[B]}$. Working in N, build an iteration j (with partial iterations $j_{\alpha\beta}$ ($\alpha \leq \beta \leq \omega_1^N$) and normal filters G_α ($\alpha < \omega_1^N$)) of $\langle (M_i, I_i) : i < \omega \rangle$, using a winning strategy for Player I in the game $\mathcal{G}(\omega_1^N \setminus E)$ from Theorem 3.5, where E is the set of countable x-indiscernibles which are not limits of x-indiscernibles (note that $x^\# \in N$, as (N, J) is iterable, so N contains the sharps for all its reals). When $j_{0\alpha}(\omega_1^{M_0})$ is in E, we put $j_{0\alpha}(A)$ in the normal filter G_α if and only if $\eta \in B$, where $j_{0\alpha}(\omega_1^{M_0})$ is the ηth successor x-indiscernible. Having completed the construction of our iteration, we have that B is constructible from $j(j'(e)), y$ and $x^\#$: B is the set of $\eta < \omega_1^N$ such that, letting ι_η be the η-th successor x-indiscernible, the unique ordinal γ^* satisfying $\phi(\gamma^*, y, \iota_\eta)$ in $L[y]$ is in $j(j'(e))$. Then $j(j')$ is an iteration of (M', I') satisfying the second conclusion of the lemma. ⊣

For the rest of this section we fix the following notation: if B is a subset of ω_1, we let F_B be the set of conditions $\langle (M, I), b \rangle$ in $\mathbb{P}_{\max}$ such that there exists an iteration $j : (M, I) \to (M^*, I^*)$ such that $j(b) = B$ and $I^* = \mathrm{NS}_{\omega_1} \cap M^*$.

Woodin defines the following axiom.

7.5 Definition. Axiom $(*)$ is the statement that AD holds in $L(\mathbb{R})$ and $L(\mathcal{P}(\omega_1))$ is a $\mathbb{P}_{\max}$ extension of $L(\mathbb{R})$.

The proofs of Theorems 7.7 and 7.8 use the following lemma.

7.6 Lemma. *Assume that axiom $(*)$ holds, and let B be a subset of ω_1 such that there exists a real z such that $\omega_1 = \omega_1^{L[z,B]}$. Then the set F_B is a filter.*

Proof. Fix an $L(\mathbb{R})$-generic filter $G \subseteq \mathbb{P}_{\max}$ such that $L(\mathcal{P}(\omega_1)) = L(\mathbb{R})[G]$. Fix a real x such that $\omega_1 = \omega_1^{L[x,A_G]}$. As in the proof of Lemma 2.7, let $\{a_\alpha : \alpha < \omega_1\}$ be the almost disjoint family of subsets of ω constructed in $L[x, A_G]$ by recursively taking a_α to be the first real in the $L[x, A_G]$ constructibility order almost disjoint from each a_β ($\beta < \alpha$). Now let $y \subseteq \omega$ be such that for all $\alpha < \omega$, $a_\alpha \cap y$ is infinite if and only if $\alpha \in B$. Let

$$p_0 = \langle (M_0, I_0), b_0 \rangle \quad \text{and} \quad p_1 = \langle (M_1, I_1), b_1 \rangle$$

be members of F_B, as witnessed by iterations j_0 and j_1 respectively, and let C_0 and C_1 be the respective critical sequences of j_0 and j_1. Let $\langle (N, J), a \rangle$ be a member of G with $x, y, z, p_0, p_1 \in H(\omega_1)^N$ and sets c_0 and c_1 in $\mathcal{P}(\omega_1)^N$ such that, for j the unique iteration of (N, J) sending a to A_G, $j(c_0) = C_0$ and $j(c_1) = C_1$. Then $c_0 = C_0 \cap \omega_1^N$, $c_1 = C_1 \cap \omega_1^N$, and c_0 and c_1 are both club subsets of ω_1^N. Since $\omega_1^{L[z,B]} = \omega_1$, $\omega_1^{L[z,b_0]} = \omega_1^{M_0}$ and $\omega_1^{L[z,b_1]} = \omega_1^{M_1}$. Since $x \in N$, $\{a_\alpha : \alpha < \omega_1^N\}$ is in N (it satisfies the same definition in N

relative to x and a that $\{a_\alpha : \alpha < \omega_1\}$ satisfies relative to x and A_G). Since $y \in N$, $B \cap \omega_1^N \in N$, and the unique iterations

$$j_0^* : (M_0, I_0) \to (M_0^*, I_0^*)$$

and

$$j_1^* : (M_1, I_1) \to (M_1^*, I_1^*)$$

sending b_0 to $B \cap \omega_1^N$ and b_1 to $B \cap \omega_1^N$ respectively are in N, and furthermore $j(B \cap \omega_1^N) = B$. Once we see that $I_0^* = J \cap M_0^*$ and $I_1^* = J \cap M_1^*$ we will be done. The two proofs are the same. For (M_0, I_0), if $E \in J \cap M_0^*$, then since $E \in J$, $j(E) \in \mathrm{NS}_{\omega_1}^{L(\mathbb{R})[G]}$. Now, $j(j^*)$ is an iteration of (M_0, I_0) sending b_0 to B, and so it is equal to j_0. Then $j(E)$ is the image of E under the tail of the iteration j_0 starting with (M_0^*, I_0^*). So $j(E) \in j_0(M_0)$, and since $j_0(I_0) = \mathrm{NS}_{\omega_1}^{L(\mathbb{R})[G]} \cap j_0(M_0)$, $j(E) \in j_0(I_0)$, and so $E \in I_0^*$. ⊣

If $G \subseteq \mathbb{P}_{\max}$ is an $L(\mathbb{R})$-generic filter, then $F_{(A_G)}$ is a filter containing G, and so by the genericity of G, $F_{(A_G)} = G$.

Now we show that any new subset of ω_1 added by forcing with $\mathbb{P}_{\max}$ generates the entire extension.

7.7 Theorem. *Assume that axiom* $(*)$ *holds. Then for every* $B \in \mathcal{P}(\omega_1) \setminus L(\mathbb{R})$*,* F_B *is an* $L(\mathbb{R})$*-generic filter for* $\mathbb{P}_{\max}$*, and* $L(\mathcal{P}(\omega_1)) = L(\mathbb{R})[F_B]$*.*

Proof. By Lemma 7.4, there is a real z such that $L[z, B]$ correctly computes ω_1. By Lemma 7.6, F_B is a filter. Now, let $\langle (M, I), a\rangle$ be a condition in G such that $z \in M$ and for some $b \in \mathcal{P}(\omega_1)^M$, $j(b) = B$, for j the unique iteration of (M, I) sending a to A_G. As in Lemma 2.10, the mapping π sending each condition $\langle (N, J), c\rangle$ below $\langle (M, I), a\rangle$ to the condition $\langle (N, J), b^*\rangle$, where b^* is the image of b by the iteration of (M, I) sending a to c, is an isomorphism. The image of G under π, F_B, is then an $L(\mathbb{R})$-generic filter in $\mathbb{P}_{\max}$. Furthermore, π is in $L(\mathbb{R})$, so G is in $L(\mathbb{R})[F_B]$. ⊣

7.8 Theorem. *Assume* $\mathrm{AD}^{L(\mathbb{R})}$ *and that for every* Π_2 *sentence* ϕ *in the language with two additional unary predicates, if* $A \in \mathcal{P}(\mathbb{R}) \cap L(\mathbb{R})$ *and*

$$\langle H(\omega_2), A, \mathrm{NS}_{\omega_1}, \in\rangle^{L(\mathbb{R})^{\mathbb{P}_{\max}}} \models \phi$$

then

$$\langle H(\omega_2), A, \mathrm{NS}_{\omega_1}, \in\rangle \models \phi\,.$$

Then for every $B \in \mathcal{P}(\omega_1) \setminus L(\mathbb{R})$*,* F_B *is an* $L(\mathbb{R})$*-generic filter and*

