Radio-Frequency Geo-location and Small Satellite Constellations

Joseph N. Pelton

Contents

Abstract

The worldwide responsibility for the allocation of radio frequencies and the coordination of their use is assigned to the International Telecommunication Union (ITU), headquartered in Geneva, Switzerland. The ITU plenary assembly known as the World Radiocommunication Conference meets every few years and agrees on the global radio-frequency allocations to be used globally. The spectrum allocations are divided into three regions globally as follows: region 1, Europe and Africa; region 2, the Americas; and region 3, Asia and Australasia. The usage for radio-frequency spectra has grown enormously in recent years for terrestrial wireless usage (i.e., the of 5G broadband cellular services, emergency and first responder services, law enforcement and defense-related applications, radio and television broadcasting, non-licensed industrial and scientific usage, and microwave relay). There has been parallel growth of non-terrestrial uses such as for aviation communications and safety, high-altitude platform systems and UAVs, plus satellites of various types. The complexity of the global frequency a

allocation tables has increased enormously as well as the problem of frequency interference and jamming.

More and more types of shared usages have emerged, and higher and higher frequencies in the electromagnetic spectrum have been allocated to these many and growing applications. As this increase in usage and types of applications has emerged, there has been growing concerns and difficulties of unintended and intended interference, jamming, and disagreements between nations and other groups and commercial interests about how to coordinate spectrum use. There are increasingly challenging discussions globally about the best processes related to frequency allocations, frequency allotments, and frequency assignments (or national licensing practices). Terrestrial systems for monitoring the usage of radio-frequency spectra are increasingly inadequate to the task of accurately and precisely determining the nature and exact location this usage. Further the deployment of a significant number of new small satellite constellations will likely increase the problem of monitoring of spectrum use and interference in coming years.

It has been decided that one way to monitor radio-frequency spectrum use much more effectively on a global scale is the deployment of satellites that can consistently monitor frequency use around the world and also identify spectrum that is not being used or underutilized in various parts of the world. The first such satellite-based commercial system to seek to provide comprehensive and near real-time monitoring of frequency use – or misuse – on a global scale is the small satellite constellation known as Hawkeye 360. This low Earth orbit satellite constellation and its types of service offerings are described below. This chapter reports on the issue of increasing need for global frequency use and monitoring and the latest efforts to monitor spectrum usage using satellite networks designed and operated for this purpose.

The Hawkeye 360 system and its intended special ability to deliver actionable data to national administrations, commercial interests, and perhaps even defense-related interests around the world on a near real-time basis are also discussed. This rapid delivery of monitoring results is to be accomplished by making arrangements with new commercial data relay constellations designed to provide near real-time information to ground stations deployed around the world that can then connect to users of this data. This arrangement avoids the need to wait to download results until the LEO-based satellite is over a particular accessible ground antenna system.

This type of commercially based frequency monitoring service, of course, could be performed by other entities in the future, but currently the Hawkeye 360 is uniquely providing this type of service on a commercial basis. Currently the greatest problem of frequency interference and jamming typically occurs with regard to terrestrial radio and television broadcasts and other types of interference and jamming problems near the ground. Nevertheless the deployment of more and more satellites, high-altitude platforms, and the use of space planes and hypersonic transportation will increasingly bring these problems to near-space

(i.e., Protospace) and outer space. There is increasing concern about the issue of space debris; congestion of Earth orbits, especially low Earth orbit; and space traffic management or space traffic control. The problem often focuses on the issue of physical collisions, but frequency interference or jamming or cyberattack could also lead to accidents in space and the disabling of satellites or lead to physical collisions. Thus frequency monitoring and control in space are also going to be increasingly important as these future trends develop.

