Tan et al. (2013) investigated the tissue distribution and pharmacokinetics of BBR and its metabolites in rats after oral administration of BBR (200 mg/kg). The results revealed that berberine was quickly distributed in the liver, kidneys, muscle, lungs, brain, heart, pancreas, and fat in a descending order of its amount. The concentrations of berberine were higher in tissues than in plasma. Metabolites of BBR, such as thalifendine, berberrubine, and jatrorrhizine were detected in the liver and kidney. Pharmacokinetic studies by Wang et al. (2004, 2005) further confirmed that berberine crosses the BBB and accumulates in the hippocampus, where it provides anti-apoptotic and neuroprotective effects.

Berberine exerts multiple pharmacological actions, such as antioxidant, anti-inflammatory, neuroprotective, analgesic, anxiolytic, and immunomodulatory actions, thereby providing preventive and therapeutic effects in neurological conditions (Kulkarni and Dhir 2008, 2010; Kumar et al. 2015; Hussein et al. 2018). In an investigation conducted on aluminum-overloaded rats, berberine improved learning and memory and protected hippocampal neurons from death by normalizing AChE, ChAT, SOD, and MAO-B activities and MDA content (Zhang et al. 2009). Kulkarni and Dhir (2008, 2010) and Kumar et al. (2015) reported that acute or chronic administration of BBR (5 mg/kg, ip) for 15 days increased the levels of neurotransmitters (norepinephrine, dopamine, and 5-HT) in discrete brain regions. Its neuroprotective role is also attributed to its ability to block potassium channels in hippocampal CA1 neurons leading to suppression of apoptosis (Wang et al. 2004). Cell death rate of neurons treated with BBR (5 μmol/L) was found to be significantly lower than that of non-treated neurons. Further, BBR was reported to protect the hippocampal CA1 region from ischemic injury by inhibiting NMDA receptor immunoreactivity in ischemic gerbil brains (reviewed in Ye et al. 2009). Hussein et al. (2018) demonstrated that rats preexposed to a mixture of heavy metals (Al, 50 mg/kg; Cd, 5 mg/kg; and Fl, 20 mg/kg) daily for 90 days, when treated with BBR (50 mg/kg/day, po) for a month, downregulated AChE expression and inhibited its activity in brain tissue and normalized the production of TNF-α, IL-1β, IL-6, and IL-12. Additionally, BBR inhibited the formation of Aβ42 and improved cognition and memory. In a few other studies, BBR has been reported to prevent or delay the process of AD (Abd El-Wahab et al. 2013; Cai et al. 2016). Thus, BBR appears to be a novel preventive and therapeutic modality for CDS in canine and felines.

Quaternary protoberberine alkaloids, such as stepharanine, cyclanoline, and *N*-methyl stepholidine were isolated from a Thai medicinal plant *Stephania venosa* Spreng (Ingkaninan et al. 2006). These alkaloids expressed inhibitory activity of AChE with IC_{50} values of 14.1±0.81, 9.23±3.47, and 31.30±3.67 μM, respectively, and have great potential for anti-CDS in canines and felines.

5.1.11 *Huperzia serrata* (Chinese Club Moss)

Huperzine A, derived from *Huperzia serrata*, is commonly used for the treatment of AD in China. It exerts anti-AChE, NMDA receptor antagonist, and neuroprotective properties (Landsberg et al. 2012). Patients with AD receiving huperzine A have shown improvement in general cognitive function, global clinical status, functional performance, and reduced behavioral disturbance compared to patients taking placebos. Thus, huperzine A has potential as nutraceutical for the treatment of CDS in elderly dogs.

5.1.12 Soybean Peptides and Isoflavones

Currently, soy proteins are being used as a source of nutrients around the world. These proteins are well-known for different functional properties and are widely recognized as a

potential source of bioactive peptides (Katayama et al. 2014; Imai et al. 2017). Soy peptides have been reported to exhibit a number of functional properties, such as hypocholesterolemic, antihypertensive, antiviral, anti-inflammatory, and immunostimulatory. Katayama et al. (2014) reported that administration of soy peptides via diet (7% w/w daily for 26 weeks) suppressed cognitive decline (Morris-Water Maze for Cognitive Testing) by induction of brain-derived neurotrophic factors (BDNF) in SAMP8 mice. These investigators demonstrated that soy peptides-fed mice improved special learning and memory when compared with control mice. Interestingly, soy peptides significantly upregulated neurotrophic factors (NGF, BDNF, and NT-3), which promote neurogenesis, neurodifferentiation, neuroprotection, and neuroplasticity. It has been suggested that the NT-3 enhancement in the brain is a potential therapeutic strategy for preventing age-related cognitive decline.

Ding et al. (2013) reported that 80 mg/kg/day of soybean isoflavone by gavage as pretreatment could alleviate the synaptic structural damage and antagonize the downregulation of expressions of proteins [(1) mRNA and protein of the synaptophysin and postsynaptic density protein 95 (PDS-95); (2) protein of calmodulin (CaM), Ca^{2+}/calmodulin-dependent protein kinase II (CaMK II), and cAMP response element-binding protein (CREB); and (3) phosphorylation levels of CaMK II and CREB (pCAM II, pCREB) induced by $A\beta_{1–42}$ in rats]. These findings suggested that soybean isoflavone pretreatment could ameliorate the impairment of learning and memory ability in rats induced by $A\beta_{1–42}$. Genistein, a major isoflavone in soybeans, provided a neuroprotective effect through anti-inflammatory activity in C6 glial cells caused by $A\beta_{25–35}$. The findings revealed that genistein could (1) alleviate $A\beta_{25–35}$-induced cell apoptosis, (2) prevent TNF-α and IL-1β release, (3) upregulate the gene and protein expression of TLR4, and (4) significantly upregulate the expression of 1κB-α in C6 cells. The study suggested that genistein may provide a neuroprotective effect via alleviating $A\beta_{25–35}$-induced inflammatory stress by regulating the TLR4/NF-κβ signaling pathway. Genistein can be an adjunctive therapy for treating cognition dysfunction syndrome in canines or felines.

5.2 Monoamine Oxidase B (MAO-B) Inhibitors

Age-related increase in monoamine oxidase B (MAO-B) is known to contribute to CNS neurodegenerative diseases (Mazzio et al. 2013). MAO-B inhibitors are indicated for patients with AD and PD as they could enhance catecholamine neuroactivity and increase dopamine levels in dogs. Currently, FDA approved Anipryl® (selegiline hydrochloride, L-deprenyl hydrochloride) is available on the market for the control of clinical signs associated with CDS in dogs. The recommended dose in dogs with CDS is 0.5–1.0 mg/kg body wt po, once daily, preferably in the morning. The extracts of several plants (such as *Phellodendron amurense*, *Cyamopsis psoralioides*, *Glycyrrhiza glabra*, *Glycyrrhiza uralensis*, and *Psoralea corylifolia*) have been reported for strong MAO-B inhibiting potency (Mazzio et al. 2013). Berberine from *Coptis chinensis* is known to inhibit MAO-B activity. The extracts of some plants (such as turmeric, comfrey, bhringraj, skullcap, kava kava, wild indigo, gentian, and green tea) are identified with lesser MAO-B inhibiting potency. Plant extracts with a strong MAO-B inhibiting activity can be used as nutraceuticals for managing the symptoms of dementia and related anxiety and sleep-cycle disorders in aging dogs.

5.3 Calcium-Buffering Proteins

Calcium-binding proteins are involved in cellular activities and functions. Cells possess numerous calcium-binding proteins that regulate calcium concentration in the cytosol by buffering free calcium ion (Moran et al. 2014). Intracellular calcium dysregulation has been associated with aging and may be linked to CDS in dogs (Milgram et al. 2015). These investigators evaluated the effects of a calcium-buffering photoprotein apoaequorin (placebo, 2.5 or 5 mg) on discrimination learning, attention, and visuospatial memory tasks in beagle dogs. Findings revealed that the apoaequorin-treated dogs showed improved performance on the discrimination learning and attention tasks, but not on the spatial memory tasks. In another study, these authors found that dogs receiving 10 mg daily dose of apoaequorin showed cognition improvement equal to those receiving 1 mg selegiline (Anipryl®). Currently, apoaequorin is one of the ingredients of Neutricks®. Moran et al. (2013) determined the No-Observed-Adverse-Effect level (NOAEL) for apoaequorin as 666.7 mg/kg body wt/day in rats, and there appears to be no concern of safety due to unusual stability of the protein by ingestion (Moran et al. 2013).

5.4 Nutraceuticals with Antioxidative, Anti-inflammatory, and Neuroprotective Properties

Literature abounds showing that oxidative stress due to excess generation of free radicals is one of the leading causes of CCD/CDS in dogs (Skoumalova et al. 2003). This is due to the fact that the brain (1) consumes a high rate of oxygen, (2) has a high percentage of PUFAs, and (3) has low levels of endogenous antioxidant activity. Studies also support that

foods and nutraceuticals enriched with antioxidants can help reduce the effects of aging on canine cognition (Cotman et al. 2002; Sechi et al. 2015). Examples of such diets include flaxseed, spinach, citrus pulp, tomato pomace, grape pomace, α-lipoic acid, vitamin C, vitamin E, choline, L-carnitine, etc. Further improvement in cognition and learning ability was observed when dogs were provided behavioral stimulus/enrichment in addition to an antioxidant-rich diet (Milgram et al. 2005; Opii et al. 2008).

Some of the common antioxidants that have been shown to improve cognition and memory are discussed below in brief.

5.4.1 Ascorbic Acid

Recently, in a rat model of AD, Olajide et al. (2017) investigated efficacy of ascorbic acid in reversing aluminum chloride (AlCl3)-induced behavioral deficits and neuropathological alterations in the prefrontal cortex and hippocampus. Administration of ascorbic acid (100 mg/kg daily for 15 days) significantly attenuated behavioral deficits in rats through inhibition of molecular and cellular stressor proteins activated by $AlCl_3$. Findings revealed that the primary mechanisms underlying ascorbic acid therapy relates to its abilities to scavenge free radicals, prevent membrane lipid peroxidation, modulate neuronal bioenergetics, and its anti-proteolytic properties. It appears that ascorbic acid supplementation may inhibit progression of neurodegenerative processes and behavioral alterations in dogs and cats.

5.4.2 Lycopene

Lycopene, a carotenoid pigment, possesses potent antioxidative, anti-inflammatory, and neuroprotective properties. In an experimental study, Zhao et al. (2017a) determined the effects of lycopene on oxidative stress-induced cognitive defects and the underlying mechanisms. The behavioral tests (Y-maze test, locomotor activity, and Morris water maze test) revealed that chronic lycopene supplementation (50 mg/kg body wt/day) alleviated D-galactose-induced cognitive impairment in CD-1 mice. Lycopene restored BDNF levels and ameliorated histopathological changes in the hippocampus of mice. Lycopene treatment activated the mRNA expressions and significantly elevated activities of antioxidant enzymes (HO-1 and NQO-1) and reduced levels of inflammatory cytokines (IL-1β and TNF-α) in the hippocampus. Furthermore, lycopene attenuated neuronal oxidative damage through activation of Nrf2 signaling and inactivation of Nf-κB translocation in a H_2O_2-induced SH-SY5Y cell model. Zhao et al. (2018) also demonstrated that lycopene supplementation significantly reduced age-associated neuroinflammation and lowered the accumulation of $A\beta_{1–42}$ in the brains of aged CD-1 mice. Hwang et al. (2017) revealed that lycopene inhibited apoptosis by reducing ROS and by inhibiting mitochondrial dysfunction and the NF-κB-target gene Nucling expression in neuronal cells. It appears that lycopene has a potential to improve cognitive impairment and memory by ameliorating oxidative stress, neuroinflammation, activation of Nrf2/NF-κB transcriptional pathway, and accumulation of $A\beta_{1–42}$.

5.4.3 Vitamin E

Vitamin E (vit E) is a potent antioxidant that may have beneficial health effects in AD by ameliorating oxidative stress and Aβ-associated free radicals (Yatin et al. 2000; Morris et al. 2005; Geraldo et al. 2014; Adalier and Parker 2016). Out of eight different forms of vit E, α-tocopherol and γ-tocopherol are the two forms that are most associated with the slowing down of cognitive decline (Morris et al. 2005). α-Tocopherol is the most bioavailable form of vit E and the most helpful in AD (Joshi and Pratico 2012), while γ-tocopherol has been found to be important for its neuroprotective effect (Morris et al. 2015). Vit E mainly acts as a chain breaking antioxidant and radical scavenger, protecting cell membranes against oxidative damage. In addition, vitamin E regulates ROS production, maintains oxidative phosphorylation in the mitochondria, and accelerates restitution of high-energy metabolites.

In a number of clinical studies, vitamin E (2000 IU/day) has been shown to delay the progression of mild to moderate AD because of its potent antioxidative and neuroprotective effects (reviewed in Adalier and Parker 2016). When vit E was given in combination with a ChE inhibitor (donepezil, rivastigmine, or galantamine), it provided greater improvement in cognition than the ChE inhibitor alone (Bittner 2009). However, when vit E was given in combination with memantine (an NMDA receptor antagonist), it did not offer any additional benefits (Dysken et al. 2014).

No clinical studies have been conducted in cognitively declined canines and felines. Of course, vita E is included in the therapeutic diet Senilife®.

5.4.4 Omega Fatty Acids

Polyunsaturated fatty acids (PUFA) are important for the formation of cellular membranes and physiological functions in the brain (Layé et al. 2018). There are two main families of PUFA, n-3 and n-6 (commonly referred as omega-3 and omega-6 fatty acids, respectively). α-Linolenic acid (ALA) is the precursor of eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), and linolenic acid (LA) is the precursor of arachidonic acid (AA). AA, DHA, and EPA are consumed in the diet, since they are not produced in the brain. The major dietary sources of ALA are green plants, nuts, flaxseed, and rapeseed oil, whereas fish oil is the main source of EPA and DHA (Layé et al. 2018).

The brain is highly enriched in AA and DHA, and both omega-3 and omega-6 PUFAs are esterified into phospholipids, which are well known to play a critical role

in the structures and functions of brain cell membranes. Brain regional distribution and accumulation of LC-PUFAs vary. For example, in adult C57BL6/J mice, the highest level of AA is found in the hippocampus (10.2%), followed by the prefrontal cortex (9.7%), the hypothalamus (8.5%), the cortex (7.7%), the cerebellum (6.5%), and the brainstem (5.5%) The highest level of DHA is found in the prefrontal cortex (14.3%) and in the hippocampus (13.7%), followed by cerebellum (12.2%), cortex (11.9%), hypothalamus (10.1%), and brainstem (8.2%) (Joffre et al. 2016). It is noteworthy that the hippocampus and cortex are important brain regions in the context of memory, although other brain regions are also involved.

In humans, higher n-3 LC-PUFA consumption is associated with a lower risk of inflammation-associated neurologic disorders (Bazinet and Layé 2014). Supplementation of patients diagnosed with AD with a DHA-risk diet led to a reduced release of proinflammatory cytokines from blood mononuclear leukocytes (Vedin et al. 2008). High levels of brain DHA are linked to the reduced expression of proinflammatory cytokines in several rodent models of acute (LPS) or chronic (aging) neuroinflammation (Orr et al. 2013). Brain PUFAs contribute to microglial homeostasis and regulate their role in neuroinflammatory cascades (Layé et al. 2018). In a randomized, double-blind, placebo-controlled clinical trial, findings did not support supplementing older adults with DHA-rich fish oil to prevent cognitive decline (Danthiir et al. 2018). In rats, Morgese et al. (2018) demonstrated that an n-3 PUFA-enriched diet prevented the Aβ-induced AD-associated depressive-like behavior and also reverted serotonin and neurotrophin levels that were reduced in the prefrontal cortex. Brain PUFA metabolism is altered in neurological conditions, such as dementia, so nutraceuticals appear to intervene and restore brain lipid metabolism. These studies suggest that omega-3 fatty acids have a great potential and can be used as nutraceuticals in canines and felines with cognitive dysfunction.

5.4.5 Medium-Chain Triglycerides

Glucose is the main energy source of neurons, and its metabolism is reduced with aging (Seibert 2017). It has been suggested that dietary medium-chain triglycerides (MCTs) can increase the levels of ketones in the blood, which can be used as an alternate energy source for neurons and cerebral functioning. Pan (2011) reported that fatty acids derived from MCTs could provide up to 20% of the brain's energy requirements, and long-term supplementation with MCTs has been shown to improve cognitive function in aged dogs. MCTs have been reported to elevate mitochondrial function to boost the level of ATP production and reduce the levels of Aβ deposits (Taha et al. 2009; Pan et al. 2010).

Coconut oil has MCTs, which are converted into ketones that can provide energy to the brain. Scientific studies and clinical trials have yet to be done to support the facts and its use in CCD.

5.4.6 Phosphatidylserine

Phosphatidylserine is a phospholipid that occurs in cell membranes. It facilitates normal function of nerve cell membranes and influences levels of various neurotransmitters. Baumeister et al. (2008) investigated the influence of phosphatidylserine on cognitive performance and cortical activity before and after induced stress. Findings revealed that chronic supplementation of phosphatidylserine significantly decreased beta-1 power in right hemispheric frontal brain regions before and after induced stress. Pedata et al. (1985) found that acetylcholine release in 24-month-old rats receiving a single administration of phosphatidylserine (15 mg/kg, ip) or phosphatidylcholine (15 mg/kg, ip) for 30 days was as low as in the 24-month-old rats receiving the Tris buffer only. These investigators suggested that chronic phosphatidylserine treatment may reduce the age-related decrease in ACh release by acting on the stimulus-secretion coupling mechanism.

Crook et al. (1991) evaluated patients with age-associated memory impairment receiving phosphatidylserine (100 mg tid) for 12 weeks. Treated patients showed improvement on both computerized and standardized neuropsychological performance tests and also on clinical global ratings of improvement. Based on the clinical literature in humans, the FDA concluded that the evidence did not support assertions that phosphatidylserine has preventative or therapeutic benefit for cognitive dysfunction and dementia in people. However, the agency did approve claim for the product as "Consumption of phosphatidylserine may reduce the risk of cognitive dysfunction or dementia in the elderly." Phosphatidylserine is one of the ingredients in Senilife® and Aktivait®, but no clinical trials have been found on phosphatidylserine alone in senior dogs.

5.4.7 *S*-Adenosylmethionine

S-Adenosylmethionine (SAMe) is an endogenous molecule that has an antioxidant property. SAMe is involved in the synthesis of some neurotransmitters and is known to play a role in the regulation of nerve cell membrane structure and function. Based on limited scientific data, SAMe showed evidence for an improvement in daytime activity and possibly some improvement in sleep problems, but it did not offer any improvement for confusion or disorientation.

5.4.8 Melatonin

Melatonin (*N*-acetyl-5-methoxytryptamine) is a naturally occurring hormone produced by the pineal gland. It has been shown to exert antioxidative, anti-inflammatory, and immunomodulatory effects (Sharman and Bondy 2016). It has been suggested that the effective range of melatonin on

cognitive function and mood may exist within physiological levels. In a number of studies, physiological melatonin levels were found to be reduced in patients with AD or major depressive disorder (Mishima et al. 1999; Wu et al. 2003). Higher melatonin levels within the physiological range were associated with lower prevalence of cognitive impairment and depressed mood (Obayashi et al. 2015). The association between physiological melatonin levels and cognitive function was independent of depressive symptoms. In a meta-analysis of ten randomized controlled trials, Hansen et al. (2014) concluded that there was no significant effect of melatonin against depression. In most of these trials, the daily dose of melatonin was 2.5–10 mg, approximately 10- to 40-fold higher melatonin levels than physiological levels, when prolonged-release tablets were used. Fast-release tablets tend to shorten the effective period of melatonin.

Leuner et al. (2007) reported that diminished neurogenesis precedes old age, and this decline can be delayed by supplementation with melatonin (Ramirez-Rodriguez et al. 2012). In addition, the maintenance of dendritic complexity is enhanced by melatonin (Ramirez-Rodriguez et al. 2012).

Melatonin is used for anxiety or disturbed sleep/wake pattern in dogs with dementia. According to the American Kennel Club website, the recommended dose of melatonin for dogs is 1 mg for under 10 lbs, 1.5 mg for 10–25 lbs, 3 mg for 25–100 lbs, and 3–6 mg for over 100 lbs. Melatonin works within just few minutes after taking it, and the effect can last for about 8 h.

5.4.9 Rosmarinic Acid

Rosmarinic acid (RosA) is a water-soluble polyphenol derived from various medicinal herbs, such as *Salvia miltiorrhiza* Bunge and *Rosmarinus officinalis*, which has been used in folk medicine to treat various forms of dementias (Zhang et al. 2016). RosA has been demonstrated to exert antioxidant, anti-inflammatory, anti-proliferative, cytoprotective, neuroprotective, and anti-depressant properties in a variety of model systems, including AD (Taguchi et al. 2017). Nuclear factor E2-related factor 2 (Nrf2) appears to be the master regulator to protect neuronal cells from oxidative stress via activating expression of the antioxidant response element (ARE)-bearing genes. In an in vitro study, Rong et al. (2018) reported that RosA attenuated Aβ-induced cellular ROS generation and lipid peroxidation in PC12 cells. RosA also mediated neuroprotection in Aβ-challenged PC12 cells. The antioxidant effects of RosA are mediated predominantly by Akt/GSK-3β/Fyn pathway through increased activity of Nrf2. Zhang et al. (2017) presented compelling evidence that inhibition of GSK-3βactivity by dietary supplements prevent cognitive impairment in transgenic AD mice. It can be suggested that RosA appears to be a promising candidate for neuroprotective treatment of CDS in canines and felines.

5.4.10 Brown Rice

Brown rice (*Oryza sativus* L.) is commonly consumed around the world. It is generally processed to remove the germ layer and bran because they are very hard, difficult to cook, and poorly digested. However, these parts contain ingredients, such as ferulic acid, gamma-aminobutyric acid (GABA), vitamin B6, vitamin B12, and folic acid (Okuda et al. 2018). Ferulic acid is an antioxidant (Kanski et al. 2002), inhibitor of Aβ production and aggregation (Ono et al. 2005), and a β-secretase modulator (Mori et al. 2013). Additionally, it destabilizes preformed β-amyloid fibrils (Ono et al. 2005) and provides neuroprotection (Yan et al. 2001).

Highly water pressurized brown rice (HPBR) treatment increases the water absorbency of brown rice without losing nutrients and enhances its digestibility. Okuda et al. (2018) administered HPBR in 3-month-old male senescence-accelerated mouse-prone 8 (SAMP8) mice for 2 months. Findings revealed that HPBR significantly reduced the levels of $A\beta_{1-42}$ in the brain, improved motor function, and ameliorated cognitive dysfunction in an AD mouse model. Recently, whole grain brown rice is also reported for a slower gastric emptying rate, compared to white rice, which in part may explain for its low glycemic response Pletsch and Hamaker (2018).

HPBR can be used as a nutraceutical for preventing cognitive dysfunction syndrome in canines and felines. Being high in dietary fiber, it may block the absorption of sugar and fat from the GI tract and contributes to its beneficial effects in diabetes or obesity (Okuda et al. 2018).

5.5 Bioactive Substances from Invertebrates for Cognitive Dysfunction

5.5.1 Royal Jelly Proteins

Royal Jelly (RJ), the main food of the early larvae of worker bees (*Apis mellifera* L.) and the honeybee queen, is secreted by nurse honeybees from their hypopharyngeal and mandibular glands. The composition of RJ is complex, as it contains proteins, peptides, free amino acids, sugars, lipids, vitamins, and water (Lin et al. 2018; Mureşan et al. 2018). Major royal jelly proteins (MRJPs) are water-soluble proteins composed of nine members with a molecular weight of 49–87 kDa. Recently, Lin et al. (2018) developed an UPLC-MS method to quantify MRJP1, MRJP2, MRJP3, and other signature peptides that could have potential applications in many health conditions. The proposed method could also be used to evaluate the quality of MRJPs to avoid adulteration, which is quite common in the case of RJ proteins.

The MRJP1, designated as apalbumin 1, constitutes 45% of water-soluble proteins and is the most abundant protein in RJ. The RJ proteins have been used as functional foods and supplements for decades. It exerts antihypertensive,

Table 2 Nutraceuticals of non-plant origin for cognition and memory improvement

Nutraceutical	Bioactive ingredient	Biological/pharmacological activity	References
Royal jelly proteins from *Apis mellifera* L.	Major royal jelly protein 1	Prevention of cognition impairment	Chen et al. (2017), Lin et al. (2018), and Mureşan et al. (2018)
Anchovy (*Coilia mystus*	Anchovy protein hydrolysate	AChE inhibitory, antioxidative, neuroprotective, and memory and cognition improvement	Zhao et al. (2017b)
Brazilian red macroalgae extract (*Ochtodes secundiramea*)	Halogenated monoterpene	AChE inhibitory	Machado et al. (2015)
Melatonin	Melatonin	Antioxidative, anti-inflammatory, immunomodulatory, antidepressant, antiaging, anti-AD	Mishima et al. (1999), Wu et al. (2003), Obayashi et al. (2015) and Sharman, and Bondy (2016)

antidiabetic, anti-obesity, and increased cell proliferation activities in addition to regulation of mouse macrophage to release TNF-α (Yoshida et al. 2017; Lin et al. 2018). Reported studies also suggest that these proteins may improve cognition and memory (Drapeau et al. 2006; Zamani et al. 2012; Pyrzanowska et al. 2014; Chen et al. 2017). Chen et al. (2017) reported that aged male rats fed MRJP for 14 weeks showed improved spatial memory up to 48.5% when compared to controls. Metabolomic analysis using time-of-flight mass spectrometry revealed that the compounds altered were nicotinate and nicotinamide, cysteine taurine, and energy metabolism pathways (Table 2).

In a number of studies, bioactive peptides from RJ have been found to possess antihypertensive property (Matsui et al. 2002, Tokunaga et al. 2004; Sultana et al. 2008). Sultana et al. (2008) investigated the renin inhibitory effect of an RJ-derived peptide (dipeptide YY). The dipeptide YY was found to inhibit human renin activity. The inhibition constant (K_1) of YY was estimated to be 10 μM when the K_m was 0.16 μM using sheep angiotensinogen as the substrate. The peptide was observed to lower blood pressure in spontaneously hypertensive rats.

Yoshida et al. (2017) investigated whether RJ could prevent obesity and ameliorate hyperglycemia in type 2 diabetes. The findings indicated that administration of RJ (10 mg/kg, po) in KK-Ay mice for 4 weeks improved hyperglycemia, which may be due to suppression of G6Pase expression through the upregulation of *AdipoQ* and *AdipoR1* mRNA and pAMPK protein expressions. RJ did not influence insulin resistance or body weight.

The RJ dose as a supplement in human diets is typically 1 g per os (Khoshpey et al. 2016). This dose contains on average 120 mg of proteins, comprising 31% MRJP1 (~37 mg), 16% MRJP2 (~19 mg), and 26% MRJP3 (~31 mg). Approximately 87% of MRJP1 are in the oligomeric form (~32 mg), and 13% of MRJP1 are present as monomer (~5 mg). Royal jelly proteins have been shown to exert antioxidative, anti-inflammatory, and immunomodulatory effects (Šver et al. 1996; Kohno et al. 2004; Jamnik et al. 2007: It can be suggested that RJ proteins can be used to improve cognition and memory in canines and felines.

5.5.2 Anchovy Peptides

In addition to cholinergic system dysfunction and oxidative stress, apoptosis of neurons plays a pivotal role in the development of memory loss (Rosello et al. 2012). Recently, Zhao et al. (2017b) demonstrated that anchovy protein hydrolysate (APH) could attenuate scopolamine-induced memory deficits in mice by regulating AChE activity. These investigators identified two strong AChE-inhibiting peptides (Pro-Ala-Tyr-Cys-Ser, PAYCS, and Cys-Val-Gly-Ser-Tyr, CVGSY), which were also shown to increase cell viability and reduce LDH release, ROS production, malondialdehyde content, and the ratio of Bax/Bcl-2 of glutamate-induced apoptosis in PC12 cells, as well as increase of SOD and GSP-px activities. Both peptides protected the PC12 cells against glutamate-induced apoptosis via inhibiting ROS production and Ca^{2+} influx. Zhao et al. (2017b) suggested that PAYCS and CVGSY might be considered as nutraceuticals for alleviating memory deficits.

5.6 Bioactive Substances from Vertebrates for Cognitive Dysfunction

During the past several decades, venoms from several species are under investigation for the treatment of a variety of pathologies, including cardiovascular disorders, pain, cancer, and several neurodegenerative diseases (reviewed in DeSouza et al. 2018). Several toxins/substances have been shown to improve cognition and memory in humans and experimental models.

Fasciculins from *Dendroaspis angusticeps* (green mamba snake), RVV-V from *Daboia russelii russelii* (Indian viper), K-49-P1-20 peptide from *Bothrops asper* (viper), SVHRP from *Buthus martensii* Karsch (scorpion), PhTx3-1 and PhTx4-5-5 from *Phoneutria nigriventer* (spider), and $BVPLA_2$ from *Apis mellifera* (honey bee) are just a few

examples. These toxins improve cognition and memory via different mechanisms of action. For example, fasciculins inhibit AChE activity, RVV-V reduces Aβ plaque deposition, SVHRP increases BDNF levels and neurogenesis and reduces Aβ plaques, and $BVPLA_2$ reduces Aβ plaque deposition and exerts an anti-inflammatory activity. These toxins have a great potential and need to be tested in canine and feline cognition dysfunction (DeSouza et al. 2018).

5.7 Nutraceuticals for Blood-Brain Barrier Protection

In neurodegenerative diseases, such as AD, disruption of the blood-brain barrier (BBB) has been reported to be one of the pathophysiologies (reviewed in Gupta and Gupta 2018). Delivery across the BBB for a nutraceutical or a pharmaceutical compound is necessary in preventing or ameliorating the neurodegenerative diseases. Various in vitro and in vivo models are available to screen these compounds for crossing the BBB and negatively or positively influencing its structure and function (Gupta et al. 2015). Recently, Li et al. (2017) has suggested a zebrafish model for assessing the delivery of natural products and drugs across the BBB. Excessive ROS generation has been suggested to be one of the main mechanisms accounting for BBB dysfunction (reviewed in Li et al. 2018). Li et al. (2018) demonstrated that astragaloside IV (obtained from *Astragalus membranaceus*) pretreatment protected the BBB endothelial cells integrity against LPS-induced BBB disruption, by activating Nrf2 signaling pathway. Findings of this study suggested that astragaloside IV might be a potential antioxidant and neuroprotective nutraceutical/drug targeting BBB. In another study, Zhang et al. (2013) demonstrated that in an ischemia model, berberine upregulated pAkt, pGSK, pCREB, and claudin-5 and downregulated NF-κB expression, thereby ameliorating BBB permeability and providing neuroprotection.

5.8 Nutraceuticals for Mitochondrial Protection and Activation

The role of mitochondria in health, disease, and toxicity has been recognized for a long time. In addition to its primary function of ATP production (through oxidative phosphorylation), mitochondria plays a vital role in the modulation of apoptosis, autophagy, aging, and signaling pathways controlling neurogenesis and neuroplasticity (Morán et al. 2012; Go et al. 2018, Meyer et al. 2018; Wu et al. 2018; Yu et al. 2018). Mitochondrial dysfunction has been implicated in a number of neurodegenerative diseases, such as Alzheimer's disease (AD), Parkinson's disease (PD), and Huntington's disease (HD). Respiratory chain dysfunction (Maurer et al. 2000; Lin and Beal 2006; Morán et al. 2012), increase in ROS production and oxidative stress (Nunomura et al. 2006; Federico et al. 2012; Go et al. 2018), mitochondrial oxidative stress-induced hyperphosphorylation of tau (Melov et al. 2007), increased endoplasmic reticulum membranes (Schon and Area-Gomez 2013), overexpression of voltage-dependent anion channel 1 protein (Shoshan-Barmatz et al. 2018), and abnormal mitochondrial dynamics (Wang et al. 2009) have been reported in the pathogenesis of AD. Reddy and Beal (2008) also reported that the accumulation of mitochondrial DNA changes might increase ROS production and reduce mitochondrial ATP in an age-dependent manner, and this may contribute to AD development.

A number of natural and synthetic compounds have been shown to protect mitochondria through multiple mechanisms, thereby reducing cognition and memory impairment (Porquet et al. 2014; Risuleo 2016; Pitt and Leung 2016; Teodoro et al. 2016).

5.8.1 Resveratrol

Resveratrol, commonly referred to as "French Paradox," is a polyphenol naturally found in grapes and red wine. It exists in both *cis* and *trans* conformations. Resveratrol is reported to increase metabolic rate by mitochondrial biogenesis, and it has been postulated as an option to prevent AD (Jayasena et al. 2013; Porquet et al. 2014). Porquet et al. (2014) elucidated the interplay between the amyloidogenic pathway, sirtuin 1 (SIRT1) and 5-adenosine monophosphate-activated protein kinase (AMPK) signaling. Findings of this investigation supported the claim of resveratrol-induced neuroprotection by maintaining the equilibrium among SIRT1 and AMPK signaling, mitochondrial status, and the inflammatory changes. The onset of AD may be delayed or mitigated employing dietary resveratrol, which is able to prevent Aβ plaque formation and cognitive loss. Marambaud et al. (2005) demonstrated a proteasome-dependent anti-amyloidogenic activity of resveratrol but stated that resveratrol does not inhibit Aβ production because it has no effect on the Aβ-producing enzymes β- and γ-secretases. Instead, it promotes intracellular degradation of Aβ via a mechanism that involves the proteasome. In the context of AD, Teodoro et al. (2016) and Jardim (2018) summarized the neuroprotective effects of resveratrol as (1) to reduce intracellular and secreted levels of Aβ; (2) to reduce Aβ fibril formation by directly binding to Aβ; (3) to activate protein kinase C, which protects against Aβ-induced apoptosis; (4) to increase glutathione production, thereby contributing to antioxidant defense; and (5) to reduce NF-κB pathway activity, causing a decrease in inflammation and neuronal cell loss. It can be suggested that resveratrol has a strong therapeutic potential in AD in humans and CDS in pets. Currently, resveratrol is included in Senilife® for canines.

5.8.2 Quercetin

Quercetin is one of the most widely distributed flavonoids, which has strong antioxidant, free radical scavenging, and anti-inflammatory properties. In a number of in vitro, in silico, and in vivo studies, quercetin has been shown to exert multiple mechanisms of actions and improve learning and memory (Phachonpai et al. 2010; Islam et al. 2013; Sabogal-Guaqueta et al. 2015; Ay et al. 2016). Ghobeh et al. (2014) used quercetin and resveratrol to protect mitochondria from amyloid fragment fibrillogenesis. Quercetin destabilizes amyloid aggregates, thereby inhibiting the fibrillation process and rescuing the mitochondrial function, providing some optimistic insights into the prevention of AD.

Curcumin, vitamin E, *G. biloba*, *B. monnieri*, and medium-chain triglycerides (MCTs) may also protect mitochondria or elevate its function to prevent/improve cognition and memory impairment by different mechanisms (Ahmed 2012; Javeri and Chand 2016; Pitt and Leung 2016; Teodoro et al. 2016).

5.8.3 Thiamine and Its Derivatives

Thiamine-dependent processes are critical in glucose metabolism and are diminished in brains of AD. In a mouse model, it has also been demonstrated that thiamine deficiency causes the impaired hippocampal neurogenesis, which is greatly involved in cognitive dysfunction at early pre-pathological legion stage (Zhao et al. 2008). In animal models, thiamine deficiency is known to exacerbate plaque formation, promotes phosphorylation of tau, and impairs memory (Gibson et al. 2013). In contrast, treatment of mouse models of AD with the thiamine derivative benfotiamine diminishes plaques, decreases phosphorylation of tau, and reverses memory deficits. Another thiamine derivative is sulbutiamine (isobutyryl thiamine disulfide), which is often used to improve mental fatigue and memory. Sulbutiamine exerts its effects by acting on dopamine and no other catecholamines. Nootropic benefits of sulbutiamine are due to its effects on dopamine, glutamatergic, and cholinergic systems. Due to its higher absorption rate than thiamine, it acts to increase the efficiency of the BBB. It can be proposed that the use of benfotiamine or sulbutiamine could provide a safe intervention to reverse biological and clinical processes of CDS progression in canines and felines.

5.9 Therapeutic Diets

Currently, therapeutic diets/prescription diets, such as Canine b/d® (brain diet: fatty acids, antioxidants, and dl-α-lipoic acid, and L-carnitine), Purina Pro Plan Bright Mind® (medium-chain triglycerides), Senilife® (*G. biloba*, resveratrol, phosphatidylserine, vitamin E, and vitamin B6), Aktivait® (DHA, EPA, α-lipoic acid, glutathione, *N*-acetyl cysteine, vitamin C, vitamin E, L-carnitine, CoQ10, phosphatidylserine, and selenium), Novifit® (*S*-adenosylmethionine), and Neutricks® (apoaequorin), Nutramind®(omega-3 fatty acids, *G. biloba* extract, vitamin B1, vitamin B3, vitamin B6, vitamin B8, vitamin B12, vitamin E, and phosphatidylserine) are available for senior dogs with CCD/CDS. Nutramind® is also recommended for cats. Such diets are often fortified with a combination of fatty acids, vitamins, antioxidants, anti-inflammatory substances, mitochondrial cofactors, etc. In a number of studies, fortified and therapeutic diets have been shown to improve cognition and memory in senior dogs and cats (Cotman et al. 2002; Head 2007; Dodd et al. 2003; Ikeda-Douglas et al. 2004; Orlando 2018).

6 Concluding Remarks and Future Directions

A high percentage of senior dogs and cats suffer from cognitive dysfunction syndrome (CDS), and often they are underdiagnosed. The diagnosis of CDS is based on clinical signs (acronym DISHA) and cognitive dementia scale. The pathophysiology of CDS is very complex due to multiple underlying mechanisms, such as cholinergic neurotransmitter (ACh) deficit, oxidative stress, neuroinflammation, and Aβ peptides aggregation and deposition. Currently, several nutraceuticals are on the market for prevention and therapeutic intervention to improve or restore cognition and memory. This chapter describes the pathophysiology of CDS in canines and felines and offers various preventive and treatment modalities, including nutraceuticals that have anti-AChE, antioxidative, anti-inflammatory, anti-amyloidogenic, immunomodulatory, antidepressant, and anxiolytic properties. The chapter also provides a brief coverage of therapeutic diets available for prevention and treatment of CDS in canines and felines. Clinical trials are needed to validate claims for the most nutraceuticals available for canines and felines.

Nutraceuticals for Calming and Stress

Anitha Alex and Ajay Srivastava

Abstract

Stress in animals is evident through the disruptive behaviors exhibited, including excessive barking, restlessness, repetitive behavior, extreme vigilance, etc. Sociability is a key factor in determining the successful adaptation of pets to their environment. Sociable dogs are more comfortable with strangers and unfamiliar situations. Thus, reducing stress and anxiety in pets is essential in providing positive social interactions and to improve the quality of their life and that of the owners. γ-Aminobutyric acid (GABA) is the main inhibitory neurotransmitter in the mammalian brain, and many anxiolytic drugs exert their action through interactions with the GABA receptors. In addition to the GABAergic system, serotonergic, dopaminergic, and noradrenergic systems are also implicated in the development of anxiety and stress in various animal models and in humans. Furthermore, the involvement of the hypothalamic-pituitary-adrenal (HPA) axis and dysregulation of the immune system may also mediate social stress in animals that produces aggression and/or depression. While a number of anxiolytic drugs are available on the market, dietary supplements and herbal extracts are shown to exert equivalent calming effects with no or minimal addictive or aversive side effects. This chapter describes the underlying mechanisms involved in the development of stress and anxiety and various nutraceuticals and substances that have potential to reduce the stress behavior and improve social interactions in canines.

1 Introduction

Stress and anxiety disorders in dogs like in humans are due to an imbalance in neurotransmitters in the brain. The key players in the pathogenesis of anxiety disorders are γ-aminobutyric acid (GABA), serotonin, dopamine, and norepinephrine. In addition, neuropeptides like cholecystokinin (CCK), oxytocin, vasopressin, atrial natriuretic peptide (ANP), and substance P are also implicated in the modulation of stress-related behaviors and anxiety (Bandelow et al. 2017; MacLean et al. 2017). The role of the hypothalamic-pituitary-adrenal (HPA) axis in the pathophysiology of anxiety disorders has also been widely studied. Studies indicate that overactivation of the HPA axis leads to the stimulation of the adrenal gland to release cortisol, dehydroepiandrosterone (DHEA), adrenaline, and noradrenaline. Cortisol, the stress hormone in humans and dogs (corticosteroids in rodents), mediates a variety of effects throughout the body and brain and exerts a negative feedback on the HPA axis, thereby inhibiting its own production (Herman and Cullinan 1997).

Stress in dogs can be recognized by their behavioral response, like active vigilance and repetitive movements such as jumping, pacing, and excessive barking. Domestic dogs are highly social animals and sociability is an essential trait for successful interaction with humans (Grigg et al. 2017). Dogs are faced with a variety of stressors in their lives, including novelty, spatial restrictions, increased noise levels, etc. Social isolation also acts as a stressor which results in alterations in reactivity to stress, social behavior, function of neurochemical and neuroendocrine systems, and physiological, anatomical, and behavioral changes in both animals and humans (Mumtaz et al. 2018). Another stress factor is veterinary hospital visits. Reducing stress levels in pets must be a priority during their hospital visits and this is often overlooked. There is mounting evidence to suggest that routine veterinary care may be contributing to lifelong patient anxiety, starting with the first puppy or kitten physical examination (Overall 2013). Reports suggest that while a "no

R. C. Gupta et al. (eds.), *Nutraceuticals in Veterinary Medicine*, https://doi.org/10.1007/978-3-030-04624-8_27

stress" environment is not possible, understanding how to create a "low stress" environment and how to handle animals in a less stressful manner greatly benefits patients, staff, and the hospital (Lloyd 2017).

Growing evidence suggests that herbal extracts and dietary nutrients can effectively reduce anxiety by altering both neurotransmitter levels and the HPA axis. For example, vitamins C, D, and E, omega-3 fatty acids, and the green tea amino acid L-theanine are dietary supplements known to increase the production of dopamine. Further, supplementation with the amino acid L-tryptophan and its precursor, 5-HTP, the B vitamins, vitamin D, selenium, and omega-3 fatty acids increases serotonin production. These amino acid supplements are neurotransmitter building blocks, and the vitamins act as cofactors in neurotransmitter biosynthesis pathways. This dietary approach can correct the underlying neurochemistry without the side effects associated with anxiolytic drugs that may simply mask the problem (Alramadhan et al. 2012).

This chapter describes the key neurotransmitters involved in anxiety and stress disorders, biomarkers of stress, various dietary supplements, and herbal products that can help in calming dogs and reducing their stress levels.

2 Neurotransmitters, Neuropeptides, and HPA Axis in Stress and Anxiety

2.1 γ-Aminobutyric Acid (GABA)

GABA is the major inhibitory neurotransmitter in the mammalian brain, and it plays a central role in the maintenance of inhibitory and excitatory balance. The fast inhibitory action of GABA is mediated through $GABA_A$ receptors, a chloride-gated ion channel. Preclinical and clinical studies strongly suggest that impairments in GABAergic neurotransmission underpin human stress and anxiety disorders (Goddard 2016). Hyperexcitability of the amygdala, in particular, is strongly associated with anxiety, hypervigilance, and an inability to regulate emotions. Several rodent models have highlighted the role of the GABA synthetic isoenzymes glutamic acid decarboxylase 65 (GAD65) and GAD67 in the expression of normal mammalian fear. Knockdown of GAD67 protein in the mouse amygdala impaired normal fear extinction and decreased sensitivity to diazepam (Heldt et al. 2012). Low cortical levels of GABA have been observed in panic disorders and may serve as a potential biomarker for panic and other related stress disorders (Goddard et al. 2004). Experiments in various animal models have implicated the role of GABA in separation anxiety and trait anxiety (Tasan et al. 2011; Feng et al. 2014). Additionally, chronic restraint stress can also lead to decreased expression of $GABA_A$ receptor subunits in the cortex and hippocampus, suggesting a role in HPA axis dysfunction and stress symptomatology (Wisłowska-Stanek et al. 2013). Several anxiolytic agents available on the market today mediate their calming effects by targeting the GABA receptors. Benzodiazepine (BZD) is a full agonist at the BZD site of $GABA_A$ receptors and allosterically enhances the physiological GABA responses. Preclinical work has further defined the role of discrete $GABA_A$ receptor subunits on the separate clinical effects of the BZDs such as anxiolysis, sedation, muscle relaxation, and anticonvulsant effects (Rudolph and Knoflach 2011).

Recent interest in dietary supplements has spiked the use of GABA as a food supplement. In Europe and the United States, GABA is considered a "food constituent" and a "dietary supplement," respectively (Boonstra et al. 2015). The calming effects of GABA by oral administration were investigated in adult Shih Tzu dogs and were found to decrease time spent standing and walking compared to non-treated dogs. Similarly, a significant depression in the urinary cortisol level was also observed at 7 h after administration. These results indicate that orally administrated GABA exerts calming effects on dogs just as in humans (Uetake et al. 2012). However, it should be noted that the ability of GABA to cross the blood-brain barrier (BBB) in humans is unclear as of now and available reports are at the very least contradictory (Boonstra et al. 2015).

There may be, however, other mechanisms through which GABA exerts its effects, such as through the enteric nervous system (ENS). In fact, gut microbiota was shown to improve mood and reduce anxiety in patients with chronic fatigue (Logan and Katzman 2005; Rao et al. 2009; Pisanu and Squassina 2017). Similarly, studies indicate that oral intake of probiotics resulted in reduced urinary cortisol and perceived psychological stress (Messaoudi et al. 2011). Certain bacterial strains such as *Lactobacillus* and *Bifidobacterium* can produce GABA in vivo and were found to be effective in increasing GABA concentrations in the ENS (Barrett et al. 2012). This might account for the reported calming effect of dietary GABA; however further research is required to support the beneficial effects of GABA through the ENS.

2.2 Serotonin (5-HT)

Serotonin or 5-HT is a monoamine found in the CNS, in blood platelets, and in the gastrointestinal tract. The principal source of serotonin release in the brain are the raphe nuclei in the brainstem. Serotonin can inhibit periaqueductal gray matter-medicated fight/flight responses from threats, while it can also facilitate amygdala-mediated anxiety responses (Deakin 2013). Animal data and genetic and neuroimaging studies in humans point to a role of the 5HT1A receptor in the neural processing of anxiety (Akimova et al. 2009). Recently, a review of the 5HT2C receptor suggested that this receptor

may play a crucial role in anxiety (Chagraoui et al. 2016). The selective serotonin reuptake inhibitor class of antidepressants (SSRIs) act by inhibiting the serotonin reuptake as the name suggests and includes citalopram, escitalopram (active enantiomer of citalopram), fluoxetine, fluvoxamine, paroxetine, and sertraline. Fluoxetine is approved for veterinary use in the treatment of canine separation anxiety. Careful attention must be paid when treating canines with SSRIs as an overdose might result in serotonin syndrome, which may clinically manifest as nausea, vomiting, mydriasis, hypersalivation, hyperthermia, ataxia, tremors, muscle rigidity, diarrhea, and seizures. The goals of treatment in this intoxication are to support the animal, prevent further absorption of the drug, support the central nervous system, control hyperthermia, and halt any seizure activity. The relative safety of SSRIs in an overdose, despite the occurrence of serotonin syndrome, makes them more desirable than other antidepressants (Fitzgerald and Bronstein 2013).

2.3 Dopamine

Dopamine is involved in reward-motivated behavior and motor control. Nervous pointer dogs have been suggested as an animal model for pathological anxiety. There was a trend for lower [HVA] and [DOPAC] levels and a significantly lower [DOPAC]/[DA] ratio in nervous dogs, suggesting decreased dopaminergic function (Gurguis et al. 1990). Social isolation stress may alter the levels of neurotransmitters such as dopamine, serotonin, GABA, glutamate, the nitrergic system, and adrenaline as well as lead to an alteration in receptor sensitivity of *N*-methyl-D-aspartate (NMDA) and the opioid system (Mumtaz et al. 2018).

2.4 Norepinephrine

NE is a catecholaminergic neurotransmitter that plays a key role in the regulation of the autonomic nervous system. The metabolism and functions of norepinephrine have been studied extensively. While hypofunction is postulated for depression, hyperfunction is suggested as the reason for anxiety disorders. Stimulation of the locus coeruleus, an area containing most of the noradrenergic cell bodies of the brain, has been shown to induce anxiety and to raise the concentration of the main central NE metabolite, 3-methoxy-4-hydroxyphenyl glycol (MHPG) in patients with panic attacks. It also produces somatic symptoms, increases in blood pressure, and elevation of cortisol levels (Bandelow et al. 2017).

2.5 Cholecystokinin (CCK)

CCK is a neuropeptide that is widely distributed in the brain and has been shown to induce excitation of central neurons as well as inhibitory postsynaptic effects (Bourin and Dailly 2004). Reports indicate that CCK might be an important modulator of the neuronal networks that are involved in anxiety (Bandelow et al. 2017). CCK interacts with the serotonergic, GABAergic, and noradrenergic systems, as well as with endocannabinoids and neuropeptides Y and S (Zwanzger et al. 2012). CCK-B receptor expression and binding are increased in animal models of anxiety. In humans, CCK-induced anxiety may be mediated via CCK-B receptors, whereas in mice it is mediated by both CCK-B and CCK-A receptors (Li et al. 2013).

2.6 Oxytocin (OT)

In humans, OT induces a reduced response to aversive stimuli in the amygdala. It is also reported to promote trust and reduces the level of anxiety (Kirsch et al. 2005; Kosfeld et al. 2005; Heinrichs et al. 2009). Recent studies in dogs suggest that OT facilitates and responds to affiliative forms of human-animal interaction (HAI). It has been shown that in a group of Labrador retrievers and Labrador retriever/Golden retriever crosses, dogs participating in HAI exhibited a significant increase in both salivary OT (+39%) and plasma OT (+5.7%), whereas dogs in the control group with no human interaction did not. These results suggest that in dogs exposed to HAI, changes in salivary OT may reflect the extent of affiliative behavior between the dog and the human, indicating the potential of salivary OT to be a useful biomarker in studies of HAI (MacLean et al. 2017). Interestingly, the effects of oxytocin on the dogs' social behavior may not be universal, but it may be constrained by situations and other individual factors. Further research in this field is warranted, and the understanding of how OT mediates social behavior might be useful in improving its application in pharmacotherapy (Turcsán et al. 2017).

2.7 Vasopressin (AVP)

Vasopressin, along with OT, has been linked to both affiliative and aggressive behavior in domestic dogs (MacLean et al. 2017). Reports indicate that while OT may play a larger role in affiliative social behavior, anxiolysis, and inhibition of aggression, AVP may play a larger role in anxiogenesis and aggression (Coccaro et al. 1998; Thompson et al. 2006). Aggressive behavior in dogs is a serious concern,

and in the United States alone, the estimated number of dog bites is ~4.5 million annually, with approximately half of these bites directed toward children (Centers for Disease Control and Prevention 2003; Gilchrist et al. 2008). In an experiment in pet dogs with chronic aggression, dogs with a history of aggression exhibited more aggressive behavior during simulated encounters with conspecifics and had lower free but higher total plasma AVP than matched controls. In addition, in assistance dog population, dogs who behaved more aggressively toward a threatening stranger had higher total AVP than dogs who did not, suggesting the role of AVP in shaping dog social behavior (MacLean et al. 2017).

2.8 HPA Axis

The HPA axis is the main physiological system that mediates the body's stress response. It plays a pivotal role in regulating the synthesis and release of endocrine hormones associated with the central nervous system, including cortisol, a major stress hormone. Cortisol has widespread effects throughout the body and brain and passes through the BBB to downregulate the HPA axis activity by triggering negative feedback mechanisms, thereby inhibiting its own production (Herman and Cullinan 1997). Cortisol exerts its effects through interactions with glucocorticoid and mineralocorticoid receptors and regulates the expression of several genes, including cytokines (Lee and Rhee 2017). Several reports indicate that psychological stress can trigger cytokine release (Black 2003; Zalcman and Siegel 2006), and growing evidence has shown an important role of the immune system in regulating negative emotional states as well as personality (Maes et al. 2009; Réus et al. 2015; Takahashi et al. 2018). Activation of the HPA axis is implicated in many behavioral disorders including social and spatial restriction (Beerda et al. 1999). Studies indicate that when placed into a kennel environment, dogs experience a spike in cortisol levels followed by a decrease to original at-home levels (Protopopova 2016).

3 Dietary Supplements in Calming

The well-being of dogs can be affected by changes in human lifestyle, eating habits, and increased environmental and social stressors, leading to behavioral changes and anxiety, followed by negative affective moods and poor welfare (Sechi et al. 2016). A chronic anxious status and nutrition have been demonstrated to significantly affect behavior (Bosch et al. 2007). A diet supplemented with amino acids, n-3 and n-6 polyunsaturated fatty acids (PUFAs), and a well-balanced amount of proteins and fiber was considered beneficial in dogs with evident behavioral disorders (Bosch et al. 2007). Similarly, dietary supplementation with minerals like calcium, magnesium, and selenium and vitamins like C, D, and E are also reported to reduce anxiety and improve mood in both humans and animals (Carroll et al. 2000; Benton and Cook 1990; Hughes et al. 2011).

Reports indicate that omega-3 deficiency may also be associated with mood and behavioral disorders (Owen et al. 2008) and dietary omega-3 fatty acids have been shown to be effective in improving mood and reducing the risk of anxiety (Appleton et al. 2008; Kiecolt-Glaser et al. 2011). In addition, studies show that a diet high in tryptophan can lower territorial aggression score, while a high-protein diet without tryptophan supplementation can induce a high dominance aggression score in dogs (DeNapoli et al. 2000). In canines, all these pathologies have been consistently reported to be associated with oxidative stress. Vitamin C, a cofactor for many enzymes, reduces anxiety by limiting the oxidative stress from metabolites and also by limiting cortisol (Hughes et al. 2011).

Oxidative stress results from excess generation of free radicals, such as peroxide ion, nitrogen monoxide, and hydroxyl radical (Pasquini et al. 2010). An improvement of overall tissue stability and protection against oxidative stress is observed when the diet is enriched with antioxidants (Sechi et al. 2015). These reports indicate that changes in oxidative stress-related factors, such as derivatives of reactive oxygen metabolites (dROMs) and biological antioxidant potential (BAP), must be evaluated to monitor the welfare and health of dogs under stressful conditions (Passantino et al. 2014; Sechi et al. 2015). In a randomized, controlled clinical evaluation, 69 dogs of different breeds with anxiety and chronic stress were fed a control diet or a nutraceutical diet for 45 days. The results from this study showed a significant increase in the plasma concentration of serotonin, dopamine, and β-endorphins in the nutraceutical diet group, whereas a significant decrease in the levels of noradrenaline, cortisol, and dROMs was observed, suggesting benefits from the use of diet and nutraceuticals in the treatment of behavioral disorders (Sechi et al. 2016).

In another study from the same group, 24 dogs of different ages and breeds with generalized anxiety and behavioral disorders received counterconditioning and desensitization behavioral therapy combined with a nutraceutical diet for 10 days. The diet consisted of a mixed formula of fish proteins, rice carbohydrates, *Punica granatum*, *Valeriana officinalis*, *Rosmarinus officinalis*, *Tilia* spp., tea extract, and L-tryptophan, with an omega-3/omega-6 ratio of 1:0.8. The results indicated that dogs treated with specific diets showed significant improvement in times of activity and times of rest after 10 days and significant improvement in clinical and behavioral symptoms (Di Cerbo et al. 2017). Overall, these studies demonstrate the positive effects of nutraceutical diets on neuroendocrine, behavioral, and social

parameters associated with stress, anxiety, aggression, and behavioral disturbances.

Protein Hydrolysates

Studies have shown that fish hydrolysate, a natural supplement derived from fish protein, helps in reducing fear and anxiety in Beagles. In a thunderstorm model, fish hydrolysate demonstrated reduction in a hyperactivity response to thunder (Landsberg et al. 2015). Other hydrolysates derived from milk protein have also shown efficacy in improving the anxiety symptoms in rats and dogs. A comparative study conducted in 38 dogs demonstrated that alpha-casozepine (a milk protein hydrolysate) and selegiline (Anipryl) were equally effective in alleviating anxiety symptoms (Beata et al. 2007a, b). Additionally, in a placebo-controlled trial, alpha-casozepine displayed improvement in fearful behavior and anxiety in cats due to socially stressful situations. Although not elucidated clearly, some studies have shown that the antianxiety effect of alpha-casozepine may be due to its structural similarity to GABA and its binding to GABA receptors in the brain.

Pheromones

Pheromones are chemical substances which affect social behavior in mammals. In a triple-blinded, randomized, and placebo-controlled study in puppies newly adopted from a pet store, dog-appeasing pheromone (DAP) showed reductions in behaviors associated with fear of unfamiliar people and new surroundings (Mills et al. 2006). In another open clinical study, DAP was able to reduce the symptoms of anxiety in fearful dogs that showed signs of fear in response to fireworks (Sheppard and Mills 2003). These pheromones have also shown some efficacy in reducing anxiety and fear in puppies during puppy classes and resulted in improved socialization (Denenberg et al. 2005). However, 11 of the 14 reports reviewed and published in the *Journal of the American Veterinary Medical Association* suggested that there is not enough evidence to support the effectiveness of pheromones for the treatment of undesirable behavior in cats and dogs.

4 Herbal Extracts in Calming

In addition to nutrients such as amino acids, minerals, and vitamins, herbs and plant products have also been shown to be effective in treating anxiety (Head and Kelly 2009; Saeed et al. 2007). Plant extracts provide an alternative and better tool in the pharmacotherapy of psychological disorders without the adverse effects associated with anxiolytic drugs. Drugs used to treat anxiety have many negative side effects including addiction, depression, suicide, seizures, sexual dysfunction, headaches, and more (Alramadhan et al. 2012). Anxiolytic medications do not restore normal levels of neurotransmitters but, instead, manipulate the brain chemistry.

4.1 *Ginkgo biloba*

Ginkgo biloba, the oldest existing tree in the world for over 200 million years, has long been implicated in the treatment of anxiety as a part of traditional medicine (Liu et al. 2015). Nutritional supplements of *Ginkgo biloba* have been shown to be effective in reducing anxiety in various animal models. *Ginkgo biloba* extract (EGB 761) prevented stress- and corticosterone-induced impairments of spatial memory in a chronic restrain stress model in rats (Walesiuk and Braszko 2009). Similarly, daily administration of ginkgolide-A (1 or 2 mg/kg, po) resulted in an anxiolytic-like effect in mice (Kuribara et al. 2003). Further, *Ginkgo biloba* extracts were shown to activate GABA pathways and act like a benzodiazepine to reduce anxiety in patients with generalized anxiety disorder. In elderly dogs (mean age 11.4 years), administered *Ginkgo* leaf extract at a daily dose of 40 mg/10 kg body weight for 8 weeks improved the "severity of the geriatric condition." The occurrence of typical age-related behavioral disturbances is well reported in elderly dogs. A significant decrease in five of the six clinical sign scores (disorientation, sleep/activity changes, behavioral changes, general behavior, and general physical condition/vitality) was observed during the treatment period, suggesting the utility of *Gingko biloba* in elderly dogs with age-related behavioral disturbances (Reichling et al. 2006). Overall, these results support the use of *Gingko biloba* extract as a key nutritional supplement to improve mood and behavior in dogs, thus increasing the quality of life for dogs and their owners.

4.2 St. John's Wort (*Hypericum perforatum*)

St. John's wort is an aromatic perennial plant native to Europe and parts of Asia, North America, and South America and has been used traditionally for the treatment of anxiety and depression and as a nerve tonic. A large amount of clinical and animal experimental data demonstrate that it exerts its action through mechanisms similar to the tricyclic antidepressants or serotonin reuptake inhibitors (Bukhari and Dar 2013). In fact, the majority of clinical studies that compare it with antidepressant drugs found it superior to the placebo (Sarris and Kavanagh 2009; Linde et al. 2008). St. John's wort increases brain levels of serotonin and also normalizes the HPA axis by reducing inflammatory and oxidative stress (Tadros et al. 2009; Head and Kelly 2009). Reports indicate that St. John's wort alleviates stress-induced

deterioration of memory in rats (Trofimiuk et al. 2006). In a force swim test experiment, *H. perforatum* extract (30–90 mg/kg i.p.) caused a dose-dependent reduction in immobility time in rats with maximal effect seen at 90 mg/kg, similar to that seen with fluoxetine and imipramine (30–70 mg/kg i.p.) (Bukhari and Dar 2013). These studies suggest that St. John's wort demonstrates antidepressant properties similar to standard antidepressants and that the antidepressant profile of *H. perforatum* is more closely related to the selective serotonin reuptake inhibitor class of antidepressants.

4.3 Ginseng

Ginseng is the root of plants within the genus *Panax* and it is traditionally used as a medicinal herb in Korea, Japan, and China. It shows potent antioxidant activity attributed to ginsenosides, which are extracted from the roots, leaves, stems, and fruit, and it has multiple pharmacological effects (Lee and Rhee 2017). Ginseng has been shown to regulate the HPA axis and is implicated in the treatment of depression, asthma, hypertension, and post-traumatic stress disorders (Park et al. 2005; Choi et al. 2011). Ginseng was also demonstrated to attenuate the rise in the concentration of corticosterone in plasma induced by restrictive stress through suppressing the activity of ACTH in the adrenal gland, suggesting its use as potential therapy for mental disorders associated with stress (Kim et al. 2003). In addition to suppressing the occurrence of psychological diseases, ginseng also prevents stress-associated physiological diseases and regulates the immune response and the hormonal changes due to stress, thus maintaining homeostasis (Lee and Rhee 2017).

4.4 Ashwagandha (*Withania somnifera*)

Withania somnifera belonging to the family Solanaceae has been used for centuries in Indian, Chinese, and Arabic traditional medicines. *Withania somnifera* extracts (root, leaf, or fruit) have been reported to possess anti-inflammatory, antitumor, anti-stress, antioxidant, immunomodulatory, hematopoietic, and rejuvenating properties (Mishra et al. 2000).

Reports indicate that rodents treated with ashwagandha showed reduced anxiety compared to control treatment. This reduction matched the reduction in anxiety in these rodents when treated with several benzodiazepine drugs (Ramanathan et al. 2011; Mohan et al. 2011). Ashwagandha has also been shown in clinical studies to reduce anxiety in patients and was superior in action compared to the control group receiving psychotherapy (Cooley et al. 2009).

4.5 Valerian (*Valeriana officinalis*)

Valerian is a temperate root that is commonly used for the treatment of insomnia and anxiety. Valerian extracts have been shown to both increase GABA synthesis and decrease synaptic GABA reuptake (Ortiz et al. 1999), through the activation of glutamic acid decarboxylase, an enzyme involved in the synthesis of GABA (Awad et al. 2007). Valerinic acid, an active compound from Valerian root, exerts its action through allosteric modulation of $GABA_A$ receptors (Benke et al. 2009). The anxiolytic properties of Valerian root extracts are well reported in animal models and in humans, suggesting its use as an alternative to anxiolytic drugs (Benke et al. 2009; Hattesohl et al. 2008).

In addition to the abovementioned herbal extracts, there are reports on the beneficial use of rosenroot, lemon balm, chamomile, and lavender oil in reducing anxiety and stress in animals and humans (Weeks 2009; Bystritsky et al. 2008; Kennedy et al. 2006; Komiya et al. 2009). The phytochemicals contained in herbal extracts belong to different classes such as alkaloids, flavonoids, phenolic acids, lignans, cinnamates, terpenes, and saponins. The results presented here showed that all of these possess anxiolytic effects in a wide range of animal models of anxiety. The mechanisms involved may include interactions with $GABA_A$ receptors, serotonergic, noradrenergic, and dopaminergic systems. Phytochemicals also modulate the HPA axis, thereby regulating the levels of cortisol and the release of pro-inflammatory cytokines (Farzaei et al. 2016). Taken together, these studies demonstrate the potential use of phytochemicals as supplements to conventional anxiolytic therapies in order to improve efficacy and reduce adverse effects.

5 Concluding Remarks and Future Directions

Anxiety and stress can be stimulated by environmental, social, or age-related factors in dogs. The underlying pathophysiology of anxiety is diverse and may involve multiple neurotransmitters and neuroendocrine systems, including the HPA axis, neuropeptides, and deficiencies in certain dietary nutrients. While newer anxiolytics with fewer side effects and addictive potentials are available on the market, growing evidence shows that nutraceuticals are equally potent and in some cases more effective than psychotherapy. Additionally, while anxiolytics exert its action by manipulating the neurotransmitter systems in the brain, herbal supplements exert their action by bringing the levels of neurotransmitters to physiological levels to maintain homeostasis. This chapter describes the key neurotransmitter systems involved in the development of anxiety and stress as well as the various

herbal and dietary supplements that are beneficial in reducing stress and calming the animals, thus providing more meaningful and enjoyable interaction with their owners. It should be noted that standardized studies in dogs in this field are still in their infancy, and further studies with more standardized protocols are warranted to investigate and validate the results presented in this chapter.

Nutraceuticals in Cardiovascular Diseases

Csaba K. Zoltani

Abstract

Cardiac dysfunction in animals, under certain conditions, can be alleviated or prevented by the consumption of nutraceuticals. Nutraceuticals, which are naturally occurring non-drug plant components, are able to affect the genetic system and physiological systems of animals following their absorption. This chapter addresses the mode of action of specific phytotherapeutic components in common cardiac diseases of animals.

Keywords

Animal cardiac dysfunction · Cardiac diseases · Nutraceuticals · Mode of action of nutraceuticals

1 Introduction

Cardiovascular diseases in animals emulate their counterparts in humans. Heart failure (HF), the inability of the heart to deliver oxygen and nutrients to cells, is one of the primary diagnoses. There are a large number of possible dysfunctions of the heart including inflammation, blockage of blood flow due to ischemia, atherosclerosis, and disturbance of electrical activity (Francis et al. 1990). In HF, one of the dominant symptoms, reduced ejection fraction, is usually accompanied by several related dysfunctions.

Oxidative stress and disequilibrium between the generation and destruction of reactive oxygen species (ROS) in tissue mark many of these conditions. Lipidemia that results impedes blood flow, causes vascular dysfunction, and changes the nitric oxide (NO) level.

The potential medicinal value of some plants to modify these conditions has been recognized since ancient times. Nutraceuticals, through a number of different processes, provide a means to combat the onset of disease. These actions include antioxidative, anti-inflammatory, anticancer, and lipid controlling aspects. Currently, some feedstock is supplemented with additional ingredients with desirable properties to help animals to overcome potential adverse health conditions. Nutraceuticals (Wildman 2001; Lockwood 2007; Zoltani 2016) have plant ingredients that help to counter cardiac diseases.

Recently, it has been recognized that nutraceuticals may play an important role by inducing desirable signaling pathways controlling cell function and thereby correcting cardiac dysfunctions (Cicero and Colletti 2018; Ferguson et al. 2016). Free radical and platelet-dependent thrombolic activity and hypertension can be particularly influenced. Nutraceuticals such as n-3[1] fatty acids, quercetin (Larson et al. 2012; Choi et al. 2008), flavonoids, and polyphenols are important for antioxidant defenses. Besides being a regular component of feedstock, nutraceuticals are also available as plant food residues (Varzakas et al. 2016) and fruit residues (Babbar et al. 2015) and in nanoscale nutrient delivery systems (McClements 2015).

The introduction of nutraceuticals to confer cardio benefits sometimes requires preliminary transformations of the component. One involves microalgal fermentation for the production of omega fatty acids and subsequent conversion to prostaglandins, which regulate cell activity and cardiovascular function.

Capillary electrophoresis (CE) is used for the selection of the cardiac useful contents of resveratrol, green tea, and phytoestrogens from soy and flax. A large industry now exists supplying feed supplements containing these and other related items.

2 Nutraceuticals Modulate Genetic Expression

Nutraceutical components of plants are bioactive compounds that involve activation of antioxidation, signal transduction, mitochondrial integrity, and genes (Mishra et al. 2009). Anti-inflammatory effects through inhibition of transcription factors and cytotoxic cytokines are notable. Primarily, these components produce endothelial effects and can forestall undesired cardiac outcomes by reducing adhesion of lipids to the walls of blood vessels and loosen deposits and reduce oxidative stress.

When ingested, nutraceuticals induce several signaling pathways that include the transcription factors NF-κB and Nrf2. They exert their anti-inflammatory and antioxidative control through inhibition. The former, nuclear factor kappa, is a light chain enhancer of activated B cells. These are lymphocytes which are not processed by the thymus gland and are responsible for producing antibodies. In addition, it functions as a protein complex that controls the transcription of DNA, cytokine production, and aspects of cell survival and is cardioprotective during hypoxia and reperfusion injury (Brasier 2006). Overproduction of this activator promotes heart failure by promoting inflammation through cytokines that produce an endoplasmic reticulum stress response.

2.1 NF-κB Regulatory Network

In an inactivated state, NF-κB is located in the cytosol complexed with the inhibitory protein 1κBα. The latter blocks the ability of NF-κB transcription factor to bind to DNA. In the diseased heart, NF-κB is increased. It also regulates a number of genetic programs, including hypertrophy, and provides protection from hypoxia and inflammation (Gordon et al. 2011; Hayden and Ghosh 2012). It can be induced via canonical or noncanonical pathways (Valen et al. 2001). As an inductible transcription factor, NF-κB mediates transient changes in gene expression. When dysregulated, it contributes to the pathophysiology of inflammation as a regulatory molecule. Abnormal NF-κB activity and an abnormal level of miRNAs often go together, along with mutual regulation.

2.2 Nrf2 Regulates Antioxidant and Detoxification Genes

Nrf2 is a potent transcriptional activator. It is a master regulator of an antioxidant response to counteract oxidative stress. In response to oxidative stress, it acts on cytoprotective genes. By binding to antioxidant response elements (ARE), it induces antioxidant enzymes that protect against oxidation damage (Chen et al. 2015; Satta et al. 2017). Elevated expressions of Nrf2, marker of oxidative stress, target genes involved with stress resistance. A large number of molecules are Nrf2 inducers which disrupt Keap1-mediated ubiquitination, allowing Nrf2 protein to accumulate and to bind in the promoter of genes (Chen and Maltagliati 2018).

3 Nutraceuticals that Forestall the Development of Cardiac Dysfunction

Numerous nutraceutical ingredients have been identified that counter the development of cardiac dysfunction. These include antioxidants, polyphenols for control of arterial diseases, and flavonoids that block ACE (angiotensin-converting enzyme) thereby regulating arterial blood pressure and strengthening tiny capillaries that carry oxygen to all cells. Also, omega-3 polyunsaturated fatty acids, vitamins of several kinds, minerals for prevention and treatment of CVD (cardiovascular disease), and curcumin that, among other supplements, improves the condition of the arterial wall (Table 1).

3.1 Antioxidants

Antioxidants hinder the oxidation of molecules and the production of free radicals thereby preventing the onset of disease processes. Highly reactive oxygen, such as hydrogen peroxide (H_2O_2) or the hydroxyl radical, due to their instability, reacts with biological molecules oxidizing the DNA and proteins causing mutations. Enzyme inhibitions and protein degradation can ensue.

The production of ROS is part of the process of generating metabolic energy in the electron transport chain. Mitochondria are major producers of ROS. Defects resulting in the decrease of electron transfer increases ROS production and subsequent pathological conditions.

Oxidative stress, through low-density lipoprotein (LDL) oxidation, contributes to atherosclerosis culminating in cardiovascular disease (Lee et al. 2017). In animals, uric acid with a high concentration of antioxidants is catalyzed to allantoin that is beneficial in stimulating the growth of healthy tissue and repairing wounds and also acts as an antihypertensive agent through activation of the imidazoline receptor. This inhibits the sympathetic nervous system thereby also decreasing cardiac contractility.

Nutraceuticals that contain glutathione, a major antioxidant, is also a new biomarker for the detection of oxidative stress (Irino et al. 2016). The level of 2-aminobutyric acid (2-AB) in circulation indicates the metabolism of glutathione. Changes in 2-AB levels reflect the status of oxidative stress.

Table 1 Selected nutraceuticals with therapeutic potential for amelioration of cardiovascular dysfunction

Nutraceutical	Active ingredient	Affects	Effect	References
Turmeric	Curcumin/piperine	Lipid levels	Antioxidant	Aggarwal and Harikumar (2009)
		Attenuate adriamycin-induced cardiotoxicity	Anti-inflammatory	Alwi et al. (2008)
		p300-HAT inhibitory	Mutates cell signaling	
		Effect on cardiac hypertrophy	Lowers LDL	
		Corrects Ca(2+) homeostasis	Blocks NF-κB, VCAM-1	
Quercetin	Polyphenol Flavonoids	Oxidative stress, blood pressure	Inhibits vascular NADPH	Larson et al. (2012)
		Vascular function	Antioxidative	Choi et al. (2008)
			Inhibitor of NF-κB	
Seaweeds	Macroalgae	Dyslipidemia	Reduces blood lipids	Cardoso et al. (2015)
		Oxidative stress	Improves endothelial function, blood pressure	Dousip et al. (2014)
		Vascular inflammation		
Green tea	Catechin Polyphenols	Vascular effects	Maintains NO homeostasis	Grassi et al. (2013)
		Activates endothelial NO	Reduces blood pressure	
		Suppress platelet adhesion	Curtails inflammation	
		Inhibits transcription factor NF-kB		
Resveratrol	Phytoalexin, stilbene provide resistance to infection	Nuclear factor NF-κB, activates SIRT1	Regulates inflammation	Matos et al. (2012)
		Lowers LDL	Deacetylates histones	Araim et al. (2002)
		Decr endothelial cell ICAM	Transcription factors	Berman et al. (2017)
			Antioxidative	
Carotenoids	Lycopene	Endothelial cells, affect lipid metabolism	Antioxidant	Wang et al. (2014)
		Oxidative stress	Curtails free radicals	

Other indicators include levels of vitamin C, vitamin E, and melatonin.

3.2 Polyphenols

Polyphenol micronutrients contained in plants, fruits, and vegetables analogous to phytoalexin play a role in the prevention of cardiovascular dysfunctions. They are very beneficial due to their antioxidant function and their ability to generate detoxication enzymes. Their effect depends on bioavailability in intestinal absorption rate which varies with the class of polyphenols. Cardiovascular diseases are associated with oxidative stress. Polyphenols have abundant antioxidant properties (Galanakis 2017) and, in addition, regulate genes and take part in cellular signaling (Scalbert et al. 2005). The direct antioxidant action of polyphenols is unlikely. Multifaceted bioactivity is more likely (Hollman et al. 2011). Also, polyphenols are metabolized along pathways used by xenobiotics.

Endothelial damage is heavily dependent on ROS (Khurana et al. 2013) generated during physiological processes, but under excessive stress, the antioxidant system is incapable of maintaining equilibrium and ROS binding to DNA and creating pathological conditions. By modulating signaling pathways, polyphenols strengthen antioxidant and anti-inflammatory defenses.

3.3 Flavonoids

Based on the number of phenol rings and structural elements, the phenols are subdivided into several classes. Flavonoids inhibit the angiotensin-converting enzyme (ACE) activity that regulates arterial blood pressure and electrolyte balance. ACE activity depends on the structure of the flavonoid (Guerrero et al. 2012; Li et al. 2010). Wang et al. (2018) have evaluated the structure activity relationship (SAR) of flavonoids with enzyme systems for cardioprotective activity. Flavonoids modulate the activity of enzymes that lower the production of prostaglandins and leukotrienes which are mediators of inflammation (Dabbou et al. 2018).

The antioxidant and chelating properties of flavonoids are significant (Heim et al. 2002; Prochazkova et al. 2011). By inhibiting peroxidation and the attenuating processes of ROS, radical scavenging and chelating activity is curtailed. Chelation (bonding to a metal and thereby removing it from the blood) of copper or iron helps in the prevention of the formation of free radicals.

According to preclinical evidence, soy phytoestrogens (isoflavones) may be beneficial in reducing serum cholesterol levels (Sacks et al. 2006).

3.4 Polyunsaturated Fatty Acids

Essential fatty acids (EFA) Ω-3 (alpha-linoleic acid) and Ω-6 (linoleic acid) are needed for the generation of hormones, anti-inflammatory substances, and cellular membranes (Mozaffarian and Wu 2011). Fatty acids, part of prostaglandins, control inflammation. They are derived mainly from plants since they cannot be synthesized. Ω-3 and its derivatives, EPA (eicosapentaenoic acid) and DHA (docosahexaenoic acid), are also derived from oily fish. EFA deficiency is rare and undesirable.

The proper ratio of the omega-related fatty acids is important. If the ratio of Ω-6/Ω-3 is too high, free radical production is increased. EFAs act on DNA by activating or inhibiting transcription factors that may be linked to pro-inflammatory cytokine production (Calder 2004: Rudra et al. 2001).

Grass-fed animals accumulate more omega-3 than grain-fed animals whose omega-6 rises. Since metabolites of omega-6 are more inflammatory, balancing needs to be accommodated (Simopoulos 2002). Omega-3 fatty acids lower blood pressure, and a reduction in blood triglycerides levels has also been observed.

3.5 Vitamins

Calciferol (vitamin D) acts as a hormone and it regulates more than 200 genes. An association between vitamin D deficiency and endothelial dysfunction and lipid peroxidation (Tarcin et al. 2009) has been noted. Low levels of vitamin D are associated with higher incidences of cardiovascular cases. In coronary disease, the amino acid homocysteine is of importance. Hypertension and increased risk of cardiac dysfunction can be ameliorated by lowering homocysteine (HCys) levels and raising vitamin B6 levels through the use of nutraceuticals.

Forage may be deficient in the required minerals or vitamin A. Nutraceuticals can provide needed supplement (Gadberry 2012) for the daily diet.

3.6 Minerals

The association of copper deficiency abnormal cardiovascular anatomy and "falling disease" has been known for some time (Klevay 2000). Copper deficiency also increases cholesterol and contributes to abnormal electrocardiograms. Some forage is seasonally deficient in copper. Mineral levels in livestock forage are often deficient due to the use of pesticides and herbicides. A list of minerals needed for healthy animals and their function is detailed in (Greenpet 2015).

Hypertension as well as hyperlipidemia has been affiliated with low levels of Zinc (Zn^{2+}) in serum measurements. Zn^{2+} inhibition of gene expression has been associated with the NF-κB (Houston 2010).

Manganese (Mn) is known to bind to vascular smooth muscle and enhances vasodilation, thereby reducing blood pressure. In addition, it affects intracellular sodium, potassium, and calcium content.

The digestion of hay in the bovine gut distributes Mn to several organs. It accumulates in mitochondria, disrupts oxidative phosphorylation, and creates ROS. Mn is a cellular toxicant that impairs enzyme activity and receptor functions. Mn affects the autonomic nervous system with an effect on vascular function and myocardial contraction, leading to hypotension (Jiang and Zheng 2005).

High plant uptake of soil selenium can lead to unexpected diseases in animals consuming such feedstock. Excessive selenium produces free radicals causing oxidative tissue damage when the incorporation of selenium instead of sulfur in proteins disrupts cellular function (Raisbeck 2000). Deficiency of selenium in feedstock causes white muscle disease in calves and lambs. The addition of dietary selenium prevents cardiomyopathy as well as cardiovascular disease (Duthie et al. 1989). Selenium, in conjunction with glutathione peroxidase, removes lipid peroxides formed during oxidative stress with an important effect on DNA synthesis and repair (Souyoul et al. 2018).

3.7 Curcumin

Though characterized as displaying low bioavailability, curcumin ameliorates the development of heart failure and the development of cardiac hypertrophy and is beneficial in preventing atrial arrhythmia (Aggarwal and Harikumar 2009; Alwi et al. 2008). In addition, it improves arterial health and enhances nitric oxide (NO) production by activating endothelial nitric oxide synthase. This enhances the relaxation of vascular smooth muscle and the dilation of vessels. Curcumin is beneficial for the functioning of the endothelium (Gupta et al. 2013). Its powerful antioxidant action is supplemented by anti-inflammatory effects, and side effects in animals are few (Shankar et al. 1980).

Nitric oxide (NO) is synthesized from the amino acid L-arginine in endothelial cells (Tousoulis 2012). Vascular homeostasis depends on the availability of sufficient NO. Heart failure is marked by a diminished release of NO due to altered endothelial equilibrium. NO has a number of

important functions in the maintenance of vascular function. These include (a) free radical scavenging, (b) diminishing endothelial permeability, and (c) acting as an anti-inflammatory agent. This is accomplished by inhibiting the synthesis of cytokines and cell adhesion molecules. NO downregulates platelet aggregation and adherence and minimizes the vasoconstrictive effects of free Ca^{2+} in smooth muscle cells.

3.8 Colostrum

Colostrum is secreted by the female mammary glands of animals. The components of the efflux enhance the function of the immune system and its effectiveness against a variety of common pathogens. Bovine colostrum is an effective nutraceutical for the immune function for a large number of animals, including cattle, sheep, horses, cats, and mice (Taillon and Andreasen 2000; Pandey et al. 2011).

Due to the association of the *Chlamydia* bacterium with arterial plaque formation, it has been proposed that in certain cases, heart disease resembles an autoimmune response. Colostrum's proline-rich polypeptide (PRP) moderates the immune system's adverse effectors (IGF-1, IGF-2). In addition, the growth factor of colostrum acts in the regeneration of cardiac tissue.

3.9 Resveratrol

The phytopolyphenol compound resveratrol (3,5,4-′-trihydroxy-*trans*-stilbene), a nutraceutical found in grapes, berries, and peanuts, exerts anti-inflammatory activity and antioxidative effects. It also increases endothelial NO production and ameliorates the development of atherosclerosis (Matos et al. 2012) by decreasing the intercellular adhesion molecule (ICAM), vascular cell adhesion molecules (VCAM), and interleukin (Berman et al. 2017; Araim et al. 2002). Animals ingesting resveratrol benefit from the effect of improved flow-mediated dilation (FMD) (Magyar et al. 2012), which is also instrumental in overcoming the onset of endothelial dysfunction associated with myocardial perfusion defects.

3.10 EGCG (Epigallocatechin Gallate)

Countries where tea is a common beverage report a lower incidence of cardiovascular diseases. Green tea contains bioactive polyphenols including epigallocatechin gallate (EGCG) which has a potent antioxidant ability (Potenza et al. 2007; Grassi et al. 2013). In vascular endothelial cells, it activates endothelial nitric oxide synthase (eNOS) with NO-dependent vasodilator actions. Endothelial dysfunction contributes to ischemic heart failure. EGCG also binds to and breaks down apolipoprotein A-1, a protein that behaves similarly to amyloid plaques. It also attenuates nicotine cardiotoxicity (Nacera et al. 2017).

More importantly, EGCG downregulates GRK2 (Cannavo et al. 2018). Elevated levels and activity of this kinase lead to the dysfunction of cardiac and adrenal pathways. GRK2 inhibition protects the heart from remodeling and allied dysfunctions.

3.11 Coenzyme Q10

A naturally produced antioxidant, CoQ10 (ubiquinone), plays a vital role as an electron carrier in mitochondrial oxidative phosphorylation. It is significantly decreased in congestive heart failure. CoQ10 improves the function of endothelial cells of blood vessels and plays a vital role in the production of ATP, the source of energy for metabolic processes (Ubbink 2001). In ischemic dogs, CoQ10 protects against necrosis in the heart muscle. Older horses who produce increased lactic acid also benefit from CoQ10. In line with its high energy requirement, CoQ10 is concentrated in cells of organs requiring considerable energy for the heart muscle.

3.12 Carotenoids

Plant pigments cannot be synthesized by animals but are potent reactive species scavengers as they inhibit free radical and singlet lipids. Carotenoids are found in leafy vegetables and yellow/orange fruits. For example, β-carotene is a vitamin-A precursor (Cheng et al. 2017) in addition to being a fee radical scavenger.

Lycopene is a natural carotenoid with antioxidant properties and is also an inhibitor of pro-thrombotic and pro-inflammatory factors with CVD prevention characteristics (Wang et al. 2014). Significant reductions in LDL as well a reduction in systolic blood pressure have been noted.

3.13 Seaweed

Seaweeds, also referred to as macroalgae, are multicellular algae belonging to three different taxonomic groups. Their consumption modifies expressions of cardiovascular diseases, including dyslipidemia, vascular inflammation, hypertension, and oxidative stress as well as activation of the sympathetic system. In animal experiments, *Himanthalia elongate*-treated rats showed a remarkable reduction of total

triglycerides in the plasma. Similarly, *Gracilaria changii* powder significantly lowered total cholesterol, LDL, and total triglycerides in Sprague-Dawley rats (Cardoso et al. 2015; Dousip et al. 2014).

Lipids in seaweed contain abundant polyunsaturated omega-3 and omega-6 fatty acids. Macroalgae peptides incorporate amino acid residues that, as bioactive constituents, alleviate cardiovascular symptoms.

4 Soy

Isoflavone-rich soy protein marginally decreases the plasma lipid profile. The effect is caused by binding to estrogen receptors present in the vasculature. An increase in genistein, an isoflavone of soybeans, in plasma dilates constricted vessels. Improved vascular function (Lockwood 2007) helps in the normalization of blood pressure. Atherosclerotic plaque development is also delayed by consumption of soy isoflavones via inhibition of LDL oxidation, binding to estrogen receptors and inhibition of tyrosine kinase. Soy protein is high in polyunsaturated fatty acids (PUFAs), fiber, vitamins, and minerals, making it beneficial for cardiovascular health.

The USFDA is proposing to revoke the health claim that soy protein reduces the risk of heart disease (FDA 2018) but intends to allow the use of a qualified health claim. This requires a lower standard of evidence than an authorized health claim.

5 Cardiac Biomarkers in Animals

The use of biomarkers for animal health status determination, including respiratory disease, lipid peroxidation, and joint disease beside cardiac status, is now widespread (Oyama 2013; Ferreira et al. 2016). Various cardiac dysfunctions provoke neuroendocrine activation. Increases in plasma norephrine (PNE) and atrial natriuretic factor and activation of the renin-angiotensin-aldosterone systems with increased release of pro-inflammatory cytokines occur (Sisson 2004). A large number of markers, besides the conventional and widely used N-terminal prohormone of brain natriuretic peptide (NT-proBNP), troponin (hs-cTnI), and C-reactive protein (CRP), like atrial natriuretic peptide (ANP) and angiotensin-converting enzyme (ACE), are also measured.

The presence of nutraceuticals can modulate signaling pathways. Curcumin's pleiotropic activity (Gupta et al. 2013) is beneficial in improving lipid profiles in cases of acute coronary symptoms. Elevated serum creatine phosphokinase (CPK) level may indicate muscle or heart damage. When the heart is damaged, the enzyme CPK-MB (creatine kinase-muscle/brain) rises. Nutraceuticals can lower it.

Newer markers, more immediate and organ specific, have come into use. With remarkable potential, miRNAs, endogenous noncoding RNAs that can modulate posttranscriptionally gene expression, are being widely promulgated (Ono et al. 2011; Phuah and Nagoor 2014). By binding to complimentary sequences in the coding region of target messenger RNA (mRNA), they have the ability to regulate cellular activity (Small et al. 2010; Vickers et al. 2014). This ensues from mRNA degradation or alternately by attenuating protein translation. In atrial fibrillation (AF) miRNA-29 and miRNA-26 are downregulated with pathological fibrotic atrial remodeling. The inward-rectifying K^+ current increases (Luo et al. 2013). Lowering miRNA-26 promoted atrial fibrillation (AF) in mice.

Secreted from tissue, miRNAs carry markers of their origin; thus they have the attributes of a conventional biomarker (Zoltani 2014; Maegdefessel 2014). The serum level of miRNA changes remarkably subsequent to cardiac events, paralleling troponin, for example, in myocardial infarction (MI). In heart failure, miR-122 and miR-499 are notably increased.

Epigenetic changes of DNA, produced by histone modifications, constitute changes that regulate gene expression (Tokunaga et al. 2013). Nutraceuticals can reverse methylation of miRNAs (Ahmad et al. 2014; Li and Sarkar 2015). Reversal of epigenetic changes can facilitate favorable cardiac processes.

6 Cardiac Issues in Animals

Some cardiac dysfunction in animals may be alleviated with dietary changes involving nutraceuticals. The choice and extent of use to acquire the required changes vary with species.

6.1 Horses and Bovine

A mature, competitive horse requires up to 30,000 calories per day to function at a high level. The usual forage is supplemented by grains. Additional fat in the diet contains considerably more calories than do the grains. The PUFAs, linoleic acid (LA) and alpha-linoleic acid (ALA), need to be in balance. Horses are not routinely affected by coronary artery disease. Heart attack in horses generally occurs from rupture of the aorta or arrhythmia triggered by adrenaline that suddenly stops the heart (Loynachan 2010). Systolic myocardial failure, i.e., reduction in the ability of the heart to contract, causes reduction in normal blood flow. Thoroughbreds experience supraventricular premature contraction but this does not increase the risk of sudden death (Marr and Bowen 2010). Horses with cardiac problems have

elevated aldosterone concentration culminating in compromised ventricular function (Van Der Vekens et al. 2012).

For equine forage, it is known that in the inherited polysaccharide storage myopathy (PSSM), modification of the diet can remove the extra glycogen stored in their muscles. The nutraceutical hawthorn (an evergreen), when digested, dilates peripheral blood vessels improving circulation. It contains a large number of flavonoids which are potent anti-inflammatory agents. It also affects blood pressure and lipids in circulation. Cayenne (*Capsicum annuum*) is an excellent vasodilator, and digested cleavers lowers blood pressure. Omega-3 fatty acids, contained in nutraceuticals such as flax seeds, contain alpha-linolenic acid (ALA) that is converted to EPA and DHA, both important for cardiovascular health (Pomeroy 2011; Jones 1997; National Research Council 2007).

Aside from congenital and high altitude-related cardiac dysfunctions (bovine pulmonary hypertension (BPH)), there are several other diseases that may be of concern (Peek and Divers 2018) in cattle. Bovine principal heart diseases include pericarditis, brisket disease, and right-sided congestive heart failure (RHF) (Buczinski et al. 2010; Neary et al. 2016). The most commonly acquired heart disease in cattle is bacterial endocarditis that causes arrhythmia and cardiomyopathy, but in general, cardiac diseases are not frequent. White muscle disease in cattle, caused by lack of vitamin E, damages cardiac muscle and Purkinje fibers. It can be alleviated with nutraceuticals and sodium selenite that activates antioxidant enzymes (Bhattacharyya and Roy 2015).

6.2 Cats and Dogs

Over 10% of dogs have heart disease. Chronic valvular heart disease (CVHD), affecting some 85% of older dogs, constitutes about 75% of canine heart disease (Atkins et al. 2009; Harker-Murray et al. 2000). It affects the left atrioventricular or mitral valve. Males are affected more than females and it is more prevalent in smaller breeds. Endothelial cell changes are also noted. Mitral valve prolapse is a feature of CVHD.

Coronary heart disease is unusual for cats and dogs (Devi and Jani 2009). Ventricular arrhythmia is frequent in dogs with cardiomyopathy. The Boxer is prone to right ventricular cardiomyopathy (Smith et al. 2007), but when fed an Ω fatty acid dietary supplement, arrhythmia is minimized.

Some of the adverse heart conditions in animals are due to the deposition of LDL. Proprotein convertase subtilisin/kexin type 9 (PCSK9), an enzyme that regulates LDL cholesterol levels, is present in the nutraceuticals (curcumin and berberine) and alleviates this condition.

Cardiomyopathy, where the cardiac muscles are unable to maintain the required blood flow, is the primary heart disease of cats. The mitral valve leaflets are usually affected. Hypertrophic cardiomyopathy (HCM) affects 10–15% of cats. Cardiac walls thicken and become less flexible with reduction in the amount of blood pumped. The left-side build-up surrounds the lungs but it can be affected by the diet. While congestive heart failure and arterial thromboembolism (ATE) are common, arrhythmia is uncommon.

Several nutritional supplements that may be missing from the available animal foodstuffs are essential for cardiac health. Dogs suffering from heart failure are deficient in EPA and DHA which omega-3 fatty acids can provide. Boxers and Doberman Pinschers with dilated cardiomyopathy (DCM) have a carnitine deficiency. L-carnitine is an amino acid used for energy production in the heart. Cases of deficient concentrations of L-carnitine go hand in hand with raised levels of triglycerides, a marker of myocardial disease. Labradors with cardiomyopathy show clinical improvement when supplemented with L-carnitine. Normal heart function also requires taurine, an amino acid usually in high concentration in the heart. Taurine deficiency causes DCM. Cocker Spaniels also suffer from DCM that can be remedied both by L-carnitine and taurine.

Cats also need taurine, but their ability to manufacture it is restricted, and DCM, with proper diet, can be prevented. Taurine, an essential amino acid obtained from animal-based proteins, is critical for normal vision and heart muscle function. "Essential" designation for amino acids means that it must be part of the diet since cats have only a limited capability to manufacture taurine.

CoQ10, the antioxidant and energy production aid for some animals, is only marginally used in older cats and dogs. Nutraceutical nanoemulsions that use a long-chain fatty acid (coenzyme Q10) demonstrated in a rat feeding study the possibilities for the use of nonstandard techniques (Cho et al. 2014).

7 Concluding Remarks and Future Directions

Nutraceuticals are not drugs but components of plants that upon ingestion lessen, and in some cases bar, the development of cardiac dysfunction. In this role, they have attracted a large number of adherents. Cardiac problems have been alleviated by foods containing components that slow the development of processes leading to the development of cardiac disease. Dissenters of this appraisal exist (Aronson 2017). However, contrary arguments emphasize the use of dietary supplements, not their value as desirable components of feedstock. Clinical proofs of the "don't work" hypothesis are unavailable. Overwhelmingly, it is believed that the

choice of nutrients and particular components can play an important role in preventing the development of cardiac problems. The gathering of data is ongoing. Synthetic biology (Nielsen and Keasling 2016) will enhance our understanding of the issue and provide additional answers in the future.

Nutraceuticals in Hepatic and Pancreatic Diseases

Sharon M. Gwaltney-Brant

Abstract

The unique anatomy and physiology of the liver make it especially susceptible to insult from a variety of metabolic, infectious, immune-mediated, toxic, and carcinogenic sources. Many nutraceutical compounds have been utilized in an attempt to aid in the support or improvement of liver health through antioxidant, anti-inflammatory, antifibrotic, antiproliferative, or antineoplastic mechanisms. Similarly, many nutraceuticals have been investigated for their utility in managing pancreatic disorders, especially diabetes mellitus. This chapter describes the pathophysiology and effects of select nutraceuticals on the liver and pancreas.

Keywords

Antioxidant · Dietary supplement · Hepatoprotective · Hepatotoxicity · Hepatotropic · Herbal · Liver · Nutraceutical

1 Introduction

As the largest internal organ in the body, the liver has essential roles in nutrient homeostasis, filtration of particulates, protein synthesis, bioactivation and detoxification, formation of bile, and biliary secretion and excretion (Jaeschke 2008). Via its extensive portal blood supply, the liver is exposed to virtually all ingested compounds that are absorbed from the gastrointestinal tract, making it susceptible to ingested toxicants. Additionally, the liver's role in the processing, biotransformation, and detoxification can result in exposure to potentially toxic intermediates or metabolites of xenobiotics. In humans, the most common cause of acute liver failure leading to liver transplantation in the United States is hepatic injury secondary to exposure to drugs or chemicals, and liver injury is the leading cause of regulatory action against drugs (Watkins and Seef 2006).

2 Liver

2.1 Hepatic Injury and Repair

2.1.1 Mechanisms of Injury

A variety of mechanisms are involved in hepatic injury including damage, triggering of apoptosis (programmed cell death), formation of reactive intermediates, disruption of cell metabolism, cytoskeletal damage, and stimulation of autoimmune responses (Gwaltney-Brant 2016). Direct damage to hepatocellular membranes can occur via mechanical injury such as lysis caused by infectious agents (e.g., viruses, parasites), lipid peroxidation, or disruption/dysfunction of membrane proteins and transporters. Reactive oxygen species (ROS) and other electrophiles produced during inflammation or in biotransformation reactions can trigger lipid peroxidation which, in the absence of antioxidants, can propagate and expand membrane far beyond the site of original injury. Disruption of cellular membranes results in spillage of cytosolic components into the extracellular matrix, which then triggers inflammatory responses which can compound hepatocellular injury. The cause of hepatocellular injury frequently dictates the distribution of injury within the liver. For instance, bacterial hepatitis is frequently multifocal in nature with no particular pattern, while hepatic injury from reactive metabolites formed during biotransformation of xenobiotics tends to occur in centrilobular areas, where biotransforming enzymes are most plentiful (Stalker and Hayes 2007).

The liver is highly vascular with extensive blood supply, but hypoxia can still cause significant hepatocellular injury, death, and fibrosis. Its proximity to the inferior vena cava makes the hepatic vein subject to reduced outflow when abnormal cardiovascular function, such as right heart failure,

R. C. Gupta et al. (eds.), *Nutraceuticals in Veterinary Medicine*, https://doi.org/10.1007/978-3-030-04624-8_29

occurs. The resulting stasis of blood around hepatic central veins can, over time, result in development of centrilobular fibrosis. Because centrilobular hepatocytes are already relatively oxygen deprived, they are more prone to hypoxic injury during situations where oxygen carrying capacity of the blood is compromised (e.g., anemia).

Apoptosis (programmed cell death) is a normal component of cell turnover, but it can also be triggered by a variety of pathologic situations including hepatotoxicosis, ionizing radiation exposure, neoplasia, and infection by hepatotropic viruses (Elmore 2007; Wang 2014). Unlike cellular necrosis, apoptosis is an energy-requiring process that eliminates nonessential or pathologically injured cells. Apoptosis is an ordered, systematic "shutdown" of cellular function culminating in condensation and fragmentation of cytoplasmic and nuclear component without loss of cell membrane integrity. Cellular fragments are quickly phagocytosed by local macrophages, but inflammatory responses are generally not triggered. Compared to cellular necrosis which generally involves multiple adjacent cells and is accompanied by an inflammatory response, apoptosis results in spotty cell loss with minimal to no associated inflammation.

Generation of free radicals within hepatocytes can occur during xenobiotic biotransformation, normal metabolic processes involving redox reaction, inflammatory states mediated by nitric oxide, and exposure to ionizing radiation (Bischoff and Ramaiah 2007). Free radicals have unpaired electrons that make them highly susceptible to binding macromolecules including lipoproteins of cell membranes, enzymatic proteins, and nucleic acids. The process of free radical binding to macromolecules generates additional free radicals, resulting in a snowballing effect of free radical generations. Cells have antioxidant scavenger molecules, particularly glutathione (GSH), that react with and detoxify free radicals, breaking up their propagation; however, excessive free radical formation can deplete cellular antioxidants, resulting in binding of free radicals to vital cellular structures. Free radical damage can alter cell permeability, inactivate membrane-associated proteins, and alter polarity of organelle membranes. DNA damage induced by free radicals can interfere with gene transcription or translation, resulting in decreased protein synthesis. Inactivation of enzymatic proteins can interfere with normal cell metabolism, leading to cellular degeneration, necrosis, or apoptosis. Disruption of proteins that compose the hepatocyte cytoskeleton can result in loss of cell-to-cell adhesion, rounding of hepatocytes, and release of free hepatocytes into the systemic circulation (Stalker and Hayes 2007).

Reactive oxygen species (ROS) are normally formed in the process of mitochondrial cellular respiration, and endogenous antioxidant systems exist to intercept these ROS before they can cause oxidant injury to the mitochondrion. Increased risk of mitochondrial oxidative injury can occur from increased ROS production, impaired electron transport with increased reduced intermediates, increased mitochondrial membrane permeability, and reduced or depleted antioxidant stores. Depending on the nature and severity of mitochondrial injury, cell death due to apoptosis or necrosis may ensue.

2.1.2 Response to Injury

The liver's response to injury depends on the type of insult, extent of insult, duration of insult, cell populations affected, systemic response to insult, and collateral damage. Despite a large list of potential causes of liver injury (e.g., infectious, inflammatory, neoplastic, toxic, metabolic processes), the types of responses of the liver to injury are quite limited. The clinical manifestations of these responses will vary based on the severity and extent of hepatic injury that occurs. The most general response of hepatocytes to nonlethal insult is hepatocellular degeneration, characterized by cellular swelling (Crawford 2005). Degenerate hepatocytes can accumulate a variety of substances including fat, pigment, glycogen, and copper. Oftentimes hepatocellular degeneration is a reversible, transient event; however, with more severe injury, degeneration can progress to cell death via necrosis or apoptosis. With infectious or inflammatory insults, the influx of inflammatory cells can contribute to hepatocellular injury due to ROS or other mediators produced by inflammatory cells. Cholestatic hepatic disease can occur with hepatic injury that interferes with the ability of hepatocytes to excrete bile into canaliculi or that later transport bile through the biliary tree. Cholestasis may be caused by metabolic derangements in hepatocytes, hepatocellular swelling, impediments to canalicular transport, or mechanical obstruction of the biliary tree or gall bladder. Cholestatic disease can result in systemic buildup of biliary solutes within the blood and other tissues, leading to the yellow-orange cast of icterus or jaundice. Steatosis (fatty liver, hepatic lipidosis, hepatosteatosis) is a common marker of moderate to severe hepatocellular insult. Hepatocytes become distended with lipids, a condition that, early on, is generally benign and reversible; however, over time steatosis can progress to steatohepatitis, which can result in chronic progressive hepatic injury, fibrosis, and possibly neoplasia.

The liver has an extensive capacity for repair and regeneration following acute or chronic insults. The extent of regeneration that can occur depends on the balance between a variety of hepatocellular factors including cell cycle regulation, metabolism, angiogenesis, cell adhesion, and extracellular matrix components (Duarte et al. 2015). Deposition of excessive extracellular matrix proteins most commonly begins in the periportal areas, centrilobular areas, or within the space of Disse (the space between apical hepatocyte membrane and adjacent endothelial cells), and it interferes with the exchange of nutrients and oxygen between hepatocytes and the sinusoidal blood, furthering

hepatocellular stress and interfering with normal hepatocellular function (Jaeschke 2008). Hepatic stellate cells produce the majority of hepatic extracellular matrix proteins, whose activation is the initial step in hepatic fibrosis. Activation of hepatic stellate cells occur in the presence of products formed during hepatocellular injury, such as ROS and lipid peroxidation products, or by cytokines released by damaged sinusoidal endothelial cells, Kupffer cells, activated platelets, or inflammatory cells. Hepatic stellate cell activation leads to alteration of the extracellular matrix through the replacement of non-fibrillar basement membrane matrix with fibril-forming collagens. As collagen deposition progresses, disruption of the hepatic architecture by fibrous scars results in islands of regenerating hepatocytes surrounded by bands of dense fibrous connective tissue, a condition known as cirrhosis. Cirrhotic areas are poorly functional, and hepatic failure occurs when sufficient liver tissue is affected. Hepatic cirrhosis is not as commonly identified in veterinary species as it is in humans, where viral hepatitis, alcohol, and nonalcoholic steatosis are common causes (Jaeschke 2008).

Chronic liver injury with inflammation and/or cirrhosis may progress to hepatocellular carcinoma (Jaeschke 2008). In humans, hepatocellular carcinoma has been strongly associated with viral hepatitis, metabolic disorders such as hemochromatosis, nonalcoholic steatosis, and toxicants such as aflatoxin, alcohol, and exogenous androgens, although absolute proof of cause and effect has yet to be discovered.

2.2 Nutraceuticals and the Liver

2.2.1 *S*-Adenosylmethionine

S-Adenosylmethionine (SAMe) is an endogenous compound created through enzymatic conversion of dietary methionine (Center 2004). In health, sufficient SAMe is generated through de novo synthesis via dietary intake of methionine, protein catabolism, and salvage pathways involving trimethylglycine or methyltetrahydrofolate and vitamin B_{12} (Bottiglieri 2002). SAMe functions as a methyl group donor in transmethylation pathways, as a precursor to sulfur containing compounds in transsulfuration pathways, and in production of polyamines via polyamine pathways (Friedel et al. 1989). SAMe is involved in more than 100 reactions catalyzed by methyltransferases including biosynthesis of phospholipids, biosynthesis of L-carnitine, biosynthesis of creatine, formation of neurotransmitters and neural receptors, and reactions involving RNA, DNA, proteins, and other endogenous metabolites (e.g., steroid hormones) (Bottiglieri 2002; Friedel et al. 1989). Transsulfuration pathways in the liver provide endogenous sulfur compounds including sulfates, taurine, and GSH, and hepatic SAMe serves as the major source of hepatic GSH (Center 2004). SAMe therefore is a major contributor to hepatic and systemic redox status, influencing resistance to oxidative injury and protection from toxic electrophiles or adducts produced during xenobiotic metabolism. Polyamine pathways impact cell replication, tissue regeneration and growth, DNA synthesis, and cell response to apoptotic signals. Polyamine pathways generate methylthioadenosine (MTA) via decarboxylation of SAMe; MTA is a major hepatocyte signaling molecule and can be used to regenerate methionine (Mato et al. 2002). SAMe administration is associated with alteration of hepatic disease progression, increase in hepatic GSH stores, improved hepatic mitochondrial function, and reduction in cytokine-mediated detrimental effects (Center 2004; Center et al. 2005a, b). Restoration of hepatic and mitochondrial GSH stores in patients with liver disease improves tolerance to injury from free radicals, cholestasis, and ischemia-reperfusion. SAMe was shown to increase GSH levels and improve redox potential in hepatocytes of normal cats (Center et al. 2005a). Dogs receiving SAMe in conjunction with CCNU (lomustine) therapy for malignancies had improved liver values and were less likely to have therapy discontinued due to CCNU-induced hepatopathy than were dogs that received CCNU alone (Skorupski et al. 2011). SAMe improved oxidative status in dogs on long-term prednisolone but did not prevent vacuolar hepatopathy from developing (Center et al. 2005b). Several case reports have been published on the use of SAMe in dogs with toxicant-induced hepatopathy with the suggestion that SAMe improved outcome, although without a control group, the role of SAMe in these cases is no certain (Schmid and Hovda 2016; Wallace et al. 2002).

SAMe is used in veterinary medicine as an adjunct therapy in the management of necroinflammatory, metabolic, and cholestatic hepatopathies, primarily in dogs and cats (Vandeweerd et al. 2013). SAMe has been shown to aid in restoring hepatocellular function, attenuate free radical production, mitigate cytokine-induced injury, reduce inflammation, enhance detoxification mechanisms and toxicant elimination, improve membrane function, and stimulate hepatocellular repair (Center 2004). Oral dosages of 20 mg/kg of stabilized salt or 53 mg/kg of enteric-coated tablets resulted in significant increases in plasma SAMe concentrations in dogs and cats. SAMe is absorbed across the small intestine and must be administered as enteric-coated formulations in order to be absorbed in pharmacologically relevant oral doses (Center 2004). Maximum plasma levels occur with 1–4 h in dogs and 2–8 h in cats. SAMe appears to be generally well tolerated, with occasional anorexia, nausea, or food refusal occurring within a few hours of administration. Rarely, anxiety may occur which may require discontinuation of SAMe administration. In humans, coadministration of SAMe with a monoamine oxidase inhibitor was associated with development of serotonin syndrome. Toxicity studies in rodents revealed an oral LD_{50} of greater

than 4650 mg/kg; and rats receiving 200 mg/kg body weight per day for 104 weeks showed no adverse effects (Center 2004). Similarly, no toxic effects were noted in cats receiving 40–65 mg/kg per day for over 100 days or in dogs receiving 20 mg/kg daily for 6 months.

2.2.2 *N*-acetylcysteine

N-acetylcysteine (NAC) is the acetylated form of the amino acid cysteine that serves as a thiol donor in metabolic reactions; only the L-isomer of NAC is used therapeutically. NAC can serve as a rapid source of sulfhydryl groups whether administered intravenously or orally. Oral bioavailability is low due to extensive first-pass metabolism in the intestine and liver. NAC is deacetylated to cysteine in enterocytes and hepatocytes, where it stimulates GSH synthesis via enhanced glutathione-S-transferase activity, enhances detoxification of many hepatotoxic agents, and has direct antioxidant activity against free radicals such as HOCl, superoxide, $OH^{\cdot}$, and H_2O_2 (Center 2004). NAC enhances red blood cell GSH, maintains hepatocyte fluidity, maintains antioxidant enzyme activity within cells, promotes GSH synthesis, mitigates formation of toxic adducts, indirectly promotes cytochrome P450 oxidase activity by enhancing NADP and GSH reduction, supports energy production by accelerated recovery of mitochondrial GSH, and protects against hepatic ischemia-reperfusion injury by inhibiting Kupffer cell activation and improving sinusoidal microcirculation (Saito et al. 2010; Vandeweerd et al. 2013). NAC also attenuates neurological effects associated with hepatic failure, including encephalopathy, cerebral edema, and coma (Bémeur et al. 2010).

NAC is generally recommended for situations where severe hepatotoxicosis is imminent or present, such as in acetaminophen toxicosis, and in situations involving oxidative damage to red blood cells, such as Heinz body anemia (Center 2004). In veterinary medicine, NAC has been recommended for hepatotoxicoses associated with acetaminophen, diazepam (cats), NSAIDs (dogs), mushrooms, and hepatic lipidosis syndrome with associated Heinz body anemia and/or hemolysis (dogs) (Avizeh et al. 2010; Center 2004; DeClementi 2018; Puschner 2018; Taboada 2017). Dosages used in veterinary medicine have been derived from human dosages for acetaminophen toxicosis: 140 mg/kg of 5% NAC solution as loading dose followed by 70 mg/kg q 6–8 h for 5–7 treatments (DeClementi 2018; Sellon 2013; Webster and Cooper 2009). Historically, evaluation of hepatic function at the end of the NAC dosing interval was recommended, with continuation of NAC q 6–8 h for up to 17 treatments if evidence of significant hepatic injury is present (DeClementi 2018). However, recent evidence that prolonged NAC treatment may actually impair liver regeneration following acetaminophen-induced injury has caused many to question the benefit of NAC therapy beyond 24 h following toxic insult (Athuraliya et al. 2009; Yang et al. 2009). Both oral and intravenous routes have been used in veterinary medicine. Although an approved intravenous formulation of NAC is available, its cost often makes it impractical for veterinary patients, so nebulization solutions of acetaminophen are frequently utilized; however, such solutions are not sterile, so administration through a millipore filter is required for intravenous administration (DeClementi 2018). Adverse effects of NAC administration include nausea, vomiting, and anaphylactic reactions; gastrointestinal upset can largely be mitigated via careful dilution of NAC solution (Bateman et al. 2014).

2.2.3 Silymarin

Silymarin is an extract of the milk thistle plant (*Silybum marianum*), a plant that has been used medicinally for centuries in Europe. Silymarin comprises 65%–80% of milk thistle extract and is itself composed of the flavonoid taxifolin and a mixture of at least seven flavolignans including silibinin, isosilbinin, silychristin, isosilychristin, and silydianin (DerMarderosian and Beutler 2014). Silybin A and B, stereoisomers of silibinin, are the most biologically active compounds in silymarin. Silymarin has antioxidant effects against ROS and lipid peroxidation, mitigating oxidative damage to hepatocellular and mitochondrial membranes and reducing GSH depletion. Silymarin enhances hepatocellular regeneration by acceleration of DNA synthesis and gene transcription/translation (Center 2004). Silymarin exhibits antifibrotic activity in the liver, inhibiting reactive collagen formation in animal models of hepatotoxic and cholestatic liver injury. Stimulation of bile acid synthesis by silymarin results in enhanced bile flow as well as enhanced levels of the hepatoprotective bile acid UDCA. Silymarin has shown hepatoprotective and hepatotrophic activities in a variety of experimental xenobiotic-induced hepatotoxicoses including those caused by hepatotoxic mushrooms (α-amanitin), acetaminophen, phalloidin, cyanobacteria (microcystin), iron, cisplatin, and methotrexate. Results of clinical trials of silymarin in humans have been equivocal and confounded by methodological flaws that make it difficult to compare studies, although individual studies generally show some improvement in outcome (Center 2004). Evaluation of the few clinical case reports is confounded by the fact that commercial products vary widely in silymarin content with no assurance of purity.

Silymarin is water insoluble with poor oral bioavailability, although bioavailability is reportedly improved by complexing silibinin with phosphatidylcholine (Center 2004). Silymarin is eliminated primarily via bile as glucuronide or sulfate conjugates and undergoes enterohepatic recirculation. Therapeutic dosing recommendations are complicated by the lack of standardization of various milk thistle products. Published dosages for veterinary species

include 50–150 mg/kg silibinin IV in dogs for treatment of amanitin toxicosis and 15–100 mg/kg silymarin IV in dogs, rabbits, and rodents given α-amanitin 10 min prior to silybin administration (Center 2004; Vogel et al. 1984). However, difficulty in extrapolation of these intravenous dosages to oral dosages and lack of standardized milk thistle products complicate dosing recommendations. Dosing comparable to human oral dosing recommendations for chronic hepatitis would be ~7–15 mg/kg per day; dosing up to 40–50 mg/kg per day would be comparable to doses used to control fibrosis in rats with obstructive biliary disease. In humans, adverse reactions reported with silymarin treatment have included mild diarrhea and hypersensitivity reactions (urticaria, pruritis).

2.2.4 Vitamin E

Vitamin E is an essential vitamin that serves as the most important lipid-soluble antioxidant (Center 2004). There are eight enantiomers of vitamin E in nature, but it is α-tocopherol that is most bioavailable and upon which nutritional recommendations should be based. Vitamin E is absorbed by the proximal intestine with the extent of absorption being dependent upon the amount of co-ingested lipid, amount of secreted bile, and presence of digestive esterases. Absorbed vitamin E is transported to the liver as mixed micelles, whereupon it is extracted and shuttled to lysosomes. A specific α-tocopherol transfer protein then sorts the various vitamin E forms and expedites their transfer to lipoproteins.

Vitamin E functions as a component of an antioxidant network that includes GSH, ubiquinol, vitamin C, cysteine, and SAMe. A major role for vitamin E is to mitigate propagation of membrane peroxidation damage through catalytic termination of membrane peroxidation reactions. An oxidized tocopheryl radical is produced that is then reduced back to its functional state via reactions with water- and lipid-soluble antioxidants such as vitamin C and ubiquinol (Center 2004). Non-antioxidant functions of vitamin E are performed via inhibition of protein kinase C, which modulates inflammation, has antiproliferative effects on vascular smooth muscle, inhibits platelet aggregation and adhesion, suppresses inflammatory cells, suppresses injurious immune responses, and reduces free radical production and inhibition of cyclooxygenase and 5-lipoxygenase (Azzi et al. 2002).

Hepatic concentrations of α-tocopherol are decreased in hepatic disease; plasma α-tocopherol levels do not reliably reflect liver concentrations, so should not be used to determine vitamin E status (Center 2004). Vitamin E should be considered in combination with other antioxidants, such as SAMe, for management of hepatobiliary disorders that are likely to involve oxidative membrane injury, such as necroinflammatory and cholestatic disorders. In dogs with chronic hepatic inflammatory disease, dosages of 7 IU/kg daily for 3 months resulted in improved liver enzyme values and hepatic glutathione status (Cantürk et al. 1998). Current dosing recommendation for dogs and cats is 10–15 IU/kg PO daily, with high doses (50–100 IU/kg) reserved for patients with chronic severe cholestatic liver disease; the latter cases may benefit from parenteral vitamin K1 administration (Center 2004; Vandeweerd et al. 2013). Adverse effects are uncommon, although interference in platelet aggregation has been reported. Vitamin E has a relatively low level of toxicity, with acute oral LD_{50}'s of >2 g/kg. In humans, chronic exposure to >5000 IU per day has been associated with alteration in other fat-soluble vitamins resulting in impaired bone mineralization (vitamin A) and/or coagulopathy (vitamin K). Excessive dosing may also promote toxopheroxy radical accumulation if other protective cofactors are out of balance or deficient. Drugs that induce cytochrome p450 enzymes can also potentiate formation of the tocopheryl radical.

2.2.5 Vitamin C

Vitamin C (ascorbic acid) is a hydrophilic vitamin with both antioxidant and prooxidant activities. Under normal physiologic conditions, vitamin C is present as reduced ascorbic acid, interacting with oxidants to be converted to its oxidized form, dehydroascorbic acid, which is readily converted back to ascorbic acid by glutathione (Jacob and Sotoudeh 2002). In excess, vitamin C can have prooxidant activity, especially in the presence of readily oxidized metals such as iron and copper through generation of oxygen-derived free radicals produced via lipid peroxidation (Center 2004). Vitamin C is an important cofactor for at least eight enzymes associated with collagen, amino acid, hormone, and carnitine synthesis and/or metabolism. Vitamin C is also involved in microsomal xenobiotic metabolism, synthesis of corticosteroids and catecholamines, conversion of cholesterol to bile acids, synthesis and modulation of components of the nervous system, and metabolism of tryptophan, tyrosine, and histamine. Vitamin C reduces a variety of ROS, regenerates vitamin E, protects against GSH depletion, and facilitates GSH regeneration. Because of its potential to potentiate certain metal-mediated tissue injury, vitamin C supplementation should be avoided in patients with high hepatic metal concentrations, particularly iron or copper. Similarly, due to its ability to induce collagen formation, vitamin C supplementation is not recommended in patients with hepatic disorders that are associated with hepatic fibrosis. Administration of high doses of vitamin C should be avoided to minimize any prooxidant activity associated with its use. Large overdoses of vitamin C have been associated with stomatitis and gastrointestinal upset in pigs and dogs and anemia and decreased reproductive performance in mink (Leveque 1969; National Research Council 1987).

2.2.6 α-Lipoic Acid

α-Lipoic acid (α-lipoate, thioctic acid, lipoic acid, 1,2-dithiolane-3-pentanoic acid) was originally classified as a vitamin until it was determined that plants and animals are capable of endogenously synthesizing the molecule (Zicker et al. 2002). In plant and animal tissues, α-lipoic acid is covalently bound to lysine residues. It has a key role in energy production by serving as a cofactor of mitochondrial enzymes, catalyzing the decarboxylation of pyruvate, branched-chain α-keto acids and α-ketoglutarate. Its thiol structure makes α-lipoic acid attractive to thiophilic toxicants such as heavy metals.

α-lipoic acid is readily absorbed from the gastrointestinal tract, with a bioavailability of ~30% (Center 2004). Once internalized in cells, α-lipoic acid is reduced to dihydrolipoate (DHLA) by several enzymes; intracellular DHLA and extracellular α-lipoic acid form a redox couple, functioning as antioxidants as they are exchanged across cellular membranes. Lipoamide, another metabolite of α-lipoic acid, serves as an essential cofactor for a number of enzyme systems, primarily within the mitochondria. Free α-lipoic acid interacts with several different biochemical pathways as a substrate, an inhibitor, or an effector (Bustamante et al. 1998).

The use of α-lipoic acid as an antioxidant in the management of liver disease has been extensively investigated in humans and animals (Bustamante et al. 1998). It is thought that α-lipoic acid works synergistically with vitamins A and C and GSH in an "antioxidant network" that enhances recycling of these compounds, and α-lipoic acid may play a role as a conditionally essential nutrient in aging mammals (Ames 1998; Podda et al. 1994). Additionally, α-lipoic acid has been studied for its ability to enhance glucose uptake into skeletal muscles, which makes it of interest to athletes and diabetics. Studies of α-lipoic acid in aging dogs have shown conflicting results in regard to effects on cognition, with some studies showing a positive effect and others showing no effect (Christie et al. 2009; Milgram et al. 2007).

α-lipoic acid has been included as an ingredient in some commercial extruded dog foods (Zicker et al. 2002). At the levels occurring in these foods, α-lipoic acid appears to have a low level of toxicity, with a maximum tolerated oral dosage in laboratory beagles of 126 mg/kg and LD_{50} of 400–500 mg/kg (Hill et al. 2004; Loftin and Herold 2009). However, dogs accidentally ingesting large amounts of α-lipoic acid supplements have been reported to experience hypoglycemia, liver injury, renal failure, and death (Loftin and Herold 2009). Cats appear to be approximately ten times more sensitive than other species, with hepatocellular damage occurring at 30 mg/kg (Hill et al. 2004). Certain disease states, such as thiamine deficiency, can result in enhanced toxicity of α-lipoic acid, significantly lowering toxic dosages (Gal 1965). The American Society for the Prevention of Cruelty to Animals' Animal Poison Control Center considers dosages of α-lipoic acid of >5 mg/kg (cats) and > 50 mg/kg (dogs) to be of concern for toxicosis (Loftin and Herold 2009).

2.2.7 Lecithin

Lecithin is a mixture of phosphatidylcholines, fatty acids, carbohydrates, and other compounds (DerMarderosian and Beutler 2014). Polyenylphosphatidylcholine (PPC) is the substance that is thought to be responsible for the hepatoprotective effects of lecithin, principally through its dilinoleoylphaphatidyl choline (DLPC) moiety (Center 2004; Lee et al. 2015). Both PPC and DLPC have been shown to inhibit hepatic fibrogenesis, attenuate oxidative hepatocellular and mitochondrial membrane injury, reduce accumulation of reactive oxygen species, and conserve hepatocellular and mitochondrial GSH levels. Anti-inflammatory activities of PPC and DLPC occur through inhibition of Kupffer cell activation, while reduced activation of hepatic stellate cells accounts for some of their antifibrotic activities. DLPC has been shown to attenuate oxidative injury from a variety of toxic hepatic insults, with the exception of iron toxicosis where DLPC aids in restoration of GSH levels but does not control oxidative injury caused by iron (Aleynik et al. 2000).

In humans, PPC has been used primarily in alcohol hepatotoxicosis but has also been shown to be beneficial in chronic necroinflammatory liver diseases as well as acute hepatopathy (Center 2004). Although no controlled clinical studies in veterinary species have been performed, general dosing recommendations for veterinary patients are 25–50 mg/kg PPC per day. PPC appears to have a wide margin of safety, with no reported adverse effects in humans receiving therapeutic dosages. Very large ingestions in humans (>25 g/day) have resulted in gastrointestinal distress, sweating, hypersalivation, and anorexia; one study in humans receiving tacrine and lecithin had gastrointestinal distress and hepatitis reported as adverse effects (DerMarderosian and Beutler 2014).

2.2.8 Ubiquinol

Ubiquinones are endogenous lipid soluble benzoquinone antioxidants synthesized in all animal tissues; ubiquinol (coenzyme Q_{10}) is the reduced form of ubiquinone (DerMarderosian and Beutler 2014). Ubiquinones function in oxidation-reduction reactions in the mitochondrial respiratory chain and protect against lipid peroxidation. Ubiquinol acts as an antioxidant that reduces vitamin E and vitamin C following their interactions with oxidants. In hepatic disease, mitochondrial dysfunction results in decreased ubiquinol availability, increasing the risk of oxidative injury (Center 2004). Ubiquinol-mediated support of endothelial cell function may be of benefit in hepatic ischemia-reperfusion injury. Few clinical studies of ubiquinol in veterinary patients exist,

and dosing recommendations are extrapolated from human studies. In general, a dosage of 1–2 mg/kg PO per day could be considered (Center 2004).

2.2.9 Ursodeoxycholic Acid

For centuries, Chinese medicine utilized Yutan, a compound derived from the dried bile of Chinese black bears, to aid in treatment of hepatobiliary disorders (Vandeweerd et al. 2013). Investigation into Yutan identified the major active principle in the bile as ursodeoxycholic acid (UDCA), a hydrophilic bile acid; subsequently, synthetic forms of UDCA are available as FDA-approved human drugs. Beneficial effects of UDCA stem from a variety of activities including replacement of more toxic endogenous bile acids, cytoprotection of hepatocytes and biliary epithelium, antioxidant activity, immunomodulation, suppression of anomalous major histocompatibility foci, enhancement of biliary excretion of toxic compounds, stimulation of bile secretion, mitigation of bile acid-induced mitochondrial injury, and reduction of bile acid-induced hepatocellular apoptosis (Center 2004). The hepatoprotective effects of UDCA are specific for bile acid-induced injury and do not extend to injury from direct or indirect toxic exposure or from ischemia-reperfusion injury. Studies in humans and laboratory animals have failed to show a benefit from use of UDCA in cases of hepatosteatosis; for this reason, UDCA should be used cautiously, if at all, in patients, particularly cats, with severe hepatic lipidosis (Center 2004).

Orally administered UDCA is absorbed from large and small intestines, and $>$ 60% of an absorbed dose is taken up by the liver. As with other bile acids, UDCA is conjugated with glycine or taurine in a species-dependent fashion and is excreted in the bile. In patients with cholestasis, UDCA becomes the predominant bile acid in both the liver and systemic circulation. In general, UDCA may be of benefit in patients with necroinflammatory or cholestatic liver disorders where cholestasis is a concern, although published studies showing efficacy in veterinary patients are lacking. Dosages of 10–15 mg/kg PO with food in one or two divided doses have been recommended for veterinary patients (Center 2004).

3 Pancreas

3.1 Pancreatic Dysfunction

The pancreas has both endocrine and exocrine functions. The main function of the acinar cells of the exocrine pancreas is the synthesis and secretion of digestive enzymes including the inactive proenzymes of chymotrypsin, trypsin, collagenase, phospholipases, elastases, and carboxypeptidases, as well as active lipase and amylase (Jubb and Stent 2016). The endocrine pancreas islet cells secrete the hormones insulin, glucagon, somatostatin, pancreatic polypeptide, adrenomedullin, and ghrelin. Broadly speaking, the exocrine pancreas mediates digestion, while the endocrine pancreas regulates blood glucose concentrations. Exocrine pancreatic dysfunction results in a maldigestion syndrome termed exocrine pancreatic insufficiency (EPI), resulting in diarrhea, weight loss, and proliferation of small intestinal microflora. Pancreatic islet dysfunction most commonly causes decreased or absent insulin secretion resulting in diabetes mellitus, characterized by hyperglycemia, glucosuria, polydipsia, polyuria, and weight loss. Pancreatitis, an inflammation of the pancreas, can result in damage to acinar and islet cells, predisposing to diabetes or exocrine pancreatic insufficiency, or, in severe cases, both.

3.2 Nutraceuticals and the Pancreas

3.2.1 Enzymes

For most veterinary patients with EPI, the use of commercial pancreatic enzyme extracts derived from beef or pork pancreas will provide the degree of digestion of food needed to resolve most clinical signs (Steiner 2010). Plant-derived digestive enzymes that have been recommended as substitutes for pancreatic enzymes include papain, bromelain, and ficin; however, there are no studies to demonstrate efficacy comparable to pancreatic-derived enzymes for EPI (Silver 2012). Supplementation with fat-soluble vitamins (A, D, E, K) is also recommended in EPI patients (Steiner 2010).

3.2.2 Nutraceuticals and Diabetes

A large number of nutraceuticals have been investigated for their ability to alter blood glucose levels in humans, but extrapolation to veterinary species is complicated by the fact that insulin and blood glucose responses can vary between species. For instance, xylitol is a 5-carbon sugar alcohol derived from willow bark that is used as a sweetener by human diabetics because it has no impact on blood insulin or glucose levels; in contrast, xylitol administration to dogs can cause an intense and prolonged spike in insulin secretion from the pancreas, leading to hypoglycemia that can be potentially life threatening (Dunayer 2006). Extrapolating between veterinary species is also difficult with regard to diabetes mellitus, since the type of diabetes tends to differ: diabetic dogs generally have an absolute lack of insulin due to islet cell destruction (human Type 1 diabetes), while diabetes mellitus in cats is more similar to human Type 2 diabetes, i.e., β-cell dysfunction and impaired tissue response to insulin (Reusch 2010). Table 1 highlights some nutraceutical compounds that have been investigated for human diabetes mellitus; no studies in veterinary species exist, and extrapolation of results to veterinary patients should be done with

Table 1 Nutraceutical effects in diabetes

Nutraceutical	Active constituent	Proposed mechanism of action	Adverse effects	Reference
α-Lipoic acid	α-Lipoic acid	↓ insulin resistance	Hypoglycemia, hepatotoxicity	Hill et al. (2001), Jacob et al. (1995), Loftin and Herold (2009)
Chromium	Chromium	↑ insulin binding, ↑ insulin receptor numbers, ↑ insulin sensitivity of cells	Renal injury at high doses	Anderson (2000)
Garlic	S-allyl cysteine sulfoxide	↓ fasting glucose	Can cause Heinz body anemia in cat and dog	Sheela and Augusti (1992), Tang et al. (2008)
Green tea	Polyphenols	↑ insulin sensitivity of cells	Caffeine can have adverse effects; vitamin K may interfere with therapeutic anticoagulants	Potenza et al. (2007)
Ubiquinol (coenzyme Q_{10})	Ubiquinol	Improves long-term glycemic control in Type 2 diabetes	None found	Afolayan and Olubunmi (2014)

extreme caution. For details on nutraceuticals/plant extracts in canines and felines, readers are referred to Chapter "Nutraceuticals in Gastrointestinal Conditions" in this book.

4 Concluding Remarks and Future Directions

Hundreds of nutraceuticals have been investigated for their potential benefit or harm in hepatic or pancreatic disease, but further studies are needed for most to determine clinical efficacy of the individual agents. Although research has shown that many nutraceuticals possess potential medicinal activities that are measurable at the cellular and/or molecular level, demonstrating clinical efficacy can be much more problematic. Reports of positive clinical response of veterinary patients to nutraceuticals are largely no more than anecdotal evidence or individual case reports where confounding factors such as coadministered compounds (e.g., drugs, herbals, other nutraceuticals), questionable nutraceutical purity, or lack of effective control populations make it difficult to determine any real effect from nutraceuticals. Commercially available nutraceuticals frequently vary considerably between brands (and often between lots within a brand) in quality and content of active components; many manufacturers consider their formulations "proprietary" and refuse to divulge contents, and researchers frequently use purified and/or extracts of individual constituents of nutraceuticals rather than the products as available for use, making it difficult to make comparisons between studies. Herbal, supplement, and nutraceutical products are poorly regulated in many countries, leaving the consumer at the mercy of the manufacturer in terms of product quality and safety (Seeff et al. 2015).

Nutraceutical compounds that work well in vitro may have poor bioavailability or rapid elimination that interferes with their ability to reach plasma concentrations required for them to have any therapeutic effect. Compounds that achieve good plasma levels may be unable to distribute to target tissues due to inability to pass through physiological barriers due to physiochemical properties (e.g., lipophilicity, pH) or due to the presence or absence of appropriate transporter molecules (e.g., p-glycoprotein transporters). Other nutraceuticals may have beneficial effects on some tissues but may be harmful to other tissues within the body. For instance, the hepatoprotective compound silymarin has been shown to enhance the growth of mammary tumors (Malewicz et al. 2006); similarly, silibinin has hepatoprotective properties but can promote progression of ethanol-dependent hepatocellular carcinoma when coadministered with ethanol (Brandon-Warner et al. 2012).

Nutraceuticals demonstrating antioxidant, anti-inflammatory, and/or antifibrotic activities in the liver may inhibit or minimize acute injury induced by endogenous and exogenous hepatotoxic agents or may prevent or slow progression of chronic liver disorders such as hepatic lipidosis, chronic active hepatitis, liver storage diseases, and hepatic carcinogenesis. However, because alteration of hepatic metabolic enzymes, decreased inflammatory/immune responses, and stimulation of hepatocellular proliferation can cause unfavorable consequences such as interference with therapeutic agents, diminished hepatic immune surveillance, or increased risk of hepatic neoplasia, potential adverse effects of nutraceuticals must be researched and documented. Most nutraceuticals lack long-term safety and carcinogenicity data

and lack the regulatory requirement to track adverse effects. Illness and death in humans and animals have been reported to be associated with the contamination or intentional adulteration of nutraceuticals with biotoxins, heavy metals, mycotoxins, pesticide residues, pharmaceuticals, toxic plants, and other potentially hazardous substances (Seeff et al. 2015; Mittelman et al. 2016; Brown 2017; Gupta et al. 2018). These issues will need to be addressed through further research before the safety and efficacy of nutraceutical products can be determined.

Nutraceuticals in Periodontal Health and Diseases in Dogs and Cats

Ramesh C. Gupta, Denise M. Gupta, Rajiv Lall, Ajay Srivastava, and Anita Sinha

Abstract

Periodontal diseases are the most common diseases of domestic dogs and cats. Conventional treatment of periodontal diseases rests with broad-spectrum antibiotics and antiseptics. Due to rising healthcare costs, severe side effects, and drug resistance, complementary and alternative medicines are a preferable choice for patients with periodontal diseases. This chapter describes several nutraceuticals and herbal complementary medicines that can be used singly or in combination for prevention and treatment of periodontitis in dogs and cats.

Keywords

Nutraceuticals · Veterinary nutraceuticals · Oral health · Periodontal diseases

1 Introduction

Currently, about 3.9 billion people suffer from periodontal diseases associated with gum and tooth decay. Periodontal diseases are more frequently encountered in dogs and cats than in humans due to lack of oral health hygiene. According to the American Veterinary Dental College (AVDC), 80% of dogs and 70% of cats suffer from periodontal diseases. Periodontal disease affects dogs and cats of all ages, although it is more common in older animals. It can include sore, swollen, bleeding gums, infected teeth, caries, plaque buildup, and tartar. In animals, periodontal disease is an often overlooked health problem which may be directly or indirectly linked to an increased risk of cardiovascular disease, arthritis, diabetes, and even neurodegenerative disease (chronic cognitive dysfunction syndrome in dogs and cats).

In a number of studies, the influence of diet on oral health in dogs and cats has been reported (Gawor et al. 2006; Logan 2006; Chandler 2014; Oba et al. 2018). Plant products have been used to improve dental health and promote oral hygiene for a long time (reviewed in Kumar et al. 2015). Ganesan (2008) provided a list of 114 plant species belonging to 51 families which have potential for use in periodontal diseases. Ganesan (2008) reported that leaves were the dominant plant part used in oral care (25.44%), followed by root (20.17%), seed/nut/fruits (18.42%), bark (14.03%), stem (12.28%), whole plant (9.65%), and gum/latex (8.77%). Most of the plant extracts and products are used, in various forms such as mouthwash, paste, or powder, to relieve toothache, gingivitis, stomatitis, ulcers, gum bleeding, and other disorders.

In conventional treatment of periodontal diseases, various antimicrobial or antiseptic agents are applied locally in the form of fibers, films, gels, microparticulate systems, or nanoparticulate systems (Puri and Puri 2013). Based on required duration of action, drug or phytochemical agents can be applied locally using sustained release devices [(a) drug delivery for less than 24 h, (b) require multiple applications, and (c) follow first-order kinetics] or controlled delivery devices [(a) duration of drug release exceeds 24 h, (b) administered once, and (c) follow zero-order kinetics]. Due to rising healthcare costs, side effects, and drug resistance, complementary and alternative medicines are preferred over modern medicines. This chapter describes some nutraceuticals and plant extracts that can be used for various periodontal diseases in dogs and cats.

2 Pathophysiology of Periodontal Diseases

Pathophysiology of periodontal diseases is complex due to multifactorial etiologies. The oral cavity consists of the teeth, gums, hard palate, and soft tissue. Periodontium consists of four tissues (free and attached gingiva, periodontal ligament, alveolar bone, and root cementum) and protects the teeth. Dental problems may include plaque, tartar, tooth decay, gingivitis, and periodontal diseases (Muhammad and Lawal 2010). Gum deterioration, often characterized by swelling, bleeding and pain, is the leading cause of tooth loss. Periodontitis is considered the second most important cause of tooth loss in humans and animals. Clinical features that may be useful in the early detection of onset of periodontitis include overt gingival inflammation, dental calculus and a high rate of caries, restorations, and tooth loss (Albandar et al. 1997).

Periodontitis can be defined as an inflammatory process, initiated by the formation of plaque biofilm, which leads to loss of periodontal attachment to the root surface and adjacent alveolar bone and may ultimately result in tooth loss. In both gingivitis and periodontitis, inflammation is the result of microorganisms present in dental plaque (Newman et al. 2006). Initially, the bacteria in plaque are predominately non-motile, Gram-positive aerobes, including *Staphylococcus* spp. and *Streptococcus* spp., but many others are also present. As the plaque biofilm thickens and matures, Gram-negative anaerobes become predominant. Bacteria in subgingival plaque secrete toxins and metabolic by-products, initiating gingivitis and the inflammatory process. Organisms most often associated with periodontal disease include *Bacteroides fragilis*, *Peptostreptococcus*, *Porphyromonas gulae*, *Porphyromonas salivosa*, *Porphyromonas denticanis*, *Prevotella intermedia*, *Treponema* spp., *Bacteroides splanchnicus*, and many others. Recently Singh et al. (2016) emphasized the role of periopathogens (*P. gingivalis*, *A. actinomycetemcomitans*, *P. intermedia*, *F. nucleatum*, etc.) in periodontal diseases.

Periodontal pathogens can induce reactive oxygen species (ROS) overproduction and thus may cause collagen and periodontal cell breakdown (Soni et al. 2012). In fact, periodontitis is associated with reduced antioxidant capacity and increased oxidative damage (Lima et al. 2017). Oxidative stress induces inflammation and bone loss contributing to the pathological progression of periodontal diseases. During periodontitis, the inflammatory process is marked by neutrophils that invade periodontium and induces the release of proteolytic enzymes and production of ROS (D'Aiuto et al. 2010). An imbalance between pro-inflammatory and anti-inflammatory response results in periodontal breakdown (Preshaw 2008). The continuous exacerbation of inflammation culminates with collagen fiber destruction and bone resorption (Zheng et al. 2015).

In the field of periodontal health and diseases, various diagnostic markers are used such as plaque accumulation (PLA), plaque index (PI), gingival index (GI), bleeding on probing (BOP), sulcus bleeding index (SBI), periodontal probing depth (PD), clinical attachment level (CAL), and oral hygiene index-simplified (OHI-S) (Pannuti et al. 2003; Nagata et al. 2008; Khairnar et al. 2013). Recently, Kajiura et al. (2016) reported that soluble form of IL-6 reporter (sIL-6R) and calprotectin concentrations in gingival crevicular fluid are useful biomarkers in the evaluation of periodontitis. Figure 1 shows dental tartar in the dog.

According to Dr. Alexander M. Reiter (School of Veterinary Medicine, University of Pennsylvania), periodontitis in dogs and cats is classified in four stages:

Stage 1: There is gingivitis only, without attachment loss; the height and architecture of the alveolar margin are normal.

Stage 2: There is early periodontitis with <25% of attachment loss or, at most, there is a stage 1 furcation involvement in multirooted teeth. There are early radiographic signs of periodontitis. The loss of periodontal attachment

Fig. 1 Tartar in dog teeth

is <25% as measured by probing of the clinical attachment level or by radiographic determination of the distance of the alveolar margin from the cementoenamel junction relative to the length of the root.

Stage 3: There is moderate periodontitis, with 25–50% of attachment loss as measured by probing of the clinical attachment level or by radiographic determination of the distance of the alveolar margin from the cementoenamel junction relative to the length of the root, or there is a stage 2 furcation involvement in multirooted teeth.

Stage 4: There is advanced periodontitis, with >50% of attachment loss as measured by probing of the clinical attachment level or by radiographic determination of the distance of the alveolar margin from the cementoenamel junction relative to the length of the root, or there is a stage 3 furcation involvement in multirooted teeth.

In advanced periodontitis, teeth may fall out and are sometimes swallowed by dogs and cats (Fig. 2).

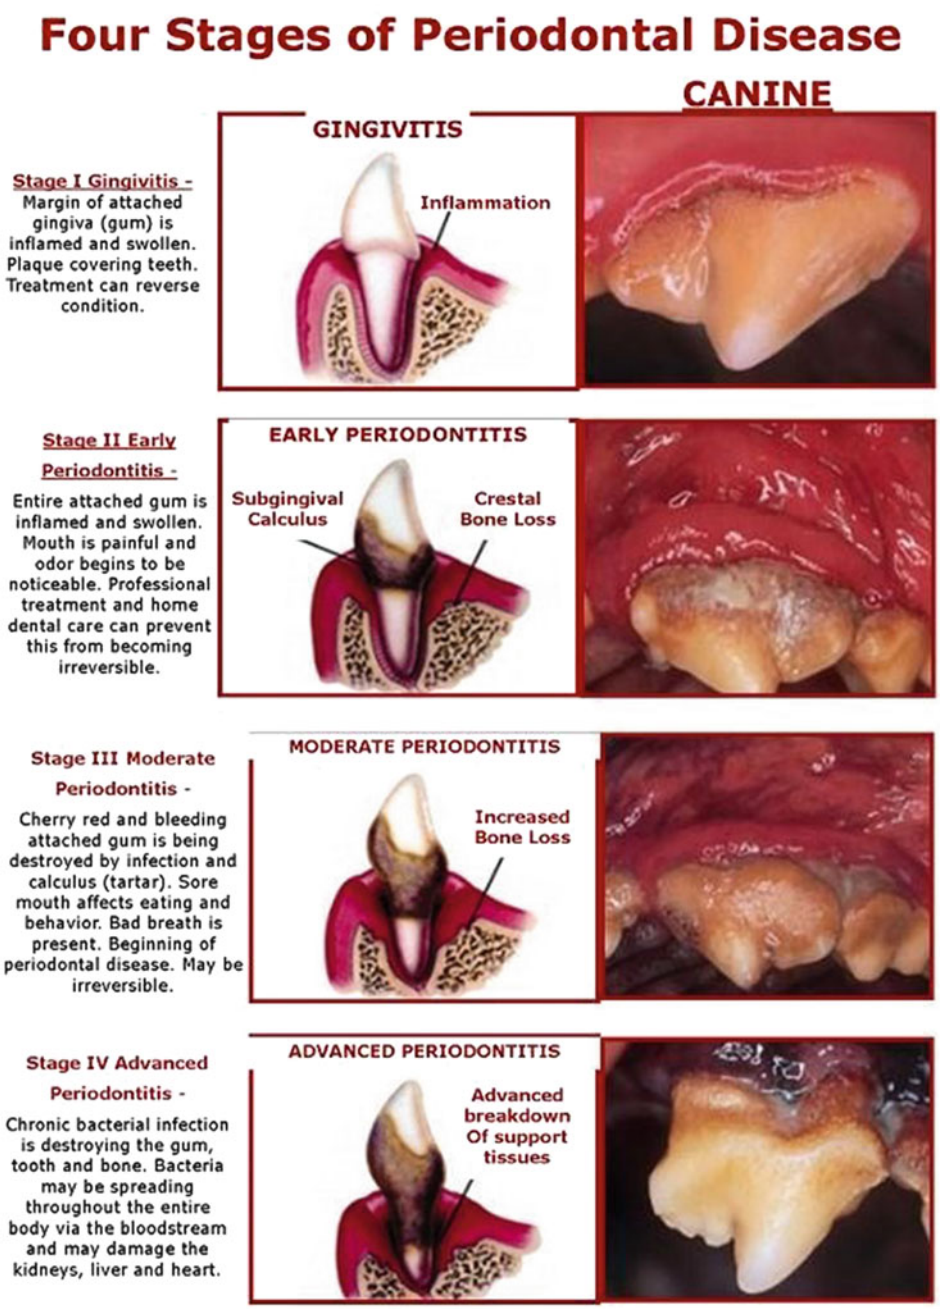

Fig. 2 Four stages of periodontal disease in canine

3 Nutraceuticals in Periodontal Diseases

As in humans, periodontal diseases in dogs and cats can be treated with four objectives: (1) remove built-up plaque and tartar, (2) fight bacteria which cause infection, (3) reduce inflammation, and (4) stop bleeding.

Some commonly used nutraceuticals are discussed here in brief, and the rest are listed in Table 1.

3.1 *Calendula Officinalis*

Calendula officinalis (*C. officinalis*), commonly known as pot marigold, is an annual medicinal herb. More than 100 phytoconstituents have been identified in different parts of this plant. The flowers of *Calendula officinalis* contain flavonol glycosides, triterpene oligoglycosides, oleanane-type triterpene glycosides, saponins, and a sesquiterpene glucoside. The petals and pollen contain triterpenoid esters and the carotenoids flavoxanthin and auroxanthin (antioxidant). The leaves and stems contain other carotenoids, mostly lutein (80%), zeaxanthin (5%), and beta-carotene. In essence, the plant is very rich in quercetin, carotenoids, lutein, lycopene, rutin, ubiquinone, xanthophylls, and other antioxidants. The flavonoid quercetin is considered to be of great importance for treating periodontitis due to its antioxidative and anti-inflammatory properties (Napimoga et al. 2013; Li et al. 2016).

By having these many phytoconstituents, *C. officinalis* extract exerts antioxidative, anti-inflammatory, antibacterial, antiviral, antifungal, and hemostatic activities (Preethi et al. 2009; Preethi and Utta 2006; Parente et al. 2012). In an experimentally induced periodontitis in rats, Lima et al. (2017) demonstrated that 11 days of ligature caused bone loss, breakdown of collagen fibers, and increased immunostaining for DKK-1 while reducing WNT 10b and β-catechin expressions. Periodontitis reduced glutathione (GSH), superoxide dismutase (SOD), and catalase (CAT) and increased malondialdehyde (MDA). All findings were reversed by 90 mg/kg of *C. officinalis*. Lima et al. (2017) suggested that *C. officinalis* reduced oxidative stress and bone loss and preserved collagen fibers in rats with experimental periodontitis involving the WNT signaling pathway. In a clinical trial, Khairnar et al. (2013) reported that patients with gingivitis receiving *C. officinalis* (2 ml tincture with 6 ml of distilled water) showed reduction in dental plaque and gingivitis. In a number of other experimental and clinical studies, *C. officinalis* (in gel, tincture, or mouthwash) has shown positive effects against gingivitis and periodontitis (Lauten et al. 2005; Yusoffs and Kamin 2006; Preethi and Utta 2006; Machado 2010; Saini et al. 2012; Khairnar et al. 2013; Tanideh et al. 2013).

C. officinalis extract appears to be a promising nutraceutical for treating periodontitis in dogs and cats after achieving positive effects in multicentered, long-term clinical trials.

3.2 Pau d'Arco

Pau d'Arco (*Tabebuia impetiginosa*), also called "ipê roxo" or "purple lapacho," is a huge canopy tree native to the Amazon rainforest and other tropical parts of South America and Latin America. There are indications that its use may actually predate the Incas. The Guarani and Tupi Indians call the tree "Tajy," which means "to have strength and vigor." In South American herbal medicines, Pau d'Arco has been indicated for many health conditions, including malaria, anemia, fever, colitis, arthritis, respiratory problems, colds, cough, flu, fungal infections, rheumatism, snakebite, poor circulation, boils, syphilis, and cancer.

The bark of Pau d'Arco contains many phytochemicals, including quinoids (anthraquinones, furanonaphthoquinones, lapachones, and naphthoquinones), benzenoids, and flavonoids. Pau d'Arco's beneficial health effects stem from its lapachol and β-lapachone content (Lagrota et al. 1983; Giuraud et al. 1994). The structural formula of lapachol and β-lapachone are shown in Fig. 3. Typically, Pau d'Arco bark contains 2–7% lapachol. A good-quality Pau d'Arco bark contains approximately 4% lapachol. These phytoconstituents exert antimicrobial, antifungal, antiviral, antitumorus, antileukemic, and anti-inflammatory activities.

Pau d'Arco increases blood flow to tissues, helping to detoxify them while providing antibacterial, anti-inflammatory, antifungal, antioxidative, and antiviral benefits. Due to its many biological/pharmacological properties, Pau d'Arco currently takes center stage in herbal medicines commonly used in South and Central America for treating ulcerations and other inflammatory conditions. Pau d'Arco appears to be an excellent nutraceutical for oral hygiene and periodontitis in dogs and cats after establishing proper dosage and clinical trials.

Studies revealed that Pau d'Arco is safe for prevention and treatment of periodontal treatment, since its reported LD_{50} for lapachol is 1.2–2.4 g/kg body wt in rats and 487–621 mg/kg in mice.

3.3 *Echinacea purpurea* (Coneflowers)

Echinacea purpurea plant contains several chemical compounds, including polysaccharides, caffeic acid derivatives (including chicoric acid), alkylamides, and glycoproteins. Phytoconstituents of *E. purpurea* exert anti-inflammatory, antimicrobial, and analgesic effects. Kumar

Table 1 Nutraceuticals/plant extracts having potential for prevention/treatment of periodontal diseases

Nutraceuticals/plant extracts	Active ingredients	Pharmacological effects	References
Abrus precatorius Linn.	Abrusogenin, stigmasterol, β-sitosterol, monoglycerides, triglycerides	Strengthening gum and teeth, dentifrice, antibacterial, antifungal	Ganesan (2008) and Ragasa et al. (2013)
Acasia arabica Wild.	Polyphenolics, gallic acid, catechin, chlorogenic acid, robidandiol	Antioxidative, antiviral, antimicrobial, antifungal, anti-plaque, anti-gingivitis	Ganesan (2008) and Pradeep et al. (2010)
Acacia farnesiana Linn.	Phenolic compounds, galloylglycoside	Antioxidative, antibacterial, dentifrice, anti-gingivitis	Ganesan (2008) and Ramli et al. (2011)
Acacia nilotica L. (babool)	Androstene, D-pinitol, catechins, gallic acid, rutin	Antioxidative, antibacterial, antifungal, anti-gingivitis, anti-plaque	Amos et al. (1999), Gilani et al. (1999), Shekhawat and Batra (2006), Bushra et al. (2007), Bachayaa et al. (2009), and Umaru et al. (2016)
Acalypha indica L. (Indian copper leaf)	Hexanedioic acid, bis(2-ethylhexyl) ester	Anti-toothache	Siddamallayya et al. (2010) and Chaichoowong et al. (2017)
Achyranthes aspera L. (devil's horsewhip)	Triterpenoid saponins, ecdysterone, achyranthine	Anti-toothache	Mahmood et al. (2005)
Allium sativum L.	Allicin (diallyl disulfide sulfoxide), alliin (*S*-allylcysteine sulfoxide), ajoene	Anti-toothache	Gupta (2006)
Aloe ferox Mill.	3,6 Octatriene, 3-cyclohexane-1-heptanol, bornylene, 1,3-cyclopentadiene, 1,3-cyclopentadiene	Anti-toothache	Gupta (2006) and Magwa et al. (2010)
Aloe vera L.	Salicylic acid, enzymes, vitamins, minerals, fatty acids	Dentifrice, anti-plaque, anti-gingivitis	Scherer et al. (1998), Wynn (2005), De Oliveira et al. (2008), Bhat et al. (2011), Sajjad and Subhani Sajjad (2014), Subhash et al. (2014), and Petrovic et al. (2015)
Althea officinalis L. (marshmallow)	Polysaccharides, flavonoids, coumarins, phenolic acid, sterols	Antimicrobial, anti-inflammatory, anti-periodontitis	Iauk et al. (2003)
Anacardium occidentale L.	B-Phellandrene, limonene, methyl chavicol, germacrene, linalool, β-cadinol, bisabolene	Sore gum, toothache	Kayode and Omotoynibo (2009)
Areca catechu Linn.	Arecoline, guvacoline, procyanidins, catechin, epicatechin	Dentifrice	Ganesan (2008) and Patil et al. (2009)
Arnica montana L.	Thymol, pseudoguaianolide, sesquiterpene lactones, flavanone glycosides	Antimicrobial, anti-periodontal	Koo and Jeon (2009) and Iauk et al. (2003)
Berberis vulgaris (barberry)	Berberine, berbamine, jateorrhizine, palmatine, oxycanthine	Antioxidative, anti-inflammatory, antibacterial, anti-gingivitis	Makarem et al. (2007), Palombo (2011), and Tu et al. (2013)
Azadirachta indica (neem)	Gallotannins	Glucosyl transferase inhibitory, antibacterial, anti-plaque	Wolinsky et al. (1996), Pai et al. (2004), Bhambal et al. (2011), and Singh et al. (2016)
Blood root (*Sanguinaria canadensis*)	Alkaloids	Bacteriostatic, anti-inflammatory, anti-bone loss, anti-tooth loss	Pai et al. (2004)
Cajanus cajan (Linn.) (pigeon pea)	Cajanstilbene acid, pinostrobin, vitexin, orientin	Antioxidative, anti-gingivitis	Ganesan (2008) and Wu et al. (2009)
Calendula officinalis L. (pot marigold)	Triterpine, oligoglycosides, saponins, quercetin, sesquiterpene glucoside, lutein, flavoxanthin, rutin, auroxanthin, zeaxanthin, carotenoids, lycopene	Antioxidant, anti-inflammatory, immunostimulating, anti-plaque, anti-gingivitis, wound healing, antimicrobial, antifungal	Iauk et al. (2003), Chakraborthy (2008), Preethi et al. (2009), Machado (2010), Parente et al. (2012), Khairnar et al. (2013), Li et al. (2016), and Lima et al. (2017)
β-Caryophyllene (*Origanum vulgare* L.; *Cinnamomum* spp.; *Piper nigrum* L.; *Cannabis sativa* L.)	β-Caryophyllene	Antibacterial, anti-plaque	Gertsch et al. (2008) and Pieri et al. (2016)

(continued)

Table 1 (continued)

Nutraceuticals/plant extracts	Active ingredients	Pharmacological effects	References
Chitosan	Chitosan	Antibacterial, antifungal, anti-plaque, anti-gingivitis	Ikinci et al. (2002), Uraz et al. (2012), Costa et al. (2014), and Husain et al. (2017)
Clove (*Syzygium aromaticum*)	Eugenol, eugenin, eugenitin, acetyl eugenol, β-caryophyllene, vanillin, crategolic acid, bicornin, caempesterol, sesquiterpenes	Antioxidative, anti-inflammatory, antibacterial, antiviral, immunostimulatory, anti-gingivitis, anti-toothache	Pinto and Santos (2017), Nagababu and Lakshmaiah (1992), Kumaravelu et al. (1996), and Rodrigues et al. (2009)
Colgate herbal toothpaste	Calcium carbonate, chamomile, sage, myrrh, eucalyptus, sodium monofluorophosphate	Anti-plaque, anti-gingivitis	George et al. (2009)
Commiphora myrrha (myrrh)	Sesquiterpenes (furanoeudesma-1,3-diene, curzarene)	Antibacterial, ant-inflammatory, anti-pyorrhea, astringent, analgesic, anti-gum diseases and mouth ulcers, antispasmodic	Dolara et al. (2000), Zhu et al. (2003), and Tipton et al. (2006)
Ceylon cinnamon Powder	Cinnamaldehyde, cinnamyl acetate, cinnamyl alcohol	Antimicrobial, anti-inflammatory	–
Citrus sinensis (orange peel extract)	Alkaloids, anthraquinones, tannins, phenolics, triterpenoids, saponins, flavonoids	Antimicrobial, Anti-caries	Shetty et al. (2016)
Coenzyme Q10	Coenzyme Q10	Antioxidative, anti-inflammatory, anti-periodontitis, anti-gingivitis	Nakamura et al. (1974), Hanioka et al. (1994), Pradeep et al. (2010), Soni et al. (2012), and Singh et al. (2016)
Echinacea purpurea (purple coneflowers)	Chicoric acid, alkylamides, caffeic acid, glycoproteins, polysaccharides	Antimicrobial, anti-inflammatory, immunomodulatory, analgesic, anti-gingivitis, anti-periodontitis	Kumar et al. (2009) and Modarai et al. (2011)
Eucalyptus extract/ eucalyptol oil	Borneol, 1,8-Cineol, globulol, *p*-cymene, limonene, α-pinene, cryptone, α-terpineol	Antibacterial, anti-gingivitis, anti-gum bleeding, anti-plaque	Nagata et al. (2008), Sebei et al. (2015), and Singh et al. (2016)
Folate	Folate	Anti-gingivitis	Vogel et al. (1978) and Pack (1984)
Fragaria vesca	Myrthenol, nonal, linalool, geraniol	Anti-plaque, anti-tartar	–
Grapefruit seed extract (GSE) (*Vitis vinifera*)	Proanthocyanidins	Antibacterial, antioxidative, anti-inflammatory, immunostimulatory, antifungal	Garlet et al. (2004), Houde et al. (2006), Baydar et al. (2006), La et al. (2009), Govindaraj et al. (2010), and Özden et al. (2017)
Green tea	Epicatechin, epicatechin gallate, epigallocatechin, (−)-epigallocatechin-3-gallate	Antioxidative, anti-inflammatory, antibacterial, preventing bone resorption, anticariogenic	Yu et al. (1992), Hirasawa et al. (2002), Yun et al. (2004), Coimbra et al. (2006), Kushiyama et al. (2009) and Chatterjee et al. (2012)
Hamamelis virginiana L.	Hamamelitannins, catechins, proanthocyanin, quercetin, saponins	Anti-inflammatory, astringent, antimicrobial, anti-periodontitis	Erdelmeier et al. (1996) and Iauk et al. (2003)
Hyaluronic acid	Hyaluronic acid	Periodontal regeneration, bacteriostatic	Pirnazar et al. (1999) and Bansal et al. (2010)
Hydrastis canadensis (goldenseal)	Isoquinolone alkaloids (hydrastine, hydrastinine, berberine, berberastine, canadine, canalidine, tetrahydroberberastine	Antibacterial, anti-inflammatory, immunostimulating	Baghele (2017)
Illicium verum Hook (Chinese star anise)	A-pinene, farnesol, α-terpineol, safrol, anisaldehyde, β-phellandrene, p-cumicaldehyde, limonene, shikimic acid	Antioxidative, antimicrobial, antibacterial, antifungal, anti-periodontitis	Iauk et al. (2003), Chouksey et al. (2010)
Matricaria chamomilla L. (chamomile)	Terpenoids, flavonoids, chamazulene, α-bisabolol, umbelliferone	Antioxidative, anti-inflammatory, antiseptic, fungistatic, anti-periodontitis, anti-sore gum and teeth	Singh et al. (2011)
Mellissa officinalis L.	Citronellal, geraniol	Antimicrobial, anti-periodontitis	Iauk et al. (2003), Abdellatif et al. (2014)

(continued)

Table 1 (continued)

Nutraceuticals/plant extracts	Active ingredients	Pharmacological effects	References
Mentha piperita L. (peppermint)	Menthol, menthone, menthyl acetate, 1,8-cineole, limonene, β-pinene, β-caryophyllene, flavonoids	Antioxidative, anti-inflammatory, analgesic, antiulcer, cytoprotective, chemopreventive, anti-gingivitis	Blumenthal et al. (1998), Kumar et al. (2009), and Taheri et al. (2011)
Origanum vulgare (oregano oil)	Polyphenols, flavones	Antioxidants	Petrovic et al. (2015)
Parodontax®	Sodium bicarbonate, sodium fluoride, chamomile, echinacea, sage, myrrh, rhatany, peppermint oil	Anti-gingivitis, anti-plaque, anti-periodontitis	Pannuti et al. (2003) and Ozaki et al. (2006)
Pau D'Arco	Quinods, quercetin, benzenoids, flavonoids, lapachol, lapachenol, deoxylapachol, α-lapachone, β-lapachone, tabebuin, anisic acid, anthraquinones, etc.	Anti-infective, anticancer, anti-inflammatory, antimicrobial, antiviral, antifungal, anti-stomatitis, anti-abscess	Morrison et al. (1970) and Giuraud et al. (1994)
Propolis extract (*Apis mellifera* L.)	Flavonoids, phenolic acids, terpenes, aromatic acids, chalcones	Antioxidative, antimicrobial, cavity cleaning, anti-tartar, anti-plaque, wound healing	Koo and Jeon (2009), Gebaraa et al. (2003), Coutinho (2012), Campos et al. (2014), Srivastava et al. (2016), de Moraes Porto et al. (2018), and Kubiliene et al. (2017)
Quercetin	Quercetin	Antioxidative, anti-inflammatory, immunomodulatory	Liang et al. (2011), Napimoga et al. (2013), and Li et al. (2016)
Red clover (*Trifolium pretenase* L.)	Formononetin, biochanin A, daidzein, genistein	Antioxidative, anti-inflammatory, antibacterial, anticancer	Ramos et al. (2012) and Petrovic et al. (2015)
Red thyme oil (*Thymus vulgaris*)	Terpinene, thymol	Antibacterial, antifungal	Borugă et al. (2014)
Rosemary (*Rosmarinus officinalis* L.)	Borneol, 1,8-cineol, α-pinene, limonene, rosmarinic acid, linalool, camphor, camphene, verbenone, linalool	Antioxidative, anti-inflammatory, antibacterial, antifungal, antimutagenic, chemopreventive	Bozin et al. (2007), Santoyo et al. (2005), Hussain et al. (2010), Lee et al. (2015), and Petrovic et al. (2015)
Royal jelly (Rojelexin™, Vets Plus, Inc.)	10-Hydroxy-δ2-decenoic acid, apismin, royalactin, royalisin, jelleines, apolipophorin III	Antibacterial, antifungal, anti-plaque	Shiga et al. (2010), Eick et al. (2014), Pasupuleti et al. (2017), and Lin et al. (2018)
Salvadora persica (miswak)	*N*-benzylbenzamide, stigmasterol, β-sitosterol, spiculesporic acid, methyl hexadecanoate	Antimicrobial, anti-plaque, anti-gingivitis, anticarcinogenic	Almas (2001), Almas and Almas (2014), and El-Hefny et al. (2017)
Salvia officinalis L. (sage)	α-Thujone, β-thujone, camphor, α-pineno, β-pineno, borneol, tannic acid, cornsole, cornsolic acid, chlorogenic acid	Antibacterial, antifungal, antiviral, anticandidal, anti-stomatitis, anticaries, anti-plaque, anti-gingivitis, astringent	Delamare et al. (2007), Pierozan et al. (2009), George et al. (2009), Porte et al. (2013), Ghorbani and Esmaeilizadeh (2014), Narayanan and Thangavelu (2015), and Petrovic et al. (2015)
Sodium hexametaphosphate (SHMP)	Hexametaphosphate	Anti-calculus	Stookey et al. (1995, 1996), White and Gerlach (2000), and Oba et al. (2018)
Tea tree oil (*Melaleuca alternifolia*)	Terpine-4-ol, γ-terpinene, 1,8-cineole, α-cymene, δ-cadinene, globulol	Antimicrobial	Carson et al. (2006)
Terminalia chebula	Hydrolysable tannins (gallic acid, chebulic acid, punicalagin, chebulanin, corilagin, chebulinic acid), triterpenoids, phenolic compounds	Antibacterial	Muhammad et al. (2012) and Nayak et al. (2014)
Turmeric/curcumin	Curcuminoids	Antioxidative, anti-inflammatory	Chaturvedi (2009)
Vitamin C	Vitamin C	Antioxidative	Turesky et al. (1970)

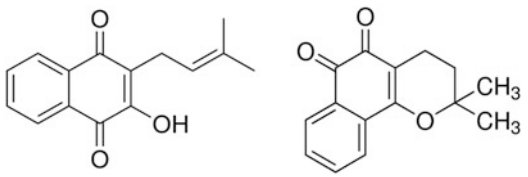

Fig. 3 Structural formula of lapachol (left) and β-lapachone (right)

et al. (2009) reported anti-inflammatory and antibacterial effects of *E. purpurea*. *E. purpurea* extract fights against gingivitis and periodontal disease by stimulating the immune system against bacterial infections (Modarai et al. 2011). Its analgesic property soothes aching gums and teeth. In humans, a mouth rinse with *Echinacea*, sage, mint oil, and chamomile is used in gingivitis and periodontal treatment (Modarai et al. 2011). Unlike many other plant products, *E. purpurea* extract is safe for use in pregnant dogs and cats.

3.4 Barberry

Barberry (*Berberis vulgaris*) plant contains two classes of alkaloids: protoberberines (berberine, berbamine, jateorrhizine, and palmatine) and bisbenzylisoquinolines (oxycanthine). Berberine is the main active compound and most studied alkaloid for its multiple pharmacological actions, including anti-inflammatory, anti-cyclooxygenase, and anti-inducible nitric oxide synthase (for details, refer to chapter "Glucosinolates and Organosulfur Compounds"). Barberry extract and berberine alkaloids are used for many health conditions throughout the world. It has been suggested that berberine may decrease periodontal tissue degradation through the regulation of matrix metalloproteinases (MMPs) during the progression of periodontal diseases (Tu et al. 2013). Berberine gel has been found to reduce the oral biofilm by 56% and gingival index by 33%. (Makarem et al. 2007). These authors also assessed the effect of berberine gel on periodontal inflammation. The only significant finding was reduction in the number of inflammatory cells infiltrating the oral mucosa. Palombo (2011) demonstrated that berberine was found to be more effective against bacteria (*Aggregatibacter actinomycetemcomitans* and *Porphyromonas gingivalis*) by inhibiting their collagenase activity. Berberine appears to be a promising nutraceutical for periodontal diseases in canines and felines. For details on berberine, refer to chapter "Glucosinolates and Organosulfur Compounds."

3.5 Rosemary

Rosemary (*Rosmarinus officinalis* L.) is an evergreen perennial plant which has needle-like leaves. Its phytoconstituents include borneol, 1,8-cineol, α-pinene, limonene, camphor, camphene, verbenone, rosmarinic acid, and linalool (Santoyo et al. 2005; Hussain et al. 2010). These phytochemicals exert powerful antioxidative, anti-inflammatory, antibacterial, antifungal, antimutagenic, and chemopreventive properties (Huhtanen 1980; Bozin et al. 2007; Hussain et al. 2010; Petrovic et al. 2015). Santoyo et al. (2005) reported that antimicrobial activity in rosemary oil is due primarily to borneol, followed by camphor and verbenone. Significant activation of alkaline phosphatase by rosmarinic acid may induce mineralization in osteoblasts which could prevent bone metabolic diseases (Lee et al. 2015). It can be suggested that rosemary oil has a nutraceutical potential for prevention and treatment of periodontitis.

3.6 Babool

Babool (*Acacia nilotica*) is a tropical tree native to Indian and African subcontinents. Other names for babool tree are babul, booni, Egyptian thorn, thorn mimosa, thorny acacia, prickly *Acacia*, and gum Arabic tree. The leaves, roots, bark, fruit, and gum extracts of babool have been used in various Ayurvedic herbal preparations for centuries. Babool extract has an anti-inflammatory compound, androstene steroid. The extract also has other chemical compounds such as D-pinitol, kaempferol, gallic acid, ellagic acid, (+/−) catechin, (−)-epigallocatechin, and rutin. In addition, the extract has cyclitols, fatty acids, seed oils, nonprotein amino acids, terpenes, saponins, hydrolyzable tannins, flavonoids, and niloticane (Malviya et al. 2011). Its extract contains a total phenolic content ranging from 9.2 to 16.5% (Bushra et al. 2007) and tannins and gallic acid from 24 to 42% (Rahaman 2010).

By having these phytochemicals, babool extract is known to exert hemostatic, antioxidative, anti-inflammatory, antispasmodic, analgesic, immunostimulating, antibacterial, antifungal, anti-platelet, antiparasitic, and galactogogue activities (Amos et al. 1999; Gilani et al. 1999; Bushra et al. 2007; Bachayaa et al. 2009; Umaru et al. 2016). In addition to its use as an antihypertensive, antidiabetic, antimicrobial, anti-inflammatory, and antiprotozoal (*Entamoeba histolytica* in dogs and cats), babool stick and toothpaste have been used for oral health. In an in vitro study, Sharma et al. (2014) demonstrated that an aqueous babool extract, in a dose (5%, 10%, and 50%)-dependent manner, exhibited antimicrobial activity against *Streptococcus mutans*. In another in vitro study, Sunitha et al. (2015) reported that toothpaste having babool extract provided greater inhibitory effect against *S. mutans* than other commonly used toothpastes. It has been suggested that babool extract has inhibitory effect against *S. mutans* equal to that of chlorhexidine. These findings suggest that babool-based toothpaste can be

indicated in dogs and cats for oral health and periodontal diseases.

Based on acute toxicity in mice, aqueous extract of babool root extract is safe up to a dose of 2000 mg/kg; and its NOEL in rats is reported to be <250 mg/kg/day.

3.7 Chitosan

Chitosan is an anti-abrasive fiber obtained from crustaceans (shrimp, lobsters, and crabs) exoskeleton. Its structural formula is shown in Fig. 4. Chitosan with a molecular weight of >100 kDa is poorly soluble in water, and its bioavailability is about 1–3%.

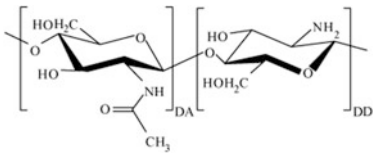

Fig. 4 Structural formula of chitosan

Chitosan has emerged as a potential material for biodental applications due to its unique properties such as bioactivity, antimicrobial activity, and biocompatibility (Husain et al. 2017). For details of its applications in dentistry, see Fig. 5.

Chitosan is also directly applied to gums to treat inflammation and to prevent dental caries. Ikinci et al. (2002) reported that chitosan in combination with chlorhexidine gluconate showed a greater activity compared to chlorhexidine alone. In combination, chlorhexidine is needed at a lower concentration, thereby avoiding its unwanted side effects. Chitosan is known to exert antimicrobial activity against *P. gingivalis*, especially with high molecular weight chitosan. In other studies, chitosan proved to be an effective antibacterial and antifungal agent (Uraz et al. 2012; Costa et al. 2014). Costa et al. (2014) reported that chitosan-containing mouthwash was capable of interfering with all microorganisms' adherence and biofilms with superior activity to other commercially available mouthwashes. By having antimicrobial, antifungal, and adhesive properties, chitosan in a mouthwash, film, or gel appears to be an ideal for local delivery systems for prevention or therapy of periodontal diseases.

Fig. 5 Potential applications of chitosan materials in dentistry (Courtesy of Dr. Shehriar Husain and his co-investigators 2017)

3.8 Royal Jelly

Royal jelly (RJ) is secreted by honeybees from their hypopharyngeal and mandibular glands. RJ consists of water (50–60%), proteins (18%), carbohydrates (15%), lipids (3–6%), mineral salts (1.5%), and vitamins (Pasupuleti et al. 2017). RJ proteins contain major royal jelly proteins (MRJPs), apismin, royalactin, royalisin, jelleines, and apolipophorin III, free amino acids, glucose oxidase, sugars, lipids, vitamins, etc. (Lin et al. 2018). MRJPs may contain nine types of water-soluble proteins with a molecular weight of 49–87 kDa. Additionally, there are some signature peptides that could have potential applications in many health conditions, including periodontal diseases.

Honey, having RJ proteins, has been used for the treatment of many oral diseases, including periodontitis, stomatitis, and halitosis. In addition, it has been applied for the prevention of dental plaque, gingivitis, and mouth ulcers. The antibacterial and anti-inflammatory properties of honey can stimulate the growth of granulation tissue, leading to the repair of damaged tissue cells. Antibacterial activity against *P. gingivalis* has been well documented (Eick et al. 2014; Pasupuleti et al. 2017). Shiga et al. (2010) reported that honey consumption ameliorates halitosis due to its strong antibacterial activity resulting from its methylglyoxal component.

Royal jelly-based product Rojelexin™ (Vets Plus, Inc., Menomonie, WI), by containing royalisin, 10-hydroxy-δ2-decenoic acid, and jelleines, exerts an antimicrobial effect. 10-Hydroxy-δ2-decenoic acid, which is a major component of the lipid fraction of Rojelexin™, exhibits antibacterial and antifungal activities. The structural formula of 10-hydroxy-δ 2-decenoic acid is shown in Fig. 6.