$$H(\omega_2) = H(\omega_2)^{L(\mathbb{R})[F_B]}.$$

Proof. Let $\mathcal{P}$ denote $\mathcal{P}(\omega_1) \setminus \bigcup\{L[x] : x \in \mathbb{R}\}$ (under $\mathrm{AD}^{L(\mathbb{R})}$ this is the same as $\mathcal{P}(\omega_1) \setminus L(\mathbb{R})$, but we want to make the relevant syntax more explicit). The sentence asserting that F_B is a filter for every $B \in \mathcal{P}$ is Π_2 in $H(\omega_2)$ with parameters for NS_{ω_1} and the set of $\mathbb{P}_{\max}$ conditions, and by Lemma 7.6, this sentence holds in the $\mathbb{P}_{\max}$ extension of $L(\mathbb{R})$. If $X \in L(\mathbb{R})$ is a dense subset of $\mathbb{P}_{\max}$, then the statement that $F_B \cap X$ is nonempty for every $B \in \mathcal{P}$ is Π_2 in $H(\omega_2)$ with parameters for $\S_{\omega_1}$, X and the set of $\mathbb{P}_{\max}$ conditions, and this sentence holds in the $\mathbb{P}_{\max}$ extension of $L(\mathbb{R})$ by Theorem 7.7. Thus, for every $B \in \mathcal{P}$, F_B is $L(\mathbb{R})$-generic. Finally, the following statement is Π_2 in $H(\omega_2)$ with parameters for NS_{ω_1} and the set of $\mathbb{P}_{\max}$ conditions, and holds in the $\mathbb{P}_{\max}$ extension: for every $E \subseteq \omega_1$ and for every $B \in \mathcal{P}$ there is a $\mathbb{P}_{\max}$ condition $\langle (M, I), b\rangle$ and an iteration $j : (M, I) \to (M^*, I^*)$ such that $E \in \mathcal{P}(\omega_1)^{M^*}$, $j(b) = B$ and $I^* = \mathrm{NS}_{\omega_1} \cap M^*$. Fixing a set $B \in \mathcal{P}$, then, since $\{x, B\} \in L(\mathbb{R})[F_B]$, $H(\omega_2) \subseteq H(\omega_2)^{L(\mathbb{R})[F_B]}$. ⊣

Theorem 7.7 gives us another way to characterize the $\mathbb{P}_{\max}$ extension of $L(\mathbb{R})$, this time without mention of $\mathbb{P}_{\max}$. For the definition below, we fix the following notation. If g is a filter contained in $\mathrm{Col}(\omega, {<}\omega_1)$, then for each $\alpha < \omega_1$ we let

$$S^g_\alpha = \{\beta \mid \exists p \in g\ p(0, \beta) = \alpha\}$$

and, for each $\tau \subseteq \omega_1 \times \mathrm{Col}(\omega, {<}\omega_1)$, we let

$$I_g(\tau) = \{\alpha \mid \exists p \in g\ (\alpha, p) \in \tau\}.$$

7.9 Definition. Axiom $\binom{*}{*}$ is the statement that $x^\#$ exists for every real number x and if X is a nonempty subset of $\mathcal{P}(\omega_1)$ which is definable from real and ordinal parameters then there exists a real x and a set

$$\tau \subseteq \omega_1 \times \mathrm{Col}(\omega, {<}\omega_1)$$

such that $\tau \in L[x]$ and such that for all filters $g \subseteq \mathrm{Col}(\omega, {<}\omega_1)$, if g is $L[x]$-generic and if for each $\alpha < \omega_1$, S^g_α is stationary, then $I_g(\tau) \in X$.

The converse of the following theorem also holds (see [39, Sects. 5.7, 5.8]), though its proof is beyond the scope of this chapter.

7.10 Theorem. *Axiom $(*)$ implies that axiom $\binom{*}{*}$ holds in $L(\mathcal{P}(\omega_1))$.*

Proof. First note that AD implies that the sharp of every real exists. Now let G be an $L(\mathbb{R})$-generic filter such that $L(\mathcal{P}(\omega_1)) = L(\mathbb{R})[G]$, and fix a set X as in the statement of axiom $\binom{*}{*}$. Let $p = \langle (M, I), a\rangle$ be a condition in G such that for some $b \in \mathcal{P}(\omega_1)^M$, p forces that $j(b) \in X$, for j the unique iteration of (M, I) sending a to A_G. Let x be a real such that $\langle (M, I), a\rangle \in H(\omega_1)^{L[x]}$. Now, if $g \subseteq \mathrm{Col}(\omega, {<}\omega_1)$ is $L[x]$-generic, then as in the proof of Lemma 2.8, in $L[x][g]$ there is an iteration

$$\{M_\alpha, G_\beta, j_{\alpha\delta} : \beta < \alpha \leq \delta \leq \omega_1\}$$

of (M, I) such that for each $\beta < \omega_1$ and each set $e \in \mathcal{P}(\omega_1)^{M_\beta} \setminus j_{0\beta}(I)$ there is an $\alpha < \omega_1$ such that $S^g_\alpha \setminus j_{\beta\omega_1}(e)$ is nonstationary. Let σ be an $\mathrm{Col}(\omega, {<}\omega_1)$-name in $L[x]$ for the embedding $j_{0\omega_1}$ corresponding to such an iteration, and let τ be the set of pairs $(\alpha, p) \in \omega_1 \times \mathrm{Col}(\omega, {<}\omega_1)$ such that $p \Vdash \check{\alpha} \in \sigma(\check{b})$. Now suppose that $g \subseteq \mathrm{Col}(\omega, {<}\omega_1)$ is $L[x]$-generic and that each S^g_α is stationary. Then σ_g is an iteration of (M, I), and since there exists a real z such that

$$\omega_1^{L[z,\sigma_g(a)]} = \omega_1,$$

$\sigma_g(a)$ is not in $L(\mathbb{R})$. Then Theorem 7.7 implies that $G_{\sigma_g(a)}$ (as in the statement of that theorem) is an $L(\mathbb{R})$-generic filter for $\mathbb{P}_{\max}$. Since each S^g_α is stationary, σ_g witnesses that $\langle (M, I), a\rangle$ is in $G_{\sigma_g(a)}$, which means that $\sigma_g(b)$ is in X. Since $\sigma_g(b) = I_g(\tau)$, we are done. ⊣

Theorem 7.10 has the following immediate corollary. By a perfect subtree of $2^{<\omega_1}$ we mean a tree of height ω_1 such that every node is extended by a pair of incompatible nodes, and such that every countable increasing sequence has a node extending it.

7.11 Corollary. *Assume $\mathrm{AD}^{L(\mathbb{R})}$, and let $G \subseteq \mathbb{P}_{\max}$ be an $L(\mathbb{R})$-generic filter. Let ϕ be a unary formula with parameters for elements of $L(\mathbb{R})$ and suppose that there exists a subset of ω_1 in $L(\mathbb{R})[G] \setminus L(\mathbb{R})$ satisfying ϕ. Then there is a perfect subtree T of $2^{<\omega_1}$ such that every subset of ω_1 corresponding to a path through T satisfies ϕ.*

Given an ordinal β, Martin's Maximum$^{+\beta}$ ($\mathrm{MM}^{+\beta}$, derived from [7]) is the statement that whenever P is a partial order such that forcing with P preserves stationary subsets of ω_1, $\langle D_\alpha : \alpha < \omega_1\rangle$ is a sequence of dense subsets of P and $\langle \tau_\alpha : \alpha < \beta\rangle$ is a sequence of P-names for stationary subsets of ω_1, there is a filter $G \subseteq P$ such that $G \cap D_\alpha$ is nonempty for each $\alpha < \omega_1$ and $\{\gamma < \omega_1 \mid \exists p \in G\ p \Vdash \check{\gamma} \in \tau_\alpha\}$ is stationary for each $\alpha < \beta$.

It is shown in [17] that $\mathrm{MM}^{+\omega}$ does not imply axiom $(*)$, if the existence of a supercompact limit of supercompact cardinals is consistent with ZFC. The question of whether $\mathrm{MM}^{+\omega_1}$ implies axiom $(*)$ remains open. We mention the following two test cases, consequences of axiom $(*)$ which have not been shown from large cardinals to be provably forceable by a semi-proper partial order. We omit the proofs, as they appear in full in [39] (Theorem 7.12 appears in [39] as Theorem 5.74(5) and Theorem 7.15 appears as Theorem 6.124).

7.12 Theorem. *Suppose that axiom $\binom{*}{*}$ holds. Then for every $A \subseteq \omega_1$ which is not constructible from a real, there exist a real x and an $L[x]$-generic filter $g \subseteq \mathrm{Col}(\omega, {<}\omega_1)$ such that $L[x][g] = L[x, A]$.*

The statement of Theorem 7.15 requires the following definitions.

7.13 Definition. A tree $T \subseteq \{0,1\}^{<\omega_1}$ is *weakly special* if for all countable $X \prec \langle H(\omega_2), T, \in\rangle$, if $b : \omega_1 \cap X \to \{0,1\}$ is a cofinal branch of T_X not in M_X, then there is a bijection $\pi : \omega \to \omega_1^{M_X}$ definable in the structure $\langle M_X, T_X, b, \in\rangle$, where $\langle M_X, T_X, \in\rangle$ is the transitive collapse of X.