1 Introduction

The pattern of increase in the use of the electromagnetic spectrum can be revealed in the way that the spectrum bands, and the naming for frequency bands, has taken place as we have moved up and up the spectrum to higher and higher frequencies. We have today the following names for frequency bands as we move to higher and higher frequency. The range of frequencies that is characterized as ultrahigh frequencies (UHF) is 100 times lower than what we now call extremely high frequencies (EHF). In a linguistic sense, this makes no sense. When we first started to use the ultrahigh frequencies, there was not the technology or the imagined possible use or need for possible exploitation of the extremely high frequencies that are now being used by satellite communications and many other purposes.

High frequency (HF): 3–30 MHz
Very high frequency (VHF): 30–300 MHz
Ultrahigh frequency (UHF): 300–3000 MHz
Super high frequency (SHF): 3–30 GHz
Extremely high frequency (EHF): 30–300 GHz

In the nineteenth, twentieth, and now twenty-first century, we have gone from just the telegraph to the television, to the radio, to television, to direct broadcast satellite television, to the Internet, to 5G broadband cellular and streaming services and the Internet of Everything services. We have gone from no satellites to over 20,000 television channels distributed or broadcast via satellite, to perhaps as many as 20,000 satellites in operation in Earth orbit by 2030. Our ability to monitor, regulate, and control the use of the electromagnetic spectrum around the world has fallen behind our technological ability to use EM spectrum more and more intensively. Indeed our call for more and more usage associated with 5G broadband cellular, corporate enterprise networks, Instagram posts, and television streaming services is accelerating every day. The ability to keep up with the regulation and control such runaway growth in spectrum usage is lagging behind.

The process of frequency monitoring and control is the responsibility of individual nations within their own borders. The ITU has a process of coordination with respect to systems that operated internationally. In the case of satellite systems, the national administration that is a member of the ITU submits a filing that is then published by the ITU so that all of its members have the chance to determine if there is potential frequency interference. Nations are invited to seek a means to limit, minimize, or eliminate interference on their own. If this process is not successful, then ITU officials seek to oversee a process to reach agreement on an interference mitigation plan. In some cases this can be quite complex. In the case of the Iridium mobile satellite system, for instance, there is a coordinated interference reduction plan first worked out in 1998 whereby the Iridium system cells go electronically silent when passing over radio telescope facilities. And unfortunately Iridium did not fully comply with the “recommended” interference reduction plan. Since this was only part of the ITU-R recommended noise reduction plan without any enforcement mechanism, this is now an ongoing problem. This interference reduction in the case of radio astronomy facilities all over the world is a particularly challenging assignment today. Such a geographic dependent cessation of satellite transmissions is quite difficult to achieve, particularly in the extended area represented by the National Radio Astronomy Observatory’s Very Large Array in New Mexico. Today the range of difficulties involved with reduction of interference to radio astronomy facilities around the world just keeps expanding (Kimbrough 2019).

The deployment of perhaps 20,000 small satellites in low and medium Earth orbit satellites will thus make the problem of frequency coordination increasingly difficult. This is not only for LEO and MEO satellite but for GEO satellites which will be potentially subject to interference as LEO and MEO systems pass through the geostationary orbit arc. Thus the deployment of satellite systems like the Hawkeye 360 frequency monitoring satellite constellation can become an extremely important tool that can be used by national frequency management offices as well as regional bodies and the ITU to detect the sources of interference and improved spectrum management capabilities.

Even so, the challenges remain quite large and difficult to implement and enforce. The great bulk of frequency management and interference reduction responsibility falls to the many national governments around the world that are charged with this responsibility. The technical capabilities to detect and pinpoint the source of frequency interference and to have the resources to manage and enforce laws and regulations in this area vary enormously around the world. Even those countries with the technical means to detect interference and to enforce local laws and resources do not always have the enforcement personnel to address these issues in the timely and urgent manner that is desirable.