This bioactive component of RJ has been found less than one-fourth as active as penicillin against *Micrococcus pyogenes* and less than one-fifth as active as chlortetracycline against *E. coli*. A dental paste consisting Rojelexin™ and honey showed a potent synergistic effects against oral pathogenic bacteria, such as *S. mutans* and *P. gingivalis*.

3.9 Propolis

Bees (*Apis mellifera* L.) collect a resinous exudate called propolis or bee glue from different plant sources to protect them from bee pathogens. Analysis of propolis has revealed more than 600 chemicals, including flavonoids, phenolic acids, terpenes, and aromatic acids. The majority of these compounds are lipophilic and are therefore easily dissolved in ethanol or methanol (Dantas Silva et al. 2017; Kubiliene et al. 2017). Recent reports suggest that Brazilian red propolis with the sap of *Dalbergia ecastophyllum* has unique components (such as isoflavonoids, propolones/guttiferones, terpenes, chalcones, and phenolic compounds) (Machado et al. 2016; Rufatto et al. 2017), which differ from other propolis produced in Brazil and around the world. The chemical composition of propolis varies significantly depending upon the flora of a particular location (reviewed in detail by de Moraes Porto et al. 2018). Propolis has been used in folk medicine and complementary therapies since ancient times. During the past decade, propolis has been shown to exert multiple biological and pharmacological effects, such as antioxidative, anti-inflammatory, immunomodulatory, antiseptic, antibacterial, antifungal, antineoplastic, cardioprotective, and hepatoprotective properties (Cornara et al. 2017; Dantas Silva et al. 2017).

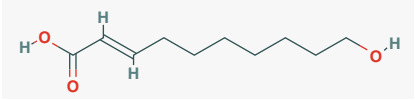

Fig. 6 Structural formula of 10-hydroxy-δ2-decenoic acid

Propolis products, containing microemulsions or nanostructured lipids, have been used for wound healing (Zilius et al. 2016; Rosseto et al. 2017). Recently, Cao et al. (2017) explained the underlying mechanism of propolis in wound healing. An ethanol extract of Chinese propolis (EECP) induced the expression of antioxidant-related genes, such as HO-1, GCLM, and GCLC, which has great implications for the potential of propolis to alleviate oxidative stress in wound tissues, and therefore it can be a promising nutraceutical for wound healing.

In a number of clinical studies, propolis has been indicated for treatment of periodontal diseases. Gebaraa et al. (2003) evaluated the effect of subgingival irrigation with propolis extract based on clinical and microbiological parameters. Findings revealed that propolis treatment (irrigation with a hydroalcoholic solution of propolis extract twice/week) for 2 weeks caused a decrease in total viable counts of anaerobic bacteria, an increase in the proportion of sites with low levels of *Porphyromonas gingivalis*, and a decrease in the number of sites with detectable presence of yeasts. In a similar clinical study, Coutinho (2012) also reported that subgingival irrigation, with propolis extract as an adjuvant to periodontal treatment, was more effective than scaling and root planing as assessed by clinical and microbiological parameters.

Dental caries is considered a chronic and multifactorial disease that occurs as a result of the dissolution of tooth mineral by acids derived from bacterial fermentation of dietary carbohydrates, mainly by *Streptococcus* and *Lactobacillus* ssp., which are involved in the initiation and progression of the lesions, respectively (Karpinski and Szkaradkiewicz 2013). Recently, de Moraes Porto et al. (2018) reported that ethyl acetate extract of Brazilian red propolis (EARP) and micellar nanocomposites loaded with EARP (MNRP) showed antimicrobial activity for the main agents causing

dental caries (*Streptococcus mutans* and *Lactobacillus acidophilus*) and for *Candida albicans*. MNRP at concentrations of 0.3 and 0.6% used as a cavity cleaner do not compromise the aesthetics or microtensile bond strengths of the dentin/resin interface. Propolis extract can be applied topically as a gel or toothpaste.

Srivastava et al. (2016) reported that Proclean (Vets Plus Inc., Menomonie, WI, USA), which contains the bioactive compound propolis, exhibited antibacterial activity in an in vitro study and anti-inflammatory, anti-tartar, anti-plaque, and anti-halitosis effects in dogs.

Based on all these findings, it can be suggested that propolis extract can be used as a nutraceutical for preventing and treating periodontal diseases in dogs and cats.

3.10 Cinnamon Powder

The healing properties of Ceylon cinnamon come primarily from three essential oils (cinnamaldehyde, cinnamyl acetate, and cinnamyl alcohol). Cinnamon phytoconstituents exert antimicrobial (antiseptic), anti-inflammatory, carminative, cholesterol-lowering, and mild anesthetic properties. Additionally, cinnamon is a source of calcium, manganese, and fiber.

In periodontal diseases, the daily recommended dose of cinnamon is: small dogs and cats-1/8th tsp a day, medium dogs-1/4th tsp a day, and large dogs-1/2 tsp a day.

3.11 *Hydrastis canadensis* (Goldenseal)

Hydrastis canadensis, also known as goldenseal, orange root, or yellow puccoon, consists of isoquinoline alkaloids (hydrastine, berberine, berberastine, hydrastinine, tetrahydroberberastine, canadine, and canalidine). Pharmacological effects come from berberine and hydrastine. Antibacterial activity is from berberine (Baghele 2017). Other properties include anti-inflammatory and immune-stimulating activities. It needs to be mentioned that this herb may not be as safe as others and is contraindicated in pregnant dogs and cats.

3.12 Oregano

Oil of *Origanum vulgare* contains polyphenols, including numerous flavones, which are antioxidants. It exerts antibacterial, antiviral, and antifungal activities. In 2005, the US Federal Trade Commission brought legal action against a firm that had claimed oregano oil treated colds and flu or relieved bacterial and viral infections. Herbal products having oregano essential oil were found to have numerous anti-disease effects and so were being sold as unauthorized, misbranded drugs subject to seizure and federal penalties. Oregano oil is safe for dogs, but not for cats.

3.13 Sage

Sage (*Salvia officinalis* L.) is a perennial low shrub native to the Middle East and Mediterranean regions. Presently, it is cultivated throughout the world. Essential oils of sage leaves contain α-thujone, β-thujone, α-pineno, β-pineno, and camphor. In folk medicine, *S. officinalis* extract has been used for the treatment of many diseases and conditions, including seizure, tremor, ulcers, gout, rheumatism, inflammation, dizziness, paralysis, diarrhea, and hyperglycemia. In recent years, phytochemicals in *S. officinalis* have been found to exert antioxidative, anti-inflammatory, antibacterial, antiviral, antifungal, anticaries, anti-plaque, antinociceptive, spasmolytic, carminative, antiseptic, astringent, hypoglycemic, antihidrotic, and anti-dementic properties (Bozin et al. 2007; Delamare et al. 2007; Pierozan et al. 2009; Sookto et al. 2013; Ghorbani and Esmaeilizadeh 2014; Petrovic et al. 2015). *S. officinalis* is used in dental practices for the management of periodontal diseases and to prevent halitosis (Smullen et al. 2012; Narayanan and Thangavelu 2015). The thujones and phenolic acids exert antiseptic and antibiotic action, and tannins exert astringent action. In an in vitro study, Smullen et al. (2012) found that the extracts of *S. officinalis* and *Rosmarinus officinalis* inhibited glucosyl transferase activity, glucon production, and plaque formation and suggested that the extract of these plants can be used as an anti-plaque agent. Sookto et al. (2013) reported anticandidal activity of *S. officinalis* against *Candida albicans* and indicated that it can be used as an antifungal agent in periodontal diseases. Sage extract is often used in toothpaste. It can also be indicated for treatment of periodontal diseases in dogs and cats after clinical studies.

3.14 *Aloe vera*

Aloe vera contains salicylic acid, enzymes, vitamins, minerals, fatty acids, and sugars. *Aloe vera* has strong antioxidative, anti-inflammatory, analgesic, immunostimulating, antibacterial, antiviral, and antifungal properties (Scherer et al. 1998; Bhat et al. 2011; Sajjad and Subhani Sajjad 2014). Sajjad and Subhani Sajjad (2014) reported anti-inflammatory activity of *Aloe vera* by providing evidence of its inhibitory action on the cyclooxygenase pathway, thereby reducing prostaglandin E_2 production.

Scherer et al. (1998) found that a mouth rinse containing *Aloe vera* reduced gingival inflammation, lesions, and bleeding. In another study, Bhatt et al. (2011) demonstrated that *Aloe vera* gel, when applied sublingually, significantly

decreased pocket depth and showed a relative decrease in gingival index and plaque index (reviewed in Petrovic et al. 2015). In a number of studies, *Aloe vera* (gel, toothpaste, or mouthwash) is reported to prevent periodontal diseases and caries (Wynn 2005; Subhash et al. 2014).

3.15 Peppermint

The herb peppermint (*Mentha piperita* L.) is a cross between two types of mint (watermint and spearmint) which grows throughout Europe and North America. Mint has been used for a variety of health purposes (irritable bowel syndrome, headache, common cold, muscle aches, etc.) for thousands of years (McKay and Blumberg 2006; Ford et al. 2008). Peppermint oil contains several phytoconstituents of medicinal importance, including menthol (40.7%), menthone (23.4%), menthyl acetate, 1,8-cineole, limonene, β-pinene, β-caryophyllene, and flavonoids. Phytoconstituents of peppermint exert antioxidative, anti-inflammatory, analgesic, antiulcer, cytoprotective, and chemopreventive activities. Peppermint oil, when applied locally, or leaf extract given orally, produces an analgesic effect (Blumenthal et al. 1998) and reduces toothache and gingival inflammation (Taheri et al. 2011). Essential oil and leaf extract of peppermint reduce periodontal bacteria (Kumar et al. 2009).

3.16 Grape Seed Extract

Grape seed extract (GSE), obtained from *Vitis vinifera* or other *Vitis* spp., is very rich in proanthocyanidins. Proanthocyanidin A (polyhydroxyflavan-3-ol) is a 20–50 times more potent antioxidant than vitamin C or vitamin E. The structural formula of proanthocyanidin A is shown in Fig. 7.

GSE exerts antioxidative, anti-inflammatory, antibacterial, antifungal, and antiparasitic activities. Govindaraj et al. (2010) demonstrated the antioxidative effect of proanthocyanidin (40 mg/kg body wt) in an experimental periodontitis rat model that was induced by injecting *E. coli* endotoxin. Recently, Özden et al. (2017) reported that rats with ligature-induced periodontitis receiving GSE (200 mg/kg body wt, orally) showed an anti-inflammatory effect (lower inflammatory cell number), higher connective tissue attachment level, and lower osteoclast density. Since microbial dental biofilm accumulation is the primary etiologic factor for periodontal disease and the biofilms are highly resistant to antibiotics, GSE appears to be useful due to its antibacterial action. Also, in several other studies, GSE has been found to ameliorate periodontitis by suppressing oxidative stress and inflammation, matrix metalloproteinases, osteoclast factors, immunostimulating, and antibacterial effects (Nuttall et al. 1998; Li et al. 2001; Garlet et al. 2004; Baydar et al. 2006; Houde et al. 2006; Furiga et al. 2009; La et al. 2009). All these findings suggest that GSE can be used as a nutraceutical for the prevention and treatment of periodontitis in canines and felines.

3.17 Myrrh (*Commiphora myrrha*)

Myrrh (*Commiphora myrrha*) or Myrrha (Latin) gets its name from the daughter of Thesis, king of Syria. The tree is native to Saudi Arabia, Oman, Yemen, Somalia, Eritrea, and Ethiopia. Its use has been described in Roman literature, the Bible, the Hebrew Bible, the Koran, and Ayurvedic, Unani, and Chinese medicine. Myrrh is used as a fragrance in cosmetics and as a flavoring agent in food and beverages. Myrrh contains chemical constituents such as sesquiterpenes (furanoeudesma-1,3-diene and curzarene), sterols, and steroids (Zhu et al. 2003). Myrrh oil is extracted from the tree trunk, stem, and branches by steam distillation. Myrrh's gum resin and its main chemical constituent (furanoeudesma-1,3-diene) are shown in Fig. 8.

Resin and oil of myrrh have been used for many centuries to treat swollen gums, mouth ulcers, etc. Phytoconstituents of myrrh exert antibacterial, antiviral, antifungal, antiseptic, astringent, antispasmodic, amoebocidal, anti-inflammatory, analgesic, and hypoglycemic properties (Dolara et al. 2000; Tipton et al. 2006). In Greek culture, when soldiers went to battle, myrrh was an essential part of their combat gear because of its extremely high antiseptic and

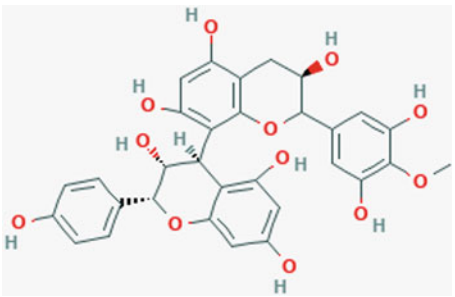

Fig. 7 Structural formula of proanthocyanidin A

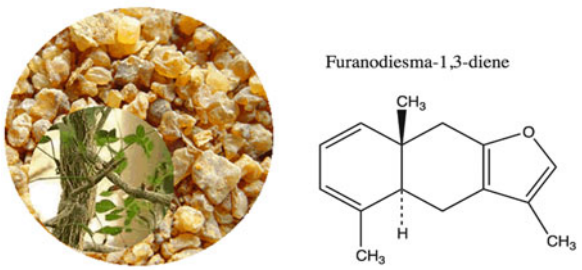

Fig. 8 Myrrh's gum resin and active principles (furanoeudesma-1,3-diene)

anti-inflammatory properties. It was used to clean wounds and to prevent infection and gangrene. Myrrh is an excellent antiseptic in the mouth for sore throat, gum sores, toothache pain, and pyorrhea. Currently, myrrh is used in toothpastes, dental powders, gargles, and mouthwashes. It is noteworthy that myrrh is considered safe in pregnant dogs when used in small amounts. It is not recommended for cats.

3.18 Green Tea

Green tea (*Camellia sinensis*) is a shrub native to Tibet, Western China, and Northern India. The active compounds present in green tea are polyphenols called catechins (epicatechin, epicatechin gallate, epigallocatechin, and (−)-epigallocatechin-3-gallate). Among all catechins, (−)-epigallocatechin-3-gallate (EGCG) is the principal catechin with maximal biological activity. Its structural formula is shown in Fig. 9.

Green tea leaves may contain flavonoids, including catechins and their derivatives, up to 30% on a dry weight basis. Of course, green tea also contains many other compounds, such as carotenoids, tocopherols, ascorbic acid, caffeine, L-theanine, etc. Green tea has been used to rinse and brush the teeth. *Streptococcus mutans* could be inhibited completely after contact with green tea extract for 5 min. There is no drug resistance after repeat cultures. The clinical effects showed that the plaque index and gingival index decreased significantly after green tea extract was used. In a number of studies, local application of green tea has been shown to promote periodontal health by antioxidative and anti-inflammatory effects, preventing bone resorption and dental caries, and limiting the growth of certain bacteria (*Porphyromonas gingivalis*, *Prevotella intermedia*, *Prevotella nigrescens*, *Streptococcus mutans*) associated with periodontal diseases (Sakanaka et al. 1996; Hirasawa et al. 2002; Coimbra et al. 2006; Kushiyama et al. 2009; Chatterjee et al. 2012). *P. gingivalis* has been reported to stimulate the activity and expression of several groups of matrix metalloproteinases (MMPs), and EGCG has inhibitory effects on the activity and expression of MMPs (Chatterjee et al. (2012). EGCG prevents bone resorption that occurs in periodontal diseases by inhibiting the expression of MMP-9 in osteoblasts and formation of osteoclasts (Yun et al. 2004). The anticariogenic effect of green tea is also well established (Yu et al. 1992).

3.19 Clove

The clove (*Syzygium aromaticum*) is an evergreen tropical tree native to India and Indonesia's Spice Islands (Aka and Maluku). Dried flower buds are commonly used as a spice in the cuisines of India, Africa, the Middle East, and other parts

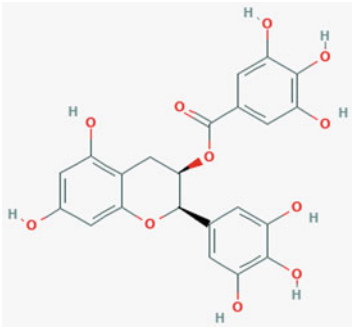

Fig. 9 Structural formula of (−)-epigallocatechin-3-gallate (EGCG)

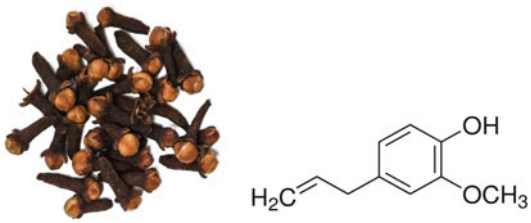

Fig. 10 Clove (left) and its active principle eugenol (right)

of the world. Its use dates back to the fourth century BC. In China (200 BC), clove was used as "mouth perfume." In both Ayurvedic and Chinese medicines, clove has been used for many human ailments. In the tenth century, the Arab dentist Al-Gazzar used clove for controlling mouth odors and pain. The clove and the structural formula of its active principle eugenol are shown in Fig. 10.

Essential oil of clove, consisting of 80–95% eugenol, exerts antibacterial, antiviral, and immunostimulatory activities. Eugenol also has analgesic and antiseptic properties. Essential oil of clove also contains other chemical constituents, such as eugenin, eugenitin, acetyl eugenol, β-caryophyllene, vanillin, crategolic acid, bicornin, caempesterol, and sesquiterpenes (Table 1). Clove oil is known to reduce the bacteria that cause gum diseases and promotes the growth of good bacteria, thereby creating a balanced oral biome. Furthermore, pathogenic bacteria do not develop resistance to clove oil, as they do against antibiotics. Clove oil has proven to be effective against *P. gingivalis*. Eugenol also fights the growth of many fungi, including *Candida albicans* and *C. tropicalis*.

Clove is reported to have the highest antioxidant value (15,188.2 mg (poly)phenols/100 g fresh weight) compared to any other natural plant product (Pinto and Santos 2017), thereby exerting a strong anti-inflammatory effect. Rodrigues et al. (2009) reported that mice treated with water extract of clove showed inhibition of macrophages which produce pro-inflammatory cytokines (IL-1βand IL-6). In an in vitro study, these investigators demonstrated that eugenol in essential oil of clove also inhibited the production of these cytokines. Findings of this study and of others confirmed

that eugenol exerts antioxidative and anti-inflammatory effects (Nagababu and Lakshmaiah 1992; Kumaravelu et al. 1996), and it may be useful to prevent or treat periodontal diseases in dogs and cats. Clove can be applied topically in the form of a gel, toothpaste, or oil.

3.20 *Eucalyptus*

There are more than 700 species of *Eucalyptus*, and most are native to Australia. Presently, *Eucalyptus* are widely cultivated in the tropical and temperate world, including the Americas, Europe, Africa, the Mediterranean Basin, the Middle East, China, and the Indian subcontinent. Eucalyptus leaves contain many phytoconstituents, including borneol, 1,8-cineol, globulol,

p-cymene, limonene, α-pinene, cryptone, α-terpineol, and many others (Sebei et al. 2015). Nagata et al. (2008) reported that *Eucalyptus* extract chewing gum (60–90 mg/day) had significant effects on plaque accumulation, gingival index, bleeding on probing, and periodontal probing depth. Findings revealed that the use of *Eucalyptus* extract chewing gum may promote periodontal health. Also, *Eucalyptus* extract/oil possesses antibacterial activity against cariogenic and periodontopathic bacteria, and therefore it is used in toothpastes.

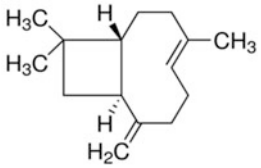
3.21 Chamomile

Chamomile (*Matricaria chamomilla* L.), also known as "star among medicinal species," is native to Southern and Eastern Europe. Currently, the plant is grown in Germany, France, Hungary, Brazil, Russia, India, North and South America, Australia, New Zealand, and many other countries. Phytoconstituents present in *M. chamomilla* L. include 28 terpenoids, 36 flavonoids, and 52 additional compounds with potential pharmacological activity. Chamomile oil (blue oil) also consists of sesquiterpene derivatives and traces of monoterpenes. Components such as α-bisabolol and cyclic ethers are antimicrobial, umbelliferone is fungistatic, and chamazulene and α-bisabolol are antiseptic (Singh et al. 2011). Some of these phytoconstituents exert antioxidative, anti-inflammatory, antiseptic, antispasmodic, anti-periodontitis, and anti-sore gum activities. Chamomile is a nutraceutical which can be used for many periodontal diseases.

3.22 β-Caryophyllene

The sesquiterpene β-caryophyllene (BCP) is found in large amounts in the essential oils of many different spice and food plants, such as oregano (*Origanum vulgare* L.), cinnamon (*Cinnamomum* spp.), and black pepper (*Piper nigrum* L.).

Fig. 11 Structural formula of caryophyllene (right)



BCP is also present in large amounts in essential oil (up to 35%) of *Cannabis sativa* L (Gertsch et al. 2008). The structural formula of β-caryophyllene is shown in Fig. 11.

In both lipopolysaccharide (LPS) and carrageenan models of inflammation, BCP induced anti-inflammatory effect (Gertsch et al. 2008). Upon binding to the cannabinoid 2 (CB2) receptor, BCP inhibits adenylate cyclase, leads to intracellular calcium transients, and weakly activates the mitogen-activated kinases, Erk ½ and p^{38} in primary human monocytes, thereby exerting anti-inflammatory effect.

Recently, Pieri et al. (2016) evaluated the antimicrobial activity of BCP against bacteria from canine's dental plaque in vitro and in vivo. Bacterial adherence of three *Enterococcus* sp., one *Streptococcus* sp., one *Haemophilus* sp., one *Aerococcus* sp., one *Bacillus* sp., and one *Lactococcus* sp. was inhibited by subinhibitory concentration. An in vivo assay showed reduction in dental plaque formation by BCP, with final plaque coverage of 23.3±2.6% of the total area of the teeth, a significant difference compared to chlorhexidine (37.5±3.7%).

The study concluded that BCP has antimicrobial activity against the proliferation of dog's dental plaque-forming bacteria representing a suitable alternative to the use of chlorhexidine in prophylaxis and treatment of periodontal diseases of dogs.

3.23 Thyme

Thyme oil is obtained from *Thymus vulgaris*. Orally, thyme has been indicated in many health conditions, such as bronchitis, pertussis, sore throat, colic, arthritis, dyspepsia, gastritis, diarrhea, enuresis, flatulence, skin disorders, urinary disinfectant, and as an appetite stimulant. Topically, thyme oil is used as a counterirritant, an antiseptic in mouthwashes and liniments. Thymol has been shown to be effective in reducing plaque formation, gingivitis, and cavities due to its antimicrobial and antioxidant properties. It has also been used in combination with chlorhexidine as a dental varnish to prevent caries. By having antibacterial and antifungal activities, thyme oil is used in toothpastes (Meeker and Linke 1998; Borugă et al. 2014).

3.24 Folic Acid

Folic acid has been clinically tested in mouthwash solutions to treat gingivitis and maintain normal gum tissue. In a

number of clinical studies, folic acid has been found to be effective in gingivitis via multiple mechanisms including anti-inflammatory effects (Pack 1984). Folic acid binds with bacterial endotoxins and renders them neutral. However, when taken as a dietary supplement, folic acid does not produce positive results. Therefore, topical application of folic acid to the gum is advised.

3.25 Coenzyme Q

Coenzyme Q10 (CoQ10) is a naturally occurring compound present in the mitochondria. Deficiencies of CoQ10 have been recognized in many health conditions, including periodontal diseases. It serves as an endogenous antioxidant, and initially its concentration is increased as a compensatory mechanism in the diseased gingiva to suppress periodontal inflammation. CoQ10 can ameliorate collagen degradation (Soni et al. 2012). Clinical investigators and dentists recommend CoQ10 supplementation, particularly in diabetic patients and others who are at risk for periodontal diseases (Hanioka et al. 1994; Pradeep et al. 2010; also reviewed in Soni et al. 2012). Topical administration of CoQ10 (Perio-Q®) to the gingiva as a sole treatment has been shown to decrease gingival crevicular fluid (GCF) flow and probing depths and improve clinical gingival attachment (Hanioka et al. 1994; Singh et al. 2016).

3.26 Hyaluronic Acid

Hyaluronic acid (HA) is a mucopolysaccharide present in all living organisms. Studies have shown that HA exerts antioxidative, anti-inflammatory, anti-edematous, and antibacterial activities and thereby may prevent or ameliorate periodontal diseases in humans and animals (Cristina et al. 2013). Bansal et al. (2010) emphasized that HA may (1) act as an antimicrobial agent adjunct to scaling and root planing, (2) accelerate bone regeneration in periodontal bony defects, (3) act as an autologous cell HA graft in mucogingival surgeries, and (4) act as a carrier for platelet-derived growth factor (PDGF) and bone morphogenetic protein (BMP-2) in regenerative therapies. HA has been shown to have a bacteriostatic effect against *Prevotella oris*, *Staphylococcus aureus*, and *Aggregatibacter actinomycetemcomitans*, which are commonly found in periodontal wounds (Pirnazar et al. 1999). Currently, HA is available in the form of a gel (Gingigel®), sponge, or membrane.

3.27 Sodium Hexametaphosphate (SHMP)

One of the most used supplements to control periodontal diseases in the pet food industry is phosphate salts, among them the sodium polyphosphate or hexametaphosphate (Oba et al. 2018). SHMP is an AAFCO-approved mineral sequestrant for tartar control. SHMP binds salivary calcium making it less available for precipitation as dental calculus (Stookey et al. 1996; White Gerlach 2000). The nutritional safety of SHMP rests with the fact that this compound is known to be converted to orthophosphate in the presence of strong acids, such as hydrochloric acid in the stomach, and orthophosphate can be utilized by the host. Stookey et al. (1995) reported that feeding a single daily snack of two HMP-coated plain biscuits (0.6% HMP) decreased calculus formation by nearly 80%. It is suggested that the coating of dry dog chow or plain dog biscuits with HMP is an effective means of reducing calculus formation in dogs.

3.28 Parodontax®

Parodontax® is an herbal toothpaste (Glaxo Smith Kline, Middlesex, UK) which consists of sodium bicarbonate, sodium fluoride, chamomile, echinacea, sage, myrrh, rhatany, and peppermint oil. Although Parodontax® provided significant improvement in oral health and can be used as an alternative to regularly used standard toothpastes, it presented no significant clinical advantage over conventional toothpastes with fluoride (Pannuti et al. 2003). In another study, Ozaki et al. (2006) compared the efficacy of Parodontax® with Colgate Total (Colgate-Palmolive Co, New York, NY, USA) containing 0.3% triclosan, 2.0% copolymer, and 0.243% sodium fluoride. Although both types of toothpaste reduced plaque and gingivitis, no additional benefit of the Parodontax® could be observed over Colgate Total.

3.29 Colgate Herbal Toothpaste

George et al. (2009) assessed the effects of Colgate herbal toothpaste (Colgate-Palmolive India, Mumbai, India) containing calcium carbonate, chamomile, sage, myrrh, eucalyptus, and sodium monofluorophosphate and compared the effects with a conventional Colgate toothpaste containing calcium carbonate, sodium monofluorophosphate, triclosan, and silicate. Based on parameters used in this study (plaque index, gingival index, etc.), findings revealed no significant difference in effectiveness in these two types of toothpaste.

3.30 Probiotics

Probiotics are nonpathogenic living bacteria (including *Lactobacillus acidophilus*, *Lactobacillus casei*, *Bifidobacterium infantis*, and *Streptococcus thermophilus*) which are given orally to activate the immune system. The application of

these bacteria as an adjunct to scaling and root planing appears to inhibit the periopathogenic recolonization of the periodontal pocket, thereby achieving and maintaining periodontal health (Lagdive and Lagdive 2014). The use of probiotics in prevention and treatment of periodontal diseases has been indicated for decades (Meurman 2005; Wim et al. 2008; Yanine et al. 2013; Lagdive and Lagdive 2014). Yanine et al. (2013) reported that for the primary outcome, probing pocket depth, there was no clinical beneficial effect of probiotics. For secondary outcomes, probiotics have shown small benefits on plaque index and gingival inflammation. Vanderpool (2009) used replacement therapy for regeneration of periodontal osseous defects in Beagles by local application of *Streptococcus sanguinis*, *Streptococcus salivarius*, and *Streptococcus mitis*. There is currently insufficient evidence demonstrating the benefits of systematic preventative use of probiotics in patients with periodontal diseases (Yanine et al. 2013). Therefore, more studies need to be done before their use can be justified in periodontal diseases. No negative effects of probiotics use on oral health have been reported to date.

4 Concluding Remarks and Future Directions

Phytochemicals such as alkaloids, tannins, essential oils, and flavonoids exert antimicrobial, antiseptic, antiviral, antifungal, antioxidative, anti-inflammatory, and immunomodulatory activities, thereby improving oral hygiene and preventing gum disease, tooth decay, and periodontitis. This chapter describes the pathophysiology of periodontal diseases in brief and common nutraceuticals that can be used to prevent or treat periodontal diseases in canines and felines. Future investigations need to be conducted on clinical studies in canines and felines for judicious use of nutraceuticals in periodontal diseases.

Nutraceuticals in Gastrointestinal Conditions

Jamil Talukder

Abstract

The health of the digestive system is important in order for it to perform its physiological functions appropriately. The physiological parameters of the digestive system depend on the types of food ingested and the presence of bioactive compounds therein. Ingested foodborne bioactive compounds, or phytochemicals, can play an important role in the mediation of the pathophysiology of the digestive system. Pathological conditions are mostly treated with different drugs, and almost all the drugs have undesirable effects. Therefore, adverse effects and toxicity of drugs led scientists to consider alternatives, functional foods, safer bioactive compounds, or nutraceutical-based approaches for the management of gastrointestinal (GI) conditions. In the last few decades, many nutraceuticals with antioxidative, anti-inflammatory, fatty acid, probiotic, and prebiotic properties have been discovered that ameliorate the signs of GI disease. More preclinical and clinical studies will lead us into a new era of nutraceuticals for the management of gut health and conditions in animals.

Nutraceuticals · Veterinary nutraceuticals · Gastrointestinal diseases

1 Introduction

The digestive system is primarily responsible for the digestion of food, absorption of nutrients and water, and expelling wastes from the body. The feeding of commercial food has increased the number of conditions caused due to improper nutrition. Adequacy and safety of the food supply are of great interest to consumers (Buchanan et al. 2011). Generally, pet owners do not refuse to provide foods that can support the health and wellness of their animals, but at the same time, they doubt their safety. For instance, the incorporation of corn and wheat which have documented antioxidant and anticancer activities (Wood et al. 1994) into pet foods has been perceived as negative by a subgroup of pet owners. These owners believe that they are of lower quality or of poor nutritional value for dogs and cats, despite them matching the Association of American Feed Control Officials (AAFCO) standards (Carter et al. 2014). Pet owners have shown an increased interest in holistic natural diets.

Obesity is recognized as a one of the most important health issues. Heart disease continues to be a primary cause of death in most developing countries worldwide, followed by cancer, osteoporosis, arthritis, and many others. Thus, appropriate food is an integral part for normal body functions as well as for the digestive system that helps in the absorption of nutrients, prevention of nutritional deficiencies and malnutrition, repair of damaged intestinal epithelium, restoration of normal luminal bacterial populations, promotion of normal gastrointestinal (GI) motility, and maintenance of normal immune functions (Zoran 2003). In addition, the GI tract contains some multifaceted microorganisms, including both pathogenic and nonpathogenic bacteria. It has been reported that more than 400 bacterial species inhabit the GI tract (Eckburg et al. 2005). Normal bacterial species and their populations are altered by ingesting different kinds of foods including drugs such as antibiotics. Despite undesirable effects, veterinarians have to prescribe antibiotics to treat animals for bacterial diseases. Further, pet owners who are frustrated with the expensive, high-tech disease-treatment approach in modern medicines are seeking complementary or alternative beneficial products. Functional foods provide health benefits if they are consumed on a regular basis as part of a varied diet. They provide health benefits beyond the provision of essential nutrients, such as vitamins, minerals, water, proteins, carbohydrates, and fats (Hasler 2000).

R. C. Gupta et al. (eds.), *Nutraceuticals in Veterinary Medicine*, https://doi.org/10.1007/978-3-030-04624-8_31

Medicinal plants and naturally available ingredients have been used for centuries for the prevention, control, and treatment of several conditions. Recently, there is an increasing interest in examining potential of novel compounds which may prevent or treat different ailments including increased growth, immunomodulator, or antimicrobial actions. Plants contain several bioactive compounds, including phytosterols, phytoestrogens, polyphenols, and polyunsaturated fatty acids (PUFAs), which are used as nutraceuticals or functional foods and are appealing options for different ailments (Foster et al. 2005). Therefore, scientists are now focusing more on the examination of nutraceuticals for their protective and disease preventing potential with little or no side effects (Nicoli et al. 1999; Kaur and Kapoor 2001; Adelaja and Schilling 1999). This chapter describes the benefits and rationale for the use of nutraceuticals in the GI disorders.

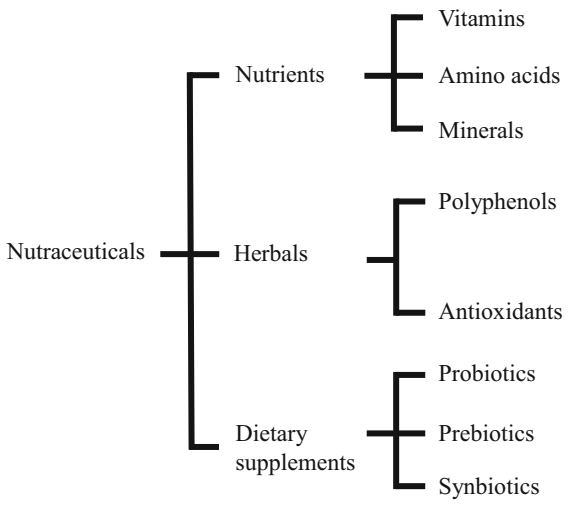

Fig. 1 Categories of nutraceuticals and representative compounds. Adopted from Larussa et al. (2017)

2 Phytochemicals for Gastrointestinal Conditions

Plants that contain many phytochemicals are bioactive in nature and provide many health benefits. These are known as nutraceuticals. They induce anti-inflammatory responses, scavenge free radicals, maintain a homeostatic regulation of the gut microbiota, and activate the intestinal T regulatory cells (Saxena et al. 2014). Phytochemicals contain phytoestrogens, phenolic compounds, and secondary metabolites and exhibit their effects on intestinal inflammation (Mosele et al. 2015; Jarosová et al. 2015). These compounds are classified as flavonoids, isoflavonoids, lignans, ellagitannins, coumestans, and stilbenes (Bilal et al. 2014; Gaya et al. 2016). A single plant can contain many types of phytoestrogens, and different parts of the plant can contain different amounts of phytoestrogens (Jarosová et al. 2015). The main sources of these phytoestrogens are fruits, vegetables, and whole grains (Sirotkin and Harrath 2014). Flavonoids are transformed by bacterial species in the intestine, but they can also represent a substrate for the human gut microbiota. This may influence intestinal absorption (Fig. 1).

Flavonoids influence and regulate the intestinal barrier and its permeability. It has been demonstrated that flavonoids have a direct trophic influence on *Akkermansia* but not on mucin production (Cassidy and Minihane 2017). Flavonoids provide an antimicrobial effect, offering protection against pathogenic bacteria, fungi, and viruses. In this era of antimicrobial resistance, flavonoids may be considered suitable alternatives to antibiotics, especially in mild/moderate infections or in their prevention (Iranshahi et al. 2015).

Aloe vera is one of the common herbal remedies that has been used in GI conditions such as diarrhea, including inflammatory bowel disease (IBD), for centuries in several cultures around the world. It contains several compounds (anthraquinones, carbohydrates, vitamins, minerals, enzymes, and amino acids) with many beneficial effects. Moreover, it is considered an important and natural source of prebiotics. It was observed that the leaf gel, due to oxidation, leads to fermentation and regulates bacterial growth. Several research groups have reported the presence of lactic acid bacteria after the fermentation of *Aloe vera* pulp, laying the groundwork for studying its probiotic effects. Furthermore, Langmead et al. (2004) also used *Aloe vera* in the treatment of ulcerative colitis (UC).

Turmeric (*Curcuma longa*) is commonly used as a spice, food preservative, and a coloring agent in foods. It contains a class of phenols, known as curcuminoids. In a clinical study, oral administration of curcumin proved to be a therapeutic agent in the maintenance of UC (Hanai et al. 2006; Lang et al. 2015). Curcumin can also be used as enema (Singla et al. 2014) and was demonstrated to be very effective in chronic enteritis such as IBD, without raising concerns regarding its safety (Suskind et al. 2013). IBS is the most common functional GI disorder, and treatment focuses primarily on the relief of symptoms (Lacy and Lee 2005). Those symptoms classically include abdominal discomfort or pain, bloating, flatulence, and fecal urgency. Phytochemicals such as peppermint oil, artichoke leaf extract, and turmeric have been used in small uncontrolled trials and have shown clinical benefit (Bundy et al. 2004). Curcuminoids act as an anti-inflammatory agents. It suppresses the nuclear factor kappa-light-chain-enhancer of the activated B cells (NF-κB)-related inflammatory pathway. It subsequently inhibits TNF-α, IL-12, and IL-2 (Fig. 2, adopted from Larussa et al. 2017). Thus, curcumin modulates the immune response as a safe and promising agent for the treatment of chronic diarrhea (Vecchi Brumatti et al. 2014) without producing adverse effects (Holt et al. 2005; Hsu and Cheng 2007; Langhorst et al. 2013).

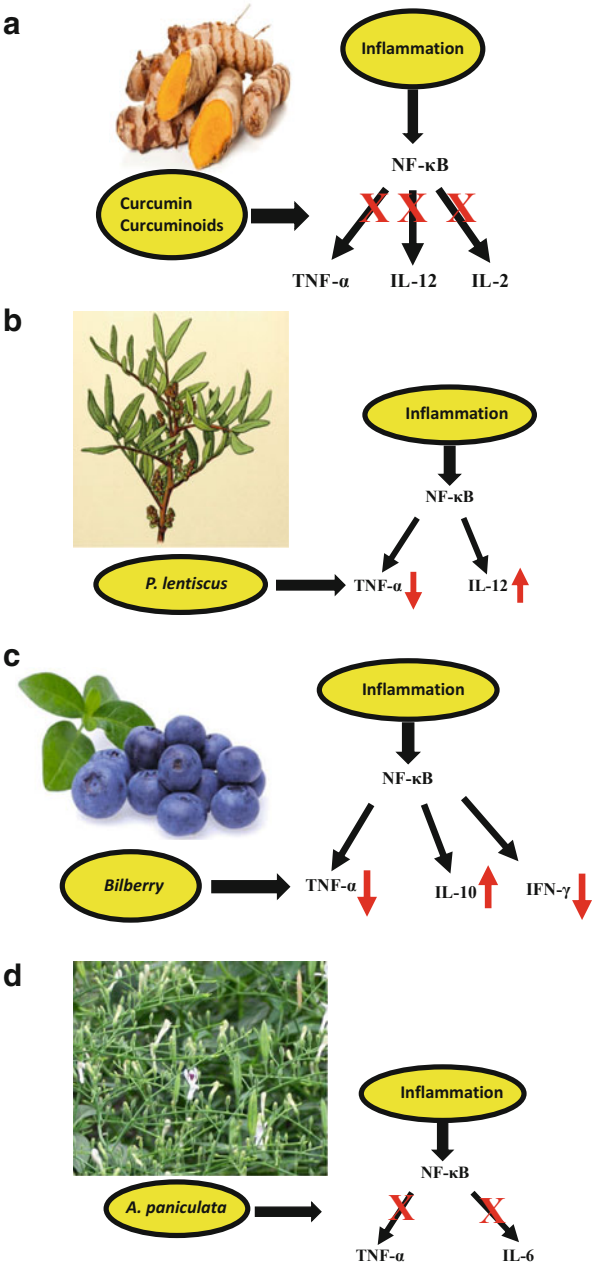

Fig. 2 (**a**–**d**) Phytochemicals and their interactions with inflammatory pathways. *IL* interleukin, *NF-kB* nuclear factor kappa-light-chain-enhancer of activated B cells, *TNF-α* tumor necrosis factor-alpha

Capsaicin is present in hot chilies, and it requires calcium to inhibit SNAT2-mediated methionine transport and causes apoptosis and DNA damage in enterocytes (Talukder et al. 2018).

Ginger (rhizome of *Zingiber officinale*) has been widely used for centuries in GI disorders such as dyspepsia. It has a protective role in gastric ailments and irritations such as ulcers, vomiting, nausea, stomach ache, spasm, and GI cancer. It increases GI motility (Micklefield et al. 1989), and it also reduces blood pressure (Ghayur and Gilani 2005). Ginger contains gingerols, zingerone, shogaols, paradols, and related compounds (Connell and McLachlan 1972). The prokinetic activity of ginger extract revealed that it enhances the intestinal travel of charcoal meal in mice. This propulsive effect of the extract, similar to that of carbachol, was blocked in atropine-pretreated mice, a standard cholinergic antagonist. In addition, prokinetic activity showed an atropine-sensitive dose-dependent spasmogenic effect in vitro as well as in isolated rat and mouse stomach fundus tissues. In atropinized tissue, it showed spasmolytic activity via the inhibition of 5-HT- and K^+-induced contractions. A spasmolytic effect was also observed in other gut preparations either as noncompetitive inhibition of agonist dose-response curves, inhibition of high K^+ (80 mM)-induced contractions, or displacement of Ca^{2+} dose-response curves to the right, indicating a calcium antagonist effect. Phytochemical analysis revealed the presence of saponins, flavonoids, and alkaloids in the crude extract. In addition, the presence of a spasmolytic constituent(s) of the calcium antagonist type may explain its use in hyperactive states of the gut such as colic and diarrhea (Muhammad and Anwarul et al. 2005). Therefore, ginger has a unique combination of spasmogenic and spasmolytic activities mediated through cholinergic and calcium antagonist mechanisms, respectively.

Fruits and vegetables contain many flavonoids, which belong to the polyphenols class, and show promising health benefits. Therapeutic usages of flavonoids have been investigated along with their mode of actions in different GI disease conditions (Hoensch and Oertel 2015). Flavonoids from myrrh and chamomile demonstrate nutritional, anti-inflammatory, and immunomodulatory properties in chronic enteritis (Langhorst et al. 2013) with diarrhea. Furthermore, *Boswellia serrata* is a well-known herb for its benefits in enteritis. Recent studies demonstrate significant improvement in intestinal epithelial barrier preservation and oxidative and inflammatory damage attenuation in ulcerative colitis (Holtmeier et al. 2011; Gupta et al. 1997).

Anthocyanin, also a flavonoid, is responsible for the blue, purple, and red colors of flowers and fruits. In addition, anthocyanins act as antioxidants that directly restrict both gene expression and receptor-mediated inflammatory signaling pathways (Biedermann et al. 2013). The supplementation of mouse diet with blueberries or black currants provided a significant change in gut microbiota by promoting the anaerobic bacteria *Bacteroidetes* and *Actinobacteria*, probably through their antioxidative effect (Overall et al. 2017). Furthermore, bilberry contains anthocyanin, and very recently it has been revealed that it reduces pro-inflammatory cytokines IFN-γ and TNF-α along with enhanced levels of the immunoregulatory cytokine IL-10 in UC (Roth et al. 2016).

A subclass of flavonoids is called "isoflavonoids," of which substantial amount is found in soy, soy protein, and miso. The isoflavones are conjugated to glucose and not

active in their primary form. Isoflavones are converted into different compounds by the gut microbiota as well as enterocytes, and they are well absorbed by the microbes and by the gut and go through enterohepatic circulation (Vitale et al. 2013; Catinean et al. 2018). Additionally, these metabolites have an estrogen-like activity (Laparra and Sanz 2010). Isoflavonoids contain many glycosides, such as genistein, daidzein, and glycitein. Daidzein is metabolized by gut bacteria to equol (Franke et al. 2014; Catinean et al. 2018), which plays an important role in the health benefits of soy. It also has strong estrogenic activity and antioxidant capacity. The main bacteria that contribute to the conversion of the isoflavonoids into equol inhabit the distal portion of the gut and belong to the family *Coriobacteriaceae* (Guadamuro et al. 2017; Catinean et al. 2018). The isoflavones also inhibit tyrosine kinases, have antioxidant activity, bind to and activate peroxisome proliferator regulators α and γ, inhibit enzymes in steroid biosynthesis, strongly influence natural killer cell function and the activation of specific T-cell subsets, and inhibit metastasis (Stephen 2010). Along with the isoflavonoids, ellagitannins and lignans are metabolized by gut bacteria into equol, urolithins, and enterolignans, which have high bioavailability and estrogenic/antiestrogenic effects, antioxidant, anti-inflammatory, and antiproliferative effects (Gaya et al. 2016; Catinean et al. 2018).

A group of polyphenols is known as lignans, its precursors are found in a wide variety of plant-based foods, including seeds such as flaxseeds, soybeans, strawberries, carrots, cabbage, onion, garlic, and cucumber (Blanck et al. 2003; Peterson et al. 2011). They are rich in the omega-3 fatty acid, alpha-linolenic acid, aminolevulinic acid, etc. All of which have been shown to have many potential health benefits. They can be used to improve digestive health, lower blood pressure, and bad cholesterol, reduce the risk of cancer, and may benefit people with diabetes. Polyphenols are also abundant in cocoa powder, dark chocolate, berries, beans, nuts, vegetables (red onion, spinach), soy, tea (black and green), and red wine (Manach et al. 2004; Catinean et al. 2018). There is a bidirectional relationship between polyphenols and gut microbiota. The polyphenols' bioavailability is increased by the microbiota, while unabsorbed polyphenols are involved in maintaining the equilibrium of microbiota in the gut. Suggested mechanisms imply protection against GI disorders and pathogens, strengthening intestinal epithelial tight cell junctions, increasing mucus secretion, stimulating cytokines, and modulating the immune response (Ozdal et al. 2016; Catinean et al. 2018).

Quercetin, a specific polyphenols, is one of the most studied compounds in relationship with gut microbiota. Quercetin is derived from plants that belongs to the flavonols, a subclass of flavonoid compounds. It can be found in apples, berries, grapes, onions, tea, tomatoes, seed, and nuts but also in medicinal botanicals like *Hypericum perforatum*, *Ginkgo biloba*, and *Sambucus canadensis* (Li et al. 2016; Catinean et al. 2018). It was demonstrated that quercetin has a modulatory role in gut microbiota when overweight animals were fed a high-fat sucrose diet. Furthermore, quercetin ameliorates the *Firmicutes/Bacteroidetes* ratio in high-fat sucrose diet-fed rats by increasing the titer of *Bacteroides vulgatus* and *Akkermansia muciniphila*, which have been inversely correlated to obesity. Moreover, it can decrease the titer of *Eubacterium cylindroides* and *Bilophila wadsworthia*, bacteria associated with diet-induced obesity (Etxeberria et al. 2015; Catinean et al. 2018).

Pistacia lentiscus is an evergreen shrub found in the Mediterranean region. It contains oleo-gum-resin which acts as an immunomodulatory agent on peripheral blood mononuclear cells. It inhibits TNF-α and stimulates the macrophage migration inhibitory factor (MIF). It has been observed that oleo-gum-resin reduces TNF-α secretion and increases MIF in Crohn's disease (CD). Subsequently, it also inhibits migration of monocytes and chemotaxis in chronic GI disease conditions in CD (Kaliora et al. 2007).

Andrographis paniculata extract is used to treat chronic inflammatory diseases. The herbal extract HMPL-004 has been reported to significantly reduce the transcriptional activity of NF-κB and decrease secretions of pro-inflammatory cytokines such as TNF-α and IL-6. Its benefits in active UC were addressed by two randomized, double-blind, 8-week trials, showing a decrease in the total Mayo score of 3 points as well as a 30% reduction in rectal bleeding (Tang et al. 2011; Sandborn et al. 2013).

One of the most commonly consumed beverages is tea (*Camellia sinensis*) either green or black. These contain high concentrations of flavanols (epicatechin and catechin) and their esters. High levels of unabsorbed compounds of tea remain in the gut and play an important role in the intestine's health. Caffeic acid, for example, inhibits the growth of many intestinal pathogenic bacteria, such as *E. coli*, *Salmonella*, *Pseudomonas*, *Clostridium*, and *Bacteroides* (Lee et al. 2006). The main active compounds in green tea are polyphenols. They have important antioxidant and anti-inflammatory effects and influence the activity of NF-kB (nuclear factor kappa B), COX-2 (cyclooxygenase-2), and the level of IL-2 (interleukin-2) (Oz et al. 2013). Black tea also contains several metabolites such as benzoic, phenylacetic, and phenylpropionic acids with antimicrobial properties (Van Duynhoven et al. 2013).

The aromatic plant *Oregano vulgare* is being used for phyto-therapeutic purposes. Carvacrol and thymol are two main phenols from oregano, and they have antimicrobial activity in particularly on *E. coli* (Fournomiti et al. 2015; Lopez-Romero et al. 2015). In an experimental study on pigs, it was demonstrated that oregano oil has protective effects against villous atrophy and epithelial cell necrosis and at

the same time it decreases the seric endotoxin levels (Zou et al. 2016).

Alkaloids with a quaternary ammonium structure such as berberine modulate the intestinal microbiota and show antimicrobial activity on *Firmicutes* and *Bacteroidetes*. Berberine exerts cytostatic, antiproliferative, and antioxidant properties. Therefore, berberine may contribute to the increase of intestinal gene expression of fasting-induced adipose factor (Fiaf) in mice, which acts as a lipoprotein lipase inhibitor (Zhang et al. 2015a, b; Xu et al. 2017). The alkaloid is considered a broad spectrum antibiotic which may increase *Bacteroides* and decrease *Ruminococcus* in the terminal ileum and colon (Guo et al. 2016).

Blue-green algae, a kind of cyanobacteria, e.g., Spirulina (*Arthrospira platensis*), mostly used as a food supplement, has the capacity to inhibit the growth of Gram-positive and Gram-negative bacteria (*Staphylococcus aureus*, *Bacillus subtilis*, *E. coli*, *Pseudomonas aeruginosa*, etc.). This antibacterial effect is due to an extracellular metabolite produced by Spirulina. In addition, the microbiota's modulatory effect of spirulina was attributed to the active compounds found in this plant (glutamate, aspartate, carbohydrates, or phenolic compounds). These substances have well-known antimicrobial and bacteriostatic effects as well as the capacity to stimulate the growth of probiotics (Beheshtipour et al. 2013; Finamore et al. 2017). Due to this effect, the Spirulina biomass can become a natural product which could be added to fermented milk to increase the production of *Lactobacillus* and also the number of viable cells which reach the intestine (Bhowmik et al. 2009).

L-Glutamine (GLN) is a well-known amino acid which plays an important role in the gut and has an important contribution to generating energy. Talukder et al. (2008a, b) discovered the presence of two different types of GLN co-transporters in the intestine. GLN is degraded by enterocytes and intestinal luminal bacteria and oxidized by the Krebs cycle, forming ATP (Wang et al. 2014). GLN causes a change in the intestinal bacteria community and increases the intestinal immunity by affecting the NF-kB, MAPK (mitogen-activated protein kinase), and PI3K-Akt (phosphatidylinositol-3-kinases-protein kinase B) signaling pathways (Ren et al. 2014). Figure 2 summarizes the interactions between some phytochemical agents and the inflammatory network (adopted from Larussa et al. 2017).

3 Dietary Lipids and Fat-Soluble Vitamins for Gastrointestinal Conditions

Lipids, also known as fats, play many important roles in the animal body, from providing energy to producing hormones. Dietary lipids are one of the most active nutritional substrates modulating the immune response, in particular, the gut mucosal immune system. Polyunsaturated fatty acids (PUFA) are also called "essential fatty acids" as these are crucial to the body's function. These are introduced externally through the diet (Escott-Stump and Mahan 2000). PUFAs have been classified into two categories: omega-3 (n-3) fatty acids and omega-6 (n-6) fatty acids. The major omega-3 fatty acids are α-linolenic acid (ALA), eicosapentaenoic acid (EPA), and docosahexaenoic acid (DHA). ALA is the precursor of EPA and DHA. EPA and DHA are found mainly in fatty fishes such as mackerel, salmon, herring, trout, and blue fin tuna and in fish oils. The principal sources of ALA are mainly flaxseed, soybeans, canola, some nuts (e.g., walnuts), and red/black currant seeds (Trumbo et al. 2002). Omega-6 PUFAs mainly consist of linoleic acid (LA), γ-linolenic acid (GLA), and arachidonic acid (ARA). LA occurs mainly in vegetable oils, e.g., corn, safflower, soybean, and sunflower. ARA is found in animal products such as meat, poultry, and eggs. The roles of PUFAs have been widely investigated during inflammatory processes in chronic enteritis (Larussa et al. 2017). The most interesting fatty acids are the n-6 PUFA AA, which is the precursor of inflammatory eicosanoids like prostaglandin E_2 (PGE_2) and leukotriene B_4, and the n-3 PUFAs EPA and DHA, which are abundant in fish oils.

The modifying action of the lipid mediator profile is exerted by n-3 PUFAs mainly acting as a competitive substrate, which decreases the production of the eicosanoids from AA, but also reducing leukocyte chemotaxis and inflammatory cytokine production (Calder 2008). A rising incidence of enteritis has been reported in recent years particularly with dietary changes including a higher intake of n-6 PUFAs and a reduced consumption of n-3 PUFAs (Marion-Letellier et al. 2013). A correlation between a higher intake of LA, an n-6 PUFA, and an increased risk of UC has been reported (Tjonneland et al. 2009; Larussa et al. 2017), suggesting a possible role for dietary linoleic acid in the etiology of the disease. On the other hand, oleic acid, which is the predominant ingredient of olive oil, was found to be inversely associated with UC development (de Silva et al. 2014). In agreement with this finding, a prospective large study showed an inverse association between greater long-term intake of long-chain n-3 PUFAs and the risk of UC, confirming the protective effect of n-3 PUFA intake, while no specific fatty acids appeared to be associated with the risk of CD (Uchiyama et al. 2010). Another study showed that a dietary intervention focused on lowering n-6/n-3 PUFA ratio was effective in maintaining disease remission in IBD, possibly through the increasing of n-3 PUFA intake (Ananthakrishnan et al. 2014; Larussa et al. 2017). Fish oil supplementation in IBD resulted in n-3 PUFA incorporation into gut mucosal tissue and modification of inflammatory mediator profiles, showing how readily colonic lipids, prostaglandins, and

thromboxane synthesis can be altered by dietary changes (Hillier et al. 1991; Larussa et al. 2017).

A trial of dietary supplementation with fish oil in UC showed a 56% decrease of the mean disease activity index and a 4% decrease in placebo. Moreover, fish oil ingestion revealed a well-tolerated profile in all groups without any alteration in routine blood exams (Aslan and Triadafilopoulos 1992; Larussa et al. 2017). A recent study has identified an endogenous lipid mediator, resolvin E1, which is generated from eicosapentaenoic acid in vivo and demonstrates potent anti-inflammatory activity, suggesting a mechanism by which omega-3 fatty acids can modulate inflammatory pathways (Arita et al. 2005).

An interesting role in the nutraceutical scenario used with chronic enteritis has been proposed for the fat-soluble vitamins, such as A, D, E, and K. The deficiency of vitamin D, whose main source is endogenous production in the skin upon exposure to sunlight, was found to be significantly associated with IBD (Del Pinto et al. 2015; Larussa et al. 2017). Dogs with a chronic enteropathy (CE) have a lower vitamin D status than do healthy dogs. Vitamin D status has been associated with a negative clinical outcome with IBD in humans. Gow et al. (2011) compared serum vitamin D metabolites and plasma parathyroid hormone concentrations in dogs with IBD and normal albumin concentration, dogs with IBD and hypoalbuminemia, healthy dogs, and hospitalized ill dogs with non-gastrointestinal illness. They observed that concentrations of serum 25-hydroxyvitamin D were lower in hypoalbuminemic dogs with IBD than in the healthy dogs, hospitalized ill dogs, and normoalbuminemic dogs with IBS. Dogs with IBD and hypoalbuminemia had a higher plasma concentration of parathyroid hormone and a lower plasma concentration of ionized calcium than hospitalized ill dogs. Dogs with IBD had a positive correlation between serum 25-hydroxyvitamin D concentrations and serum albumin, serum calcium, and plasma ionized calcium concentrations. Furthermore, evidence supports an immunological role of vitamin D in chronic enteritis both promoting tissue barrier formation through the expression of cell adhesion proteins and stabilization of tight junctions between epithelial cells and inhibiting the production of pro-inflammatory cytokines through the activation of vitamin D receptor (Mouli and Ananthakrishnan 2014). Results from a randomized controlled trial support the benefits of vitamin D supplementation in UC patients, since a decrease in erythrocyte sedimentation rate (ESR) and c-reactive protein (CRP) levels was found in the treatment group (Jørgensen et al. 2010). It has been suggested that vitamin K may be involved in the modulation of disease activity and maintenance of bone health in IBD patients. Nakajima et al. (2011) evaluated vitamin K levels of patients with IBD by measuring serum undercarboxylated osteocalcin and found a significant correlation with the clinical activity index of CD. The complexity of these interactions has been highlighted by Kuwabara et al. (2009), who found that a low plasma concentration of vitamin K was an independent risk factor for low bone mineral density in IBD patients, but these low levels were associated with the patients' fat intake, and not with the intake of vitamin K. This suggested a malabsorption rather than a poor dietary intake.

4 Dietary Peptides and Amino Acids for Gastrointestinal Conditions

Amino acids (AA) are the building blocks of protein that includes essential and nonessential AA. Dietary peptides and amino acids have been shown to modulate intestinal immune functions and influence inflammatory responses, being involved in reducing inflammation, oxidative stress, and apoptosis in the gut (Zhang et al. 2015a, b; Larussa et al. 2017). Processes that lead to bioactive peptide release include in vivo enzymatic digestion in the GI tract both by human and microbiota enzymes or in vitro food processing. Any protein source can produce bioactive peptides, with milk being the most studied. However, bioactive peptides from egg, fish, meat, algae, or soy have also been reported (Martínez-Augustin et al. 2014). Milk-derived products are already in clinical use for the treatment of chronic enteritis, such as casein-based enteral feeds which are used for the treatment of CD and whose efficacy might be due, in part, to the presence of the anti-inflammatory cytokine transforming growth factor-β (Richman and Rhodes 2013; Larussa et al. 2017).

Colostrum is a form of milk produced by the mammary glands of mammals just prior to birthing. Bovine colostrum is a rich source of nutrients, antibodies, antimicrobial peptides (e.g., lactoferrin, lactoperoxidase), and growth factors. Talukder et al. (2002, 2003) discovered the transport of colostral macromolecules into the cerebrospinal fluid (CSF) via plasma in newborn and young calves. They also found the characteristics of the lactoferrin receptor in bovine intestine: higher binding activity to the epithelium overlying Peyer's patches (Talukder et al. 2003). Talukder and Harada (2007) also observed that bovine lactoferrin protects lipopolysaccharide (LPS)-induced diarrhea modulating nitric oxide (NO) and PE_2 in mice. In addition, lactoferrin ameliorates PE_2-mediated inhibition of Na^+-glucose cotransport in enterocytes (Talukder et al. 2014). Furthermore, beneficial properties of colostrum have been demonstrated during an initial study with UC patients treated by enema administration (Khan et al. 2002). An amelioration in body composition, with a decrease in fat percentage, has been obtained in CD patients after whey and soy protein dietary supplementation (Machado et al. 2015). Considering that a reduction of

body fat contributes to the control of inflammation, these nutritional strategies may be useful as alternative or ancillary treatments in IBD. The current available information indicates a potential for food-derived peptides to counteract acute and chronic intestinal inflammation. Experimental studies in animal models evaluating isolated AAs such as tryptophan, glutamine, cysteine, and arginine offer promising in CD (Coëffier et al. 2010).

5 Probiotics, Prebiotics, and Synbiotics

Probiotics are "live microorganisms" that benefit the host by modulating mucosal and systemic immunity and provide nutritional and microbial balance in the intestinal tract. In fact, coevolution led to a symbiotic relationship between the host and microorganisms and thereby developed a bidirectional signaling system through the intestinal lining that contains immune cells such as lymphocytes and dendritic cells. More than 400 species of bacteria have been identified from GI tract including beneficial (e.g., *Bifidobacterium* and *Lactobacillus*) and pathogenic (e.g., *Enterobacteriaceae* and *Clostridium* spp.) Beneficial bacteria use fibers (prebiotic) for fermentation and provide indispensable nutrients to the intestinal cells and the host as well. These nutrients include amino acids such as Arg, Cys, and Gln and short-chain fatty acids (SCFA) such as acetate, propionate, and butyrate (O'Sullivan et al. 2005). These SCFAs are being used as a source of basal metabolic energy (10–30%) by different cells of the host including colonocytes and hepatocytes; 5% of SCFAs is excreted in the feces (O'Sullivan et al. 2005). The SCFAs are important for the liver to regulate glucose homeostasis and lipogenesis. Colonocytes require butyrate, the most important and integral part of energetic metabolism, whereas acetate and propionate are used as substrates for lipogenesis, gluconeogenesis, and protein synthesis (Catinean et al. 2018). Furthermore, beneficial bacteria make vitamins K and B complex, bile acid, and neutralize dietary carcinogens such as nitrosamines. They also convert prodrugs into active metabolites. The indigenous intestinal microbiota is known as autochthonous. They compete with pathogenic bacteria (allochthonous) for nutrients and adherence to mucosal lining and produce different types of antigens, known as bacteriocins. Bacteriocins are potential to inhibit the growth and replication of allochthonous or kill them. In contrast, allochthonous can be detrimental by making toxins or other harmful metabolites. Accordingly, both autochthonous and allochthonous may affect the GI homeostasis as well as systemic physiology of the host. However, autochthonous are essential for the host to protect GI mucosa and its immune system. Different factors such as diet, drugs, and toxins can affect the usual abundance and diversity of gut microbiota (microbiome), known as dysbiosis. The diet includes "prebiotic." The latter is a nondigestible, dietary carbohydrate metabolized by gut microorganisms for their growth and development. Thus, dysbiosis directly alters the production of SCFAs. The proper development and maintenance of GI homeostasis including secretion of antibodies in the lumen against harmful antigens or allochthonous require certain types and loads of microflora for interaction with the mucosal immune system (Catinean et al. 2018). That is why they are known as the most adaptable and renewable metabolic organ of the body and their biological effects are summarized in Table 1.

Table 1 Biological effects of probiotic bacteria

Modulation of host immune response
Enhanced antibody production
Enhanced natural killer cell activity
Modulation of dendritic cell phenotype and function
Modulation of NF-kB and AP-1 pathway
Altered cytokine release
Induction of regulatory T cells
Induction of PPAR-g
Modulation of apoptosis
Inhibition of proteasome activity
Enhanced epithelial barrier function
Enhanced tight junction protein phosphorylation
Upregulation of mucous production
Enhanced epithelial cell glycosylation
Increased sIgA production
Antimicrobial effects
Decreased luminal pH
Stimulation of defensin secretion
Secretion of antimicrobial peptides
Inhibition of pathogenic bacterial invasion
Blockade of bacterial adhesion to epithelial cells
Release of nitric oxide

Nowadays, a variety of probiotics including their strains are being used to support GI health such as "probiotic chewable tablets" produced and marketed by Chr. Hansen A/S, Denmark, containing *Bifidobacterium animalis* subsp. *lactis*. In addition, probiotic bacteria, e.g., *Enterococcus faecium SF68*, and yeast, e.g., *Saccharomyces boulardii*, are also directly used in foods, particularly fermented milk products. Investigations on probiotics with regard to their medicinal use leading to determine new genera and strains with many health benefits such as *Lactobacillus plantarum* isolate (PCS20, PCS22, PCS25, and PCS26) from Slovenian cheese with high antimicrobial (Maragkoudakis et al. 2010) and immunomodulatory (Bengmark 1998) competences. Utilization of beneficial microorganisms was considered to benefit health through alterations in gut microbiota, and thereby single or mixed microbial culture preparations are commonly considered to use. Thus, it has been claimed that benefits of probiotics depend on types of probiotic strains (de Vrese and Schrezenmeir 2008; Bengmark 1998; Nissen et al. 2009). Although benefits of probiotics on gut health and in diarrhea

are documented, unlikely the dose of probiotics or the duration of such treatments are not clearly defined (Minelli and Benini 2008), while the dose for treatment of an acute illness by a specific probiotic may be lower or higher in the order of tenfold or hundredfold or more in terms of colony-forming units (CFU). In addition, clinical studies did not show conclusive results of the relationship among strains of probiotics and type of infections such as acute or chronic GI infections and immunological or inflammatory disease (Minelli and Benini 2008). The concentration of probiotics needed to obtain a clinical effect is often quoted as $\geq$106 colony-forming units (CFU) per mL in the small bowel and $\geq$ 108 CFU per mL in the colon. In acute infectious diarrhea, it is postulated that higher doses of probiotics for short courses are more effective than lower doses. It has been also suggested that the advantages of probiotics for health can only be achieved if proper strain or product selection and dose guidelines are followed in either food or medicine (Kalliomaki et al. 2010; Douglas and Sanders 2008). In addition to the importance and application of probiotics for GI, it has been shown the benefits in alleviating symptoms of allergies (Yao et al. 2010; Kalliomaki et al. 2010), respiratory and urinary tract infections (Kaur et al. 2009), AIDS (Trois et al. 2008), and cancer (Kumar et al. 2010). It has been demonstrated that the effects of probiotics depend also on the interactions between the respective microorganisms and the gut immune system and the duration of treatment in chronic diseases such as allergic, inflammatory, and/or immune diseases. Moreover, it has been revealed that probiotics improve in alleviating symptoms associated with osteoporosis, obesity, fatigue, autism, and aging and reducing the risks of type 2 diabetes (Douglas and Sanders 2008).

In order to evaluate the usefulness of probiotics, it is essential to identify the specific target groups of individuals with more specific higher susceptibilities to the potential effects of probiotics. Furthermore, depending on functional evidence of different probiotics, the International Life Sciences Institute (ILSI) categorized probiotics in four areas of application. Areas include (1) metabolism, (2) chronic intestinal inflammatory and functional disorders, (3) infections, and (4) allergy (Rijkers et al. 2010). The main goals of ILSI were to substantiate the current body of information on probiotic benefits. The ILSI also provided the pros and cons including recommendations to design the next generation of probiotic research.

The main probiotic preparations currently on the market belong to a large group of bacteria designated as lactic acid bacteria (e.g., *Lactobacillus*, *Streptococcus*, *Bifidobacterium*), which are important and normal constituents of the GI microflora. These are presented in Table 2. However, studies are also investigating potential probiotic roles of other microbes such as yeast (*Saccharomyces boulardii*), which are not normally found in the gastrointestinal tract. Probiotic strains exert their beneficial effects through a variety of mechanisms (Cong et al. 2003) that are unique to each strain (Table 2). Whether living microorganisms are required, or even whether oral administration is necessary for clinical benefit, is still uncertain and might depend on the particular bacterial strain. For instance, several recent studies in animal models have demonstrated that nonviable bacterial components may have beneficial effects.

The mechanisms of probiotic action are poorly understood (Oelschlaeger 2010). Probiotics may act by modulating the host's immune system, affecting other microorganisms directly, or acting on microbial products, host products, or food components (Oelschlaeger 2010). The effectiveness of a probiotic depends on its metabolic properties, the set of molecules presented at its surface, the components it secretes, and the integral parts of the microorganism such as its DNA or peptidoglycan (Oelschlaeger 2010). DNA isolated from the VSL3 probiotic compound attenuated colitis, an effect

that was dependent upon Toll-like receptor (TLR)-9 (Rachmilewitz et al. 2004). TLRs comprise a family of pattern recognition receptors that function in the maintenance of intestinal homeostasis by recognizing and responding to conserved molecular products of microorganisms (Abreu et al. 2005). Another study demonstrated that isolated DNA from VSL3, but not from *E. coli*, inhibited nuclear factor-kB (NF-kB) activation and pro-inflammatory cytokine secretion (Jijon et al. 2004). Furthermore, probiotic compounds might not even have to be taken orally to have benefit. Sheil et al. (2004) showed that subcutaneous administration of *Lactobacillus salivarius* attenuated colitis and pro-inflammatory cytokine production in a mouse model. This suggests that in the future it may be possible to use nonviable and purified probiotic bacterial components for the treatment of GI diseases.

The term prebiotic refers to dietary carbohydrates that stimulate the growth of gut bacteria or probiotics when these are administered externally. A prebiotic is a nondigestible compound that through its metabolization by microorganisms in the gut modulates the composition and/or activity of the gut microbiota, thus conferring a beneficial physiological effect on the host. Prebiotic is defined as "a selectively fermented ingredient, or a fiber that allows specific changes, both in the composition and/or activity of the gastrointestinal microflora, resultantly conferring benefits on the wellbeing and health of the host" (de Vrese and Schrezenmeir 2008; Douglas and Sanders 2008).

A prebiotic agent must fulfill certain criteria, such as not being hydrolyzed and absorbed in the first part of the gastrointestinal tract and is fermented by a limited number of beneficial bacteria in the colon (e.g., *Lactobacillus*). Moreover, the prebiotic must be able to stimulate or metabolically activate the growth of these beneficial bacteria, in order to change the microflora into those that are healthier. The main effects of prebiotics include modulation of gut microbiota composition, production of energy metabolism, increasing mineral absorption, regulation of immune function, and improvement of the intestinal barrier functions. Other more specific effects of prebiotics on health are indirect, namely, prevention of diarrhea or obstipation, modulation of the metabolism of the intestinal flora, cancer prevention, effects on lipid metabolism, stimulation of mineral adsorption, and immunomodulatory properties.

Prebiotics form a group of diverse carbohydrate ingredients that is poorly understood regarding their origin, fermentation profiles, and dosages required for health effects, although they do provide nutraceutical and nutritional value (Douglas and Sanders 2008). Fructooligosaccharides (FOS), galactooligosaccharides (GOS), xylooligosaccharides (XOS), lactulose, the nondigestible carbohydrate inulin, cellulose, resistant starches, hemicelluloses, and pectins are currently the most used prebiotics. Today, only bifidogenic, nondigestible oligosaccharides (particularly inulin, its hydrolysis product oligofructose, and (trans)galactooligosaccharides) fulfill all the criteria for prebiotic classification (de Vrese and Schrezenmeir 2008). In the last few years, successful attempts have been reported to make infant formula more breast milk-like by the addition of fructo- and (primarily) galactooligosaccharides.

Soy beans and lactose from cow's milk are the main sources of GOS. These are included especially in different foods. Probiotics and prebiotics share unique roles in human nutrition, largely centered on manipulation of populations, or activities of the microbiota that colonize the human GI tract (Douglas and Sanders 2008).

Regular consumption of probiotics or prebiotics has health implications that include enhanced immune function, improved colonic integrity, decreased incidence and duration of intestinal infections, downregulated allergic response, and improved digestion and elimination (Douglas and Sanders 2008). It is noteworthy that human subjects and their enteric microbiota have evolved together to reach a state of mutual tolerance. There is mounting evidence from both animal models and human studies to suggest that IBD is a result of a malfunction of this mutual relationship (Hedin et al. 2007). Probiotics and prebiotics, however, have been investigated in clinical trials as treatments for IBD, with conflicting results (Hedin et al. 2007). While there is consensus about the value of probiotics and prebiotics, their influence on bowl health in terms of Crohn's disease is less convincing (Hedin et al. 2007). This may be attributed to variations in methodologies; differences in the range of probiotic, prebiotic, and combination (synbiotic) treatments tested; and variability in test subjects used, such as different patient groups (Hedin et al. 2007). The "synbiotics" are synergistic combinations of pro- and prebiotics (de Vrese and Schrezenmeir 2008). Figure 3 depicts the interactions between nutraceuticals and gut microbiome and other associated disease conditions (adopted from Larussa et al. 2017).

6 Concluding Remarks and Future Directions

Physiology of the digestive system and its microbiome greatly depends on the types of foods ingested. Pharmaceutical drugs, especially antibiotics, significantly alter the gut microbiome which is very critical for normal GI functions and can be restored by using nutraceuticals including probiotics, prebiotics, and phytochemicals (phytoestrogens and polyphenols). Recent developments in nutraceutical research, including elucidation of the mechanism of action, is very promising which will greatly help understanding of new nutraceuticals to control different GI conditions. Future basic and applied nutritional research will pave the way. In

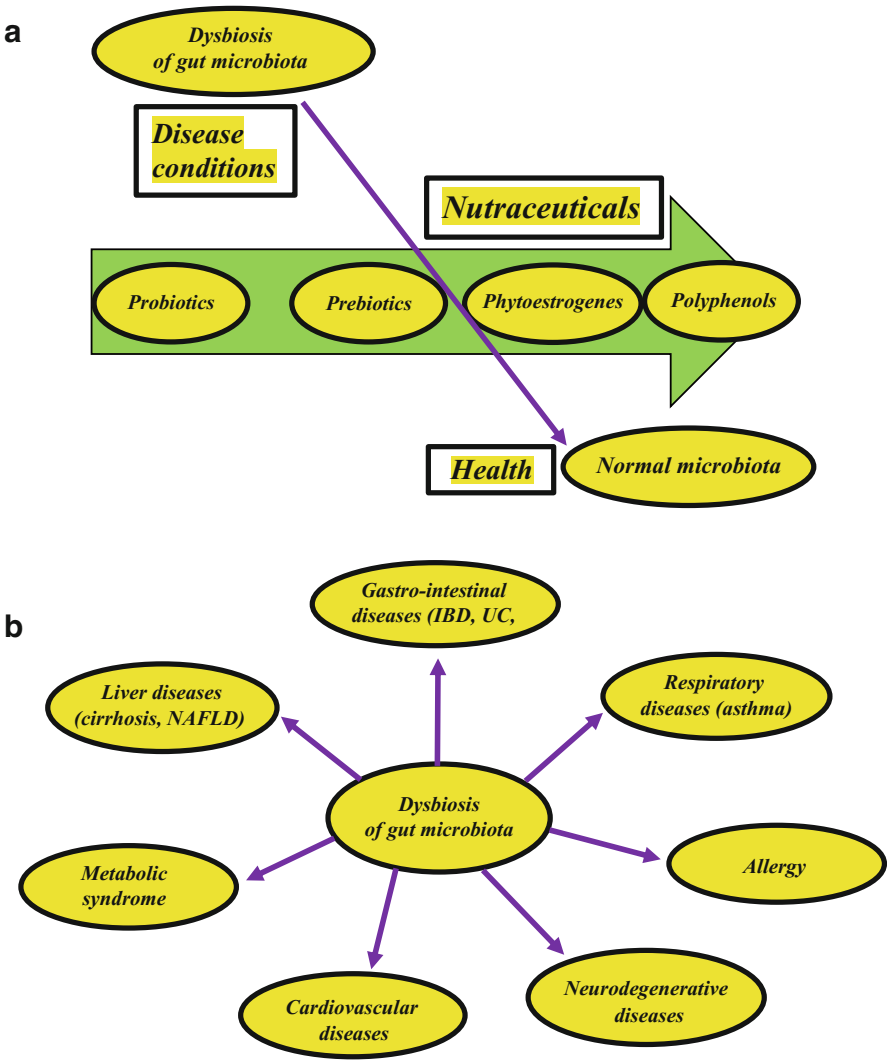

Fig. 3 (**a**, **b**) The role of nutraceuticals on intestinal microbiota. Gut microbiota and associated other disease conditions

this regard, in vitro and clinical trials are very important to elucidate the mode of actions along with appropriate doses for different animals, including humans. Therefore, scientists and healthcare professionals must work together to improve scientific understanding of nutraceuticals for different GI conditions to improve the quality of life. The nutraceutical revolution will lead us into a new era of medicine and health for animals and humans.

Nutraceuticals in Reproductive Disorders

Moges Woldemeskel

Abstract

Reproductive disorders or abnormalities that occur in male and female reproductive tracts are induced by infectious and noninfectious agents and various other conditions. In the contemporary world, common use of synthetic chemicals in cosmetics and other items for domestic day-to-day uses undoubtedly contributes to the noninfectious causes of reproductive abnormalities. In both animals and humans, modern drugs are used to treat reproductive disorders. However, unwanted side effects that follow often pose severe problems and concerns, consequently increasing global use of natural products including nutraceuticals to treat reproductive abnormalities. In this chapter, the use of nutraceuticals in the treatment and management of female and male reproductive tract abnormalities is briefly highlighted.

Keywords

Nutraceuticals · Veterinary nutraceuticals · Reproductive disorders

1 Introduction

Since the ancient time, plant products and their crude extracts are used in traditional medicine for the treatment of various disorders until the development of synthetic drugs (Patel and Patel 2017). Despite development of modern synthetic drugs, medicinal plants still serve as mainstream therapeutics and are central in traditional medicine (Akhtar et al. 2017) in many parts of the world. More than 40% of prescription drugs in the world were mainly derived from herbal source (Patel and Patel 2017). Although modern medicine is at the forefront in treating diseases, plant-based remedies in alternative medicine are still highly used throughout the world, mainly in the developing countries (Fadus et al. 2017). Nowadays, medicinal plants play a key role in health care as more than 80% of the world's populations rely on the traditional medicine for their primary health care (Patel and Patel 2017). This is largely because natural products are effective and relatively nontoxic and have remedial doses far below their toxic levels (Fadus et al. 2017).

Nutraceuticals are natural products derived from various food sources that provide health benefits in addition to nutritional values (Kalra 2003; Larussa et al. 2017). Nutraceuticals can be substances such as vitamins, minerals, amino acids, fatty acids, herbs, and botanical products or substances derived from other sources taken as dietary supplements including pyruvate, chondroitin sulfate, steroid hormone precursors, etc. (Chauhan et al. 2013).

Natural products or nutraceuticals have been shown to elicit antiaging, anticancer, and other health-enhancing effects. A key target of the effects of natural products may be the regulation of microRNA expression which results in cell death or prevents aging, diabetes, and cardiovascular and other diseases. Nutraceuticals have also been proposed to exert their effects on cancer stem cells by interacting with the expression of microRNAs (McCubrey et al. 2017).

Various nutraceuticals have been in use for centuries to heal different types of diseases in humans and animals including diseases that inflict male and female reproductive system. This chapter gives a brief account on some nutraceuticals used in the treatment of reproductive diseases in males and females.

2 Nutraceutical in Female Reproductive Abnormalities

Disorders caused by microorganisms, physical agents, and other etiologies are known to affect female reproductive system. However, due to environmental pollution, use of

synthetic chemicals in cosmetics and other items for domestic day-to-day uses, and other risk factors, currently neoplasm (cancer) is the major disease that affects reproductive tracts in women and also in pet animals. Various forms of cancer therapeutics are available nowadays. However, all the currently available cancer therapeutic options are expensive, and none of them are safe. On the contrary, traditional plant-derived medicines or nutraceuticals are relatively safe and are used in the treatment of diseases of female reproductive tract. Some nutraceuticals effective in the treatment and management of female reproductive diseases mainly cancerous diseases are briefly highlighted below.

2.1 Effects of Nutraceuticals on Breast Cancer

Breast cancer is the second leading cause of death in women worldwide, and more than one million women are diagnosed with breast tumor (Sayeed and Ameen 2015; Mandal et al. 2017) with approximately 458,000 deaths each year (Sayeed and Ameen 2015). It is also the second most frequent cancer in women in the USA with about 246,660 new breast cancer cases and 40,450 breast cancer-related deaths estimated in 2016 (Siegel et al. 2016). Citing several authors, Mandal et al. (2017) reported that chronic inflammation is suggested to contribute to development and progression of breast cancers. Therefore, agents that inhibit chronic inflammation may be effective in the prevention and treatment of breast cancer. Several natural products, phytochemicals, and dietary agents with anti-inflammatory properties have shown promise in the prevention and treatment of breast cancer (Mandal et al. 2017).

Distinct subtypes of breast tumor would response differently to treatment, which made breast cancer extremely intractable. Currently, surgical resection, adjuvant chemotherapy, radiotherapy, and hormone therapy represent the main treatment options for early-stage breast cancer. However, the development of drug resistance and major side effects have weakened the efficacy of these therapies. Besides, triple-negative breast cancer does not respond to hormone therapy. Due to poor efficacy of modern therapies, prevention of the occurrence of breast cancer appears to be the best strategy for which diet- and nutrition-based approach has been considered as an effective method. A group of dietary natural products have shown a potential role in prevention and treatment of cancers (Li et al. 2017).

A recent review summarized the potential role of dietary natural products and their major bioactive components in prevention and treatment of breast cancer. Several epidemiological and experimental studies suggested the inverse correlation between intake of vegetables and fruits and incidence of breast cancer. Many dietary natural products such as soy, pomegranate, mangosteen, citrus fruits, apple, grape, mango, cruciferous vegetables, ginger, garlic, black cumin, edible macro-fungi, and cereals could affect the development and progression of breast cancer. Experimental studies indicated that their anti-breast cancer effects involve various mechanisms of action such as downregulating estrogen receptor α expression and activity; inhibiting proliferation, migration, metastasis, and angiogenesis of breast tumor cells; inducing apoptosis and cell cycle arrest; and sensitizing breast tumor cells to radiotherapy and chemotherapy. Epidemiological studies suggested that high consumption of some dietary natural products might reduce the recurrence and increase the survival rate of breast cancer patients. Therefore, use of natural dietary substances could be a practical approach for the prevention and treatment of breast cancer (Li et al. 2017). One widely known such compound is beta-sitosterol, a plant-derived nutrient with anticancer properties against breast cancer, prostate cancer, colon cancer, lung cancer, stomach cancer, ovarian cancer, and leukemia (Sayeed and Ameen 2015). Other natural products and plant extracts with similar effects on breast cancer are given below.

Berberine is a natural isoquinoline alkaloid extracted from plants such as *Berberis (B) aquifolium*, *B. vulgaris*, *B. aristata*, and *Tinospora cordifolia* (Imanshahidi and Hosseinzadeh 2008). The antitumor effects of berberine in various human cancer cells have been reported. Its effect was evaluated on triple-negative breast cancer (TNBC), a cancer defined by negative expression of estrogen receptor, progesterone receptor, and human epidermal growth factor receptor 2. Because of lack of standard molecular targets, the current viable targeted therapies are not useful for TNBC patients. TNBC is insensitive to the antihormone receptor (HR) and HER2-targeted drugs and has higher incidence than HR- and HER2-positive patients. Berberine inhibited tumor cell proliferation and migration and induced cellular apoptosis. It activates caspase-9/cytochrome c-mediated apoptosis to inhibit the growth of TNBC breast cancer cells in vitro and in vivo. Therefore, berberine is a potential treatment agent for TNBC (Zhao et al. 2017). Furthermore, it was reported that berberine can bind to the vasodilator-stimulated protein overexpressed in breast cancer cells and suppress tumor proliferation and growth (McCubrey et al. 2017).

Resveratrol, a polyphenol found in various plants, is also reported as one of the agents effective against breast cancer. Experimentally, it inhibited the proliferation of cancer stem cells isolated from breast cancer cell lines. Resveratrol reduced the presence of mammospheres in breast cancer cell lines, inhibited tumor formation of the mammospheres in mice, and also induced autophagy in the breast mammospheres (Fu et al. 2014).

Soy isoflavones have also been reported by many studies to have a protective role against breast cancer, though some adverse effects have also been reported. Whether soy isoflavones promote or inhibit the growth of breast cancer

seemed to be dose dependent (Xie et al. 2013); thus the dosage and long-term safety of soy isoflavones need to be further investigated before they are recommended as supplement for breast cancer patients (Li et al. 2017).

Curcumin, a substance in turmeric, has been reported to exert antitumor development effects on breast cancer. It is shown to have effects on drug transporter expression in breast cancer cells with cancer stem cell properties. Curcumin could increase the tumoricidal effects of mitomycin-C, and it could also increase the sensitivity of breast cancer cell lines to various chemotherapeutic drugs such as cisplatin, doxorubicin, and paclitaxel. The combination of curcumin and mitomycin-C together prevented the sphere-forming capacity of breast cancer cell lines (Zhou et al. 2015).

Li et al. (2017) citing various studies indicated that fruits that normally contain high content of polyphenols have great antioxidant activity and may help reduce risk of cancer. Fruits, such as pomegranate, mangosteen, and citrus fruits, have shown inhibitory activities on breast cancer cells. For example, pomegranate inhibited breast cancer growth and metastasis through various mechanisms such as inhibiting breast cancer cell growth by inducing cell cycle arrest, inducing apoptosis, exerting antiproliferative effects on rat mammary tumorigenesis, and significantly decreasing cell viability of breast cancer cell lines. Pomegranate juice and its components blocked metastatic processes of breast cancer cells and proliferation of breast cancer cell lines in vitro indicating a potential role of pomegranate for the prevention of estrogen-responsive breast cancers. Whole pomegranate seed oil and fermented pomegranate juice polyphenols inhibited the tumor lesion formation in a murine mammary gland organ culture suggesting a chemopreventive property and adjuvant therapeutic potential of pomegranate. Pomegranate seed oil and fermented juice concentrate suppressed preneoplastic mammary gland lesions ex vivo in a mouse mammary organ culture model, and oral administration of pomegranate juice concentrate reduced the volume and weight of xenografted tumors in female athymic nude mice. Pomegranate emulsion containing most bioactive phytochemicals present in the whole fruit exerted a significant chemopreventive activity against DMBA-initiated mammary tumorigenesis in female rats. It reduced the incidence, total burden, and average weight of mammary tumors with a concomitant inhibition of intratumor cell proliferation and induction of apoptosis (Mehta and Lansky 2004; Banerjee et al. 2012; Li et al. 2017; Mandal et al. 2017).

Several in vitro and in vivo studies reported anti-breast cancer activities of mangosteen (*Garcinia mangostana*). Crude methanolic extract of mangosteen pericarp inhibits proliferation and induces apoptosis on breast cancer cell line; phenolics from the fruit pericarp produced cytotoxicities against human breast cancer cell lines; and alpha-mangostin treatment significantly increased survival rate of mice with mammary tumors and greatly suppressed tumor volume and lymph node metastases. Furthermore, studies report that citrus fruits such as orange, lemon, grapefruit, pomelo, and lime have an impact on overall health of a patient including reducing the risk of developing various cancers. A number of studies pointed out an inverse association between citrus fruits intake and the risk of breast cancer. For example, polysaccharides from Korean citrus hallabong peels inhibited angiogenesis, and extracts from a citrus fruit Citrus hassaku Hort. ex Tanaka, also known as phalsak, and lemon citrus extract induced apoptosis in breast cancer stem cell lines. Furthermore, extracts of apples, grape, mango, strawberries, peach, and other citrus fruits are reported to have effect on breast cancer cells in vivo and in vitro through inducing apoptosis, inhibiting cell proliferation, prevention of breast cancer cell growth, decreasing tumor volume, and activation of oxidative stress in cancer cells. Generally, intake of fruits is beneficial for the prevention and treatment of breast cancer, pomegranate, mangosteen, apple, citrus fruits, grape, and mango showing the most promising effects. The anti-breast cancer action of these fruits might be attributed to the presence of bioactive components such as ellagitannins in pomegranate and mangostin in mangosteen (Li et al. 2017).

Vegetables also are reported to have effect on breast cancers. In experimental studies, several vegetables, especially cruciferous vegetables, have shown inhibitory effect on breast cancer cells. For example, intake of broccoli, cauliflower, watercress, and Brussels sprouts was inversely associated with risk of breast cancer (Bradlow 2008; Thomson et al. 2016). Indole-3-carbinol found in *Brassica* vegetables showed anti-breast cancer action since it could interact directly with the estrogen receptor and inhibit its activity or through estrogen-independent actions, such as blocking cell cycle progression, metastasis, and inducing apoptosis (Li et al. 2017). Daily intake of fresh carrot juice might also benefit patients with breast cancer (Butalla et al. 2012). Generally, isothiocyanates and indole-3-carbinol and its metabolite 3,30-diindolylmethane found in cruciferous vegetables have shown a potential role in the prevention and treatment of breast cancer. The underlying mechanisms mainly include downregulating estrogen receptor alpha and repressing estrogen receptor signaling, inducing apoptosis and cell cycle arrest, and inhibiting metastasis of breast cancer cells (Li et al. 2017).

Consumption of certain spices is also known to have anti-breast cancer effect. Several studies suggested that ginger, garlic, and black cumin have shown promising anti-breast cancer effects among various spices. Bioactive components in spices, such as gingerols and shogaols in ginger, and organosulfur substances including diallyl disulfide, diallyl trisulfide, *S*-allyl mercaptocysteine, and allicin in garlic have anti-breast cancer activities and help in reducing risks of developing breast cancer. Methanolic extract of ginger

(*Zingiber officinale*) exhibited inhibitory effect on cancer cell proliferation in breast cancer cell lines. The anti-breast cancer property of ginger might be attributed to its bioactive constituents such as gingerols and shogaols (Lee et al. 2008; Joo et al. 2016). A supercritical CO_2 extract of black cumin (*Nigella sativa*) exhibited pro-apoptotic and anti-metastatic effect on breast cancer cell lines in vitro. Thymoquinone, a major bioactive component isolated from the seeds of *Nigella sativa*, has shown potent chemopreventive and chemotherapeutic activities and antiproliferative effect on breast cancer (Schneider-Stock et al. 2014; Li et al. 2017).

Other spices such as capsaicin, piperine isolated from black pepper (*Piper nigrum*), saffron (*Crocus sativus*), clove (*Syzygium aromaticum*), wasabi (*Wasabia japonica*), rosemary (*Rosmarinus officinalis*), and coriander are reported to have anti-breast cancer activities in vitro and in vivo experimental models. However, it should be noted that the role of capsaicin in cancer is controversial. Some studies have indicated that capsaicin itself was mutagenic and promote tumor formation and might increase the cancer risk in humans (Li et al. 2017), warranting more detailed studies to determine its real impact and benefit in breast cancer.

Several kinds of edible macro-fungi have shown inhibitory effect on breast cancer. Mushroom intake might be inversely associated with risk of breast cancer. A significant inverse association between mushroom consumption and breast cancer incidence was found in postmenopausal women in Korea. Several mechanisms such as inhibiting proliferation, inducing apoptosis, and suppressing angiogenesis have been found to explain the anti-breast cancer effects of edible macro-fungi. The anti-breast cancer effects of edible macro-fungi are mainly attributed to the polysaccharides with different molecular weights present in the fungi. A number of studies also indicated an inverse association between cereal fiber intake and breast cancer risk. For example, *sorghum* suppressed tumor growth, induced cell cycle arrest, and inhibited metastasis in nude mice bearing breast cancer xenografts, young barley (the grass of the barley plant) exhibited significant antiproliferative and pro-apoptotic activities in rat breast tumor model and in human breast cancer cells in vitro, and wheat (*Triticum aestivum*) flour inhibited growth of breast cancer cells and induced apoptosis in vitro. Sorghum, barley, and wheat have shown the potential to inhibit growth of breast cancer cells, mainly through inducing apoptosis and cell cycle arrest and inhibiting metastasis (Hong et al. 2008; Li et al. 2014, 2017).

In addition to their direct effect on cancers, dietary natural products have synergistic effect with anticancer therapies. This is very important because chemotherapy and radiotherapy frequently used nowadays in cancer therapy exhibit certain toxic adverse effects, and drug resistance is a common cause of chemotherapy failure and disease recurrence. Some dietary products and their bioactive components have shown synergistic effects with chemotherapy or radiotherapy by enhancing their therapeutic effect or reducing the adverse side effects (Li et al. 2017).

Certain vitamins and minerals are also beneficial in reducing risk of developing various cancers including breast cancer. For instance, experimental studies suggest a protective effect of B vitamins on breast cancer risk. A large prospective study also suggested dietary, supplemental, and total pyridoxine and thiamin intakes were associated with decreased breast cancer risk and have a potential protective effect against breast cancer in middle-aged women (Egnell et al. 2017). Moreover, Tsuji et al. (2015) citing various experimental studies in animal models indicated that selenium deficiency impairs immune response to infection, cancer, and other stimuli. These included reduction in CD4+ T-cell response in selenium-deficient mice challenged with a peptide/adjuvant and increased tumor growth and spread in a mouse model of breast cancer indicating that selenium may play an important role in the prevention of breast cancer development.

2.2 Effects of Nutraceuticals on Cervical Cancer

A number of diseases can affect the cervix in women. However, cancer is the major disease condition affecting the cervix and is globally among important causes of mortality in women. Several natural products (nutraceuticals) are reported to be effective in treating and/or reducing risk of cervical cancer in women. For example, McCubrey et al. (2017) citing several studies indicated that berberine and curcumin may be promising agents for treatment of cervical cancer. In a study on cancer cell lines, it was reported that *Aloe vera* alone or its simultaneous use with cisplatin exhibited antineoplastic effects in breast and cervical cancers by inducing apoptosis and modulation of expression of effector molecules. These results signify that *Aloe vera* may be an effective antineoplastic agent to inhibit cancer cell growth and increase the therapeutic efficacy of conventional drugs like cisplatin promoting the development of plant-derived therapeutic agents for novel cancer treatment strategies (Hussain et al. 2015). Due to the effect of various nutraceuticals on inhibiting tumor growth and reducing risk of cancer development in general, consumption of natural plant products and other nutraceuticals undoubtedly will help in minimizing the risk of developing cervical cancer.

2.3 Effect of Nutraceuticals on Diseases of Uterus

Different types of diseases including infectious diseases and neoplasms may affect uterus in females. A number of modern

medicinal therapies have been in use to treat uterine diseases. However, nutraceuticals, as was described earlier, are gaining increased preference due to side effects that follow treatment with modern drugs and well-documented efficacy of nutraceuticals in fighting various infections and diseases. Nutraceuticals that promote overall health of individuals with anti-inflammatory and anticancer effects described earlier certainly have impact on the treatment and prevention of uterine diseases. For example, berberine was reported to inhibit proliferation of human uterine leiomyoma cells (Wu et al. 2015). Some nutraceuticals have a synergetic effect, work in concert with various modern drugs, and may enhance the effect of modern medicines on cancer cells. Berberine and metformin induced lipolysis-stimulated lipoprotein receptor, which is a component of tricellular tight junctions in endometrial cancer cells and suppressed cell migration and invasion (McCubrey et al. 2017).

Endometriosis is a common gynecological disease that affects women and other primate females. Treatment options for endometriosis include surgery and medication, mainly pain medications such as nonsteroidal anti-inflammatory agents or hormone therapy including gonadotropin-releasing hormone agonists and androgens. Although such treatments can improve some symptoms, there is no cure for endometriosis. Trials have been conducted to determine effects of some natural products on endometriosis. It was reported that *Pueraria* flower extract suppressed adhesion of human endometriotic cells to human mesothelial cells and significantly inhibited the migration of endometriotic cells. It also significantly suppressed endometriotic lesion formation in a mouse model suggesting that *Pueraria* flower is an anti-endometriotic agent for the inhibition of endometriotic cell adhesion and endometriotic cell migration and establishment of endometriosis-like lesions and has a potential use in the treatment and prevention of endometriosis (Kim et al. 2017).

2.4 Effect of Nutraceuticals on Ovarian Cancer

Ovarian cancer is the most lethal gynecological malignancy in developed countries. This is due to the lack of specific symptoms that hinder early diagnosis and to the high relapse rate after treatment with radical surgery and chemotherapy (Áyen et al. 2018). A number of studies reported effects of different nutraceuticals on ovarian cancer. Berberine suppressed proliferation of ovarian cancer cells, and in concert with cisplatin, it induced death of ovarian cancer cells and augmented the effects of cisplatin in inducing cell cycle arrest in ovarian carcinoma cells (McCubrey et al. 2017). Resveratrol was also found to kill ovarian cancer stem cells. Further studies reported that bitter melon extracts contain compounds that inhibit growth of many types of cancers including growth of ovarian cancer and ameliorate resistance to common chemotherapeutic compounds (Yung et al. 2016). Bitter melon extracts inhibited ovarian cancer growth via activation of various signaling cascades. Alpha-momorcharin, a ribosome-inactivating protein present in bitter melon extracts, may in part be responsible for the anticancer effects (McCubrey et al. 2017). Dietary calcium was significantly associated with a reduced risk of ovarian cancer, and increased dietary calcium intake might be inversely correlated with the risk of ovarian cancer (Song et al. 2017). Briefly, large numbers of natural products that have significant effect on overall health of animals and humans are beneficial in minimizing risk of developing ovarian cancer and in the management of clinical disease.

2.5 Effects of Nutraceuticals on Other Disorders of Female Reproductive System

In different parts of the world, natural products, mainly of plant origin, are used in the treatment and management of various conditions and symptoms associated with female reproductive system. For example, in India, the bark of *Adenium obesum* is used as an abortifacient agent, and in Omani ethnic community, it is used for the treatment of venereal diseases, among many others (Akhtar et al. 2017).

Some nutraceuticals are also used in the treatment of a number of reproductive tract-associated ailments in females. For instance, *Agnus castus* has also been used in the treatment of many female conditions including menstrual disorders such as amenorrhea and dysmenorrhea, premenstrual dysphoric disorder, corpus luteum insufficiency, hyperprolactinemia, infertility, acne, disrupted lactation, cyclic breast pain, cyclical mastalgia, and inflammatory conditions. It was further indicated that *Agnus castus* and magnolia, combined with soy isoflavones plus lactobacilli, were effectively and safely used in the treatment of vasomotor symptoms in postmenopausal women, mainly with poor quality of sleep. Such alternative treatments are preferred to hormone replacement therapy due to adverse side effects, poor compliance, and fear of increasing the risk of cancer or weight gain associated with hormone therapy (De Franciscis et al. 2017).

Many studies indicated that combined supplementation with vitamin E and selenium, given a few weeks before calving, either by injection or orally can significantly reduce the incidence of retained placenta in cattle. It was also indicated that selenium as sodium selenite injected 3 weeks prepartum, with or without oral vitamin E, reduced incidence of metritis from 83 to 57%. Furthermore, an injection of 50 mg selenium (sodium selenite) 3 weeks before parturition

reduced the incidence of cystic ovaries from 47 to 19% (Hemingway 2003).

Nutraceuticals such as garlic that are effective against bacteria (Zardast et al. 2016) and other plant products including *Balanites aegyptiaca* and *Capparis erythrocarpos* known to be effective against fungi (Anywar et al. 2014) may help in the management and treatment of bacterial and mycotic reproductive tract infections.

3 Nutraceutical in Male Reproductive Abnormalities/Diseases

Abnormalities in male reproductive system can be induced by infectious organisms, exposure to environmental toxins, and individual's lifestyle among others. Male reproductive disorders such as sexual dysfunction, infertility, cryptorchidism, hypospadias, and testicular cancer are diseases of much concern currently (Bonde 2010). Among many abnormalities and diseases of the male reproductive system, prostate cancer is the major problem. Benign prostatic hyperplasia also affects large numbers of men above 50 years of age. It was reported that unhealthy dietary pattern was associated with increased risk of prostate cancer, while a healthy dietary pattern was associated with decreased risk of prostate cancer (Bagheri et al. 2018). This section will highlight on the use of some nutraceuticals on disorders and diseases of the prostate gland.

3.1 Effects of Nutraceuticals on Diseases of Prostate Gland

Plant-based healthy diet and lifestyles are reported to play an important role in reducing risks of developing prostate diseases and cancer in men. A number of trials have been made to look into the effect of nutritional plants and plant derivatives on prostate cancer. According to the World Health Organization, one-third of all cancer deaths are preventable through an increased consumption of natural compounds capable of modulating key molecular signaling cascades that ultimately inhibit cancer cell proliferation and induce apoptosis. A number of dietary phytochemicals including curcumin, ursolic acid, epigallocatechin-3-gallate, resveratrol, sulforaphane, and 6-shogaol have shown potential chemopreventive effects in vitro and in vivo in either animal models or in clinical studies on several cancers, including prostate cancer. Combination of ursolic acid, curcumin, and resveratrol administered to mice allograft model of prostate cancer through the diet, either alone or in combination, produced synergistic effects on tumor size and weight, indicating that synergistic combinations of natural compounds may be important for cancer therapeutic interventions (Lodi et al. 2017). Curcumin has been shown to have some effects on signaling pathways implicated in prostate cancer. It has effect on cancer-associated fibroblasts, which are important in regulation of epithelial to mesenchymal transition in tumor cells and in the induction of stem cell characteristics (McCubrey et al. 2017).

Other plant derivative compounds such as beta-sitosterol are reported to have anticancer properties against prostate cancer among many others (Sayeed and Ameen 2015). Berberine also decreased prostate cancer growth and cellular testosterone formation. It suppressed migration and invasion of prostate cancer cells and decreased expression of certain mesenchymal genes such as bone morphogenetic protein-7, nodal growth differentiation factor, and SNAIL, normally associated with shorter survival of prostate cancer patients. Moreover, berberine inhibited hypoxia-inducible factor-1 alpha and vascular endothelial growth factor expression in prostate cancer cells and increased their radiosensitivity in vitro and in vivo. Berberine also targets epidermal growth factor receptor signaling to suppress proliferation of prostate cancer cells in vitro and was shown to increase induction of apoptosis (McCubrey et al. 2017).

Other plants such as pomegranate fruit has been gaining a widespread reputation as a dietary supplement as well as a functional food due to emerging scientific evidence on potential health benefits, including prevention and treatment of erectile dysfunction in male subjects among many other effects. Pomegranate contains phytochemicals, including flavonoids (anthocyanins and catechins), flavonols (kaempferol and quercetin), flavones (apigenin and luteolin), conjugated fatty acids, hydrolyzable tannins, and related compounds, which are thought to be responsible for various biological and pharmacological activities including cancer preventive and therapeutic effects against many cancers including prostate cancer (Mandal et al. 2017).

Apart from prostate cancer, benign prostatic hyperplasia is known to commonly affect most men over the age 50. Various modern drugs are prescribed for benign prostatic hyperplasia. A cure for benign prostatic hyperplasia without side effects is not available so far. Due to adverse effects of the drugs, it is desirable to develop effective and long-term safety herbal medicines to inhibit the progress of benign prostatic hyperplasia (Chung et al. 2016). Pumpkin seed has long been used to treat micturition disorders and is found to substantially improve lower urinary tract symptoms associated with benign prostatic hyperplasia. The observed symptom relief is accompanied by a clinically significant improvement in International Prostate Symptom Score (IPSS)-related quality of life (Vahlensieck et al. 2015). Another study showed that garlic may have suppressing effects on benign prostatic hyperplasia. Its administration decreased relative prostate weight ratio and suppressed mRNA expression level of androgen receptor, dihydrotestosterone serum levels, and

growth of prostatic tissue in benign prostatic hyperplasia-induced rats. Garlic administration prevented progress of benign prostatic hyperplasia by regulating inflammatory responses through decreased levels of inflammatory proteins and apoptosis, which will be related to antioxidant properties of garlic and its components suggesting that garlic has a great potential as a treatment for benign prostatic hyperplasia (Chung et al. 2016).

Generally, many nutraceuticals with known antibacterial and antifungal properties such as garlic (Zardast et al. 2016) and potent antifungal and antibacterial nutraceutical plant species such as *Balanites aegyptiaca* and *Capparis erythrocarpos* (Anywar et al. 2014) will have potential to treat bacterial- and fungal-induced reproductive diseases in humans and animals.

4 Concluding Remarks and Future Directions

Reproductive disorders in males and females including infertility, infection-associated inflammation, cancer, and many other abnormalities are among common problems in humans and animals. Environmental pollution due to immense industrial developments, use of pesticides in profit-oriented modern agriculture, and chemicals in various household uses in humans and animals have immensely contributed to reproductive disorders mainly in industrialized and developing countries. In the present day, modern drugs are routinely prescribed to manage and treat reproductive abnormalities and other diseases. However, common occurrence of side effects of modern medical treatments has made the patients to resort to the use of traditional and alternative medicine, mainly nutraceuticals, to prevent or minimize the incidence of reproductive abnormalities and to treat clinical diseases. As a result, use of natural products including nutraceuticals to tackle with reproductive disorders has increased. Encouraging results supported by research undertakings and clinical trials are inspiring more hope in the future use of nutraceuticals for the treatment of various reproductive diseases in animals and humans.

Nutraceuticals in Genitourinary Maladies

Robert W. Coppock

Abstract

Nutraceuticals are used as prophylactics and remedies for genitourinary maladies in domestic animals and have been used throughout recorded history. They are also used to control and improve reproductive performance, improve the storability of semen and enhance ovum maturation, and improve in vitro fertilization. In the last decade, the effects and mechanisms of oxidative stress on reproductive performance and immune dysfunction have been elucidated. The antioxidative effects of certain nutraceuticals during periods of the reproductive cycle with high oxidative stress improve reproductive performance and reduce infections and other gentiourinary diseases. This chapter also reviews the current use of nutraceuticals to prevent and treat genitourinary diseases.

1 Introduction

Nutraceuticals can be defined as products isolated or purified from plants and animal products in formulations not usually associated with feed ingredients. The definition can also include functional feedstuffs and probiotics which are fed as part of an unusual diet. The functional ingredient is considered to go beyond basic nutritional needs and functions to reduce the risk of disease and have physiological benefits. Probiotics are live microorganisms that are administered orally and parenterally to improve health. There is an incorrect assumption that nutraceuticals cannot be harmful because they are a natural product produced in a plant or animal or have an antioxidative activity (Vrolijk et al. 2015). Antioxidants at pharmacological levels can cause pathophysiological interferences with the formation of reactive oxygen species (ROS) required for physiological functions. There is a common assumption that numerous nutraceuticals reduce the toxicity of in vivo free radicals. ROS are produced in the body as by-products of metabolism and for physiological functions. The ROS are reactive electron seekers and in excess can cause uncontrolled chain reactions leading to cell injury and death. Biochemically important ROS include superoxide anion ($O_2^{-\bullet}$), peroxyl ($ROO^{\bullet}$), alkoxyl ($RO^{\bullet}$), and hydroxyl radical ($OH^{\bullet}$) which is produced by the Fenton reaction (peroxide reaction with Fe^{2+}). Lipid-soluble hypochlorous acid (HOCl) is another ROS formed. Reactive nitrogen species can be formed including nitrogen dioxide ($^{\bullet}NO_2$) and nonradical peroxynitrite ($ONOO^{-}$). ROS can have important physiological functions. For example, immunocytes produce in vivo ROS (singlet oxygen, hypochlorous acid, etc.) to target and inactivate microbial pathogens. Homeostatic mechanisms provide for the destruction of ROS. When the production of ROS overwhelms the capacity for neutralization of ROS, the condition is known as oxidative stress. Oxidative stress and associated endoplasmic reticulum stress activate the nuclear factor kappa B (NF-κB) pathway. For example, there is molecular genetic evidence

R. C. Gupta et al. (eds.), *Nutraceuticals in Veterinary Medicine*, https://doi.org/10.1007/978-3-030-04624-8_33

that endoplasmic reticulum stress occurs during a negative energy balance in postpartum dairy cows (Gessner et al. 2014). Stress in the endoplasmic reticulum is linked to imbalance between incoming protein load and protein-folding capacity. The imbalance results in accumulation of unfolded or misfolded proteins in the lumen of the endoplasmic reticulum. The unfolded proteins' response triggers upregulation of endoplasmic reticulum chaperones. These include immunoglobulin heavy-chain binding protein that assists in refolding of proteins, attenuation of protein translation, and upregulation in degradation of misfolded proteins. If the stress in the endoplasmic reticulum cannot be corrected, cell death by apoptosis can occur. The endoplasmic reticulum stress transducers are activated causing a cascade of macromolecular reactions that result in pathophysiological and pathology observations, namely, oxidative stress, insulin tolerance, hepatic steatosis, and inflammation. Oxidative stress associated with oxylipid metabolism has recently been reviewed (Mavangira and Sordillo 2018). Oxylipids can contribute to oxidative stress or regulate specific sites of ROS production and can be biomarkers of oxidative stress. Detailed dietary management is important for reproductive success and controlling oxidative stresses that are associated with reproductive dysfunctions and diseases. For example, older mares with ovulation problems fed a proprietary feed that had balanced fats, carbohydrates, protein, fiber, vitamins, and minerals ovulated significantly sooner than mares fed oats (25 days vs. 39 days) (Jones 1997). Terrestrial animals hydrobionts exposed to anthropogenic pollutants have increased oxidative stress. There is substantial interest in the use of nutraceuticals to improve the genitourinary health of domestic animals.

2 Oxidative Stress in Dairy Cows

There is substantial interest in the use of nutraceuticals in the dietary management of dairy cows during the parturient and postpartum intervals. The critical period in the reproductive cycle of dairy cattle, especially in high production dairy cows, is the last 3 weeks of pregnancy (9-month gestation period) and the first 3 weeks of lactation. Dairy cows genetically selected for high milk production cannot consume enough feedstuffs to match the energy requirement for peak milk production. At calving time, the immune system of cattle also has decreased functionality. Dairy cows within a breed have a large variation in the physiological capacity to adapt to metabolic stress of lactation. Oxidative stress is linked to a decrease in immune function which increases the susceptibility of cattle, especially dairy cattle, to metritis and mastitis. A dairy cow has a dry period (cessation of milking 50–70 days before parturition) that is considered an interval of metabolic rest. Omitting the dry period increases serum or plasma levels of ceruloplasmin, cholesterol, and ROS and decreased levels of bilirubin and paraoxonase (Mayasari et al. 2017). In the last 2 weeks antepartum and the first 3 weeks postpartum, there is increased mobilization of nonesterified fatty acids from adipose tissues because of negative energy balance. This is linked to the increased risk for hepatic steatosis and ketosis. In the week before parturition, the odds of retained placenta increase by 5% with each 0.1 mMol increase in serum cholesterol or fatty acids (Quiroz-Rocha et al. 2009). There are scientific suggestions that cows with higher antioxidant activity have lower occurrences of retained placenta. Dairy cattle also have a period of physiological insulin resistance before calving and immediately after parturition (De Koster and Opsomer 2013). Prolonged insulin resistance is a pathophysiologic condition that has similarities to insulin resistance in humans. Oxidative stress is considered a causative factor for insulin resistance in cattle (Abuelo et al. 2015). The most common antioxidants used in dairy cows are vitamin E (α-tocopherol) and selenium (Se). Dry dairy cows on a diet that met or exceeded the NRC-USA nutrient recommendations received daily intramuscular injections of vitamin E and sodium selenate proprietary product[1] for approximately 15 days before parturition (Abuelo et al. 2016). Administering these antioxidants increased insulin sensitivity. Supplementing dairy cow ration with extracts[2] from grape seed and grape marc meal (1% of dry matter intake) reduced the hepatic mRNA abundance of hepatokine fibroblast growth factor 21 (Gessner et al. 2014). Hepatokine fibroblast growth factor 21 is associated with reduced hepatic steatosis and improved insulin sensitivity. Lipolysis was decreased and insulin-dependent glucose uptake was increased. The extract from grape offal did not change the antioxidative system and endoplasmic reticulum stress and did increase milk yield. Dairy cattle were supplemented with 175 mg of extracts[3] of green tea (95%) and curcuma (5%)/kg dietary dry matter from 3 weeks peripartum to week 9 postpartum (Winkler et al. 2015). Cows supplemented with the extracts had increased energy-corrected milk production and decreased hepatic cholesterol and triacylglycerols at week 1 and week 3 postpartum. There was a trend for decreased hepatic mRNA for haptoglobin and fibroblast growth factor 21.

3 Melatonin and Seasonal Breeders

Melatonin (*N*-acetyl-5-methoxytryptamine) has applications for manipulating reproduction and use as an antioxidant. Phytomelatonin has been identified in plants, for example, *Thymus vulgaris* L., *Glycyrrhiza uralensis* Fisch., *Salvia officinalis* L., and *Hypericum perforatum* L. (Arnao and Hernandez-Ruiz 2018). Melatonin has a key role in the modulation of sexual activity in seasonal breeders (Saxena 2017). Melatonin modulates neuroendocrine functions, pregnancy endocrinology, fetal circulation, and timing of parturition. Melatonin also has a modulation role in immune functions. The four major interests in melatonin are its use to improve in vitro fertilization and to alter seasonality of breeding in domestic animals, fetal programing, and its use as an antioxidant (Kutzler 2015; Brockus et al. 2016; Mura et al. 2017; Saxena 2017; El Allali et al. 2018). Dietary melatonin at pharmacological levels increases both umbilical and fetal blood flow in sheep (Lemley and Vonnahme 2017). Ewes and rams in northern Sardinia received subcutaneous implants containing 18 mg melatonin in February to May, and fertility parameters were monitored (Mura et al. 2017). The ewes and rams treated in April and May had significantly improved fertility rate, and the ewes had a decreased time to pregnancy. Treatment of doe and buck rabbits (New Zealand White) with 3 mg melatonin orally/rabbit/day for 60 days was comparable to 14 or 16 h of light for improving reproductive parameters (Mousa-Balabel 2011). At 170 days of gestation, pregnant heifers bred with sex-sorted semen received 20 mg melatonin orally/head/day for the duration of pregnancy (Brockus et al. 2016). Treatment with melatonin during pregnancy increased postnatal growth in the F_1 heifers and likely is evidence of fetal programing. At 220 days of gestation, high-milking Holstein cows were administered melatonin implants[4] (18 mg melatonin/implant, subcutaneously) to give a total dose of 216 mg melatonin, and bred heifers (220 days of gestation) were administered 162 mg melatonin by subcutaneous implants (Garcia-Ispierto et al. 2013). The temperature humidity index during the study was 80 units. No differences between treated and control animal were observed for retained placenta and metritis. Odds ratio found that the likelihood of repeat breeders and subsequent pregnancy loss was lower in the treated animals. Treatment with melatonin significantly reduced prolactin levels but did not alter total milk production and milk somatic cell counts. Camels are seasonal breeders during short photoperiods and ovulation is mating-induced. Female dromedary camels were conditioned to artificial light of 16 hours daylight and 8 hours dark for 41 days and then moved outdoors (May in Morocco) and implanted with 18 mg melatonin subcutaneous implants[5] to give a dose of 0.64 mg melatonin/kg body weight (El Allali et al. 2018). The melatonin treatment advanced the onset of follicular growth by 3.5 months and suppressed plasma prolactin. Fertility parameters were not included in the study. The use of melatonin to suppress estrus in queens (female cats), a long-day breeder, has varying success (Kutzler 2015; Schafer-Somi 2017). Estrous suppression can last for 4 months. In male cats, melatonin subcutaneous implant (18 mg) reduced semen quality parameters.

4 Herbs

4.1 Raspberry (*Rubus idaeus* L.)

Raspberry is used in veterinary and human medicine as a nutraceutical. In humans, raspberry leaf preparations are used to prevent nausea associated with pregnancy, to increase uterine efficiency during labor and delivery, and to decrease the risk of postpartum hemorrhage (Holst et al. 2009). Simpson et al. (2001) reported that oral administration of raspberry leaf tablets to pregnant women tended to shorten the second stage of labor. Women were administered a 2.4 g raspberry leaf table twice a day or placebo starting at week 32 of pregnancy and continuing to delivery. No significant differences were observed for medical management of birthing, mode of birthing, labor pain management, birthing-associated blood loss, blood pressure (tendency to increase in treatment group), birth weight, Apgar score, meconium-stained amniotic fluid, infant special care needs, and gestation interval. The strength of uterine contractions was decreased in postpartum women after they were orally administered raspberry leaf extracts and intrauterine pressure subsequently measured (Holst et al. 2009). A toxicity study was done in rats on the safety of red raspberry leaf,[6] kaempferol,[4] and quercetin[7] (Johnson et al. 2009). The doses of red raspberry leaf, kaempferol, and quercetin were 10 mg/day/rat administered from gestation day zero to parturition. The dose was based on studies showing the pharmacology of kaempferol and quercetin. Fertility parameters were measured, and female offspring were monitored until puberty (vaginal opening). There were no differences between treatment and controls for litter size, birth weight, total litter weight, sex ratio, and survival to weaning. Treatment with red raspberry leaf significantly increased gestation period (22.4 $\pm$ 0.37 vs. 20.8 $\pm$ 0.63 days for controls), and 78% of dames treated with red raspberry leaf whelped. The time to vaginal opening of the F_1 females born to dams receiving red raspberry life was significantly decreased. The F_1 females born to dams receiving red raspberry leaf were

[4] Melovine®, CEVA Salud Animal (Barcelona, Spain)

[5] Melovin®, Ceva, Ceva Santé Animale (Libourne, France)

[6] Nature's Way, Canmore, Alberta, Canada

[7] Sigma Aldrich, Oakville, Ontario, Canada

bred, and fertility parameters were observed. There are no differences between treated and control for time to mating, mating success, pregnancy success, gestation period, live birth index, litter size, birth weight, total litter weight, sex ratio, or postnatal survival to post birth day 21. For kaempferol and quercetin, the only effect was the F_o females receiving quercetin had significantly increased weight gains during pregnancy. An ethnoveterinary study in British Columbia found that *Rubus idaeus* infusion (made with 250 mL boiling water and 150 mg leaves/kg body weight) is given orally once a day to dogs for increasing uterine tone and facilitate whelping (Lans et al. 2009). It is also used to support milk production.

4.2 Black Cohosh (*Actaea racemosa* L.) and Blue Cohosh (*Caulophyllum thalictroides*)

Black cohosh (squawroot or papooseroot) is a popular herb for women's health issues and has historical use by aboriginal peoples (Dietz et al. 2016). The primary use of the rhizomes and roots is for ameliorating the signs of menopause. In homeopathic medicine, blue and black cohosh formulations are used to establish labor (Smith 2010). There are conflicting reports in the literature on the efficacy of blue and black cohosh. There are reports for black cohosh being used as nutraceutical treatment of canine uterine infections (Lans et al. 2009).

4.3 Flax (*Linum usitatissimum* L.)

Flaxseed is used as a nutraceutical in veterinary medicine for improving semen resistance to freezing and thawing and to promote lactation in pets and cattle (Lans et al. 2009; Kumar and Bharati 2013; Kargar et al. 2017). It is also used to ameliorate the signs of menopause in women (Dietz et al. 2016). Flaxseeds are resistant to digestive actions, and thus it is recommended that seed be fractured before oral administration. They contain the secoisolariciresinol diglucoside lignans that are metabolized to estrogenic-like molecules. The secoisolariciresinol diglucosides, the primary lignans in flaxseed, are poorly absorbed and are metabolized by colonic microorganisms. The products of microbial fermentation of flaxseed meal are absorbed. There are concerns that high dietary intake of flax can result in hyperestrogenism of the fetus. A multigenerational study in rats using 20 or 40% of the diet as flaxseed or 13 or 26% of the diet as flax meal was done to investigate the effects of flaxseed on the F_1 generation (Sprando et al. 2000a, b). The females were exposed to the flaxseed diets from day 0 of pregnancy to weaning of the pups. At 21 days of age, randomly selected males were fed the same diet as the females for 70 days. For the F_1 males, no significant effects across treatment groups were observed in the testicular weights, epididymal weights, seminal vesicle weights, and testicular morphology. Also, for the F_1 males, no significant differences were observed for homogenization-resistant spermatid counts, daily sperm production rates, percentage of sperm abnormalities, levels of testosterone in the seminiferous tubular fluid, and testicular histopathology. Significant differences in endocrine parameters were observed in the F_1 males when flaxseed-treated rats were compared to control rats (no flaxseed). Serum luteinizing hormone was increased in the F_1 male rats receiving the 20 and 40% flaxseed diets, and serum testosterone and luteinizing hormone were increased in rats from the 26% flax meal group. Also, there were significant increases in caudal epididymal weights and increase caudal epididymal sperm numbers/g epididymis from the 20 and 40% flaxseed groups. In the 13% and 26% flax meal treatment groups, there were increased epididymal sperm numbers/g epididymis. Prostate weights were significantly decreased in the 20% flaxseed and 13 and 26% flax meal treatment groups. New Zealand White rabbits (8-month-old) were provided a diet supplemented with 5% extruded flaxseed for 5 weeks and semen parameters studied (Mourvaki et al. 2010). The high linolenic acid increased the dietary omega-3 (ω-3)/omega-6 (ω-6) (fatty ω-3/ω-6) fatty acid ratio by increasing the ω-3 fatty acids in spermatozoa and decreasing the ω-6 fatty acids. Spermatozoa from the treated bucks had increased membrane integrity and track speed. There was an increase in the phospholipids in the prostate granules. Flaxseed meal and ground flaxseed are considered efficacious in Uttar Pradesh, India, as a galactagogue in cattle (Kumar and Bharati 2013). The seed cake or crushed seeds are mixed with jaggery or gum of *Sterculia urens*. A study in Nili-Ravi buffalo bulls showed that supplementation of the diet with flaxseed oil significantly increased libido, semen volume, percent live sperm, spermatozoa numbers/mL of semen, mass activity, percent motility, and the integrity of spermatozoa membrane (Shah et al. 2016). The bulls were orally administered 0, 125, and 250 mL flaxseed oil for 12 weeks. Mating behavior was evaluated when semen was evaluated at day 0 and weekly starting on week 5. Flaxseed oil and vitamin E dietary supplement were found to improve the freeze-thaw semen evaluation parameters of cloned Bakhtiari goats (Kargar et al. 2017). Flaxseed oils have been shown to improve male and female fertility. Flaxseed oil has been shown to be a replacement dietary supplement for fish oil for improving the success of in vitro fertilization of ovum from dairy cows and for modifying the lipids and semen characteristics of rooster semen (Bongalhardo et al. 2009; Moallem et al. 2013). Flaxseed oil does not contain the bioconcentrated persistent organic pollutants associated with fish oil, an important issue in food safety and medicine.

4.4 Maca (*Lepidium meyenii* Walpers)

4.4.1 Background

Lepidium meyenii, also known as maca, is in the Brassicaceae family (Cruciferae, contain glucosinolates) and is cultivated in the Peruvian highlands. The hypocotyl is a fleshy root that is used internationally as a nutraceutical and locally consumed as a nutraceutical and as a root vegetable. Maca has traditionally been used to improve sexual function and fertility in domestic animals and humans (Clement et al. 2010, 2012; Lee et al. 2016; Beharry and Heinrich 2018). Maca is credited for offsetting the adverse effects of high altitude and harsh climate and thereby improving reproductive performance of domestic animals and humans (Leon 1964). A study in humans provides evidence that black and red maca decreases signs of chronic mountain sickness and improves mood and sexual desire (Gonzales-Arimborgo et al. 2016). A study in rats using a decoction of *Lepidium meyenii* showed that the decoction equivalent to 0.6 g of root/day administered for 21 days offset the effects of high altitude (4349 m) on epididymal spermatozoa numbers (Gonzales et al. 2004). Using a proprietary process, *Lepidium meyenii* roots were extracted with methanol, ethanol, or water, and the fractions were purified by chromatographic processes to concentrate macaene and macamide and other plant chemicals including campesterol, stigmasterol, and beta-sitosterol (Zheng et al. 2000). The extracts were standardized on macaene and macamide and novel polyunsaturated fatty acids and their amides. Male mice were orally administered mecca extract preparations at 40 mg/g body weight for 22 days. The number of sexual intromissions the male mice accomplished in 3 h with receptive females was recorded. For the maca extract treated mice, the intromissions increased 2.39 and 2.55 times, more than the control male mice. In castrated rats receiving oral doses of 45, 180, and 1800 mg of extract/kg body weight decreased the latent period between electrical stimulation and observed penile erection by 71 ± 12, 73 ± 12, and 41 ± 13 seconds, respectively, as compared to castrated untreated rats. Feeding rats a proprietary[8] hydrous ethanol extract of maca (*Lepidium meyenii*, different ecotypes of red, yellow, and black maca) at 2% of diet increased the testosterone production of cultured Leydig cells and alleviated decline with aging (Yoshida et al. 2018). Feeding this product also caused a transient increase in serum testosterone. There is limited data from controlled studies in humans (Lee et al. 2016). In healthy men, maca improved laboratory parameters for semen evaluation (motility, sperm counts, and morphology). In men classified with infertility, there was consistent improvement in sperm motility, and one study showed improvement in sperm numbers, motility, and vitality. Fertility was not reported. There are reports of maca being used to improve reproductive parameters in domestic animals.

4.4.2 Bulls

A Swiss study on *Lepidium meyenii* roots in peripubertal breeding bulls, using a crossover experimental design, showed that a 10-week supplementation increased spermatozoa numbers (Clement et al. 2010). A 1000 kg batch of hypocotyls (approximately 50% yellow color, 25% reddish color, and 25% black color) was milled to powder (0.8 mm particle size), and the powder was mixed into a basal concentration. Seventy-eight bulls, 55–84 weeks of age from five different breeds, kept at a commercial bull stud, were, at by-weekly intervals, ejaculated by established semen collection procedures. The bulls were fed no maca for 10 weeks, maca 233 mg powder/kg body weight/day for 10 weeks, or maca for the last 10 weeks of the study. Maca supplementation did not affect testes circumference, mating behavior, and semen volume. Supplementing the diet for 10 weeks increased spermatozoa numbers in the second 10 weeks when no additional maca supplement was provided. Other parameters improved in originally marginal bulls were DNA fragmentation index and motility.

4.4.3 Stallions

Yellow maca, grown in the highlands of Peru, has been studied in stallions used at a commercial stud farm (Del Prete et al. 2018). The yellow strain of *Lepidium meyenii* hypocotyls were traditionally dried and milled (0.8 mm) into flour. The treated stallions received 3 g of maca flour/kg body weight for 60 days (spermatogenic cycle is 57 days). Treatment with maca did not change the levels of serum testosterone and ejaculate volume. From day 60 (end of maca treatment) until 120 (end of study), the concentration of spermatozoa and total sperm counts were significantly increased (doubled) in semen from the maca-treated horses. Treatment with maca significantly improved acrosome integrity at study days 60, 90, and 120. At study day 120, DNA fragmentation was significantly reduced in semen from the treated stallions. Semen was evaluated after ejaculation and after processing for cooled shipping at 24, 48, and 72 h of storage. During cooling and storage, the total motility, progressive motility, and acrosomal integrity declined slower in semen from maca-treated horses.

5 Dietary Lipids

5.1 Background

Lipids are used as nutraceuticals to improve reproductive performance. Lipids in cell membranes have a temperature transitional point where they change from liquid-like

properties to crystalline-like with rigid properties. Having a transition point at a lower temperature is a factor in survivability of spermatozoa at rethawing. Increasing the *cis*-double bonds, shorter hydrocarbons, and increased cholesterol in the membrane lipids decrease the temperature at which transition point occurs. Polyunsaturated acids are divided into ω-3, ω-6, and ω-9 fatty acids. These fatty acids have the first double bond located at 3, 6, or 9 carbons, respectively, from the methyl end of the fatty acid molecule. Mammals cannot synthesize the ω-3 and ω-6 fatty acids making them essential dietary fatty acids. The ω-6 linoleic acid and α-linolenic acid (a ω-3 fatty acid) must be provided in the diet, and eicosapentaenoic acid, docosahexaenoic acid, and arachidonic acid are synthesized from these essential precursors (Gulliver et al. 2012). The ω-6 linoleic acid is most abundant in vegetable oils. The enzymatic pathways for the polyunsaturated fatty acids in eicosanoids for reproduction have been reviewed (Wathes et al. 2007). The polyunsaturated fatty acids are precursors for eicosanoids which include the prostaglandins. In mated mammalian females, the critical period for pregnancy is the interval from insemination to implantation of the embryo. Lipid catabolism by the embryo before implantation is an important source of energy. Polyunsaturated fatty acids are also important in membrane fluidity of spermatozoa. Oversupplementation with polyunsaturated fatty acids has a risk of being harmful. The testicles contain arachidonic acid, docosapentaenoic acid, and docosahexaenoic acid with the ratios varying between species. Adequate dietary polyunsaturated fatty acids are important for fertility (Gulliver et al. 2012). Resistance of spermatozoa to cold preservation is considered linked to the levels of ω-3 polyunsaturated fatty acids (e.g., linolenic, eicosapentaenoic, and docosahexaenoic acids) in their cell membranes. An Austrian study in Shetland pony stallions showed that ω-6-docosapentaenoic acid was the predominant polyunsaturated acid in equine spermatozoa (Aurich et al. 2018). This study also showed a January to June increase in the relative content of docosapentaenoic acid and an increase in ω-6-arachidonic acid. The ratio of ω-3/ω-6 polyunsaturated fatty acids in stallion sperm decreased from January to June.

5.2 Fish Meal and Oils

Boars were placed on a diet supplemented with 75 mL cod liver oil/day/boar for 12 weeks (Paulenz et al. 1995). Cod liver oil is rich in ω-3 polyunsaturated acids. The spermatozoa were analyzed for fatty acid composition. Supplementing with cod liver oil increased the levels of the ω-3 docosahexaenoic acid and decreased the levels of ω-6 docosapentaenoic acid compared to levels in spermatozoa in semen from the control group. No differences were observed between groups in the negative effects of freezing on semen evaluation parameters. A study showed fish oil supplemented diets in boars alters testicular steroid production (Castellano et al. 2011). Duroc boars were provided a diet supplemented with 62 g hydrogenated fatty acids/boar/day, 60 g of menhaden fish oil (contained 10.8 g of docosahexaenoic acid and 9.0 g of eicosapentaenoic acid)/boar/day, or 60 g tuna oil (containing 19.8 g docosahexaenoic acid and 3.9 g of eicosapentaenoic acid)/boar/day for 7 months. Body condition and testicular lipid and protein content were not different among groups. Lipid classes of phosphatidylcholine, phosphatidylethanolamine, and sphingomyelin were significantly different between groups. Supplementing with fish oils decreased ω-6/ω-3 fatty acid ratio in phosphatidylcholine with ω-6 fatty acids being the most affected. The fish oil diets increased the ω-3 fatty acids compared to the ω-6 fatty acids in phosphatidylethanolamine. Fish oil diets decreased the ω-6/ω-3 fatty acid ratio in sphingomyelin. The levels of testicular testosterone, dihydrotestosterone, and estradiol were measured. Testosterone was 46% lower in the boars receiving the diet supplemented with tuna oil, and estradiol was also lower compared to the boars receiving the menhaden fish oil supplemented diet. Three different breeds of boar pigs (Duroc, Large White, and Pietrain) were supplemented with fish oil 0.3 kg/boar/day for 26 weeks to determine the effect of supplemental ω-3 fatty acids on semen parameters by breed (Yeste et al. 2010). Semen was collected once a week and evaluated for ejaculate volume, concentration of spermatozoa, viability, acrosome and mitochondrial sheath integrity, motility, morphology, and osmotic resistance. Of these parameters, the supplemented diet positively affected both sperm morphology in Large White and Pietrain breeds and the osmotic resistance of Pietrain spermatozoa. This study shows that different breeds of pigs respond differently to ω-3 fatty acids. The addition of fish oil plus thyme (*Thymus vulgaris*) was studied in stallions to determine their potential for improving semen storability (chilled at 5 °C) (Garmsir et al. 2014). Stallions received a basal diet, a diet supplemented with fish oil at 2.5% of dry matter intake, a diet supplemented with thyme at 0.02% of dry matter intake and a diet supplemented with fish oil plus thyme. The semen parameters for the stallions fed fish oil and thyme were improved at 24 and 48 h of storage. In a 2 × 2 crossover study design using eight stallions, adding 250 g/day/stallion for 14 weeks of a nutraceutical[9] high in docosahexaenoic acid (DHA), an ω-3 fatty acid, has been shown to improve storability of stallion semen (Brinsko et al. 2005). The proprietary nutraceutical consisted of wheat, fish oil, soybean meal, DL-tocopherol acetate, dried yeast, and ascorbyl palmitate. The nutraceutical contained 25% crude fat and 30% ω-3 fatty acids. The fish oil consisted of approximately 25% DHA, ~5% eicosapentaenoic acid, and ~ 34% ω-3 fatty acids.

[9] ProSperm, Minitube of America (Verona, WI)

Ejaculates from the artificial vagina were divided and evaluated as fresh, cooled, and frozen-thawed semen. Testicular volume was not changed by treatment. The mean sperm concentration from the stallions was 1.8 times higher ($p = 0.03$) in the treated horses. The level of DHA/billion spermatozoa was three times higher ($p = 0.002$) in the treated stallions. The ratio of DHA to docosapentaenoic acid (a ω-6 fatty acid) was significantly increased. Total motility, progressive motility, and average path velocity in fresh semen were not changed by treatment. After 48 h of cold storage, there was a trend for spermatozoa from treated stallions to have greater motility ($p = 0.03$). The percent of live sperm with intact acrosomes and the percent of sperm with damaged chromatin were not reduced by treatment with the nutraceutical. The numbers of stallions in this study were small, and the effects of DL-tocopherol acetate are unknown, and fertility was not a parameter in the study. A study in rams showed that fish oil supplement was superior to palm oil and sunflower oil for improving semen parameters before and after freezing and thawing (Esmaeili et al. 2014). Fish oil also increased serum testosterone. Another study in rams showed that supplementing the diet with fish oil had positive effects on semen parameters and changed the composition of fatty acid profiles of spermatozoa and the effects continued for 2 months after cessation of supplementation (Alizadeh et al. 2014). A study in Zandi rams showed that supplementing the diet with ω-3 fatty acids improved the fertility of frozen semen (Masoudi et al. 2016). The rams were fed a diet supplemented with fish oil or palm oil at 3% of dry matter for 60 days. Semen was collected and frozen using a soybean lecithin or egg yolk extender. The semen and spermatozoa parameters were not significantly different between diets. For fertility, the fish oil diet significantly improved fertility rate, parturition rate, and lambing rate. The extender used was not significant in the fertility outcomes. Holstein bulls were fed fish oil at 1.2% of the dry matter for 13 weeks, and their semen was evaluated (Khoshvaght et al. 2016). After 7 weeks, the fish oil diet significantly increased semen volume, progressive motility, and sperm viability of fresh semen. For thawed frozen semen, the progressive motility was significantly increased and abnormal spermatozoa significantly decreased. A dietary study in dogs showed that fish oil and fish oil plus vitamin E decreased the sensitivity of canine spermatozoa to lipid peroxidation (Risso et al. 2017). The effects of supplementing ewes with salmon oil and linseed oil source of (ω-3 fatty acids) or with sunflower oil (source of ω-6 fatty acids) for 6 weeks were studied on ovarian function, oocytes, and embryo quality (Wonnacott et al. 2010). Ovarian follicle size and numbers were not different between treatment groups. The diet high in ω-3 fatty acids did increase progesterone in follicular fluid. There was selective uptake of saturated fatty acids by the oocytes, predominantly stearic acid. Blastocysts from both groups had high levels of polyunsaturated fatty acids, predominantly linoleic acid.

5.3 Vegetable Oils

The use of nutraceuticals to improve the in vitro portability of stallion semen for artificial insemination is attracting attention. Nutraceuticals are also employed to improve the storability of stallion semen. Many stallions, fertile by natural mating, produce semen that does not meet the accepted standards after it is cool or cryopreserved (Arruda et al. 2010). Consequently, there is a loss of inherent fertility. Increasing dietary sources of polyunsaturated fatty acids have been shown to increase fertility in stallions. A crossover study in eight stallions conducted over 60 days showed a proprietary reproductive nutraceutical[10] improved the laboratory parameters for fresh, cooled, and frozen semen (Freitas et al. 2016). The nutraceutical, administered by oral drench for 9 weeks, contained vitamins A, B12, B6, and E, folic acid, β-carotene, L-carnitine, amino acids, ω-3 and ω-6 fatty acids, selenium, zinc, copper, and chromium. The stallions, previously assessed to meet a national semen standard (Brazil CBRA[11]), were ejaculated once a week and on the tenth week were then ejaculated every other day for four ejaculations. Semen was evaluated at collection, cooled semen was evaluated at 24, 36, and 48 h, and frozen semen was evaluated upon thawing. Semen was evaluated according to the CBRA standard. For fresh semen, the nutraceutical treatment did not change ejaculate volume, sperm concentration, numbers of abnormal spermatozoa, color, and apparent density. In fresh semen, supplementation with the proprietary nutraceutical increased ($p < 0.05$) total motility, trajectory speed, as well as plasma and acrosomal membrane integrity. In cooled semen, nutraceutical treatment preserved acrosomal membrane integrity ($p < 0.05$), total motility (≥36 h), and velocity (≤36 h). In frozen semen, supplementation increased ($p < 0.05$) spermatozoa progressive motility and plasma membrane integrity. The addition of 100 mL of linseed oil/day/stallion and a 30 mL of a proprietary antioxidant[12]/day/stallion for 84 days (November to February in Austria) attenuated a seasonal decline in motility and membrane integrity of cooled-stored semen (Schmid-Lausigk and Aurich 2014). Vegetable oils, administered intrauterine, have been used to suppress estrus in mares. Mares receiving infusions of sterile coconut oil or sterile peanut oil on day 10 of the estrus cycle had prolonged diestrus (Wilsher and

[10] Reproductive Garanhões, JCR Nutraceuticals, Vetnil (Louveira, Spain)

[11] Brazilian College of Animal Reproduction (http://www.cbra.org.br/portal/index-ar.htm)

[12] Myostem Protect, Audevard (Clichy, France)

Allen 2011). Increased uterine fluid and vaginal discharges were not observed. The use of peanut oil to suppress estrus was studied in mares using a crossover-designed study (Campbell et al. 2017). Ten days after ovulation, each mare received 1 mL of filtered (0.22 μm) sterile peanut oil[13] intrauterine using the same sterile technique used for embryo transfer or a sham treatment without any substance injected. Peanut oil infusion did not significantly increase the duration of the luteal phase but did increased erosion of endometrial epithelium and increased eosinophilic infiltration. Fractionated coconut oil was found to be ineffective in prolonging diestrus in mares (Diel de Amorim et al. 2016). Landrace boars were fed 75 and 150 mg of algal supplement[14]/boar/day for 19 weeks (Murphy et al. 2017). The algal preparation also contained ethoxyquin (6-ethoxy-2,2,4-trimethyl-1,2-dihydroquinoline). The algal supplement increased oral intake of docosahexaenoic acid. Semen parameters and fertility indices were evaluated. The algal supplement increased semen volume and numbers of spermatozoa. There were no significant differences between control and treated boars for the fertility parameters. The supplement increased semen output by 3–4 more insemination dose packages of semen. Canine spermatozoa are very sensitive to freezing and thawing.

Considerable improvements have been made through improved laboratory procedures including semen extenders. Studies have shown that dietary supplements can improve the "ruggedness" of canine spermatozoa. Supplementing canine diet with a nutraceutical[15] containing a high content of ω-3 and ω-6 fatty acids improved semen parameters (Rodrigues et al. 2017). In a crossover study, seven mixed breed stud dogs were on a commercial dog food diet and were conditioned for 8 weeks to semen collection (digital manipulation to ejaculation). After the conditioning period, semen was collected for 5 weeks and evaluated as fresh and thawed semen for volume, motility, vigor, spermatozoa numbers, and morphology. For 8 weeks, the dogs received the nutraceutical dietary supplement [containing 39.97 mg ω-3 fatty acids (eicosapentaenoic, docosahexaenoic) and 283.40 mg ω-6 fatty acid (linoleic acids)]/10 kg body weight. The supplementation regimen increased sperm motility, and concentration, but did not improve freezeability. In another study, stud dogs were on a commercial dog food or the commercial dog food supplemented with 7.2 mg ω-3-linoleic acid/kg body weight/day, 25 mg ω-6-linolenic acid/kg body weight/day, 10.1 mg ω-9-oleic acid/kg body weight/day, and 1 IU vitamin E/kg body weight/day (da Rocha et al. 2009). The supplement was provided for 60 days. The fatty acid supplement increased semen volume, spermatozoa concentration, and motility, and there was an improvement in storage at 38 °C for 4 h.

6 Carnitine

6.1 Background

L-Carnitine [(–)-(*R*)-3-hydroxy-4-(trimethylammonio)butyrate] is a quaternary ammonium compound found in animal and plant products. It is essential in intermediary metabolism, and its primary function is to transfer the acetyl moiety and activated long-chain fatty acids from one cellular compartment to another including mitochondrial membranes (Rebouche 2004; Adeva-Andany et al. 2018; Ringseis et al. 2018). This process assures the availability of coenzyme A. Mitochondrial β-oxidation of saturated straight-chain fatty acids is a catabolic biochemical pathway that ultimately generates acetyl-CoA, NADH+, and FADH2 from fatty acyl-CoA esters. L-Carnitine is important in regulating the acetyl-CoA/CoA ratio, and free CoA has feedback regulatory activity on pyruvate dehydrogenase complex and influences glucose metabolism. In pregnant sows, L-carnitine increases insulin-like growth factor in blood (Eder 2009). Piglets born to L-carnitine-supplemented sows have increased numbers of primary muscle fibers. All mammals can synthesize carnitine from lysine and methionine in a process requiring methylation of protein-bound lysine in a rate-limited step by N^{ϵ}-trimethyllysine hydroxylase. The liver is the primary tissue containing the enzyme γ-butyrobetaine dioxygenase required for the final reaction to form carnitine from γ-butyrobetaine. Carnitine in blood is taken up by tissues using the organic cation/carnitine transporter 2 (OCTN2), and this mechanism is also used to conserve carnitine by uptake from the glomerular filtrate. The OCTN2 transporter is the primary mechanism for uptake of carnitine from the small intestine. Some xanthines compete for the OCTN2 transporter. Plants, especially legumes and Gramineae (Poaceae) and their seeds, are considered an important source of N^{ϵ}-trimethyllysine. The highest dietary sources of carnitine are animal products. Ruminants may obtain carnitine and its precursor from their indigenous microbiome. Intravenous infusion studies have shown that the reuptake of carnitine by the kidney tubules is saturable. Carnitine is excreted in milk. The uptake of dietary carnitine in humans is estimated to be 0.05–0.25 of the dose, and there is some evidence to support that absorption may be rate limited. There is evidence that dietary uptake of L-carnitine in young piglets is 90–95% in young pigs receiving diets containing 25–100 ppm with absorption decreasing with increasing above these dietary levels (Fischer et al. 2009). In this study, levels of L-carnitine in the liver, kidney, heart, and skeletal muscle were also increased.

Feeding hens a diet with added L-carnitine increases the levels of L-carnitine and L-acetylcarnitine in eggs (Peebles et al. 2007). Chronic inflammation likely upregulates the in vivo absorption of total carnitine and acetylcarnitine (acid soluble), and absorption is increased by inflammation-linked upregulation of the OCTN2 gene expression. This is evidence that the OCTN2 is important in transferring carnitine from maternal blood to the fetus. Pregnant sows fed a diet supplemented with 50 ppm L-carnitine had increased levels of L-carnitine in fetal hearts and livers (Xi et al. 2008). The activity of the pyruvate dehydrogenase complex was increased in the heart and the activity of carnitine palmitoyltransferase in the liver but did not alter its Michaelis constant (K_m). In women, blood levels of total carnitine, acetylcarnitine (acid soluble), and nonesterified carnitine decrease during pregnancy, especially in the second and third trimester (Cho and Cha 2005). During the first and second trimesters, urinary excretion of total carnitine, nonesterified carnitine, and acylcarnitine (acid-soluble) was significantly higher, and urinary excretion decreased as pregnancy progressed. In sows, plasma carnitine does not decrease during pregnancy (Eder 2009). L-Carnitine is important for long-chain fatty acid transport inside the mitochondria and synthesis of phosphates rich in energy that improve sperm motility and survival including preparation of semen for artificial insemination. The ability of mitochondria to metabolize lipids and balance ATP supply is critical for oocyte fertilization and subsequent developmental activities (Van Blerkom 2011). L-Carnitine is essential for mitochondrial lipid metabolism in the oocyte. There are high concentrations of L-carnitine in the epididymis and spermatozoa where it serves as a vehicle for acyl groups for oxidation (Ng et al. 2004). A study on epididymides from 10-month-old Pietrain boars showed L-carnitine levels in luminal fluid increased distally with the highest levels occurring in the cauda epididymis, and the L-carnitine level in spermatozoa was not changed (Pruneda et al. 2007). Other studies in multiple species have shown that the levels of L-carnitine increase in the caudal epididymides. In many species there is a positive correlation between L-carnitine in seminal fluid and the numbers of spermatozoa. L-Carnitine has similar functions in other energy-demanding tissues including the heart. By active processes, L-carnitine is transported into epididymal plasma. Free L-carnitine in seminal fluid is directly related to sperm counts and motility (Brooks 1979; Sheikh et al. (2007). L-Carnitine has been shown to protect the testicle. A study in rats showed that dietary supplementation with L-carnitine is protective against the oligospermia induced by busulfan, an alkylating anticancer drug (Abd-Elrazek and Ahmed-Farid 2018). Double-blind placebo studies in 60 men with asthenozoospermia showed both L-carnitine and L-acetylcarnitine, given orally, improved sperm motility and semen scavenging capacity for hydroxyl and peroxyl radicals (Balercia et al. 2005). Twelve men spontaneously impregnated their partner. Of these, 9/12 of the men were receiving L-carnitine plus L-acetylcarnitine (three men for 3 months and two men for 5 months) and two impregnations occurred by men receiving acetyl-L-carnitine treatment (one for 2 months and one for 5 months) and one pregnancy occurred after 2 months of washout (carnitine treatment not specified). Similar results have been reported for another study in men (Lenzi, et al. 2003). A recent literature review did not provide clear evidence of L-carnitine improving the fertility of women (Showell et al. 2017). Another review considers L-carnitine and L-acetylcarnitine to improve female fertility, and more research is needed to understand their use in therapeutic regimens (Agarwal et al. 2018).

6.2 Bovine

A study evaluated the therapeutic use of L-carnitine and acetyl-methionine in a proprietary formulation[16] as an addition to standard propylene glycol treatment regimen for bovine ketosis diagnosed by >1.2 mMol blood levels of β-hydroxybutyrate (Jeong et al. 2018). The study also included follow-up to determine if treatment with L-carnitine decreased the probabilities for postpartum reproductive diseases. Treatment with the proprietary product improved the chances for recovery. Milk yields were improved on days 30 and 40 postpartum by the addition of the proprietary formulation to the propylene glycol regimen. Postpartum reproductive organ complications and the interval to first insemination were not different between groups.

6.3 Equine

A study in 25 young Maremmano stallions showed that L-carnitine and L-acetylcarnitine are present in seminal plasma (Stradaioli et al. 2000). Both L-carnitine and L-acetylcarnitine are higher in the first ejaculate when compared to the second ejaculate collected 1 h later. Seminal L-acetylcarnitine was positively correlated with total motile morphologically normal spermatozoa, and both L-carnitine and L-acetylcarnitine in semen and seminal plasma were positively correlated with spermatozoa concentration. L-Carnitine has a history of being used to improve fertility of stallions (Zeyner and Harmeyer 1999). Supplementing the diet with 20 g of L-carnitine/day for 60 days improved oligoasthenospermia in stallions (Stradaioli et al. 2004). Supplementation increased the progressively motile spermatozoa at 30 and 60 days in the oligoasthenospermic stallions and increased free carnitine in seminal plasma. L-Acetylcarnitine in semen was positively correlated with total motile spermatozoa that had normal morphology. Stallions with normal semen did not have

[16] Metabolase®, Fatro (Bologna, Italy)

improvements in their semen parameters. Arruda et al. (2010) cited a study that showed supplementing stallions with good, intermediate, and bad semen with 10 g of L-carnitine/horse/day for 90 days was an effective treatment for improving semen parameters. Shetland pony stallions were, for 7 weeks, fed a proprietary[17] mixture that provided tocopherol 300 mg/day, ascorbic acid 300 mg/day, L-carnitine 4000 mg/day, and folic acid 12 mg/day (Deichsel et al. 2008). No overall improvement in semen parameters was observed in semen after it was chilled at 5 °C for 24 h. There was a small decrease in the overall observations in morphological defects. Morris and Gibb (2016) reported that 6 weeks of oral supplement with 60 g of L-carnitine/day/stallion was required to improve fertility using fresh semen for artificial insemination.

6.4 Porcine

6.4.1 Sows

Research studies show sows supplemented with L-carnitine during gestation give variable results in improvement in sow reproductive performance (Eder 2009). However, the overall finding is that supplementing sows with L-carnitine improved their reproductive performance. Feeding 100 mg L-carnitine/sow/day during gestation significantly increased total litter and individual pig birth weights and the number of live births (Musser et al. 1999). The effects of supplementation with 150 mg of L-carnitine/sow/day during gestation and 250 mg/sow/day during lactation over three reproductive cycles showed that litter and piglet weights at birth and weight gains of piglets and weaning weights were increased, but litter size, stillborn piglets, and piglets fit for rearing were not changed by L-carnitine supplementation (Ramanau et al. 2002). Sows receiving 125 mg L-carnitine/day had an increased litter size of 2.8 piglets/ litter, and sows receiving 25 and 50 ppm L-carnitine/day had an increased litter size of 0.5 and 0.6 piglets/ litter, respectively (Eder 2009). Supplementing the diet of sows with L-carnitine increased the total sucking time (1–4 days of age) and increased weight gains (Birkenfeld et al. 2006). This study had two modules. The first module used 26 sows (German Landrace crossed with Large White) bred artificially to Pietrain boars. During pregnancy the treated sows were given 125 mg L-carnitine/day and 250 mg L-carnitine/day during lactation. At birth, the number of piglets in the litter was standardized, and the piglets were suckled by their mothers for 28 days. In the second module, the litters were standardized at birth, and the piglets from the L-carnitine-treated sows were placed on control sows, and piglets from the control sows (no L-carnitine supplement) were placed on the treated sows. In module one, comparisons of treated and control sows showed that the sow body weights and the numbers and birth weight of piglets born were not significantly different. On study days 3, 6, and 9, the duration of sucking/day was significantly higher as were body weight gains for piglets born to sows administered L-carnitine. In module 2, comparisons of the body weights and number of live piglets born were not significantly different treatment and control sows. The piglets from the L-carnitine-treated sows had significantly increased sucking time on day 3 and greater weight gains in the first 14 days. These results show the effects of in utero exposure of piglets to L-carnitine and also suggest that the de novo synthesis of L-carnitine may not meet the demands of pregnancy. The effects of L-carnitine supplementation during pregnancy (125 mg L-carnitine/day) and lactation (250 mg/day) were studied in sows that were on a low protein and energy diet during lactation (Ramanau et al. 2005). Feed intake for treated and control sows and the number of piglets born alive and birth weights were not different between the L-carnitine and control sows. Litter gains for treated sows was significantly higher (20%) than control sows. The sows treated with L-carnitine produced 18% more milk than control sows, and the milk composition was not different between groups. Sows in both groups had a decrease in body weight; however, sows treated with L-carnitine retained more back fat.

6.4.2 Boars

A study in Pietrain boars showed that oral supplementation with L-carnitine improved semen quality (Jacyno et al. 2007). The boars, 1.5–2.0 years of age, were orally administered 500 mg of L-carnitine for 5 weeks. The boars were ejaculated once a week and the semen evaluated. Ejaculates from each boar collected before administration of L-carnitine were used as control values. Administration of L-carnitine significantly increased total semen volume (11%), the volume of sperm-rich fraction (10%), and total ejaculate sperm count (11.5%) and reduced the activity of asparagine aminotransferase (measure of spermatozoa membrane integrity, activity increases as membrane quality decreases). The effect was observed 1 week after administration of L-carnitine. The effects of dietary L-carnitine were studied in semen from mature (~2 years old) Hampshire × Pietrain cross boars (Cerovsky et al. 2009). The boars were given 2 g of L-carnitine/day in their diet for 8 weeks. None of the indices of semen quality were significantly improved. In a study, terminal line boars aged 285 days and 504 days were fed diets supplemented with 500 mg of L-carnitine for 16 weeks (Kozink et al. 2004). Supplementing the diet with L-carnitine did not improve the storability of chilled semen. A study on L-carnitine supplementation was done in Pietrain, Duroc, and Large White boars to determine its effects on semen parameters (Yeste et al. 2010). Boars were supplemented with 0 or 625 mg L-carnitine/day for 20 weeks and semen parameters evaluated. Photoperiod and temperature increased

[17] Stallion®, Pavo Pferdenahrung GmbH (Goch, Germany)

across the study period. Supplementing the Duroc and Large White boars did not improve ejaculate volume, sperm concentration, sperm motility, sperm viability, the osmotic resistance of spermatozoa, and sperm morphology. The authors considered increased temperature and photoperiod to be detrimental to sperm morphology (increased numbers of immature spermatozoa), and sperm morphology was improved in Pietrain boars by supplementing with L-carnitine.

6.5 Poultry

6.5.1 Roosters

Avian spermatozoa have higher concentrations of unsaturated fatty acids than mammalian spermatozoa. Lipid peroxidation products can be used to index avian semen quality. The effects of dietary L-carnitine on rooster semen have been studied. At 58 weeks of age, Leghorn roosters (mature) were fed a diet supplemented with 500 ppm L-carnitine for 5 weeks (Neuman et al. 2002). Compared to controls, L-carnitine did not change feed consumption or body weight. Circulating levels of esterified fatty acids and L-carnitine were increased. The numbers of spermatozoa in semen from birds fed L-carnitine significantly increased on experimental weeks 3 and 4, and lipid peroxidation/billion spermatozoa decreased. Semen volume, relative testicular weights (correct for body mass), and viability were not changed. This study was repeated starting with 32-week-old roosters (immature) and feeding treated birds a diet containing 500 ppm L-carnitine for 5 weeks. Significantly greater weight gains were observed in control birds, and feed consumption was not significantly different between treated and control groups. On the fourth week of the study, the treated birds had a significant increase in spermatozoa numbers. Young roosters treated with L-carnitine had significantly lower lipid peroxidation/billion sperm, a decline in percent dead spermatozoa, and significantly lower numbers of giant cells in the testicle. These finding suggest that L-carnitine reduces lipid peroxidation of spermatozoa and increases testicular efficiency for producing viable spermatozoa. Another study on L-carnitine, using three different age groups, was done in a university strain of White Leghorn roosters (Zhai et al. 2007). The first study fed a diet containing 0, 125, 250, and 500 ppm L-carnitine for 8 weeks to roosters starting at 46 weeks of age. The second study fed the same levels for 17 weeks, and the third study fed 0 or 125 ppm L-carnitine from hatch to 37 weeks of age. In the first study, feed consumption and sperm viability were not changed by dietary L-carnitine. Roosters consuming the diet containing 125 ppm L-carnitine had significantly increased sperm concentration. Semen volume among diets within sampling times was not changed. In the second study, feeding L-carnitine for 8 weeks did not affect feed consumption, body weight, semen volume, and sperm vitality. There was a trend for roosters consuming the 125 ppm L-carnitine diet to have increased seminal concentration of spermatozoa. In the third study, 18-day-old embryos were injected in ovo into the amniotic fluid with 0, 1, or 2 μMol of L-carnitine, and the percent hatching was unaffected by treatment (Zhai et al. 2008a). At hatching roosters from each of embryo treatments were placed on a diet containing 0 or 125 ppm L-carnitine for 37 weeks. At 17 weeks of age, there was no effect of the in ovo exposure to L-carnitine on semen volume and sperm concentration. Dietary L-carnitine did increase sperm concentration (10^9/mL) from 22 to 37 weeks of age and decreased body weight. There were no differences in semen volume.

6.5.2 Hens

Zhai et al. (2008a) showed that hens, exposed to 2 μMol of L-carnitine in ovo, laid heavier eggs with larger albumen and shell mass. Another study using fertile Ross x Ross cross-hatching eggs, the amniotic fluid was injected with 0.0, 2.0, or 8.0 mg L-carnitine and this treatment produced a trend for increased hatchability and increased length of incubation (Keralapurath et al. 2010). There were no differences in slaughter yields. Another study showed that hens on a diet containing 25 ppm L-carnitine for 16 weeks produced progeny with improved carcass traits (Kidd et al. 2005). Another study was done in fertile eggs from Ross 308 hens fed diets containing 0 or 25 ppm L-carnitine starting when the hens were 21 weeks of age (Peebles et al. 2007). Eggs were collected at weeks 25, 30, 32, and 38 and incubated. Administration of L-carnitine to hens did not decrease incubation mortalities or hatchability of total fertilized eggs, and there were no differences between the yolk, albumen, or shell weights of the eggs from treated and control hens. Supplementing the diet of hens with 125 ppm L-carnitine did not improve egg hatchability (Zhai et al. 2008b).

7 Nutraceuticals in Assisted Reproduction

7.1 Carnitine

7.1.1 Semen

The spermatozoa of water buffalo (*Bubalus* spp.), compared to cattle, are more susceptible to the negative effects of freezing and thawing. The addition of L-carnitine to the extender used in cryopreservation of water buffalo semen significantly improved motility and decreased capacitation-like damage of spermatozoa (Longobardi et al. 2017). Lisboa et al. (2012) found that adding L-carnitine and L-acetylcarnitine to skim milk-based extenders increased semen motility and plasma membrane integrity of chilled equine semen after 48 h of cooling (5 °C). There were no differences between the semen preparations containing

L-carnitine, L-acetylcarnitine, or both L-carnitine and L-acetylcarnitine. The benefits of adding carnitine, methionine, and inositol to bovine semen extender were studied in a freeze-thaw model (Bucak et al. 2010). The addition of carnitine and inositol at the 7.5 mMol levels improved post-thawing subjective motility. Methionine and carnitine at 2.5 and 7.5 mMol and inositol at 7.5 mMol decreased the percentage of total spermatozoa abnormalities. The computer-assisted sperm motility analysis (CASA) showed that total motility was improved by carnitine and inositol, and all of the additives decreased DNA damage. A study was done on L-carnitine and pyruvate to improve spermatozoa parameters adversely affected by chilling of stallion semen (Gibb et al. 2015). Semen was collected from Welch or crossbred pony stallions and prepared for storage (room temperature) with the addition of 10 mMol each of L-carnitine, pyruvate, or L-carnitine + pyruvate or without L-carnitine and pyruvate. The semen receiving the addition of L-carnitine and pyruvate maintained acceptable motility (>34%) for 72 h. Supplementing semen with L-carnitine significantly improved motility parameters and reduced oxidative stress. Pyruvate + L-carnitine further improved motility parameters. Poultry spermatozoa are susceptible to lipid peroxidation when cryopreserved. In a freeze-thaw study using semen from Green-legged Partridge chickens (Polish breed of domestic chicken), L-carnitine at 1 mMol and taurine at 1 and 10 mMol significantly increased mitochondrial potential of thawed spermatozoa (Partyka et al. 2017). L-Carnitine and taurine at 1 mMol also significantly reduced apoptosis and membrane reorganization.

7.1.2 Oocytes

In vitro maturation of oocytes has many incentives including cost savings. However, ROS reduces the productivity of in vitro maturation of oocytes. The arrested metaphase II oocytes may shift their metabolism toward using lipid substrates. In vitro matured porcine oocytes were co-incubated with spermatozoa using IVF media plus the addition of L-carnitine at 0, 3, 6, 12, or 24 mMol (Lowe et al. 2017). Blastocyst formation was not decreased with the addition of 3 mMol L-carnitine. Oocytes or spermatozoa were incubated for 1 h with 3 mMol L-carnitine for pre-fertilization for ova or sperm, respectively, or for the first 30 min of in vitro fertilization or the first 5.5 h of in vitro fertilization. The cleavage rate was significantly higher for 1 h pre-fertilization incubation of oocytes and spermatozoa. The blastocysts were vitrified and thawed. The post-warming survival of the blastocysts was increased for the oocytes pre-incubated with 3 mMol L-carnitine. One-hour incubations of oocyte with L-carnitine added to the medium did not significantly change the percentages of sperm-penetrated, fertilized oocytes and pronucleus formation but did significantly increase the cleavage rate of the oocytes. Adding at 0.5 mg L-carnitine/mL to fluids used to mature camel oocytes increased the rate of maturation and fertilization (Fathi and El-Shahat 2017). The rate of embryo development (morula and blastocyst) was increased. The addition of L-carnitine to culture media at 0, 0.3, 0.6, and 1.2 mg/mL was investigated in bovine oocytes (Phongnimitr et al. 2013). Supplementation of the medium with 0.6 mg/mL of L-carnitine significantly improved the survival of blastocysts. The addition of 0.3 and 0.6 mg of L-carnitine to the culture media significantly improved the maturation rate, and the addition of 1.2 mg of L-carnitine significantly decreased the maturation rate. Supplementation of the in vitro maturation fluid for bovine oocytes improved the nuclear maturation and embryo development after in vitro fertilization. However, the addition of L-carnitine did not improve embryo development after vitrification. A study on the effects of L-carnitine on in vitro maturation of bovine oocytes showed that the overall effect of adding L-carnitine to the incubation medium was beneficial (Knitlova et al. 2017). Addition of L-carnitine to incubation medium for the meiotically less competent oocytes showed significantly higher fertilization rates than the control meiotically less competent oocytes. L-Carnitine addition to incubation fluid improved blastocyst yield on days 7 and 8 in oocytes classified as meiotically more competent. A study on L-acetylcarnitine in laboratory matured ovine oocytes to determine the effects on blastocyst rate and effects on intracellular organelles and lipid droplets (Reader et al. 2015). The oocytes were matured in media containing 0.0 or 2.0 mMol L-acetylcarnitine and then fertilized with thawed ram semen in IVF media. The addition of L-acetylcarnitine significantly doubled the blastocyst rate. In the in vitro matured oocytes, there was no difference in mitochondrial volume, numbers of mitochondria, and mitochondrial copy number. L-Acetylcarnitine did increase cytoplasmic volume, causing a trend for increasing vesicle volume and altered distribution of lipid droplets. A study in ovine embryos investigated the effects of L-carnitine at 3.72 mMol to vitrification and warming solutions (Saraiva et al. 2018). Parameters in the study were mortality; cell numbers; autoptic cells and apoptotic index; gene expression for carnitine palmitoyltransferase I and II, carnitine O-acetyltransferase, and peroxiredoxin-1; and levels of ROS. None of these parameters were altered by the addition of L-carnitine.

8 Coconut (*Cocos nucifera* L.)

Coconut water is used as semen extender and as a medium for embryo freezing. An important incentive for using plant-source semen extenders is the likelihood of regulators removing some disease-linked import restrictions on semen. Coconut water-based media compared to media without coconut

water were shown to be a suitable holding solution for bovine immature cumulus-oocyte cell complexes (Cordeiro et al. 2006). Coconut water was investigated as a medium and as an additive to minimum essential media for caprine primordial follicles and was not found to improve survival or follicular diameters (Martins et al. 2005). The effect of a proprietary[18] coconut water extender (sold as a powder) on the fertility of frozen-thawed dog semen was determined (Uchoa et al. 2012a). Following artificial insemination, a 60% conception rate, 50% parturition rate, and a mean birth rate of 3.4 ± 0.6 puppies were reported. A proprietary coconut water extender was used to dilute fresh stored (chilled) dog semen (Uchoa et al. 2012b). Semen was collected, extended with Tris-egg yolk or the proprietary coconut water extender, cooled to 5 °C for 6 h, and then warmed to 37 °C for 30 s and the bitches were inseminated. For semen parameters, there was no significant difference between extenders. All of the bitches inseminated by a stud dog conceived (20/20) verses 18/20 pregnancies for bitches bred by artificial insemination. There were no significant differences for liter size, and the bitches inseminated with semen extended with proprietary coconut water extender gave birth to significantly higher percentage of female puppies. In another study, coconut water-based semen extender was examined for canine semen (Cardoso et al. 2006). The coconut water from green coconuts was filtered. Coconut extender formula was 50% coconut water, 25% ultrapure water, and 25% sodium citrate, and the control extender was an egg yolk extender. Diluted semen was frozen and stored in at –196 °C for 1 week and thawed at 37 °C and semen parameters evaluated. There was no difference between coconut water extender and the egg yolk extender for the semen parameters evaluated. The effects of coconut water on improving the post-thawing parameters were studied in boar semen (Bottini-Luzardo et al. 2013). The treatment groups were using different extender recipes: Group 1, bidistilled water, lactose, and egg yolk; Group 2, bidistilled water, lactose, and egg yolk glycerol and Orvus ET paste (a surfactant); Group 3, coconut deionized water, lactose, and egg yolk; and Group 4, in natura coconut water, lactose, and egg yolk. Coconut water added to the recipes were filtered coconut water without modifications (in natura) and filtered coconut water deionized to remove excess calcium ions. Parameters to evaluate the spermatozoa were motility, acrosomal integrity, membrane integrity, and mitochondrial activity. The semen was evaluated at thawing and 30 and 60 min after thawing. The addition of deionized coconut water significantly improved the post-thawing parameters for boar semen, and the addition of filtered in natura coconut water significantly reduced the post-thawing parameters for boar semen. Reconstituted coconut water from powdered coconut water[19] was studied as a freezing solution for cryopreserved boar semen (Silva et al. 2015). This freeze-thaw study showed that reconstituted coconut water plus dimethylformamide freezing solution produced the highest-quality spermatozoa. The study used an automated cooling control curve for cooling and freezing the semen. Coconut water has been studied as an extender for equine semen (London et al. 2017). Semen extenders used were coconut water, coconut water with a proprietary antioxidant,[20] egg yolk extender, and egg yolk extender with proprietary antioxidant. The diluted semen was frozen and stored in liquid nitrogen (–196 °C). No significant difference in the post-thawing semen parameters were shown between the semen extenders. Virgin coconut oil[21] (VCO) was studied as an additive for chilled and frozen-thawed semen from Brangus-Simmental bulls (Tarig et al. 2017). The semen was diluted with 8% VCO in Tris extender which contained different concentrations 0% (control), 4%, 8%, 12%, 16%, and 20% egg yolk. Semen chilled at 4 °C was evaluated at 24, 72, and 144 h. Frozen semen was thawed and evaluated at 7 and 14 days. For both preservation methods, semen parameters were significantly improved for 8% VCO and 20% egg yolk.

9 Quercetin

Quercetin [2-(3,4-dihydroxyphenyl)-3,5,7-trihydroxychromen-4-one] has been studied as additive to semen extenders and as a testicular protectant. A study in semen from Holstein bulls showed that the addition of quercetin (25, 50, 100, and 200 μg/mL) to extended bull semen significantly improved the tail length, tail DNA, and tail movement (Avdatek et al. 2018). The addition of quercetin and dimethylacetamide to Mahabadi goat semen improved the post-thawing motion kinetics and suppressed lipid peroxidation (Seifi-Jamadi et al. 2017). Quercetin (0.15 mMol) added to sex-sorted and unsorted cryopreserved stallion semen improved post-thaw motility and zona binding ability and reduced DNA fragmentation (Gibb et al. 2013). There were no effects on the motility, acrosome integrity, or viability of sex-sorted spermatozoa. Rats administered 50 mg quercetin/kg body weight/day for 70 days concurrent with 20 mg fenitrothion (pesticide)/kg body weight ameliorated the testicular toxicity of fenitrothion (Saber et al. 2016).

10 Vitamins and Selenium (Se)

10.1 Background Chemistry

Vitamin E is an antioxidant and is referred to as a radical formation chain breaker because it breaks the cascading propagation of free radical formation (Burton and Ingold 1981). Vitamin E exist in eight analogs (α-, β-, γ-, and δ-tocopherols and α-, β-, γ-, and δ-tocotrienols), and they all have antioxidant activity (Zingg 2015). The vitamin E molecule is irreversibly chemically altered when it reacts as an antioxidant, and the reactive site is the hydroxyl on the chromane moiety. The differences between the vitamin E analogs in their in vivo activity may be analog-specific antioxidant activities, their specific interactions with enzymes, structural proteins, alterations of the physical-structural properties of membrane lipids, enrichment kinetics, and differences in biotransformation products. The α-tocopherol (α-T) form has different kinetics which includes selectively being enriched in mammals by specific proteins that have expression polymorphism between individuals. Vitamin E is absorbed by small intestinal enterocytes from micelles by scavenger receptor class BI and CD36 and exported by assemblage into chylomicrons. α-T is 50 times higher in plasma than the other seven analogs. Important in this enrichment process is the α-T-transport protein, and this transporter also enriches the levels of hepatic α-T. Vitamin E modulates signal transduction of enzymes (reviewed by Zingg 2015). These mechanisms include modulation of signal transduction enzymes by direct binding or altering their redox regulation. Vitamin E, in membranes, may alter signal transduction by counteracting lipid oxidation and, in modulation, by employing different mechanisms and alter lipid raft domains. Vitamin E can compete for lipid mediator binding sites on lipid transport proteins and thereby modulate transport traffic, enzymatic activity, and signaling functions. A common theme for vitamin E activity is enzyme-membrane interaction that modulates or otherwise affects signal transduction and gene expression.

10.2 Vitamin E in Reproduction

Studies have shown that supplementation with vitamin E improves reproductive parameters and excessive vitamin E maybe harmful. In a Japanese study, cows with stillbirths had significantly higher vitamin E and significantly lower levels of vitamin A and Se (Uematsu et al. 2016). No evidence of viral diseases (Akabane, Aino, Chuzan, Peaton, D'Aguilar, Shamonda, BVDV, Parainfluenza 3 virus, and Bovine-Herpesvirus-1) was found. A study in dairy cows showed that administration of vitamin E (DL-α-tocopherol) decreased retained fetal membranes and stillbirths (Pontes et al. 2015). The treated cows were administered 1000 IU of DL-α-tocopherol on days 19.2 ± 4.3, 12.9 ± 3.3, and 6.2 ± 2.9 days before calving. The cows administered vitamin E also had improved nonreturn first service and subsequent decreased pregnancy loss. The diet of Aohan fine-wool rams was supplemented with 0, 20, 200, 1000, or 2400 IU vitamin E/sheep/day for 12 months, and behavior, semen, and testicular parameters were measured (Yue et al. 2010). Supplementing the diet with 200 IU of vitamin E significantly increased libido and total sperm output and increased the activity of superoxide dismutase and glutathione peroxidase in testicular cell membrane. Supplementing with 20 and 200 IU of vitamin E increased sperm motility. All of the rams supplemented with vitamin E had, compared to control rams, had decreased testicular mitochondrial malondialdehyde, and the mitochondrial malondialdehyde in the group supplemented with 200 IU vitamin E was significantly lower than the other treated groups. Vitamin E at 2400 IU increased abnormal spermatozoa. A study in male ferrets (*Mustela nigripes*) showed, for semen parameters, dietary interactions between meat source (beef, horse meat, and whole prey) and vitamin E (Santymire et al. 2015). The daily diets were control horse meat diet, horsemeat supplemented with vitamin E at 400 IU/kg dry matter, horsemeat + whole prey, horsemeat diet + vitamin E daily + whole prey, or beef diet. Diets and blood were assayed for vitamins A and E and Se. Electroejaculates were collected monthly and evaluated for concentration of spermatozoa, morphology, and sperm motility index. Vitamin A in the horsemeat diet was 150% higher than label specification, and the beef diet contained 20% of the label specification for vitamin A. Supplementation with vitamin E increased blood levels of vitamin E. Ferrets fed beef, compared to ferrets fed horse meat, had significantly higher sperm concentration. Ferrets fed beef or horse meat + prey + vitamin E had the largest testicles, and feeding prey tended to increase sperm motility index, testicular size, and percentages of normal acrosomes. Overall, diets did not affect semen volume and percent normal acrosomes. Supplementing with vitamin E tended toward fewer normal spermatozoa. Mating successes and the number of kits born were not influenced by diet. This study shows that diet and the interactions with supplements can have an effect on semen parameters. This study also provides evidence that wild carnivores in habitats with limited dietary choices could have dietary impacts in reproduction. Semen from dogs does not have good post-storage scores. This is generally attributed to the formation of free radicals due to oxidation of fatty acids in the spermatozoa and subsequent disruption of the cell membrane. Stud dogs, in a randomized double-blind study with each dog serving as its own control, were supplemented with vitamin E and selenium (Kirchhoff et al. 2017). Studs of known fertility and normospermia were selected for the study. They were fed a basal diet (control) or a basal diet and randomly assigned to a

group receiving 0.1 mg/Se/dog/day, 100 mg vitamin E/dog/day, or 100 mg vitamin E and 0.1 mg Se/dog/day. The volume of the sperm-rich fraction did not differ between groups. Treatments with vitamin E and selenium reduced the number of sperm-head defects. No other semen parameters were improved.