7.14 Definition. $\Phi^+_\diamondsuit$ is the statement that for each $A \subseteq \omega_1$ there exists a $B \subseteq \omega_1$ such that, letting $T_B = \{0,1\}^{<\omega_1} \cap L[B]$,

- $A \in L[B]$,
- T_B is weakly special,
- every branch of T_B is in $L[B]$.

7.15 Theorem. *Axiom* $(*)$ *implies* $\Phi^+_\diamondsuit$.

One consequence of Theorem 7.15 is that there are no weak Kurepa trees (subtrees of $\{0,1\}^{<\omega_1}$ of cardinality $\aleph_1$ with $\aleph_2$ many cofinal branches) in any $\mathbb{P}_{\max}$ extension.

8. Larger Models

The forcing construction $\mathbb{P}_{\max}$ can be applied to larger models than $L(\mathbb{R})$, if they satisfy (ostensibly) stronger forms of determinacy.

8.1 Definition. A set of reals A is *$^\infty$-borel* if there exists a set of ordinals S, an ordinal α and a binary formula ϕ such that

$$A = \{y \in \mathbb{R} \mid L_\alpha[S, y] \models \phi(S, y)\}.$$

The ordinal Θ is defined to be the least ordinal which is not a surjective image of $\mathbb{R}$. The notion of continuity in the definition below refers to the discrete topology on λ, not the interval topology. *Dependent Choice* (DC) is a weak form of the Axiom of Choice saying that every tree of height ω with no terminal nodes has a cofinal branch; *Dependent Choice for Sets of Reals* ($\mathrm{DC}_\mathbb{R}$) is the restriction of DC to trees on the reals.

8.2 Definition (ZF + $\mathrm{DC}_\mathbb{R}$). AD^+ is the conjunction of the following two statements.

- Every set of reals is *$^\infty$-borel*.
- If $\lambda < \Theta$ and $\pi : \lambda^\omega \to \omega^\omega$ is a continuous function, then $\pi^{-1}(A)$ is determined for every $A \subseteq \omega^\omega$.

It is an open question whether AD implies AD^+, though it is known that AD^+ holds in all models of AD of the form $L(A, \mathbb{R})$, where A is a set of reals (some of the details of the argument showing this appear in [9]).

The following consequences of AD^+ are enough to prove that $\mathbb{P}_{\max}$ conditions exist in suitable generality.

8.3 Theorem (ZF + $\mathrm{DC}_\mathbb{R}$). *If* AD^+ *holds and* $V = L(\mathcal{P}(\mathbb{R}))$ *then*

- *the pointclass* Σ^2_1 *has the scale property,*
- *every* Σ^2_1 *set of reals is the projection of a tree in* HOD*,*
- *every true* Σ_1*-sentence is witnessed by a* $\underset{\sim}{\Delta}^2_1$ *set of reals.*

Adapting the proof of Theorem 4.13, then, we have the following.

8.4 Theorem. *Suppose that $\Gamma \subseteq \mathcal{P}(\mathbb{R})$ is a pointclass closed under continuous preimages and that $L(\Gamma, \mathbb{R}) \models \mathrm{DC}_{\mathbb{R}} + \mathrm{AD}^+$. Then for every set of reals A in $L(\Gamma, \mathbb{R})$ there is a $\mathbb{P}_{\max}$ precondition (M, I) such that*

- $A \cap M \in M$,
- $\langle H(\omega_1)^M, A \cap M, \in\rangle \prec \langle H(\omega_1), A, \in\rangle$,
- (M, I) *is A-iterable.*

The corresponding parts of the proof of Theorem 5.1 then go through to give the following.

8.5 Theorem. *Suppose that $\Gamma \subseteq \mathcal{P}(\mathbb{R})$ is a pointclass closed under continuous preimages such that $L(\Gamma, \mathbb{R}) \models \mathrm{DC}_{\mathbb{R}} + \mathrm{AD}^+$. Suppose that $G \subseteq \mathbb{P}_{\max}$ is $L(\Gamma, \mathbb{R})$-generic. Then the following hold in $L(\Gamma, \mathbb{R})[G]$:*

- $\mathcal{P}(\omega_1) = \mathcal{P}(\omega_1)_G$,
- I_G *is the nonstationary ideal,*
- $\utilde{\delta}^1_2 = \omega_2$,
- I_G *is saturated.*

If there is no surjection in $L(\Gamma, \mathbb{R})$ from $\mathbb{R} \times \mathrm{On}$ onto Γ, then Γ is not wellordered in the $\mathbb{P}_{\max}$ extension of $L(\Gamma, \mathbb{R})$. Producing a model of Choice then requires the following step, which appears with proof in [39] as Theorem 9.36. The statement ω_2-DC says that $<\!\omega_2$-closed trees of height ω_2 with no terminal nodes have cofinal branches.

8.6 Theorem. *Suppose that $\Gamma \subseteq \mathcal{P}(\mathbb{R})$ is a pointclass closed under continuous preimages such that $L(\Gamma, \mathbb{R}) \models \mathrm{DC}_{\mathbb{R}} + \mathrm{AD}^+ +$ "Θ is regular". Suppose that $G \subseteq \mathbb{P}_{\max}$ is $L(\Gamma, \mathbb{R})$-generic. Then $L(\Gamma, \mathbb{R})[G] \models \omega_2$-DC.*

The axiom $\mathrm{AD}_{\mathbb{R}}$ is the statement that all two player games of perfect information of length ω where the players play real numbers are determined. This statement easily implies $\mathrm{DC}_{\mathbb{R}}$ and in the context of DC is properly stronger than AD^+. Theorem 8.7 below lists some properties of the $\mathbb{P}_{\max}$ extension of a model of $\mathrm{AD}_{\mathbb{R}}$ + "Θ is regular". Many of the corresponding proofs proceed by finding a $\mathbb{P}_{\max}$ condition satisfying axiom $(*)$ and satisfying the conclusion of Theorem 8.4 for a suitable set A. We emphasize that the first conclusion of Theorem 8.7 says that in the $\mathbb{P}_{\max}$ extension of $L(\Gamma, \mathbb{R})$, $L(\mathcal{P}(\omega_1))$ is a $\mathbb{P}_{\max}$ extension of $L(\mathbb{R})$, not (merely) $L(\Gamma, \mathbb{R})$.

Martin's Maximum$^{++}(\mathfrak{c})$ is the restriction of Martin's Maximum$^{+\omega_1}$ to partial orders of cardinality the continuum, which it implies is $\aleph_2$. (The notation comes from Woodin [39, p. 36], where $\mathrm{MM}^{+\omega_1}$ is called Martin's Maximum^{++}.) The statement $\diamondsuit(S^{\omega_2}_\omega)$ says that there is a sequence

$$\{A_\gamma : \gamma < \omega_2 \wedge \mathrm{cf}(\gamma) = \omega\}$$

such that each A_γ is a subset of γ and such that for every $B \subseteq \omega_2$, the set of $\alpha < \omega_2$ of countable cofinality such that $B \cap \alpha = A_\alpha$ is stationary. Woodin shows in [39, Sect. 5.2] that $\diamondsuit(S^{\omega_2}_\omega)$ follows from Martin's Maximum. Part (4) of the conclusion of Theorem 8.7 is due to Daniel Seabold [28]. *Chang's Conjecture* is the statement that for each function $F : [\omega_2]^{<\omega} \to \omega_2$ there exists an $X \subseteq \omega_2$ of ordertype ω_1 such that $F``[X]^{<\omega} \subseteq X$ (i.e., that the set of subsets of ω_2 of ordertype ω_1 is stationary, in the sense of [19]). It is an open question whether Chang's Conjecture holds in the $\mathbb{P}_{\max}$ extension of $L(\mathbb{R})$ whenever $L(\mathbb{R})$ satisfies AD. This question has been resolved (negatively) for $\mathbb{Q}_{\max}$ (see Remark 10.7).

Parts (5), (6) and (7) of Theorem 8.7 show that $\mathbb{P}_{\max}$ can be used to produce consistency results at ω_2 as well as at ω_1. We let $\mathrm{NS}^\omega_{\omega_2}$ denote the nonstationary ideal on ω_2 concentrating on the ordinals of cofinality ω. The ideal $\mathrm{NS}^\omega_{\omega_2}$ is *weakly presaturated* if for every $S \in \mathcal{P}(\omega_2) \setminus \mathrm{NS}^\omega_{\omega_2}$ and every function $f : S \to \omega_2$ there exist a ordinal $\gamma < \omega_3$ and a bijection $\pi : \omega_2 \to \gamma$ such that

$$\{\alpha \in S \mid f(\alpha) < \mathrm{ot}(\pi[\alpha])\} \notin \mathrm{NS}^\omega_{\omega_2}.$$

A normal ideal I on ω_2 is *semi-saturated* if whenever U is a set generic V-normal ultrafilter on ω_2 contained in $\mathcal{P}(\omega_2) \setminus I$, $\mathrm{Ult}(V, U)$ is wellfounded.