Table 1 Recommended scope of frameworks for national frequency plans (ITU-R guidelines for national frequency plans)

Frameworks: Telecommunication act of the country
Should give explicit reference chapters and articles about spectrum utilization
Should establish independent responsible authority for spectrum management
Should recognize key functions of responsible authority for spectrum management
Should consolidate radio licensing regime
Should equip spectrum management authority with powerful regulations to supervise spectrum utilization
Should recognize international nature and harmonized usage of spectrum

2 Basic Concepts of Frequency Allocation and Interference Reduction

The ITU has developed a sort of primer for how each country should oversee and organize radio-frequency spectrum management within its own territory. These guidelines for a regulatory framework are indicated below in Table 1 (ITU Frequency Allocation Table Training n.d.).

The ITU, in these essential briefing materials, recommends that in addition to the global frequency allocation table, each country should develop its own frequency allocation table and that it be structured as provided in Chart 1 (ITU Frequency Allocation Table Training S n.d.).

3 Hawkeye 360 Constellation

The first in a series of small satellites to carry out frequency usage mapping and analytics has now been launched and shown to be fully function. The Falcon 9 launch of the 'trio' of Hawkeye 360 satellites was accomplished on December 3, 2018 with precision and placed in the desired orbit. This system is thus now checked out and functional in its so-called Pathfinder phase (see Fig. 1).

Hawkeye 360's objective is to continue to launch at least six clusters of three satellites to create a fully functional global network. Beyond this 18-satellite network, the ultimate design is to deploy 30 satellites (in clusters of 3 with 10 clusters of 3) in orbit. The 18-satellite constellation would allow for rapid revisit coverage with a goal for rapid revisit coverage. When the full constellation of 30 small satellites is deployed, the rapidity of updated service is planned to drop down every 10–20 min. The first "trio" of these satellites is known as RFGEO. These three satellites were designed and manufactured by Space Flight Laboratories (SFL) of the University of Toronto, in cooperation with Deep Space Industries and Hawkeye 360. Hawkeye 360, in light of the success of the initial "trio," has contracted to build a second trio of these Hawkeye 360 satellites that are to be launched as soon as can be scheduled

after they are complete and certified for launch (https://www.spaceitbridge.com/hawkeye-360-launches-commercial-rf-signal-mapping-from-space.htm).

These satellites are to be followed by the building and deployment of an augmented design of a dozen more satellites to complete a network of 18 satellites in the constellation. With the success of this deployment of a global constellation consisting of 6 “trios” of satellites, then the complete constellation of 30 satellites will subsequently be deployed assuming there is sufficient commercial demand for these services that are for the first time being offered as a commercial service..

The mission objectives for the Hawkeye 360 constellation have been clearly stated as follows:

> Space-based detection of RF signals allows HawkEye 360 to locate and characterize difficult-to-visualize wireless spectrum information in a more accurate and efficient

> manner when compared to terrestrial detection and image analysis. By taking RF data and turning it into information, HawkEye 360 will be able to give commercial enterprises and governments better knowledge to make critical decisions. (Microsatellites: Hawkeye 360 Pathfinder 2014)

One of the key milestones in the evolving Hawkeye 360 program came with the decision to award the contract for designing and building the platforms for the first three of their RF geo-location satellites to the University of Toronto Institute of Aerospace Analysis and the Space Flight Laboratory (SFL) in partnership with Deep Space Industries. The SFI team in partnership with Deep Space Industries (DSI) had established a track record by using their 15 kg small satellite design known as NEMO. This resulted in the successful 2014 two satellite formation experiment known as CanX-4/CanX-5 mission that was funded by the Canadian government.

Hawkeye 360 was seeking a low-cost small satellite platform that could fly in close but highly accurate formation so that through a triangulation process, the exact geo-location of radio-frequency emissions could be very accurately pinpointed. The precursor CANX-4/CANX-5 was a highly close fit to the needs for their intended RF geo-location satellite project. The facts that these satellites could be rapidly designed and built and their construction costs were considered quite reasonable were added incentives. Thus Deep Space Industries were selected for the precision propulsion system, and SFL was selected to build the small satellite bus (Ibid.).