11 Ancillary Nutraceuticals

Various algae cultures and extracts have been reported to improve reproduction in domestic animals. Boars were given 1.5 mL of *Spirulina platensis* extract/day for 5 or 10 days (Granaci 2007). The author concluded that the *Spirulina* extract increased ejaculate volume, motility, farrowing rate, and number of piglets born. No other reports on *Spirulina* extract in pigs were found. Pen restrained ram lambs were fed a diet supplemented with dried grape pomace (from wine making, *Vitis* spp.) at 0, 5, and 10% of dietary dry matter for 74 days and testicular parameters measured (Zhao et al. 2017). This study investigated offsetting effects of grape seed pomace on the negative effects of restraint effects on testicular size from pen-rearing rams. After feeding grape pomace, the rams were euthanized and the testicles removed. Feeding grape pomace reduces testicular ROS and malondialdehyde and increased testicular weights and testicular length. Evaluation of spermatozoa isolated from the epididymis showed that feeding grape pomace at 10% of dry matter significantly increased spermatozoa numbers by 10% and decreased sperm deformities. Grape pomace at the 10% level significantly increased motility and testicular gene expression of superoxide dismutase. Supplementing the diet of mares with 100 g L-arginine/mare/day for 17 days did not increase the recovery of embryos (Kelley et al. 2014). The mares had spontaneous ovulations and artificial inseminations. Carotenoid terpenoids are found in feedstuffs and added to animal feeds to improve reproduction, reduce oxidative stress, and prevent deficiencies. Deficiencies in vitamin A are known to cause reproductive dysfunctions and other health issues. β-carotene is a precursor for the synthesis of vitamin A. The levels of natural β-carotene in feedstuffs are difficult to predict, and nutritionist recommend that the daily requirements of vitamin A be added to the ration. A 2-year study in Swedish Holsteins cows showed that lactating dairy cows kept under organic farming methods without supplementation of vitamins A and E did not report an increase in occurrences of infertility (Johansson et al. 2014). Italian trotting mares on grass hay and grain supplement were studied peripartum for the effects of a β-carotene[22] supplement on reproduction parameters (Trombetta et al. 2010). Immediately following birthing, the mares were supplemented with 1 g β-carotene/mare for 15 days. In control mares, β-carotene was decreased for 5 days and then stabilized, whereas β-carotene along with vitamin A was increased in the treated mares. Estradiol was significantly increased by β-carotene treatment. There was a suggestion that the parturition to ovulation interval was shortened. In another study, mares were supplemented with 1 g β-carotene[23]/day for 56 days, starting 2 weeks before parturition (Kuhl et al. 2012). β-carotene was excreted in the milk, especially in the colostrum. Mares were bred on the first postpartum heat (foal heat), and 7/7 of the control mares conceived and 5/12 of the β-carotene-supplemented mares conceived. The effects of carotenoids from *Haematococcus pluvialis* microalgae on performance parameters were studied in mink (Korhonen and Huuki 2015). The body weight of the mothers was significantly higher in the females fed the carotenoids from *H. pluvialis*, but the number of kits whelped/female was not increased. The number of barren females was higher in the control group (16 vs. 13) as was the 46-day kit losses (40 vs. 26).

The YiShenJianPi recipe for traditional Chinese medicine has been shown to improve tripterygium glucoside-induced oligoasthenozoospermia in BALB/c mice (Sheng et al. 2017). The decoction was made from the YiShenJianPi recipe which contains 30 g *Cuscuta chinensis* seeds, 30 g *Lycium* spp. fruit, 30 g *Schisandra* spp. fruit, 10 g *Codonopsis pilosula* root, 10 g *Astragalus membranaceus* root (unprocessed), 10 g *Citrus reticulata* skin (dry), 6 g *Bupleurum* spp., 6 g *Cimicifuga foetida* rhizomes, 6 g *Ligusticum chuanxiong* rhizomes, and 6 g *Carthamus tinctorius* flowers. The mice were given tripterygium glucoside orally at a dose of 40 mg/kg body weight for 4 weeks to induce oligoasthenozoospermia. The tripterygium glucosides, from *Tripterygium wilfordii* Hook F. (thunder god vine), have been shown to induce infertility in men and rats (Qian 1987) and are prescribed for arthritis. The doses of YiShenJianPi recipe decoction were 1.35 mg/kg/day and 2.70 mg/kg/day for 4 weeks. The mice receiving the low dose of the YiShenJianPi recipe plus the tripterygium glucoside had improved spermatogenesis and mitochondrial function in spermatozoa.

12 Urinary Diseases

12.1 Background

Urinary tract infections occur when virulent organisms multiply and persist in the urinary tract and cause pathological and pathophysiological issues. Urinary tract infection is associated with breaches in the innate and adaptive

[22] Rovimix® containing 10% β-carotene 10%, Istituto delle Vitamine SpA (Milano, Italy)

[23] Blattiviko beta 8000, Blattin Mineralfutterwerk (Seitschen, Germany)

components of the immune system and is also a complication associated with anatomical and neurological pathologies. Urinary infections, especially in older animals, develop a history of reoccurrence (Raditic 2015). Although the molecular mechanisms that lead to chronic urinary infections are not completely understood, oxidative stress is being identified as one of the "cornerstones" for causation (Ratliff et al. 2016). As the importance of oxidative stress in renal disease becomes better understood, the interest in and use of functional foods and nutraceuticals are increasing. The recurrence of urinary tract infections and uroliths, and resistance of microorganisms to antimicrobial chemotherapeutics, is increasing the use of nutraceuticals in veterinary and human medicine. Infections can be ascending or localized to a specific site such as the urinary bladder or the renal pelvis. Antimicrobial pharmaceuticals are usually effective in treating urinary tract infections, but recurrences following the therapeutic regimen are common. Antibiotics also disrupt the corpus microbiome. *Escherichia coli* accounts for about 50% of the urinary infections in cats and dogs. The type 1 fimbriae of *E. coli* and other *Enterobacteriaceae* that cause urinary tract infections adhere to the mannose sugar residue in mucous and cell membranes. The adherence is enabling for infection to be established and spread. Uroliths are a common urinary disease in companion animal medicine. Infections, especially organisms that are urease positive, can increase the occurrence of struvite crystals (Gomes et al. 2018). The formation of uroliths generally consists of distinct stages. These are supersaturation, nucleation, growth, aggregation, and retention. Calcium oxalate uroliths are precipitated calcium oxalate with the oxalate being from dietary and metabolic sources. There is increasing evidence that the microbiome can affect the incidence of uroliths (Mehta et al. 2016). The finding in human medicine suggests that oxalate uroliths are associated with a microbiome that has decreased oxalate-degrading microorganisms. Nutraceuticals are being studied for their prophylactic effects on preventing kidney damage linked to oxidative stress. Ethanol and petroleum ether extracts of avocado (*Persea americana*), walnut (*Persea americana*), flaxseed (*Linum usitatissimum*), and arugula (*Eruca sativa*; syns. *E. vesicaria* subsp. *sativa*) were shown to protect rats from the toxic effects of cisplatin (Al-Okbi et al. 2014). Each group of rats was orally administered the plant seed extracts at 250 mg/kg body weight for 20 days and then administered 7.5 mg cisplatin/kg body weight. Administration of the nutraceutical extracts reduced plasma malondialdehyde levels (measure of lipid peroxidation) in the rats treated with cisplatin. Pretreatment with the extracts significantly decreased chromosome aberrations compared to the group administered cisplatin only. Histopathology comparison of the control rats (no nutraceutical or cisplatin), cisplatin by itself, and nutraceutical plus cisplatin showed that the arugula extracts (*E. sativa*) provided 70% protection and flaxseed extracts 50% protection against the nephrotoxic effects of cisplatin. In veterinary and human medicine, a diet high in fruits and vegetables has been shown to be protective against kidney disease (Hall et al. 2016; Manfredini et al. 2016).

12.2 Fruits

A diet high in fruits and vegetables has been shown in veterinary and human medicine to be protective against kidney disease (Hall et al. 2016; Manfredini et al. 2016). The increased excretion of citrates and malates are beneficial in reducing the occurrence and recurrence of uroliths.

12.2.1 Cranberry (*Vaccinium* spp.) and Pears (*Pyrus* spp.)

Whole cranberries (*Vaccinium macrocarpon* Aiton, *V. oxycoccos*, and *V. vitis-idaea*) and cranberry juice have been used for hundreds of years as remedies for urinary health issues (Davidson et al. 2014, Anon 2016; Zhao et al. 2018). The levels and chemical profile of type A proanthocyanidins and the efficacy of cranberry-source products all vary with the *Vaccinium* spp. and growing conditions. Cranberry extracts are produced by various methods. There is evidence to show that proanthocyanidin group of phytochemicals in cranberries blocks the adhesion of bacterial types 1 and 2 fimbria to the mannose moiety in urinary tract cells and mucous (Abascal and Yarnell 2008). Cranberry juice also reduces the formation of urinary biofilms. A study, using a small number of animals in client-owned dogs with a history of greater than three recurrent urinary tract infections, showed that oral administration of cranberry extract[24] prevented the development of urinary tract infections. The in vitro portion of this study also showed that the urine from dogs receiving cranberry extract prevented adherence of *Escherichia coli* to Madin-Darby canine kidney cells (Chou et al. 2016). The urine from the cranberry extract treated dogs did not have bacteriostatic activity. The concentrations of proanthocyanidin phytochemicals (polyphenol flavonoids) in the cranberry extract were not reported. Pears are being recommended in human medicine as a prophylactic for uroliths (Manfredini et al. 2016). The organic acids in pears are likely important in the prevention of uroliths. Pears contain antioxidant and anti-inflammatory compounds (Li et al. 2012). The antioxidant compounds are the polyphenols, namely, arbutin, catechin, chlorogenic acid, quercetin, and rutin. The anthocyanins levels were correlated with antioxidant activity, and triterpenoids are strongly correlated to anti-inflammatory activity. No reports in the veterinary literature were found for

[24] Cranimals (West Vancouver, BC, Canada)

the use of pear or its extracts being prescribed as a prophylactic or for treatment of uroliths.

12.3 Herbal Remedies

Goldenseal (*Hydrastis canadensis* L.) contains berberine which has antibacterial properties and is used for cystitis in human medicine (Abascal and Yarnell 2008). It has efficacy for the treatment of infections stemming from *E. coli*. Goldenseal is also used as an ethnotherapeutic to treat canine and feline uterine infections in traditional medicine in British Columbia, Canada (Lans et al. 2009). Berberine in goldenseal blocks fimbriae expression of *E. coli* and adhesion of *Streptococcus pyogenes* to epithelial cells. Buchu Berg. (syn. *Barosma betulina* Bartl.) has historical usage for urinary infections and calculi, and the extracts have antibiotic activity (Abascal and Yarnell 2008; Moolla and Viljoen 2008). High doses cause hepatotoxicity in rats. There appears to be no reports of its use in veterinary medicine. Ethanol extract of *Poria cocos* Wolf. (syn. *Wolfiporia extensa* Peck.) was studied in rats using an adenine-induced renal failure model (Zhao et al. 2013). Concurrent with the adenine treatment, one group of mice was administered 60 mg of the dried *Poria cocos* extract (reconstituted in 1 mL). The authors concluded that ten of the biomarkers studied in a metabonomic profile showed that *Poria cocos* extract was protective to the kidney. Extracts of the epidermis of *Poria cocos* sclerotia were tested in rats for diuretic activity (Feng et al. 2013). The ethyl acetate extract had the most diuretic activity and increased the excretion of sodium and chlorine ions. The ethyl acetate extracts (epidermis of *Poria cocos* sclerotia) were further characterized chemically and studied in vitro in HK-2 cultures for inhibition of fibrosis (Wang et al. 2018). The triterpenes, identified as PZG and PZH, inhibited the upregulation of collagen I expression and podocyte injury. Ethanol extract of *Poria cocos* has antifungal (*A. fumigatus*, *C. albicans*) and antibacterial (*Acinetobacter baumannii*, *S. aureus*) activity (Zhang et al. 2013). An extract containing triterpenes, polysaccharides, and steroids from *Poria cocos* has been tested in vivo for its antioxidant activity and prevention of renal cell injury linked to urolithiasis (Schulman et al. 2016). The authors concluded this extract is a candidate prophylactic for urolithiasis. Raspberry (*Rubus idaeus* L.) has been reported to be effective in human medicine as treatment and prophylactic for uroliths. In Chinese traditional medicine, raspberry fruit is considered a cure for renal disease, and raspberry leaf is considered a mild diuretic. Using a glyoxylate-induced calcium oxalate nephrolithiasis in mice model, the efficacy of raspberry root extract was investigated (Ghalayini et al. 2011). The mice were administered 100 or 200 mg/kg/day of raspberry root extract for 12 days. The kidneys were examined by histopathology and the kidneys analyzed for calcium. The treatment with raspberry root extract reduced calcium oxalate deposits in the kidneys of mice receiving glyoxylate. The renal weights of kidneys from mice receiving glyoxylate were significantly higher from mice receiving glyoxylate plus raspberry root extract. Calcium levels in kidneys from the mice receiving glyoxylate plus raspberry root extract were not significantly different from control mice (no glyoxylate or raspberry root extract treatment). A study in rats using hot water and hot methanol extracts from air-dried wild raspberry fruit had a potassium-conservative diuretic effect (Zhang et al. 2011). The decoctions were dried, and the rats were given the extracts at 3 g/kg body weight, hydrochlorothiazide was administered as a reference standard, and control rats were administered 10 mL of water/kg body weight. The rats administered hydrochlorothiazide had the highest urinary output followed by the rats receiving the methanol extract of wild *Rubus idaeus* fruit. The extracts from cultivated raspberry fruit did not have diuretic properties. Both water and solvent extracts of *Rubus rosaefolius* Sm. leaves have diuretic properties in rats (de Souza et al. 2017). Its folk medical use is to treat hypotension. *Rubus idaeus* does not appear to have use in veterinary medicine for urinary maladies other than in traditional Chinese medicine applied to veterinary medicine. Quercetin is bioflavonoid and is the most abundant polyphenol in fruits and vegetables. It is present as a glycoside in eaten plant material and as the aglycone in supplements and is important in the pharmacokinetics of absorption. Common fruits that contain quercetin are apples, cranberries, cherries, and grapes, and vegetables containing quercetin are onion, peppers, and asparagus. High doses of quercetin (over 1 g/day) may be harmful to preexisting kidney damage. Quercetin may be a promoter of estrogen-dependent neoplastic cells. The pharmacokinetics and toxicology of quercetin have recently been reviewed (Andres et al. 2018). It is considered a candidate drug for renal disease in companion animal and human medicine (Pollen 2001; Nirumand et al. 2018). Concurrent administration of quercetin has been shown to reduce the renal toxicity of ciprofloxacin in rats (Elbe et al. 2016).

12.4 Lipoic Acid

Naturally occurring lipoic acid exists as lipoyllysine and is synthesized de novo in mammalian cells. α-Lipoic acid [(*R*)-5-(1,2-dithiolan-3-yl) pentaenoic acid] is a nutraceutical used as a mitochondrial nutrient, as an antioxidant, and as an equalizer for geriatric-linked decrease in the activity of pyruvate dehydrogenase. The α-lipoic acid molecule is a disulfide derivative of octanoic acid and in the oxidized form has an intermolecular disulfide bond. The 1,2-dithiolate ring is reactive with redox-sensitive molecules. Cells reduce α-lipoic

acid to dihydrolipoic acid and both forms are present extracellularly. Molecule per molecule, α-lipoic acid is more reactive than glutathione and *N*-acetylcysteine (Zhang and McCullough 2016). α-Lipoic acid is amphipathic and is soluble in both the aqueous and lipid environments. Symmetric dimethylarginine is being recognized in veterinary medicine as a biomarker of renal function and an endogenous marker chemical for calculating glomerular filtration rate. Having more sensitive biomarkers available provides sensitive parameters for evaluation of the efficacy of nutraceuticals prescribed as kidney protectorates. The dose of DL-α-lipoic acid ranges from 2.5 to 25 mg/kg/day in dog foods. Extruded dog foods have lower bioavailability of DL-α-lipoic acid (Zicker et al. 2010). There are reports of intoxications by DL-α-lipoic acid in cats and dogs (Hill et al. 2004; Loftin and Herold 2009). Observed toxic doses in dogs are 191–210 mg DL-α-lipoic acid/kg body weight for dogs. Dose levels of 30–60 mg DL-α-lipoic acid/kg body weight are toxic to cats with a dose of 60 mg/kg body weight causing fatalities in cats. A dog ingested an estimated dose of 210 mg DL–αlipoic acid/kg body weight and was presented for veterinary care 60 h later. The clinical observations were hyperesthesia, hypoglycemia, acute hepatic insult, and oliguric renal failure. The dog was euthanized 76 h following ingestion. Treatment in dogs is symptomatic including aggressive treatment of hypoglycemia. Although used, the efficacy of *S*-adenosyl methionine, *N*-acetylcysteine, and silymarin for treatment of DL-α-lipoic acid intoxication in dogs has not been reported. A dog, after ingesting 191 mg DL-α-lipoic acid/kg body weight, was hospitalized and treated symptomatically. It was discharged 4 days later with meds and 4 months later was reported by the owner as asymptomatic. The toxicology of DL-α-lipoic acid has been studied in detail in cats with cats shown to be ten times more sensitive than humans, dogs, or rats. A dose of 30 mg DL-α-lipoic acid/kg body weight is toxic to cats, and a dose of 60 mg/kg can be fatal. The calculated maximum tolerated single oral dose for cats is 13 mg DL-α-lipoic acid/kg body weight. In cats, clinical signs of intoxication include ptyalism, hyperesthesia, and some degree of anorexia. There does not appear to be any distinct gross lesions for DL-α-lipoic acid intoxication. Hepatic histopathology observed in cats is swollen, granular to vesicular cytoplasm, loss of distinct sinusoidal linings, and lack of lipid or glycogen stores in the centrilobular regions of the liver. Histopathology observed by ultrastructural microscopy is expanded space of Disse, loss and disruption of hepatocyte sinusoidal microvilli, disruption of junctional complexes and bile canaliculi, and loss of glycogen stores. In the cell, DL–αlipoic acid is enzymatically transformed to dihydrolipoic acid by glutathione reductase, lipoamide dehydrogenase, and thioredoxin reductase. Dihydrolipoic acid is excreted from cells and then reoxidized or metabolized. Cell culture research has shown dihydrolipoic acid to be a trigger causing a caspase 3 cascade in mitochondria leading to apoptosis.

12.5 Mannose and Methionine

Bacteria, to infect epithelial cells, need to adhere before infiltrating the cells. Some bacteria have specific virulence factors for adherence to uroepithelium. Uropathogenic *E. coli* has adhesin lectin fimbriae H virulence factor that enables the bacteria to adhere to the oligomannosides of the glycoprotein uroplakin Ia on the uroepithelium. D-mannose has been shown to be effective in reducing the recurrence of urinary tract infections in women. An in vitro study showed that D-mannose reduced the adherence of the equine pathogens *E. coli*, *Pseudomonas aeruginosa*, and *Streptococcus zooepidemicus* to equine endometrial cells (King et al. 2000). There are reports of successful use of D-mannose to treat primary and recurrent urinary tract infections in horses, dogs, and cats. The reported side effect is diarrhea. D,L-methionine had been reported as a treatment for infection-linked struvite uroliths in dogs (Raditic 2015). The dose used was 100 mg D,L-methionine/kg body weight every 12 h for up to 4 months.

13 Nutraceutical Recipes and Candidate Nutraceuticals

Herbal remedies and probiotics are used in the treatment of urolithiasis. A desired efficacy of herbal supplements is to dissolve and prevent the recurrence of the uroliths and be efficacious as a treatment and prophylactic for urinary cystitis. CrystalClair[25], a new product based on the Pai Shi Tang formula of traditional Chinese medicine, was developed to treat urolithiasis in dogs and cats (Wen and Johnston 2012). Four to 60 weeks of treatment with 33.3 mg CrystalClair/kg body weight was effective in dissolving uroliths in 19/33 dogs and 7/13 cats. Treatment was effective in 2/8 dogs with calcium oxalate uroliths. This preparation is recommended as a prophylactic in dogs and cats with known history of urolithiasis. No side effects were reported. *Poria cocos* mushroom (Fu-Ling) has been used in traditional Chinese medicines as an ingredient in remedies for renal disorders. This mushroom, considered a candidate nutraceutical for veterinary medicine, grows around pine trees and contains triterpenoids (poriatin), polysaccharides, and steroids. Canephron N[26] is a nutraceutical produced in Germany used for the inflammation of the urinary tract and urolithiasis and as antispasmodic and antibacterial (Naber 2013). The ingredients are centaury (*Centaurium erythraea* Rafn.), lovage (*Levisticum officinale* Koch.), and rosemary

[25] CrystalClair, Natural Solutions, (Speonk, NY). Contains: abutilon, vaccaria, plantain seeds, lygodium, pyrrosia leaf, achyranthes, alisma, lindera, licorice, glechoma, phellodendron, eupolyphaga, earthworm, scorpion, centipede. http://www.naturalsolutionsvet.com/product.html?pid=81

[26] Bionorica SE (Neumarkt, Germany)

(*Rosmarinus officinalis* L.). These plants contain flavonoids, phenolic glycosides, phthalides, secoiridoids, phenolcarboxylic acids, and essential oils. There is one report of liver dysfunction associated with Canephron N (Sychev et al. 2011). In this occurrence, concurrent medications with Canephron N were risperidone and clomipramine, and the Naranjo scale[27] was defined as probable. The conclusion is this Canephron N has benefit and is safe. No reports were found on its use in veterinary medicine. A study was done of the toxicology of *C. erythraea* in mice and rats (Tahraoui et al. 2010). *C. erythraea* plants were harvested in north Morocco during May and June. The plants were air-dried, milled, and extracted with water. Mice were given 1–15 g of extract/kg body weight and no adverse effects were observed. Rats were orally administered 0, 100, 600, and 1200 mg of extract/kg body weight for 90 days. All the hematological parameters except mean corpuscular volume were not significantly different from controls. Liver and urinary parameters were not significantly changed, and in the 600 and 1200 mg/day groups, blood glucose and triglycerides were significantly decreased. *C. erythraea* may be a candidate nutraceutical for use in veterinary medicine. A crossover-designed study on herbal recipes Alisma, San Ren Tang, and Wei Ling Tang in healthy, spayed female cats on treatment and off treatment did not show any differences in urinary parameters (Daniels et al. 2017). Parameters measured were 24 h urinary analyte excretions, 24 h urine volume, urine pH, and 24 h urinary saturation for calcium oxalate or struvite. A canine diet[28] containing fish oil, lipoic acid, vitamins C and E, L-carnitine, fruits, vegetables, and egg and chicken proteins, formulated to control sodium intake and provide protein with a high biological value, was shown to improve renal function in aging dogs (Hall et al. 2016). Renal function was indexed on serum symmetric dimethylarginine and creatinine.

14 Probiotics

The probiotics are being explored in human and veterinary medicine as prophylactic to reduce the risk and recurrence of genitourinary disease. There is substantial interest in the total corpus microbiome and its interactions in chronic urogenital diseases. Oxalate-containing uroliths are difficult to dissolve with various therapies and generally have to be removed by mechanical and surgical procedures. Oxalate is absorbed in all segments of the small intestine, and there is evidence that a large amount of oxalate is absorbed in the large intestine (Peck et al. 2016). Focusing on the gut microbiome, *Oxalobacter formigenes* in the large intestine can induce oxalate secretion by the enterocytes into the lumen where it is metabolized by gut microbes (Miller and Dearing 2013). Oxalate-degrading bacteria, such as *O. formigenes*, *Bifidobacterium* spp., *Porphyromonas gingivalis*, and *Bacillus* spp., degrade oxalate in the gut (Peck et al. 2016). The colon has the ability to regulate absorption and secretion of oxalate and has a major influence on oxalate homeostasis in the body. *O. formigenes*, a Gram-negative and obligate anaerobe, is considered important in maintaining oxalate homeostasis. There is evidence that therapies using antimicrobials likely alter the oxalate homeostasis by altering the gut microbiome. *O. formigenes* may be a candidate probiotic in veterinary medicine. Bacteria[29,30] from two probiotics were studied in vitro for metabolizing oxalate (Cho et al. 2015). The bacteria present in the probiotics were *Lactobacillus* spp., *Bifidobacterium* spp., and *Enterococcus* spp. Two *L. acidophilus* isolates decreased oxalate in the culture; *L. plantarum* increased oxalate in the culture medium. The general conclusion is that *Lactobacillus* spp. and its strains are likely variable in their ability to degrade oxalate. Lactic acid bacteria in the canine gut have in vitro capacity to degrade oxalate (Ren et al. 2011). These isolates are *Leuconostoc mesenteroides* (RL75), *Lactococcus garvieae* (CD2), *Lactococcus lactis* subsp. *lactis* (CS21), *Enterococcus faecium* (CL71 and CL72), and *Enterococcus faecalis* (CD14, CS62, and CD12). Many of these are used in probiotics, but there are no reports of their use in probiotics for urolithiasis. In the management of cystitis, there is increasing interest in using probiotic infusions to alter the microbiology of the urinary bladder to control chronic cystitis.

15 Ethnoveterinary Medicine

The use of plant extracts, decoctions, infusions, tinctures, and other formulations for the treatment of animal maladies is recorded throughout written history. There is an increased interest in investigating the historic and current use of botanicals and other nutraceuticals in veterinary medicine especially in documenting efficacy and safety. Table 1 shows that many rural areas use plant preparations and nutraceuticals. The cost of modern drugs is increasing the interest in researching the efficacy of ethno-nutraceuticals.

Table 1 Examples of ethno-nutraceuticals used as genitourinary remedies for domestic animals

Condition (species)	Plant scientific name	Plant parts	Route of administration	Reference
Prevent retained placenta and hemorrhage (bovine, ovine)	*Adiantum capillus-veneris* L.	Fronds made into a decoction	Oral	Uncini Manganelli et al. (2001)
Prevent postpartum issues (bovine, ovine)	*Laurus nobilis* L.	Decoction made from leaves	Oral	
	Linum usitatissimum L.	Decoction made from seeds; boiled seeds, can be mixed with other plants	Oral	
	Malus sylvestris L.	Mixed with other seeds and decoctions	Oral	
(Bovine, lagomorph)	*Rubia peregrina* L.	Whole plant without roots	Oral	
(bovine)	*Apium nodiflorum* L.	Infusion made from the whole plant	Oral	
	Parietaria diffusa Mert. et Koch.	Decoction mixed with wheat flower	Oral	
Retained placenta (ruminants)	*Acacia sinuata* Lour., Merr.	Tea from stem, bark, and roots	Oral	Upadhyay et al. (2011)
	Acacia catechu L.	50 g crushed with 3–4 leaves of *Cassia occidentalis* L.	Oral	Kumar and Bharati (2013)
	Curcuma longa L.	Turmeric powder with jiggery oil	Oral	
	Cynodon dactylon L.		Oral	
	Ficus carica L. *Ficus racemosa* L.	Boiled crushed fruits and jiggery; water shake	Oral	
	Butea monosperma Lam.	Crushed root tea; may be mixed with other plants	Oral	
	Flacourtia indica Burm.	Leaf tea with whey	Oral	
	Hordeum vulgare L.	Grains with fodder	Oral	
	Pennisetum americanum L.	Leaves mixed with barley tea	Oral	
	Saccharum officinarum L.	Fresh or boiled leaves in water given with fodder; other variants used	Oral	
	Tridax procumbens L.	Leaves (25 g) mixed with cow dung ashes given with water	Oral	
	Triticum aestivum L.	Given with jaggary		
	Ziziphus nummularia Burm., Wight & Arn.	Crushed roots in water	Oral or topical on uterus	
	Narcissus tazetta L.	0.25 kg leaves mixed with gurr and flour and boiled	Oral	Aziz et al. (2018)
	Visnaga daucoides Gaertn.	Infusion made from fruit for 3 days	Oral	
Retained placenta and uterine infection (ruminants)	*Alchemilla vulgaris* L.	90 mL of tincture from aerial parts	Oral	Lans et al. (2007)
	Hedera helix L.	Handful of aerial parts	Oral	Lans et al. (2007)
Uterine dislocation (ruminants)	*Anisomeles indica* Linn.	Ground root nixed with butter milk	Oral	Upadhyay et al. (2011)
Prolapsed uterus (ruminants)	*Butea monosperma* Lam., Taub.	Crushed root tea; may be mixed with other plants	Oral	Upadhyay et al. (2011)
	Flacourtia indica Burm. f., Merr.	Leaf tea with whey	Oral	
	Ichnocarpus frutescens L.	Leaf paste mixed with ginger and boiled	Oral	
Leucorrhoea (ruminants)	*Bauhinia racemosa*, Lamk.	Plant juice mixed with vegetable oil	Oral	Upadhyay et al. (2011)
Prevent abortion (ruminants)	*Corchorus depressus* L. *Hordeum vulgare* L.	Leaf paste mixed with Hordeum vulgare flour	Oral	Upadhyay et al. (2011)
	Pedalium murex L.	Plant juice	Oral	
Diuretic, abortion (bovine, ovine, porcine)	*Petroselinum sativum* Hoffm.	Fresh plant, increased dose can cause abortion	Oral	Uncini Manganelli et al. (2001)

(continued)

Table 1 (continued)

Condition (species)	Plant scientific name	Plant parts	Route of administration	Reference
Urinary issues (ruminants)	*Dichrostachys cinerea* Wight & Arn.	Stem bark powder	Oral	Upadhyay et al. (2011)
Kidney stone (canine)	*Costus spiralis* Jacq.	Leaf infusion, add to drinking water	Oral	Antonio et al. (2015)
	Echinodorus grandiflorus Cham & Schltdl.	Leaf infusion, add to drinking water	Oral	
	Phyllanthus tenellus Roxb.	Leaf infusion	Oral	
Hematuria (ruminants)	*Abutilon indicum* L.	200 g crushed	Oral	Kumar and Bharati (2013)
	Acacia nilotica subsp. *indica* Benth.	250 g crushed with 4–5 leaves of *Syzygium cumini* (L.), *Mangifera indica* (L.), and *Aegle marmelos* (L.)	Oral	
	Aegle marmelos L.	100 g crushed with 3–4 leaves of *Abutilon indicum* (L.)		
Urinary infection (bovine, ovine)	*Potentilla reptans* L.	Infusion	Oral	Uncini Manganelli et al. (2001)
	Costus spiralis Jacq.			
Postpartum hemorrhage (ruminants)	*Euphorbia microphylla* Lam.	Whole plant with chapatti	Oral	Upadhyay et al. (2011)
Increase fertility (Bovine)	*Allium sativum* L.	Bulb crushed and mixed with whey for 6–8 days	Oral	Aziz et al. (2018)
	Alocasia macrorrhizos L.	About 100 g crushed with a dash of camphor	Oral with bread of *Triticum aestivum* given 3× daily for 2 week	Kumar and Bharati (2013)
(Bovine, ovine, caprine)	*Heracleum candicans*	200 g fresh root mixed with wheat flour and given for 3 days	Oral	Kumar and Bharati (2013)
Abnormal estrus (elephantine)	*Allium cepa* L.	Fresh bulbs with butter	Oral	Jayakumar et al. (2017)
	Aloe vera L., Burm.	Fresh leaves with fodder	Oral	
	Citrullus vulgaris Thunb., Matsum & Nakai.	Fruit	Oral	
	Curcuma longa L.	Fresh rhizome with camphor	Oral	
	Lycopersicum esculantum L.	Fresh fruit	Oral	
	Musa paradisiaca L.	Liquid from fresh stem	Oral	
Musth (elephantine)	*Allium cepa* L.	Fresh bulbs with curds	Oral	Jayakumar et al. (2017)
	Musa paradisiaca L.	Liquid from fresh stem and fruit	Oral	
	Myristica fragrans Houtt.	Fruit powder given with fodder	Oral	
	Piper nigrum L.	Powdered seeds with rock salt	Oral	
Improve fertility (bovine, ovine)	*Avena sativa* L.	Germinated *caryopses*	Oral	Uncini Manganelli et al. (2001)
	Prunus avium L.	Leaf	Oral before breeding	
Increase egg production (gallus)	*Stellaria media* L., Vill.	Leaves added to chicken feed	Oral	
(Poultry)	*Urtica dioica* L.	Seeds	Added to feed	
	Urtica urens L.	Seeds, used with other plants	Added to feed	
Improved heat symptoms and other reproduction parameters (ovine)	*Lepidium meyenii* Walpers.	Tuber	Oral	Thesis cited in Hermann and Bernet (2009)
Higher number of ejaculated sperms with increased motility (bovine)				

16 Concluding Remarks and Future Directions

The efficacy of nutraceuticals is often a controversy. Important in the efficacy debate are unsupported claims for proprietary nutraceuticals. There are studies that have shown nutraceuticals to be efficacious. This is also the rational that veterinarians and physicians, to wisely use nutraceuticals, must be specifically trained in materia medica of nutraceuticals and ethnopharmacology. Nutraceuticals are being increasingly considered in medical management when conventional medical therapeutics are not efficacious. This includes the use of ethnic medical and homeopathic recipes in veterinary medicine. There is also intermingling of conventional and nutraceutical therapies. Nutraceuticals are a mixture of phytochemicals and generally are polyvalent in their actions. The interactions of stimulating-inhibiting multiple receptors with phytochemicals are essentially unknown but generally are considered essential for their efficacy. Future research will likely refine the actions and interactions of phytochemicals and increased refinement of phytochemicals considered to be the most potent and efficacious. Oxidative stress is being investigated, and its contribution to disease and methods of prevention are being elucidated. There is increasing evidence that in ovo and in utero exposures to phytochemicals in nutraceuticals have epigenetic effects on the offspring. The most likely advancement is prescribing nutraceuticals for prevention and remission of chronic debilitating diseases and in understanding mechanisms of action for phytochemicals at the molecular level.

Nutraceuticals in Obesity and Metabolic Disorders

Rhian B. Cope

Abstract

This chapter examines a number of proposed nutraceuticals. Functional foods are not specifically addressed. Each section of the chapter is divided into an evaluation of the "proof-of-concept" studies that purport to demonstrate efficacy, an examination of the claimed modes and mechanisms of action of each nutraceutical, and, where available, a brief discussion of any identified key adverse effects. Nutraceutical agents covered include curcumin, *Lagenaria siceraria* (bottle gourd), *Trigonella foenum-graecum* (fenugreek), *Emblica officinalis* (Indian gooseberry), *Murraya koenigii* (curry tree), *Vigna* sp. (black gram), *Camellia sinensis* (tea), *Hibiscus sabdariffa*, *Hypericum perforatum* (St. John's wort), avocado, capsicum, and rosemary. While potential nutraceutical products and ingredients continue to be a frequent source of "proof-of-concept" scientific publications, high-quality human clinical trial data is often lacking. Substantial translational scientific work is still needed for many nutraceuticals in terms of assessing their safety and demonstrating their efficacy in humans and animals.

Keywords

Veterinary nutraceuticals · Obesity · Metabolic disorders

1 Introduction

In this chapter, the term nutraceuticals will be considered separately from the functional foods concept. A nutraceutical is defined as a pharmaceutical-grade and standardized nutrient (or dietary supplement or food additive), whereas a functional food is a food given an additional function by the existence or addition of a specific food component. Foods can, of course, be fortified with a specific nutraceutical, and such products would then be considered a functional food; however, for reasons of expediency and simplicity, this chapter will focus on specific plant species from which various claimed anti-obesity nutraceutical extracts have been derived. Common foods which claim to have anti-obesity effects such as peanuts, citrus fruits, and pomegranates are not covered by this chapter. This chapter is not intended as a review of the pathophysiology of obesity and metabolic syndrome(s); however, a brief introduction to some key concepts in the pathogenesis of these diseases that are relevant to nutraceuticals is provided. Current proposed nutraceuticals are particularly those with claimed effects on dietary fat bioavailability, antioxidative and anti-inflammatory effects, modification of lipogenesis and pre-adipocyte maturation, increased lipid metabolism, and satiety. However, many critical modes of action remain incompletely understood.

2 Curcumin ((1E,6E)-1,7-bis(4-hydroxy-3-methoxyphenyl)-1,6-heptadiene-3,5-dione)

Curcumin is the major curcuminoid (linear diarylheptanoid) found in turmeric. Human phase I and phase II clinical trials have demonstrated that this food coloring and flavoring agent are relatively well tolerated (Soleimani et al. 2018). Some trial subjects developed diarrhea, headache, skin rashes, and yellow stools. Overall, oral curcumin dosing at 6 g/day for 4 to 7 weeks was reasonably well tolerated in humans. Orally bioavailable curcumin formulations were reasonably well tolerated following a dosage of 500 mg BID for 30 days. However, there is more limited information on curcumin nano-formulations. Curcumin was not genotoxic in classical assays, was not a reproductive toxin in animals following oral dosing studies, showed no toxic effects in humans, and was

safe at the dose of 6 g/day orally for 4–7 weeks. While curcumin has multiple pharmacological actions, it has poor oral bioavailability and is rapidly excreted (Purpura et al. 2018). Phospholipidation and nanoparticle dose forms co-dosed with piperine have been used to increase oral bioavailability. Curcumin inhibits several CYP450 enzymes, glutathione-*S*-transferases, and UDP glucuronosyltransferases. Thus, its use may be associated with drug interaction effects.

Due to its anti-inflammatory actions, curcumin treatment has been applied to a wide range of inflammatory conditions, including obesity and metabolic disorders. Within the inflammation, signaling milieu curcumin interacts directly with cyclooxygenase 2, DNA polymerase, lipoxygenase, glycogen synthase kinase 3b, and tumor necrosis factor alpha. It also modulates the actions of a number of signal transducers (AP-1, beta-catenin, STAT, and PPARc).

The antioxidative and anti-inflammatory effects of curcumin have been evaluated in several small human clinical trials. In a human double-blind placebo-controlled trial, the effect of curcumin and phospholipidated curcumin on antibody titers to heat shock protein 27 (a biomarker of inflammation and oxidative stress) was evaluated in patients with metabolic syndrome (Mohammadi et al. 2018). Dosing with 1 g/day for 6 weeks with curcumin or phospholipidated curcumin had no significant ($p > 0.6$) effect on heat shock protein 27 titers. However, oral dosing of patients with metabolic syndrome with curcumin (1 g/day, with or without 10 mg/day of piperine) for 6–8 weeks resulted in a significant ($p < 0.05$) increase in serum prooxidant-antioxidant balance (Ghazimoradi et al. 2017; Panahi et al. 2015); however, curcumin dosing had no beneficial effects on circulating levels of vitamin E (Mohammadi et al. 2017). A human double-blind placebo-controlled trial that evaluated the effect of curcumin or phospholipidated curcumin on serum copper, zinc, and zinc/copper ratio demonstrated that, compared with placebo, both curcumin and phospholipidated curcumin complex, given at a dose of 1 g per day for 6 weeks, were associated with a significant ($p < 0.05$) increase in serum zinc and serum zinc/copper ratio in patients with metabolic syndrome (Safarian et al. 2018). In this trial, phospholipidated curcumin (1 g = 200 mg of curcumin) was significantly ($p < 0.05$) more efficacious in this effect of curcumin. This is likely due to the higher bioavailability of the phospholipidated dose form. Based on the results of a double-blind randomized control trial, the effects of curcumin (1 g/day) combined with piperine (10 mg/day) resulted in increased serum adiponectin, decreased serum leptin, and decreased leptin/adiponectin ratio (a biomarker of atherosclerosis) (Panahi et al. 2016, 2017). These changes were claimed to reflect a decrease in the level of systemic inflammation as measured by circulating TNF-alpha levels.

A limited number of human clinical trials have also examined the effects of curcumin on obesity and dyslipidemias. A small, preliminary human randomized clinical trial demonstrated that patients who did not lose body weight (<2% reduction) after 30 days of diet and lifestyle intervention had increased weight loss (about 2–5%) and increased reductions in BMI (about 2–6%) cf. controls after daily oral dosing with 800 mg/day of curcumin complexed with sunflower phospholipids and 8 mg of piperine. The plasma lipid-modifying effects of a bioavailable curcumin complex (1 g/day with 10 mg of piperidine, dosing for 8 weeks) were evaluated in patients who had been diagnosed with metabolic syndrome (Panahi et al. 2014). In this trial, curcumin was more effective than placebo in reducing serum LDL-C, non-HDL-C, total cholesterol, triglycerides, and Lp(a) and elevating HDL-C concentrations. Similar effects were observed in a second trial which utilized TID dosing at 630 mg/day (Yang et al. 2014).

Overall, while there is reasonable quality preliminary, small-scale human clinical trial evidence that bioavailable forms of curcumin may have beneficial effects on metabolic syndrome, obesity, and dyslipidemias, evidence of overall long-term beneficial outcomes in patients with metabolic syndrome and obesity is lacking (Hariri and Haghighatdoost 2018).

3 *Lagenaria siceraria* (Bottle Gourd)

Bottle gourd, a plant native to India, has a long history of ethnopharmacological use. Traditional medical uses of the plant include (1) as an aliuretic, purgative, and laxative; (2) as a diuretic for cardiogenic ascites; (3) for the relief of headache and toothache; (4) as an anticonvulsant; (5) as a treatment for boils, tetanus, fever, wounds, and rheumatism; (6) as a treatment for asthma and coughs; (7) as an anticancer agent; (8) as a treatment for alopecia; and (9) as an antidote for poisoning. The plant is reputed to have cardioprotective, antihyperlipidemic, antioxidative, antihyperglycemic, analgesic, anti-inflammatory, immunomodulatory, and hepatoprotective effects in humans. Fresh bottle gourd juice is considered an effective treatment for obesity in India.

Small controlled studies have claimed that consuming freshly prepared bottle gourd fruit extract once/day for 90 days reduced plasma total cholesterol (marginal), plasma triglycerides, plasma low-density lipoproteins, and BMI as well as having antioxidative properties in humans (Kaur et al. 2015; Katare et al. 2014). These findings are supported by studies in rats where oral dosing of bottle gourd methanol extracts at 100–400 mg/kg body wt/day resulted in dose-dependent reductions in plasma total cholesterol, triglycerides, low-density lipoproteins levels, and increased

plasma high-density lipoproteins (Ghule et al. 2006, 2009). Based on the results of this small study, fresh bottle gourd juice may have some limited beneficial effects on dyslipidemias in humans.

Overall, while there is reasonable preliminary exploratory data on the possible beneficial effects of bottle gourd products on dyslipidemia in humans, evidence of long-term beneficial outcomes in patients is lacking.

4 *Trigonella foenum-graecum* (Fenugreek)

One of the world's oldest medicinal plants, fenugreek, originated in India and North Africa (Kaur et al. 2015). There are three groups of medicinal compounds found in the plant: steroidal saponins, galactomannans, and isoleucine. Fenugreek is an important source of the drug precursor diosgenin which is used in the synthesis of steroidal drugs.

While fenugreek is generally considered a safe product, patients with allergies to the plant or allergies to chick peas (cross-reactive with fenugreek) should avoid it (Kaur et al. 2015). Consumption of fenugreek is known to cause dizziness, transient diarrhea, and flatulence. Hypoglycemia and reduced T3 levels have been reported in some patients. Fenugreek contains coumarin and consumption may result in increased prothrombin times and a bleeding tendency. Fenugreek should be avoided during pregnancy because it stimulates uterine contractions in animal studies. Because fenugreek is rich in dietary fiber it may decrease the oral bioavailability of drugs. Since fenugreek induces hypoglycemia, concurrent use with other hypoglycemic agents may exacerbate their pharmacological effects.

The ability of fenugreek preparations to attenuate postprandial glycemia and insulinemia is reputed to be due to its soluble dietary fiber effects (Repin et al. 2017). These effects are claimed to be due to modification of ingesta viscosity and delaying of gastric emptying. The effects of fenugreek soluble dietary fiber on these types of parameters are about the same as with other sources of soluble dietary fiber.

The fenugreek steroidal saponins are claimed to have antihypercholesterolemia and anti-hyperlipidemia effects in humans (Kassaian et al. 2009). The mechanism of these effects is not completely understood but may be a manifestation of increased soluble dietary fiber intake.

Galactomannans are polymers of galactose and mannose present in the seeds of fenugreek. They are hydrophilic and form viscous aqueous solutions at low concentrations (Kaur et al. 2015) and have been used as gastric "fillers" in an attempt to stimulate satiety and decrease caloric intake. Isoleucine is an amino acid precursor which regulates insulin secretion.

5 *Emblica officinalis* (syn. *Phyllanthus emblica*; Indian Gooseberry)

Indian gooseberry is an important dietary source of vitamin C and minerals in many areas of India and has a long history of use as a traditional medicine (treatment of fever, anti-inflammatory, diuretic, hair and liver tonic, and digestive aid) (Kaur et al. 2015). The fruit also has religious significance and has been used to make ink due to its high tannin content.

Preparations of Indian gooseberry have been demonstrated to decrease serum cholesterol, low-density lipoprotein, and triglycerides in humans and are PPAR-alpha agonists (Kaur et al. 2015; Akhtar et al. 2011). They are also reported to exert some of their effects due to their antioxidant and free radical scavenging properties (D'souza et al. 2014).

6 *Murraya koenigii* (Curry Tree)

The leaves of this plant are commonly used in Indian cooking (typically in curries). The plant also has a long history of use as a traditional medicine, and it is known for having antioxidant, antitumor, anti-inflammatory, antihyperglycemic, hypoglycemic, and hypolipidemic effects (Kaur et al. 2015). Curry tree products act as hypoglycemics by increasing hepatic glycogen storage and decreasing gluconeogenesis. Part of the nutraceutical effects of the curry tree may be due to the actions of the carbazole alkaloid mahanimbine. In mice, mahanimbine inhibits the obesogenic effects of a high-fat diet including reducing body weight gain; preventing hyperlipidemia, fat accumulation in adipose tissue, and hepatic steatosis; improving glucose clearance; and improving insulin responsiveness (Jagtap et al. 2017).

7 *Vigna* sp. (Black Gram, Black Lentil, Cow Pea, Black-Eyed Pea, Adzuki Bean, Mung Bean)

Black lentils (*Vigna mungo*) have been used as a safe, high-protein traditional food source in Nepal and India for millennia. The claimed benefits of consuming black lentils are (Kaur et al. 2015):

- The high-fiber, low glycemic index properties of this food are supposedly able to modulate lipid homeostasis in people with a high saturated fat diet.
- The high-fiber, low glycemic index properties of this food reputedly help to maintain blood glucose control in people with diabetes mellitus.

- Diets reputedly high in black lentils have some benefit in controlling body weight since they are claimed to have satiety effects, thus limiting overall food consumption.
- Black lentils inhibit alpha amylase. Alpha amylase inhibition is known to delay carbohydrate absorption and to reduce peak postprandial plasma glucose concentration.

Other members of the *Vigna* genus are reputed to have similar effects. In a human randomized double-blind crossover trial, consumption of *V. unguiculata* protein reduced total cholesterol (12%), LDL cholesterol (18.9%), non-HDL cholesterol (16%), and apoB (14%) and increased HDL cholesterol (+2.7%); however, no effects on the serum inflammasome were noted (Frota Kde et al. 2015). Adzuki bean consumption by mice with high-fat diet-induced nonalcoholic liver disease resulted in reduced fasting blood and hepatic triglyceride and cholesterol levels with evidence of effects on hepatic lipogenesis and decreased inflammation (Kim et al. 2015).

8 *Camellia sinensis* (Tea)

Claims regarding the health benefits of the three main types of tea, black, oolong, and green, extend back in history for thousands of years. More research effort has been devoted to *Camellia sinensis* than any other potential nutraceutical. However, despite this substantial research effort, a definitive consensus on the health benefits and appropriate uses of tea as nutraceuticals and complimentary medicines has not yet been reached (Jurgens et al. 2012).

There are three main categories of claimed beneficial nutraceutical compounds in tea:

- Xanthine bases and methylxanthines (caffeine, theophylline, and theobromine)
- Essential oils
- Polyphenolic compounds (notably epigallocatechin, epigallocatechin gallate, epicatechin gallate, and gallocatechin gallate)

Various studies have demonstrated that tea phytochemicals appear to have beneficial effects on obesity and metabolic syndrome in high-fat diet animal models. The following studies are representative of the findings in rodents. Green tea phytochemicals administered in drinking water to Wistar rats at concentrations up to 3.2 g/L over a period of 26 weeks reduced visceral adipose tissue accumulation by about 40% versus control (no dose response) (Tian et al. 2013). The effect was claimed to be due to modulation of the erk1/2-PPARγ-adiponectin pathway. Oral dosing of mice fed a high-fat diet containing 400 mg/kg body wt/day of green tea extract (containing 15 μg/mg epigallocatechin, 95 μg/mg epigallocatechin gallate, 20.8 μg/mg epicatechin gallate, and 4.9 μg/mg gallocatechin gallate) for 8 weeks was associated with an increase in hormone-sensitive lipase and perilipin in mesenteric adipose tissue, thus reputedly increasing lipolysis and reducing low-grade inflammation (as measured by TNF-alpha levels and reductions in TLR4, MYD88, and TRAF6 proinflammatory signaling) and reducing body weight by about 16% versus control (Cunha et al. 2013).The anti-obesity effects of tea are not only associated with leaf and leaf extract products. Ethanolic extracts of the fruit peel of the tea plant which is normally regarded as an agricultural waste product have been demonstrated to have anti-obesity effects in rats (Chaudhary et al. 2014). In this study, administration of 100 mg/kg body wt/day of an ethanolic green tea fruit peel extract as part of a high-fat diet fed to rats for 50 days resulted in about a 25% reduction in body weight and a 74% reduction in adipose tissue fat pad weights versus control.

Suggested modes of action of tea extracts on obesity and metabolic syndromes include inhibition of pancreatic lipase, appetite-repression activity, downregulation of adipogenesis, thermogenesis, alterations in lipid metabolism including increased lipolysis and decreased lipogenesis, increased antioxidant defenses, changes in gut microflora, increased whole-body fat utilization, increased fat oxidation, and anti-inflammatory effects (Grove et al. 2012; Yuda et al. 2012; Moon et al. 2007; Wolfram et al. 2006; Lu et al. 2012; Axling et al. 2012; Basu et al. 2010; Park et al. 2011).

The presumed major phytochemical of tea is (−)-epigallocatechin 3-gallate within the polyphenol fraction, responsible for anti-obesity effect.

The safety properties of tea have been best studied for green tea preparations. The consumption of moderate amounts of green tea as a beverage is currently regarded as safe. Concentrated great tea extracts have reportedly been associated with hepatotoxicity in a small number of people. However, the US National Center for Complementary and Integrative Health has concluded that in the case of green tea "definite conclusions cannot yet be reached on whether green tea is helpful for most of the purposes for which it is used" (National Center for Complementary and Integrative Health 2016).

9 *Hibiscus sabdariffa*

This well-studied plant is commonly prepared as a soft drink and is used to reduce inflammation, hypertension, and liver disorders. In the monosodium glutamate-induced obese mouse model, *Hibiscus sabdariffa* calyces aqueous extract administered at 120 mg/kg body wt/day for 60 days resulted

in an approximately 22% reduction in body weight gain versus control and reduced liver steatosis (Alarcon-Aguilar et al. 2007). Reductions in body weight and adipose tissue weight versus control have also been demonstrated in obese rats treated with extracts from this plant (Gamboa-Gómez et al. 2015). Similar results have been achieved in other animal models. Promising results have also been noted in human clinical trials where consumption of *H. sabdariffa* extract for 12 weeks resulted in weight loss, reduced BMI, reduced body fat, reduced waist-to-hip ratio, and reduced liver steatosis in subjects with a BMI $\geq$ 27 and those between the ages of 16 and 65 years (Chang et al. 2014).

The critical phytochemicals identified in this plant are phenolic and flavonoid compounds (Peng et al. 2011). Multiple putative modes of action relating to the plant's anti-obesity, antimetabolic disorder, and hepatoprotective effects have been proposed including downregulation of the genes coding for free fatty acid synthase and sterol regulatory element-binding proteins, inhibition of lipid droplet accumulation in adipocytes and adipocyte hypertrophy, antioxidant effects, anti-inflammatory effects, and downregulation of pancreatic lipases (Gamboa-Gómez et al. 2015; Kim et al. 2003).

10 *Hypericum perforatum* (St. John's Wort)

A limited database of studies suggests that St. John's Wort may have anti-obesity effects in addition to its well-known uses as a sedative, an anxiolytic, and an antidepressant. Oral dosing of high-fat diet-induced obese rats with a St. John's Wort extract at 100 and 200 mg/kg body wt/day for 15 days resulted in 12% and 15% reductions in body weight (respectively) versus control as well as reducing blood total cholesterol and low-density cholesterol in normal rats (Husain et al. 2011). The same extract normalized dyslipidemia and improved insulin sensitivity in fructose fed rats. Similar results with extracts of other *Hypericum* sp. have been reported by other investigators (García-de la Cruz et al. 2013).

Possible relevant modes of action for *Hypericum* sp. extracts have included modulation of the serotonin system which, in turn, may reduce food intake, suppress appetite, and reduce anxiety (Ganji et al. 2017). Reduced oxidative stress, inhibition of inflammation, inhibition of adipogenesis, attenuation of insulin-sensitive glucose uptake by adipocyte, and limiting the differentiation of pre-adipocytes have also been associated with the anti-obesity effects (Richard et al. 2012).

The specific anti-obesogenic compounds in St. John's Wort have not been fully described but may include hyperforin, hypericin, flavonoids, and condensed tannins.

The safety and drug interactional properties of St. John's Wort extracts are well known with the most important ones being serotonin syndrome-like effects and drug-drug interactional effects due to induction of CYP3A4 and CYP1A2 (reviewed in Coppock and Dziwenka 2016; Gupta et al. 2018).

11 *Persea americana* (Avocado)

Anti-obesity effects associated with avocados have been reported for fruit, leaf, and oil extract products (Brai et al. 2007). Eight weeks of dosing of rats with hypercholesterolemia induced by a high saturated fat diet with 10 mg/kg body wt/day of aqueous and methanolic extracts of avocado leaves resulted in a 25% reduction in body wt gain versus controls. Likewise, rats fed defatted avocado fruit pulp (100 g/kg of diet) for 28 days had a 26% reduced body weight gain and reduced total hepatic fat levels versus controls; however, when this diet and cholesterol were co-fed, higher serum cholesterol occurred (Naveh et al. 2002). In the case of avocado pulp, the anti-obesity effects were attributed to reduced food consumption. Similar effects have been reported for alcoholic fruit extracts (100 mg/kg body wt/day for 14 weeks) and hydroalcoholic extracts (Padmanabhan and Arumugam 2014; Monika and Geetha 2016). These effects were associated with antioxidant effects, changes in adiponectin and PPARγ, alterations in key lipid metabolic enzymes, and lower blood LDL and lipid peroxides. The key anti-obesity compounds in avocado products have not yet been defined. Avocados are a safe food in humans (Mahmassani et al. 2018); however, they are toxic to a variety of domestic animals and birds (Hargis et al. 1994; Stadler et al. 1991; Burger et al. 1994).

12 *Capsicum annuum* (Capsicum)

Capsicum extracts have been reported to be anti-adipogenic in animal models. A dietary 13.35% capsicoside G fraction (dosed at 10 and 100 mg/kg body wt/day) isolated from capsicum seeds modulated the obesogenic effects of a high-fat diet in C57BL/6J mice (Sung et al. 2016). Key effects included reduced epididymal adipose tissue weight, reduced adipocyte hypertrophy, reduced hepatic steatosis, and reduced expression of adipocyte differentiation regulators (PPARγ, CCATα, and sterol regulatory element-binding protein 1c). Likewise, C57BL/6 mice fed a high-fat diet with a green pepper juice supplement (10 mL/kg body wt/day) had lower weight gain, decreased serum triglycerides, reduced serum cholesterol and LDL, and lower abdominal fat (subcutaneous and visceral) volume versus controls (Kim and Park 2015).

Anti-obesogenic effects of capsaicinoids from *Capsicum* sp. have also been demonstrated in a limited human clinical trial. A dose of 6 mg/day for 12 weeks resulted in a small reduction in abdominal adiposity versus placebo.

Various modes of action have been described for the anti-obesity effects of capsicum including inhibition of adipogenesis, changes in gut microflora with a resulting reduction in chronic low-grade inflammation, antioxidant effects, modulation of inflammation, and alteration in lipoprotein metabolism (Kim et al. 2018; Kang et al. 2017; Marrelli et al. 2016; Yu et al. 2012).

13 *Rosmarinus officinalis* (Rosemary)

Rosemary is a well-known medicinal spice with a long history of use as an herbal abortifacient; however, there is now an expanding body of animal data demonstrating potential efficacy in obesity and metabolic disorders. Dosing of high-fat diet-induced obese mice with 200 mg/kg body wt/day of a rosemary leaf extract resulted in reduced weight gain by about 64% accompanied by an approximate 57% reduction in fat mass gain (Harach et al. 2010). This was accompanied by increased fecal lipid excretion and an approximate 39% reduction in hepatic triglyceride levels. Similar results were obtained when the rosemary leaf extract was standardized to a 20% carnosic acid content and dosed at 500 mg/kg body wt/day of the extract (Ibarra et al. 2011). Several investigators have now replicated these findings (Zhao et al. 2015).

The best investigated active anti-obesity compound in rosemary is carnosic acid which has a number of potentially relevant modes of action including inhibition of gastric lipase, modulation of genes involved in metabolism (SIRT1, PPARγ coactivator 1α, glucose-6-phosphatase, ACC, and low-density lipoprotein receptor), modulation of PPARγ, activation of the AMPK and PPAR pathways, increased hepatic glycolysis and fatty acid oxidation, decreasing inflammation, decreasing leptin, increasing adiponectin, modifying the cecal microbiome, inhibition of cecal beta-glucosidase, increasing fecal short-chain fatty acid and fiber excretion, stimulation of muscle glucose uptake via modulation of the PME-1/PP2A/PKB signaling axis, modulation of TLR4-MyD88 signaling in adipocytes, and reducing hepatic lipogenesis while increasing hepatic lipolysis (Romo-Vaquero et al. 2012, 2014a, b; Tu et al. 2013; Park and Mun 2014). Carnosic acid inhibits TLR4-MyD88 signaling pathway in LPS-stimulated 3T3-L1 adipocytes (Park and Sung 2015).

Rosmarinic acid, another bioactive compound in rosemary, has also been shown to suppress adipogenesis, lipolysis, and inflammation in adipocytes. Therefore, it appears to be a promising natural product for improving adipose mobilization in obesity (Rui et al. 2017).

The safety properties of rosemary and rosemary extract have been well-documented. The key effects are on male fertility, establishment/maintenance of pregnancy, and changes in estrogen metabolism.

14 Concluding Remarks and Future Directions

While obesity and metabolic disorders continue to be an ever-increasing, worldwide public health problem, a market will soon exist for nutraceutical products that target these diseases. Accordingly, molecule mining in the nutraceutical area is likely to continue in the foreseeable future. While there is an increasing body of proof-of-concept-type literature in various animal models, there remain relatively few large, high-quality clinical trials. Mechanistic data is also often of a preliminary, explorative nature. Given the current status quo, substantially more translational research is required to fully establish the therapeutic credibility of many of these materials.

Nutraceuticals for Diabetes in Dogs and Cats

Ramesh C. Gupta, Rajiv Lall, Anita Sinha, and Ajay Srivastava

Abstract

Diabetes is a serious health issue in dogs and cats that is usually treated through the use of injectable insulin. There are more than 90 million pet dogs in the United States, and 1 in every 400–500 dogs suffers from diabetes. Diabetes typically occurs later in life, usually around 7–10 years of age, with certain breeds being at a higher risk of developing this disease. Traditional diabetic management in dogs and cats includes food monitoring, glucose monitoring (which is done with the use of a canine-specific glucometer), moderate exercise, medication, and insulin therapy. Often times, dog and cat owners decline diabetic treatment because they either do not feel confident in giving insulin injections or because they simply cannot afford treatment, as traditional insulin therapy and medication are expensive. Therefore, it is beneficial to determine the efficacy and safety of a potential oral formulation for diabetic management. An oral formulation of nutraceutical(s) may provide an easier administration (noninvasive) method and provide lower costs to dog and cat owners by not requiring additional supplies such as needles and syringes. This chapter describes various plant extracts and nutraceuticals that have potential for anti-diabetic and antihyperglycemic effects in diabetic dogs and cats.

1 Introduction

In humans, type 2 diabetes mellitus (T2DM) is a chronic metabolic disorder that has become the fourth leading cause of death in developed countries (Lee 2016). More than 415 million individuals with diabetes were reported in 2015, with five million deaths in 2015 (WHO 2016). Clinically, about 90% of diabetic patients are reported to be T2DM, which is characterized by insulin resistance and β-cell dysfunction. Among animal species, dogs suffer with diabetes more often than other species. Currently, the global dog population is approximately 900 million. There are more than 90 million pet dogs in the United States. Statistics show that approximately one in every 200 cats and one in every 400–500 dogs are diagnosed with diabetes. Diabetes typically occurs later in life, usually around 7–10 years of age in dogs, with certain breeds (dachshunds, schnauzers, poodles, cairn and Australian terriers, springer spaniels, keeshonds, samoyeds, and golden retrievers) being at a higher risk of developing this disease. It is interesting to note that in keeshonds, diabetes is inherited as an autosomal recessive trait. Seventy percent of dogs with diabetes are female and 30% are male. Unlike dogs, male cats are more prone to diabetes. Burmese cats have been reported to have a higher risk of diabetes than other breeds of cats. T2DM is characterized by pancreatic β-cell dysfunction, which causes hyperglycemia and may lead to several secondary complications, such as neuropathy, nephropathy, and cardiac failure.

Traditional diabetic management in dogs and cats may include diet monitoring, moderate exercise, and therapy with insulin and other glucose-lowering drugs to control blood glucose concentrations. However, therapeutic drugs may produce side effects, including weight gain, GI disturbances, and heart failure. Often times, dog owners decline diabetic treatment because they either do not feel confident in giving insulin injections or because they simply cannot afford treatment. Recently, glucagon-like peptide-1

R. C. Gupta et al. (eds.), *Nutraceuticals in Veterinary Medicine*, https://doi.org/10.1007/978-3-030-04624-8_35

(GLP1) has been reported to be effective against T2DM following oral or parenteral administration (Lee 2016).

It is beneficial to determine the efficacy and safety of a potential oral formulation of natural alternative medicines for diabetic management. An oral formulation of nutraceutical (s) may provide an easier administration (noninvasive) method and provide lower costs to dog and cat owners by not requiring additional supplies such as needles and syringes.

Commonly used plant extracts which have anti-diabetic potential may include *Berberis vulgaris*, *Trigonella foenum-graecum*, *Momordica charantia*, *Curcuma longa*, *Moringa oleifera*, *Gymnema sylvestre*, *Azadirachta indica*, *Aloe vera*, *Panax ginseng*, and many others. Extracts of these and other plants may exert anti-diabetic effects by multiple mechanisms (Patel et al. 2012; Nair et al. 2013; Gupta et al. 2017). Nutraceuticals have also been implicated in diabetes-associated secondary complications, such as nephropathy, cardiopathy, retinopathy, pancreatitis, and wounds. Additionally, nutraceuticals can prevent or reverse T2DM-induced alterations in microbiota marked by enterobacteria performance and a decrease in the number of beneficial bacteria (Villarruel-López et al. 2018).

This chapter describes various plant extracts and nutraceuticals that have potential for anti-diabetic and antihyperglycemic effects in dogs and cats.

2 Pathophysiology of Diabetes Mellitus

The pathophysiology of diabetes mellitus (DM) is very complex, and the exact mechanism of action is yet to be established. Type 2 diabetes mellitus (T2DM) is the most common form of diabetes. Insulin resistance in target tissues is a characteristic feature and major contributing factor to T2DM (Araki and Miyazaki 2007; DeFronzo and Tripathy 2009; Kang et al. 2016). Mitochondrial dysfunction and oxidative stress (due to increased ROS production) have been linked to the development of insulin resistance in diabetes (Kaneto et al. 2007; Kim et al. 2008; Matsuzawa-Nagata et al. 2008; Kangralkar et al. 2010; Raza et al. 2011). Additionally, impaired phosphatidylinositol 3-kinase (PI3K)/AKT pathway in diabetes is one of the main mechanisms of insulin resistance induced by the increased level of ROS (Wang et al. 2011; Naveen and Baskaran 2018). An increase in insulin resistance leads to elevated gluconeogenesis and reduced glycogen synthesis in the liver, thereby causing decreased insulin secretion from pancreatic β cells, and hyperglycemia (reviewed in Yan et al. 2018). The PI3K/AKT pathway plays an important role in the insulin signaling pathway, which is considered the key regulator relevant to gluconeogenesis and glycogen synthesis (Whiteman et al. 2002). Critical targets in DM include α-amylase, α-glucosidase, dipeptidyl peptidase-IV (DPP-IV), aldolase reductase, peroxisome proliferator-activated receptor gamma (PPAR-γ), 5′ adenosine monophosphate-activated protein kinase (AMP kinase), and glucose transporter type 4 (GLUT4) (Naveen and Baskaran 2018). Naveen and Baskaran (2018) have classified DM-associated complications into two categories: (1) microvascular (nephropathy, neuropathy, and retinopathy) and (2) macrovascular (heart attack, stroke, and peripheral vascular disease).

Alterations of endothelial homeostasis, due primarily to proinflammatory cytokines and reduced adiponectin secretion, appear to be two key events in insulin resistance and hyperglycemia. These conditions are associated with altered gene expression and cell signaling in the vascular endothelium, thereby affecting release of endothelium-derived factors, activation of NADPH oxidase, uncoupling of endothelial NOS (eNOS), and the expression of endothelin-1. This cascade of events often results in an imbalance between the production of vasodilator and vasoconstrictor mediators and the induction of adhesion molecules.

3 Experimental Diabetes Models

A number of animal models are used to experimentally induce DM by injecting diabetogenic chemicals (Reed et al. 2000; Etuk 2010; King 2012). Streptozotocin (STZ) is the most commonly used drug for induction of diabetes in rats and mice (Balamurugan et al. 2003). A single dose of streptozotocin (80 mg/kg in rats and 150 mg/kg in mice) is given intraperitoneally to DM. Diabetes develops gradually and may be assessed after a few days, approximately 4 days for mice and 7 days for rats (Etuk 2010). Usually, a serum glucose level of about 180–500 mg/dL indicates the induction of DM. In rats, DM can also be induced by intraperitoneal (IP) injection of alloxan (100 mg/kg of body weight). Lenzen (2008) induced hyperglycemia (>200 mg/dL) in rats after 72 h by injecting alloxan monohydrate (150 mg/kg, IP). Alloxan has been used to produce experimental diabetes in rats, mice, rabbits, and dogs (Etuk 2010). With proper dose selection, either drug can induce type 1 or type 2 DM.

Either of these two drugs, with half a dose when given alone, can also be given in combination with a high-fat diet (Reed et al. 2000; Parveen et al. 2011). In a rat model of diabetes, a high-fat diet (40% of calories as fat) is often given for 2 weeks before streptozotocin or alloxan injection (Reed et al. 2000).

STZ causes selective pancreatic islet β-cell cytotoxicity mediated through the release of nitric oxide (NO) and oxidative/nitrosative stress (Raza et al. 2011). NADPH oxidase type 4 (NOX4) overexpression has been reported in livers of STZ-induced rats. This results in rapid reduction in pancreatic islet pyridine nucleotide concentration and subsequent

β-cell necrosis. The action of STZ on mitochondria generates superoxide dismutase (SOD) anions, which leads to diabetic complications. STZ partly destroys the β cells bringing about inadequate insulin discharge and creating type 2 diabetes (reviewed in Jayaprasad et al. 2015). Alloxan is a urea derivative which causes selective necrosis of the pancreatic islet β cells. Szkudelski (2001) and Lenzen (2008) described in detail the mechanism of STZ and alloxan in the pancreas and β cells.

4 Diabetic Monitoring

Blood glucose measurement is usually carried out with a canine- or feline-specific blood glucometer and test kit. Clinically normal dogs and cats have blood glucose values ranging from 79–103 mg/dL and 74–216 mg/dL, respectively. Recently, Corradini et al. (2016) suggested the use of a flash glucose monitoring system (FGMS) to measure interstitial glucose (IG) concentrations continuously for days or weeks. The method is painless, but mild erythema at the site of the application was found in five out of ten dogs at the end of the wearing period, i.e., 14 days. The FGMS is found to be easy to use and accurate for IG glucose measurement in diabetic dogs. Using a commercially available kit, glycosylated hemoglobin A1 was measured in the blood of dogs and cats for monitoring the status of diabetes, but the test was not found to be of any value (Delack and Stogdale 1983). In humans, glycosylated HbA1c is a routine index of T2DM, as it is a biomarker for identifying stress hyperglycemia and diabetic hyperglycemia. A number of factors can affect blood glucose levels' monitoring (Ginsberg 2009). In dogs and cats, however, HbA1c does not correlate well with diabetes, so glycated serum protein assay (GSP; glycated albumin; Diazyme Laboratories, Poway, CA, USA) is recommended (Kouzuma et al. 2002). Animal fasting blood glucose levels above 200 mg/dL are considered diabetic.

5 Prevention and Management of Diabetes in Animals

Like humans (Brouns 2018), moderate exercise, low-carbohydrate high-fat diet, and therapeutic drug medications may be recommended to prevent and manage diabetes in dogs and cats. Feinman et al. (2015) reported that dietary carbohydrate restriction is the best approach in diabetes management by improving insulin sensitivity and significant weight loss. Wyk et al. (2016) and Brouns (2018) further emphasized that quality but not quantity of carbohydrates appears to be a key aspect to be considered. When glucose availability is in decline due to low-carbohydrate diet, two metabolic processes (gluconeogenesis and ketogenesis) come into play (Wyk et al. 2016; Hall 2017). Switching from a high-carbohydrate to a low-carbohydrate high-fat (LCHF) diet may lead to weight loss, reduction of appetite, improved insulin sensitivity, fewer fluctuations in blood glucose levels, and lower fasting blood glucose levels (Brouns 2018). Also, the metabolic effects of LCHF diets may lead to improvements of various disease risk factors, including cardiovascular diseases (Westman et al. 2007; Accurso et al. 2008; Volek et al. 2008; Feinman et al. 2015).

5.1 Common Plants/Nutraceuticals with Anti-diabetic and Antihyperglycemic Potential

Commonly used plant extracts which have anti-diabetes potential may include *Berberis vulgaris*, *Trigonella foenum-graecum*, *Momordica charantia*, *Curcuma longa*, *Moringa oleifera*, *Gymnema sylvestre*, *Azadirachta indica*, *Aloe vera*, *Panax ginseng*, and many others. Extracts of these plants may exert anti-diabetic effects by multiple mechanisms: (1) increase insulin secretion, (2) activation of glycogenolysis, (3) increase hepatic glycolysis, (4) adrenomimeticism, (5) pancreatic β-cell potassium channel blocker activity, (6) cAMP activation, and (7) modulation of glucose absorption from the intestine (Patel et al. 2012; Gupta et al. 2017). Some important plants and their active principles with anti-diabetic potential are discussed here in brief, while others are listed in Table 1.

5.1.1 Berberine

Berberine (BBR) is an isoquinoline alkaloid commonly obtained from plants of genera *Berberis*, *Coptis*, *Hydrastis*, and *Argemone*. BBR has a molecular weight of 336.361 and its structural formula is shown in Fig. 1.

The pharmacokinetics and PBPK aspect of berberine have been described in detail in chapter "Glucosinolates and Organosulfur Compounds" of this book. In a number of studies, BBR has been shown to exert antihyperglycemic and anti-diabetic effects (Chen and Xie 1986; Dong et al. 2012). Mechanisms involved in antihyperglycemic effect of BBR may include:

1. Decreased glucose absorption by inhibiting α-glucosidase
2. Reduced glucose transport through the intestinal epithelium
3. Activation of adenosine 5′-monophosphate-activated protein kinase (AMPK)
4. Increased glucokinase activity
5. Induction of glucose transport by enhancing GLUT1 gene expression

Table 1 Nutraceuticals and plant extracts with potential of hypoglycemic and anti-diabetic effects

Nutraceuticals/plants	Active ingredient	Effect	References
Acacia arabica, *Acacia nilotica*	Flavonoids, saponins	Hypoglycemic	Rather et al. (2015)
Acacia karroo Hayne	Phenols, flavonoids, tannins, saponins, and cardiac glycosides	Hypoglycemic, anti-diabetic, α-amylase inhibitor, suppressed phosphorylation of Akt1, antioxidative	Njanje et al. (2017)
Aconitum carmichaelii	Aconitan A	Hypoglycemic	Hikino et al. (1989)
Achyranthes rubrofusca	–	Anti-diabetic	Geetha et al. (2011)
Adansonia digitata	–	Hypoglycemic, anti-diabetic	Tanko et al. (2008)
Aloe vera (*Aloe barbadensis*)	β-sitosterol, campesterol, anthraquinones, saponins	Anti-diabetic, antioxidative, anti-inflammatory, immunomodulatory	Can et al. (2004)
Argemone mexicana, *Berberis aristata*, *Berberis aquifolium*, *Berberis vulgaris*, *Coptis chinensis*, *Coptis trifolia*, *Hydrastis canadensis*	Berberine	Anti-diabetic, hypoglycemic	Chen and Xie (1986), Kong et al. (2009), Dong et al. (2011, 2012), Xia et al. (2011), Kumar et al. (2015), Lan et al. (2015), Pang et al. (2015)
Artanema sesamoides Benth	Alkaloids, flavonoids, saponins	Anti-diabetic, antihyperglycemic, antioxidative, cytoprotective	Selvan et al. (2008)
Artocarpus altilis	β-sitosterol, polyphenol, lutein	Anti-diabetic	Nair et al. (2013), Ragasa et al. (2014)
Artocarpus heterophyllus (jackfruit)	Artocarpin, artocarpecin, morin, dihydromorin, cycloartinone, cynomacurin	Anti-diabetic, anti-inflammatory, antioxidative, immunomodulatory	Prakash et al. (2009), Nair et al. (2013)
Balanites aegyptiaca Del. (desert date)	Furostanol, balanitines (1–7)	Anti-diabetic, antioxidative	Chothani and Vaghasiya (2011), Abou Khalil et al. (2016)
Barleria prionitis Linn.	Berlerinoside	Anti-diabetic, antihyperglycemic	Dheer and Bhatnagar (2010)
Beta vulgaris L. var cicla (chard)	Pectin, saponins, flavonoids, polysaccharides, ascorbic acid	Hypoglycemic, anti-diabetic	Yanarday and Colak (1998)
Bovine casein hydrolysate	Eleven casein medium-sized peptides, amino acid leucine	Insulinotropic, antihyperglycemic	Drummond et al. (2018)
Butea monosperma	Butrin, isobutrin, butin, palasitrin, butein	Hypoglycemic, anti-diabetic	Deore et al. (2008)
Caralluma edulis	–	Antioxidative, antihyperglycemic, anti-diabetic	Wadood et al. (1989)
Cassia kleinii	Terpenoids, coumarins, saponin	Anti-diabetic, antihyperglycemic	Babu et al. (2002, 2003a, b)
Catharanthus roseus	Catharanthine, ursolic acid, daucosterol, β-sitosterol, lochnericine, quercetin, kaempferol	Anti-diabetic	Singh et al. (2001), Wu et al. (2017)
Chloroxylon swietenia	Iridoid glucoside	Anti-diabetic	Jayaprasad et al. (2015)
Chromium trivalent	Chromium trivalent	Antihyperglycemic, anti-diabetic	Ryan et al. (2003), Biswas et al. (2010), Rains and Jain (2011), Hua et al. (2012), Fleck et al. (2014)
Cinnamomum zeylanicum Cinnamon	(E)-Cinnamaldehyde	Anti-diabetic, anti-obesity	SubashBabu et al. (2007), Anand et al. (2010), Nair et al. (2013), Soliman et al. (2012, 2013), Muhammad and Dewettinck (2017)
Cissus sicyoides	Tannins, alkaloids, steroid-triterpenes, amino acids, kaempferol, quercetin, saponins, quinones, phenolics, sabadin	Anti-diabetic, hypoglycemic, anti-inflammatory	Viana et al. (2004)
Citrus sinensis L. and other citrus fruits' peel	Phenolics, flavonoid diosmin	Anti-diabetic, antihyperglycemic, antioxidative, anti-inflammatory, insulinotropic, cytoprotective, increased expression of PPARγ	Cova et al. (1992), Jain et al. (2014), Hsu et al. (2017), Sathiyabama et al. (2018)
Clitoria ternatea	Polyphenols	Antioxidative, postprandial glucose suppression	Chusak et al. (2018)

(continued)

Table 1 (continued)

Nutraceuticals/plants	Active ingredient	Effect	References
Coscinium fenestratum	Not yet identified	Anti-diabetic	Shirwaikar et al. (2005)
Costus pictus D. Don, *Costus igneus* Nak (insulin plant)	Ergastanol, stigmasterol, lupeol, quercetin, diosgenin	Anti-diabetic, antioxidative	Jayasri et al. (2008), Hegde et al. (2014)
Curcuma longa (turmeric)	Curcumin and curcuminoids	Anti-diabetic, antioxidative, anti-inflammatory, anti-apoptosis, anti-diabetic cardiomyopathy, antihyperlipidemic	Javeri and Chand (2016), Rao and Najam (2016), de Melo et al. (2018), Zheng et al. (2018)
Ferocactus latispinus	–	Antihyperglycemic, antihyperlipidemic	Perez-Gutierrez and Mota Flores (2010)
Ferocactus histrix	–	Antihyperglycemic, antihyperlipidemic	Perez-Gutierrez and Mota Flores (2010)
Fish oil	Eicosapentaenoic acid, docosahexaenoic acid	Improved insulin sensitivity, antihyperglycemic	Menchetti et al. (2018)
Fructus arctii	Lignans	Anti-diabetic	Xu et al. (2008)
Galega officinalis L.	Diterpenes, triterpenes, phytosterols, and flavonoids	Anti-diabetic, hypoglycemic, immunomodulating, and lymphocyte apoptosis inhibiting	Nagalievska et al. (2018)
Hippophae rhamnoides L. (sea buckthorn)	Proanthocyanidins, isorhamnetin, quercetin	Hypoglycemic, sensory properties	Zhang et al. (2010c), Ma et al. (2017)
Hypoxis hemerocallidea	Phytosterols, sterolin	Anti-diabetic, antinociceptive, anti-inflammatory	Mahomed and Ojewole (2003), Ojewole (2006)
Lagerstroemia speciosa (L) Pers (banaba)	Corosolic acid, ellagitannins, lagerstroemin, flosin B, and reginin A	Hypoglycemic, antihyperglycemic, anti-diabetic	Mishra et al. (1990), Tanquilut et al. (2009)
Momordica charantia (bitter melon)	Glycosides (momordins I and II), saponins, alkaloids, triterpenes, steroids	Antihyperglycemic, anti-diabetic	Ahmed et al. (2004), Miura et al. (2004)
Mangifera indica	Antioxidants	Anti-diabetic, antioxidative, anti-inflammatory, immunomodulatory	Bhowmik et al. (2009), Etuk and Muhammed (2010), Irondi et al. (2016)
Melatonin	Melatonin	Anti-diabetic, antioxidative	Shieh et al. (2009), Sharman and Bondy (2016)
Moringa oleifera Lam (drum stick tree or horse rider tree)	Polyphenols (quercetin-3-glycoside, rutin, and kaempferol)	Antihyperglycemic, anti-diabetic, α-amylase, and α-glucosidase inhibiting	Jain et al. (2010), Gupta et al. (2012), Yassa and Tohamy (2014), Stohs and Hartman (2015), Khan et al. (2017), Villarruel-López et al. (2018)
Mucuna pruriens leaf extract	Monoterpenes and alkaloids	Anti-diabetic	Tanko et al. (2012)
Origanum vulgare L. (oregano)		Antioxidative, anti-obesity, anti-diabetic	Sabino et al. (2018)
Panax ginseng, *P. japonica*, *P. notoginseng*, *P. quinquefolius*, *P. vietnamensis* (ginseng)	Ginsenosides Rb2 and Rh2, protopanaxatriol, (20R)-protopanaxadiol, Rg1, Rc, Rd, Re, Rf, Rg2, Rh1, Rb1, pyroglutamic acid, peptidoglycan panaxan B	Antihyperglycemic, hypoglycemic	Tomoda et al. (1985), Cho et al. (2006), Lee et al. (2006), Yang and Wu (2016)
Persea americana Mill	Saponins, tannins, phlobatannins, flavonoids, alkaloids, polysaccharides	Hypoglycemic	Antia et al. (2005)
Phyllanthus niruri		Anti-diabetic	Okoli et al. (2011)
Piper betle		Anti-diabetic	Nair et al. (2013)
Polygonatum odoratum	Homoisoflavonoids (apigenin, luteolin, quercetin, maringenin, hesperitin, genistein), phloretin, polygonatumoside F, polygonatumoside G	Glucose transporter 2 inhibiting, antihyperglycemic	Liu et al. (2018), Wang et al. (2018)
Quercus robur L. *Quercus ilex*	Quercitol, cyclitols	Hypoglycemic, anti-diabetic	Worawalai et al. (2018)

(continued)

Table 1 (continued)

Nutraceuticals/plants	Active ingredient	Effect	References
Rehmannia glutinosa	Catalpol	Anti-diabetic, antihyperglycemic, antioxidative, anti-apoptotic, anti-insulin resistance, anti-gluconeogenesis, elevating glycogen synthesis	Shieh et al. (2011), Zhou et al. (2015), Yan et al. (2018)
Resveratrol	Resveratrol	Antioxidative, antihyperglycemic, anti-diabetic	Bhatt et al. (2012), Rouse et al. (2014)
Royal jelly	Royal jelly proteins	Antihyperglycemic	Fujii et al. (1990)
Ruta graveolens	Rutin	Antihyperglycemic, antihyperlipidemic, antioxidative	Ahmed et al. (2010)
Sarcopoterium spinosum	Triterpenes, tannins	Hypoglycemic	Reher et al. (1991)
Shilajit	Dibenzo-α-pyrones, dibenzo-α-pyrones chromoproteins, fulvic acid	Anti-diabetic, antioxidative, anti-inflammatory, immunomodulatory	Bhavsar et al. (2016)
Sida cordifolia	Alkaloids, flavonoids, lignin, glycosides, saponins, phytosterols	Anti-diabetic, anti-hypercholesterolemic, anti-inflammatory, hypoglycemic, hepatoprotective	Kaur et al. (2011), Sivapalan (2015)
Sophora tonkinensis	Flavonoids	Anti-diabetic	Huang et al. (2016)
Sphaeranthus indicus	β-sitosterol	Anti-diabetic	Prabhu et al. (2008)
Stevia rebaudiana Bertoni (stevia)	Diterpene glycosides (stevioside, steviolbioside, rebaudiosides (A,B, C,D,E), and dulcoside A) and polyphenols	Anti-diabetic, antioxidative, hepatoprotective, renoprotective, immunomodulatory, antihypertensive	Geuns et al. (2007), Stoyanova et al. (2011), Shivanna et al. (2013), Saleh et al. (2016), Ahmad and Ahmad (2018), Nichol et al. (2018)
Strychnos potatorum L.f.	Isomotiol, sitosterol, compesterol, galactomannan, galactan	Anti-diabetic, antioxidative	Dhasarathan and Theriappan (2011)
Terminalia arjuna	Phytosterol, lactones, flavonoids, phenolics, tannins, glycosides	Anti-diabetic	Parveen et al. (2011)
Trigonella foenum-graecum (Fenugreek)	Diosgenin, trigonelline, galactomannan	Antihyperglycemic	Zia et al. (2001), Garg (2016)
Vernonia amygdalina	Alkaloids, saponins, tannins, flavonoids	Anti-diabetic, antihyperglycemic	Etuk and Muhammed (2010)
Viburnum dilatatum	Polyphenols	Antihyperglycemic, α-glucosidase inhibitory	Iwai et al. (2006)
Virgin olive oil	Polyphenols, tyrosol, hydroxytyrosol, secoiridoids	Anti-insulin resistance, anti-mitochondrial dysfunction, anti-diabetic, antioxidative, anti-inflammatory	Lama et al. (2017), Celano et al. (2018)
Wheat-based rusks	Amylose	Antihyperglycemic, anti-diabetic	Vetrani et al. (2018)
Zingiber officinale (ginger)	Gingerol, gingerenone A, shogaols, paradol, 1-dehydro-10-gingerdione	Antioxidant, anti-inflammatory, antihyperglycemic, anti-diabetic, anti-diabetic nephropathy	Rafieian-Kopaei and Nasri (2014), Rahmani et al. (2014), Roufogalis (2014)

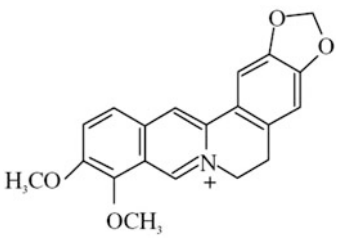

Fig. 1 Structural formula of berberine

6. Increased glucose uptake from blood to target organs, such as skeletal muscle and adipose tissue
7. Enhanced glucose metabolism by stimulation of glycolysis
8. Inhibition of gluconeogenesis in liver
9. Increased insulin receptor (*InsR*) expression and improved insulin secretion and sensitivity
10. Inhibition of the intracellular accumulation of ROS/RNS, cellular apoptosis, and inflammation that characterize vascular injury

In clinical trials, BBR has been shown to significantly lower fasting blood glucose, hemoglobin A_{1c}, triglyceride, total cholesterol, and LDL-C and increase insulin receptor expression in patients with type 2 diabetes receiving BBR (1 g daily or 500 mg three times a day) (Li 2007; Yin et al. 2008; Zhang et al. 2010a, b). It is interesting to note that BBR has positive effects in treating diabetes-associated complications such as nephropathy, neuropathy, and cardiomyopathy (Pang et al. 2015; Imenshahidi and Hosseinzadeh 2015; Zhang and Chen 2012; Lan et al. 2015). Clinical trials have yet to be carried out in dogs and cats to establish the right dose and efficacy of BBR against diabetes and associated complications.

5.1.2 Curcumin

The root of *Curcuma longa* is the source of turmeric (yellow powder), which consists of a group of phytoconstituents commonly called curcuminoids. Curcuminoids include curcumin (diferuloylmethane), demethoxycurcumin, and bisdemethoxycurcumin (BMC). Turmeric powder and the structural formula of curcumin (enol and keto form) are shown in Fig. 2.

Chemically, curcumin is a diarylheptanoid, a natural phenol responsible for turmeric's yellow color. Curcumin's tautomerism exists in the enolic form in organic solvents and in the keto form in water (Manolova et al. 2014).

So far, curcumin has not led to any drug development due to several factors, such as chemical instability, water insolubility, lack of selective target activity, low bioavailability, limited tissue distribution, and extensive metabolism (Anand et al. 2013; Metzler et al. 2013; Nelson et al. 2017). However, it is a very popular ingredient in many nutraceuticals/dietary supplements around the world. Presently, its largest market is in North America.

Curcumin appears to prevent and ameliorate diabetes and its complications (nephropathy, retinopathy, and cardiopathy) by multiple mechanisms (Abo-Salem et al. 2014; Wu et al. 2014; Javeri and Chand 2016). Inflammation of micro and macro blood vessels and peripheral nerves in the body plays a major role in the pathophysiology of diabetes. Long-term low-dose feeding of curcumin may prevent and ameliorate progression and prevalence of diabetes in humans and animals. Castro et al. (2014) rationalized the therapeutic efficacy of curcumin in diabetes by modulating immune cells responsible for β-cell death in a mouse model of type 1 diabetes.

Curcumin has been shown to significantly increase the expression of AMPK and PPARγ, and reduced the expression of Il-6 and NF-κB, thereby ameliorating chronic inflammation in diabetic mice (Abo-Salem et al. 2014; Jiménez-Flores et al. 2014). Additional benefits of curcumin in diabetes may be due to its antioxidative property (Menon and Sudheer 2007; Javeri and Chand 2016).

Recently, Hariri and Haghighatdoost (2017) suggested that curcumin in a more soluble and bioavailable form can reduce body weight and obesity, but long-term clinical trials need to be carried out. In a number of other studies, various formulations of curcumin have been developed for improved

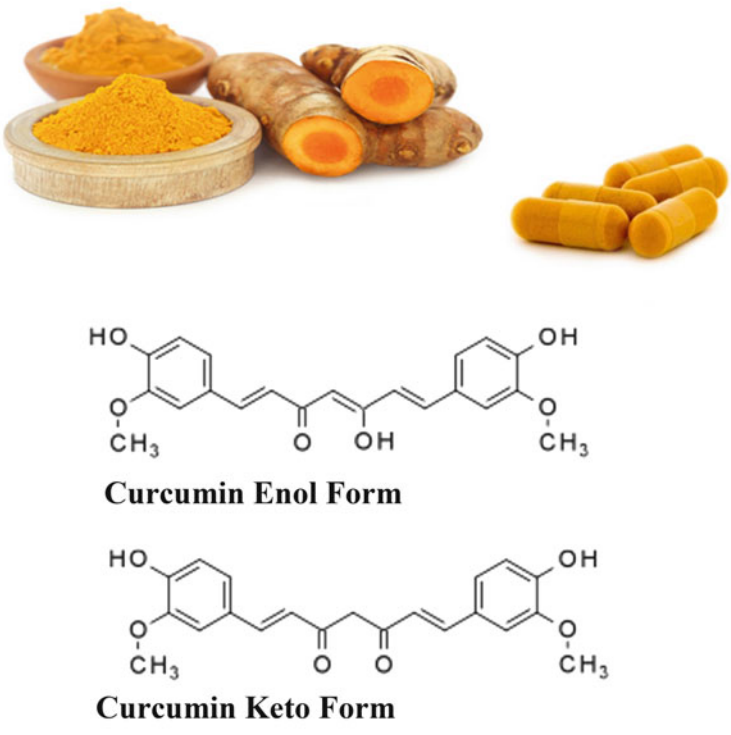

Fig. 2 Structural formula of curcumin (upper, enol form; lower, keto form)

bioavailability (Liu et al. 2006; Antony et al. 2008; Cuomo et al. 2011; Sasaki et al. 2011; Jager et al. 2014; Yallapu et al. 2015). Purpura et al. (2018) demonstrated that γ-cyclodextrin curcumin formulation (CW8) significantly improved the absorption of curcuminoids in healthy humans.

Clinical studies in dogs and cats have yet to be carried out to establish the therapeutic dose, efficacy, and safety in diabetic dogs and cats. In preliminary clinical studies, patients receiving curcumin up to 8 g/day for 3–4 months showed no toxicity, though some subjects complained mild nausea and diarrhea (Hsu and Cheng 2007). Details on various aspects of curcumin, including its beneficial health effects in other diseases, can be found in chapter "Standardized Turmeric and Curcumin" of this book.

5.1.3 Fenugreek

Fenugreek seeds are obtained from the *Trigonella foenum-graecum* L. plant which is commonly cultivated in India, China, and the Mediterranean and North African regions. The seeds are known to contain many phytoconstituents, including flavonoids, steroidal saponins diosgenin, galactomannan fiber, amino acid 4-hydroxyisoleucine, vitamins, and the alkaloid trigonelline. Ribes et al. (1986) reported that the defatted part of the fenugreek seed, called subfraction "a" which contains the seed parts like testa (seed coat) and endosperm (a source of stored food), has been associated with the antihyperglycemic effect in diabetic dogs. The structural formula of trigonelline and diosgenin is shown in Figs. 3 and 4, respectively.

In addition to trigonelline, the seeds of fenugreek contain other alkaloids such as gentianine and carpaine. 4-Hydroxyisoleucine has been shown to cause an increase in glucose-dependent insulin secretion (Sauvaire et al. 1998) and lower elevated plasma triglycerides and total cholesterol. Haeri et al. (2012) observed antihyperglycemic and antihyperlipidemic (triglycerides and total cholesterol) effects in STZ-treated rats. The antihyperglycemic effect from fenugreek seeds can also be due to galactomannan and diosgenin (reviewed in Garg 2016). All findings taken together from various studies show that phytoconstituents in seeds of fenugreek can exert antihyperglycemic effect by multiple mechanisms (such as antioxidative, decreased lipid peroxidation, anti-inflammatory, increased insulin secretion, decreased insulin resistance, decreased gluconeogenesis, increased hepatic glycogen content, and others) and therefore present fenugreek seeds as a nutraceutical for diabetic dogs and cats. One drawback with fenugreek for anti-diabetic effect is that a relatively high dose for the antihyperglycemic effect is required. For further details on therapeutic efficacy and safety of fenugreek, readers are referred to Garg (2016) and chapter "Fenugreek for Animals, Birds, and Fish Health" by Kumar and co-authors in this book.

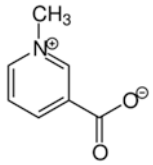

Fig. 3 Structural formula of trigonelline

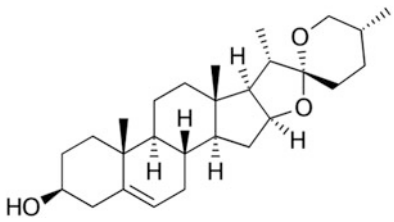

Fig. 4 Structural formula of diosgenin

Fig. 5 *Left*: Dried cinnamon bark and powder obtained from *Cinnamomum* tree. *Right*: Structural formula of (E)-cinnamaldehyde

5.1.4 Cinnamon

Cinnamon is an aromatic spice in powder form (Fig. 5) obtained from the dried bark of several species of the *Cinnamomum* tree (*Cinnamomum zeylanicum* Blume). In the United States, two varieties of cinnamon (Ceylon and cassia) are available. Ceylon cinnamon is considered a true cinnamon and is quite expensive. Although cinnamon bark powder contains many phytoconstituents, (E)-cinnamaldehyde is the main component. Cinnamon bark powder and the structural formula of (E)-cinnamaldehyde are shown in Fig. 5.

Cinnamon powder contains the second highest amount of antioxidants next to cloves. In prediabetics, consumption of 500 mg cinnamon/day for 12 weeks may reduce oxidative stress by 14%. In addition, cinnamon may increase insulin secretion, increase insulin sensitivity, and lower blood glucose by moving glucose into cells. However, the effects of cinnamon on hemoglobin A1C are conflicting. Shen et al. (2010) demonstrated that streptozotocin-induced diabetic rats receiving aqueous extract of *C. zeylanicum* (30 mg/kg/day for 22 days) were rescued from hyperglycemia and nephropathy. These rats were found to have upregulation of uncoupling

protein-1 (UCP-1) and glucose transporter 4 (GLUT4) in their brown adipose tissues as well as in their muscles. In 3T3-L1 adipocytes, cinnamon extract upregulated GLUT4 translocation and increased glucose uptake. Cinnamon extract exhibited its anti-diabetic effect independently from insulin by at least two mechanisms: (1) upregulation of mitochondrial UCP-1 and (2) enhanced translocation of GLUT4 in the muscle and adipose tissues.

In humans, the daily dose of cinnamon is from 1 to 4 g. No clinical trials have yet been undertaken in dogs and cats.

5.1.5 *Stevia rebaudiana*

Stevia rebaudiana (commonly called stevia) is native to Paraguay. Leaves of this plant contain multiple active principles including diterpene glycosides (stevioside; steviolbioside; rebaudiosides A, B, C, D, and E) and dulcoside A. A sweet taste is attributed to stevioside and rebaudiosides. Antihyperglycemic effect occurs due to stevioside. The structural formula of stevioside is shown in Fig. 6.

Recently, Ahmad and Ahmad (2018) reported that diabetic rats receiving an aqueous extract of *Stevia rebaudiana* leaf (200, 300, 400, and 500 mg/kg body wt) for 8 weeks showed (in a dose-dependent manner) a decrease in blood glucose (–73.24%), fasting blood glucose (–66.09%), and HbA1c hemoglobin (5.32%), while insulin (17.82 μIU/mL) and liver glycogen (45.02 mg/g) levels were significantly improved. In another study, Saleh et al. (2016) demonstrated that stevioside administration in diabetic rats exhibited an insulinomimetic effect. Stevioside increased insulin and leptin secretion, normalized hepatic and renal biomarkers, and restored alterations in antioxidant activity and lipid profiles. These authors also reported that for mRNA expression, stevioside upregulated the expression of PK and IRS-1 genes, which are downregulated in diabetic rats, and was very effective in the downregulation of CPT-1 mRNA expression. At the cellular level, stevioside normalized the histopathological changes induced in the pancreas.

Stevia is known to exert antioxidative, antihyperglycemic, antihyperlipidemic, immunomodulatory, hepatoprotective, renoprotective, and antihypertensive effects (Jeppesen et al. 2003; Gregersen et al. 2004; Lailerd et al. 2004; Chen et al. 2005; Hossain et al. 2011; Stoyanova et al. 2011; Lemus-Mondaca et al. 2012; Shivanna et al. 2013). Recently, in a meta-analysis, Nichol et al. (2018) compared the glycemic impact of non-nutritive sweetener (NNS) stevioside with other NNS (aspartame, saccharin, and sucralose) and concluded that the glycemic impact of these sweeteners did not differ by type of NNS. In conclusion, stevia exerts insulin-like effects and appears to be a promising nutraceutical for the management of diabetes and its associated complications.

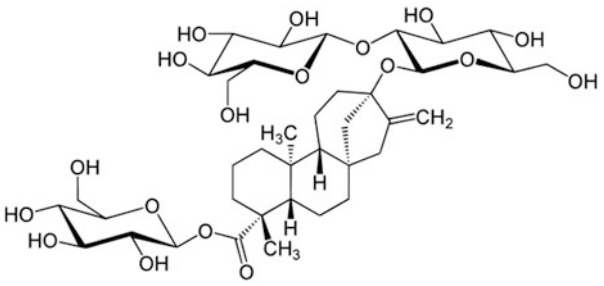

Fig. 6 Structural formula of stevioside

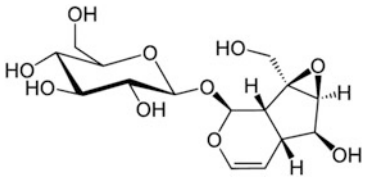

Fig. 7 Structural formula of catalpol

5.1.6 Catalpol

Catalpol is a natural product (an iridoid glucoside) isolated from the root of *Rehmannia glutinosa*. The structural formula of catalpol is shown in Fig. 7.

Catalpol exerts antioxidative, anti-inflammatory, anti-apoptosis, and anti-diabetes properties (Shieh et al. 2011; Zhou et al. 2015). Catalpol has been shown to have beneficial effects against glucose/lipid metabolic disorder and insulin resistance in diabetes (Yan et al. 2018). Zhou et al. (2015) reported that catalpol ameliorated insulin resistance in high-fat diet (HFD)-induced diabetes in mice. Shieh et al. (2011) and Bao et al. (2016) demonstrated that catalpol could improve insulin resistance, decrease blood glucose levels, and promote glucose uptake through increasing the protein expression of glucose transporter-4 (GLUT4) in skeletal muscle and adipose tissues in db/db mice and STZ-induced rats. Catalpol reduced high-fat diet-induced insulin resistance and adipose tissue inflammation by suppressing the JNK and NF-kappaB pathways. Recently, Yan et al. (2018) found that catalpol (100–200 mg/kg/day)-treated T2DM mice via gavage ameliorated hepatic insulin resistance by acting on the AMP-activated protein kinase (AMPK)/NADPH oxidase type 4 (NOX4)/phosphatidylinositol 3-kinase (PI3K)/AKT pathway. The suppressive effect of catalpol on glucosamine-induced NOX4 overexpression was weakened by a knockdown of AMPK with short interfering RNA (siRNA). Catalpol exhibited the effects of decreasing hepatic gluconeogenesis and increasing hepatic glycogen synthesis both in vivo and in vitro (Yan et al. 2018). These findings suggest that catalpol could be a novel nutraceutical to manage hyperglycemia and T2DM in animals and humans.

5.1.7 *Moringa oleifera* Lam

Moringa oleifera is an Indian tree that has been cultivated in many other countries including Mexico. This tree is commonly referred to as the "drum stick tree" or the "horse riding tree." The flowers, leaves, and seeds of *M. oleifera* have been found to be of medicinal value. The therapeutic use of *M. oleifera* leaves has been evaluated in diabetes because the leaves lower blood glucose concentrations after ingestion as they contain polyphenols such as quercetin-3-glycoside, rutin, kaempferol, and glycoside (Jaiswal et al. 2009; Arora et al. 2013; Edoga et al. 2013; Al-Malki and El Rabey 2015). Divi et al. (2012) reported a decrease in fasting blood glucose, oral glucose tolerance test, and postprandial glucose in diabetic rats following *M. oleifera* therapy. Furthermore, the anti-diabetic effect of *M. oleifera* seed powder has been observed in rat models with the decreased blood glucose, the amelioration of lipid peroxide level, and the diminished levels of IL-6 and immunoglobulins A in comparison with diabetic positive control in both insulin-resistant and insulin-deficient bioassays (Anudeep et al. 2016; Gopalakrishnan et al. 2016). Recently, Villarruel-López et al. (2018) reported that consumption of the leaves of *M. oleifera* (50 mg/day) by alloxan monohydrate (150 mg/kg, IP)-induced hyperglycemic/diabetic rats showed hypoglycemia. These authors found that *M. oleifera* leaf powder revealed no adverse effect. The beneficial effects of *M. oleifera* might also be due to its antioxidants, vitamins, and a protease-resistant glycoprotein that functions as dietary fiber (Georgewill et al. 2010; Gupta et al. 2012; Vongsak et al. 2013; Khan et al. 2017). The *M. oleifera* extract has been found effective against diabetes-related complications such as retinopathy (Kumar Gupta et al. 2013). Recently, Khan et al. (2017) suggested that the aqueous extracts of the *M. oleifera* leaf can be used as phytopharmaceuticals for the management of diabetes by using them as adjuvants or alone. In a number of studies, *M. oleifera* has been evaluated for its safety and toxicity (Asare et al. 2012; Awodele et al. 2012; Stohs and Hartman 2015).

M. oleifera has a great potential for its use as anti-diabetic nutraceutical, if it is used in a recommended dose, which is yet to be established through clinical trials in dogs and cats.

5.1.8 *Momordica charantia*

Momordica charantia (bitter melon) is a commonly used vegetable in India, China, and many other countries. Phytoconstituents present in the fruits of this plant include alkaloids, glycosides, saponins, triterpenes, steroids, and fixed oils. Joseph and Jini (2013) reported that consumption of bitter melon lowered blood glucose concentrations by increasing hepatic utilization of glucose and decreasing hepatic glucose output. In a number of studies, bitter melon has shown antihyperglycemic activity, and in normoglycemic rats it produced hypoglycemic activity (Ojewole et al. 2006). Therefore, bitter melon should be used with a great deal of caution in diabetic patients, especially if given as an adjuvant to glucose-lowering drugs (Chan et al. 2016). In addition to hypoglycemia, bitter melon may produce other side effects, such as diarrhea, abdominal pain, headache, fever, atrial fibrillation, and urinary incontinence. In pregnant women, bitter melon has been shown to cause bleeding, contractions, stimulation of menstruation, and miscarriage (reviewed in Gupta et al. 2018).

5.1.9 Diosmin

Diosmin (diosmetin 7-rutinoside) is one of the natural flavone glycosides present in citrus, hyssop, and rosemary. The structural formula of diosmin is shown in Fig. 8.

Diosmin has been demonstrated to improve glucose metabolism in diabetes (Hsu et al. 2017). Its pharmacokinetic profile indicates that diosmin is transformed by gut microbiota to diosmetin, which is absorbed and rapidly distributed throughout the body with a long half-life (26–43 h) in healthy volunteers (Cova et al. 1992). In type 1 DM (T1DM) patients, a diosmin-containing flavonoid mixture showed a decrease in glycosylated hemoglobin and an increase in glutathione peroxidase. Pari and Srinivasan (2010) demonstrated that in T2DM rats, diosmin affected the rate-limiting enzymes of carbohydrate metabolism and was found to reverse the abnormalities in glycoprotein components. In a number of studies, endogenous and exogenous β-endorphin has been shown to increase circulating insulin in humans and animals with DM (Curry et al. 1987; Cheng et al. 2002; Liu and Cheng 2011; Hsu et al. 2017). In essence, diosmin exerts antioxidative, anti-inflammatory, increased insulin secretion by enhanced β-endorphin, decreased glycosylated hemoglobin, and antihyperglycemic activities. Therefore, it has the potential to be a promising nutraceutical for diabetic humans and animals after proper clinical trials in dogs and cats.

5.1.10 Ginseng

Ginseng is the root of plants (genus *Panax*), including Chinese ginseng (*P. notoginseng*), Japanese ginseng (*P. japonica*), Korean ginseng (*P. ginseng*), Vietnamese ginseng (*P. vietnamensis*), and American ginseng (*P. quinquefolius*). Ginseng contains many active ingredients, called ginsenosides

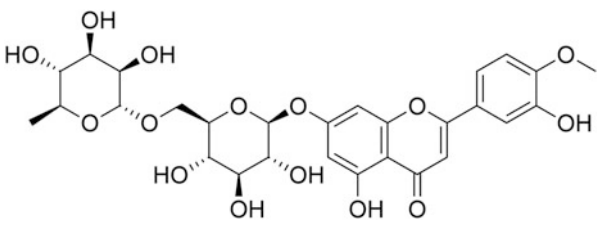

Fig. 8 Structural formula of diosmin

(ginseng saponins). Ginseng has been reported to exert hypoglycemic effect since the early 1970s. Red ginseng was found to be superior over white ginseng for its hypoglycemic effect. The ginsenosides Rb2 and Rh2, protopanaxatriol, (20R)-protopanaxadiol, Rg1, Rc, Rd, Re, Rf, Rg2, Rh1, and Rb1, acidic peptide, adenosine, pyroglutamic acid, and peptidoglycan panaxan B may be responsible for the glucose-lowering effect in diabetes (reviewed in Yang and Wu 2016). Ginsenoside Rh2 exhibited its efficacy in improving DM through reducing blood glucose level and increasing insulin sensitivity in STZ-induced diabetic rats (Lai et al. 2006; Lee et al. 2007). In another study, Xiang et al. (2008) showed that ginsenoside Re had an anti-diabetic effect in mice. In many clinical studies, T2DM patients receiving ginseng have shown an antihyperglycemic effect (Kim et al. 2011). Currently, the recommended anti-diabetic dose of ginseng is 200 mg/day (Natural Medicines Comprehensive Database 2014). Ginseng can be indicated as an alternative natural therapy for diabetic dogs and cats after proper long-term clinical trials. For further details on ginseng, readers are referred to Yang and Wu (2016).

5.1.11 *Costus pictus* and *Costus igneus*

Costus pictus D. Don and *Costus igneus* Nak (commonly called insulin plants) are native to Central and South America. Currently, these plants are also used as an herbal cure for diabetes in America and India. Phytochemical analysis of these plants has revealed the presence of various antioxidants (ascorbic acid, α-tocopherol, β-carotene, terpenoids, and flavonoids), triterpenoids, alkaloids, tannins, saponins, steroids, etc. Devi and Urooj (2008a, b) reported that people with diabetes in India consume one leaf a day to keep their blood glucose under control. In a number of experimental and clinical studies, extracts of these plants have shown antioxidative and anti-diabetic effects (Devi and Urooj 2008a, b; Elavarasi and Saravanan 2012; Hegde et al. 2014). In a cross-sectional study, patients consuming either one fresh leaf or one tablespoon of shade-dried powder/day of *C. igneus*, in conjunction with other modalities of treatment, had effectively produced glycemic control in diabetes (Shetty et al. 2010). Such clinical trials need to be conducted in diabetic dogs and cats before these plant extracts or their constituents can be indicated as nutraceuticals.

5.1.12 Touchi Extract

Touchi extract is a fermented soybean product used for thousands of years in China and Japan. It lowers blood glucose level by inhibiting intestinal α-glucosidase activity. Currently, the recommended dose of Touchi extract is 300 mg before each meal.

5.1.13 Herbal Products Used in Combination Against Diabetes

In complementary and alternative medicine, it is a common practice to use nutraceuticals/plant extracts in combination to attain optimal therapeutic effects. For an antihyperglycemic effect in diabetes, the extracts of *Curcuma longa* and *Eugenia jambolana* (Rao and Najam 2016), or *Cinnamomum tamala* and *Aloe vera* (Singh et al. 2015), or *Balanites aegyptiaca* (desert date) and *Petroselinum sativum* (parsley) provide superior results over when they are used alone (Abou Khalil et al. 2016). In a recent investigation, Rouse et al. (2014) found that resveratrol (0.1–10 μmol/L) and curcumin (1–100 pmol/L) regulated insulin secretion under glucose-stimulated conditions. Additionally, treating β-cell lines and human islets with these polyphenols led to increased intracellular cAMP levels in a manner similar to 3-isobutyl-1-methylxanthine, a classic phosphodiesterase (PDE) inhibitor. Resveratrol and curcumin treatment significantly downregulated the mRNA expression of most of the 11 PDE isozymes, including PDE3B, PDE8A, and PDE10A, which have been inked to regulation of insulin secretion in islets. Both resveratrol and curcumin, in addition to antioxidative and anti-inflammatory activities, inhibited PDE activity in a dose-dependent manner and enhanced pancreatic β-cell function. Currently, many other nutraceuticals/plant alkaloids are used in combination to ameliorate antihyperglycemic and anti-diabetic effects in humans and animals.

5.2 Herbo-Mineral/Metal Nutraceuticals

5.2.1 Shilajit

Shilajit is a pale-brown to blackish-brown herbo-mineral exudate from the sedimentary rocks of the Himalayan Mountains at an altitude of about 10,000 ft. Shilajit has been used for more than 3000 years for both preventative health and treating many diseases in humans, including diabetes, arthritis, hypertension, immune dysfunction, cognition impairment, and arthritis (Agarwal et al. 2007; Lawley et al. 2013). It consists of humus and organic plant (*Styrax officinalis*, *Trifolium repens*, and others) materials. In a number of studies, shilajit has been found to be effective against diabetes. Bhattacharya (1995) reported that oral administration of 50–100 mg/kg of a processed and standardized shilajit attenuated streptozotocin-induced diabetes in rats. Shilajit also increased pancreatic islet superoxide dismutase activity, leading to a decrease in free radical production. Kanikkannan et al. (1994) found that processed shilajit (1.0 mg/kg, sc) prevented streptozotocin-induced diabetes in rats. Shilajit

(100 mg/kg) produced a significant reduction in blood glucose levels and also produced beneficial effects on the lipid profile. The anti-diabetic effect of shilajit could be due to its major constituents (dibenzo-α-pyrones (DBP), DBP-chromoproteins, and fulvic acids with DBP core) exerting antioxidative, anti-inflammatory, and inhibition of alpha-glucosidase and alpha-amylase activity (Aparna et al. 2014; Bhavsar et al. 2016). For further details on shilajit, readers are referred to chapter "Neem Extract" in this book.

5.2.2 Chromium

The use of trivalent chromium in TM2D humans (especially insulin resistant) has become more common because its mechanism of action for antihyperglycemic effect is well explained at the molecular level (Biswas et al. 2010; Hua et al. 2012), and it has been found successful in clinical trials (Ryan et al. 2003). In addition to alleviating insulin resistance, the potential effect of chromium in regulating oxidative stress, and inflammation has been reported (Rains and Jain 2011). A daily dose of 120 μg trivalent chromium is recommended for humans. The FDA allows up to 1000 μg chromium/day. Above this dose, renal toxicity may ensue. In a randomized double-blinded study, moderately osteoarthritic dogs receiving 500 μg trivalent chromium twice daily for a period of 150 days showed no adverse effect (Fleck et al. 2014). Trivalent chromium can be a good adjunct to nutraceutical therapy in diabetic dogs and cats after valid clinical trials.

6 Concluding Remarks and Future Directions

Diabetes in canines and felines is a serious health concern around the world. Etiopathologies and underlying mechanisms of action in diabetes are very complex. Currently, management of diabetes, hyperglycemia, hyperlipidemia, and diabetes-associated complications (cardiac, renal, and nerve damage) relies on diet monitoring, moderate exercise, and pharmacotherapeutic medicines, including insulin injections. Due to the high cost and side effects of synthetic medicines, alternative complementary medicines/nutraceuticals are receiving enormous interest in the scientific community as well as from pet owners. For a large number of nutraceuticals, in vitro and in vivo studies have been conducted for efficacy and safety evaluation, while large-scale clinical trials are completely lacking in dogs and cats. Some of the nutraceuticals have shown strong potential for an anti-diabetic effect and deserve further evaluation in clinical trials. Also, when nutraceuticals are given in conjunction with conventional therapeutic medicines, they need to be evaluated for any possible toxic interactions.

Acknowledgment The authors would like to thank Ms. Robin B. Doss for her technical assistance in preparation of this chapter.

Nutraceuticals for Wound Healing: A Special Focus on *Chromolaena odorata* as Guardian of Health with Broad Spectrum of Biological Activities

Mohamed Ali-Seyed and Kavitha Vijayaraghavan

Abstract

Nutraceuticals are any material, either whole or in part, that may be considered a hybrid of nutrition and pharmaceuticals. This special characteristic, aside from providing good health, leads to treatment of wounds and prevention of certain diseases. Nutraceuticals have gained significant attention due to their presumed safety and promising nutritional and therapeutic outcomes. An important aspect of the use of traditional medicinal remedies in the treatment of burns and wounds is the potential to improve healing and reduce downtime in order to ease the financial burden on the affected patients and their families. Although several medicinal plants and their pharmaceutical preparations/formulations are available for wound care and management, it remains necessary to search for efficacious treatments, as certain current formulations cause adverse effects or lack efficacy. Several herbal medicines have displayed marked activity in the management of wounds, and various natural compounds/extracts have verified in vivo wound healing potential; therefore they are considered as potential drugs of natural origin. *C. odorata* is considered a tropical weed. It exhibits numerous relevant medicinal properties on an appreciable scale and is known in some parts of the world as a traditional medicine used to treat various ailments. Besides the above, volatile oils of the plant are considered a possible source of a nutraceutical to be used for clinical purposes. To understand its precise role as nature's gift for healing wounds and its contribution to affordable health care, this plant must be scientifically assessed based on the available literature. This is crucial to its potential future drug design, development, and application for the treatment of wounds in both animal and human medicine and cost-effective health care.

C. odorata · Bioactive principles · Invasive weed · Natural products · Wound healing nutraceuticals

1 Introduction

Wounds are physical injuries that can be classified as open or closed based on the underlying cause (Eming et al. 2002) and on the basis of the physiology of wound healing. Wounds are popularly categorized by their level of chronicity as either acute or chronic (Strodtbeck 2001). An acute wound is an injury to the tissue that normally proceeds through an orderly and timely reparative process resulting in sustained restoration of anatomic and functional integrity. Acute wounds follow trauma or inflammation, are caused by external damage to intact skin, and usually heal within 6 weeks. Surgical wounds, bites, burns, minor cuts and abrasions, and more severe traumatic wounds such as lacerations, crushes, or gunshot injuries are examples of acute wounds. Acute wounds are generally caused by cuts or surgical incisions and complete the wound healing process within the expected time frame (Menke et al. 2008).

Wounds that fail to progress through the normal stages of healing lead to a state of pathologic inflammation. These wounds require either a prolonged time to heal or recur frequently. The most common frequent causes of chronic wounds are local infection, hypoxia, trauma, foreign bodies, and systemic problems such as diabetes mellitus, malnutrition, immunodeficiency, or medications (Menke et al. 2008). Chronic wounds, in addition to failing to heal after 6 weeks, have characteristic pathological associations due to underlying endogenous mechanisms associated with a predisposing condition that ultimately compromises the integrity of dermal

and epidermal tissue, inhibiting or delaying healing (Krishnan 2006). Pressure ulcers, venous leg ulcers, and diabetic foot ulcers are examples of chronic wounds (de la Torre and Chambers 2008). These wounds are visible evidence of an underlying condition such as extended pressure on the tissues, compromised tissue perfusion as a consequence of impaired arterial supply (peripheral vascular disease) or impaired venous drainage (venous hypertension) and metabolic diseases such as diabetes mellitus (DM), or even poor nutrition.

2 Pathophysiology of Wound and Wound Healing

It is well known that there is no definite method for classifying wounds. However, there are many different types of wounds ranging from mild to severe to potentially fatal, and some of these are classified as follows:

(a) Wounds can be referred to by their anatomical site, e.g., abdominal or axillary wound.
(b) Based on the underlying cause of the wound, this type of wound is called open or closed. In this class, bleeding is clearly visible as blood escapes from the body. It is further classified as incised, laceration, abrasion or superficial, puncture, gunshot, or penetration wound (Schultz 1999).
(c) Wounds with or without tissue loss (e.g., surgery) or burns (Poul Holm et al. 1974).

The wound healing process has been studied for decades. The proper healing of wounds is essential for the restoration of disrupted anatomical integrity and disturbed function of the affected area (Edlich et al. 2005). Healing is a complex and intricate process initiated in response to an injury that serves to restore the function and integrity of the damaged tissues (Wietecha and DiPietro 2013). In developing countries, such as Africa and Asia, injury to the skin is common, and a general lack of medical resources often results in a chronic state of healing (Starley et al. 1999). Chronic wounds, in particular, are a major concern for both patients and clinicians, and they affect a large number of patients, leading to a serious reduction in their quality of life. Impaired and aberrant wound healing imposes a huge financial burden in the developed world and is an insurmountable problem in the undeveloped one (Wound Forecast to 2021).

Current estimates indicate that nearly six million people suffer from chronic wounds worldwide (Wound Forecast to 2021; WHO 2014). In the USA alone, combat-related and other traumatic wounds lead to over 300,000 hospitalizations annually. The restoration of the affected area in wound injury survivors is the main aim of quality rehabilitation. Surgical wounds account for the vast majority of skin injuries. Approximately 80% of these wounds use some form of closure product such as sutures, staples, and tapes, while other wound management strategies use hemostatic products, fabric bandages, and surgical dressings (Belmont et al. 2010).

Wound healing is a normal biological process in the human body as well as in animals and is achieved through four precisely and highly programmed phases: (1) hemostasis, (2) inflammation, (3) proliferation, and (4) remodeling (Burford et al. 2007). Each phase is characterized by the infiltration of specific cell types into the wound site (Redd et al. 2004), all of which interact and communicate via chemical signals to optimize repair. Wound healing processes are well-organized biochemical and cellular events that lead to the growth and regeneration of wounded tissue. It involves the activity of an intricate network of blood cells, cytokines, and growth factors which ultimately leads to the restoration of normal conditions in the injured skin or tissue (Clark 1991). Upon onset of the inflammatory response, fibroblasts begin to proliferate and migrate into the wound area. Collagen and fibronectin are subsequently deposited in the wound bed, serving as a temporary matrix on which epithelial cells can migrate (Rørth 2007). Throughout the process, cells often migrate in groups.

While understanding how cells move together in tissue repair is important, this process is also fundamentally relevant to other complex events such as morphogenesis and tumor metastasis (Friedl 2004). There are two mechanisms of collective migration that have been identified (Martin 1997). First, lamellipodial crawling involves active migration of cells at the wound edge, mediated primarily through cell-extracellular matrix (ECM) interactions in the wound area (Trepat et al. 2009). This process is commonly observed in adult wound healing and is well-studied in in vitro wound healing models (Bindschadler and McGrath 2007). The second mechanism is known as the purse string model, and it is the primary mode of cell movement in fetal wound healing (Bullard et al. 2003). Following injury, an actomyosin cable assembles around the periphery of the wound and contracts to close the wound by transmitting tension through intercellular junctions (Tamada et al. 2007). While the lamellipodial crawling mechanism results in rapid wound closure, the purse string mechanism leads to scarless wound healing.

The aim of wound care is to promote wound healing in the shortest time possible, with minimal pain, discomfort, and scarring to the patient, and this must occur in a physiologic environment conducive to tissue repair and regeneration (Bowler et al. 2001). Wound healing processes are known to be influenced by many factors including infections, nutritional status, drugs and hormones, type and sites of wound, and wasting diseases like diabetes. The healing process may also be hampered by the presence of oxygen free

radicals or microbial infection. Due to such a poor hygienic status, wound infection is still one of the most common diseases in developing countries (Hussein et al. 2011). Besides the above, multiple local disturbances and systemic disease can result in impaired wound healing (Eming et al. 2002). The resulting prolonged inflammation and toxic microenvironment are the main reasons for a transition from the acute to chronic state (Amadeu et al. 2004).

3 Wound Healing: A New Multi-spectrum Twenty-First-Century Perspective

Despite the tremendous advances in the pharmaceutical industry, the search for more effective and lower cost therapeutic approaches for wound healing remains a challenge for modern medicine due to the chronic nature of therapy and related side effects (Ghosh and Gaba 2013). Many new approaches, such as gene therapy (Petrie et al. 2003) and tissue-engineered skin, have met with limited success. In the search for new therapeutic options, plants and their metabolites are a great source of novel biomolecules. The application of plant-based medicines provides, in principle, a cost-effective therapy. A major criticism of herbal medicines, however, is that they are not subjected to the rigors of their pharmaceutical counterparts (Barreto et al. 2014). However, over the last 20 years, in vitro tests developed to investigate wound healing have exploited all of these processes as targets for enhancing its management. The different phases of the wound healing process overlap, and an ideal plant-based remedy should affect at least two of the different processes before it can be considered to have some scientific support for its traditional use (Burford et al. 2007).

Plants serve as potential resources for the traditional and modern systems of medicines, nutraceuticals, food supplements, folk medicines, pharmaceutical intermediates, and chemical entities (Soni and Singhai 2013). They also serve as possible resources for the treatment of various human diseases because of their potential efficacy and proven safety for animal and human use (Hashemi and Davoodi 2011). In folk medicine, herbal plants have been used widely in facilitating wound healing with a high degree of success (Kumar et al. 2007). Some of these plants either possess pro-wound healing activities or exhibit antimicrobial and other related properties which are beneficial in overall wound care (Dawn et al. 2008). This has inspired much research aimed at validating claims and discovering mechanisms which possibly explain the potential of these herbs on wound repair processes. Some examples of wound healing plants (Table 1) include korphad, *Aloe vera* (Maenthaisong et al. 2007); Madeira vines, *Anredera diffusa* (Moura-Letts et al. 2006); jungle geranium, *Ixora coccinea* (Upadhyay et al. 2014); Indian mulberry, *Morinda pubescens* (Mathivanan et al. 2006); simple-leaf chaste tree, *Vitex trifolia*; and peacock chaste tree, *Vitex altissima* (Manjunatha et al. 2007).

4 Models of Wound and Wound Healing

In recent years, it has been well justified that the incorporation of both in vivo and in vitro models are imminent for investigators in all scientific discipline especially in wound care research. This is not surprising because any bioactive principle or new product developed by researchers or pharmacological industries needs both basic and translational research to verify, reproduce, and acquire data as the result of this model experimentation may lead to both preclinical and clinical trial outcomes for improved wound healing. In general, these models are usually adopted in a stepwise order that starts with in silico and in vitro assays and in vivo animal models followed by advanced clinical evaluations. The most commonly used models are briefed below by Wilhelm et al. (2017).

4.1 In Vitro Assays

In vitro assays are laboratory-based tests, which provide abundant opportunities for observing the outcome of test materials/healing agents/plant extracts/drugs on particular or various cell types (e.g., fibroblasts and keratinocytes) and help determine which concentrations of the agent may be effective in vivo. In vitro assays bring results rapidly which help the investigator not only costs but also time. In addition to providing valuable results in a short span of time, they hold a reasonable humane appeal since they usually do not involve the use of animals or humans (Perez and Davis 2008). Another noteworthy characteristic of in vitro testing is the ability to screen multiple agents or samples simultaneously. Besides the above, these tests will help in screening of antimicrobial resistance of pathogenic organisms but also aid to find inhibitory concentrations.

4.2 In Vitro Models of Wound Healing

In vitro assays are playing an important role in finding out the killing efficiency of numerous healing agents against many pathogenic microorganisms and their roles in augmenting the wound healing process (Perez and Davis 2008). This will help investigative the effect of the wound healing agents use in an animal model(s). These tests enable finding of test agents' presence in blood, wound fluid, and others like immune cells and enzyme proteases, which can be influenced by the activity of test agents. However, in vitro assays are not

Table 1 Nutraceuticals/plant extracts with potential for wound healing

Nutraceutical/plant extract	Active ingredient	Effect	References
Acalypha indica	Flavonoids, saponins, sterols, polyphenols, triterpenoids	Wound healing	Reddy et al. (2002)
Aloe vera	β-Sitosterol	Angiogenesis	Moon et al. (1999)
Butea monosperma	Flavonoids, tannins, saponins, glycosides, steroids, and triterpenoids	Wound healing	Murti and Kumar (2012), Bopage et al. (2018)
Camellia sinensis (green tea)	Epigallocatechin-3-gallate	Anti-inflammatory	Li et al. (2016)
Centaurea sadleriana Janka	Flavonoids	Wound healing	Csupor et al. (2010)
Centella asiatica	Asiaticoside	Wound healing	Shukla et al. (1999)
Ceylon cinnamon	(E)-Cinnamaldehyde	Wound healing	Farahpour and Habibi (2012)
Chromolaena odorata	Alkaloids, flavonoids, saponins, phenolics, anthraquinones, tannins, glycosides, stigmasterol, scutellarin, tetramethyl ether (scu), chromomoric acid C-1	Antioxidative, lipid peroxidative inhibitory, anti-inflammatory, increased collagen synthesis, wound healing	Oludare et al. (2000), Phan et al. (2001a, b), Vijayraghavan et al. (2017a, b)
Copaifera langsdorffii	Oleoresin, diterpenes, sesquiterpenes, copaivic acid	Antioxidative, anti-inflammatory, antimicrobial, wound healing	Paiva et al. (2002)
Curcuma longa	Curcumin/curcuminoids	Antioxidative, anti-inflammatory, antimicrobial, wound healing	Chereddy et al. (2013), Mohanty and Sahoo (2017)
Euphorbia hirta Linn.	Alkaloids, flavonoids, glycosides, saponins, tannins	Anti-inflammatory	Tuhin et al. (2017)
Ficus racemosa L.	Lupeol acetate, β-sitosterol	Antibacterial, antifungal, enhanced cell migration, wound healing	Murti and Kumar (2012), Bopage et al. (2018)
Heliotropium indicum	Pyrrolizidine alkaloids, indicine-N-oxide, tannins, saponins, heliotrine	Wound healing	Reddy et al. (2002)
Plagiochasma appendiculatum Lehm.	Saponins, flavonoids, and sesquiterpenes	Antimicrobial, antioxidative, wound healing	Singh et al. (2006)
Plumbago zeylanica	Terpenoids and alkaloids	Wound healing	Reddy et al. (2002)
Royal jelly	Royal jelly proteins	Wound healing	Fujii et al. (1990)
Saba florida Benth	Flavonoids, tannins, and other secondary metabolites	Wound healing	Omale and Isaac (2010)
Wrightia tinctoria	Triterpenoids, steroids, and saponins	Wound healing	Veerapur et al. (2004)
Phyllanthus	Phyllanthin, hypophyllanthin	Wound healing	Yadav et al. (2017)
Jungle geranium	Triterpenoids (lupeol), aromatic acrid oils, tannins, saponins, flavonoids (rutin, formononetin, β-sitosterol)	Wound healing	Upadhyay et al. (2014)
Indian mulberry, *Morinda pubescens*	Phenols, alkaloids, triterpenoids, steroids, carboxylic acids	Wound healing	Mathivanan et al. (2006)
Ixora coccinea	Alkaloids, glycosides, steroids, fixed oils, terpenes, tannins, and flavonoids	Wound healing	Upadhyay et al. (2014)
Peacock chaste tree	Volatile oil, resin, terpenes, flavonoids, glucosides, alkaloids	Wound healing	
Vitex trifolia; *Vitex altissima*	Volatile oil, resin, terpenes, flavonoids, glucosides, alkaloids	Wound healing	

capable of mimicking or reproducing conditions such as natural phases of wound healing, immune responses, or disease like diabetes.

In vitro assays have been recognized for their role in integrating variety of cells and tissues. A mostly used in vitro technique for studying wound healing is the scratch assay, in which a confluent monolayer of cells scratched to form an artificial gap, and cells are observed as they migrate and proliferate to close the gap (Ling et al. 2007). It is comparatively straightforward assay to assess the effect of therapeutic compounds, endogenous biochemical, and genetic alterations on the behavior of the monolayer (Stamm et al. 2016). However, these experiments are time consuming equal to in vivo equivalents and are often considered unrepresentative of healing processes in humans and can have complex levels of experiment based experimental variation (Ansell et al. 2012; Johnston et al. 2016; Pampaloni et al. 2007).

On the other hand, time-lapse microscopy of scratch assays represents an appropriate test to examine cellular process outcomes, which may be used as the base of further studies (Pampaloni et al. 2007). However, in reality cells in in vivo exist in a three-dimensional physiological environment that is not mimicked by monolayers, because the in vivo environment is entirely different from the plastic on which they are routinely cultured (Stamm et al. 2016). However, this shortcoming may be overcome by using advanced 3D culture techniques. Recent commercially available skin substitutes enable and mimic the structure of human skin (Groeber et al. 2011) most of which consist of separate layers comprising dermal and epidermal components. The dermis is simulated using a hydrogel, for example, collagen, populated with dermal fibroblasts, over which layers of keratinocytes are cultured (Stamm et al. 2016).

Since 3D skin substitutes are more complex in nature than monolayer cells, the effects of immune cells and blood vessels are still excluded. Following wounding with a scalpel or punch biopsy, time-lapse microscopy, histological analysis, or PCR may be conducted to investigate closure rates, cell and tissue morphology, and gene expression. These skin substitutes may also use to assess the toxicology or mode of action of a range of topical treatments; however they are limited in their ability to assess responses to novel dressings or other delivery modes (Groeber et al. 2011). Basic cellular processes, such as the secretion of biochemicals that regulate wound healing, may also be elucidated using this experimental approach (Maarof et al. 2016); however, the ability to culture skin substitutes over a long period of time may hinder their use in studying the later advanced phases of cutaneous healing (Ansell et al. 2012). However, there are some new techniques that have been developed to overcome this limitation: ex vivo culturing of human skin samples has been shown to permit experiments to be conducted over longer periods of time, for example, in the study of keloid disease (Bagabir et al. 2012).

4.3 In Vivo Models

In recent years, subjecting of animal models in wound healing investigations has tremendously increased as it coincides with the number of new products introduced yearly. Interestingly, the number of animal wound healing models has almost doubled every 10 years. However, numerous types of in vivo models are available, and each has some unique benefits and disadvantages.

4.4 Small Animals as Wound Healing Models

Numerous previous studies have extensively established appropriate animal models for mammalian wound care investigations, and most of them are successful in overcoming some of the logistical difficulties associated with clinical trials. The animal model system includes not only higher animals but also involve *Drosophila melanogaster* and zebra fish to investigate barrier repair in epithelial surfaces, providing important insights into the processes involved (Razzell et al. 2011; Richardson et al. 2013).

Despite varied options and many animal species available for studying human wound healing process, rodents are being the mostly accepted and generally employed animals with the majority of experiments conducted in mice (Galiano et al. 2004; Ansell et al. 2012; Dunn et al. 2013). In many ways, they are beneficial for wound care investigation for various reasons as these small model animals are less expensive, easy to obtain and handle, and require less space. Besides the above, these animals often have multiple offspring, which develop quickly permitting investigations to proceed through numerous generations. Not only these animals commonly have accelerated modes of healing compared to humans; thus experiment duration takes for days, compared to weeks or months required for human experiments (Nunan et al. 2014). Moreover, few species of small mammals can be altered genetically easily and provide a wound model closer to human disease conditions. In addition, other advantages of involving these small animals in experiments using microbes like bacteria or virus infection for developing infectious disease models (Grose and Werner 2004; Scheid et al. 2000).

4.5 Higher Animals as Wound Healing Models

Although rat, mouse, rabbit, and guinea pig wound models exist and in practice, porcine skin is structurally and biochemically more similar to humans (Sullivan et al. 2001; Seaton et al. 2015) than other mammals used for estimating wound healing therapies (Watson and Moore, 1990; Summereld and Ricklin 2015). However, pigs are less frequently employed than rodents in studies of cutaneous healing, because of reasons such as high cost, lack of genetic tools, and difficulty handling them. Besides the above, other model systems are available to study the mechanistic aspects of healing process, for example, the rabbit ear chamber and the Algire chamber study used for visualizing vascularization and determining angiogenesis (Nunan et al. 2014).

4.6 Human Models of Wound Healing

Despite having the availability of numerous animal models for various experiments, their anatomical and physiological differences distinctly affect the outcome of healing mechanisms. In order to avoid species-specific misinformation, direct human involvement or human sample

requirement is needed to dissect out the actual wound healing mechanisms in detail. To support this, much new molecular and novel technological advancements (Ho et al. 2017) are available in our hand, which enable us to investigate even tiny pinch of human skin tissue samples making it possible to decipher wound healing mechanisms in situ in humans.

It is obvious to expect that improved human-based model systems definitely serve a better choice to reveal the actual acute wound healing process as pathology and physiology of healing which occur among the patient are better correlated and identical; however, this study requires more human volunteers to generate several types of wound models. To support this claim, a review of such models is recently presented by Wilhelm et al. (2017) which are highlighted below:

As per Gao et al. (2013), partial- or full-thickness wounds can be used to recreate more accurate clinical situation where tissue damage occurs in conjunction with tissue loss. This can be done by either excising the tissue or obtaining a punch biopsy to generate these types of wounds. Wounds of this nature normally heal by reepithelialization, dermal reconstitution, and wound contraction permitting us to analyze different phases of the healing or of the entire healing process.

Partial Thickness

According to Xu et al. (2012), a partial-thickness injury is limited to the epidermis and superficial dermis, with no damage to the dermal blood vessels. Healing occurs by regeneration of other tissues. To demonstrate this few standard methods are available including tape stripping.

A report by Lademann et al. (2009) described the term "tape stripping" as the simplest partial-thickness injury of the skin involves removal of stratum corneum with adhesive tape. In this model of wounding, the epidermal compartment is generally left intact. However, the report cautioned that due to removal of stratum corneum layers, the permeability of the skin is temporarily compromised, but this can be measured using transepidermal water loss analysis.

Abrasive Wound Model

A slightly more invasive wound model was established by Wilhelm et al. (2017). In this report authors claimed that they induce uniform abrasions and can be used to evaluate the healing properties of a variety of wound care products (Wigger-Alberti et al. 2009). This model consists of inflicting standardized, superficial abrasions by repeatedly abrading skin with a surgical brush until the first signs of uniform glistening and punctuate bleeding are also observed.

Blister Model

This model was originally designed to measure drug concentrations in various parts of the skin (Kiistala 1968) but later engaged for wound healing investigations as well. A blister is formed as a result of the separation of the epidermis and dermis, at the basal membrane between the lamina lucida and the lamina densa (Chávez et al. 2011).

Full-Thickness Wound Models

Previous studies (Brown et al. 2002; Sørensen et al. 2010) have suggested based on their result outcomes that this model requires complete removal of the epidermis and dermis to the depth of fascial planes or subcutaneous fat and disrupts dermal blood vessels. This can be done using a number of devices to inflict a lesion in a standardized fashion (e.g., punch biopsy, scalpel, dermatome, and laser). Importantly, punch biopsy wounds are widely used in wound healing research both in animal models and human volunteer studies. Hence, both animal and clinical studies have been successfully used to elucidate the overall mechanisms and outcomes of wound healing, whereas it can be difficult to analyze individual mechanisms and cellular processes using in vitro assays.

5 Formulations of Nutraceuticals and Their Delivery Systems for Wound Healing

Nutraceuticals have gained more attention in recent years due to their recognized safety and promising nutritional and therapeutic outcomes. Although it may be easy for an innovator or maker to develop a pharmaceutical (tablets, powders, capsules, suppositories, etc.) which contains a bioactive food, however, it is relatively challenging to obtain a satisfactory bioavailability for such nutraceuticals (Gaurav et al. 2012; Johnson and Wang 2015). Bioavailability is often jeopardized by the following factors such as low solubility, stability, and/or permeability of the bioactive component. Advanced development of targeted delivery using nanotechnology for pharmaceutical applications has opened a new path for stability, solubility, and/or permeability enhancement of some of the challenging nutraceuticals (Yallapu et al. 2011, 2013).

Concurrently, nutraceuticals are also receiving increasing consumer acceptance, generating demand for new product innovations based on superior delivery systems. Most current delivery systems for nutraceutical products are based on direct application or ingestion (Gaurav et al. 2012). These oral delivery systems pose issues relative to their unacceptable odor and taste as well as degradation of the nutraceutical itself during its transport from the digestive system to the site of desired action. Direct delivery system like topical application circumvents some of these issues due to their application near or at the site of affliction (Hassan 2012).

In recent years, there have been significant advances with biomaterial delivery systems to satisfy the clinical need, especially in wound healing. However, there are some limitations that still exist with regard to therapies involving proteins, genes, and small molecule drugs. Once these problems are addressed, these delivery systems can effectively enable their full therapeutic benefit (Boateng et al. 2008; Koria 2012). In the context of wound healing, a delivery system should fulfill the following for its cargo: (a) maintain bioactivity through protection from proteolysis in the wound bed, (b) localize bioavailability by preventing rapid dilution in wound fluid and systemic uptake and distribution, and (c) facilitate release or presentation within the wound at a physiologically relevant rate and duration. If these goals are achieved, a successful delivery system will also minimize the dosage and application frequency necessary for efficacy. A detailed review by Johnson and Wang (2015) summarized and highlighted the recent advances in drug delivery systems for wound healing applications and also identified five recently developed vehicle types such as (1) hydrogels, (2) scaffolds, (3) particles, (4) complexes, and (5) coacervates and emphasized their advantages and wound healing efficacies without any side effects.

Hydrogels are one of the most highly utilized delivery vehicles. They are versatile, able to form from nearly any water-soluble polymer. They also feature a number of tunable parameters such as porosity, swelling ratio, and cross-link density to offer some control over release rate. A final advantage is that to an extent, they may mimic the mechanical properties of granulation tissue and maintain a moist wound environment (Boateng et al. 2008; Drury and Mooney 2003).

Scaffold is a general term, but in this section, we will specifically discuss porous scaffolds which are implanted rather than injected or polymerized in situ as is possible with hydrogels. This is usually not a drawback for wound healing applications as most wounds are superficial and relatively easy to access for manipulation. In fact, a scaffold may be the best choice when good mechanical properties or a long degradation time are desired. Their 3D structure also encourages cell infiltration and enables strategic patterning of stimuli to precisely direct tissue regeneration (Drury and Mooney 2003). Natural materials are often utilized in scaffolds similar to hydrogels, though they need not necessarily be hydrophilic.

Particles. Nano- and microparticles are another highly studied type of drug delivery system which holds certain advantages over hydrogels and scaffolds. With respect to wound healing applications, particles may by injected by a fine-gauge needle into the healthy tissue surrounding the wound so as not to complicate healing within the wound bed. They may also be tuned through numerous parameters to have complex release profiles unobtainable with gels and scaffolds (Soppimath et al. 2001; Kumari et al. 2010).

Complexes and conjugates. A fourth type of delivery system comprises complexes and conjugates. Conjugates are typically formed by chemical bonds, while complexes are typically formed by physical interactions. Both approaches seek to sequester soluble drugs in order to stabilize and extend their half-life or to provide targeting and facilitate their interactions with cell receptors. Polyethylene glycol (PEG) was attached to fibroblast growth factor-1 (FGF-1) to improve its thermal and structural stability in vivo (Huang et al. 2011). Another very interesting approach involves engineering ECM mimetics, considering its significance in orchestrating the regenerative process (Lutolf and Hubbell 2005; Uebersax et al. 2009; Schultz and Wysocki 2009).

Coacervates are an interesting new class of drug delivery vehicles developed only recently for controlled release of proteins and small molecule drugs. Coacervates are nanometer-sized liquid droplets, held together and apart from their environment by hydrophobic forces (Overbeek and Voorn 1957).

6 Nutraceuticals/Phytochemical Extracts from *C. odorata* for Wound Healing

Although many wound healing plants are reported and serve as important sources for a variety of nutraceuticals/extracts/phytochemicals (listed in Table 1), it is very difficult to discuss all of these in one review or book chapter. Hence, the aim of the present chapter is to provide up-to-date information about the properties of *C. odorata* (Fig. 1a–c), one of the potential wound healing plant that belongs to Compositae or Asteraceae family of flowering plants that is being investigated for its diverse pharmacological activity. The Compositae family is also rich in terpenoids (essential oil), which can be used for food flavoring or liqueur flavors. Volatile oils of the plant are considered a possible source of nutraceuticals for clinical purposes. Phenolic substances are also important in the preparation of modern medicines (Heywood et al. 1977).

C. odorata (L.) King and Robinson (formerly known as *Eupatorium odoratum* L.) belongs to the kingdom Plantae (Table 2). The genus *Chromolaena* includes 1200 species of small herbs, shrubs, or under shrubs distributed chiefly in the USA, with a few in Europe, Asia, and tropical Africa (GISD 2006). It is an ornamental plant considered to be one of the top 100 most invasive environmental weeds of wastelands, roadsides, and other exposed areas in many parts of the world (Chakraborty et al. 2011). *C. odorata* has numerous common vernacular various countries, which are listed in Table 3.

Though *C. odorata* has been known for its negative impact as an invasive weed, the potential medicinal uses are enormous (Vaisakh and Pandey 2013). Many parts of the *C. odorata* plant are used in the indigenous system of

Division	Magnoliophyta—flowering plants			
Class	Magnoliopsida—dicotyledons			
Subclass	Asteridae			
Order	Asterales			
Family	Asteraceae—Aster family (sunflower family)			
Genus	Chromolaena DC.—thoroughwort			
Species	*Chromolaena odorata* (L.) King & H. Rob.—Jack in the bush Common names: Siam weed, Christmas bush, and common floss flower			
C. odorata General impacts	It forms dense stands preventing establishment of other species, both due to competition and allelopathic effects. When dry, it becomes a fuel, which may promote wild bushfires (PIER 2001). It causes skin complaints and asthma in allergy-prone people. It is a major weed in plantations and croplands, including plantations of rubber, oil palm, forestry, and coffee plants			

medicine. In fact, traditional healers in some parts of Africa explore the plant as a source of medicine in curing different ailments, which are listed in Table 4. The plant is also known for its medicinal properties especially in the treatment of wounds (Phan et al. 2001a, b).

Phytochemicals or bioactive principles are naturally occurring plant substances/chemicals synthesized during secondary metabolism and are called primary and secondary metabolites (Brielmann et al. 2006). Specific phytochemicals have been identified as being responsible for particular pharmacological actions and medicinal properties of these plants. While the primary metabolites play essential roles in the life of the plants, secondary metabolites are often referred to as phytochemicals and are generally used in defense mechanisms against enemies such as herbivorous animals, viruses, parasites, and bacteria, of which 12,000 have been isolated and are preferred as alternative therapeutic options to synthetic drugs (Lai 2004). With time, plants containing these phytochemicals have been shown to serve as sources of medicine for humans and animals (Omokhua et al. 2016) because they may possess biological activities including antioxidant, antibacterial, antifungal, antipyretic, anthelmintic, antispasmodic, anti-inflammatory, and wound healing effects. Phytochemicals can also be used as antiseptics, fragrances, dyes, insecticides, stimulants, and poisons (Zulak et al. 2006).

Table 3 Common vernacular for *C. odorata* in various countries

Country	Common names
English (UK)	Siam weed, triffid weed, bitter bush, Jack in the bush, Christmas bush, baby tea
African	Sekou toure, acheampong, jabinde, matapa, mighbe
Chamorro	Masigsig, masigsig
Cameroon	Bokassa
Chinese:	Fei ji cao
Central Africa	Bokassa
Cote d'Ivoire	Sekou toure
Chuukese	Otuot
Democratic Republic of the Congo	*Matapa mbala* (the invader), *Lantana ngouabi*
Filipino	Agano, huluhagonoi
French	Fleurit-Noël, herbe du Laos
German	Siam kraut
Ghana	Acheampong weed
Guam	Kesengesil
India	Gandhi gulabi, communist weed, sam-solokh, tongal-lati, Sam-rhabi, bagh dhoka, tivra gandha, pokok kapal terbang, rumput jepun, rumput Siam, ropani, seekhrasarpi
Indonesia	Kumpai jepang (Japanese grass), rumput gol kar (business party grass), kirinyu, independent shrub
Kosraean	Mahsrihsrihk
Laos	Herbe du Laos, French weed
Malaysia	Siam weed
Myanmar	Bizat, tawbizat, curse of Ceylon, Kal-bun, Kombat-nong-rim, Rel-hlow, Campur grass
Nepal	Banmara (killer of the forest)
Palauan	Kesengesil, ngesngesil
Philippines	Devil weed, gonoy hagonoy, triffid weed, paraffin weed
Pohnpeian	Masigsig, masikisik, wisolmat, wisolmat en rehnwel
Spanish	Santa Maria
South Africa	Armstrong weed, kingsweed, triffid weed, paraffin weed
Thailand	Saab sua, yah sua mop
Trinidad	Christmas weed
Vietnam	Co hoi, communist weed

Phytochemical extraction involves the separation of the medicinally active fraction from the plant using selective solvents. These include classes of preparations known as decoctions, infusions, fluid extracts, tinctures, pilular extracts, or powdered extracts. Phytochemicals found in most medicinal plants include alkaloids, terpenes, and glycosides (tannins, saponins, anthraquinones, flavonoids, etc.) (Trease and Evans 2002). The herbal extract thus obtained may be ready for use as a medicinal agent as such, or it may be further processed to be incorporated in any dosage form. An extract may be further processed through various techniques of fractionation to isolate individual chemical entities to be used as modern drugs (Handa 2008). There are many processes patented throughout the world for the extraction of plant ingredients.

C. odorata possess many secondary metabolites such as terpenes, alkaloids, and glycosides. Polyphenols like flavonoids and tannins are abundant in the Asteraceae family. Many of these phytochemicals possess various pharmacological activities which are very useful to human welfare (Panda et al. 2010). Phytochemical studies on the extracts of *C. odorata* from various parts of the plant (Fig. 2) have indicated the presence of tannins, terpenoids, cardiac glycosides, saponins, anthraquinones, phenols, and alkaloids (Anyasor et al. 2011; Vijayaraghavan et al. 2013). About 44 different compounds have been isolated from *C. odorata* extracts using GC-MS (Raman et al. 2012). Because of the presence of these phytochemicals, the plant is said to have anthelmintic (Panda et al. 2010), antioxidant (Raman et al. 2012; Vijayaraghavan et al. 2013), analgesic, anti-inflammatory, antipyretic, antispasmodic (Owoyele and Soladoye 2006; Chakraborty et al. 2011), antimicrobial (Chomnawang 2005), antimalarial, and antioxidant properties as well as wound healing potential (Anyasor et al. 2011). Eupolin, a product from *C. odorata* leaves for soft tissue burns and wounds has been licensed for use in Vietnam (Raina et al. 2008).

Previous investigation of the leaves and stems of *C. odorata* revealed the presence of essential oils, steroids triterpenes, and flavonoids (Suksamran et al. 2004). Flowers of this plant species have been subjected to investigation for essential oils, fats, alkaloids, and flavonoids (Odunbaku et al. 2008). The reported isolated chemical constituents from various extracts of *C. odorata* are shown in Table 5.

6.1 Chemical Constituents of *C. odorata*

C. odorata has been the subject of chemical analyses in several research studies (Zhang et al. 2012; Heiss et al. 2014). The chemical groups that have been identified in this plant are monoterpenes, sesquiterpene hydrocarbons, triterpenes/steroids, alkaloids, and flavonoids. The leaves of this plant have been found to be a rich source of flavonoids including quercetin, sinensetin, sakuranetin, padmatin, kaempferol, and salvigenin, which were isolated and identified. The leaves of *C. odorata* have the highest amount of allelochemicals (Afolabi et al. 2007) isolated from a plant. A study in Vietnam showed that the aqueous extract of the leaf contained flavonoids (salvigenin, sakuranetin, isosakuranetin, kaempferide, betulenol, 2-5-7-3 tetra-o-methyl quercetagetin, tamarixetin, two chalcones, and odoratin and its alcoholic compound), essential oils (geyren, bornyl acetate, and beta eubeden), saponin triterpenoids, tannins, organic acids, and numerous trace substances (Zhang et al. 2012). Another study by Heiss et al. (2014)

Table 4 Description of traditional usage of different parts of the *C. odorata* plant for curing ailments and wounds

Category of use	Description of traditional usage	References
Coughs and colds	The plant is squeezed in water, and the extract is taken to cure colds and coughs	Timbilla et al. (2003)
Skin diseases	The leaf is squeezed in water to bathe	Morton (1981)
Wounds and antiseptic	The leaves are squeezed, and the juice is directly applied to the wound	Inya-Agha et al. (1987)
Dysentery	The leaves are squeezed and taken as a tonic	Gill (1992)
Headache	The leaves are squeezed and taken as a tonic	
Toothache	The leaves are squeezed, and the juice is applied to the aching part	
Malaria fever	A decoction of the leaves with *Azadirachta indica* is prepared, and the water is taken	Idu and Onyibe (2007)
Antiseptic	The juice of the leaves, sometimes mixed with water, is used to stop bleeding	Gill (1992)
Stomach problems	Fresh leaves are squeezed in water, and the juice is taken as a tonic	Idu and Onyibe (2007)
Antiseptic and hemostatic	Fresh juice from the leaves is used to arrest bleeding in fresh cuts and nosebleeds	Phan et al. (2001a), Idu and Onyibe (2007)
Diarrhea	The leaves are squeezed with water, and the decoction is taken as a tonic	Amatya and Tuladhar (2011), Bhargava et al. (2011)
Skin eruption	The fresh leaves are squeezed, and the juice is applied to affected areas of the skin	

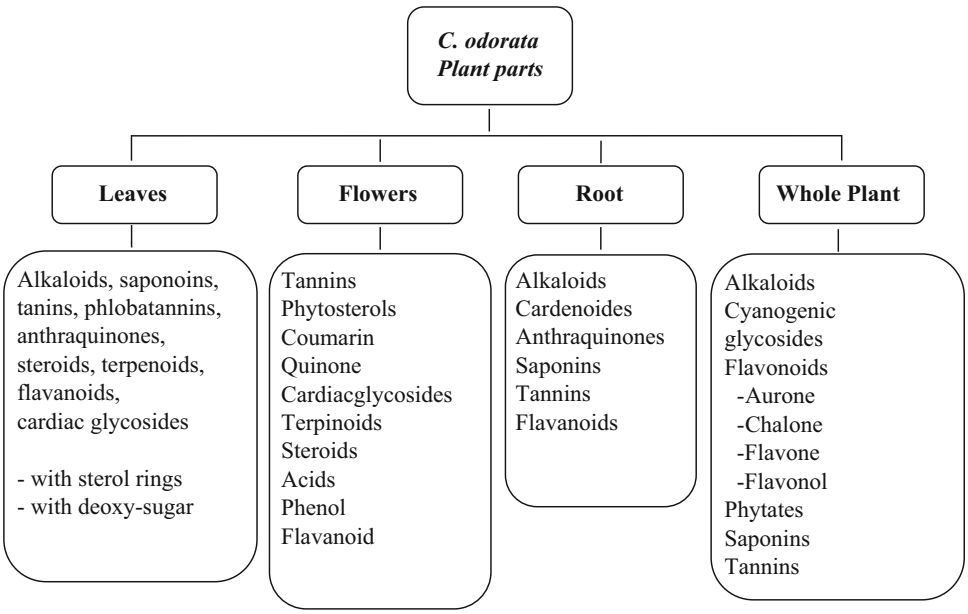

Fig. 2 Nutraceuticals/plant extracts of *C. odorata* with the potential for wound healing

showed that the crude ethanol extract of *C. odorata* contains phenolic acids (protocatechuic, p-hydroxybenzoic, p-coumaric, ferulic, and vanillic acids) and complex mixtures of lipophilic flavonoid aglycones (flavanones, flavonols, flavones, and chalcones). To date, studies on *C. odorata* have resulted in the isolation of 17 compounds such as 5aα,6,9,9aβ,10-pentahydro-10β-hydroxy-7-methylanthra[1,2-d][1,3]dioxol-5-one, 1,2-methylenedioxy-6-methylanthraquinone, 3-hydroxy-1,2,4-trimethoxy-6-methylanthraquinone, 3-hydroxy-1,2-dimethoxy-6-methylanthraquinone, and 7-methoxy-7-epi-medioresinol, as well as 12 known compounds including odoratin, 3β-acetyloleanolic acid, ursolic acid, ombuin, 4,2′-dihydroxy-4′,5′,6′-trimethoxychalcone, (−)-pinoresinol, austrocortinin, tianshic acid, cleomiscosin D, (−)-medioresinol, (−)-syringaresinol, and cleomiscosin A (Zhang et al. 2012). Figure 3 shows the structure and composition of some of the important bioactive principles in *C. odorata* such as stigmasterol (**1**), scutellarin, tetramethyl ether (scu, **2**), flavonoids (**3a–3l**) (Pandith et al. 2013a, b), and the phytoprostane compound chromomoric acid C-1 (Heiss et al. 2014).

6.2 Pharmacological Activities of *C. odorata* Leaf Extracts

In Africa, Thailand, and Vietnam, the juice of the leaf is used as a hemostatic on wounds (Phan et al. 2001a) and as an anti-inflammatory, and also decoction of the flowers is used as

Table 5 Phytochemical extracts and their chemical constituents from various parts of *C. odorata* plant

Parts of plant	Chemical constituents	References
Flower (aqueous extract)	3,5,4′-Trihydroxy-7-methoxyflavanone 5,7,3′′′′-Trihydroxy-5′-methoxyflavanone 3,5,7-Trihydroxy-4′-methoxyflavanone	Odunbaku et al. (2008)
Flower	Akuranetin Persicogenin 5,6,7,4′-Tetramethoxyflavanone 4′-Hydroxy-5,6,7-trimethoxyflavanone 2′-Hydroxy-4,4′,5′,6′-tetramethoxychalcone 4,2′-Dihydroxy-4′,5′,6′-trimethoxyflavanone Acacetin Luteolin	Suksamran et al. (2004), Pisutthanan et al. (2005)

Whole plant—aboveground parts (dichloromethane extract)	2′-Hydroxy-3,4,4′,5′,6′-pentamethoxy-chalcone 2′,4-Dihydroxy-4′,5′,6′-trimethoxychalcone Scutellarein tetramethyl ether Sinensetin 2′-Hydroxy-4,4′,5′,6′-tetramethoxychalcone	Ling et al. (2007)
Whole plant (ethanol and methanol extract)	Aromadendrin 4′-methyl ether Eriodictyol 7,4′-dimethyl ether Naringenin 4′-methyl ether Taxifolin 4′-methyl ether; taxifolin 7-methyl ether Quercetin 7,4′-dimethyl ether Kaempferol 4′-dimethyl ether Quercetin 3-*O*-rutinoside Quercetin 4′-methyl ether Quercetin 7-methyl ether	Suksamran et al. (2004), Ling et al. (2007)
Leave (ethanol extract)	Tamarixetin Trihydroxymonomethoxyflavanone Pentaethoxyflavanone Dihydroxytrimethoxychalcone Eupatilin 5,6,7,4′-Tetramethoxyflavanone 5-Hdroxy6,7,3′,4′-tetramethoxyflavone Kaempferide Protocatechuic acid *p*-Coumaric acid *p*-Hydroxybenzoic acid Ferulic acid Vanillic acid Sinensetin Rhamsetin Tetrahydroxymonomethoxyflavanone	Phan et al. (2001b)

tonic, antipyretic, and heart tonic (Bunyapraphatsara and Chokechajiaroenprom 2000). The leaf extracts have been used for the treatment of leech bite, soft tissue wounds, burnt wounds, skin infection, and dento-alveolitis (Phan et al. 2001b; Owoyele et al. 2008). Figure 4 listed various pharmacological activities of leaf extracts of *C. odorata*. Other uses of the leaf extracts include treatment of diabetes (leaf infusion) and skin rashes (crushed leaves) (Obute and Adubor 2007). A formulation prepared from the aqueous extract of the leaves of *C. odorata* has been licensed for clinical use in Vietnam to treat skin irritations (Ling et al. 2007). More support for the medicinal use of the leaves of *C. odorata* includes a study which showed that methanol extract of the leaves had anti-inflammatory, antipyretic, and antispasmodic properties in mice (Taiwo et al. 2000). Aqueous extract of the leaf of *C. odorata* showed anti-inflammatory activity in rat (Vijayaraghavan et al. 2017a, b). Besides the above, extracts of leaves of *C. odorata* have been found to encourage proliferation of fibroblasts and delay the visible signs of skin aging such as wrinkles and hyperpigmentation. This knowledge was used to formulate a cosmetic composition containing extracts of *C. odorata* for the prevention of normal skin conditions due to chrono-aging or photoaging (Donovan 2007).

6.3 Plant-Derived Agents and Their Wound Healing Mechanism

The use of medicinal plants in health care is a common practice. Numerous medicinal plants have been reported to possess wound healing activity and to be useful in the

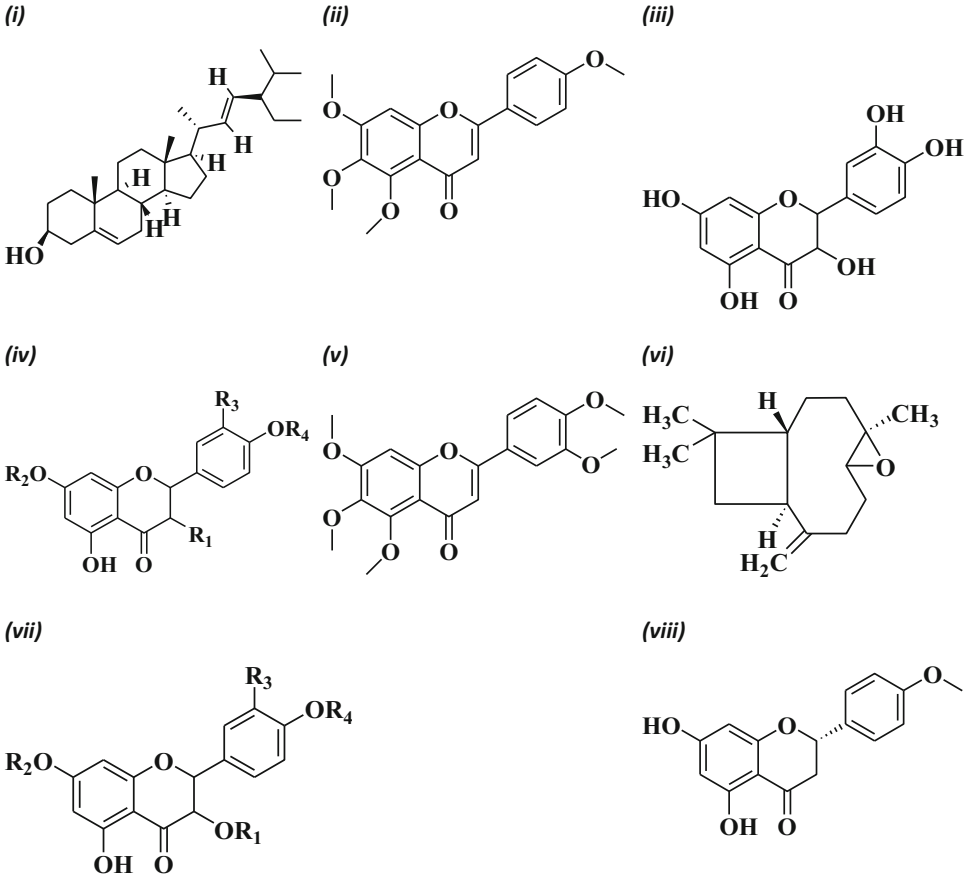

Fig. 3 Chemical structures of bioactive principles of *C. odorata*. (i) Stigmasterol. (ii) Scutellarein tetramethyl ether (Scu). (iii) Quercetin. (iv) Aromadendrin 4′-methyl ether: $R_1 = OH$; R_2, $R_3 = H$; $R_4 = CH_3$. (iv) Eriodictyol 7,4′-dimethyl ether: $R_1 = H$; R_2, $R_4 = CH_3$; $R_3 = OH$. (iv) Naringenin 4′-methyl ether: R_1, R_2, $R_3 = H$; $R_4 = CH_3$. (iv) Taxifolin 4′-methyl ether: R_1, $R_3 = OH$; $R_2 = H$; $R_4 = CH_3$. treatment of wounds (Soni and Singhai 2013). To support this claim, a study (Manju et al. 2013) found that almost 31% of these plants have been used to treat wounds, 29% have been used for cuts, and 10% for burns, whereas 22% have been used for cuts and wounds. Some of these plants have been scientifically screened for evaluation of their wound healing activity in different pharmacological models and patients, but the potential of most remains unexplored. In a few cases, active chemical constituents were identified (Biswas and Mukherjee 2003). In addition, aromatic plants have a long history of use in treating wounds. The essential oils obtained from the various parts of the plants are very effective in treating small to medium wounds, skin abrasions, excoriations, skin infections, and other topical health problems provided an appropriate concentration of the essential oil is used (Kerr 2002).

Many biological experiments as well as pharmaceutical validation studies (Sirinthipaporn and Jiraungkoorskul 2017; Stanley et al. 2017) have revealed that various herbal extracts promote faster wound healing than standard reference control and non-medicated groups. A number of secondary metabolites, nutraceuticals, and active compounds isolated from plants have been demonstrated as active principles responsible for facilitating wound healing in animal models (Chaudhari and Mengi 2006). Furthermore, some of the most important examples include tannins from *Terminalia arjuna* (Chaudhari and Mengi 2006); oleanolic acid from *Anredera diffusa* (Moura-Letts et al. 2006); polysaccharides from *Opuntia ficus-indica* (Trombetta et al. 2005); gentiopicroside, sweroside, and swertiamarin from *Gentiana lutea* (Ozturk et al. 2006); shikonin derivatives (deoxyshikonin, acetyl shikonin, 3-hydroxy-isovaleryl shikonin, and 5,8-odimethyl acetyl shikonin) from *Onosma argentatum* (Ozgen et al. 2006); asiaticoside, asiatic acid, and madecassic acid from *Centella asiatica* (Hong et al. 2005); quercetin, isorhamnetin, and kaempferol from *Hippophae rhamnoides* (Fu et al. 2005); curcumin from *Curcuma longa* (Jagetia and Rajanikant 2004); oleoresin from *Copaifera langsdorffii* (Paiva et al. 2002); proanthocyanidins and resveratrol from grapes (Khanna et al. 2002); acylated iridoid glycosides from *Scrophularia nodosa* (Stevenson et al. 2002); phenolic acids (protocatechuic, p-hydroxybenzoic, p-coumaric, ferulic, and vanillic acids) from *C. odorata* (Phan et al. 2001a, b); glycoprotein fraction of *Aloe vera* (Choi et al. 2001); (+)-epi-alpha-bisabolol from *Peperomia galioides* (Villegas et al. 2001); fukinolic and cimicifugic acids from *Cimicifuga* spp. (Kusano et al. 2001); and xyloglucan from *Tamarindus indica* (Burgalassi et al. 2000).

It is important to note that wound healing is complicated and involves a number of processes, including inflammation,

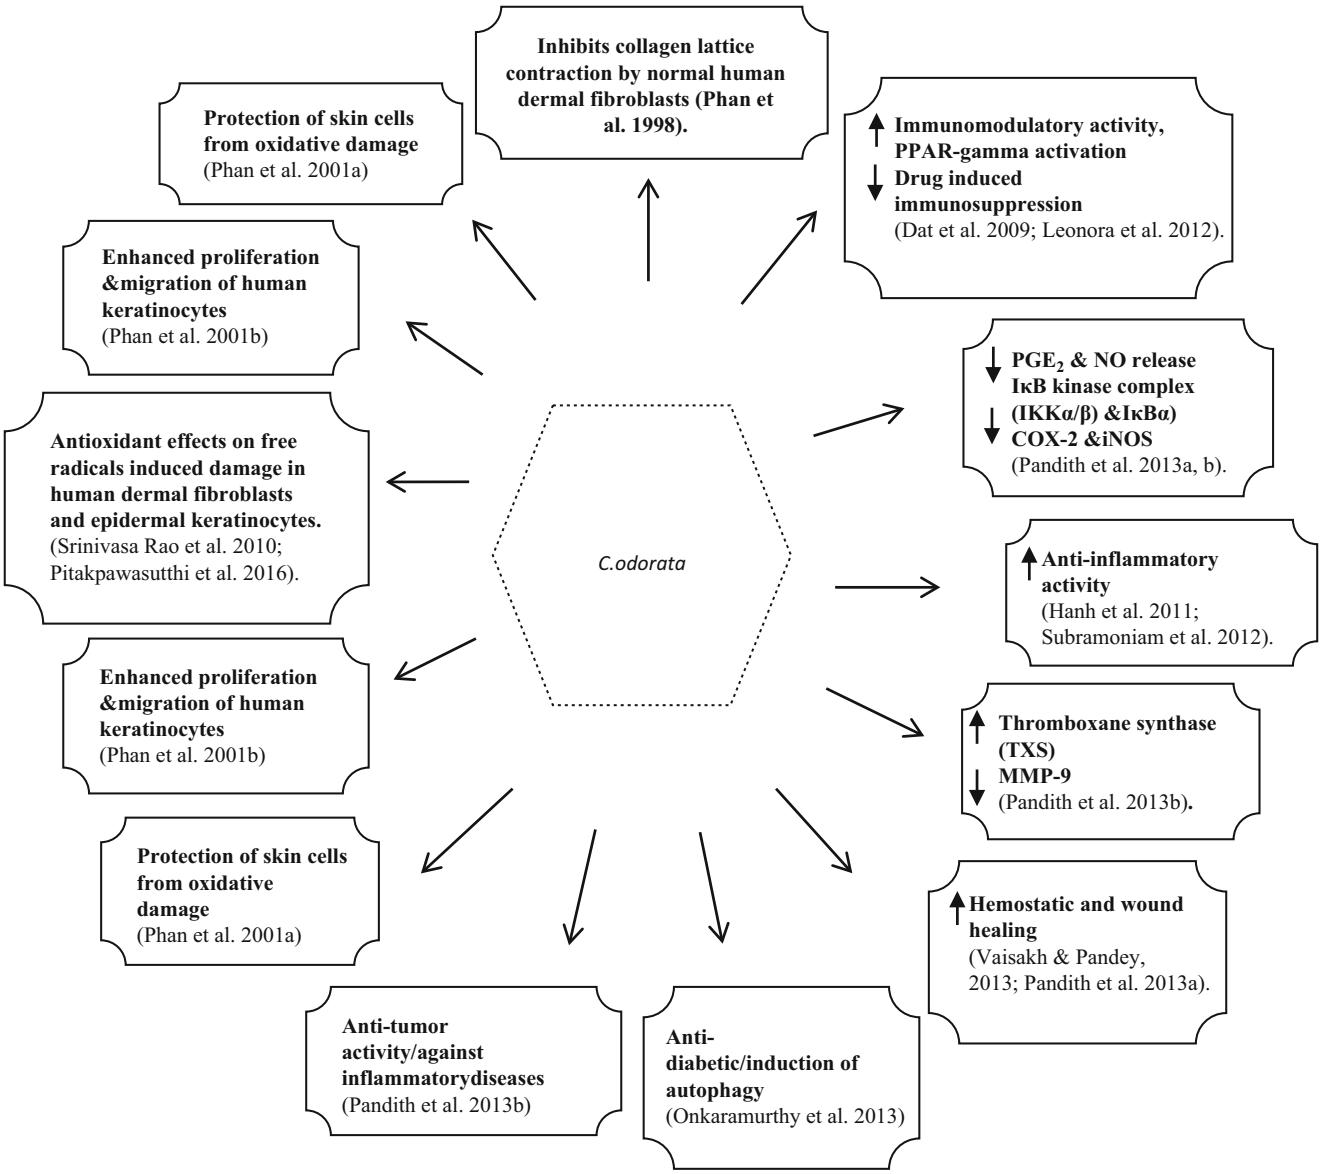

Fig. 4 Various pharmacological activities of leaf extracts of *C. odorata*

epithelization, antioxidant defense, biochemical changes (hydroxyproline), granulation, neovascularization, and wound contraction (Joshi et al. 2013). Medicinal plants heal wounds via several mechanisms such as upregulation of vascular endothelial growth factor (VEGF) and transforming growth factor beta 1 (TGF-β1), activation of nuclear factor-κ appa B (NF-κB), activation of interleukin-8 (IL-8), increased expression of iNOS and alpha-1 type 1 collagen, and antioxidant activity (Mirmalek et al. 2016; Shen et al. 2017). It is well known that VEGF is responsible for angiogenesis. These growth factors act on their respective receptors present in keratinocytes and macrophages and carry out their important functions during wound healing. Insufficient vascularization is the common feature of the chronic and non-healing wound. In diabetic animal models, delayed wound healing has been demonstrated in which poor vascularization is the factor responsible for delayed wound closure, epithelialization, and granuloma tissue formation (Stallmeyer et al. 2001). TGF-β is a major factor in the recent research of wound healing. It acts via intracellular serine/threonine kinase receptors to the intracellular mediators (SMAD) pathway which regulates cell proliferation (Klass et al. 2009). TGF-β causes migration of leukocytes into the injured tissue. As a result, monocytes transform into macrophages and clear the area of debris and itself to release TGF-β and other growth factors, which in turn help in the formation of granulation tissue (Behm et al. 2012).

The phosphatidylinositol 3-kinase (PI3K) pathway plays a crucial role in wound healing by rendering proliferation of cells. Activation of PI3K pathway causes phosphorylation of

Akt (serine/threonine-specific protein kinase) at serine 473 residues. This signaling pathway has been revealed to be essential for directional migration of corneal and skin epithelial cells in response to wound or injury (Zhao et al. 2006). Medicinal plants are reported to induce wound healing via the phosphatidylinositol-4,5-bisphosphate 3-kinase (PI3K) pathway. For example, *C. officinalis* tincture encourages wound healing through activation of the PI3K pathway (Dinda et al. 2015). Aqueous extract of Korean red ginseng also kindles in vivo and in vitro angiogenesis through activation of the PI3K/Akt pathways (Kim et al. 2007).