8.7 Theorem. *Suppose that $\Gamma \subseteq \mathcal{P}(\mathbb{R})$ is a pointclass closed under continuous preimages such that $L(\Gamma, \mathbb{R}) \models \mathrm{AD}_\mathbb{R} +$ "Θ is regular". Suppose that $G \subseteq \mathbb{P}_{\max}$ is $L(\Gamma, \mathbb{R})$-generic, and let*

$$H \subseteq \mathrm{Col}(\omega_3, H(\omega_3))^{L(\Gamma,\mathbb{R})[G]}$$

be an $L(\Gamma, \mathbb{R})[G]$-generic filter. Then the following hold in $L(\Gamma, \mathbb{R})[G][H]$:

1. *Axiom $(*)$,*
2. *Martin's Maximum$^{++}(\mathfrak{c})$,*
3. *$\diamondsuit(S^{\omega_2}_\omega)$,*
4. *Chang's Conjecture,*
5. *$\mathrm{NS}^\omega_{\omega_2}$ is precipitous,*
6. *$\mathrm{NS}^\omega_{\omega_2}$ is weakly presaturated,*
7. *there is a normal semi-saturated ideal on ω_2 containing $\mathrm{NS}^\omega_{\omega_2}$.*

9. Ω-Logic

In this section we will briefly describe the relationship between $\mathbb{P}_{\max}$ and Woodin's Ω-logic as presented in [39] (our presentation of Ω-logic, however, will follow the one in [44]; many basic facts about Ω-logic are proved in [1]). Let T be a set of sentences and let ϕ be a sentence, both in the language of set theory. Then $T \models_\Omega \phi$ (ϕ is Ω_T-valid) if for every forcing construction P and every ordinal α, if $V^P_\alpha \models T$ then $V^P_\alpha \models \phi$. We will define below the conjectured proof-theoretic complement to this model-theoretic notion.

A set of reals A is *universally Baire* if it is κ-universally Baire for all cardinals κ (see Definition 7.2). Woodin has shown that if δ is a limit of Woodin cardinals, then a set of reals is $<\delta$-universally Baire if and only if it is $<\delta$-weakly homogeneously Suslin (a proof is given in [19]). Given a universally Baire set of reals A, a transitive model N of ZFC is said to be A-*closed* if, whenever P is a partial order in N and $G \subseteq P$ is V-generic (not just N-generic), then $N[G] \cap A(G)$ is in $N[G]$. Lemmas 9.2 and 9.3 give useful reformulations of A-closure, and are relatively easy to prove (see [1]). The proof of Lemma 9.2 uses the following fact, which will show up again in the proof of Theorem 9.4 and in Sect. 10.1. For a proof of Theorem 9.1, see [10, p. 516] or [19, Appendix].

9.1 Theorem (McAloon). *If $\mathbb{P}$ is a partial order and forcing with $\mathbb{P}$ makes $\mathbb{P}$ countable, then $\mathbb{P}$ is forcing-equivalent to* $\mathrm{Col}(\omega, |\mathbb{P}|)$.

Theorem 9.1 implies that every partial order $\mathbb{P}$ regularly embeds into $\mathrm{Col}(\omega, |\mathbb{P}|)$, which is forcing-equivalent to $\mathbb{P} \times \mathrm{Col}(\omega, |\mathbb{P}|)$.

9.2 Lemma. *Given a universally Baire set of reals A, a model M of* ZFC *is A-closed if and only if for all ordinals $\gamma \in M$, the set of pairs $(\tau, p) \in H(|\gamma|^+)^M$ such that τ is a* $\mathrm{Col}(\omega,\gamma)$*-name in M for a real, p is a condition in* $\mathrm{Col}(\omega,\gamma)$ *and p forces in V that the realization of τ is in $A(G)$ is in M.*

Lemma 9.3 shows that for countable models, it is not necessary to consider V-generic filters. The point is that, even without assuming the existence of large cardinals, if

- A is a universally Baire set of reals,
- M is a countable transitive model of ZFC,
- P is a partial order in M,
- p is a condition in P, and
- τ is a P-name in M for a real number

then p forces in V that τ_G is in $A(G)$ if and only if there exists (in V) a collection $\{D_i : i < \omega\}$ of dense subsets of P such that $\tau_g \in A$ for every M-generic filter $g \subseteq P$ containing p and intersecting each D_i.

9.3 Lemma. *Let A be a universally Baire set of reals and let M be a countable transitive model of* ZFC*. Then M is A-closed if and only if for each partial order P in M there exists (in V) a collection $\{D_i : i < \omega\}$ of dense subsets of P such that $M[G] \cap A \in M[G]$ for every M-generic filter $g \subseteq P$ intersecting each D_i.*

By Lemma 9.3 (and the fact that the set of wellfounded ordinals of an illfounded model of ZFC is not an element of the model), if A is the set of reals coding wellorderings of ω (under some fixed recursive coding), then (expanding to the class of ω-models of ZFC) A-closure is equivalent to wellfoundedness.

Let T be a theory containing ZFC and let ϕ be a sentence, both in the language of set theory. Then $T \vdash_\Omega \phi$ (T implies ϕ in Ω-logic) if there exists a set of reals A such that

- $L(A, \mathbb{R}) \models \mathrm{DC}_\mathbb{R} + \mathrm{AD}^+$,
- every set of reals in $L(A, \mathbb{R})$ is universally Baire,
- for every countable A-closed model M and every ordinal $\alpha \in M$, if V_α^M satisfies T then V_α^M satisfies ϕ.

A sentence ϕ is Ω_{ZFC}-*consistent* if ZFC $\nvdash_\Omega \neg\phi$. The first two conditions above ensure that the set of reals A is sufficiently canonical, and hold of all universally Baire sets of reals in the presence of a proper class of Woodin cardinals. The third condition says that A serves as a sort of proof of ϕ, in the sense that ϕ holds in all models which are closed under a certain function corresponding to A.

The following theorem shows that statements which can be forced to hold (along with ZFC) in suitable initial segments of the universe are Ω_{ZFC}-consistent. The proof shows the stronger fact that for every universally Baire set of reals A, all forceable statements hold in models N which are A-closed in the stronger sense that $N[G] \cap A \in N[G]$ for all N-generic filters G.

9.4 Theorem. *Suppose that A is a universally Baire set of reals and that κ is a strongly inaccessible cardinal. Then any forcing extension (in V) of any transitive collapse of any elementary submodel of V_κ containing A is A-closed.*

Proof. Since A is universally Baire and κ is strongly inaccessible, A is universally Baire in V_κ. To see this, fix a partial order P in V_κ and trees S and T witnessing the universal Baireness of A for P. Let ρ be a P-name in V_κ for all the reals of the P-extension, let θ be a regular cardinal greater than $|S^{<\kappa}|$, $|T^{<\kappa}|$ and κ and let X be an elementary submodel of $H(\theta)$ of cardinality less than κ containing $\{S, T\}$ and the transitive closure of ρ. Then the images of S and T under the transitive collapse of X are in V_κ and witness the universal Baireness of A for P.

Now let X be an elementary submodel of V_κ with A as an element, and let M be the transitive collapse of X. Let P be a partial order in X, let $\bar{P}$ be the image of P under the transitive collapse of X, and let $g \subseteq \bar{P}$ be an M-generic filter. Let τ be a P-name in X for a partial order, and let $\bar{\tau}$ be the image of τ under the transitive collapse of X. We want to see that whenever $h \subseteq \bar{\tau}_g$ is a V-generic filter, then $M[g][h] \cap A(h)$ is in $M[g][h]$. Let $\gamma \in X \cap \kappa$ be a cardinal greater than $|P * \tau|$ and let S and T be trees in X witnessing the universal Baireness of A for $\mathrm{Col}(\omega, \gamma)$. Then S and T project to complements in any forcing extension of V by either $P * \tau$ or $\bar{\tau}_g$.

Let σ be a $\bar{\tau}_g$-name in $M[g]$ for a real. Let $\bar{S}$ and $\bar{T}$ be the images of S and T under the transitive collapse of X. Let $h \subseteq \bar{\tau}_g$ be V-generic. Then σ_h is in exactly one of $(p[S])^{V[h]}$ and $(p[T])^{V[h]}$, and by the elementarity of the collapsing map, σ_h is in exactly one of $(p[\bar{S}])^{M[g][h]}$ and $(p[\bar{T}])^{M[g][h]}$. Since $(p[\bar{S}])^{M[g][h]} \subseteq (p[S])^{V[h]}$ and $(p[\bar{T}])^{M[g][h]} \subseteq (p[T])^{V[h]}$, and since $A(h) = (p[S])^{V[h]}$, σ_h is in $A(h)$ if and only it is in $(p[\bar{S}])^{M[g][h]}$. Putting all of this together, we have that

$$M[g][h] \cap A(h) = (p[\bar{S}])^{M[g][h]},$$

which shows that $M[g]$ is A-closed. $\dashv$

Woodin has shown that the axiom $(*)$ is Ω_{ZFC}-consistent.