NF-κB activation is noticed in both immune and nonimmune cells affected by chronic inflammation. Activation of NF-κB increases the expression of proinflammatory mediators which organize and sustain the inflammatory processes that cause tissue damage. However, there are many reports that inhibition of NF-κB may cause harmful effects to the organisms and may sometimes cause inflammatory disease. The beneficial effect of NF-κB in epithelial cells has been reported. NF-κB signaling has a major role in the maintenance of immune homeostasis in epithelial cells (Wullaert et al. 2011). It has been demonstrated that plant extract can promote wound healing by NF-κB activation. The n-hexane extract of *C. officinalis* has been reported to increase the activity of transcription factor NF-κB in human immortalized keratinocytes and dermal fibroblast cells (Nicolaus et al. 2017).

Interleukin-8 (IL-8) is a proinflammatory cytokine. Keratinocytes are rich in interleukin-8. The effect of recombinant interleukin-8 on migration and adhesion of HaCaT keratinocytes has been demonstrated. It was found that IL-8 increased the migration and adhesion of HaCaT keratinocytes. Interestingly it was also observed that inhibition of phospholipase C-γ (PLC-γ) completely eradicated the migration of HaCaT keratinocytes. Thus, IL-8 directs migration via PLC-γ pathway. Medicinal plant extracts also endorse wound healing by activation of IL-8. The n-hexane extract of *C. officinalis* was found to increase the activity of IL-8 in human immortalized keratinocytes (Nicolaus et al. 2017).

Nitric oxide (NO) is a small gaseous radical (Pang et al. 2018). Synthesis of NO has been reported during the proliferative phase after wound formation (Vijayaraghavan et al. 2017a, b). Increased inducible nitric oxide synthase (iNOS) expression release NO regulates collagen formation, cell proliferation, and wound contraction (Witte and Barbul 2002). Moreover, iNOS regulates keratinocyte proliferation (Frank et al. 1998). The polysaccharide-rich extract of *C. ferrea* has been to increase the expression of iNOS (Pereira et al. 2016).

Alpha-1 (α-1) type 1 collagen is encoded by Col 1α (I) gene. This gene contributes to wound healing by the production of pro alpha-1 (I) chain which is a component of type 1 collagen. This pro alpha-1 (I) chain combines with another pro alpha-1 (I) chain and also with a pro alpha-2 (I) chain to produce a molecule of type 1 pro-collagen, which undergoes processing and rearrangement to produce type 1 collagen fibers. It has been demonstrated that topical application of ointment of *D. elata* showed upregulation of alpha-1 type 1 collagen encoded by Col 1α (I) gene contributes to wound healing.

Rho family GTPase like Rac-1, Rho-A, and Cdc-42 plays a pivotal role in fibroblast cell proliferation and migration (D'Souza et al. 2011). Cell cycle regulators such as cyclins and cyclin-dependent kinase 1 and 2 are involved in cytoskeleton formation in fibroblasts (Yoshizaki et al. 2004). *C. tamurana* has been reported to increase the migration of mammalian cells toward the wounded area through activation of Rac-1, Rho-A, and Cdc-42 m-RNA and Cdk 1 and 2 genes.

Much evidence suggests that wounds experience oxidative stress due to increased activity of neutrophils and resultant oxidants and myeloperoxidase (MPO; a peroxidase enzyme) activity. Increased activity of neutrophil resultant oxidants and MPO activity causes tissue damage in the chronic wound (Song et al. 2008). Generation of reactive oxygen species (ROS) results in cell toxicity via oxidative stress in chronic wounds and delay wound healing (Mikhal'chik et al. 2006). The antioxidant activity of medicinal plants is due to the presence of various phytochemicals (Pawar et al. 2007). To support this claim, it has been reported that topical application of bioadhesive gel of ethanolic extract of *L. macrophylla* (5% w/v) increased the activity of catalase, superoxide dismutase, and glutathione and decreased MPO activity (Joshi et al. 2016). Thus, medicinal plants potentiate wound healing by multiple mechanisms.

6.4 *C. odorata* as Nature's Wound Healer

In recent years, chemical research has increased interest in the medicinal effects of *C. odorata* as this plant is used as an antibacterial, antispasmodic, antiprotozoal, antitrypanosomal, antifungal, antihypertensive, anti-inflammatory, astringent, diuretic, hepatotropic (Hanh et al. 2011), immunomodulatory (Taleb-Contini et al. 2006), and anticancer agent (Harun et al. 2012; Kouamé et al. 2013). Traditionally, fresh leaves or a decoction of *C. odorata* has been used throughout Vietnam and other parts of the world for many years as well as in other tropical countries for the treatment of leech bites, soft tissue wounds, burns, skin infections, rashes, diabetes, and dentoalveolitis and as an insect repellent (Vaisakh and Pandey 2013). A poultice of the leaves is traditionally applied to cuts or wounds to stop bleeding and promote healing (Wang et al.

2014). A product made from *Chromolaena* spp. named eupolin has already been licensed for use in Vietnam for the treatment of soft tissue burns and wounds (Ayyanar and Ignacimuthu 2005; Raina et al. 2008). The fresh leaves and extract of *C. odorata* are a traditional herbal treatment in some developing countries for burns, soft tissue wounds, and skin infections (Sirinthipaporn and Jiraungkoorskul 2017; Stanley et al. 2017).

C. odorata has been the subject of chemical analyses in several research studies (Zhang et al. 2012; Heiss et al. 2014). Determination of the phytochemical profile of plants helps with understanding the class of compounds present which are responsible for the wound healing process (Karodi et al. 2009; Sirinthipaporn and Jiraungkoorskul 2017; Stanley et al. 2017). The chemical groups that have been identified in this plant are monoterpenes, sesquiterpene hydrocarbons, triterpenes/steroids, alkaloids, and flavonoids. The leaves of this plant have been found to be a rich source of flavonoids including quercetin, sinensetin, sakuranetin, padmatin, kaempferol, and salvigenin, which were isolated and identified. The leaves of *C. odorata* have the highest amount of allelochemicals (Afolabi et al. 2007) isolated from a plant. A study in Vietnam showed that the aqueous extract of the leaf contained flavonoids (salvigenin, sakuranetin, isosakuranetin, kaempferide, betulenol, 2-5-7-3 tetra-o-methyl quercetagetin, tamarixetin, two chalcones, and odoratin and its alcoholic compound), essential oils (geyren, bornyl acetate, and beta eubeden), saponin triterpenoids, tannins, organic acids, and numerous trace substances (Zhang et al. 2012). Another study by Heiss et al. (2014) showed that the crude ethanol extract of *C. odorata* contains phenolic acids (protocatechuic, p-hydroxybenzoic, p-coumaric, ferulic, and vanillic acids) and complex mixtures of lipophilic flavonoid aglycones (flavanones, flavonols, flavones, and chalcones). To date, studies on *C. odorata* have resulted in the isolation of 17 compounds such as 5aα,6,9,9aβ,10-pentahydro-10β-hydroxy-7-methylanthra [1,2-d][1,3]dioxol-5-one, 1,2-methylenedioxy-6-methylanthraquinone, 3-hydroxy-1,2,4-trimethoxy-6-methylanthraquinone, 3-hydroxy-1,2-dimethoxy-6-methylanthraquinone, and 7-methoxy-7-epi-medioresinol, as well as 12 known compounds including odoratin, 3β-acetyloleanolic acid, ursolic acid, ombuin, 4,2′-dihydroxy-4′,5′,6′-trimethoxychalcone, (−)-pinoresinol, austrocortinin, tianshic acid, cleomiscosin D, (−)-medioresinol, (−)-syringaresinol, and cleomiscosin A (Zhang et al. 2012).

One major application of *C. odorata* in traditional medicine is in the treatment of wounds. It is essential that any treatment of a wound must include the following (Badoe et al. 2000): (a) stopping excessive loss of blood without damaging blood supply to the wound site, (b) preventing or clearing residual bacterial infection, and (c) encouraging formation of fibroblasts at the wound site. Iwu (1993) showed that with its astringent properties, the leaf of *C. odorata* is able to arrest bleeding at wound sites. Furthermore, a previous study has shown that the leaf extracts of *C. odorata* are capable of preventing the growth and even causing the death of bacteria that could infect wounds. Moreover, Donovan (2007) showed that the leaf extracts of *C. odorata* do encourage proliferation of fibroblasts. This takes care of the third condition given for treatment of wounds (Badoe et al. 2000). Consequently, the leaf of *C. odorata* has all the properties required for effective treatment of a wound. Its uses in traditional medicine to treat wounds are therefore scientifically justified.

In addition, flavonoids have been shown to exhibit their actions through their effects on membrane permeability and by inhibiting membrane-bound enzymes such as ATPase and phospholipase A2 (Li et al. 1983). Flavonoids serve as health-promoting compounds due to the presence of anion radicals (Hausteen 1983). Flavonoids significantly inhibit lysosomal enzyme secretion and arachidonic acid release from membranes by inhibiting lipoxygenase, cyclooxygenase, and phospholipase A2 (Kuponiy and Ibibia 2013). The inhibition of arachidonic acid release in the inflamed cells would provide less arachidonic substrate for the lipoxygenase and cyclooxygenase pathways. This, however, leads to a lesser quantity of endoperoxides, prostaglandins, prostacyline, and thromboxane, as well as hydroperoxy, hydroxyl eicosatrienoic acids, and leukotrienes (Garbor 1986). Such an effect confirms the decrease in histamine which is known to act in the first stage of the inflammatory process (Farquar 1996). However, some flavonoids behave as a powerful protective agent against inflammatory disorders. They reduce edema formation and inhibit the synthesis of prostaglandin E_2, prostaglandin F_2, and thromboxane B2 (Kuponiy and Ibibia 2013). Hence, the anti-inflammatory action of the selected plant drug might be attributed to the presence of flavonoids as reported in the earlier works.

Phenol was also present in a moderate quantity in *C. odorata*. Phenols have been found to be of great importance as they protect the human body from oxidative stress (Robards et al. 1999). The presence of these phenolic compounds in this plant might have contributed to the antioxidant and antimicrobial properties as reported by Baravkar et al. (2008). Phenols are responsible for blocking specific enzymes that cause inflammatory disorders. They also modify the prostaglandin pathways and thereby protect platelets from clumping (Duke 1992). Tannins were also present both in aqueous and alcohol extracts. Tannins are useful as a dietary supplement for the maintenance of health due to their antioxidant, antimicrobial, and anti-inflammatory properties (Santos-Buelga and Scalbert 2000). Tannins are known to be useful in treating inflamed or ulcerated tissues (Motar et al. 1985).

Besides the above, both in vitro wound assay and in vivo studies have demonstrated that the leaf extracts of *C. odorata*

possibly enhance the proliferation of fibroblasts, endothelial cells, and keratinocytes; stimulate keratinocyte migration; upregulate the keratinocyte-induced production of extracellular matrix proteins and basement membrane components including collagen VII, anchoring fibrils, and fibrillin microfibrils; and inhibit collagen lattice contraction by fibroblasts (Kusano et al. 2001; Subramoniam et al. 2012).

Despite the natural cascades of the healing process, healing progression may be delayed by an infection mediated via various mechanisms, like decreased blood supply, which can promote impaired leukocyte function, prolong inflammatory and debridement phases, and produce proteolytic enzymes. Therefore, infection is the major impediment to the wound healing process, and antibacterial compounds play a major role (Annan and Houghton 2008; Kahkeshani et al. 2013; Kumari et al. 2013). Medicinal plants with their antioxidant, anti-inflammatory, and antimicrobial activities have an extensive potential for the management and treatment of wounds (Trabucchi et al. 1986; Trombetta et al. 2006; Akinmoladun et al. 2010).

Inflammation is a response to any tissue injury in the body caused by infection, trauma, chemicals, heat, or unrecognized particles (Kim et al. 2007). Inflammation, which constitutes a part of the acute response, results in a coordinated influx of neutrophils to the wound site which, through their characteristic "respiratory burst" activity, produce free radicals (Pan et al. 2008). Topical applications of compounds with free-radical-scavenging properties in patients have shown to considerably improve wound healing and protect tissues from oxidative damage (Pisutthanan et al. 2005).

Proinflammatory cytokines like cyclooxygenase-2 (COX-2) and inducible nitric oxide synthase (iNOS) play a critical role in inflammation (Hanh et al. 2011). In addition, proinflammatory mediators such as prostaglandin E_2 (PGE_2) and nitric oxide (NO) enhance the expression of proinflammatory cytokines, including tumor necrosis factor (TNF)-α and interleukin (IL)-1β. Previous studies have demonstrated that *C. odorata* has anti-inflammatory activity both in vitro and in vivo (Karodi et al. 2009; Park et al. 2012). The scutellarein tetramethyl ether (Scu) (4′,5,6,7-tetramethoxyflavone), isosakuranetin, and stigmasterol have also been reported to possess anti-inflammatory activity (Csupor et al. 2010).

Based on available literature, *C. odorata* would be a useful pharmaceutical ingredient for the management of various wounds including the chronic ones. However, further studies must be conducted in various wound models, and research at the cellular and molecular levels are required to identify specific mechanism that could induce healing in those wounds. Wound healing is a very complex, multifactor sequence of events involving several cellular and biochemical processes. The various processes of wound healing will help to regenerate and reconstruct the disrupted anatomical continuity and functional status of the skin. Initially wound healing involves an acute inflammatory phase followed by the synthesis of collagen and other extra cellular macromolecules, which are later removed to form a scar (Mukherjee 2002). The use of a single model for a wound healing study is inadequate, and no reference standard exists that can collectively represent the various phases of wound healing. For example, drugs, which influence one phase, may not necessarily influence another.

The available reports highlight the fact that the inclusion of antioxidant and antipathogenic microbial rich extract or fractions of *C. odorata* as a potential healing agent would also benefit both animal and human health. The data obtained from various studies are useful for future research aiming to further identify the specific bioactive principles other than Scu and stigmasterol (Pandith et al. 2013a; Vijayaraghavan et al. 2017a, b) that are indeed responsible for the healing efficacy of *C. odorata*. Figure 5 depicts the possible mechanism of action and other pharmacological roles of bioactive compounds of the plant extracts.

Overall, several herbal medicines have shown marked activity in the management of wounds, and therefore, *C. odorata* can be considered as an alternative treatment source. Furthermore, various natural compounds with verified in vivo wound healing potential can be considered potential natural drugs. The novelty with this plant includes the new opening in the field of antimicrobial, antioxidant, and especially wound healing potential of *C. odorata*, based on the available literature, which are crucial to its potential future drug design, development, and application for the treatment of wounds in biological systems. In summary, the present review concludes that *C. odorata* is a promising wound healing agent in treating various ailments as a veterinary or alternative medicine in animals and humans, respectively, in the future after further preclinical and clinical trials.

7 Concluding Remarks and Future Directions

Many healthy subjects and patients are taking potentially bioactive products for the prevention and treatment of multiple conditions, including wounds and infections. This forms the basis of a worldwide, multimillion dollar major commercial industry. While the scientific validity of the use of a number of these products is lacking, in the past few years much effort has been made to provide solid knowledge of the mechanisms underlying the beneficial effects of nutraceuticals. Scientifically rigorous research is warranted in order to identify novel compounds to be used alone or in combination with standard drugs in wound healing. Also, future research should be aimed at further increasing the efficacy of a promising nutraceutical, trying to use it as a chemical template for combinatorial synthesis. Finally,

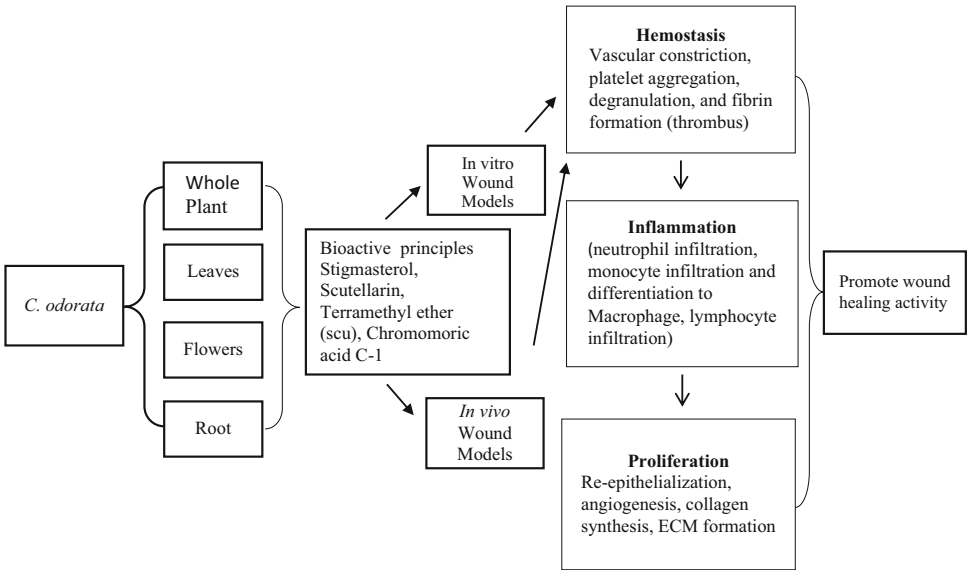

Fig. 5 Possible mechanism of action of bioactive compounds from various parts of the plant extracts of *C. odorata*

researchers in this area should focus on understanding of the molecular action of each nutraceutical and test the possible synergistic effects with other nutraceuticals and/or derivatives, food components, or conventional drugs. However, one must keep in mind that just because isolated compounds start from a natural food, they are not necessarily safe and natural, and therefore, strict quality control and regulatory issues are mandatory. The judicious application of nutraceuticals is based on the objective assessment of the clinical evidence and subjective characterization of the risk, merits, economic prices, and probable drug interactions. Future clinical studies are necessary to determine whether these compounds will be as interesting as preventive or therapeutic agents as they are in preclinical studies.

Competing Interests Authors have declared that no competing interests exist.

Nutraceuticals in Dermatological Disorders

Moges Woldemeskel

Abstract

Dermatological disorders refer to skin abnormalities that could be induced by various agents including infectious organisms, noninfectious physical agents, and immunological reactions. Various modern medicinal drugs are being used to treat different types of skin disorders. Although some of them are effective, unwanted side effects are often observed. Currently, there is an increased tendency to use traditional medicine including use of nutraceuticals which are in use since ancient times, are effective to treat and manage skin disorders, and cause no apparent side effects. This chapter briefly highlights on the use of some nutraceuticals in the treatment of skin disorders.

Keywords

Veterinary nutraceuticals · Dermatological disorders

1 Introduction

Skin is one of the largest immunologic organs of the body and is affected by both external and internal factors, as well as innate and adaptive immune responses. Dermatological disorders refer to skin abnormalities caused by various agents including infectious organisms, noninfectious or physical agents, and immunological reactions. Skin disorders such as atopic dermatitis, contact dermatitis, urticaria, angioedema, psoriasis, and autoimmune blistering disorders are immune-mediated conditions. Most of these diseases are chronic, inflammatory, and proliferative, in which both genetic and environmental factors play important roles in their development (Fonacier et al. 2010).

e-mail: mwoldem@uga.edu

Skin disorders are often seen in both humans and animals since the skin is the most external organ exposed to various physical, biological, and chemical agents. Due to diverse causes underlying skin (dermatological) disorders, methods used to treat dermatological abnormalities also are diverse. These vary from the use of traditional methods that encompass different natural agents, herbal medicine including nutraceutical products, to the application of modern medicine.

Herbal medicine is gaining popularity both in developing and developed countries due to its low cost and fewer side effects. Plants contain different types of phytoconstituents in the form of either primary metabolite or secondary metabolite, and many drugs used in the modern medicine are mainly derived from the medicinal plants (Patel and Patel 2017). Different types of natural bioactive compounds or foodstuff that provides extra health benefits in addition to basic nutritional values (nutraceuticals) have been in use for several generations to treat skin diseases in humans and animals as part of traditional medicine. For example, *Adenium obesum* (Lav, *Apocynaceae*) is generally used for the treatment of wounds and other skin diseases in Omani ethnic community (Akhtar et al. 2017). In this chapter, a brief overview will be given on the role of nutraceuticals in allergic skin diseases, atopic dermatitis, infectious skin diseases, and skin tumors.

2 Nutraceuticals in Dermatitis

Different types of agents are incriminated as underlying factors in skin disorders. Some skin diseases are associated with microbial infections, others are associated with exposure to irritants such as chemicals in cosmetics, while many others are immunological in origin and result from hypersensitivity responses to environmental allergens (Fonacier et al. 2010).

Since skin is constantly exposed to the external environment, any insult to skin may induce reactive response

R. C. Gupta et al. (eds.), *Nutraceuticals in Veterinary Medicine*, https://doi.org/10.1007/978-3-030-04624-8_37

including various types of dermatitis. Dermatitis is an inflammation of skin caused by infectious and noninfectious agents that may come in contact with skin. For example, atopic dermatitis is a common, recurring chronic inflammatory disease characterized by pruritus and eczema and is commonly associated with hypersensitivity to allergens, more frequently with allergic diseases such as allergic rhinitis and asthma (Kim et al. 2016).

Different types of dermatitis elicited by infectious and noninfectious agents are treated using modern medicine as well as traditional medicine including nutraceuticals. This section will briefly describe effects of some nutraceuticals used in the treatment of different types of dermatitis. *Aloe vera*, a plant which has a long history of popular and traditional use, is one such example. It is used in traditional Indian medicine for various skin diseases and infections. The first case report of the beneficial effects of *Aloe vera* in the treatment of skin and wound healing was published in 1935, with fresh whole-leaf extract reported to provide rapid relief from itching and burning associated with severe radiation-induced dermatitis and skin regeneration. Later on, numerous studies reported the role of topical *Aloe vera* application alone or in combination with others for the management of different skin conditions including wound healing, psoriasis, dermatitis, burn injuries, and surgical wounds. Foster et al. (2011) citing several authors summarized results of a number of clinical trials in which *Aloe vera* is positively indicated in the treatment of skin disorders. For example, a trial of wound healing management after the full-faced dermabrasion of patients with acne vulgaris demonstrated that the saturation of a standard polyethylene wound gel dressing with *Aloe vera* significantly reduced time to reepithelization compared to use of the standard dressing alone. It was reported that polysaccharides, particularly mannose-containing polysaccharides, cellulose, and pectic polysaccharides, comprise the major part of *Aloe vera* gel. Acetylated glucomannan is primarily responsible for the gel's mucilaginous properties and has been found in vitro and in animal studies to modulate immune function through macrophage activation and cytokine production and accelerate wound healing. In a randomized, double-blind, controlled trial of *Aloe vera* or placebo cream in 60 patients with chronic psoriasis, the cure rate of *Aloe vera* was 83%, with no relapses at 1 year of follow-up, compared to only 7% in the placebo group (Foster et al. 2011).

Furthermore, other various plant nutraceuticals are used to treat skin diseases in general. To give some examples, ethnobotanical studies indicate that Rasaut, decoction of *Berberis aristata*, was commonly used to treat skin disorders. Malani tribal communities from Himachal Pradesh, India, also use *Berberis aristata* to cure various skin diseases (Nimisha et al. 2017). In another report (Patel and Patel 2017), it was shown that topical anti-inflammatory activity of bioactivity-guided fractionation of methanolic extract of the leaves of *Santolina insularis* mainly luteolin, which is among the active constituents of the extract, prevented ear edema in croton oil-induced dermatitis in mouse ear more effectively compared to the standard drug indomethacin. The effect of other nutraceuticals on specific categories of skin abnormalities is highlighted in various sections below.

3 Nutraceuticals in Otitis Externa

Otitis externa is an inflammation or infection of skin of external ear canal and ear pinna. Otitis externa can be caused by bacteria, viruses, parasites, and noninfectious agents in animals. Among skin diseases that affect dogs, chronic, recurrent otitis externa poses one of the most frustrating pathologies of daily veterinary clinical practice (Rosser 2004; Pietschmann et al. 2013).

Many studies, in dogs and humans, affirm benefits of nutraceutical administration in the treatment of otitis externa. For example, the effect of a commercial nutraceutical diet composed of fish hydrolyzed proteins, rice carbohydrates, *Melaleuca alternifolia*, *Tilia cordata*, *Allium sativum* L., *Rosa canina* L., zinc, and omega-3/omega-6 (1:0.8 ratio), with anti-inflammatory and antioxidant activities as an adjuvant, was clinically evaluated in the treatment of different ages and breeds of dogs afflicted with chronic otitis externa. The dogs were also pharmacologically treated with a topical product (OTOMAX, Schering-Plough, Kenilworth, NJ, USA) eight drops a day for 7 days. The commercial nutraceutical diet has been proven effective, in combination with drugs, in relieving otitis externa-related symptoms and in reduction of the main symptoms of otitis externa such as external ear canal occlusion, erythema, odor, and mucus when compared to those that received the standard diet (Di Cerbo et al. 2016). In another study, the use of medical grade honey demonstrated overall effectiveness in the management of otitis externa in a population of dogs. The results obtained such as rapid onset of clinical and cytological improvement, positive owner evaluations, in vitro biocidal results, and durability of clinical resolution during follow-up were encouraging (Maruhashi et al. 2016). There also are several nutraceuticals claimed to have effect on various skin lesions but need scientific evaluation to confirm their specific effect on otitis externa.

4 Nutraceuticals in Infection-Associated Dermatitis

Skin diseases are often associated with infectious agents such as bacteria and parasites. Different types of treatments using various antibiotics and physical agents such as irradiations

are used to treat skin diseases. Current treatments for some chronic skin conditions are not effective; for example, microbial drug resistance has hindered the effectiveness of antibiotics in the treatment of chronic wounds, and ultraviolet radiation therapy used to treat psoriasis and atopic dermatitis may induce development of skin cancer (Gasparro 2000). This section will highlight on the use of nutraceuticals in alleviating and treating some infection-associated skin disorders/diseases. For example, a study was made on the effect of an immune-modulating diet in treating canine leishmaniosis in dogs that received no specific prior treatment for the disease. Canine leishmaniosis is a zoonotic disease that affects humans and dogs and is caused by the protozoan parasite *Leishmania infantum*. Several clinical manifestations have been described in leishmaniosis in dogs, and the clinical appearance and evolution of the disease appear to be influenced by complex interactions between the parasite and patient's genetic and immunological profile.

A diet supplement that contained *Ascophyllum nodosum*, *Cucumis melo*, *Carica papaya*, *Aloe vera*, astaxanthin from *Haematococcus pluvialis*, *Curcuma longa*, *Camellia sinensis*, *Punica granatum*, *Piper nigrum*, *Poligonum* spp., *Echinacea purpurea*, *Grifola frondosa*, *Glycine max*, and omega-3 and omega-6 unsaturated fatty acids from fish oil induced an intriguing immune modulation in leishmaniosis-affected dogs undergoing 12 months of treatment with standard pharmacological therapy. The immune-modulating diet appears to regulate the immune response in the affected dogs during the standard pharmacological treatment. The presence of nutraceuticals in the diet correlates with the decrease of Th1 cells and with the increase of regulatory T-cells in sick dogs. It was shown that pharmacological treatment alone was unable to induce long-lasting changes in pro-inflammatory response and to modulate regulatory T-cells in sick dogs, while the combination with immune-modulating diet was associated with a significant restoration of regulatory T-cell level and with the decrease in Th1 inflammatory response. Therefore, the administration of the specific dietary supplement improved the clinical response to the standard treatment in a model of canine leishmaniosis (Cortese et al. 2015) signifying the importance of nutraceutical supplement in the treatment of infection-associated skin diseases.

Other studies also indicate that various plant-based nutraceuticals were also effective against microbial-induced skin diseases. *Nerium oleander* (*Apocynaceae*) and *Aloe vera* are among the widely used herbal remedies that possess numerous activities such as antibacterial, antiviral, antifungal, and antioxidative activities and are used in treating skin diseases. Wound healing effect of *Aloe vera*-based extract of the *Nerium oleander* leaf based on its antioxidant, anti-inflammatory, and DNA repair capacity was investigated and compared with the traditional silver sulfadiazine treatment in Wistar albino rats with skin burn injury that received topical application twice a day for 2 weeks. Thermal injury-induced alterations were significantly reversed by the treatment. The healing effect of the extract was also supported by histological findings, suggesting that *Aloe vera*-based extract of the *Nerium oleander* leaf is a promising remedy for treating skin burn injury (Akgun et al. 2016).

Moreover, reports indicate that among other natural products, honey also has a healing effect on infection-associated skin diseases. Honey is being used since ancient times as a traditional medicine and has recently received attention as a complementary and alternative treatment in modern medicine. It is mainly composed of various sugars, phenolic acids, flavonoids, enzymes, amino acids, proteins, phytochemicals, and other miscellaneous compounds (Ahmed and Othman 2017). Traditionally, it has been used around the world to treat skin disorders associated with microbial infections and immunological reactions. In a traditional Hindu system (Ayurvedic) medicine, for example, honey is used to treat cuts and wounds, eczema, dermatitis, burns, and Fournier's gangrene. McLoonea et al. (2016) citing several authors indicated that the skin healing properties of honey have been largely attributed to its antimicrobial properties; a plethora of in vitro studies have demonstrated antimicrobial activity of honeys from all over the world against dermatologically important microbes. More recent in vitro research suggested that honeys of diverse floral origins can modulate the skin immune system through both immunostimulatory and anti-inflammatory effects (McLoonea et al. 2016).

There is also biologic evidence to support the use of honey in modern wound care. Honey has been shown to have effect against various bacterial species including *Escherichia coli*, *Pseudomonas aeruginosa*, *Staphylococcus aureus*, *Acinetobacter*, and *Stenotrophomonas*. Its antimicrobial activity has been shown to be directed against even antibacterial-resistant strains such as methicillin-resistant *Staphylococcus aureus* and vancomycin-resistant *Enterococcus* (Lee et al. 2011). Maruhashi et al. (2016) also reported that success was attained using honey against multidrug-resistant bacteria.

Plant products are also used against parasite-induced skin diseases or dermatitis. In Oman, various preparations of the plant material (bark and leaves) from *Adenium obesum* are used to treat skin diseases in humans. In Kenya, the stems and powder from the barks of *Adenium obesum* are used against skin parasites in camels and cattle. The crude extracts from root and bark are also used to prepare a lotion for the treatment of different skin diseases and to eliminate lice (Akhtar et al. 2017). Effects of such plant-based products on specific infection-associated skin lesions should be confirmed through scientific experiments and well-designed clinical studies.

5 Nutraceuticals in Allergic/Atopic Dermatitis

Allergic dermatitis is a type of dermatitis that develops due to a skin reaction to allergens that come in contact with the skin. It often develops in animals with a hereditary tendency to develop Ig-E-mediated allergic reaction to environmental agents such as house mite dust proteins, plant pollens, mold spores, and various other allergens. It commonly occurs in pets such as dogs and cats and in humans (Gross et al. 2005).

Usually, anti-inflammatory drugs and steroids are used to treat allergy-associated dermatitis. However, due to safety concerns consequent to the side effects of the drugs, use of nutraceuticals and certain food supplements to alleviate the clinical signs and help in the treatment of allergic dermatitis is increasing. As a result, scientific studies on nutraceuticals are also being undertaken in increasing rate. For example, flaxseed (*Linum usitatissimum*) supplementation was evaluated on the skin-test response in atopic horses that displayed allergic response to extracts from *Culicoides* spp. It was observed that supplementation with flaxseed for 42 days reduced the mean skin-test response to the extracts of *Culicoides* spp. with a significant decrease in the area of allergic reaction. In this study it was noted that flaxseeds were able to reduce the skin-test response of atopic horses, alter the fatty acid profile of the hair, reduce inflammation, and did not elicit any negative side effects suggesting a promising benefit of flaxseed to mitigate skin response to *Culicoides* extract elicited atopic dermatitis in horses (O'Neill et al. 2002).

It is worth noting that cutaneous allergic response may occasionally occur associated with food allergy, a clinical syndrome caused by an acute or chronic immunological reaction following food ingestion. Food intolerance, a non-immunological abnormal physiological response toward some specific foods or food additives, may also be observed associated with ingestion of certain food. Due to their often-difficult differentiation, these phenomena are generally included in the generic non-specific adverse food reaction syndrome, which can also involve the cutaneous system and are most often referred to as cutaneous adverse food reactions.

The effect of nutraceutical diet on indoor-housed domestic cats with cutaneous adverse food reactions, which among others included drooling, skin lesions such as back and neck intense itching, and neck eczema and had high amount of oxytetracycline as determined by oxytetracycline enzyme-linked immunosorbent assay (ELISA), was studied. The cats were grouped into those that received a standard feed and those that received a nutraceutical diet composed of a mixed formula of fish hydrolyzed proteins, rice carbohydrates, *Aloe vera*, *Arctium lappa*, *Malva sylvestris*, *Ribes nigrum*, *Allium sativum*, and omega-3 and omega-6 fatty acids at the ratio of 1:3 for 60 days. The nutraceutical diet was found to significantly reduce intensity of pruritus and severity of skin lesion with a significant improvement in the clinical picture of affected cats (Mazzeranghi et al. 2017).

Supplementation with some nutraceuticals is known to augment and support treatment effects of other chemical methods of treatment of skin conditions in humans and animals. For example, in humans, vitamin D supplementation decreased severity of atopic dermatitis and improved the associated symptoms and clinical signs in patients with atopic dermatitis particularly in pediatric patients (Kim et al. 2016).

Similarly supplementation of dogs suffering from atopic dermatitis with zinc methionine was documented to provide benefit in conjunction with treatment with two effective anti-inflammatory medications: glucocorticoids and ciclosporin (cyclosporine), which are known to have certain adverse side effects. The study provided evidence supporting a potential benefit of adjunctive zinc methionine supplementation in dogs with mild to moderate, chronic, nonseasonal canine atopic dermatitis. Dogs receiving glucocorticoids may be more likely to benefit from zinc methionine supplementation. The exact role of zinc and the potential benefits of supplementation in atopic dermatitis in humans are largely unknown. Interestingly, serum zinc levels have been found to be lower in atopic children compared to healthy children (McFadden et al. 2017). Furthermore, Tsuji et al. (2015) citing various studies in animal models indicated that selenium deficiency enhanced type-I allergic response in a mouse model of active cutaneous anaphylaxis indicating the importance and potential significance of selenium in managing cutaneous allergic response.

6 Nutraceuticals in Skin (Cutaneous) Tumors (Neoplasms)

Skin (cutaneous) neoplasms are tumors that develop in skin due to uncontrolled growths of various components of skin and associated connective tissues. Large numbers of skin tumors are recognized in various animal species. In veterinary medicine canines (dogs) are among animal species that often develop skin cancers. For example, Raditic and Bartges (2014) indicated that cancer is an important disease in dogs and accounts for 27% of all deaths in purebred dogs in the United Kingdom.

The incidence of cancer is continually rising (Ranzato et al. 2014), and chemical drugs are often prescribed for the treatment of cancer in humans and animals. However, chemical drugs possess limited therapeutic capacity for the treatment of patients with cancers consequent to the occurrence of resistance (Mao et al. 2018). Furthermore, the currently available cancer therapeutic options are expensive, and none of them are safe (Sayeed and Ameen 2015) due to

serious side effects that often appear in patients treated with chemical drugs (Mao et al. 2018). However, traditional plant-derived medicines or compounds are relatively safe (Sayeed and Ameen 2015). Henceforth, phytomedicines are increasingly gaining importance since they are used more readily and are relatively safe. Nutraceuticals rich in phytochemicals provide a promising source of compounds with chemopreventive effects because they are inexpensive and most of them show no evidence of toxicity (Ranzato et al. 2014).

In addition to inherited factors, diet sources are also reported to be closely involved in the pathogenesis of diverse neuropsychiatric disorders and cancers. Nutraceutical antioxidants, which have a wide distribution in diverse sorts of foods, fruits, vegetables, and minerals, exhibit potent neuroprotection and anticancer properties in vivo and in vitro. Currently, natural products or nutraceuticals also commonly called medical foods are increasingly employed for adjunctive therapy of patients with neuropsychiatric disorders and cancers. Nutraceuticals are reported to exert neuroprotection and suppressed tumor growth possibly through the differential modulations of redox homeostasis (Mao et al. 2018).

In dogs, nutraceuticals including some vitamins are reported to have an effect in reducing risks of certain cancers. There is evidence that growth of canine mast cell tumors is inhibited by vitamin D, and Labrador retriever dogs with low vitamin D levels have an increased risk in developing mast cell tumors (Pucheu-Haston et al. 2015). Furthermore, in Scottish terrier dogs, an inverse relationship was reported between the consumption of vegetables and the risk of developing transitional cell carcinoma of the urinary bladder (Raghavan et al. 2005). A study also showed that a combination of turmeric and rosemary extracts diminished the growth of cancer cells in vitro. Although the bioactive molecules inducing these effects are not definitely identified, it was suggested that the high concentrations of curcuminoids and carnosic acid are likely involved (Levine et al. 2016). Experimental and pharmacological trials have also demonstrated that curcumin as an anti-inflammatory agent is effective in managing and treating skin cancers among others (Fadus et al. 2017).

Retinoids are natural or synthetic derivatives of vitamin A (retinol) that exert profound effects on the growth and differentiation of many cell types both in vivo and in vitro. Retinoid is a term used to describe the entire set of vitamin A-derived compounds, including naturally occurring vitamin A, its metabolites, and synthetic analogs (Zhang and Duvic 2003; de Mello Souza et al. 2010). Retinoids suppress premalignant lesions such as oral leukoplakia, cervical dysplasia, and xeroderma pigmentosum in people and actinic keratosis in dogs (de Mello Souza et al. 2010). Retinoids have long been used alone or in combination with other agents in cutaneous T-cell lymphomas, a heterogeneous group of lymphoproliferative disorders characterized by localization of malignant T-lymphocytes to the skin (Zhang and Duvic 2003). In dogs, retinoids have been used in dermatology as a differentiation agent for cases affected by actinic keratosis, sebaceous adenitis, and benign pilomatrixomas. Few studies have demonstrated the effects of retinoids in canine cancer. Various retinoids derived from retinoic acid have long been used alone or in combination with other agents in cutaneous T-cell lymphomas. A 42% response rate to retinoid treatment has been observed in dogs with cutaneous lymphoma indicating that retinoid and rexinoid receptor-binding drugs may have an impact on the treatment of dogs with cutaneous lymphoma. Moreover, positive results have also been recorded with in vitro canine mast cells and canine osteosarcoma cell lines (de Mello Souza et al. 2010). The advantage of using retinoids as well as the other biological response modifiers is that they can be orally administered, are non-immunosuppressive, may boost immune function by inducing an antitumor response, and may induce apoptosis of the malignant T-cells (Zhang and Duvic 2003). In another study, it was indicated that hydrophobic flavonoids from *Scutellaria baicalensis* and magnolol isolated from *Magnolia officinalis* have also been reported to have antitumor activities in various tumors (Chen et al. 2013; Raditic and Bartges 2014).

7 Concluding Remarks and Future Directions

As part of the body system constantly exposed to external agents, the skin is affected by an array of abnormalities elicited by infectious and noninfectious agents and immune disorders. Nowadays, wide spread use of synthetic cosmetic products of chemical origin applied to the skin has undoubtedly increased the incidence of skin diseases including allergic dermatitis and cutaneous neoplasms. Various applications of modern medicine most of which leave unintended side effects are often prescribed to manage and treat skin diseases. Due to the undesirable side effects of modern medical treatments, there is an increased tendency to use traditional and alternative medicine, mainly nutraceuticals to prevent or minimize the rate of occurrence and also to treat clinical skin diseases. Consequently, many studies and research undertakings on nutraceuticals are progressing with encouraging results indicating the promising effects and potentials that nutraceuticals have in the future for the treatment of various dermatopathies in humans and animals.

Nutraceuticals in Mastitis

Robert W. Coppock

Abstract

Acute and chronic forms of mastitis are the costliest disease in the dairy industry. Resistance of microbial pathogens to antimicrobials approved for clinical use is a significant threat to controlling mastitic pathogens and is a public health issue. In some countries, the cost of antimicrobial drugs reduces their usage, and ethnic remedies are being used. Organic dairies have prioritized the maintenance of mammary health and the use of nutraceuticals to prevent and treat mastitis. In some jurisdictions, dairy animals on organic farms that receive antibiotics are disqualified for life as dairy animals. There is conflicting evidence on the efficacy of nutraceuticals, homeopathy, and traditional medicine in treating mastitis and a lack of standards for evaluation of these remedies. Studies are showing that nutraceuticals can be efficacious. Phytotherapeutics generally are complex chemical mixtures and can be multifaceted in mechanisms of action. Intramammary infusions of probiotics and bacteriocins are being shown to be efficacious, and their mechanisms of action include being an immune stimulant. Immunotherapy with antibodies and immune system components can be efficacious. Intermingled treatments with nutraceuticals and pharmaceuticals can be more efficacious than either treatment alone.

1 Introduction

Mastitis, inflammation of the mammary gland, is one of the most significant and costly diseases affecting lactating ruminants (Arsenault et al. 2008; Cooper et al. 2016; Aghamohammadi et al. 2018). The mammary glands, also referred to as the udder in some species, are susceptible to infection by a wide variety of microorganisms. Milk in the mammary gland is also an excellent culture media for many microorganisms (Rainard 2017). Infectious mastitis exists in subclinical and clinical forms. Treatment of clinical infections with antibiotics and other therapeutics has increased risk of recurrence especially when a bacteriological cure is not achieved (Gomes and Henriques 2016; Jamali et al. 2018). The worldwide cost to the dairy industry is estimated to be 35 billion US dollars in direct losses, and this loss does not include the loss of valuable genetics due to culling and deaths. Cows with mastitis can also have reduced fertility and metabolic dysfunctions (Ribeiro et al. 2016). The pathogenesis of mastitis has been reviewed (Akers and

R. C. Gupta et al. (eds.), *Nutraceuticals in Veterinary Medicine*, https://doi.org/10.1007/978-3-030-04624-8_38

Nickerson 2011; Lainesse et al. 2012; Bhattarai et al. 2018). In summary, the innate immune system is the first defense mechanisms. Pathogenesis of infection is due primarily to ascending infection, inflammation that may block the milk duct drainage system, inflammation of the alveoli with sloughing, and apoptosis of secretory cells with appearance of fibroblasts and poorly differentiated cuboidal epithelium. Acute and chronic infections generally cause some loss of secretory function. There is a reduction in milk production, and this is associated with an increase in milk somatic cell counts (SCC, primarily white blood cells). Biomarkers of mastitis include increase milk SCC, bacteria isolated in secretions from the mammary gland, bacteria in milk identified by colony plate counts, cardinal signs of inflammation in the mammary gland, and proteomic changes in mammary secretions. There is widespread use of antibiotics as dry cow prophylactics and therapeutics for mastitis. For treating mastitis in small ruminants, the preferred antimicrobial chemotherapeutic may not have regulatory approval. There are animal welfare and public health issues associated with mastitic animals in the dairy industry. Antimicrobial resistance is an increasing concern in milk-producing species and the animal-to-animal and zoonotic spread of these organisms (Holmes and Zadoks 2011; Tavakol et al. 2012; Saini et al. 2013). The route of administration of antibiotics is important in development of resistance for penicillins, third-generation cephalosporins, and macrolides with the risk being low for strategic intramammary and intrauterine administration (Nobrega et al. 2018a). A recent Canadian study showed that there is antibiotic resistance in non-aureus staphylococci isolated from milk collected from the mammary gland (Nobrega et al. 2018b). The pattern of antibiotic resistance was found to be species-dependent with *Staphylococcus gallinarum* being resistant to quinupristin/dalfopristin combination at a prevalence of 98%. *S. cohnii* and *S. arlettae* were resistant to erythromycin with a prevalence of 63 and 100%, respectively. The resistance of bacteria from milk to vancomycin, fluoroquinolones, linezolid, and daptomycin was prevalent at <1%. The formation of intramammary biofilms may also be a factor in antimicrobial resistance (Gomes et al. 2016). A public health concern is milk can be an important source of antimicrobial chemotherapeutics and antibiotic-resistant microorganisms entering the human food chain (Kromker and Leimbach 2017). These are important drivers to identify and use alternatives to antibiotics to prevent and treat mastitis in food-producing species. Organic farming and economics can also be an important driver in the regional use of nutraceuticals to prevent and treat mastitis (Mushtaq et al. 2018). There is considerable debate on the bacteria that constitute the normal flora of the mammary gland of ruminants (Rainard 2017). Bacteria isolated from the mammary gland demonstrate in vitro antibacterial activity against mastitic pathogens (Al-Qumber and Tagg 2006). A recent review of the literature on qualitative analysis of treatments for infectious mastitis other than antimicrobials concluded that alternative treatments are essentially ineffective (Francoz et al. 2017). Government regulations for organic farming vary between government jurisdictions. In the USA, a dairy animal producing milk certified as organic that receives an antibiotic treatment is banned for life as a producer of organic milk. Recommending a balanced diet using the least cost ingredients to maximize production has been the hallmark of nutritional recommendations. The use of antioxidants in the peripartum period is gaining attention in the prevention of mastitis linked with oxidative stress (Abuelo et al. 2015). The role of diet in preventing mastitis and other diseases in dairy animals is gaining more attention especially in organic farming. Organic farms have been reported to have a lower occurrence of mastitis, and the credit is given to proactive management, reduced animal stressors, better focus on mammary gland health, and feeding more forages (Hamilton et al. 2006; Ruegg 2009). Compliance with organic farming standards results in better udder health (Honorato et al. 2014).

2 Alternative Therapies

Herbal remedies have been practiced in veterinary and human medicine for more than 60,000 years (Boothe 2004). Classical plant source therapeutics include salicylates, cardiac glycosides, quinine, opium, and morphine. Alternative therapies include phytotherapy (herbalism, herbal medicine), acupuncture, homeopathy and ethnic medicine (Table 1) (Hektoen 2004; Mushtaq et al. 2018). Holistic medicine emphasizes the ability of the body to heal itself and the influence of the external environment and diet on both the cause of disease (health protection) and its important role in healing (restoration). Holistic medicine seeks a natural therapy with minimal unwanted side effects. Veterinary homeopathy is commonly used on farms producing animal-sourced organic products (Loken 2001). Herbal remedies contain a mixture of phytochemicals, and it is generally assumed this cocktail of chemicals target multiple receptors and have complex interactions important for healing processes (Spinella 2002). The current concept in pharmacology is based on specific target receptors and minimizing the number of drugs used to simply pharmacodynamics. This is contrasted to herbal medicines that have multiple lignans that target multiple receptors, a phyto-shotgun approach to impacting multiple targets (Spelman et al. 2006).

2.1 Antimicrobial Activity of Plant Extracts

Ethyl acetate extract of powered *Terminalia chebula* Retz. fruit was tested in vitro as an antimicrobial against mastitic pathogens isolated from dairy cows (Kher et al. 2018). At 500 μg/mL, the *T. chebula* extract was as efficacious as amoxicillin. Extracts of *T. chebula* are also used as an ethnic drug for urinary infections. Plants, growing in the northeast

Table 1 Examples of ethnic phytoremedies for mastitis

Condition (species)	Scientific name	Plant parts	Route of administration	Reference
Mastitis	*Gloriosa superba* L.	Crushed root tea	Oral	Upadhyay et al. (2011)
(Bovine)	*Vitex negundo* Linn.	Root juice	Oral	
(Ruminants)	*Achillea millefolium* L.; *Arctium* spp.; *Salix* spp.	Tea[a] made from aerial parts, burdock root, and willow bark with honey and salt added	Cotton cloth is dipped in warm infusion and put on udder	Lans et al. (2007)
	Teucrium scorodonia L.	Tincture	Infused into udder	
	Galium aparine L.	Infusion (steeping) made from 15 mL of cleavers in 80 mL of water	Oral	
(Bovine, ovine)	*Avena sativa* L.	Germinated *caryopses*	Poultice	Uncini Manganelli et al. (2001)
(Bovine)	*Sambucus nigra* L.	Udders—used as a topical fumigate	Topical	
(Bovine, ovine, porcine)	*Malus sylvestris* L.	May be mixed with other seeds and decoctions	Oral	
Bovine, ovine)	*Vitis vinifera* L.	Fruit, shoots mixed with vinegar	Topical	
(Bovine)	*Foeniculum vulgare* Miller.	Fruits added to hay, decoction of flowers cooked in wine	Oral	
(Bovine, ovine)	*Salix alba*	Added to decoctions of other plants	Oral	
(Ovine)	*Urtica dioica* L.	Added to udder sling	Topical	
(Bovine)	*Allium cepa* L.	200 g crushed with 2–4 flower buds of *Syzygium aromaticum* L. and oil of Brassica napus L.	Oral	Kumar and Bharati (2013)
Mastitis (Ruminants)	*Bunium persicum* Boiss.	Seeds (80 g)	Oral. Ground and mixed with wheat flour	Amber et al. (2018)
	Oryza sativa L.	Seeds (1–2 g)	Oral. Decoction (1–2 glasses)	
	Triticum aestivum L.	Fruit and seeds (500 g)	Oral. Ground and mixed with fodder	
	Allium sativum L.	Bulbs (100 g)	Oral. Ground and mixed with butter	
Prophylactic (Bovine)	*Buxus sempervirens* L.	Leaves	Used as bedding	Uncini Manganelli et al. (2001)
Galactagogue (Bovine)	*Ficus carica* L.	Leaves added to forage	Oral	

[a]0.33 cup (about 80 mL) of each herb; about 700 mL of water used

region of Pakistan and used in ethnoveterinary practices to treat clinical mastitis in cattle and buffalo, were tested in vitro for antimicrobial activity against mastitic pathogens (Amber et al. 2018). The plants studied were *Allium sativum* L., *Bunium persicum* Boiss., *Oryza sativa* L., and *Triticum aestivum* L. (Table 1). The crude extract, alkaloids, flavonoids, and saponins were dissolved in dimethyl sulfoxide and standardized at 50 mg/mL and used for determining antibacterial activity. Dilutions were used to determine the minimum inhibitory concentration. Multidrug-resistant strains of *Escherichia coli*, *Klebsiella pneumoniae*, and *Staphylococcus aureus* were used as test bacteria. The alkaloids of *Allium sativum* had the largest bacteria inhibiting zones (*K. pneumoniae* strains and *S. aureus*) when compared to crude extract, flavonoids, and saponins. The alkaloids and crude extract of *Bunium persicum* showed significantly higher inhibitory activity. The alkaloids from *Allium sativum* and *Bunium persicum* had antimicrobial inhibitions similar to sensitive antibiotics. For the alkaloids, flavonoids, and saponins from *Allium sativum*, the minimum inhibitory concentration range for all multidrug-resistant bacteria studies was 25–50 mg/mL. For *Bunium persicum* this range was 12.5–50 mg/mL, and for *Oryza sativa* and *Triticum aestivum*, the range was 25–50 mg/mL. In the plants studied, alkaloids were in the highest concentration followed by flavonoids, and the lowest level was saponins. The in vitro anti-algal activities against mastitic strains were done on the essential oils from *Thymus vulgaris* L., *Origanum vulgare* L., *Origanum majorana* L., *Mentha* x *piperita* L. (hybrid), and *Allium ursinum* L. against *Prototheca zopfii*. (Grzesiak et al. 2018a).

Marjoram oil from *Origanum majorana* had the highest antialgal activity followed by oregano oil (*Origanum vulgare*). Oregano essential oil contains carvacrol, thymol, and monoterpene hydrocarbons and has antibacterial activity. A proprietary intramammary product[1] containing 0.9 mL of oregano oil in 9.1 mL of a diluent was compared to an intramammary product[2] containing 10 g gentamycin and saline control for the treatment of clinical mastitis (Cho et al. 2015). Treatment was twice a day for 3 days, and oregano was given in single and double doses to two different groups. Study enrollment criteria were clinical mastitis that had not responded in 1 week to previous therapy, milk SCC >200,000 cells/mL, and detection of *S. aureus* and/or *E. coli* in milk. Treatment with gentamycin and oregano decreased clinical signs of mastitis and milk SCC, and *S. aureus* and/or *E. coli* were not detected in milk. In the quarters[3] receiving saline, clinical and laboratory signs of mastitis increased. The pharmacokinetics of carvacrol, thymol, and diallyl disulfide has been studied in dairy cattle (Mason et al. 2017). The approximate plasma half-life ($t_{½}$) of thymol is 1.6 h and carvacrol is 1.5 h, and no levels of diallyl disulfide could be measured in plasma. The tissue $t_{½}$ of thymol was 13.9–31.5 h and 16.9–25 h for carvacrol with the slowest depletion being for liver. Topical and intramammary administration resulted in measurable levels in plasma, kidney, and liver up to 72 h. The efficacy of *Linum usitatissimum* (flax or linseed) oil was studied in vitro and in vivo against mastitic organisms (Kaithwas et al. 2011). The linseed oil was extracted from macerated flax seeds using petroleum ether and had a specific gravity of 0.952 g/mL, 5.5% palmitic acid, 4.7% stearic acid, 19.1% oleic acid, 13.7% linoleic acid, and 57.4% linolenic acid. The antimicrobial activity of linseed oil against *S. aureus* and *Streptococcus agalactiae* was comparable to cefoperazone and exceeded cefoperazone against *Candida albicans*. Cattle selected for intramammary infusions of linseed oil had localized clinical signs of mastitis plus positive milk SCC. Treatment groups were linseed oil infusion, linseed oil infusion plus a proprietary cefoperazone[4] intramammary formulation, or a proprietary cefoperazone intramammary formulation. All treatments were given for 7 days. Milk SCC were not increased by treatments, and the SCC were reduced on study day 7 with the SCC being lower in the milk from cows treated with cefoperazone. Total microbial counts were reduced 87.7% by linseed oil treatment and 93% by linseed oil plus cefoperazone and cefoperazone alone.

2.2 Traditional Chinese Medicine

The treatment of mastitis, in traditional Chinese medicine, is focused on increasing blood flow, reduction of heat, removal of toxic material, and relief of tumefaction and pain (Lu et al. 2008). The formulas used in traditional Chinese prescriptions for dairy cow mastitis generally include ingredients that increase blood flow. To investigate herbal drugs, hemorheology was studied in rabbits using the high molecular weight dextran model. Decoctions were made from giant knotweed rhizome (*Rhizoma Polygoni Cuspidati*), safflower (*Flos Carthami*), red sage root (*Radix Salviae Miltiorrhizae*), and chuanxiong rhizome (*Rhizoma Chuanxiong*). These herbal materials were purchased from a commercial company[5] and are widely used in China to cure "blood stasis." The rabbits in each group were orally administered 1.0 mL of the assigned decoction/kg body weight once a day for 7 days. Red sage root was the most potent in reducing dextran-induced blood stasis in the rabbit high molecular weight dextran-induced blood stasis model and is considered first choice in a recipe for bovine mastitis. *Atractylodis macrocephalae* Koidz. (white atractylodes) has a history of its rhizome being used in traditional Chinese medicine. It has phenolics with antioxidant properties and polysaccharides with immune-stimulating activities (Li et al. 2012; Xu et al. 2015). The concentrated and purified atractylodes polysaccharides were studied as an immune stimulant in dairy cows with an infectious mastitis or cows with SCC >500,000 cells/mL (Xu et al. 2015). Briefly, the purified polysaccharide (89.63%) (RAMP) was suspended in rapeseed oil containing sorbitan monooleate (Span[6] 80) and polyethylene glycol sorbitan monooleate (Tween[7]-80), and the final product contained 8% Tween-80 and 12, 24, and 36 mg of RAMP/mL. The irritancy of the final product was tested in one cow that had a somatic cell count <500,000 cells/mL and negative milk cultures. The mammary lymph node of this cow was injected with 36 mg of RAMP. No clinical signs or laboratory evidence of inflammation was observed. Cows selected for Experiment 1 had milk SCC >500,000 cell/mL, and cows in Experiment 2 had at least one mammary quarter that was positive for mastitic bacteria and milk SCC >500,000 cell/mL. All cows in Experiments 1 and 2 received injections of 0, 12, 24, or 36 mg of RAMP in the area of the supramammary lymph node. For Experiment 1, 3 weeks after treatment, there were temporal declines in milk SCC and milk N-acetyl-β-D-glucosaminidase, but there were no significant differences between treatment and control groups. In Experiment 2, the 32 mg RAMP/mL group, there were significant decreases in milk SCC and milk N-acetyl-β-D-

[5] Dahua Traditional Chinese Medicine Company (Nanjing, Jiangsu Province)

[6] Sigma-Aldrich

[7] Sigma-Aldrich

glucosaminidase. Composite milk sample, when compared to the control group, had significant reduction in milk SCC. There was significant reduction in bacterial infections in the majority of the infected mammary quarters. The isolated bacteria were *S. aureus*, *Streptococcus agalactiae*, *Streptococcus dysgalactiae*, *Streptococcus uberis*, coagulase-negative (-) staphylococci, and other unidentified bacteria. The chemistry of RAMP is rhamnose, arabinose, xylose, mannose, glucose, and galactose with molar ratios of 1.00:2.49:2.07:4.94:11.33:1.35. Berberine is used in traditional Chinese medicine and is reported to have both antibacterial and anti-inflammatory activities. Berberine hydrochloride (berberine) is an isoquinoline-type quandary ammonia alkaloid. It is isolated from Berberidaceae (barberry), Rutaceae (citrus), and Ranunculaceae families. The anti-inflammatory activity of berberine[8] has been studied in a mouse mastitis model (Wang et al. 2018). Briefly, 50 μL of *E. coli* lipopolysaccharide (LPS) solution (0.2 mg LPS/mL) was injected into the milk ducts of lactating mice using the two largest mammary glands of the five ventral pairs. Treatment groups were control (LPS only); three groups receiving intraperitoneal injections of LPS plus 5, 10, and 20 mg berberine/kg body weight, respectively; and a group receiving LPS plus 5 mg dexamethasone (intraperitoneally)/kg body weight. The berberine and dexamethasone were injected 1 h before LPS and 12 h after LPS administration. The effects of berberine were significant for decreasing neutrophil infiltration and decreasing the mRNA expressions and secretion of tissue necrosis factor (TNF)-α, IL-1β, and IL-6 in a dose-dependent manner. Treatment with berberine suppressed LPS-linked toll-like receptor 4 (TLR4) and NF-κB p65 activation and the phosphorylation of I-κB. The histopathology of LPS infusion was inflammatory exudates and cellular exfoliation, and these were decreased by berberine and dexamethasone treatments.

2.3 Treatment with Essential Oils

Sage (*Salvia officinalis*) essential oils were evaluated in sheep as treatment by infusion for chronic mastitis (Alekish et al. 2017). The minimum inhibitory concentration of sage essential oil to *S. aureus* was 120 mg/mL, and the minimum bactericidal concentration was 6.1 mg/mL. The milk SCC were decreased at 24 and 48 h. Oregano oil from *Origanum vulgare* L. was evaluated as a treatment for bovine mastitis associated with *E. coli* and *S. aureus* being shed in milk (Byung-Wook et al. 2015). Clinical mastitis in this study was defined as milk SCC >200,000 cells/mL and *E. coli* or *S. aureus* being shed in milk. Treatments were controls, which received intramammary infusions of either sterile saline, antibiotic treatment with 10 g of gentamycin[9] or a commercial preparation of oregano oil[10] given at single or double dose; all treatments were administered twice a day for 3 days. Treatment with saline and oregano oil resulted in swelling of some quarters. Milk SCC were decreased in the quarters treated with gentamycin and oregano oil. In the gentamycin and oil of oregano groups, *E. coli* or *S. aureus* were not detected in milk at cessation of treatment (study day 4). Treatment with gentamycin and oil of oregano also decreased the white blood cell numbers in blood. Other essential oils have been evaluated in vitro for their antibacterial activities against mastitic pathogens (Ananda Baskaran et al. 2009). The compounds[11] studied were carvacrol and thymol from oregano oil, eugenol from oil of clove, and *trans*-cinnamaldehyde from cinnamon bark extract. Test organisms were *Streptococcus agalactiae*, *Streptococcus dysgalactiae*, *Streptococcus uberis*, *S. aureus*, and *E. coli*. Of these, *trans*-cinnamaldehyde was the most effective in killing bacteria, and its killing activity persisted for 14 days. Carvacrol, thymol, and eugenol also were effective in killing the five pathogens but less effective than *trans*-cinnamaldehyde. A proprietary herbal gel[12] was studied as a treatment for subclinical mastitis (Bhatt et al. 2014). Ten grams of the herbal gel contained 200 mg *Eucalyptus globulus*, 200 mg *Glycyrrhiza glabra*, 40 mg *Curcuma longa*, 1.0 g *Cedrus deodara*, 40 mg *Paederia foetida*, and 1 g sulfur. The herbal gel was applied to the udder after the morning and evening milking for 5 days. Parameters studied were cytokine and milk SCC and bacteria colony-forming units in milk. The transcriptional activity of cytokines in milk (IL-6, IL-8, IL-12, GM-CSF, IFN-γ, and TNF-α) was significantly increased on study day 5 and significantly reduced on study day 21. The shedding of bacteria in milk significantly decreased on study days 5 and 21, but there were no reductions in milk SCC.

2.4 Honey

Honey, a plant source food-store made by honey bees, is one of the oldest reported traditional medicines (Mandal and Mandal 2011). The antibacterial activity of honey is variable and is linked to its floral species makeup (Stagos et al. 2018). Honey is a nutraceutical prepared by bees from selected sugar-containing plant material. The honey bee (*Apis mellifera*) is the predominate producer of honey used in traditional and allopathic medicine. However, honey made

[12] Mastilep, Dabur Ayurvet Ltd. (Ghaziabad, India)

by other bees is also used and is credited for substances not found in honey made by *Apis mellifera* (Cortopassi-Laurino et al. 2006). A branch of alternative medicine known as apitherapy is focused on the use of honey as a remedy. The chemistry of honey is in part determined by the plant source of the nectar. For example, honey from *Leptospermum scoparium* (manuka honey) has demonstrated antibacterial activity against Gram-positive, Gram-negative, aerobic, and anaerobic bacteria. Unresponsive wounds and infections have rekindled an interest in the use of honey as a therapeutic. The antibacterial activity of Egyptian honey and essential oils from black cumin and onion was studied in mastitic pathogens isolated from sheep and goats (Abdalhamed et al. 2018). The authors concluded that Egyptian honey and essential oils from onion and black cumin have a strong antibacterial activity against mastitic bacteria isolated from sheep and goats. The essential oils had more antibacterial activity against Gram-positive and Gram-negative bacteria when compared to honey. The honey from non-stinging bees in Australia has antibacterial activity against Gram-positive and Gram-negative bacteria and is used in traditional medicine (Boorn et al. 2010). The pH is 3.85, 25% water, and reducing sugar activity of 54.2/100 g. The plant source of honey precursors is important in its antibacterial activity (Almasaudi et al. 2017). The antibacterial activities of honey from manuka, *Nigella sativa* L., and Sidr (*Ziziphus spina-christi* L.) flowers against *S. aureus* were studied in vitro. Honey from the manuka flower showed a bactericidal effect on both methicillin-resistant and methicillin-sensitive *S. aureus*. Honey from the Sidr and *N. sativa* flowers had a bacteriostatic effect. The antibacterial activity of honey is credited to the hydrogen peroxide, polyphenolic content, and undefined proteinaceous compounds.

2.5 Ginseng Root

Ginseng root from *Panax ginseng* Meyer. has been used as a phytopharmaceutical in traditional Oriental traditional medicine for over 2000 years. It is considered one of the most valuable herbs in Korea, Japan, and China. Ginseng is known to contain polyacetylene, ginsenoside, acid polysaccharide, insulin-like acid peptide, and anti-oxidative aromatic compound (Choi 2008). The biological response modification of ginseng Rg_1 extract was studied in a mouse model of induced *S. aureus* mastitis (Silvestrini et al. 2017). The extract was 27% Rg_1 ginsenoside[13] and did not contain endotoxins (<0.05 ng/mL limit of detection). Irritation tests were done to determine the tolerance of intramammary Rg_1 by infusing 100 μL of 3 mg/mL, 10 mg/mL, or 50 mg/mL of Rg_1 into the teat ducts of lactating mice. There was no observable macroscopic pathology, but there was histopathology. For the mammary glands receiving infusions of 3 and 10 mg Rg_1/mL, some neutrophilic and mononuclear exudates were observed in the interlobular stroma and in the lumen of the alveoli at 6, 24, 48, and 72 h post-infusion. The infusion of the 50 mg RG1/mL solution caused, at 24 h, a moderate exudate of neutrophils, macrophages, and lymphocytes. At 48 h, there were neutrophils, eosinophils, and mast cells surrounding the alveoli and milk ducts. Seventy-two hours later there were massive numbers of neutrophils, eosinophils, and mast cells in the interstitium and in the lumen of milk ducts and alveoli. Mice in Group 1 receive milk duct infusions of 100 μL sterile saline followed 72 h later with 100 μL intraductal inoculation of 10^6 colony-forming units of *S. aureus* solution. Mice in Group 2 received 100 μL of 50 mg GR1/mL followed 72 h later with an intraductal infusion of 100 μL *S. aureus* solution. Mice in Group 3 received an intraductal infusion of 100 μL *S. aureus* solution. The pretreatment with Rg_1 significantly increased clearance of *S. aureus*. Rg_1 infusion significantly increased mammary gland expression of mRNA expression for IL-1α, TNF-α, TLR2, and TLR4 and the secretion of NF-κB-p65. This study demonstrated the potential for ginseng extract to act as a biological response modifier by increasing the immune response to *S. aureus* infection in the mammary gland. A efficacy study was done on Rg_1 in dairy cows for eliminating subclinical *S. aureus* mastitis (Hu et al. 2001). Cows with clinical mastitis were injected subcutaneously with 8 mg of Rg_1 for 6 days. Control cows received injections of sterile saline. Treatment with Rg_1 tended to decrease SCC/mL of milk and the numbers of *S. aureus*-infected quarters. The in vitro phagocytosis and oxidative burst were significantly increased 1 week after RG1 treatment regimen. Another study on ginseng extract in dairy cattle in late lactation showed that the ginseng (Indena SPA[14])-induced inflammatory reactions would likely favor removal of organisms causing chronic mastitis (Baravalle et al. 2011). The 23.9% ginseng extract consisted of protopanaxatriol ginsenosides Rg_1, R_f, and R_e, calculated as Rg_1, and protopanaxadiol ginsenosides R_c, R_d, Rb_2, and Rb_1 calculated as Rb_1. The final solution contained 3 mg ginseng extract/mL in 0.89% saline. The experimental unit was a mammary quarter, which was grouped as control (no injections), saline injection, and 10 mL of the 3 mg ginseng extract/mL. There was cessation of milking following the intramammary infusions. Milk was collected at 24, 48, and 72 h following treatment, and the cows were slaughtered 7 days after treatment and mammary tissues examined by histopathology, histochemistry, and Western blot procedure. At 24 h, moderate swelling was observed in the ginseng extract-treated quarters. The

[13] Indena®, SpA (Milan, Italy)

[14] Indena SpA (Milan, Italy)

mammary gland pro-inflammatory TNF-α was significantly increased in quarters receiving the ginseng extract treatment as was the number of monocytes/macrophages (determined with CD14 antibody). A follow-up study on ginseng extract (Indena SPA®) provided insights into the mechanisms of actions (Baravalle et al. 2015). Cows with laboratory and clinical signs of mastitis at the termination of milking were used on the study. The experimental unit was a mammary gland quarter. Quarters were infused with 10 mL of a 3 mg ginseng extract/mL extract, saline, or no treatment. Cows were not milked after infusion. This study showed that ginseng extract stimulates the expression of TRL2 and TRL4 in mammary tissue.

2.6 Candidate and Proprietary Herbal Remedies

Tinospora cordifolia has traditional history as a phytoremedy in human and veterinary medicine and has antibacterial, immunomodulatory, and antioxidant effects. Hydromethanolic (50:50) extract of *Tinospora cordifolia* Wild. was studied as a remedy in mastitic cows (Mukherjee et al. 2010). Cows in groups 1 and 2 did not have laboratory or clinical evidence of mastitis, and cows in groups 3 and 4 had had evidence of clinical mastitis and were shedding pathogenic bacteria in their milk. For groups 2 and 3, a solution of 100 mg of powdered *Tinospora cordifolia* extract diluted to 7.5 mL in sterile phosphate buffer was administered intramammary for 5 days, and group 4 was administered phosphate buffer without *T. cordifolia* extract. Infusion of the extract initially increased milk SCC, and then milk SCC were significantly reduced on study day 15. The total bacterial counts in milk were reduced on study day 3. Infusion of *T. cordifolia* extract increased the phagocytic activity of polymorphonuclear cells and increased their lysosomal enzymes in milk. In cows treated with *T. cordifolia* extract, the level of interleukin-8 increased. This study shows that the hydromethanolic extract of *T. cordifolia* is a candidate phytopharmaceutical for the treatment of bovine mastitis.

A proprietary product (Phyto-Mast[15]) containing extracts of *Angelica sinensis*, *Gaultheria procumbens*, *Thymus vulgaris*, *Glycyrrhiza uralensis*, vitamin E, extracted thymol, methyl salicylate, glycyrrhizin, and α-pinene was evaluated as a treatment for bovine mastitis (Pinedo et al. 2013). In Colorado (USA), from February to September, dairy cows on one organic farm with clinical mastitis were enrolled in the study, and cows with systemic signs (hyperpyrexia) were excluded. Mastitis was scored on a 1–3 scale with number 3 being the most severe. Treatment cows, after milking and striping, received 15 mL intramammary infusion of the proprietary product every 12 h for 3 days. Control cows were milked and stripped and did not receive any infusion. Milk samples for microbiology were taken before treatment and on study days 14 and 48. There were no significant differences between groups for parity, days in milk, and mastitis severity scores occurring before treatment. Pathogens identified in milk were 10.3% *S. aureus*, 20.1% *E. coli*, and 40.3% coagulase (-) streptococci, and there were no differences between groups for pretreatment occurrences of *S. aureus* and *E. coli*. Two cows in each group were removed from the study because of systemic signs of mastitis. There were no differences between groups for bacteriological cures and clinical cures. There was a significant effect in the treated group for reduced milk SCC after clinical mastitis. A pharmacokinetic study on this phytoceutical (Phyto-Mast) in lactating goats (alpine genetics) showed thymol was absorbed systemically following one 5 mL intramammary treatment (McPhee et al. 2011). After intramammary treatment, thymol was detected in plasma at 15 min and in milk 12 h later and was not detected in plasma 4 h later. Methyl salicylate was not detected in milk. Phytopharmaceutical mastic products were tested for their antibacterial actions in milk (Mullen et al. 2017). These products were intramammary Phyto-Mast, topical Uddersol,[16] and intravulvar Dr. Paul's CEG tincture.[17] Methods used were the Delvotest®-P[18] and Charm® SL Beta-lactam.[19] None of these phytopharmaceuticals gave a positive test in milk at concentrations expected to occur in raw milk.

3 Dry Cow Treatments

Dry cow therapy is treating dairy animals with medications and teat sealers at the end of lactation (drying off). Mullen et al. (2014) reported a multi-year study, comparing proprietary antibiotic dry cow treatment to dry cow treatments with proprietary herbal products. The first treatment group was intramammary antibiotic (penicillin–dihydrostreptomycin[20]) and a bismuth subnitrate[21]-based teat canal sealant. A second group was treated with a proprietary phytopharmaceutical (Phyto-Mast), the third group received Phyto-Mast and a phyto-based teat canal sealant (Cinnatube),[22] and the fourth group did not receive any treatment. Antibiotic treatment was limited to the experimental farm because of the inclusion of organic dairy farms. The production data was standardized to 305-day mature equivalent lactation. Indicators of effect were change in milk somatic cell score from dry-off sample to freshening for cow and quarter data, changes in milk microbiology from dry-off to subsequent

[22] New AgriTech Enterprises (Locke, NY)

lactation and cull rate. Comparing the pre- and posttreatment lactations, no significant differences were observed in milk production, milk SCC, and cure rates (19% infected quarters at dry off). The rate of new infections was not significantly different except the Cinnatube significantly decrease reinfections (15 ± 7%) compared to controls (35 ± 11%). Overall, the herbal dry cow treatments were similar to antibiotic therapy, and no side effects were observed with the herbal products. Active ingredients in Cinnatube are olive oil, tea tree oil, beeswax, calendula oil, and eucalyptus oil.[23] A proprietary teat sealer (intra-teat canal) was compared to homeopathic drying off treatments (per oral) for preventing a recurrence of mastitis (Klocke et al. 2010). Eight homeopathic remedies were selected as a best fit from the Veterinary Materia Medica.[24] The homeopathic remedies represented were mercurius solubilis, lachesis mutus, sulfur, calcium carbonicum, calcium phosphoricum, *Pulsatilla pratensis*, sepia, and silica. The homeopathic remedies were given orally over the last 5 days of lactation. Treatment groups were untreated cows, teat sealer, and homeopathic remedies. No clinical mastitis was observed during the dry period. During the 100 days following calving, eight clinical cases of mastitis were observed, and the occurrences were not significantly different between treatment groups. The occurrences were 3% for the untreated control group, 9% for the homeopathic group, and 11% for the teat sealer group. Eighty percent of the quarters were culture negative, and there were not differences between groups.

4 Homeopathy

Homeopathy, a medical system based on like cures, is encouraged by the European Union Regulations for organic farming and is commonly used on organic dairy farms. It is estimated that in parts of Europe, 34–51% of occurrences of clinical mastitis are treated by homeopathic remedies (Keller and Sundrum 2018). Organic agriculture in Europe encourages the use of homeopathic products before the use of conventional medications. For mastitis, dairy farmers intermingle conventional veterinary therapies with homeopathy. Their choice of therapies is linked to experience, clinical efficacies, severity of the disease, costs, and a desire to use fewer synthetic chemicals in agricultural production. Studies on the efficacy of homeopathy treatments are difficult because practitioners of homeopathy vary in their choices of remedies. There are differences in research findings on the efficacy of homeopathy in the treatment of ruminant mastitis (Mathie and Clausen 2014). A randomized double-blind study in Germany found no difference between homeopathy treatments and placebo (Ebert et al. 2017). In a Norwegian study, herds using homeopathy therapies were not significantly different in milk yield, culling rates, mastitic pathogens, bulk milk SCC, and dry mammary quarters (agalactia due to disease) (Hektoen 2004). A study in Norwegian dairy cows, using a stratified semi-crossover design, found that there were no differences between homeopathic and antibiotic treatment on study days 7 and 28 (Hektoen et al. 2004). Treatment groups were placebo, homeopathic remedy, and a standardized antibiotic regimen. Comparison was done on Score 1 and Score 2 with Score 1 being tallies of acute signs of mastitis and Score 2 being tallies of chronic signs of mastitis. Observable changes in milk without other signs of intramammary inflammation were defined as mild mastitis. The presence of acute inflammation of the mammary gland without systemic clinical signs was defined as moderate mastitis, whereas severe mastitis was defined as moderate mastitis plus systemic signs of disease, e.g., elevated body temperature, etc. For all groups, Score 1 was significantly reduced by study day 7. For percent reductions in Score 1 for days 0–7, there was no significant differences between homeopathic and placebo. There was a significantly larger reduction in percentage Score 1 for cows on the antibiotic regimen. For Score 1, comparisons of the area under the curve (AUC) for the interval of days 0–28 showed the homeopathy was not significantly different from the antibiotic group and the placebo group. The AUC for the antibiotic group was significantly different from the placebo group. For all groups, Score 2 percentage was significantly reduced from day 0 to day 28. From day 0 to 28, the homeopathic group showed the largest percentage reductions in Score 2 followed by the antibiotic group and placebo group, but the groups were not significantly different from each other. The AUCs for the groups were not significantly different from each other. The homeopathy treatment had more microbiological negative outcomes. The resistance of Gram-positive organisms to antibiotics was not considered a factor in this study. A study using 180 lactating dairy cows (milk yield of 6500–10,000 kg of milk/cow/year) with clinical mastitis[25] found that antimicrobial or alternative remedies should be based on milk pathogens identified (Keller and Sundrum 2018). Cows meeting the criteria of mastitis for homeopathic treatment were repertorized individually according to Hahnemann's theory and standardized using a software repertory of mastitic remedies and choices made by a veterinary homeopath. Antibiotics were commercial mastitic products used according to label and the German guidelines for prudent veterinary use of antimicrobial pharmaceutics. Milk samples were collected before treatment and on study days 7, 14, and 28 and tested for the pathogens and the milk SCC determined. Isolated pathogens were *S. aureus*, *Streptococcus uberis*, *Streptococcus dysgalactiae*, *E. coli*, *Klebsiella* spp., *Enterococcus* species, *Serratia* spp., other coliform bacteria, *Streptococcus*

[23] http://newagritech.com/

[24] Steingassner HM (1998) Homoopathische Materia Medica fur Veterinarmediziner (Wien: Wilhelm Maudrich, Vienna)

[25] Criteria of International Dairy Federation (Brussels, Belgium)

dysgalactiae, other aesculin-positive streptococci, coagulase (-) staphylococci, *Corynebacterium bovis*, and yeasts. On day 7, cows treated with antibiotics had 81%, homeopathic remedies 43%, and controls 45%, respectively, elimination of mastitic pathogens. Similar results were observed on study day 14. On day 28, the cows treated with antibiotics had the higher bacteriological cures and the lowest nonresponsive rate. In cows with clinical mastitis and negative pretreatment milk cultures, there were no differences between treatment and control cows. Decrease in milk SCC was 39%, 34%, and 27%, respectively, for antibiotic, homeopathic, and control groups. Total cure rate did not differ between treatment methods. Cows that achieved a somatic cell count of 100,000 cells after treatment were independent of treatment strategy. There was an increase in the number of cows in the antibiotic treatment group that became nonresponsive to treatment. There was evidence that antibiotic treatment of infections caused by *E. coli* is contraindicated. For non-*E. coli* infections, antibiotics were the best treatment for udder recovery.

5 Probiotics, Bacteriocins, and Bacteriophages

5.1 Background

There is evidence that the lactating mammary gland can have its own unique microbiome. The emerging concept is that milk as it leaves the nipple is not sterile and is an important source of bacteria for "building" the gut microbiome of the neonate (Fernandez et al. 2013; Gomez-Gallego et al. 2016). Some authors view breast milk as a source of probiotics for the infant. The emerging concept for infectious mastitis in humans is that a cause can be an upset in the microbiome of the mammary gland. Factors influencing the mammary gland microbiome of lactating women include mode of delivery (vaginal vs. cesarean section), previous antimicrobial chemotherapy, stage of lactation, gestational age, body mass index, concurrent pathophysiology, the time of day the milk sample is collected, and geographic location (Gomez-Gallego et al. 2016; Kumar et al. 2016). There is evidence that the secretory mammary gland of ruminants does not have a unique microbiome (Rainard 2017). The mammary-associated microbiome of ruminants may exist at the teat orifice and in the teat canal. For example, suckling of ewes by lambs dynamically changes the microbiota of the teat duct and can transfer infectious organisms (Gougoulis et al. 2008). The multiple small milk ducts exiting at the nipple could be reservoirs for the human mammary microbiome. Studies of the microbiome associated with each species of animal are influencing medical recommendations and altering the criteria for prescribing antibiotics in the management of microbial infections.

The intramammary formation of biofilms by coagulase (-) staphylococci, *S. aureus*, *E. coli*, and *Enterococcus faecalis* is likely important in chronic and subclinical mastitis (Olson et al. 2002; Gomes and Henriques 2016; Gomes et al. 2016). There is evidence that when a biofilm is formed, there is less expression of virulence factors that excite clinically evident intramammary immune responses (Le and Otto 2015). Sessile bacteria in biofilms can be 10–1000 times less sensitivity to antibiotics that the planktonic bacteria living outside the biofilm. Bacterial gene expression of virulence can be down regulated in the biofilm versus the virulence gene expression in non-biofilm planktonic forms. This is evidence that strains of *S. aureus* isolated from animals in the same herd can produce biofilms with uniquely differing compositions (Ceotto-Vigoder et al. 2016). *Lactobacillus* spp. can inhibit the formation of biofilms by species of *Streptococcus*, and epigallocatechin gallate in green tea is effective against formation of biofilms by some organisms (Yang et al. 2012). The polysaccharide intercellular adhesin/poly-N-acetylglucosamine is important in the formation of biofilms along with proteins. Biofilms provide pathogens with a mechanism that disrupts immune defenses and decrease the susceptibility of pathogens to antibiotics. Some bacteriocins are effective against biofilms. Eighteen strains of *S. aureus* isolated from cattle were found to produce biofilms (Ceotto-Vigoder et al. 2016). Eight of these strains produced distinctive biofilms and were selected for determining their sensitivity to nisin and lysostaphin. For planktonic *S. aureus*, the minimum inhibitor concentration of nisin ranged from 15.6 to 500 μg/mL and 3.9 to 50 μg/mL for lysostaphin. Detachment of the biofilm and death of sessile cells were observed at 0.4 μg lysostaphin/mL, and 100 μg nisin/mL caused notable reduction in *S. aureus* viability. This study suggests that lysostaphin alone or in combination with nisin is candidate for control of *S. aureus* bovine mastitis. The use of plant extracts in inhibiting biofilm formation is a promising area for combination therapeutics. *S. aureus* "hides" intracellularly from the immune system, and this is considered to be one of the mechanisms for the existence of chronic infectious mastitis.

5.2 *Lactococcus lactis* and Bacteriocins

Antibiotic resistance has increased the interest in bacteriocins and bacteria producing bacteriocins. Bacteriocins are natural peptides that are ribosomally synthesized and posttranslationally modified to augment functionality (Allen et al. 2014). This group of peptides are produced by Gram-positive lactic acid bacteria (Bedard and Biron 2018). Some bacteriocins, e.g., nisin, have governmental approval for use by the food industry. Non-aureus staphylococci are heterogeneous group of approximately 50 species that are commonly isolated from aseptically collected milk samples. This is evidence that the bacteriocins produced by the resident non-aureus staphylococci protect the mammary gland from mastitic pathogens by the production of bacteriocins. The antibiotic resistance of *S. auras* isolated from dairy cows with subclinical mastitis was studied in eastern

Poland (Szweda et al. 2014). The sensitivity of *S. auras* was tested against 20 antibiotics and the bacteriocins lysostaphin and nisin. The decreasing order of antibiotic resistance was streptomycin > β-lactams > amoxicillin > ampicillin. All of the isolates resistant to amoxicillin and ampicillin were also resistant to penicillin. The minimum inhibitory concentration for lysostaphin was 0.008–0.5 μg/mL, and all the *S. auras* isolates were considered to be sensitive. For nisin, 18/39 *S. auras* isolates were considered to be above 32 μg/mL and considered to be resistant. A study in Flanders region of Belgium found that herds participating in a veterinary herd health management program had decreased overall use of antibiotics for mastitis control (Stevens et al. 2016). Selectively drying off cows and treating cows with homeopathic substances also decreased antibiotic usage. The use of critically important antibiotics (fluoroquinolones and third- and fourth-generation cephalosporins) was associated with the way subclinical mastitis was managed. Studies provide evidence that mammary gland-sourced non-aureus staphylococci genomes provide evidence that >21% of these isolates are possible producers of bacteriocins (Carson et al. 2017). *Lactococcus lactis* strain V7, a lactic acid bacterium isolated from healthy cows in Brazil, was studied in bovine mammary epithelial cell culture as pathogenicity modifiers of *S. aureus* and *E. coli* (Assis et al. 2015). V7 *L. lactis* inhibited the internalization of *S. aureus* and *E. coli* into the epithelial cells but had limited activity against the adhesion of *S. aureus* to cell surfaces. Also, it did not inhibit the adhesion of *E. coli* to epithelial cells. The V7 *L. lactis* itself induced production of CXCL8 cytokine which increased the CXCL8 response to *E. coli*. *Lactobacillus* spp. have been isolated from dairy cattle and studied as candidate probiotics for prevention and treatment of bovine mastitis (Espeche et al. 2012; Frola et al. 2012). A study on the antagonistic activity of *Lactobacillus perolens* CRL 1724 and *Lactobacillus plantarum* CRL 1716 showed that *L. perolens* CRL 1724 was superior in growth antagonizing co-aggregation of mastitic pathogens (Frola et al. 2012). CRL 1716 also had greater adhesion index to mammary epithelial cells. The teat canals of two lactating cows were infused with 10^3 and 10^6 colony-forming units of *L. perolens*. At 24 h after inoculation, no clinical signs of mastitis were observed and a twofold increase in milk SCC was observed. Since the 10^6 colony-forming units were well tolerated, nine quarters in three cows were inoculated. There was a significant increase in milk SCC at 24 h and 48 h and then returned to pre-inoculation values. At study day 15, 22% of the quarters continued to shed *L. perolens* CRL 1724. A study in a mouse mastitis model showed that *Lactobacillus lactis lactis* LMG[26] 7930 infusion into the mammary gland was unpredictable in the severity of the resulting mastitis (Camperio et al. 2017). The histopathology of intramammary inoculation of *Lactobacillus perolens* CRL 1724 was studied in dairy cattle (Frola et al. 2013). Dairy cows in late lactation (average of 14 kg of milk/day), with no clinical and laboratory evidence of mastitis, were inoculated intramammary after the evening milking with one million colony-forming units of *L. perolens* CRL 1724 in 1 mL. The unit of study was a mammary quarter with three quarters being infused and one quarter used as control. Following infusion of 1 mL of 10^6 colony-forming units of *L. perolens* CRL 1724 per quarter, there were no physical signs of mastitis or changes in the appearances of milk stripped from the udder. The milk SCC increased to 4.5×10^6 cells/mL and returned to 10^6 cells/mL in 7 days. Histopathology was increased as was neutrophilic exudate in the epithelium of the teat cistern and congestion was observed. There were colonies of Gram-positive bacteria adhered to the cistern epithelium. The immune response following the intramammary infusion of *Lactococcus lactis* DPC 3147, a food-grade organism, was studied in dairy cattle (Beecher et al. 2009). This strain of *L. lactis* also produces the lacticin 3147 bacteriocin. Following intramammary infusion, *L. lactis* was recovered in milk up to 72 h, and no *L. lactis* was recovered from the mammary quarters that were not infused with live bacteria. At 7 h post-infusion with *L. lactis*, signs of inflammation were observed including swollen mammary gland, elevated body temperature, and elevated milk SCC, and clots were observed in the milk. All infused cows continued to have signs of udder inflammation at 7 days post-infusion. A notable increase was observed in immune gene expression, and these were for interleukin (IL)-1b and IL-8, with highest expression corresponding to peaks in milk SCC. A study in dairy cattle with chronic or acute mastitis compared mammary infusions of *L. lactis* DPC3147 (food grade) to infusions of antibiotic approved for intramammary use (Klostermann et al. 2008). The antibiotic infusion[27] contained amoxicillin (200 mg), clavulanic acid (50 mg), and prednisolone (10 mg). In treatment of chronic mastitis, live cultures of *L. lactis* DPC3147 were efficacious in treating infectious mastitis (*Staphylococcus aureus*) with 7 infected quarters becoming pathogen-free compared to 5 of the 11 quarters treated with antibiotic. In the treatment of acute mastitis, 15/25 cases *L. lactis* DPC3147 and 18 of 25 cases treated with antibiotic did not show clinical signs following treatment. A concurrent study investigated the mammary gland immune response to *L. lactis* DPC3147 (Crispie et al. 2008). Compared to control mammary quarters, the quarters infused with *L. lactis* DPC3147 had a large increase in milk leukocytes. The recruitment of leukocytes in the quarters treated with antibiotic treatment (formulation contained prednisolone) was significantly less. Infusion of quarters with heat-killed *L. lactis* DPC3147 produced an immunocyte response similar to the live culture. Milk amyloid A and haptoglobin were increased by infusion of

[26] BCCM/LMG Bacteria Collection (Belgium)

[27] Synulox, Pfizer Animal Health (New York, USA)

both the live bacteria and freeze-dried bacteria with the highest response occurring with infusion of the freeze-dried cells.

Lactococcus lactis LMG 7930 was studied in vitro as a candidate probiotic for mastitis control (Armas et al. 2017). The *L. lactis* LMG 7930 strain is a known nisin producer and is used in the production of Swiss cheese. This strain was shown to be sensitive to antibiotics, have medium surface hydrophobicity, not accept electrons, have low auto-aggregation, and have no co-aggregation ability with pathogens. The strain has antagonism against many microbial pathogens isolated from the mammary glands of sheep and cattle. In the bovine mammary epithelial cell line BME-UV1d, *L. lactis* LMG 7930 was adhesive with epithelial cells and had low internalization rate. In a study on the efficacy of live cultures of *Lactococcus lactis* in Italian ewes, mammary infusions of *L. lactis* caused transient clearance of mastitic pathogens and *L. lactis* itself caused mild to moderate mastitis (Mignacca et al. 2017). Live culture was chosen because it has increased immunomodulatory activities compared to heat-killed cells and cell-free extracts. In mammary glands infected with coagulase-negative staphylococci and treated with *L. lactis*, 92% were negative for coagulase (-) staphylococci 3 days after treatment and coagulase (-) staphylococci reappeared in milk cultures after treatment was stopped (day 7). This is evidence that *L. lactis* were unable to colonize the mammary gland. The milk SCC increased with infusion of *L. lactis*. The *L. lactis* infusions were ineffective against *Staphylococcus aureus*. However, IL-1β, IL-8, and chemokine receptor *CXCR1* expression was increased on the average of 7000-fold, 4400-fold, and 2700-fold, respectively, and the increases corresponded to peaks in milk SCC.

5.2.1 Nisin

The bacteriocin nisin, produced by *L. lactis*, has been studied as a treatment for clinically evident mastitis in dairy cows (Cao et al. 2007). Milk samples were collected immediately before treatment and 1 and 2 weeks after treatment for bacteriology and milk SCC. Intramammary infusions were 2.5 million international units (IU) of nisin (nisin Z[28]) or 800 mg gentamycin.[29] The clinical cure rate was 90.2% and 91.1% for nisin and gentamycin, respectively. The *S. aureus* bacteriology cure rate at 2 weeks was 6/11 for nisin and 2/6 for gentamycin, and for *Streptococcus agalactiae* the bacteriology cure rate was (15/18) for nisin and 11/22 for gentamycin. Milk SCC at 2 weeks were not statically different between treatment groups but had an apparent trend to be higher for the nisin-treated quarters. For *S. aureus*, the resistance rate to gentamycin was 35.3% and penicillin 82.5%, and there was no observed resistance to nisin. Inhibition of milk fermentation by lactic streptococci was 36 h for nisin and 72 h for gentamycin. The irritation of nisin Z was studied in a cow that did not have clinical and laboratory evidence of mastitis (Wu et al. 2007). Three quarters were injected with 1.25 million, 2.5 million, or 5.0 million IU of nisin in 20 mL volume, and one quarter was injected with 20 mL of sterile saline. The milk SCC and N-acetyl-beta-D-glucosaminidase (NAGase, an indirect measure of milk SCC and a possible measure of epithelial damage) tended to increase with the IUs of nisin infused into the mammary gland. Five million units of nisin Z caused clinical signs of mammary inflammation. The efficacy of nisin Z (2.5 million IU) as a treatment for subclinical infectious mastitis was also studied in 90 cows. Bacteria isolated from the mammary glands were *S. aureus*, coagulase (-) staphylococci, and *Streptococcus agalactiae* at 27.8%, 31.1%, and 33.0% of the cows, respectively. Unspecified bacteria were isolated from 7.8% of the cows. The treated cows received intramammary infusions of 2.5 million IU of nisin Z/day (morning) for 3 days, and control cows were not treated. Milk SCC and NAGase were reduced with treatment. Nisin Z treatment reduced the intramammary infections by 43.5% and 65.2% at week 1 and 2, respectively. Treatment with nisin Z resulted in bacteriologically cures for *S. aureus* and *Streptococcus agalactiae* at 50% and 90.9%, respectively. Fifteen percent of the control cows had bacteriological recoveries, and no decrease was observed in milk SCC. There were 20 isolates of *S. aureus*, and the resistance to penicillin, gentamicin, cefamezin, norfloxacin, and sulfamethoxazole–trimethoprim combination was 80%, 45%, 5%, 75%, and 90%, respectively. Nisin Z was detected in milk at 75.8 ± 36.5 IU/mL and 5.7 ± 7.3 IU/ml at 24 and 48 h, respectively, after termination of therapy. The minimum inhibitory concentration of nisin Z for *S. aureus* was 75.5 ± 70.8 IU/mL. The efficacy of nisin Z[30] was studied in combination with a bacterin made from *S. aureus* strain CQ399RP (Guan et al. 2017). The criteria for chronic mastitis were $\geq 5 \times 10^5$ white blood cells/mL of milk and one quarter infected with *S. aureus*. Cows (75) meeting study criteria were randomized into treatment groups. Group 1 received an injection of bacterin into the supramammary lymph node 1 week before the start of nisin Z infusions and a booster 1 week after nisin infusions. Nisin Z (2.5 million IU) was infused into the mammary gland once a day for three consecutive days. Group 2 received the three nisin Z infusions, and Group 3 consisted of untreated control cows. For Group 1, bacteriological cures were 68.0%, 72.0%, and 72.0%, respectively, at 2, 4, and 6 weeks after treatment and 44.0%, 40.0%, and 40.0%, respectively, for Group 2. Nisin A[31] and cefazolin[32]

[31] Omu Milk Products Co., Ltd. (Fukuoka, Japan)

[32] Meiji Seika Pharma Co., Ltd. (Tokyo, Japan)

combination was studied in vitro as a possible treatment for mastitis (Kitazaki et al. 2017). Nisin A in combination with cefazolin showed synergistic interactions against *S. aureus* and *Enterococcus faecalis* and additive interactions against *Staphylococcus intermedius*, *Streptococcus agalactiae*, *Streptococcus dysgalactiae*, and *E. coli*. The organisms were isolates from cases of clinical and subclinical mastitis in the Fukuoka Prefecture of Japan, and the antimicrobial interactions were determined in a checkerboard assay.

5.3 Experience in Human Medicine

Women that have previously had mastitis are at increased risk for developing mastitis in subsequent lactations. *Lactobacillus salivarius* PS2 was studied as an orally administered probiotic in women that experienced mastitis in a previous lactation (Fernandez et al. 2016). Women in the treatment group received 9 $\log_{10}$ colony-forming units of *L. salivarius*/day from week 30 of pregnancy until delivery. The number of women that developed mastitis was significantly lower in the treatment group. Women volunteers with non-abscessed staphylococcal mastitis refractory to cloxacillin, clindamycin, clindamycin, amoxicillin/clavulanic acid, and erythromycin were selected for a double-blind study using nisin isolated from *Lactococcus lactis* ESI 515 (Fernandez et al. 2008). Criteria were pain during breastfeeding, fissures in the nipple and surrounding area, staphylococcal milk counts $>4\log_{10}$/mL, milk leukocyte counts >6 $\log_{10}$/mL, and no antibiotic treatment for the 2 previous weeks. Treatment was 2 weeks of applying ~0.1 nisin solution (6 μg/mL) to the nipple and surrounding area after each nursing episode. Treatment with nisin significantly lowered milk bacterial colony-forming units. A study was done in women using *Lactobacillus fermentum* CECT5716 and *L. salivarius* CECT5713 isolated from non-mastitic breast milk as an oral treatment for mastitis (Arroyo et al. 2010). The orally administered probiotic treatments were compared to physician prescribed antibiotic regimens. Antibiotic treatments were amoxicillin–clavulanic acid, amoxicillin, cotrimoxazole, cloxacillin, and erythromycin. Before treatment the dominant bacterial species isolated from breast milk were *S. epidermidis* (73% of the women), *S. aureus* (43%), and *S. mitis* (30%), other bacterial species (<5%), and *Lactobacilli* spp. (0%). Pain in the breasts was scored from 0 (very painful) to 10 (no pain). On day 21 of treatment, the bacterial counts in the women receiving oral *L. fermentum* CECT5716 and *L. salivarius* CECT5713 treatments were significantly lower than the women receiving antibiotic treatments. Breast pain was correlated with bacterial plate counts, and the probiotic groups were not significantly different but had significantly lower pain scores compared to antibiotic groups. *L. fermentum* CECT5716 and *L. salivarius* CECT5713 were isolated from the milk of women receiving these probiotics. Women in the probiotic groups had lower recurrences of mastitis.

6 Bacteriophages and Their Products

Bacteriophages are viruses that attack and kill bacteria (Gomes and Henriques 2016). A problem with using bacteriophages is they may not infect bacteria inside the mammary gland because of the interfering–inactivating actions of milk and other mammary secretions. Bacteriophages can be specific in attacking one species of mastitis causing *Staphylococcus*, or the bacteriophage can be polyvalent including activities against biofilms. Specific proteins isolated from bacteriophages are being tested in vivo for their antibacterial activity. Two bacteriophage proteins are expressed inside the bacteria; the holing protein creates a pore in the cell membrane allowing endolysin to pass through the pore and hydrolyze the peptidoglycan in the cell wall liberating the newly formed bacteriophages. Endolysin produced by recombinant procedures in *E. coli* was tested as a therapeutic for *S. aureus* mastitis in dairy cattle with clinical signs of mild mastitis (Fan et al. 2016). The endolysin gene sequence (trx-SA1) was isolated from a bacteriophage identified as IME-SAG1 in the Myoviridae family. Five udder quarters with *S. aureus* mastitis were treated with the Trx-SA1 recombinant endolysin by intramammary infusion. Twenty milligrams of endolysin was dissolved in physiological saline and infused once a day for 3 days. Milk SCC and shedding of pathogens decreased with remission of clinical signs. Treatment with endolysin was not effective in mammary quarters infected with *E. coli* and *Streptococcus agalactiae*.

7 Vitamin and Mineral Supplementation

Vitamin E has been studied as a nutraceutical to prevent mastitis in dairy cattle. Dairy cattle in the immediate peripartum and postpartum period is at risk for oxidative stress, ketosis, insulin resistance, and hepatic steatosis. Decreased immune functions can be associated with oxidative stress. The effects of vitamin E supplementation during the dry period (interval between lactations) were investigated in a double-blind study for its effects on reducing occurrences of clinical and subclinical mastitis (Bouwstra et al. 2010a, b). This study was in Holstein heifers and in cows producing 8000–10,000 kg of milk/year and having a mean dry period of 6 weeks. The study was controlled for housing, method of milking, season of the year, and diet. Animals in the low supplemented group received 100 g of a mineral mix/day/cow providing 135 IU of DL-α-tocopheryl-acetate/day/cow

and cows and heifers in the high group received 3000 IU of DL-α-tocopheryl-acetate/day/cow. Supplementation was started at dry off and continued until parturition (mean of 8 weeks). Blood was collected at dry off, 4 and 2 weeks before calculated parturition, and 24 h after calving. Subclinical mastitis was defined as SCC >100,000 cells/mL of milk. Cows in the group receiving 3000 IU vitamin E/day had higher occurrences of clinical and subclinical mastitis than cows receiving 135 IU vitamin E/day. Blood levels of vitamin E were increased by vitamin E supplementation as was the vitamin E/cholesterol ratio. Additionally, this study showed that blood level of vitamin E above 14.5 μmol/L is a risk factor for increased clinical mastitis. This risk was 3 times higher in the unsupplemented group and 1.5 times higher in the supplemented groups. The blood levels of heifers at the start of the study were 9.10 μmol/L. The mechanism of action can be excessive vitamin E interfering with oxidative reactions normally occurring in immune system responses. A parenterally administered proprietary product[33] was studied for its effect on reducing subclinical mastitis (Ganda et al. 2016). The study was conducted from January to April in upstate New York, USA, and enrolled 620 cows. The cows were on a total mixed ration that met or exceeded their nutrient requirements as recommended by the US National Research Council. Enrollment requirements were SCC >200,000 cells/mL milk, <150 days pregnant, and no treatment with antibiotics in the current lactation. Treated cows received 5 mL of the proprietary product administered once parenterally, and control cows received 5 mL of saline. Each mL of the test product contained 60 mg zinc, 10 mg manganese, 5 mg selenium, and 15 mg copper. A random selection of cows had blood drawn on study day 0 and again on study day 30 and the serum analyzed for calcium, magnesium, phosphorus, copper, iron, potassium, manganese molybdenum, selenium, and zinc. Body condition scores, lactation number, milk yield, days in milk, and linear scores of somatic cell numbers at enrollment were also parameters in the study, and these parameters were not significantly different. There was a 10-month follow-up period. Serum calcium and magnesium were significantly higher in the control cows, and also there was a tendency for molybdenum to also be higher in the control cows. There was no difference between groups for the other elements measured in serum. There were no significant differences between groups for cures from subclinical mastitis and milk SCC and no significant interactions between treatment and lactation on milk SCC. There was a tendency within lactation for the treatment to cure subclinical mastitis in cows with three or more lactations. There was an overall tendency for treatment to reduce chronic clinical mastitis especially in primiparous cows. Independent of treatment, cows with lower serum zinc levels at mastitis diagnosis and higher serum levels of selenium and phosphorus 30 days later had more cures. A Swedish study on vitamin E (RRR-α-tocopheryl-acetate[34]) supplementation of dairy cattle did not reduce the occurrences of mastitis (Persson Waller et al. 2007). The cows were in herds with high occurrences of mastitis and were supplemented with 1.61 g of RRR-α-tocopheryl-acetate as a top dressing for 4 weeks before calculated calving and 2 weeks after actual calving.

8 Teat Dips

The teat duct is a portal of entry for pathogens, and the first responder is the innate immune system (Mavrogianni et al. 2007). Maintaining teat health is important in preventing mammary infections. Teat dips are used to decrease bacterial numbers on the teat especially at the teat orifice. The IMAU 80065 and IMAU 10155 strains of *Lactobacillus plantarum* were studied as a teat dip for cattle (Yu et al. 2017). Cows with milk SCC >200,000 cells/mL were selected for the study. Teats were dipped after milking in a preparation of *L. plantarum* (5×10^{10} colony-forming units/mL) or a commercial[35] teat dip. Teat dipping with the probiotic lactic acid bacteria was considered efficacious in reducing mastitis-associated bacteria. The milk SCC of the cows with teats dipped in probiotic lactic acid bacteria decreased and were significantly lower than cows that had teats dipped in the commercial teat dip. A teat dip made from a recipe using 2–3 drops of liquid soap, tea tree oil, peppermint oil, lavender oil, and grape seed extract at one drop each added to 350 mL of potable water was found to be the most likely source of *Pseudomonas aeruginosa* causing mastitis in dairy goats (Kelly and Wilson 2016). The teat dip itself also supported the growth of *P. aeruginosa*. *Prototheca* microalgae can be a cause of mastitis and is difficult to treat because of its resistance to antimicrobial chemotherapeutics. A proprietary[36] vegetable rinse formulation was studied for its antiseptic activity against *Prototheca zopfi* (Grzesiak et al. 2018b). The *P. zopfi* strains tested were isolated from cows with subclinical mastitis. The minimal microbicidal concentrations of were 0.002–0.019%. The ingredients in this product are decyl polyglucose, cornstarch, and coconut oil. The active ingredient is decyl polyglucose, a compound widely used in cosmetics. The finding suggests that this product has potential as a teat wash and teat dip.

9 Immunotherapy

Egg yolk immunoglobulin IgY from hens vaccinated against mastitic strains of *S. aureus* were evaluated in cows with experimentally induced and naturally infected *S. aureus* mastitis (Zhen et al. 2009). Criteria for cows with natural infections were clinical signs of mastitis, milk SCC >500,000 cells/mL and bacterial plate counts of 100–200 *S. aureus* colony-forming units/mL of milk, and no antibiotic treatment in the past 90 days. For *S. aureus*-induced mastitis, the cows before inoculation were clinically normal, milk SCC <100,000 cells/mL of milk, <10 colony-forming units of *S. aureus*/mL of milk, and no antibiotic treatment in the past 90 days. The *S. aureus* inoculation to induce mastitis was 10^7 colony-forming units/mL. Treatments were intramammary infusions of 10 mL of 20 mg of IgY/mL or 10 mL of 100 mg of penicillin/mL immediately after morning and evening milkings or no infusions. The cure rates for IgY were 83.3% for experimentally induced mastitis and 50% for clinical mastitis. Cure rate for penicillin treatment was 66.7% and 33.3%, respectively, for experimental and clinical mastitis. The treated cows were significantly different from control untreated cows for milk SCC and bacterial counts. Bovine platelet concentrate has been investigated as a therapeutic for mastitis (Lange-Consiglio et al. 2014). A healthy cow on each of three farms was used to donate platelets. The quarters of cows with mastitis were divided into three treatment groups: antibiotics, antibiotics plus platelets, and platelets without antibiotics. Cows with acute and chronic mastitis were enrolled in the study. The platelet concentrate was standardized at 10^9 platelets/mL. Cows in the groups receiving platelets received 5 mL of the platelet concentrate for 3 days. For acute mastitis, platelet concentrate group was not statistically different from the antibiotic alone group, and for chronic mastitis, platelet concentrate alone was significantly better than antibiotic alone. For both acute and chronic mastitis, antibiotic plus platelet concentrate was significantly better than antibiotic alone, and this combination also significantly reduces the rate of relapses.

10 Concluding Remarks and Future Directions

Nutraceuticals have increased use for prevention and treatment of mastitis. Medical reasons include increased antimicrobial resistance to approved antimicrobial chemotherapeutics, public health concerns regarding human exposure to antibiotic-resistant microorganisms in animal-source foods, restrictions on antibiotic use in organic farming, and increase interest in the use of alternative medicine. The interactions between the immune system and nutrition and body antioxidant status as it pertains to health of the mammary gland are important in prevention of mastitis. Advances in metabolomics will likely provide strategic profiles for mammary gland health. Increased understanding of the microbiome and the interactions of microbial populations in maintaining mammary health and immune modulation will increase.

Nutraceuticals in Immune Disorders

Moges Woldemeskel

Abstract

Immune disorders in animals and humans may occur due to derangements in the body immune system in responses to various substances such as allergens, infections, chronic immune deficiency diseases, autoimmune diseases, and disruption in the immune system due to various other conditions. Modem medicine has been in use for long to treat different types of immune disorders. Many of these in fact have unintended side effects, although may be effective in treating diseases or alleviating the associated symptoms. Nutraceuticals are in use in traditional medicine throughout the world for centuries despite emergence of modem medicine. Nowadays, there is an increased tendency to look into nutraceuticals for the treatment of various diseases and conditions in humans and animals due to their efficacy in treating diseases and the fact that they cause no unintended side effects. This chapter briefly highlights on the use of nutraceuticals in immune disorders.

Keywords

Nutraceuticals · Immune disorders · Veterinary medicine

1 Introduction

The term "nutraceutical" was coined in 1989 by Stephen DeFelice and combines two words: "nutrient" and "pharmaceutical" (Kalra 2003). Nutraceutical is a broad term used to describe any product derived from food sources that provide health benefits including prevention and treatment of disease beyond its intrinsic nutritional value (Kalra 2003; Larussa et al. 2017). It was proposed that nutraceuticals can be grouped into three broad categories: (1) substances with established nutritional functions, such as vitamins, minerals, amino acids, and fatty acids, also defined as nutrients; (2) herbs or botanical products as concentrates and extracts, often called herbals; and (3) reagents such as pyruvate, chondroitin sulfate, and steroid hormone precursors that are derived from other sources and serve specific functions, such as sports nutrition, weight-loss supplements, and meal replacements, also indicated as dietary supplements (Chauhan et al. 2013). Medicinal plants constitute a natural reservoir for medicines worldwide and are part and parcel of nutraceuticals. They serve mainstream therapeutics and are central in folklore medicine (Akhtar et al. 2017).

Natural plant products have been used as the foundation of several medical treatments. Although modern western medicine has become the forefront of clinical practice today, natural plant products continue to be used as remedies in alternative medicine throughout the world. It is estimated that 80% of individuals in developing countries depend primarily on natural products to meet their healthcare needs. In the United States, it has been found that around one in three Americans uses natural medicinal products daily. Natural products are not only effective but are relatively nontoxic and have therapeutic doses well below their toxic levels (Fadus et al. 2017). In general, nutraceuticals are natural bioactive compounds or foodstuff that provide extra health benefits in addition to basic nutritional values. Nutraceuticals often refer to active ingredients found in functional foods and involve extracting, purifying, concentrating, and assaying such ingredients (Alkhatib et al. 2017). Various nutraceuticals have been in use for centuries to heal ailments in humans and animals as part of traditional medicine. This chapter gives a brief account of the use of nutraceuticals in diseases and condition with an underlying immune disorders or dysfunction, including degenerative and metabolic diseases, and diseases associated with hypersensitive or overactive immune system.

2 Nutraceuticals in Regulation of Immune System

Immune system comprises of various cells, proteins, molecules, tissues, and organs that protect the body from harmful agents. Appropriate nutrients are necessary for the varied cells of the immune system to function optimally and respond to injury and invading viruses and bacteria. Dietary extremes, especially protein-energy malnutrition, have profound effects in decreasing immune function and increasing risk of opportunistic infections (Nieman and Mitmesser 2017). It was indicated in the 2016 Global Nutrition Report that one in three people worldwide is malnourished in one form or another (Global Nutritional Report 2016, 3).

Nutritional deficiencies have a negative effect in body defense against various infections by lowering the immune system. For example, Tsuji et al. (2015) citing various reports on animal models indicated that selenium (Se) deficiency impairs immune response to infection, cancer, and other stimuli, indicating the importance of the role of selenium in immune response. Examples include a reduction in CD4+ T-cell response in selenium-deficient mice challenged with a peptide/adjuvant, increased tumor growth and spread in a mouse model of breast cancer, enhanced type I allergic response in a mouse model of active cutaneous anaphylaxis, and increased immunotoxicity resulting from arsenic exposure (Tsuji et al. 2015).

More recently, natural substances mainly food supplements derived from plants that have been fed to farm animals evoked attention as a substitute to antibiotic growth promoters (Zhang et al. 2017). They are found to be beneficial in improving growth performance, digestive function, and the absorption of nutrients. They are also helpful in improving the ability to fight against infection and reducing the incidence of diarrhea. Recent studies have demonstrated that isoquinoline alkaloids can regulate metabolic processes, innate immune system**,** and digestive functioning in animals. Supplementation with isoquinoline alkaloids from *Macleaya cordata* extract increases feed intake and weight gain. It was found that ingestion of extract of *Macleaya cordata* increases the expression of ZO-1 and claudin-1 and hence helps in preventing substances with allergenic properties and toxigenic substances entering the intestines (Montagne et al. 2007). This indicates and supports the understanding that the use of extract of *Macleaya cordata* as a feed additive can promote intestinal mucosal growth and improve defense systems (Liu et al. 2016). It was also demonstrated that dietary supplementation with alkaloids reduced the level of serum amyloid A (SAA), a group of apolipoproteins produced in reaction to cytokines stimulated by monocytes or macrophages. Serum amyloid A apolipoproteins are closely associated with inherent immunity and are involved in the pathogenesis of chronic inflammatory diseases (Eklund et al. 2012). Hence, dietary supplementation with isoquinoline alkaloids extracted from *Macleaya cordata* boosts the immune system and regulates metabolic process and finally promotes growth and development. It is reported to be beneficial to swine and poultry through enhancing increase in feed consumption, body mass, and weight gain, as well as the concentration of serum amino acids. It boosts the innate immune system by regulating phagocytes, haptoglobin, and amyloid A (Ni et al. 2016).

Furthermore, in vitro studies and studies on inflammatory bowel disease-animal models have shown that nutraceuticals, such as herbal products or vitamins, are generally accepted as safer alternative or supplementation to conventional therapy. They are involved in several biological processes, including antioxidant defenses, cell proliferation, and gene expression, which could account for their role in the maintenance of the mucosal barrier integrity, the control of the inflammatory pathways, and the modulation of the immune response (Larussa et al. 2017). For example, it was demonstrated in experimental animal model that levels of interferon-γ and other cytokines were reduced in selenium-deficient mice. Additional studies in mouse knockouts have demonstrated that the selenoproteome, as well as individual selenoproteins such as Selk and Sep15, appears to play direct roles in supporting immune function. The important roles that selenoproteins play in regulating cellular oxidation states, catalyzing redox reactions with protein and chemical substrates, Ca^{2+} signaling, protein folding, and the downstream effects of these functions will likely be identified as the molecular mechanisms to explain the importance of dietary selenium in supporting the immune systems (Tsuji et al. 2015). Mushroom polysaccharides have also been demonstrated to have positive effects in the function of the immune system. Alpha (α)- and β-glucans derived from fungi and other food sources have been shown to possess effective immunostimulating activity (Zhang et al. 2017).

3 Anti-inflammatory Effects of Nutraceutical

Inflammation and inflammatory reactions underlie many human and animal diseases. Several anti-inflammatory drugs are prescribed to manage inflammatory reactions and inflammation-associated pain and diseases. However, the side effects of drugs used to treat inflammatory conditions particularly during chronic inflammatory diseases such as rheumatoid arthritis with various medications such as steroidal, nonsteroidal, and immunosuppressive drugs may be more difficult to manage than the disease itself. Safe anti-inflammatory nutraceuticals that can be used as

complementary to anti-inflammatory drugs may lead to the reduction in dose level of such drugs, thereby reducing their side effects (Al-Okbi 2014).

Various nutraceuticals are known to exert anti-inflammatory effect and help in treating and managing many diseases and conditions in humans and animals. Foods rich in antioxidants and anti-inflammatory bioactive constituents, for example, phenolic compounds, polyunsaturated fatty acids, phytosterols, tocopherols, and carotenoids, may be a good source of nutraceuticals of beneficial effect toward chronic inflammatory disease. Among many others, fish oil, primrose oil, black cumin, fenugreek, liquorice, coriander, tomato, carrot, sweet potato, broccoli, green tea, rosemary, hazelnut, walnut, wheat germ, and date extracts are examples of such sources (Al-Okbi 2014). For example, oral administration of methanol and aqueous extracts of edible portion of date fruits is reported to suppress inflammation significantly by 67.8% and 61.3%, respectively (Al-Okbi 2014). Ayurvedic herb which belongs to the family Berberidaceae is also used since ancient times as an anti-inflammatory agent for osteoporosis, joint pain, fever, eyes, and skin infections. Furthermore, topical instillation of aqueous extract of *Berberis aristata* showed potent anti-inflammatory activity against endotoxin-induced uveitis as well as against turpentine liniment-induced ocular inflammation in rabbits (Nimisha et al. 2017).

Among many other natural products, curcumin is an anti-inflammatory agent that has been used for treating medical conditions for many years (Fadus et al. 2017). Curcumin belongs to the family of natural compounds collectively called curcuminoids. It is the principal natural curcuminoid, which is a class of phenols found in the plant *Curcuma longa*, a rhizomatous herbaceous perennial flowering plant commonly used as a spice, food preservative, and a coloring agent in foods (Vecchi Brumatti et al. 2014; Larussa et al. 2017). Curcumin possesses remarkable beneficial properties as an antioxidant, anti-inflammatory, anticancer, and neuroprotective agent (Vecchi Brumatti et al. 2014). Several experimental and pharmacologic trials have demonstrated efficacy of curcumin as an anti-inflammatory agent. It has been shown to be effective in treating and managing chronic conditions such as rheumatoid arthritis, inflammatory bowel disease, Alzheimer's disease, and other common malignancies (Fadus et al. 2017).

The anti-inflammatory mechanism of action exerted by various nutraceuticals is different and depends on their nature and structure whether steroidal or nonsteroidal (Al-Okbi 2014). For example, the anti-inflammatory mechanism of curcumin works mainly through the suppression of the nuclear factor kappa-light-chain-enhancer of activated B-cell (NF-κB)-related inflammatory pathway, with subsequent inhibition of tumor necrosis factor (TNF)-α, interleukin (IL)-12 and IL-2, thus affecting the immune response modulation and representing a safe and promising agent (Vecchi Brumatti et al. 2014; Larussa et al. 2017) as is reported in the suppression of inflammation in inflammatory bowel disease (Vecchi Brumatti et al. 2014).

Polyphenols from various plants also have potent anti-inflammatory effects. They are naturally occurring compounds found largely in fruits such as grapes, apple, pear, cherries, and berries, in vegetables, cereals, and beverages (Pandey and Rizvi 2009). They are secondary plant metabolites which also have been shown to exert anti-oxidative and anti-inflammatory effects in cell culture, rodent, and human studies (Gessner et al. 2016).

Due to the fact that oxidative stress and inflammation are highly prevalent in farm animals, polyphenols are considered as promising feed additives in the nutrition of farm animals. A large number of studies with either cell cultures, such as intestinal cells, immune cells, endothelial and smooth muscle cells, adipocytes, or experimental animal models of inflammation including intestinal inflammation, systemic inflammation associated with obesity, metabolic syndrome, and atherosclerosis, demonstrated that isolated polyphenolic compounds or extracts, from polyphenol-rich plants such as green tea, hop, cocoa, and grape, suppress experimentally induced inflammatory processes (Gessner et al. 2016). Effects of polyphenols against inflammation are mediated by complex cellular mechanisms, most of which are linked with an inhibition of nuclear factor kappa-light-chain-enhancer of activated B cells (NF-κB), the major regulator of inflammation. Polyphenols are able to block the activation of NF-κB by inhibiting phosphorylation and proteasomal degradation of inhibitory kappa B (IκB), an effect which is in part due to the antioxidant properties of polyphenols (Vendrame and Klimis-Zacas 2015). In general, increasing evidence from studies with pigs, poultry, and cattle indicates that plant polyphenols are helpful to alleviate both local and systemic inflammatory conditions, which are of particular relevance during the weaning phase in monogastric species and during the periparturient period in dairy cattle, and thereby improve animal's performance. The main reason for improvements of animal's performance, such as increases in gain-to-feed ratio and milk yield, in response to plant polyphenols is that phenols reduce the effect of inflammatory condition that decreases feed intake, increases energy requirement for the production of fever, and induces several hormonal changes shifting the metabolism into a more catabolic state in farm animals (Gessner et al. 2016).

4 Nutraceuticals in Degenerative and Metabolic Diseases

Degenerative and metabolic diseases develop due to chronic or continuous insults to cells, tissues, and organs in humans and animals resulting in increased disruption of morphology and functions (metabolism) of tissues and organs over time.

Normal age-associated bodily wear or lifestyle choices such as exercise or nutritional habits may underlie development of degenerative and metabolic diseases. Natural feed supplements are known to prevent or slow the development of degenerative diseases and alleviate the disease signs, symptoms, and pain associated with clinical diseases. For example, natural dietary supplement, consisting of extract from five plant sources that contained *Cynara scolymus*, *Silybum marianum*, *Taraxacum officinale*, *Curcuma longa* (curcumin), and *Commiphora mukul*, is reported to prevent nonalcoholic fatty liver disease and atherogenesis by modulating the expression of different genes involved and avoiding renin-angiotensin system imbalance. The natural dietary supplement prevents liver fat accumulation and development of atherosclerotic lesions and improves hyperlipidemia (Amato et al. 2017).

A randomized controlled trial (Williams et al. 2017) in obese, older individuals also showed that fruit and vegetable concentrate supplementation has the potential to improve the metabolic profile of overweight and obese individuals by reducing blood lipid levels and systemic inflammation, as well as improving body composition. The degree of the improvements is found to be clinically significant, as the reduction in total cholesterol observed in the full cohort is estimated to be equivalent to a weight loss of 4 kg and an 8–9% reduction in cardiovascular disease risk. All obese individuals are likely to gain some benefit from supplementation with fruit and vegetable concentrate; however, it appears likely that the greatest improvements are in those with high baseline systemic inflammation or blood lipids. All in all, it was indicated that in obese individuals, who typically have a low fruit and vegetable intake, supplementation with fruit and vegetable concentrate may be beneficial to improve the metabolic profile and consequently reduce the risk of developing chronic inflammatory disease (Williams et al. 2017) and thereby decrease the development of various metabolic diseases.

Chronic inflammation is associated with a broad spectrum of neurodegenerative diseases of aging in humans including Alzheimer's disease, Parkinson's disease, amyotrophic lateral sclerosis, Parkinson-dementia complex of Guam, all of the tauopathies, and age-related macular degeneration, as well as various degenerative diseases such as osteoarthritis, rheumatoid arthritis, atherosclerosis, and myocardial infarction (McGeer and McGeer 2004). Therefore, nutraceuticals such as fruit and vegetable concentrates that reduce chronic inflammation would help to alleviate the clinical disease or development of such degenerative diseases. For example, polysaccharides and other constituents of mushrooms have been demonstrated to repair oxidative damage and suppress neuroinflammation displaying a great potential to develop therapies for neurodegenerative conditions (Zhang et al. 2017).

A systematic review (Zhai et al. 2017) provided some evidence that coenzyme Q10 (CoQ10) supplementation may partly improve the process of inflammatory state in patients with metabolic diseases, although further well-designed studies, with larger sample size, are needed to confirm its efficacy in metabolic disease-associated inflammation.

5 Nutraceuticals in Hypersensitivity (Allergic) Disorders and Other Inflammatory Diseases

Hypersensitivity or allergic reactions and diseases occur in humans and animals when the body immune system overreacts after exposure to various foreign agents often known as allergens that illicit such reaction. This will be manifested in various forms depending upon the affected tissues, organs, or systems in the body. It could be seen as allergic dermatitis in skin or inflammatory bowel disease in the gastrointestinal tract. Various nutraceuticals including those from plant origin are used in treating and/or reducing the clinical effects of allergic reaction-associated diseases. For example, aloe vera gel, a plant extract known for medicinal purposes in several cultures for centuries, is one of the common herbal therapies used for inflammatory bowel disease, despite a lack of large trials confirming its efficacy (Hilsden et al. 2003). Langmead et al. (2004) demonstrated the induction of clinical response in patients with ulcerative colitis after a 4-week treatment with oral administration of aloe vera gel, although no significant effects were observed on endoscopic and histological outcomes.

In another study (Del Pinto et al. 2015), inflammatory bowel disease was found to be significantly associated with deficiency of vitamin D. Evidence supports an immunological role of vitamin D in inflammatory bowel disease, both promoting tissue barrier formation through the expression of cell adhesion proteins and stabilization of tight junctions between epithelial cells and inhibiting the production of pro-inflammatory cytokines through the activation of vitamin D receptor (Mouli and Ananthakrishnan 2014). Furthermore, Larussa et al. (2017) citing several authors indicated that supplementation with vitamin D is reported to result in lower relapse rates and improvement in Crohn's disease activity index and is demonstrated to have a beneficial effect in patients with ulcerative colitis. Dietary peptides and amino acids (AAs) have also been shown to modulate intestinal immune functions and influence inflammatory responses, being involved in reducing inflammation, oxidative stress, and apoptosis in the gut and may be useful as alternative or ancillary treatments in Inflammatory Bowel Disease (Zhang et al. 2015).

6 Concluding Remarks and Future Directions

Nutraceuticals in different forms including herbs and other plant products have been in use for centuries. Despite development of modern medicine, traditional medicine that uses herbs and nutraceuticals is still in use with an increasing tendency throughout the world. With the exposure of humans and animals to polluted environment, synthetic products for day-to-day uses, and food contaminated with chemicals and pollutants, various diseases including allergic reactions and immune mediated diseases are befalling humans and animals in increased rates. Due to unintended side effects modern drugs used to treat various diseases, and the efficacy of natural products in the treatment and management of various diseases in animals and humans without out much side effects, nutraceuticals have a lot in store in the future as part of alternative medicine.

Plant and Food Derived Immunomodulators as Nutraceuticals for Performance Enhancing Activities

Bhanushree Gupta, Vidya Rani Singh, Surabhi Verma, Neha Meshram, Leena Dhruw, Rahul Sharma, Kallol K. Ghosh, and Ramesh C. Gupta

Abstract

The progress in research has prompted a new age for food- and plant-derived products that are of incredible benefit and are widely utilized as immunomodulators and vitality supporters in the form of nutraceuticals. They are even being regarded as agents with the potential to cure numerous diseases. These functional products are processed from plants in the form of phytochemicals, as well as from food sources such as soy products, mushrooms, and milk. A considerable number of these nutraceuticals have relevant physiological functions and important biological activities. The present aggregated information about nutraceuticals undoubtedly provides extraordinary opportunities for use by nutritionists, doctors, food technologists, and chemists.

Keywords

Immunomodulators · Bioactive peptides · Nutraceuticals · Nutritional food · Performance-enhancing nutraceuticals

1 Introduction

In the rapidly growing field of biomedical research, the demand for functional foods (i.e., nutraceuticals) has been highly commercialized in response to increasing awareness of the effects of diet on health (Orlando 2018). As these foods provide additional nutrients to the body, they are broadly utilized as an additional source of energy for the body. Nutraceutical are substances present in food or isolated from food that provide medical or health benefits, including benefits in the treatment and prevention of diseases (DeFelice 1992). They are also known as designer foods and include isolated nutrients, dietary supplements, and herbal products from nature, as well as processed food products such as cereals, soups, and beverages. This chapter focuses on plant-derived and animal-derived nutraceuticals.

From a vast amount of research over the years, plant-derived phytochemicals such as flavonoids and polysaccharides have been distinguished for their immunomodulatory attributes (Jantan et al. 2015). Immunodrugs incorporate natural and synthetic organic operators; for example, cytokines and antibodies for single targets or pathways have been utilized to treat immune-related illnesses, but with only limited success. Various illnesses can be treated with immunomodulation utilizing plants, rather than by other means. The discovery and isolation of particular immunomodulatory operators and power boosters of plant origin have the potential to eliminate side effects and reduce the high manufacturing costs of synthetic drugs (Baxter 2007). This chapter features the importance of plants as creators of active functional molecules of varied types with conceivable uses in animals and their well-being.

The chapter also focuses on the food sector, which has shown uninterrupted growth in food proteins, offering health benefits beyond serving the nutritional needs of the body. Such nutritional interventions can be of immense benefit in enhancing the health of immune-compromised and healthy individuals. Numerous ongoing research studies describe the

Authors Vidya Rani Singh, Surabhi Verma, Neha Meshram, and Leena Dhruw have contributed equally.

potential for use of fish oils in the treatment of atopic dermatitis and psoriasis. Treatment with dietary n-3 fatty acid supplements offers exciting novel possibilities in malignant diseases (Fürst and Kuhn 2000). The roles of traditional soy foods in disease prevention and treatment have gained worldwide recognition because of their antidiarrheal, hypolipidemic, anticarcinogenic, and antiosteoporotic effects. Bioactive peptides have also been established as being protective against harmful pathogens present in the environment, as well as in humoral and cell-mediated immune functions. Thus, they have prospects of being incorporated as ingredients in functional foods, nutraceuticals, and pharmaceuticals, where their biological activities may assist in the control and prevention of diseases. They can be produced from a wide range of food materials, including those from animal sources (e.g., milk), as they provide immense power-boosting capability and have wide immunoregulatory features (Gill et al. 2000).

Hence, we can conclude that nutraceuticals have an advantage over medicines because of their immense capability as immunomodulators and power boosters. They are also of great advantage as they lack side effects and naturally supplement the diet (Chauhan et al. 2013). A great advantage of nutraceuticals is their safety, while their great disadvantage is their relatively poor effectiveness. However, this apparent disadvantage may sometimes be deceptive.

2 Plant-Derived Immunomodulators

The immune system is responsible for the mechanisms of host defense. Assistance of the body to defend against foreign substances, pathogens, toxins, and noncompatible living cells is provided by the immune system (Licciardi and Underwood 2011). The immune system has been categorized into two broad categories: the adaptive immune system (which provides specific or acquired immunity) and the innate immune system (which provides nonspecific immunity).

Plant-derived compounds have appreciable immunomodulatory characteristics. Alkaloids, flavonoids, diterpenoids, and glycosides are the major types of plant-derived immunomodulatory agents. In addition, curcumin, resveratrol, quercetin, capsaicin, etc., are of therapeutic importance (Jantan et al. 2015).

Use of medicinal plants for immunomodulation is an alternative to ordinary chemotherapy for the treatment of various diseases—for example, immunosuppression. Nutraceuticals may be useful in circumstances such as improper functioning of the immune system. Products of *Emblica officinalis* (from the Euphorbiaceae family)—also known as *amla* or the Indian gooseberry—have significant antifungal, antibacterial, and antidiabetic properties (Dhir et al. 1991). Apart from these properties, this fruit has also demonstrated cytoprotective properties in acute cadmium toxicity (Khandelwal et al. 2002). The juice of *shankhpushpi* (*Evolvulus alsinoides*, from the Convolvulaceae family) has been found to improve the healing of ulcers, and the leaf extract has been used as a remedy for whitlows on fingers and toes (Sethiya et al. 2011).

2.1 Alkaloids

Alkaloids are usually used in the form of salts. Two examples are caffeine and codeine, which have stimulant and analgesic activities, respectively. Some alkaloids, such as salts of nicotine and anabasine, are used as insecticides. Modified alkaloids are the main sources of many synthetic and semisynthetic drugs, which are designed in such a way as to enhance or change the primary effect of the drug and reduce unwanted side effects. Piperine, an immunomodulatory agent, is a type of alkaloid, which has the following activities: it reduces the levels of the proinflammatory cytokines interleukin (IL)-1β, IL-6, and tumor necrosis factor (TNF) α; it downregulates expression of cyclooxygenase (COX)-2, nitric oxide synthase (NOS) 2, and nuclear factor (NF) κB; and it inhibits eicosanoid generation by inhibiting phospholipase A2 (PLA2) and thromboxane A2 (TXA2) synthase activity (Vaibhav et al. 2012).

2.2 Flavonoids

Flavonoids are a large class of plant pigments, which have a structure based on, or similar to, that of flavones. Various forms of flavonoids are flavanols, phloroglucinols, isoflavones, quinones, etc.

As an example, butein is a chalcone that suppresses nitric oxide (NO) production by attenuating inducible nitric oxide synthase (iNOS) expression, and it inhibits translocation of NF-κB (Wang et al. 2014). Quercetin—a flavanol involved in decreased expression of proinflammatory cytokines, NF-κB, and iNOS—also reduces expression of vascular cell adhesion molecule (VCAM) 1 and E-selectin. Epigallocatechin-3-gallate, a member of the flavanol class, inhibits reactive oxygen species (ROS) generation, mitogen-activated protein kinase (MAPK) phosphorylation, adhesion molecule expression, and signal transducer and activator of transcription (STAT) 3 and activating transcription factor (ATF) 2 translocation through induction of heme oxygenase (HO) 1 and suppressor of cytokine signaling (SOCS) 3 expression. The isoflavone daidzein decreases TNF-α, IL-1β, monocyte chemoattractant

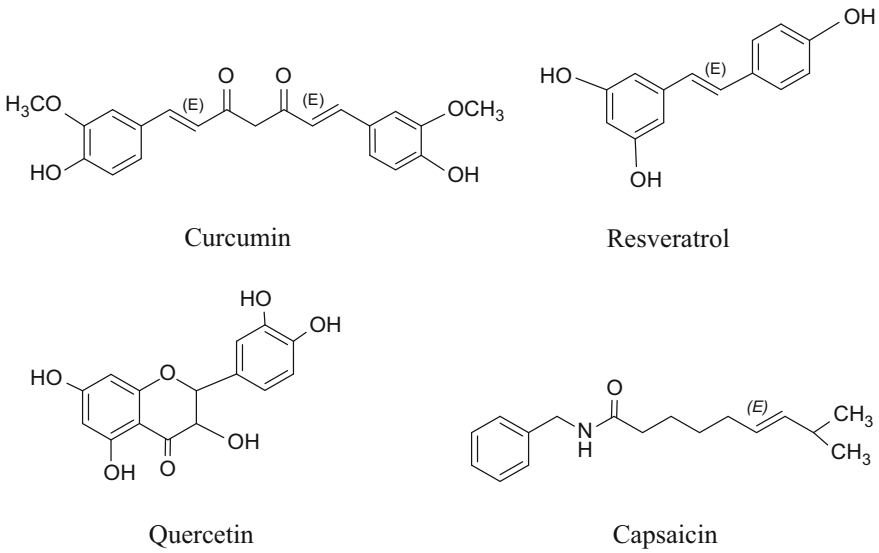

Fig. 1 Chemical structures of selected plant-derived immunomodulators

protein (MCP) 1, NO, and iNOS expression at the messenger RNA (mRNA) level (Rabinovitch et al. 1996). The phloroglucinol myrtucommulone inhibits prostaglandin E_2 (PGE_2) production by inhibiting microsomal prostaglandin E synthase (mPGES) 1 activity without significantly inhibiting COX enzyme activity. Thymoquinone, an active principle in *Nigella sativa* L., belongs to the quinines and performs the mechanisms of lipopolysaccharide (LPS)-induced fibroblast proliferation and H_2O_2-induced 4-hydroxynonenal generation (Wang et al. 2014).

2.3 Terpenoids

Terpenoids are the substances that are responsible for the odor of plants and flowers. They are found broadly in the leaves and products of higher plants such as conifers, citrus, and eucalyptus. 1,4-Deoxyandrographolide (from *Andrographis paniculata*) is a terpenoid that has an immunomodulatory action and enhances multiplication of lymphocytes (Kumar et al. 2004) (Fig. 1).

2.4 Curcumin

Curcumin is a characteristic diarylheptanoid compound found in the rhizome of *Curcuma longa* and related species. The therapeutic advantages of curcumin have been known for hundreds of years. An assortment of natural and pharmacological properties of curcumin have been described, including inhibition of cancer cell growth, angiogenesis, and cell proliferation; and induction of apoptosis (Bhaumik et al. 2000; Surh et al. 2001).

2.5 Resveratrol

Resveratrol (which synthetically is (5-[(E)-2-(4-hydroxyphenyl) ethenyl benzene-1,3-diol) is a subsidiary of stilbene and phytoalexin. It is found in different dietary items and plants, including grapevines, red wine, and peanuts. Like curcumin, resveratrol has been found to exert a number of pharmacological effects, such as antimicrobial, chemopreventive, anticancer/proapoptotic, mitigating, and cell reinforcement properties. Provocative atoms are emphatically hindered by resveratrol.

Resveratrols are chiefly found in grapes, nuts that abates myeloperoxidase (MPO) movement and mPGES-1 to basal levels; inhibits iNOS and COX-2 articulation (Youn et al. 2009); reduces the expert incendiary cytokines IL-8, TNF-α, IFN-γ, and IL-1α; and increases levels of the mitigating cytokine IL-10 (Vang et al. 2011).

2.6 Quercetin

The flavanol quercetin (which chemically is 2-(3,4-dihydroxyphenyl)-3,5,7-trihydroxy chromen-4-one) belongs to the family of polyphenols, representing very extensively spread secondary plant metabolites. Quercetin is found in a variety of food such as tea, capers, red onions, broccoli, berries, grapes, and apples. Quercetin has been found to exert antimutagenic, antioxidative, anti-inflammatory, anticancer/chemopreventive, neuroprotective, antihypertensive, and blood glucose–lowering effects (Middleton et al. 2000). Quercetin activates various kinases, which phosphorylate eukaryotic initiation factor (eIF) 2, thus inhibiting cell translation (Ito et al. 1999). The mechanism

behind these actions is decreased expression of proinflammatory cytokines, NF-κB, iNOS, VCAM-1, and E-selection.

2.7 Capsaicin

Capsaicin (which synthetically is (E)-N-[(4-hydroxy-3-methoxyphenyl) methyl]-8-methylnon-6-enamide) is a hydrophobic alkaloid found in stew peppers (*Capsicum* species from the Solanaceae family) and is responsible for the trademark zestiness/sharpness of the natural products of this sort. It has been utilized in customary drugs for counteraggravation and as a topical rubefacient to calm pain in joints and muscles. An 8% capsaicin cutaneous patch has recently been approved to treat neuropathic pain in nondiabetic adults in the European Union (EU) and to treat neuropathic pain associated with postherpetic neuralgia in the USA (Caterina et al. 1997). Capsaicin has been found to inhibit the NF-κB pathway, iNOS expression, and COX-2 activity in macrophages in a transient receptor potential vanilloid (TRPV) 1–independent manner (Kim et al. 2004).

3 Food-Derived Immunomodulators

Immunomodulatory agents derived in the form of food from animals and plants have several regulatory functions in the immune system (Hartmann et al. 2000). Through use of these immunomodulatory agents, long-lasting immunity and other beneficial effects can be achieved in animals. Food production efficiency can be enhanced with the aid of these agents, as they boost the immune system and its functioning in animals, regulating certain immune factors (through suppression or stimulation). Bioactive peptides are widely known in the field of science because of their beneficial biological functionality, induced by food protein hydrolysates. They can be produced from the by-products of food protein bioprocessing and also from a wide range of food materials from both animals (egg, cheese, milk, beef, and chicken and fish skin) and plants (soy, soy products, wheat, and biofortified crops).

3.1 Bioprocessing of Bioactive Peptides from Proteins

Bioactive peptides serve as immunomodulatory agents because of the presence of different functional groups that have various structure-dependent activities. These functional properties of bioactive compounds can be determined on the basis of their unique three-dimensional structures. This determination can be done according to the type and nature of the amino acids present in the primary sequences of the food protein hydrolysates. Proteins can be produced from bioactive peptides by various reported methods, such as:

1. Enzymatic hydrolysis with digestive enzymes
2. Fermentation of food proteins with proteolysis starter cultures
3. Proteolysis by enzymes derived from microorganisms or plants

3.1.1 Enzymatic Hydrolysis with Digestive Enzymes

The most commonly used method for obtaining bioactive peptides is enzymatic hydrolysis of entire molecules. The enzymes utilized are from plants, bacteria, or fungi, or can be of gastrointestinal origin. Protein source production by proteolytic enzymes and their precursors, by use of recombinant DNA technology, has been reported (Korhonen and Pihlanto 2006). Ordinarily used enzymes are chymotrypsin, pepsin, alkalase, trypsin, papain, and pancreatin, which are either utilized alone or mixed with other enzymes. By enzymatic hydrolysis, production of bioactive peptides is performed using the optimized condition of the enzyme(s), and the type of peptides generated is subjected to the hydrolytic specificity of the enzyme(s). Additionally, with this method, specific enzyme combinations can be used to determine the fate of a protein molecule when it goes through the digestive system. For example, sequentially digested *Brassica carinata* protein—isolated in vitro with trypsin, chymotrypsin, and carboxypeptidase A—has been used to produce peptides with cancer prevention properties and angiotensin-converting enzyme inhibitor activities (Pedroche et al. 2007). Bioactive peptides generated with this type of enzyme combination are believed to stimulate those produced by the digestive system (Pedroche et al. 2007). In addition, the production of numerous novel peptides is led by combination of various enzyme treatments. The use of immobilized catalysts over the conventional soluble enzymes for production of bioactive peptides is gaining momentum. In a study by Pedroche et al. (2007), bioactive peptides were produced from *B. carinata* hydrolyzed by immobilized enzymes on a glyoxal agarose support.

3.1.2 Fermentation of Food Proteins with Proteolysis Starter Cultures

Another widely known technique for bioactive peptide production is fermentation of food proteins with proteolytic starter cultures. The proteolytic system of lactic acid bacteria (LAB) offers shifted enzymatic specificities. In the production of bioactive peptides, LAB offer cell envelope–associated proteinases (CEPs) and also intracellular peptidases—for example, endopeptidases, aminopeptidases, tripeptidases, and dipeptidases—for possible application. For

the production of probiotics and bioactive peptides, the probiotic microbes of the genera *Lactobacillus* and *Bifidobacterium* have been broadly studied (Alhaj et al. 2010). The activities of peptidases are influenced by the development states of the production microorganisms; thus, the development of peptides by this method can be controlled to some extent (Korhonen and Pihlanto 2006).

3.1.3 Proteolysis by Enzymes Derived from Microorganisms or Plants

Research on commercial production of bioactive peptides is progressing and is made possible by the development of optimized production techniques. Advances in bioseparation technologies (utilized in sanitizing and isolating biomolecules) combined with chemical engineering convective mass exchange principles could offer a practical and versatile production stage for immunomodulatory peptides. To date, the strategies that have been utilized for peptide fractionation and advancement are those that enable to regain bioactive peptides with minimal destruction. Briefly, they include ion exchange, ultrafiltration, and gel filtration technologies. Coupled techniques—for example, ultrafiltration in a membrane reactor followed by enzymatic hydrolysis and, likewise, ion exchange membrane chromatography—have been utilized (Chabeaud et al. 2009; Pedroche et al. 2007). Utilization of a combination of techniques is also becoming popular for filtration, production, separation, and identification of bioactive peptides. Such methods lead to products of high yield, as well as high purity. For isolation and enrichment of bioactive peptides, the electromembrane filtration technique is utilized (Bargeman et al. 2002). This technique combines membrane filtration and electrophoresis and thus is a very effective one for use on strongly charged biomolecules. Moreover, key operating parameters—for example, the electrical field strength, the kind of membrane, the salination of the hydrolysates, and the hydrolysate concentration—can be controlled to enhance the product transfer and separation rates (Bargeman et al. 2002).

3.2 Biological Activities of Bioactive Peptides

Various biological activities such as antihypertensive, antioxidant, immunomodulatory, anticancer, antimicrobial, and lipid-lowering activities have been exhibited by food protein hydrolysates.

3.2.1 Antihypertensive Activity

Among the vast number of bioactive peptides, most peptides from exogenous sources are antihypertensive peptides—for example, ovalbumin, which is present in egg white protein. These food-derived antihypertensive peptides not only have been well researched but also have wide applications, such as in functional and designer foods. Nowadays, hypertension has become a major and genuine medical issue in animals, particularly in developed nations, and is considered a risk factor for developing cardiovascular disease. Antihypertensive peptides have been attracting interest because of their wide effectiveness in lowering blood pressure. They have proved to be effective in preventing or treating hypertension, mainly by inhibiting angiotensin-converting enzymes, which play a key role in regulation of blood pressure and electrolyte homeostasis. Ile-Pro-Pro (IPP) and Val-Pro-Pro (VPP) peptides have been, for the most part, described and analyzed as inhibitors of angiotensin I–converting enzymes. Angiotensin I–converting enzyme (ACE; peptidyl dipeptide hydrolase; EC 3.4.15.1) is a key enzyme in the renin–angiotensin system. This enzyme controls extracellular fluid volume and arterial vasoconstriction either by converting angiotensin I to the vasoconstrictor angiotensin II or by inactivating bradykinin (a vasodilatory peptide) and enkephalin. Inhibition of ACE in this manner results in an decrease in blood pressure, helping to control hypertension (Petrillo and Ondetti 1982).

3.2.2 Antioxidant Activity

Oxidation plays a critical role in the body for the survival of cells and also in nourishment. A side effect of oxidative digestion, being fundamental for the survival of cells, is generation of free radicals and other ROS, resulting in oxidative changes. At the point when an excess of free radicals is formed, they can overpower protective enzymes such as superoxide dismutase, catalase and peroxidase, causing dangerous and deadly impacts on cells, similar to apoptosis, by oxidizing cell proteins, membrane lipids, DNA, and enzymes, and thereby disrupting cell processes (Sharma et al. 2011). Proteins, protein hydrolysates, singular peptides, and amino acids appear to exhibit significant antioxidant activity. Antioxidative bioactive peptides have been derived from many hydrolyzed food proteins such as caseins, whey proteins, egg yolk protein, porcine myofibrillar proteins, and aquatic by-product proteins (Pihlanto 2006). They are effective against enzymatic and nonenzymatic peroxidation of lipids and fundamental fatty acids such as free radical scavengers and metal particle chelators. During hydrolysis by proteolytic enzymes, caseins can release antioxidative peptides (Korhonen and Pihlanto 2006). Peptides derived from α-s-casein have demonstrated free radical–scavenging activity and inhibited enzymatic and nonenzymatic lipid peroxidation (Sharma et al. 2011). Other than being critical for survival of cells in an organism, inhibition of oxidative forms is of great importance for food quality. Development of free radicals results in detectable effects on food quality such as

rancid flavor, unacceptable taste, and reduction of shelf life, while intake of food containing lipid oxidation products has been linked to different diseases, including cancer, diabetes, and cardiovascular disease (Ryan et al. 2011).

3.2.3 Cytomodulatory and Anticancer Activities

Proteins, peptides, and amino acids have been implicated in preventing the development of different types of cancer. Milk proteins and their peptide derivatives play roles in cancer prevention. Casein phosphopeptides (CPPs) have demonstrated anticarcinogenic activity (Bouhallab and Bouglé 2011). The anticancer activities of these proteins may be at least partially attributable to encrypted bioactive peptides. Numerous peptides in different sizes from various sources have demonstrated anticancer effects in in vivo studies (Yu et al. 2014). There is increased evidence that by acting as specific signals that may affect the viability of cancer cells, milk-derived peptides may have cytomodulatory activities (Gobbetti et al. 2007). Bioactive peptides with cytomodulatory activities have been found during bacterial hydrolysis of casein in commercial yogurt starter cultures, which affected colon cell Caco-2 kinetics in vitro (Macdonald et al. 1994). Bioactive peptides with antiproliferative activity toward leukemia cells have been found during digestion of bovine skimmed milk with a cell-free extract of the yeast *Saccharomyces cerevisiae* (Roy et al. 1999). Modulation of cell viability, such as through proliferation and apoptosis, in different human cell culture models has been shown by many purified peptides equivalent to sequences of casein. Hartmann et al. (2000) reported that cytomodulatory peptides derived from casein fractions inhibit cancer cell growth or stimulate the activity of immune-competent cells and neonatal intestinal cells. The fragments 1–18 and 105–117 from β-casein have been shown to influence the viability—as well as the proliferation, differentiation, and apoptosis—of different cell types (Phelan et al. 2009).

3.3 Immunomodulatory Effects

The association between nutrition and immunity has long been recognized. Bioactive peptides derived from different protein sources have been shown to exert immunomodulatory effects in in vitro and in vivo studies. However, such studies have generally focused on evaluation of the impacts of peptides and protein hydrolysates on particular immune systems, and only a limited number of investigations have analyzed their effects on nonspecific (intrinsic) immune systems (Shahidi and Zhong 2008). Bioactive peptides from caseins and whey proteins are known to have immunomodulatory impacts.

3.4 Functional Ingredients of Bioactive Peptides as Immunomodulators

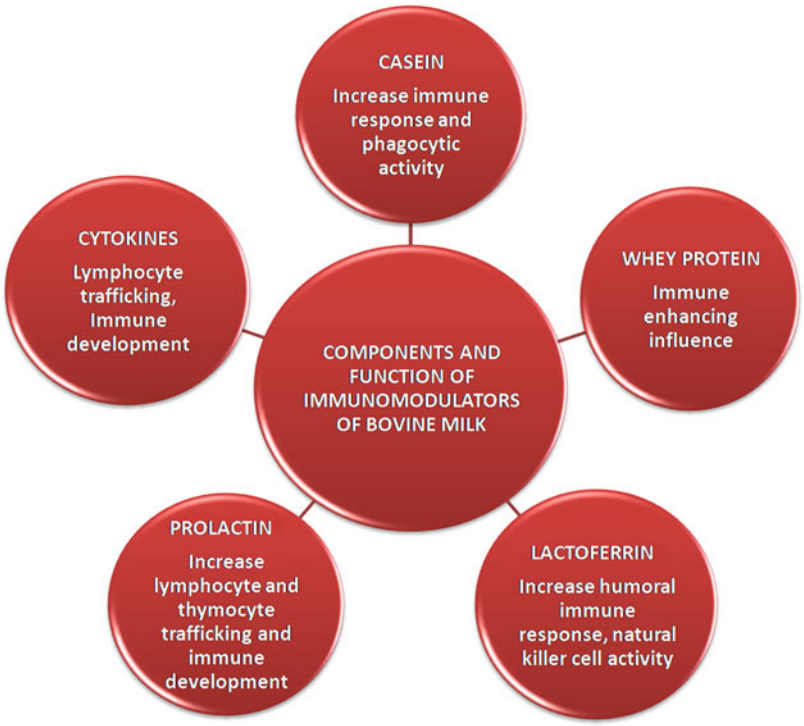
The functional groups present in various biologically active peptides serve as an immense source of energy and also act as immunomodulators when taken in the form of nutraceuticals. The main sources of bioactive peptides that act as immunomodulators are milk, mushrooms, eggs, cheese, beef, seafood, rice, corn, soy, and wheat (Dominic and Danquah 2012).

3.4.1 Milk Components as Immunomodulators

Milk is possibly the best-known source of nutrients. Aside from this, some milk components such as casein, lactoferrin, prolactin, and cytokines are milk growth factors. Immunoglobulin from milk facilitates passive immunity and contributes to protection against harmful environmental pathogens. Milk-derived proteins and peptides have wide immunoregulatory features, making milk the most important food consumed worldwide. Table 1 lists the components of milk that are responsible for immunomodulatory properties.

1. Casein: This is the major protein in milk and is a source of amino acids for young animals. The action of mammalian intestinal proteinases results in production of some peptides, derived from caseins, which have been found to retain immunoenhancing properties in vitro. The phosphopeptide residues 59–75 from bovine casein (generated by bovine trypsin digestion) and residues 1–25 from b-casein demonstrate mitogenic activity in mouse spleen cells, mouse thymocytes, or rabbit Peyer's patch cells; and a stimulatory effect on immunoglobulin production in mouse spleen cells (Otani et al. 2010).
2. Whey proteins: These are important immunoregulators for animals. Bovine whey proteins have immunoenhancing effects in mice. They include various protein such as γ-globulin, β-lactoglobulin, α-lactalbumin (αLA), bovine serum albumin (BSA), lactoferrin (LF), lactoperoxidase (LP), and some growth factors such as interleukins, epidermal growth factor, insulin-like growth factor, and transforming growth factor. These proteins have important biological activities. Some major and minor whey proteins are now commercially available as a result of advances in milk protein fractional technology (Wong et al. 1997).
3. Lactoferrin: This is an 80-KDa glycoprotein, which is involved in binding of iron and occurs in the milk of all mammals. It shows diverse effects on the host defense system. Apart from its function as a growth factor and its antimicrobial action, lactoferrin has been found to exhibit various immunomodulatory effects. In cell culture experiments it has been shown that lactoferrin and peptides derived from it influence the production of

Table 1 Bovine milk and its Immunomodulatory components with their bioactivities (Park 2009)



cytokines involved in immune and inflammatory actions in the body (Yada et al. 2002).

4. Prolactin: This is a 23-KDa single-chain polypeptide secreted from lactotroph cells of the anterior pituitary gland in vertebrates. It enhances immune function in fish. Prolactin stimulate the phagocytic activity of fish leukocytes. Prolactin is necessary to maintain circulating levels of immunoglobin in rainbow trout (Yada et al. 2002).
5. Cytokines: These are present in mammary glands and play important roles in development of the immune system in neonates. Immune factors are transferred from mothers to neonates through the placenta or via breast feeding and protect offspring from pathogens until maturation of the immune system (Nguyen et al. 2007).

3.4.2 Mushrooms

Mushrooms have great importance in medicines and nutraceuticals used to improve health. Some species of mushroom—such as *Lentinula edodes*, *Schizophyllum commune*, *Ganoderma lucidum*, and *Coriolus versicolor*—have been used as immunomodulators and anticancer agents.

Polysaccharide K (PSK; Krestin) and polysaccharopeptide (PSP) are both isolated from *C. versicolor* and are used as immune and chemotherapeutic agents for the treatment of cancer. PSP inhibits tumor cell proliferation through immunomodulatory activity. Schizophyllan (SPG) is a mushroom-derived polysaccharide, isolated from *S. commune*, which stimulates the immune system and activates NK cells, spleen cells, lymphoid cells, and bone marrow cells; and enhances the production of immunomodulatory cytokines. Two immunomodulatory β-glucans derived from *G. lucidum* are polysaccharides with a β-D-(1–3)-glucan backbone and branching characterized by β-D-(1–6) linkage, and have immunomodulatory and antioxidant properties.

Factors Influencing Bioactivity of Mushroom-Derived Immunomodulators

The major factors influencing the activity and confirmation of polysaccharides (glycosidic linkage and helical structure) are as follows:

1. The presence of (1–3)-β linkage in the main chain of glucans is an important structural feature for immunostimulatory and anticancer activity.
2. The triple helical structure of (1–3)-β-glucan can be recognized by glucan receptors, correlating with immunomodulatory activity.

Another factor that influences the immunomodulatory activities of polysaccharides is the degree of branching. Polysaccharides with a greater degree of branching demonstrate higher immunomodulatory and anticancer activities.

Immunoceutical Potential of Mushroom Polysaccharides

Glucans, mannans, galactans, and fructans are the most important immunostimulatory and anticancer polysaccharides. Among all of them, glucans are the most auspicious immunostimulatory and anticancer polysaccharides. Glucans are D-glucose-based polymers, mostly joined by β-glycosidic linkages and, in some cases, by α linkages. While the most active immunostimulators are β-glucans, α-glucans are nonactive, but α-glucans with (1–4) and (1–6) glycosidic linkages shows immunostimulatory activity (Zhang et al. 2017).

3.4.3 Eggs

Chicken egg white derivative (CWD), active egg white product (AEWP), and chicken egg white–derived immunoactive peptide (EF 203) have been shown to enhance nonspecific immunity in mice, piglets, cattle, and rainbow trout (Hirota and Yang 1995).

4 Clinical Applications of Food-Derived Nutraceuticals

Nutraceuticals have been used in the prevention and treatment of various common diseases in animals such as cardiovascular disease, cognitive dysfunction, cancer, osteoarthritis, and periodontal disease, providing evidence for their pharmacological potential in a wide range of animal diseases in numerous clinical trials. Nutraceuticals have been administered in animal supplements in many forms such as capsules, tablets, and powders, with or without prescription by veterinarians (Lerman and Lockwood 2007).

5 Concluding Remarks and Future Directions

Various diseases can be treated by immunomodulation through utilization of therapeutic plants rather than pharmacotherapy. Immunomodulatory peptides may likewise be included in the categories of nourishment and medication, and their use may be expanded in the form of supplements. Food proteins have been shown to offer health benefits beyond the need for bodily nourishment. There has been critical advancement in our understanding of the structures and bioactivity of polysaccharides, obtained from organisms and other nourishment sources, which appear to have viable immune-empowering actions. Studies have established the effects of certain lifestyle-related practices on a few parameters of the immune system. By implication, peptides with antihypertensive, antimicrobial, and immunomodulatory properties might be utilized to help prevent or control lifestyle-related diseases such as hypertension, proliferation, and cardiovascular disease. Further research on the bioactivity of polysaccharides is expected to lead to development of novel therapeutic and nutraceutical agents for curative and preventive applications against diseases, including cancer.

Nutraceuticals for the Prevention and Cure of Cancer

Subash Chandra Gupta, Anurag Sharma, Shruti Mishra, and Nikee Awasthee

Abstract

Despite better healthcare system and advanced technology, the morbidity and mortality due to cancer are high in the western countries as compared to that in eastern world. Conversely, an increase in cancer incidence has been reported in the eastern world during recent years most likely due to the changes in lifestyle and food habits. The available cancer drugs provide only little benefits to the patients. Accumulating evidence suggests that Mother Nature has been a great source of medicine in as much as almost 70% of the current drugs have originated from Nature. Nutraceutical that refers to the food or food products with nutritional values has emerged as novel agents for cancer prevention and cure. Contrary to rationally designed drugs, nutraceuticals are multi-targeted and inexpensive and are reportedly safe. Chemically, nutraceuticals are diverse and can target multi-steps of tumor development. The anticancer potential of nutraceuticals has been demonstrated at the molecular, cellular, animal, and human levels. The cancer-related molecular targets of nutraceuticals include pro-inflammatory molecules, protein kinases, receptors, transcription factors, etc. Some of the common nutraceuticals with anticancer activities include caffeic acid, capsaicin, curcumin, epigallocatechin gallate, flavopiridol, genistein, resveratrol, sanguinarine, and tocotrienol. Nutraceuticals have also been structurally modified for better bioavailability and efficacy. These agents are also used in combination to enhance the efficacy of existing drugs. In this chapter, we discuss the therapeutic potential of nutraceuticals against cancer. The advantages and disadvantages associated with the use of nutraceuticals are discussed.

Keywords

Cancer · Efficacy · Nutraceutical · Prevention · Safety · Treatment

Abbreviation

5-LOX	5-lipoxygenase
8-OHdG	8-hydroxy-2′ -deoxyguanosine
AKBA	acetyl-11-keto-beta-boswellic acid
AMPK	5′ adenosine monophosphate-activated protein kinase
AP-1	activator protein-1
APC	adenomatous polyposis coli
Bax	bcl-2-associated X protein
Bcl-2	B-cell lymphoma-2
Bcr-abl	breakpoint cluster region-Abelson murine leukemia viral oncogene
CAPE	caffeic acid phenethyl ester
COX-2	cyclooxygenase-2
CRC	colorectal cancer
DNA	deoxyribonucleic acid
EGCG	epigallocatechin gallate
EGFR	epidermal growth factor receptor
ERK1/2	extracellular signal-regulated kinase 1/2
GAS-5	growth arrest specific-5
GSH	glutathione
GST	glutathione S-transferase
HIF-1	hypoxia-inducible factor-1
ICAM	intercellular adhesion molecule
IGF-1	insulin-like growth factor-1
IGF1-R	insulin-like growth factor 1 receptor
IGFBP-3	insulin-like growth factor binding protein-3
IKK	IκB kinase
IL	interleukin

Keap-1	Kelch-like ECH-associated protein-1
lncRNA	long noncoding ribonucleic acid
M1G	pyrimido[1,2-a]-purin-10(3H)-one
MDA	malondialdehyde
MEG-3	maternally expressed-3
MMP	matrix metalloproteinase
mTOR	mammalian target of rapamycin
NF-κB	nuclear factor kappa-light-chain-enhancer of activated B cells
NIK	NF-κB-inducing kinase
NO	nitric oxide
NOS	nitric oxide synthase
Nrf2	nuclear factor erythroid 2 (NFE2)-related factor 2
PAI-1	plasminogen activator inhibitor-1
PAK	p21-activated kinase-1
PGC-1α	peroxisome proliferator-activated receptor gamma coactivator 1-alpha
PGE_2	prostaglandin E_2
PI3K	phosphoinositide 3-kinase
PMA	phorbol myristate acetate
PPAR-γ	peroxisome proliferator-activated receptor gamma
PSA	prostate-specific antigen
RASSF-1α	Ras association domain-containing family 1 alpha
SIRT-1	sirtuin 1
STAT3	signal transducer and activator of transcription 3
TIMP-2	tissue inhibitor of metalloproteinase-2
TNF-α	tumor necrosis factor alpha
VCAM	vascular cell adhesion molecule
VEGFR	vascular endothelial growth factor receptor
Wnt	wingless

1 Introduction

In 1971, an extensive campaign was launched by Richard Nixon, the then President of the USA for the cure of cancer. Since this campaign, the pathogenesis of the disease is relatively well understood. However, the disease continues to be major causes of death worldwide. The incidence and death because of cancer are likely to double by 2030 as compared to that in 2002. Unless we rethink the approaches for the cure, the mortality and morbidity due to cancer are unlikely to be significantly reduced.

Carcinogenesis is a multi-step process during which a series of events determine the fate of a cell from normal to a malignant state. Majority of the cancer-related deaths are due to the metastasis of the tumor. However, most drugs are designed to kill the cancer cells and not to prevent the spread. It is estimated that more than 500 genes are dysregulated in any given cancer. Yet, most current cancer therapeutics are based on the modulation of only a few targets, which is unlikely to be effective. The current focus for cancer therapy is either to design a drug that can hit several targets or to combine multiple mono-targeted agents. Accumulating evidence suggests that a multi-targeted approach has a higher possibility of success as compared to mono-targeted therapy. Some of the rationally designed multi-targeted drugs made by pharmaceutical companies are lapatinib, sunitinib and sorafenib. These drugs have added a little to the overall survival of the patients. However, they produce numerous side effects when taken for a long period of time. Additionally, these drugs are highly expensive and cannot be afforded by more than 80% of the world population. For example, a combination of Erbitux and Avastin for colon cancer treatment is known to make the therapy worst rather than better (Mayer 2009).

It is estimated that as much as 90% of cancer-related deaths are linked with inappropriate lifestyle and diet. For example, tobacco use and food habits significantly contribute to the development of gastric cancer (Pavithra et al. 2018). The association of lifestyle factors with cancer incidence is reported for the cancer of the bladder (Fankhauser and Mostafid 2018), breast (Bougnoux et al. 2010), gastrointestinal tract (Bjelakovic et al. 2008), kidney (Tahbaz et al. 2018), lung (Cranganu and Camporeale 2009; Goralczyk 2009), and prostate (Er et al. 2017). Implication of these statements suggests that much of cancer can be prevented by changing lifestyle and food habits. For example, the consumption of foods rich in vegetables and fruits is negatively related with the cancer risk (Block et al. 1992; Steinmetz and Potter 1996; Reddy et al. 2003; Benetou et al. 2008; Freedman et al. 2008). Approximately 35% of cancer deaths can be avoided by the use of the appropriate nutrition (Doll and Peto 1981; Hardy et al. 2003). Further, appropriate diet can help to reduce as much as 90% of certain cancers (Doll and Peto 1981; Hardy et al. 2003). The dietary intake of vegetables, fruits, and grains reduces the incidence of ovarian cancer in women (Plagens-Rotman et al. 2018).

During recent years, an emphasis has been given to the use of nutritional agents called nutraceuticals for cancer prevention and treatment. To our knowledge, the word nutraceutical (nutrition + pharmaceutical) was first coined in 1989 by Stephen L. DeFelice (Brower 1998; Kalra 2003). The food or food component that can provide health benefits is referred to as nutraceuticals (Brower 1998; Zeisel 1999). The Mother Nature is a great source of nutraceuticals. Nutraceuticals have demonstrated potential against breast cancer, colorectal cancer, pancreatic cancer, prostate cancer, squamous cell carcinoma, and many others (Gupta et al. 2010). Nutraceuticals can target multi-steps of tumor development. The nutraceuticals are diverse regarding their chemical

structures. A number of epidemiological studies support the benefits of nutraceuticals in the cancer prevention and cure.

2 Anticancer Activities of Nutraceuticals

2.1 Molecular and Cellular Level

The molecular basis for the anticancer activities of nutraceuticals is relatively well explored. We now know that nutraceuticals can hit the cancer cells at the molecular, cellular, animal, and human levels. The common cancer-related molecular targets modulated by nutraceuticals include growth factor receptors [epidermal growth factor receptor (EGFR), insulin-like growth factor 1 receptor (IGF1-R), vascular endothelial growth factor receptor (VEGFR)], pro-inflammatory mediators [5-lipoxygenase (5-LOX), cyclooxygenase-2 (COX-2), interleukins, tumor necrosis factor alpha (TNF-α)], protein kinases [5′ adenosine monophosphate-activated protein kinase (AMPK), breakpoint cluster region-Abelson murine leukemia viral oncogene (Bcr-abl), mammalian target of rapamycin (mTOR), phosphoinositide 3-kinase (PI3K), Ras/Raf], and transcription factors [activator protein 1 (AP-1), β-catenin/Wnt, nuclear factor kappa-light-chain-enhancer of activated B cells (NF-κB), nuclear factor erythroid 2 (NFE2)-related factor 2 (Nrf2), peroxisome proliferator-activated receptor gamma (PPAR-γ), sonic hedgehog, and signal transducer and activator of transcription 3 (STAT3)]. Additionally, nutraceuticals are known to trigger proteasome and epigenetic changes leading to the cancer prevention and treatment (Pandey et al. 2017). Being a crucial regulator of tumorigenic proteins, transcription factors represent an important target of nutraceuticals (Shishodia et al. 2007b). Among all nutraceuticals, much is known about curcumin. Chemically, curcumin is a polyphenol derived from the Indian spice turmeric (Gupta et al. 2012). This polyphenol can suppress NF-κB activation induced by TNF-α in leukemia cells by inhibiting IκBα phosphorylation and degradation (Singh and Aggarwal 1995). Curcumin also suppresses TNF-α-induced COX-2 expression and NF-κB activation in human colonic epithelial cells (Plummer et al. 1999). The polyphenol also suppressed IκB degradation and the activities of NF-κB-inducing kinase (NIK) and IκB kinase (IKK) that may contribute to its inhibitory effects on NF-κB activation. The potential of curcumin in suppressing proliferation and metastasis and inducing apoptosis is mediated through its negative effects on NF-κB activation (Bharti et al. 2003, Philip and Kundu 2003). Curcumin can also sensitize cancer cells to chemotherapeutic agents through its inhibitory effects on NF-κB activation (Kunnumakkara et al. 2009). Apart from transcription factors, curcumin can also modulate the activities of protein kinases. For example, curcumin downregulated EGFR and the activity of extracellular signal-regulated kinase 1/2 (ERK1/2) in pancreatic and lung cancer cells (Lev-Ari et al. 2006). In malignant glioma cells, curcumin suppresses PI3K/AKT pathway (Aoki et al. 2007). Other protein kinases negatively regulated by curcumin include the phosphorylase kinase, pp60c-src tyrosine kinase, protein kinase C, and protamine kinase (Shishodia et al. 2007b).

Bharangin is a poorly studied diterpenoid quinone methide that is derived from *Pygmacopremna herbacea*. Our group recently demonstrated the anticancer activities of this diterpenoid against breast cancer (Awasthee et al. 2018). Moreover, okadaic acid-induced NF-κB activation was also suppressed by this diterpenoid. For the first time, we also demonstrated that the diterpenoid modulates the expression of long noncoding ribonucleic acids (lncRNAs). While the expression of tumor suppressor lncRNAs such as growth arrest specific-5 (GAS-5) and maternally expressed-3 (MEG-3) was induced, the expression of H19 (oncogenic lncRNA) was suppressed by the diterpenoid. It is likely that bharangin exhibits anticancer activities by modulating lncRNA expression and abrogating NF-κB activation. We are further exploring the in-depth mechanism for the activities of bharangin against breast cancer.

Resveratrol is a polyphenol and phytoalexin, the major source of which is grapes (Gupta et al. 2011). This phytoalexin suppresses constitutive NF-κB activation and induces pro-apoptotic activities in breast (Banerjee et al. 2002) and pancreatic cancer cells (Mouria et al. 2002). Sanguinarine is an alkaloid that suppresses NF-κB activation in response to inducers such as interleukin (IL)-1, okadaic acid, phorbol ester, and TNF (Chaturvedi et al. 1997). Caffeic acid phenethyl ester (CAPE) suppresses NF-κB activity in a direct manner. More specifically, this agent inhibits the binding between p65-p50 complex and DNA and leading to the suppression of NF-κB-dependent target gene transcription (Natarajan et al. 1996). Epigallocatechin gallate (EGCG) is an antioxidant chiefly present in green tea. This antioxidant suppresses NF-κB activation and malignant transformation of mouse JB6 cell line (Nomura et al. 2000). EGCG also suppresses p65 acetylation and NF-κB-associated gene expression induced by a range of stimuli (Choi et al. 2009b). Gallic acid obtained from gallnuts, green tea, oak bark, and sumac can also abrogate NF-κB activity (Choi et al. 2009c).

The nutraceuticals can also induce cell cycle arrest in cancer cells. The bark of *Boswellia serrata* is a rich source for acetyl-11-keto-beta-boswellic acid (AKBA) which is a pentacyclic triterpene. This polyphenol exhibits anticancer activities against colon cancer cells by inducing G1 phase cell cycle arrest (Liu et al. 2006). Similarly, a decrease in the activities of cyclin-D1 and p21-activated kinase (PAK)-1 by curcumin was associated with its ability to suppress G1/S

phase transition (Cai et al. 2009). β-Escin also induces G1/S phase cell cycle arrest in HT-29 colon cancer cells (Patlolla et al. 2006). Similarly, thymoquinone induces G1/S phase cell cycle arrest in prostate cancer cells (Kaseb et al. 2007). Concomitant with these observations, an upregulation in the expression of p21 and p27 while downregulation in the expression of androgen receptor and E2F-1 was observed (Kaseb et al. 2007). Other nutraceuticals known to exhibit antiproliferative effects by the induction of cell cycle arrest include berberine (Liu et al. 2009), deguelin (Murillo et al. 2009), emodin (Kuo et al. 2002), fisetin (Khan et al. 2008), guggulsterone (Shishodia et al. 2007a), piceatannol (Lee et al. 2009), silibinin (Mateen et al. 2010), silymarin (Ramakrishnan et al. 2009), sulforaphane (Bryant et al. 2010), and quercetin (Hung 2007). In human colon cancer cells, fisetin downregulated COX-2 expression and inhibited prostaglandin E_2 secretion (Suh et al. 2009). This was accompanied by decreased activities of wint (Wnt) signaling, EGFR, and NF-κB and a concomitant suppression in cyclin-D1 expression (Suh et al. 2009). Some nutraceuticals have also been shown to suppress cancer cell proliferation by suppressing NF-κB activation and the gene products regulated by this transcription factor. Examples of such nutraceuticals are anacardic acid (Sung et al. 2008), diosgenin (Shishodia and Aggarwal 2006), isoeoxyelephantopin (Ichikawa et al. 2006), noscapine (Sung et al. 2010), pinitol (Sethi et al. 2008), and ursolic acid (Shishodia et al. 2003).

The invasion and metastasis which are the major causes of cancer-related deaths can also be suppressed by nutraceuticals. The molecular basis for the negative effects of nutraceuticals on the invasiveness of cancer cells is most likely through modulation of matrix metalloproteinases (MMPs) and inhibition of NF-κB activation. For example, resveratrol can suppress the migration and invasion of lung cancer cells (Liu et al. 2010). The suppression in invasion activity by resveratrol was accompanied by the suppressed activity of NF-κB and reduced expression of MMPs (Liu et al. 2010). Similarly, silibinin inhibited the invasion of SCC-4 tongue cancer and A459 lung cancer cells (Chu et al. 2004, Chen et al. 2006). This was accompanied by suppression in the expression of MMP-2 and u-PA and increased expression of tissue inhibitor of metalloproteinase (TIMP)-2 and plasminogen activator inhibitor-1 (PAI-1) (Chu et al. 2004, Chen et al. 2006). The invasiveness of MCF-7 breast cancer cells induced by phorbol myristate acetate (PMA) was suppressed by silibinin possibly through its inhibitory effects on MMP-9 expression (Lee et al. 2007). Other nutraceuticals known to suppress cancer cell invasion include lycopene (Huang et al. 2005), myricetin (Ko et al. 2005), piperine (Pradeep and Kuttan 2004), quercetin (Vijayababu et al. 2006), and sanguinarine (Choi et al. 2009a).

2.2 Animal Level

The anticancer potential of nutraceuticals is demonstrated in cancer-bearing rodent models. For example, curcumin inhibited the ovarian tumor growth in orthotopic mice model most likely by negatively regulating the activities of NF-κB and STAT3 pathway (Lin et al. 2007). In mice implanted with Caki-I renal carcinoma cells, caffeic acid suppressed hypoxia-inducible factor-1 (HIF-1) and VEGF expression, angiogenesis, and vascularization (Jung et al. 2007). Capsaicin abrogates skin tumor formation and NF-κB activation induced by PMA in mice (Han et al. 2001). Silibinin suppresses tumor growth in mice model implanted with human colorectal carcinoma (Singh et al. 2008). Silibinin also induced antiangiogenic activities and downregulated the expression of COX, HIF-1α, nitric oxide synthase (NOS), and VEGF in nude mice (Singh et al. 2008). Diallyl sulfide can reduce the VEGF level in the serum of mice implanted with B16F-10 melanoma cells (Thejass and Kuttan 2007). Ursolic acid also suppresses capillary formation in C57BL/6 mice implanted with melanoma cells (Kanjoormana and Kuttan 2010). Ursolic acid can also suppress the levels of nitric oxide (NO) pro-inflammatory cytokines and VEGF in the serum of tumor-bearing animals (Kanjoormana and Kuttan 2010). Sulforaphane can inhibit lung metastasis and the activation of MMPs in the mice model of melanoma (Thejass and Kuttan 2006). Vanillin suppresses tumor cell angiogenesis induced by hepatocyte growth factor in a mouse model (Lirdprapamongkol et al. 2009). The suppression in angiogenesis by vanillin was mediated through its inhibitory effects on PI3K/AKT signaling and VEGF expression (Lirdprapamongkol et al. 2009).

2.3 Clinical Potential of Nutraceuticals

The pleiotropic activities of nutraceuticals have provided a basis for examining their clinical potential for cancer prevention and treatment. The pharmacokinetics, safety, and efficacy of nutraceuticals have been demonstrated in cancer patients. Nutraceuticals are known to modulate molecular targets such as 8-hydroxy-2′ -deoxyguanosine (8-OHdG), AMPK, BCL-2-associated X protein (Bax), B-cell lymphoma 2 (Bcl-2), caspases, COX-2, glutathione (GSH), glutathione S-transferase (GST), intercellular adhesion molecule (ICAM), IGF-1, insulin-like growth factor binding protein-3 (IGFBP-3), IKKβ, interleukins, kelch-like ECH-associated protein 1 (Keap-1), pyrimido[1,2-a]-purin-10(3H)-one (M1G), MMPs, malondialdehyde (MDA), NF-κB, Notch, Nrf-2, p53, phosphorylated protein kinase strain Ak thymoma (pAkt), peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC-1α), prostaglandin E_2 (PGE_2), prostate-specific antigen (PSA), STAT3, Ras

association domain-containing family 1 alpha (Rassf-1α), sirtuin 1 (SIRT-1), TNF, vascular cell adhesion molecule 1 (VCAM-1), VEGF, and wingless/integrated (Wnt) in cancer patients (Gupta et al. 2013; Pandey et al. 2017). In the clinical trial, nutraceuticals have been used both individually and in combination. Curcumin is probably one of the extensively studied nutraceuticals in the human subjects. The promising effects of this nutraceutical have been reported in patients with bladder, breast, cervical, colorectal, liver, oral, skin, and pancreatic cancer (Hsu and Cheng 2007, Gupta et al. 2013). Curcumin's anticancer potential in cancer patients was probably first demonstrated in 1987 in a clinical trial comprising of 62 patients (Kuttan et al. 1987). The daily intake of 3.6 g curcumin for 29 days reduces inducible prostaglandin E_2 (PGE_2) production in blood samples of colorectal cancer (CRC) patients (Sharma et al. 2004). In phase II clinical trial, curcumin's potential in 25 advanced pancreatic cancer patients was evaluated. Curcumin was administered orally at 8 g per day (Dhillon et al. 2008). While limited absorption was observed, curcumin was well-tolerated and produced beneficial effects in some patients (Dhillon et al. 2008).

Resveratrol has demonstrated therapeutic potential in patients with breast cancer, multiple myeloma, and colon cancer. In one study, the effects of resveratrol on prostaglandin PGE_2 expression and DNA methylation were evaluated in 39 women with breast cancer (Rasyid and Lelo 1999). Resveratrol was administered to the patients at 5 mg and 50 mg/day for 12 weeks. The DNA methylation of cancer-related genes [adenomatous polyposis coli (APC), CCND-2, p16, RASSF-1α] was evaluated after resveratrol administration. Resveratrol was found to significantly suppress RASSF-1α methylation. Furthermore, the level of PGE_2 was also decreased in the nipple aspirate fluid of patients. These observations provide evidence for the health benefits of resveratrol against breast cancer (Rasyid and Lelo 1999). More studies involving a larger cohort of patients will further confirm the potential of resveratrol against breast cancer (Rasyid and Lelo 1999). When administered in combination with ellagic acid and quercetin, resveratrol was found safe and well tolerated in prostate cancer patients (Zuccotti et al. 2009).

Capsaicin is known to provide temporary relief in cancer patients with oral mucositis pain (Pyun et al. 2008). The topical application of capsaicin also reduces neuropathic pain in cancer patients post-surgery (Ellison et al. 1997). Ginger, the commonly used spice in the Indian kitchen, has been reported to reduce chemotherapy-associated nausea and vomiting in cancer patients (Levine et al. 2008, Pillai et al. 2011). Flavopiridol is an alkaloid obtained from the bark of *Dysoxylum binectariferum*. This alkaloid can enhance the efficacy of imatinib in hematological malignancies (Bose et al. 2012). In combination with bortezomib, flavopiridol is well tolerated and effective in patients with indolent non-Hodgkin lymphoma of relapsed/refractory multiple myeloma (Holkova et al. 2014). Flavopiridol also enhances the potency of doxorubicin in advanced sarcoma patients (Luke et al. 2012).

3 Concluding Remarks and Future Directions

Nutraceuticals have demonstrated the potential for cancer prevention and cure both by preclinical and clinical studies. The therapeutic potential of nutraceuticals against chronic diseases is based on their ability to disrupt several cancer-related cell signaling pathways. Nutraceuticals have been consumed since ancient time and thus the safety is not a concern. However, the total number of clinical studies on nutraceuticals is far less as compared to preclinical studies. Moreover, most studies are focused on killing the cancer cells. Over 90% of cancer-related deaths are because of the spread of the tumor to secondary organs. More studies are required to examine if nutraceuticals can suppress metastasis of tumor cells. How nutraceuticals discriminate between normal and cancer cells should also be thoroughly examined. Strategies are also required to enhance the bioavailability of nutraceuticals. In our opinion, more emphasis on clinical research is required so that nutraceuticals can be indicated for human and animal ailments.

Acknowledgment The support in the laboratories of Gupta (ECR/2016/000034) and Sharma (ECR/2016/001863) comes from Science and Engineering Research Board. Gupta's laboratory is also supported by University Grants Commission [No. F.30-112/2015 (BSR)]. SM is an ICMR-JRF (3/1/3/JRF-2016/LS/HRD-65-80388).

Expanding Metabolic Targets in Cancer by Select Combinations of Vitamin C and EGCG with Different Natural Compounds

Aleksandra Niedzwiecki, Bilwa Bhanap, M. Waheed Roomi, and Matthias Rath

Abstract

Worldwide, cancer is the second leading cause of death. Currently about ninety percent of cancer deaths are attributed to metastasis with no effective treatment options to control it. Current standard cancer treatments such as surgery, chemotherapy, and radiation are associated with multiple side effects. Nutraceuticals including vitamins, minerals, amino acids, and several phytochemicals derived from diet are known to have antioxidant and anticancer properties. However, individual compounds have limited anticancer efficacy as compared to their use in combinations. In this chapter, we describe the efficacy of different combinations of vitamin C and green tea polyphenol (-) epigallocatechin-3-gallate (EGCG) with other natural components and their cancer preventive mechanisms. Properly chosen micronutrient combinations can overcome the metabolic limitations of individual components and enhance the scope of their therapeutic efficacy. In this aspect, our in vitro and in vivo studies have shown that synergy-based interaction of selected micronutrients is effective in controlling key mechanisms of cancer, such as inhibition of cancer cell proliferation, invasion, metastasis, triggering apoptosis, and reducing angiogenesis, among other mechanisms. This nutrient synergy combination is safe and effective in targeting multiple mechanisms of cancer, and it should be investigated further in a clinical setting.

1 Introduction

Cancer is a generic term describing more than 125 different types of diseases that share certain common characteristics, such as uncontrolled growth of abnormal cells, invasion, and metastasis. It is the second leading cause of death in the world, and it is estimated that by 2030 over 11 million deaths per year will be attributed to cancer alone worldwide (https://www.cancer.gov/about-cancer/understanding/statistics).

Conventional cancer treatments such as surgery, chemotherapy, and radiation have a limited efficacy and are associated with several devastating side effects (Jemal et al. 2010). A comprehensive evaluation of the benefits of chemotherapy in over 22 types of cancer showed that it can increase the chance of 5-year survival by only 2.1% in the USA and 2.6% in Australia (Morgan et al. 2004). Even the newer cancer drug regimens approved by the US Food and Drug Administration between 2002 and 2014 improved overall survival by merely 2.1 months (Fojo et al. 2014; Mayor 2018).

Since many studies show that high consumption of fruits and vegetables has been associated with prevention, inhibition, and even reversal of cancers, there has been a rapidly growing trend in cancer research to investigate natural compounds (Adlercreutz 1990; Miller 1990; Amin et al. 2009).

Since 90% of cancer deaths occur secondary to metastasis, any successful anticancer treatment has to target this stage of cancer development (Mehlen and Puisieux 2006; Taketo 2011). Rath and Pauling proposed a universal approach to controlling cancer by ensuring optimal synthesis and integrity of connective tissue surrounding cancer cells and, as such, reinforcing the natural barrier curbing their spread and invasion. This process is largely dependent upon nutrients not produced in the human body, such as vitamin C and lysine (Rath and Pauling 1990; Rath and Pauling 1992). Studies following this direction have confirmed the efficacy of this approach. Among others, a study with a mouse model

R. C. Gupta et al. (eds.), *Nutraceuticals in Veterinary Medicine*, https://doi.org/10.1007/978-3-030-04624-8_42

mimicking human metabolism in respect to a lack of endogenous ascorbate synthesis (GULO-/-) demonstrated that dietary vitamin C can inhibit tumor growth and metastasis by facilitating the formation of the collagen barrier around tumors (Cha et al. 2011). This direction also led to the development of a new strategy aimed at simultaneous control of key mechanisms of cancer by using specific combinations of natural compounds and enhancing their efficacy through mutual synergy (Niedzwiecki et al. 2010).

Most published scientific research on the anticancer effects of micronutrients has been conducted using single compounds, and vitamin C was quite extensively studied in various aspects of cancer (Yun et al. 2015; Gonzalez and Miranda-Massari 2014; Cha et al. 2013). As such, many clinical studies investigated effective vitamin C dosage ranges, methods of its delivery (IV or oral intake), and other aspects (Gonzalez and Miranda-Massari 2014). However, there are not many studies focusing on enhancing vitamin C's anticancer effects by combining it with other natural compounds. In addition to vitamin C, there has been steadily increasing interest in dietary phytochemicals in the prevention and treatment of cancers (Donaldson 2004). Although some of the phytochemicals such as EGCG, curcumin, resveratrol, and quercetin have shown anticancer properties in vitro, they have not been very potent as individual compounds in in vivo anticancer studies. This might relate to their metabolism and limited bioavailability after consumption.

In our "nutrient synergy" approach to cancer, we studied different combinations of vitamin C and EGCG with several micronutrients. This pioneering research conducted for over a decade has resulted in developing nutrient combinations with pleiotropic mechanistic effects against cancer (i.e., cell growth, invasion, metastasis, angiogenesis, and apoptosis). These could be achieved with lower doses of individual compounds and, as such, maintaining cellular metabolic balance under control.

This chapter evaluates the anticancer efficacy of vitamin C and (-) epigallocatechin-3-gallate (EGCG) from green tea used in combinations with other individual nutrients, nutrient mixtures, and in synergy with select natural compounds. All of these studies provide further supportive evidence that diet-based protection against cancer may partly derive from synergy among dietary phytochemicals directed against specific molecular targets in responsive cancer cells and provide the basis to explore this principle in designing safe and effective nutrient combinations against cancer.

2 Vitamin C in Combination with Individual Natural Compounds

The majority of micronutrients studied in combination with vitamin C for their anticancer effects were antioxidants and, as such, targeted redox-related cellular mechanisms known to affect cancer cells metabolic pathways involved in cellular growth and death cycles. Experimental and human studies with antioxidant combinations in the treatment of cancer reviewed by Prasad (2004) highlighted the need for nutritional protocols, including high doses of multiple dietary antioxidants and their derivatives, in order to improve oncologic outcomes and decrease the toxicity of conventional treatments. Furthermore, clinical studies involving 8521 patients using beta-carotene; vitamins A, B, C, D_3, E, and K3; and selenium, cysteine, and glutathione as single agents or as an adjunct to radiation or chemotherapy demonstrated that these antioxidants and nutrients did not interfere with therapeutic modalities for cancer but rather increased the anticancer activity and decreased their side effects (Simone et al. 2007).

2.1 Vitamin C with Selenium

Zheng et al. (2002) investigated the effects and mechanisms of the combination of ascorbic acid and sodium selenite on growth and redifferentiation of human gastric cancer cells. They found that the combination induced the redifferentiation of human gastric cancer cells and inhibited cell growth by enhancing the antioxidant enzymes, inducing the formation of H_2O_2, and altering the cell redox status.

2.2 Vitamin C with Copper

A mixture of vitamin C and cupric sulfate administered orally significantly inhibited human mammary tumor growth in mice (Chen et al. 2015). Satoh et al. reported that cytotoxicity induced by sodium ascorbate or sodium 5,6-benzylidene-L-ascorbate and inter-nucleosomal DNA cleavage in human promyelocytic leukemic HL-60 cells were significantly enhanced by the addition of either CuCl or $CuCl_2$. In contrast, addition of either $FeCl_2$ or $FeCl_3$ inhibited the cytotoxic activity of ascorbate. Copper also stimulated gallate or caffeate-induced apoptotic cell death, whereas iron was inhibitory (Satoh and Sakagami 1997a). The apoptotic effects of sodium ascorbate in addition to other antioxidants (gallic acid, n-propyl gallate, and caffeic acid) in human promyelocytic leukemia HL-60 cells were enhanced by $CuCl_2$ or deferoxamine mesylate, an iron chelator, but were reduced by $FeCl_3$. ESR spectroscopy showed that both $CuCl_2$ and $FeCl_3$ enhanced the ascorbyl radical intensity but reduced the gallate and caffeate radical intensity. They concluded that copper and iron ions modified the cytotoxic activity of these antioxidants differently, and their radical intensity was not the sole determinant of cytotoxic activity (Satoh et al. 1997).

2.3 Vitamin C with Glutathione

To address the efficacy of high-dose intravenous ascorbic acid (AA) and intravenous glutathione (GSH), which are often co-administered to cancer patients with unclear efficacy and drug-drug interaction, Chen et al. (2011) tested the effects of AA, GSH, and their combination on cytotoxicity of ten cancer cell lines. Although all treatments (AA, GSH, and AA + GSH) improved survival rate, AA + GSH inhibited the cytotoxic effect of AA alone and failed to provide further survival benefit. Thus, the pro-oxidative anticancer mechanism of pharmacologic AA was confirmed, and the administration of GSH with AA was shown to provide no additional benefit compared with AA alone. The antagonism between ascorbate and glutathione suggests that intravenous AA and high doses of GSH should not be co-administered to cancer patients on the same day. However, the study has been rebuked by others as using an inadequate animal model (athymic mice that make their own vitamin C) and using inappropriate levels of glutathione and, therefore, having little relevance to human cancer patients (Dettman et al. 2012).

2.4 Vitamin C with Methylsulfonylmethane (MSM)

In addition to providing pain relief to cancer patients, a sulfur organic compound, methylsulfonylmethane (MSM), is considered to potentiate anticancer effects of most vitamins and other nutrients, such as vitamin C; coenzyme Q10; all B vitamins; vitamins A, D, and E; amino acids; selenium; calcium; magnesium; and many others. It has been shown that MSM improves the cellular uptake of these nutrients and can prolong lives (Mindell 1997; Ley 1998; Jacob 1983).

2.5 Vitamin C with Retinoic Acid

Retinoic acid, ascorbic acid, and vitamins D and E have been implicated in prevention of the development and progression of breast cancer. Ascorbic acid combined with retinoic acid demonstrated significantly higher inhibition of human breast cancer MCF-7 cell proliferation than did vitamin C or retinoic acid independently (75.7% compared to 20.7% and 23.3%, respectively) (Kim et al. 2006). In addition, evaluation of the gene expression profiles of the treated and untreated cells by radioactive cDNA microarray analysis revealed that 29 genes were upregulated and 38 genes were downregulated after the combination treatment (Kim et al. 2006). The nature of these genes suggests that the mechanism by which retinoid acid and ascorbic acid act synergistically in inhibiting human breast cancer cell proliferation may involve the expression of genes that induce differentiation and block cell growth, in addition to the upregulation of antioxidant enzymes and proteins involved in apoptosis, cell cycle regulation, and DNA repair by altering their gene expression.

2.6 Vitamin C with Quercetin

Quercetin as a multiple cell signaling inhibitor and vitamin C as an antioxidant with potent anticancer activity were combined to investigate their effects on oxidative stress levels in breast cancer cells. The study investigated the induction of nuclear factor erythroid 2-related factor 2 (Nrf2) at the gene and protein levels as a mediator of cellular oxidative stress. The results showed that the combination of these two compounds has a significant effect on Nrf2 genes, especially in MDA-MB231 cells which have higher expression of this factor than the MCF7 cell line and can modulate endogenous levels of oxidative stress (ROS). These aspects are important in decreasing side effects of chemotherapy and overcoming chemo drug resistance (Mostafafavi-Pour et al. 2017).

2.7 Vitamin C with Select Amino Acids and Plant Extracts

Satoh and Sakagami (1997b) investigated the effect of 20 amino acids on the radical intensity of four antioxidants, sodium L-ascorbate, sodium 5,6-benzylidene-L-ascorbate, gallic acid, and caffeic acid, using ESR spectroscopy. Results demonstrated that methionine and methional did not significantly affect the radical intensity of these antioxidants while methionine sulfoxide slightly enhanced the radical intensity of sodium ascorbate and sodium 5,6-benzylidene-L-ascorbate, but not that of gallic acid and caffeic acid. Cysteine, N-acetyl cysteine, and glutathione significantly reduced the radical intensity and cytotoxic activity of these antioxidants except for sodium 5,6-benzylidene-L-ascorbate. The other amino acids were inactive. Furthermore, the study indicates that these antioxidants induce cytotoxicity via their prooxidant action (Satoh and Sakagami 1997c).

Konno (2007) tested eight commercially available natural products for possible effects on the growth of human bladder cancer T24 cells. He found that of these products, only two mushroom extracts, GD- or PL-fractions, induced significant cell death. Furthermore, when nontoxic concentrations of the GD- or PL-fractions were combined with a nontoxic concentration of vitamin C, the combination became highly cytotoxic, resulting in >90% cell death. Maitake mushroom (GD fraction) also induced apoptosis in human prostate cancer PC-3 cells, with >95% cell death at 480 μg/ml (Fullerton

et al. 2000). The same result was obtained with a much lower concentration of GD (30–60 μg/ml) combined with 200 μM ascorbic acid (Fullerton et al. 2000). Li et al. (2010) investigated the effects of theaflavin-3-3′-digallate, a major theaflavin monomer in black tea, in combination with ascorbic acid, and ECGC, the main polyphenol in green tea, on human lung adenocarcinoma SPC-A-1 cellular viability and cell cycle. MTT assay showed that the 50% inhibitory concentrations of theaflavin-3-3′-digallate, EGCG, and ascorbic acid on SPC-A-1 cells were 4.78 μmol/L, 4.90 μmol/L, and 30.62 μmol/L, respectively. Both black tea and green tea polyphenols in combination with ascorbic acid at a molar ratio of 1:6 demonstrated synergistic inhibition of SPC-A-1 cell proliferation (54.4% and 45.5%, respectively), and significantly held SPC-A-1 cells in G_0/G_1 phase, suggesting that the combination with ascorbic acid enhances their anticancer activity (Li et al. 2010).

2.8 Vitamin C with Calcitriol

Calcitriol, the hormonal form of vitamin D_3, sensitizes breast cancer cells to reactive oxygen species (ROS)-dependent cytotoxicity induced by various anticancer modalities. Calcitriol combined with H_2O_2, which is released during IV vitamin C treatment, increased the breast cancer MCF-7 cell death rate by 78% compared to H_2O_2 alone (Weitsman et al. 2005). Some additives, however, actually inhibited the effectiveness of vitamin C. For example, vitamin C lost 95% of its cancer killing power when glutathione was co-injected, and the tumor shrinkage normally seen with vitamin C alone was inhibited (Chen et al. 2011).

2.9 Vitamin C with Vitamin K3 (Menadione)

Combinations of vitamin C with vitamin K3 have been researched as a multipronged strategy against a variety of tumor cells. The precise pathways by which interaction of these nutrients displays anticancer activities are not well established. However, it has been shown that it involves the production of reactive oxygen species (ROS) by redox cycling of vitamin C in association with K3 which may surpass the cancer cellular defense system and induce cell death. Studies have also shown that co-administration of vitamin C and vitamin K3 in a ratio 100:1, respectively, results in a necrotic type of cell death by autoschizis (Verrax et al. 2003). In addition, co-administration of these vitamins reactivated acid and alkaline DNAses inhibited in cancer cells, which was associated with inhibition of tumor growth and metastasis both in vitro and in vivo (Taper 2008).

2.10 Vitamin C with Vitamin E

A combination of vitamin E (alpha-tocopherol acetate) and vitamin C showed radioprotective and pro-apoptotic effects when administered to rats before and after exposure to Y-irradiation (Vasileva et al. 2016). A small clinical trial of vitamin C and E complex showed that short-term supplementation with these nutrients has protective effect against radiation-induced xerostomia in patients with head and neck cancer. The final follow-up showed that the vitamin intake did not affect overall and disease-free survival (Chung et al. 2016).

Overall clinical evidence of anticancer efficacy of vitamin C taken together with vitamin E has brought mixed results, with some studies showing beneficial effects and others not (Coulter et al. 2006; Gaziano et al. 2009). The differences related to the doses and sources of these nutrients used in the studies, populations tested, methods of recoding data, duration of studies, types of cancer, etc. could lead to definite conclusions.

3 Vitamin C in Combination with Multiple Nutrients

3.1 Vitamin C with Lysine, Proline, and Green Tea (EGCG)

Netke et al. investigated the effect of a specific combination of ascorbic acid (100 μM), proline (140 μM), and lysine (400 μM) on proliferation and invasive properties of several human cancer cell lines: breast (MDA-MB-231), colon (HCT116), and skin (melanoma, A2058) (Netke et al. 2003). The nutrient combination showed significant antiproliferative and anti-invasive effects against these cell lines. Addition of 20 μg/ml of EGCG to this nutrient combination further enhanced the antiproliferative effects and inhibition of matrix invasion in these cell lines. For example, Matrigel™ invasion by breast cancer cells and human melanoma cells in the presence of ascorbic acid, proline, lysine, and 20 μg/ml of EGCG was stopped completely (Netke et al. 2003).

3.2 Vitamin C with Carotenoids, Vitamin E, and Retinoic Acid

A study by Prasad et al. indicated that while natural compounds used individually at doses 50 μg/ml of vitamin C, 10 μg/ml carotenoids, 10 μg/ml of alpha-tocopherol succinate, and 7.5 μg/ml retinoic acid did not affect growth of melanoma cells, their combination reduced cell number by

56%. Increase of ascorbate level in this mixture to 100 μg/ml resulted in further reduction of melanoma growth by 87% (Prasad et al. 1994).

4 Green Tea Polyphenol (EGCG) in Combination with Other Natural Compounds

Tea and in particular the polyphenols contained in green tea have potent antioxidant and anti-inflammatory properties contributing to their anticancer and other health benefits. Green tea contains between 30 and 40% of water-extractable polyphenols, among which EGCG has been the most studied and demonstrated the greatest potential for its anticarcinogenic properties. Yet, the other components like epicatechin, epigallocatechin, and epicatechin gallate also help to enhance the actions of EGCG as a part of the green tea extract.

EGCG is important in stimulating the production of the glutathione S-transferase (GST) enzyme that plays an important role in the body's defense against cancer. However, EGCG has multifaceted action in cancer prevention and carcinogenesis. When used alone, EGCG tends to reach higher concentrations only in the digestive system, and its overall bioavailability gradually decreases due to oxidation and metabolism. As such, much less EGCG reaches the blood and other tissues, indicating that the potency of EGCG is lost during its absorption from the digestive tract. For example, in a specialized mouse model of human carcinogenesis, Shimizu et al. showed that the administration of EGCG to mice in their drinking fluid significantly decreased small intestinal tumor formation (Shimizu et al. 2008). Therefore, researchers turned to using combinations with other phytochemicals to enhance the anticancer potency of EGCG.

4.1 EGCG with Resveratrol

Resveratrol is a polyphenol present in grapes, red wine, purple grape juice, peanuts, blueberries, and cranberries. It is believed that plants produce resveratrol to protect them from bacterial and fungal infections. It has been shown that EGCG and resveratrol are important in cancer chemoprevention due to their pro-apoptotic effects (Aggarwal et al. 2004; Manson 2005). As such, in vitro studies by Ahmad et al. (2007) in prostate cancer cells (PC-3) showed that the pro-apoptotic effects of resveratrol and EGCG may be due to modulation of casein kinase 2 (CK2). CK2 is a multifunctional protein kinase involved in cell growth, proliferation, survival of cancer cells (Litchfield 2003), and inhibition of apoptosis (Guo et al. 2001). In one of the in vivo studies evaluating the combination of EGCG with resveratrol, George et al. (2011) concluded that the resveratrol and tea polyphenols act synergistically in inhibiting growth of established skin tumors when compared to any of these antioxidants used alone. As such, they observed lower numbers of tumors and also reduced tumor volume.

4.2 EGCG with Curcumin

Curcumin is the most abundant natural phenol (curcuminoid) present in the Indian curry spice, turmeric, which is obtained from the rhizomes of the *Curcuma longa* plant, and it is used extensively in South Asian cooking and food preservation. In the past few decades, curcumin has been studied for its antioxidant, anti-inflammatory, and immune modulation properties. By acting as a free radical scavenger, curcumin can prevent oxidative DNA damage, which is associated with triggering the cancer process. The anticancer properties of curcumin include various cellular mechanisms such as reduction of cancer cell growth, initiation of apoptosis, inhibition of collagen digesting MMP enzymes, and prevention of angiogenesis (Anand et al. 2008). The anticancer actions of curcumin are thought to relate to its characteristic inhibitory action observed in animal models during cancer initiation steps or in suppressing the promotion and progression various stages of carcinogenesis (Ferreira et al. 2015; Rao et al. 1995).

Studies have shown that curcumin can act in synergy with other polyphenols. For example, Khafif et al. (1998) and his team demonstrated that a combination of EGCG and curcumin inhibited growth of premalignant and malignant oral epithelial cells by different mechanisms, and a combination of these two phytochemicals allowed for reduced dose of each individual compound without compromising anticancer efficacy. Since low bioavailability of individual tea polyphenols has been a limiting factor in their anticancer action, the concomitant administration of curcumin has shown to have a synergistic effect in inhibiting growth of breast cancer cells (Somers-Edgar et al. 2008). Also, enhanced apoptotic effect of this combination was demonstrated in chronic lymphocytic leukemia (Angelo and Kurzrock 2009).

Experimental data from Saha et al. shows that epicatechin acts in synergy with EGCG and curcumin in inhibiting cancer cell growth and inducing apoptosis in lung cancer PC-9 cells (Saha et al. 2010). Also, in vivo studies conducted by Zhou et al. (2013) showed that the combination of EGCG and curcumin reduced tumor growth and tumor burden in a lung cancer xenograft in nude mice model. They also noticed that it protected mice from cancer-induced weight loss, without any adverse side effects.

While exploring the cancer stem cells model in nutraceutical chemoprevention, Chung and Vadgama (2015) showed

that EGCG combined with curcumin suppresses a breast cancer stem cells model which suggests that this approach could be used as a targeted therapy for breast cancer.

4.3 EGCG with Quercetin

Quercetin is an important phytochemical present in fruits and vegetables such as onions, apples, berries, and citrus bioflavonoids complex. It has strong antioxidant and anti-inflammatory properties. Quercetin is also essential in facilitating absorption of vitamin C and preventing its destruction in the body. As an anticancer agent, quercetin selectively inhibited cancer cell proliferation and was shown to be effective in inducing cancer cell apoptosis without harming normal cells (Hirpara et al. 2009; Jagtap et al. 2009). Inhibition of lymphoma cell proliferation by quercetin is thought to be due to arrest in G_1 phase of cell cycle (Lee et al. 2006).

When used alone, green tea has limited anticancer action because of the extensive methylation of EGCG in the body. Wang and his team demonstrated that quercetin can increase cellular uptake of EGCG and inhibit its methylation (Wang et al. 2013). These researchers used two types of prostate cancer cells—PC-3 and LNCaP—to study the effects of a combination of EGCG and quercetin. They found that although simultaneous administration of EGCG and quercetin resulted in decreased absorption of quercetin by the cells, it still led to increased apoptosis and inhibited proliferation of these cancer cells (Wang et al. 2012). Further studies of this combination in prostate cancer xenografts in mice showed that it can inhibit tumor growth by 45%, which was more than achieved with either of these nutrients alone (Wang et al. 2014b).

Focusing on prostate cancer stem cells, Tang and the team showed that EGCG used with quercetin was more potent than used alone. Such a combination decreased the self-renewal capacity of prostate cancer stem cells, inhibited migration and invasion capacity, and also induced cancer cell apoptosis (Tang et al. 2010). In vivo research and clinical evidence show that quercetin can help in increasing the levels of available green tea phenols in the blood (Kale et al. 2010a; Gawande et al. 2008). Therefore, the addition of quercetin can markedly enhance the anticancer activity of green tea extract.

4.4 EGCG with Sulforaphane

Antioxidant properties, including the ability to inhibit tumor growth, induce apoptosis, and facilitate detoxification of pro-carcinogens, are some of the mechanisms by which cruciferous/*Brassica* vegetable extracts act as chemopreventive agents. High intakes of *Brassica* vegetables have been associated with lower risk of cancers, including colon, lung, pancreatic, as well as hormone-dependent breast and prostate cancers. The active phytochemical in these vegetables is a sulfur compound called sulforaphane, which is derived from glucosinolates. Sulforaphane has potent antioxidant and anticancer activity. Studies have reported that when used alone, sulforaphane inhibits cell proliferation and induces apoptosis in leukemia cells (Suppipat et al. 2012).

In vitro studies using the EGCG and sulforaphane combination in colon cancer cells (HT-29 AP-1) showed their synergistic effects resulting in decreased cell viability and decreased cancer cell activity (Nair et al. 2008). Similarly, the EGCG and sulforaphane combination was tested in ovarian cancer cells which were sensitive to paclitaxel (SKOV3-ip1) and resistant to paclitaxel (SKOV3TR-ip2) by Chen et al. They reported that sulforaphane inhibited cell viability in both types of the ovarian cancer cells and EGCG was shown to enhance this effect. This combination also increased apoptosis by downregulating hTERT and Bcl-2 and by inducing DNA damage in paclitaxel-resistant ovarian cancer cells (Chen et al. 2013).

5 EGCG in Combinations with Multiple Nutrients

5.1 EGCG with Genistein and Quercetin

EGCG, genistein and quercetin are predominant phytoestrogens present in Asian diet. Individually they are shown to reduce the risk of several cancers including breast, prostate, and endometrial cancers. Hsieh and Wu tested the combination of these three compounds in prostate cancer (CaP) cells and noted significant synergistic effect in inhibition of cell proliferation. Similar synergistic action was also observed with this combination in enhancing the expression of tumor suppressor gene p53 and the enzyme quinone reductase type 1 which prevents p53 demethylation (Hsieh and Wu 2009).

5.2 EGCG with Phytic Acid and Inositol

Phytic acid and inositol are present in grains, beans, and legumes and have antioxidant activity. Due to their iron-binding capacity, a diet high in phytic acid may lead to iron deficiency. On the other hand, Jariwalla et al. reported that this property of phytic acid is advantageous in decreasing iron-mediated colon cancer in animals and that phytic acid inhibits cell proliferation even after stimulation by carcinogens (Jariwalla et al. 1977). Also Khatiwada et al. used a combination of EGCG, phytic acid, and inositol to

study azoxymethane-induced colon cancer tumors in male rats. According to their results, oral administration of the three components showed greatest reduction in the tumors formed. As such, rats in the control group developed 36 tumors that were significantly larger compared to 3 tumors developed in the group that received green tea, phytic acid, and inositol (Khatiwada et al. 2011).

5.3 EGCG with Resveratrol and Vitamin E

Hsieh and Wu (2008) showed that green tea extract combined with resveratrol and vitamin E isoform (gamma-tocotrienol—GT3) is effective and acts synergistically in suppressing proliferation of estrogen receptor-positive MCF-7 breast cancer cells, modulating gene expression, and increasing antioxidant activity, as compared to each of these three phytochemicals used alone. The results showed that there were approximately 33%, 50%, and 58% inhibition of cell proliferation by $>$ or $=$50 mcM EGCG, $>$ or $=$25 mcM resveratrol, and $>$ or $=$10 mcM GT3, respectively, added as single agents. When a suboptimal dose (10 mcM) of each phytochemical was used, a significant additive effect in suppression of cell proliferation was observed with the combination of resveratrol and GT3, whereas the three phytochemicals added together did not produce more pronounced inhibition of cell proliferation. However, a significant additive effect in reducing cyclin D1 and Bcl-2 expression was found when GT3 was added with either EGCG or resveratrol. Functional synergism among the three phytochemicals was only observed in the induction of quinone reductase NQO1.

5.4 EGCG with Curcumin and Arctigenin

Wang et al. (2014a) showed that a combination of EGCG with curcumin and arctigenin (anti-inflammatory lignan from seeds of *Arctium lappa*) significantly increased antiproliferative effects against breast and prostate cancer cells compared to that achieved with individual compounds. In addition, using these nutrients in a combination had additional benefits such as an increased ratio of Bax to Bcl-2 proteins and decreased activation of NFκB and other pathways involved in the cancer cells migration.

5.5 EGCG and Other Catechins with Quercetin and Sulforaphane

A combination of green tea catechins (EGCG, ECG, and CG), sulforaphane, and quercetin has been shown to be superior in inhibition of cell viability, migration, and MMP-2 and MMP-9 expression than any of the compounds used alone. Moreover, these nutrients complemented each other in inhibiting the progression of pancreatic cancer stem cells by controlling their excessive proliferation and induction of microRNA (miR-let-7), the low level of which has been associated with poor outcome for cancer patients and the inhibition of the K-ras gene (Appari et al. 2014).

5.6 EGCG with Curcumin, Resveratrol, Quercetin, and Cruciferex™

Based on the anticancer, antioxidant properties of several phytochemicals, a unique synergy-based combination was tested by Roomi et al. in multiple cancer cell lines. This phytobiological mixture (PB) includes 400 mg quercetin, 400 mg Cruciferex™ (cabbage, cauliflower, broccoli, and carrot extract), 300 mg curcumin, 50 mg resveratrol, and 300 mg standardized green tea extract.

In vitro testing of PB in head and neck squamous cell carcinoma (HNSCC) cells exhibited a significant dose-dependent toxicity (52%), complete inhibition of MMP-2 and MMP-9 enzymes, and inhibition of cell invasion through Matrigel™. The in vivo studies testing growth of tumor xenografts in nude mice showed that dietary intake of PB (0.5%w/w) inhibited HNSCC tumor growth by 67.6% (Roomi et al. 2015a).

The efficacy of this combination of nutrients in decreasing cell proliferation, inhibition of MMP-2 and MMP-9, and achieving virtually 100% inhibition of cell invasion through Matrigel™ was also confirmed in chondrosarcoma (SW-1353), fibrosarcoma (HT-1080), and melanoma cells (A-2058) (Roomi et al. 2017a, b). Another preliminary study showed that PB can inhibit cell proliferation and induce apoptosis in breast cancer cell lines MDA-MB-231 and MCF-7 (Alqarni et al. 2017).

6 Novel Approach to Cancer Through Synergistic Combination of Vitamin C with EGCG and Other Nutrients

Our research based on a multipronged strategy toward cancer led to the development of a specific nutrient combination (NM) simultaneously targeting key mechanisms of cancer. This particular combination (Table 1) includes vitamin C, EGCG, and several natural compounds aimed at protecting the integrity of the extracellular matrix as a biological barrier against cancer invasion and metastasis (Rath and Pauling 1992).

The micronutrients in this synergistically acting complex have displayed anticancer efficacy in over 50 types of human cancer cells in vitro and in vivo. Its pleiotropic effects

include, among others, inhibition of cancer cell growth, invasion and metastasis, curbing angiogenesis, and stimulation of apoptosis. Individual components of NM showed lower anticancer efficacy than its entire composition (Netke et al. 2003; Roomi et al. 2012c).

6.1 Inhibition of Tumor Growth (Xenografts)

Evaluation of effects of NM on xenografts in murine models demonstrated significant reduction in tumor size and tumor burden in several human and murine cancer cell lines. Examples are presented in Table 2.

6.2 Inhibition of Metastasis and Invasion

The effectiveness of the NM in controlling metastasis and invasive parameters has been confirmed in several studies.

6.2.1 Metastasis

The anti-metastatic efficacy of NM was tested in various mouse models using various routes of nutrient administration (i.e., diet, IP, and IV) and cell introduction, such as by intravenous, subcutaneous, and direct organ injections. The results summarized in Table 3 show strong anti-metastatic effect of this combination.

Table 1 Nutrient composition of NM

Components of NM	Concentrations in 1000 μg/ml solution
Ascorbate	900 μM
Lysine	1100 μM
Proline	1100 μM
Arginine	500 μM
N-acetyl-cysteine	250 μM
EGCG (from green tea)	150 μM
Selenium	85 μM
Copper	7 μM
Manganese	4 μM

6.2.2 Inhibition of MMPs and Cancer Cell Invasion Through Matrigel™

The inhibition of cancer cell invasion by NM can be attributed to its inhibitory effect on the secretion and activity of MMPs and uPA, the enzymes responsible for digestion of the extracellular matrix surrounding cells. It has been shown that uPA and various MMPs, notably the MMP-2 and MMP-9, are elevated in several types of human cancers that have been associated with a poor prognosis (Fingleton 2006; Mannello et al. 2005). Using gelatinase zymography, we evaluated MMP-2 and MMP-9 secretion in many human and nonhuman cancer cell lines, some of which express only MMP-2 or only MMP-9 and some express both (Roomi et al. 2010a, 2015b). We also evaluated the effects of NM on uPA and natural inhibitors of ECM proteolysis, TIMP1, and TIMP2 (Roomi et al. 2013, 2014b). Our study showed a correlation between MMPs activities and the invasive properties of cancer cells (Roomi et al. 2010b). Thus, by inhibiting the ECM proteolytic activity in several different cancer cell lines, the NM inhibits not just multiplication but also the spread of cancer. The results showed that NM had a strong inhibitory effect on MMP secretion in all cancer cell types tested without and under the PMA stimulation. Summary of the anti-invasion potential of NM on select cancer cell lines summarized in Table 4 shows that NM can completely block invasion of various types of cancer cells, but its effective concentrations differ.

6.3 Inhibition of Angiogenesis

Since growth and metastasis of all malignant tumors require an adequate blood supply, targeting inhibition of tumor-induced angiogenesis represents a promising approach in cancer therapy (Yang et al. 2017). Tumor angiogenesis involves interplay of several different factors, including

Table 2 Effect of NM-enriched diet on tumor weight and burden in select xenograft studies

Cancer cell line	Tumor growth inhibition	Tumor burden inhibition	Reference
SK-Hep-1	42% ($p = 0.09$)	36% ($p = 0.005$)	Roomi et al. (2010c)
Colon HCT-116	63% ($p = 0.0002$)	46% ($p = 0.0005$)	Roomi et al. (2005a)
Prostate PC-3	47% ($p < 0.0001$)	53% ($p = 0.0002$)	Roomi et al. (2005b)
Lung A-549	44% ($p = 0.001$)	47% ($p < 0.0001$)	Roomi et al. (2006a)
Melanoma A2058	57% ($p < 0.0001$)	31%	Roomi et al. (2006b)
Cervical HeLa	59% ($P = 0.001$)	N/A	Roomi et al. (2014c)
Head and neck squamous cell carcinoma OHSU-974	47% ($p = 0.0009$)	N/A	Roomi et al. (2012a)
Glioblastoma U-87MG	53% ($p = 0.015$)	48% ($p = 0.010$)	Roomi et al. (2016a)
Breast 4T1	50% ($p = 0.02$)	53.4% ($p =< 0.000$)	Roomi et al. (2014a)
Osteosarcoma MNNG-HOS	53% ($p = 0.0001$)	N/A	Roomi et al. (2006d)
Ovarian ES-2	59.3% (p, 0.0001)	58.7% ($p < 0.0001$)	Roomi et al. (2016b)

Table 3 Effects of NM on organ metastasis tested in different experimental designs

Cancer cell type	Route of cancer cells administration	NM delivery	Inhibition of metastasis in organs	Reference
Melanoma B16FO	Intravenous	Diet 0.5% IV IP	63% to lungs 86% to lungs 86% to lungs	Roomi et al. (2006c)
Melanoma B16FO	Intra-spleen	Diet 0.5%	55% to liver	Roomi et al. (2009)
Melanoma B16FO	Intratesticular	Diet 1%	No peritoneal metastasis in 50% animals, in others only mild compared to control	Roomi et al. (2012b)
Breast cancer 4T1	Subcutaneous	Diet 0.5%	87% to lungs (number of colonies) 60% (by lung weight) Reduced metastasis to liver and spleen	Cha et al. (2013)
Breast cancer 4T1	Orthotopic inoculation into kidney	Diet 0.5%	Reduced metastasis to lungs and spleen compared to control	Roomi et al. (2018)
Ovarian cancer A2780	Intraperitoneal injection	Diet 0.5%	Lung metastasis reduced by 100%	Roomi et al. (2017c)

Table 4 Effective doses of NM resulting in complete inhibition of cancer cell invasion through Matrigel™

Concentration of NM resulting 100% inhibition of cell invasion		
100 mg	500 mcg	1000 mcg
Breast (MBA-MB-231)	Cervical cancer (HeLa)	Bladder cancer (T-24)
Breast (MCF-7 estrogen sensitive) + estradiol	Colon (HCT 116)	Cervical cancer (DoTc2451)
Osteosarcoma (MNNG/U2OS)	Lung carcinoma (A-549)	Fibrosarcoma (HT-1080)
Testicular (NT2/DT)	Pancreas (MIA PACA-2)	Glioma (A-172)
Fanconi Anemia (FAA:P220)	Prostate (LNCaP and DU-145)	Hepatocellular carcinoma (SK-Hep-1)
	Rhabdomyosarcoma	Liposarcoma (SW-872)
	Thyroid (SW 579)	Melanoma (A2058)
	Fanconi anemia (GM13022;FA-A:PD20;)	Ovarian (SK-OV-3)
		Prostate (PC-3)
		Renal carcinoma (786-0)
		Synovial carcinoma
		Chondrosarcoma (SW1353)
		Head and neck (HNSCC)
		Tongue (SC-255)

ECM degradation and rebuilding, which has been associated with activity of MMPs and other proteolytic enzymes. Based on in vivo and in vitro models of angiogenesis, we demonstrated that anti-MMP and uPA efficacy of the NM has been associated with its anti-angiogenic properties (Roomi et al. 2005c, 2007). In addition to its effect on MMPs inhibition, the NM showed its inhibitory effects on the secretion of pro-angiogenic factors such as VEGF, IL-6, IL-8, FGF, TGF-β, and angiopoietin-2 (Roomi et al. 2007). These factors affect the endothelium directly or indirectly by activation of surrounding cells to produce other pro-angiogenic factors or modulation of receptors/receptor activities (Yoshida et al. 1997).

6.4 Pro-apoptotic Effects of NM

Pro-apoptotic effects of NM have been demonstrated in leukemia cancer cell lines showing its stimulatory effect on cancer cell cycle arrest, DNA fragmentation, and increased expression of pro-apoptotic genes (p53, Bax, P21) and inhibition of Bcl2a (Harakeh et al. 2006) (Fig. 1).

In addition, NM pro-apoptotic effects have been documented in vivo such as in cervical HeLa cell xenografts in nude female mice fed NM (Roomi et al. 2014c). The immunohistochemical staining for terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL) showed abundant apoptosis in both control and NM-treated tumors; however, more apoptosis occurred in tumors from the NM-treated group, which displayed uniform areas of homogeneous apoptotic cells with peripheral areas of non-apoptotic cells, and some apoptosis was detected in the cells of the fibrous capsule of NM-treated tumors. Control tumors showed high staining for Bcl-2, a pro-survival, anti-apoptotic protein, whereas a reduced level of Bcl-2 was detected in the NM-treated tumors. The NM-treated tumors had vast regions of Bcl-2-free cells, which were clearly nucleated with considerably less Bcl-2 expression.

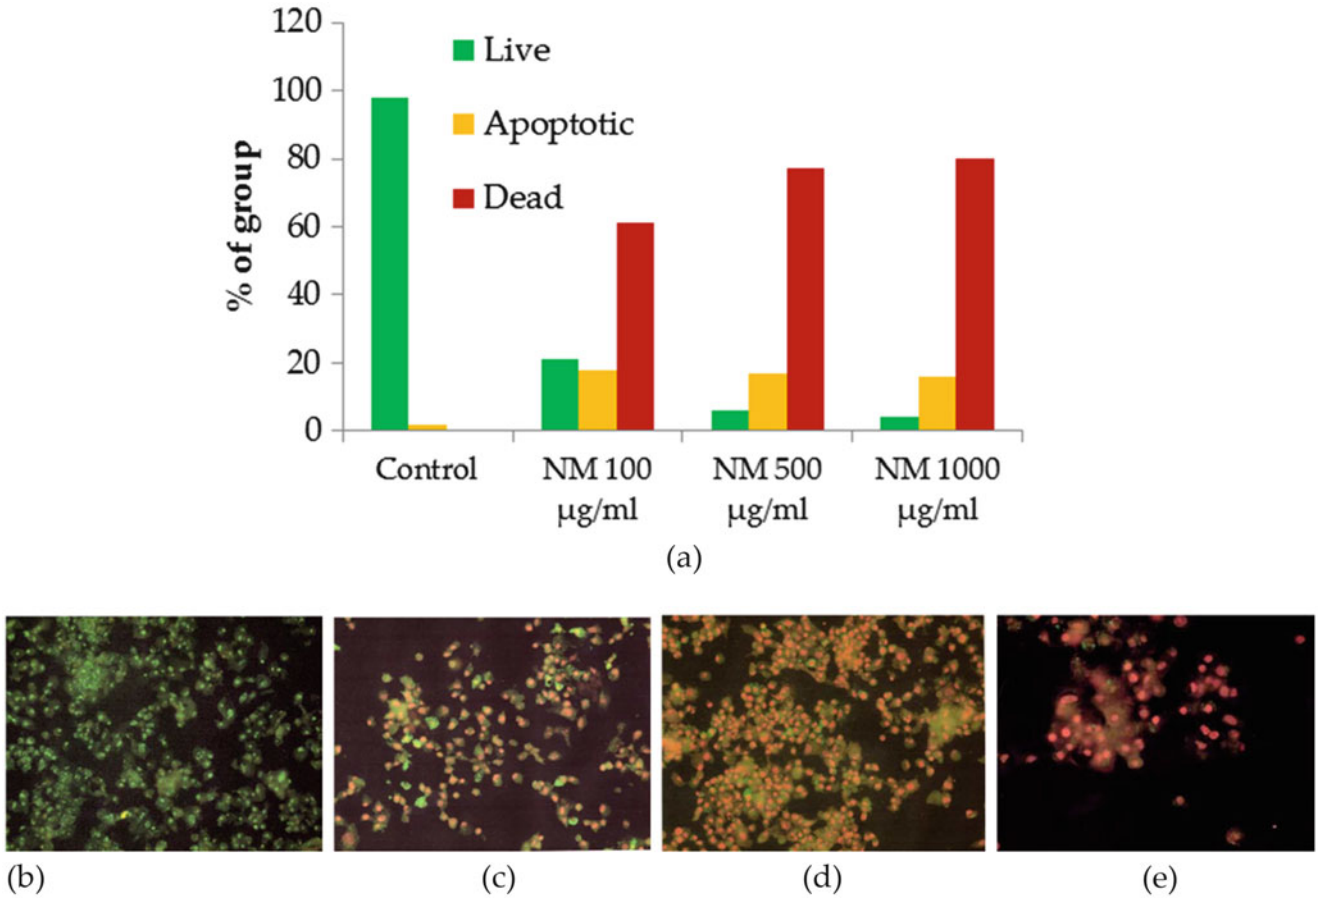

Fig. 1 Effect of NM on apoptosis of HepG2 cells—Green Poly Caspases. Quantitative analysis (**a**) and photomicrographs of HepG2 cells exposed to NM concentrations of 0 (**b**), 100 (**c**), 500 (**d**), and 1000 (**e**) µg/ml (Roomi et al. 2012c)

6.5 Anti-inflammatory Effects of NM

Inflammatory proteins such as Cox-2 contribute to carcinogenesis and promote growth of human tumors and have been found to be elevated in cancer patients (Greenhough et al. 2009; Colotta et al. 2009). We observed that Cox-2 expression in bladder cancer T-24 cells exposed to NM was reduced in a dose-dependent fashion (Roomi et al. 2010d). In addition, in vivo study of the effect of dietary NM supplementation on HeLa cell xenografts in nude female mice showed strong inhibition of the tumor growth with mean tumor weight reduced to 59% ($P = 0.001$) This was accompanied by a lower intensity of staining for Cox-2 and iNOS in tumors developed in the NM group compared to the control group (Roomi et al. 2015c).

6.6 Therapeutic Effects of NM

The therapeutic potential of a nutrient combination in NM compared to green tea extract is exemplified in the study of Kale et al. on the treatment of MNU-induced mammary tumors in Wistar rats (Kale et al. 2010b). Different micronutrient treatment regimens were provided after rats had developed palpable tumors to simulate intervention treatment approaches in clinical settings. The administration of NM resulted in markedly higher (85%) inhibition of tumor growth, compared to green tea extract alone (50%). Moreover, among tumors that developed in NM-treated mice, the majority (90%) were nonmalignant.

7 Concluding Remarks and Future Directions

Nutrients and phytochemicals have proven anticancer properties. However, individual compounds have limited efficacy as compared to select combinations of specific nutrients. Such combinations can overcome some metabolic inadequacies of individual components and through their mutual interactions enhance their therapeutic efficacy. Future research on vitamin C and EGCG in cancer should include its use in combination with other nutrients in targeting selective cancer mechanisms. Our results show that a combination of vitamin C and EGCG with select micronutrients and phytochemicals allows for expanding and simultaneously

Table 5 Experimentally confirmed anticancer effects of natural compounds synergistically combined in nutrient mixture (NM)

Process in cancer	Beneficial effects/mechanisms
Oxidative stress	Scavenging free radicals Reduced oxidative stress
Cancer cell growth and survival	Inhibition of cell proliferation Cell cycle arrest Induction of apoptosis
Tumor growth and metastasis	Inhibition of angiogenesis Inhibition of cancer cells adhesion and invasion Inhibition of proteolytic destruction of connective tissue (MMPs, uPA) Increased synthesis of proteolysis inhibitors TIMP 1 and 2, PAI1 Prevention of MMP dimers formation Tumor encapsulation Inhibition of tumor growth and burden Anti-metastatic effects
Genetic	Inhibition of oncogene expression Induction of tumor suppressor genes
Support systems	Immune system support Anti-inflammatory effects (inhibition of COX2, inducible iNOS) Prevention of chemically induced cancers
Metabolic effects	Modulation of glycolytic and epithelial mesenchymal transition (EMT) genes expression

targeting several mechanisms specific to cancer (Table 5). Moreover, unlike toxic chemotherapy and radiation treatments, the nutrient synergy combination is nontoxic. Studies using the clinically relevant doses of NM have shown a lack of adverse effects on vital organs such as the heart, liver, and kidneys.

Future studies in natural compounds should focus on expanded utilization of their cancer preventive properties through nutrient synergy. Synergistic combinations of nutrients and phytochemicals can offer a safe and effective therapeutic alternative for the current extremely toxic cancer treatments.

Acknowledgments We are grateful to Ms. Cathy Flowers for her valuable comments and edits.

Nutraceuticals for Control of Ticks, Fleas, and Other Ectoparasites

Ramesh C. Gupta, Robin B. Doss, Ajay Srivastava, Rajiv Lall, and Anita Sinha

Abstract

The ticks, fleas, mosquitoes, and other ectoparasites, in addition of being nuisance, transmit infectious diseases in companion and livestock animals and wildlife. The use of ectoparasiticides on companion and farm animals appears to be inevitable. Currently, synthetic insecticides of various classes are used to combat ectoparasites on animals. Some of the synthetic insecticides are used as ovicides or larvicides, while others are used as adulticides. But due to their greater toxicity, lack of selective toxicity, and pesticide resistance in insects, their use has been on decline. During the past two decades, the quest for natural products as an alternative to synthetic pesticides has been recognized. This chapter describes some biopesticides which can be used to control ectoparasites in pets and farm animals.

Keywords

Nutraceuticals · Biopesticides · Ectoparasites · Ectoparasiticides · Ovicides · Larvicides · Adulticides

1 Introduction

The blood-sucking ticks, fleas, mosquitoes, biting flies, and other ectoparasites commonly infest pets, livestock, and wildlife. These ectoparasites pose a serious global health concern as they transmit infectious diseases and in some cases cause atopic dermatitis. Therefore, the use of ectoparasiticides on companion and farm animals appears to be inevitable. Currently, synthetic insecticides of various classes are used to combat ectoparasites on animals (Gupta 2006; Marrs, 2012; Marrs and Dewhurst 2012). Some of the synthetic insecticides are used as ovicides or larvicides, while others are used as adulticides. Currently, commonly used ectoparasitic products on pets include Frontline, Advantage, Revolution, Certifect, Activyl, Parastar Plus, Bio Spot Defense, VetGuard, Vectra-3D, and Seresto. These products can have an individual or multiple insecticides (fipronil, imidacloprid, selamectin, amitraz, etofenprox, indoxacarb, dinotefuran, permethrin, cyphenothrin, or spinosad). Some of these products also have piperonyl butoxide to synergize the effect of pyrethrin/pyrethroid and s-methoprene as larvicide.

Currently, the most widely used synthetic insect repellent chemicals are dimethyl phthalate (DMP), N,N-diethyl-m-toluamide (DEET), and picaridin. DEET is recommended by the American Academy of Pediatrics (AAP), the EPA and the CDC for its insect-repellent properties. These chemicals are effective against mosquitoes and other biting insects, but they are known to produce adverse effects, such as contact dermatitis, toxic encephalopathy in children, and skin eruptions (reviewed in Kim et al. 2005; Kitchen et al. 2009).

Due to greater toxicity, lack of selective toxicity, development of insect resistance to synthetic insecticides, and rising costs (WHO 1992; Gupta 2006; Bissinger and Roe 2010; Nicoletti et al. 2016a, b; Lin 2015; Mougabure-Cueto and Picollo 2015), their use has been declining. During the past two decades, the quest for natural products as an ecological alternative that replaces synthetic pesticides has been recognized as a necessity (Berenbaum 1989; Castillo et al. 1998; Purohit et al. 2011; Wink 2012). The botanical pesticides have been used for at least 2000 years in Asia and Middle East (Thacker 2002; Isman and Machial 2006). By now, thousands of plants have been tested for insect repellency and insecticidal effects. Intense research efforts are underway to find plant extracts and phytotoxicants that have repellent, larvicidal, and adulticidal effects against ticks,

fleas, lice, flies, mosquitoes, and other ectoparasites. The inhibition of enzymes, such as acetylcholinesterase (AChE), butyrylcholinesterase (BuChE), tyrosinase, α-amylase, endonucleases, cellulase, and others, is used for insect control, altering the central nervous system (CNS), and growth (Sami 2014; Sami et al. 2016; Pulido et al. 2017). Some plant extracts or phytochemicals may also exhibit appetite suppression, reduction of reproductive activity, or direct toxicity in predatory insects (D'Incao et al. 2013). Interestingly, Weldon et al. (2011) also reported that some topically applied natural compounds (present in citrus peel) and monoterpenes, including geraniol, citronellol, citral, carveol, geranyl acetate, α-terpineol, citronellyl acetate, and carvone, are converted into more potent arthropod deterrents when oxidized on the integument of anointed animals.

In developing countries, plant extracts are commonly used to repel or kill ticks, flies, and other ectoparasites. For example, 28 plants from Ethiopia showed promising repellency activities against adult *Rhipicephalus pulchellus* ticks, with *Calpurnia aurea* displaying the highest toxicity toward the ticks (Zoroloni 2007). Currently, in the USA and Europe also, the use of biopesticides is becoming popular (Jaenson et al. 2006; Garboui 2008). This chapter describes some biopesticides which can be used to control ectoparasites in pets and farm animals. A partial list of biopesticides is given in Table 1.

2 Nutraceuticals for Control of Ticks, Fleas, and Other Ectoparasites

2.1 Neem Extract

Neem tree is native to Indian subcontinent, Australia, Africa, and Central and South America. Neem tree extract has been found to exert antidiabetic, antioxidant, anti-inflammatory, immunostimulant, antitumor, antimicrobial (antibacterial, antiviral, and antifungal), antiparasitic (insecticidal and anthelmintic), skin diseases, fever, hepatoprotective, anti-snake venom, and spermicidal activities (Kumar and Navaratnam 2013; Kumar et al. 2016). Ancient Indian texts call it "the curer of all ailments." The National Academy of Sciences published a report in 1992 entitled "Neem: A tree for solving global problems" (NAS 1992). In 2012, the United Nations declared the neem tree as the "Tree of the Twenty-First Century."

The importance of neem products to control arthropods, especially of medical and veterinary significance, has been recognized for more than half-a-century (WHO 1981; Vietmeyer 1992; Kumar and Navaratnam 2013: Nicoletti et al. 2016a, b; Benelli et al. 2015, 2016). Neem products exhibit a wide range of effects including antifeedancy (Tianyun and Mulla 1998; Lucantoni et al. 2006), ovicidal (Tianyun and Mulla 1998; Abdel-Ghaffar et al. 2012), larvicidal (Sinniah et al. 1994; Ziba 1995; Howard et al. 2011; Nicoletti et al. 2012), fecundity suppression (Tianyun and Mulla 1998), insect growth regulation (Mordue and Blackwell 1993; Mordue and Nisbet 2000), and repellency (Sharma and Dhiman 1993; Sharma et al. 1993; Singh et al. 1996). Simmonds et al. (2004) compared antifeedant and insecticidal activity of nimbin and salannin photooxidation products with neem limonoids. Chemical structure of azadirachtin A is shown in Fig. 1.

In a series of publications, Sami and co-workers (Sami and Akhtar 1993; Sami and Shakoori 2007; Sami 2014; Sami et al. 2016) have shown that neem phytoconstituents may produce insecticidal effect by targeting multiple molecules, such as alpha-amylase, acetylcholinesterase, endonucleases, cellulase, and others. Neem extracts have hormones that mimic and interfere with the life cycle of parasites, inhibit their ability to feed, and prevent the eggs from hatching. Abdel-Ghaffar et al. (2012) found a single treatment of head lice with a neem seed extract highly effective.

Different parts (roots, bark, leaves, fruits, and seeds) of neem tree may contain up to 300 phytochemicals. Recently, Benelli et al. (2016) reported that neem oil formulations usually show a range of different azadirachtins amounts, ranging from 1000 to 4000 mg/kg. Insecticidal activity of neem extract and its phytoconstituents is reported in about 100 published papers. Insect growth regulatory activity of neem-borne molecules weakens the cuticle defense system of the young instars causing easy penetration of pathogenic organisms. Emulsified formulations of neem oil showed an excellent larvicidal potential against different mosquito genera, including *Aedes*, *Anopheles*, and *Culex* (reviewed in Benelli et al. 2016). Mosquitocidal activity has been demonstrated for volatile organosulfur compounds from neem seeds (di-n-propyl-disulfide, $LC_{50} = 66$ ppm against third instar larvae of *Aedes aegypti*) (Balandrin et al. 1988).

The use of neem oil as an insecticide, as insect repellent, and in antifeedant activities has been approved by the US EPA (2012). The two most commonly used insecticides are NeemAzal and Fortune AZA, and both are extracts from neem seed kernels. Mosquitocidal effect of neem kernel oil appears to be due to azadirachtin A, salannin, nimbin, and nimbolid (Nicoletti et al. 2012, 2016a, b). Benelli et al. (2013, 2015, 2016) further emphasized that several minor constituents of neem are able to synergize the insecticidal effect of major constituents. Currently, in the USA and other countries, dozens of neem oil-based biopesticides are available on the market. But in the EU community, there is only one product that is margosa extract, which is derived from the extraction with supercritical CO_2 of neem kernels. Bark and roots of a neem tree appear to be excellent sources of bioinsecticides for the control of ectoparasites like fleas and ticks.

It has been suggested that unlike synthetic insecticides, the neem products are less likely to induce insect resistance

Table 1 List of plants with insect repellent and/or insecticidal property

Source	Biopesticide	Bioactivity	References
Allium sativum, *A. Ursinum*, *A. porrum*, *A. cepa* (garlic and onion)	Organosulfur compounds, allicin, and ajoene	Insect repellent effect, insecticidal, tickicide, trypanothione reductase inhibitory, trypanocidal, leishmanicidal, and antioxidative	Nchu (2004), Weiner et al. (2009), McGaw and Eloff (2010), Singh and Singh (2010), Goncharov et al. (2016), Krstin et al. (2018a, b)
Aristeguietia glutinosa	Two labdane diterpenoids	Anti-*Trypanosoma cruzi*	Varela et al. (2012, 2014)
Azadirachta indica (neem tree)	Azadirachtin A, di-n-propyl-disulfide, meliacin, meliacinol, meliatetraolenol, sesquiterpene, salannin, nimbin, and nimbolid	Ovicidal, larvicidal, mosquitocidal, antioxidative, anti-inflammatory, immunostimulant, spermicidal, antibacterial, antiviral, antifungal, and insect repellent	Mulla and Tianyun (1999), Okumu et al. (2007), Kumar and Navaratnam (2013), Benelli et al. (2015, 2016), Kumar et al. (2016), Nicoletti et al. (2016a, b)
BioUD®	2-Undecanone derived from wild tomato plants	Insect repellent	Bissinger et al. (2009)
Calpurnia aurea	–	Tick repellent	Zoroloni (2007)
Castor bean leaf	Trypsin inhibitors	Larvicidal and insecticidal	Rossi et al. (2012)
Cymbopogon nardus, *C. winterianus* (citronella)	Citronella, citronellal, 1,8-cineol, Z-citral, α- citral, and α-pinene	Insect repellent	Ansari and Razdan (1995), Kim et al. (2005), Sakulku et al. (2009), Goodyer et al. (2010), Miro Specos et al. (2010), Maia and Moore (2011)
Eucalyptus globoidea	Globoidnan A	Tick repellent	Mkolo (2008)
Eucalyptus citriodora, *E. globulus* (lemon eucalyptus oil)	*P*-Methane-3,8-diol	Repels mosquitoes, biting flies, and gnats	Trigg (1996), Barasa et al. (2002), Carroll and Loye (2006), and Maia and Moore (2011)
Eugenia caryophyllata (clove oil)	Sesquiterpenes, eugenol, thymol, carvacrol, cinnamaldehyde	Mosquito repellent, insect repellent, acaricidal, ovicidal, larvicidal, antimicrobial, antiviral, antifungal, antioxidative, and anti-inflammatory	El-Hag et al. (1999), Kim et al. (2003), Yang et al. (2003), Jirovetz et al. (2006), Chaieb et al. (2007), Shapiro (2012)
Pelargonium graveolens (geranium oil)	(-)-10-Epi-γ-eudesmol, citronellol, linalool, geraniol, isomenthone, geranyl formate, β-caryophyllene, germacrene D, etc.	Insect repellent, tick repellent	Tabanca et al. (2013)
Lavandula angustifolia (lavender)	Linalool, linalyl acetate, 1,8-cineole, camphor, β-pinene, and terpinene-4-ol	Tick repellent, mosquito repellent, insecticidal	Mkolo (2008), Attia et al. (2016)
Lippia javanica	–	Anti-tick	Nchu (2004)
D-Limonene	D-Limonene	Insecticidal, antioxidative, anti-inflammatory, antibacterial, and antifungal	Sun (2007), Kim et al. (2013), D-Limonene (2017)
Melia azedarach L. (chinaberry tree)	Triterpenes, limonoids, melianol, melianone, vanillin, and vanillic acid	Anti-*Triatoma infestans*, insecticidal, repellency, and antifeedant	Han et al. (1991), Carpinella et al. (2003), Szewczuk et al. (2003), Dadé et al. (2018)
Mentha piperita (peppermint)		Larvicidal, insecticidal, repellent, growth, and reproduction inhibition	Ansari et al. (1999), Kumar et al (2011)
Pinus longifolia (pine oil)	Eugenol, isoeugenol, eugenyl acetate, K-terpineol, K-pinene, B-pinene, cineol, camphor, and caryophyllene	Mosquito repellent and larvicidal (only at high concentration)	Ansari et al. (2005)
Roldana barba-johannis	Sargachromenol, sargahydroquinoic acid, and sargaquinoic acid	Insect growth inhibitory	Céspedes et al. (2004)
Senna italica ssp. *arachoides*	–	Acaricidal effect, tickicide, antifeedant	Thembo (2006)
Tagetes minuta (marigold oil)	Terpene (ocimenone)	Anti-tick, mosquito-larvicidal	Green et al. (1991)
Tanacetum vulgare L.	α-Pinene, β-pinene, pinocamphone, 1,8-cineole, α-thujone, β-thujone, verbenol, and verbenone	Tick repellent	Pålsson et al. (2008)
Thymus vulgaris Thymol	α-Terpinene, carvacrol, thymol, *p*-cymene, linalool, and geraniol	Insect repellent and insecticidal	Reviewed in Maia and Moore (2011)

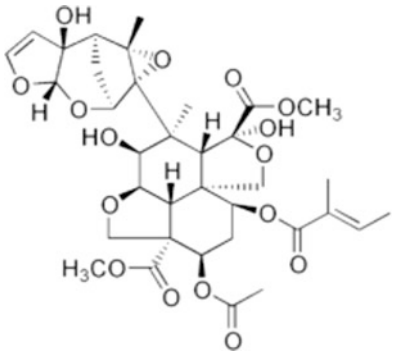

Fig. 1 Chemical structure of azadirachtin A

due to their multiple modes of action (Mulla and Tianyun 1999).

2.2 *Melia azedarach* L.

Melia azedarach L. (also called chinaberry tree) is originated from the Himalaya's region in India. Its phytochemical constituents include triterpene limonoids, melianol, melianone, meliandiol, vanillin, and vanillic acid (Han et al. 1991). Acetonic extract of *M. azedarach* has been demonstrated to exert insecticidal and repellent activities against *Triatoma infestans* (kissing bug) (Dadé et al. 2018), a vector for *Trypanosoma cruzi*, a monoprotozoan parasite responsible for Chagas disease transmission in humans and dogs. In addition to antiparasitic (Valladares et al. 1999), extracts prepared from *Melia azedarach* L. have antibacterial, antiviral, antifungal, and antioxidant properties.

2.3 *Senna italica* ssp. *arachoides*

Thembo (2006) demonstrated that *Senna italica* ssp. *arachoides* ethyl acetate extracts had a concentration-dependent acaricidal effect on *Hyalomma marginatum rufipes*. When *S. italica* ssp. *arachoides* aqueous extracts were fed to guinea pigs and rabbits, the feeding performance of adult *H. m. rufipes* ticks appeared to be impaired.

2.4 Garlic and Onion

The benefits of garlic (*Allium sativum*) and onion (*Allium cepa*) bulbs in health and diseases (including parasitic diseases) have been recognized since ancient times. Chemical analysis of the extracts of these two plants has revealed the presence of several sulfur secondary metabolites (allicin, ajoene, and others) and one (zwiebelane) in the onion (Singh and Singh 2010; Goncharov et al. 2016; Krstin et al. 2018a, b).

Garlic extract has been found to be effective against a host of protozoa, including *Opalina ranarum*, *Balantidium entozoon*, *Entamoeba histolytica*, *Trypanosoma*, *Leishmania*, *Leptomonas*, and *Crithidia* (Greenstock and Larrea 1972: Saleheen et al. 2004; Wabwoba et al. 2010; Sadeghi-Nejad and Saki 2014; Goncharov et al. 2016). Nchu (2004) analyzed the repellent effects of extracts of *Allium species*, as well as the direct toxicity, against adults of *Hyalomma marginatum rufipes*. Findings revealed that acetone extracts of *A. porrum* exhibited high repellency index (65–79.48%) and the dichloromethane extract of *A. sativum* was toxic to 100% of ticks within an hour of exposure.

Recently, Krstin et al. (2018a) evaluated antiparasitic activities of garlic and onion against *Trypanosoma brucei brucei* and *Leishmania tarentolae*. Both garlic and onion extracts inhibited the growth of trypanosomes and leishmanias and killed parasites efficiently. The extracts inhibited trypanothione reductase activity irreversibly in *Trypanosoma brucei* through disulfide bond formation between SH groups of vital redox compounds and sulfur-containing secondary metabolites. Krstin et al. (2018b) reported that dichloromethane extracts from *Allium ursinum* and *Tulbaghia violacea* are capable of inhibiting trypanothione reductase and consequently mediate a growth inhibition of the parasites. The mechanism for antiparasitic activity of garlic and onion appears to be related to the amount and the profile of sulfur-containing compounds. Garlic extract was found to be five times more potent than onion extract for trypanocidal effect due to abundance of organosulfur compounds (especially ajoene) and inhibition of trypanothione reductase activity. These authors and others confirmed the hypothesis that the sulfur-containing compounds produced in the alliinase pathway, such as in garlic and onion, are responsible for the antiparasitic activity (Weiner et al. 2009: Krstin et al. 2018a, b). It needs to be pointed out that the garlic extract also decreased the mitochondrial membrane potential significantly in a dose-dependent manner in trypanosomes (Krstin et al. 2018a) and may lead to apoptosis in protozoa (Ly et al. 2003). It has been reported that the combination of garlic and onion with common trypanocidal and leishmanicidal drugs resulted in a synergistic or additive effect to enhance antiparasitic activity (Krstin et al. 2018a).

2.5 Citronella and Citronellal

Oil of citronella is obtained from a perennial grass *Cymbopogon nardus* or *Citronella winterianus*. It has been used as an insect repellent since 1948. Citronella oil has many phytoconstituents (such as 1,8-cineol, citronellal, Z- and

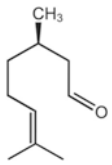

Fig. 2 Chemical structure of citronellal (main component in citronella oil)

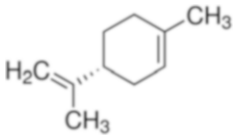

Fig. 3 Structural formula of D-limonene

α-citral, and α-pinene), but citronellal or rhodinal (3,7-dimethyloct-6-en-1-al), which is a monoterpenoid, is the main compound that gives a distinctive aroma for insect repellency. Chemical structure of citronellal is shown in Fig. 2.

Kim et al. (2005) evaluated the actual repellent efficacy of two natural compounds (citronella and citronellal) in vitro and in the field against *Culex pipiens pallens*. Percentage repellency of the three controlled bands (impregnated with 30% citronella extract, 15% citronella extract, and 30% citronellal extract) were calculated at 86%, 73%, and 78%, respectively, in vitro, and 80% on the band impregnated with 30% citronella extract in field. It appears that these two natural aroma chemicals have high repellent efficacy against mosquitoes, fleas, ticks, and other insect vectors. Currently, citronella is one of the most widely used natural repellents on the market used at a concentration of 5–10% (Maia and Moore 2011). Repellent effect of citronella has been reported to be prolonged by delayed release rate using nanoformulation (Sakulku et al. 2009) or microencapsulation (Miro Specos et al. 2010).

As insect repellent, citronellal is commercially available in lemon balm, and citronella is available in sprays, candles, lotions, gels, and towelette wipes. Neither citronella nor citronellal in citronella oil has insecticidal activity. When used according to the label, citronella products are not expected to cause harm to pets, humans, or the environment. Based on laboratory animal studies, oil of citronella poses minimal or no risks to wildlife.

2.6 D-Limonene

D-Limonene (1-methyl-4-(1-methylethenyl) cyclohexane) is a monocyclic monoterpene, and it is obtained from citrus fruit (lemon and orange) peels. Structural formula of D-limonene is shown in Fig. 3.

D-Limonene is commonly used as fragrance in perfumery, aftershave lotions, bath products, personal care products, dietary supplements, chemoprevention, and botanical insecticides (D-Limonene 2017). It exerts antioxidative, anti-inflammatory, antibacterial, and antifungal properties. Additionally, D-limonene increases peristalsis. D-Limonene is listed in the Code of Federal Regulations as generally recognized as safe (GRAS) for a flavoring agent. Currently, a number of D-limonene-containing products as shampoo, soaps, etc. are available as ectoparasiticides for dogs and cats.

D-Limonene is considered to have a fairly low toxicity. The oral LD_{50} for D-limonene in male and female mice is reported to be 5.6 and 6.6 g/kg body wt, respectively, while LD_{50} in male and female rats is reported to be 4.4 and 5.1 g/kg body wt, respectively (Sun 2007). In 1990, the National Toxicology Program (NTP) investigated the toxicity of D-limonene (>99% pure) at doses ranging from 413 to 6600 mg/kg daily administered to rats and mice 5 days/week for 3 weeks. No signs of compound-related toxicity were noted at doses <1650 mg/kg daily. D-Limonene does not pose a mutagenic, carcinogenic, or nephrotoxic risk to humans. D-Limonene applied to the skin may cause irritation, but otherwise appears to be safe for use (Kim et al. 2013).

2.7 Lavender Oil

Lavender oil is an essential oil obtained from *Lavandula angustifolia*. Phytochemical analysis of *Lavandula angustifolia* by GC/MS revealed the presence of linalool (38.57%), followed by linalyl acetate (29.95%), 1,8-cineole (13.66%), camphor (13.13%), β-pinene (3.14%), and terpinene-4-ol (1.54%) (Attia et al. 2016). It has been used in aromatherapy and as insect (mosquitoes, fleas, flies, and other biting insects) repellent for many centuries. Lavender oil exerts analgesic, insecticidal, antiseptic, and calming properties. These properties of lavender are suitable in both preventing insect bites and soothing insect bites and stings. Lavender oil is used to prevent the spread of infection caused by a bug bite and control the itching and inflammation often associated with bug bites. Lavender-containing products are often available in the form of skin lotion, soap, and shampoo. Lavender oil (5%) has been used to treat skin irritation caused by mites laying eggs under the skin and scabies. In case of inflammation caused by mosquito bite, apply a cold compress and the mixture of lavender and tea tree oil, 1–2 drops every hour or until the inflammation subsides.

If lavender oil causes skin irritation at the site of application, then consider mixing it with olive oil (50:50). In high doses, ingestion of lavender oil may cause endocrine disruption by inhibiting the effects of androgen and mimicking the actions of estrogen, thereby producing gynecomastia.

2.8 Peppermint Oil

Peppermint oil is obtained from *Mentha piperita*. Peppermint has natural insect repellent and larvicidal properties (Ansari et al. 1999). In case of mosquito bite itch, the

mixture of peppermint oil (10 drops) and tea tree oil (10 drops) in a carrier oil can relieve the discomfort by soothing and healing effect.

2.9 Pine Oil

Pine oil is obtained from *Pinus longifolia*. Pine has several phytochemicals, including eugenol, isoeugenol, eugenyl acetate, K-terpineol, caryophyllene, K-pinene, B-pinene, B cineole, and camphor (Ansari et al. 2005). Ansari et al. (2005) found that pine oil showed strong repellent action against *An. culicifacies* (malaria vector) and *Cx. quinquefasciatus* (pest mosquito), but larvicidal effect was observed only at very higher doses.

2.10 Lemon Eucalyptus (*Eucalyptus citriodora*) Oil

Eucalyptus citriodora is a lemon-scented gum tree. Eucalyptus oil (an essential oil) is extracted from the leaves and consists of several phytoconstituents, including *p*-methane-3,8-diol and eucamol (Barasa et al. 2002; Maia and Moore 2011). The oil protects the skin from mosquitoes, ticks, and other biting insects, and the effect lasts for several hours. Like citronella, eucalyptus oil needs to be applied regularly to maintain skin protection. Trigg (1996) evaluated eucalyptus-derived insect repellent (PMD), having *p*-methane-3,8-diol as an active ingredient, and compared its repellent effect against DEET. The eucalyptus-based products provided complete protection from insect biting for 6–7.75 h and found to be as effective as DEET. Another product, Mosi-guard Natural (MASTA, London, UK), comprising *p*-methane-3,8-diol and isopulegol and citronella, is available on the market as insect repellent (Carroll and Loye 2006). Insect repellent products derived from eucalyptus are available in the form of spray or lotion.

In laboratory animals, p-methane-3,8-diol showed no adverse effects, except eye irritation. These products pose minimal or no risks to wildlife or the environment.

2.11 Soybean Oil

Soybean oil is an active ingredient in a commercial insect repellent product BiteBlocker™, which has been on the market since 2001. In an experimental study, Campbell and Gries (2012) reported that soybean oil exhibited no repellent effect against *Aedes aegypti* L.

2.12 Cedar Oil

Cedar oil is commonly sprayed (misting) on pet's skin to protect from ectoparasites. Cedar oil kills ticks, fleas, flies, mites, mosquitoes, gnats, chiggers, and other biting insects. It also works as an insect repellent. Cedar oil has lasting parasiticidal and repellent effect and leaves anti-itch healing and a cedar scent on the pet's skin. It is safe to use on puppies and kittens as well. Cedar oil spray can be used on carpet against fleas and ticks. The oil dissolves eggs and larvae and impairs breathing of insects by blocking breathing pores.

2.13 Geranium Oil

Geranium oil is obtained from the leaves and stalks of the *Pelargonium capitatum* or *P. graveolens*. It contains many phytoconstituents, including (-)-10-epi-γ-eudesmol, citronellol, linalool, geraniol, isomenthone, geranyl formate, β-caryophyllene, germacrene D, etc. (Tabanca et al. 2013). Tick repellency is mainly due to (-)-10-epi-γ-eudesmol. It is recommended that to protect dog's skin, mix 20 drops of geranium oil in 3 tablespoons of almond oil, and apply 3–4 drops to sections of the dog's fur, especially the collar area. Using almond oil as a carrier enhances the solution's effectiveness since ticks hate the sulfur odor. Geranium oil may not be safe for cats.

2.14 Clove Oil

Clove oil is extracted from *Eugenia caryophyllata* and consists of several phytoconstituents, including sesquiterpenes, eugenol, thymol, carvacrol, and cinnamaldehyde (Zheng et al. 1992; Jirovetz et al. 2006; Chaieb et al. 2007). Clove oil is reported to repel mosquitoes, ticks, mites, and other biting insects (Kim et al. 2003; Shapiro 2012). Additionally, clove oil exerts an ovicidal and larvicidal effect against *Culex pipiens* and *Pediculus capitis* (Yang et al. 2003) and ticks and mites (El-Hag et al. 1999). The compound eugenol appears to be responsible for insect repellency as well as for acaricidal activity toward *Dermatophagoides farinae* and *D. pteronyssinus* (Perrucci et al. 1995; Kim et al. 2003), in addition to antioxidative, anti-inflammatory, analgesic, and antibacterial activities (Jirovetz et al. 2006; Chaieb et al. 2007). Clove oils should be used on pets with caution, as an overdose may result in toxicity. The clinical signs may include salivation, vomiting, seizure, muscle tremors, and even death. Like humans, animals taking NSAIDs, blood thinners, or medication for diabetes, or cardiac conditions, should not be treated with clove oil. It is noteworthy that dogs and cats can have a much more intense reaction to clove oil than humans.

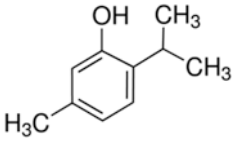

Fig. 4 Structural formula of thymol

2.15 Thyme Oil

Thyme oil is extracted from *Thymus vulgaris*. It contains many phytoconstituents, including α-terpinene, carvacrol, thymol, *p*-cymene, linalool, and geraniol (Maia and Moore 2011). The structural formula of thymol is shown in Fig. 4.

Thymol exhibits insect repellent and insecticidal effects. Mechanism of action of thymol in insects is not well understood. It is suggested that thymol acts upon the neuronal synapses by blocking the production of a neurotransmitter acetylcholine. In *Drosophila melanogaster*, thymol exerts insecticidal effect by binding to GABA receptors and inhibiting the enzyme activity of cytochrome P450 and glutathione-S-transferase. Frequent use of thymol on pets may be needed, as it breaks down by photooxidation. In farm animals, the use of thymol appears to be impractical as they face the sun most of the day. Due to its short life, thymol leaves no residue in food, milk, or meat. Thymol on pets should be used with a caution, as it may be a skin and eye irritant and may cause skin sensitization. Overall, thymol is considered to be safe, as its oral LD_{50} is reported to be 980 mg/kg and dermal LD_{50} >2000 mg/kg body wt in rats.

3 Concluding Remarks and Future Directions

Many blood-sucking ectoparasites bite or sting at human and animal skin; cause inflammation, allergies, and dermatitis; and transmit deadly diseases. Various plant products are available that exert ovicidal, larvicidal, adulticidal, and repellent effects against ticks, fleas, mosquitoes, and other biting ectoparasites via multiple mechanisms. These biopesticides are (1) easily available, (2) are inexpensive, (3) are rapidly biodegradable, (4) leave no insecticide residue in the food/feed, and (5) offer greater safety to nontarget species. Additionally, there is no development of insect resistance to these biopesticides. Some important plant extracts that are commonly used or have potential for ectoparasiticidal or insect repellent effects are discussed in this chapter. The quest for new biopesticides and repellents with greater efficacy and safety will continue.

Acknowledgments The authors would like to thank Ms. Robin B. Doss for her technical assistance in the preparation of this chapter.

Nutraceuticals in Specific Animal Species

Nutraceuticals in Cattle Health and Diseases

Begüm Yurdakok-Dikmen and Ayhan Filazi

Abstract

As a result of growing consumer demand for "clean, green, and ethical" products related to public awareness of environmental and health risks of veterinary medicinal products—and the increase in antimicrobial resistance, leading to loss of effectiveness—beef and dairy producers are striving to find effective alternatives. Nutraceuticals provide a valuable tool for prevention and control of diseases in ruminants through their antioxidant, anti-inflammatory, and antimicrobial effects. Nutraceuticals with beneficial effects on the rumen microbiota contribute to increases in productivity and profitability, since the rumen plays an important role in the immune system and nutrition. The beneficial effects are not restricted to cattle health but also impact the environment as a result of their positive impacts on methane emissions. These compounds also have the potential to increase the "healthy fats" in the final products, which are favored for human health. Therefore, nutraceuticals (including probiotics, prebiotics, and synbiotics), dietary lipids, proteins and peptides (including antimicrobial peptides), algae (macroalgae and microalgae), and phytonutraceuticals (tannins, saponins, and essential oils) are valuable tools in cattle health and disease. Meanwhile, many factors affect the efficacy of nutraceuticals, including the source, production technique, and concentration of the compound, along with the physical condition, diet, species, and rumen pH of the animal. To achieve the maximum benefits of nutraceuticals, more studies should be performed to assess their efficacy and toxicity in different ruminant species with different physiological conditions.

1 Introduction

Use of nutraceuticals has received increasing attention for the improvement of animal health, welfare, and productivity in herd health management. For both beef and dairy herd management, preventive medicine is the milestone in the control of risks related to diseases. Preventive medicine requires a well-planned and comprehensive approach. Risk assessment within the locality, disease management plans, vaccination, and biosecurity increase direct costs but are critical for production and efficacy. Avoidance of diseases through immediate accurate diagnosis and early treatment is directly linked to the health of the immune system, where nutrition plays a pivotal role (Ingvartsen and Moyes 2013). An emphasis on nutraceuticals has revealed their potential for support of the immune system.

Nutraceuticals—comprising nutrients, dietary supplements, herbal products, and processed foods (including dietary fiber, probiotics and prebiotics, polyunsaturated fatty acids, antioxidant vitamins, and phytoactive compounds)—induce a wide array of biological process in organisms (Das et al. 2012). Because of the development of resistance to conventional drugs and consumer demand (influenced by social and cultural changes) for more natural/organic animal products, breeders seek alternative and complementary therapeutics in herd medicine. These motives have promoted the value of nutraceuticals, where complex multitarget polypharmacological mechanisms such as activation of antioxidant defense and anti-inflammatory pathways—along with beneficial effects on cells through integrity, survival, proliferation, and differentiation—are exhibited (Dormán et al.

B. Yurdakok-Dikmen (✉) · A. Filazi

R. C. Gupta et al. (eds.), *Nutraceuticals in Veterinary Medicine*, https://doi.org/10.1007/978-3-030-04624-8_44

2016; Mandel et al. 2005). Nutraceuticals influence the maintenance of gut and metabolic health, while also stimulating immune function, which could eventually prevent complex inflammatory diseases such as mastitis, metritis, or bovine respiratory disease.

Conservation of the great diversity of microorganisms in the rumen is at the core of productivity and emissions of methane gas and ammonia in ruminants. Meanwhile, to reach the increasing demands of the human population, intensive production systems compromising cattle health and welfare have increased metabolic and infectious diseases globally. Therefore, the industry continually seeks alternative strategies for breeding to comply with consumer demands, also bearing in mind animal welfare. Prudent use of nutraceuticals has the potential to help ensure clean, green, and ethical production. Nutraceuticals have the potential to improve nutrient retention and utilization in the rumen, where significant productivity improvements, along with reduction of greenhouse gas emissions, are possible (McGrath et al. 2018). Nutraceuticals derived from various sources (animals, microorganisms, plants, minerals, and algae) exert their effects through various mechanisms such as antimicrobial, anti-inflammatory, and antioxidant effects in ruminants. Meanwhile, there is a lack of species-specific, dose-correlated, and product-specific studies (detailing sources, production techniques, and storage) and physiologically normalized studies (detailing differences in disease and other physiological conditions), making it difficult to adjust use of nutraceuticals appropriately for each breeding facility. This chapter briefly reviews major nutraceutical compounds and their effects on ruminants.

2 Major Classes of Nutraceuticals Used in Cattle

2.1 Probiotics

Probiotics are defined as live, nonpathogenic microorganisms, found in nature and/or in the gastrointestinal (GI) tract of ruminants, which confer beneficial health effects on the host upon ingestion of adequate amounts, mainly by improving the balance of the healthy microflora (beneficial bacteria). Stimulation of healthy microflora improves mucosal immunity, increases digestive capacity, and prevents colonization by harmful bacteria (Uyeno et al. 2015). The mechanisms of action of probiotics are production of antimicrobial substances and inhibitory metabolites (bacteriocins, diacetyl, organic acids), competition with pathogens for gut adhesion sites and nutritional sources, production of nutrients that are beneficial to beneficial bacteria, metabolism/detoxification of undesirable compounds and xenobiotics (by affecting the binding ability of toxins secreted by pathogens), immunomodulation, and production/stimulation of enzymes (Auclair 2001; Retta 2016). GI microbial characteristics differ depending on the region (rumen, large intestine) and host age (preweaned/weaned), including the microbial functions involved in host nutrition in terms of microbial protein synthesis, immunological responses, digestion of polymers, and pathogenesis of harmful bacteria. Therefore, contrary to a common belief, probiotics have greater potential benefits in ruminants than in monogastric animals (Wallace and Newbold 1992).

Probiotics are mainly used in young animals to promote optimal maturation of the rumen microbiota. In adult animals their main use is for reducing the risk of pathogen colonization. In dairy production they are mainly used to increase milk yield and quality, while in beef production their main use is for promotion of weight gain. However, in both dairy and beef production they are also used to promote health by limiting acidosis and increasing feed efficacy (Chaucheyras-Durand and Durand 2010). Their positive effects on dairy production are also related to stabilization of the pH in the rumen, increases in dry matter consumption and energy production/microbial protein, and reduction of the somatic cell count in milk (Maamouri et al. 2014; Suarez and Guevara 2018).

In mammals, Bacteroidetes and Firmicutes are the major bacterial communities in the GI tract. *Fibrobacter*, Archaea, and other protozoan species are also commonly found in the rumen, and *Atopobium*, bifidobacteria, and *Fibrobacter* are also common in the large intestine (Uyeno et al. 2015). Overall, the microorganism composition in the rumen includes bacteria (10^{10}–10^{11}/ml); archaeons such as *Methanobacterium* spp. and *Methanobrevibacter* spp. (10^{8}–10^{9}/ml); protozoans comprising entodiniomorphs, *Holothrix*, and flagellate species (10^{5}–10^{6}/ml); and ruminal fungi such as *Neocallimastix*, *Piromyces*, *Caecomyces*, *Orpinomyces*, and *Anaeromyces* spp. (10^{3}–10^{4}/ml) (Vohra et al. 2016).

Probiotics for ruminants are selected mainly for targeting the rumen, since this complex ecosystem comprising bacteria, anaerobic fungi, and ciliate protozoa is responsible for degradation and fermentation of dietary compounds (Chaucheyras-Durand and Durand 2010). Thus, probiotics used in ruminants are commonly yeast based (*Saccharomyces cerevisiae*) and fungus based (*Aspergillus oryzae*). Meanwhile, other Gram-positive bacteria such as *Lactobacillus* (*L. acidophilus*, *L. brevis*, *L. bulgaricus*, *L. casei*, *L. cellobiosus*, *L. curvatus*, *L. delbrueckii*, *L. fermentum*, *L. lactis*, *L. plantarum*), *Streptococcus* (*S. cremoris*, *S. lactis*, *S. thermophilus*, *S. faecium*), *Leuconostoc mesenteroides*, *Propriobacterium*, *Pediococcus*, *Bifidobacterium* (*B. adolescentis*, *B. infantis*, *B. longum*), *Bacillus* (*B. cereus*, *B. lentus*, *B. natto*), Gram-negative bacteria such as

Bacteriodes (*B. amylophilus*, *B. capillosus*, *B. ruminicola*), yeasts (*Saccharomyces boulardii*, *Torulopsis* candida), and fungi (*Aspergillus niger*) are also used (Chaucheyras-Durand and Durand 2010).

Several modes of action have been described for the effects of yeasts, including increases in the number of total culturable bacteria (through provision of vitamins and dicarboxylic acids, removal of oxygen-favoring anaerobiosis, and a reduction in the ammonium concentration) and the flow of microbial protein, enhancing the amino acid supply to the small intestine and stabilizing the pH through various processes such as competition of lactic acid–producing and/or mannitol-utilizing bacteria (*Megasphaera elsdenii* and *Selenomonas ruminantium*). Moreover, glucans and other macromolecules in the inner part of the yeast cell wall stimulate amplification of host defenses, especially the inflammatory response and the reticuloendothelial system (Auclair 2001; Suarez and Guevara 2018).

Probiotic strains can be administered separately or in combination; mixtures are favored because of their wide range of synergistic effects, which are mainly related to their different mechanisms of action (Chapman et al. 2011; Hatoum et al. 2012). On the other hand, multistrain probiotics may inhibit each other and possible produce antagonistic effects. For instance, *Lactobacillus* within a mixture has been to induce greater efficacy than *Bifidobacterium*; therefore, most mixtures contain *Lactobacillus*. Higher feed conversion efficacy and better growth performance have also been shown in goats fed *L. acidophilus* and *S. cerevisiae* mixtures (Jinturkar et al. 2009) and in lambs fed *Pediococcus acidilactici* and *P. pentosaceus* (Saleem et al. 2017). Commercial cocktails are available that include *Lactobacillus*, *Bacillus*, *A. oryzae* fermentation extract, and cultures of *Saccharomyces* yeast, along with enzymes such as α-amylase, β-glucanases, hemicellulases, and cellulases for ruminants (Chapman et al. 2011). For effective results, specific preliminary studies with the probiotic yeasts or their mixtures are recommended, since the mechanism of action and the success rate depend on the yeast strain, viability, and feed composition (Chiquette 2009).

2.2 Prebiotics

Prebiotics are defined as nondigestible, nonviable ingredients—usually selectively fermented dietary compounds—that confer benefits on host health through the growth and/or activity of gastrointestinal microbiota (Callaway et al. 2012; Roberfroid et al. 2010). Prebiotics that have been confirmed to provide beneficial health effects are mainly nondigestible carbohydrates and oligosaccharides with different molecular structures. Oligosaccharides include fructo-oligosaccharides (FOS; oligofructose and inulin), galacto-oligosaccharides (GOS), transgalacto-oligosaccharides (TOS), and lactulose. These have been found to stimulate the growth of bifidobacteria and lactobacilli, leading to significant changes in the gut microbiota (Gaggìa et al. 2010).

Lactulose—a synthetic disaccharide consisting of galactose and fructose—has been shown to affect the morphology of the intestine through decreases in ileal villus depth and the surface area of lymph follicles from Peyer's patches, with an increase in growth performance in preruminant calves receiving a milk replacer containing *Enterococcus faecium* (Fleige et al. 2007). In another study, a mixture of essential oils (EOs; carvacrol, caryophyllene, p-cymene, cineole, terpinene, and thymol) and prebiotics (arabinogalactans) was tested in newborn calves for promotion of immunity and stimulation of appetite; small amounts (1.25 g per calf daily in a 24:20 milk replacer) were confirmed to induce the aforementioned beneficial effects (Froehlich et al. 2017).

Fiber is defined as the fraction of carbohydrate in the feed that is resistant to digestion by enzymes produced by cattle. Fibers such as cellulose, hemicellulose, lignin, and soluble fibers (fructans, pectins, galactans, and beta-glucans) are mainly found as structural components of cell walls. The digestive actions of rumen microorganisms allow access to the nutritive potential of fibers necessary for proper rumen function and a source of energy (Moreira et al. 2013). As an approximation, it is recommended that 25% of dry matter in feed is neutral dietary fiber, with the other 75% being a forage fiber source. The physical properties of the fiber are important for stimulation of chewing activity (particle size) and establishment of biphasic stratification of ruminal contents. Long forage forms a fiber mat, which floats in the rumen and has a function in particle sorting, by trapping fine particles and slowing their rate of breakdown by reducing ruminal microbial exposure. As the chewing activity increases, salivation also increases, favoring the growth of cellulolytic microbes and production of acetic acid, where a higher acetate to propionate ratio favors synthesis of milk fat (Mirzaei-Aghsaghali and Maheri-Sis 2011; Tackett et al. 1996).

For beef cattle receiving a high-forage diet, where the animals graze or free-choice hay is supplemented, dietary fiber is sufficient. Inadequate fiber can damage the rumen wall, while greater amounts do not guarantee effectiveness, since at a smaller particle size (if it is ground or chopped too finely), rumen health may not be promoted. Promotion of effective fiber supplementation improves overall performance. Effective neutral detergent fibers (cottonseed, Bahia grass, Bermuda grass, corn, soybean, wheat, distiller's grain) in beef cattle feeds can be provided as dried grain, hulls, middlings, cracked corn, normal chop, or fine chop (Parish 2007).

Even though the milk yield is decreased with dry matter intake, with a physically effective neutral detergent fiber

intake of 30–33%, the milk fat yield is increased (3.5%), with greater milk energy efficacy, and the risk of subacute ruminal acidosis is decreased (Zebeli et al. 2008). Prevention of a drop in the milk fat percentage by use of fiber also depends on the physical form of the fiber (the preferred forage mean particle length is ≥0.64 cm) (Woodford et al. 1986) and the humidity (increased fiber results in an increased rectal temperature and increased stress) (Tsai et al. 1967).

2.3 Synbiotics

The synergistic effects of a combination of prebiotics and probiotics, in increasing the survival and deposition of viable beneficial microbiological organisms to retain a healthy natural microbial environment in the rumen, are much greater than those seen with use of probiotics or prebiotics alone (Hamasalim 2016; Radzikowski 2017). A greater improvement in the average daily gain and a greater decrease in fecal *Escherichia coli* were observed in suckling female calves fed a combination of probiotics (1 g of seven bacteria and two yeast strains) and prebiotics (4 g of polysaccharides from *S. cerevisiae* cell walls) (Roodposhti and Dabiri 2012). Moghani suckling lambs supplemented with 3 g of a synbiotic (containing *E. faecium*, a prebiotic derived from chicory, and sea algae as an immune-modulating substance) in their diet had greater body weight, greater body weight gain, increased feed intake, and a better feed conversion ratio. Coliform bacteria were reduced (as were serum cholesterol levels), and lactic acid bacteria were increased, indicating the potential of this supplement as a growth promoter (Moarrab et al. 2016). The effects of synbiotic fermented milk (containing *S. thermophilus*, *L. acidophilus*, and *Bifidobacterium bifidum*)—in synergy with some active ingredients of herbal hydrosols and honey (apple acid)—on sexual activity, semen characteristics, and testosterone levels in Aradhi and Damascus goat bucks were evaluated, and enhanced libido and semen physical characteristics were observed (Al-Sobayil et al. 2008).

2.4 Dietary Lipids

Dietary lipids play important roles in nutrition and biological functions, providing sources of essential fatty acids and energy, and increasing absorption of fat-soluble nutrients. The major lipid constituents in dairy cow nutrition are triglycerides, glycolipids, phospholipids, and free fatty acids (Drackley 2004). The usual ratio in feed is 2–4% lipids, since they directly contribute 50% of the fat in milk. Rumen microorganisms are able to hydrogenate unsaturated fatty acids, including linoleic and linolenic acids, among others; about 90% are hydrogenated into saturated fatty acids (Tiven et al. 2016). As the free fatty acids attach to feed, along with microbial particles, they have a tendency to negatively affect fermentation, especially fermentation of fibrous carbohydrates, and, as a result, the milk production and the fat percentage in the milk decrease (>8%). Their use is supported to increase diet energy density and to increase the forage to concentrate ratio for an optimal milk fat percentage (Palmquist and Conrad 1978; Zhang et al. 2011).

Among dietary lipids, polyunsaturated fatty acids (PUFAs) contain two or more double bonds between carbon atoms and, depending on the position of the methyl group in the carbon chain, are categorized as n-3 (fish, fish oil, nuts) and n-6 (vegetable oils). They can be produced endogenously from linoleic acid (n-6), as the precursor of arachidonic acid and linolenic acid (n-3), and the precursor of eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) (Kadegowda and Yu 2016; Palou and Bonet 2007). As n-3 PUFAs cannot be synthesized by ruminants, these animals have an absolute requirement for some fatty acids in the n-3 and n-6 families, which are considered essential and must be provided in an appropriate ratio. Dairy cows consume a diet predominantly containing PUFAs, where rumen microorganisms split fatty acids from the glycerol backbone to be further fermented into volatile fatty acids. PUFAs provide precursors for prostaglandin synthesis, modulating the key enzymes related to prostaglandin and steroid metabolism, and improving male reproductive performance, as PUFAs are important in sperm membrane integrity. Studies have revealed beneficial effects such as improvements in sperm motility, viability, and testis development, leading to improved fertility parameters in ruminants (Van Tran et al. 2016). The inclusion of PUFAs has also been shown to modulate the immune response through various mechanisms, including reductions in tissue levels of immunosuppressive agents such as arachidonic acid and prostaglandin E_2, which are especially important in reduction of transport stress and feed yard entry stress in ruminants. PUFAs also have the potential to modify the composition of milk fatty acids, while also improving productive performance and metabolic health (Bragaglio et al. 2015; Savoini et al. 2010). The selection of sources for PUFAs is important for relative protection from rumen biodegradation. Reduction of emissions of methane, as a greenhouse gas produced in the rumen, is considered a social and environmental priority. PUFA-enriched diets, such as linseed-rich or fish oil–supplemented diets, have the potential to help mitigate enteric methane production (Savoini et al. 2010). Another important aspect is related to increasing public understanding of the relationships between diet and health regarding consumption of red meat and dietary n-3 intake in humans, as manipulation of beef cattle diets with enriched fatty acids alters the fatty acid composition in beef (Vahmani et al. 2015).

Conjugated linoleic acids (CLAs) are isomers of linoleic acid with isolated double bonds; *cis*-9, *trans*-11-CLA (CLA1) and *trans*-10, *cis*-12-CLA (CLA2) are the most active isomers. *Cis*-9 and *trans*-11 CLA are the intermediates in biohydrogenation of linoleic acid to stearic acid in the rumen by ruminal bacteria; which are the major CLA isomers in milk fat. It may also be synthesized in the mammary gland by the endogenous conversation of transvaccenic acid or linolenic acid by the desaturase enzyme. CLA exhibits anticancer, antioxidant, antiatherosclerotic, and antiobesity effects in human and animals (Kelly 2001). Therefore, an increase in CLA in beef meat and milk has beneficial effects on human health; for that reason, breeders are focusing on increasing the amount of this compound through diet. Feeding CLA to beef cattle for extended periods of time, especially in high-grain diets, has been found to increase the CLA content of meat (Mir et al. 2004).

2.5 Nutraceutical Proteins and Peptides

Biologically active peptides are specific protein fragments derived either through natural enzymatic digestion or through fermentation of food products, promoting body function or condition and enabling prevention and/or treatment of diseases or disorders. Depending on the type and concentration, biological peptides exert different health effects, enhancing the nutrient absorption system, defense system, regulatory system, and nervous system (de Mejia and Dia 2010; Mine and Shahidi 2005). For both beef and dairy cattle, dietary proteins of "bypass" or "undegradable" quality (which escape rumen fermentation), along with other microbial proteins produced through rumen fermentation, are important sources of amino acids. Therefore, besides their nutraceutical effects, these proteins have a major importance in ruminant nutrition. Meanwhile, the source of proteins and the processing procedures are important for the pharmacological effects, along with intactness of certain bioactive protein subunits. Some examples of nutraceutical proteins and peptides (casein phosphopeptides (CPPs), milk whey protein, egg white proteins, soybean proteins, and antimicrobial peptides) used in ruminants are briefly reviewed here.

CPPs are phosphorylated casein-derived peptides. These compounds are able to bind and solubilize macroelements (calcium, magnesium, iron), along with trace elements (zinc, barium, chromium, nickel, cobalt, and selenium). Potential applications of CPPs include prevention of osteoporosis, hypertension, anemia, and dental caries; and humanization of bovine milk (with increased phosphorus levels) (FitzGerald 1998).

Acid, sweet (liquid whey), and casein wheys are highly nutritious co-products of cheese and yogurt production plants. Sweet whey, administered in a concentration of 12–20 L per cow per day, has been found to increase the milk yield, calcium content, and magnesium content, along with the technological properties of milk, in lactating cattle (El-Shewy 2016). As a partial replacement for concentrate (control) feed, 40 L per cow per day of liquid acid whey was found to improve milk fat and protein yields without affecting milk composition (Salem and Fraj 2007). Whey was found to improve the grass and legume silage quality and digestibility, reduced ammonia nitrogen concentrations, and had a favorable effect on growth rates in calves that were fed milk replacers containing up to 89% dried whey (Schingoethe 1976). A whey protein emulsion gel was found to protect unsaturated fatty acids from rumen biohydrogenation, leading to better absorption of these compounds in the small intestine for eventual incorporation into milk fat (Carroll et al. 2006).

Among egg white proteins, ovalbumin, ovotransferrin, ovomucoid, ovomucin, and lysozyme are major groups with great potential for use in the food and pharmaceutical industries. They have antimicrobial, anticancer, antioxidant, metal binding/transporting, and nutrient supplementation effects in organisms (Abeyrathne et al. 2013). The effects of ovalbumin, as a dietary nitrogen source, on peptide concentrations in sheep rumens have been evaluated. In comparison with casein, ovalbumin was found to degrade slowly and therefore did not give rise to significant peptide levels (Broderick and Wallace 1988); this could have been attributable to its potential to stimulate the growth of proteolytic bacteria and other predominant proteolytic species (Tsuda et al. 1991). Another study on the effects of unmarketable egg powder as a protein supplement in preruminant lamb milk replacer reported undesirable effects on the digestive system, indicating that this is unsuitable for lamb feed (Wereme et al. 2016).

Soybean peptides have a great ability to bind to bile acid, reducing cholesterol by restricting reabsorption of the bile acid in the ileum (Ahmad et al. 2014). A slight decrease in low-density lipoprotein (LDL) cholesterol has been reported, but there were no associated effects on high-density lipoprotein (HDL) cholesterol, triglycerides, lipoprotein (a), or blood pressure (Xiao 2008). Black soybean peptides have also been reported to have antidiabetic effects through suppression of hepatic endoplasmic reticulum stress and maintenance of insulin resistance (Ahmad et al. 2014). However, safety concerns regarding their negative impacts on thyroid function (induction of hypothyroidism) and reproductive functions (estrogenic effects), along with an increase in estrogen-related carcinogenesis, restrict their potential use as nutraceuticals in humans (Xiao 2008; Xiao et al. 2004). In both beef and dairy diets, soybean meal is among the most commonly used proteins; as their ruminal bypass content is higher, treated soybeans or soybean meals are favored. Properly treated soybeans are able to increase milk production and improve growth (Radivojević et al. 2011; Ure et al. 2005). Conversely, in one study, no improvement in milk production was observed with feeding of rumen-undegraded protein

from expeller soybean meal or greater amounts of rumen-degraded protein from solvent-extracted soybean meal (Colmenero and Broderick 2006).

Bacterial resistance to many classes of antibiotics is of great concern, given its implications for public health. Use of alternatives such as antimicrobial peptides (AMPs) for adjustment of ruminal fermentation, promotion of feed intake, and secretion of endogenous enzymes with immunological properties are favored, while resistance to these compounds is also expected in near future. AMPs are generally short cationic hydrophobic sequenced peptides (<100 amino acids) within a linear or cyclic structure, which constitute an innate immune defense system and exist in nearly all classes of organisms as a biological weapon (Ageitos et al. 2017). Because of their antiprotozoal and nitrogen-binding affinity, and their effects in promoting optimal ruminal flora, proteins are prevented from undergoing ruminal deamination, to be further used for the animal's own nutrition. This is important especially in dairy production systems, where high levels of energy and protein supply are required (Cheema et al. 2011).

Cattle anionic peptides (BNBD-1–3, 6–11, 13; BNBD-4, 5, 12; tracheal antimicrobial peptide (TAP), lingual antimicrobial peptide (LAP), enteric β-defensin (EBD), indolicidin, dodecapeptide), sheep anionic peptides (sheep BD-1, 2; SMAP 28, 29, 34; OaBac5a, b, 6), goat antimicrobial peptides (BD-1, 2; ChBac5), and several other innate AMPs have been identified in various ruminant tissues, providing antibacterial effects on both Gram-positive and Gram-negative bacteria. Colostrum in ruminants contains numerous cytokines and AMPs, including lactoferrin, defensin, and cathelicidins (Cheema et al. 2011; Wang et al. 2016).

Lactoferrin, as an iron-binding glycoprotein with antimicrobial and antioxidant properties, is approved for decontamination of beef carcasses. Lactoferrin interferes with adhesion/colonization, detaches microorganisms from biological surfaces, inhibits multiplication, neutralizes endotoxins, and boosts the immune system, implying the potential to be used against foodborne pathogens (Acuff 2005). Rectal administration of bovine lactoferrin has been shown to induce antimicrobial and immunomodulatory activities against *E. coli* O157:H7 infections in cattle (Kieckens et al. 2018). Partial antigenic identity has been observed between bovine, goat, and sheep lactoferrin, and, in terms of immunochemical properties, the circular dichroism (CD) spectra were similar (Shimazaki et al. 1991). Lactoferrin also exhibits antiviral, antifungal, and antiparasitic activities (Jenssen and Hancock 2009). Kappacin, a heterogeneous C-terminal fragment of bovine milk kappa-casein casinomacropeptide (CMP), has antibacterial affects, along with biological effects such as suppression of gastric secretion, depression of platelet aggregation, antiviral effects (influenza), inhibition of cholera toxin binding, and immunomodulatory effects (Malkoski et al. 2001). Not just the milk but also the rumen microbiome has been investigated as an underexplored resource for novel antimicrobials. Lynronne-1, Lynronne-2, and Lynronne-3, isolated from bovine rumen, were found to be effective against many clinically important multiresistant pathogens, including methicillin-resistant *Staphylococcus aureus* (MRSA) (Oyama et al. 2017). A large number of AMPs are present in ruminants, which are yet to be exploited for their useful effects. Meanwhile, not only AMPs originating from an animal's own tissues but also other AMPs derived from various different organisms could be potentially used against infectious microbial diseases in ruminants (Cheema et al. 2011). AMPs derived from insects (cecropins and defensins), from amphibians (magainin, limnochariin, hylaranin), and from mammals (defensins and cathelicidins) have potential antibacterial effects, while subtilosin and cathelicidin have potential antiviral effects (Wang et al. 2016).

2.6 Algae

Microalgae (diatoms—Bacillariophyceae, green algae—Chlorophyceae, golden algae—Chrysophyceae, and blue-green algae—Cyanophyceae) and macroalgae (Chlorophyta, Phaeophyta, Chrysophyta, and Rhodophyta) have been studied in both human and animal health and nutrition since ancient times. Depending on the chemical structure and the environmental conditions, they have a wide range of applications, including production of biodiesel from their biolipid oil, fertilizers, feed additives, therapeutic agents, and cosmetics. Through sustainable production (with optimization of water, CO_2, nutrients, heat, light, harvesting systems, and drying systems), various types of algae have become available for animal feed. Numerous bioactive molecules (PUFAs, omega-3 fatty acids such as EPA and DHA, chlorophyll, carotenoids, sterols, etc.), along with high vitamin and mineral content, account for the health-improving properties of algae. Supplementation of dairy cattle feed with algae or algal oil rich in n-3 fatty acid has been reported to positively affect the fatty acid content of milk (Stamey et al. 2012). Extracts of chlorellin isolated from the green microalgae *Chlorella vulgaris* have been shown to induce antibacterial activity against Gram-positive and Gram-negative bacteria (Alwathnani and Perveen 2017; Pratt et al. 1944). Similarly, *Chroococcus dispersus*, with a high chlorellin content, has been reported to have a wide spectrum of antimicrobial activities, including antifungal and antibacterial activities (Ghasemi et al. 2007). Dried spirulina (with a 60% content of rich essential amino acids, though with reduced amounts of methionine, cysteine, and lysine) is highly nutritious and has potential as a replacement in feedlot diets (Nicoletti 2016). Calcium spirulan (Ca-SP)—which is isolated from a marine blue-green alga, *Arthrospira platensis* (previously called *Spirulina platensis*)—has been

found to be active against many types of virus, including measles, influenza, herpes simplex virus (HSV) 1, Coxsackie virus, mumps, and human immunodeficiency virus (HIV) (Hayashi et al. 1996). The carbohydrate fractions of *A. platensis* have been found to be digested efficiently (up to 20%) in comparison with *Chlorella* or *Scenedesmus obliquus*, with an increase in body condition in dairy cows, increases in bodyweight and back fat thickness in weaned lambs, and an increase in bodyweight in lambs being observed. Use of *Schizochytrium* spp., on the other hand, did not have a major effect on carcass weight (Madeira et al. 2017).

Seaweeds—such as subspecies of macroscopic, multicellular, marine algae found in Chlorophyceae (green seaweeds), Rhodophyceae (red seaweeds), and Phaeophyceae (brown seaweeds)—are good sources of some water-soluble vitamins (B_1, B_2, B_{12}, C) and fat-soluble vitamins (β-carotene with vitamin A activity, vitamin E) with antioxidant capacity and have health benefits such as decreasing blood pressure, preventing cardiovascular disease, and reducing the risk of cancer (Škrovánková 2011). Polysaccharides in seaweeds—such as galactans and xylans (in green algae); alginate, laminarin, and sulfated fucose-containing polymers (in brown algae); agars; carrageenans; xylans; sulfated galactans; and porphyrans and minor polysaccharides such as ascophyllan and sugar alcohols—induce prebiotic actions, leading to an increase in productivity and health enhancement in animals (Evans and Critchley 2014).

Seaweeds (*Ulva* spp., *Laminaria ochroleuca*, *Saccharina latissima*, *Gigartina* spp., and *Gracilaria vermiculophylla*) have also been shown to have beneficial effects on gas and methane production and ruminal fermentation parameters in cattle; *Gigartina* presented the lowest value for gas production (Maia et al. 2016). Among seaweeds, brown seaweed *Ascophyllum nodosum* (rockweed) is best known for use in animal feed applications. Commercially available products of brown seaweed have been found to induce beneficial effects on resistance to stressors such as mixing, livestock transportation, exposure to foodborne toxins, and excessive heat or temperature, boosting the immune system, increasing productivity, and reducing the numbers of pathogenic microorganisms (*E. coli* O157:H7 strain, *Salmonella* spp., *Campylobacter* spp., and *Clostridium*) (Allen et al. 2001; Evans and Critchley 2014). The effects of supplementation with brown seaweed by-products (BSB) in Holstein cows were evaluated; BSB did not compromise ruminal fermentation and animal performance at lower levels. Estrogen, triiodothyronine, and thyroxine levels were found to be higher after 3 months of pregnancy, and BSB supplementation did not affect the daily milk yield and composition (Hong et al. 2015).

Research on the effects of phlorotannins isolated from *A. nodosum* on in vitro ruminal digestion of mixed forage or barley grain showed that they reduced methane and total gas production and reduced ruminal fermentation and protein degradation in a dose-dependent manner (Wang et al. 2008). In heat-stressed wether lambs, brown seaweed–treated conserved forage was found to enhance the antioxidant status and immune function (Saker et al. 2004). Mineral levels in brown seaweeds are generally lower than those in green and red seaweeds, while protein levels are higher (Makkar et al. 2016). Mixtures of brown, red, and green seaweeds are also available as feed supplements. As seaweeds are low in cellulose and rich in specific polysaccharides (alginate, laminarin, and fucoidan) and in mannitol, they have an ability to change the rumen microflora substantially, for a high degree of adaptation of the rumen flora (Makkar et al. 2016). However, seaweeds accumulate heavy metals (arsenic), iodine, and other minerals (Bouga and Combet 2015), which requires careful consideration, since this has the potential to be detrimental to both animal and human health.

2.7 Phytonutraceuticals

Secondary metabolites of plant extracts, with various chemical structures and biological activities, are unique resources for pharmaceuticals, food additives, and fine chemicals. They have long been studied in ruminants as alternatives to conventional drug treatments and for their potential to increase productivity. The demand for, and interest in, secondary compounds in plants have increased, with the aims of improving meat and milk quality, and increasing immunity to pathogenic diseases. Major secondary compounds (metabolites in plants) used in farming systems include phenolic compounds (simple phenolics, condensed tannins), saponins, and EOs rich in terpenes (Vasta and Luciano 2011).

Tannins have been considered antinutritive/toxic compounds because of their negative effects on the digestion and absorption of proteins, polysaccharides, and minerals, resulting in reduced animal performance, along with ulcerative, irritative, hepatotoxic, and nephrotoxic effects. The tannins that were used were majorly hydrolyzable tannins, which were further depolymerized in the rumen to gallic acid, with pyrogallol and resorcinol, as metabolized products of gallic acid, being responsible for cellular damage. On the other hand, condensed tannins are not degraded and hence do not cause these toxic effects (Jerónimo et al. 2016). Tannins have several effects on ruminal health, depending on the animal species, its ruminal pH, and the type and concentration of the tannin used. Tannins form indigestible complexes and decrease the rumen turnover rate, which prevents their degradation in the rumen and makes them

eventually available in the intestine. This increases the efficacy of protein digestion and improves animal health (Mueller-Harvey 2006; Naumann et al. 2017). Other major effects of both hydrolyzable and condensed tannins in ruminants are attributed to their anthelmintic effect on larval motility and their inhibition of egg hatching (Naumann et al. 2017; Williams et al. 2014). Monomers of condensed tannins (prodelphinidin, galloyl, procyanidin) were found to affect larval exsheathment of parasitic nematodes in small ruminants (Brunet and Hoste 2006). Tannins also have an effect on lipid metabolism. Depending on the biohydrogenation steps, the microbial species, and the animal's physiology, increases in beneficial fatty acids (such as linolenic acid, vaccenic acid, and rumenic acid) in meat and milk can be achieved (Morales and Ungerfeld 2015). Moreover, condensed tannins form complexes with proteins and polysaccharides in the rations to reduce the digestibility of dry and organic matter for production of metabolic H_2 to be further utilized by methanogens to reduce CO_2 to CH_4 (Piñeiro-Vázquez et al. 2015).

Saponins are amphipathic glycosides with surface active properties, which are widely distributed in nature in marine and plant sources. Saponins produce a variety of biological effects, including hypocholesterolemic, hypolipidemic, immune potentiating, anti-inflammatory, antioxidant, neurohepatoprotective, anticarcinogenic, and antifungal effects (including antibacterial, antifungal, antiprotozoal, antiviral, and antimollusk effects), inhibition of dental caries, and inhibition of platelet aggregation. Because of their detergent properties and pronounced inhibition property of forestomach motility, saponins form a stable foam in the rumen, and some types lead to photosensitization, followed by liver and kidney degeneration, along with other gut problems (Addisu and Assefa 2016; Westendarp 2005). Like tannins, saponins are able to suppress intestinal and ruminal ammonia production through inhibition of proteolytic microorganisms. Moreover, the decrease in methane production is related to defaunation, along with inhibition of methanogenesis or a decrease in the expression of methane-producing genes (Patra and Saxena 2009). Tea saponin has been found to increase the methane yield in lactating dairy cows, presenting a contradiction to the methane reduction effects of saponins (Guyader et al. 2017). A meta-analysis on the methane-mitigating properties of saponin-rich sources showed that the effects were source dependent and concentration dependent (Jayanegara et al. 2014). Among commercially available saponins, *Yucca schidigera* extract has attracted great interest for its manure deodorization and hazardous gas mitigation/methane-decreasing properties (Sun et al. 2017). Yucca extracts were found to be more effective in mitigating methane than tea and *Quillaja saponaria* (Jayanegara et al. 2014). Saponins have also been found to increase the effectiveness of oral vaccines by altering the permeability of the oral mucosa, along with having immune enhancing properties. There are a number of purified or semipurified chemical adjuvants available that are derived from *Q. saponaria*, such as Quil A, Spikoside, and the defined fractions QS-21 and Iscoprep 703. Quil A is widely used as a adjuvant veterinary medicine in equine influenza virus, canine parvovirus, and feline leukemia virus (FeLV) vaccines (Kirk et al. 2004; Spickler and Roth 2003).

EOs are volatile aromatic compounds produced by plants. They are multicomponent chemical combinations with terpenes and terpenoids (20–70%) as their major constituents (Kumari et al. 2014). EOs have antiseptic, antimicrobial, antioxidant, and free radical–screening activities (Ballester-Costa et al. 2017; Patra 2011). The most studied EOs are thyme, oregano, clove, cinnamon, rosemary, dill, eucalyptus, garlic, and anise. Inhibition of methane formation (mainly through reduction of feed degradation) and rumen fermentation–modulating effects have been observed consistently with thyme (thymol), oregano (carvacrol), cinnamon (cinnamaldehyde), and garlic (allicin) (Cobellis et al. 2016). Total volatile fatty acid concentrations were found to be only slightly affected or decreased by EO; the effects were dependent on the rumen pH. Only limited information on the effects of EOs on the performance of ruminants is available; minor changes have been observed to occur in a diet-dependent manner (Patra 2011). A feedlot finishing diet containing thyme and cinnamon EO had beneficial effects on performance and rumen fermentation in Holstein calves consuming a high-concentrate diet, and these EOs could be further adopted as ruminal fermentation modifiers in beef production systems (Vakili et al. 2013). Even though EOs have been shown to be promising feed additives for mitigation of methane and ammonia emission, and have antioxidant, antimicrobial, and immune enhancing effects, their efficacy varies as a result of environmental factors such as light, temperature (considerable loss of activity was recorded with a pelleting temperature of 58 °C in feed), moisture stress, dosage (as adaptation occurs, the need for an increase in dose is inevitable), and the diet of the animal (Cobellis et al. 2016).

3 Concluding Remarks and Future Directions

The ban on antibiotics as growth promoters, along with antimicrobial resistance and demand from consumers for drug-free animals and with food products of high quality, create challenges for breeders to seek alternative methods for control and prevention of pathogens. Nutraceuticals provide

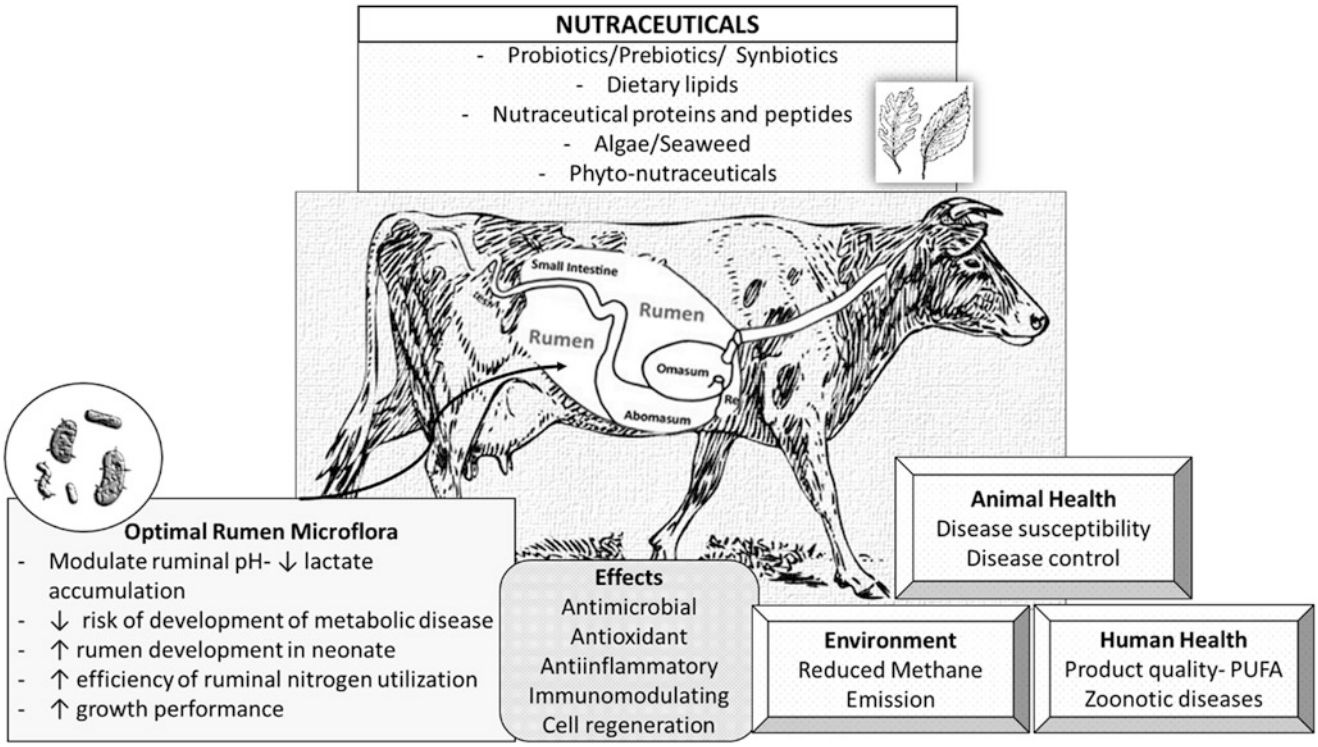

Fig. 1 Effects of nutraceuticals on cattle health

valuable tool in terms of feed additives, mainly focusing on host-protecting functions (antioxidant, anti-inflammatory, antimicrobial, and cell survival effects) to increase productivity. In ruminants, the rumen microbiota plays a fundamental role in the function of the immune system, as well as nutrition; therefore, nutraceuticals are expected to have mainly rumen-modulating effects. Ruminant livestock production also influences the environment through emission of methane and excretion of nitrogen in large quantities, contributing to global methane emissions. Therefore, nutraceuticals not only are important for ruminant health but can also influence public health through inhibition of methane emissions, as well as decreasing pathogenic bacteria in animal-origin food products. Major nutraceutical compounds with potential in ruminants include dietary fiber, probiotics, prebiotics, dietary lipids, proteins and peptides (including antimicrobial peptides), algae (macroalgae and microalgae), and phytonutraceuticals (tannins, saponins, and essential oils) (Fig. 1).

Since many factors affect the efficacy of nutraceuticals—including the source, the technique used for production, and the concentration of the compound, along with the physical condition, diet, species, and rumen pH of the animal—more studies on these natural and potent compounds should be performed to assess their efficacy and toxicity in order to obtain cost-effective benefits.

Nutraceuticals in Equine Medicine

A. Sankaranarayanan

Abstract

The use of nutraceuticals in equine medicine is rapidly growing into a global multibillion-dollar industry. With the introduction of Dietary Supplement Health and Education (DSHEA) legislation in 1994, the regulation of nutraceuticals for animals has become rather vague but was partially rescued by the formation of the National Animal Supplements Council (NASC) in 2002. In equine practice, nutraceuticals are commonly used as performance enhancers as well as joint supplements. In both instances, research in humans as well as horses has been of critical importance. Lameness in horses is one of the most important conditions impacting their usefulness, and nutraceuticals are used commonly in its treatment. Products containing glucosamine and chondroitin sulfate have been shown to be effective with some level of scientific support. There are many others, like undenatured type II collagen, manganese, antioxidants, and vitamin C, which have also been employed with varying levels of success. As performance enhancers, L-carnitine, creatine, branched-chain amino acids, and HMB have all been used, with HMB showing promise. In spite of the initial euphoria, it is a challenging time for the nutraceutical industry to generate quality clinical data to support efficacy and safety claims on its products to ensure sustained growth.

Veterinary nutraceuticals · Equine health · Equine medicine

1 Introduction

Since the late 1990s, there has been an explosive growth in the nutraceutical industry both in human and animal nutrition, transforming it into a global multibillion-dollar industry. It is therefore no surprise that in equine medicine also, nutraceuticals are growing rapidly in demand both by horse owners and veterinarians as evidenced by the variety and volume of products introduced into the market. Despite this trend, it is ironic that the very definition of nutraceuticals is vague and there is no regulatory definition. The term "nutrient" is defined by the Association of American Feed Control Officials (AAFCO) as "a food constituent in a form and at a level that will help support the life of an animal". The major classes of feed nutrients are proteins, fats, carbohydrates, minerals, and vitamins. AAFCO defines a "drug" as "a substance intended for use in the diagnosis, cure, mitigation, treatment or prevention of disease in man or other animals". The term nutraceutical was coined by DeFelice (1995) as a combination of the words, "nutrient" and "pharmaceutical," and is defined as "food or part of a food that provides medical or health benefits, including prevention and/or treatment of a disease." The North American Veterinary Nutraceutical Council (NAVNC) defines nutraceutical as a substance which is produced in purified or extracted form and administered orally to patients to provide agents required for normal body structure and function and administered with the intent of improving the health and well-being of animals (Crandell and Duren 2001).

DeFelice (1995) was optimistic that the nutraceutical revolution would change the food industry dramatically but it would also depend on the ability of the industry to demonstrate clinical benefits of these products and its ability to patent them. For the sustained growth of the nutraceutical industry, this would be an important factor.

2 Regulatory Scenario

Regulations on nutraceuticals for the use in animals are rather vague and confusing. This is partly due to the very nature of nutraceuticals and their position between nutritional products (animal foods/feeds) and animal drugs/pharmaceuticals. In 1994, the US Congress passed the Dietary Supplement Health Education Act (DSHEA) that was signed into law in October of that year by President Bill Clinton. This led to the creation of dietary supplements, a subset of food, under the Federal Food, Drug, and Cosmetic Act that allowed production and marketing of dietary supplements for human use. While dietary supplements for human consumption were discussed in the Congress, the case of dietary supplements for animals was neither mentioned nor considered. Perhaps at that time, the dietary supplement industry for animals was not well developed, or possibly, the purpose of the DSHEA was specifically to meet the increasing demand for dietary supplements for human use.

The US Food and Drug Administration, Center for Veterinary Medicine (FDA-CVM) is responsible for the regulation of animal food and drugs. It works in close association with agencies like AAFCO and other state authorities in enforcing federal and state laws to ensure that manufacturers of animal feed and drugs comply with regulations. Vitamins, minerals, and feed additives that are generally recognized as safe (GRAS) have been on the market for several years in the category of dietary supplements for animals and are listed in the official publication of the AAFCO.

With the introduction of the DSHEA, ingredients similar to that used in human dietary supplements have been marketed as components of dietary supplements for animals. Many of them contain ingredients that may be unsafe food additives or unapproved new animal drugs. This has led to the publication of a notice by the US FDA in the Federal Register of 1996 clarifying that the DSHEA does not apply to animals. The FDA-CVM's concern was that these animal dietary supplements do not have scientific data to show that they are safe for animals. The result of such reasoning is that products marketed for animals that are similar to human dietary supplements can only legally be placed under one of two categories—animal food or animal drug.

An animal food does not require any pre-market approval by the FDA-CVM, but under the DSHEA it is required to be pure and wholesome and contains no harmful or deleterious ingredients and must be labeled as such. It is only of nutritive value. On the other hand, an animal drug is an article intended for the use in the diagnosis, cure, treatment, or prevention of disease. Under the DSHEA, a new animal drug must have scientific data showing it to be effective and safe as a part of its new animal drug application (NADA). Simply, if a product on the market is not approved for the use in a condition, it shall be considered illegal and subject to regulatory action.

This has led to a complex legal situation as elegantly summarized by the National Animal Supplements Council (NASC), a 501(c)6 not-for-profit organization established as a corporation in Utah with primary offices in Southern California (https://nasc.cc). With the increased demand for animal dietary supplements, this has created an unusual situation for the industry. There are a growing number of ingredients commonly used in human dietary supplements that are not approved for the use in animals. This lack of legal status for dietary supplements for animals has led to imminent proposals by regulatory bodies to remove many of these products from the market. In response to this, the NASC was formed in April 2002.

The NASC surveys revealed that there are over 400 ingredients currently marketed by NASC members that are unapproved for the use in animal feed products. To address this issue, NASC submitted ingredient definition applications in 2002 and 2003, petitioning the FDA-CVM to allow the use of glucosamine and MSM in animal feed as their nutritional requirements had not been established in animals until then. These products are recognized by consumers as being used for purposes other than nutritional, like being used in managing disease conditions such as osteoarthritis. These considerations mandate the industry in complying with the law and market such products as animal drugs. Marketing products as animal drugs requires filing a new animal drug application (NADA) with the FDA-CVM with supporting data on their safety and efficacy. Though this appears to be straightforward, in reality this could be problematic. First, the industry would need to protect its intellectual property rights since considerable investments will have to be made in the product development. However, courts have held that natural substances cannot be protected via intellectual property rights. Secondly, consumers can access human dietary supplements for animal use and may avoid expensive animal products developed and marketed through the NADA process. Obviously, all these make the regulatory position of nutraceuticals for animals rather complex.

3 Nutraceuticals

The US Federal Food, Drug, and Cosmetic Act defines a dietary ingredient as a vitamin, mineral, herb or other botanical, amino acid, or dietary substance for the use by man to supplement the diet by increasing the total dietary intake or a concentrate, metabolite, constituent, extract, or combination of the preceding substances. The term as used covers a broad list of products which are used in human nutrition and have become popular in the equine nutraceutical industry. The

nutraceuticals provide functional benefits by increasing the supply of structural building blocks in the body and thereby mitigating disease signs and/or improving the performance of animals. Most of the scientific data generated on nutraceuticals come from human research, whereas only a limited number of nutraceuticals used in equines have been clinically evaluated. It is also observed that in equine practice, nutraceuticals have been used more commonly as performance enhancers than for treating disease conditions. This chapter shall focus on nutraceuticals in equine medicine that are supported by equine and human clinical research.

4 Nutraceuticals as Joint Supplements

Osteoarthritis is one of the most common causes of lameness in horses. An imbalance in articular cartilage matrix synthesis and degradation is responsible for this joint pathology. The degradation of the articular cartilage ultimately leads to deteriorating compressive and tensile stiffness. Increased levels of interleukin-1β (IL-1β) in the cartilage structures mediate the deterioration of the cartilage via increased nitric oxide (NO) levels and activation of matrix metalloproteinases (MMPs). Conventionally, nonsteroidal anti-inflammatory drugs (NSAIDS), joint injections, and physical therapy are employed in these conditions. However, oral joint supplements are also commonly used by horse owners as simple supplement or replacement for conventional therapies. Hence, it is not surprising that arthritis and joint disease are two of the most common conditions in horses where nutraceuticals are used. A wide range of nutraceutical products are available to treat these conditions. The nutraceuticals are considered to provide structural building blocks and thereby provide functional benefits in such conditions. Providing building blocks can mitigate disease signs and improve performance of the horse. Commonly, joint supplements contain glucosamine, chondroitin sulfate, a combination of glucosamine and chondroitin sulfate, avocado-soybean unsaponifiables, methylsulfonylmethane (MSM), oral hyaluronan gel, green-lipped mussel extract, Epiitalis, etc. However, this chapter shall focus on those with available scientific data to support their activity.

4.1 Glucosamine and Chondroitin Sulfate

Glucosamine is a natural compound found in cartilages. It is harvested from the shells of shellfish or prepared in a laboratory. There are several forms of glucosamine such as glucosamine sulfate, glucosamine hydrochloride, *N*-acetyl glucosamine, etc. Chondroitin sulfate (CS) is a major component of the extracellular matrix (ECM) of connective tissues like the cartilage, bone, skin, ligaments, etc. It is a sulfated glycosaminoglycan (GAG) and is composed of long unbranched polysaccharide chain with a repeating disaccharide structure of *N*-acetylgalactosamine and glucuronic acid. CS is responsible for the resistance, elasticity, and other biomechanical properties of the cartilage. Chondroitin sulfate and glucosamine have been used clinically for joint diseases for almost 50 years. Since they have been investigated together in many clinical and animal studies, they are considered here together for their use as joint supplements.

Several studies in humans have shown that glucosamine decreases pain and improves mobility in those suffering from osteoarthritis. In a double-blind clinical trial (Lopez Vaz 1982), glucosamine (1.5 g) was compared with ibuprofen (1.2 g) daily over a period of 8 weeks. Though the pain score decreased with ibuprofen in the first 2 weeks, glucosamine fared better at the end of 8 weeks. Both drugs were well tolerated.

Glucosamine has been shown to prevent experimentally induced cartilage degradation of equine articular cartilage explants. Cartilage disks harvested from the weight-bearing region of articular surface were cultured. These cartilages were shown to increase the production of NO, release peptidoglycan, and increased MMPs in response to LPS or IL-1 added in the media. Fenton et al. (2000) demonstrated that all these responses were prevented by glucosamine that had been added to the media. The authors postulated that glucosamine may prevent cartilage matrix degradation by inhibition NO production. It is known that the NO levels are increased in synovial fluid of diseased joints and induce chondrocyte apoptosis, inhibition of cell proliferation, and activation of MMPs. Alternatively, glucosamine may simply directly quench the increased NO or act as an antioxidant and prevent MMP-mediated degradation of cartilage matrix. The second mechanism proposed was the direct inhibition of MMPs by glucosamine.

In a study on horses with degenerative joint disease treated with a glucosamine-chondroitin sulfate compound to determine its effectiveness in decreasing lameness, it was found that within 2 weeks of treatment, the lameness grade, flexion test, and stride length were all significantly improved (Hanson et al. 1997). A further significant improvement occurred at 4 weeks of treatment.

It is essential for any therapeutic agent to be absorbed sufficiently so that it reaches its site of action to exert its pharmacological effect. In this context, the bioavailability of any drug is critical for its action. Du et al. (2004) showed that glucosamine hydrochloride and chondroitin sulfate are orally bioavailable in horses by determining the C_{max} and T_{max}. However, the oral bioavailability of CS has been debated for some time due to its large molecular structure. At the same time, however, it is also known that oral administration of CS does provide relief from pain and a slowing of the progression of osteoarthritis in animals. CS may also be

metabolized to unsaturated disaccharides. In vitro studies on Caco-2 cell culture also suggested higher permeability for low-molecular-weight CS. To resolve this issue, Eddington et al. (2001) conducted a study in horses to determine the oral bioavailability of CS by determining the disaccharides formed after oral administration and to determine the influence of its molecular weight. The study found that disaccharides formed specifically following the breakdown of chondroitin sulfate in horse plasma samples after oral dosing of 8.0 and 16.9 kDa molecular weight CS. It was interpreted that CS or fragments of the CS molecule are absorbed after its oral administration. The bioavailability associated with 8.0 kDa CS was higher than the 16.9 kDa CS.

Laverty et al. (2005) examined the concentration of glucosamine in synovial fluid and its pharmacokinetics in serum of horses following clinically relevant oral and iv dose levels. The maximum concentration of glucosamine in serum was ~300 μM following iv dosing and ~6 μM following oral dosing. The corresponding synovial concentrations were 9 μM–15 μM and 0.3 μM–0.7 μM, respectively. Based on these concentrations, the investigators concluded that the therapeutic benefit of dietary glucosamine may be secondary to its effects on non-articular tissues such as the intestinal lining, liver, or kidney. The mean bioavailability of glucosamine was 5.9%, and its mean elimination half-life was 2.82 h. Therefore, even the mechanism of action of glucosamine needs further elucidation.

How do glucosamine and chondroitin sulfate work in joint inflammation and pain? Osteoarthritis is associated with degeneration of the articular cartilage and excess production of proinflammatory cytokines. It is recognized that IL-1β is a proinflammatory cytokine that can induce the catabolic cascade. At physiologically relevant concentrations, glucosamine and chondroitin sulfate have been shown to regulate gene expression and synthesis of nitric oxide (NO) and prostaglandin E_2 and can exert anti-inflammatory properties (Chan et al. 2005). Further, glucosamine can stimulate glycosaminoglycan (GAG) and proteoglycan synthesis and decrease proteoglycan degradation, thereby preserving cartilage.

4.2 Miscellaneous Joint Supplements

Joint supplements containing glucosamine and chondroitin sulfate are also marketed with manganese, various antioxidants including vitamin C, or herbal anti-inflammatory compounds.

Undenatured type II collagen (UC-II), a natural ingredient containing glycosylated undenatured type II collagen (Bagchi et al. 2002), has been shown to modulate joint health both in osteoarthritis (OA) and rheumatoid arthritis (RA). Oral intake of small amounts of glycosylated UC-II (10 mg/day) over 42 days in five female subjects suffering from significant joint pain greatly reduced pain including morning stiffness, stiffness following periods of rest, etc. Similarly, in a placebo-controlled clinical study, Gupta et al. (2009) evaluated undenatured type II collagen (UC-II) against glucosamine and chondroitin in arthritic pain in horses. The horses were evaluated for overall pain, pain upon limb manipulation, pain after physical exertion, and liver and kidney functions. Although the glucosamine- and chondroitin-treated group showed significant reduction in pain, its efficacy was less as compared to UC-II. Clinically, the UC-II-treated animals tolerated the treatment well without any signs of toxicity. All the parameters monitored, i.e., body weight, body temperature, respiration rate, pulse, liver functions (bilirubin, GGT, and ALP), and kidney functions (BUN and creatinine), remained unchanged.

In an experimentally induced equine acute synovitis model, two nutraceutical supplements AT (Cavalor ArtiTec, Nutriquine NV, Belgium) and HP (Hydro-P, Sonac, The Netherlands) were investigated concerning inflammation and biomarkers of cartilage metabolism (Van de Water et al. 2016). Synovitis was induced in the right intercarpal joint by injection of 0.5 ng lipopolysaccharide (LPS) of *E. coli*. Synovial fluid samples were analyzed for total nucleated cell counts (TNCC), total protein (TP), and a comprehensive set of biomarkers of inflammation (PGE_2, IL-6, MMPs, CP-11, and CAG). Both nutraceuticals significantly lowered TP, TNCC, and PGE_2. There were no serious adverse effects.

The market for joint supplements has several other products like New Zealand green-lipped mussel, shark cartilage, a lipid extract from the herb Biota orientalis, etc. For further details on nutraceuticals in equine osteoarthritis, readers are referred to some other publications elsewhere (May et al. 2015; Gupta 2016; Chap. 26).

5 Nutraceuticals as Performance Boosters

The nutraceutical market is replete with nutraceutical products for horses, claiming to delay fatigue, increase stamina, build muscle, reduce recovery time, etc. These so-called ergogenics are supposed to boost horses' exercise performance capacity. The term "ergogenic" is derived from the Greek word "ergo" meaning "work." Unfortunately, many such supplements are not supported by scientific evidence. There are several mechanisms by which various foods or nutritional supplements work to enhance physical performance. However, it is essential to consider the information available on a given supplement and determine the scientific rationale and validity of such claims. Some of the most commonly used nutraceuticals for such purposes are discussed here.

5.1 Carnitine

L-carnitine is a conditionally essential nutrient that plays an important role in mitochondrial β-oxidation. As it is involved with the utilization of fatty acids for energy in the muscle cell, it is believed that supplementation of carnitine would be muscle glycogen-sparing and reduce lactic acid production, thereby improving muscle function and endurance. As a dietary supplement for athletes, L-carnitine has been investigated for its potential to enhance β-oxidation during exercise (Huang and Owen 2012). While some studies have shown a positive impact on VO (2 max) and other performance measures, others have found contradictory results. As L-carnitine is known to enhance vascular endothelial function, it can also improve blood flow to muscle tissues and decrease hypoxic stress and its resulting sequelae. The authors concluded that L-carnitine is regarded as a safe supplement for athletes and has been shown to positively impact the recovery process after exercise. In horses, it has been shown (Zeyner and Harmeyer 1999) that oral supplementation of 5–50 g of L-carnitine/day elevated the carnitine concentration in blood plasma to about twice its basal concentration. However, no clear relationship existed between an orally administered dose of carnitine and the increase of L-carnitine. It is essential to unequivocally demonstrate an increase in muscle carnitine levels following supplementation of carnitine.

5.2 Creatine

Creatine is intricately involved in energy metabolism in the muscles. Creatine is converted into phosphocreatine which anaerobically donates phosphate to adenosine phosphate, creating ATP. Increasing the available ATP can facilitate muscle contraction and therefore may contribute to increased stamina. Inadequate phosphocreatine is considered a major cause of muscle fatigue during intense exercise. On this basis, it is common to supplement the diet of the horse with creatine for improved performance. There are several studies on human volunteers on the effect of creatine supplementation on exercise performance and endurance. In one such study, Becque et al. (2000) investigated the effects of 6 weeks of oral creatine supplementation during a periodized program of arm flexor strength training on arm flexor 1RM, upper arm muscle area, and body composition. It was found that creatine supplementation during arm flexor strength training leads to greater increases in flexor muscular strength, upper arm muscle area, and fat-free mass than strength training alone. However, in horses, creatine supplementation did not appear to provide benefits. In a study on oral creatine supplementation on the performance of quarter horses used in barrel racing, Teixeira et al. (2016) found that supplementation with 28 g of creatine/100 kg body weight, orally for 45 days significantly altered LDH activity, plasma glucose, and PCV. However, there was no change in time scores, heart rate, and plasma lactate; the variables are considered to be performance indicators. The authors concluded that there was no improvement in equine athletic performance due to creatine oral supplementation. The lack of effect of creatine supplementation on equine performance could be due to the poor bioavailability of creatine in horses. In a study undertaken to examine the oral absorption of creatinine in the horse by Sewell and Harris (1995), a single dose of creatine monohydrate only modestly increased the creatine levels. Even after 13 days of feeding 0.15 g/kg body weight of creatine, there was no effect on the muscle content of creatine. Unlike humans, horse has limited ability to absorb creatine when given orally. This is understandable as the horse is normally exposed to very low levels of creatine in its herbivorous diet and as a species does not have ability to orally absorb creatine. This is unlike humans where the diet has animal meat and fish which contain high levels of creatine. Hence, dietary supplements containing creatine are unlikely to improve the performance in horses.

5.3 Amino Acids

Amino acids and protein supplements are considered to have the ability to build muscle mass thereby influencing the performance of the horse. In addition, branched-chain amino acids (BCAA) have the ability to positively impact muscle glycogen content which may have some bearing on fatigue. In male endurance-trained cyclists, treatment with BCAA has shown an interesting muscle glycogen-sparing effect as compared to placebo. It is believed that this glycogen-sparing effect could translate into a delayed muscle fatigue during sustained exhaustive exercise (Blomstrand et al. 1996). In addition, treatment with BCAA may provide carbon intermediates for the citric acid cycle when endogenous carbohydrate reserves are depleted. This could further add to the delay in the onset of fatigue (Wagenmakers 1999).

Central mechanisms of fatigue play an important role in exercise performance. Increase in brain 5-hydroxytryptamine (5-HT) is known to cause a deterioration in sport and exercise performance. Currently, there is evidence that exercise increases the plasma levels of free tryptophan (fTRP) leading to an increase in the ratio fTRP/BCCA, which is associated with increased brain 5-HT and consequently increased fatigue. It has been shown that brain 5-HT levels may be manipulated with drugs and have a predicted effect on brain-mediated exercise fatigue. However, the influence of nutritional manipulations of the fTRP/BCAA ratio on

performance is not well established, partly because of methodological problems. Carbohydrate feeding during prolonged exercise, however, has led to dramatic reductions in fTRP/BCCA and enhanced performance. However, it has been difficult to distinguish between the effects of carbohydrate feedings on direct effect of muscles and central effects (Davis 1995).

Since BCAA and tryptophan compete with each other to enter into the central nervous system (CNS), BCAA supplementation could reduce tryptophan entry and thereby delay the onset of fatigue. Farris et al. (1998) infused horses intravenously with tryptophan to increase its entry into the CNS and predictably decreased the time to fatigue by about 15%. This was taken as evidence that an increase in circulating tryptophan can decrease endurance performance in horses. However, this could not be replicated with oral administration of tryptophan. Again, BCAA supplementation in large quantities did not have expected influence on endurance performance.

Mikulski et al. (2015) investigated the effectiveness of oral BCAA and L-ornithine L-aspartate supplementation (BCAA + OA) in healthy men to reduce plasma ammonia concentration and enhance psychomotor performance during exhaustive exercise. At the end of prolonged exercise, the plasma ammonia concentration was higher in the BCAA + OA group than in the placebo group. Decreases in plasma ammonia during recovery were significantly higher in the BCAA + OA group than in the placebo group. It was concluded that BCAA + OA is a useful way to improve multiple choice reaction time during high-intensity exercise and accelerate the elimination of ammonia at the recovery stage after exercise in healthy young men.

Unfortunately, the beneficial effects of BCAA supplementation on exercise performance could not be demonstrated consistently. In a study on trotter horses (Stefanon et al. 2000), the horses were treated for 4 weeks of supplementation with a BCAA mixture (9.0 g L-leucine, 4.5 g isoleucine, and 4.5 g L-valine) 1 hour before training. BCAA supplementation resulted in higher alpha-ketoisocaproate in supplemented horses. However, BCAA treatment for 4 weeks did not affect any markers of energy metabolism like plasma lactate, glucose, allantoin, or pyruvate concentration. Similarly, in a study (Casini et al. 2000) on the effect of BCAA supplementation on metabolic response to a 1600 m run on a treadmill in standardbred trotters, lactate, ammonia, total protein, urea, uric acid, creatinine, FFA, creatinine kinase, LDH, and AST were monitored. However, none of these parameters showed any statistical difference between groups. The results suggested that BCAA supplementation was not effective in enhancing performance in healthy and well-fed horses.

5.4 HMB (β-Hydroxy β-Methyl Butyrate)

In both horses and humans, nutritional ergogenic aids have been used along with an appropriate training program to improve physical ability. HMB is a metabolite of essential amino acid leucine and is produced endogenously both in animals and man. It is a common dietary supplement in exercise enthusiasts. HMB is involved in cholesterol biosynthesis, and it is believed that during heavy training and exercise, supplementation with HMB may help synthesis of cholesterol in the muscle tissue, mitigate muscle damage, and promote maximal growth and function. In a normal horse diet like alfalfa, HMB is present only in small quantities.

In one study, horses given HMB supplement had lower muscle tissue breakdown as compared to controls (Nissen et al. 1997). In another study conducted to determine the effect of oral supplementation of HMB and γ-Oryzanol (GO) on indices of exercise-induced muscle damage in Thoroughbred race horses (Ostaszewski et al. 2012), it was found that the creatine kinase and lactate levels were lower in the treated group as compared to the controls. It was concluded that HMB and GO supplementation provide prevention of exercise-induced muscle damage. Again, in a meta-analysis of randomized controlled clinical trials, it was found that HMB supplementation reduced LDH and CK serum levels in adults following exercise-induced muscle damage showing its effectiveness as a muscle damage recovery agent (Rahimi et al. 2018). Feeding HMB improves endurance and reduces muscle damage in horses.

6 The Use of Nutritional Supplements in Dressage and Eventing Horses

A survey conducted on the use of nutritional supplements in dressage and eventing horses (Agar et al. 2016) showed that a wide range of supplements was used and most owners and riders perceived that they were important to their horses' health and performance. The main health and performance issues identified for dressage horses were energy/behavior, lameness, and back and muscle problems. For eventing horses, it was stamina and fitness levels, lameness, and energy/behavior. In both disciplines, lameness and/or joint problems were identified as important issues in addition to behavioral problems. The authors concluded that despite the low levels of evidence for most supplements, this study showed that they were widely used across both disciplines. Most owners stated that they felt that the supplements made a marked difference to their horse. Since such food supplements are widely used and their perceived value is great for the horse's health and performance, the veterinary

profession should have an understanding of owners/riders' opinions and concerns.

7 Concluding Remarks and Future Directions

Nutritional and health supplements are frequently used to improve health and/or performance, in addition to prevention of deficiencies of vitamins, minerals, electrolytes etc., in man and animals. The equine nutraceuticals' market has grown greatly in the last 25 years, but there are concerns for its sustained growth. Since the term nutraceuticals was coined, it has not been fully appreciated that the term does not have any regulatory meaning. Unfortunately, this has encouraged only limited attention to the evaluation of safety and efficacy of the products and the quality of manufacture. Until the industry develops capabilities and a capacity to demonstrate the clinical benefits of its products and the ability to manufacture with adherence to quality of its processes, it will continue to be a challenging time for the nutraceutical industry.

Nutraceuticals for Camelids

Tarun K. Gahlot

Abstract

Nutraceuticals are becoming increasingly popular within the veterinary profession and are popularly used in camelids as dietary supplements for improving health, preventing disease, and providing nutritional supplementation. Camel milk is among such dietary supplement with profound nutraceutical values. About 16 active nutraceuticals have been identified and discussed. These are galactolipid natural emulsifiers; natural tocotrienol antioxidants; oat-derived beta glucans; phospholipids; bioavailable trace and macro minerals; nanotechnology components and simple sugars "oligosaccharides"; natural buffering and yeast cultures; omega-3 fatty acids; prebiotics; vitamin D3, phosphorus, calcium, and yeast cultures; digestible milk proteins; glutamic acid; methylsulfonylmethane (MSM); microscopic toxin binder; nucleotides; and vitamin C. Nutraceutical supplementation improves cartilaginous health within the joint as well as maintains the skin and hair coat quality. These have a profoundly beneficial impact on the health of the body, and antioxidant compounds may help in the prevention of cancer.

1 Introduction

Nutraceuticals are becoming increasingly popular within the veterinary profession. An animal's well-being can be improved by a diet containing nutraceuticals. They have been described by the North American Veterinary Nutraceutical Council as a "non-drug substance that is produced in a purified or extracted form and administered orally to provide agents required for normal body structure and function with the intent of improving the health and well-being of animals."

Nutraceuticals are commonly used in a large animal health care. Vitamin and mineral supplements for livestock and horses are used in range, pasture, and equine stable environments. Nutraceutical supplementation improves cartilaginous health within the joint as well as maintains the skin and hair coat quality. These have a profoundly beneficial impact on the health of the body, and antioxidant compounds may help in the prevention of cancer.

Camelids are modified ruminants or "pseudoruminants." Like ruminants, they use foregut fermentation to break down cellulose in fibrous plant species. But in contrast to ruminants, their forestomachs are made up of three compartments rather than the true ruminants' (sheep, goats, cattle, deer) four. The three sections of a camelid forestomach are called C-1, C-2, and C-3; each compartment has a specialized function to perform. Ruminants and camelids dedicate the majority of their digestive capacity to the fermentation of plant fiber. It is important for camelids to eat plenty of fibrous material to sustain normal health, and, as such, the consumption of concentrated hard feeds should always be kept to a minimum. Natural foregut digestion should be maintained because it is crucial for the health and vitality of New World Camelids.

The nature of the feed can have dramatic effects on well-being, as all food goes straight into the fermentation vat of the forestomach where factors like motility, gas eructation, regurgitation, remastication, and re-swallowing are all part of the normal feeding process.

R. C. Gupta et al. (eds.), *Nutraceuticals in Veterinary Medicine*, https://doi.org/10.1007/978-3-030-04624-8_46

Camel milk is among such dietary supplement with profound nutraceutical values. From a medicinal point of view, it has a rich content of protective minerals and proteins that could have a vital role for enhancing immune defense mechanism (Yagil 1982). It contains higher amount of zinc which offer significant role in the development and maintenance of a normally functioning immune system (Hansen et al. 1982). Camel milk has insulin-like activity and regulatory and immunomodulatory functions on β-cells. It contains a good amount of protective proteins, including lysozyme, lactoferrin, lactoperoxidase, peptidoglycan recognition protein (PGRP) enzyme, immunoglobulin G, and secretory immunoglobulin A. These immune factors are present at greater concentrations in camel milk (El Agamy et al. 1992).

Nutraceuticals appear to be of benefit in both the treatment and prevention of disease because they often possess unique chemical actions that are unavailable in pharmaceuticals, e.g., ability of silymarin in milk thistle to protect liver cells from damage and quercetin (found in a variety of plants) to stabilize certain cells of the immune system (mast cells) to avoid allergic reactions.

The effectiveness and dosage of nutraceuticals should be well scrutinized as there is no regulatory agency charged to determine guidelines for nutraceuticals. Some animals may be potentially allergic to the plant or feed source of the nutraceutical product; hence trials of these products should be conducted thoroughly. There are many active nutraceuticals whose composition and mode of action are discussed below in brief.

2 Active Nutraceuticals

1. *Galactolipid Natural Emulsifiers*
   Galactolipids are phosphorus-free glycoglycerolipids in plants and are in fact a combination of sugar and fat molecules which create the suitable medium for the absorption of active ingredients across the gut wall. Galactolipids make up the bulk of photosynthetic membranes. Oxygenic photosynthesis in *Cyanobacteria* and plants depends on the presence of galactolipids. Recently, it has been demonstrated that the galactolipid, 1,2-di-*o*-alpha-linolenoyl-3-*o*-beta-D-galactopyranosyl-sn-glycerol (1), may be important for the anti-inflammatory activity of dog rose (*Rosa canina*), a medicinal plant with documented anti-inflammatory effect in diseases such as arthritis. This galactolipid also occurs in relatively high concentrations in certain legumes (e.g., common bean, pea), leafy vegetables (e.g., kale, leek, parsley, perilla, and spinach), stem vegetables (e.g., asparagus, broccoli, and brussels sprouts), and fruit vegetables (e.g., chili, bell pepper, and pumpkin). Furthermore, compound 1 has been isolated from spinach and several medicinal plants by bioassay-guided fractionation as a galactolipid with possible cancer-preventive effects (Christensen 2009).
2. *Natural Tocotrienol Antioxidants*
   Tocotrienol antioxidants are a natural form of vitamin E. They are 40–60 times more readily bioavailable than other forms of vitamin E and help to maintain the integrity of the cells forming the lining of the gut to aid absorption. Recent mechanistic studies indicate that other forms of vitamin E such as γ-tocopherol (γT), δ-tocopherol (δT), and γ-tocotrienol (γTE) have unique antioxidant and anti-inflammatory properties that are superior to αT in the prevention and therapy against chronic diseases. These vitamin E forms scavenge reactive nitrogen species (ROS), inhibit cyclooxygenase (COX)- and 5-lipoxygenase (5-LOX)-catalyzed eicosanoids, and suppress pro-inflammatory signaling such as NF-κB and STAT3/STAT6. Unlike αT, other vitamin E forms are significantly metabolized to carboxychromanols via cytochrome P-450 (CYP4F2)-initiated side-chain ω-oxidation. Long-chain carboxychromanols, esp. 13′-carboxychromanols, are shown to have stronger anti-inflammatory effects than unmetabolized vitamins and may therefore contribute to beneficial effects of vitamin E forms in vivo (Jiang 2014).
3. *Oat-Derived Beta Glucans*
   Beta glucans have prebiotic properties that support beneficial bacteria in the gut to promote healthy absorption. Six grams of β-glucan from oats added to the AHA Step II diet and moderate physical activity improved lipid profile and caused a decrease in weight and, thus, reduced the risk of cardiovascular events in overweight male individuals with mild to moderate hypercholesterolemia (Reyna-Villasmil et al. 2007).
4. *Phospholipids*
   Phospholipids have emulsifying properties and have been shown to actively influence nutrient digestibility and absorption.
5. *Bioavailable Trace and Macro Minerals*
   Bioavailable trace minerals are essential minerals, provided in a digestible form to supply the needs of productive camelids. The supplementation with high levels of available zinc has shown very positive results, and selenium yeast is proven to be 20 times less toxic than inorganic selenium, which is very beneficial to health.
   Spears (2003) found that absorption of selenium and copper is much lower in ruminants than in nonruminants. The low absorption of these minerals in ruminants is due to modifications that occur in the rumen environment.

Selenium bioavailability is reduced by high dietary sulfur and the presence of cyanogenetic glycosides in certain legumes. Feeding organic selenium from selenomethionine or selenized yeast results in much higher tissue and milk selenium concentrations than are obtained with selenite. High dietary molybdenum in combination with moderate to high dietary sulfur results in the formation of thiomolybdates in the rumen. Thiomolybdates greatly reduce copper absorption, and certain thiomolybdate species can be absorbed and interfere systemically with copper metabolism. Independent of molybdenum, high dietary sulfur reduces copper absorption perhaps via formation of copper sulfide. High dietary iron also reduces copper bioavailability. Dietary factors that affect bioavailability of zinc in ruminants are not well defined. Phytate does not affect zinc absorption in ruminants because microbial phytase in the rumen degrades phytate. Manganese is very poorly absorbed in ruminants, and limited research suggests that high dietary calcium and phosphorus may reduce manganese absorption. Chelated minerals provide bioavailable forms of essential vitamins, copper, manganese, and zinc, which are required by important metabolic processes in a young developing cria.

6. *Nanotechnology Components and Simple Sugars Oligosaccharides*
   Oligosaccharides are used to support the immune system. The harmful organisms being absorbed into the bloodstream are blocked by high levels of macrophagic activity. In conjunction with a natural, high-quality forage diet, exposure to pathogenic molds/fungi will be reduced, and if there is a problem, the active self-defense mechanism will deal with them.
7. *Natural Buffering and Yeast Cultures*
   Natural buffering material and yeast cultures help to stabilize the pH in the foregut and encourage the development of beneficial fiber-digesting bacteria. This is important when feeding cereal-based feeds as starch is converted into lactic acid, which can increase acidity and create an unfavorable environment for the fiber-digesting bacteria.
8. *Omega-3 Fatty Acids*
   Omega-3 fatty acids provide a daily source of essential fat components. Omega-3 fatty acids are widely recognized as anti-inflammatory compounds and balance the pro-inflammatory omega-6 fatty acids in the correct ratio. Omega 3's are also found in large concentrations in spermatozoa and are essential for maintaining cell wall integrity and preventing moisture/oil loss from the skin. Healthy skin means high-quality fiber production.
   Gulliver et al. (2012) found that specific effects of omega-3 polyunsaturated fatty acids (*n*-3) on reproductive success in ruminants have not been examined in detail. There is strong evidence linking consumption of diets high in *n*-3 with reduced circulating peripheral inflammatory markers such as PGF(2α). Inflammatory eicosanoids including PGF(2α), in particular, can significantly affect reproduction outcomes such as the onset of estrus, embryo survival, and parturition. There appears to be an evidence linking *n*-3 supplementation with longer time to estrus and parturition associated with reduced PGF(2α), the effects of *n*-3 on other measurable outcomes of reproductive success, such as pregnancy rate, embryo survival, and intergenerational effects on the health, and production of offspring are largely unknown.
   Increasing omega fatty acids in tissues of the cow has been shown to provide benefits on reproductive performance, immunity and disease resistance, and positive hormonal shifts (Jenkins 2004).
9. *Prebiotics*
   Prebiotics provide specific nourishment for friendly, fiber-digesting bacteria to maintain good digestion and release nutrients for growth, breeding, and performance.
10. *Vitamin D3, Phosphorus, Calcium, and Yeast Cultures*
    Vitamin D3, phosphorus, calcium, and yeast cultures contain high levels of vitamin D3, available phosphorus, and calcium in a very palatable form. All three are crucial for healthy skeletal development, and additional yeast cultures are added to significantly improve the digestibility of phosphorus from normal feed.
11. *Digestible Milk Proteins*
    Milk proteins, particularly caseins, are highly digestible in the intestine and are a high quality source of amino acids. Readily digestible milk proteins provide key amino acids for supporting the growth of all tissues with high protein contents, namely, muscles, ligaments, tendons, hair, and hooves.
12. *Glutamic Acid*
    Glutamic acid is a natural flavor enhancer and an important nutritional support for natural healing and gut health during times of stress.
13. *Methylsulfonylmethane (MSM)*
    MSM is a source of sulfur, which helps to form cross-links with other molecules that maintain the strength and integrity of connective tissues. It is also essential for the manufacture of collagen.
14. *Microscopic Toxin Binder*
    A blend of microscopic adsorbent compounds that aid the natural expulsion of biotoxins, including mycotoxins, found in feed and the environment.
15. *Nucleotides*
    Cell division is the basis of growth and development and involves the splitting of RNA and DNA. Nucleotides provide essential structured units for the production of

RNA and DNA in cells and are very important to sustain normal healthy development.

16. *Vitamin C*
    Vitamin C is required for the formation of collagen in the body that forms the matrix of connective tissues in mammals. Supplementation of vitamin C therefore can help in tissue growth, tissue healing following trauma, and immune system of the camelids.

3 Concluding Remarks and Future Directions

Nutraceutical products are often included in animal feeds but are widely available in many forms, including capsules, tablets, powders, etc. Nutraceuticals are used for the prevention and treatment of common diseases in animals including cardiovascular disease, osteoarthritis, periodontal disease, cognitive dysfunction, and cancer, with their validation through clinical trials. Camelids are used these days as an industry of meat, wool/hair, and milk, in addition to the breeding and sports. Nutraceuticals might play a pivotal role in maintaining health of various body systems of these camelids. The veterinary nutraceuticals can be obtained from vet shops, veterinary practices, pharmacies, and the Internet.

Nutraceuticals in Poultry Health and Disease

Ayhan Filazi and Begüm Yurdakok-Dikmen

Abstract

The use of antibiotics at subtherapeutic doses with the aim of accelerating growth in poultry animals has either been prohibited or restricted in many countries, as it causes antibiotic-resistant microorganisms to develop and is a danger to consumers' health. Excluding antibiotics from the diets of poultry animals has caused various performance and health problems; therefore, there is an increasing need for alternative natural substances that can create similar effects. For this purpose, various feed additives have been developed for the improvement of growth and influence health in a positive way. These substances play an important role in the development and continuity of the animals' normal physiological functions and health and in protecting them against infectious diseases. Some of these substances are known as "nutraceuticals." In this section, nutraceuticals such as probiotics, synbiotics, enzymes, organic acids, and phytobiotics and their mechanism of action and possible use in the improvement of growth, immune system, and welfare are discussed.

Keywords

Nutraceuticals · Poultry · Probiotics · Prebiotics · Synbiotics · Organic acids · Enzymes · Phytobiotics

1 Introduction

In poultry farming, the most important targets are accelerating growth and increasing the efficiency of feed. In order to obtain optimal performance in the livestock, many factors, including the animals' genetics, quality of feed, environmental conditions, and diseases, must be considered (Rinttila and Apajalahti 2013). As is the case among all animals, poultry animals' digestive tracts are their most important system for mediating the intake and use of feed. It also bears significance with respect to exposure to environmental pathogens (Yegani and Korver 2008). When the functions of the digestive system are disrupted, digestion and the absorption of feed are disrupted, which endangers the animals' health and performance. Intestinal mucosa functions both as an aid in the absorption of nutrients and as a barrier against negative intestinal content and host interior tissues (Rinttila and Apajalahti 2013). The dynamic balance between the intestines' mucosa layer, epithelium cells, microbiota, and immune cells enables their mucosal functions (Schenk and Mueller 2008). Disruption of this dynamic balance due to a negative composition of feed and/or infectious disease influences the health and performance of poultry animals in a negative way. Antimicrobials have been used at subtherapeutic doses in poultry raising for many years, with the aim of maintaining this balance and improving the animals' development (Filazi et al. 2017). However, since long-term use of antibiotics causes drug-resistant microorganisms to develop, to avoid threats to consumer health and reduce the negative environmental effects, antibiotics have either been prohibited or significantly limited in many developed and developing countries (Filazi et al. 2015). Excluding antibiotics from the diet of poultry animals has caused performance problems in these animals and an increase in incidents of certain poultry animal diseases, such as necrotic enteritis and dysbacteriosis (Huyghebaert et al. 2011). With this in mind, there is an increasing need for alternative natural substances that can create similar effects. In response, various feed and feed additive substances have been developed to help the animals to grow and to have a positive impact on their health. These substances play an important role in changing and maintaining normal physiological functions and animal health and in helping to protect against infectious diseases. Some of these are known as "nutraceutical" (Das et al. 2012).

R. C. Gupta et al. (eds.), *Nutraceuticals in Veterinary Medicine*, https://doi.org/10.1007/978-3-030-04624-8_47

While nutraceuticals are used in humans as an alternative treatment for cancer, diabetes, osteoporosis, and depression, in poultry animals, they are used to regulate the intestinal bacteria population and the immune system and for protecting and treating enteric infections, for correcting intestinal morphology, and for increasing growth performance (Sugiharto 2016).

Generally, it is accepted that the balance between the numbers of useful bacteria and pathogen bacteria (at least 85% of total bacteria are composed of useful bacteria) bears vital importance for the host and that a disruption in this balance damages poultry animals' intestinal health (the morphology of the intestinal wall is disrupted, and immune responses are induced) (Choct 2009). In this case, chickens need more energy and their development slows down. To overcome microbial infections in chickens, inflammatory response is important (Kogut 2013). By contrast, if inflammation cannot be controlled, it can cause intestinal damage and disrupt digestive function (Brisbin et al. 2008). Furthermore, extreme inflammation can disrupt the hosting metabolism (Kogut 2013). In short, intestinal microbiota is important for maintaining immune balance and avoiding inflammation (Lan et al. 2005). Commensal bacteria show anti-inflammatory activities with short-chain fatty acids (SCFAs), which they synthesize to avoid intestinal damage (Brestoff and Artis 2013). With the addition of nutraceuticals to the diet, it is possible to change the population of microorganisms in poultry animals' intestines and to facilitate the growth of useful bacteria (Adil and Magray 2012).

Another effect of nutraceuticals is related to their ability to reduce the undesirable/adverse effects of antimicrobials. Oral or parenteral applications of antibiotics cause a reduction of the population of intestinal microbiota regardless of the site of infection (Sullivan et al. 2001). Thus, since varieties of intestinal bacteria change, irritable intestine syndrome and *Clostridium difficile* infections can be observed (Rashid et al. 2012). Furthermore, considering the undesirable outcomes of systematic antimicrobial use, an intestinal microbiota reservoir of antibiotic-resistant genes can form, and bacteria strains' horizontal gene transfer may increase in the form of carbohydrate composition changes. Then, the population of certain intestinal bacteria increases, and metabolic activities contributing to digestion change can occur in the immune responses of the distal organs. The only way to reduce or eliminate this type of probable negative effect among intestinal microbiota is to use more special products for a specific infection factor (Frei et al. 2015). Within this context, applications such as nutraceuticals are often applied.

The purpose of this section is to discuss those nutraceutical substances used in poultry animals to improve their development, to regulate their immune systems, and to maintain their health. This section also features a discussion of nutraceuticals' probable effect mechanisms.

2 Probiotics

The use of exogenous bacteria (probiotics) to maintain health and avoid disease has been common for years, despite its quite complex outcomes (Huyghebaert et al. 2011). It is well known that the microorganism types used in modern probiotic preparations are quite variable, though mostly *Lactobacillus* (LAB) and *Bifidobacteria* are used. Among these are microorganisms such as *Lactobacillus bulgaricus*, *L. acidophilus*, *L. casei*, *L. helveticus*, *L. lactis*, *L. salivarius*, *L. plantarum*, *Streptococcus thermophilus*, *Enterococcus faecium*, *E. faecalis*, and *Bifidobacterium* spp. (Khaksefidi and Rahimi 2005; Kabir 2009). Some commercial probiotic samples used in poultry are depicted in Table 1.

Due to their beneficial effects, probiotics are commonly used to ward off infection by pathogen microorganisms in various settings, including poultry animals, and to provide a protective and effective means of increasing body weight, regulating feed/food intake and digestibility, improving immune responses, and reducing mortality rates (Armut and Filazi 2012).

Ideal probiotic is not expected to be influenced negatively by normal microflora activities in the digestive system. The beneficial effects in the host environment depend on the quick and easy growth of the probiotic in the environment, be resistant against various pH values and organic acids, regulate intestinal immune system cells, adhere to intestinal cells, and not disrupt intestinal tissues and permeability (Kum and Sekkin 2012; Musa et al. 2009). In this respect, it is important for probiotics to show a direct inhibiting impact on pathogens and/or to have high intestinal colonization resistance. In such cases, probiotics inhibit the effectiveness of pathogen bacteria through the mediation of different mechanisms and reduce the frequency and duration of diseases. They can show their beneficial effects on health via the host's digestive system, immune system, metabolism, and/or mental health. Generally, they reveal their beneficial effects on health as being special for strains and, even if they are from the same type, may not show their effect on one strain but will reveal in another. For this reason, due to similarities in metabolisms, some of their features may be common (Fijan 2014).

The effects of probiotics on poultry animals can be summarized as follows:

1. With their competing and antagonistic effects, they maintain normal intestine microflora against pathogen bacteria.
2. By increasing digestive system activities or bacterial enzyme activities and by reducing ammoniac production, they cause changes in the birds' metabolism.
3. By regulating feed intake, they regulate digestion.
4. By enabling the dissolution of organic substances that bacteria mediate, they contribute to their absorption.

5. By increasing antibody levels or macrophage activities against pathogen microorganisms or by promoting cytokine secretion, they stimulate the immune system and enable immunomodulation.
6. They inhibit the production of bacterial toxins.
7. By influencing water quality in the intestines in a positive way, they control certain microorganisms, such as protozoon and coccidiosis (Khaksefidi and Rahimi 2005; Lan et al. 2005; Kabir 2009; Brisbin et al. 2010).

It has been stated that, in our time, to enhance the effectiveness of probiotics and to provide a combination of effective features, commercial products with different effect mechanisms comprised of a variety of probiotic combinations could be used. However, we should note that bacterial strains used for probiotic purposes can exhibit differences that are unique for hosts or different types (Musa et al. 2009). The main point to keep in mind with these products is that microorganisms bearing the features of probiotics are not effective against all types of diseases, so to obtain the expected benefits from a special strain for disease, one must know the appropriate dosage (generally 10^9 cfu/kg feed for poultry animals) and period of use. Further, an adjuvant that contains a probiotic microorganism can have side effect risks and prove harmful to some metabolic activities (Mikelsaar 2011).