9.5 Theorem. *Suppose that there exists a proper class of Woodin cardinals and that there is an inaccessible cardinal which is a limit of Woodin cardinals. Then the theory*

$$\mathrm{ZFC} + (*)$$

is Ω_{ZFC}-consistent.

The proof of Theorem 9.5 requires one to force axiom $(*)$ over larger models than $L(\mathbb{R})$, in particular, models of the form $L(S, \mathbb{R})$, where for some strongly inaccessible limit of Woodin cardinals κ, S is a $<\kappa$-weakly homogeneous tree. A proof that such models can satisfy AD^+ appears in [19]. It is not known whether there are large cardinals whose existence implies that one can force over V to make axiom $(*)$ hold. Woodin has conjectured that (ordertype) ω^2 many Woodin cardinals are sufficient. Of course, if $\mathrm{MM}^{+\omega_1}$ implies axiom $(*)$ (we discussed this question in Sect. 7) then one supercompact cardinal is sufficient.

9.6 Definition. Woodin's Ω *Conjecture* asserts that if there exist proper class many Woodin cardinals then for every sentence ϕ, $\emptyset \models_\Omega \phi$ if and only if $\emptyset \vdash_\Omega \phi$.

Recall that for a set x, $x^\dagger$ is a set of the same cardinality as x coding a theory extending ZFC + “There exists a measurable cardinal” with constants for each member of x and for two classes of indiscernibles (above and below the measurable cardinal). If there exist proper class many Woodin cardinals, then the set D of reals coding (under some fixed recursive coding) pairs (x, i), where x is a real number, i is an integer and $i \in x^\dagger$ is universally Baire. Any D-closed model M then has the property that for any set x, $x^\dagger$ exists in any forcing extension of M where x is countable, which since $x^\dagger$ is unique means that $x^\dagger$ exists in M already (an easy way to say this uses the fact that $\mathrm{Col}(\omega, |x|)$ is homogeneous, though this is not necessarily the most direct way). Thus for every ordinal $\alpha \in M$, there exist an inner model N of M containing V_α^M (definable in M), an ordinal $\kappa > \alpha$ which is a measurable cardinal in N and a set μ which is a κ-complete nonprincipal measure on κ in N such that all iterates of N by μ are wellfounded. As in Example 1.7, then, if M is a D-closed model and I is a normal precipitous ideal on ω_1^M in M, then every rank initial segment of M satisfying ZFC° is a rank initial segment of a model N such that (N, I) is iterable, and so (M, I) is also iterable. Using this we have that every Π_2 sentence for $\langle H(\omega_2), \mathrm{NS}_{\omega_1}, \in\rangle$ which is Ω_{ZFC}-consistent with the existence of a precipitous ideal on ω_1 holds in the $\mathbb{P}_{\max}$ extension. Using the canonical inner models for Woodin cardinals one can do more, however.

9.7 Theorem. *If there is a proper class of Woodin cardinals, then for every set of reals A in $L(\mathbb{R})$, every Ω_{ZFC}-consistent Π_2 sentence for $\langle H(\omega_2), \mathrm{NS}_{\omega_1}, A, \in\rangle$ holds in the $\mathbb{P}_{\max}$ extension of $L(\mathbb{R})$.*

In the next few paragraphs we will sketch a proof of Theorem 9.7 (an actual proof is beyond the scope of this chapter). This will require introducing some concepts from inner model theory (see [34, 27], for instance).

Given a set of reals A such that $A = L(A) \cap \mathbb{R}$, $A^\#$ is a set of reals coding the theory of $L(A)$ in the language with constants for each real and ω many ordinal indiscernibles (see [33]; again, this is not a characterization of $A^\#$, which is unique if it exists). If $\mathbb{R}^\#$ exists then each set of reals in $L(\mathbb{R})$ is definable in $L(\mathbb{R})$ from a real and a finite set of these indiscernibles.

The following theorem (due to Woodin) is proved in [19].

9.8 Theorem. *Suppose that δ is a limit of Woodin cardinals below a measurable cardinal. Then $\mathbb{R}^\#$ is $<\delta$-weakly homogeneous, and if M is any forcing extension of V by a forcing construction in V_δ then $(\mathbb{R}^\#)^V = (\mathbb{R}^\#)^M \cap V$.*

For each set a, let $M(a)$ denote the minimal model of ZFC + "There exist infinitely many Woodin cardinals below a measurable cardinal". (i.e., the unique fine structural, fully iterable model of this theory which comes out shorter in comparison with every other such model of this theory). This theory implies that $\mathbb{R}^\#$ is $<\lambda$-weakly homogeneously Suslin, and so there exist in $M(a)$ trees S and T on $\omega \times \lambda$ witnessing in $M(a)$ that $\mathbb{R}^\#$ and its complement are $<\lambda$-universally Baire. Furthermore, from the point of view of V, S and T project to a subset of $\mathbb{R}^\#$ and a subset of $\mathbb{R} \setminus \mathbb{R}^\#$, respectively.

The property of $M(a)$ that we need is the following: if δ is a Woodin cardinal in $M(a)$ below λ, γ is an ordinal below δ and y is a subset of ω, then there exist a partial order P (this partial order was discovered by Woodin and is usually called the *extender algebra*) of cardinality δ in $M(a)$ and an elementary embedding $j : M(a) \to M'$ with critical point greater than γ such that

- y is M'-generic for $j(P)$,
- $p[j(S)] \subseteq \mathbb{R}^{\#}$,
- $p[j(T)] \subseteq \mathbb{R} \setminus \mathbb{R}^{\#}$.

There is a universally Baire function f taking a real x coding an a in $H(\omega_1)$ to a real $f(x)$ coding $M(a)$. If x and y code the same element of $H(\omega_1)$ then $f(x)$ and $f(y)$ code the same model. If B is the set of reals coding pairs (x, i) such that $i \in f(x)$, then, every B-closed model of ZFC contains $M(a)$ for every set a in M.

Now let ϕ be a Π_2 sentence for $H(\omega_2)$ (of the form $\exists X \forall Y \psi(X, Y)$) with predicates for NS_{ω_1} and a given set of reals A in $L(\mathbb{R})$. Let z be a real number coding a given $\mathbb{P}_{\max}$ condition and a real which codes A relative to $\mathbb{R}^{\#}$. Suppose that N is a countable B-closed model of ZFC satisfying ϕ and containing z. Let a be a wellordering of $H(\omega_2)^N$ in N. Then $H(\omega_2)^{M(a)} = H(\omega_2)^N$. Let γ be the least strongly inaccessible cardinal in $M(a)$ above the least Woodin cardinal. Let S and T be trees in $M(a)$ witnessing the $<\lambda$-universal Baireness of $\mathbb{R}^{\#}$ and its complement, where λ is the least limit of Woodin cardinals in $M(a)$. We want to see that whenever we make NS_{ω_1} precipitous by any forcing in $V_\gamma^{M(a)}$ (getting a generic filter g) and then iterate $V_\gamma^{M(a)[g]}$ by NS_{ω_1}, we iterate correctly for $\mathbb{R}^{\#}$. Given this, if g is such a generic filter for a forcing preserving stationary subsets of $\omega_1^{M(a)}$ then $V_\gamma^{M(a)[g]}$ is an A-iterable model such that $\exists Y \psi(X, Y)$ holds in $H(\omega_2)^{V_\gamma^{M(a)[g]}}$ for all $X \in H(\omega_2)^{V_\gamma^{M(a)}}$, and by a density argument then, ϕ holds in the $\mathbb{P}_{\max}$ extension.