Our information is still limited as to why bacterial populations become unstable when a single probiotic is added. For this reason, and to strengthen the natural bacteria population and eliminate competitive pathogens, generally complex microbial mixtures are applied. We know that this approach is especially successful in poultry animals. In those animals treated with a mixture of commensal anaerobic bacteria, studies have shown significant reductions in the population of intestinal *Salmonella* (Markowiak and Śliżewska 2018). The most important concern related to probiotics is that of antibiotics resistance in them and the transportation of this property to intestinal bacteria. Competent authorities and industrial institutions have begun to publish reports evaluating the transfer risk of antibiotic resistance to probiotics stating their concerns (Nawaz et al. 2011).

3 Prebiotics

Prebiotics, which are also known as "diet fibers," cause special changes in the composition and/or effectiveness of digestive tract flora and induce beneficial physiological impacts not only in the colon but also throughout the body. They may also reduce the risks associated with various pathogens (Fernandez et al. 2016). A prebiotic substance should stimulate the activity of intestinal bacteria and/or

their development in a selective way and should not be influenced by gastric activities, hydrolyzed by digestive system enzymes, digested in the intestines, or be digested at a significantly low rate (Kolida and Gibson 2011).

Unlike probiotics, prebiotics are nonliving components; host cells do not use them. While probiotics are most effective in the small intestine, prebiotics are most effective in the colon (Kum and Sekkin 2012). Prebiotics bearing these features that are widely used in modern poultry animals include inulin, fructooligosaccharides (FOS), lactulose, oligofructose, galacto-oligosaccharides (GOS), trans-galacto-oligosaccharides (TOS), mannanoligo saccharides (MOS), soy oligosaccharides (SOS), xylo-oligosaccharides (XOS), lactitol, pyrodextrins, and isomalto-oligosaccharides (IMO) (Gibson and Barret 2010; Huyghebaert et al. 2011; Kim et al. 2011; Alloui et al. 2013). Legumes, fruits, and cereals are natural sources of prebiotics. However, the majority of substances used today have been synthesized industrially via chemical and enzymatic methods (Markowiak and Śliżewska 2018).

In the modulation of intestine microbiota, probiotics and prebiotics share common mechanisms (Huyghebaert et al. 2011). Still, the composition and metabolism of prebiotics are significantly different. Prebiotics reveal their osmotic impact when they are not fermented, but they stimulate the activity and/or development of one or limited number of bacteria when they are fermented in a selective way. Then, they increase the formation of SCFAs by reducing the rate of nitrogenous products, reducing the effectiveness of reductant enzymes, and regulating the immune system. As a result of these basic influences, prebiotics increase gas production in the intestines (carbohydrate, methane, and hydrogen) and fecal weight; they help users to avoid constipation, regulate the intestinal habitat, slightly reduce pH levels in the colon, increase the synthesis of proteins providing mineral absorption or increase the ratio of active carrier proteins, and reduce the ratio of toxic, mutagenic, genotoxic metabolites, bile acid, and cancer-developing enzymes (Roberfroid et al. 2010). In addition to the positive effects of prebiotics, it should also be considered that, considering their varying amounts and application periods, different effects can result so that, despite the use of probiotics, in the application of extreme dosages, swelling can occur in the intestines, extreme gas formation can be seen, or diarrhea can be observed, depending on the dose. In short, there can be negative aspects regarding the disposal of specific pathogens, since they cannot show an effect that is as strong as that of antibiotics (Kum and Sekkin 2012).

In poultry animals, prebiotics reduce mortality caused by intestinal pathogens and strengthen hosting defense systems. It is not known exactly how prebiotics achieve this effect. It is likely that this occurs when LAB numbers in the intestines are increased and these bacteria bind to the sites where pathogens will be binding (competitive antagonism) (Alloui et al. 2013). SCFA production caused by prebiotics increases the acidity levels of the intestines, which compresses the pathogens in them. Furthermore, as prebiotics enable the pathogens in the intestine to be removed quickly, they also improve the animal's immune response (Kim et al. 2011). Prebiotics have a direct interaction with the immune cells in the intestines and enable beneficial microorganisms to be colonized more successfully in these places. In this way, they strengthen the immune system in an indirect way (Janardhana et al. 2009).

A study conducted with broiler chickens (Kim et al. 2011) found that the addition of prebiotics to the diet (FOS and MOS used separately) did not change feed consumption, feed efficiency, or death rates, when compared with control groups. However, it did cause an increase in live weights. By contrast, some authors (Biggs et al. 2007; Janardhana et al. 2009) have stated that the addition of prebiotics to the diet revealed no increase in the live weights of broiler chickens. These differences can be explained relative to the types of prebiotics used in each study and the features that are unique to each prebiotic. For example, inulin and FOS are prebiotics preferred for bifidobacteria; for this reason, they avoid the settlement of pathogen bacteria in the hosting intestines, which promotes the growth of bifidobacteria. MOS (for pathogens such as *E. coli* and *Salmonella* spp.) has an effect as a receptor analog; however, it can bind to pathogens and cause their elimination together with the contents of the intestine (Huyghebaert et al. 2011).

Furthermore, some studies have found that prebiotics regulate the barrier features of the intestine's epithelium, which they provide energy for large bowel cells, and that they prevent diarrhea related to antibiotics. They also reduce kidney load by increasing nitrogen extraction from the bowel and reduce low-density lipoprotein and serum triglyceride ratios in the liver while increasing immunoglobulin A production in the immune system. Due to these different effects, prebiotics can be employed in different areas among poultry animals, mainly to increase their feed conversion rate, to create an immunomodulator effect, to improve product quality (such as reducing cholesterol levels in eggs), to regulate intestine microbiota, and to reduce the effectiveness of pathogen microorganisms (Roberfroid et al. 2010).

4 Synbiotics

Synbiotics are defined as a mixture of probiotics and prebiotics which enable for live microbial food/feed additives to remain alive in the digestion tract and which enable their implantation, causing positive influences on the host, which stimulate growth in a selective way and/or which stimulate metabolism of one or limited number of bacteria metabolism

Table 2 Some commercial synbiotic samples used in poultry

Probiotics	Prebiotics
Enterococcus faecium	Fructooligosaccharides
Bifidobacterium animalis, *Pediococcus acidilactici*, *Enterococcus faecium*, *Lactobacillus reuteri*, *Lactobacillus salivarius*	Inulin
Lactobacillus: *acidophilus*, *casei*, *salivarius*, *plantarum*, *rhamnosus*, *brevis*; *Bifidobacterium*: *bifidum*, *lactis*; *Streptococcus thermophilus*	Inulin

No trade names given

(Kolida and Gibson 2011). While prebiotics are selected independently for their complementary effect, probiotics are selected to provide desired beneficial effects in the host. In a synbiotic, a probiotic is chosen to provide beneficial effects in the host, and a prebiotic must be a specific component that stimulates the growth and/or metabolism of a selected probiotic microorganism. In this synergistic effect, the effect of a prebiotic, when taken below the required dosage, is limited, so a low amount of the probiotic is needed. Further, the selected prebiotic should be more interested in the probiotic with which it will be used, and it should be selective in its ability to promote the growth and development of the host. In other words, it is required that the prebiotic support the development of those probiotic microorganisms that are selectively preferred (Kum and Sekkin 2012).

Some authors have argued that probiotics are not activated by prebiotics but that the impact area of probiotics is in the small intestines, while the impact area of prebiotics is in the large intestines. If this is true, we cannot describe a synbiotic impact between the two components but instead must regard this as a synbiotic relationship with their individual mechanisms better described as synergism (Cerezuela et al. 2011). Nonetheless, no matter what kind of relationship there is between them, various studies conducted with animals have shown that combinations of prebiotics and probiotics have beneficial effects in regulating intestine flora, in avoiding septicemia, and in dealing with inflammatory and irritable intestine diseases, colon cancer, bone disease, and certain surgical diseases (Kolida and Gibson 2011). Some commercial synbiotic samples used in poultry today are given in Table 2.

Current data related to the effects of synbiotics on animal health are quite limited. More advanced metagenomic research needs to be conducted in this respect. However, they have been proven to reduce pathogens in the intestines, so probiotics and prebiotics have a synergic effect (Markowiak and Slizewska 2018).

In a study conducted with a probiotic and FOS, researchers found that, when these were used separately, the colonization of *S. enteritidis* in the broiler intestines was reduced, and, when they were combined, they were more effective (Fukata et al. 1999). Furthermore, a combination of *Enterococcus faecium* and FOS has been shown to increase growth in broilers similar to avilamycin, which triggers significant growth in the villus of the small intestines (Awad et al. 2009). In a similar way, when a combination of FOS and *Bacillus subtilis* was applied to 720 broiler chicks, it caused an increase in average daily body weights and improvement in feed efficiency. A reduction in both diarrhea and death rates was also observed in the animals (Li et al. 2008). It has been stated that, when a prebiotic composed of *Bacillus subtilis*, *B. licheniformis*, and *Clostridium butyricum* bacteria and yeast cell wall and xylose oligosaccharides was given to the broilers during their raising period, it increased their body weights, improved feed efficiency, increased breast size, reduced abdominal fat, increased muscle pH, reduced losses during cooking, reduced the formation of malondialdehyde, and reduced the chromium content of leg muscles. In return, this synbiotic both improved the performance of broilers and had a positive effect on meat quality and relevant oxidative features (Cheng et al. 2017). Synbiotics were shown to induce more positive effects on performance parameters than antibiotics; including the reduction of the abdominal fat. As performance parameters are major influence of the industry, synbiotics as antibiotic substitutes are expected to play as a competitive advantage (Toghyani et al. 2011).

5 Exogenous Enzymes

Exogenous enzymes are primarily obtained from *Bacillus subtilis*, *Lactobacillus acidophilus*, and *Streptococcus faecium* bacteria; *Trichoderma longibrachiatum* and *Aspergillus oryzae* fungi; and *Saccharomyces cerevisiae* yeast (Slominski 2011). Various exogenous enzymes, including beta-glucanase, xylanase, amylase, alpha-galactosidase, protease, lipase, and phytase, have been added to poultry animals' feed for many years (Adeola and Cowieson 2011). Exogenous enzymes are significantly important, especially for chickens fed with raw feed materials such as corn and soya, which include anti-nutritive components that make digestion and the absorption of feed in the digestive tract difficult (such as polysaccharides and protease inhibitors) (Yegani and Korver 2008). Further, when these additive substances are inserted into the feed in an extraordinary way to reduce feed costs, they cannot be completely digested or used by the chickens; for this reason, exogenous enzymes may be required (Costa et al. 2008). In such cases, exogenous enzymes address deficiencies in specific endogenous enzymes that are needed to hydrolyze anti-nutritional factors

in the feed and to digest those raw materials that cannot otherwise be digested by chickens (Sugiharto 2016).

When enzyme addition to feed is compared with other animals, it is clear that enzyme additives are preferred primarily among poultry animals. This is because, in poultry animals, the passage speed of feed through the digestive system is short; they do not develop a microbial flora nor produce other enzymes to break down these exogenous enzymes to break down plant cell walls. Similarly, it has been observed that the use of glucanase in feed containing barley and rye and the use of cellulase in rough feed containing high amounts of cellulose are helpful (Slominski 2011).

When xylanase was added to feed, we can observe an increase in the ratios of lactic and organic acids, a reduction in ammoniac production, and a rise in SCFA concentrations (Adeola and Cowieson 2011). Similarly, the intestines of poultry animals fed with a diet containing xylanase display an increase in LAB numbers, coliform, and *Salmonella* (Nian et al. 2011). By contrast, other studies have revealed that the addition of xylanase does not change the numbers of LAB and coliform in the jejunum of poultry animals (Yang et al. 2008). These differences may be attributable to enzyme activity that is influenced by various factors, such as the temperature, moisture, feed composition, age and breed of the animal, and—chiefly—pH level of the intestinal channel (Yang et al. 2008; Adeola and Cowieson 2011).

The combined use of probiotics with enzymes enables the polysaccharides of cereal grains in the cell wall that are not being digested to become splintered (especially wheat and barley), so that intestinal viscosity is increased by the reduction in polysaccharides as the digestibility of nutrients and its metabolic energy values are improved. Further, it has been found that exogenous enzymes reduce the development and fermentation of harmful microorganisms in the intestine and discourage colonization. In this respect, enzymes can be considered an alternative feed additive substance to antibiotics, which are commonly used to regulate growth and development in poultry raising (Kum and Sekkin 2012).

In order for exogenous enzymes to show their effects, chickens must not to be influenced by endogenous digestion enzymes in the digestive tract or at low pH levels (<4) (Sugiharto 2016). To derive the maximum benefit from enzymes, it is recommended that more than one enzyme should be used as a combination since there might be a presence of different types and varieties of anti-nutritive components in feed. In short, the beneficial effects of enzyme combinations are dependent on feed composition (Adeola and Cowieson 2011).

6 Organic Acids

Organic acids are found widely in nature as normal components of plant and animal tissues. They also commonly form in the cecum of poultry animals as a result of the microbial fermentation of carbohydrates (Huyghebaert et al. 2011). Various organic acids have different physical and chemical features that can be used by adding them to feed or drinking water. This can be done either alone or in combination with one another. A combined use of organic acids has been shown to be more effective than using them alone (Menconi et al. 2014).

Certain organic acids (such as formic and propionic acid) have been used for many years to protect feed; they and their salts are referred to as "feed preservative" in European Union countries. Those with short chains (C1–C7) have antimicrobial effects. These include simple monocarboxylic acids, such as formic, acetic, propionic, and butyric acids; carboxylic acids with hydroxyl, such as lactic, malic, tartaric, and citric acids; and carboxylic acids with double bonds, such as fumaric and sorbic acids (Shahidi et al. 2014).

Organic acids have weak acidic features and they can partially become dissociated. Some of them can exist as sodium, potassium, or calcium salts. The advantages of salts are that they are generally odorless and less corrosive, they can dissolve more in water, and they are solid and less volatile than acids during the preparation of feed, so they can be easily processed (Huyghebaert et al. 2011). Organic acids are widely used in poultry animals due to their antimicrobial features, their ability to regulate the intestines, and their positive effects on bowel health, nutrition use, performance, egg efficiency, and quality (Khan and Iqbal 2016).

Some studies have observed a significant increase in crypt depth and villus height, width, and area in the small intestines of broiler chickens whose feed received organic acid additives, either alone or in combination (Adil et al. 2010; Kum et al. 2010; Rodríguez-Lecompte et al. 2012). Similar results have also been obtained related to the salts of organic acids (Paul et al. 2007). Increase in villus height causes bowel epithelium, which serves as a natural barrier against the strengthening of toxic substances and pathogen bacteria in the intestine. In this way, organic acids or their salts reduce the colonization of intestinal pathogens, due to their antimicrobial effects and their ability to increase villus height. In addition, they increase digestion and the absorption of nutrient (Iji and Tivey 1998). In some studies (Adil et al. 2010), when organic acids were added to broiler chickens' diets, there was increase in the LAB numbers in ileum and cecum, a reduction in the numbers of *Enterobacteriaceae* and *Salmonella* spp., and an increase in body weight and feed efficiency. The application of organic acids in poultry animals leads to improvement in performance and health when they are used at both high and low dosages, and they can cause a reduction in the height of the bowel villus and in crypt depth (Smulikowska et al. 2009).

With the addition of organic acids to drinking water, researchers have observed a reduction in pathogens in the stomach/proventriculus and in the water, an improvement in bowel microflora, an increase in feed digestion, and an

acceleration in growth (Hamed and Hassan 2013). Similarly, it has been shown that organic acid mixtures (fumaric acid, calcium format, calcium propionate, potassium sorbate, calcium butyrate, calcium lactate, and hydrogenated vegetable oil) are more effective than polypeptide structured antibiotics as a growth factor for reducing *E. coli* and *Salmonella* spp. in the intestines (Hassan et al. 2010).

The antimicrobial features of organic acids depend on their being transformed from not being dissociated into a dissociated form, their pKa values, and their hydrophobic features. Organic acids pass from the semipermeable membrane of bacteria to the cell cytoplasm in dissociated form in a freeway (Van Immerseel et al. 2006). Thus, in the cell where pH is nearly 7, they depress bacterial enzymes (such as decarboxylases and catalases), and nutrition transport systems are dissociated. As the bacterial cell wall normally has a lipid structure, the hydrophobicity of acid enables it to show its antimicrobial activity. In this way, hydrophobic organic acids bind with lipid materials and disrupt the activities of the bacteria (Huyghebaert et al. 2011).

Not all organic acids are effective on microflora. Each acid has a unique antimicrobial activity spectrum. pKa values of most organic acids with antimicrobial activity vary between 3 and 5. Among these, while lactic acid is more effective on bacteria, acetic, formic, and propionic acid have wider antimicrobial activity, including yeast and fungus. Substances such as sorbic and fumaric acid mainly have antifungal effects (Kum et al. 2010). It has been demonstrated that organic acid salts (such as ammonium formate and calcium propionate) reduced coliform numbers in broilers, but they do not affect clostridiums (Paul et al. 2007). Furthermore, calcium propionate depressed the fungi in feed better than ammonium formate, due to the antifungal impact of propionic acid or propionate (Zha and Cohen 2014). Another study showed that adding potassium diformate to the diet with a ratio of 0.45% significantly reduced mortality caused by necrotic enteritis (Mikkelsen et al. 2009).

Sodium butyrate (in two different forms, coated with herbal oil and not being covered with it) can deter *Salmonella* colonization in the digestive tract of broilers, but only its form covered with herbal oil can reduce *Salmonella* colonization in the liver; thus, as related to *Salmonella*, the form that is covered with herbal oil is more effective than the uncoated form (Fernández-Rubio et al. 2009). With this in mind, we can predict that herbal oils protecting sodium butyrate are more durable against acidic pH, as they allow some part of the butyrate to go further into the bowel. Some authors (Hamed and Hassan 2013) have asserted that most fatty acids with short chains, such as propionic and formic acid, are metabolized and absorbed from the upper digestive tract of poultry animals, so that they change the microflora of hosts in the lower part of digestive tract in a limited way. For this reason, some researchers (Fernández-Rubio et al. 2009; Van Immerseel et al. 2006) have proposed that fatty acids with short chains should be given in a microencapsulation form, in order for them to be effective in the lower parts of digestive tract as well. A protective lipid matrix that is used for microencapsulation enables organic acids to be effective along the whole digestive tract. For example, the addition of an organic acid, prepared in an encapsulation form, to the diet with a ratio of 0.2% caused useful microflora (LAB) in the bowel of poultry animals to increase and the levels of harmful microflora to be reduced (Gheisari et al. 2007).

Among SCFAs, butyrate has the greatest bactericidal effect against acid-sensitive bacteria such as *E.coli* and *Salmonella* (Kwon and Ricke 1998). In in vitro studies, depending on the carbon chain length and pH values of organic acids and on the condition that there is a sufficient amount of acid molecules in the environment not being dissociated and that they remain with bacteria for a long time, it has been suggested that bacteria pass easily from the cell membrane; reduce intracellular pH levels; disrupt the intracellular amino acid metabolism, cytoplasmic membrane structure, proteins, and electron carriage system; and reduce intracellular ATP production and revealed bactericide/static effects in return. Since this effect of organic acids originates from anion accumulation, which occurs during their dissolution, it has no impact on bacteria that are acid-resistant (Patten and Waldroup 1988).

7 Polyunsaturated Fatty Acids

The two most important main types of polyunsaturated fatty acids (PUFAs) are omega-3 and omega-6 fatty acids. Neither of these can be produced by the body; they must be acquired from the diet. For this reason, they are classified, for people, as "essential fatty acids." Examples of omega-3 fatty acids are α-linolenic acid (ALA), eicosapentaenoic acid (EPA), and docosahexaenoic acid (DHA). Examples of omega-6 acids include linolenic acid (LA) and arachidonic acid (AA). According to a study (Sioen et al. 2006), adding PUFAs such as omega-3 regularly causes beneficial effects related to physiological functions. Further, the PUFA content in modern diets is low, with respect to omega-3 fatty acid ions. Thus, the omega-6:omega-3 fatty acid ratio is high. This imbalance between omega-3 and omega-6 is an important factor in the pathogenesis of various diseases, such as cancer and inflammatory and autoimmune diseases. By proactively adding omega-3 fatty acids to the diet, the ratio of omega-6:omega-3 can be reduced (Simopoulos 2004). Poultry meat is known to be the main source of PUFA in humans' food (Sioen et al. 2006), and the addition of fish by-products (López-Ferrer et al. 2001a) and flax seed oil (López-Ferrer et al. 2001b) to the feed of poultry animals has increased omega-3 fatty acids in poultry meat (especially ALA).

However, since these products increase the lipid oxidation of meat, they can lead to a reduction in flavor (Bou et al. 2001). In one study (Ponte et al. 2008), researchers demonstrated that feeding free-range chickens green plants could cause an increase in live weights.

It has been found that, in poultry animals, fish oil and corn oil are widely used as omega-3 and -6 sources. Fish oil increases immune responses, and corn oil reduced immune response (Yang and Guo 2006). Furthermore, in broilers whose feed received omega-3 (a tuna oil, sunflower oil, and palm oil combination) additives, increases were seen in spleen weights, infectious bronchitis disease, Newcastle diseases, antibody titers, interleukin-2, and interferon-γ concentrations. Immune responses in poultry animals were enhanced in return (Maroufyan et al. 2012). However, in another study (Al-Khalifa et al. 2012), the opposite was found: the addition of omega-3 in the diet (via fish oil) reduced immune responses in broiler chicken (phagocytosis and lymphocyte proliferation).

Conjugated linoleic acid (CLA) is another PUFA type used to support poultry feed and increase immune responses in chickens (Zhang et al. 2005). When CLA is added to the diet, it promotes the growth of immune tissues such as thymus and bursa in chickens and stimulated T lymphocyte proliferation while increasing antibody production. These studies suggest that unexpected outcomes could result, due to the biological differences (gender, age, and breed), type of essential fatty acid introduced, diet composition, and balance difference between omega-3 and omega-6 fatty acids in the diet with regard to the factors influencing poultry animals' immune response (He et al. 2007).

Finally, omega-3 has shown an antimicrobial effect in an in vitro environment (Kankaanpaa et al. 2001). Still, some researchers argue that omega-3 and CLA do not have much effect on general microbiota in the chicken intestine (Chanuwat et al. 2011).

Information about increases in the performance of poultry animals due to PUFAs is also debatable. While some authors (Roy et al. 2008; Chanuwat et al. 2011) have asserted that the addition of omega-3 (eicosapentaenoic and docosahexaenoic) or CLA to the diet supports the growth of poultry animals, others (Zhang et al. 2005; Cho et al. 2013) have asserted that these do not influence the growth performance. Similarly, different types and sources of PUFAs, the feed composition of animals, and their biological variations can explain these debatable outcomes.

8 Phytobiotics

Phytobiotics are natural bioactive components that can be extracted from various herbal sources such as plants and spices (Windisch et al. 2008). Active components of phytobiotics are generally terpenoids, phenols, glycosides, alkaloids, and similar secondary components (Huyghebaert et al. 2011). Phytobiotics are divided into four classes related to their source and processing features: (1) plants (blooming, nonwoody, and nonpermanent plants), (2) spices (plants with a dense odor or flavor that are generally added to human food), (3) essential oils (volatile lipophilic components), and (4) oleoresins (extracts obtained from non-watery solutions) (Windisch et al. 2008; Yang et al. 2009).

In phytobiotics, the content and chemical composition of the active substance varies according to the plant part that is used (seed, leaf, etc.), geographical sources, and harvesting season (Windisch et al. 2008). Several studies have shown that phytobiotics promote growth and have antimicrobial, antioxidant, and anti-inflammatory properties. However, when we evaluate these studies closely, we can notice that some outcomes are contradictory (Mohammadi Gheisar and Kim 2018).

Some studies found that the addition of a phytogenic mixture to broiler chickens and meat-type duck feed at a ratio of 0.075% led to increases in body weight and feed efficiency (Mohammadi Gheisar et al. 2015a, b). According to the authors, phytobiotics show antimicrobial activity, stimulate the secretion of digestion enzymes, and increase the flavor of feed, which increases their consumption in return. In this way, an increase is seen in poultry animals' growth performance. However, other studies have asserted that the addition of phytobiotics to broiler chickens and laying hens' feed caused a significant reduction in feed intake (Maass et al. 2005; Roth-Maier et al. 2005). There was an increase in trypsin, maltase, and pancreatic amylase activities of broilers (Jang et al. 2007) and in the mucosa secretion of the intestines (Jamroz et al. 2006), with the addition of essential oils to their diet. This reduced the adhesion of pathogens and provided microbial balance in the animals' bowels (Brenes and Roura 2010).

The antimicrobial effects of phytobiotics have been the subject of many studies (Burt 2004; Si et al. 2006; Panghal et al. 2011; Giannenas et al. 2013). Most of them have shown that phenolic components, such as thymol, carvacrol, phenylpropane, limonene, geraniol, and citronellal, are the most effective antimicrobials. Antimicrobial impact of phytobiotics was found to be dependent on the settlement place of the functional hydroxyl and alkyl groups in their structures (Yang et al. 2015). For example, certain terpenes (such as carvacrol and thymol) have similar antimicrobial effects, but their influence against Gram-negative or Gram-positive bacteria differed relative to the settlement place of one or more functional groups in their molecules (Salehi et al. 2018). The Labiatae plant family, which includes plants such as thyme, oregano, and sage, the most well-known phytobiotics, has attracted the most interest in this regard. Hydrophobic essential oils adhere to the cell membranes of pathogens and break up the membrane structures, leading to ion loss in bacteria in return (Burt 2004).

Various substances that are not phenolic but which are obtained from limonene and *Sanguinaria canadensis* also

have antimicrobial effects (Newton et al. 2002; Burt 2004). In some studies of broiler chickens, the effectiveness of essential oils against *E. coli* and *Clostridium perfringens* has been revealed (Jamroz et al. 2006; Mitsch et al. 2004), and certain phytobiotics have also proven effective against *Eimeria* factors (Oviedo-Rondon et al. 2006). Phytobiotics also increased the microbial hygiene of carcass. For example, the addition of oregano essential oil to the diet at a ratio of 0.1% had a beneficial impact on the microbial load of specific pathogens or total live bacteria in broiler carcasses (Aksit et al. 2006). However, current data are significantly limited in revealing phytobiotics as reliable for increasing carcass hygiene.

The antioxidant features of phytobiotics are another characteristic that attracts a great deal of attention. Plants such as rosemary, oregano, and thyme, which are part of Labiatae plant family, and their extracts have high antioxidant effects (Brenes and Roura 2010). This impact has been revealed in meat-type ducks whose diets received thyme additives (Mohammadi Gheisar et al. 2015b) and in broiler chickens to whose diets *Artemisia annua* was added (Cherian et al. 2013). These phytobiotics can have a positive effect on certain antioxidant enzymes, such as glutathione peroxidase and superoxide dismutase, which help to regulate the lipid metabolism in animals in return (Franz et al. 2010). Other studies have shown that plant varieties such as ginger, curcuma, anise, and coriander; spices such as black pepper (*Piper nigrum*), red pepper (*Capsicum annuum* L.), and chili (*Capsicum frutescens*); and plants rich with flavonoids (such as green tea) and anthocyanins (such as various fruits) have antioxidant activities (Nakatani 2000; Wei and Shibamoto 2007; Yatao et al. 2018). The use of most of these plants is limited in animal feeding, due to their sharp odor and taste, which are attributed to their active substances.

While some authors (Abd El-Ghany and Ismail 2014; Diaz-Sanchez et al. 2015) claim that phytobiotics accelerate development in broilers in ways similar to antibiotics, others (Karimi et al. 2010; Al-Mufarrej 2014) claim that they (thyme and black cumin (*Nigella sativa* L.)) do not influence broilers' growth. The type and dose of phytobiotics used in these studies can explain the differences in these diets.

Regarding the effects of phytobiotics used as feed additive substances on the intestinal health and growth performance of poultry animals, these substances and their contents vary depending on biological factors (plant types, places where they are raised, and harvesting conditions), production methods (extraction/distillation, stabilization), and storage conditions (light, temperature, oxygen pressure, and period).

9 Concluding Remarks and Future Directions

Following the prohibition of antibiotics in poultry animal as a growth factor, the need for alternative feed additive substances increased. Feed additive substances, or nutraceuticals, are now being used with the aim of accelerating growth in the poultry sector, avoiding disease, and regulating animals' immune systems. Nutraceuticals provide significant hope in these respects. However, their use in the treatment of diseases and their impact mechanisms remain debatable. In order to feed the world's population, which is constantly increasing, and to produce higher quality and less expensive animal feed, we must increase the varieties and sources of nutraceuticals. Further studies on nutraceuticals are needed among large poultry flocks before they can be used in the commercial poultry industry.

Part V

Safety and Toxicity Evaluation of Nutraceuticals and Functional Foods

Safety and Toxicity Evaluation of Nutraceuticals in Animal Models

Nikolay Goncharov, Vladislav Sobolev, Maxim Terpilowski, Ekaterina Korf, and Richard Jenkins

Abstract

Nutraceuticals are derived from various natural sources such as medicinal plants, marine organisms, vegetables, and fruits. Most of them possess antioxidant or anti-inflammatory properties and are claimed to provide protection against many diseases if taken regularly. At the same time, toxicological studies of nutraceuticals have been limited, so the safety of many of them cannot be guaranteed. Animals share many genetic, anatomical, and physiological similarities with humans, and they continue to be widely used in preclinical studies of drugs, in spite of a lack of their validity which is due to the great phenotypic differences. The absence of toxicity in animals provides little probability that adverse reactions will also be absent in humans. There are currently thousands of researchers involved in the development of alternatives to animal use in the life sciences. Statistical machine-learning tools, once developed, might become a powerful means to explain the complex physiological effects of nutraceuticals. The use of different models and algorithms can provide a more scientific basis for risk assessment of nutraceuticals for humans.

Abbreviations

ADI	Acceptable daily intake
ADRs	Adverse drug reactions
ALA	α-linolenic acid
ARRIVE	Animals in Research: Reporting In Vivo Experiments
BMD	Benchmark dose
BMDL	Benchmark dose lower bound
CDDs	Chlorinated dibenzo-*p*-dioxins
DHA	Docosahexaenoic acid
DNEL	Derived no-effect level
DSHEA	Dietary Supplement Health and Education Act
EDI	Estimated daily intake
EGCG	(−)-epigallocatechin-3-gallate
EPA	Eicosapentaenoic acid
ETs	Ellagitannins
GRAS	Generally recognized as safe
GTE	Green tea extract
HBA	Harm-benefit analysis
LOAEL	Lowest-observed-adverse-effect level
LRs	Likelihood ratios
MOA	Mode of action
MOE	Margin of exposure
NHPs	Nonhuman primates
NOAEL	No-observed-adverse-effect level
OSC	Organosulfur compounds
PARNUTS	Particular nutritional uses
PAs	Pyrrolizidine alkaloids
PFS	Plant food supplement
PODs	Points of departure
RfC	Reference concentration
RfD	Reference dose
ROS	Reactive oxygen species
RPF	Relative potency factors
RYR	Red yeast rice
TEFs	Toxic equivalency factors
TTC	Threshold of toxicological concern

R. C. Gupta et al. (eds.), *Nutraceuticals in Veterinary Medicine*, https://doi.org/10.1007/978-3-030-04624-8_48

1 Introduction

The food products used as nutraceuticals can be categorized as dietary fiber, prebiotics, probiotics, polyunsaturated fatty acids, antioxidants, and other different types and constituents of natural foods. They help in preventing and even combating some health problems such as obesity, cardiovascular diseases, cancer, osteoporosis, arthritis, diabetes, excess cholesterol, etc. (Das et al. 2012; Gupta 2016). Many individuals drink herbal teas for prophylactic purposes or as alternatives to caffeinated beverages. There is also a huge industry of producing food supplements for participation in sports. The perceived advantage of nutraceuticals over medicines is that they are generally regarded as having no side effects, whereas their perceived disadvantage is relatively poor effectiveness, which is claimed to be overcome either by increasing the dosage or by consuming them over longer periods of time. However, such perceptions may be rather deceptive because of our poor understanding of the mechanistic properties of nutraceuticals and their incompetent administration. Far too often, the decision to consume nutraceuticals is based on marketing claims rather than available evidence-based research. In sport activities, it has been shown that with a sufficient calorie intake, nutraceuticals or other supplementation is not necessary to help elite athletes perform better, and many controlled studies have failed to confirm the advertised ergogenic effects of nutritional supplements (Mason and Lavallee 2012; Desbrow et al. 2014).

These days, Americans spend over $28 billion on nutraceuticals and dietary supplements (Ronis et al. 2018). In the USA, dietary supplements are defined and regulated according to the Dietary Supplement Health and Education Act (DSHEA) of 1994 (Mueller 1999). According to the DSHEA, a dietary supplement is a product that contains such dietary ingredients as vitamins, minerals, amino acids, herbs, and botanicals. The term nutraceutical is not defined by US law but is generally understood to refer to a purified product derived from a human food source, which can provide health benefits beyond the basic nutritional value of usual foods. The European legislation also does not mention the term "nutraceuticals," and these could be dealt within the Foods for Particular Nutritional Uses (PARNUTs) regulatory framework (Directive 89/398/EEC 1989). PARNUTs includes foods for special medical purposes or for particular nutritional needs, once their safety and efficacy have been properly assessed by in vitro and in vivo studies. However, in contrast to the manufacture of pharmaceuticals, which requires documented evidence for the effectiveness and safety of drugs, there is no need for demonstrating the efficacy of dietary supplements or nutraceuticals. Consequently, as a rule, they are brought to the market without the support of clinical trials, so there is a lack of studies of adverse effects. A few case reports of symptoms appearing after intake of nutraceuticals do not reveal cause-effect relations. Only accumulation of many cases over time can ultimately establish that intake of a nutraceutical can result in adverse effects, and it has turned out that the risk of adverse effects is rather significant (Ronis et al. 2018).

Plants synthesize many secondary metabolites whose role may be in the defense mechanisms against herbivores and parasites, so consumption of nutraceuticals over a long and even a short period of time should be of great concern. The most popular stimulators of physical or mental adaptation are essentially nutraceuticals—caffeine, nicotine, ethanol and tetrahydrocannabinol—which at the same time can be toxic and not only for addicts. Moreover, numerous human and animal intoxications have been associated with naturally occurring herbal components, including pyrrolizidine alkaloids (PAs), tannins, and safrole (Manteiga et al. 1997). Some toxic impurities are also components of foods being consumpted as a source of nutraceuticals (Shimshoni et al. 2015; Hassanin et al. 2017). Impurities can also be supplied with artificial or not entirely natural additives: many of the resveratrol-containing nutraceuticals are enriched in this compound by adding purified resveratrol that has been extracted from the root of the Japanese knotweed *Polygonum cuspidatum* (Espín et al. 2007).

The most compelling evidence for potential health-beneficial effects of nutraceuticals seems to derive from descriptive and correlative epidemiological data (Sauer and Plauth 2017). On the other hand, the problem of scarce and inconsistent reports on effects of nutraceuticals often lies in the sphere of inadequate testing models or quasi-scientific explanation of experimental data obtained (Goncharov et al. 2016a). The physiological context is of high importance for evaluating effects of diet supplements, some of which were observed in in vitro experiments and must be very cautiously extrapolated to the in vivo context. The in vitro effects of nutraceuticals can be irrelevant in terms of their in vivo properties. Bioavailability, metabolism and tissue distribution are very important factors that need to be established for clear understanding of the biological effects of nutraceuticals. Once distributed within the body, nutraceuticals or their derivatives interact with many different target proteins with very different specificity (Sauer and Plauth 2017). Gut microbiota is one of the principal targets, and sometimes it is a real puzzle as to the true bioactive compounds responsible for the systemic biological activity.

Animals have played a principal role in biomedical experimental research throughout history (Franco 2013). To reduce or avoid unethical procedures, a strategy of 3Rs (reduction, refinement, and replacement) is being applied for animal testing, and alternatives to laboratory use of animals have

been introduced (Doke and Dhawale 2015). Nonetheless, it is imperative to obtain more information on safety and efficacy based on in vivo preclinical and clinical studies, and it is highly important to reach a better understanding of the mechanism of action and bioavailability of these products (Santini et al. 2018).

2 Toxic Actions of Nutraceuticals

The most important dietary phytochemicals are isothiocyanates, glucosinolates, organosulfur compounds (OSC), terpenoids (carotenoids, monoterpenes, and phytosterols), and various groups of polyphenols (anthocyanins, flavones, flavan-3-ols, isoflavones, stilbenoids, ellagic acid (EA), ellagitannins (ETs), etc.) (Ismail et al. 2016). Some of these have a protective effect against toxic compounds, such as carbon tetrachloride, as was shown with green tea extract (GTE) in male hamsters (Elgawish et al. 2015). Also, positive effects of lecithin and/or gallic acid in neurotoxicity induced by aluminum oxide in experimental rats have been demonstrated (Hassanin et al. 2017).

Toxic properties of nutraceuticals are not as extensively studied as those of pharmaceuticals. Indeed, there are little data to suggest that nutraceuticals and dietary supplements are toxic. An interesting variable worth mentioning in this context is the matter of funding for research on their effectiveness and safety. Multiple articles disclose that funding is contributed by the companies which market the product for retail purposes (Vaughan et al. 2014). However, they are not necessarily safe for everybody. Supplements with active ingredients that provide a physiological effect can also cause adverse effects. For example, some metabolites of (−)-epigallocatechin-3-gallate (EGCG) are suspected not to diminish but to enhance oxidative stress and cause liver injury, the mitochondria being a possible target (Mazzanti et al. 2009, 2015; James et al. 2018). Besides GTE and EGCG, a number of herbal medicinal products are associated with a spectrum of hepatotoxicity events, such as Ayurvedic and Chinese herbs, black cohosh, chaparral, germander, greater celandine, Herbalife, Hydroxycut, kava, pennyroyal, skullcap, usnic acid, and PAs (Bunchorntavakul and Reddy 2013). The soy-derived isoflavones genistein and daidzein with its metabolite equol were shown to possess estrogenic properties, including the ability to produce uterine hypertrophy, reduce testis size, inhibit androgen production, etc. (Tan et al. 2006; Akingbemi et al. 2007; Ronis et al. 2014, 2016). There have been case reports of endometriosis in women consuming isoflavone supplements, so there is a risk of estrogen-sensitive cancers in consumers of these products (Mahady et al. 2003).

α-Linolenic acid (ALA) is the precursor of longer-chain omega-3 fatty acids, eicosapentaenoic acid (EPA), and docosahexaenoic acid (DHA). Although there are limited toxicological data, ALA is considered to be safe as a dietary ingredient. However, it should be noted that ALA like other fatty acids can produce lipid peroxidation products under exposure to air or UV radiation, which may produce adverse effects if not controlled appropriately. Moreover, prostate cancer and macular degeneration risks should be also considered in relation to dietary intake of ALA, although the overall evidence on the association of ALA with those risks remains mixed and inconclusive (Kim et al. 2014). In some experiments, administration of ETs to rats inhibited the initiation and progression of chemically induced colon and esophageal cancers (Stoner et al. 2006). In other experiments no effect was shown on the number or size of adenomas in the small intestine of mice upon administration of either pure EA or diets with ETs (Päivärinta et al. 2006). These contradictory results may be due to different types of tumors but also due to different animal models used. More importantly and less advertised are reports in which ETs were shown to cause liver necrosis and nephrotoxicity in cattle (Filippich et al. 1991; Oelrichs et al. 1994).

There are plenty of plants that contain OSC, the toxicity of which varies in different species and different cells within a body (Munday 2012; Goncharov et al. 2016b). However, if the elevated toxicity is within cancer cells, it would undoubtedly be a positive event for the organism. There is much evidence indicating that they modulate the activity of several metabolizing enzymes that activate (phase 1 enzymes: CYP2E1, CYP1A1, and CYP1A2) or detoxify (phase 2 enzymes: NAD(P)H:quinone oxidoreductase 1, glutathione *S*-transferases, UDP-glucuronosyltransferases, etc.) carcinogens, through inhibition of histone deacetylase activity and inhibition of the formation of DNA adducts in several target tissues (Navarro et al. 2011; Zhang et al. 2013). Ironically, the persistent activation of antioxidant systems via genetic alterations in Nrf2 and Keap1 also contributes to carcinogenesis. Some cancers hijack the Nrf2/Keap1 system with mutation in these genes, which persistently activate antioxidant peroxiredoxin/sulfiredoxin systems in the cancer cells (Toyokuni 2014). Positive effects of OSC in mammals often come from their selective toxic effects on microorganisms. Thus, garlic has been proven to be toxic to a plethora of Gram-positive, Gram-negative, and acid-fast bacteria, including *Salmonella*, *Escherichia coli*, *Pseudomonas*, *Proteus*, *Staphylococcus aureus*, *Klebsiella*, *Micrococcus*, *Bacillus subtilis*, *Clostridium*, *Mycobacterium*, and *Helicobacter* (Bayan et al. 2014).

Red yeast rice (RYR) is a kind of functional food obtained from fermentation with the red yeast *Monascus purpureus*, containing a bioactive component monacolin K (chemically

identical to lovastatin), which has been recognized as a key component in cholesterol reduction. In a study on the safety of RYR, cases of myalgia and/or an increase in creatine phosphokinase were observed, as well as liver injury and gastrointestinal reactions, and, in some cases, hospitalization (Mazzanti et al. 2017). Furthermore, there is another risk factor in RYR—the toxic metabolite mycotoxin citrinin—which is a serious obstacle to the use of RYR as a dietary supplement, since exposure to citrinin can cause nephrotoxicity (Vanacloig-Pedros et al. 2016; Patel 2016).

Some green teas and/or herbal infusions can be contaminated by PAs that are produced by various weed plants and possess acute and chronic toxicity, genotoxic, mutagenic, and carcinogenic properties (Habs et al. 2017). 1,2-Unsaturated PAs should be of special concern because they are genotoxic carcinogens (Chen et al. 2017). Reactive metabolites of PAs are formed in vivo after metabolic activation via CYP3A4 enzymes in the liver and can cause hepatic sinusoidal obstruction syndrome and livestock poisoning (Wiedenfeld and Edgar 2011; Jurgens et al. 2012). Another source of PAs is honey collected from plants producing PAs (Merz and Schrenk 2016).

Selected consumption of Chinese botanical preparations raises concern of exposure to alkenylbenzenes (Ning et al. 2018). Also, methyleugenol and related alkenylbenzenes were found in a series of nutmeg-based plant food supplements (PFS) and pesto sauces, though their toxicities based on estimated daily intake (EDI) and the margin of exposure (MOE) approach are insignificant, and consumption of pesto sauces would only be of concern if consumed on a daily basis over longer periods of time (Al-Malahmeh et al. 2016, 2017). The next section is devoted to these and other indices relevant for estimation of safety and toxicity of nutraceuticals.

3 Safety and Toxicity Studies with Animal Models: Foundations, Problems, and Alternatives

The biological activity of a phytochemical is usually carried out using in vitro and/or in vivo tests. In vitro testing is frequently performed with much higher concentrations of investigated compounds compared to those tested in vivo. Another significant problem for in vitro research is whether testing is necessary, or even possible, for the relevant metabolites which can be found in vivo in varying concentrations in different organs and tissues. On the other hand, extrapolation of the results obtained in an animal model to humans is not entirely adequate due to differences in their physiology, and there are also differences between animal species which may result in contradicting interpretations of experimental data (Espín et al. 2007).

Ideally, a combination of several in vitro models with at least two animal models should be adopted to give a clear understanding of the mechanistic and toxic properties of compounds, including nutraceuticals. People can avoid consuming nutraceuticals as food additives when curing an acute disease, but the question is whether they can be used as therapeutic adjuvants or in a prophylactic manner to avoid diseases. If yes, is it necessary to test them on safety and toxicity? If yes, is it necessary to use animal models? Animal models are used to ascertain the target organs affected by active components, assuming that they are well characterized, their impurities (if any) are also well characterized, and the manufacturing process is standardized (Kruger and Mann 2003). Various animal species—such as fishes, amphibians, birds, mice, rats, hamsters, rabbits, guinea pigs, dogs, cats, and primates—have been and continue to be used in science for a long time. Rodents are the most commonly used laboratory animals, making up nearly 80% of the total of animals used in the EU, followed by cold-blooded animals (9.6%) and birds (6.3%) (European Commission 2010; Franco 2013).

3.1 Foundations

Toxicity studies include (1) repeat-dose general toxicity studies, (2) pharmacokinetic/toxicokinetic studies, (3) reproductive toxicology, (4) genotoxicity studies, (5) carcinogenicity studies, and (6) special pharmacology studies, which can include in vitro and in silico studies and thus provide explanations for toxic findings in animal studies (Kruger and Mann 2003). To assess the toxic potential of a chemical, toxicologists have to assess the acute, subacute, subchronic and chronic toxicity. For acute toxicity studies, a dose is administered to animals and symptoms observed over 14 days. In subchronic studies, which are the most popular among toxicologists and adequate for nutraceuticals, animals receive several doses of a chemical over 90 days. At the end, animals are sacrificed and samples are taken for hematological and biochemical analyses, organ weights, and histopathological examination. The usual way of evaluation of genotoxicity potential is through a micronucleus test, and a negative control should be incorporated. Points of departure (PODs) in toxicological studies are defined as the points on a dose-response curve established from experimental data corresponding to an estimated lowest-observed-adverse-effect level (LOAEL), no-observed-adverse-effect level (NOAEL), or statistical benchmark dose (BMD) (Augustin et al. 2013). They mark the beginning of extrapolation to toxicological reference dose (RfD) or reference concentration (RfC). In the EU, RfD may be called derived no-effect level (DNEL). The US EPA defines RfD or RfC as follows (ChemSafetyPRO 2018):

- Reference dose (RfD) is an estimate (with uncertainty spanning perhaps an order of magnitude) of a daily oral or dermal exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime. Its unit is usually mg/kg bw/day or mg/kg.
- Reference concentration (RfC) is an estimate (with uncertainty spanning perhaps an order of magnitude) of a continuous inhalation exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime. Its unit is usually mg/L or ppm.

In the USA, many nutraceuticals have been classified as "generally recognized as safe" (GRAS), with acceptable NOAEL (Augustin et al. 2013). In the design of animal studies, an important parameter that must be considered is the margin of exposure (MOE) between the NOAEL and the anticipated or estimated level of daily intake (EDI) by humans. For a food additive, an acceptable daily intake (ADI) is usually derived by applying a safety factor of 100-fold to the NOAEL determined in animal studies. If the EDI falls below the ADI, then exposure is considered to be safe. This concept is applicable for nutraceuticals consumed by humans in amounts not exceeding 1.5 g/day (equal to around 25 mg/kg/day), since this level of intake can be supported by applying a 100-fold safety factor to a NOAEL in a rat model of testing (about 5% of the rat's diet) (Kruger and Mann 2003). The concept of the 100-fold safety factor should not be applied for drugs or nutrients, since effects found in animal studies would not be a toxicological response to the active ingredients but may be due to their physiologic or pharmacologic activities.

In this context an example of inadequate animal studies should be mentioned, in which hepatotoxic potential of GTE and EGCG was registered. A very high single dose of EGCG (500–750 mg/kg) intragastrically to C57BL/6J mice daily on an empty stomach for 3 days caused hepatic inflammation, necrosis and hemorrhage. Hepatotoxicity was associated with increased oxidative stress and decreased superoxide dismutase and glutathione peroxidase levels (James et al. 2018). For comparison, in our studies of possible effects of GTE on endurance and fatigue in a rat model of forced swimming, GTE was administered in quantity equaling an EGCG dosage of 6 mg/kg (two orders of magnitude less than that used by James et al. 2018) for 2–3 weeks twice daily after taking of food, and no hepatotoxicity was found; moreover, GTE was shown to increase the swimming duration, as compared with control animals that consumed water (Novozhilov et al. 2015). Later studies confirmed those results, and additionally it was found that administration of GTE increased endurance due to involvement of slow-twitch muscles whose adaptation is associated with enhanced expression of genes responsible for the subtle regulation of calcium balance in the muscles (Korf et al. 2017). Unfortunately, there are lots of examples of how experiments with animals serve to justify the obviously prejudiced position of researchers, irrespective whether this position boils down to praising or mocking nutraceuticals. Some other problems are discussed in the next section.

3.2 Problems and Alternatives to Animal-Based Studies

A list of methodological problems concerning animal-based research were devised in 2004 (Pound et al. 2004): (1) variations in drug dosing schedules and regimens, (2) variability in the way animals are selected for study, (3) choice of comparison therapy (none, placebo, vehicle), (4) small experimental groups and simplistic statistical analysis, (5) nuances in laboratory technique that may influence results, (6) selection of a variety of outcome measures and their relevance to the human clinical condition, and (7) length of follow-up before determination of disease outcome and its relevance to disease latency in humans. Several years later, the ARRIVE (Animals in Research: Reporting In Vivo Experiments) guidelines were designed to improve the standard of reporting of research using animals (Kilkenny et al. 2010). They consist of 20 items on the minimum information that all scientific publications reporting research with animals should include. If this is done, there is a good reason to combine many studies which adhere to specific criteria in systematic reviews and/or meta-analyses, in order to reach more reliable conclusions regarding experimental research with animals. At the same time, there are claims that any animal model fails as a predictive modality for human response to drugs and disease.

The problem is not an absence of side effects, as many side effects from drugs were observed in animal models, but there were no predictive value for humans. Therefore, systematic reviews and meta-analyses of animal-based research by any means cannot be good tools for trying to reach conclusions regarding human interventions (Greek and Menache 2013). According to some analytical studies, the correlation of adverse effects found in animal models for those observed in humans was estimated to be 63% in non-rodent experiments and 43% in experiments with rodents (Olson et al. 2000). The basis of many publications of this kind is that animals are of no help at all in experimental medicine, because regardless of the way a problem is approached, animal and humans will always differ in complex (Greek and Menache 2013). However, in this and similar publications, the real potential and perspective development of science is not fully taken into account.

We cannot completely abandon animal models just now; the affirmative view is a populistic claim, often from people having little or no competence and responsibility. Yet we must think about the elaboration of algorithms for system analysis and integrative approaches, in order to minimize the use of animals and to maximize the scientific benefit they can bring to human society. It is particularly important with regard to searching for new integrative biomarkers of various pathological state and invariant functional changes—irrelevant of species membership, in different animals and humans—induced by different chemicals or their complex mixtures (Goncharov et al. 2017b). Biomarkers are used not only as diagnostic or prognostic indicators but also to formulate theories of pathogenesis (Ghezzi et al. 2018). Two problems were identified in the use of biomarkers in mechanistic studies: the first arises in the case of multifactorial diseases, where different combinations of multiple causes result in patient heterogeneity; the second arises when a pathogenic mediator(s) is (are) difficult to measure. The latter applies in the case of the oxidative stress theory of disease, where the causal components are ROS which have very short half-lives; it is usual to measure the traces left by the reaction of ROS with biological molecules, rather than the ROS themselves. Different facets of biomarkers and their different values and meanings in multifactorial diseases and system medicine have recently been discussed (Ghezzi et al. 2018; Goncharov et al. 2017b). This seems to be especially helpful and promising for preclinical and clinical studies of nutraceuticals, most of which are involved in redox regulations and used in relatively low quantities. Subchronic toxicological studies of very low concentrations of aliphatic hydrocarbons with metabolomic and chemometric techniques revealed novel metabolic markers of the toxic effect: a ratio of concentrations of pyrophosphate and oxalate in the blood plasma of rats was found to be the most sensitive marker, termed the "pyrophosphate index." This finding helped us to put forward a hypothesis on the redox balance violation as the leading pathogenetic mechanism of neuropathies associated with hydrocarbons chronic intoxication, irrespective of animal species; the hypothesis needs to be tested with several other species of animals (Ukolov et al. 2017).

Combinatorial biomarkers are considered more specific and sensitive than single markers in medical diagnostics and prediction, yet even detection of these combinatorial biomarkers requires deep computational analysis. The principles of analytic combinatorics, together with linear and kernel ridge regression, helped to identify several strongly correlated combinatorial biomarkers of muscle damage with high prediction accuracy scores, which could also be a common platform for animal and human studies (Terpilowski et al. 2018). Metabolomic studies with application of chemometrics and other computational methodology often reveal that not minor and exotic but very simple biochemical parameters and their derivatives could be very sensitive biomarkers with high prognostic value. For example, albumin is among the few selected biomarkers that provide insight into the risk of death from all causes (Fischer et al. 2014; Hui et al. 2014). Albumin is a major plasma protein and contributes greatly to the plasma protein-SH pool. Homocysteinylation of albumin at Cys34 makes it increasingly susceptible to oxidative degradation (Prakash et al. 2008). The future search for new properties of albumin from different species under the influence of nutraceuticals is considered to be very important, via in vivo, in vitro and in silico studies (Goncharov et al. 2017a, c).

Toxic equivalency factors (TEFs) and MOE approaches are used for plant food supplements (PFS) containing different toxic substances, such as alkenylbenzenes (Al-Malahmeh et al. 2017). Initially, an interim concept of TEFs was proposed for chlorinated dibenzo-*p*-dioxins (CDDs), and in acute experiments with rats, an assumption was proved that interactions of four homologous CDDs were strictly additive (Stahl et al. 1992). For nutraceuticals or their toxic ingredients such as PAs, risk assessment is usually estimated after (sub)chronic application to animals, and the interim relative potency factors (RPF) conception was proposed as the dose metric having a higher potential for toxicological risk assessment, as compared with TEFs (Merz and Schrenk 2016). This novel approach was built on the foundation of predicted human exposures to metabolites in various compartments (such as food and water), the threshold of toxicological concern (TTC) and the concept of comparative toxicity (Terry et al. 2015). The ultimate aim was to address the human safety of the metabolites with the minimum number of in vivo studies while at the same time ensuring that human safety would be considered addressed on a global regulatory scale. The third component, comparative toxicity, was primarily designed to determine whether the metabolites had the same or similar toxicity profiles to their parent molecule and also to one another. The ultimate goal was to establish whether the metabolites had the potential to cause key effects—such as cancer and developmental toxicity, based on mode-of-action (MOA) studies—and to develop an RPF compared to the parent molecule. The MOA for the primary effects of the parent molecule was elucidated in detail, and a series of in silico, in vitro, and/or in vivo experiments were conducted on the environmental metabolites to assess relative potency of their toxicity profiles when compared to the parent. This strategy of comparative assessment—utilizing MOA data, relative potency, hazard characterization, readacross, predicted exposure and TTC—provided a robust database, which minimized animal use yet comprehensively assessed the hazard and human risk presented by these metabolites (Terry et al. 2015).

Animal and two-dimensional cell culture models have had a profound impact on medical research, despite inherent flaws and differences when compared with in vivo and clinical observations. Three-dimensional (3D) tissue models are a natural progression and extension of existing techniques that seek to plug the gaps and mitigate the drawbacks of two-dimensional and animal technologies (Konar et al. 2016). Most exogenous compounds, the more so nutraceuticals, have multiple cellular and molecular targets with low levels of specificity and different levels of toxicity to many of them. For example, some thiols and disulfides are used as nutraceuticals in complex cardiovascular or cancer therapy (Cerella et al. 2011; Ried and Fakler 2014) and, at certain concentrations, they can be toxic to endothelial cells (Prokofieva and Goncharov 2014) and red blood cells (Munday 2012; Alzoubi et al. 2015; Mindukshev et al. 2016), with ROS being mediators of their toxic effects. Development of a methodology for cytophysiological screening of various substances, including pharmaceuticals and nutraceuticals, is an urgent need of our days. Intuitively, there should be a strong correlation between cellular responses in vitro and the final efficacy of the therapy, though this correlation has yet to be proved.

3.3 Cytotoxic Power

The development of tools for interventions aimed at improving human health requires a comprehensive knowledge of the cellular reactions to positive or negative stimuli, correlating these in vitro and ex vivo obtained data with final in vivo therapeutic or toxic effects (Mindukshev et al. 2016). One of these tools could be the conception of "cytotoxic power," the initial version of which was published recently (Goncharov et al. 2018). The currently existing terms "apoptotic index" and "apoptotic potential" are insufficient for adequate qualitative evaluation and analysis of the proapoptotic activity of chemical agents within the wide range of therapeutic or toxic doses, so a new concept of cytotoxic power was introduced as an alternative to these terms related to apoptosis and other types of cell death. This concept is being further developed these days, and the essence of it is as follows: In in vitro experiments, the final calculation of the effective values is made on the basis of quantitative ratios of a substance and cells studied. The cytotoxic power (P) of the substance can be quantitatively represented as the product of the amount of substance (S) in moles acting on a certain number of cells (n) and the intensity of development of cytotoxic processes (I) in the same number of cells per unit time (t):

$$P = \frac{IS}{n^2 t}$$

The concept and corresponding algorithm to calculate the power makes it possible to perform a valid transformation of the quantum dependence into a graded one, based on the multimarker search strategy and, along with relatively universal and non-specific cytotoxicity indicators for a given tissue, to identify and use tissue-specific indicators (markers)—components of the so-called phenom. With each type of cell death, markers can be identified, the concentrations of which gradually increase or decrease before the death of the cell. The level of expression of each marker depends on the dose (amount) of the cytotoxic substance. Importantly, we observe expression by living cells, no matter what percentage of dead cells are registered; moreover, we can additionally observe the expression by cells in the stage of early apoptosis or autophagy, since these are also kinds of living cells. Thus, the intensity of signal development reflects an increase in the number of discrete, functionally coupled and relatively stable though transient intracellular structures that are constituents of the cell's phenom; we call them "phens," F, then $I = F/t$. The conventional unit for measurement of the cytotoxic power of a substance is "molphen"—the amount of nanomols that changes the intensity of expression of phenotypic markers (constituents of phens) by 100 arbitrary units per hour from the moment of exposure to 1000 cells. This definition, not claiming completeness, emphasizes the fractional number of phens in relation to the number of cells, as well as the different initial state of the cells, which explains the different rates of cell death in the population. The concept of cytotoxic power can help to integrate the data obtained with various cells in in vitro studies with those obtained in vivo.

4 Unresolved Issues

Animals are used in research when there is a need to find out what happens in the whole living body, which is far more complex than the sum of its parts. It is difficult, and in most cases simply not yet possible, to replace the use of living animals in research with alternative methods. There are four main reasons why animals are used in research (Anon 2018a): (1) to advance scientific understanding; (2) as models to study disease; (3) to develop and test potential forms of treatment; and (4) to protect the safety of people, animals and the environment. At the same time, animal models have shown very low potential to significantly contribute toward the development of human clinical interventions (Knight 2008). While the presence of toxicity can add considerable evidential weight for human risk, the likelihood ratios are extremely inconsistent, varying by over two orders of magnitude for different classes of compounds and their effects (Bailey et al. 2014). Questions remain about the adequacy of existing guidelines and whether researchers, review boards

and funders have fully implemented the "3Rs" (Ferdowsian and Beck 2011). Researchers have acknowledged the central role of the 3Rs and the need for more transparency regarding animal use in biomedical studies through the Basel Declaration (Anon 2018b). The harm-benefit analysis (HBA) is the cornerstone of animal research regulation and is considered to be a key ethical safeguard for animals (Pound and Nicol 2018). On the other hand, the emphasis on practical benefits has the drawback of driving researchers into speculation on the societal benefit of their research and, therefore, into promising too much, thereby leading to a loss of trust and credibility (Grimm et al. 2017; Eggel and Grimm 2018). Thus, the concepts of benefit and benefit assessment require a reevaluation in a spirit that embraces the value of knowledge per se. The generation of scientific knowledge has been utilized to great benefit for humans, animals and the environment. The HBA, as it currently stands, tends to turn this idea upside down and implies that research is of value only if the resulting findings bring about immediate societal benefit (Grimm et al. 2017).

In the search for mechanistic properties of nutraceuticals, it often seems useless to artificially break down effects to single molecule-protein interactions just to satisfy the "mechanistic research paradigm" (Weinberg 2010). Moreover, it may happen that the emerging properties of additive, synergistic, or inhibitory molecular interactions and resulting effects of nutraceuticals lead to an overall beneficial physiological output that cannot be traced back to a single molecular event. Nowadays, omics-based methodologies and adequate data analyses allow for efficient determination of systemic effects (Sauer and Luge 2015; Goncharov et al. 2015). "Big data" analysis, i.e., statistical machine-learning tools, will become increasingly important to complex biological phenomena and causality structures to develop appropriate computational models for prediction (Sauer and Plauth 2017). For example, new approaches based on nonlinear state space reconstruction were developed to differentiate causality from correlation and to efficiently analyze weakly connected dynamic biological systems (Sugihara et al. 2012). Omics-based biology should be more often consulted to solve complex biological problems. One of them is epigenetic mechanisms and their modulation by nutraceuticals, which have been shown to target enzymes involved in epigenetic gene regulation (Gerhauser 2018). Another complex problem is that the gut microbiota and microbial metabolites might be important mediators of diet-epigenome interactions. Only a few microbial metabolites, including folate, phenolic acids, *S*-(−)equol, urolithins, isothiocyanates, and short- and long-chain fatty acids, have been tested with respect to their potential to influence epigenetic mechanisms (Gerhauser 2018).

The concepts described in this chapter can help to greatly enhance the prognostic value of in vitro research to finally reject—who knows?—the in vivo studies at all. The methodology of safety and toxicity studies should be biased to in vitro and in silico models, the more so when nutraceuticals are the object of research. Both ethical and financial considerations favor these scientific endeavors. Animals should not be sacrificed for the sake of healthy people seeking to be even healthier. Future directions of nutraceutical testing are certainly bound to the development of a methodology of cytophysiological screening in vitro, together with in silico simulations of molecular interactions and computational algorithms for enhancing prognostic value of research. These should be indispensable supplements to the methodology of investigating natural supplements, i.e., nutraceuticals. These supplements, taken together, would greatly add to human health and our associated knowledge.

Evaluation of Safety and Efficacy of Nutraceuticals Using *Drosophila* as an *in vivo* Tool

Anurag Sharma, Clinton D'Souza, Vipin Rai, and Subash Chandra Gupta

Abstract

The word nutraceutical refers to the natural bioactive compounds including functional food, medicinal food, and phytochemicals. The sources of nutraceuticals such as fruits, legumes, nuts, spices, and vegetables have been consumed since ancient time. The safety and efficacy of nutraceuticals has been examined using experimental models such as cell lines and rodents. During recent years, an emphasis has been given on the use of alternative experimental models from animal right organization. In this regard, the fruit fly, *Drosophila*, has emerged as an ideal alternative animal model to study the disease pathogenesis. More specifically, the high conservation of genome sequences, reduced genetic redundancy, short life cycle, and ease in the genetic manipulations are some of the advantages associated with *Drosophila*. The efficacy of nutraceuticals for human use against cancer, aging, and neurodegenerative diseases has also been examined using *Drosophila*. *Drosophila* has also been used to examine the safety of nutraceuticals. The metabolism, dose-response, and the pharmacological and toxicological profile of nutraceuticals have been examined. The common nutraceuticals evaluated using *Drosophila* include curcumin, celastrol, and genistein. The safety and efficacy of combination therapy has also been examined using *Drosophila*. In this chapter, we discuss the utility of *Drosophila* in examining the safety and efficacy of nutraceuticals against chronic diseases. The advantages and disadvantages associated with this experimental model are discussed.

Keywords

Alternative animal model · *Drosophila melanogaster* · Efficacy · Nutraceutical · Toxicity testing · Safety evaluation

1 Introduction

The modern medicine is highly advanced in the human society today. However, the concept of using our local food and natural products as medicine for the disease cure and improving quality of life was first recognized way back in the fifth century by Hippocrates. We now know that Mother Nature is a rich source of medicine and that as much as 70% of the current drugs have their origin from the Nature. The term nutraceutical (nutrition + pharmaceutical) that refers to a food or part of a food with nutritional values was first coined in 1989. Nutraceuticals are the natural bioactive compounds, which include dietary supplementary functional food, medicinal food, and phytochemicals. The use of nutraceuticals for chronic diseases has received considerable attention during the last two decades. Nutraceuticals have been consumed as dietary supplements since ancient time. It is estimated that on an average, 70% of Americans and 20% of Europeans are using nutraceuticals in some form every day (Ronis et al. 2018; The Lancet Gastroenterology Hepatology 2018). Growing scientific evidence indicates the beneficial effects of nutraceuticals for overall health or managing some health conditions (Cencic and Chingwaru 2010; Gupta et al. 2010a; Das et al. 2012; Abdelhamid et al. 2018). Although nutraceuticals are generally believed to be safe, some investigators have reported that these molecules

produce unexpected side effects and toxicity (Hudson et al. 2018; Ronis et al. 2018). Therefore, it is critical to evaluate the safety and efficacy of the nutraceuticals before they can be prescribed by the physicians.

Nutraceuticals exert their beneficial and harmful effects by interaction with multiple cell signaling molecules. However, the molecular basis for the efficacy of nutraceuticals continues to grow. In this context, the development of inexpensive, rapid, reliable, and high-throughput in vitro and in vivo assays will help in examining the metabolism, dose-response, and pharmacological and toxicological profile of these molecules. *Drosophila melanogaster*, an alternative to mammalian system, has been used as a versatile model in basic and applied biomedical research. This chapter provides a brief overview of the utility of *Drosophila* as an alternative model system to examine the efficacy and safety of nutraceuticals.

2 *Drosophila melanogaster* as a Model Organism

The choice of a model organism has always been at the core of biological research for many decades. Prokaryotes, protists, fungi, plants, and animals have been used as model organisms for a long time. Mice, rats, hamsters, rabbits, chicken, guinea pigs, *Xenopus*, primates, dogs, and cats are being used as surrogates to human. However, due to regulatory, scientific, and ethical concern, reduction or ban in the use of higher mammalian organism in research and testing has been recommended. In this context, Russell and Burch (1959) proposed "if animals were to be used in experiments, every effort should be made to replace them with non-sentient alternatives." Further a "3R" strategy has been developed which refers to *R*efinement, refining the experimental protocols to minimize unnecessary suffering to the animals; *R*eduction, reducing the animal numbers per experiment; and *R*eplacement, developing alternative methods which avoid or replace the use of animals (Tannenbaum and Bennett 2015). *D. melanogaster*, commonly known as "fruit fly," fulfills the criteria of "3R" and has been enormously used in biomedical research. In 1901, William Castle (1867–1962) laid the foundation of fly genetics. However, the power of fly genetics was truly explored by T. H. Morgan (1866–1945) and H. J. Muller by two great discoveries: (1) the concept of sex-linked inheritance (1926) and (2) mutation in genes by ionizing radiation (1945), respectively. At present, the versatility of this model has been proven in various disciplines of biomedical and basic research such as disease modeling, pharmacology, toxicology, genetics, development, and behavior (Pandey and Nichols 2011; Jansen et al. 2014; Rand et al. 2014). *Drosophila* embryos, larvae, and adults have been used to assess the efficacy and safety of various nutraceuticals. The following features make *Drosophila* an alternative model in nutraceutical research:

1. Closest invertebrate model organism to human; flies and human share functional homology with two-thirds of the human disease genes.
2. Fewer genes in flies reduce redundancy as compared to vertebrates.
3. Short life cycle (~10–12 days) and life span (60–70 days); high reproductive potentiality offers to study the effect of nutraceuticals on several generations.
4. *Drosophila* model has produced substantial insights in understanding the pathogenesis of human diseases.
5. *Drosophila* can be easily fed with nutraceuticals through food and the impact of the agents can be assessed at cellular and organismal levels. Likewise, the efficacy of the nutraceuticals can be examined by using fly disease model.
6. The conservation of signaling pathways and their regulators between flies and mammals may be pertinent to decipher the mechanistic insights into efficacy and safety of nutraceuticals.
7. The maximum information associated with *Drosophila* such as gene sequence, availability of transgenic lines, mutants, and RNAi stocks is available in the online database "FlyBase" (http://flybase.org/).
8. Use of *Drosophila* as an alternate animal model conforms to the regulations of animal rights organization and is recommended by European Centre for the Validation of Alternative Methods (ECVAM).

3 Utility of *Drosophila* in Examining the Anticancer Potential of Nutraceuticals

In recent years, nutraceuticals have emerged as potent agents for the prevention and treatment of cancer (Gupta et al. 2010a; Salami et al. 2013). Monotargeted drugs once called smart drugs or magic bullets have added only little to the overall survival of cancer patients. Moreover, these drugs produce numerous side effects and cannot be afforded by more than 80% of the human population. Accumulating evidence from preclinical and clinical studies suggests that nutraceuticals can target multiple cancer-related pathways. In addition, these agents have been consumed since ancient time and thus have well tested safety. *Drosophila* has been used as an alternate animal model to examine the efficacy of nutraceuticals. Numerous lines of evidence support the vital contribution of *Drosophila* not only in deciphering the fundamental molecular mechanism but also facilitating the drug development for cancer (Rudrapatna et al. 2012; Yadav et al. 2016). Also, *Drosophila* has been well established to deliver valuable information about the mode of action of various nutraceuticals in cancer models.

The health benefits of cruciferous vegetables such as broccoli and cabbage have been well documented (Armah et al. 2015). Lozano-Baena et al. (2015) reported antimutagenic property of Ethiopian mustard *Brassica carinata* and its glucosinolate sinigrin using somatic mutation and recombination test (SMART) assay in *Drosophila*. The anticancer effect of artemisinin and curcumin was studied by Das et al. (2014). *Lethal(2)giant* is a tumor suppressor gene and its deletion leads to a brain tumor in fly (Froldi et al. 2008). The administration of artemisinin and curcumin to *lethal(2)giant* organism enhanced ROS production (beyond the threshold) and was beneficial in several aspects of cancer pathogenesis. *UBIAD1/heix* (tumor suppressor gene) mutation in *Drosophila* exhibits strong lymphoma phenotypes including hypotrophy in the brain, hyperplasia of lymph gland (*Drosophila* hematopoietic organ), and hemocyte over proliferation. Vitamin K2 is a fat-soluble vitamin that has various health benefits including anticancer activities. Recently, Dragh et al. (2017) demonstrated that vitamin K2 exposure to *Drosophila* larvae prevents lymphoma progression by restoring mitochondria function. Many studies established that chemical and physical stressors can produce DNA instability, which may lead to malignant transformation (Wakeford et al. 2010; Rodgers et al. 2018). Nagpal and Abraham (2017) evaluated the antigenotoxic effect of β-carotene and tea polyphenols in γ-radiation-exposed *Drosophila*. The group demonstrated that co-exposure of β-carotene and tea polyphenols was able to decrease the γ-radiation-induced sex-linked recessive lethal (SLRL) mutation. Likewise, Kaya (2003) suggested the antigenotoxic effect of ascorbic acid against ethyl methanesulfonate (EMS), methyl methanesulfonate (MMS), and *N*-nitroso-*N*-ethylurea (ENU) exposure to *Drosophila*.

4 Utility of *Drosophila* in Examining the Efficacy of Nutraceuticals Against Aging

Aging is a multifactorial biological process that leads to a progressive decline in physiological and cognitive function (Khan et al. 2017). Although aging itself is a complex biological process, genetic and environmental factors make it even more complex. Therefore, the development of effective interventions for promoting healthy aging is one of the major and challenging biomedical concerns. Among different theories of aging, the free radical theory of aging is directly connected to nutraceuticals due to their free radical scavenging activities. Compared to other conventional biological models in aging research, *Drosophila* is a valuable organism to assess the efficacy and to identify the mode of action of nutraceuticals due to its short life span and well-defined genetics. Superoxide dismutase 1 (SOD1) and Forkhead box O (dfoxo), the critical players of the antioxidant defense system, are associated with aging. Laslo et al. (2013) and Wang et al. (2014a) demonstrated that supplementation of freeze-dried acai (*Euterpe oleracea*) pulp and cranberry promotes healthy aging in *SOD1* knockdown and *dfoxo* mutant flies. Similarly, riboflavin administration to *Drosophila* promoted the survival with increased reproductive capacity through modulation in antioxidant stress pathway (Zou et al. 2017). In addition, Chandrashekara et al. (2014) showed that curcumin supplementation leads to increased survival of *Drosophila* through modulation in energy metabolism such as increased levels of glycogen levels and pAkt and aconitase activity. Recently, transcriptome data of palm fruit juice (PFJ)-exposed *Drosophila* larvae and larval fat bodies revealed the modulation of stress-responsive genes (*heat shock proteins 70 and 26, SOD2, TOR*) that might be associated with increased longevity phenotype after PFJ supplementation to *Drosophila* (Leow et al. 2018). Nectarine (*Prunus persica* var. nectarine; subspecies of peach) contains dietary fibers, ample amount of vitamin C, β-carotenoids, and polyphenols that can promote a healthy life. Study on *Drosophila* showed that nectarine supplementation (4%) modulates glucose metabolism and controls oxidative damage leading to increased life span of the organism (Boyd et al. 2011). In another study, pharmacological inhibition of kynurenine from tryptophan by supplementation of berberine (bioactive component of natural Chinese medicine *Rhizoma coptidis*) leads to increase the life span of *Drosophila* (Navrotskaya et al. 2012). High-fat diet is associated with increased body weight and a decrease in life span (Muller et al. 2013; Lamont et al. 2016). Likewise, *Drosophila* fed with high-fat diet showed increased body weight and shortened life span. The effects of rosemary (perennial herb) extract on *Drosophila* life span under high-fat diet condition were evaluated by Wang et al. (2017). The group observed that supplementation of rosemary rescued the fat diet-induced body weight and enhanced the life span of *Drosophila* through increased antioxidant enzyme (SOD and CAT) activity and decreased *methuselah* expression. Similarly, supplementation of Royal Jelly proteins to *Drosophila* prolonged the life span via increased activity of the antioxidant enzyme and EGFR-mediated signaling pathway (Xin et al. 2016).

5 Utility of *Drosophila* in Examining the Efficacy of Nutraceuticals Against Neurodegenerative Diseases

The progressive and complex nature of neurodegenerative diseases poses a serious threat to human being worldwide. According to World Alzheimer's Report in 2015, an estimated 46.8 million people are affected with Alzheimer's disease (AD). Furthermore, this number is expected to touch

75 million in 2030. Likewise, more than ten million people are suffering with Parkinson's disease (PD) worldwide. Since the last decade, *Drosophila* has been extensively used to study various neurodegenerative diseases (Lu and Vogel 2009). Moreover, the use of this model to examine the therapeutic values of various agents has increased significantly. Epicatechin gallate (EC), a well-known antioxidant extracted from the green tea, has demonstrated multiple therapeutic potential (Chu et al. 2017). Siddique et al. (2014b) evaluated the efficacy of EC on transgenic *Drosophila* PD model (expression of human alpha synuclein in the fly brain using the UAS-Gal4 system) in the neurons. The results showed improved climbing ability and reduction in oxidative stress and apoptosis in the brain of diseased *Drosophila* after EC supplementation. The same group examined the therapeutic application of an Indian herb *Ocimum sanctum* L. (known as tulsi) against *Drosophila* PD model. Supplementation of *Ocimum sanctum* was found to enhance the locomotory ability in *Drosophila* PD model. This could be due to a reduction in the oxidative stress in the fly brain (Siddique et al. 2014a). Faust et al. (2009) used *Drosophila* DJ-1A model of PD to evaluate the therapeutic potential of Chinese herb celastrol and the antibiotic minocycline. The results revealed that administration of celastrol and minocycline inhibits the loss of dopaminergic neuron and restores the brain dopamine levels in the brain of *Drosophila* PD model. Likewise, spirulina (*Arthrospira platensis*), a biomass of cyanobacteria, is usually considered as superfood (Karkos et al. 2011). Administration of this spirulina to paraquat-sensitive PD *Drosophila* (DJ-1$\beta^{\Delta 93}$) increases life span and locomotor activity and decreases cellular stress in the organism (Kumar et al. 2017). The *Drosophila* strain mutant for PTEN-induced putative kinase 1 (PINK1B9) gene is another prevailing tool to study PD (Song et al. 2013).

Poddighe et al. (2014) examined the neuroprotective effects of *Mucuna pruriens* (contain genistein and polyunsaturated fatty acids) in *Drosophila* PINK1B9 mutant. The authors observed that supplementation of 0.1% *Mucuna pruriens* in the food of PINK1B9 mutant improved survival, rescued impaired climbing behavior, and restored brain bruchpilot and tyrosine hydroxylase expression. In another study, the neuroprotective effect of α-lipoic acid was studied against amyotrophic lateral sclerosis (ALS) using transgenic *Drosophila* (carrying G85R and G93A hSOD1 mutations) (Wang et al. 2018). The author observed that supplementation of α-lipoic acid exhibits a neuroprotection against ALS by upregulating antioxidant activity through the activation of the ERK/Akt pathway. Moreover, loss of *parkin* in *Drosophila* brain is associated with PD through evaluated oxidative stress and mitochondria dysfunction (Julienne et al. 2017). Administration of folic acid to *parkin* knockdown in *Drosophila* brain was associated with amelioration of locomotor ability, reduced mortality, oxidative stress, and restored energy metabolism in the organism (Srivastav et al. 2015). Mohandas et al. (2017) showed that manganese exposure to *Drosophila* induces locomotory dysfunction which can be ameliorated by supplementation of whey protein isolate. Likewise, paraquat exposure to *Drosophila* leads to severe neurodegeneration through altered mitochondria content, increased ROS production, and accelerated aging. The authors showed that administration of eicosapentaenoic and docosahexaenoic acid (omega-3 fatty acid) in combination with PQ protects the organism against neurodegeneration by inhibiting H_2O_2 production and reducing the levels of glutathione and oxidized proteins (de Oliveira Souza et al. 2017). Formation of amyloid plaques due to the aggregation of amyloid-β peptides is one of the hallmarks of AD (Murphy and LeVine 2010). The effect of flavonoid derivative against *Drosophila* AD model (expression of $A\beta_{42}$ in *Drosophila* brain tissue using brain driver; elav-Gal4) was evaluated by Singh et al. (2014). The authors observed that oral administration of flavonoid to AD flies exhibited anti-Aβ activity by improving motor function and increasing longevity. The authors also observed 70% rescue in eye degeneration ($A\beta_{42}$ expression using eye-specific driver; ey-gal4) phenotype by oral administration of flavonoid at 100 μM. In another study, a neuroprotective effect of *Curcuma longa* was observed in another transgenic *Drosophila* model (BACE-1 expression using brain- and eye-specific driver) (Wang et al. 2014b).

6 Utility of *Drosophila* in the Toxicity Evaluation of Nutraceuticals

During the last two decades, several simple and reliable cellular and organismal assays have been developed in *Drosophila* model for toxicity evaluation (Sharma et al. 2012; Chandra et al. 2015; Pandey et al. 2015). These assays can be used to evaluate the safety of nutraceuticals (Fig. 1). Genistein is a plant-derived estrogen with therapeutic potential against human diseases such as cancer, osteoporosis, and cardiovascular diseases (Miao et al. 2012; Spagnuolo et al. 2015; De Gregorio et al. 2017). Altun et al. (2011) observed a 45% reduction in mean life span of *Drosophila* population after genistein exposure. However, Siddique et al. (2018) demonstrated the reduction of PD symptoms in genistein-exposed transgenic *Drosophila*. The excessive consumption of green tea polyphenol (GTP) produces negative effects in *Drosophila* (Lopez et al. 2016). The exposure of *Drosophila* larvae to GTP (10 mg/mL) was found to delay the development of an organism. Furthermore, reduction in reproductive output, morphological defects in reproductive organs, and reduction in the survival of female organisms were observed. The exposure of *Drosophila* to *Croton campestris* and *Duguetia furfuracea* (medicinal plants originating in Brazil;

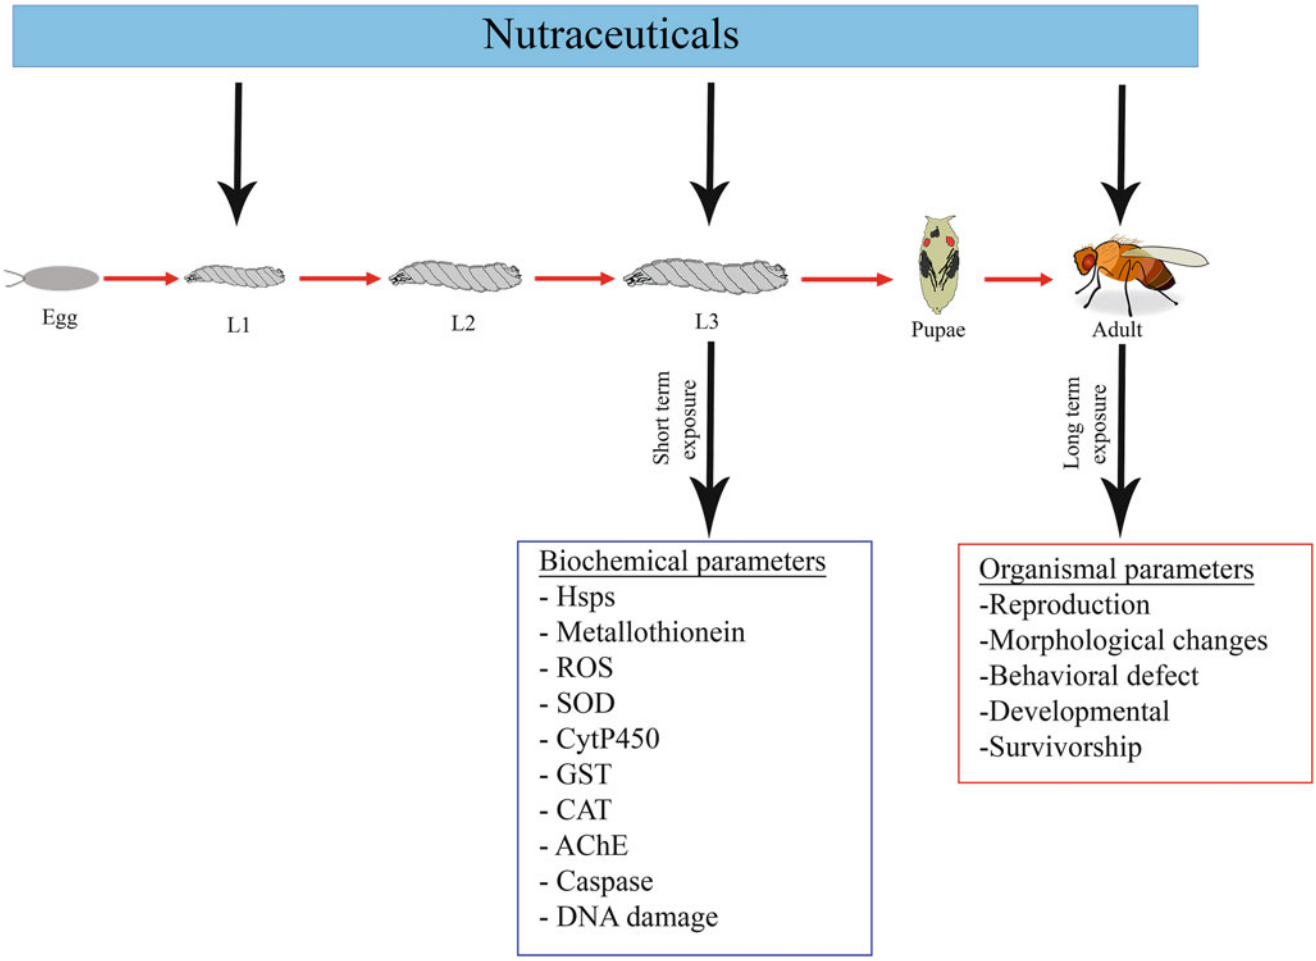

Fig. 1 Schematic diagram showing the utility of *Drosophila* in the assessment of efficacy and toxicity of nutraceuticals at the molecular and organismal level

used to treat numerous health problems) was found to increase mortality and impaired locomotor behavior due to oxidative stress (Valeria Soares de Araujo Pinho et al. 2014; Junior et al. 2016). Boulahbel (2015) examined the developmental and reproductive effect of neem oil on *Drosophila*. Neem oil exposure to *Drosophila* resulted in reduced pupal weight and fecundity and fertility.

Transgenic *Drosophila* has also been used for the assessment of nutraceutical toxicity. Using transgenic technology, the safety- and toxicity-associated genes are easily assessed. For example, expression of heat shock proteins (HSPs) is considered as first-tier bioindicator of cellular stress. Ample evidence has shown that the activity of *hsps* (*hsp70*, *hsp83*, *hsp26*) promoter can be evaluated by tagging it with a reporter gene such as *β-galactosidase* or *GFP* for the assessment of toxicity (Gupta et al. 2010b). Equally, the activity of glutathione S-transferases (GST) is directly proportional to increased ROS levels. Transgenic *Drosophila* carrying GST promoter tagged with β-galactosidase or GFP (*GST-lacZ or GST-GFP*) can be used for the easy assessment of ROS levels after nutraceutical administration (Veal et al. 2002; Sykiotis and Bohmann 2008; Louradour et al. 2017). Expression of the *reaper* and *hid* is considered as the initiators of cell death (Xu et al. 2009). Assessment of β-galactosidase in *reaper-lacZ* or *hid-lacZ* transgenic *Drosophila* can be used as cell death evaluation after nutraceutical administration (Fan et al. 2010; Wu et al. 2015). The Gal4/UAS system is one of the most powerful tools for in vivo target gene expression. The yeast transcriptional activator Gal4 binds to the upstream activating sequence (UAS) and activates transcription. Gal4 activity stimulates the transcription of a reporter gene under the control of UAS in *Drosophila* (Duffy 2002). This system can be used to decipher the molecular insights of the nutraceuticals.

7 Concluding Remarks and Future Directions

Due to the increasing popularity of nutraceutical use in our daily life, the safety and efficacy assessment of these agents are crucial. This chapter describes the *Drosophila* as an excellent in vivo model system for efficacy and safety

Table 1 Assessment of safety and efficacy of nutraceuticals and plant extracts using *Drosophila* model system

S. no.	Name of the agent	Source of the agent	Effect of the agent	References

assessments of nutraceuticals (Table 1). Because of significant similarity with the human genome, short life span, and high reproductive capacity, *Drosophila* can be used for the assessment of safety and efficacy of nutraceuticals. Several assays at the cellular and organismal level have been developed in this model to give a comprehensive view of safety/efficacy of nutraceutical compounds. In addition, reporter gene assay and the UAS-Gal4 system can also be utilized for the rapid assessment and to decode the mechanistic understanding of these agents, respectively.

Acknowledgment Gupta's and Sharma's laboratories are supported by Science and Engineering Research Board (ECR/2016/000034 to SCG and ECR/2016/001863 to AS). Additionally, Gupta's laboratory is supported by University Grants Commission [No. F.30-112/2015 (BSR)]. Biomarkers of Foods and Nutraceuticals: Applications in Efficacy, Safety, and Toxicity

Ramesh C. Gupta, Ajay Srivastava, Anita Sinha, and Rajiv Lall

Abstract

Currently, nutraceuticals, primarily plant extracts or their constituents, are used for prevention and treatment of diseases in both humans and animals. The use of nutraceuticals (commonly referred to as herbal supplements), compared to modern medicines, has become more popular because they (1) offer health benefits, (2) are effective in prevention and treatment of diseases, (3) have a wide margin of safety, (4) are more compatible with other nutraceuticals and/or modern medicines in polypharmacy, (5) are inexpensive, and (6) are easily available and do not require physician's prescription. Countless plant extracts have been investigated for their detailed phytochemistry, phytopharmacology, and phytotherapy/phytomedicine. A single plant can have more than one hundred phytoconstituents with many of them having biological and pharmacological potential. This makes evaluation of phytoconstituents efficacy and safety very complicated and challenging. Another challenging issue with nutraceuticals is contamination with metals, pesticides, and mycotoxins and adulteration with illegal drugs. Compared to modern medicines, nutraceuticals lack information on pharmacokinetics/toxicokinetics and interaction with other nutraceuticals and therapeutic drugs and biomarkers. The presence of food compounds, phytochemicals, and/or their metabolites in body fluids and tissues serves as biomarkers. This chapter describes the biomarkers of common foods of nutritional value and plant extracts of nutraceutical potential.

Keywords

Biomarkers · Nutraceuticals · Veterinary nutraceuticals · Phytochemicals · Polyphenols · Functional foods · Phytotherapy

1 Introduction

The necessity and importance of biomarkers in the field of dietary/functional foods and nutraceuticals have been well recognized around the world (Davis and Milner 2007; Caligiani et al. 2010; Gupta 2016; Savolainen et al. 2017). Biomarkers are often used to identify exposure of animals and humans to a type and composition of food, plant extracts, or their ingredients and for the evaluation for efficacy and safety. Dietary ingredients not only provide required nutrients but also aid in managing certain chronic diseases, such as diabetes, cardiovascular, gastrointestinal, cognition, cancer, and other health conditions. Phytochemistry of plant extracts has proven to be very complex because a single plant can have more than one hundred chemical constituents, for example, *Perilla frutescens* L. (Yu et al. 2017a). As a result, a plant extract can exert multiple biological and pharmacological effects. Molecular targets and mechanisms have been identified for many bioactive components present in foods and nutraceuticals (Gupta 2016). Different plant extracts can be used in combination with an objective to be more effective than a single plant extract against a disease, and biomarkers can aid in explaining the dosage-toxicity-efficacy relationships (Shen et al. 2017). A large number of plant extracts exert antioxidant and anti-inflammatory effects, and therefore they are used in prevention and treatment of many diseases in animals and humans (Gessner et al. 2016; Gupta 2016). By now, the consequences of oxidative stress and inflammation in animal health and their impact on the animal industry are well recognized. Many phytochemicals have anti-inflammatory and analgesic effects and therefore can be

indicated in pain management (Alonso-Castro et al. 2017; Tamrat et al. 2017). Those nutraceuticals that exert immunomodulatory and apoptotic activity against tumor or neoplastic cells can be employed as antitumor and/or anticancer agents (Ayeka et al. 2017; Davis and Milner 2007; Yu et al. 2017a, b). In production animals, nutraceuticals are used to enhance their growth and performance, in addition to preventing and treating diseases. Today, the use of prebiotics, probiotics, and synbiotics is greater than ever before in both monogastrics and ruminants. Some nutraceuticals, such as resveratrol, are used for life extension, in addition to their antioxidative and cardioprotective activities (Gessner et al. 2016). Many nutraceuticals are used to ameliorate poisonings caused by metals, pesticides, mycotoxins, and venoms. This chapter is prepared to address some of the biomarkers of exposure, effects, and susceptibility to foods, nutraceuticals, and the plant extracts that have potential for nutraceutical use.

2 Complexities in Food and Nutraceutical Biomarkers

In the food and nutraceutical industries, biomarkers play pivotal roles in identification and quantification of chemical ingredients, pharmacokinetics and toxicokinetics, food-herb-drug interactions, safety and toxicity evaluations, and decision-making policies. Biomarkers are also important for identification and quantitation of illegal drugs that are involved in adulterating nutraceuticals (Gupta 2016; Cheng et al. 2017). However, it needs to be mentioned that biomarker research is very expensive, as it requires highly qualified chemists, biochemists, pharmacologists, and toxicologists, as well as state-of-the-art equipment.

Matrices of both food and phytoextracts are complex and require highly sophisticated and sensitive equipment, such as HPLC-MS, HPLC-DAD-MS, UPLC-PDA, UHPLC-MS-MS, UHPLC-Q-TOF-MS, GC-MS, GC-MS-MS, MALDI-TOF-MS, NMR/MRI, micellar electrokinetic chromatography, and many others. Currently, an *omics* (nutrigenomics, proteomics, metabolomics, and nutriphenomics) approach has also become very useful in identifying biomarkers in the field of food and nutraceutical research. In food science, separation, isolation, identification, confirmation, and quantification of bioactive compounds are needed before they can be qualified and validated as biomarkers.

Complexity comes from multiple compounds present in a single food ingredient. For example, anthocyanins in the Chilean maqui berry are characterized by using HPLC-DAD-ESI/MS^n and NMR spectroscopy (Brauch et al. 2017). Soybean extracts contain genistein, daidzein, genistin, daidzin, glycitein, malonylgenistin, acetyl genistin, malonyldaidzin, and many other bioactive compounds; and their identification, confirmation, and quantification are conducted by 1H NMR spectrometry (Caligiani et al. 2010). Scientists have extensively explored the use of NMR and MRI to develop a wide range of applications for food research and manufacturing. MRI offers not only information about the chemical composition and internal structure of certain foods but also permits monitoring of internal compositional and structural modification of foods when they experience different agricultural practices and industrial processes (Marcone et al. 2013). Recently, Rossi et al. (2017) identified 32 proteins (including novel storage proteins: phaseolins, legumins, and lectins) in the Brazilian common bean (*Phaseolus vulgaris* L.) using 2-D gel electrophoresis and tandem mass spectrometry (MS/MS). The fermentation process further complicates identification and quantification of compounds as it modifies the chemical structures of their metabolites.

The matrix of a plant extract is even more complex than the food matrix. For example, bee pollen from nectar plants (*Brassica campestris* L., *Camellia sinensis* L., *Nelumbo nucifera* Gaertn.) is characterized for identification and quantitation of bioactive compounds (phosphatidylcholine, phosphatidylethanolamine, phosphatidylglycerol, phosphatidylserine, lysophosphatidylcholine, ceramide, diglyceride, triglyceride, fatty acids, phenols, flavonoids, carbohydrates, vitamins, and minerals) using UPLC-Q-exactive orbitrap/MS-based lipidomics (Li et al. 2017a). Very recently, Sima et al. (2018) used micellar electrokinetic chromatography (chemometric assessment) and HPLC to fingerprint and authenticate herbal medicines. Measurement of an individual phytochemical and/or its metabolite(s) needs to be quantitated in the body fluid and/or tissues to serve as biomarkers of exposure. Biomarkers of effects are also measured in the body fluids. For example, ABTS for antioxidative state and cytokines and prostaglandins for anti-inflammatory activity serve as biomarkers. Similarly, for anticancer, immunomodulatory, antidiabetic, and other health effects, biomarkers have been identified that are measured in body fluids.

3 Analysis of Antioxidant Activity

Oxidative stress plays a major role in etiologies of several diseases in humans and animals, and protein thiolation index (PTI) is commonly used as a biomarker (Giustarini et al. 2012). To counteract oxidative stress, antioxidants are used. Antioxidants are an extremely heterogeneous family of compounds, and a distinction between direct antioxidants (such as vitamin E, curcumin, ascorbic acid, phenols, polyphenols) and indirect antioxidants (catalase, superoxide dismutase, glutathione peroxidase) has been made (Amorati and Valgimigli 2015a, b). The antioxidant activity of phytochemicals and plant extracts can be measured using

ABTS (2, 2-azinobis (3-ethylbenzothiazoline-6-sulfonic acid), DPPH (2, 2-diphenyl-1-picrylhydrazyl), FRAP (ferric reducing antioxidant power), ORAC (oxygen radical absorbance capacity) assays, and others (Ou et al. 2002; Cheng et al. 2006; Thaipong et al. 2006; Amorati and Valgimigli 2015a, b). Results in these assays are expressed in μmol Trolox [(±)-6 hydroxy-2,5,7,8 tetra-methylchromane-2-carboxylic acid] equivalents (TE)/100 g or 100 mL sample. Among common solid and liquid foods, the total antioxidant capacity (TAC) was found to be maximum in red wine (dry) (247,800) and least in the red pepper (40) (Kusano and Ferrari 2008).

In humans, animals, birds, and fish, the separate measurement of different antioxidant molecules is not practical, and their antioxidant effects are additive, so measurement of TAC is advised (Erel 2004). The other names for TAC are total antioxidant activity (TAA), total antioxidant power (TAOP), total antioxidant status (TAS), and total antioxidant response (TAR). Various methods have been developed to measure TAC, but the ABTS-based method is the most widely used, and the results of TAC are expressed in mmol TE/L. TAC, measured by ABTS or any other test, is currently used as a biomarker of antioxidative status. In some studies, plasma and urinary levels of the antioxidant flavonols (quercetin and kaempferol) are used as biomarkers for dietary intake (De Vries et al. 1998).

4 Analysis of Anti-inflammatory Activity

A large number of nutraceuticals, including phytochemicals, exert anti-inflammatory activity. In experimental animal models (mostly rats and mice), inflammation is induced by injecting carrageenan or formalin into the paws, and the volume of raw paw edema or the volume of the exudates in air pouch is measured (Omote et al. 1998; Ajayi et al. 2017; Fahmy et al. 2017; Tamrat et al. 2017). The anti-inflammatory effect of a nutraceutical can be determined by measuring the reduction in the volume of paw edema and/or air pouch exudate and reduction in inflammatory mediator (histamine, bradykinin, substance P, nitric oxide, IL-1β, IL-6, TNF-α, PGE_2, glutamate, aspartate, myeloperoxidase, and others) release in rat, mouse, or any other lab animal. These inflammatory mediators can be measured in the body fluids (primarily in serum) and be used as biomarkers of inflammatory and anti-inflammatory activities.

5 Analgesic Activity

The radiant heat tail-flick test, as originally described by D'Amour and Smith (1941) with slight modifications (Milind and Monu 2013), is performed to measure analgesic activity.

6 Biomarkers of Foods and Nutraceuticals

In the case of foods and functional foods, the biomarkers are bioactive compounds that are present. These compounds can be identified and quantitated in the food ingredient and in body fluids (mainly plasma and urine) and tissues, and they often serve as biomarkers of food intake. Some of the biomarkers of common foods are listed in Table 1. Plasma levels of alkylresorcinol C17 and alkylresorcinol C19 serve as good biomarkers of whole grain wheat and rye intake; β-alanine for beef; eicosapentaenoic acid (EPA) and 3-carboxy-4-methyl-5-propyl-2-furanpropanoic acid (CMPF) for fish; linoleic acid for seeds, nuts, and vegetable oil; etc. (Table 1).

During food processing, foods can be contaminated with a number of chemicals, such as acrylamide, 3-monochloropropane-1, 2-diol (3-MCPD) esters, glycidyl esters, furan, acrolein, etc. Recently, Rietjens et al. (2018) reported that detecting residues of these contaminants or their metabolites and adducts in urine, blood, or tissue can serve as biomarkers of exposure and aid in physiologically based pharmacokinetics, biomonitoring, and risk assessment.

The presence of chemical compounds and/or their metabolites in body fluids/tissues of animals and humans serves as biomarkers of phytochemicals/marine organisms and other nutraceutical consumption. The nutraceuticals and their biomarkers are listed in Table 2. Some biomarkers are specific, while others are neither specific nor validated. These biomarkers not only indicate exposure to a particular nutraceutical but also as a further guide for pharmacological and therapeutic interventions. A majority of phytoconstituents exert antioxidative and anti-inflammatory activities, while others exert immunomodulatory, anti-apoptotic, antiplatelet aggregating, anticancer, anti-osteoarthritic, anti-acetylcholinesterase, anti-butyrylcholinesterase, and many other properties. Furthermore, some biomarkers are useful in the practice of polypharmacy where herb-herb or herb-nutraceutical may not be compatible.

These biomarkers can aid in identifying the food or nutraceutical consumed and also in pharmacokinetics and toxicokinetics of phytochemicals, interaction in polypharmacy, and phytotherapy.

7 Biomarkers of Polyphenols and Related Compounds: A Pharmacokinetic Perspective

7.1 Rationale

Plants produce a variety of secondary metabolites, including phenolic compounds, commonly referred to as polyphenols. There are more than 500 dietary polyphenols belonging to the classes of phenolic acids, flavonoids, lignans, and stilbenes,

Table 1 Biomarkers of some common foods/functional foods and their contaminants

Diet	Biomarker(s)	References
Chicken	Anserine in urine	Cheung et al. (2017)
Fish	Trimethylamine *N*-oxide in urine, species-specific protein (masses) pattern, DNA barcoding, eicosapentaenoic acid (EPA), 3-carboxy-4-methyl-5-propyl-2-furanpropanoic acid (CMPF), and n-3 fatty acids	Cheung et al. (2017), Stahl and Schröder (2017), and Savolainen et al. (2017)
Meat (beef)	β-Alanine and heterocyclic amines	Savolainen et al. (2017) and Hsiao et al. (2017)
Fish and meat	Carnosine, acylcarnitines (acetylcarnitine, propionylcarnitine, 2-methylbutyrylcarnitine), polyunsaturated fatty acids, amino acids	Marcone et al. (2013) and Cheung et al. (2017)
Shrimp	Arginine kinase peptide	Ortea et al. (2009)
Dairy foods	Amino acids, peptides and proteins, food colloids, essential fatty acids	Mariette (2009)
Eggs	Alpha-tocopherol, cholesterol, and gamma linolenic acid	Mariette (2009) and Savolainen et al. (2017)
Common bean (*Phaseolus vulgaris* L.)	Phaseolins, legumins, lectins	Rossi et al. (2017)
Soybean (*Glycine max.*)	Isoflavones (genistein, genistin, daidzein, biochanin, malonylgenistin, malonyldaidzin, acetyl genistin), saponins, amino acids, organic acids, etc.	Caligiani et al. (2010)
Cereals, wheat, rye, and other grains	β-Glucan, alkylresorcinols C17 and C19, and octacosanol	Ross et al. (2003), Woo et al. (2011), and Savolainen et al. (2017)
Avocados	Oleic acid	Savolainen et al. (2017)
Mushroom (*Russula senecis*)	Monosaccharides, polysaccharides, and β-glucan	Khatua and Acharya (2017)
Brassica vegetables (Brussels sprouts, broccoli, cauliflower, cabbage, mustard)	Glucosinolates	Bischoff (2016)
Liquid foods	Amino acids, organic acids, anthocyanins, phenolic compounds	van Gorsel et al. (1992) and Belton et al. (1996)
Margarine and vegetable oil	Oleic acid, linoleic acid, and α-tocopherol	Savolainen et al. (2017)
Food process-related contaminants	Acrylamide, 3-MCPD esters, glycidyl esters, furan, and acrolein, their metabolites and adducts in urine, blood, and tissues	Rietjens et al. (2018)

and as a result, their chemistry is very complex. Some of the groups of polyphenols are mentioned here in brief with suitable example(s) in parentheses. Hydroxybenzoic acids (a monomer gallic acid and a dimer ellagic acid, collectively referred to as ellagitannins) are common ingredients used in nutraceuticals. Flavonoids that are commonly found in plant extracts include flavonols (quercetin), flavones (apigenin), flavanols [(−)-epicatechin and proanthocyanidin B2)], flavanones (naringenin), anthocyanins (anthocyanidins: cyanidin, delphinidin, malvidin, pelargonidin, peonidin, and petunidin), and isoflavones (genistein) (Pinto and Santos 2017). It needs to be mentioned that there are about 700 anthocyanins reported to be isolated from plants (Faria et al. 2014). In humans, the major polyphenol classes consumed are biflavones (45%), anthocyanins (17%), and flavonols, flavones, and flavanones (16%). There are variations, of course, during different seasons and in different countries.

Polyphenols can act as antioxidants by quenching reactive oxygen species (ROS) or indirectly by altering gene expression via intracellular signaling cascades by reducing NFκB or enhancing nuclear factor-like 2 (Nrf2), thus stimulating the body's own antioxidant and detoxification mechanism (Bohn 2014). Polyphenols exert multiple phytopharmacological mechanisms and effects and thereby prevent chronic diseases, such as diabetes, cardiovascular, neurodegenerative, cancer, and many other illnesses.

7.2 Analysis of Total Phenolic Content

The total phenolic content (TPC) can be measured spectrophotometrically on a microplate reader (EPOCH 2 BioTek, BioTek Instruments Inc., Highland Park, Winooski, USA) according to Folin-Ciocalteu's method (Bailon-Moscoso et al. 2017). The amount of TPC is expressed in mg gallic acid equivalent (GAE)/g sample. The polyphenol content has been reported to be maximum in the cloves (15,188.2 mg/100 g) and least in the whole grain pasta and cauliflower (21.9 mg/100 g and 22.3 mg/100 g, respectively) (Pinto and Santos 2017).

Table 2 Potential biomarkers of selected plant extracts, marine organisms, and nutraceuticals

Plant extract/nutraceutical	Potential biomarker(s)	Biological/pharmacological effect(s)	References
Açai (*Euterpe oleracea*)	Lignans (dihydrobenzofuran, tetrahydrofuran, etc.), (+)-lariciresinol, (+)-pinoresinol, (+)-syringaresinol	Antioxidative, cytoprotective	Chin et al. (2008a)
Acacia nilotica (L.) (Babul)	Tannins, flavonoids, alkaloids, fatty acids, and polysaccharides	Antioxidative, anti-inflammatory, antidiarrheal, antihypertensive, antispasmodic, antibacterial, anthelmintic, antiplatelet aggregatory, anticancer, and acetylcholinesterase inhibitory	Rather et al. (2015)
Alpinia galanga	1,8-cineole, β-bisabolene, β-selinene, α-selinene, farnesene, 1, 2-benzenedicarboxylic acid, germacrene B, 1′S′-1′-acetoxychavicol acetate, and α-fenchyl acetate	Anti-inflammatory, antioxidant, analgesic, psychostimulant, hypoglycemic, anti-allergic, antimicrobial, gastroprotective, antiplatelet, anticancer, immunostimulatory, cholesterol reducing	Chudiwal et al. (2010) and Srivastava et al. (2017)
Amaranth (*Amaranthus hypochondriacus* L.)	Amaranth Alb, amaranth Glob, 11S globulin tetrapeptides, and polyphenols	ACE inhibitor, antihypertensive, antioxidative, hypocholesterolemia, immunomodulatory, antitumor, hypoglycemic, anti-anemia	Rastogi and Shukla (2013), Soriano-Santos and Escalona-Buendia (2015), and Quiroga et al. (2017)
Ashwagandha (*Withania somnifera*)	Anaferine, anahygrine, withanine, somniferine, withaferin-A, withanolides, withanol, diosgenin, sitoindosides, etc.	Antidepressant, antifungal, antimicrobial, antimalarial, chondroprotective, cholinesterase inhibiting and promoting learning and memory in Alzheimer's, antioxidative, anti-inflammatory, antiaging, anxiolytic, and antitumor	Choudhary et al. (2004) and Bharti et al. (2016)
Astaxanthin (*Haematococcus pluvialis*)	Astaxanthin	Antioxidative	Satoh (2016)
Astragali radix	Astragaloside IV, calycosin, and formononetin	Pain relieving, antioxidative, anti-inflammatory, and anti-arthritic	Maresca et al. (2017)
Baccharis dracunculifolia DC	Caffeic acid, *trans*-cinnamic acid, *p*-coumaric acid, and ferulic acid	Antioxidative, anti-inflammatory, and immunomodulatory	Figueiredo-Rinchel et al. (2017)
Barleria lupulina Lindl.	Alkaloids, saponins, tannins, flavonoids, and proteins	Antioxidative, antibacterial, and immunomodulating	Kumari et al. (2017)
Bee pollen from nectar plants (*Brassica campestris* L., *Camellia sinensis* L., *Nelumbo nucifera* Gaertn.)	Phosphatidylcholine, phosphatidylethanolamine, phosphatidylglycerol, phosphatidylserine, ceramide, phenols, flavonoids, fatty acids, carbohydrates, vitamins, and minerals	Antioxidative, anti-inflammatory, anticarcinogenic, antibacterial, fungicidal, hepatoprotective, anti-atherosclerotic, and immune-regulating properties	Denisow and Denisow-Pietrzyk (2016) and Li et al. (2017a)
Berberine (*Berberis vulgaris*, *Berberis aristata*, *Berberis aquifolium*, *Berberis canadensis*, *Coptis chinensis*, *Argemone mexicana*)	Berberine, thalifendine, berberrubine, and jatrorrhizine	Antidiabetic, cardiovascular and metabolic disorders, gastroenteritis, and neurodegenerative diseases	Kumar et al. (2015)
Bidens pilosa L. leaves extract	Catechin, kaempferol, ferulic acid, gallic acid, and paclitaxel	Antioxidative, anti-inflammatory, analgesic, antimicrobial, immunosuppressive, antiproliferative, antitumor, and anticancer	Fotso et al. (2014) and Singh et al. (2017)
Blueberry (*Vaccinium corymbosum*)	Anthocyanins/anthocyanidins (delphinidin, cyanidin, petunidin, peonidin, and malvidin)	Anticancer	Aqil et al. (2014)

(continued)

Table 2 (continued)

Plant extract/nutraceutical	Potential biomarker(s)	Biological/pharmacological effect(s)	References
Blue-green algae	C-phycocyanin	Antioxidative, anti-inflammatory, antihyperalgesic, selective COX-2 inhibitor, and cartilage repair in osteoarthritis	Shih et al. (2009), Pieloch (2006), and Martinez et al. (2015)
Brassica juncea	Sinapic acid	Peroxynitrite scavenging activity	Zou et al. (2002)
Butea monosperma Lam.	Aurones, butin, butein, butrin, isobutrin, chalcones, palasitrin, coreopsin, and others	Anti-diarrhea, antidiabetic, astringent, and diuretic	Khan et al. (2017)
Calafate (*Berberis microphylla*)	Polyphenols	Antioxidative	Ruiz et al. (2010)
Cassia absus	Chaksine, iso-chaksine, chrysophanol, and aloe emodin	Antioxidative, anti-inflammatory, antihypertensive, antifertility, antibacterial, antifungal, antihyperglycemic, anti-glycation, alpha-amylase, and inhibitory	Ahmad et al. (2018)
Calophyllum brasiliense	Jacareubin	Antibacterial, antitumor, anticancer, and gastroprotective	Garcia-Nino et al. (2017)
Cashew nut shell liquid (*Anacardium occidentale*)	Anacardic acids	Anti-Alzheimer's disease, anti-apoptotic, antioxidative, and antibacterial	Filho et al. (2018)
Cat's claw (*Uncaria guianensis* and *U. tomentosa*)	Indole alkaloid, tannins, rutin, ellagic acid, gallic acid, flavonoids, sterol, proanthocyanidin, etc.	Antioxidative, anti-inflammatory, and wound healing	Clark (2007)
Celastrus regelii and *Tripterygium wilfordii* (thunder god vine)	Celastrol	Antioxidative, anti-inflammatory, anticancer, anti-osteoarthritic, and insecticidal	Wang et al. (2018)
Chilean maqui berry/blackberry (*Aristotelia chilensis*)	Gallic acid, luteolin, myricetin, and quercetin	Free radical scavenging and antioxidative, anti-inflammatory, hypoglycemic, and anti-hemolytic	Cespedes et al. (2017)
Chromolaena odorata leaf extract	Stigmasterol and scutellarein tetramethyl ether	Antioxidative, lipid peroxide inhibitory, hydrogen peroxide inhibitory, and wound healing	Vijayaraghavan et al. (2017)
Cinnamon oil and cinnamon extract (*Cinnamomum zeylanicum*)	Cinnamic acid, cinnamyl acetate, cinnamaldehyde, eugenol, benzoic acid, and benzaldehyde	Bactericidal, bacteriostatic, fungicidal, fungistatic, antidiabetic, antiparasitic, antioxidative, anti-hyperlipidemia, antihypertensive, and cardioprotective	Gupta et al. (2008) and Ranasinghe et al. (2017)
Copaiba oil (*Copaifera multijuga* Hayne; *Copaifera duckei* Dwyer; and *Copaifera langsdorffii* Desf.)	Oleoresin, β-caryophyllene, β-bisabolene, α-bergamotene, copalic acid methyl ester	Anti-inflammatory, antibacterial, and lavicidal	Rodrigues et al. (2014), Lucca et al. (2015), and Xavier et al. (2017)
Corymbia citriodora	α-Citronellal, citronellol acetate, isopulegol, and eucalyptol	Antifungal and antioxidant	Salem et al. (2018)
Cupressus macrocarpa Hartw.	Terpinen-4-ol, α-phellandrene, α-citronellol, and α-citronellal	Antibacterial and antifungal	Salem et al. (2018)
Curcumin/turmeric (*Curcuma longa*)	Curcumin, mitocurcumin	Neuroprotective, antioxidative, anti-inflammatory, anti-osteoarthritis, anti-Parkinson's, anti-Alzheimer's, antidiabetic, anti-cardiovascular diseases, anticonvulsant, anti-obesity, anticancer, and wound healing	Henroitin et al. (2010), Aggarwal et al. (2013), Comblain et al. (2015), Javeri and Chand (2016), Risuleo (2016), Levine et al. (2017), Jayakumar et al. (2017), and Mohanty and Sahoo (2017)
Date palm pollen (*Phoenix dactylifera* L.)	Phenols and flavonoids	Cardiopreventive, ACE inhibiting, and antioxidative	Daoud et al. (2017)
Daylily (*Hemerocallis fulva*)	Phlomuroside, lariciresinol, adenosine, quercetin, isorhamnetins, and pinnatanine, roseoside	Lipid peroxidation inhibitory, antioxidative, anti-inflammatory, and anti-jaundice	Zhang et al. (2004)

Plant extract/nutraceutical	Potential biomarker(s)	Biological/pharmacological effect(s)	References
Drosera rotundifolia, *D. anglica*, *D. intermedia*, *D. madagascariensis*	2′-*o*-galloylhyperoside, myricetin-3-*o*-β-glucopyranoside, kaempferol, and others	Anti-respiratory diseases	Zehl et al. (2011)
Essential oils from *Piper hispidimervium*, *P. sarmentosum*, *P. hancei*	Asaricin	Anticholinesterase	Xiang et al. (2017)
Eucalyptus bark (*Eucalyptus globulus* and *Eucalyptus macrocarpa*)	Pinoresinol, vomifoliol, methyl gallate, rhamnazin, rhamnetin, eucalyptone, eriodictyol, quercetin, taxifolin, engelitin, catechin, eupatriol, macrocarpals, and several terpenoids	Lipid peroxidation inhibitory, antibacterial	Yamakoshi et al. (1992) and Yun et al. (2000)
Fenugreek (*Trigonella foenum-graecum*)	Diosgenin, trigonelline, coumarin, galactomannan, 4-hydroxyisoleucine	Anti-hyperglycemic, hypolipidemic, antimetabolic syndrome, anti-inflammatory, anticancer, galactogogue, hepatoprotective, and enhancing male libido	Garg (2016)
Ficus racemosa	Lupeol and β-sitosterol	Antibacterial, antifungal, and wound healing	Bopage et al. (2018)
Ficus sycomorus	Flavonoids, saponins, tannins, triterpines, phenols, and cardiac glycosides	Antioxidative, antidiabetic, antidepressant, and spatial memory enhancing, antiepileptic, anticonvulsant	Foyet et al. (2017)
Flaxseed	Lignans (secoisolariciresinol, enterodiol, enterolactone, enterolignan), α-linolenic acid	Anti-inflammatory, antidiabetic, antihyperlipidemic, antihypertensive, antimetabolic syndrome, anti-obesity	Machado et al. (2015), Di et al. (2017), and Yu et al. (2017a, b)
Forskolin (Forsk) (*Coleus forskohlii*)	Forskolin	Anti-inflammatory, anticancer, anti-obesity, anticancer, increasing cAMP, and enhancing protein biosynthesis	Risuleo (2016)
Garlic (*Allium sativum*)	Alliin, allicin, *S*-alkyl-L-cysteine sulfoxides, diallyl thiosulfinate, sodium-2-propenyl thiosulfate, diallyl sulfide, plasma C-peptide, and many others	Antimicrobial, antioxidative, anti-inflammatory, antimutagenic, anticancer, anti-asthmatic, immunomodulatory, prebiotic, and antidiabetic	Goncharov et al. (2016) and Wang et al. (2017)
Glycyrrhizae radix	18 β-Glycyrrhetinic acid	Anti-inflammatory, anti-asthmatic	Kim et al. (2017)
Glycyrrhiza uralensis Fisch.	Licorice compounds (glycyrrhizin, glabridin, liquiritin, isoliquiritin, isoliquiritigenin)	Immunomodulatory, anti-inflammatory, anticancer, and antitumor	Ayeka et al. (2017)
Guava (*Psidium guajava*)	Phytofluene, β-carotene, β-cryptoxanthin, lycopene, cryptoflavin, lutein, neochrome	Antioxidative	Thaipong et al. (2006)
Grape seed (*Vitis vinifera*)	Proanthocyanidin	Antioxidative, anti-osteoarthritic	Jayaprakasha et al. (2001) and Woo et al. (2011)
Green tea (*Camellia sinensis*)	Epigallocatechin-3-gallate, epicatechin, epigallocatechin, catechin, gallocatechin, theaflavin, apigenin, luteolin, quercetin, myricetin, and cyclodextrin	Antioxidant, anti-inflammatory, anti-apoptotic, genital warts, immunomodulatory, anti-obesity, antidiabetic, antimicrobial, anticancer, wound healing, and anti-cardiovascular diseases	Tarachiwin et al. (2007), Clarke et al. (2014), Svoboda et al. (2015), Coppock and Dziwenka (2016), Li et al. (2016), Bacanli et al. (2017), and Oda and Murakami (2017)
Gymnosperma glutinosum	Dihydrotucumanoic acid	Antinociceptive, anti-inflammatory, antimicrobial, antidiarrheal	Alonso-Castro et al. (2017)
Hempseed oil	Polyunsaturated fatty acids	Atopic dermatitis	Callaway et al. (2005)
Honeybees	Propolis	Antiseptic	Bacanli et al. (2017)
Hymenaea martiana	Engeletin	Antidiabetic	Ye et al. (2017)
Indian blackberry/jamun (*Syzygium cumini* L.)	Anthocyanins, ellagic acid/ellagitannins, and polyphenolics	Antioxidative, antiproliferative	Aqil et al. (2012)

(continued)

Table 2 (continued)

Plant extract/nutraceutical	Potential biomarker(s)	Biological/pharmacological effect(s)	References
Indian frankincense (*Boswellia serrata*)	Boswellic acids: β-boswellic acid, acetyl-β-boswellic acid, 11-keto-β-boswellic acid, and acetyl-11-keto-β-boswellic acid	5-Lipoxygenase inhibitor, anti-inflammatory, anti-arthritic, prostate tumor inhibitor, neuroprotective in Parkinson's disease	Pang et al. (2009), Poeckel and Werz (2006), Siddiqui (2011) and Ameen et al. (2017)
Indian gooseberry/Amla (*Phyllanthus emblica*)	Hydrolysable tannoids (emblicanin A, emblicanin B, punigluconin, pedunculagin), punicafolin, phyllanemblinin, and other polyphenols	Antioxidative, anti-inflammatory, anti-arthritis	Fleck et al. (2013) and May et al. (2015)
Juniper (*Juniperus communis* L.)	α-Pinene, chlorogenic acid, rutin, apigenin, and quercetin	Antioxidative, anti-inflammatory, genoprotective, immunostimulatory, and antifungal	Fierascu et al. (2018)
Knotweed (*Reynoutria* spp.)	Resveratrol, polydatin, rutin, reynoutrin, emodin, physcion, citrorosein, lapathoside A, quercetin, and kaempferol	Antioxidative, anti-inflammatory, neuroprotective, antibacterial, antifungal, and antitumor	Patocka et al. (2017)
Limnophila aromatica	Phenols and flavonoids	Antioxidative	Do et al. (2014)
Limonene (oil from citrus plants, orange, lemon, grapefruit)	Limonene (*p*-Mentha-1,8-diene)	Anti-gastric diseases and antiproliferative effect in cancer cells	Bacanli et al. (2017)
Lycopene	Lycopene	Free radical scavenging and antioxidative, anti-inflammatory, neuroprotective, anti-dementia, anticancer	Bacanli et al. (2017) and Zhao et al. (2017)
Lotus (*Nelumbo nucifera* Gaertn)	Polyphenols (gallic acid, catechin, peltatoside, rutin, isoquercitrin, miquelianin, and astragalin)	Antioxidative, hepatoprotective, and anticancer	Horng et al. (2017)
Mangosteen (*Garcinia mangostana*)	Xanthones, mangostanin, and α-mangostin	Antioxidative, anti-inflammatory, antiproliferative, neuroprotective, hypoglycemic, anti-obesity, and quinone reductase induction	Chin et al. (2008b) and Ovalle-Magallanes et al. (2017)
Melastoma malabathricum and *Muntingia calabura*	Gallic acid, ellagic acid, quercetin, vitexin, isovitexin, myricetin, kaempferol, naringenin, luteolin, diosmetin, apigenin, and many other polyphenols	Gastroprotective, antiulcer, gastric secretion inhibitory, antinociceptive, cytoprotective, antioxidative, free radical scavenging, anti-lipid peroxidation, anti-inflammatory, and antipyretic	Zakaria et al. (2007) and Halim et al. (2007)
Mulberry bark powder (*Ramulus mori*)	Flavonoids, polysaccharides, resveratrol, phenolic acids	Antioxidative, anti-inflammatory, anti-apoptotic to pancreas cells, and antidiabetic	Yin et al. (2017)
Maqui berry (*Aristotelia chilensis*)	Anthocyanins, polyphenols	Antioxidative, antibacterial, antidiabetic	Rojo et al. (2012), Genskowsky et al. (2016), Brauch et al. (2017), and Li et al. (2017c)
Marine organisms (*Cladiella krempfi*, *Klyxum molle*, and others)	Diterpenes: krempfielins, hirsutalins, klymollins, klysimplexin, klysimplexin sulfoxide, simplexin, cladieunicellin, and others	Anti-inflammatory, anti-arthritic	González et al. (2015)
Naringin (from grapefruit and related citrus species)	Naringin	Antioxidative, anti-inflammatory, antimicrobial, and anticancer	Bacanli et al. (2017)
Neem extract (*Azadirachta indica*)	Azadirachtins, nimbin, nimbidin, nimbolide, margolone, gedunin, catechin, epicatechin, gallocatechin, epigallocatechin, and several others	Nutritive, anxiolytic, antimicrobial, antiparasitic, immunomodulatory, antioxidative, antidiabetic, antitumor, chemopreventive, pest control, wound healing	Tandan et al. (1995), Tepsuwan et al. (2002), Aruwayo and Maigandi (2013), and Kumar et al. (2016)
Nigella sativa	Thymoquinone	Antioxidant, anti-inflammatory, anticancer, pro-apoptotic effect, anti-autoimmune diseases, anti-asthma, antidiabetic	Gupta et al. (2016)

(continued)

Table 2 (continued)

Plant extract/nutraceutical	Potential biomarker(s)	Biological/pharmacological effect(s)	References
Nonea micrantha	Crodacid, neophytadiene, vanicol, chrysarobin, clionasterol, and many others	Cholinesterase inhibiting and promoting learning and memory and antioxidative	Choudhary et al. (2017)
Ocimum gratissimum (Ocimum oil)	Rutin, rosmarinic acid, chicoric acid, kaempferol, caffeic acid, *trans*-ferulic acid, quercetin, vicetin, salvigenin, nevadensin, and cirsimaritin	Anti-inflammatory and antioxidative, antirheumatism, anti-bronchitis, antimicrobial	Ajayi et al. (2017)
Olax nana	Gallic acid derivatives, flavonoids, rutin, tannins, sterols, saponins, and terpenoids	Antioxidative, free radical scavenging, anticholinesterase, and alpha-glucosidase inhibiting	Ovais et al. (2018)
Olive oil	Tyrosol, hydroxytyrosol, (phenyl-ethyl alcohols, lignans, and secoiridoids)	Antioxidative	Servili et al. (1999), Carrasco-Pancorbo et al. (2005), and Marcone et al. (2013)
Panax notoginseng Ledeb saponins	Ginsenoside Rgl, ginsenoside Rbl, and ginsenoside Rd	Antioxidative, anti-pancreatitis, anti-apoptotic, anti-autophagy, and anticancer	Liu et al. (2018)
Phyllostachys heterocycla var. *pubescens*	2,6-Dimethoxy-*p*-benzoquinone	Antibacterial	Nishina et al. (1991)
Pinus sylvestris L.	Phenolic compounds	Anti-inflammatory	Karonen et al. (2004)
Pueraria lobata	Puerarin	Antihypertensive, anti-genotoxic, and against fever, diarrhea, and eye disorder	Bacanli et al. (2017)
Rabdosia rubescens (Donglingcao)	Oridonin	Antioxidative, anti-inflammatory, immunomodulatory, and anticancer	Wu et al. (2018)
Ramaria largentii Marr & D. E. Stuntz (wild edible mushroom)	Protocatechuic acid, vanillic acid, sterols, phenolic compounds, and triterpenes	Antioxidative and anti-genotoxic	Aprotosoaie et al. (2017)
Resveratrol	*Trans*-resveratrol, *cis*-resveratrol, *trans*-resveratrol-glucuronoside cinnamic acid, *p*-coumaric acid	Antioxidative, antitumor, antiviral, anti-atheroma	Risuleo (2016)
Rhodiola rosea L.	Salidroside, rosarin, rosavin, and rosin	Antioxidative, anti-inflammatory, antidiabetic, anticancer, and antiviral	Marchev et al. (2017)
Rhizoma smilacis Glabrae	Astilbin	Antioxidative, anti-inflammatory, immunomodulatory and anti-hepatic, anti-arthritic, and anti-renal injury	Gao et al. (2017)
Rosmarinic acid (*Rosmarinus officinalis*, *Perilla frutescens*)	Rosmarinic acid, apigenin, caffeic acid, catechin, ferulic acid, luteolin, *m*-coumaric acid, and carnosic acid	Chemopreventive, antiangiogenesis, antiproliferative, antitumor, growth promoting, antioxidative, anti-inflammatory, antidepressive, immunomodulatory, antimicrobial, antidiabetic, anti-allergic, hepato- and renal-protective, and anti-Alzheimer's disease	Baba et al. (2004), Krajčovičová and Melus (2013), Alagawany et al. (2017), Levine et al. (2017), Yu et al. (2017a, b), and Rong et al. (2018)
Royal fern (*Osmunda regalis* root)	Tannins, glycosides, steroids, saponins, and ferulic acid	Anticancer	Schmidt et al. (2017)
Royal jelly proteins	Dipeptide YY	Renin inhibiting, ACE inhibiting, antihypertensive, wound healing	Fujii et al. (1990) and Sultana et al. (2008)
Safflower seed oil cake (*Carthamus tinctorius* L.)	Carthatins	Acetylcholinesterase-inhibiting activity	Peng et al. (2017)
Saffron (*Crocus sativus* L.)	Crocin-1, crocetin, *trans*-crocetin, safranal	Anti-apoptotic, antioxidative, anti-inflammatory, anticancer, antitumor, neuroprotective, cardioprotective, hepatoprotective	Lautenschläger et al. (2014) and Hoshyar and Mollaei (2017)

(continued)

Table 2 (continued)

Plant extract/nutraceutical	Potential biomarker(s)	Biological/pharmacological effect(s)	References
Sarcandra glabra	Sesquiterpenes, phenolic acid, flavonoids, chalcones, polysaccharides, coumarins, triterpenoids	Antioxidative, anti-inflammatory, immune-modulatory, anticancer, antidiarrheal, and antirheumatism	Tsai et al. (2017)
Saururus chinensis	Sauchinone	Antioxidative, anti-inflammatory, chondroprotective, and anti-osteoarthritic	Gao et al. (2017)
Sclerocarya birrea (A. Rich.) Hochst (Marula extract/oil)	Quinic acid, catechin, epigallocatechin gallate, and epicatechin gallate	Antiaging, anti-elastase, and anti-collagenase	Shoko et al. (2018)
Scutellaria baicalensis Georgi	Baicalin and baicalein	Antioxidative, anti-inflammatory, anticancer, anti-dementia, antimicrobial, antipyretic, and anti-jaundice	Jeong et al. (2011)
Shilajit	Dibenzo-α-pyrones, dibenzo-α-pyrone-chromoproteins, fulvic acids	Antioxidative, immunomodulatory, anti-inflammatory, analgesic, learning augmentation, antidiabetic, antiulcerogenic, anti-osteoarthritic, cardioprotective, and antimicrobial	Aggarwal et al. (2007), Wilson et al. (2011), Lawley et al. (2013), and Bhavsar et al. (2016)
Spirulina platensis/*Arthrospira platensis*	C-phycocyanin	Nutritive, anti-anemia, antioxidative, antimicrobial, anti-inflammatory, anti-allergy, antidiabetic, chemopreventive, anticancer, and neuroprotective	Sarada et al. (2011) and Wan et al. (2016)
Stenoloma chusanum (L.) ching	Filicinic acid, chlorogenic acid, pyracrimycin, theophylline, chaplacin, bisabolenone, and scadenone	Antioxidative, anti-tyrosinase, and antitumor	Wu et al. (2017)
Tamarind seed and pericarp (*Tamarindus indica* L.)	2-Hydroxy-3,4-dihydroxyacetophenone, methyl 3,4-dihydroxybenzoate, 3,4-dihydroxyphenyl acetate, (+)-catechin, (−)-epicatechin, proanthocyanidins, and procyanidins	Free radical scavenging, antioxidative, and antidiabetic	Tsuda et al. (1994), Maiti et al. (2004), Sudjaroen et al. (2005), and Sandesh et al. (2014)
Tea tree oil (*Melaleuca alternifolia*)	Terpinen-4-ol, terpinolene, and 1,8-cineole	Antifungal, antibacterial, anti-pneumonic, anti-lice, anti-inflammatory	Carson et al. (2006) and Li et al. (2017b)
Terminalia chebula	Chebulagic acid, chebulinic acid, chebulic acid, gallic acid, ellagic acid, tannic acid, corilagin, triterpenoids, polyphenolic compounds, and ascorbate	Antioxidative, anti-inflammatory, analgesic, anti-arthritic, antiproliferative, adaptogenic, immunomodulatory, and cytoprotective	Upadhyay et al. (2014) and Murdock et al. (2016)
Terminalia muelleri Benth. (Australian almond)	Isoorientin, vitexin, ellagic acid, ellagitannin	Anti-inflammatory and analgesic	Fahmy et al. (2017)
Thyme and oregano oil	Carvacrol and γ-terpinene	Antioxidative, antibacterial, antimycotic, and antiplatelet	Bacanli et al. (2017)
Tibouchina granulosa	Proanthocyanidins, flavonoid glycosides	Anti-inflammatory	Sobrinho et al. (2017)
Tiger milk mushroom (*Lignosus rhinocerotis*)	A- and β-glucan, phenolic compounds, polysaccharide	Anti-inflammatory, antioxidant, anticoagulant, fibrinolytic, antimicrobial, anti-obesity, anticancer, hepatoprotective, antitumor, antiviral, neuroprotective, and immunomodulatory	Nallathamby et al. (2018)
Turbinaria ornata	Sulfated polysaccharides	Anti-inflammatory, anti-rheumatoid arthritis	Ananthi et al. (2017)

(continued)

Table 2 (continued)

Plant extract/nutraceutical	Potential biomarker(s)	Biological/pharmacological effect(s)	References
Ursolic acid (*Malus pumila*, *Ocimum basilicum*, and many others)	Ursolic acid	Anti-arthritis, antiulcer, anticancer, antidiabetes	Bacanli et al. (2017)
Wheat bran oil	Sterols, oryzanol-like compounds, tocopherols, and carotenoids	Free radical scavenging, antioxidative, and hypolipidemic	Talawar et al. (2017)
Wild blueberries (*Vaccinium angustifolium* Aiton and *V. myrtilloides* Michaux)	Anthocyanins	Antioxidative	Chorfa et al. (2016)
Wild garlic (*Allium ursinum*)	Methyl isorinate, alliins (methylalliin, methiin, and allylalliin), organosulfur compounds (allyl methyl disulfide and allicin), and phenolic compounds	Antioxidative, antimicrobial, calcium channel inhibition, spasmolytic, antiplatelet, and other GI disturbances	Hiyasat et al. (2009) and Pavlovic et al. (2017)

7.3 Nutraceutical-Gut Microbiota Interaction and Biomarkers of Bioavailability

Upon ingestion, food/nutraceuticals first encounter the gut microbiota, which is considered a metabolic organ. Bacteria appear to participate in the metabolism of polyphenols of phase I and phase II reactions. Common reactions include deglycosylation, dehydroxylation, demethylation, or conjugation. Some examples of metabolites formed from isoflavones by the microbiota are (1) dihydrodaidzein, equol, and *O*-desmethylangolensin (*O*-DMA) from daidzein, (2) dihydrogenistein from genistein, (3) urolithin B from ellagitannins, (4) enterodiol and enterolactone from secoisolariciresinol di-*O*-glucoside, and (5) flavanone 8-prenylnaringenin from prenylchalcone isoxanthohumol. Biomarkers often explain how the nutraceuticals affect the level and composition of gut microbiota and how the gut microbiota affects the nutraceutical levels, their bioavailability, and metabolism.

From the interaction between nutraceuticals and microbiota, one or more of the following outcomes can be expected (Faria et al. 2014; Most et al. 2017; Williams and Clifford 2017; Tomas-Barberan et al. 2018):

1. Level and composition of microbiota can be altered by nutraceuticals (e.g., polyphenols and resveratrol).
2. Nutraceuticals can be metabolized, and their bioactivity can be altered.
3. Microbiota can alter the bioavailability and other aspects of pharmacokinetics of nutraceuticals.
4. The interaction of nutraceuticals with microbiota can influence the metabolomic profile.
5. Polyphenols may offer prebiotic activity by modulating the microbiota composition.
6. Gender and inter-individual variabilities play a significant role.

In some cases, phytopharmacological and phytotherapeutic outcome from these factors proves to be conflicting. For example, some reports indicate that dietary polyphenols promote growth of the gut microbiota (Roopchand et al. 2015), while others suggest that they are antimicrobial (Marin et al. 2015). Based on these interactions, qualitative and quantitative biomarkers can be identified and validated. For example, enterolactone and hydroxytyrosol are considered good biomarkers of lignan and olive phenolic alcohol intake, respectively.

In general, microbiological fermentation decreases the bioavailability of the native polyphenols, but in some cases, it can give rise to metabolites that are more bioactive than the native polyphenols, for example, equol from daidzein and dihydroresveratrol from resveratrol.

Interestingly, in a very recent study, foregut microbiota of camel and cattle was shown to degrade (99%) a non-polyphenolic compound indospicine (a well-known hepatotoxin) from *Indigofera spicata* to 2-aminopimelamic acid and 2-aminopimelic acid (Tan et al. 2017).

In addition to indigenous factors, such as microbiota and digestive enzymes, the food matrix (dietary fiber, lipids, proteins, and digestible carbohydrates) can significantly affect bioavailability and bioaccessibility, uptake, and further metabolism of polyphenols (Bohn 2014).

In general, polyphenols may have greater bioavailability when they are ingested in combination with other polyphenols than when taken alone, such as in supplement. About 48% of dietary polyphenols are bioaccessible in the small intestine, while 42% become bioaccessible in the large intestine (Saura-Calixto et al. 2007). Faria et al. (2014) noted that the majority of dietary anthocyanins are not absorbed at the upper GI level, hence reaching the intestinal microbiota where they are biotransformed into their metabolites, which are then absorbed.

7.4 Absorption

Polyphenols may be transported in the blood in free form, bound to proteins, or bound to lipoproteins (Bohn 2014). Quercetin was found to be bound to albumin at over 99%. Absorption of monomers, such as epicatechin, is usually high (45%) compared to dimers of procyanidins (<1%) (Bohn 2014). Polyphenols can be absorbed by passive diffusion (e.g., chlorogenic acid) or the facilitated transport system (e.g., caffeic acid). Polyphenols, such as caffeic acid and ferulic acid, are absorbed by facilitated transport by monocarboxylic acid transporters (MCTs). Other transporters can also be involved, such as P-glycoprotein, multidrug resistance proteins (MRPs), and ATP-binding cassette transporters.

7.5 Blood/Urinary Metabolites as Biomarkers of Polyphenol Intake

The presence of polyphenols and other nutraceuticals and/or their metabolites in body fluids (mainly in serum and urine) serve as biomarkers of exposure. The relationship between polyphenol intake and specific biomarkers measured in the blood and urine is highly complex (Pinto and Santos 2017). This may be due to multiple factors: (1) poor release of polyphenols from the food matrix; (2) interaction with other food compounds and with microbiota; (3) individual polyphenols that are not digested in the digestive tract, resulting in poor absorption from the intestine; (4) extensive biotransformation by phase I and phase II reactions; and (5) rapid excretion. The method of analysis, sensitivity of instrumentation, concentration of the polyphenol metabolite in the blood/urine, and availability of standards are other factors that may influence the accuracy of metabolite analysis and identification.

Human studies suggest that a biomarker in pooled 24-h urine collection (total urinary polyphenol) and a surrogate biomarker in plasma (carotenoids) may provide a suitable estimate to assess polyphenol intake (Burkholder-Cooley et al. 2017; Pinto and Santos 2017). Of course, estimation based on urinary polyphenol excretion is limited by genetic variance, metabolism, and bioavailability.

Pérez-Jiménez et al. (2010) investigated urinary metabolites as biomarkers of polyphenol intake in humans and found that polyphenols such as daidzein, genistein, glycitein, enterolactone, and hydroxytyrosol are good biomarkers of polyphenol intake, while hesperidin, naringenin, (−)-epicatechin, (−)-epigallocatechin, quercetin, and three microbial metabolites of isoflavones (dihydrodaidzein, equol, and *O*-desmethylangolensin) are less suitable biomarkers of intake. Additional urinary metabolites are in the form of conjugates (sulfate and glucuronide). By now, about 160 polyphenol metabolites have been identified in urine, and only some of them could be ascribed with certainty to known precursors (Pérez-Jiménez et al. 2010). Likewise, quantitation of parent and/or metabolites in urine can be used to determine the intake of other nutraceuticals. It needs to be pointed out that the value of urinary metabolites of polyphenols or other classes of phytochemicals as biomarkers of intake depends on their specificity, sensitivity, and variability.

7.6 Biomarkers of Polyphenol Tissue Exposure

Following absorption, polyphenols can be distributed in most tissues, and they cross the blood-brain barrier. Tissue levels of polyphenols and their metabolites are better biomarkers than plasma concentrations, and they serve as better biomarkers of health effects than their intake because of a large individual variability in absorption and metabolism.

7.7 Excretion

Polar compounds such as gallic acid and isoflavones excrete via the kidney, while apolar compounds such as curcumin excrete via bile.

8 Biomarkers of Toxicity and Safety Evaluation of Foods and Nutraceuticals

For the toxicity and safety assessment of foods and nutraceuticals, serum samples are analyzed for biomarkers of liver (alanine aminotransferase, ALT; aspartate aminotransferase, AST; gamma-glutamyl transferase, GGT; alkaline phosphatase, ALP; and bilirubin), kidney (blood urea nitrogen (BUN) and creatinine), and heart (creatine kinase (CK) and troponin) functions. Other serum biomarkers specific for liver injury include microRNA-122 (miR-122), glutamate dehydrogenase (GLDH), caspase-cleaved cytokeratin-18 (cc-K18), and full-length keratin-18 (FL-K18) (Longo et al. 2017). FL-K18 is passively released from necrotic cells, while cc-K18 is released from apoptotic cells after loss of membrane integrity, and the ratio of cc-K18 to FL-K18 is regarded as the "apoptotic index." In hepatotoxicity, macrophage colony-stimulating factor (CSF-1) is also used as a biomarker. The "apoptotic index" has been proposed to estimate the relative contributions of necrosis and apoptosis to cell death. Some of these biomarkers may not typically satisfy Hy's law criteria. Kinetics of all these hepatotoxicity biomarkers can be interpreted using DILIsym® software, which is a mechanistic mathematical

model for drug-induced liver injury (Shoda et al. 2014). In case of acute kidney injury, biomarkers, such as neutrophil gelatinase-associated lipocalin (NGAL), kidney injury molecule-1 (KIM-1), and high-mobility group box protein 1 (HMGB1), can also be taken into consideration while assessing effects of herbal medicines (Oh et al. 2017). Currently, intense research is underway for more tissue-specific and tissue-sensitive biomarkers, such as microRNAs, which are still considered mechanistic biomarkers for mechanistic modeling (Penman et al. 2014; Gupta 2014).

9 Biomarkers of Nutraceuticals with Toxic Potential

During the last few decades, the global use of nutraceuticals has increased tremendously for humans and animals and so has health risks emerging from active components as well as from toxic contaminants of supplements (Gupta 2016; Gupta et al. 2018). Some plant extracts are inherently toxic by virtue of having toxic phytoconstituents, while others are likely to be contaminated with other plant alkaloids (e.g., pyrrolizidine alkaloids), metals (arsenic, cadmium, lead, and mercury), pesticides (insecticides, herbicides, fungicides, PCBs, PAHs, etc.), and mycotoxins (aflatoxins, ochratoxin A, citrinin, T-2, and HT2) (Gupta et al. 2018). Sometimes, nutraceuticals are also adulterated with drugs of abuse. Some common plant extracts that are used as nutraceuticals are mentioned here with their toxic principle in parentheses: St. John's wort (hypericin), goldenseal (hydrastine), ginkgo biloba (ginkgotoxins), kava (flavokawain B), ephedra (ephedrine), pennyroyal oil (ketone pulegone), *Aristolochia* (aristolochic acid), bitter melon (momordins and vicine), lychee (hypoglycin A), comfrey (pyrrolizidine alkaloid), green tea (epigallocatechin-3-gallate), and many others (Gupta et al. 2018). Additionally, some plants, such as *Indigofera spicata*, that are edible, high in protein, and easily digestible by livestock are toxic by having a phytotoxin indospicine (Tan et al. 2017).

Detection of a phytotoxic principle and/or its metabolite (s) in the blood, urine, or tissue often serves as a biomarker of exposure, and the level of exposure can serve as a biomarker of effect. Adverse effects associated with toxic plant extracts may include from minor nausea, vomiting, or GI upset to as severe as liver, kidney, or cardiac failure, seizures, or death (Gupta et al. 2018). Most nutraceuticals are multi-targeted small molecules, and they affect multiple signaling pathways to exert their effects. There are even some nutraceuticals that exert tissue-specific adverse effects. For example, the target organs for toxicity of *Aristolochia*, comfrey, and ephedra are the renal, hepatic, and cardiac systems, respectively. In addition to residue detection, nutraceutical/contaminant-induced tissue damage can be evaluated using conventional biomarkers, as described in the previous section (Gupta et al. 2018).

Detection of residue of a metal, pesticide, mycotoxin, or drug of abuse in body fluids confirms the exposure to contaminants. Many times, toxicity outcome arises from toxic herb-drug interaction in polypharmacy. For further details, readers are referred to Gupta (2016) and Gupta et al. (2018).

10 Concluding Remarks and Future Directions

Biomarkers are of utmost importance, as they offer a plethora of information on various aspects of foods and nutraceuticals, including identification of food ingredients and phytochemicals, pharmacokinetics and toxicokinetics of phytochemicals, interaction with other nutraceuticals and modern medicines in the case of polypharmacy, toxicity and safety evaluation of nutraceuticals, clinical trials, and their regulations. Choice of the most promising biomarkers that are validated plays a vital role in the field of nutrition and nutraceuticals and in the assessment of associations with health and disease outcome. With a rapid advancement in equipment and biotechnologies, novel biomarkers are continuously emerged with a greater sensitivity and reproducibility, and the quest will continue. Thus, with the aid of validated biomarkers, the food and nutraceutical industries will have a greater confidence in high quality foods and nutraceuticals.

Acknowledgment The authors would like to thank Ms. Robin B. Doss for her technical assistance in preparation of this chapter.

Toxicology and Drug Interactions of Nutraceuticals

Rhian B. Cope

Abstract

This chapter attempts to summarise and tabulate many of the better known adverse toxicological and drug–drug interactional effects of nutraceuticals and botanical supplements. Because of the large scope of these subjects, an extensive literature list is provided in the "References" section of the chapter. The safety properties of nutraceuticals are, in general, poorly studied, and there is absolutely no reason to assume that these products are "safe" for use in humans or animals despite claims of longstanding cultural or dietary use. Given this context it is possible that many problems currently go unrecognised and the burden of adverse effects may be substantially underestimated. This situation will likely continue until a shift towards a regime premarket regulatory approval with mandatory post-market pharmacovigilance is applied in higher-risk and/or data-poor substances.

Keywords

Veterinary nutraceuticals · Toxic interactions

1 Introduction

The best-known adverse effects of nutraceuticals and herbal supplements involve hepatotoxicity and drug-drug interactions. Due to the monumental scope of these issues, this chapter has taken the approach of summarizing the well-known adverse effects of nutraceutical and botanical supplements. Since most regulatory jurisdictions often require minimal to no information or studies on the adverse effects of nutraceuticals and herbal supplements, the available data is often of lower quality and is exploratory in nature. Often the critical safety properties of nutraceuticals are poorly studied, and much of the information is based on in vitro studies, small-scale exploratory studies in laboratory species, limited case series and single case reports.

Currently there is no reason to suspect that the classical high-risk organs and systems associated with well-characterised pharmaceuticals (CNS, liver, kidney and the cardiac conduction system) are not also at risk from poorly characterised nutraceutical and herbal extract products. In many jurisdictions, post-market safety evaluation can be at best described as minimal and, at worst, haphazard or absent. While the relatively lax regulatory approach that is currently applied to nutraceutical products remains, often an overwhelming lack of systematically evaluated safety data on many of these products will also remain. Furthermore, much of the current database is simply observational, and often there is a substantial lack of mechanistic and mode of action data.

Perhaps the saving grace in this situation is that, based largely on Poisons Information Centre data, most nutraceutical-/supplement-associated adverse events are minor although apparent adverse effects are relatively common. However serious adverse events and fatalities have certainly been detected. Given the known incidence of adverse events amongst study populations that is now available from the human pharmaceutical clinical trial literature, it is likely that the adverse effects of nutraceuticals are often seriously underestimated.

2 Hepatotoxicity

As noted in the introduction, unexpected hepatotoxicity is the best studied major cause of adverse events associated with nutraceutical and supplement use. Two major types of hepatotoxicity have been identified:

R. B. Cope (✉)
Australian Pesticides and Veterinary Medicines Authority, Armidale, NSW, Australia
e-mail: rhian.Cope@apvma.gov.au

R. C. Gupta et al. (eds.), *Nutraceuticals in Veterinary Medicine*, https://doi.org/10.1007/978-3-030-04624-8_51

- Classical Type A chemical-driven hepatotoxicity due to the inherent hepatocellular damage induced by the active ingredient and/or its metabolite(s) and/or its impurities. This type of hepatotoxicity has a predictable individual and population-dose responses and temporality that often has a well-characterised mode of action, and the majority of an appropriately exposed population will develop liver damage. Classical examples include many human pharmaceuticals, various mycotoxins such as the aflatoxins and plant toxins such as the pyrrolizidine alkaloids.
- Classical Type B idiosyncratic hepatotoxicity that occurs without warning is often non-predictable using classical toxicological techniques, usually does not have a clear or predictable dose response, often does not have predictable temporality postexposure, may occur rarely or sporadically across populations and may be associated with a particular hypersusceptible subpopulation and/or may have an immune-mediated component. Classical examples are the drugs troglitazone and trovafloxacin.

Important and well-described Type A hepatotoxicity due to sources of nutraceuticals is summarised in Table 1. Critically, often only limited information is available for many nutraceuticals; thus this summary cannot be regarded as anything like comprehensive. Furthermore, since Type B hepatotoxicity can be difficult to identify in large populations, this type of hepatotoxicity may be seriously underestimated with nutraceutical products (especially since these products are usually not subjected to systematic post-market safety evaluation).

Greater detail on specific agents listed in Table 1 can be found by referring to the papers in the "References" section of this chapter.

Classical Type B hepatotoxicity in humans has been recorded with black cohosh (*Actaea racemosa*, Franco et al. 2017). Classical immune-mediated hepatitis secondary to the formation of protein adducts has been identified. Autoimmune hepatitis has also been associated with the use of *Echinacea purpurea*-containing products (Enbom et al. 2014; Franco et al. 2017; Kocaman et al. 2008; Lim et al. 2013; Lynch et al. 2006; Teschke 2010a, b; Whiting et al. 2002).

3 Known Drug–Drug Interactions of Nutraceuticals

A comprehensive detailed description of the large number of drug–drug and xenosensor interactions of nutraceuticals would be the subject for an entire textbook on its own! Because of the length restrictions of this chapter, this information has been summarised in Table 2. Further details can be found in the relevant references. It is important to remember that these effects are not necessarily adverse in the biological sense: many are classical examples of the adaptive mechanisms that come into play when the body encounters a xenobiotic and enacts a series of stereotypical biochemical responses in an attempt to detoxify and/or enhance the excretion of the unwanted substance. Unfortunately, these responses can also be adverse and/or can affect the pharmacokinetic behaviour of many other substances. When referring to Table 1, it is important to remember that CYP1A2, CYP2C9, CYP2C19, CYP2D6, CYP3A4 and CYP3A5 members of cytochrome P450 enzyme family metabolise approximately 90% of current human pharmaceuticals.

4 Cardiovascular Effects

There is currently a serious lack of systematic evaluation of the possible cardiovascular effects of nutraceuticals and nutritional supplements. Sympathomimetic toxicity associated with caffeine and/or *Ephedra* sp.- (now banned in many countries) and/or *Yohimbe* sp.-containing products is now well-known (Gurley et al. 2015). Psychiatric adverse effects have also been associated with such products.

Citrus aurantium L. (bitter orange) use has been associated with adverse effects on the cardiovascular system including angina, hypertension, tachycardia, ventricular extrasystoles, and ischemic colitis (Gange et al. 2006; Stohs 2017; Sultan et al. 2006). The putative toxic principles are the sympathomimetic stimulant amines, synephrine and octopamine (Stohs 2017). The use in combination with other sympathomimetics may exacerbate these effects and has reputedly resulted in angina, acute myocardial infarction, ischaemic stroke and exercise-induced syncope. Co-morbidities are often present in the reported human adverse experience reports making definitive conclusions regarding causality less absolute (Stohs 2017). As with other sympathomimetic substances, bitter orange psychosis has also been described (Retamero et al. 2011).

Ginkgo biloba-based products have been ventricular arrhythmias (Cianfrocca et al. 2002). *Cimicifuga racemosa* (black cohosh) use has been associated with reversible heart block with bradycardia and cutaneous vasculitis in humans (McKenzie and Rahman 2010).

Hypertension and hypokalemic effects on the heart and skeletal muscle are classical well-known effects of glycyrrhetic acid derived from *Glycyrrhiza glabra* (liquorice). Chaste tree (*Vitex agnus castus*) products are known to cause arteriospasm (Daniele et al. 2005).

5 Allergic and Skin Effects Not Associated with Hepatotoxicity

Citrus aurantium L. (bitter orange) use has been associated with allergic bronchospasm (Felix et al. 2013). IgE-mediated and other types of hypersensitivity have reputedly associated

Table 1 Potential Type A hepatotoxicity due to nutraceuticals

Herbal supplement	Key compound or product form	Effects or circumstances	References
Ginseng *Panax ginseng*, *P. quinquefolius*	Extract	Possibly due to interaction with imatinib	Bilgi et al. (2010)
Greater celandine *Chelidonium majus*	Extract	Reports of hepatocellular injury and cholestasis in humans	Hardeman et al. (2008), Stickel et al. (2003), Teschke et al. (2011) and Teschke et al. (2012a, b)
Black pepper *Piper nigrum*	Piperidine	Experimental evidence of redox damage in rodents	De Souza Grinevicius et al. (2016) and Piyachaturawat et al. (1995)
St. John's wort *Hypericum perforatum*	Extract	Possibly due to interaction with copaiba and or due to a drug–drug or drug chemical interaction	Agollo et al. (2014), Domínguez Jiménez et al. (2007) and Valentao et al. (2004)
Green tea *Camellia sinensis*	Epigallocatechin-3-gallate	Hepatotoxic in rodents and humans. Cases in humans are reputedly due to *N*-nitroso-fenfluramine and/or epigallocatechin-3-gallate	Wang et al. (2015)
	Extract		Emoto et al. (2014), Federico et al. (2007), Galati et al. (2006), Gloro et al. (2005), Mazzanti et al. (2009), Mazzanti et al. (2015), Pillukat et al. (2014), Teschke et al. (2014) and Vial et al. (2003)
Germander *Teucrium* sp.	Extracts, teucrin A, teuchamaedryn A	Hepatoxic in rodents and humans	Goksu et al. (2012), Kouzi et al. (1994), Lekehal et al. (1996) and Sezer and Bozaykut (2012)
Camphor *Cinnamomum camphora*	Topical cream	Since case report of hepatotoxicity in a human child	Uc et al. (2000)
Kava kava *Piper methysticum*	Extract	Hepatotoxic in humans	Teschke (2010a, b)
Pennyroyal oil *Mentha pulegium*, *Hedeoma pulegioides*	Oil, (R)-(+)-pulegone, pulegone, menthol, menthone	Hepatotoxic in rodents and in humans	Anderson et al. (1996), Bakerink et al. (1996), Gordon et al. (1982), Gordon and Khojasteh (2015) and Sztajnkrycer et al. (2003)
Gardenia *Fructus gardenia*	Extract	Hepatotoxic in rodents	Yamano et al. (1988) and Yang et al. (2006)
	Geniposide		Wei et al. (2014)
Garlic *Allium sativum*	Homogenate	Hepatotoxic in rodents	Oboh (2006) and Rana et al. (2006)
Monocrotaline, dehydromonocrotaline, dehydrorectronecine	Found in many plant species, classically *Crotalaria* sp.	Classical hepatotoxic and pulmonary vasculotoxic pyrrolizidine alkaloids	Mingatto et al. (2007)
Garcinia cambogia	Extract	Hepatotoxic in humans	Corey et al. (2016)
Mistletoe *Viscum coloratum*	Extract	Hepatotoxic in humans	Kim et al. (2015)
Bitter orange *Citrus aurantium*	Not stated	Hepatotoxic in humans	Teschke and Andrade (2016)
Chaste tree *Vitex agnus-castus*	Not stated	Hepatotoxic in humans	Daniele et al.(2005)
Valerian (*Valeriana officinalis*)	Not stated	Hepatotoxic in humans	Cohen and Del Toro (2008)

with immunostimulation by products containing *Echinacea* sp. (Mullins and Heddle 2002). Allergic reactions to domestic bee royal jelly and propolis are well-known. Cutaneous pseudolymphoma has been associated with *Cimicifuga racemosa* (black cohosh) use (Meyer et al. 2007).

Cinnamon-containing products are well-known causes of adverse effects on the skin and oral cavity mucosa including contact sensitisation; stomatitis with swelling and burning of lips, tongue and cheeks; exacerbation of rosacea; and hyperkeratotic plaques covering most of the dorsal and lateral tongue and involving the buccal mucosa, allergic leukoplakia of oral mucosa and squamous cell carcinoma of the tongue (Campbell et al. 2008; Cohen and Bhattacharyya 2000; Mihail 1992; Pilapil 1989; Siqueira et al. 2009; Tremblay and Avon 2008; Westra et al. 1998).

Soybean (*Glycine max*) products are a well-known cause of serious allergic reactions in humans as are ginseng-containing products.

Table 2 Known potential drug–drug interactions of nutraceuticals

Herbal supplement	Key compound or product form	Effects	References
Inhibition of cytochrome P450 family enzymes			
Mangosteen (*Garcinia mangostana*)	Aqueous extract	Inhibition of CYPs 2C8, 2C9, 2C19	Foti et al. (2009)

Grape seed *Vitis vinifera*	Extract	”	Kluth et al. (2007)
Garlic *Allium sativum*	Daillysulfide	”	Zhou et al. (2014)

Chaste tree (*Vitex agnus castus*) products have been associated with allergic reactions with pruritus, erythema, gastrointestinal symptoms and acneform facial inflammation (Daniele et al. 2005). Headache, weight gain and persistent gastroenteritis have also occurred in humans.

Grapes (*Vitis vinifera*) are a suspected cause of allergic-like reactions including oral syndrome, urticaria, angio-edema, hypotension and respiratory distress, anaphylaxis and exercise-induced anaphylaxis. The major allergens in grapes are endochitinases A and B, a lipid transfer protein and a thaumatin-like protein.

6 Adverse Effects on the Coagulation System

Consumption of *Ginkgo biloba* leaves and extracts has been associated with hemorrhagic events including subdural hematoma (Bebbington et al. 2005; Castellote Varona and Atienza Morales 2005; Meisel et al. 2003; Miller and Freeman 2002; Pedroso et al. 2011). The effects are reputedly associated with the antiplatelet activity of ginkgosides with ginkgolide B being the likely main terpenoid responsible for

these effects. Co-ingestion of *Ginkgo biloba* products with pharmaceuticals that act on coagulation (aspirin, ibuprofen and warfarin) appears to exacerbate these anticoagulation effects of this plant. Foods containing soybean and its isoflavones were responsible for bleeding when combined with estradiol.

7 Adverse Effects on the Central Nervous System

Ginkgo biloba-associated induction of CYP2C19 catabolism of phenytoin and valproic acid has been associated with fatal breakthrough seizures in humans (Kupiec and Raj 2005). Hypokalemic encephalopathy is a classical effect of liquorice toxicity. *Harpagophytum procumbens* (Devil's claw) is claimed to act as a cyclooxygenase 2 inhibitor (Grahame and Robinson 1981). Apart from the predictable adverse effects on the gut, products containing this material have been associated with throbbing frontal headache, tinnitus, anorexia and loss of taste for food. *Panax ginseng* (ginseng)-containing products have been associated with stimulant effects, such as nervousness and tremor and maniacal episodes (Gonzalvez-Seijo et al. 1995; Vasquez and Aguera-Ortiz 2002).

8 Effects on the Musculoskeletal System

Myopathy with severe asthenia and rhabdomyolysis in humans has been associated with *Cimicifuga racemosa* (black cohosh) use (Minciullo et al. 2006). Secondary rhabdomyolysis is also a noted effect of sympathomimetic substances, and the risk of this effect should always be recognised in cases of overdose with these substances. Rhabdomyolysis and hypokalemic paralysis are classical effects that occur with liquorice toxicity (Sundaram and Swaminathan 1981).

9 Endocrine and Reproductive System Effects

The estrogenic effects of soybean isoflavones are well-known. Associated side effects have been detected in both biological sexes and include pseudohormonal activity-related precocious thelarche; uterine fibroids; ureteral Müllerian carcinosarcoma associated with endometriosis, gynaecomastia, hypogonadism and erectile dysfunction; gastric cancer; testicular cancer; and reproductive disorders (Balk et al. 2005; Dinsdale and Ward 2010; Kwack et al. 2009; Martinez and Lewis 2008; Nagata et al. 2009; Nan et al. 2005; Noel et al. 2006). Hypothyroidism associated with excessive iodine intake has been associated with the consumption of soy milks (Bell and Ovalle 2001; Crawford et al. 2010). Fatal hypernatremia has also been associated with excessive consumption of soy milks (Furukawa et al. 2011). Hypochloremic alkalosis has occurred in infants fed with soy-based milk replacers (Linshaw et al. 1980).

Glycyrrhetic acid in liquorice is an inhibitor of 11-β-hydroxysteroid dehydrogenase type 2, the enzyme that is needed to inactivate cortisol before it binds the aldosterone receptor inside principal cells (Francini-Pesenti et al. 2008; Hukkanen et al. 2009; Russo et al. 2000; Sundaram and Swaminathan 1981). The net effect is an aldosterone-like effect which results in the suppression of the renin-angiotensin-aldosterone axis, blood volume expansion, hypertension, hypertension encephalopathy, hypokalemia and metabolic alkalosis. Chaste tree (*Vitex agnus castus*) products have been associated with intermenstrual bleeding or disorders (Daniele et al. 2005; Loch et al. 2000; Prilepskaya et al. 2006; Propping et al. 1991).

10 Concluding Remarks and Future Directions

Botanical nutraceutical products and supplements should not be regarded as clinically and toxicologically inert irrespective of whether or not the substance has a long history of dietary or cultural use. While, fortunately, severe reactions appear to be somewhat uncommon, fatalities and major adverse events have been recorded. However, what is extremely clear is that there is usually a very limited body of premarket and post-market pharmacovigilance data on many common botanical products. Given this context it is possible that many problems currently go unrecognised and the burden of adverse effects may be substantially underestimated. This situation will likely continue until a shift towards a regime premarket regulatory approval with mandatory post-market pharmacovigilance is applied in higher-risk and/or data-poor substances.

Newer Trends in Nutraceutical Research and Product Development

Proteomics in the Evaluation of Nutraceuticals and Functional Foods

Christina Wilson-Frank

Abstract

Nutraceuticals and functional foods are used in veterinary medicine as preventative or supportive treatments for disease and to improve animal health. Although the purported health benefits of nutraceuticals and functional foods in animals is well-documented, understanding the molecular mechanisms involved in the nutritive health benefits and disease outcome on a cellular level is warranted. Proteomics-based techniques are evolving as a promising tool that may provide the scientific knowledge to link diet and disease in nutritional research. The use of proteomics in nutrition research has transformed into the disciplines of nutriproteomics and foodomics. Although more studies are warranted to garner a deeper understanding of the mechanisms responsible for the health benefits of these nutritive substances in animals, nutriproteomics and foodomics applications have offered new insights into the molecular mechanisms of action and changes in protein expression of a variety of nutritive substances.

Keywords

Foodomics · Functional Food · Nutraceutical · Nutriproteomics · Probiotic · Proteomic

1 Introduction

Proteomics studies encompass the qualitative and quantitative, global analysis and characterization of the entire protein complement in a cell, organism, or tissue that change in response to an external stimulus or due to a specific disease state. The measurable changes in the proteome have been used to identify potential biomarkers for specific disease states and to elucidate the mechanism of action of xenobiotics or other substances. In proteomics-based research, the first step in characterizing changes in the proteome requires separation of intact proteins or peptides. Adequately separating this complex, heterogeneous components have proven to be an analytical challenge, largely due to the large dynamic range of proteins and the microheterogeneity of protein expression in the samples. For example, a typical serum proteome can contain approximately 20,000 proteins, creating an analytical challenge when attempting to adequately isolate or separate them for identification (Anderson and Anderson 2002; Issaq et al. 2005). Emerging protein separation technologies, which include two-dimensional gel electrophoresis (2-DGE), two-dimensional in-gel electrophoresis (2-DIGE), and multidimensional high-performance liquid chromatography (HPLC), offer multidimensional levels of separation which increase resolution and isolation of proteins from complex mixtures (Görg et al. 2000; Hamdan and Righetti 2002; Issaq et al. 2005; Zhang et al. 2010). Therefore, the ability to better isolate proteins and peptides that change in complex biological samples with disease or in response to stimuli has improved and continue to evolve. In addition to the challenge of separating mixtures of proteins, the use of mass spectrometry-based instrumentation for identifying and quantifying changes in proteins has imposed significant advancements in that technology. Recent advancements in hybrid mass spectrometers have provided significant, high-throughput automation with exceptional sensitivity and improved resolving power of proteins. Specifically, advancements in matrix-assisted laser desorption/time-of-flight tandem mass spectrometry (MALDI/MS/MS) and electrospray ionization/tandem mass spectrometry (ESI/MS/MS) technologies have improved quantifying and isolating proteins and peptides significantly and are the two most common mass spectrometers used in proteomics investigations (Li et al. 2017).

Proteomics has been utilized in a wide variety of studies in biomedical research. However, many new disciplines are exploiting the utility of proteomic investigations. For example, the interaction of functional foods and nutraceuticals with medicine and pharmacology has presented a new challenge for the nutraceutical industry. Therefore, new disciplines such as "nutriproteomics" and "foodomics" aim to exploit advances in proteomics-based technologies in order to understand how nutraceuticals, functional foods, or other dietary nutrients influence protein expression. Scientific studies assessing the efficacy and safety of these nutraceuticals and functional foods, in addition to identifying any potential drug interactions, are lacking. As the use of nutraceuticals and functional foods in humans and animals continues to evolve, it will become important to have a complete understanding of how these nutritive components affect health and disease outcome. Therefore, nutriproteomics and foodomics aim to accomplish that need through characterizing nutritive bioactive proteins, identifying biomarkers important for disease regulation, assessing the safety of current and new nutraceuticals, and identifying mechanisms by which nutraceuticals and functional foods impact health outcomes. In veterinary medicine, there are several nutraceuticals and functional foods being used in animals in order to prevent disease and promote health or quality of life. This chapter describes proteomics investigations that have been conducted in order to elucidate the mechanism of action of nutraceuticals and functional foods used in veterinary medicine.

2 Nutriproteomics

2.1 *S*-Adenosylmethionine (SAM-e)

SAM-e is a naturally occurring, methyl donor involved in methyltransferase reactions, and supplementation has been shown to restore hepatic glutathione levels and reduce liver injury in animals and humans (Guo et al. 2015). Hepatic glutathione concentrations decrease in cats and dogs with liver disease (Center et al. 2002). Therefore, SAM-e supplementation has been recommended as a supportive treatment in canines and felines with liver disease or hepatotoxicity. SAM-e has been used as supportive treatment in animals with hepatotoxicity originating from acetaminophen toxicosis (Wallace et al. 2002; Webb et al. 2003), blue-green algae toxicosis (Bautista et al. 2015; Sebbag et al. 2013), and xylitol intoxication (Schmid and Hovda 2016). Although SAM-e has been used as a hepatoprotectant, the exact mechanism by which it protects the liver had not been explicitly defined. However, recent proteomic-based research of the effects of SAM-e on the liver after ethanol exposure have shed some light on the potential molecular targets involved in hepatoprotective effects of SAM-e. In two studies conducted in Sprague-Dawley rats, changes in the liver mitochondrial proteome were evaluated after exposing the rats to ethanol, with and without SAM-e supplementation (Andringa et al. 2010; Bailey et al. 2006). In one study, rats were fed control or ethanol diets, supplemented or not supplemented with SAM-e, for 5 weeks (Bailey et al. 2006). Using SDS-PAGE and immunoblot analysis, the investigators were able to show that SAM-e prevented alcohol-mediated decreases in hepatic mitochondrial respiration and cytochrome c oxidase. Metabolic stress has been associated with mitochondrial protein synthesis inhibition causing upregulation of the protein prohibitin (Bailey et al. 2006). Ethanol exposure caused a significant increase in this protein; whereas the control group and the group fed ethanol and SAM-e had no increase in this protein. This suggested that SAM-e protected the hepatic mitochondria from protein synthesis inhibition by ethanol. In another study, rats were fed control or ethanol diets, also supplemented or not supplemented with SAM-e, for 31 days. Using 2-DGE and MALDI/MS, 30 proteins had significantly changed with ethanol exposure or SAM-e or exposure to both. The types of proteins include chaperones, beta-oxidation proteins, sulfur metabolism proteins, and dehydrogenase enzymes. Ethanol was shown to decrease key mitochondrial proteins GRP78, Hspd1, and PDI/T3BP. SAM-e prevented ethanol-dependent decreases in these chaperone proteins thus preserving mitochondrial function. Therefore, these proteomic studies suggest that the heptoprotective effect of SAM-e against ethanol toxicity may be mediated through protecting proteins that are key to mitochondrial biosynthetic pathways and energy. Proteomics studies using human hepatoma cells in order to assess SAM-e's hepatoprotective effects in hepatocellular carcinoma have revealed a potential molecular target for SAM-e in the liver (Schroder et al. 2012). Using 2D-DIGE and HPLC/MS/MS, 128 proteins were identified that were involved in apoptosis, cell proliferation, and cell survival. However, human DEAD-box protein 3 (DDX3X) was downregulated when the enzyme that synthesizes SAM-e was downregulated. The investigators concluded that DDX3X may be a primary target of SAM-e and a chief intermediate of its antitumor effect. Therefore, reduced SAM-e in the liver may cause upregulation of DDX3X and contribute to the pathogenic process (Schroder et al. 2012). In these studies, proteomic evaluations suggest that SAM-e supplementation may prevent oxidative damage to hepatic mitochondria and downregulate proteins key to pathogenesis of hepatocellular carcinoma.

2.2 Glucosamine and Chondroitin

There are several nutraceuticals being used to treat osteoarthritis in animals which may include, but are not limited to, glucosamine, omega-3 fatty acids, chondroitin sulfate, and

green-lipped mussel powder (Gupta 2016). These nutraceuticals are used as an alternative treatment for osteoarthritis due to their purported anti-inflammatory benefits. In animals, the most common nutraceuticals being used are glucosamine and chondroitin. Glucosamine is an aminosaccharide that is a natural component in cartilage and is commonly sold as glucosamine sulfate or glucosamine hydrochloride as a supplement (Blum et al. 2006). Chondroitin sulfate is a glycosaminoglycan and is a functional component in proteoglycans in cartilaginous tissue (Pomin 2015). It is a common nutraceutical that is used in humans and animals with arthritis and osteoarthritis. While giving these nutraceuticals can be beneficial to the animal, the efficacy of these supplements and how they affect biological processes have not entirely been defined. One group of researchers conducted a review of 22 studies and the efficacy of nutraceuticals to alleviate clinical signs of osteoarthritis in horses, dogs, and cats (Vandeweerd et al. 2012). The nutraceuticals considered in this review included the use of glucosamine hydrochloride, chondroitin sulfate, omega-3 fatty acids, green-lipped mussel powder, and a variety of other types of treatments. Upon completion of the literature review, this group concluded that the evidence for efficacy was low for all nutraceuticals except for omega-3 fatty acids. However, since this review, proteomics research has been able to elucidate the potential targets of some of these nutraceuticals, which ultimately highlighted their anti-inflammatory potential. For example, in one study using 2-DIGE, protein microarrays and HPLC/MS, changes in the serum proteome of nine men and nine women taking glucosamine and chondroitin for osteoarthritis were assessed (Navarro et al. 2015). In this study, individuals took three capsules of 500 mg glucosamine hydrochloride and 400 mg chondroitin sulfate; whereas the control group was administered capsules containing crystalline cellulose for 28 days. Proteomic analysis revealed that C-reactive protein concentrations were significantly lowered in patients taking glucosamine and chondroitin when compared to the placebo group. The protein microarray results also revealed that the effects of glucosamine and chondroitin reduced proteins involved in the cytokine activity pathway. Based on their results, they concluded that glucosamine and chondroitin supplementation can lower systemic inflammation. Interestingly, some of the proteins and pathways impacted by these nutraceuticals were also suggested to be associated with reducing the risk of colorectal and lung cancer.

2.3 Omega-3 Fatty Acids

Omega-3 fatty acids, such as docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA), have been used as a nutraceutical supplement in the treatment of a variety of canine diseases, including cancer (Bauer 2011). DHA supplementation in dogs with stage III lymphoma has been associated with producing longer survival times and periods of remission when used in combination with doxorubicin (Bauer 2011; Ogilvie et al. 2000). DHA and EPA supplementation in dogs given for nasal, malignant carcinomas has been shown to decrease harmful inflammatory eicosanoids as well as suppress some of the detrimental effects of radiation therapy (Hansen et al. 2011). In order to better understand the mechanism by which omega-3 fatty acids exert their anticancer properties, a proteomic evaluation of C6 glioma and SH-Y5Y cancer cells lines was compared to normal primary astrocytes after treatment with 100 μM DHA (Das and Das 2016). Two-dimensional in-gel electrophoresis and MALDI/MS/MS analyses identified six proteins that were altered with DHA treatment. The proteins annexin A2, pyruvate kinase M2, and annexin A2 were downregulated with DHA treatment, whereas aldo-keto reductase 1B8 and glutathione *S*-transferase P1 were upregulated in the cancer cells. These results suggest that DHA induces apoptosis in cancer cells by regulating the expression of the proteins identified in this study in order to activate apoptotic pathways promoting cancer cell death.