Towards a contradiction, choose a bad generic filter g and bad iteration k. Let $j : M(a) \to M'$ be an embedding (with critical point above γ) such that we can add g and k to M' by forcing with the extender algebra for the image of the least Woodin cardinal in $M(a)$ above γ. Then $M'[g, k]$ has a bad iteration of $V_\gamma^{M(a)[g]}$ in it, and by Lemma 1.5 this iteration extends to an iteration of $M'[g]$ (which we will also call k), which means that

$$k(\mathbb{R}^{\#} \cap V_\gamma^{M(a)[g]}) = p[k(j(S))] \cap k(V_\gamma^{M(a)[g]})$$

and

$$k((\mathbb{R} \setminus \mathbb{R}^{\#}) \cap V_\gamma^{M(a)[g]}) = p[k(j(T))] \cap k(V_\gamma^{M(a)[g]}).$$

But $j(S)$ and $j(T)$ are $<j(\lambda)$-universally Baire in M', so they project to complements in $M'[g, k]$. Furthermore,

$$p[j(S)] \subseteq \mathbb{R}^{\#}$$

and

$$p[j(T)] \subseteq \mathbb{R} \setminus \mathbb{R}^{\#}.$$

Since $p[j(S)] \subseteq p[k(j(S))]$ and $p[j(T)] \subseteq p[k(j(T))]$, $p[j(S)] = p[k(j(S))]$ and $p[j(T)] = p[k(j(T))]$, contradicting that k is a bad iteration. This completes our sketch of the proof of Theorem 9.7.

Another strengthening of Theorem 0.2, using the absoluteness of $\mathbb{R}^{\#}$, is the following.

9.9 Theorem. *Suppose that there exists a proper class of Woodin cardinals. Then for every sentence ϕ, either* ZFC $\vdash_\Omega L(\mathbb{R}) \models \phi$ *or* ZFC $\vdash_\Omega L(\mathbb{R}) \not\models \phi$.

Since $\mathbb{P}_{\max}$ is a homogeneous forcing extension of $L(\mathbb{R})$, this gives the following.

9.10 Theorem. *Suppose that there exists a proper class of Woodin cardinals. Then for every sentence ϕ, either*

$$\text{ZFC} + (*) \vdash_\Omega L(\mathcal{P}(\omega_1)) \models \phi$$

or

$$\text{ZFC} + (*) \vdash_\Omega L(\mathcal{P}(\omega_1) \not\models \phi.$$

Since $\mathbb{R}^{\#}$ is not in $L(\mathbb{R})$, the Continuum Hypothesis (plus the existence of $\mathbb{R}^{\#}$) implies that $L(\mathcal{P}(\omega_1))$ is not contained in a forcing extension of $L(\mathbb{R})$. Moreover, Woodin has shown (see Theorem 10.183 of [39]) that if ψ is any sentence for which Theorem 9.10 holds with ψ in the place of axiom $(*)$, then ZFC + ψ implies in Ω-logic that the Continuum Hypothesis is false.

10. Variations

The $\mathbb{P}_{\max}$ method is fairly flexible, and the partial order $\mathbb{P}_{\max}$ can be varied in a number of ways. We present here two types of variations. The first is an example of the utility of $\mathbb{P}_{\max}$ for manipulating ideals on ω_1. The second illustrates a method for producing extensions which are Π_2-maximal for $H(\omega_2)$ relative to a fixed Σ_2 sentence. Several other variations appear in [39, 45]. Still others appear in [4, 20].

10.1. Variations for NS_{ω_1}

An ideal I on ω_1 is $\aleph_1$-*dense* if the Boolean algebra $\mathcal{P}(\omega_1)/I$ has a dense subset of cardinality $\aleph_1$. In unpublished work, Woodin showed that starting from a huge cardinal one can force the existence of a normal $\aleph_1$-dense ideal on ω_1. Shelah later showed [29] that, starting from a supercompact cardinal, one can force that the nonstationary ideal restricted to a fixed stationary subset of ω_1 is $\aleph_1$-dense. The $\mathbb{P}_{\max}$ variation $\mathbb{Q}^*_{\max}$ discussed here, when applied to a model of the form $L(\mathbb{R})$ satisfying AD, produces a model of ZFC in which NS_{ω_1} is $\aleph_1$-dense; by unpublished work of Woodin, this shows that the Axiom of Determinacy and the $\aleph_1$-density of NS_{ω_1} are equiconsistent. To date, $\mathbb{P}_{\max}$ variations are the only known means for producing models in which NS_{ω_1} is $\aleph_1$-dense.

Using the result of Shelah mentioned above, the partial order $\mathbb{Q}_{\max}$ below can be used to obtain the $\aleph_1$-density of NS_{ω_1} from a supercompact cardinal below ω Woodin cardinals below a measurable. This hypothesis is not optimal, but unlike with $\mathbb{Q}^*_{\max}$, we can give all the details here (aside from one argument, we have already done so).

By Theorem 9.1, the $\aleph_1$-density of a σ-ideal on ω_1 is witnessed by a function from ω_1 to $H(\omega_1)$ of the following form.

10.1 Definition. Given a normal $\aleph_1$-dense ideal I on ω_1, $Y_{\mathrm{Col}}(I)$ is the set of functions $f : \omega_1 \to H(\omega_1)$ satisfying the following conditions (where for each $p \in \mathrm{Col}(\omega, \omega_1)$ we let $S^f_p = \{\alpha < \omega_1 \mid p \in f(\alpha)\}$):

- for each $\alpha < \omega_1$, $f(\alpha)$ is a filter in $\mathrm{Col}(\omega, 1 + \alpha)$
- for each $p \in \mathrm{Col}(\omega, \omega_1)$, $S^f_p \notin I$,
- for each $S \in \mathcal{P}(\omega_1)/I$, there exists a condition $p \in \mathrm{Col}(\omega, \omega_1)$ such that $S^f_p \setminus S \in I$.

10.2 Definition. The partial order $\mathbb{Q}_{\max}$ consists of the set of pairs of the form $\langle (M, I), f\rangle$ satisfying the following conditions:

1. M is a countable transitive model of ZFC°,
2. I is a normal $\aleph_1$-dense ideal on ω_1^M in M,
3. (M, I) is iterable,
4. $f \in (Y_{\mathrm{Col}}(I))^M$.

The order on $\mathbb{Q}_{\max}$ is as follows: $\langle (N, J), g\rangle < \langle (M, I), f\rangle$ if $M \in H(\omega_1)^N$ and there exists an iteration $j : (M, I) \to (M^*, I^*)$ such that

- $j(f) = g$,
- $j, M^* \in N$,
- $I^* = M^* \cap J$.

If $\langle (M, I), f\rangle$ is a $\mathbb{Q}_{\max}$ condition, then by the normality of I in M, the image of f under any iteration of (M, I) determines the entire iteration.

The only new argument we need to give in the $\mathbb{Q}_{\max}$ analysis is the following. The corresponding versions for iterating sequences of models and for building descending ω_1-sequences of conditions are essentially the same.

10.3 Lemma. *Suppose that J is a normal $\aleph_1$-dense ideal on ω_1, and let g be a function in $Y_{\mathrm{Col}}(J)$. Suppose that $\langle (M, I), f\rangle$ is a condition in $\mathbb{Q}_{\max}$. Then there is an iteration $j : (M, I) \to (M^*, I^*)$ of length ω_1 such that*

- $\{\alpha < \omega_1 \mid j(f)(\alpha) \neq g(\alpha)\} \in J$,
- $I^* = M^* \cap J$.

Proof. The second conclusion follows from the first. Let

$$\langle M_\alpha, G_\beta, j_{\alpha\delta} : \beta < \alpha \leq \delta \leq \omega_1\rangle$$

be any iteration of (M, I) satisfying the condition that whenever $\beta < \omega_1$ is such that $j_{0\beta}(\omega_1^M) = \beta$ and $g(\beta)$ is M_β-generic for $\mathrm{Col}(\omega, \beta)$, then G_β is the corresponding filter in $\mathcal{P}(\omega_1)^{M_\beta}/j_{0\beta}(I)$, i.e., for each $p \in \mathrm{Col}(\omega, \beta)$, $S_p^{j_{0\beta}(f)} \in G_\beta$ if and only if $p \in g(\beta)$. It is immediate that G_β is M_β-generic, and that the choice of G_β makes $j_{0(\beta+1)}(f)(\beta) = g(\beta)$. It remains to see that the set of $\beta < \omega_1$ such that $g(\beta)$ is not M_β-generic for $\mathrm{Col}(\omega, \beta)$ is in J. To see this, let A be subset of ω_1 coding $\langle M_\alpha, G_\beta, j_{\alpha\delta} : \beta < \alpha \leq \delta \leq \omega_1\rangle$ under some fixed recursive coding. Then for club many $\eta < \omega_1$, $j_{0\eta}(\omega_1)^M = \eta$ and $\langle M_\alpha, G_\beta, j_{\alpha\delta} : \beta < \alpha \leq \delta \leq \eta\rangle \in L[A \cap \eta]$. Every condition in $\mathcal{P}(\omega_1)/J$ forces that (letting k be the induced elementary embedding) $k(g)(\omega_1^V)$ is a V-generic (and thus $L[A]$-generic) filter in $\mathrm{Col}(\omega, \omega_1^V)$, which means that the set of $\eta < \omega_1$ such that $g(\eta)$ is not $L[A \cap \eta]$-generic is in J. Since $M_\eta \in L[A \cap \eta]$ for club many η, we are done. ⊣

Theorem 4.10 plus the result of Shelah mentioned above gives the following.