3 Foodomics

3.1 Probiotics

Probiotics are microorganisms that confer health benefits to humans and animals by promoting digestion, strengthening the gastrointestinal epithelium, and modulating gut microbiota and immune response (Wang et al. 2018a, b). The use of probiotics in veterinary medicine is becoming more prevalent, particularly with regard to preventative and supportive treatment for gastrointestinal disorders and infectious diseases (Bybee et al. 2011; Mudronova et al. 2018; Wang et al. 2018a, b). The most widely used probiotics include *Bifidobacterium* and *Lactobacillus* spp. (Cho et al. 2015; Solano-Aguilar et al. 2018). Although probiotics are well-recognized for their health benefits in animals, identification of molecular markers of their health-promoting activity and elucidation of the processes by which probiotic bacteria can exert health benefits in animals are still warranted. However, recent proteomics-based research has been rewarding and offers some insight into the molecular mechanisms of probiotic action and the role of bacterial proteins.

In the past few years, the genomes of some probiotic species have been sequenced. Having these genome sequences available has made protein identification possible through the use of proteomics-based technologies. For example, 2-DGE with MALDI/TOF MS and HPLC/MS/MS have been used to elucidate the molecular mechanisms of

probiotics with respect to how they adapt to the gastrointestinal tract environment and to identify proteins that may help explain the health benefits of probiotic use. One of the major challenges of probiotics is surviving the adverse environmental conditions in the gastrointestinal tract, such as acidic pH and exposure to bile. Proteomics has been able to offer some insight into how *Bifidobacterium spp*. and *Lactobacillus spp*. counteract and overcome these challenges.

Bifidobacteria and *Lactobacillus* are commonly added to fermented dairy products, which are acidic in nature. These bacteria have to cope with acidic stress during production of the functional food and also upon ingestion when exposed to the acidic conditions in the stomach. Proteomics investigations have been able to shed some light on how these bacteria adapt to these acidic conditions. For example, proteomics studies have revealed that *Bifidobacterium longum* overexpress the proteins AtpA and AtpD and induce H^+-F_1F_0-ATPase when in acidic conditions (Matsumoto et al. 2004; Cotter and Hill 2003). It is known that these proteins, particularly H^+-F_1F_0-ATPase, play a major role in the acid resistance of gram-positive bacteria. This enzyme is a proton pump that can extrude protons from the cell cytoplasm rendering the bacteria acid-tolerant. The effect of acidic pH on protein expression in *Lactobacillus reuteri* has also been investigated using proteomics. Approximately 40 proteins were identified that changed with exposure to an acidic environment and encompassed proteins involved in transport and binding, pH homeostasis and stress, carbon energy metabolism, and amino acid biosynthesis (Lee et al. 2007). Proteins overexpressed by *L. reuteri* in response to low pH included glyceraldehye-3-phosphate dehydrogenase, phosphoglycerate mutase, and pyruvate kinase. This overexpression is likely due to the fact that cells modify their energy metabolism and carbohydrate transport in acidic environments. Similar to *Bifidobacterium*, *L. reuteri* was also found to overexpress F_1-ATPase to enhance acid tolerance.

These probiotic bacteria have also adapted bile resistance mechanisms in order to survive exposure to bile salts in the gastrointestinal tract. Deconjugated bile salts are toxic to bacteria and can damage to cell membranes, cause protein denaturation, or induce DNA and RNA damage (Begley et al. 2005). Understanding some of the underlying mechanisms by which these probiotic bacteria have become tolerant of bile stress conditions has been accomplished through proteomics. The effect of bile salts on the stress tolerance of *Bifidobacterium longum* has been examined using 2-DGE and MALDI/TOF MS (Sanchez et al. 2005). This proteomic study focused on identifying changes in expression of cytosolic protein patterns under bile salt stress. Thirty-four proteins changed with bile salt stress with xylulose 5-phosphate/fructose 6-phosphate phosphoketolase significantly upregulated. This protein is a key enzyme in the bifidobacterial shunt. The other proteins that changed were primarily associated with bile exposure are involved in stress response, metabolism, protein synthesis and glycolysis, and pyruvate catabolism. This suggests that activation of proteins in these pathways was intended to protect the bacteria from oxidative stress, nucleic acid damage, and pH acidification. This study also highlighted that multiple proteins involved in many pathophysiological pathways are responsible for bile salt tolerance in *Bifidobacterium longum*. In order to protect the cell membrane from bile salt damage, proteomic evidence has shown that *Bifidobacterium* also increase production of exopolysaccharides (Ruas-Madiedo et al. 2009). Exopolysaccharides are surface-associated polysaccharides that cover bacterial cells and form the "capsule" (Nwodo et al. 2012). Proteomic evidence has revealed that bile-tolerant strains of *Bifidobacterium* increase production of exopolysaccharides to make it more tolerant of bile stress and the acidic environment in the gastrointestinal tract. Proteome levels were also investigated in *Lactobacillus rhamnosus* GG in response to bile salt stress (Koskenniemi et al. 2011). Forty-two proteins were differentially expressed, of which, 14 proteins increased under bile stress and also correlated with changes in the transcriptome. The proteins identified include those involved in pathways associated with cell envelope properties, active removal of bile compounds from the bacterial cell, stress responses, and metabolic processes. Interestingly, although proteins involved in thickening the exopolysaccharide layer were identified, the authors noted that a protein dedicated to the active removal of bile compounds from the cell walls was significantly upregulated providing a means by which this bacterium is bile tolerant. Although more research needs to be done with respect to the molecular mechanisms of probiotic health effects, proteomics has been instrumental in enhancing our understanding of some of the underlying molecular mechanisms of probiotic bacteria and how they overcome challenges when used to treat gastrointestinal disorders.

4 Concluding Remarks and Future Directions

Nutraceuticals and functional foods hold significant promise in ameliorating animal health and preventing disease. Although the clinical applications and health benefits of these nutritional disciplines is well-assessed, there is still a need to garner a deeper understanding of the molecular mechanisms responsible for their purported health benefits.

Proteomics is evolving as a promising tool that may provide this scientific knowledge to link diet and disease in nutritional research. Additionally, more long-term studies may be warranted to better understand their role and benefits for medical conditions and overall animal health.

Nanoparticles and Molecular Delivery System for Nutraceuticals Bioavailability

Gianfranco Risuleo and Camillo La Mesa

Abstract

This contribution discusses methods for transferring exogenous materials and drugs, particularly, into biological tissues. The focus is on matrices such as micelles, vesicles, and oil-based dispersions as well as carbon nanotubes. An *ensemble* of physical forces takes a fundamental role in drug dispersion and includes van der Waals (vdW), steric (ST), double layer, (DL), osmotic (OS), etc. Combination of these forces is responsible for drug uptake in matrices and for their release in tissues. Uptake of exogenous either macro- or small molecules into cargo particles and their transfer to recipient cells is the result of complex processes, concomitant to drug partition among supramolecular aggregates and the bulk. Similar conclusions apply to drug release, mostly as to the kinetic features are concerned; therefore, adsorption of nutraceuticals and release within target organs are particularly relevant. These complex features can be accounted for on thermodynamic grounds and expressed as the combination of different forces. In what follows some details on the energies to be considered are outlined. These include terms controlling the fate of transfectants. We will consider first the forces responsible for the formation of such supramolecular entities on physicochemical grounds and the drug uptake; finally, we will review the actual possibility of transfecting cargo-mediated aggregates of nanoparticle/drug complexes to cells or tissues of interest and their bioactivity upon release within the cell matrix.

1 Introduction

Due to the complexity of the topics this chapter deals with, the authors have decided to introduce no figures and/or tables within the text. Two are the reasons at the basis of this choice: first, the figures referring specifically to the chemico-physical part would have been, possibly, not promptly intelligible for the general reader, who in the vision of the authors is rather interested in the more general features of nanoparticles and in their fabrication. The second reason is that figures illustrating very specific aspects and experimental results obtained either in cultured cells or in living animal model systems, would have not added more general information about their potential usage in human and veterinary medicine. As a matter of fact, also in this chapter, the authors intentionally tried to adopt a very plain language, meant to reach an as broad as possible audience. In other words, we aimed at composing a text comprehensible both to scientists active in biomolecular research on natural compounds, where the biochemical/physical part is fundamental, and to the layman interested in alternative ways to look at nutrition and health care in humans and other animals. The authors feel, as a matter of fact, the exploding interest in emerging habits of nutrition and health care should be everybody's endowment.

One final word of warning, the review may seem somewhat repetitious, but this was done on purpose. The reader may skip some parts considered too specialized or out of the

Gianfranco Risuleo is on retirement.

Obituary: The chapters authored by C. La Mesa and G. Risuleo are dedicated to the memory of Adalberto Bonincontro, an outstanding collaborator but, mainly, a lifelong friend. Most of the work reviewed here would have not been possible without his continuous, active participation, and support. Many works co-authored by the three of us are to be found among the references.

field of interest. The same information will be reiterated in different points of the chapter. In any case, the abundant references given at the end of the main text will allow the reader to deepen the subjects of interest.

2 Advanced Matrices for Drug Vehiculation: Chemical-Physical Aspects of the Nanomaterials for Molecular Delivery

The uptake of drugs into cells and biological tissues is the result of a complex balance between many physical forces jointly contributing to these processes; their role is hierarchically controlled by the related energy contributions. From a thermodynamic viewpoint, one must consider drug uptake in a given tissue in analogy with partitioning of a species between immiscible fluids such as water and oil, for instance (Leo et al. 1971; Bolhassani and Rafati 2011; Florence and Attwood 1988). This oversimplified view of what effectively takes place in real systems is extremely useful in current formulation strategies.

Also, drug absorption in an organ is the result of a complex behavior, dictated by the fact that the former is never dispersed uniquely in that tissue. Partition depends on the similarity (in terms of polarity, for instance) of the species with the tissue. This implies that, for a drug to be effective toward a specific organ, chemical structure, specific dispersion, and transfer strategies are needed. Given the complex hydrophilic-lipophilic balance inherent to all biological tissues (Porter 1993; Barkat et al. 2011), we must rely on strategies capable to substantially disperse the drug to be transferred in the target organ, thus minimizing its partition into undesired tissues and increasing its topical efficiency. These strategies will increase the dose in the organ, still decreasing the overall amount of drug in the formulation (that is, the products result less toxic to the human body).

Whatever the carrier is, its features are optimized when it behaves in analogy with a bullet hitting an organ. In other words, the formulation containing the drug shall be selective toward a given tissue, termed target. This hypothesis is never fulfilled in practice, irrespective of the care used to optimize the formulation and on the drug quality, as well. Think to oil-based dispersions, for instance; these dissolve lipophilic drugs in more or less substantial amounts. Available oil-based dispersions do not easily disperse in biological matrices, when their viscosity, partly responsible for drug mobility, is high. It is not surprising, thus, that oil-based dispersions are intended for long-medium-term transfer procedures. In addition, one must consider if such dispersions are to be used for injection or skin treatment.

On this line, we must be aware of the preferred strategies to be fulfilled in practice. In what follows, we report on some aspects related to drug partition in selected carriers (Cammasab et al. 1997) and explain which contributions must be optimized to make the uptake effective. In a first approximation, we remind that a drug is partitioned among two immiscible fluids according to what is dictated by the Gibbs energy of transfer among two phases. Such relation quantifies the drug partition coefficient by equalizing the chemical potential of the chemical dissolved in immiscible liquids. The physical properties of the liquids (i.e., dipole moment, dielectric permittivity, viscosity, interfacial tension, hydrogen bonding capacity, and so forth) are relevant. Water and nontoxic octan-1-ol are jointly reference solvents; they represent highly polar and strongly nonpolar media, respectively (Andersson and Schräder 1999; Moriguchi et al. 1992). It is well known, in fact, that the partition coefficient of a drug between two media depends on the gradient in dielectric permittivity among two fluids and is rationalized by the Born equation (Monk 1961). Originally developed for ion partitioning between two fluids, the equation relates the Gibbs energy of transfer from the aqueous phase to oil to the gradient of dielectric permittivity among them, eWa and eO, respectively, according to

$$\Delta \ln K_{\mathrm{P,wa,O}} = \Delta(1/\varepsilon) = K[(\varepsilon_{\mathrm{Wa}} - \varepsilon_{\mathrm{O}})/\varepsilon_{\mathrm{Wa}}\varepsilon_{\mathrm{O}}]. \quad (1)$$

The above relation refers to the bare physical properties of the above media and does not explicitly account for temperature, T, ionic strength, I, and pH effects (although these, or the respective gradients, can be somehow inserted in the original theory). The model works well for immiscible liquids such as water and octan-1-ol, if the temperature of the two phases is the same. Although octan-1-ol is considered a reference solvent, it is rarely used in formulation.

What strange methods are possible in drug delivery? All these must guarantee the uptake of a significant amount of the drug in the target tissue; the latter can be polar or not. This fact has consequences on the best way required to dissolve the drug therein. In some instances, drugs are transformed in acid salts (in the form of hydrochlorides, usually) when target tissues are strongly polar. Alternatively, they may form complexes with crown ethers (Muzzalupo et al. 2007; Vintiloiu and Leroux 2008) or species of the like and with cyclodextrins, as well (Loftsson et al. 2005). The latter are saccharide units joined together to form a hole, whose width depends on the number of sugar units in the molecule. When crown ethers are intended for ion transport, cyclodextrins find preferential use with small hydrophobic species. More refined methods rely on drug transport by gels (Qiu and Park 2012), dendrimers, carbon nanotubes (Patri et al. 2005; Bianco et al. 2005), and many other supramolecular entities, some of which are discussed below.

We focus on two selected dispersants, representative of liquid-like and solid-like behavior, respectively. Cat-anionic

vesicles (Pucci et al. 2014a–c) and carbon nanotubes, CNTs, are representatives of nearly spherical and strongly anisometric entities, in turn. Vesicles retain hydrophilic species in the interior and outer surface but hydrophobic in the bilayer, whereas CNTs adsorb polar species on the outer surface only when they are properly functionalized. The amount of small-sized chemicals that can be uptake in the nanotubes' interior is moderate. Thus, CNTs retain very small amounts of molecules in the inside polar region. What is more, vesicles have significant curvature elasticity, when CNTs are relatively stiff. In some sense, thus, vesicles and CNTs are at the extreme limits of the drug dispersant class.

The stability of drug-based formulations depends on the dispersing matrices. In particular, surface energy terms become more and more significant as the size of the drug/carrier adducts decreases. In fact, the surface tension of such systems, g, is expressed as

$$d\Delta G/dA = \gamma \tag{2}$$

Equation (2) explains how the surface area can be controlled, and an increase/decrease of it is at the basis of an optimal working strategy.

These facts offer the opportunity to extend the application to colloid-like carriers; among them, carbon nanotubes, micelles, polymer-surfactant systems, vesicles, or liposomes are the most appealing (Weinstein and Leserman 1984; La Mesa 2005; Fadel and Fahmy 2014; Grumezescu 2018).

3 Vesicles and Related Aggregates

Such entities are jointly characterized by peculiar surface energy terms. However, carriers based on the above species largely differ each other in solvent capacity toward drugs. In such systems, hydrophobic and surface energy terms overlap and combine with electrostatic ones. Micelles, polymer-surfactant systems, liposomes, and vesicles are characterized by the presence of charges on the respective surfaces. This fact implies many outstanding effects, which jointly contribute to:

(i) Micelle/vesicle stabilization
(ii) The formation of an electrical double layer around such entities
(iii) Size modulation
(iv) Conformation of the polymer chain in case of polymer-surfactant systems and so forth

Macromolecules as those indicated in (iv) are surfactant adjuvants in modern drug transfer procedures. For instance, tablets contain sodium dodecyl sulfate, SDS, or potassium carboxylates, with polyethylene oxide, PEO, and/or polyvinylpyrrolidone, PVP, (to mention but a few) (Karthik 2016). The two chemicals in each of these formulations operate in associated form (as polymer-surfactant complexes) as dispersants and viscosity modulators (La Mesa 2005). We, deliberately, do not consider here the use of polymer-surfactant systems in baby diapers although putative usage of these systems is at times advertised in commercials. As a matter of fact, the scientific literature in support or discouragement of these aids is not corroborated by evidence (Degouy et al. 2014).

Turning back to the supramolecular association modes, let us point out that similarly charged polar heads, located at interfaces, repel each other. That process counteracts the hydrophobic effect; it is somehow modulated from counterions partly adsorbing at the interface and reducing the net charge on the aggregates. In this way, a denser/looser polar head packing is favored and the surface area optimized. Indirectly the volume contributions to the system energy (which are opposite in sign to surface ones) are also modulated. The surfactant self-assembly mode obtained in this way is defined as "packing constraint" (PC theory, see below, as discussed in Tanford 1980; Safran et al. 1990; Nagarajan 2002). Originally defined by Israelachvili et al. (1976), it has some points in common with the nucleation of a particle, be it a solid or a fluid. Association of surfactants is determined by the balance of surface and volume energy terms, of opposite sign. The chemical potential of the species in question depends on such contributions and defines the aggregate size better compatible with the minimum Gibbs energy. This fact finds analogy with the nucleation of oil droplets dispersed in a given medium (Morris et al. 1997); they start to form and grow in size only when a critical radius is attained. Surfactant aggregation, conversely, is determined by the balance of the (attractive) transfer of hydrocarbon chains in the micelle interior and is counteracted by the combination of surface tension and surface charge density terms.

The PC theory has significant advantages compared to the classical nucleation theory. In particular, it dictates the optimal size a surfactant molecule/ion must have to pack into entities of a given curvature, be it positive or negative. In doing so we combine surface energy terms and volume effects (jointly contributing to the chemical potential of a given species) with the preferred geometry of the aggregates we would get. Advantages due to the above considerations are horrific in modern formulation strategies and can be obtained by proper experimental actions, by adding salts or co-surfactants, for instance. Among many other advantages, the PC theory explains why added salt favors the formation of rod-like micelles with respect to spherical ones (Hayashi and Ikeda 1980; Alargova et al. 1997; Zoeller and Blankschtein 1998). It also accounts for the residual surface charge density

that controls the formation of thermodynamically stable cat-anionic vesicles (Bonincontro et al. 2007, 2008). The acronym indicates that such mixtures contain both cationic and anionic species in variable amounts. The latter vesicles are appealing transfectants for a series of reasons (Jung et al. 2001; Lo et al. 2010; Barbetta et al. 2011; Coey et al. 2011; Louzao and van der Hest 2013; Pucci et al. 2014a–c), namely:

(i) The surface charge density modulation favors an optimal vesicle size.
(ii) An optimal packing of the alkyl chains into bilayers is possible.
(iii) Drug uptake in the vesicle interior, or in the outer surface, is favored.
(iv) An optimal bilayer and curvature elasticity can be obtained.

As to the biological consequences of using vesicles of the cat-anionic type, a relevant one finds origin in the low cytotoxicity of such vesicles (orders of magnitude lower than the surface-active agents from which they are made of) (Moroi and Matuura 1988; Muzzalupo et al. 2006). Consider that when SDS is strongly cytotoxic and cetyltrimethylammonium bromide, CTAB, or didodecyldimethylammonium bromide, DDAB, even more, vesicles formed by blends of such substances are poorly toxic, if not at all (Kuo et al. 2005; Aiello et al. 2010). This point is quite counter-intuitive to the common sense, unless one is aware of the fact that surfactant toxicity toward biological tissues depends on its solubility in molecular form. It is not surprising, therefore. In fact, the concentration of surfactant(s) in molecular form coexisting with cat-anionic vesicles is orders of magnitude lower than that pertinent to aggregates made by a single surfactant. This behavior is rationalized by the so-called surfactant-surfactant interaction parameter (Muzzalupo et al. 2006), determined by comparison with the behavior expected from ideal mixing of the given species. Cooperativity is concomitant to a decrease in the concentration of molecular surfactant in the bulk and is proportional to b. In other words, the mentioned process finds analogy with metathesis. Further refinements are possible if alkanols or sterols or else are added to cat-anionic formulations; in particular, the latter chemicals favor a denser alkyl chain packing and a more robust character to the bilayers. In selected cases polymers adsorb on the vesicle surface and anchor thereon thanks to the combined action of ionic interactions and alkyl chain uptake, if hydrophobically modified polymers, HMPs, are used (Sallustio et al. 2004). The latter possibility has been used to modulate vesicle size (Pucci et al. 2014a–c) and, eventually, to favor its faceting. More advantages are on the possibility to pack different vesicles in superstructures.

Drugs can be selectively partitioned on the outer/inner vesicle surface, on its interior, and in the inner aqueous pool. Therefore, different formulation possibilities (such as surface adsorption, selective uptake in hydrophobic, or, conversely, polar matrices) are in our hands, depending on the chemical nature of the drug to be transferred. This is the reason for a wide-spread use of cat-anionic formulations in many different biomedical fields. Biological implications and suggestions for an optimal and selective use of the most common (and most promising too) cat-anionic mixtures are outlined below. What has been considered in case of the cat-anionic species mentioned above can be extended to many more species. For sure it holds for phospholipid mixtures (Lozano et al. 2009). More recently, efforts have been made by collaborating research groups active in the field. The basic idea underlying the working hypothesis is that surfactants having amino acids as polar head group are characterized by a very low cytotoxicity (Pinazo et al. 2011; Colomer et al. 2012; Mezei et al. 2012). If we consider, in addition, that the amount of surfactant in molecular form coexisting with vesicles is, as a rule, extremely low (in the micromole range), it is reasonably assumed that catatonic vesicles built up accordingly have very low, if any, cytotoxicity (Muzzalupo et al. 2017; Tavano et al. 2017). Furthermore, such a hypothesis was substantially demonstrated, mostly when pH controls the vesicle state of charge. At the best of our knowledge, these are among the most promising results in the field.

4 Carbon Nanotubes

Many systems made of extended carbon moieties are potential candidates for transfection technologies. However, when almost nothing is actually known on the potentialities offered by graphene derivatives, those based on functionalized fullerenes (Nakamura and Isobe 2003) have got some success. Even more successful are those based on carbon nanotubes, CNTs. These species have potentialities of substantial interest in biomedical applications. First, they have inner cavities; second, their outer surfaces can be properly functionalized, when it is required (as we will see below, this procedure is nearly compulsory). In addition, they have outstanding physical-mechanical properties such as elasticity and conductive/semi-conductive behavior. In terms of what is stated in many books and reviews, their properties are mostly engineering-intended (Hone et al. 1999; Arroyo and Belytschko 2004); we include in the category the preparation of new hard materials for tissue engineering. However, substantial efforts have been recently made by diverse scientists to make them suitable for refined bio-intended applications (Popov et al. 2007; Heister et al. 2013; Amenta and

Aschberger 2015). To proceed along this line, one must be aware of the fact that the high aspect ratios (i.e., the tube to diameter ratio) pertinent to CNTs and, mostly, the strongly hydrophobic character of their outer surfaces substantially hinder the preparation of biomedically relevant advanced materials. In particular, high axial ratios imply that long filaments of CNTs (several nm's long) easily form scaffolds by simply pressing or in other ways. As a rule, reticulation procedures are not strictly required, since the strong hydrophobic character of CNTs ensures a substantial interaction energy and significant aggregation.

Nanotubes are obtained since very specific five-/six-carbon ring ratios ensure them a proper surface curvature. Carbon monolayer rolling may stop to give single-walled carbon nanotubes, SWCNTs, or, later, multi-walled ones, MWCNTs. As to surface properties, there is no substantial difference among two such classes, which, however, largely differ in elasticity, rigidity, and so forth. Their chemical reactivity is mostly active on the outer surfaces, properly functionalized by drastic oxidation procedures, using HNO3/H2SO4 mixtures or H2O2 or other agents (Ajayan et al. 1993; Tsang et al. 1993). In the above cases, carboxylate or OH group attach on the surface, whereas the overall CNT length is drastically reduced. In this way the elastic properties of CNTs are minimized, whereas chemical reactivity largely increases. Such duality gives the opportunity to distinguish among engineering-intended, the former, and bio-inspired CNTs. Surface functionalization, in fact, is the key strategy leading to biocompatibility.

Pristine CNTs are poorly stabilized in aqueous media and associate by vdW interactions to form bundles. This fact strongly reduces possible applications and must be severely minimized. This is the reason why surface coverage is relevant. That process can be obtained by covalent functionalization procedures, as outlined above, or by non-covalent ones. Among the most used ones let us mention surfactant (Bandyopadhyaya et al. 2002; Islam et al. 2003; Wang 2009; Vaisman et al. 2006) or polymer (Liu 2005; Spitalsky et al. 2010; Huang and Terentjev 2012) adsorption. The former category implies the adsorption of medium-long-chain surfactants, be they ionic or not. It is well acquainted, however, that the efficiency in surfactant adsorption is inferiorly and superiorly limited. The rationale for that unexpected behavior arises by depletion phenomena (Tardani et al. 2012). The surfactant, to put it simply, partitions between the surface state and the bulk, where it may also form micellar aggregates, that is, ions, micelles, and surface bound states. The chemical potential of the surface-active species depends on the balance between all such states. As a result of unbalanced osmotic effects in the bulk, the surface-adsorbed species tend to detach from the nanotubes and form more micelles. Thus, non-more surface-covered CNTs directly interact to form bundles and will easily separate out from the solution. Note that the latter effect is non-peculiar to CNTs and has been brilliantly explained some years ago by De Gennes (1981).

An alternative to surfactants relies on polymers. Most of them do suffer from the same drawbacks outlined above; in many instances, adsorption is moderate and superiorly limited, mostly in the case of small proteins (Bomboi et al. 2013). There are exceptions to these general rules; the most prominent is that observed when single-stranded DNA adsorbs onto CNTs. For those non-explicitly aware of that method, we remind that the stable form of double-stranded DNA can be transformed in two filaments by the action of heat. At 95.0 °C, on average, the double helix melts into two filaments, which can remain for long time in such state if the solution is thermally quenched. Addition of CNTs allows efficient surface coverage. The difference between printing, surfactant-stabilized, and single-stranded covered nanotubes is astonishing. The solubility of the former two states is in the mg kg^{-1} range, when the latter can be as high as some wt%. This fact allowed to determine in some detail the phase diagram of ss-DNA/CNT systems and to visualize the formation of nematic order therein (Tardani et al. 2012, 2013; Tardani and Sennato 2014). The only possibility to use such formulations for biomedical purposes is that due to the possible adsorption of drugs on functionalized nanotubes. In other words, CNTs would act as surfaces on which polymer-drug adducts are adsorbed!

The only significant advantages of formulations based on biopolymers and CNTs are due to their high biocompatibility, as demonstrated by some of us in selected cases (Muzi et al. 2016a, b; Risuleo and La Mesa 2016). Thus, even though the quantity of vehiculated drug is moderate, the whole strategy is effective. Alternatively, we may use CNT-based formulations by taking into account the presence of a cavity therein; the latter can be filled with small drugs, as it has been demonstrated in the case of anticancer therapy based on cis-platinum (Muzi et al. 2015a, b). The latter species enters the nanotube cavities, the whole process being controlled by the sizes of the respective species. Once the inner complexes with cis-platinum are released in the infected tissue, a slow drug release occurs. The driving force for it is the result of a combination of diffusion, concentration gradients, and ion concentration in the target organ.

5 Nanomaterials as Cargos of Biological Molecules: Potential Usage in Advanced Therapeutic Strategies

The number, nature, and sophistication of molecular carriers for the delivery of exogenous material within a living cell are diversified and, in many cases, serve different purposes.

Therefore, for the sake of conciseness, we will focus mainly on three different nanoparticles, i.e.:

- Cationic liposomes
- Cat-anionic vesicles
- Single-walled carbon nanotubes

The largest part or the results discussed here were obtained in our or closely collaborating laboratories: as a matter of fact, nanoscience, though in a still quickly developing stage, requires a multidisciplinary effort where scientist with diverse but complementary expertises participates. However, achievements of other research groups will be also taken into account.

6 Liposomes

Due to their biocompatibility, liposomes are among the most studied drug delivery systems. Also, the possibility of targeting them in a selective manner to different tissues and the favorable cost/production facility plays an important role in their application as therapeutic agents in advanced medicine. Several physicochemical parameters determine the validity of liposomes as cargo particles for the transport of specific molecules be they: macromolecule such as DNA, RNA, and proteins or small molecules like hormones, natural compounds, and/or drugs in general. The type and amount of lipid in their formulation are crucial. For instance, liposomes based on cationic lipids are not found in nature but are synthesized in the chemistry laboratory. Since they are endowed of a net positive charge, they may promptly interact with negatively charged cell membrane and nucleic acids (Simberg et al. 2004). Relatively, recent works have evidenced their ability as carriers of nucleic acids and vaccine carrier/adjuvants (Joseph et al. 2006; Lonez et al. 2008). The possibility of using this type of liposome as drug carriers for neoplastic and other diseases has also been examined; in particular, cationic liposomes are able to deliver specifically their payload to embryologically different tissues such as tumors of endothelial origin, to the lungs and liver and gastrointestinal tract. Therefore, they have become a very attractive tool for oral administration of therapeutic agents in cancer therapy. A further important observation is the interaction of this type of liposome does not interfere with the morpho-functional features of the target cells as observed by optical and SFM imaging as well as NMR-metabolomic studies (Piccioni et al. 2007).

Finally, the antibacterial action of cationic liposomes has been also examined in Gram-negative or antibiotic-resistant pathogenic microorganisms: as a matter of fact, liposomes may increase the bacterial membrane permeability, which consequently causes a higher susceptibility to drug uptake (Hamblin and Hasan 2004; Bombelli et al. 2008; Cosimati et al. 2013; Stefanutti et al. 2014). For an insight into the role played by the cell membrane permeability in the uptake of exogenous molecules, the routes of internalization and the intracellular trafficking the reader should also address a previous chapter of this book written by the same authors and references therein. For the potential usage of liposomes in antiproliferative (anticancer) therapy, the reader is advised to address the following recent reviews: Heidarli et al. 2017; Olusanya et al. 2018; Deshantri et al. 2018.

7 Cat-Anionic Vesicles

Cat-anionic vesicles are supramolecular aggregates formed by mixing in non-stoichiometric ratios cationic and anionic surfactant species (Letizia et al. 2007). Surfactants of opposite charge tend to aggregate in aqueous polar solvents. The electrostatic interactions between the polar heads and hydrophobic tails favor the formation of self-assembled and organized supramolecular structures. An extensive analysis of the parameters governing the formation and morphology can be found in the classical work by Israelachvili and collaborators (Israelachvili et al. 1977). Vesicles may easily interact with DNA, RNA, or other biopolymers, resembling in this case the above discussed liposomes. In this case also, the complexes vesicle/macromolecule, commonly defined lipoplexes, assume a fundamental importance in biotechnological and biomedical applications: as a matter of fact, their intrinsic structural and functional properties attribute them the capacity to deliver genetic material across the cell membrane via plasma membrane fusion and/or endocytosis. Work from our laboratory showed that it is possible to form complexes between DNA and vesicles with an excess positive charge at the surface, which could be potentially delivered within the cell (Bonincontro et al. 2008). But concerning their biocompatibility, some *caveats* are to be considered: vesicles may show a cytotoxic effect, which is directly related to time of exposure and dose of administration as well as to the nature of the composing cat-anionic moieties. Literature on this specific aspect exists (Kuo et al. 2005; Vlachy et al. 2009; Lozano et al. 2011), and work from our laboratory showed that SDS-DDAB are far more cytotoxic than those formed with SDS and CTAB as hydrophobic counterion (Russo et al. 2013) ; furthermore, these latter ones (SDS-CTAB) are able to "hit" tumor cells more efficiently than normal mouse fibroblasts which show a higher survival/proliferation rate as compared to the previous cell population (Aiello et al. 2010). However, despite their cytotoxicity, it is possible to adjust the experimental conditions such as time and dose of treatment, to allow a successful vesicle-mediated transfection with subsequent expression of exogenous genetic material (Loftsson et al. 2005; Muzzalupo et al.

2007). With respect to this crucial aspect, one main interest in the use of nanoparticles as molecular carriers of genetic material consists in ascertaining the fate of this material, be it DNA or RNA, upon entry in the recipient cell: i.e., is the transfected macromolecule stable? Does it maintain its functional features? Can the genetic features encoded within the macromolecule be transformed into the mature functional product? We addressed this question by transfecting messenger RNA into recipient cells and measuring the level of the encoded gene product by standard CAT-assays. The sharp and clear-cut result is that the transfected cat-anionic/RNA lipoplex is efficiently metabolically translated into protein which exhibits functional epitopes promptly recognized by the cognate antibody as shown by ELISA assays (for a study of the effects of nanoparticle-mediated gene transfer on the overall cell metabolism, see Aiello et al. 2010; Russo et al. 2013; Cosimati et al. 2013; Stefanutti et al. 2014). Finally, pilot studies indicate that vesicles may be utilized in anticancer therapy (for recent reviews, see Wright 2008; Freire et al. 2015; Han et al. 2017).

8 Nanotubes

To recapitulate quickly, carbon nanotubes (CNTs) are rolled graphene sheets forming cylinders or quasi-cylindrical structures; these are found in single- (SWCNTs) or multi-walled concentric CNTs (MWCNTs) shapes. Nanotubes have very numerous potential applications in biochemistry, nanomedicine, pharmacology, and industry such as avionics as well as space engineering (see, for instance, Prato et al. 2008; Ménard-Moyon et al. 2010; Venkatesan et al. 2014; Shtansky et al. 2018, Krishna et al. 2018; Mohajeri et al. 2018).

Curiously enough, graphene was recently implied in the development of ultrathin highly resistant condoms: research was funded/sponsored by a very well-known head of an informatics company, but we will not expand on this aspect though will provide a useful link for the reader interested in this spearhead research (https://www.extremetech.com/extreme/171417-bill-gates-funds-creation-of-thin-light-impenetrable-graphene-condoms).

We will restrict, instead, our discussion to drug delivery and potential therapy, including diagnosis when appropriate. The development of biotechnologies based on nanotubes requires the evaluation of a few preliminary but essential aspects. In fact, as with other nanoparticles, the CNT biocompatibility must be carefully assessed both in cell culture systems and animal models: in this latter case, for instance, the ascertainment that they are not toxic and do not elicit immune responses is chiefly important. Also, since the cell membrane is the first barrier encountered by the nanotube upon cell entry, a further problem should be considered. CNTs are poorly dispersible in aqueous solution; thus, they establish van der Waals interactions (see also above, in this chapter) which cause their aggregation in large bundles which may be detrimental to membrane integrity and/or may hinder their passage across it (Holt et al. 2010). Initially, bundled, non-purified, and long SWCNTs have been associated with toxicity and negative cellular effects. Several dispersant molecules improve dispersibility, albumins in particular. Recent investigations conducted in our laboratories demonstrated that non-covalent carbon nanotubes/BSA complexes did not alter the cell viability. These nanocomposites were administered to different cell line murine fibroblasts (NH3T6), human embryonic kidney cells (HEK-293), or murine macrophages (RAW-294). No significant changes in the cell viability was monitored in 3T6 and HEK 293 cells after exposure to different concentrations of pristine or BSA-CNTs. A cytotoxic effect, on the contrary, was observed in the case of murine macrophages treated with both pristine and BSA-stabilized CNTs. Toxicity was diminished when CNTs were coated with BSA; this evidences that this protein enhances the biocompatibility. In any case, the good dispersion quality of these BSA-CNT complexes caused a good internalization both phagocytic (macrophages) and non-phagocytic (fibroblasts) cell types. Observations performed by transmission electron microscopy showed that the complexes penetrate the cells by a passive diffusion or endocytosis which is an active energy-dependent mechanism of assumption. However, crossing of the plasma membrane caused no alterations of the dielectric parameters of the cell membrane measured by a biophysical approach: electrorotation (Bonincontro and Risuleo 2015; Muzi et al. 2015a, b, 2016a, b).

As a second recapitulation, we will discuss in this section the role of graphene. Graphene is at the basis of the nanotube technology and consists of a one-atom-thick planar sheet of carbon atoms densely packed in a honeycomb crystal lattice. Graphene can display different forms which are conventionally combined under the so-called graphene family materials and include the few-layer graphene (FLG), graphene oxide, reduced graphene oxide, graphene nanosheets, ultrafine graphite, graphene ribbons, and graphene dots. In any case, FLG is constituted by 2–10 graphene layers (Bianco et al. 2013) and shares the basic structural element of other carbon allotropes, including carbon nanotubes and fullerenes, but their history is quite recent. However, from its discovery, graphene has been the object of exciting interest in many fields of basic science and industry: this is mainly due to graphene's extraordinary features. As a matter of fact, graphene-based nanotechnology represents nowadays an area of scientific research and industrial applications in full expansion (Liang and Chen 2010). Graphene was firstly

exploited in material sciences but recently has become a very good tool in electronics, photonics, composite materials, energy generation, energy storage, and sensors as well as biological applications (see also the web-link cited above). Last but not least, FLG is easily produced in high yield and at a relatively low cost (Novoselov et al. 2012). A new *caveat* is that the rapid increase in production and applications of FLG implies its potential release into the environment, especially into the aquatic compartment generally considered as a fragile and sensitive macro-sphere. With respect to this, the release of FLG could occur more or less accidentally from inadequate or uncontrolled disposal of such commercial products and the chemical modification and degradation following the waste: possible ecosystem risks induced by FLG were examined and are found in literature (Hu and Zhou 2013); also, a recent review discusses the toxicity of GFMs toward the aquatic environment including bacteria, crustaceans, nematodes, and fish (Zhao et al. 2014). The idea is that the toxicity of different aquatic organisms and the impact of FLG against aquatic organisms may not be as high as carbon nanomaterials such as fullerenes and carbon nanotubes. However, results are controversial. In fact, the biological response often depends on the intrinsic structural nature of graphene, such as number of layers, rigidity, hydrophobicity, dose and purity of the material under scrutiny, and, finally, the use of diverse cell/organism models (Bianco 2013). Based on the results from our laboratory on *Xenopus laevis* larvae, FLG is substantially nontoxic (Muzi et al. 2016a, b). These data are consistent with the literature available on FLG ecotoxicity on different organisms like *Pseudomonas aeruginosa*, *Caenorhabditis elegans*, and *Vibrio fischeri* (Gollavelli and Ling 2012; Zanni et al. 2012; Guo et al. 2013; Pretti et al. 2014). Analogous studies on crustaceans such as *Artemia salina* produced similar results as far as oxidative stress and life span and showed that FLG did not induce oxidative stress in the bacteria, but 70% of bacterial viability was lost after 5 h of exposure to 250 mg L^{-1} of the material. They also showed no effect on the lifespan is concerning. In our case, only the Xenopus larvae growth rate seemed to be affected by the material to some extent. Indeed, the larval size was decreased by about 40% only upon exposure to the highest concentrations of FLG. This profile response is usually observed in Xenopus larvae exposed under the same conditions to carbon nanotubes (Muzi et al. 2016a, b). Several hypotheses have been proposed to explain this phenomenon. For instance, the uptake of carbon-based nanomaterial may lead to digestive and respiratory obstructions causing exchange gas dysfunctions (Mouchet et al. 2011).

9 Concluding Remarks and Future Directions

In this multifaceted overview of the large and diversified group of carbon nanoparticles, we discussed the fabrication and the effects of liposomes, vesicles, and nanotubes. The effects of the administration of these nanocomposites were examined both in cultured cells and, in the case of few-layer graphene sheets, also in living animals: namely, *Xenopus laevis* larvae. Results were, when appropriate, compared to published literature data, and no relevant discrepancies could be detected between data from our studies and work conducted in other laboratories. The final conclusion is that, in general, nanoparticles can be considered a safe, though very efficient, tool to use in a number of different biomedical fields. These range from diagnostics to potential therapy of proliferative and/or immunosuppressive diseases in humans and other animals. Nanoparticles are internalized within the target cells where they deliver their molecular cargo. According to the presented data discussed in this work, very little, if any, permanent damage is inflicted to the animal assuming the exogenous material: therefore, one can safely conclude that neither the cell membrane, first barrier encountered by nano-complex upon cell entry, nor the overall cell metabolism suffers a significant damage. This renders nanoparticles very attractive in advanced biomedicine, which is the field of our main interest. Also, toxicity does not seem to be a primary concern in the usage of such particles. As very often repeated, the nanotechnological field is going through a process of ever-growing expansion: it is no easy task to predict what the developments will be in a medium to long time span. Who would have envisaged only a few decades ago the development of advanced imaging techniques, of noninvasive microsurgery, telemedicine: science fiction? The answer is negative! Science proceeds through inspiration but, as T.A. Edison[1] (*chapeau!*) put it, also through a lot of perspiration. Therefore, our auspices and ambition are that this review will serve mainly young scientist to find a spurt for their work.

In any case, a final consideration is needed: a very important side of the works discussed in this review regards the interdisciplinary character of the nanotechnological approach. A number of diversified expertises are required, ranging from basic science, molecular biology, physical chemistry, and biophysics, to economy and marketing. With respect to this, however, some socioeconomical aspects cannot be disregarded. A few words should be spent, namely, as far as their usage on field is concerned; that is, in spite of the relatively simple laboratory techniques required for their

[1] "Genius is one percent inspiration, ninety-nine percent perspiration." Oral statement reported by Harper's Monthly, September 1932.

fabrication and the relatively low cost, will it be possible, as things stand now, to apply these technologies also in disadvantaged situations? Will personnel be available to carry out these procedures in those unfavorable conditions? These questions deserve a prompt answer and when required a remedy.

Nanosupplements and Animal Health

Alessia Bertero, Leon J. Spicer, Teresa Coccini, and Francesca Caloni

Abstract

Nanosupplements have raised great attention in recent years, particularly in animal production industry and veterinary science where they are constantly being developed and expanded because of their peculiar characteristics largely due to their dimensions that go from approximately 1 up to 100 nm. Interestingly, in this nanodimensional size range, substances acquire new characteristics, different from those of the bulk material from which they originate, leading, in some cases, to an increased suitability of these materials for specific uses. In this scenario, the regular inclusion of nanosupplements in animal feed or water to benefit the quality and the quantity of the product obtained, as well as the production cycle, is likely possible in the near future. These compounds have many potential applications: as growth promotants, enhancers of the ruminal flora, anti-inflammatories, immune system stimulants, etc. Research in this field has made considerable progress, but there are still many gaps to be filled, given that, for example, the mechanisms of action of nanoparticles remain unknown as well as the health and environmental implications of a widespread use of this particular type of dietary supplement, especially but not only in terms of reproductive/developmental toxicity and environmental pollution.

1 Introduction

1.1 Nanoparticles

Nanoparticles (NPs) are particles with a size range that goes from approximately 1 to 100 nm and derive from both natural and anthropogenic sources (Klaine et al. 2008). Fumes originating from volcanoes, the fine fraction of desert sand, and aquatic colloids (Ostiguy et al. 2006) are some examples of NPs naturally produced, while anthropogenic ones could be produced intentionally or unintentionally, like NPs generated from welding fumes (Nowack and Bucheli 2007; Ostiguy et al. 2006). The intentionally produced NPs are also designated as engineered NPs (Maurer-Jones et al. 2013), and the technology that deals with NPs production and use is referred to as nanotechnology. NPs properties (Ostiguy et al. 2006; Batley and McLaughlin 2010; Schodek et al. 2009) allow their use in a wide range of applications in different areas from chemical industry to medical applications (Farré et al. 2009; De Berardis et al. 2010).

1.1.1 Nanoparticle Classification

NPs can be classified in relation to their composition, dimensionality, morphology, uniformity, and state of agglomeration (Buzea et al. 2007). NPs can be synthesized from different materials and characterized in function of their composition: carbon NPs, metal NPs, metal oxide NPs, non-metal NPs, and others (Burda et al. 2005; Berube et al. 2011). Dimensionality and morphology play an important role in relation to NPs toxicity (Buzea et al. 2007), and the chemical and electromagnetic properties of NPs may influence their agglomeration state (Corbierre et al. 2005; Han et al. 2009;

R. C. Gupta et al. (eds.), *Nutraceuticals in Veterinary Medicine*, https://doi.org/10.1007/978-3-030-04624-8_54

Shen et al. 2009), losing some of their typical characteristics and behaving like larger particles (Buzea et al. 2007).

2 Nanosupplement Delivery

Nutraceutical NPs and NPs as delivery systems are areas of growing interest in veterinary medicine and the feed industry (Hill and Li 2017). The use of nano-nutritional supplement delivery systems adds several advantages compared to the traditional forms of nutritional supplements. Nanocarrier delivery systems as well as nano-molecules are more efficient in reaching the site of action; thus, the influence in the target sites can be optimized, also minimizing the undesirable side effects. Many nanostructures, including liposomes, polymers, etc., have been studied as nanodelivery systems. The two main groups are the nanodevices and nanomaterials. Nanoscale devices include biosensors and various detectors, the latter of which are characterized by surface modification, due to the nanodimension, or coatings, that enhance their biocompatibility.

Nanomaterials can also be divided into nanocrystalline and nanostructured materials. Nanocrystallines are directly obtained from bulk materials and are characterized by higher performance in terms of absorption and biological actions. They are employed, for example, in drug encapsulation for drug delivery. Nanostructured materials can be made from raw nanomaterials to obtain certain shapes with a specific purpose such as quantum nanotubes (Bhatia 2016). Another categorization identifies four groups: metals, polymers, natural compounds, and nanostructured materials (Hill and Li 2017).

Independently from the form in which the NPs are administered, there are the following mechanisms of action: NPs can act as the functional unit, as a delivery vehicle for materials that can be conjugated to their surface or encapsulated within (Hill and Li 2017).

For nutritional supplement delivery the most used NPs are:

2.1 Metallic NPs

This type of NP is characterized by a very small size (<100 nm), resulting in a higher surface area and so a high functional area. This form of nanodelivery is emerging as a good delivery carrier and biosensor. Moreover, some metallic NPs proved to have antimicrobial properties and to be a useful tool in mineral nutrition since the nanomineral particles show higher potential than their conventional counterpart and thus the quantity required is reduced (Sri Sindhura et al. 2014).

Another advantage of NPs administration is that a lot of nanominerals can efficiently and easily be synthesized with physical, chemical, and biological methods (Swain et al. 2015) which are not expensive. Moreover, they are stable and can be modified via conjugation with different functional groups (Jain et al. 2007). Despite their great potential and advantages, metallic NPs show a wide range of toxic effects that cannot be ignored. Various metals have been used to prepare NPs. Copper, silver, gold, and zinc are most commonly used (Ghosh et al. 2008; Mishra et al. 2010). Among them, one of the most used metallic NP in animal science is zinc oxide. It is a good alternative to conventional zinc as an animal feed supplement, because of its higher bioavailability, but studies have also pointed out many other effects of zinc oxide such as growth promotion, antibacterial actions, and immunomodulatory effects (Partha et al. 2016). Other nanometals used are selenium, chromium, and calcium, which showed positive effects on various apparatuses and physiological activities (Hosnedlova et al. 2018; Hill and Li 2017).

2.2 Natural NPs

Some NPs can be defined as naturally occurring NPs. For example, some casein isoforms are able to assemble around calcium, proteins, and other hydrophobic substances (Haham et al. 2012). These micelles can be used to incorporate hydrophobic nutrients (Semo et al. 2006), such as vitamin D, increasing in vivo vitamin bioavailability after the stomach's proteolytic cleavage of casein occurs, leading to the release of encapsulated vitamins.

Another molecule potentially useful in nutrient delivery is cruciferin, a promising nanocarrier for the delivery of nutraceutical compounds. Studies were performed using this NP made from the canola protein cruciferin, which could encapsulate both hydrophobic and hydrophilic substances, protecting them from an in vitro simulated acid environment like that of the stomach and releasing them in an in vitro simulated intestinal environment (Akbari and Wu 2016).

2.3 Polymeric Micelles

Polymeric micelles are nano-aggregates usually characterized by a spheroidal shape in which the hydrophobic molecules constitute the core of the structure, surrounded by a hydrophilic shell. The hydrophilic phase can be made of phospholipid micelles, pluronic micelles (which consist of the hydrophilic polyethylene oxide and the hydrophobic polypropylene oxide), polyamino acid micelles, and polyester micelles surrounded by biocompatible polymers (Koo et al. 2005).

This nanodelivery system is produced through self-assembly of amphiphilic polymers in an aqueous environment, so they are easy to prepare. Moreover, the micelles are characterized by a low toxicity and great versatility due to the available combinations. Polymeric micelles are mainly used for the delivery of therapeutic agents, above all anticancer drugs.

2.4 Polymeric NPs

Polymeric NPs are made combining a biodegradable polymer (that has to be biocompatible and nontoxic) with the active substance. The latter can be adsorbed on the surface of the polymer, encapsulated within the polymeric NP or even dissolved on it. The polymer can be natural or synthetic. Among natural polymers, the most widely used is chitosan (a linear polysaccharide) but also gelatin, albumin, and sodium alginate. These natural compounds were introduced to overcome some toxicological problems showed by synthetic polymers (Vyas and Khar 2002).

Polymeric NPs are a huge group that include a variety of NPs such as nanocapsules (which are characterized by a vesicular structure) and nanospheres (which are a matrix system and the matrix is uniformly dispersed). More specifically, nanocapsules are structures with an inner cavity in which the active substance is confined, and this core cavity is surrounded by single polymeric membrane, whereas in the nanosphere, the active substance is disseminated throughout the polymer matrix. The characteristics of this type of nanodelivery system can be varied and optimized in order to obtain the desired kinetics and dynamic properties. These delivery systems and in particular natural polymer-based NPs are mainly used in cancer therapy, delivery of vaccines, drug, and targeted antibiotics where they lead to a significant increase of the delivery efficiency.

2.5 Nanocapsules

Minute micelles (nanocapsules) can be used as carriers for essential oils, polyphenols, antioxidant, coenzyme Q10, vitamins, minerals, and micronutrients reaching a better bioavailability of these compounds (El Amin 2006). The encapsulation protects them from oxidation without any undesirable off-tastes.

2.6 Liposomes

Liposomes are lipid vesicles synthesized by hydration of dry phospholipids, which can consist of one or more lipid bilayers (five or even more) concentrically arranged around an aqueous core. This structure resembles those of cell membranes allowing a ready fusion with them. The high biocompatibility of liposomes and their capability to preserve, dissolve, and deliver water- or fat-soluble molecules make them a powerful and flexible tool especially as a drug delivery system. The type of lipid composition and the number of phospholipid bilayers can be modified changing their charge and their physical-chemical properties in order to optimize the suitability of this system for a specific use. Despite the flexibility of liposomes, they are mainly suitable for topical, intravenous, and intramuscular administration and have a limited oral bioavailability due to their susceptibility to gastrointestinal degradation. So far, liposomes have been studied for drug, vaccine, and gene delivery, and as imaging agents, with encouraging results.

However, their application in animal science is limited by their short shelf life, the complex production techniques, and their high costs (Underwood and van Eps 2012). Recently, in a study performed by Colom et al. (2015), the efficacy of bacteriophages encapsulated in liposomes in reducing *Salmonella* in poultry was investigated. In broilers experimentally infected with *Salmonella*, the mix containing liposome-encapsulated bacteriophages was administered orally every day for 6 days post-infection. This formulation prevents the sedimentation in the drinking water and simplifies the addition to the feed; moreover, the results showed a prolonged intestinal residence time for the encapsulated bacteriophages and a good release of the phage in the intestine with a strong and long-lasting protection against *Salmonella* colonization.

2.7 Nanoemulsions

Nanoemulsions are a multiphase colloidal dispersion of two immiscible liquids, typically oil and water, using a surface film made of surfactant. In this system, the active substance is usually carried by the dispersed phase. The manufacturing techniques are cheap and simple; moreover, nanoemulsions are usually characterized by a great stability. By varying the aqueous solution, the type of oils, and surfactants, a large variety of nanoemulsions with peculiar properties can be prepared, adapting the formulation to the molecule to be encapsulated, thus optimizing the delivery system (Vandamme and Anton 2010). El-Sherbiny et al. (2016) performed a study on a new type of supplement made of nanoemulsified oils (soybean, fish, and rapeseed oils). The oils were used either in a raw form or in a nanoemulsified form and were tested using rumen batch cultures. Results proved that the nanoemulsified oil mixture was more effective than the raw oils in preserving polyunsaturated fatty acids in the biohydrogenation environment of the culture, showing that the oil-in-water nanoemulsions may represent an efficient and manageable approach to the supplementation

of unsaturated lipids that could be easily administered with the drinking water.

2.7.1 Lipid NPs (LNPs)

These delivery systems are carrier systems characterized by a solid lipid matrix (that can be made of highly purified triglycerides, complex glyceride mixtures, and waxes) (Müller and Lucks 1996), usually prepared with an oil-in-water emulsion technique. This structure of physiological lipids, usually stabilized by surfactants, allows it to obtain a protective action toward core materials and to increase the oral bioaccessibility of lipophilic materials such as flavonoids (Ban et al. 2015). This is obtained thanks to a higher residence time because of their capability to adhere to the gastrointestinal wall and enter the intervillar spaces. Moreover, this system protects the core material from the physical and biochemical damage that can occur during its passage in the gastrointestinal tract (Li et al. 2015). When LNPs enter the small intestine, duodenal and bile juices, together with digestive enzymes, separate LNPs into monoglycerides and fatty acids which are taken up into micelles, containing the nutraceuticals, that contact the surface of the enterocytes where absorption occurs (McClements and Xiao 2012). Another innovative application of LNPs is linked to their ability to be delivered into the central nervous system, leading to an improved activity of the encapsulated drug because of the protecting action of the nanolipids and the increased absorption surface. In a study performed by Valdes et al. (2018), two antibiotics, minocycline and ciprofloxacin, were incorporated in LNPs of solid phase and intrathecally injected in rats. The encapsulated antibiotics showed to be at least 50% more efficient than the antibiotic alone proving the efficiency of this nanodelivery system (Valdes et al. 2018).

LNPs have also been investigated as an mRNA delivery system. Since the main concern related to the mRNA technology is its immunogenic properties and its poor stability, the use of LNPs seemed to be suitable to avoid these critical points. In a recent study performed by Sedic et al. (2018), modified mRNA, encoding for human erythropoietin, was formulated in LNPs and administered intravenously in rats and monkeys. Successively, a significant increase in red blood cell parameters was recorded, demonstrating the possibility to induce, via LNPs, therapeutic levels of proteins with modified mRNA (Sedic et al. 2018).

2.8 Nanocrystals

Nanocrystals are aggregates of many particles of the active substance in crystalline form which are coated with one or a combination of surfactants in order to achieve the stabilization of the structure. This type of nanosystem is used to overcome absorption and bioavailability issues related to the administration of certain drugs. In a study performed by Pensel et al. (2018), albendazole nanocrystals (ABZ-NCs) were used to treat mice experimentally infected with *E. multilocularis*, and this nanoform of the drug had greater chemoprophylactic and clinical efficacy than classic albendazole, probably due to an increased systemic availability of albendazole sulfoxide (Pensel et al. 2018).

3 Animal Production

3.1 Growth

Nowadays, nanosupplements are raising more and more attention and interest, particularly in animal production industry where they are constantly being developed and expanded (Thornton 2010; Hill and Li 2017; Pinar et al. 2018). The regular inclusion of nanosupplements in animal feed or water to benefit the quality (and the quantity) of the product obtained, as well as the production cycle, is likely possible in the near future. Indeed, many studies have been performed, in several species, to investigate the action of NPs in animal production and verify their potential role in enhancing animal growth and, as a consequence, meat production.

3.1.1 Pigs

Copper is a microelement routinely added to all swine diets in order to enhance growth. Indeed, copper fed at 125–250 ppm had a positive effect on growth, particularly of the weaned pigs (Holden et al. 2002). The mechanism of action by which copper exerts its effect lies in its antibacterial properties (Cromwell 2001) and in its ability to stimulate the immune capacity. Despite all these positive effects, copper supplementation had some disadvantages such as an increased environmental contamination because when fed at a high level, copper digestibility and absorption drop. As a consequence, there is a high copper excretion in feces increasing environmental pollution. In this context, supplementation with nano-copper has been studied in order to enhance digestibility and therefore increase absorption and decrease fecal excretion of this important growth promotant.

The effect of nano-copper supplementation on digestibility and bioavailability of this element in pigs and the effects of nano-copper on growth and serum parameters have been investigated. Findings showed that nano-copper (administered at 50 mg/kg) enhanced growth performance as well as the digestibility and bioavailability in the nano-copper-supplemented pigs compared with pigs fed with copper sulfate (at the same dose). Furthermore, copper excretion was reduced. Regarding the serum parameters, IgG, γ-globulin, total globulin protein levels, and superoxide

dismutase activity (the activity of this enzyme is reduced in pigs with copper deficiency) were increased by nano-copper supplementation (Eguia et al. 2009).

Silver is another element that has had been investigated to assess its potential as a NP additive in diets for weanling pigs. When weanling pigs were fed a diet supplemented with 0, 20, or 40 mg nano-silver/kg, in the second week after weaning, the daily growth was increased linearly with dose of silver NPs. Moreover, the ileal concentration of total bacteria was decreased with increasing concentration of nano-silver in the diet, also showing a linear relation (Fondevila et al. 2009).

Regarding the productive performance, feed intake was higher in animals fed a diet supplemented with 20 mg nano-silver/kg with no silver retention detected in kidneys or skeletal muscles although traces were found in the liver (1.354 and 2.445 μg silver/g dry liver for 20 and 40 mg nano-silver/kg diets, respectively). Taken together, these results indicate that the effect of the nano-silver on feed intake and growth performance could be related also, as for copper, to its antimicrobial properties.

Another NP studied as dietary supplement in pigs is chromium, and its effects on growth, carcass characteristics, pork quality, and tissue presence were investigated in finishing pigs. This element increases insulin activity thus being fundamental in the maintenance of normal glucose tolerance as well as protein synthesis and nucleic acid and lipid metabolism (Anderson 1987).

In swine, feeding chromium picolinate increases lean percentage in meat and lowers fat deposition in the longissimus muscle (Xi et al. 2001). In this scenario, chromium NP may bring advantages in the use of this element as a dietary supplement because of its unique properties.

The addition of nano-chromium (200 μg/kg) to the diet for 35 days (Wang and Xu 2004) decreased the feed/gain ratio by 3.56% compared with animals fed a control diet without integration of chromium, suggesting a positive effect on growth performance. Pigs that ate the supplemented diet had an increased carcass lean percentage (14.06%), longissimus muscle area (19.96%), longissimus muscle (16.33%), and semimembranosus (14.87%) weight, while the carcass fat percentage (25.53%) and the backfat thickness (18.22%) were decreased. Simultaneously, an increment of the chromium content was found in many organs (liver, kidney, and heart) and in the longissimus muscle. These findings suggest that the dietary supplementation of 200 μg/kg chromium NP could be convenient because of the proven effect on growth performance and carcass characteristics. Nevertheless, the increase in chromium concentrations in longissimus muscle and other organs has to be taken in account for potential human health implications (Wang and Xu 2004).

3.1.2 Ruminants

Selenium plays important roles as antioxidant and in reproductive, endocrine, and immune systems. Selenium deficiency has been reported to cause white muscle disease and many other pathological symptoms (Rock et al. 2001). Since diets for ruminants are almost exclusively based on plants and selenium concentrations in plants can be extremely variable (Juniper et al. 2009), a supplementation of this element may be necessary, especially in particular geographical areas characterized by selenium-deficient soils, such as China.

The bioavailability of selenium is related to its form. Sodium selenite is the usual selenium source used as a supplement in animal feeds, while the selenium-enriched yeast is the most common organic form used. Recently, nano-selenium has gained increased attention due to its high bioavailability and low toxicity (Zhang et al. 2008). Studies have evaluated effects of elemental nano-selenium on selenium retention, growth performance, selenium concentrations in blood and tissues, and serum oxidant status of goats. The effect of feeding inorganic (0.3 mg/kg selenium as sodium selenite), organic (selenium yeast), and elemental nano-selenium on growing male goats (from weaning to maturity) has been investigated (Shi et al. 2011b). In this study, body weight was increased in bucks supplemented with selenium, with higher values detected for the nano-selenium and selenium yeast supplementations. Serum GSH-Px, SOD, and CAT and selenium retention of whole blood, serum, and organs were higher in the animals fed with the nano-selenium supplementation compared to the animals that received selenium yeast and sodium selenite as supplementation, thus demonstrating that the dietary supplementation of elemental nano-selenium could be more efficient when compared to inorganic or organic selenium (Shi et al. 2011b).

3.1.3 Chickens

Chickens reared for meat are often kept in large groups characterized by high animal densities and raised rapidly to slaughter. In this difficult farming condition, antibiotics have been used as growth promoters/feed additives because of their ability to stimulate immunity thus favoring better growth performance, but this has fostered antibiotic resistance (Wegener 2003). In the context new growth promoter research, biodegradable polymer NPs have received increased attention.

Chitosan, a nontoxic and biodegradable carbohydrate polymer, has many actions such as immuno-enhancing and antibacterial activities. Copper-loaded chitosan NPs improve growth performance and have action on microbiota in cecal digesta (Han et al. 2010). Specifically, the effects of dietary copper-loaded chitosan NP supplementation on growth performance, hematological and immunological values, and

cecal microbiota in broiler chickens have been evaluated, demonstrating that copper-loaded chitosan NP administration could enhance growth performance, immune system, and protein synthesis, as well as have a beneficial action on the cecal microbiota, especially when administered at a dose of 100 mg/kg. At this concentration, the average daily gain, the contents of IgA, IgG, IgM, and complement C3-C4, and serum protein and albumin were increased, together with populations of *Lactobacillus* and *Bifidobacterium* in cecal digesta, and importantly, the population of coliforms was decreased. The concentration of urea nitrogen in serum was also decreased. These promising results seem to indicate the copper-loaded chitosan as a possible substitute for chlortetracycline in dietary supplementation (Wang et al. 2011a).

Another element studied in chickens in its nanoform is chromium. Its trivalent (more stable) and hexavalent states are biologically active. Trivalent chromium appears to be involved in the activity of glucose tolerance factor (GTF) that facilitates cellular binding and enhances the action of insulin. Dietary supplementation of trivalent chromium decreased the negative impact of high environmental temperatures on the broiler performance (Sahin et al. 2002b). Whether chickens receive adequate supplementation of chromium or not depends on their stress status, since it has been demonstrated that stress is responsible for the depletion of the body reserves of chromium (Ahmed et al. 2005). Moreover, it should be considered that most of the poultry diets are almost entirely composed of ingredients of plant origin, which are usually characterized by low contents of chromium (Giri et al. 1990). It is already known that chromium from organic complexes (i.e., chromium picolinate) and high-chromium yeast is better absorbed compared to chromium from inorganic compounds such as chromium chloride, but recently nano-chromium was found to exhibit greater absorption and bioavailability in comparison with chromium picolinate and chromium chloride (Zha et al. 2007, 2008).

A comparative investigation on the effects of a 6-week supplementation with three different forms of chromium (nano-chromium, chromium picolinate, and chromium chloride at a dosage of 500 μg/kg) has been performed on 1-day-old male broiler chickens. The supplementation of nano-chromium and chromium picolinate was found to significantly increase the average daily gain, feed efficiency, carcass yields, and lean muscles while decreasing the abdominal fat. In particular, nano-chromium significantly increased protein content of breast and thigh muscles and decreased fat and cholesterol levels in thigh muscles. Moreover, all the chromium supplementation (nano-chromium, chromium picolinate, and chromium chloride) resulted in significant increases of chromium content in the serum, liver, and kidney with nano-chromium inducing also significant increments of chromium in breast and thigh muscles. Based on these results, it can be stated that the supplementation of chromium, particularly if used in the nanoform, may help improve the growth performance and carcass traits of broiler chickens (Zha et al. 2009), but further research is needed.

3.2 Gastrointestinal Function

3.2.1 Ruminants

Selenium, in the form of selenocysteine, plays an important role in animal nutrition as component of more than 30 selenoenzymes and acts also as an antioxidant. Several kinds of selenium sources have been used as supplements in ruminants. Despite this, little is known about the influence of nano-selenium as a ruminant nutritional supplement on ruminant metabolism and performance.

Evaluation of the effects of nano-selenium (at a dosage of 0.3, 3, and 6 g of nano-selenium/kg dry matter, for a period of 20 days) on feed digestibility, rumen fermentation, and excretion of purine was performed on ruminally cannulated sheep (Shi et al. 2011a). Mean ruminal pH and ammonia nitrogen content were quadratically decreased with increasing nano-selenium supplementation, while total ruminal volatile fatty acid concentration was linearly and quadratically increased with increasing nano-selenium supplementation. Mean ruminal pH remained in the physiologic range for cellulolytic bacterial activity with all the dosages of selenium administration. Regarding the in situ ruminal digestion kinetics of *Leymus chinensis* and soybean meal, with increase of nano-selenium supplementation, the soluble fraction, fractional degradation rate, and the effective degradability of *Leymus chinensis* were linearly and quadratically increased. Conversely, slowly degradable fraction was quadratically decreased. Likewise, nutrient digestibility in the total tract and urinary excretion of purine derivatives were quadratically increased by increasing nano-selenium supplementation. All these digestive parameters taken together indicated that nano-selenium supplementation improves rumen fermentation and thus feed utilization. It also enhanced rumen microbial activity and digestive microorganism and enzyme activity. According to this data, the optimum dose in sheep appeared to be about 3.0 g/kg dietary dry matter (Shi et al. 2011a).

Another nano-element studied for its action on rumen fermentation pattern was zinc. The in vitro effect of five levels of nano-zinc oxide supplementation, namely, 0 (control), 50, 100, 200, and 400 mg/kg of dry matter on rumen fermentation, was investigated (Chen et al. 2011). These researchers found that supplementation of nano-zinc oxide did not affect the rumen pH, but it enhanced the growth of ruminal microorganisms and increased ruminal microbial protein synthesis and the energy utilization efficiency in the early phase (6–12 h) of incubation (Chen et al. 2011). Moreover, an increase in concentrations of volatile fatty acids,

microbial crude protein production, and the fermentation of organic matter was found. Conversely, the concentration of ammonia nitrogen and the ratio of acetate to propionate were significantly lowered with the supplementation of 100 and 200 mg/kg of zinc oxide NP at the 6th and 12th hours of in vitro culture. Thus, supplementation of nano-zinc oxide may enhance the growth of ruminal microorganisms and increase the ruminal microbial protein synthesis and the energy utilization efficiency in vitro, but additional studies are needed.

3.2.2 Chickens

Nanominerals have proven to act on the cecal microbiota of chickens, with promising effects. The administration of dietary copper-loaded chitosan to broilers at dosages of 0 (negative control group), 50, 100, and 150 mg/kg and, at positive control, 50 mg/kg of chlortetracycline was compared. Nano-copper addition increased the populations of *Lactobacillus* and *Bifidobacterium*, while it decreased the population of coliforms in cecal digesta, and these effects were stronger at a dose of 100 mg/kg. Compared with the positive control, the populations of *Lactobacillus* and *Bifidobacterium* were increased by 3.31 and 3.85%, respectively, and the population of coliforms was lowered by 5.71%. The mechanism underneath the growth of *Lactobacillus* and *Bifidobacterium* is not clear, but it has been supposed that nano-copper inhibits some of microbiota establishing a better environment for proliferation of *Lactobacillus* and *Bifidobacterium* (Wang et al. 2011a). The impact on broiler immune system in this study is summarized in Sect. 5.1.

Another NP potentially useful for its gastrointestinal action in poultry is silver. The effects of low dose of silver NPs were investigated as a potential replacement for antibiotic coccidiostats. Coccidiosis is a big issue in poultry farms, since it has been responsible for poor production performance for many years. Moreover, signs of resistance development have been evident recently, raising the need for the research of new ways to control this parasite.

The effect of low-dose supplementation (15 mg/l) of silver NPs in the drinking water of broilers was evaluated as a substitute for coccidiostats. The results showed that the coccidiostat treatment group had a significantly lower weight gain compared to unmedicated controls but had the lowest lesion score of cecal lesions. The silver NP group had, numerically, a slightly better score than the untreated group, and both the silver NP group and the coccidiostat group had 50% less oocysts in the fecal samples compared to the control group. These results demonstrate that the administration of silver NPs did not alter growth performance but may be suitable to control coccidia in broiler intestines in terms of oocyst excretion (Chauke and Siebrits 2012).

3.3 Reproduction

Some NPs have been proven to enhance fertility and protect spermatozoa. The mechanisms of action are not fully understood but appear to be related to the functional groups that they carry and that characterize them.

3.3.1 Ruminants

The effects of the oral administration of nano-selenium (ration supplemented with 0.3 mg/kg selenium for 12 weeks, namely, the duration needed to reach to sexual maturity) on reproductive parameters such as testicular ultrastructure, semen quality, and semen glutathione peroxidase activity of male goats have been evaluated (Shi et al. 2011b). Findings showed a significant increase in testicular selenium levels, semen glutathione peroxidase, and ATPase activity in animals supplemented with nano-selenium compared with the control animals (fed with an unsupplemented ration which was present 0.06 mg/kg of selenium). Conversely, the nanosupplementation did not influence the semen quality parameters (volume, density, motility, and pH) although sperm abnormality rate of the control group was significantly higher than those of the supplemented group. Transmission electron microscopy examination was also performed, and while the spermatozoa from goats in the control group displayed marked midpiece abnormality, the supplemented group did not, pointing out that the selenium deficiency affected the sperm tail midpiece. Moreover, in samples from the control group, the mitochondria pattern was less tight than normal with gaps between organelles that showed also an abnormal shape and extensive vacuolation (Shi et al. 2010).

Nano-antioxidants represent a field with great potential in animal reproduction, and they could be used to prevent and treat infertility problems (Partha et al. 2016). Among nano-antioxidants, nano-zinc could be a suitable tool since it has a high antioxidant feature. Studies show that a zinc deficiency can be responsible for poor sperm quality and that this element is involved in the mechanisms that control sperm motility via its action on the ATP system involved in contraction and through the regulation of phospholipid energy reserves. In goats, zinc has also an influence on the development of the sperm tail. In this context, poor zinc supply in diets can be a discriminating risk factor for poor-quality semen and male infertility (Croxford et al. 2011; Colagar et al. 2009). In females, zinc deficiency has been reported to be responsible for high incidence of abortions and stillbirths (Campbell and Mills 1979), thus nanosupplementation of antioxidants should be investigated in order to prevent reproductive problems before and during pregnancy and after calving such as retained placenta.

The effect of different concentrations (1, 10, and 100 μg/ml) of titanium oxide NPs (size <100 nm) on buffalo spermatozoa in terms of viability, membrane integrity, capacitation ability, and DNA integrity has been examined. The results showed a significant decrease in cell viability and membrane integrity after 6 h of exposure to the titanium oxide NPs and a dose-dependent increase in the DNA fragmentation. These findings, together with the demonstration of the presence of titanium oxide NPs inside the head and plasma membrane of spermatozoa, suggest that these NPs may impair sperm functionality (Pawar and Kaul 2014).

3.3.2 Chickens

In poultry, supplemental dietary chromium picolinate increases production at low temperatures, and higher doses of chromium picolinate can increase egg production (Yildiz et al. 2004). Moreover, organic chromium supplementation, particularly at 1200 ppb, increased performance criteria and egg quality (Sahin et al. 2002a). The effects of different levels of NPs of chromium picolinate (0 ppb, 500 ppb, and 3000 ppb of nano-chromium integration for 60 days) on performance, egg quality, and mineral retention of layer hens have also been evaluated. These researchers found that supplemental nano-chromium significantly improved egg quality and retention of chromium and zinc but decreased shell ratio in 60th day eggs (Sirirat et al. 2013). Thus, feeding chromium picolinate improved egg quality in all three studies, but whether nano-chromium picolinate can be more effective at lower doses will require further study.

3.3.3 Other Animals

Several studies have shown that selenium in nanosize has better biocompatibility and efficacy in comparison to inorganic and organic selenocompounds (Wang et al. 2007). For these reasons, together with the antioxidant properties and the lower toxicity exerted by this compound, nanosized selenium is considered to be a good choice for replacing other forms of selenium in nutritional supplements.

Selenium is an important regulator of the male reproductive system in rats (Behne et al. 1982), and deficiency of this element has been associated to decreased fertility, low sperm motility, and alteration of the midpiece of the spermatozoa. These alterations are responsive to selenium supplementation, but, interestingly, they do not respond to vitamin E supplementation, highlighting the importance of this element in male reproduction in rats (Wu et al. 1979). Nevertheless, providing additional selenium sources to animals that already have adequate selenium levels and maximal selenoprotein activity (i.e., the phospholipid-hydroperoxide glutathione peroxidase of the testis) could potentially expose them to a risk of toxicosis.

The effects of the oral administration of selenium NPs (0.08, 0.2, 0.4, 0.8, 2.0, 4.0, and 8.0 mg selenium/kg body weight, for 2 weeks) on male reproductive performance of rats have been assessed. The results showed that selenium NPs administered in a supranutritional dose had a positive effect on the reproductive function of the rats. The supplementation promoted concentration, vitality, and motility parameters of spermatozoa. The concentration of serum testosterone was significantly higher in the rats that received selenium (0.8 mg selenium/kg body weight) in comparison with those in the control group. Moreover, dosages of 4.0 and 8.0 mg selenium/kg body weight significantly improved phospholipid-hydroperoxide glutathione peroxidase in the testis. Damaging effects were only observed at 8.0 mg selenium/kg body weight (Liu et al. 2017).

3.4 Reproductive and Developmental Consequences of NP Formulations

Reproductive and developmental consequences of NP formulations have to be taken into consideration, especially in breeding animals. Considering the potential reproductive toxicity of NPs, it should be underlined that the biocompatibility (and thus the toxic potential) is influenced not only by the type of material and the dosages but also by the results of the interactions of a number of complex factors. Besides chemical composition, surface, shape, and polarity, other characteristics have to be considered, such as the suspending medium that strongly influences the surface potential (SP) of the nanoparticles (Taylor et al. 2012). The effect of the SP had been well illustrated in a work by Ding et al. (2010). The SP is often referred to as zeta potential, and it is known that NPs with higher SP showed a faster cell uptake and enhanced cell nuclear targeting. On the other hand, NPs with too high SP may exert cytotoxic effects destabilizing the cell membrane and thus leading to cell damage. Specifically, an increased loss of cell viability was described after exposure cell culture (human gastric carcinoma cell line BGC 823) to gold NPs with a zeta potential of 40 mV, compared with 20 and 30 mV (Ding et al. 2010). A further effect is added by the surface modifications. Massich et al. (2010) observed a cytotoxic effect of gold NPs in the presence of citrate (a stabilizing agent used during NP production), but no cytotoxic effect was detected when other substances were used during the production process (e.g., bovine serum albumin).

3.4.1 NP Transport into Reproductive Tissues

Mammalian gametes and embryos, despite being protected by biological barriers, are highly sensitive to the effect of NPs. In fact, several studies reported that most NPs have the ability to effectively cross biological barriers including those of the reproductive tract. NP-induced disruption of the blood-testis barrier has been reported and could lead to significant

reproductive consequences. Kim et al. (2006) synthesized a biocompatible silica-overcoated magnetic NP with 50 nm thickness to use as a model of nanomaterial. Then this compound was administered intraperitoneally for 4 weeks to mice at dosages of 100, 50, and 25 mg/kg. After this period NPs were detected in testes and uterus as well as in many other organs, demonstrating that NPs of 50 nm diameter, although in this study did not show apparent toxicity, can penetrate the blood-testis barrier (Kim et al. 2006). In addition, polymethyl (2-14C) methacrylate NPs (Araujo et al. 1999) and gold NPs (Balasubramanian et al. 2010) were found in rat testes after oral and intravenous administration, respectively. Also, the toxicity of silver NPs (size of 60 nm) was studied, using rats and feeding them for 28 days with 30, 300, and 1000 mg/kg of silver NPs. Then silver distribution was investigated demonstrating that after exposure to silver NPs a clear accumulation was detected in various organs including the brain and testis (Kim et al. 2008).

Regarding the female gonads, to date, no studies have been performed to investigate whether NPs have the ability to penetrate into ovaries, but considering the abovementioned data, this possibility has to be considered. Conversely, several studies have been performed, using rodent models, to verify the ability of NPs to cross the placental barrier, but the results reported are far from conclusive. NPs were found to cross the placenta barrier in some studies (Semmler-Behnke et al. 2007; Takahashi and Matsuoka 1981), but in other studies this ability was not seen (Challier et al. 1973; Sadauskas et al. 2007). For example, in mice, 10 nm silver NPs did not appear to across the placenta in pregnant mice (Austin et al. 2016). Other in vivo studies (Takeda et al. 2009; Yamashita et al. 2011) were performed on pregnant mice proving the ability of titanium dioxide NPs to cross the placental barrier after intravenous injection with embryotoxic effects.

Taken together, these results seem to indicate that the placental barrier could be crossed by some NPs but only in certain conditions that are still unknown, so further studies should be performed to clarify the mechanisms that regulate this phenomenon particularly in farm animals.

3.4.2 Embryonic and Developmental Effects of NPs

Developmental defects in association with metallic NPs have been described. The majority of studies on embryo toxicology have concentrated on using mice and zebrafish (*Danio rerio*) embryos as a model to assess NP toxicity in vertebrates since it is an established system for NP toxicity assay (Chakraborty et al. 2016). Heiden et al. (2007) using zebrafish embryos evaluated developmental toxicity of low-generation G3,5-G4 (full-generation dendrimers are amine-terminated, while half-generation dendrimers terminate with carboxylic acid groups) Starburst™ polyamidoamine dendrimers (a highly branched peptide dendrimer), and Arg-Gly-Asp-conjugated dendrimers (dendrimers bioconjugated with selective ligands—Arg-Gly-Asp—which are produced to target cells that express integrin receptors and show potential use as drug delivery system). Their results showed that G4 dendrimers, characterized by amino functional groups, were toxic and caused decreased development and growth in zebrafish embryos at sublethal concentrations. Conversely, G3,5 dendrimers, characterized by carboxylic acid terminal functional groups, did not show any toxic effect in zebrafish embryos.

The effects and distribution pattern in zebrafish embryos of silver NPs have also been assessed (Asharani et al. 2008), with results showing a concentration-dependent increase in mortality and hatching delay in the embryos exposed to silver NPs. Moreover, abnormal body axes, twisted notochord, decreased blood flow, pericardial edema, and cardiac arrhythmia were described in embryos treated with silver NPs together with an increased apoptosis, demonstrating a concentration-dependent toxicity for this nanocompound. Conversely, silver ions and stabilizing agents did not show any significant effects on the embryos. Silver NPs were found in several embryo organs such as the brain, heart, yolk, and blood (Asharani et al. 2008).

Another target of NP toxicity in offspring is the respiratory system, as observed by Fedulov et al. (2008). Fedulov and coworkers demonstrated that neonates of mice exposed intranasally to titanium dioxide NPs at day 14 of pregnancy had a higher risk to develop airway hyperresponsiveness and allergic inflammation, thus demonstrating that allergic susceptibility was increased in prenatally exposed mice (see Sect. 4).

Effects of Embryonic Exposure to NPs in Chickens

Research in the area of nanoreprotoxicology has also been conducted on chicken embryos. In this species, the injection of NPs made of gold (Zielinska et al. 2009), silver (Sikorska et al. 2010), silver-palladium alloy (Studnicka et al. 2009), and silver-copper alloy (Sawosz et al. 2009) caused no abnormal development; only silver-copper alloy NPs caused limited signs of inflammation in the liver. An investigation performed by Hao et al. (2017) on chickens evaluated liver dysfunction at a molecular level (gene and protein expression) in offspring, after maternal oral exposure to zinc oxide NPs. Two groups were analyzed: one group fed with basal diet added with ZnSO4 (considered as the control group since ZnSO4 is a common diet additive for chickens) and one group fed with basal diet added with zinc oxide NPs. The given concentration of zinc was 200 mg/kg of feed for all the groups. It was found that zinc oxide NPs may be toxic on offspring liver development, primarily influencing lipid

synthesis, growth, and causing lesions or apoptosis. Thus, this NP should be taken into account as a possible agent of reproductive, embryonic, and developmental toxicity.

Nervous System Effects of NPs

Studies exploring embryo toxicology of NPs in mammals are less numerous than those for regarding fish and chickens (Taylor et al. 2012). However, considering titanium dioxide NPs, there are indications that point toward a nervous system toxicity after conception. Takeda et al. (2009) studied the effects of titanium dioxide NPs administered subcutaneously to pregnant mice. They observed that the titanium dioxide NPs were transferred to the offspring causing alterations in the genital apparatus and the cranial nerve systems. The presence of NPs in the offspring was confirmed in the damaged organs (i.e., brain and testis) via electron microscopy. Moreover, Shimizu et al. (2009) showed in mice that maternal exposure to anatase titanium dioxide NPs causes changes in the expression of genes associated with brain development, cell death, response to oxidative stress, and mitochondria in the brain during the perinatal period. Genes associated with inflammation and neurotransmitters are also affected, but in a later stage. Furthermore, the effects of the prenatal exposure to titanium dioxide NP on the central nervous system in mice have been investigated by measuring the levels of dopamine and its metabolites in various brain regions (Takahashi et al. 2010). It has been found that dopamine concentrations, as well as concentrations of its metabolites, were increased in the prefrontal cortex and neostriatum of the fetuses in the titanium oxide-treated group, thus demonstrating that this NP can affect the development of the central dopaminergic system in exposed fetuses.

The developmental and neurobehavioral effects of surface-coated nanosized titanium dioxide on mice fetuses, following maternal exposure by inhalation during pregnancy, were also investigated. When adults, the prenatally exposed fetuses displayed neurobehavioral alterations, tending to avoid the central zone of the open field, and exposed female offspring showed enhanced prepulse inhibition. Conversely, cognitive function was not affected. The effects of developmental exposure to titanium oxide NPs, after the oral administration in gestation, on synaptic plasticity in rats' hippocampal dentate gyrus (DG) area were also studied (Gao et al. 2011). Synaptic plasticity in this brain area is thought to be associated with determined complex functions of the central nervous system, such as learning and memory processes. Gao et al. (2011) also found that the exposed offspring showed a significant alteration of the nervous parameters of the hippocampal region, suggesting that the developmental brain is susceptible to titanium oxide NPs and that this NP may affect synaptic plasticity in this area.

Another NP, namely, silica NPs, has also been found to exert neuronal effects. Metabolic effects of silica NP exposure during neuronal differentiation in vitro were investigated. SH-SY5Y cells were exposed to silica NPs before and during differentiation; NP exposure impaired mitochondrial function depending on the time of exposure (before and during neuronal differentiation). Exposure during differentiation affected mitochondrial activity, and this may have consequences on neuronal cell differentiation (Ducray et al. 2017a), because mitochondria play a fundamental role during this process (Almeida and Vieira 2017). Specifically, neuronal differentiation results in a decreased cellular respiration rate since differentiated cells are characterized by lower glycolytic activity compared to undifferentiated cells. Moreover, it has been discovered that silica NPs were mainly taken up by microglial cells in the hippocampal cultures, but NPs were also found in differentiated SH-SY5Y cells. The uptake was time- and concentration-dependent. NP aggregates and single particles were found in the cytoplasm and in the endoplasmic reticulum, but not in other organelles. Although NP exposure did not impair cell viability, the neuronal differentiation markers indicated again a reduction in neuronal differentiation induction after the exposure (Ducray et al. 2017b). Based on these studies, NP exposure embryonically clearly has neurological effects on offspring, but how embryonic exposure to various NPs affect behavior in farm mammals will require further study.

3.4.3 Effects of NPs on Sperm Function

As mentioned earlier (Sect. 3.3.1), some NPs, such as titanium oxide, are spermatotoxic exerting a cytotoxic effect and causing high amount of DNA fragmentation on buffalo spermatozoa, impairing sperm functionality (Pawar and Kaul 2014). Other studies on sperm toxicity were conducted on NPs obtained from titanium (mice; Miura et al. 2017; rats; Morgan et al. 2017), nickel (marine invertebrates; Gallo et al. 2016), gold (mice; Zakhidov et al. 2010), polyvinyl alcohol-coated iron oxide (bovine; Makhluf et al. 2006), europium dioxide and europium hydroxide in conjunction with polyvinylpyrrolidone and polyvinyl alcohol (bovine; Makhluf et al. 2008), and zinc oxide and titanium dioxide (human; Gopalan et al. 2009). Polyvinyl alcohol-coated iron oxide did not show any detrimental effect on spermatozoa, while zinc oxide NPs and titanium oxide NPs caused sperm damage. Nickel NPs induced oxidative stress causing lipid peroxidation and DNA fragmentation and altered mitochondrial membrane potential and sperm morphology. Moreover, sperm exposure to nickel NPs impaired the fertilizing ability and caused developmental anomalies in the offspring. Very small gold NPs (2.5 nm diameter) caused failure of chromatin decondensation process, probably due to an interaction with

molecules of double-helix DNA. However, none of these studies investigated the mechanisms of action of the various NP sperm toxicity, and thus further investigations are needed.

Toxicity studies using silver, molybdenum trioxide, and alumina NPs were performed on mouse spermatogonial stem cells (Braydich-Stolle et al. 2005, 2010). A concentration-dependent cytotoxicity for all the NPs was found, with AgNP being the most toxic. In its case, the toxicity is probably due to interactions of NPs with a cell proliferation associated, intracellular kinase. Using mice's whole testicular cell cultures, Asare et al. (2012) reported decreased cell metabolic activity and cell viability after 24–48 h exposure to 100 μg/ml of 20 nm silver NPs. Whether these effects would be realized in farm animals will require further study.

3.4.4 Effects of NPs on Oocyte Function

Nano-toxicity in oocyte maturation has only been investigated in a few studies. In a research by Hou et al. (2009), rat preantral follicles were cultured in the presence of titanium dioxide NPs, and the effect on follicle development and oocyte maturation was observed. The follicle survival rate, the formation rate of antral follicles, and the release rate of cumulus-oocyte complexes decreased with increased titanium dioxide NP concentration in the culture medium (12.5, 25, and 50 μg/ml), whereas the same medium added with dioxide microparticle did not show detrimental effects on follicles, thus demonstrating that the toxicity is related to the nanodimensions.

Another combined in vivo and in vitro study (Hsieh et al. 2009) evaluated the effect of CdSe core quantum dots on mouse oocyte maturation, fertilization, and the subsequent embryo development (pre- and post-implantation). The CdSe core quantum dots caused a significant reduction of the oocyte maturation, fertilization, and in vitro embryo development rates, but this did not occur when the CdSe core quantum dots were ZnS-coated; thus, this surface modification was able to prevent the cytotoxic effect. Moreover, when oocytes were in vitro matured with a concentration of 500 nM CdSe core quantum dots to the maturation medium, the post-implantation resorption increased, while placental and fetal weights decreased. In addition to the action due to direct NP administration to animals, NP accumulation in the environment caused by the latest increase use of these products in many fields, must be considered and regarded as a possible future issue, which could have a great impact on veterinary species.

4 Anti-inflammatory Activity

Disease prevention potential of dietary supplements (i.e., polyphenols) has raised great attention in recent years, and many studies both in vitro and in vivo have been performed in animals and humans. In this context, a wide range of biological activities has been reported for polyphenols, ranging from anticancer and antioxidative effects to activities related to the prevention of chronic diseases.

There are challenges related to the use of polyphenols and in particular curcumin, a water-insoluble molecule extracted from the turmeric plant *Curcuma longa*, as a dietary supplement. These issues are primarily related to the scarce solubility of this molecule that impairs its oral bioavailability. Thus, different size of high-speed and high-pressure homogenated oil (medium-chain triacylglycerols)-in-water nanoemulsions were used to encapsulate curcumin to improve its anti-inflammatory activity, and the effects were evaluated using a mouse ear inflammation model. The results proved that, compared to 1% curcumin in 10% Tween 20 water solution, 1% curcumin emulsions had a greater anti-inflammatory effect showing a stronger inhibition on ear edema. Moreover, this effect was enhanced when the emulsion droplet size was smaller than 100 nm (Wang et al. 2008).

The oral bioavailability in mice of three different chitosan polymers used to produce curcumin nanocapsules has also been investigated (Marin et al. 2017). The chitosan polymers, characterized by high muco-adhesive capacity and safety (Wang et al. 2011b), differed in terms of molecular weight and degree of deacetylation (Marin et al. 2017).

Curcumin-loaded nanocapsules were given orally at a dose of 25 mg/kg. Interestingly, the bioavailability of curcumin nano-formulated was ninefold higher compared with those of the non-formulated curcumin (curcumin suspensions). Moreover, nanocapsules could cross the blood-brain barrier (BBB). Regarding the distribution of a curcumin nano-formulation, it has been observed that curcumin-loaded poly(lactic-co-glycolic acid) NPs, administered intravenously to rats, are distributed to the liver, heart, spleen, lung, kidney, and brain. Moreover, nano-formulation proved to significantly increase the AUC (area under concentration—time curve), the half-life, and the mean residence time of curcumin in all these organs, but not in the heart (Tsai et al. 2011).

5 Immunity

Feeding nano-zinc to livestock and poultry has produced encouraging immunity responses, since it has been observed that nano-zinc enhances the immunity of the animals.

5.1 Chickens

Supplementation of nano-zinc (at a dose of 0.06 ppm) is effective in improving immunity status of broilers (Sahoo et al. 2014). The effects of different types of zinc

supplementations on broiler chickens (15 ppm inorganic zinc, 15 ppm and 7.5 ppm organic zinc, and 0.3, 0.06, and 0.03 ppm nano-zinc) have been investigated. The cellular immune response was assessed by cutaneous basophilic hypersensitivity (CBH) test in using PHA-P (phytohaemagglutinin phosphate), while the humoral immune response was tested by the antibody production in response to sheep red blood corpuscles (SRBC) injection.

Significantly higher titer levels were observed in the groups fed with 15 ppm organic zinc and 0.06 ppm nano-zinc when compared to the group fed just with basal diet without zinc and to the group which had the inorganic zinc supplementation, while the CBH response was found higher in the group supplemented with 15 ppm of organic zinc. The antibody titer response to SRBC was significantly greater in the groups that received the organic zinc integration at a dose of 15 ppm and in those that received the nano-zinc integration at a dose of 0.06 ppm. The percent weight of bursa was significantly higher in the group that received the nano-zinc (dose of 0.06 ppm). In summary, dosages of 0.06 ppm nano-zinc added to the basal diet improved the immunity and health status of the broiler birds.

Another nanomineral tested in poultry regarding the immunity effect is copper. In several in vitro studies (Małaczewska 2014), copper NPs have been shown to have an immunotropic effect. In this matter, an in vivo study was performed by Ognik et al. (2018). They employed 308 male chickens raised until the age of 42 days and divided into groups that received basal diet with no copper integration and nano-copper supplementation at a dose of 0.5 mg/kg body weight/day and 1.5 mg/kg body weight/day. The correction of the deficient basal diet of chickens with a quantity of nano-copper exceeding the National Research Council (NRC) recommendation (National Research Council 1994) by 54% led to an increased antioxidant potential of the body and inhibited lipid peroxidation, and when the supplementation of nano-copper rose the total copper intake to a level exceeding the recommendation by 96%, signs of deterioration of the antioxidant system started to emerge with a decreased level of glutathione plus glutathione disulfide and increased levels in SOD, CAT, ceruloplasmin activity, and lipid hydroperoxide content. Conversely, an increase of just 7% over recommendations was followed by a deterioration in red blood cell parameters and stimulation of the immune system with an increase of IL-6, IgA, IgM, and IgY. These results, taken all together, indicate a simultaneous enhancement of the antioxidant system, and immune defense of chickens is achievable by supplementing their diet with nano-copper up to 12 mg/chicken in a period of 6 weeks.

Another NP evaluated in poultry in attempt to enhance the immunity was copper-loaded NPs. Diet supplementations were administered to broilers at dosages of 0, 50, 100, and 150 mg/kg of copper-loaded chitosan NPs, and the results were compared with those obtained feeding the animals with diets supplemented with chlortetracycline as positive control. Immune organ indexes (the thymus, spleen, and bursa of Fabricius) in broilers given dietary supplementation of 100 mg/kg of copper-loaded chitosan NPs were increased by 31.27, 22.64, and 19.61%, respectively (all statistically significant), compared to the control group. Moreover, the nano-copper administration increased the concentrations of immunoglobulins, complements, and lysozyme in serum, and, compared with the control group, the supplementation of 100 mg/kg significantly increased the serum concentrations of IgA, IgG, IgM, C3, C4, and lysozyme. Notably, the concentrations of IgA and C3 in broilers that received 100 mg/kg of copper-loaded chitosan NPs were significantly higher than those in the broilers receiving 50 mg/kg of chlortetracycline in the diet (Wang et al. 2011a).

5.2 Other Animals

The effects of the nanocomposite magnesium and silicon oxide (MgO-SiO2) on the immunity and tissue alterations of adult male rats exposed to aflatoxin B1 (AFB1) have been evaluated (Essa et al. 2017). Exposure to aflatoxin-contaminated feeds can cause the suppression of the cell-mediated immune responses, affect the function and count of T-lymphocytes, suppress the phagocytic activity, and impair the complement activity in many species such as poultry, pigs, and rats (Marin et al. 2002; Ottinger and Kaattari 2000; Cusumano et al. 1990). In this regard, the efficacy of the nanocomposite magnesium oxide and silicon oxide (MgO-SiO2) in reducing the toxic effects of AFB1 on the immunity and histological alterations has been tested in rats (Essa et al. 2017). The animals were divided into four groups: group 1 (control group; not fed AFB1 or the nanocomposite), group 2 was fed contaminated feed (200 ppb AFB1), group 3 was fed 200 ppb AFB1 and 0.5 g/kg nanocomposite of MgO-SiO2, and group 4 was fed only 0.5 g/kg nanocomposite of MgO-SiO2. The experiment lasted 8 weeks.

Rats fed MgO-SiO2 nanocomposite supplement exhibited significantly reduced AFB1 contents in the serum and liver. Conversely, the feces content was significantly increased indicating that MgO-SiO2 NPs affected the absorption of AFB1 causing an increased fecal excretion. The latter observation suggests that the dietary supplementation of MgO-SiO2 nanocomposite may offer a good protection against the toxic effects of AFB1 by preventing its absorption because of its absorbent capacity and the higher surface reactivity compared to traditional (non-nanosized) commercial products. Moreover, the cellular immune response, the total and differential leukocytic counts, the phagocytic activities of neutrophils and macrophages, the lymphocyte

transformation, and the lysozyme activity were severely reduced in group 2 fed with diet added with 200 ppb AFB1 compared to group 3 fed with the AFB1-contaminated fed but supplemented with the nanocomposite MgO-SiO2. These further suggest that supplementation with NPs of MgO-SiO2 can indirectly mitigate AFB1 effects by preventing AFB1 to act on the immune system.

In summary, the nanocomposite of MgO-SiO2 at a dose of 0.5 g/kg feed could be considered an effective adsorbing agent for AFB1, because of its ability to prevent the development of severe toxic effects on immunity and organs in rats. It should also be considered that it is an inexpensive and accessible feed additive that can be a useful tool, especially in hot, humid tropical and subtropical climates, for the prevention of aflatoxicosis in animals.

6 Risks and Challenges

Because of the great and rapid increase in interest in NPs both in human activities and veterinary and human medicine, regulatory ecotoxicity testing of these types of chemicals is becoming an issue of fundamental importance for our contemporary society, and great efforts have been made at the OECD to ensure that OECD test guidelines (TGs) fit the nanomaterials. In this context, the project MARINA (http://www.marina-fp7.eu/) has been born to develop and validate the Risk Management Methods for Nanomaterials. Eight OECD TGs were adapted in order to cover the two main variants of NPs, such as the ion-releasing and inert NPs. Thus, guidelines were developed to test a minimum of one ion-releasing NP (Ag) and two inert NPs (TiO2) (Hund-Rinke et al. 2016). Because standardized toxicity testing can underestimate the ecotoxicity, other factors such as exposure and resource availability may be needed to be considered to correctly estimate the effect of a toxicant (Stevenson et al. 2017).

7 Concluding Remarks and Future Directions

Nanotechnology has great potential for widespread applications in veterinary science including drug and vaccine delivery and diagnostic imaging. However, a balance between safety and effectiveness and risk and benefit will be mandatory including considerations of NP accumulation in the environment. Future in vitro and in vivo research studies will play a key role in developing the use of this technology in veterinary medicine as well as directing its correct and conscious use, which implies, in a one health perspective, the protection of animals, humans, and the environment.

Adsorption, distribution, mechanism of action, pathway of toxicity, and possible adverse effects on a species-specific basis need to be clarified for nanomaterials and NPs. Information regarding effects of NPs on farm animal metabolism and reproductive function are scarce and more need to be conducted. Also, studies using microarray technology will aid in discovering novel genes involved in the process of cellular functions (Türkez et al. 2017). Moreover, the real goal for veterinary nanotechnology is to have a positive impact in veterinary profession and to be useful for practitioners, as well as positively influencing animal healthcare.

Veterinary Nutraceuticals Stability Testing

Dan DuBourdieu

Abstract

Nutraceuticals have gained increasing importance in veterinarian use over the past 30 years. However, the stability of many of these nutraceuticals is a challenge to manufacturers to maintain over a 2-year shelf life. Factors that affect nutraceutical stability include environmental conditions, chemical instability, matrix interactions, packaging, and other issues. Certain nutraceuticals, such as glucosamine sulfate, have very short stability in finished products, whereas others, such as chondroitin sulfate, are very stable. Testing nutraceuticals involves monitoring them under real-time and accelerated conditions to determine how much they will degrade. The strategies that companies use to increase the stability of nutraceuticals involve quality by design, encapsulation methods, and advances in packaging techniques.

Keywords

Veterinary nutraceuticals · Nutraceutical stability · Nutraceutical testing

1 Introduction

Nutraceuticals have gained increasing prominence for veterinary use over the past 30 years and have turned into a billion-dollar industry. This trend reflects a shift in the mind-set of manufacturers, veterinarians, and animal owners. Rather than relying solely on medicinal or drug products for the prevention and treatment of diseases, nutritional alternatives for both disease management and health promotion are readily available in conventional pet foods as well as individual supplements. This trend comes from a highly regulated environment of drugs where manufacturing is tightly controlled and where the stability of active ingredients is completely known in finished products. However, the nutraceutical manufacturing environment is currently not as controlled as the drug manufacturing environment. Expiration dates are not required on nutraceutical labels from a regulatory standpoint in the USA. This has led to justifiable concerns about the stability of shelf life of nutraceuticals used in both the human and veterinary arenas and the concern whether the nutraceutical is still effective. The primary reason for stability testing is the concern for the well-being of the animal suffering from the disease for which the product is designed. A second important concern is to protect the reputation of the manufacturer by assuring that the product will retain fitness for use with respect to all functionally relevant attributes for as long as they are on the market. As such, manufacturers, veterinarians, and pet owners wish to know whether the nutraceuticals that are being used are stable and will still be efficacious, even 2 years or longer after the date of manufacture.

Stability testing of nutraceutical products is a complex set of procedures involving considerable cost, time, and scientific expertise in order to build in quality, efficacy, and safety in a nutraceutical formulation. The most important steps during the developmental stages of a nutraceutical ingredient include the actual ingredient analysis and stability studies that are required to determine and assure the identity, potency, and purity of ingredients, as well as those of the formulated products (Bajaj et al. 2012). Stability/shelf life for a drug or nutraceutical can be defined as the capacity of that substance or product in a specific container-closure system to remain within established specifications to maintain its identity, strength, quality, and purity throughout the retest or expiration dating periods. Stability testing thus evaluates the effect of environmental factors on the quality of the nutraceutical substance or a formulated product which is utilized for prediction of its shelf life, to determine proper storage conditions, and for suggested labeling instructions. Moreover, the data generated during stability testing is an important requirement for the manufacturer to have to properly use.

In the USA, approximately 90% of veterinarians sell some type of novel ingredient such as nutraceuticals. Close to 30% of pet owners have used or considered the use of novel ingredients such as nutraceuticals and herbs/botanicals in their animals. Consumers often look for expiration dates on products, but US federal regulations do not currently require expiration dating for nutritional supplements. Manufacturers would like at least a 2-year stability on their nutraceutical products if possible, meaning that the listed "active" ingredients on the label will still be able to meet the label claim if retested at 2 years post manufacturing. The best a consumer can do is examine the label for date of manufacturing and hope that the product will be stable for at least 2 years, following proper storage. However, manufacturers, veterinarians, and consumers should be aware that not all nutraceuticals may meet this label claim.

2 Factors That Affect Stability of Nutraceuticals

There are a number of issues that can affect the concentration and stability of nutraceuticals in their raw and finished formats. These include environmental conditions, chemical instability, matrix interactions, packaging, and other intangible issues. A nutraceutical product may undergo change in appearance, consistency, content uniformity, clarity (solution), moisture content, particle size and shape, pH, and package integrity, thereby affecting its stability. Such physical changes may be because of impact, vibration, abrasion, and temperature fluctuations such as freezing, thawing or shearing, etc. Chemical reactions like solvolysis, oxidation, reduction, racemization, etc. that occur in the nutraceutical products may lead to the formation of degradation products, loss of potency of active nutraceutical ingredient, and loss of excipient activity like antimicrobial preservative action and antioxidant activity. Stability of a nutraceutical product can also be affected because of microbiological changes like growth of microorganisms in non-sterile products and changes in preservative efficacy. For details, see Fig. 1.

One source of problems for nutraceutical stability is the starting raw material itself, such as actives from plants. Plants

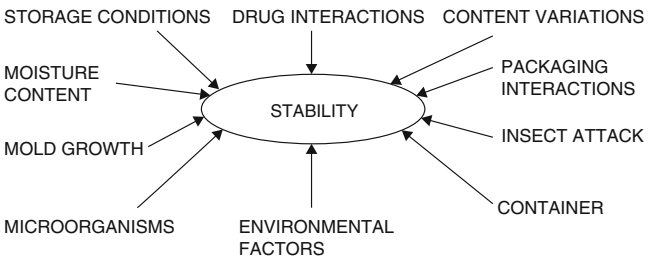

Fig. 1 Factors affecting nutraceutical stability

containing nutraceutical actives are collected or harvested either from cultivated sources or wild sources at certain times of the year and then are typically dried. The plant material then goes through a garbling step to remove extraneous matter such as dirt or non-desired plant parts or other adulterants. This should be done before it is baled or packaged. These raw materials can then be processed further to partially or more fully purify a particular active compound (i.e., the specific nutraceutical) of interest. For many botanical and herbal nutraceuticals, environmental conditions such as rainfall, altitude, temperature, soil, and storage conditions as well as different harvesting procedures; time and method of collection; manufacturing processes such as selecting, drying, purifying, and extracting; and genetic variability can create substantial variability in the product quality and stability and in the concentration of plant chemicals within different products. Nutraceuticals derived from animals or other sources parallel the same basic issues as the collection of plant-based nutraceuticals.

Phyto-formulations often suffer degradation during storage via oxidation, hydrolysis, crystallization, emulsion breakdown, enzymatic deterioration, and chemical reactions with the additives and excipients. Each ingredient, whether therapeutically active or inactive, in a dosage form can affect stability. Temperature and moisture are the two major factors that affect quality and stability of most herbal products. A chemical reaction increases by 2–3 times for every 10 °C rise in temperature. Moisture absorbed on to the surface of a solid nutraceutical often increases the rate of decomposition if it is susceptible to hydrolysis. The presence of enzymes in the product also increases the rate of chemical degradation. Light is also a prominent factor affecting phyto-formulations by generation of free radicals. The environmental factors of oxygen and carbon dioxide can affect stability. Similarly, factors such as particle size, pH, the properties of water and other solvents employed, the nature of the container, and the presence of other chemicals resulting from contamination or from the intentional mixing of different products can influence stability. Nutraceuticals derived from animal sources are also affected by these chemical and physical reactions. Table 1 demonstrates the susceptibility of those vitamins typically found in various nutraceutical preparations to several external factors.

Many herbal formulations are complex mixtures of different components obtained during an extraction process. This is not surprising since the efficacy of many plant-based nutraceuticals is not based on a single pure compound such as drug might be, but rather the efficacy is from groups of compounds in the plant. Each component has variable shelf life, activity, concentration, and consistency. This creates a problem during storage condition determination as it is not easy to determine the stability of the final herbal preparation based on the activity and stability profile of a single

Table 1 External factors that affect vitamin stability

component. However, most manufacturers will base any stability label claims from a single compound due to the complicated and costly nature of the analytical work required to get at least some sort of stability measurement.

Moisture content above a critical value and mold growth in natural products can cause an interaction of the active components with the packaging material. Natural medicines and nutraceuticals often suffer physical instability due to the presence of impurities and reaction with the container. Conditions like the growth of microorganisms and insect feeding affect the secondary metabolites and chemical composition of plants. Volatile active components of natural medicines and nutraceuticals have a problem of volatility and decreasing activity following long-term storage. Interactions of active components with other ingredients of formulations, such as additives, cause alteration in the novel drug activity. Herbal formulations have many active constituents, such as alkaloids, glycosides, tannins, flavonoids, etc., and each component will have different stability conditions. Therefore, actual stability conditions for the herbal formulation are different than for its individual components.

Packaging of the final product also has great bearing on the stability of the nutraceutical. Whether the packaging does not allow moisture, light, or air to reach the nutraceutical and whether the packaging has any kind of ability to moderate temperature will greatly affect the overall stability of the final product.

3 Categories of Nutraceuticals and Their Stability

There are many types of nutraceuticals. Each of these has their own inherent stability, and manufacturers have to be aware that some are going to be more stable than others for the particular matrix that the nutraceutical is delivered in. The top categories of supplements used in veterinary situations include joint protectants, antioxidants, fatty acids with anti-inflammatory ability, and probiotics.

The joint protectants that are commonly used include glucosamine, chondroitin sulfate, and methylsulfonylmethane. Some of these ingredients are not very stable. For example, glucosamine is not a stable compound in its free-base form. It is known to degrade quickly in aqueous solutions (Hrynets et al. 2015). There are numerous more stable forms of glucosamine available to consumers. These different forms include glucosamine sulfate, glucosamine hydrochloride, and *N*-acetyl-glucosamine. These different chemicals have some similarities. However, they may not have the same effects when taken as a dietary supplement, nor the same stability. From the results presented in Table 2, it is clear that glucosamine sulfate is a particularly unstable substance since it is readily oxidized and strongly

Table 2 Glucosamine sulfate stability at different temperatures and humidity

360	40.4	84.1	–

Table adapted from Senin (1987)

hygroscopic. The conditions under which it is kept are clearly very important (particularly the ambient relative humidity) and must be rigorously controlled. Only at temperatures less than 15 °C, with a relative humidity not greater than 30%, can a stability of about 4–5 months be obtained, while at 25 °C, under the same conditions of relative humidity, signs of degradation are shown even after about 60 days. Further, if the conditions of temperature and humidity are such as to be considered normal (25 °C and 60% relative humidity), the first signs of degradation appear even after 4 h, and the glucosamine sulfate is completely decomposed after just 36 h (Senin 1987). It is known that glucosamine salts destruct in solutions to 5-hydroxymethylfurfural (Shu 1998; Kompantsev 2012).

On the other hand, glucosamine hydrochloride is more stable than the sulfate form at an acid pH, and degradation begins when the temperature reaches 190 °C. Consequently, it is more stable under conditions of pasteurization and at an acid pH. Its stability in foods has been studied (EFSA 2009). For example, in lemonade and 100 % juice held at 100 °C for 5 min, there is a 100% recovery of glucosamine. Similarly, there is 100% recovery in isotonic drinks at pH 3.0, juice at pH 3.0, and "fitness water" at pH 2.9, all held at room temperature for 9, 24, and 17 months, respectively. However, the stability of glucosamine HCl in finished products of solid matrices such as tablets will still be dependent on the amount of moisture, pH, and temperature that the finished product has been subjected to. It is expected that degradation will have occurred since the date of manufacture in most products to a degree. While the amount may still meet label claims after 2 years, it will depend on the particular product. Unfortunately, there is no simple way to tell from the label, unless testing occurred on the finished product at 2 years past the manufacturing date and that information is stated somewhere. Fortunately, manufacturing groups will continue to research ways to further stabilize glucosamine in finished products.

The stability of chondroitin sulfate (CS) used in joint products has a much better track record for stability than glucosamine. CS raw material held at room temperature has little degradation over a year (Fig. 2). CS has been studied under acidic, neutral, and basic conditions at 30 and 60 °C, and CS is remarkably stable under neutral conditions at low temperature. However, it degrades at 60 °C, producing low-molecular-mass fragments and desulfated products (Volpi et al. 1999).

Methylsulfonylmethane (MSM) is an organosulfur compound having a sulfonyl functional group that is often used in joint products. It occurs naturally in some plants and is used in disease related to chronic pain, inflammation, and arthritis. MSM appears to be fairly stable due to its ability to withstand high temperatures (Trivedi et al. 2015). The shelf life of MSM can be 5 years in pure preparations according to manufacturers.

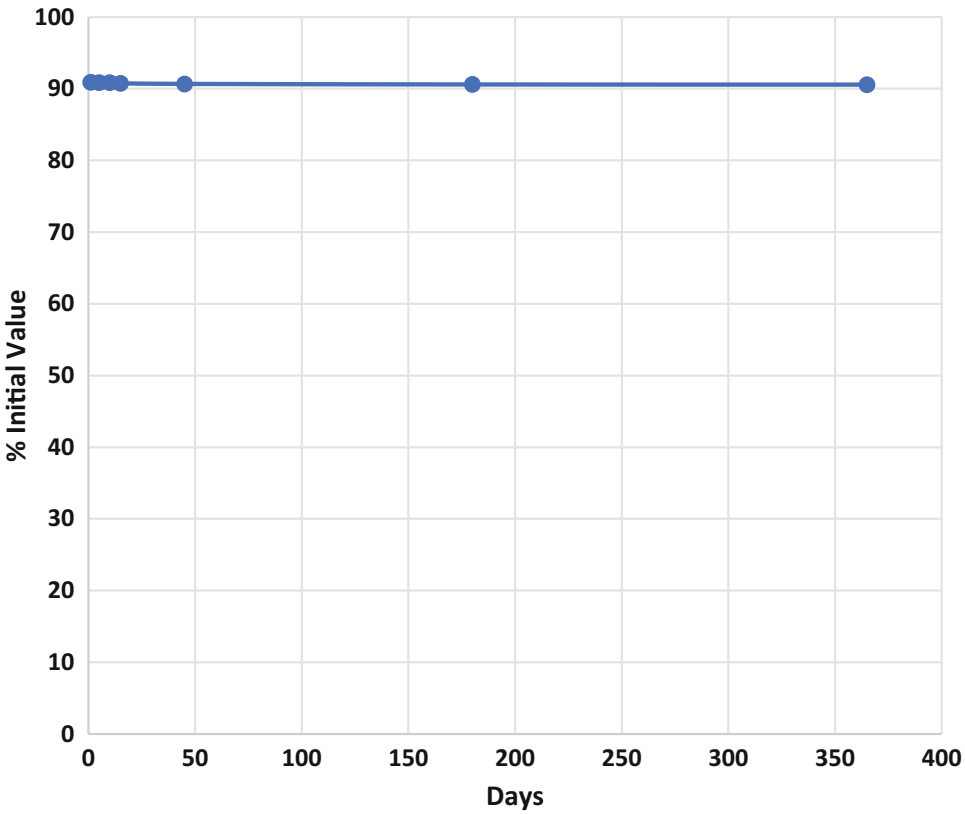

Fig. 2 Stability of chondroitin sulfate at room temperature

Antioxidants refer to a heterogeneous group of compounds that prevent free radical damage to cell membranes, proteins, and DNA. They are beneficial in inflammatory diseases, aging, and certain cancers. Common antioxidants used as supplements in food or direct oral intake include vitamins E and C (ascorbic acid), various bioflavonoids found in plants, and carotenoids such as astaxanthin found in marine life. Many of these antioxidants have poor long-term stability and therefore a shortened shelf life of the finished products. Analytical work has shown (Oyetade et al. 2012) that packaging materials, exposure to air, storage temperature conditions, and matrix type can significantly affect the stability of vitamins that have been used as antioxidants. A significant negative correlation exists between ascorbic acid decline, which depends on the storage temperatures, and matrix type as seen in Table 3 (table adapted from Oyetade et al. 2012). Ascorbic acid content was more stable when stored under refrigeration.

The stability of other individual vitamins in premixes and finished feeds varies according to a number of factors (Table 4).

Minerals are more resistant to manufacturing processes than vitamins. Minerals are naturally occurring fundamental substances that maintain proper bone health and the nervous and the muscular system and have the ability to assimilate nutrients. However, they do undergo changes when exposed to heat, air, or light. Minerals such as copper, iron, and zinc are also affected by moisture and may react with other matrix components such as proteins and carbohydrates. Various forms of iron are used in fortification. Among the most popular are ferrous sulfate and elemental iron powders because of their relatively high bioavailability. Other potential iron sources include ferric orthophosphate, sodium iron phosphate, ferrous fumarate, and iron-EDTA. The stability of different forms of iron depends on various factors, including the nature of the final nutraceutical product that it is added to, particle size, and exposure to heat and air (Table 4).

Proteins, such as enzymes, possess greater biochemical and structural complexity compared to most single active ingredients used in nutraceutical products. Thus, the formulation and delivery of proteins and enzymes into stable, well-characterized, and efficacious nutraceutical products represent significant challenges to the formulator. Tablets are a suitable dosage form for application of these materials as they provide ease of administration, metering accuracy, robustness, good stability, and efficient production. However, simple compression of a bulk material, either powder or granular, to a robust tablet is dependent on a great number of influences, mainly compression force, particle deformation, and formation of adhesive forces. Therefore, the physical and chemical properties of proteins and enzymes can be influenced by formulation and technological factors, such as excipients, temperature, storage conditions, compression, or shear forces (Manning et al. 1989).

There has been a surge in clinical evidence regarding the therapeutic benefits of probiotic bacteria including *Lactobacillus*, *Bifidobacteria*, and *Enterococcus* species to gut health and a growing commercial interest in food and/or nutraceutical applications of these bacteria (Park et al. 2016). One beneficial effect of probiotics on human and animal gut flora is the restoration of impaired intestinal barrier function. Regular intake of probiotic strains stimulates the growth of preferred microorganisms, crowds out potentially detrimental strains, and reinforces the natural defense mechanisms. However, the formulation of probiotic bacteria along with other ingredients, or even alone, in a stable dosage form is hampered by their extremely poor viability during the preparation process and/or storage period. The majority of microorganisms generally exhibit extreme liability to oxygen, temperatures, low pH, and additives (Kailasapathy and

Chin 2000). Moreover, the viability of living bacteria in gastric fluid is rather poor. Few of them exhibit resistance to adverse environmental conditions to colonize the mucosal membrane of the small and/or large intestine. To help overcome these stability problems, enteric coating techniques have been explored in order to protect living bacteria from the unfavorable interaction within the dosage form and adverse gastrointestinal environments (pH, enzymes, bile salts, etc.) and to deliver bacteria to the intestine of animals. For example, *L. acidophilus* and *Enterococcus faecalis* were coated (encapsulated) and imbedded in tablets and compared with corresponding bare bacteria, the uncoated bacteria, in tablets under ambient storage conditions (25 °C/60% relative humidity) for 6 months (Fig. 3). The particular coating procedures clearly helped maintain stability and viability of the bacteria (Park et al. 2016).

Omega-3 long-chain polyunsaturated fatty acids including EPA and DHA are substances with a range of important structural and regulatory functions in animal physiology. Deficiencies in their dietary intake and tissue levels are related to chronic disease susceptibility. Omega-3 fatty acids have been shown to be beneficial in dogs with atopic dermatitis, pruritis, lymphoma, arthritis, and chronic valvular disease. The National Research Council has recognized omega-3 fatty acids as an essential nutrient for dogs and cats. As such, a substantial number of finished products are produced with EPA-/DHA-containing oils derived from marine sources, notably from anchovy and cod liver. Other sources, such as purposefully grown microalgae, are of growing importance. Preparing solid formulations, such as powder and tablets, that contain omega-3, can be challenging as the necessary production processes expose the unsaturated omega-3 fatty acids to high temperatures, light, and mechanical stress in the presence of air. When added to laboratory rodent formulations, these fatty acids are subject to rapid and/or extensive oxidation and other chemical changes by exposure to air, light, or heat during processing of pellets or when stored for various lengths of time (Lytle et al. 1992). Under ambient and real-life conditions, the absolute oxidative stability of EPA-/DHA-containing oils cannot be achieved, but it can be slowed down considerably by limiting the exposure to air and by reducing the rates of peroxidation and additional reactions secondary to primary oxidation, for example, by maintaining sufficiently high concentrations of reduced antioxidants and by limiting exposure to predisposing factors such as heat and light (Bannenberg et al. 2017). The use of encapsulation technology for fatty acids can help delay degradation, as well as enhance stability.

4 Stability Testing Methods

Stability testing is a routine procedure performed on nutraceutical substances and products and is employed at various stages of product development (Mehta 2009). In the early stages, accelerated stability testing (at relatively high temperatures and/or humidity) is used to determine the type of degradation products which may be found after long-term storage. Testing under less rigorous conditions (i.e., those recommended for long-term shelf storage) at slightly elevated temperatures is used to determine a product's shelf life and expiration date. The major aim of nutraceutical stability testing is to provide reasonable assurance that the products will remain at an acceptable level of fitness/quality throughout the period during which they are available for supply to the animal and will be fit for their consumption until the patient uses the last unit of the product.

Real-time stability testing is the best way of establishing accurate values. In real-time stability tests, a product is stored at recommended conditions and tested/monitored for the period of time in the packaging that the nutraceutical product is intended to be marketed in. However, real-time testing is very time consuming and can take years to complete. Real-time stability testing is normally performed for a longer duration of the test period to allow significant product degradation under recommended storage conditions. The long-term test storage conditions usually are 25 ± 2 °C/60 ± 5% relative humidity (RH) in stability chambers. These are

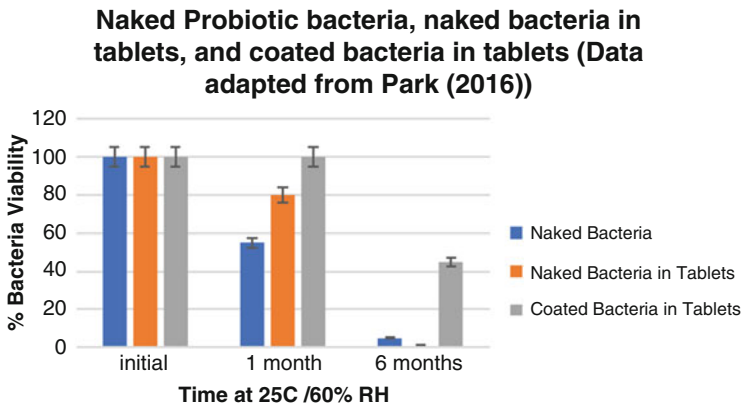

Fig. 3 Coated probiotic bacteria stability in tablets

specialized environmental chambers that can simulate storage conditions and enable evaluation of product stability based on real-time, accelerated, and long-term protocols. Samples also should be kept refrigerated long term at 5 °C and frozen long term at –20 °C to see what happens to the product when cooled or frozen and then thawed.

It is always recommended to follow the procedures given in official compendia if possible for any particular nutraceutical, as results obtained using the official tests in general find better acceptance. If alternate methods are used, they are required to be duly validated. However, assay of the nutraceutical should be carried out using a stability-indicating method, established by carrying out stress tests on the nutraceutical under forced decomposition conditions. This method should be validated for specificity, accuracy, precision, and linearity, in the range within which the nutraceutical is expected to fall during stability studies. For the assay of degradation products, the validated method should also include the limits of detection/quantification. The methods reported in literature should be used after confirming reproducibility and carrying out minimal validation of linearity, range, etc. All analytical methods are required to be validated before initiating the stability studies. Similarly, the acceptance criteria for analytical results, as well as that for the presence of degradation products, should also be fixed before doing the assays. These acceptance criteria should also include individual and total upper limits for degradation products.

The test period depends upon the stability of the product. This period should be long enough to indicate clearly that no measurable degradation occurs and must distinguish degradation from inter-assay variation. During analysis, data is collected at an appropriate frequency such that a trend analysis is able to distinguish instability from day-to-day ambiguity. Frequency of testing should be such that it is sufficient to establish the stability profile of the new nutraceutical substance. For products with a proposed shelf life of at least 24 months, the testing frequency at long-term storage conditions should be every 3 months over the first year, every 6 months over the second year, and annually thereafter through the proposed shelf life expiration date, if such a date is going to be put on the label. Stability studies at developmental stages are generally carried out on a single batch, while studies intended for registration of new product or unstable established product are done on the first three production batches. In general, the selection of batches should constitute a random sample from the population of pilot or production batches. The reliability of data interpretation can be increased by including a single batch of reference material for which stability characteristics have already been established. Stability of the reference material also includes the stability of reagents, as well as consistency of the performance of the instrument to be used throughout the period of stability testing. However, system performance and control for drift and discontinuity resulting from changes in both reagents and instrumentation must be monitored.

Since manufacturers typically are not going to wait 2–3 years before launching a nutraceutical product, an accelerated stability testing program is used concurrently with real-time studies. In accelerated stability testing, a product is stressed at several high (warmer than ambient) temperatures, and the amount of heat input required to cause product failure is determined (Fig. 4). Accelerated conditions of 40 ± 2 °C/75 ± 5% RH is commonly used as well as minimum of three time points, including the initial and end points [0, 3, and 6 months is recommended (Magari 2003)].

Accelerated stability testing is done to subject the product to a condition that accelerates degradation. This information is then projected to predict shelf life or used to compare the relative stability of alternative formulations by using the Arrhenius equation. Arrhenius equation gives the dependence of the rate constant of a chemical reaction on the absolute temperature, a pre-exponential factor, and other constants of the reaction:

$$k = A\mathrm{e}^{-E_a/(RT)}$$

where k is the rate constant, T is the absolute temperature (in kelvins), and A is the pre-exponential factor, a constant for each chemical reaction. According to collision theory, A is the frequency of collisions in the correct orientation, E_a is the activation energy for the reaction (in the same units as

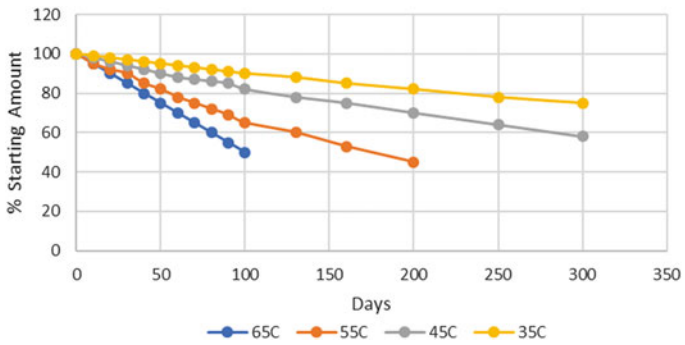

Fig. 4 Example of accelerated stability testing at different temperatures for determining degradation of an active compound

$R \times T$), and R is the universal gas constant. This equation describes the relationship between storage temperatures and degradation rate. Using Arrhenius equation, projection of stability (an estimate) from the degradation rates observed at high temperatures for some degradation processes can be determined. When the activation energy is known, the degradation rate at low temperatures may be estimated from those observed at "stress" temperatures at any particular time. Real-time results can be graphed and compared to the estimated degradation curve generated from accelerated stability testing data and the Arrhenius calculations (Fig. 5).

The results produced from the Arrhenius equation usually provide an early indication of the product shelf life, thus shortening the development schedule. In addition to temperature, stress conditions applied during accelerated stability testing are moisture, light, agitation, gravity, pH, and packaging. In accelerated stability testing, the samples are subjected to stress, refrigeration after stressing, and then simultaneously assay. Because the duration of the analysis is short, the likelihood of instability in the measurement system is reduced in comparison to real-time stability testing. Further, in accelerated stability testing, comparison of the unstressed product with stressed material is made within the same assay, and the stressed sample recovery is expressed as percent of unstressed sample recovery. For statistical reasons, the treatment in accelerated stability projections is recommended to be conducted at four different stress temperatures. However, for thermolabile and proteinaceous components, relatively accurate stability projections are obtained when denaturing stress temperatures are avoided. While estimated degradation from Arrhenius calculations can give some idea about what may occur in real life, accelerated data should not be solely relied upon by manufacturers for what truly happens under real-life conditions. Real-time data has to occur simultaneously with accelerated studies to fully determine what occurs for the stability of any nutraceutical.

5 Regulatory Guideline Aspects Related to Nutraceutical Stability

The Dietary Supplement Health and Education Act of 1994 is a statute of US federal legislation which defines and regulates dietary supplements and how nutraceuticals are at least partially regulated. Under the act, supplements are effectively regulated by the FDA for good manufacturing practices (GMP). The act has been criticized because supplement manufacturers are not required to demonstrate supplements' safety before marketing them. To help nutritional supplement companies make sure they have the necessary data to support expiration dating on product labels, NSF International, the developer of US national standard for dietary supplements, helped create a voluntary Stability Testing Guideline (NSF 2011). This guideline outlines the science-based criteria necessary to support expiration dating in order to comply with the current GMP for nutraceutical supplements. The guideline suggests that nutritional supplement companies identify the physical, chemical, and microbiological characteristics of their product under long-term storage. It specifies that companies understand the impact of manufacturing, packaging, labeling, distribution, and holding/warehouse processes may have on a product's stability. Factors involved in stability testing include dietary ingredient strength, chemical fingerprints, microbial growth, preservative content, moisture content, pH, viscosity, and oxidation, among other parameters, such as the product's container-closure system.

To assure that optimally stable molecules and products are manufactured, distributed, and given to patients, regulatory authorities in several countries have made provisions in the drug regulations for the submission of stability data by the manufacturer. These same basic drug principles hold true for nutraceuticals. Basic purpose of these regulatory guidelines was to bring uniformity to testing from manufacturer to manufacturer. These guidelines include basic issues related

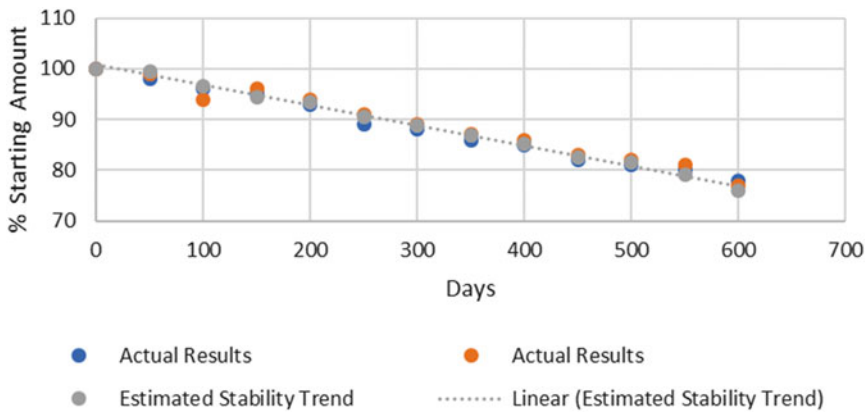

Fig. 5 Example of real-time stability compared to estimated stability

to stability, data requirements for the application dossier, and steps for their execution. Such guidelines were initially issued in the 1980s. These were later made uniform by the International Conference on Harmonization (ICH 2003) in order to overcome the bottleneck to market and register products in other countries. The ICH was a consortium formed with input from both regulatory agencies and industry from the European commission, Japan, and the USA.

6 Concluding Remarks and Future Directions

Stability testing is a key procedural component in the pharmaceutical development program for a new drug, and the same principles are beginning to be applied to the nutraceutical industry. Stability tests are carried out so that recommended storage conditions and shelf life can be included on the label to ensure that the drug or nutraceutical is safe and effective throughout its shelf life. Over a period of time and with increasing experience and attention, the regulatory requirements have been made increasingly stringent to achieve the above goal in all possible conditions to which the product might be subjected during its shelf life. While expiration dates are currently not required on nutraceuticals in the USA as of 2018, the trend is for nutraceuticals to become more and more regulated and tightly controlled for manufacturing, as is currently carried out in the drug industry. One approach to this is quality by design (QbD). QbD is a systematic approach to pharmaceutical product development that begins with predefined objectives and emphasizes product and process understanding and process control, based on sound science and quality risk management. The same approach is starting to be used by the nutraceutical industry. It means designing and developing formulations and manufacturing processes to ensure a predefined quality. Thus, QbD requires an understanding of how formulation and process variables influence product quality (Lionberger et al. 2008). QbD is a scientific, risk-based, holistic, and proactive approach to pharmaceutical development that will work for the nutraceutical industry. It is a deliberate design effort from product conception through commercialization.

One way the nutraceutical industry is currently dealing with stability issues is to simply add more of the nutraceutical to any particular formulation than would be stated on the label at time of manufacturing. Taking into account that decay of the nutraceutical will occur, it is hoped that the overage of the particular active nutraceutical will be enough so that when decay does occur, there will be enough left to meet any label claims. While this approach may be simple in theory, it may be costly to do or impractical in certain formulations or simply undesirable for other reasons like palatability. Another strategy is to use chemical salt forms of the nutraceutical that make the molecule inherently more stable. Encapsulation strategies of nutraceuticals is an area where much research effort is undergoing (Thakur et al. 2011; Ruiz and Campos 2017). Development of encapsulation systems based on lipophilic nutraceuticals' binding ability with some globular proteins is an area that holds promise. Newer packaging strategies to limit moisture, light, and air are another way to help maintain nutraceutical stability. Apart from simply keeping nutraceutical products refrigerated to maintain stability, packaging that helps prevent temperature from affecting the active ingredients will be a step forward using various temperature-controlled packaging solutions. Structurally, nutraceutical packages may be more experimental and unique than pharmaceutical containers in order to intrigue the novelty-oriented baby-boomer generation. Regardless of the strategies used, the goal of manufacturers will still be to achieve the longest shelf life for the active agent and give assurance to the veterinarian and the animal owner that the animal is receiving an effective nutraceutical.

Part VII

Regulatory Aspects and Country-Specific Requirements for Nutraceuticals

Basic Regulatory Guidelines for Veterinary Nutraceuticals

Dan DuBourdieu, Anita Sinha, and Rajiv Lall

Abstract

Close to 30% of pet owners use nutraceuticals on their animals. Veterinary nutraceuticals face regulations from regulatory authorities including the Food and Drug Administration, the American Federation of Feed Control Officials, states, and countries. These regulations can be confusing as to how nutraceuticals for veterinary use can be marketed legally. Trade organizations such as the National Animal Supplement Council recommend guidelines to manufacturers in coordination with the regulatory agencies, at both the state and federal level to help establish a system of regulatory oversight. This approach helps clarify the regulatory environment for veterinary nutraceutical manufacturer to continue manufacturing and marketing their products.

Keywords

Veterinary nutraceuticals · Regulations

1 Introduction

Close to 30% of pet owners have used nutraceuticals of one type or another for their animals, while in the USA, approximately 90% of veterinarians recommend some type of nutraceutical ingredient (Boothe 2017). As such, the global pet food nutraceutical market is estimated to reach a value of $8.25 billion by 2023 (Mordor Intelligence 2018). Clearly this is a large market. Therefore, how nutraceuticals are regulated is of obvious interest to manufacturers and veterinarians and to the animal owners that use them. The American Veterinary Medical Association recognizes the importance of these medicaments through its guidelines regarding complementary or alternative medicine, which includes veterinary nutraceutical therapy (AVMA 2018). While the nutraceuticals for human use have some regulatory framework that surround them, the use of nutraceuticals for veterinary use is somewhat more murky and confusing from a regulatory standpoint. Veterinary nutraceuticals' manufacturing and use are regulated by a number of entities including governmental agencies, trade groups, and indirectly by customer requirements. How these various entities work together to regulate veterinary nutraceuticals is what manufacturing companies must have an understanding of in order to market their nutraceutical products for veterinary use.

2 DSHEA

Dr Stephen DeFelice coined the term "nutraceutical" from "nutrition" and "pharmaceutical" in 1989 (Kalra 2003). The term nutraceutical is commonly used in marketing pieces but has no real regulatory definition. Attempts to put some sort of regulatory aspects surrounding nutraceuticals started in the early 1990s. In 1994, the Dietary Supplement Health Education Act (DSHEA) was passed by the US Congress and signed into law by President Clinton in October. This legislation created a specific category of products, dietary supplements, as a subset of food under the Federal Food, Drug, and Cosmetic Act that allowed the marketing of dietary supplements for human use. Unfortunately, when the issue was debated in Congress, animals were not considered, and language was not included in the legislation to allow similar products for animals to be regulated as "dietary supplements" as provided for people. DSHEA established supplements intended for human consumption as a new class of food for purposes of federal regulation. But importantly, DSHEA does not allow dietary supplement manufacturers to make unapproved health claims, such as cure, prevent, mitigate, treat, or diagnose a disease. That is where problems occur in marketing veterinary nutraceuticals since manufacturers want

D. DuBourdieu (✉) · A. Sinha · R. Lall
Vets Plus Inc., Menomonie, WI, USA
e-mail: dand@vets-plus.com

R. C. Gupta et al. (eds.), *Nutraceuticals in Veterinary Medicine*, https://doi.org/10.1007/978-3-030-04624-8_56

to make these unapproved health claims with nutraceuticals but are not allowed to and get into trouble when they do make these claims.

DSHEA defines a dietary supplement as a product intended to supplement the diet which contains at least one or more of the following ingredients: a vitamin, a mineral, an herb or other botanical, an amino acid, a dietary substance for use to supplement the diet by increasing total dietary intake, or a concentrate, metabolite, constituent, extract, or combination of any of the previously mentioned ingredients. The main effect of DSHEA was to remove certain dietary ingredients from regulation as food additives, which requires premarket approval. Quite a few animal supplement products are being sold as a result of DSHEA, and these products generally contain similar ingredients to those in human dietary supplements. Examination of the *Congressional Record*, when the bill was finalized, shows Congress neither specifically included nor excluded the application to animals. Although it may have been reasonable to at least include animals which are not intended for human consumption, such as dogs, cats, and horses, the topic of animals was overlooked, probably for the principle reason that the animal supplement industry did not really exist to any significant degree in 1994. In addition, the primary purpose of the legislation was to address the increasing consumer demand for dietary supplements for people. However, the Food and Drug Administration (FDA) published a notice in the *Federal Register* in 1996 explaining why the FDA believes that DSHEA does not apply to animals (Schultz 1996). The FDA believed many of the types of products marketed for animals contained ingredients that may be unsafe food additives or unapproved new animal drugs, making the products unsafe for the animals. The Center for Veterinary Medicine (CVM) was concerned about these products because the CVM did not have scientific data to show that they are safe or even contain the ingredients listed on the label. Thus, many substances that are permitted in human dietary supplements may not be legally sold in animal supplements. In announcing that DSHEA does not apply to animal products, CVM reasoned that many substances that qualify as dietary supplements for human consumption, such as botanicals, have a history of use in humans that can be used to establish reasonably safe levels. However, the same is not true for many of the same ingredients in animals as evidential support concerning the use of such substances is incomplete or unavailable. Animals may react very differently to substances than humans, and even small doses can cause adverse effects. Moreover, each animal species requires different nutrients, absorbs and metabolizes nutrients differently, and can exhibit different toxic reactions to food and its components. Because CVM has determined that DSHEA does not apply to animal supplements, many claims that are permitted for human dietary supplements are not permitted for animal nutritional supplements. The courts have interpreted "food" as a substance that provides nutrition, taste, or aroma. Thus, claims on animal food and supplement products that establish the intended use of the product to affect the structure or function of the body of animals in a manner other than via nutrition, aroma, or taste cause the product to be a drug.

3 FDA/CVM

The primary agency responsible for the regulation of animal food and drugs is the Food and Drug Administration's Center for Veterinary Medicine. FDA/CVM works closely with the states through regulatory associations like the Association of American Feed Control Officials (AAFCO) to ensure both federal and state laws are followed and companies remain in compliance. The CVM generally takes the position that animals on balanced rations, such as companion animals (i.e., dogs, cats, and horses), do not require extra nutritional supplementation beyond their typical feed. This is because CVM believes that dog and cat foods are rich in nutrients and that most animals either receive adequate amounts of vitamins, minerals, protein (essential amino acids), fat (fatty acids), and carbohydrates from their diet or are able to synthesize them from a ration balanced to observe National Research Council's nutrient requirements (FDA 2015a). There is no requirement that animal foods have premarket approval by CVM. The Federal Food, Drug, and Cosmetic Act does require that animal foods, like human foods, be pure and wholesome, contain no harmful or deleterious substances, and be truthfully labeled. When a substance, including one considered food, is intended to be used for the treatment or prevention of disease or for a "nonfood" structure/function effect, FDA considers it a drug. Drugs are an article intended for use in the diagnosis, cure, mitigation, treatment, or prevention of disease or an article intended to affect the structure or function of the body other than food. In the drug definition, the courts have interpreted "food" as something that provides nutrition, taste, or aroma. If a food affects the structure or function of the body, it does so by these properties (e.g., a food may provide nutrients such as calcium to support proper bone structure). However, if a substance affects the structure or function of the body apart from its nutritive value, such as improvement in joint function, it may be considered a drug. Structure/function effects extending beyond the "food" umbrella also include claims for improved or increased production and performance and alteration or improvement in function. A new animal drug must be shown to be safe and effective for its intended use by adequate data from controlled scientific studies as part of a New Animal Drug Application (NADA). If a product on the market is not approved, it may be deemed an adulterated drug and subject to regulatory action.

Most animal health supplements were considered "drugs of low regulatory priority" by the FDA, but a subtle shift has

occurred, and the FDA/CVM now views these supplements as "un-approved drugs for which enforcement discretion may be exercised" based on their content, labeling, intended use, and overall conduct of the company. If the product is intended as a source of minerals and vitamins for a nonhuman food chain animal (dogs, cats, and horses), it is classified as a nutritional or feed supplement and regulated by the FDA and individual state feed control officers through the AAFCO Model Bill. Most states follow the recommendations of the AAFCO. Nevertheless, CVM generally does not object to the over-the-counter marketing of dietary supplements in tablet, capsule, powder, or liquid form for companion animals similar to dietary supplements marketed to humans. However, CVM takes the position that such products should provide meaningful amounts of each of the nutrients they are represented to contain and that the nutrients should be of known value for the intended or target animal. The FDA uses the Nutritional Requirements of Dogs and Cats (National Research Council 2006) to arrive at a level of supplementation that represents the best information presently available for these species. FDA typically accepts as adequate those products providing a meaningful level of nutrition when compared with the NRC recommendations.

Generally, the CVM will not object to the marketing of nutritional supplements for oral administration to companion animals provided they conform to the following restrictions: there is a known need for each nutrient ingredient represented to be in the product for each animal for which the product is intended; the label represents the product for use only in supplementation of, and not as a substitute for, good daily rations; the product provides a meaningful but not excessive amount of each of the nutrients it is represented to contain; the product is neither overpotent nor under-potent nor otherwise formulated so as to pose a hazard to the health of the target animal; the labeling should bear no disease prevention or therapeutic representations, including growth promotion; and the labeling should not be otherwise false or misleading.

The FDA does send warning letters to manufactures in certain cases. But typically, the rationale is not because the supplement is not effective but rather because of the language used in describing the supplement. When the language is acceptable to the FDA, then the product can be sold again. For example, a supplement maker was accused by the FDA of selling a product that the FDA called an unapproved kidney disease drug for pets but was then allowed to continue selling the same product as a supplement instead with a new product name and different marketing (JAVMA 2015).

4 AFFCO

In general, the FDA requires that animal feed be pure and wholesome, contain no harmful or deleterious substances, and be truthfully labeled. Currently, only those substances that are (1) listed as generally recognized as safe (GRAS) in FDA regulations at 21 C.F.R. Part 582, (2) listed as an approved food additive in FDA regulations at 21 C.F.R. Part 573, or (3) listed as a defined ingredient in the Official Publication of the Association of American Feed Control Officials (the AAFCO book) are permitted in animal feed, including animal/pet supplements that are being sold as feed. AAFCO is a voluntary membership association of local, state, and federal agencies charged by law to regulate the sale and distribution of animal feeds and animal drug remedies. Although AAFCO has no regulatory authority, most states have adapted AAFCO guidelines when regulating animal/pet food. AAFCO provides a forum for the membership and industry representation to achieve three stated main goals: safeguarding the health of animals and humans, ensuring consumer protection, and providing a level playing field of orderly commerce for the animal feed industry (AFFCO 2018). These goals are achieved by developing and implementing uniform and equitable laws, regulations, standards, definitions, and enforcement policies for regulating the manufacture, labeling, distribution, and sale of animal feeds—resulting in safe, effective, and useful feeds by promoting uniformity among member agencies.

The CVM categorizes ingredients in animal supplements as one of two types: (1) a nutritional ingredient (intended to provide nutrition) or (2) a non-nutritive ingredient (does not provide nutrition). The AAFCO Official Publication (OP) contains nutrient profiles for cats and dogs that list the ingredients considered to be essential nutritive ingredients. According to the CVM, a claim that an animal supplement affects the structure or function of the body based on its nutritive value (a nutritional ingredient) is considered a food claim, and the product will be categorized as a food. For example, calcium is listed as an essential nutritive ingredient in the AAFCO OP for both dogs and cats. Thus, a claim that a supplement that contains dried milk provides calcium to support proper bone structure would be a permitted food claim, and the supplement would be categorized as a food. Conversely, a claim that an animal supplement affects the structure or function of the body apart from its nutritive value (a non-nutritive ingredient) is considered a drug claim, and the product will be categorized as a drug. Moreover, claims for (1) improved or increased production and performance, (2) alteration or improvement in function, or (3) treatment or prevention of disease are also considered drug claims, regardless of whether the ingredient is nutritive or non-nutritive. FDA has explicitly stated that pet supplements should not "bear such vague therapeutic suggestions as promotion of 'health,' 'stamina,' 'strength,' or that they are of any special value for breeding purposes or for show or racing purposes or for working animals, or that by virtue of their formulation [i.e., 'chelated,' 'timed release,' 'natural'] they are superior to the ordinary vitamin-mineral preparations of commerce" (FDA 2015a). Likewise, direct or implied representations

for the product as a tonic, conditioner, or toner are considered drug claims. Because of all this, the labeling of various nutraceuticals for animals typically will say something about "maintains normal conditions or supports something" for whatever the nutraceutical is really intended for, as a way of getting around drug claims.

On a case-by-case basis, CVM has permitted some exceptions and agreed to exercise regulatory discretion for certain references to "nutritional support" for specific organs or body functions. For instance, CVM has explained that it would not object to a claim that vitamin E serves as an antioxidant in the body of animals. AAFCO has obviously considered that nutraceuticals will be used by manufacturers and veterinarians and indirectly lists them in a sort of tacit way in the AFFCO book. AFFCO categorizes ingredients that are approved for use in different ways. Various ingredients that might be considered to be nutraceuticals can fall into these various categories. For example, various botanical or plant-based nutraceuticals can be found listed under the category of "Spices and other natural seasonings and flavorings." Others can be found listed under the category of "Essential oils, oleoresins (solvent-free) and natural extractives (including distillates)." Still other nutraceuticals can be found listed in other categories.

5 Claims for Probiotics

FDA has issued a special Compliance Policy Guide (CPG) related to products that are purported to contain live (viable) microorganisms (bacteria and/or yeast). FDA refers to such products as "direct-fed microbial products (probiotics)" (FDA 2015b). FDA's policy is as follows: a direct-fed microbial product with label/promotional claims for disease cure, mitigation, treatment, or prevention is a new animal drug and is adulterated under Section 501(a)(5) unless it is the subject of a NADA. If the claims are in promotional material that cannot be documented as labeling, the product is misbranded under Section 502(f)(1). A direct-fed microbial product with label/promotional claims for affecting the structure or function of the body is a new animal drug because the claims are not derived from its food properties (i.e., the product does not act only as a source of nutrition in the animal's body) and is adulterated under Section 501(a)(5) unless it is the subject of an approved NADA. Such claims are usually improved animal productivity claims. If the claims are in promotional material that cannot be documented as labeling, the product is misbranded under Section 502(f)(1). Ordinarily, a direct-fed microbial product that is not labeled/promoted with any therapeutic or structure/function claims but that contains one or more microorganisms not listed in the AAFCO Official Publication is a food additive and is adulterated under Section 402(a)(2)(C), unless it is the subject of a food additive regulation.

A direct-fed microbial product listed by the AAFCO Official Publication and labeled with the AAFCO-approved label statement for live microorganism content, and not labeled or promoted with any therapeutic or structure/function claims, will be regulated as a food as defined in Section 201(f)(3) and usually will not require FDA regulatory attention. It is anticipated that the states will monitor these products. However, if FDA has safety concerns about these products, it will treat them as not generally recognized as safe and will regulate them as food additives subject to FDA enforcement attention. AAFCO has adopted a standard statement for viable microorganism labeling. The AAFCO statement is, "Contains a source of live (viable) naturally occurring microorganisms," followed by a listing of each of the microorganisms and the content guarantee, as colony-forming units per gram. The guarantee expression is specified in Regulation 4(g) of the Uniform State Feed Bill in the AAFCO Official Publication. Additionally, AAFCO specifies that there should be a verifiable method to test the veracity of the microorganism-guaranteed content specified in the labeling.

A product containing microorganisms listed by the AAFCO Official Publication but not purported to contain live microorganisms and with no label/promotional representations other than as a source of designated nutrients will be regulated as a food as defined in Section 201(f)(3). Although claims as nutrient sources could be misleading, depending on directions for use, this type of product usually will not require FDA regulatory attention. It is anticipated that the states will monitor these products. However, if FDA has safety concern about these products, it will treat them as not generally recognized as safe and will regulate them as food additives subject to FDA enforcement attention.

6 Trade Organizations Related to Veterinary Nutraceuticals

The interest in veterinary nutraceuticals in the early 1990s resulted in the formation of several trade organizations. The North American Veterinary Nutraceutical Council (now defunct) was formed in 1996 by interested persons in industry, practice, and academia. It defined a veterinary nutraceutical as "a [non-drug] substance which is produced in a purified or extracted form and administered orally to a patient to provide agents required for normal body structure and function and administered with the intent of improving the health and well-being of animals." The commonality among novel ingredient products is that legally they are neither food, food additives, nor drugs as recognized by the FDA. As such, they undergo no premarket approval process, and neither safety, efficacy, nor manufacturing is assured. At least two groups have formed in North America with an interest in veterinary nutraceuticals: the Nutraceutical Alliance (2018)

based in Canada and the National Animal Supplement Council (NASC 2018), based in the USA. Founded in 2013, the Nutraceutical Alliance provides an interface between product development, product testing, animal and literature research, product registration, and the regulatory environment.

NASC is a nonprofit trade organization founded in 2001 that is comprised of companies committed to providing health supplements and nutritional supplements of the highest quality for companion animals, primarily dogs, cats, and horses. The NASC has taken an assertive approach in trying to implement voluntary actions among nutraceutical manufacturers that will cause regulators to respond to their products in a positive fashion. NASC is trying to make sure that veterinary nutraceuticals that are on the market are safe to use on animals. Novel ingredients often are used without doctor supervision. Up to 70% of humans do not report herbal use to physicians, in part because of their failure to recognize the products as drugs. Likewise, pet owners often do not cite nutraceutical or herbal use when queried regarding drug therapy for their pet. The availability through medically recognized and trusted sources often leads the consumer to assume both their accuracy in labeling, efficacy, and safety. Yet, the lack of regulations and guidelines should lead to the "buyer beware." NASC created a quality seal as a way for consumers to know that when they buy a product, they buy from a reputable manufacturer. Only NASC member companies operating under the stringent guidelines of NASC for manufacturing, labeling and adverse event reporting, and demonstrating responsible participation are permitted to use the NASC Quality Seal.

The FDA/CVM would consider marketing claims that if an ingredient used in an animal affects the structure or function of the body, then the active ingredient is generally considered a drug. This has led to confusion when it comes to marketing nutraceuticals. For example, glucosamine is not listed as an essential nutritive ingredient in the AAFCO Official Publication for either dogs or cats. Thus, a claim that a pet supplement helps to improve joint function based on glucosamine in the product would be a drug claim, and the supplement would be considered a drug. With the above FDA/CVM thinking in mind, many unapproved ingredients are currently marketed for use in animal supplements, including burdock, echinacea, ginseng, horsetail, and nettles. Currently, none of these ingredients are permitted for use in pet supplements with approval from the FDA/CVM or AFFCO. Obviously, the veterinary nutraceutical industry has a problem regarding marketing claims about whether glucosamine or any other nutraceutical is a drug or not.

The increased consumer demand for animal health supplements creates a significant issue for the industry in that many ingredients, even common ones found in human dietary supplements such as glucosamine, chondroitin, methylsulfonylmethane (MSM), etc., are not approved for use in animal food/feed. Surveys conducted by NASC indicate that there are over 400 ingredients currently marketed by NASC members that are unapproved for use in animal feed products. However, trade organizations have taken steps to be able to market glucosamine and these other nutraceuticals legally in the USA and other countries. In response to the "unapproved" status of these ingredients, NASC submitted ingredient definition applications in 2002 and 2003 petitioning FDA/CVM to allow the use of glucosamine and MSM in animal feed. These ingredients were chosen because nutritional requirements for them have not been established in any animals, including "healthy animals." Additionally, due to the marketing of human products, consumers recognize the use of these and other ingredients for purposes other than nutritional, i.e., providing benefits to support the structure and/or function of the body, or their use with specific medical conditions such as osteoarthritis.

7 Legally Marketing an Animal Nutraceutical in the USA

Nutraceutical products such as dietary supplements for humans that marketed for animals have only two possible legal categories under US law. They are either an animal food/feed or they are a drug. Dietary supplements, such as vitamins and minerals, fall into the category of animal feeds. Dietary supplements for animals such as vitamin and mineral products have been marketed for many years. Most of these products include ingredients that are approved food additives, generally GRAS substances, or ingredients listed in AFFCO. But for many nutraceuticals, these determinations leave the industry with only one other option under current law: marketing nutraceutical products as animal drugs consistent with their intended use. Legally marketing nutraceutical products as animal drugs requires the submission of a New Animal Drug Application to the FDA/CVM that demonstrates criteria for safety and efficacy have been satisfied. Submission of NADA for animal health supplements is problematic because of costs associated with development and with patent protection of natural substances. The courts have held that natural substances cannot be protected via intellectual property such as patents (Harrison 2014). The isolation and purification of an active ingredient from a plant may not be enough to allow patentability. Since many nutraceutical agents come from plants, this causes problems for manufacturers. Patents allow a company to recover the considerable investment in product development with an appropriate selling price of the product. The consumer has the ability to purchase human dietary supplements that may be similar in formulation and a less

expensive alternative for their companion animals than a patented animal product that has been through the NADA process.

In sum, in order to ensure that a pet supplement is legally marketed as an animal feed, each of the ingredients in the pet supplement should be listed in one of the three following methods: (1) FDA regulations at 21 C.F.R. Part 573 as an approved food additive, (2) FDA regulations at 21 C.F.R. Part 582 as a GRAS substance, or (3) the ingredient definitions in the AAFCO book (although the status of this category of ingredients is subject to change). In addition, any claims that the product affects the structure or function of the body of animals should be based on an essential nutritive ingredient, according to the AAFCO nutrient profiles.

If the supplement is marketed as a feed, it is recommend that labeling the product is in accordance with FDA requirements and the AAFCO feed labeling guide. However, not all states have adopted the AAFCO model regulations, and some states have adopted the model regulations with modifications. Accordingly, it is possible that some states require changes to the label depending on the product. Many states require that animal feed products, including supplements that are sold as feed, be registered with the state before being sold in that state.

Another option is to market the product with ingredients that are not included on the three listed methods above, with the knowledge that the product will technically be considered an unapproved new drug. Generally, FDA considers these products to be "un-approved drugs for which enforcement discretion may be exercised." Animal supplements are low on FDA's priority list, and the agency has generally not been active with enforcement actions in this area. Instead, enforcement is typically handled on the state level, which makes it a state-by-state issue. Some states are much more permissive when it comes to ingredients that are not included on one of the three lists discussed previously. However, there is a chance that one or more states will object to the sale of the product, and those states could ultimately suspend or prohibit the sale of the product in the state. Ultimately, it is a business decision for the company to make depending on how much risk it is willing to take.

If a company intends to market the product as a non-feed or health product, it is recommend evaluating whether the product can be marketed as a non-feed supplement under the NASC guidelines. If so, the NASC has published templates for labels for non-feed products. However, it is important to note that some states struggle with the NASC template and will likely require the nutraceutical product to comply with the feed regulations in that state. Manufacturers that market nutraceuticals that go the route of a non-feed supplement may avoid the requirements to register with many states as an animal feed and may avoid the annual fees associated with the same; however, these companies need to register as animal remedies in those states with remedy laws.

8 Regulatory Rules in Different Countries for Veterinary Nutraceuticals

In the USA, the FDA/CVM, AFFCO, and NASC all have some say in how veterinary nutraceuticals are regulated and marketed to a greater or lesser extent depending on the organization. While the FDA is authorized to act against any unsafe product on the market, in the European Union, the European Food Safety Authority (EFSA) does not have the same mandate (Santini et al. 2018). EFSA is a European agency funded by the European Union that operates independently of the European legislative and executive institutions (Commission, Council, Parliament) and EU member states. It was set up in 2002 following a series of food crises in the late 1990s to be a source of scientific advice and communication on risks associated with the food chain. The agency was legally established by the EU under the General Food Law—Regulation 178/2002. EFSA must authorize/approve in detail any health claim before it is considered at a national or European level prior to being put on the market following a specific request from member states, European Parliament, or stakeholders. Following the EFSA opinion, each European member country can decide independently to set specific approval regulations and/or authorization. In the USA, however, manufacturers and other stakeholders do not have to register their products with the FDA because there is no need to obtain FDA approval and/or authorization before producing or selling food supplements or nutraceuticals. Surveillance activity is relegated to governmental agencies, and manufacturers are responsible for ensuring that information reported on the product label is true and not misleading. In Canada, nutraceuticals are regulated more like a drug than as a food category (L'abbé et al. 2008).

Other countries have specific legislation; for example, Indian legislation does not ascribe any specific legal status to nutraceuticals. The government of India established the Food Safety and Standards Act (FSSA) in 2006 to introduce a legislation system. FSSA does not separate functional foods, nutraceuticals, and dietary supplements; instead, each is indicated as food for a special dietary application. It considers products with beneficial health claims to be similar to food without any statements about nutraceuticals with clinical trial results. In 2015, India notified the World Trade Organization of a draft regulation for nutraceuticals and foods for special diets and medical purposes. The draft regulation defined these categories based on ingredients, labeling, additives, contaminants, and health and nutritional claims. The draft regulation also determined the criteria for the manufacturing

and sale of these categories of foods and recommended doses or consumption levels. The new regulation, namely, Food Safety and Standards for Food for Health Supplements, Nutraceuticals, Food for Special Dietary Use, Food for Special Medical Purposes, Functional Food and Normal Food Regulations 2016, is based on and framed from Section 22 of the FSSA (FSSA 2018).

Japan, by contrast, was among the first countries to face the issue of regulating food supplements and foodstuff by issuing the Food for Specified Health Uses (FOSHU) based on a voluntary request from stakeholders for approval. This legislation, originally set in 1991, evolved into the 2003 Health Promotion Law (Yamada et al. 2008). Possible approval is available for food with beneficial health activities even if these activities are not substantiated with scientific evidence if the product meets the level of FOSHU requirements (safety, nutritionally appropriate ingredient content, etc.). Even food without an assessed and defined mechanism of effectiveness for its function, namely, qualified FOSHU and standardized FOSHU, can be considered. Any reduction of disease risk claim is allowed if the reduction of disease risk is clinically and nutritionally established in one ingredient.

In general, many countries, such as Australia or China, regulate nutraceuticals simply as a category of food, and the national regulations valid for food apply (Tapsell 2008, Yang 2008). A simple registration-based approach has been adopted by some countries, such as Colombia, Brazil, and Argentina. A notification-based approach addressed to the local competent authority is valid in Mexico and Chile. Nevertheless, other countries, such as Brazil, China, and Taiwan, have stricter requirements, and prior to registration, a complete animal or human clinical study is required. Based on this information, it is foreseeable that a safety assessment and complete clinical study may be necessary before any nutraceutical or any ingredient is put on the market. Moreover, a health claim should be authorized and attributed only after a complete clinical study is proposed to the appropriate authority for approval with the aim of substantiating its safety and efficacy with respect to the claimed beneficial health effect based on an understanding of the mechanism of action and the absence of undesired side effects (Fig. 1).

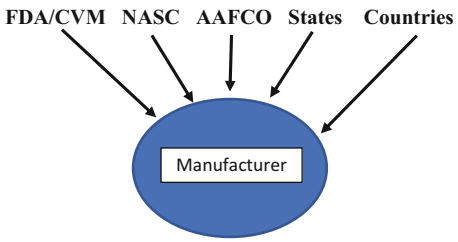

Fig. 1 Sources of nutraceutical regulations manufacturers face

9 The Future of Veterinary Nutraceutical Regulations

It is unclear how long the FDA/CVM will continue to recognize the definitions in the AAFCO Official Publication. In a memorandum of understanding entered into in 2007 and renewed in March 2015, FDA and AAFCO agreed to collaborate in the development and approval of animal feed ingredient definitions. However, also in March 2015, FDA announced its intention to bring the AAFCO ingredient definition and standards completely under the FDA GRAS and food additive framework. Specifically, the agency intends to (re)evaluate all feed ingredients that appear in the AAFCO book but are not listed in FDA regulations as GRAS or approved as food additives. FDA intends to determine whether there is sufficient scientific evidence to affirm the ingredient as GRAS or approve it as a food additive. When there is not sufficient evidence available for FDA to make a GRAS or food additive determination, the agency intends to require companies to submit food additive petitions in order to continue using an ingredient in animal feed products. Thus, while an ingredient might currently be permitted due to its listing in the AAFCO book, companies should understand that the permissibility of the ingredient is subject to change in the future (Harrison and Jackson 2016).

Because the present regulatory aspect of veterinary nutraceuticals is both complex and confusing to most veterinarians and manufacturers, a restructuring of the entire regulatory framework of dietary supplements would be helpful. A version of DSHEA for nutraceuticals intended for animals that models itself after NASC guidelines could be started. NASC already has an adverse reporting system in place that could be adopted to ensure veterinary nutraceutical safety. National competent authorities could ask manufacturers to provide data on the safety and mechanism of action supporting any claims contained on the labels of their products, especially when the term nutraceutical is used. Relevant information and data could be related to the complex of substances forming a nutraceutical and not refer to a single substance. What these new regulations will look like will depend on who wins the battle between what manufacturer want and the regulatory agencies want. A restructuring will not be easy but hopefully will result in a more clarity for veterinary nutraceutical regulations.

Regulatory Aspects of Veterinary Nutraceuticals in the USA and Canada

Daljit Vudathala

Abstract

The Food and Drug Administration (FDA) in the US provides clarification, guidance, and regulatory oversight to protect human and animal health. The Center for Veterinary Medicine (CVM), a branch of FDA, ensures safety of veterinary medical products and animal feed including pet food. Nutraceuticals are neither food nor drugs and present a regulatory challenge. Although most nutraceuticals are generally regarded as safe, there is a growing concern about their safety, quality, and efficacy. To safeguard human health, the FDA has not provided any special provision to natural supplements intended to be included in animal feed. The FDA believes that there is insufficient information on the safe use of natural products in food animals to ensure human health from potential toxic residues. However, the use of oral natural supplements is not prohibited in pets if a product is harmless and not labeled to treat or cure an ailment. In Canada, veterinary nutraceuticals are defined as "natural supplements" and are regulated by Health Canada. Guidance includes information on permitted and excluded products, manufacturing, labeling, and adverse event reporting system. All products are required to obtain a notification number (NN) prior to sale in Canada. The objective of Canadian regulations is to facilitate the approval of safe products while keeping harmful supplements off the market to protect human and animal health.

1 Introduction

Public health and safety is a core government function. Regulations and guidelines ensure consumer safety by keeping harmful food and health-care products from distribution to the consumer while enabling flow of safe products into the market. Manufacturers, distributors, and stakeholders are all expected to follow the regulations of a country where the product is going to be marketed. Regulations may require manufacturers and distributors to disclose factual information to prevent giving out inaccurate or misleading information. Accurate information of a food and health-care product empowers people to make informed choices and reduces the incidence of adverse health events.

Nutraceuticals, also known as dietary supplements or "functional foods," are part of a growing segment of the health-care industry (Childs 2000). A nutraceutical product is used to improve overall well-being, slow the aging process, prevent chronic diseases, and support bodily functions. A large number of products are currently sold in the market as alternatives to traditional medicine with the intent to prevent and treat various ailments (McKeever 2017). A common public perception is that pharmaceuticals are chemicals, synthesized in a laboratory, and therefore harmful. On the contrary, natural products are from the bounty of nature and therefore perceived to be safe. Focus on disease prevention and rising drug costs are some of the other driving forces for the increased use of nutraceuticals. A healthy diet and dietary supplements for overall well-being and prevention of chronic diseases to improve quality of life are sought by many consumers not only for themselves but also for their pets (Bauer 2001). Natural supplements to improve overall health and productivity of farm animals are routinely used as feed additives.

Products classified as nutraceuticals seem to reside in a gray area between food and pharmaceutical (Crandell and Duren 2007; Boothe 1997). Food is defined as a substance that provides nutrition, taste, or aroma. By comparison, a

R. C. Gupta et al. (eds.), *Nutraceuticals in Veterinary Medicine*, https://doi.org/10.1007/978-3-030-04624-8_57

drug is intended for diagnosis, cure, mitigation, treatment, or prevention of a disease in man or animals. Unlike human food, animal feed not only meets the nutritional requirements of a species but may also serve as a delivery mechanism of pharmaceuticals. A medicated feed can therefore be classified both as a food and a drug (US Food and Drug Adminstration 1998). Regulatory agencies make great strides to ensure the safety of humans and animals by monitoring the food supply and regulating the drug products.

2 FDA Perspective

Different branches of the Food and Drug Administration (FDA) in the US, are responsible for protecting the public health by ensuring the safety, efficacy, and security of human and veterinary drugs, biological products, and medical devices. Under the umbrella of the FDA, the Center for Veterinary Medicine (CVM) regulates products intended for use in animals (US FDA 1998). CVM ensures that animal feed, pet food, and treats are safe, are made under sanitary conditions, and are appropriately labeled. A drug is approved and then monitored for safety and efficacy throughout the life cycle of the product. Animal drugs may be administered directly or incorporated in feed.

In 1994, the FDA enacted the Dietary Supplement Health and Education Act (DSHEA) to enhance consumer safety without imposing unnecessary barriers that could slow the flow of safe products to consumers (National Institute of Health 1994). A framework of guidelines for dietary supplements (DS) was put in place to replace regulatory policy used to handle any concerns. Prior to the DSHEA, any reported adverse effects of a marketed product were handled on a case-by-case basis.

DSHEA defines a DS as a product (other than tobacco) intended to supplement the diet with one or more of the following ingredients:

(a) A vitamin
(b) A mineral
(c) An herb or a botanical
(d) An amino acid
(e) A dietary supplement used by man to supplement the diet by increasing the total dietary intake
(f) A concentrate, a metabolite, a constituent, an extract, or a combination of ingredients described in (a), (b), (c), (d), or (e)

Although dietary supplements are generally considered safe, the FDA takes action against products that are unsafe to protect consumers. According to the FDA, ingredients sold in the USA before October 15, 1994, are considered safe based on their historic use and don't need further safety evaluation. For a new dietary ingredient sold after October 15, 1994, the manufacturer must notify the FDA and provide reasonable evidence that it is safe for human consumption. Labeling requirements of a DS outlined to provide truthful information to the consumer are:

- The product must be labeled as a dietary supplement.
- Labeled not to treat, diagnose, prevent, or cure diseases.
- "Supplemental facts" replaces the "nutritional facts."
- The name of each ingredient is listed in descending order by weight or total quantities of all ingredients in a proprietary blend per serving.
- Herbs must list the part of the plant from which they originated (leaf, flower, root, etc.).
- Botanicals are listed by their common name.

The FDA received inquiries as to whether the DSHEA of 1994 was applicable to products intended for use in animals. In response, the CVM published an assessment in the Federal Register on April 22, 1996 (US FDA 1996), after examining the language, intent, and legislative history of the DSHEA. The definition of dietary supplement in the DSHEA doesn't specify if it includes products intended for use in animals other than humans. In their assessment, the FDA stated that on reviewing the complete DSHEA, it can be concluded that the Act was written for human and not animal products.

3 Inapplicability of DSHEA to Veterinary Products

The CVM concluded that the DSHEA was written without fully considering human food safety and animal health. Lack of information and safety concerns about potential residues in meat, milk, and eggs from animals given natural products was a major CVM concern (US FDA 1996). The FDA has concluded that dietary supplements intended for food-producing animals can't be given special treatment provided by the DSHEA to better protect public health. Furthermore, many products that are currently used to affect animal performance could potentially be covered as dietary supplements under the DSHEA. These products have been marketed with FDA approval after extensive scientific studies by the manufacturer to demonstrate safety and efficacy in animals and humans. The FDA believes that allowing a new product to be marketed under the provision of the DSHEA not only raises food safety concerns but provides an unfair advantage over existing products that have been approved after demonstration of safety and may act as a deterrent to develop innovative products in the future.

Finally, animal health is another concern addressed in the assessment. There is limited information on the safe use of dietary supplements in animals as compared to humans. Herbs and other botanical products have a history of use in humans to make a reasonable safety assessment for their

human use. However, the same ingredients lack sufficient safety data for use in animals. Furthermore, animal species differ in their nutritional requirements and react differently to various feed components. Absorption, metabolism, and transmission of an ingredient or its metabolites into meat, milk, or eggs can also vary in different animal species.

The assessment has concluded that to safeguard the human food supply and to protect animal health, the DSHEA of 1994 is not applicable to products for animal use. Under current regulations, natural supplements to be included in animal food are treated like any other feed additive.

4 Feed Additives

All additives in animal feed, including dietary supplements, require FDA approval after determining that the product will not leave harmful residues in meat, milk, and eggs (21 U.S.C. 348(b)(2) and (c)(5), and 21 CFR part 570) (US FDA 2018a). Approval of a feed additive intended for an animal species involves establishing a withdrawal period for the product in a finishing animal and tolerance levels in edible food. If a compound or any of its metabolites are carcinogenic, the act imposes additional requirements on its approval (21 U.S.C. 348(C) (3)(A) and 21 CFR part 500, subpart E). The use of a compound that can induce cancer in humans is prohibited for use in food-producing animals unless no residues of the carcinogenic compound can be demonstrated under conditions of use (US FDA 2012). A product may be eligible for "generally regarded as safe" (GRAS) status based on the view of qualified experts drawn from available and accepted data collected using scientific principles or through a common use in food prior to January 1, 1958 (US FDA 2018b).

Animal feed is regulated by the CVM in cooperation with state regulatory officials and partners who provide subject matter expertise in animal science and nutrition. The *Association of American Feed Control Officials* (AAFCO), a nonprofit organization with no regulatory authority, provides a forum for state and federal regulatory officials to come together and create model guidance to ensure that the regulation of animal feeds is as uniform as possible from state to state. Regulations include the establishment of uniform feed ingredient definitions and proper labeling to assure the safe use of feeds. AAFCO guidelines safeguard the health of animals and ensure consumer protection from harmful veterinary additives.

Labeling requirements for animal feed provide sufficient information to keep animals healthy and safe. A typical label includes:

- Brand name, if any
- Product name
- Purpose statement
- Guaranteed analysis
- List of ingredients
- Direction for use
- Warning or caution statements
- Name and address of manufacturer
- Quality statement

The purpose, list of ingredients, directions for use, and warning statements are all helpful in prevention of overdosing of feed additives to target animals or inadvertent exposure to nontarget species. Natural supplements to be incorporated in animal feed must meet CVM and AAFCO requirements.

5 Nutraceuticals for Pets

The CVM believes that animals on balanced rations receive an adequate amount of nutrients from natural ingredients or supplements that are added during feed manufacturing. The amounts of vitamins, minerals, protein, fat, and carbohydrates in a commercial pet food are adequate and meet the National Research Council nutrient requirements (US FDA 1995). The CVM has no objection to the marketing of oral nutritional supplements for companion animals, provided the product marketer meets the following restrictions:

1. Nutrient ingredient represented to be in the product is beneficial for each animal species for which the product is intended.
2. The product is labeled for use as a supplement and not as a substitute for good daily rations.
3. The product provides useful but not excessive amount of each of the nutrients it is represented to contain.
4. The label should not claim to cure or prevent a disease, including growth promotion.
5. The label should not make any false or misleading claims.
6. The potency and formulation of the product should not pose a health hazard to the target animal.

Non-compliance results in appropriate regulatory action against products that violate the policy with a "Warning" letter as the initial action to achieve compliance. The FDA holds the authority to take additional regulatory action against adulterated products that pose a health hazard (US FDA 1995). According to the FDA, the above policy is for oral products and excludes all injectable nutritional

supplements. Injectables are considered drugs and any issues are dealt with on a case-by-case basis.

6 Safety Concerns

Although natural products are considered safe, there is a growing concern about their safety in pets. The safety of a drug or an additive is generally assessed pre- and post-market approval. Prior to the sale of a product, studies are undertaken to identify potential adverse effects and then through surveillance studies to monitor for unexpected or previously identified adverse events. Currently, natural supplements are available for pets without pre-market approval. A product with safety data established in humans may not be safe in animals. Furthermore, a product that is safe in one species may not be safe in another. Current guidelines lack a robust post-market surveillance system to gather any adverse events.

Concerned with the safety of natural supplements, the FDA reached out to the National Research Council (NRC) to comment on safety in general and specifically the safety of three products: lutein, evening primrose oil, and garlic in pets. A committee of experts was formed to provide a safety assessment report and has published their findings (NRC 2009). The committee identified three main concerns that challenge the safety assessment of supplements:

1. Limited safety studies are conducted.
2. Lack of standardization among active ingredients.
3. Insufficient adverse event reporting system.

To strengthen the safety evidence of a supplement, the committee created a pyramid consisting of ten data supporting factors in increasing progression, starting with expert opinion as the base and meta-analysis as the apex. The list of parameters is as follows:

1. Expert opinion
2. In vitro and ex vivo research
3. Pathophysiologic rationale
4. Research in other species
5. Historical use/exposure
6. Case series/signals
7. Models of disease
8. Randomized controlled studies in target species
9. Epidemiologic studies
10. Meta-analysis

Information gathered by these various scientific means would be helpful in a safety evaluation. Safety study design needs to consider dosage and contamination in the supplement. Although the use of other species is generally helpful in assessing the safety of supplements, this provides no safety guarantee in the intended species. For example, a garlic supplement is considered safe for humans but may cause hemolytic anemia in dogs, cats, and horses (Cope 2005; Kovalkovičova et al. 2009; NRC 2009). A suitable safety study model of a supplement that naturally occurs in the diet of a surrogate and target animal that have a similar metabolic and natural dietary pattern would be preferred.

FDA regulations for veterinary DS are insufficient to fully address their safety, quality, and efficacy. Products are available for pets without any regulatory approval, and post-market surveillance is insufficient to properly monitor adverse events (Boothe 1998). Updated regulations are greatly needed to ensure safety and efficacy of products.