10.4 Theorem. *Suppose that there exists a supercompact cardinal below infinitely many Woodin cardinals below a measurable cardinal. Then for every set of reals A in $L(\mathbb{R})$ there exists a $\mathbb{Q}_{\max}$ condition $\langle (M, I), f\rangle$ such that*

- $A \cap M \in M$,
- (M, I) *is A-iterable,*
- $\langle H(\omega_1)^M, A \cap M, \in\rangle \prec \langle H(\omega_1, A, \in\rangle$.

The proof of the following is essentially the same as for $\mathbb{P}_{\max}$. The $\aleph_1$-density of I_G follows immediately from $\mathcal{P}(\omega_1) = \mathcal{P}(\omega_1)_G$ and the definition of $\mathbb{Q}_{\max}$ (letting I_G and $\mathcal{P}(\omega_1)_G$ have the definitions here analogous to those used for $\mathbb{P}_{\max}$).

10.5 Theorem (ZF). *Suppose that for every set of reals A there exists a $\mathbb{Q}_{\max}$ condition $\langle (M, I), f\rangle$ such that*

- $A \cap M \in M$,
- (M, I) *is A-iterable,*
- $\langle H(\omega_1)^M, A \cap M, \in\rangle \prec \langle H(\omega_1, A, \in\rangle$.

Then $\mathbb{Q}_{\max}$ is ω-closed and homogeneous. Furthermore, if G is an V-generic filter for $\mathbb{Q}_{\max}$, then the following hold in $V[G]$:

- $\mathcal{P}(\omega_1) = \mathcal{P}(\omega_1)_G$,
- $\mathrm{NS}_{\omega_1} = I_G$,
- ψ_{AC},
- $\underset{\sim}{\delta}^1_2 = \omega_2$,
- NS_{ω_1} *is* $\aleph_1$-*dense.*

To obtain the $\aleph_1$-density of NS_{ω_1} from the optimal hypothesis, we can use the partial order $\mathbb{Q}^*_{\max}$ below. Conditions in $\mathbb{Q}^*_{\max}$ are similar to the limit sequences used in the $\mathbb{P}_{\max}$ analysis. The utility of this approach here is that the existence of $\mathbb{Q}^*_{\max}$ conditions does not require the existence of a model with an $\aleph_1$-dense ideal on ω_1. The analyses of $\mathbb{Q}^*_{\max}$ and $\mathbb{Q}_{\max}$ are the same, once we show that $\mathbb{Q}^*_{\max}$ conditions exist in suitable generality. Showing this, however, is beyond the scope of this chapter.

10.6 Definition. $\mathbb{Q}^*_{\max}$ is the set of pairs $(\langle M_k : k < \omega\rangle, f)$ such that the following hold.

1. The set f is a function from $\omega_1^{M_0}$ to M_0 in M_0 such that for all $\alpha < \omega_1^{M_0}$, $f(\alpha)$ is a filter in $\mathrm{Col}(\omega, 1+\alpha)$.
2. Each $M_k \models \mathrm{ZFC}^\circ$.
3. Each $M_k \in M_{k+1}$.
4. For all $k < \omega$, $\omega_1^{M_k} = \omega_1^{M_0}$.
5. For all $k < \omega$, $\mathrm{NS}_{\omega_1}^{M_{k+1}} \cap M_k = \mathrm{NS}_{\omega_1}^{M_{k+2}} \cap M_k$.
6. The sequence $\langle M_k : k < \omega\rangle$ is iterable.
7. For each $p \in \mathrm{Col}(\omega, \omega_1^{M_0})$, $\{\alpha < \omega_1^{M_0} \mid p \in f(\alpha)\} \notin \mathrm{NS}_{\omega_1}^{M_1}$.
8. For each $k < \omega$ and for each $a \subseteq \omega_1^{M_0}$ such that $a \in M_k \setminus \mathrm{NS}_{\omega_1}^{M_{k+1}}$, there exists a $p \in \mathrm{Col}(\omega, \omega_1^{M_0})$ such that
$$\{\alpha < \omega_1^{M_0} \mid p \in f(\alpha)\} \cap (\omega_1^{M_0} \setminus a) \in \mathrm{NS}_{\omega_1}^{M_{k+1}}.$$

The ordering on $\mathbb{Q}^*_{\max}$ is given by letting
$$(\langle N_k : k < \omega\rangle, g) < (\langle M_k : k < \omega\rangle, f)$$
if $\langle M_k : k < \omega\rangle \in H(\omega_1)^{N_0}$ and there exists an iteration
$$j : \langle M_k : k < \omega\rangle \to \langle M^*_k : k < \omega\rangle$$
in N_0 such that

- $j(f) = g$,
- $\mathrm{NS}_{\omega_1}^{M^*_{k+1}} \cap M^*_k = \mathrm{NS}_{\omega_1}^{N_1} \cap M^*_k$ for all $k < \omega$.

Condition (5) above says that the models in the sequence need not agree about stationary sets, but rather, each subset of $\omega_1^{M_0}$ in each M_k which is stationary in M_{k+1} is stationary in all further M_j's. This extra degree of freedom is essential in constructing $\mathbb{Q}^*_{\max}$ conditions without presupposing the existence of $\mathbb{Q}_{\max}$ conditions. Conditions (7) and (8) ensure that if

$$G \subseteq \bigcup\{\mathcal{P}(\omega_1^{M_0})^{M_k} \setminus \mathrm{NS}_{\omega_1}^{M_{k+1}} : k < \omega\}$$

is a $\bigcup\{M_k : k < \omega\}$-normal filter, then (letting j be the induced embedding) $j(f)(\omega_1^{M_0})$ is a filter in $\mathrm{Col}(\omega, \omega_1^{M_0})$ meeting every dense set in each M_k, and vice-versa: if g is a filter in $\mathrm{Col}(\omega, \omega_1^{M_0})$ meeting every dense set in each M_k, then there is a $\bigcup\{M_k : k < \omega\}$-normal filter G contained in $\bigcup\{\mathcal{P}(\omega_1^{M_0})^{M_k} \setminus \mathrm{NS}_{\omega_1}^{M_{k+1}} : k < \omega\}$ such that $j(f)(\omega_1^{M_0}) = g$.

10.7 Remark. If Γ is a pointclass closed under continuous images such that $L(\Gamma, \mathbb{R}) \models \mathrm{AD}_{\mathbb{R}} +$ "Θ is regular", then the $\mathbb{Q}_{\max}$ extension of $L(\Gamma, \mathbb{R})$ satisfies Chang's Conjecture. However, for consistency strength reasons one cannot prove that Chang's Conjecture holds in the $\mathbb{Q}_{\max}$ extension of $L(\mathbb{R})$ from the assumption $\mathrm{AD}^{L(\mathbb{R})}$(see [39, p. 651]).

The utility of the $\mathbb{P}_{\max}$ approach for manipulating ideals on ω_1 is applied in other several ways in [39], notably to create a model in which the saturation of NS_{ω_1} can be destroyed without adding a subset of ω_1. In [20], a variation of $\mathbb{P}_{\max}$ is used to produce a model in which the saturation of NS_{ω_1} can be destroyed by forcing with a Suslin tree. As far as we know, these results have not been reproduced by other methods.

10.2. Conditional Variations for Σ_2 sentences

As we saw in Sect. 7, the $\mathbb{P}_{\max}$ extension of $L(\mathbb{R})$ (assuming that there exists a proper class of Woodin cardinals) satisfies all forceable Π_2 sentences for $H(\omega_2)$ with parameters for NS_{ω_1} and sets of reals in $L(\mathbb{R})$. In some cases, one can fix a Σ_2 sentence for this structure and produce a model satisfying all Π_2 sentences forceably consistent with it (and in some cases one cannot). If ϕ is a Σ_2 sentence of the form $\exists A \forall B \psi(A, B)$, where all quantifiers in ψ are bounded, the *optimal iteration lemma* for ϕ is the following statement: if

- M is a countable transitive model of ZFC°,
- I is normal ideal on ω_1^M in M,
- (M, I) is iterable,
- $a \in H(\omega_2)^M$ and $H(\omega_2)^M \models \forall b \psi(a, b)$,

- $H(\omega_2) \models \exists A \forall B \psi(A, B)$,
- J is a normal ideal on ω_1,

then there exists an iteration $j : (M, I) \to (M^*, I^*)$ of length ω_1 such that

- $I^* = J \cap M^*$,
- $H(\omega_2) \models \forall B \psi(j(a), B)$.

Roughly, the optimal iteration lemma for ϕ says that given a countable transitive iterable model of ϕ and a fixed witness for ϕ in this model, in order to prove that there is an iteration of this model mapping this witness to a witness for ϕ is V, we need assume only that ϕ holds in V. Since this assumption is necessary, in the cases where the lemma holds, it is optimal. In [31], the optimal iteration lemma is proved for the following sentences (the first four of which are defined in [2]; we direct the reader to [31] for the other two).

- The dominating number ($\mathfrak{d}$) is $\aleph_1$.
- The bounding number ($\mathfrak{b}$) is $\aleph_1$.
- The cofinality of the meager ideal is $\aleph_1$.
- The cofinality of the null ideal is $\aleph_1$.
- There exists a coherent Suslin tree.
- There exists a free Suslin tree.

Given a Σ_2 sentence ϕ as above, we can define the $\mathbb{P}_{\max}$ variation $\mathbb{P}^{\phi}_{\max}$ as follows. Since ϕ may contradict $\mathrm{MA}_{\aleph_1}$, we remove the requirement that the models satisfy $\mathrm{MA}_{\aleph_1}$ and ensure the uniqueness of iterations directly (alternately, we can usually replace $\mathrm{MA}_{\aleph_1}$ with ψ_{AC}). The partial order $\mathbb{P}^{\phi}_{\max}$ is defined recursively on the ω_1 of the selected model M.

10.8 Definition. The partial order $\mathbb{P}^{\phi}_{\max}$ consists of all pairs $\langle (M, I), a, X\rangle$ such that

1. M is a countable transitive model of ZFC°,
2. $I \in M$ and in M, I is a normal ideal on ω_1,
3. (M, I) is iterable,
4. $a \in \mathcal{P}(\omega_1)^M$ and $H(\omega_2)^M \models \forall b \psi(a, b)$,
5. $X \in M$ and X is a set (possibly empty) of pairs $(\langle (N, J), b, Y\rangle, j)$ such that
    - $\langle (N, J), b, Y\rangle \in \mathbb{P}^{\phi}_{\max} \cap H(\omega_1)^M$,

- j is an iteration of (N, J) of length ω_1^M such that $j(J) = I \cap j(N)$ and $j(b) = a$,
- $j(Y) \subseteq X$,

with the property that for each $p \in \mathbb{P}^{\phi}_{\max}$ there is at most one j such that $(p, j) \in X$.

The order on $\mathbb{P}^{\phi}_{\max}$ is implicit in the conditions on X:

$$\langle (M, I), a, X\rangle < \langle (N, J), b, Y\rangle$$

if there exists a j such that $(\langle (N, J), b, Y\rangle, j) \in X$.

For ϕ as above, we have games $\mathcal{G}^{\phi}_{\omega}$ and $\mathcal{G}^{\phi}_{\omega_1}$ which are strictly analogous to the games $\mathcal{G}_{\omega}$ and $\mathcal{G}_{\omega_1}$ for $\mathbb{P}_{\max}$.

For $\mathcal{G}^{\phi}_{\omega}$, suppose that $\langle (N_i, J_i) : i < \omega\rangle$ is an iterable pre-limit sequence (in the sense of $\mathbb{P}_{\max}$) and that there exists an $a \in \mathcal{P}(\omega_1)^{N_0}$ such that $H(\omega_2)^{N_i} \models \forall b\psi(a, b)$ for each $i < \omega$. Then given a normal ideal I on ω_1 and a set $E \subseteq \omega_1$, we define $\mathcal{G}^{\phi}_{\omega}(\langle (N_i, J_i) : i < \omega\rangle, I, E)$ to be the following game of length ω_1 where Players I and II collaborate to build an iteration of $\langle (N_i, J_i) : i < \omega\rangle$ consisting of pre-limit sequences $\langle (N^{\alpha}_i, J^{\alpha}_i) : i < \omega\rangle$ $(\alpha \leq \omega_1)$, normal ultrafilters G_{α} $(\alpha < \omega_1)$ and a commuting family of embeddings $j_{\alpha\beta}$ $(\alpha \leq \beta \leq \omega_1)$, as follows. In each round α, let

$$Q_{\alpha} = \bigcup\{\mathcal{P}(\omega_1)^{N^{\alpha}_i} \setminus J^{\alpha}_i : i < \omega\}\,.$$

If $\alpha \in E$, then Player I chooses a set $A \in Q_{\alpha}$, and then Player II chooses a $\bigcup\{N^{\alpha}_i : i < \omega\}$-normal filter G_{α} contained in Q_{α} with $A \in G_{\alpha}$. If α is not in E, then Player II chooses any $\bigcup\{N^{\alpha}_i : i < \omega\}$-normal filter G_{α} contained in Q_{α}. After all ω_1 many rounds have been played, Player I wins if $H(\omega_2) \models \forall B\psi(j_{0\omega_1}(a), B)$ and if $J^{\omega_1}_i = I \cap N^{\omega_1}_i$ for each $i < \omega$.

Similarly, given a $\mathbb{P}^{\phi}_{\max}$ condition $p = \langle (M, I), a, X\rangle$, a normal ideal J on ω_1 and a subset of ω_1 E, we let $\mathcal{G}^{\phi}_{\omega_1}(p, J, E)$ be game of length ω_1 where players I and II collaborate to build a descending ω_1-chain of conditions $p_{\alpha} = \langle (M_{\alpha}, I_{\alpha}), a_{\alpha}, X_{\alpha}\rangle$ $(\alpha < \omega_1)$ of $\mathbb{P}^{\phi}_{\max}$ conditions below p as follows. In each round α, all p_{β} $(\beta < \alpha)$ have been defined. If α is a successor ordinal (or 0), Player II chooses a condition $p_{\alpha} < p_{\alpha-1}$ $(< p)$. If α is a limit ordinal, then Player I picks a condition p_{α} below each p_{β} $(\beta < \alpha)$. Then, letting $j_{\alpha\beta}$ $(\alpha < \beta \leq \omega_1)$ be the induced commuting family of embeddings (and letting j be the embedding witnessing that $p_0 < p$), Player I wins the game if $H(\omega_2) \models \forall B\psi(j_{0\omega_1}(j(a)), B)$, and if for all $\alpha < \omega_1$, $j_{\alpha\omega_1}(I_{\alpha}) = J \cap j_{\alpha\omega_1}(M_{\alpha})$.

The arguments in [31] show that $\diamondsuit_{\omega_1}$ implies that Player I has a winning strategy in each game $\mathcal{G}^{\phi}_{\omega}(\langle (N_i, J_i) : i < \omega\rangle, I, E)$ and each game $\mathcal{G}^{\phi}_{\omega_1}(p, J, E)$ for each of the sentences listed before Definition 10.8 (typically these arguments are essentially the same as the proof of the corresponding optimal iteration lemma).

The proof of the following theorem then is a straightforward generalization of the arguments we have given for $\mathbb{P}_{\max}$.

10.9 Theorem. *Assume* $\mathrm{AD}^{L(\mathbb{R})}$*, and let* ϕ *be an* Ω_{ZFC}*-consistent* Σ_2 *sentence for* $H(\omega_2)$*. Suppose that the optimal iteration lemma for* ϕ *holds, and that the following sentences are* Ω_{ZFC}*-consistent:*

- *for all iterable pre-limit sequences* $\langle (N_i, I_i) : i < \omega\rangle$ *and for all normal ideals* I *on* ω_1*, Player* I *has a winning strategy in*

$$\mathcal{G}^{\phi}_{\omega}(\langle (N_i, J_i) : i < \omega\rangle, I, \omega_1);$$

- *for all* $\mathbb{P}^{\phi}_{\max}$ *conditions* p *and for all normal ideals* J *on* ω_1*, Player* I *has a winning strategy in* $\mathcal{G}_{\omega_1}(p, J, \omega_1)$*.*

Let $G \subseteq \mathbb{P}^{\phi}_{\max}$ *be* $L(\mathbb{R})$*-generic. Then in* $L(\mathbb{R})[G]$ *the following hold:*

- ϕ*,*
- $\mathcal{P}(\omega_1) = \mathcal{P}(\omega_1)_G$*,*
- $\mathrm{NS}_{\omega_1} = I_G$*,*
- NS_{ω_1} *is saturated.*

Furthermore, for every set of reals A *in* $L(\mathbb{R})$*,* $L(\mathbb{R})[G]$ *satisfies every* Π_2*-sentence for the structure* $\langle H(\omega_2), \mathrm{NS}_{\omega_1}, A, \in\rangle$ *which is* Ω_{ZFC}*-consistent with* ϕ*.*

The variation $\mathbb{P}^{\phi}_{\max}$ where ϕ asserts the existence of a coherent Suslin tree is studied in [16, 21].