7 Regulations in Canada

Nutraceuticals intended for animals in Canada are defined as veterinary health products (VHPs) and are regulated by Health Canada. VHPs are used to maintain or promote the health and welfare of companion and food-producing animals. However, they are not for use to treat, prevent, or cure disease. In Canada, guidance and recommendation for veterinary products come from the Veterinary Drugs Directorate (VDD) under the direction of Health Canada. An Expert Advisory Committee on Veterinary Natural Health Products (EAC-VNHP or EAC) started meeting with VDD in 2008 to discuss the issues, goals, and priorities with regard to veterinary natural health products (Health Canada 2011). The committee outlined the following objectives to:

- Protect the well-being of animals from harmful products.
- Establish safety standards for products that are intended for use in food animals to protect human food supply, health, and the environment.
- Simplify regulations to facilitate approval of products that are presumed safe while keeping harmful products out of the market.

In addition, the EAC wanted to establish quality control standards for the manufacture of products and efficient post-market surveillance to allow Health Canada to take swift action against a non-compliant or a harmful product. The EAC also wanted to create standards for efficacy claims that would be helpful to consumers in making informed decisions.

A temporary Interim Notification Pilot Program (INPP) was launched in 2012 for low-risk veterinary health products, followed by a notification program that came in effect on November 13, 2017 (Health Canada 2012, 2017). The notification program was initiated with the objective to provide a flexible and risk appropriate regulatory framework for veterinary health products (VHPs) that have a history of safe use. A compliance and enforcement approach is based on the potential risk with authority to take appropriate action against

non-compliance and to stop the sale of an unsafe product. A notification number (NN) must be obtained as part of the program within the timeframe outlined below:

- At least 30 days before selling a VHP for the first time in Canada
- At least 30 days before making a change to a VHP that is already notified in Canada
- Before importing a VHP into Canada

Health Canada has provided guidance to comply with the notification program consisting of information on:

- Included and excluded products
- Label and claim requirements
- Manufacturing guidelines
- Reporting of adverse reactions
- Compliance and enforcement

8 Included and Excluded Products

VHPs are considered low-risk drugs that may contain ingredients, such as:

- Vitamins
- Minerals
- Traditional medicines

Oral, topical, otic, and dental/periodontal products, depending upon the ingredients, are included in this category. Traditional, homeopathic, and nonmedical substances that may be used to promote or maintain health are allowed, with a required warning on the product label (Health Canada 2017). Permitted product details are available at https://health-products.canada.ca/vhp-psa/en/about/3, and a current list of permitted substances is maintained and can be obtained at https://health-products.canada.ca/vhp-psa/en/substance-list.

A number of products, depending upon the purpose, route of administration, types, and classification, are excluded from the category. A product intended to cure, treat, or diagnose an animal is excluded. Any product that needs to be injected, inhaled, or delivered via intramammary or intrauterine route is not permitted under the program. Ophthalmic, transdermal patches and implants are also not included under the VHP provision.

Product types excluded are:

- Medicated feed and pet food
- Prescription drugs and controlled substances
- Dewormers and insect repellants
- Antimicrobial and hormones except botanicals with antimicrobial and mild hormonal activity
- Teat dips
- Specified risk materials (SRMs) of ruminants with potential risk of bovine spongiform encephalopathy (BSE) causing prions and including tissues, such as brain, skull, spinal cord, tonsil, eyes, etc.
- Combination products of homeopathic and traditional Chinese medicine with other types of ingredients such as vitamins or botanicals which are not in the same healing model

A complete list and the details of the currently excluded products are available at the Health Canada website https://health-products.canada.ca/vhp-psa/en/about/4. A current list of notified products is being maintained and can be obtained at https://health-products.canada.ca/vhp-psa/en/product-list.

9 Labeling Guidance

Health Canada guidelines require that labels and claims must not be false or misleading to create an inaccurate impression regarding the benefit or safety of a VHP. A product can claim to help a bodily function but not to cure a disease. For example, a product can have a claim "Maintains balance of healthy microflora" but not "Helps combat digestive problems." Homeopathic products consisting of a single ingredient can be labeled "Homeopathic," "Homeopathic Medicine," "Homeopathic Remedy," or "Homeopathic Preparation." A homeopathic product consisting of multiple ingredients can have a general health claim based on data in *Homeopathic Materia Medica*. A traditional Chinese medicine product can have the claim of traditional use but not for treatment or prevention, if the product has been used for a minimum of 50 consecutive years and its preparation and use have not changed. An example of an acceptable claim will be "In Traditional Chinese Medicine . . . used to replenish Qi."

Specific claims are permitted under the following conditions:

- An ingredient is absent in a product, and the ingredient is a safety concern and could potentially be present in the product.
- An ingredient can be listed on a claim made if its presence in sufficient quantity would have the expected effect.
- Absence of side effects is permitted if the claim is based on scientific evidence, and the incidences of side effects don't exceed that from placebo.

In addition, the manufacturer is responsible for naming the product such that the name will not cause confusion due to sound-alike or look-alike names. Promotional terms such as safe, nontoxic, nonpoisonous, or non-allergenic are considered misleading and prohibited. However, the word "safe" can

be used in providing directions such as "for safe use, do not exceed three tablets daily." Words like "natural alternative to. . ." or "alternative to. . ." are considered misleading and not permitted as such statements can potentially delay proper treatment of an animal, when needed (Health Canada 2012).

Details of the permissible statements that can be used for general and specific claims, including reference to homeopathic and Chinese VHP, can be obtained at https://health-products.canada.ca/vhp-psa/en/about/7.

Label recommendations provided in the guidance are:

- Brand name
- Dosage form
- Notification number (NN)
- Name and address of the manufacturer or distributor
- Lot number
- Expiration date or shelf life
- Adequate directions for use
- Quantity of each active (medicinal) ingredient per dosage unit
- Net amount (net contents)
- List of excipient ingredients (i.e., non-medicinal ingredients)
- Contact information "For questions or to report a side effect"

Label requirements are written to prevent an inaccurate or misleading impression about the nature, usefulness, safety, recommended dosage, quantity, and composition of a product. Contact information readily available on the label would be helpful in reporting adverse effects to the manufacturer or to a Canadian representative of an imported product. Details and additional information about VHP label requirements can be obtained at https://health-products.canada.ca/vhp-psa/en/about/6.

10 Manufacturing Requirements

Manufacturing of VHP is required to follow Part 3—Good Manufacturing Practices (GMPs) described in the Natural Health Products Regulations (SOR/2003-196). GMP guidelines include the specification, premises, equipment, personnel, sanitation program and operation, as well as the quality assurance program of the manufacturer (Health Canada 2012).

11 Reporting of Adverse Effects

A manufacturer or a Canadian representative, if the product is imported, is required to monitor and maintain a record of adverse reactions of a marketed product. All serious adverse reactions must be reported within 15 days of receiving event information. Adverse reaction reports are used by Health Canada to issue advisories or warnings and to change safety information of a product when required. Health Canada has the authority to remove any unsafe product from the market (Health Canada 2012).

12 Compliance and Enforcement

Health Canada approaches a regulatory non-compliance based on the risk posed to the general public and has authority to take appropriate action to address complaints, where non-compliance is found (Health Canada). Applicable actions are outlined in the Compliance and Enforcement Policy (POL_001) of Health Canada and are available at http://www.hc-sc.gc.ca/dhp-mps/compli-conform/gmp-bpf/pol/pol_1_tc-tm-eng.php.

Any changes to the notified VHP that need to be made following Health Canada review and approval, and major changes may result in a new NN for the product. Major changes include route of administration, dosage, duration of use, active ingredients, recommended use or purpose, and intended species.

Clear and precise Health Canada guidelines cover all major topics to ensure the safety of DS in animals and to protect the human food supply. Objectives, lists and details of included and excluded products, labeling requirements, manufacturing guidelines, and an adverse event reporting system are clearly outlined on the Health Canada website, easily accessible to manufacturers, distributors, consumers, and the general public.

13 Concluding Remarks and Future Directions

Nutraceuticals' legal definition and the products included are somewhat dissimilar in the USA and Canada. Nutraceuticals are called "dietary supplements" in the USA and "veterinary health products" in Canada. In the USA only oral products are considered dietary supplements, whereas in Canada topical and otic products are also permitted, depending upon the ingredients. However, in both Canada and the USA, nutraceuticals are not intended to cure, treat, or prevent a disease in animals.

Regulatory variations between the USA and Canada would hinder trade and marketing of nutraceutical products. Current FDA regulations are inadequate to fully address the safety, efficacy, and quality of natural supplements. Although no special provision is being given to supplements intended to be incorporated in feed in order to protect human health, products are being sold for pets without any pre-market approval. Safety is the biggest concern. Guidelines to assess the safety of a supplement in different species and appropriate dosage are needed. Effective regulations to ensure that

manufacturing meets quality standards of products that are free of contaminants are required. In addition, a comprehensive surveillance system to report adverse events to the manufacturer is required to fully assess the safety of the marketed products. On the contrary, Health Canada has outlined extensive guidelines for natural products to ensure animal safety without creating an unnecessary barrier for the sale of safe products. Prior to the sale, the manufacturer or the distributor is required to register and provide evidence to support the claim that the product is safe and effective. Guidelines have covered types of products that are included or excluded, manufacturing standards and labeling requirements to ensure safety and efficacy. A comprehensive system to record adverse events has been established with risk-based actions to deal with non-compliance to protect the general public.

Although many challenges exist in addressing safety, efficacy, and quality of nutraceuticals, comprehensive guidelines are necessary to ensure a product's safety and usefulness. Appropriate regulations are essential to ensure a product's safety and efficacy at proper dosage. The challenges with nutraceuticals can be resolved by scientists and regulators working together both nationally and internationally to provide a harmonized approach to get safe and effective products that are alternative to traditional medicine to the market, to meet the growing demand.

Regulatory Guidelines for Nutraceuticals in the European Union

Doriana Eurosia Angela Tedesco and Petra Cagnardi

Abstract

Nutraceuticals include a wide range of substances that can be used as medicinal products, feed material, or feed additives. This makes a substantial difference in the regulatory aspect of the marketing authorization in the European Union (EU) because for obtaining the appropriate marketing authorization, different procedures have to be followed. Since specific regulations do not apply to nutraceuticals, when they are used as feed additives for animal nutrition, they shall comply with Regulation No 1831/2003 on additives for use in animal nutrition. While nutraceuticals are administered as feed ingredients, they must comply with Commission Regulation (EU) No 68/2013. If nutraceuticals are administered with medical claims or if they exert a pharmacological effect, their use must comply with Directive 2001/82/EC. The EU legislation on this topic is very detailed and complex. Nevertheless, it allows the obtaining of marketing authorization with a wide safety margin, precautionary for animal health, human health, and the environment. The Scientific Committees and panels of the European Food Safety Authority (EFSA) are responsible for producing opinions that are used by the European Commission to adopt legislation related to animal nutrition. For veterinary medicinal products, the responsibility for marketing authorization is both granted by competent national authorities of the Member States or by the European Medicine Agency (EMA). This chapter describes legislation that is relevant to the marketing authorization of nutraceuticals for animals in the EU, elucidating the different categories of use, i.e., feed materials, feed additives, and veterinary medicinal products.

Keywords

Nutraceuticals · European guidelines · Feed materials · Feed additives · Veterinary medicinal products

1 Introduction

The use of nutraceuticals in animals has seen a substantial increase in the last few years, and several issues have arisen related to the correct identification for their use and how to obtain the appropriate authorization. In the category of nutraceuticals, there are a wide range of substances that can be used as medicinal products, feed material, or feed additives. The substantial differences in the regulatory aspects for marketing authorization in the European Union (EU) are strictly correlated with the lack of specific regulations on nutraceuticals and from the difficulties in categorizing them for a specific use. If nutraceuticals are administered with medical claims or if they exert a pharmacological effect, their use must to comply with the body of European Union legislation in the pharmaceutical sector for medicinal products for veterinary use according to Commission Directive 2001/82/EC (EC 2001).

Nutraceuticals can be administered as a feed or feed additive when they do not have a medical claim or a pharmacological effect. If nutraceuticals are administered as feed ingredients, they must comply with Commission Regulation (EU) No 68/2013 (EU 2013). When used as a feed additive for animal nutrition, nutraceuticals as herbs or their extracts, probiotics and prebiotics, shall comply with Regulation (EC) No 1831/2003 on additives for use in animal nutrition (EC 2003a). Some nutraceuticals are beneficial as their inclusion in the diet favorably affects animal welfare, the maintenance of animal health and of a healthy digestive system. In

R. C. Gupta et al. (eds.), *Nutraceuticals in Veterinary Medicine*, https://doi.org/10.1007/978-3-030-04624-8_58

any case, if nutraceuticals are administered as veterinary medicinal products, feed ingredient, or feed additive, only products with appropriate marketing authorization can be used.

The complexity of the marketing authorization of veterinary medicines, especially in food-producing animals, greatly limits the presence of some nutraceuticals (herbs) among the currently allowed molecules listed in Table 1 of the Commission Regulation (EU) No 37/2010 (EU 2010). In the list of allowed molecules, homeopathic compounds are included. In this case, the high dilution prevents the possible risks correlated with the dose administered. For food-producing animals, the risk of residues in edible tissues requires the definition of maximum residual limits (MRL) for all compounds administered according to Regulation (EC) No 470/2009 (EC 2009a).

In the same way, the EU legislation for inclusion of nutraceuticals in feed additives is very complex and limits new applications for marketing authorization.

2 Guidelines for the Distinction Between Feed Materials, Feed Additives, and Veterinary Medicinal Products

The distinction between feed materials, feed additives, and other products such as veterinary drugs has implications for placing them on the market, depending on the relevant applicable legislation. In order to provide an appropriate level of legal certainty, the European Commission has recently adopted Recommendation No 2011/25/EU (EU 2011) to provide non-binding guidelines for the distinction between feed materials, feed additives, and veterinary medicinal products. The aims of these guidelines are (a) to avoid inconsistencies in the treatment of such products, (b) to facilitate the work of national competent authorities, and (c) to help interested economic operators to act in a framework that provides an appropriate level of legal certainty. Guidelines are based on the provisions laid down in the legislative framework governing the different kinds of products concerned and their particular definitions.

2.1 Feed Legislation

According to the food law legislation reported in Regulation (EC) No 178/2002 (EC 2002), the following definitions can be found. Feed is any substance or product, including additives, whether processed, partially processed, or unprocessed, intended to be used for oral feeding to animals. Regulation (EC) No 767/2009 states in detail that "feed may take the form of feed materials, compound feed, feed additives, premixtures or medicated feeding stuffs" (EC 2009b).

Feed materials are products of vegetable or animal origin whose principal purpose is to meet animals' nutritional needs, in their natural state, fresh, or preserved, and products derived from the industrial processing thereof, as well as organic or inorganic substances, that may or may not contain feed additives, which are intended for use in oral animal feeding. Feed materials are primarily used to meet animals' needs for energy, nutrients, minerals, or dietary fibers. They are usually not chemically well-defined except for basic nutritional constituents. Effects which can be justified by scientific assessment and which are exclusive to feed additives or veterinary drugs should be excluded from the objective uses of feed materials (EC 2009b).

Feed additives are substances, microorganisms, or preparations, other than feed material (a product cannot be a feed material and a feed additive at the same time), which are intentionally added to feed or water in order to perform one or more specific function. According to Regulation (EC) No 1831/2003, the feed additive shall (a) favorably affect the characteristics of feed; (b) favorably affect the characteristics of animal products; (c) favorably affect the color of ornamental fish and birds; (d) satisfy the nutritional needs of animals; (e) favorably affect the environmental consequences of animal production; (f) favorably affect animal production, performance, or welfare, particularly by affecting the gastrointestinal (GI) flora or digestibility of feed stuffs; or (g) have a coccidiostatic or histomonostatic effect. Coccidiostats and histomonostats are substances intended to kill or inhibit protozoa and are the only veterinary medicinal products used as feed additives (EC 2003a).

Feed additives are defined by their functions and are intentionally added for those specific functions. However, these functions are not exclusive to feed additives. Thus, a feed material can also exert an additive function (e.g., as a thickener), but this should not be the only intended use (EU 2011).

Veterinary medicinal products (VMPs) are any substance or combination of substances presented as having properties for treating or preventing disease in animals or any substance or combination of substances that may be used in, or administered to, animals with a view either to restore, correct, or modify physiological functions by exerting a pharmacological, immunological, or metabolic action or to make a medical diagnosis. Substance is intended to represent any matter of the following origin: human (i.e., blood and blood products), animal (i.e., microorganisms, whole animals, parts of organs, animal secretions, toxins, extracts, blood products), vegetable (i.e., microorganisms, plants, parts of plants, vegetable secretions, extracts), and chemical (i.e., elements, naturally occurring chemical

materials and chemical products obtained by chemical change or synthesis) (EC 2001).

To confirm the substantial differences between feed materials and feed additive and VMPs, the labeling or the presentation of feed materials shall not claim that it will prevent, treat, or cure a disease, except for coccidiostats and histomonostats (EC 2009b).

In the same recommendation (EU 2011), the following definitions are reported:

Feed intended for particular nutritional purposes, regulated by Commission Directive 2008/38/EC, means feed which can satisfy a particular nutritional purpose by virtue of its composition or method of manufacture, which clearly distinguishes it from ordinary feed. A list of the intended uses of animal feed stuffs for particular nutritional purposes was established. This list indicates the precise use, i.e., the particular nutritional purpose (EC 2008a). Feed intended for particular nutritional purposes does not include VMPs or medicated feeding stuffs within the guidelines of Directive 90/167/EEC (EC 2009b; ECC 1990). Particular nutritional purposes (i.e., support of liver function in the case of chronic liver insufficiency, reduction of urate stones formation, or reduction of the risk of milk fever) can be achieved by feed. Feed intended for particular nutritional purposes meets the specific nutritional needs of animals whose process of assimilation, absorption, or metabolism is, or could be, temporarily or irreversibly impaired and who can therefore benefit from the ingestion of feed appropriate to their condition (EC 2009b).

Medicated feeding stuffs are not VMPs but, according to Regulation (EC) No 767/2009, a form of feed containing medicated premixes subject to a prescription by a veterinarian (EC 2009b).

3 Nutraceuticals as Feed Material

If nutraceuticals are administered as functional feed, they need to be included in the feed ingredients. The feed materials permitted in animal nutrition are reported in the Community Catalog of Feed Materials (EU 2013). This Catalog has been created as a tool to improve the labeling of feed materials and compound feed, according to Article 24 of Regulation (EC) No 767/2009 (EC 2009b).

All feed materials reported in the Catalog comply with restrictions on the use of feed materials in accordance with the relevant legislation of the Union. Feed business operators using a feed material entered in the Catalog shall ensure that it complies with the safety and marketing requirements set forth in Article 4 of Regulation (EC) No 767/2009 (EC 2009b), for example, the botanical purity of a feed material not less than 95%, the chemical impurity level resulting from manufacturing process and from processing aids, lacking or with a fixed, maximum content according to Regulation (EC) No 183/2005 (EC 2005). Particular attention shall be paid to compliance with Regulation (EC) No 1829/2003 for feed materials that are, or are produced from, genetically modified organisms or result from a fermentation process involving genetically modified microorganisms (EC 2003b).

The feed materials, which have a natural presence of microorganisms, may be placed on the market as the intended use of the feed materials is not linked to a function exerted by microorganism(s) according to Annex I of Regulation (EC) No 1831/2003 (EC 2003a). The presence of microorganisms, as well as any function resulting thereof, shall not be claimed on the feed materials and the compound feed containing them.

In part C of Commission Regulation (EU) No 68/2013, the list of feed materials reports the name of feed materials, the description, and the compulsory declarations (EU 2013).

The use of this Catalog (EU 2013) by the feed business operators shall be voluntary. However, the name of a feed material listed in the Catalog may be used only for a feed material complying with the requirements of the entry concerned. The person who, for the first time, places a feed material on the market that is not listed in the Catalog shall immediately notify the representatives of the European feed business sectors. The representatives of the European feed business sectors shall publish a register of such notifications on the Internet and update the register on a regular basis (EC 2009b). The Catalog was last updated with Regulation (EU) 2017/1017 (EU 2017).

Among feed materials, *Medicago sativa* is one of the most important crops used as fodder for livestock, and it is known as a source of natural bioactive compounds with potential health-promoting effects (Rafińska et al. 2017). Oats (*Avena sativa*) and barley (*Hordeum vulgare*) are two cereal grains that are good sources of β-glucan, a water-soluble fiber fraction that has plasma lipid- and glycemic-lowering effects. Therefore, the use of oats and barley as functional ingredients in pet foods may be beneficial in the control or prevention of obesity, diabetes mellitus (DM), and dyslipidemia (de Godoy et al. 2013). Fenugreek presents a unique and rare nutraceutical opportunity for providing multiple health benefits (Garg 2016). Many other different feed materials with nutraceutical properties can be found in the Catalog of Feed Material (EU 2013). In Table 1 some examples are reported.

4 Nutraceuticals as Feed Additives

The conditions for the use of feed additives are established by Regulation (EC) 1831/2003. Only those additives approved under the procedure provided for in this Regulation can be placed on the market, used, and processed in animal feeding under conditions set out in the authorization (EC 2003a).

Table 1 Examples of feed materials from Commission Regulation (EU) No 68/2013 on the Catalog of Feed Materials

Number	Name	Description	Compulsory declarations
1.1.1	Barley	Grains of *Hordeum vulgare* L. It may be rumen protected	
1.4.1	Oats	Grains of *Avena sativa* L. and other cultivars of oats	
2.8.1	Linseed	Seeds of linseed *Linum usitatissimum* L. (minimum botanical purity 93 %) as whole, flattened, or ground linseed. It may be rumen protected	
2.18.11	Soya (beans)	Soya beans (*Glycine max* L. Merr.)	Urease activity if > 0.4 mg N/g × min
3.5.1	Fenugreek seed	Seed of fenugreek (*Trigonella foenum-graecum*)	
4.1.14	Fructo-oligosaccharides	Product obtained from sugar beet through an enzymatic process	Moisture if > 28 %
4.3.1	Carrots	Root of the yellow or red carrot *Daucus carota* L.	
4.4.1	Chicory roots	Roots of *Cichorium intybus* L.	
4.4.9	Inulin (the name shall be supplemented by the plant species)	Inulin is a fructan extracted from roots of *Cichorium intybus* L., *Inula helenium*, or *Helianthus tuberosus*; raw inulin may contain up to 1 % sulfate and 0.5 % sulfite	
4.5.1	Garlic, dried	White to yellow powder of pure, ground garlic, *Allium sativum* L.	
5.1.1	Acorn	Whole fruits of the pedunculate oak *Quercus robur* L., the sessile oak *Quercus petraea* (Matt.) Liebl., the cork oak of *Quercus suber* L., or other species of oak	
5.3.1	Anise seed	Seeds of *Pimpinella anisum*	
5.12.1	Broken chestnuts	Product of the production of chestnut flour, consisting mainly of particles of endosperm, with fine fragments of envelopes and a few remnants of chestnut (*Castanea* spp.)	Crude protein Crude fiber
5.25.1	Grape pips	Pips from *Vitis* L. separated from grape pulp, from which the oil has not been removed	Crude fat Crude fiber
5.28.1	Perilla seed	Seeds of *Perilla frutescens* L. and its milling products	
5.31.1	Plantago seed	Seeds of *Plantago* (L.) spp.	
5.34.1	Thistle seed	Seeds of *Carduus marianus* L.	
5.36.1	Yarrow seed	Seeds of *Achillea millefolium* L.	
6.10.1	Lucerne; [alfalfa]	*Medicago sativa* L. and *Medicago* var. Martyn plants or parts thereof	Ash insoluble, in HCl if > 3.5 % of dry matter
7.1.1	Algae (the name shall be supplemented by the plant or algae species)	Algae, live or processed, including fresh, chilled, or frozen algae. May contain up to 0.1 % antifoaming agents	Crude protein Crude fat Crude ash
7.9.1	Liquorice root	Root of *Glycyrrhiza* L.	
7.10.1	Mint	Product obtained from drying aerial parts of the plants *Mentha spicata*, *Mentha piperita*, or *Mentha viridis* (L.), regardless of their presentation	

Nutraceuticals can be used as functional feed additives. These feed additives can adequately stimulate the local defensive responses and favorably influence resident GI microflora for optimizing growth and intestinal health status. Additives protect animals against physiopathological disturbances but are also able to improve nutrient digestion and absorption (Domeneghini et al. 2006). Plants/herbs and their extracts are being used increasingly not only as sensory additives but also for other purposes, notably better growth or feed conversion, improved meat quality, and for prophylaxis. Their use is further increased as replacement additives for the antibiotic growth promoters which were prohibited at the end of 2005 (Franz et al. 2005). Among other nutraceutical substances included in the feed additives categories are probiotics, prebiotics, vitamins, antioxidants, and some amino acids.

In order to protect human health, animal health, and the environment, feed additives should undergo a safety assessment through a community procedure before being placed on the market, used, or processed within the community. Any person seeking an authorization for a feed additive or for a new use of a feed additive shall submit an application. Regulation (EC) No 1831/2003 establishes the rules governing the community authorization of additives for use in animal nutrition. Moreover, Regulation (EC) No 429/2008 (EC 2008b) provides detailed rules for the implementation of Regulation (EC) No 1831/2003 concerning the preparation and presentation of applications and the assessment and authorization of feed additives.

The applicant should specify the intended effect of the additive and make a proposal for the classification of the

Table 2 Categories of feed additives (excluding coccidiostatic or histomonostatic) and examples of the most functional groups (EC 2003a)

Categories of feed additives	Examples of functional groups
Technological additives: Any substance added to feed for a technological purpose	• Antioxidants: substances prolonging the storage life of feed stuffs and feed materials by protecting them against deterioration caused by oxidation • Stabilizers: substances which make it possible to maintain the physicochemical state of feed stuffs • Binders: substances which increase the tendency of particles of feed stuffs to adhere • Anticaking agents: substances that reduce the tendency of individual particles of a feed stuff to adhere • Acidity regulators: substances which adjust the pH of feed stuffs • Denaturants: substances which, when used for the manufacture of processed feed stuffs, allow the identification of the origin of a specific food or feed materials • Substances for reduction of the contamination of feed by mycotoxins: substances that can suppress or reduce the absorption, promote the excretion of mycotoxins, or modify their mode of action • Hygiene condition enhancers: substances or, when applicable, microorganisms which favorably affect the hygienic characteristics of feed by reducing a specific microbiological contamination
Sensory additives Any substance, the addition of which to feed improves or changes the organoleptic properties of the feed or the visual characteristics of the food derived from animals	• Colorants – Substances that add or restore color to feed stuffs – Substances which, when fed to animals, add colors to food of animal origin – Substances which favorably affect the color of ornamental fish or birds • Flavoring compounds: substances which increase feed smell or palatability
Nutritional additives	• Vitamins, provitamins, and well-defined chemical substances having similar effect • Compounds of trace elements • Amino acids, their salts, and analogs
Zootechnical additives Any additive used to favorably affect the performance of animals in good health or used to favorably affect the environment	• Digestibility enhancers: substances which, when fed to animals, increase the digestibility of the diet through action on target feed materials • Gut flora stabilizers: microorganisms or other chemically defined substances, which, when fed to animals, have a positive effect on the gut flora • Substances which favorably affect the environment

additive in one or more categories and functional groups according to its major effects (Table 2.).

Applications for authorization of feed additives should take into account different documentation requirements for food-producing and other animals. At the time of application for authorization, the applicant should send the following details and documents directly to the European Food Safety Authority (EFSA) and the inclusion into the Register of Feed Additives (European Union 2018):

(a) Name and address
(b) Identification of the feed additive, a proposal for its classification by category, and functional group and its specifications, including purity criteria
(c) A description of the method of production, manufacturing, and intended uses of the feed additive, a description of the method of analysis of the additive according to its intended use, and, where appropriate, the method of analysis for the determination of the level of residues of the feed additive, or its metabolites, in food
(d) A copy of the studies which have been carried out and any other material which is available to demonstrate that the feed additive fulfills safety criteria and has favorably effects
(e) Proposed conditions for placing the feed additive on the market, including labelling requirements and, specific conditions for use and handling, level of use in complementary feed stuffs and animal species, and categories for which the feed additive is intended
(f) A written statement that three samples of the feed additive have been sent by the applicant directly to the community reference laboratory
(g) For additives which do not belong to either technological or sensory category and for additives consisting of, containing or produced from GMOs, a proposal for post-market monitoring

Table 3 Examples of feed additives from Annex I: List of additives from the Register of Feed Additives (European Union 2018)

Category	Functional Group	Subclassification	Additive
2 (Sensory additives)	b (Flavoring compounds)	Natural products—botanically defined	*Astragalus membranaceus* L. = *A. pycnocladus* Boiss.et Haussk. ex Boiss.: *Astragalus* tincture
			Crataegus oxyacantha L.p.p. et auct.: Hawthorne tincture CoE 156
			Curcuma longa L.: turmeric extract CAS 8024-37-1 FEMA 3086 CoE 163 EINECS 283-882-1/turmeric oleoresin CAS 84775-52-0 FEMA 3087 CoE 163 EINECS 283-882-1/turmeric oil CAS 8024-37-1 FEMA 3085 CoE 163 EINECS 283-882-1/turmeric tincture CoE 163
			Echinacea purpurea (L.) Moench.: *Echinacea* absolute/*Echinacea* extract [cats and dogs]
			Eleutherococcus senticosus Rupr. et Maxim. = *Acanthopanax s.* Harms: taiga root extract/taiga root tincture

			Zingiber officinale Rosc.: ginger oleoresin CAS 84696-15-1 FEMA 2523 CoE 489 EINECS 283-634-2/ginger oil CAS 8007-08-7 FEMA 2522 CoE 489 EINECS 283-634-2/ginger tincture CoE 489
4 (Zootechnical additives)	b (Gut flora stabilizers)	Gut flora stabilizers	*Saccharomyces cerevisiae*
			Enterococcus faecium
			Bacillus subtilis

(h) A summary containing the information provided in the previous points
(i) For additives falling within the scope of community legislation relating to the marketing of products consisting of, containing, or produced from GMOs, details of any authorization granted in accordance with applicable legislation

For certain additives, safety criteria (d) for the target animals can be presumed without the need for specific information. For all other additives, safety for the target animals can be assessed by extensive literature searches for studies on target animals, toxicity data (either existing or new) from repeated dose studies in laboratory animals, or tolerance studies in target animals.

In order to satisfy the assessment of additives in animal nutrition, and the rules concerning the procedure for the authorization, the European Food Safety Authority (EFSA) has published the following guidelines:

- Guidance on the assessment of the safety of feed additives for the target species (EFSA 2017a).
- Guidance on the assessment of the safety of feed additives for the consumer (EFSA 2017b)
- Guidance on the identity, characterization, and conditions of use of feed additives (EFSA 2017c)
- Guidance on the characterization of microorganisms used as feed additives or as production organisms (EFSA 2018a)
- Guidance on the assessment of the efficacy of feed additives (EFSA 2018b).

The authorized additive entered in the Register of Feed Additives shall be kept up to date (European Union 2018). Authorizations under Regulation (EC) No 1831/2003 shall be renewable for 10-year periods. An application for renewal shall be sent to the Commission at least 1 year before the expiration of the authorization (EC 2003a).

In the Register of Feed Additives, there are many examples of authorized additives with nutraceutical properties. Some of these additives represent a real alternative to in-feed antibiotics and include organic acids, prebiotics, and probiotics. Herbs and herbal products/botanicals represent a large array of nutraceuticals (Franz et al. 2005). In the category of sensory additives, a functional group of flavoring compounds (156 natural products—botanically defined) are included. Some examples of natural products—botanically defined—and gut flora stabilizers are listed in Table 3.

5 Nutraceutical Properties Claimed on Animal Feed Labels

In addition to the mandatory labeling requirements, the labeling of feed materials and compound feeds may also include voluntary labeling particulars. The labeling and presentation of feed may draw particular attention to the presence or the absence of a substance to a specific nutritional characteristic or to a specific function. The nutraceutical property can be highlighted in the voluntary labeling of feed for animals as described in Regulation (EC) 767/2009 (EC 2009a).

At the request of the competent authority, scientific substantiation of the claim is required. This allows the accuracy of the information given on the label to be verified, including the exact percentages by weight of feed materials used. Claims concerning optimization of nutrition and support or protection of physiological conditions are permitted, unless they contain a claim such as "it will prevent, treat or cure a disease" (EC 2009b). Claims considered medicinal, such as dosage, cures, treats, remedies, prevents, relieves, heals, or repairs, should be avoided. Conversely, claims not considered as medicinal can be used, such as use, administration, application, soothes, preparation, maintains, apply, cleanses, and health/healthy (FEDIAF 2011).

The Codes of Good Labelling Practice have been created as a tool to improve the labeling of feed materials and compound feeds in order to provide industry guidance to operators for the management of claims. The codes were developed for pet food (FEDIAF 2011) and for food-producing animals (COPA-COGECA/FEFAC 2016). Some claims can be particularly useful to provide information related directly to the nutraceutical. There is scientific evidence that particular feeds can make a significant contribution toward the promotion of health (e.g., support the immune function) and reduction of disease risk (e.g., decrease the risk of developing joint disease) (FEDIAF 2011).

A functional claim describes the effect of a feed material, nutrient, component, or additive on growth, development, or normal functions of the body. The claim may concern optimization of the nutrition and support or protection of the physiological conditions (Art. 13.2 EC 2009b). These effects go beyond meeting basic nutritional needs of the animals. The code of practice on voluntary labeling is applicable to compound feeds and feed materials used for food-producing and non-food-producing animals. Table 4 lists the authorized claims that can be used on the label when the scope is to underline some characteristics related to the nutritional, compositional, and functional claims.

In animal feed stuffs intended for particular nutritional purposes (EC 2008a), functional claims should be clearly separated from particular nutritional purposes that indicate the precise use. However, this does not prevent particular nutritional products from making additional functional claims. Besides the statutory statements on the precise use (i.e., brand name dietetic pet food for cats for reduction of struvite stone recurrence, the functional claim with fish oil for a shiny coat) may be used (FEDIAF 2011).

6 Nutraceuticals as Veterinary Medicinal Products (VMPs)

According to the definition previously reported in Directive 2001/82/EC (EC 2001), nutraceutical products having a beneficial effect on animal health require a marketing authorization if medicinal claims are made or if they contain certain ingredients that exert a pharmacological effect on the target animal. Thus, they have to follow legislation for medicinal products for veterinary use (EudraLex Volume 5 2015b).

Legislation for the marketing authorization of VMPs in the EU is rather complex and must address differences correlated to legislation of the Member States and also to the veterinary species. This includes food-producing animals and companion animals. Any VMPs to be legally placed on the market in the European Union or in any Member State must be the subject of a marketing authorization granted by the competent national authorities of the State or by the European Medicine Agency (EMA). The EMA provides guidance and support to companies researching and developing veterinary medicines. This includes scientific and regulatory information on how to design and run clinical trials, compliance standards, how to establish maximum residue limits for medicines and biocides, support to innovation, and incentives for companies developing medicines for minor use/minor species (MUMS)/limited markets (EudraLex Volume 5 2015b).

The body of European Union legislation in the pharmaceutical sector of veterinary products is compiled under "The rules governing medicinal products in the European Union," EudraLex Volume 5—EU pharmaceutical legislation for medicinal products for veterinary use—which is updated periodically to take into account new legislation (EudraLex Volume 5 2015b). The basic legislation is supported by a series of guidelines that are also published in volumes 4–9 (EudraBook V1 May 2015/EudraLex V30 January 2015). All regulations, directives, and guidelines are summarized in Table 5.

6.1 Marketing Authorization Procedure of VMP in the EU

With regard to the marketing authorization procedure of VMP, the general principles of assessing the quality, safety,

Table 4 Categories of authorized claims and examples of claims (COPA-COGECA/FEFAC 2016; FEDIAF 2011)

Categories of authorized claims	Typology of claims	Definition	Examples
Nutritional and compositional claims Refers to the presence or a high or low inclusion level of a particular component	Component claims (major components)	Refer to the presence of a particular feed material which can be accompanied by a qualifier	– "Brand name" with carrots and rice – High in [substance] (e.g., energy)
	Component claims (minor components)	Refer to the presence of a particular minor component	– "Brand name" with parsley – Low in [substance] (e.g., fiber)
	Nutrient and additive claims Presence/absence of a substance	Reference to the presence or a specific level of a nutrient or additive, including fatty acids, vitamins, etc., with no further connection to health effects	– "Brand name" contains vitamin E – Enriched with omega-3 fatty acids – Contains/brings/source of/provides/concentrated in/rich in [substance]
Functional claims	Nutrient function claims	Links the presence of a nutrient/combination of nutrients contained in a product to the physiological role in growth, development, and normal functions of the body	– Contains calcium for strong healthy bones and teeth – Vitamin E helps to protect the fat in body tissues from oxidation
	Enhanced function claims Support physiological functions of the animal or enable return to normal physiological status	Describes the specific beneficial effect of nutrients or other substances, alone or in combination, on physiological functions or biological activities beyond their established role in growth, development, and normal functions of the body. No reference should be made to particular diseases or pathological states	– Contains antioxidants to support the immune system – Contains chicory to improve growth of beneficial bacteria in the gut – Contributes to good liver function – Preserves udder integrity – Supports starting growth – Facilitates digestive transit – Fosters feed/drinking water intake/digestion/appetence – Maintains bowel flora balance
	Health maintenance and decreased disease risk claims	Relates to the consumption of a nutrient or other substances, alone or in combination, that help reduce the risk of disease development or maintain physiological functions or health	– "Brand name" contains omega-3 fatty acids to maintain healthy joints

and efficacy of a product are at the core of its benefit-risk balance. The European Union currently maintains four different registration procedures (Table 6) and multiple regulatory authorities for the registration of VMPs. Historically, each EU Member State maintained its own **National Procedure** (NP), which required national assessments and resulted in licenses valid only in one country. The **Centralized Procedure** (CP) must be submitted to the EMA and will enable it to issue a marketing authorization valid in all Member States, Iceland, Norway, and Liechtenstein. The **Mutual Recognition Procedure** (MRP) allows obtaining authorizations for a product in two or more Member States. If an authorization has already been issued in one EU State, the holder may apply to one or more Member States to issue identical authorizations based on mutual recognition of the reference authorization. This procedure intends to harmonize between Member States the individual assessment of the same data set, which may result in different label claims. The

Table 5 European law on veterinary medicinal products

Name	Description
Regulation	
EudraLex—volume 5	EU pharmaceutical legislation for medicinal products for veterinary use
Guidelines	
EudraLex—volume 4	Guidelines for good manufacturing practices for medicinal products for human and veterinary use
EudraLex—volume 6	Notice to applicants and regulatory guidelines for medicinal products for veterinary use. Volume 6A, Procedures for marketing authorization; volume 6B, Presentation and content of the dossier; volume 6C, Regulatory Guidelines
EudraLex—volume 7	Scientific guidelines for medicinal products for veterinary use
EudraLex—volume 8	Maximum residue limits. Notice to applicants and guideline—Veterinary medicinal products—establishment of maximum residue limits (MRLs) for residues of veterinary medicinal products in foodstuffs of animal origin
EudraLex—volume 9	Guidelines for pharmacovigilance for medicinal products for human and veterinary use. Volume 9B—Pharmacovigilance for Medicinal Products for Veterinary Use
Directives	
Directive 2001/82/EC	Community code relating to veterinary medicinal products
Regulation (EC) No 470/2009 of the European Parliament and of the Council of 6 May 2009	Community procedures for the establishment of residue limits of pharmacologically active substances in foodstuffs of animal origin
Commission Regulation (EU) No 37/2010 of 22 December 2009	Pharmacologically active substances and their classification regarding maximum residue limits in foodstuffs of animal origin. Table 1, Allowed substances; and Table 2, Prohibited substances

Table 6 Marketing authorization procedures available in EU for VMP (EC 2001)

Type	Assessment	License validity
National Procedure (NP)	National competent authorities	Only in one country
Centralized Procedure (CP)	European Medicines Agency (EMA)	All Member States, Iceland, Norway, and Liechtenstein
Mutual Recognition Procedure (MCP)	Authorization issued in the EU, the holder applies to one or more other Member States to issue identical authorizations based on mutual recognition of the "reference" authorization	Two or more Member States
Decentralized Procedure (DCP)	No marketing authorization issued in any country. The applicant requests one country to become the Reference Member State (RMS) in the procedure and asks recognition by national authorities of a first assessment performed by one Member State	Several Member States

Decentralized Procedure (DCP) has many similarities with the MRP and can be used to obtain marketing authorization in several Member States in parallel, if the applicant does not have marketing authorization for the medicinal product in any country. The Decentralized Procedure is based on recognition by national authorities of a first assessment performed by one Member State. The applicant requests one country to become the Reference Member State (RMS) in the procedure, while submitting an application for marketing authorization in all countries simultaneously (EC 2001).

6.2 VMPs and Use in Food-Producing or Companion Animals

To increase the complexity of VMP there are the animal species characteristics. The use of VMP in companion animals is performed under the veterinary responsibility with veterinary drugs authorized for specific diseases in the specific species. The "off-label use," intended as the use of a VMP not in accordance with the summary of the product characteristics, including the misuse and serious abuse of the

product, is allowed in these animals, so as the use of drugs for human use, unless no specific veterinary product is available or following a cascade system as reported in EMA/CVMP/AWP/237294/2017 (EC 2001; EMA 2017).

When animals are reared to produce food intended for human consumption, i.e., meat, offal, milk, eggs, and honey, the focus is on the potential for pharmacologically active residues in the tissues or products of treated animals at the time of slaughter or collection, which may subsequently be ingested by the consumer.

A VMP may not be the subject of a marketing authorization for administering to food-producing species unless the pharmacologically active substances which it contains appear in Table 1 of Commission Regulation 37/2010 on pharmacologically active substances and their classification regarding maximum residue limits in foodstuffs of animal origin (EC 2001; EU 2010). This limits the possibility of therapeutic treatments in food-producing animals to those substances that have been thoroughly evaluated to be safe for animals and also for human consumer. Thus, special attention needs to be paid to products intended for use in food-producing animals, as it is often, but not always, necessary to make an application for the assessment of human food safety and MRLs (EudraLex Volume 8 2015e). In the EU, all MRL applications must be submitted to the EMA, but marketing authorization applications can be made to either the EMA, i.e., in case of Centralized Procedure, or to the national authorities, i.e., National Procedure, as reported above (EC 2001).

The general principle at the base of an MRL definition for parent compounds and/or metabolites is to use data from studies in laboratory animals to establish an acceptable daily intake (ADI) of the drug residues without risks for consumers' health. The setting of the ADI is very precautionary for human health and includes multiple safety factors and worst-case assumptions. Once the ADI has been established, the MRLs of pharmacologically active substances are set for each edible tissue (meat, offal, milk, honey, egg) so that the consumer could ingest food of animal origin every day without exceeding the ADI and consequently posing any risks for his health (EC 2009a).

In food-producing animals it is not possible to administer pharmacologically active substances that are not listed in Table 1 (EU) No 37/2010 (EU 2010). Nevertheless, when particular treatments are necessary with substances not on the list, animals have to be excluded from the production of food destined for human consumption (EC 2001, 2009a).

Considering the premises, nutraceuticals also administered in food-producing species must be listed in Table 1 of allowed substances in Commission Regulation (EU) No 37/2010 (EU 2010). The natural products botanically defined included in the list are approximately 115, varying from *Absinthium extract* to *Viscum album* and for none of these an MRL is required (EU 2010). An excerpt of the list is reported in Table 7.

6.2.1 Homeopathic Veterinary Medicinal Products

Natural products botanically defined may also be used as "homeopathic veterinary medicinal products." A simplified registration scheme has been implemented for homeopathic remedies, which are placed on the market without medical claims and where there is sufficient dilution to guarantee safety of the product.

Only homeopathic veterinary medicinal products, which satisfy all of the following conditions, may be subject to a special, simplified registration procedure:

- They are administered by a route described in the European Pharmacopoeia or, in the absence thereof, by the pharmacopoeias currently used officially in Member States
- No specific therapeutic indication appears on the labeling of the veterinary medicinal product or in any information relating thereto
- There is a sufficient degree of dilution to guarantee the safety of the medicinal product. In particular, the medicinal product shall not contain more than one part per 10,000 of the mother tincture (EC 2001)

Homeopathic medicinal products may be administered to companion animals under the responsibility of a veterinarian. In food-producing animals, the administration of homeopathic veterinary medicines is permitted if the active constituents appear in Table 1 of Commission Regulation (EU) No 37/2010 (EU 2010).

7 Concluding Remarks and Future Directions

The noun "nutraceutical" is the union of the words "nutrition" and "pharmaceutical," and nutraceutical substances can be considered as both feed and drug. In any case, they are used to promote health promotion. The complexity for obtaining a marketing authorization for nutraceuticals is related to the definition of their intention to use, i.e., feed material or feed additive or VMPs. Once the intention is defined, the EU regulatory guidelines are very detailed although complex. They are freely and easily accessible on institutional websites (e.g., EFSA, EMA, EUR-Lex, etc.) by the applicant. So, regular updates of the authorized or allowed products are available.

Table 7 Extract of some natural compounds listed as pharmacologically active substances published in Table 1 of Commission Regulation (EU) No 37/2010 (EU 2010)

Pharmacologically active substance	Marker residue	Animal Species	MRL	Target tissues	Other provisions (according to Article 14(7) of Regulation (EC) No 470/2009)	Therapeutic classification
Adonis vernalis	NA	All food-producing species	No MRL required	NA	For use in homeopathic veterinary medicinal products prepared according to homeopathic pharmacopoeias at concentrations in the products not exceeding one part per hundred only	No entry
Aloe vera gel and whole leaf extract of *Aloe vera*	NA	All food-producing species	No MRL required	NA	For topical use only	No entry
Aloes, Barbados, and Capae, their standardized dry extract and preparations thereof	NA	All food-producing species	No MRL required	NA	No entry	No entry
Echinacea	NA	All food-producing species	No MRL required	NA	For use in homeopathic veterinary medicinal products prepared according to homeopathic pharmacopoeias at concentrations corresponding to the mother tincture and dilutions thereof only. For topical use only. For use in homeopathic veterinary medicinal products prepared according to homeopathic pharmacopoeias at concentrations corresponding in the products not exceeding one part per ten only	No entry
Ginseng, standardized extracts and preparations thereof	NA	All food-producing species	No MRL required	NA	No entry	No entry
Juniperi fructus	NA	All food-producing species	No MRL required	NA	No entry	No entry
Lauri folii aetheroleum	NA	All food-producing species	No MRL required	NA	No entry	No entry
Lauri fructus	NA	All food-producing species	No MRL required	NA	No entry	No entry
Lectin extracted from red kidney beans *Phaseolus vulgaris*	NA	All food-producing species	No MRL required	NA	For oral use only	No entry
Medicago sativa extractum	NA	All food-producing species	No MRL required	NA	For topical use only	No entry
Myristicae aetheroleum	NA	All food-producing species	No MRL required	NA	For use in newborn animals only	No entry
Piceae turiones recentes extractum	NA	All food-producing species	No MRL required	NA	For oral use only	No entry
Prunus laurocerasus	NA	All food-producing species	No MRL required	NA	For use in homeopathic veterinary medicinal products prepared according to homeopathic pharmacopoeias at concentrations in the products not exceeding one part per thousand only	No entry
Sinapis nigrae semen	NA	All food-producing species	No MRL required	NA	No entry	No entry
Solidago virgaurea	NA	All food-producing species	No MRL required	NA	For use in homeopathic veterinary medicinal products prepared according to homeopathic pharmacopoeias at concentrations corresponding to the mother tincture and dilutions thereof only	No entry
Strychni semen	NA	All food-producing species	No MRL required	NA	For oral use only at doses up to the equivalent of 0.1 mg strychnine/kg bw	No entry

Regulatory Guidelines for Nutraceuticals and Food Supplements in India

P. K. Gupta

Abstract

The use of nutraceuticals and animal feed supplements is very common because animals cannot always get enough nutrients from regular meals that the owners or farmers provide. Thus, the feed supplements provide essential nutrients that are widely used for maintaining good health in animals. In some cases, if an animal does not have some specific nutrition in its diet, it may not grow properly. In India the livestock sector alone contributes nearly 25.6% of value of output at current prices of total value of output in Agriculture, Fishing and Forestry sector. India is the third-largest egg producer after China and the United States and the fourth-largest chicken producer behind China, Brazil, and the United States. The overall contribution of the livestock sector in total GDP was nearly 4.11% during 2012–2013. The animal feed industry deals with food given to animals in cattle, poultry, and aquaculture sectors as a part of animal husbandry under the control of the Department of Animal Husbandry, Dairying and Fisheries, Ministry of Agriculture. Although the animal feed industry in India is almost five decades old, this industry is still in its infancy with high reliance on imports. However, the industry is very lucrative with a large number of domestic players and various foreign multinationals striving to enter into the market. Recently, in the interest of the public, Food Safety Act of 2006 with regulation in the year 2017 is likely to be implemented very soon. The law also has a commitment to Codex Alimentarius Commission, World Trade Organization (Basic Rights and Obligations, under the SPS along with their sanitary or phytosanitary measures as per their international standards, guidelines, or recommendations. Impact of Food Safety Act of 2006) still needs to be seen after its implication in the year 2018.

Nutraceuticals · Phytochemicals · Botanical products · Dietary supplements: probiotics · Prebiotics · Antioxidants · Mineral mixtures · Functional foods · Traditional medicine · Regulation · Health foods · Veterinary medicine · Livestock census

1 Introduction

Since ancient times, mankind has made medicines from the extracts of natural materials and has used these for various purposes. In 1989 Dr. Stephen De Felice, founder of the Foundation for Innovation in Medicine, coined the term "nutraceuticals" (the combination of nutrition and pharmaceutical), which became a newly accepted word in the *Oxford Dictionary*. Nutraceuticals have come a long way since a new trend in the care of companion animals emerged in the 1990s along with similar trends in the human sector. With the passage of the Dietary Supplement Health and Education Act of 1994, the definition of nutraceuticals has been expanded to include vitamins, minerals, herbs and other botanicals, amino acids, and dietary substances that humans use as supplements (Stauffer 1999). The term nutraceutical is not well accepted within global regulatory systems, while the term dietary supplements is. The relevance and impact of nutraceuticals have become more prominent as the present generation begins to focus more on preventive healthcare than ever before (Manoj 2015).

In India, the use of animal feed supplements is very common. These supplements provide essential nutrients that

R. C. Gupta et al. (eds.), *Nutraceuticals in Veterinary Medicine*, https://doi.org/10.1007/978-3-030-04624-8_59

are widely used for maintaining good health in animals. In some cases, if an animal does not have some specific nutrition in its diet, it may not grow properly. The nutritional values of animal feeds are influenced not only by their nutrient content but also by many other factors such as hygiene, digestibility, and effect on intestinal health. Historically, in India multiple laws and regulations prescribed various standards regarding food, food additives, contaminants, food colors, preservatives, and labeling. This chapter briefly discusses regulatory guidelines for animal nutraceuticals and feed supplements as relevant to India.

2 Historical Background

India has one of the fastest-growing economies in the world and ranks among the top ten most popular destinations for investment. Recent policy reforms have been designed to accelerate the pace of foreign investment, and although entering the market is still a complex, multistep process, the potential of the functional foods category is exciting. At present, only a small amount of perishable agriculture products are processed (~ 2%) in comparison to 80% in the United States. The multiplicity of food regulation policy makers and enforcement agencies prevailing in different sectors of the food industry has contributed to considerable confusion among consumers, producers, retailers, and businesses and is detrimental to the growth of the functional food and nutraceutical industries (Keservani et al. 2014; Anon 2018).

By the mid-1990s, the food processing sector laws for public health were framed in a veritable grid of regulation including a multitude of state and national laws. In 1998, the Prime Minister's Council on Trade and Industry appointed a subjective group on food and agriculture industries which recommended a unified legislation under a single food regulatory authority. Public experts and members of the Standing Committee of Parliament encouraged the convergence of current food laws with single regulatory authorities accountable for public health and food safety in India. Further, integrating all acts and orders relating to food and eliminating multilevel and multi-departmental controls over food, special emphasis was given to nutraceuticals and functional food, a poorly defined segment with growing potential and implications for consumer health. In 2002, a national non-profit association was charged with determining that every food manufacturing company could provide scientific-based support for their products in order to protect consumers and to promote and defend a regulatory environment conducive to the industry in general as well as for consumer protection. In 2003, a Ministry of Health expert group report indicated the need to create new categories in present food laws for regulating functional food and dietary supplements. It was recommended that there should be mandatory safety testing for these products. In India, voluntary standards are developed by the Bureau of Indian Standards and National Standards body, which is comprised of representatives from various food sector stakeholder groups. In 2005, a number of committees, including the Standing Committee of Parliament on Agriculture, emphasized the need for a single regulatory body and integrated law. Finally, the Indian Food Safety Standard Bill 2005 was signed into law and promised a major impact on the Indian food processing industry. The Indian Food Safety and Standard Act came into enforcement in 2006 with two main objectives: to introduce a single statute relating to food and to provide for scientific development of the food processing industry. These standards basically deal with product certification, quality, system certification and testing, and consumer affairs. Efforts are being made to match Indian standards with international ones (Keservani et al. 2014; Anon 2006a).

3 Contribution of Livestock Sector in GDP

The livestock sector alone contributes nearly 25.6% of value of output at current prices of total value of output in the agriculture, fishing, and forestry sector. The overall contribution of the livestock sector in total GDP was nearly 4.11% during 2012–2013. As per records of the Government of India, the livestock census started in the country in the year 1919. The livestock census in 2012 was 19th in the series. The animal husbandry and livestock sectors are critical for the rural economy, especially for small and marginal farmers. They not only contribute to their income but are also their best insurance against any natural calamity. The total livestock population consisting of cattle, buffalo, sheep, goats, pigs, horses and ponies, mules, donkeys, camels, mithun, and yak in the country was 512.05 million in 2012. The total livestock population had decreased by about 3.33% from the previous census in 2007. The total bovine population (cattle, buffalo, mithun, and yak) was 299.9 million in 2012, which shows a decline of 1.57% over the previous census. Total sheep in the country was 65.06 million in 2012, down by about 9.07% from the 2007 census. Total number of pigs in the country has decreased by 7.54% over the previous census, and the total goat population has declined by 3.82% over the previous census. Total goats in the country were 135.17 million, and pigs in the country were 10.29 million in 2012. Horse and pony population have increased by 2.08% over the previous census and the total horses and ponies in the country was 0.62 million in 2012. Total mules in the country have increased by 43.34% over the previous census, and the total for the country was 0.19 million in 2012. Camel population has decreased by 22.48% over the previous census, and total camels in the country were 0.4 million in 2012. The total

Table 1 Percent of animal population during census year 2012

Animal	Percent of total livestock population (512,057 million)
Cattle	37.28%
Buffaloes	21.23%
Sheep	12.71%
Goats	26.40%
Pigs	2.01%
Mithun, yaks, horses	0.37%
Total	100.00 (−3.33% as compared to census in 2007)

donkey population in the country has decreased by 27.22% over the previous census, and the total in the country was 0.32 million in 2012.

In 19th livestock census, 37.28% were cattle, 21.23% buffaloes, 12.71% sheep, 26.40% goats, and 2.01% pigs. The latest census revealed 37.58%, 19.89%, 13.50%, 26.53%, and 2.10%. Mithun, yaks, and horses were 0.37% of the total livestock (Table 1). In addition, there are a good number of dogs, elephants, and rabbits. The population of dogs has decreased from 19.08 million in 2007 to 11.67 million in 2012, a decrease of 38.85%. The population of rabbits has increased from 0.424 million in 2007 to 0.592 million in 2012, an increase of 39.55%. The population of elephants has increased drastically from about 1000 to 22,000 in absolute terms. Considering the huge animal population, India has sufficient supply of nutrition products. However, the market demand and size of the market are not commensurate with the livestock population, especially in bovines (Anon 2014).

As far as the poultry industry is concerned, India is the third-largest egg producer after China and the United States and the fourth-largest chicken producer behind China, Brazil, and the United States. The total poultry population in the country has increased by 12.39% over the previous census, and total poultry in the country was 729.2 million in 2012. Poultry population in the country, along with change from the previous census, is summarized in Table 2. Poultry is the most organized sector in animal agriculture worth billions of dollars. The growth is 6–8% in layers and 10–12% in broilers per year against the growth of agriculture as a whole, which is around 2.5% (Anon 2016).

Table 2 Poultry population in the country along with change from the previous census

Bird	Population in millions (census 2012)	Percent change over the census 2007
Fowls	692,646	+12.13
Ducks	23,539	−14.85
Turkeys and others	13,025	+277.32
Total poultry	729,209	+12.39

− = decrease, + = increase

4 Indian Market and Animal Health Nutrition: Current Trends

Indians, Egyptians, Chinese, and Sumerians are just a few civilizations that have provided evidence suggesting that foods can be effectively used as medicine to treat and prevent disease. Ayurveda, the 5000-year-old ancient Indian health science, mentioned benefits of food for therapeutic purposes. As such, these nutraceuticals and functional foods for animal use can be categorized as follows:

(a) Substances which have established nutritional functions such as vitamins, minerals, amino acids, fatty acids, etc.
(b) Herbal/phytochemicals: herbs or botanical products
(c) Dietary supplements: probiotics, prebiotics, antioxidants, enzymes, etc.

The industry's production is about three million tons, which represents only 5% of the total potential, and feed exports are not very high. The feed industry has modern computerized facilities and the latest equipment for analytical procedures and least-cost ration formulation, and it employs the latest manufacturing technology. In India, most research work on animal feeds is practical and focuses on the use of by-products, the upgrading of ingredients, and the enhancing of productivity.

The country has entered into a period of liberalization and this is bound to influence the livestock industry. The per capita consumption of milk, eggs, and broiler meat will grow. Indian functional feed and feed industries are undergoing a very exciting phase of growth. It is estimated that cattle nutraceuticals/feed supplements are growing at a compound annual growth rate (CAGR) of 6%, while poultry nutraceuticals are growing at CAGR of 9%. The animal health nutrition market is driven by milk boosters such as calcium supplements, followed by mineral mixtures and fat supplements. Calcium supplements and mineral mixtures contribute 85% of the total nutraceutical market in the bovine segment, and bypass fat constitutes 4%. Probiotics, vitamin premix, and other supplements constitute the balance of 11%. Similarly, amino acid supplements and toxin binders constitute 58% of the total poultry nutraceuticals, followed by vitamin premixes 17%, growth promoters 6%, and enzymes and probiotics 6% (Balasubramaniam 2013).

The entry of new players is easy due to lack of regulations, as well as improper implementation of food safety laws.

There are about 450 animal health companies in India. It is estimated that nearly 200 of these are engaged in marketing or manufacturing nutraceutical products for bovines, canines, poultry, and sheep. There are about 12 multinational companies operating in India in the animal health and nutrition segments. This has led to high bargaining power for buyers, driving down the prices of nutraceuticals and therefore thin margins. With increasing middle class and demand for protein supplement, there is an increase in demand for milk, which is the source of protein. In the year 2015–2016, it was estimated that the demand for nutraceutical market will grow up to 1300 crore rupee by 2017–2018 (Balasubramaniam 2013).

5 Overview of Regulations of Other Countries

As in some other countries, Indian legislation doesn't actually assign any specific legal status to nutraceuticals. Nutraceuticals have different legal definitions predominantly based on two aspects:

1. Origin or source
2. Benefit(s) that it can provide to the consumer

The nomenclature of nutraceuticals also varies in different countries (Table 3): the United States describes them as

Table 3 Summary of the differences in regulations in different countries

Country	Regulation
United States of America	FDA regulates both finished dietary supplement products and dietary ingredients. FDA regulates dietary supplements under a different set of regulations than those covering "conventional" foods and drug products. Under the Dietary Supplement Health and Education Act of 1994 (DSHEA) (FDA 2017)
European Union (EU)	In EU food law, a regulatory framework for "functional foods" or "nutraceuticals" does not exist. The rules are numerous and depend on the nature of the foodstuff: (a) If a claim was made that implies a medicinal benefit for a nutraceutical product, the product will need to comply with the regulatory requirements for medicinal products, in respect of safety, efficacy, quality testing, and marketing authorization procedures (b) Claims regarding the beneficial effects of nutraceuticals can only be "health claims" and not "medicinal claims" (c) The regulatory frameworks of PARNUTS (foods prepared for particular nutritional purposes) or dietetic foods and of food supplements may be applicable to some "functional foods." The Novel Food Regulation applies to "functional foods" that are "new." More precisely, nutraceuticals are regulated as "food supplements." The regulations are governed by the European Food Safety Authority (EFSA) (Coppens et al. 2006)
Canada	Under the Natural Health Products Regulations, which came into effect on January 1, 2004, natural health products (NHPs) are defined as: (a) Vitamins and minerals (b) Herbal remedies (c) Homeopathic medicines (d) Traditional medicines such as traditional Chinese medicines (e) Probiotics (f) Other products like amino acids and essential fatty acids NHPs must be safe to use as over-the-counter products and not need a prescription to be sold. The Natural Health Products Directorate (NHPD) has changed its name to the Natural and Non-prescription Health Products Directorate (NNHPD) (Anon 2015)
Japan	In Japan functional foods/nutraceuticals are regulated by "food for specified health uses" (FOSHU) and must be approved by the Ministry of Health and Family Welfare after the submission of comprehensive science-based evidence to support the claim for the foods when they are consumed as part of an ordinary diet (Yamada et al. 2008). As per the FOSHU Act, functional food can have three functions: (a) Nutrition (b) Sensory satisfaction (c) Physiological improvements
Australia	In Australia, medicinal products/foods are referred to as "complementary medicines" and are regulated as medicines under the Therapeutics Goods Act, 1989, which was implemented in 1991. The law is governed by the Department of Health and Ageing, and the definition covers herbal medicines, vitamins and minerals, nutritional supplements, homeopathic medicines, aromatherapy products, and traditional medicines (Anon 2013)
Russia	Nutraceuticals are regulated under the term biologically active dietary supplements (BADS). The definition covers nutraceuticals (vitamins, minerals, amino acids, dietary fibers) and parapharmaceuticals (bioflavonoid, alkaloids, essential oils, polysaccharides). As per the rule, BADS are "foodstuffs with clinically proven effectiveness." They are recommended prophylactically and for the prevention of pharmaceutical therapy-induced side effects and the achievement of complete remission (Yuliva 2014)
India	As with other countries, Indian legislation doesn't actually assign any specific legal status to nutraceuticals. Government of India regulations for nutraceutical public use include the Food Safety and Standards Act (FSSA), which was passed in 2006, and Regulations, 2017, for implementation by the Ministry of Health and Family Welfare and is yet to be implemented (Anon 2006b)

"dietary supplements," in Canada they're referred to as "natural health products," and Japan lists them as "food for specified health uses (FOSHU)." These definitions can be general or specific. There are distinct definitions and regulations for dietary supplements and functional foods in the United States, Canada, and Europe, whereas in Japan, both dietary supplements and functional foods are governed by the same set of regulations. The United States and Canada list the attributes that a product must have to be called a nutraceutical, whereas Europe and Japan only provide general guidelines on the properties that a product should have to be named as such. Traditional and herbal medicines are included in the definition of dietary/nutritional supplements in Canada. Japan does not mention traditional herbal medicines under FOSHU, but the United States includes herbs and botanicals in its definition. The Indian definition for human health (as per the Food Safety and Security Act 2006) specifies the ingredients that a product should have, and the general properties of nutraceuticals derived from traditional medicines have been excluded from this definition. Table 3 briefly summarizes the differences in regulations in different countries.

6 Regulations

Food laws in every country are the basis for regulations of all kinds of foods including health food, dietary supplements, functional food, and nutraceuticals, for which specific guidelines/regulations are framed to regulate the manufacture, sale, and quality of the product to be used. As indicated previously, Indian legislation doesn't actually assign any specific legal status to the feeds/foods use for animals except from time to time some basic requirements/specifications for the regulation of mineral mixtures for supplementing animal feeds. Recently, laws for various foods for human use have been enacted and will be discussed later in this chapter.

6.1 Regulations of Mineral Mixtures for Supplementing Animal Feeds

Animal feed (including for poultry and aquaculture) plays a vital role in the food chain as feed is one of the most crucial contributors to ensuring safe, abundant, and affordable animal protein. Incessant population growth in India and rising affordability have led to a surge in demand for animal protein. The animal feed industry deals with food given to animals in cattle, poultry, and aquaculture sector as part of animal husbandry under the control of Department of Animal Husbandry, Dairying and Fisheries, Ministry of Agriculture (Anon 2009). Indian feed industry predominantly caters to cattle, sheep and goat, poultry, and aquaculture feed segment. Although animal feed industry in India is almost five decades old, the industry is still in its infancy with high reliance on imports. However, the industry is very lucrative with a large number of domestic players and various foreign multinationals striving to enter into the market.

Growth of the Indian animal feed market is propelled by a rise in demand for animal protein, a surge in dairy products consumption, and growth of the livestock population. However, there are various factors restraining growth of the market, including high import duties on feed ingredients, vague regulatory regime, volatility in raw material prices, and frequent disease outbreak. The market is characterized by leading trends such as the advent of nontraditional feed ingredients, genetically modified animal feed, and technological innovation in the industry (Anon 2017a).

The sale of cattle feed and mineral mixtures in India is regulated through the Regulation of Manufacture and Sale Order (Anon 2009) in accordance with the terms and conditions of a registration certificate issued by the Registering Authority. No person shall carry on the business of manufacture, sale, or distribution in any manner of cattle feed and mineral mixtures except under and in accordance with the terms and conditions of a registration certificate issued by the registering authority. Specifications for various feed supplements are laid down by the Bureau of Indian Standards (BIS 1983, 1992, 2002).

Provided further, a person who, at the commencement of this order, was carrying on the business of manufacture, sale, or distribution of cattle feed and mineral mixtures shall obtain a registration within the period of 3 months from the date of commencement of this order. Every holder of a registration certificate, who manufactures, sells, or distributes cattle feed and mineral mixtures, shall conform to the specifications, provided from time to time by the committee of experts on cattle feed and mineral mixture constituted by the secretary (ADF), Department of Animal Husbandry, Dairying and Fisheries, Government of India. On the advice of a committee of experts, the secretary (ADF) may issue necessary amendments as needed (Anon 2017a, b, c).

The last decade has seen healthy growth in India for both food, feed supplements and grew at with higher CAGR (6–12%), pharmaceuticals grew at around 15%. Nutraceuticals and feed supplements provide big opportunities for India with its huge human as well as animal population and need for nutrition and will ride on the growth of food, feed, and nutrition because farmers and breeders become increasingly health conscious for their livestock. It seems likely then that the nutraceutical and feed supplement market in India will experience exponential growth. Regulatory frameworks all around the globe have been primarily set up to achieve the objective of ensuring food safety and protection of consumer interests. Regulations for nutraceuticals on the market include the Food Safety and Standards Act (FSSA), which was passed in 2006, and

Table 4 List of various old state laws as well as the national laws that were consolidated to form the Food Safety and Standards Act, 2006 (FSS Act)

Export (Quality Control and Inspection) Act 1963
Solvent Extracted Oil Control Order 1967
Solvent Extracted Oil Control Order 1967
The Insecticide Act 1968
Meat Food Products Order 1973
Prevention of Food Adulteration Act (PFA) 1954 rules (Ministry of Health and Family Welfare) with last amendments in 1986
Bureau of Indian Standards Act 1986
Environmental Protection Act 1986
Pollution Control Act 1986
Milk and Milk Products Order 1992
The Infant Milk Substitutes Feeding Bottles and Infant Food (Regulation of Production, Supply) Act 1992 and Rules 1993
Agriculture Produce Act, Essential Commodities Act 1995 (Ministry of Food and Consumers Affairs)
Vegetable Oil Product Control order 1998

Regulations 2017 by the Ministry of Health and Family Welfare which may be implemented by the end of 2018 (Anon 2006a, b, 2017b). The passing of this act in India is a significant first step, but much more has to happen to eliminate the confusing overlap with various old laws and regulations (Table 4). Thus, the FSS Act has been formulated with an aim to establish a single reference point for all matters relating to regulation and supervision of food safety and standards.

6.2 Commitment Towards International Standards

FSSAI is also the National Codex Contact Point (NCCP) of India and functions as an interface between the Codex Alimentarius Commission (CAC) and India as a member country. The FSSAI has adopted some of the Codex Alimentarius international food standards which contribute to the safety, quality, and fairness of this international food trade (Anon 2017b).

India as a member country has a commitment toward the World Trade Organization. Accordingly, Article 2 (Basic Rights and Obligations) under the SPS Agreement states "Members shall ensure that any sanitary or phytosanitary measure is applied only to the extent necessary to protect human, animal or plant life or health, is based on scientific principles and is not maintained without sufficient scientific evidence." Under the same agreement, article 3 requires "to harmonize sanitary and phytosanitary measures on as wide a basis as possible, Members shall base their sanitary or phytosanitary measures on international standards, guidelines or recommendations, where they exist, except as otherwise provided for in this Agreement, and in particular in paragraph 3 of the article" (Anon 2017c).

7 Regulatory Requirements for Entry in India

With recent implementation of FSSA, nutraceutical regulations are evolving in India. There is a possibility that some of the contents are conflicting/confusing, but for this industry to take a shape, regulations must be streamlined. In order to enter the Indian nutraceutical market, some of the very important areas to focus include product evaluation, actual product analysis, procuring licenses, and developing India-specific health and label claims (Anon 2017c).

8 Product Evaluation

Under specific environmental conditions in Indian, formulations may behave differently and they may be classified incorrectly. Hence, due diligence in terms of determining a specific amount for each ingredient and the combination of ingredients becomes extremely crucial. In order to perform product assessment as per the Indian regulatory definition, it is of utmost importance to examine each active ingredient and additive in the context of permissibility, standards, and dosage of vitamins/minerals allowed as per the therapeutic, prophylactic, or RDA for Indians. Also, manufacturers are unclear whether their products will be classified as a food or food supplement or drug in the context of the Prevention of Food Adulteration Act 1954 and Rules 1955, Food Safety and Standards Act 2006, and Drugs and Cosmetics Act 1940 and Rules 1945. The Food Safety and Standards Rules 2011 highlight the regulatory enforcement structure and procedures that the central government proposes to make. The structure has a hierarchy from commissioner of food safety to the number of officers and designations such as

food safety officer, food analyst, etc., who will be involved in the product analysis process at different points (Keservani et al. 2014).

Various steps in the product analysis include:

1. Developing documents and authenticating them by the concerned authority
2. Sample collection (in the presence of witnesses)
3. Sample dispatch to concerned authority (different processes for bulk package and single package)
4. Food analysis
5. If analysis is not completed within stipulated period of time, further action plan by designated officer
6. Adjudication proceedings (holding inquiry, appeal procedure, hearing, etc.)

9 The Benefits

Nutraceuticals for veterinary use do not need strict regulations. In this respect, nutraceuticals offer significant advantages compared with the long development times and high manufacturing cost of drugs, whereas the efficacy testing of nutraceuticals requires less time for farmed species when compared to testing for humans (Varghese and Mishal 2014).

10 The Disadvantages

The major problems in regulations in India are:

1. Legal definitions for nutraceuticals/functional foods are somewhat different in different countries; for example, in India, functional foods can include herbal extracts, spices, fruits, and nutritionally improved foods or food products with added functional ingredients.
2. The requirements to make therapeutic claims are unrealistic—herbals are not patentable.
3. As there is no provision to patent, the dietary supplement label is inappropriate for nutraceuticals.
4. Problems such as quality control and unethical and criminal elements exist in this industry.

11 Role of Government and Public Sector Institutes

The government does not provide any subsidy or support for this sector. However, nutraceuticals and cattle feed segment is not taxable, which in itself is a noteworthy support extended by the government. The role of public sector institutes has been insignificant, and contribution to the industry is not up to the mark. However, the National Dairy Development Board (NDDB) and the Indian Council of Agriculture Research (ICAR) have done mineral mapping and developed mineral supplements required as per region, soil, and other conditions.

There are many technologies developed by universities, ICAR, etc. However, materializing these technologies into new products is highly localized and minimal. Mainly private players have played a larger role in this, and even multinational companies have a larger presence with new value-added products in this segment. Indian companies such as Indian Immunological Limited (IIL) have developed many nutrition products with the help of their parent organization; NDDB has entered into the market successfully.

12 Concluding Remarks and Future Directions

Some of the key challenges before the industry include regulation to bring in quality standards that will enable many companies to upgrade. The Bureau of Indian Standards (BIS) norms are being used for the use of feed supplements in animal, poultry, and aquaculture industries. However, the procedure in vogue has no control over various diseases that are affecting the animal and poultry industry, which can override all efforts to make livestock productive through nutraceuticals, improvement in breeding and genetic status of dairy animals, and integration of dairy sector. Although the Food Safety and Standard Act 2006 for human health defines functional food/nutraceuticals legally, there are still further effective regulations. Guidelines and suitable protocols are required to gain momentum for effective implementation across the nation. There is a need to clarify and formulate the regulatory framework for nutraceutical use in veterinary practice. If substantiation effectively enforced the Food Safety and Standard Act, there is the potential to open up tremendous opportunity for the functional food or nutraceutical industry. To conclude, the passing of the Food Safety and Standard Act 2006 was a significant first step, but a lot more has to happen to eliminate the overlap of old laws and regulations. The Food Safety and Standards Regulations 2017 announced in the *Gazette of India* that regulating manufacture, distribution, and sale of nutraceuticals, functional foods, and dietary supplements in India may prove useful in the implementation of food safety for all, but this has yet to be fully implemented. It is expected that this act may trigger the formation of a similar act for nutraceuticals and functional foods used in animals.

Uses and Regulatory Guidelines for Nutraceuticals in China

Jianhua Sun, Zhongqi Jiang, Feng Wang, and Likun Gong

Abstract

In China, nutraceuticals are not regulated as veterinary drugs but are approved as feed additives, feed premix, or feed. The use of additives in animal feed is supervised by the Ministry of Agriculture, which is responsible in evaluating, regulating, and publishing a catalog of feed additives, with advised dosing and limitations. However, detailed information is usually available in the product insert from the related company. Nutraceuticals traditionally include amino acids, vitamins, minerals, enzymes, live microorganism, antioxidants, and others. Herbal medicine additives are popular and therefore frequently used in animal feed. Among them are garlic, tea polyphenol, the extract of *Eucommia ulmoides* leaves, the extract of *Epimedium*, and the extract of *Perilla* seed. Additives are largely applied in intensive farming by a nutritionist, without the need of a prescription from a veterinarian. However, more veterinarians are increasingly prescribing nutraceuticals for pets. In this chapter, we will discuss the classification and regulatory rules of commonly used nutraceuticals approved in China for a better understanding of the regulatory provisions and rational application scenarios.

1 Introduction

A nutraceutical is a pharmaceutical-grade and standardized nutrient (Sarris et al. 2016) that has been defined as "the use of micronutrients, macronutrients, and other nutritional supplements as therapeutic agents" (AVMA 1999). However, in China, nutraceuticals do not exist as a regulatory category and are controlled as dietary supplements (premix), feed additives, or feeds. Animal nutraceuticals are regulated by the Ministry of Agriculture (MOA) which has published an essential list of feed additives for animals (Notice No. 105, 1999). This list was updated in MOA Notice No. 1224 (2009), in which the source, animals, recommended dosage, and limitations of the feed additives were all included. Eight years later, the document was updated in Notice No. 2625 (2017), in which more additives and specified limitations were included.

Since China joined the World Trade Organization (WTO) in 2001, many corporations gained access to the Chinese veterinary drug market. Within the pet market, among the categories of feed supplements available, several are from Japan, Germany, and the UK. As compared with the USA, China's animal medication industry is relatively young. However, the potential is significant not only for China's rapid economic growth but for the increasingly larger consumer demand as well.

In all, the use of nutraceuticals for animals is a relatively recent practice in China. While nutraceuticals are commonly added in livestock feeds, especially during vaccination, breeding, and egg- or milk-producing period, these dietary supplements are also becoming popular in small animal veterinarians. However, there are still some companion animal veterinarians that refuse to use nutraceuticals due to insufficient data on efficacy and safety. In addition, animal owners' acceptance of nutraceuticals may influence this decision.

R. C. Gupta et al. (eds.), *Nutraceuticals in Veterinary Medicine*, https://doi.org/10.1007/978-3-030-04624-8_60

2 Classification

Nutraceuticals are registered as animal feed premix, feed additives, or feed, rather than veterinary drugs. This classification applies as guidelines for the approved feed additives, and the feed additives were divided into amino acids, vitamins, minerals, enzymes, life microorganisms, flavoring and appetizing substances, antioxidants, and others (Notice No. 2045, 2013a, b). It is worth mentioning that as nutraceuticals, herbal medicine or their bioactive constituents are popular and frequently used in China. For example, garlic (flavoring and appetizing substance), tea polyphenol (antioxidants), and the extracts from *Eucommia ulmoides* leaves, *Epimedium*, or *Perilla* seeds are among them.

Nutraceuticals used for pets are generally cataloged according to their functions. Common products on the market include those for joint repair treatment with the main ingredients of glucosamine, chondroitin sulfate, green-lipped mussel nutrient, and vitamin and those for improving parorexia and growth promotion which contained vitamins and trace elements. In addition, products used to prevent hair dry/peeling, to promote recovery of the natural color of hair, and to increase pigmentation with lecithin combined with natural seaweed powder are also often applied. Moreover, probiotics, microelement tablets, and calcium preparations containing crushed bone, vitamin D3, calcium lactate, and calcium gluconate are also available for selection.

3 Uses of Chinese Native Nutraceuticals

3.1 Garlic (Allimin)

Garlic (*Allium sativum* L.) originated in China and is a popular ingredient for cooking due to its strong smell and delicious taste. Garlic is nutritious with rich mineral substances and trace elements. Moreover, garlic possesses various biological properties, such as immunomodulatory, anticancer, antimicrobial, antihypertensive, and antiatherosclerotic (Lin et al. 2017; Lou et al. 2018; Sheppard et al. 2018; Dubey et al. 2017; Gonen et al. 2005). Therefore, as a powerful functional food, garlic has been accepted and widely applied for more than 5000 years, both for as a food additive and for treating a wide variety of diseases.

Garlic contains allimin ($C_6H_{10}OS_2$), which is metabolized by alliinase from alliin, and is responsible for garlic's pungent flavor and aroma as well as its therapeutic benefit (Alhashim and Lombardo 2018). However, allicin is an unstable compound that is only briefly present in fresh garlic after it has been crushed. In fact, sulfur compounds, for example ajoene, may play an important role in garlic's health benefits (Demeule et al. 2004; Geng et al. 1997; Kaschula et al. 2016).

Garlic powder is traditionally and extensively used in the feeds of fish, chickens, pigs, cows, and even cynomolgus monkeys. The diet supplemented with garlic at 1.0–1.5 g/kg significantly improved performance in boiler chickens (Jimoh et al. 2013) and at 20 g/kg enhanced the resistance of African catfish fingerlings to *A. hydrophila* infection (Eirna-liza et al. 2016). As for garlic extract, the dose required depends on its allicin content. For instance, a feed with 200 mg kg garlic extract (20% allicin) could raise vaccination efficacy of *Clostridium perfringens* toxoid in rabbits (Abu El Hammed et al. 2016). Garlic powder and the structural formula of its most representative bioactive constituents are shown in Fig. 1 (structure originate from Martins et al. 2016).

3.2 Tea Polyphenol

Tea polyphenols (TPs), which contain epigallocatechin gallate (EGCG), have several beneficial properties, including anticancer, antioxidant, antidiabetic, antihypertensive, antimicrobial, and antimetabolic syndrome effects, as well as the ability to improve fertility in humans and animals (Posadino et al. 2017; Rahman et al. 2018). The structural formula of EGCG is shown in Fig. 2.

Green tea polyphenol is valuable for pigs, chickens, and other animals. For example, an extract containing 0.2% w/v polyphenols can lessen sperm injury resulting from freeze-thawing in swine (Kitaji et al. 2015), and green tea polyphenols fed at 50 and 100 mg/kg body wt for 20 days could alleviate obesity in broiler chickens via regulation of the lipid-metabolism-related genes and transcription factor expression (Huang et al. 2013).

Although tea polyphenol is a luxury for animals, there is still a huge quantity of extract to be gained from pruning and coarse old leaves of tea trees. Details of health benefits of tea polyphenol can be found in several reviews (Williamson 2017; Bag and Bag 2018; Mao et al. 2017).

3.3 Extract of *Eucommia ulmoides* Leaves

Cortex *Eucommia* (Du zhong, in Chinese), the bark of *Eucommia ulmoides* Oliver (Eucommiaceae), has been used in traditional Chinese medicine for a long time. *Eucommia ulmoides* leaves contain iridoids, lignans, flavonoids, phenols, and terpenes, and as a result, the extract of *Eucommia ulmoides* leaves has favorable effects against not only hypertension, obesity, and gastric ulcer; they also have antioxidative, anti-sedative, and anti-hypnotic properties (Deyama et al. 2001; Li et al. 2017; Hirata et al. 2011).

The extract of *Eucommia ulmoides* leaves and structural formula of chlorogenic acid are shown in Fig. 3.

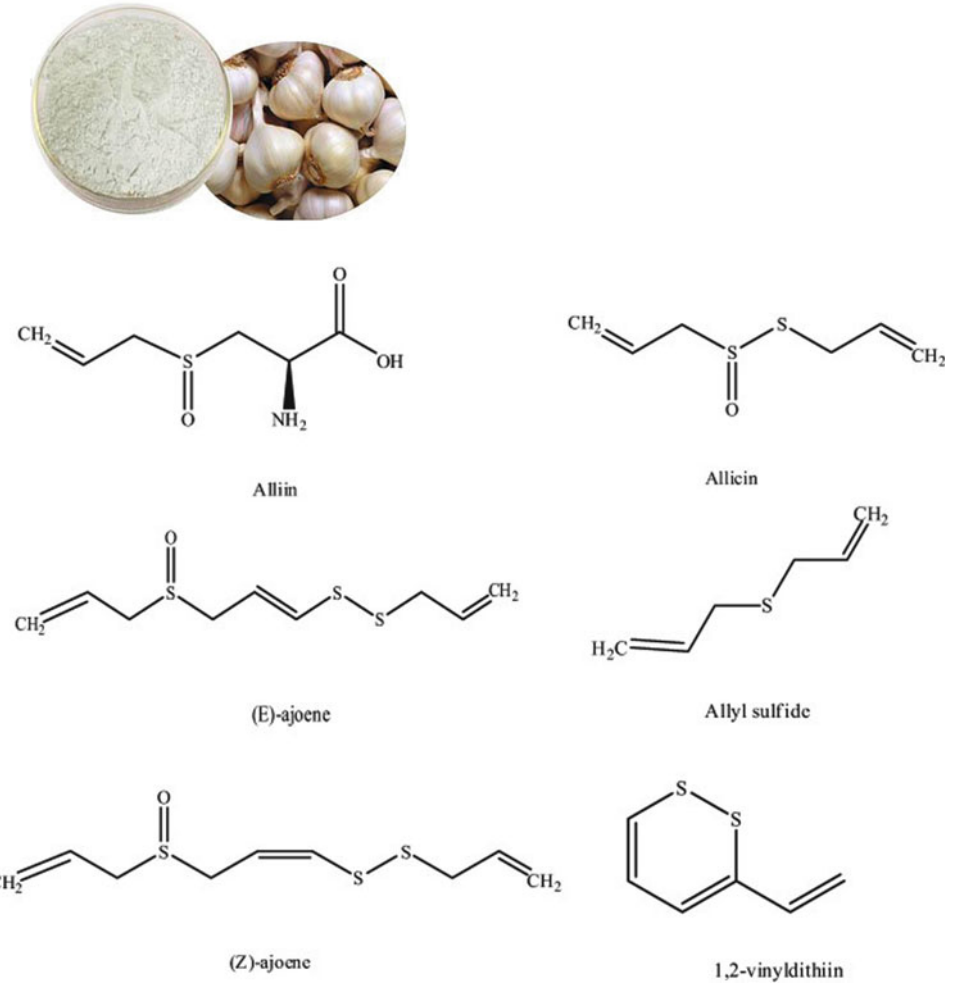

Fig. 1 Stereochemical structure of the most representative bioactive constituents from *Allium sativum* L.: alliin, allicin, allyl sulfide, (E)-ajoene, (Z)-ajoene, and 1,2-vinyldithiin

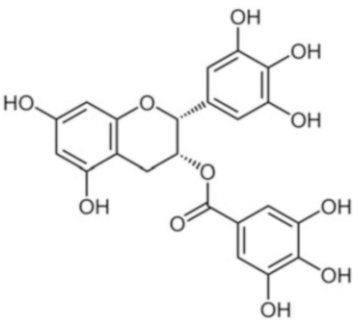

Fig. 2 Structural formula of epigallocatechin gallate

In rats and pigs, 5% of *Eucommia ulmoides* leaf extract added to a high-fat diet can reduce blood pressure and weight (Hosoo et al. 2017). Similarly, the same extract level can improve growth performance, blood indices, and meat quality for growing pigs (Lee et al. 2009).

The leaves of *Eucommia ulmoides* are also dried and used in tea for humans. Although of lower quality, the leftover

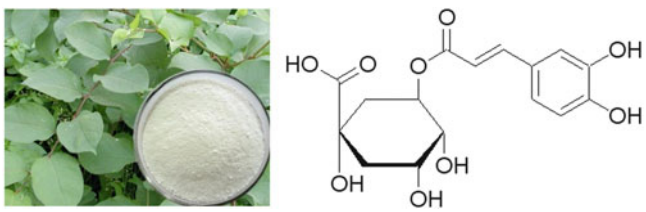

Fig. 3 *Eucommia ulmoides* and structural formula of chlorogenic acid

extract could be applied to animal feed. Currently, the recommended dose of the *Eucommia ulmoides* leaf extract in animal feeds ranges from 80 to 200 mg/kg.

3.4 Extract of *Epimedium*

As a common traditional Chinese medicine, *Epimedii folium* has been used for treating erectile dysfunction, postmenopausal syndrome, and osteoporosis for thousands of years.

Epimedium's main component is icariin (8-prenyl derivative of kaempferol 3,7-*O*-diglucoside), and it can protect the ischemic myocardium in dogs and prevent glucocorticoid-induced femoral head necrosis properties in rats. Furthermore, the extract possesses the properties of antioxidant activity and immunomodulatory effect (Wang et al. 1998, 2011; Yuan et al. 2016). The extract of *Epimedium* leaves and structural formula of icariin are shown in Fig. 4.

The extract of *Epimedium* is a double-edged sword, which may only be used in suitable animals during an appropriate period. The safe dose in feed is 150 g/kg recommended by the manufactures for breeding livestock or boiler chickens.

3.5 Extract of Perilla Seed

Perilla seed is obtained from the plant *Perilla frutescens* L. which is commonly called Zisu in Chinese, Cha-jo-ki in Korean, and Shiso in Japanese. Amino acids, linolenic acid, rosmarinic acid, and vitamin E are the main active substances in perilla seeds, and they lower blood lipids, inhibit bacteria, and are anti-inflammatory and antioxidative (Wang et al. 2016). Senavong et al. (2016) reported that an extract of perilla leaf and seed oil showed a neuroprotective effect by decreasing oxidative stress and inhibiting tau-protein hyperphosphorylation in vitro.

Müller-Waldeck et al. (2010) described that several genotypes of *P. frutescens* L. showed remarkably high contents of carotenoids, especially lutein, and various phenolic compounds. However, they also contain perilla ketone, a potent lung toxin (Guerry-Force et al. 1988). Although the toxic dose of perilla ketone in humans is unknown, it is recommended that perilla ketone-containing perilla species not be consumed. Therefore, for the safety of animals, the amount of perilla ketone in the extract of perilla seed need to be strictly controlled via perilla genotypes identification and optimization of the extraction methods.

The figure of perilla seed extract and the structural formula of alpha-linolenic acid are shown in Fig. 5. The structural formula of perilla ketone is shown in Fig. 6.

The addition of 250–350 mg/kg *Perilla frutescens* seed extracts to the diet significantly increased production performance of growing finishing pigs (Chu et al. 2011). In addition, 300 mg/kg *Perilla frutescens* seed extracts added to the diet considerably increased the laying rate, average daily egg production, and immune function of laying hens during the late laying peak period. This addition improved immune function of finishing cattle as well (Shi et al. 2015; Zhang et al. 2011). Currently, the manufacturer recommends adding a daily dose of 20–50 mg/kg *Perilla frutescens* seed extracts to animal feed.

4 Regulatory Guidelines of Nutraceuticals in China

4.1 List of Current Version of Regulatory Guidelines

The State Council is the supreme administrative agency for animal feed and feed additives in China. MOA is responsible for the management of animal feed and feed additives. Their published Notice and Decree gives guidance for animal feed production, import, and use of feed and feed additives.

(a) *Regulation for Management of Feed and Feed Additive*
State Council, Decree No.609, 2011
(b) *Approved Feed Additive*
MOA, Notice No. 2045, 2013a, b
(c) *Regulation of Safe Use for Feed Additives*
MOA, Notice No. 2625, 2017
(d) *Regulation of Feed and Feed Additives Produce*
MOA, Decree No. 3, 2012a
MOA, Decree No. 5, 2012b
(e) *Measures for Registration and Management of Imported Feed and Feed Additives*
MOA, Decree No. 2, 2014

4.2 Regulation for Management of Feed and Feed Additive

This regulation is an administrative decree issued by the prime minister. General outline of feed and feed additives management (production, management, and use) are included in this regulation, ensuring the quality and safety of animal products and maintenance of public health (Decree No. 609, 2011).

The responsibilities of MOA have also been stipulated, such as publication of the approved feed additives and feed ingredients. Moreover, the procedures for importing feed additives are also specified, and penalties for violations have furthermore been laid out. In short, this is a basic law for the management of animal health products.

4.3 Approved Feed Additive

The main ingredients of animal nutraceuticals must be included in the approved feed additive. In 1999, a total of 173 additives were permitted for use in animal feed, which included vitamins, minerals, and trace elements, feed grade enzymes, feed grade probiotics, antioxidants, and others (Notice No.105, 1999). More and more feed additives, such as oregano and carvacrol (*Origanum aetheroleum*), were added, and some imported products were also approved in Notice No. 318 (2003) and Notice No. 658 (2006).

In Notice No. 1126 (2008), several feed additives were added, and 24 new feed additives were listed, although they are still in the period of protection.

In Notice No. 2045 (2013a, b), the current version of approved feed additives, garlic, tea polyphenol, and the extracts from *Eucommia ulmoides* leaves, *Epimedium grandiflorum* Morr, and *Perilla* seeds are all included.

4.4 Regulation of Safe Uses for Feed Additives

Further guidance on the safe uses of feed additives was issued in Notice No. 1224 (2009); the source, approved animals, recommended dosage, and the maximum limitations were all included. These guidelines were updated in Notice No. 2045 (2013a, b).

As the highest administrative regulation, Notice No. 2625 (2017) stipulates the use of most animal feed additives. However, the contents are relatively brief and incomplete. For example, vitamin E is only given permission for use, but no dosage recommendation is given. This leads to different doses being published in animal trials and recommendations.

4.5 Regulation of Feed and Feed Additives Produce

In China, if the product is to be produced, it must first obtain a production license for feed or feed additives. Enterprises must apply to MOA for a production license of feed additives in accordance with MOA regulation Decree No. 3 (2012a). The evaluation committee of the production license for feed and feed additives of MOA will be responsible for the technical review for license approval.

After obtaining the production license, the enterprise must apply for a license number from the people's government at the provincial level according to MOA Decree No. 5 (2012b). In the application, product ingredients, product quality standard, test method of product ingredients, label style of product, and product description should be included. In a word, production is not permitted product license and license number are obtained.

4.6 Import of Feed and Feed Additives

In China, enterprises must apply to MOA for an import approval number before importing animal nutraceuticals in accordance with MOA Decree No. 2 (2014). Furthermore, application for a feed or feed additive that has never been used in China requires more data, such as safety evaluation test reports.

Foreign enterprises need to apply to MOA for import registration for first time export of feed or feed additives to China. Several reports about the product are required, including the analysis and evaluation report on the possible impact of the residue of the feed additive on human health, the stability test report, and the environmental impact report. If

maximum limitation is required, the maximum value and the method for the determination of effective components shall also be provided.

5 Concluding Remarks and Future Directions

The science behind the use of nutraceuticals is profoundly complicated by species, age, and state of disease. The veterinarian's knowledge of nutraceutical use is significantly less compared to that of usual veterinary drugs. Although the uses of nutraceuticals are becoming popular, sufficient animal tests and mechanism research need be conducted to better understand both their efficacy and safety.

For a large number of nutraceuticals, no recommended dosages are available and depend on manufacturer's standards. Current regulatory guidelines of MOA need to be further specified. Some herbal medicines have shown strong efficacy, but are not without potential toxicity (Gupta 2016; Gupta et al. 2018). When nutraceuticals are used in animals as therapeutic medicines, they need to be evaluated for any possible toxicity for both animal and human health.

Acknowledgment The authors would like to thank Ziqiang Wang for his technical assistance in preparation of this chapter.

Regulation of Nutraceuticals in Australia and New Zealand

Rhian B. Cope

Abstract

In the Australian and New Zealand regulatory landscape, nutraceuticals fall at the potentially very complex human food-medicine interface. Both countries have a very complex set of legislation, legislative instruments, regulations, and guidance documents. In addition, multiple different regulatory bodies and agencies may be involved. In Australia, nutraceuticals may also be subjected to various state and territorial legislation and regulatory processes in addition to the Federal system. For the most part, three main regulatory agencies are likely to be involved: the Australian Therapeutic Goods Administration which is part of the Australian Commonwealth Department of Health, the transnational agency Food Standards Australia New Zealand, and Medsafe New Zealand. To organizations that are unused to the Australian and New Zealand systems, the requirements and processes can seem like a Gordian knot. Thus, this chapter hopes to provide an introduction to these regulatory ecosystems and to demystify some of the important concepts.

Keywords

Nutraceuticals · Veterinary nutraceuticals · Regulation in Australia and New Zealand

1 Introduction

Whether or not products at the human food-medicine interface are regulated as foods or medicines in Australia and New Zealand remains a somewhat complex issue. Within Australia, these products potentially fall either under the Australian Therapeutic Goods Act 1989 where they may be evaluated as a complimentary medicine or a medicine. In New Zealand, they may be regarded as a drug, or they may fall under the Dietary Supplements Regulations 1985, which, in turn, falls under the Food Act 2014. However, depending on the health effects claimed, they may potentially be regarded as a "novel food" or a "food for special medical purposes" under the Food Standards Code, administered by the transnational agency Food Standards Australia New Zealand and by a second-tier layer of legislation at the New Zealand and Australian state and territory level. In New Zealand, they could also be classified as a dietary supplement which is regulated under the Dietary Supplements Regulations 1985, which fall under the Food Act 2014. It could also be regulated as a supplemented food as per the New Zealand Food (Supplemented Food) Standard 2016.

As can already be comprehended by reading the above paragraph, the decisions on what laws, regulatory processes, and regulatory standards apply to a specific nutraceuticals product in Australia and New Zealand can be very confusing.

The objective of this chapter is to (hopefully) demystify some of these issues.

2 What Is and Is Not a Therapeutic Good in Australia

In Australia, a product that is ingested (i.e., swallowed) is regulated as either a food or as a therapeutic good (i.e., a medicine, a complementary medicine, or a medical device). The key issues of whether or not a product is a food or a medicine are the nature of the health benefit claims made by the product. Critically, just because a product is ingested by mouth and makes some type of health-based claim does not automatically make it a therapeutic good. Likewise, just because the physical form of the product is "medicine-like" (e.g., a capsule, a tablet, a powder, etc.) also does not

R. B. Cope (✉)
Australian Pesticides and Veterinary Medicines Authority, Armidale, NSW, Australia
e-mail: rhian.Cope@apvma.gov.au

R. C. Gupta et al. (eds.), *Nutraceuticals in Veterinary Medicine*, https://doi.org/10.1007/978-3-030-04624-8_61

automatically make it either a therapeutic good, a dietary supplement, or a food.

Therapeutic goods in Australia are regulated by 26 different Acts, Regulations, and Legislative Instruments (!). Within Australia, a therapeutic good is specifically defined in Section 3 of the Therapeutic Goods Act 1989 act as the following:

> therapeutic goods means goods:
>
> (a) that are represented in any way to be, or that are, whether because of the way in which the goods are presented or for any other reason, likely to be taken to be:
> (i) for therapeutic use; or
> (ii) for use as an ingredient or component in the manufacture of therapeutic goods; or
> (iii) for use as a container or part of a container for goods of the kind referred to in subparagraph (i) or (ii); or
> (b) included in a class of goods the sole or principal use of which is, or ordinarily is, a therapeutic use or a use of a kind referred to in subparagraph (a) (ii) or (iii);
>
> and includes biologicals, medical devices and goods declared to be therapeutic goods

The above is generally interpreted to cover any product for use in humans in connection with:

1. Preventing, diagnosing, curing, or alleviating a disease, ailment, defect, or injury
2. Influencing inhibiting or modifying a physiological process
3. Testing the susceptibility of persons to a disease or ailment
4. Influencing, controlling, or preventing conception
5. Testing for pregnancy
6. Helping protect the skin from the damaging effects of UV radiation

This also includes things that:

1. Are used as an ingredient or component in the manufacture of therapeutic goods
2. Are used to replace or modify of parts of the anatomy
3. Make therapeutic claims on a label or in advertising (including packaging)

The following dichotomous key works through the seven fundamental questions that producers of nutraceuticals for the Australian market need to answer in order to determine where their product falls on the therapeutic good-nutraceutical interface.

1. Is the product for oral use in humans?
   (a) Yes: Go to 2.
   (b) No: The issue of the food-medicine interface does not apply and the product may be a therapeutic good.
2. Has the Secretary of the Australian Commonwealth Department of Health declared that particular goods or classes of goods are therapeutic goods (called a Section 7 Declaration under the Therapeutic Goods Act 1989)?
   (a) Yes: The issue of the food-medicine interface does not apply and the product is a therapeutic good.
   (b) No: Go to 3.
3. Has the Secretary of the Department of Health declared that particular goods or classes of goods are foods (called a Section 7AA declaration under the Therapeutic Goods Act 1989)?
   (a) Yes: The product is not a "therapeutic good." It is likely to be "food" within state/territory food regulation legislation and/or regulated under other state/territory legislation.
   (b) No: Go to 4.
4. Does the product fit into one of the standards in the Food Standards Code (food additive, vitamins and minerals, processing aid, novel foods, etc.; see http://www.foodstandards.gov.au/code/Pages/default.aspx)
   (a) Yes: The product is not a "therapeutic good." It is likely to be "food" within state/territory food regulation legislation and/or regulated under other state/territory legislation.
   (b) No: Go to 5.
5. Does the product have a tradition of use as a food for humans in Australia and the form of the product has not been substantially altered (e.g., not purified, refined, compositionally altered, etc.)?
   (a) Yes: The product is not a "therapeutic good." It is likely to be "food" within state/territory food regulation legislation and/or regulated under other state/territory legislation.
   (b) No: Go to 6.
6. Do any of the following apply: (a) is the product represented in *any way* to be for therapeutic use (is it a therapeutic good or a therapeutic device)?; (b) likely to be *taken for therapeutic use* because of the way that it is presented?; and (c) likely to be *taken for therapeutic use* for any other reason?
   (a) Yes: The product is a therapeutic good and is assessed and regulated as per the Therapeutic Goods Act 1989.
   (b) No: Go to 7.
7. Is the product in a class of goods the sole or principal use of which is, or ordinarily is, a therapeutic use?
   (a) Yes: The product is a therapeutic good and is assessed and regulated as per the Therapeutic Goods Act 1989.
   (b) No: If it is not a biological or medical device, the product is not a "therapeutic good." It may be "food" within state/territory food regulation legislation.

If the above dichotomous key determines that the product is a therapeutic good, then some specific regulatory consequences apply:

1. The Therapeutic Goods Act 1989 enables the Therapeutic Goods Administration to regulate therapeutic goods that are imported into Australia and/or those which are shipped, transported, or sold across state or territory borders. It does not regulate products that are formulated or compounded within a state or territory that are not shipped, transported, or sold across a national, state, or territory border (e.g., compounded and sold by a practitioner only within a state or territory of Australia, also called extemporaneously compounded). Extemporaneously compounded substances are regulated by state and territory authorities.
2. Therapeutic goods intended solely for the purpose of export are required to be listed (not registered) on the Australian Register of Therapeutic Goods before export is commenced.
3. The Therapeutic Goods Administration may take against the importer, exporter, manufacturer, or supplier if the product is not included in the Australian Register of Therapeutic Goods (ARTG) or is otherwise not exempt or approved under the Therapeutic Goods Act 1989.
4. If the product may be a health risk to the public (e.g., it contains substances that are only available when prescribed by a health professional), the TGA can publish an alert to the public, and if necessary, order a recall of the product.
5. If a product is not a therapeutic good and it is in the ARTG, the TGA can take action under Section 9F of the Therapeutic Goods Act 1989 to remove the product.

3 What is a Complementary Medicine in Australia?

Some classes of nutraceuticals, which meet the definition of a therapeutic good, may be classified as a complementary medicine in Australia. As a general rule, the regulatory rigor applied to complementary medicines is lower than that applied to a medicine or medical device. The pre-market approval evaluations of complementary medicines are typically focused on product safety and manufacturing quality. The standard of evidence to demonstrate efficacy is much lower than that required for a medicine or drug: the focus of the pre-market evaluation is on human safety and manufacturing quality and consistency. They may be listed on the ARTG if certain requirements are met.

A complementary medicine is defined as a therapeutic good consisting wholly or principally of one or more designated active ingredients, each of which has a clearly established identity and each of which has a traditional use. Designated active ingredients may include (but are not limited to):

1. An amino acid
2. Charcoal
3. A choline salt
4. An essential oil
5. A homeopathic preparation
6. A microorganism, whole or extracted, except a vaccine
7. A mineral including a mineral salt and a naturally occurring mineral
8. A mucopolysaccharide
9. Nonhuman animal material (or a synthetically produced substitute for material of that kind) including dried material, bone and cartilage, fats and oils, and other extracts or concentrates
10. A lipid, including an essential fatty acid or phospholipid
11. A substance produced by or obtained from bees, including royal jelly, bee pollen, and propolis
12. A sugar, polysaccharide, or carbohydrate
13. A vitamin or provitamin

Complementary medicines are regulated as per the Australian Regulatory Guidelines for Complementary Medicines (https://www.tga.gov.au/publication/australian-regulatory-guidelines-complementary-medicines-argcm). As discussed above, extemporaneously compounded and dispensed substances may be exempt from Australian Federal Regulation under specific conditions; however, they may be subject to regulation by state and territory authorities.

4 What Is and Is Not a Therapeutic Product in New Zealand and How Are They Regulated?

Therapeutic products and medical devices in New Zealand are potentially regulated by up to 19 different pieces of legislation (!). New or changed medicines and related products that are classifiable as therapeutic products require pre-market evaluation to establish safety, quality, and efficacy as well as being subjected to a post-market assessment process. The term "therapeutic product" is a comprehensive term that is applied to products that are intended to be used in or on humans for a therapeutic purpose as defined by Section 4 of the Medicines Act 1981. A therapeutic product is designed to:

1. Prevent, diagnose, monitor, alleviate, treat, cure, or compensate for a disease, ailment, defect, or injury.
2. Influence, inhibit, or modify a physiological process.
3. Test the susceptibility of persons to a disease or ailment.

4. Influence, control, or prevent conception.
5. Test for pregnancy
6. Investigate, replace, or modify parts of the human anatomy.

Under the New Zealand approach, products are regarded as having a therapeutic purpose if:

1. The product contains one or more ingredient(s) that have a pharmacological action.
2. A therapeutic purpose is claimed for the product (usually on the label or in promotional material).
3. A therapeutic purpose is implied for the product (usually on the label or in promotional material).
4. The product contains a medicine listed in the First Schedule to the Medicines Regulations or a Notice in the New Zealand Gazette issued under Section 106 of the Medicines Act 1981 (unless the product is in a form that cannot be administered to a human being for a therapeutic purpose).

In order for a product not to be regarded as having a therapeutic purpose, the label and promotional material must (at the very least) avoid the following:

1. A trade name that conveys an intended therapeutic purpose
2. Words such as remedy, medicated, or therapeutic
3. Statements that a product will/can/may prevent or treat a disease or condition or give relief from symptoms of a disease or condition
4. Statements of traditional therapeutic use or use by ethnic groups for a therapeutic purpose
5. Directions for use that infer a therapeutic purpose such as "dosing instructions" or instructions to "apply to the affected area"
6. Statements to the effect that the law prevents the supplier from making therapeutic claims that they consider they should be able to make about the product

Critically, nutritional statements (i.e., statements regarding a normal biochemical or nutritional characteristic of a product) are not regarded as therapeutic claims.

Section 2 of the Medicines Act 1981 treats herbal remedies as a subcategory of therapeutic products provided that they do not contain a prescription, restricted or pharmacy-only medical ingredient. To be defined as an herbal remedy, the product must be derived from a plant material that has been dried, crushed, subjected to aqueous or ethanolic extraction, or be a mixture of the plant-derived material with an inert substance.

Section 94 of the Medicines Act 1981 also identifies another class of substances termed "related products." These are products that are primarily foods, dentifrices, or cosmetics that also have a therapeutic purpose. Related products much not contain a prescription, restricted or pharmacy-only medicine ingredient.

In New Zealand, dietary supplements are controlled by the Dietary Supplements Regulations 1985. These products are defined by Regulation 2 as an edible substance, in a controlled dosage form, which is intended to supplement the intake of substances normally derived from food. These substances must not be marketed or promoted for a therapeutic purpose.

5 What is a Novel Food in Australia and New Zealand

Some nutraceuticals that are not therapeutic goods or therapeutic products may be classified as a novel food as per Australia New Zealand Food Standards Code—Standard 1.5.1. Like complementary medicines, these products require pre-market approval before sale and use. Typically, a very extensive and detailed pre-market evaluation is carried out by Food Standards Australia New Zealand, a transnational agency. Additional regulation may occur at the Australian state and territory level or in New Zealand.

A novel food is a substance or proposed food ingredient that has no history of traditional use. The term "no history of traditional use" is specifically defined as follows (https://www.legislation.gov.au/Details/F2017C00324):

> (a) a food that does not have a history of human consumption in Australia or New Zealand; or
> (b) a substance derived from a food, where that substance does not have a history of human consumption in Australia or New Zealand other than as a component of that food; or
> (c) any other substance, where that substance, or the source from which it is derived, does not have a history of human consumption as a food in Australia or New Zealand.
> (d) The presence of a food in a food for special medical purposes or the use of a food as a food for special medical purposes does not constitute a history of human consumption in Australia or New Zealand in relation to that food for the purposes of this section.

The pre-market evaluation of novel foods in Australia typically involves an in-depth and detailed assessment of the public health and safety considerations having regard to:

1. The potential for adverse effects in humans
2. The composition or structure of the food
3. The process by which the food has been prepared
4. The source from which it is derived
5. Patterns and levels of consumption of the food
6. Any other relevant matters

Typical categories of novel foods may include (a) plants or animals and their components; (b) plant or animal extracts; (c) herbs, including extracts; (d) dietary macro-components; (e) single chemical entities; (f) microorganisms, including probiotics; and (g) foods produced from new sources or by a process not previously applied to food.

6 Concluding Remarks and Future Directions

Taking a helicopter view, the critical issue that must be addressed by a nutraceutical producer in Australia and/or New Zealand is whether or not a therapeutic claim will be made by the product. Although the Australian and New Zealand regulatory landscapes are complex, the first overriding principle in both systems is that if a product makes any sort of therapeutic claim in any form of media (labeling, packaging, promotional, advertising, etc.) regarding the substance, then it will be potentially regulated as a therapeutic good or therapeutic product. The second overriding principle is that if the product contains any drug or pharmaceutical substance (including anything that is chemically related to a drug or pharmaceutical active substance), then it will potentially be regulated as a therapeutic good or therapeutic product. The third overriding principle is that, irrespective of what regulatory category a nutraceutical falls under in Australia and New Zealand, the human safety and quality characteristics of the product remain paramount. Both countries have very substantial legal and regulatory processes for the restriction and/or removal of products that have human safety concerns. If nutraceutical producers have any doubts about the legalities of their products and how they may be regulated, they should contact the Australian Therapeutic Goods Administration, Medsafe New Zealand, or Food Standards Australia New Zealand *before* producing, importing, or marketing their products.

Regulatory Guidelines for Nutraceuticals and Dietary Supplements for Animals in Turkey

Ayhan Filazi and Begüm Yurdakok-Dikmen

Abstract

Due to global trend in healthy food from farm to fork which compromises human health, food safety, and environmental protection, consumers today are more sensitive to contaminant-free foods of animal origin. These contaminants are mainly fertilizers, biotechnological additives, agricultural products, pesticide residues, veterinary medicines, chemical additives, genetically modified products, and contaminants arising from product processing, maintenance, transport, and storage. To increase both the quantity of animal products and the hygiene quality and standards of those goods, feed additives are being widely used. The ability to identify additive substances used in animal nutrition—in both feed and feedstuffs—is very important when investigating the effects of these substances on human health. In Turkey, nutraceuticals are listed as "feed/food supplements" in Law on Veterinary Services Plant Health Food and Feed. All legislation and guidelines being implemented for this purpose in Turkey comply with European Union legislation. This chapter provides information on regulations pertaining to the approval of feed additives used in Turkey, as well as those pertaining to the launch and control of those additives.

Keywords

Animal · Feed supplement regulatory guidelines · Legislation · Nutraceuticals · Turkey

1 Introduction

Feed, which is used in animal nutrition, constitutes an important link in the food production chain. Feed produced to meet animal nutrition requirements features a balanced and appropriate mixture and plays an important role in increasing animal production and bringing about economical animal breeding. Animal-breeding targets are about obtaining maximum efficiency per animal; these targets need to be met if animal-derived food quantities are to be reliable, so as to protect public health. An important point in obtaining safe animal-derived food is the reliable production of feed in accordance with hygiene rules. To ensure farm-to-table food safety, feed needs to be produced, transported, stored, and used in accordance with good production practices and hygiene rules at all stages, from primary production to final product acquisition (Dorne and Fink-Gremmels 2013).

Livestock production comprises an important part of Turkey's agricultural sector and economy. The growing demand for animal products on account of increased population, along with growing export demands, has increased the expectations placed on both local breeders and large companies vis-à-vis sustainable clean/green/ethical production. Turkey has a distinct advantage, situated in the center of three different climate zones and three different kinds of soil conditions with a unique geography leading to optimal growth of various plant- and animal-derived products.

According to the Turkish Statistical Institute's (2017) animal production statistics, there were increases in bovine, small ruminant, and poultry numbers, along with their products, relative to 2016. The numbers of livestock in Turkey, by species, are as follows: bovine (cattle and buffalo), 16,105 million heads; small ruminant (sheep and goats), 44,312 million heads; broiler chickens, 221,245 million units; and laying hens, 121,556 million units (Turkish Statistical Institute 2017). These large numbers indicate the application of intensive management systems supported by major technological innovations and structural changes. With these systems, sustainable development is directly linked to sustainable animal nutrition and disease control practices—practices that should be carefully applied to ensure safe, efficient, and high-quality animal production yields. Disease prevention and control management to protect the economy

A. Filazi (✉) · B. Yurdakok-Dikmen

R. C. Gupta et al. (eds.), *Nutraceuticals in Veterinary Medicine*, https://doi.org/10.1007/978-3-030-04624-8_62

and enhance food security are expected to be promoted in the form of drug-free production systems, mainly in response to resistance issues and public demand. Meanwhile, cost-effective methods are still in high demand among producers. Given the increased threat of antimicrobial resistance in treating both human and animal health in Turkey (Yilmaz et al. 2016), alternative strategies by which to retain optimal production strategies and cope with increasing numbers of animals have emerged. Nutraceuticals play an important role in drug-free production systems, since their anti-inflammatory, antioxidant, and microbiota-modulating effects are key to conserving animal health.

During the process of harmonizing Turkish legislation relating to food and feed safety with European Union (EU) legislation (Regulation 178/2002/EC, 2002), the first Veterinary Services Plant Health Food and Feed law (Law No 5996, 2010) were prepared.

The secondary legislation on the feed issue prepared in accordance with this Law is as follows:

1. The Regulation on Feed Hygiene (27 December 2011)
2. The Regulation on Animal By-products and Derived Products not Intended for Human Consumption (24 December 2011)
3. The Regulation on Placing on the Market and Feed Use (27 December 2011)
4. The Communiqué on Undesirable Substances in Animal Feed (19 April 2014)
5. The Regulation on the Official Control of Feed and Food (17 December 2011)
6. The Regulation on Feed Additives for Use in Animal Nutrition (18 July 2013)
7. The Communiqué as Regards the Preparation and the Presentation of Applications and the Assessment and The Authorisation of Feed Additives (27 May 2016)

These legislations were all prepared in compliance with the European Unions and updating regularly according to the EU legislation. This chapter is aimed to give information about regulatory guidelines for nutraceuticals and dietary supplements in animals in Turkey.

2 Applications Relating to Feed Hygiene Regulation

Feed hygiene regulation (Regulation 2011/28155, 2011a) has been prepared as per EU Regulation No. 183/2005/EC, the purposes of which are to provide the general rules concerning feed hygiene and the conditions required for the registry and approval of feed enterprises, enable feed traceability, and make necessary arrangements regarding these subjects. According to this Regulation, feed enterprises are divided into two categories—namely, registered enterprises and approved enterprises. According to *The Regulation on Animal By-products and Derived Products Not Intended for Human Consumption* (Regulation 2011/28152, 2011), rendering enterprises (meat–bone meal, chicken meal, fish meal, etc.) and enterprises that produce cat or dog food are obligated to obtain approval from the relevant competent authorities. Apart from these, all other enterprises are required to be registered. As of July 2018, approximately 13,600 feed enterprises were approved and registered in Turkey (Table 1). In the mixed-feed sector in 2017, nearly 23 million tons of mixed feed were produced in total, most of which was broiler chicken feed (Ministry of Agriculture and Forestry 2018).

Feed enterprises are obligated to comply with the hygiene rules specified in this Regulation, at every stage of production, operations, and distribution (excluding primary production). According to this Regulation, feed operators are obligated to establish and implement a feed safety system that is based on Hazard Analysis and Critical Control Points (HACCP) principles in production. When operating in accordance with the HACCP principles, it is critical to identify and control those hazards that may have adverse effects on the reliability of any animal feed produced and marketed; in this way, safe and reliable feed production is assured (Regulation 2011/28155, 2011a).

With risk assessment, the probability of occurrence of a physical, chemical, or biological factor or situation that can have a negative impact on feed safety, as well as the intensity

Table 1 Number of registered and approved feed enterprises in Turkey[a]

Operating type	Number of enterprises	Approved/ registered
Mixed feed-producing enterprises for food animals	322	Approved
Enterprises that produce their own mixed feed	108	Approved
Feed additive-producing enterprises	15	Approved
Premix-producing enterprises	100	Approved
Cat-dog food-producing enterprises	29	Approved
Rendering enterprises	77	Approved
Feed additive and premix sales enterprises	1002	Approved
Mixed-feed-producing enterprises for food animals	193	Registered
Enterprises that produce their own mixed feed	443	Registered
Block mineral (licking block)-producing enterprises	23	Registered
Feed additive- and premix-producing enterprises	28	Registered
Retail storage and sales shops	11,237	Registered
Fish meal-producing enterprises	23	Registered
Total	13,600	Registered

[a]Reference: Ministry of Agriculture and Forestry 2018

of probable impacts, is evaluated, where a risk score of danger is determined. By scoring dangers in this way, it is possible to assign greater importance to those risks with higher scores. After classifying dangers in terms of their scores, if a danger with a high-risk score were to occur, it would be important to apply control measures to either eliminate the danger or mitigate it to an acceptable level. This process can be readily applied to hazards as they pertain to feed and feedstuffs.

3 Applications Relating to the Regulation on Placing on the Market and Feed Use

This Regulation (Regulation 2011/28155, 2011b) was prepared in accordance with EU Regulation No. 767/2009/EC, with the aims of ensuring top-level feed safety, protecting animal and public health, adequately informing users and consumers, and regulating conditions related to the market launch of feed, as well as the quality thereof. According to this Regulation, feed that is not safe cannot be launched to the market. Feed enterprises have an obligation to ensure that the feed they launch to the market is safe and that it is labeled, packed, and put on the market in accordance with their features and intended usage. This Regulation also specifies that all feed content components be specified on the product labeling, along with their weight ratios (in descending order). Compliance with this feed Regulation demands that all feed be labeled in this manner before being launched to the market.

4 Applications Relating to the Communiqué on Undesirable Substances in Animal Feed

This Communiqué (Communique 2014/11, 2014) is prepared in accordance with EU Directive No. 2002/32/EC. "Undesirable substances" in animal feed are materials that are in the feed apart from pathogenic elements and which pose potential hazards for animal and human health and the environment or which may have a negative impact on animal production. This Communiqué specifies the maximum allowable limits for substances not desired in the feed. As these substances constitute a chemical hazard within the audit scope of the Communiqué, inspections are carried out by searching for and analyzing inorganic contaminants and nitrogenous compounds, mycotoxins, plant toxins, organic chlorinated compounds (including dioxins and PCBs), and harmful botanical contaminations. Also inspected are approved feed additives that cannot help but be transported with other feeds. If the values determined in the course of this analysis exceed the maximum limits imposed by the Communiqué, the feed is considered "unsafe feed," and it cannot be neither used to feed animals nor placed on the market.

5 Applications Relating to the Regulation on the Official Control of Feed and Food

This Regulation (Regulation 2011/28145, 2011) is prepared in accordance with EU Regulation No. 882/2004/EC. To ensure safe food and feed supplies, this Regulation aims to help control all production and distribution stages from the field to the table and to promote investigations regarding whether or not the conditions specified in the legislation are being fulfilled. Feed inspections executed as per this Regulation are carried out within the context of the annual feed control plan. Inspections are also executed in response to notifications and complaints. Inspections carried out within the framework of the feed control plan are scheduled while mainly considering the results of investigations conducted in the previous year, as well as the enterprise's production capacity, its feed varieties, possible product hazards, risks incurred by such hazards on animal and human health and the environment, and similar factors. Risk analysis is conducted each year, and the conditions underlying them are also revised each year. During those inspections, feed enterprises are investigated with respect to compliance with hygiene conditions, and whether the feed being produced and/or launched to the market is controlled in terms of compliance with feed safety regulations. Feed samples taken during feed safety inspections are analyzed on a risk basis (i.e., against chemical and biological hazards) and with respect to labeling compliance. On a risk basis, analyses are undertaken with respect to undesired substances in the feed (e.g., heavy metals, mycotoxins, anticoccidials, pesticides, and dioxins), substances that are prohibited from being added to feed (certain animal-derived proteins in ruminant feed, antibiotics), microbiological contamination (*Salmonella* or *Enterobacteriaceae*), and those concerning biosafety legislation compliance. In particular, the frequency of risk-based control testing and analysis is expected to be increased each year.

6 Applications Relating to the Regulation on Feed Additives for Use in Animal Nutrition

In Turkey, processes relating to feed additives are carried out as per the provisions of *The Regulation on Feed Additives for Use in Animal Nutrition* (Regulation 2013/28711, 2013), which aims to protect human and animal health, animal welfare, and the environment. This Regulation sets forth procedures and principles for the authorization, inspection,

and labeling of feed additive products and premixtures that are destined for the market. This Regulation does not apply to veterinary medicinal products, with the exception of coccidiostats and histomonostats used as feed additives. Additionally, this Regulation is based on articles 21, 22, 24, 25, 26, and 43 of Law 5996, the basic legislation in Turkey on food quality control/food safety, consumer protection, *Codex Alimentarius*, international trade, inspection, offenses/penalties, animal feed/feedstuffs, animal health, animal welfare, plant protection, and pests/diseases. It is also prepared in accordance with EU Regulation No. 1831/2003/EC. Processes relating to the approval of a new feed additive substance not stated in the recorded list of feed additive substances are carried out as per *The Communiqué as Regards the Preparation and the Presentation of Applications and the Assessment and The Authorization of Feed Additives* (Communique 2016/15, 2016). This Communiqué also complies with EU Regulation No. 429/2008/EC.

Regarding feed additive substances and premixes, controls are carried out especially with regard to searches for heavy metals and antibiotics and to ensure compliance with label information regulations. The use of antibiotics as feed additive substances has been prohibited since 2006. However, in cases where disease is seen in an animal, exceptions are allowed—in which case, if a treatment drug is used and administered in tandem with its feed, approved feed-producing enterprises may produce feed containing antibiotics but only under a veterinarian's prescription. Such veterinary medical premixes must be approved by the relevant competent authorities.

Feed additives are used in animal production to improve product capacity and to ensure hygiene quality and standards compliance. Feed additives are generally provided from abroad by companies that produce mixed feeds or trade in feed additives in pure, concentrated, or premixed forms. Feed additives that are imported in pure or concentrated forms are presented for use after they have been diluted to certain ratios with an appropriate carrier at premix preparation facilities. Feed additives can be added as a single additive premix with a mixed feed carrier substance, in the form of mixtures containing more than one effective substance; in the form of special premixes, such as vitamin concentrates; as mixed premixes containing vitamin-trace minerals or amino acids; or as minerals or complementary feed containing macro and trace elements. Feed additives that are used in mixed feed for poultry animals at significant ratio levels (for various purposes) are generally used at lower ratios in mixed feed for bovine and ovine animals, so as to contain more vitamin/trace element premixes.

Feed additives are substances with organic or inorganic structures that are added to feed to ensure optimal nutrition substance consumption, increase animal product quantity, improve feed use by aiding with digestion and metabolism, protect animal health, influence animal product quality positively, facilitate the preparation and storage of feed, or derive economic benefits in other ways (Regulation 2013/28711, 2013). Although they are used at lower ratios in mixed feed, their effectiveness and importance are much higher.

According to EU Regulation No. 2013/28711 and Turkish Legislation, the term "feed additives" refers to substances, microorganisms, or preparations, other than feed material and premixtures, that are intentionally added to feed or water in order to perform, in particular, one or more of the following functions:

1. Favorably affect feed characteristics
2. Favorably affect animal product characteristics
3. Favorably affect the color of ornamental fish and birds
4. Satisfy the nutritional needs of animals
5. Favorably affect the environmental consequences of animal production
6. Favorably affect animal production, performance, or welfare, particularly by affecting the gastrointestinal flora or digestibility of feedstuffs
7. Have a coccidiostatic or histomonostatic effect

Today, a large number of additives are used in support of animal nutrition. In Turkey, only the use of EU-approved feed additives is allowed (European Union Register of Feed Additives 2018). Table 2 lists the categories of feed additives approved by the relevant competent authority (Ministry of Agriculture and Forestry 2018).

6.1 Technological Additives

6.1.1 Preservatives

These substances or microorganisms protect feed against deterioration, as caused by either microorganisms or their metabolites. Some of the materials currently used as preservatives are lactic acid, acetic acid, propionic acid, sorbic acid, DL-malic acid, potassium sorbate, calcium acetate, sodium propionate, calcium propionate, ammonium propionate, ammonium formate, calcium lactate, citric acid, orthophosphoric acid, potassium sorbate, sodium diacetate, calcium acetate, sodium formate, potassium diformate, calcium formate, fumaric acid (poultry and pigs, young animals fed with milk replacers, other animal species), sodium bisulfate (pets and other non-food-producing animals other than cats and mink, cats, mink), sodium nitrite (dogs, cats), sodium benzoate 140 g/kg + propionic acid 370 g/kg + sodium propionate 110 g/kg (pigs, poultry, bovines , sheep, goats,

Table 2 Additives used in feeds in Turkey

Group	Feed additives
1) Technological additives	a) Preservatives b) Antioxidants c) Emulsifying and stabilizing agents, thickeners, and gelling agents d) Acidity regulators e) Binders, anticaking agents, and coagulants f) Substances that control radionuclide contamination g) Silage additives
2) Sensory additives	a) Colorants b) Flavoring compounds
3) Nutritional additives	a) Vitamins, provitamins, and chemically well-defined substances bearing similar effect b) Trace element compounds c) Amino acids, their salts, and analogs d) Urea and its derivatives
4) Zootechnical additives	a) Digestibility enhancers b) Gut flora stabilizers c) Substances which favorably affect the environment d) Other zootechnical additives
5) Coccidiostats and histomonostats	–

rabbits, horses), and *Lactobacillus fermentum* + *L. plantarum* + *L. rhamnosus* (dogs). The use of formaldehyde as a feed preservative has been banned since February 7, 2018.

6.1.2 Antioxidants

Antioxidants are substances that prolong the storage life of feedstuffs and feed materials by protecting them against oxidation-induced deterioration. Some antioxidants are synthetic; others are natural, and in recent years, their use has increased. Materials used for this purpose include ascorbic acid, sodium ascorbate, calcium ascorbate, ascorbyl palmitate, tocopherol extracts from vegetable oils, tocopherol-rich extracts from vegetable oils (delta rich), alpha-tocopherol, propyl gallate, butylated hydroxyanisole, butylated hydroxytoluene, and ethoxyquin. Some aromatic plants (e.g., sage, rosemary, laurel, clove, thyme, cumin, peppermint, and cinnamon) have been used as antioxidants.

6.1.3 Emulsifying and Stabilizing Agents, Thickeners, and Gelling Agents

Emulsifiers are substances that make it possible to form or maintain within feedstuffs a homogeneous mixture of two or more immiscible phases. These are used to provide a homogenous distribution of feed, and they are typically added to feed in an oil form to provide energy. Stabilizers are substances that make it possible to maintain the physiochemical state of feedstuffs; they are used to increase the stability of vitamins, essential amino acids, and certain medicines that are added to feed in very small amounts. Thickeners, meanwhile, are substances used to increase the viscosity of feedstuffs, while gelling agents are substances that give feedstuffs more texture through the formation of a gel. Such substances include lecithins (only as emulsifying agent), sodium alginate [fish; pets and other non-food-producing animals (nonfood fur animals)], agar [pets and other non-food-producing animals (nonfood fur animals)], carrageenan [pets and other non-food-producing animals (nonfood fur animals)], locust bean gum (Carob gum), guar gum, tragacanth, acacia (Gum arabic), xanthan gum, polyoxyethylene (20)-sorbitan monooleate, microcrystalline cellulose, methylcellulose, ethyl cellulose, hydroxypropyl cellulose, hydroxypropyl methylcellulose, carboxymethylcellulose, glyceryl polyethyleneglycol ricinoleate, polyethyleneglycol ester of fatty acids from soya oil [calves], sorbitan monolaurate, and cassia gum (dogs, cats).

6.1.4 Acidity Regulators

Acidity regulators are substances that adjust feedstuff pH. DL- and L-Malic acid (cats, dogs), sodium hydroxide (cats, dogs, ornamental fish), and sodium bisulfate are used for this purpose.

6.1.5 Binders, Anticaking Agents, and Coagulants

Binders are substances that increase the tendency of feedstuff particles to adhere to one another, while anticaking agents reduce this tendency. Coagulants allow liquid feedstuffs to darken to a semisolid clotting state. Some substances used for these purposes are sodium ferrocyanide, potassium ferrocyanide, silicic acid (precipitated and dried), colloidal silica, kieselgur (diatomaceous earth, purified), calcium silicate (synthetic), sodium aluminosilicate (synthetic), kaolinitic clays (free of asbestos), natural mixtures of steatites and chlorite, vermiculite, sepiolite, sepiolitic clay, lignosulphonates, natrolite-phonolite, clinoptilolite of volcanic origin (pigs, poultry), and perlite.

6.1.6 Substances That Control Radionuclide Contamination

Substances used to control radionuclide contamination suppress the absorption of radionuclides or promote their excretion. Substances used as radioactive cesium binders (^{137}Cs and ^{134}Cs) include ferric (III) ammonium hexacyanoferrate (II) [ruminants (domestic and wild); calves prior to the state of rumination; lambs prior to the state of rumination; kids prior to the state of rumination; pigs (domestic and wild)] and bentonite [all animal species].

6.1.7 Silage Additives

Silage additives are substances (including enzymes or microorganisms) incorporated into feed to improve silage production. Enzymes used for this purpose include

alpha-amylase (from *Aspergillus oryzae* or *Bacillus amyloliquefaciens* or *Bacillus subtilis*), beta-glucanase (from *Aspergillus niger*), cellulase (from *Aspergillus niger* or *Trichoderma longibrachiatum*), and xylanase (from *Trichoderma longibrachiatum*). The microorganisms used in the production of the silage are *Enterococcus faecium*, *Lactobacillus brevis*, *L. buchneri*, *L. plantarum*, *L. fermentum*, *L. casei*, *L. kefiri*, *L. diolivorans*, *L. paracasei*, *L. rhamnosus*, *Propionibacterium acidipropionici*, preparation of *L. plantarum*, and *Pediococcus pentosaceus*. In addition, organic acids and chemicals such as ammonium propionate, potassium sorbate, formic acid, sodium formate, propionic acid, sodium propionate, ammonium propionate, and sodium benzoate are also used in the production of silage.

6.2 Sensory Additives

6.2.1 Colorants

Colorants are substances that add or restore feedstuff color; these, when fed to animals, add colors to food of animal origin and when consumed can favorably affect the color of ornamental fish or birds. They are commonly used in the poultry sector to improve the color of chicken meat and eggs. For this purpose, plant materials (e.g., yellow corn, alfalfa, corn gluten, and red pepper powder) containing various levels of coloring materials, as well as carotenoids such as lutein, zeaxanthin, capsanthin, and lycopene extracted from natural sources, are used. Synthetic sources such as ethyl ester of beta-apo-8′-carotenoic acid, citranaxanthin, tartrazine, sunset yellow, and Ponceau 4 R (dogs, cats) are also used. Substances that enhance or restore the color of feedstuffs include quinoline yellow (non-food-producing animals), azorubine (carmoisine) (cats and dogs), and patent blue V (non-food-producing animals).

Substances that, when fed to animals, add colors to food of animal origin include astaxanthin dimethyldisuccinate (salmon, trout), red carotenoid-rich *Paracoccus carotinifaciens* (salmon, trout), canthaxanthin (chickens for fattening and minor poultry species for fattening, laying poultry and poultry reared for laying), and astaxanthin (fish, crustacean).

Finally, substances that favorably affect the color of ornamental fish or birds include canthaxanthin (ornamental fish and ornamental birds except ornamental breeder hens; ornamental breeder hens) and astaxanthin (ornamental fish). Other colorants are tartrazine (grain-eating ornamental birds, small rodents, ornamental fish), sunset yellow FCF (grain-eating ornamental birds, small rodents, ornamental fish), Ponceau 4 R (ornamental fish), erythrosine (ornamental fish), indigotine (ornamental fish), beta-carotene (canaries), and red iron oxide (ornamental fish).

6.2.2 Flavoring Compounds

Flavoring compounds are substances that, when added to feedstuffs, enhances feed smell or palatability. Some of the substances allowed for this purpose are indole, beta-alanine, taurine, citronellol, methoxyacetophenone, phenylmethanethiol (cats, dogs), alpha-methylcinnamaldehyde, diphenyl ether, alpha-hexylcinnamaldehyde, ethyl phenylacetate, isobutyl phenylacetate, 3-methylbutyl phenylacetate, phenethyl phenylacetate, methyl cinnamate, ethyl cinnamate, benzyl cinnamate, phenethyl acetate, phenethyl butyrate, cinnamyl acetate, phenylacetic acid, phenylpropanal, cinnamyl alcohol, cinnamaldehyde, ethyl butyrate, geranyl formate, geranyl propionate, neryl propionate, geraniol, and nerol.

6.3 Nutritional Additives

6.3.1 Vitamins, Provitamins, and Chemically Well-Defined Substances Bearing Similar Effects

Salts and the analogs of amino acids and vitamins or provitamins are added to feed to meet animals' nutritional requirements. For this purpose, substances such as vitamins A, B, C, D, E, and K and their salts, calcium-D-pantothenate L-carnitine, folic acid, omega-3 and omega-6, etc., among others, are used.

6.3.2 Trace Element Compounds

Among the trace elements added to feed are iron, selenium, potassium, copper, cobalt, calcium, manganese, zinc, molybdenum, and their salts.

6.3.3 Amino Acids, Their Salts, and Analogs

Some of the allowable substances that fall under this category are lysine; L-threonine, L-histidine, and L-tryptophan produced through fermentation with *Escherichia coli*; and L-arginine, L-valine, and sodium DL-methionine produced by *Corynebacterium glutamicum*.

6.3.4 Urea and Its Derivatives

These additives are generally used as protein sources, and they are added to the diets of ruminant animals that have functional rumen. The most commonly used compounds are urea, biuret, urea-phosphate, and diureidoisobutane.

6.4 Zootechnical Additives

6.4.1 Digestibility Enhancers

These substances enhance diet digestibility, through action on target feed materials when fed to animals. For this

purpose, polysaccharides (lipases, phytases, pectinase, amylase, and cellulase) from various fungi (e.g., *Trichoderma reesei*, *T. viride*, and *Aspergillus niger*) or from certain bacteria (e.g., *Bacillus subtilis*) are used to break down polysaccharides that cannot be digested in the intestinal environment of poultry. Certain enzymes (cellulase, xylanase, endoglucanase, exoglucanase, amylase, and proteases) are also used to improve digestion and improve rumen performance.

6.4.2 Gut Flora Stabilizers

Gut flora stabilizers have a positive effect on gut flora. Substances whose chemical properties have been so described, or microorganisms that have a positive effect on intestinal microflora, help comprise this group. Enzymes, probiotics, prebiotics, essential oils, and plant extracts are used to regulate digestive and intestinal microflora, and these additives are multifunctional. The microorganisms most commonly used to produce probiotics are *Lactobacillus* and *Streptococcus* bacteria, which produce lactic acid. *Saccharomyces cerevisiae* from yeasts and *Aspergillus niger* and *A. oryzae* from fungi are also widely used in commercial probiotic production. Some probiotics are *Saccharomyces cerevisiae*, *Enterococcus faecium*, *Pediococcus acidilactici*, *Lactobacillus acidophilus*, *Bacillus subtilis*, *B. amyloliquefaciens*, *B. licheniformis*, *Clostridium butyricum*, *Bifidobacterium animalis* ssp. *animalis* + *Lactobacillus salivarius* ssp. *salivarius* + *E. faecium*, *E. faecium* + *L. acidophilus* + *L. helveticus* + *L. delbrueckii* ssp. *lactis* + *L. delbrueckii* ssp. *bulgaricus* + *Streptococcus thermophilus*, and *L. lactis* + *Carnobacterium divergens* + *L. casei* + *L. plantarum* + *S. cerevisiae.*

Prebiotics are intact nondigestible feed additives that increase the number and activity of beneficial bacteria living in the intestines and which thus positively improve animal health. The most commonly used prebiotics are mannan oligosaccharides, fructooligosaccharides, chitosan oligosaccharides, and beta-glucans.

Herbal extracts and essential oils—both of which are natural in recent times—offer antimicrobial efficacy, promote growth, and improve feed efficiency. Aromatic plants, extracts, and oils such as thyme, rosemary, sage, clove, laurel, cinnamon, cumin, coriander, ginger, mustard, garlic, and mint are used as additives.

6.4.3 Substances That Favorably Affect the Environment

Substances that favorably affect the environment include substances used to reduce the formation of methane gas in ruminants, as well as phytase enzyme, which has been shown to enhance plant phosphorus utilization in poultry. Methane production by rumen microorganisms leads to the attenuation of both methane gas production (i.e., from the feed energy) and pollution from the methane emitted into the atmosphere. To prevent methane production, oils, chloral, hemiacetate products of starch and halogenated compounds (tetrachloride methylene chloride, bromochloromethane), and anticoccidials (e.g., lacoloside and monensin) are used. Another supplement is phytase, which is used to increase plant phosphorus use among poultry. The enzyme phytase is used both to increase vegetative phosphorus use and prevent phosphorus pollution by reducing phosphorus levels in groundwater and the soil.

6.4.4 Other Zootechnical Additives

Toxin binders are used to prevent mold growth in feed. For this purpose, compounds such as organic acids (propionic, sorbic, benzoic, and acetic acids), organic acid salts (such as calcium propionate and potassium sorbate), organic dyes, and copper sulfate are used. Adsorbent materials such as polyvinylpolypyrrolidone polymers, aluminum silicate compounds, activated charcoal, hydrate sodium calcium aluminosilicate (HSCAS), bentonite, perlite, diatomaceous earth, and zeolite are used as toxin binders in feeds.

Buffer substances are typically used in ruminants to prevent pH attenuation in the rumen—a condition that typically stems from the use of large amounts of intense feed. In recent years, sodium bicarbonate has been widely used for this purpose; also used are buffer materials such as various salts from volatile fatty acids, phosphate salts, ammonium chloride, and sodium sulfate.

Chitosan is a product obtained by deacidifying chitin into a nontoxic and bioavailable biopolymer structure that resembles cellulose found in arthropoda (crabs and shrimp); it is useful, in that it promotes enhanced digestibility, growth performance, energy and protein utilization, and rumen fermentation.

6.5 Coccidiostats and Histomonostats

Coccidiostats and histomonostats are substances administered to kill or otherwise inhibit protozoa. They are substances used to protect *Eimeria* species placed in the intestines of poultry from protozoa that can cause coccidiosis (i.e., bloody diarrhea). Some substances are allowed by law to be used (e.g., monensin sodium, decoquinate, robenidine hydrochloride, lasalocid A sodium, halofuginone hydrobromide, narasin, salinomycin sodium, maduramicin ammonium alpha, diclazuril, semduramicin sodium, nicarbazin, and diclazuril); however, there are withholding periods for each of these substances, and adherence to such regulations is essential.

7 Concluding Remarks and Future Directions

Turkey has great potential with respect to animal production. Nutraceuticals are being widely used to increase the number of animal products generated and improve hygiene quality and standards adherence. The ability to determine the substances added both to feed and to products obtained for animal nutrition purposes is essential, as doing so is critical to determining the effects of these substances on human health. All guidelines and pieces of legislation being applied in Turkey for this purpose comply with current European Union legislation.

Uses and Regulation of Nutraceuticals for Animals in the Philippines

Jacob Anderson C. Sanchez and Geraldine C. Sanchez

Abstract

The Philippines is an archipelagic country in Southeast Asia with many requirements for food animals. Traditional veterinary practices are still thriving, and their application to animal health exists among rural communities. Herbal treatments for animals listed in this chapter are mostly used for gastrointestinal disorders such as diarrhea, constipation, bloating, and dysentery. These herbs which are known to possess medicinal benefits for animals were put together based on applications of herbs in treating human diseases. The top ten medicinal plant species approved by the Philippine Department of Health-Food and Drug Administration (DOH-FDA) for therapeutic purposes are lagundi for cough and asthma, sambong as an anti-urolithiasis, ampalaya for lowering of blood sugar and as an antidiabetic, garlic as antihypercholesterolemia, guava for oral/skin antiseptic, tsaang gubat for mouthwash, yerba buena as an analgesic or antipyretic, niyog-niyogan as an antihelminthic, acapulco as an antifungal, and ulasimang-bato as an anti-hyperuricemia. The Philippine research and regulatory bodies include the Department of Agriculture (DA), DA-Bureau of Animal Industry (DA-BAI), Department of Health (DOH)-Philippine Institute of Traditional and Alternative Health Care (PITAHC), DOH-FDA, and Philippine Natural Health Products Industry (PNHPI). In 2017, a total of 497 companies were accredited by DA-BAI; however, these are not categorized based on whether or not they sell synthetic drugs or nutraceuticals. The use of nutraceuticals for veterinary purposes in the Philippines is still in its infancy. It is imperative for veterinary universities in the Philippines to innovate the utilization of food or feeds for animals with certain medicinal benefits. In response to this growing need, the Pampanga State Agricultural University, through the Department of Agriculture-Bureau of Agricultural Research, has established the Nutraceutical Research Laboratory (NRL).

Uses and regulation · Nutraceutical · Food animals · Philippines

1 Introduction

The Philippines is an archipelagic country in Southeast Asia with many requirements for food animals. Except for poultry, the production of pork, beef, chevon, mutton, and duck meat largely depends on backyard farmers. Therefore, it is common that traditional veterinary practices are still thriving and their application in animal health exists among rural communities. Herbal treatments for animals listed in this chapter are mostly used for gastrointestinal disorders such as diarrhea, constipation, bloating, and dysentery. These herbs which are known to possess medicinal benefits for animals were put together based on applications of herbs in treating human diseases. The top ten medicinal plant species approved by the Philippine Department of Health-Food and Drug Administration (DOH-FDA) for therapeutic purposes are lagundi (*Vitex negundo*) for cough and asthma, sambong (*Blumea balsamifera* L.) as an anti-urolithiasis, ampalaya (*Momordica charantia* L.) for lowering of blood sugar and an antidiabetic, garlic (*Allium sativum*) as anti-hypercholesterolemia, guava (*Psidium guajava*) for oral/

skin antiseptic, tsaang gubat (*Carmona retusa*) for mouthwash, yerba buena (*Mentha arvensis*) as an analgesic or antipyretic, niyog-niyogan (*Quisqualis indica*) as an anthelminthic, acapulco (*Cassia alata*) as an antifungal, and ulasimang-bato (*Peperomia pellucida*) as an anti-hyperuricemia. The Philippine research and regulatory bodies include multi-stakeholders such as the Department of Agriculture (DA), DA-Bureau of Animal Industry (DA-BAI), Department of Health (DOH)-Philippine Institute of Traditional and Alternative Health Care (PITAHC), DOH-FDA, and the Philippine Natural Health Products Industry (PNHPI). In 2017, a total of 497 companies were accredited by DA-BAI; however, these are not categorized as to whether or not they sell synthetic drugs or nutraceuticals. Most are still relying on commercially available synthetic drugs either produced locally or imported. It can be said that nutraceuticals for veterinary purposes in the Philippines are still in its infancy. Therefore, it is imperative for veterinary universities in the Philippines to innovate by doing research in relation to utilization of food or feeds with certain medicinal benefits in animals (Abelarde 2013). In response to this growing need, the Pampanga State Agricultural University, through the Department of Agriculture-Bureau of Agricultural Research, has established the Nutraceutical Research Laboratory (NRL). This chapter describes the uses and regulations of nutraceuticals in the Philippines.

2 Regulation of Nutraceuticals

The Philippines is an archipelagic country with 7107 islands where provinces are either landlocked or surrounded by different bodies of water. Its people are comprised of different ethnicities and religions on major islands, namely, Luzon, Visayas, and Mindanao. While there are a variety of other factors, it is the geographical, social, and religious factors (FAO 2002) that influence the Philippine animal industry.

People in Luzon are mostly Christians, and their primary source of meat is poultry, pork, and beef. Visayas is made up of several islands making them a prolific producer of fishery products. Mindanao is a combination of Christians and Muslims. It is also a rich source of fisheries, but their production system is focused on *halal foods*. Therefore, research initiatives are focused to meeting the increasing demand for and consumption of meat products.

The bureaus and research agencies that focus on these commodities are the Department of Agriculture (DA), DA-Bureau of Agricultural Research (DA-BAR), DA-Bureau of Animal Industry (DA-BAI), Philippine Carabao Center (PCC), DA-Livestock Biotechnology Center (DA-LBC), and Department of Science and Technology-Philippine Council for Agriculture, Aquatic, and Natural Resources Research and Development (DOST-PCAARRD).

Meanwhile, the Philippine Statistics Authority (PSA) has reported that in 2016, the volume of livestock and poultry production was highest for pork, followed by chicken, beef, carabeef, and chevon, with the least in duck meat (PSA 2018). The major sources of meat in the country are derived from food animals such as large ruminants (cattle and carabao), small ruminants (goats and sheep), swine, and poultry (chicken and duck) (BAI 2015).

Although efforts to promote animal health by the government and private sector are in place, with reference to current statistics of the PSA, the Philippine animal industry remains largely dependent upon backyard farmers rather than commercial producers with the exception of the poultry industry. Therefore, it is common that traditional veterinary practices are still thriving and their application in animal health exists among rural communities.

The Food and Agriculture Organization (FAO) of the United Nations and the Regional Animal Production and Health Commission for Asia and the Pacific (APHCA) documented that even before the arrival of modern medicine and western veterinary medications, Filipinos had already been using herbs for treatment of animal diseases (FAO 1992). It is believed that a trial-and-error method by "herbolarios" or traditional faith healers was used in the application of any herb, and this knowledge and skill was passed on to the next generation. Through the years, medicinal plants that worked well are still being used, while those that did not were forgotten.

Contrary to popular belief, herbs which are known to possess medicinal benefits for animals were actually put together based on applications of herbs in treating human diseases. In fact, a document produced by the FAO tabulated the summary of plants used, prescription indications, and regions where these are reported or practiced. A majority of these herbs are used in the treatment of gastrointestinal disorders.

For example, in treating diarrhea, the following plants are used: guava (*Psidium guajava*), caimito (*Chrysophyllum cainito*), banana (*Musa* sp.), bamboo (*Bambusa spinosa*), duhat (*Syzygium cumini*), sambong (*Blumea balsamifera*), and lagundi (*Vitex negundo*). Their leaves are prepared into a decoction by boiling in water and added to the drinking water of pigs (FAO 1992).

In treating constipation, the milk extract from meat of coconut (*Cocos nucifera*) is given to pigs, cattle, and carabao. Also, the leaves of kangkong (*Ipomoea aquatica*) or fresh fruit of papaya (*Carica papaya*) are given as food to animals.

For bloating in cattle, carabao, goats, and sheep, the meat of a matured coconut is prepared into an extracted juice and given orally to the affected animal. Another practice is a

decoction of luya (*Zingiber officinale*), vinegar, and water orally administered to goats.

Dysentery is treated with a decoction of banaba (*Lagerstroemia speciosa*) leaves and given as a drench to pigs, carabao, and cattle. The fruit of chico (*Achras zapota*) is mixed with animal feed, and the leaves of tawa-tawa (*Euphorbia hirta*) and bangka-bangkaan (*Rhoeo discolor*) or fresh flowers of alibangbang (*Bauhinia malabarica*) are infused in water and drenched daily to the animal.

Although the medicinal plants, as mentioned in the introduction part of this chapter, are already approved by the DOH-FDA, their utilization is mostly as a food or dietary supplements for humans, and they are labeled as "no approved therapeutic claims." Still, there are some attempts by local pharmaceutical industries to manufacture and commercialize nutraceuticals for veterinary purposes.

In order to preserve and promote the utilization of the aforementioned medicinal plants for health and nutraceutical purposes, the Philippines enacted the Republic Act 8423 otherwise known as the Traditional and Alternative Medicine Act (TAMA) of 1997 (LawPhil Project 2018). This act created the Philippine Institute of Traditional and Alternative Health Care (PITAHC) to accelerate the development of traditional and alternative health care in the Philippines, providing for traditional and alternative health-care development fund and for other purposes. The PITAHC is an agency of the Department of Health (DOH).

The mandate of the PITAHC is to promote quality, safety, efficacy, accessibility, and acceptable traditional and complementary medicine (T&CM) products, technologies, and modalities, as well as the protection of Philippine traditional medicine (PTM). These mandates are strengthened by the Governance Commission for GOCCs (GCG) in 2012 giving emphasis that PITAHC is a research institution whose budgetary affairs shall now be under the Department of Budget and Management (DBM). However, in a meeting of the PITAHC Board of Trustees in October 2015, they affirmed that the thrust of PITAHC is primarily in research and not in manufacturing.

Meanwhile, the Department of Agriculture-Bureau of Animal Industry accredits and recognizes veterinary drugs and product manufacturers or distributors in the country (BAI 2018). There are a total of 497 accredited companies, but these are not categorized whether they sell synthetic drugs or nutraceuticals. Most are still relying on commercially available synthetic drugs either locally produced or imported. Hence, it can be said that nutraceuticals for veterinary purposes in the Philippines are still in its infancy.

To accelerate the market of nutraceuticals for veterinary purposes, there has recently been an effort from industries to organize themselves and form the Philippine Natural Health Products Industry (PNHPI), which is represented by the Chamber of Herbal Industries of the Philippines (CHIPI). The CHIPI is an association of companies that manufacture, develop, research, distribute, and trade the supply of herbal products. It also drafted the PNHPI Roadmap FY 2014–2030 which categorized natural health products into (a) natural ingredients (plant parts, extracts, oil, semi-processed) and (b) finished products for human, household, veterinary, and green fertilizer/pesticide use.

To address the limitations in the regulations of nutraceuticals or functional foods, the DOH-FDA drafted the Administrative Order on the "Rules and Regulations Governing Nutrition and Health Claims of Pre-packaged Food Products Distributed in the Philippines" (Bagchi 2014). At present, nutraceutical products are evaluated based on research evidence through the regulations of the DOH-Food and Drug Administration, formerly Bureau of Food and Drugs (BFAD). It issues several rules and guidelines on probiotics, formulation, labeling, and technical specifications which serve as its basis for evaluation.

Product information and other requirements must include (1) list of ingredients, (2) physical, chemical, and microbiological characteristics: (3) presentation of actual sample for sensory evaluation; (4) presentation of sample label in which the nutraceutical claims are given emphasis on the active ingredient but not on the finished product; (5) shelf life and methods to determine such; and (6) a description of the manufacturing process (Tecson-Mendoza 2007). Several studies are also conducted by the Department of Science and Technology-Food and Nutrition Research Institute (DOST-FNRI) including various state universities and colleges. Research on nutraceuticals is essentially multidisciplinary covering basic agriculture, clinical pharmacology, toxicology/mutagenicity, dosage formulation, manufacturing research, and phytochemistry (Mallillin and Bautista-Batallones 2004).

Several studies on nutraceuticals have been conducted, but many of these remain unpublished and underutilized. This may be linked to the small number of industries which adopt and utilize such technologies. However, the growing interest of the public for buying healthy alternatives has resulted in a number of small to medium enterprises (SMEs) in the country to develop nutraceutical products (capsules, healthy beverages, and teas) which are all for human consumption but not for veterinary uses. Therefore, it is imperative for veterinary universities in the Philippines to also innovate by doing investigations in relation to utilization of food or feeds for animals with certain medicinal benefits.

Fig. 1 Kauna-Unahang Nutraceutical Research and Development Facility Sa Buong Bansa, Pinasinayaan Pampanga

In response to this growing need, the Pampanga State Agricultural University, through a funding grant from the Department of Agriculture-Bureau of Agricultural Research, has established the Nutraceutical Research Laboratory (NRL) (Fig. 1). This laboratory has tissue culture, microbiology, and an animal facility to conduct experiments using laboratory mice. The laboratory, headed by Dr. Geraldine C. Sanchez, project leader of NRL, has been permitted to operate as an animal model research facility from the Bureau of Animal Industry.

The NRL has already produced several research outputs on the antidiabetic properties of mushrooms (*Pleurotus florida*, *Coprinus comatus*, *Ganoderma lucidum*, *Volvariella volvacea*), red mold rice, and brown rice extracts; anticlastogenic of red mold rice, pigeon pea, black rice, turmeric, and mulberry; and hypocholesterolemic of pigeon pea. Currently, the following experiments are being conducted: (1) the role of *Moringa* on estrous cyclicity and follicular dynamics, (2) soybean as fertility enhancer among native pigs, and (3) anticlastogenecity of *Malabar* nightshade.

3 Concluding Remarks and Future Directions

The Philippines is an archipelagic country comprised of people of multiethnic backgrounds. The country has a rich history of using herbal medicines, yet it lacks evidence-based rationale and concept. In response to this growing need, investigations are carried out at various universities, including the Pampanga State Agricultural University, through a funding grant from the Department of Agriculture-Bureau of Agricultural Research. The Nutraceutical Research Laboratory (NRL) has taken the lead. The future of nutraceutical use in the prevention and treatment of animal diseases seems bright in the Philippines.

Regulatory Guidelines for Nutraceuticals in South Africa

V. Naidoo and E. Mokantla

Abstract

South Africa, as a country, does not include the term 'nutraceutical' within its drug-controlling legislation by direct definition. Nonetheless, substances that can be considered nutraceuticals are available as complementary medicines, animal feed and/or stock remedies. Generally, the available veterinary remedies are controlled by the National Department (Ministry) of Agriculture for over-the-counter use, especially since the country is constrained by the total number of veterinarians in the country. Examples of available substances include arnica oil, chondroitin and specified probiotic antimicrobial strains. As with allopathic medicines the regulatory systems in South Africa take into account the safety, quality and efficacy of the product under consideration for market authorisation. However unlike allopathic medicines, where a complete global set of information is required in the registration dossier, the registration requirements for the complementary medicines and foodstuffs place predominant focus on quality in manufacture while adopting a more stepped approach for safety and efficacy, i.e. the greater the risk(s) associated with a specific claim, the greater the scientific information that will be required to support said claims of efficacy and associated safety.

1 Introduction

South Africa, as a country, does not include the term 'nutraceutical' within its drug-controlling legislation by direct definition. However, when no direct medical claims are made for a nutraceutical, it is registrable either as a complementary medicine or as an animal feed under one of two regulatory acts administered by the National Department [Ministry] of Health (DoH) and by the National Department [Ministry] of Agriculture, Forestry and Fisheries (DAFF), respectively, with the latter predominating. Table 1 lists some examples of products available in South Africa that can be generally regarded as veterinary nutraceuticals.

E. Mokantla
Department of Agriculture, Forestry and Fisheries, Pretoria, South Africa

2 Legislative Framework in South Africa

South Africa is a vast country (1.22 million square kilometres in area) that can be best described as semi-arid, making it most suitable for livestock production, which is carried out in approximately 70% of the country. The 2010 census documented the following estimates of production animal numbers in both the commercial sector and the rural farming sector (Scholtz et al. 2013): 13.6 million beef cattle, 1.4 million dairy cattle, 24.6 million sheep, 7 million goats, 3 million ranched wildlife animals, 1.1 million pigs, 113 million broiler chickens, 31.8 million layer chickens and 1.6 million ostriches. It was also estimated that nearly 5 million households provide homes to over 8 million cats and dogs (Durham 2011). Despite the size of the country and its population of 55 million people, the country is served by only approximately 3500 veterinarians. Further to this, a large portion of the country is still rural, with the communities in these areas being constrained in terms of the type of veterinary services they can afford. To overcome the limitation in veterinary services and to mitigate the cost of veterinary treatment versus the value of the animal, the country has adopted a dual regulatory system whereby prescription medicines are limited to veterinary use through the DoH, while the DAFF makes a large number of medication and feedstuffs available over the counter, without any veterinary intervention, for direct use by the farmer.

R. C. Gupta et al. (eds.), *Nutraceuticals in Veterinary Medicine*, https://doi.org/10.1007/978-3-030-04624-8_64

Table 1 Examples of veterinary nutraceuticals available in South Africa

Brands/products	Ingredient(s)	Uses
Eukanuba, Hills, Royal Canin	Prescription veterinary diets	Management of pets with urinary conditions, dermatological conditions, obesity, arthritis, etc.
Calmeze	L-Tryptophan, vitamin B_6, L-theanine, vitamin B_1, vitamin B_3	Calmeze can be mixed into the animal's food or given directly by mouth prior to events that are likely to cause fear or anxiety
Allerderm	Skin lipid complex, glycotechnology, defensin technology	Helps maintain skin barrier integrity and the skin's natural microbial balance
Arthridese	Homeopathic remedy	To assist in relief of chronic inflammation and arthritic discomfort
Canigest	Rapeseed oil, kaolin, fructo-oligosaccharides, mannan-oligosaccharides, pectin, glutamine, roast meat flavouring, *Enterococcus faecium*	Complementary feedstuff for dogs and cats, combining a probiotic, prebiotic, glutamine, kaolin and pectin; it is particularly suitable for feeding to dogs to assist in nutritional management of digestive tract upsets
Digesteaze	Amylase, protease, lipase	Enzyme supplement for exocrine pancreatic insufficiency, derived from fresh porcine pancreas
Equifox Pharmacalm Plus	L-Tryptophan	Concentrated calming paste for use in emergencies to help horses cope with stressful situations without removing the 'edge' required for performance
Fart Eze	Enzyme, probiotic, yucca extract	Supplement for control of flatulence and faecal odour in dogs
GCS Joint Care Advanced Chews	Collagen type 11, omega-3, chondroitin sulphate, glucosamine, green-lipped mussel extract, MSM	Nutritional supplement that supports joint health in dogs
GCS Joint Care Advanced Powder	Glucosamine, chondroitin sulphate, manganese, ascorbic acid	Nutritional supplement to assist management of degenerative joint conditions in dogs
Fulvic Force	Fulvic acid	Helps in the growing of superior-quality birds that are healthier, are bigger and produce finer-quality meat; reduces the need for antimicrobial drugs; helps produce eggs that are larger and have thicker shells with far less cracking
Clostat	*Bacillus subtilis* strain PB6	Helps to maintain the balance of microflora in the intestinal tract of poultry

MSM methylsulphonylmethane

This control falls under two acts: the Medicines and Related Substances Control Act 1965 (Act No. 101 of 1965, which is administered by the DoH and is known commonly as the Medicines Act) and the Fertilizers, Farm Feeds, Agricultural Remedies and Stock Remedies Act 1947 (Act No. 36 of 1947, which is administered by the DAFF and is commonly known as the Stock Remedies Act). Both acts follow the same manner of control and are supported by both regulations and guidelines, which are periodically reviewed. In general, South Africa follows International Cooperation on Harmonisation of Technical Requirements for Registration of Veterinary Medicinal Products (VICH) guidelines as a result of the country's observer status in the VICH programme. Both acts also share a similar governance structure in that registrations require complete evaluation of a submitted dossier by technical advisers, who hold qualifications in the fields of chemistry, veterinary pharmacology, toxicology, microbiology, virology and/or clinical veterinary medicine in all applicable major species as required. The only major difference between the two acts is evident in the intended use of the products. Since the Medicines Act tends to control products restricted to the veterinary professional (veterinary medicines), that act ensures that every product is supported by a full scientific package insert. In contrast, the Stock Remedies Act, of which the main function is to allow over-the-counter availability of products to non-veterinary professionals, places major focus on ensuring that the supporting package insert/leaflet is written in clear, simple, nonambiguous language that makes it easy to follow the instructions. Further, the act places major emphasis on ensuring that the outer packaging and accompanying marketing material include no items or markings (direct or indirect) that could misrepresent how to use the product.

The Medicines Act controls the following categories of substances:

- *Medicine*: This means any substance or mixture of substances that is used or purports to be suitable for use—or that is manufactured or sold for use—in diagnosis, treatment, mitigation, modification or prevention of disease or an abnormal physical or mental state (or symptoms thereof) in man; or in restoring, correcting or modifying any somatic, psychic or organic function in man. Medicines are controlled by means of the schedules

Table 2 Schedules of the Medicines Act in South Africa

Schedule numbers[a]	General categories	Control requirements	Examples
S0	Over-the-counter medicines	Available for sale in any shop without restriction; may be advertised to the public	Aspirin, paracetamol, antiseptics
S1	Pharmacy over-the-counter medicines	Available over the counter from any pharmacy without requiring consultation with a pharmacist; may be advertised to the public	Topical preparations of local anaesthetics, probiotics above a defined CFU value, medical dewormers
S2	Pharmacy prescription medicines	Available from any pharmacy following consultation with a pharmacist; may not be advertised to the public	Medical NSAIDs, NSAID/codeine products, contraceptive medications
S3	Prescription-only medication	Chronic medication requiring a prescription from a medical doctor or veterinarian	Veterinary NSAIDs, hormone replacement therapies
S4		General group of medicines prescribed by a medical doctor or veterinarian	Antimicrobials, systemic medications
S5		Potentially dependence-producing medicines	Anaesthetics, tranquillisers, sedatives, behavioural modifiers
S6		Dangerous dependence-producing medicines	Opioids, synthetic opioids, veterinary euthanasia formulations
S7	Banned substances	Undesirable medicinal substances	Amphetamines, cannabis, cannabinoids, cocaine, phencyclidine
S8	Medicines available for use only with a special permit	Restricted-use medicines	Any S7 substance

CFU colony-forming unit, *NSAID* nonsteroidal anti-inflammatory drug
[a]Since S2–S8 medicines and substances are not directly available to the public, they may not be advertised to the public

of the act (S0–S8), with different access controls per schedule. In general, S0 covers over-the-counter human medicines, S1 and S2 cover medicines that are prescribable by a pharmacist, S3–S6 medicines are under the control of a medical or veterinary doctor, S7 medicines are banned substances and S8 medicines are banned substances with restricted medical use potential (Table 2).

- *Veterinary medicine*: This means any substance or mixture of substances that is used or purports to be suitable for use—or that is manufactured or sold for use—in connection with vertebrates, for treatment, diagnosis, prevention or cure of any disease, infection or other unhealthy condition; or for maintenance or improvement of health, growth, production or working capacity; or for curing, correcting or modifying any somatic or organic function; or for correcting or modifying behaviour. Veterinary medicines fall under same scheduling system mentioned above for medicines, with the exception that the schedules make provision for exclusion of active ingredients under the control of the Stock Remedies Act.
- *Complementary medicine*: This means any substances or mixture of substances that originates from a plant, fungus, alga, seaweed, lichen, mineral, animal or other substance as determined, and that is used or purports to be suitable for use—or that is manufactured or sold for use—in maintaining, complementing or assisting innate healing power or physical state or mental state; or to diagnose, treat, mitigate, modify, alleviate or prevent disease or illness (or symptoms or signs thereof) or an abnormal physical or mental state in a human being or animal; and is used as a health supplement or in accordance with the following disciplines: herbal substance/preparation; traditional Chinese, Ayurvedic and Unani Tibb substances; and homeopathic substances and aromatherapy. Complementary medicines are generally meant for over-the-counter sales and are freely available to the public at most health shops, supermarkets and pharmacies.
- *Health supplement*: This means any substance, extract or mixture of substances that may supplement the diet or have a nutritional physiological effect. This category includes prebiotics, probiotics and other supplements sold in pharmaceutical dosage forms not usually associated with a foodstuff, and excludes injectables. As is the case for complementary medicines, health supplements can be sold from any retail outlet.
- *Medical device*: This means any instrument, appliance, material, machine, apparatus, implant or diagnostic reagent that is used or purports to be suitable for use—or that is manufactured or sold for use—in diagnosis, treatment, mitigation, modification, monitoring or prevention of disease or abnormal physical or mental states (or symptoms thereof); or for restoring, correcting or modifying any somatic, psychic or organic function; or for diagnosis or prevention of pregnancy; and that does not achieve its purpose through chemical, pharmacological, immunological or metabolic means.

Table 3 Products that can be considered nutraceuticals and their registration process in South Africa

Legal categories	Act numbers	Descriptions	Examples
Complementary medicines	101/65	Generally substances that are not controlled as allopathic medicines within the schedules of the act, with a primary function of supporting the immune system and thereby promoting wellness	Homeopathic remedies, Western herbalism, Eastern medicines
Health supplements	101/65	Generally substances that exert physiological effects through nutritive effects	Probiotics, glucosamine
Stock remedies	36/47	Medicinal substances that are usually available for over-the-counter sale for animal use	Arnica oil, camphor cream
Farm feeds and pet foods	36/47	Substances that support animal nutrition and those that have a physiological effect in a manner that does not make them stock remedies	Green-lipped mussel, chondroitin, glucosamine
Zootechnical additives	36/47	Enzymes and/or probiotics used for management of gut health in animals	Defined bacterial strains

The Stock Remedies Act controls the following categories of substances:

- *Fertilisers*: This includes any substance that is intended or offered to be used for improving or maintaining the growth of plants or the productivity of the soil.
- *Agricultural remedies*: This includes any chemical substance or biological remedy, or any mixture or combination of substances or remedies, that is intended or offered for use in destruction, control, repelling, attraction or prevention of any undesired microbe, alga, nematode, fungus, insect, plant, vertebrate, invertebrate or any product thereof.
- *Farm feed*: This includes any substance obtained by a process of crushing, gristing or grinding; any substance obtained by addition to, or removal from, another substance; any condimental food, vitamin or mineral substance or other substance that possesses, or is alleged to possess, nutritive properties; any bone product that is intended or sold for feeding of domestic animals or livestock; or any stock lick or substance that can be, and is, used as a stock lick, whether or not such a stock lick or substance possesses medicinal properties. It also includes 'complete pet food', which is a pet food that contains all necessary nutrients in the correct quantities and proportions for the physiological needs of the animal. It is within this category that veterinary nutraceuticals are controlled in South Africa and, as is the case for the complementary medicines (as mentioned above), they are available for open sale from any retail outlet.
- *Stock remedies*: This includes any substance that is intended or offered to be used in connection with domestic animals, livestock, poultry, fish or wild animals (including wild birds) for diagnosis, prevention, treatment or cure of any disease, infection or other unhealthy condition; or for maintenance or improvement of health, growth, production or working capacity. Stock remedies generally cover medicines used for treatment of ectoparasites, endoparasites or tickborne diseases; certain antimicrobials; and injectable vitamins/minerals. This category also includes complementary veterinary medicines such as arnica and aromatic oils. In general, stock remedies are meant for open sale at any retail outlet. However, there are some restrictions on certain products, since a degree of veterinary supervision is required for their use.
- *Zootechnical additives*: This includes digestibility-enhancing substances, gut flora stabilisers (which include microorganisms or other chemically defined substances that have a positive effect on the gut flora) and substances that favourably affect the environment (Table 3).

3 General Control of Veterinary Nutraceuticals

As is evident from the above, veterinary nutraceuticals can fall under the control of the DoH or the DAFF, depending on which category the medicine falls into. Not surprisingly, the registering company can choose which act they register their product under. In general, the DAFF remains the main point of registration of nutraceutical remedies and is estimated to control 90% of all medications available for use in animals in the country. The latter is linked to the focus of the DAFF on animal health, and this department has controlled medicinal substances for a substantially longer period than the DoH. Also, the registration of complementary medicines with the DoH as a medicine category is relatively new and came into effect only in 2013.

3.1 Registration Requirements

As with medicines, the regulatory systems in South Africa take into account the safety, quality and efficacy of a product being considered for market authorisation. However unlike

medicines (and stock remedies), for which a complete global set of information is required in the registration dossier, the registration requirements for complementary medicines and foodstuffs place the predominant focus on quality in manufacturing, with adoption of a more stepped approach for safety and efficacy, in that the greater the risk, the greater the study requirements are to support the said claims of safety and efficacy. A major difference is readily evident for health supplements, for which claims of efficacy are not allowed, and these products need to be labelled with the following wording: 'Health supplements are intended only to complement health or supplement the diet'.

Registration of Complementary Medicines (Act 101 of 1965)

The following requirements are in place for complementary medicines:

- *Quality control*: The DoH requires compliance with good manufacturing practice (GMP), good laboratory practice (GLP) and good agricultural and collection practices (GACP) in the manufacturing of complementary medicines, according to the guidelines stipulated by the South African Health Products Regulatory Authority (a new body that replaced the Medicines Control Council of South Africa in 2018). The regulations further stipulate that to be regulated as a complementary medicine, a product needs to be free of any substances contained in the schedules of the act—that is, it cannot contain or be co-formulated with an active pharmaceutical ingredient; be used as a means to avoid being controlled as a medicine (or veterinary medicine); or generally contain any chemically defined isolated constituent of a plant, fungus, alga, seaweed, lichen, animal or mineral, or a combination of such constituents, that has a pharmacological effect. It is, however, allowed for a complementary medicine to contain inactive ingredients as long as they are classified as being Generally Regarded as Safe (GRAS) by the US Food and Drug Administration (FDA).
- *Safety*: It is required for complementary medicines to demonstrate their safety, which may be determined through a literature review and/or submission of original study data, as per other pharmaceutical active ingredients. The amount of information required will depend on the documented historical use of the product and the risks associated with its use.
- *Efficacy*: For registration, appropriate evidence in support of efficacy for the proposed indication(s) and claims needs to be submitted, depending on the nature of the said claims. Claims are divided into those made for minor disorders and those made for major disorders. Disorders considered minor are usually linked to a product that has nonspecific indications and usually a history of traditional use supporting the said indication. Major indications are claims made towards the treatment of a specific disease (e.g. treatment of diabetes), which generally require more information to prove efficacy. For high-risk claims or where traditional use has not been established, efficacy needs to be supported by appropriate preclinical and/or clinical evidence.

Registration of Farm Feeds (and Pet Foods) (Act 36 of 1947)

The following requirements are in place for farm feeds and pet foods:

- *Manufacturing*: The act makes mention that the place of manufacturing, packing, marking, labelling and/or storage needs to be kept orderly and clean and supported by equipment that is both suitable for the purpose and maintained in good working order so as to allow for uniform distribution of the feedstuff in the mixed food. In terms of the quality system, the feed manufacturer needs to establish critical points in manufacturing and ensure that they are controlled. The regulations make special mention that feeds and feedstuffs used in manufacturing must be protected against damage, contamination and deterioration; and that different additives and premixes must be kept separate from each other to avoid cross-contamination.
- *Quality*: Quality control on foods is not limited to manufacturing standards; it also considers interactions and is very specific that a formulation should not contain any ingredient(s) that could lead to the loss of one or more of the nutrients in the product. Since products may be of animal origin, the quality standard indicates that animal-derived products must first be sterilised so that any contaminating microorganisms are reduced to a level at which they pose no danger to the health or productive capacity of the animals fed on the said product, or no longer pose a disease risk to the country. The act also contains a list of prohibited substances that may not be included in animal feeds.
- *Efficacy*: The requirements firstly limit feeds to a physical form that can be consumed by oral ingestion. In general, when a food is to be registered for a particular nutritional purpose, information needs to be generated to support its precise use so as to demonstrate that the particular nutritional purpose attributed to the product is appropriate. For microorganisms specifically, the name and taxonomic classification of each microorganism needs to be provided, according to the latest published information in the International Codes of Nomenclature (ICN). In addition, all relevant morphological, physiological and molecular

characteristics necessary to provide the unique identification of the strain and the means to confirm its genetic stability needs to be described.

- *Safety*: It is a requirement that the safety of the target animals of the feed or the ingredients used are supported with appropriate data. A material safety data sheet must be provided. If necessary, measures for prevention of occupational risks and means of protection during manufacturing, handling, use and disposal shall be proposed.

4 Concluding Remarks and Future Directions

South Africa, as a country, has a dual regulatory system to allow for availability of medicines, which was developed to allow for treatment of animals by animal owners and farmers within a landscape that is constrained by the veterinary capacity of the country. Within this dual regulatory system, although products that can be considered nutraceuticals are not considered, the country does allow for their registration within one of the subcategories within the drug control acts, with the majority of products used in animals being controlled as farm and pet foods.

Correction to: Evaluation of Safety and Efficacy of Nutraceuticals Using *Drosophila* as an *in vivo* Tool

Anurag Sharma, Clinton D'Souza, Vipin Rai, and Subash Chandra Gupta

Correction to:
Chapter 49 in: R. C. Gupta et al. (eds.),
***Nutraceuticals in Veterinary Medicine*,**
https://doi.org/10.1007/978-3-030-04624-8_49

The original version of Chap. 49 was inadvertently published with the incorrect chapter title "Evaluation of Safety and Efficacy of Nutraceuticals Using *Drosophila* as an *in vitro* Tool" whereas it should be "Evaluation of Safety and Efficacy of Nutraceuticals Using *Drosophila* as an *in vivo* Tool". The chapter has now been corrected and approved by the author.

The updated online version of this chapter can be found at