In order for the triangulation to be calculated with sufficient accuracy, the relative position of the three satellites each had to be located with exact precision in space relative to each other. As SFL and DSI have indicated, their design was based on the following four critical attributes:

- Compact inter-satellite communication link developed by SFL to share data in real time
- High-performance attitude control system also developed by SFL to maintain precise small satellite pointing
- High-efficiency Comet-1 propulsion system developed by Deep Space Industries (DSI)

The initial “trio” of small satellites were launched in December 2018, and their performance checked out with sufficient accuracy that the follow-on contract for three more pathfinder satellites were placed with UTIAS-SFL and Deep Space Industries in March 2019.

The search is now on by Hawkeye 360 to find government, corporate, and defense agency customers that believe that this new system will be able to provide RF geo-location information and usage data (or abusive data) that is not possible with terrestrial detection methods – or at least not available with sufficient precision. Primary applications are now thought to be in the communications, broadcasting, transportation, and data analysis markets as well as to assist governments with their regulatory oversight. Other key applications could be to assist with the emergency rescue signals associated with downed aircraft, ship wrecks, mountain climbers and wilderness trekkers, or other lost individuals. The completely global geo-location capability across a wide range of frequencies is currently a quite unique capability, even though others might be able to pursue these RF geo-location techniques since this is not a technologically unique set of technologies (https://www.utias-ISF.net).

The final member of the technical team beyond Hawkeye 360, Deep Space Industries, and Space Flight Laboratories is GomSpace of Denmark. This NewSpace company is arranging the ground segment for the receipt of the signals from the low Earth orbit satellites. This too is a complex undertaking. In this instance the relativistic speeds of the orbiting spacecraft have to be taken into consideration to ensure the accuracy of the geo-location determinations, just as must be done with the GNSS position determinations (News n.d.).

4 The Global RF Geo-location Market

The commercial satellite application market is today widely established. The satellite communications and remote sensing servicing markets are well established and represent a $100 billion dollars a year in revenues. The current small satellite constellations are seeking to “extend” those markets. In the case of the small satellite systems for telecommunications, the thrust is toward extending the networking and Internet access capabilities in unserved regions of the world. There is also the additional objective of extending networking capabilities for corporate enterprise networks and to support 5G broadband Internet services. In the case of remote sensing system, there has been a focus on so-called analytics and the more rapid updating of strategic information that is partially enabled by lower capital and operating costs and quicker turnaround of analytical data.

The entirely new field of RF geo-location analytics is, in effect, a totally new enterprise that requires a new market development strategy. The dilemma that this market presents is that it is, at once, a giant new opportunity in so many different areas and because it is a totally new way of using satellite applications that those who might use these services will need to learn how to use them for the first time.

The strategy that Hawkeye 360 is using has a certain well-conceived logic to it. First it is deploying the network on a gradual basis and doing so with cost-effective satellite manufacturing and launch deployment services to limit their operating costs as a customer base is established. Secondly it has identified a number of key service areas where their RF geo-location services can best be strategically provided and seeking contracts in each of those areas.

Already Hawkeye 360 has contracted with the Government of New Zealand to use data provided from the Hawkeye 360 for radio use regulation and to support law enforcement activities. Assuming this activity in New Zealand is a success, then marketing this service to other governments will proceed with much great success. Other initial target areas are in the areas of sea transportation to monitor suspicious activities at sea such as pirate operations, drug smuggling, coast guard enforcement, etc.; land transportation to route long-distance bus or trucking operations more efficiently; and air transportation for air safety for planes, helicopters, drones, and autonomous vehicles.

One of the most obvious areas is to provide support to broadcasters of radio and television that are often subject to intentional and unintentional interference and jamming. This applies not only to terrestrial over-the-air broadcasters and to satellite systems providing either radio or television distribution or direct broadcasting. Currently the ITU process for overseeing the usage of RF spectrum on a global basis is highly decentralized with local authority for oversight being placed with the national government to administer their national RF allocation, allotment, and licensed assignment of frequencies to users within their country. This means that if the government in question has officially or unofficially sanctioned jamming of unwanted radio or television transmission, whether from terrestrial or satellite sources, there is no enforcement processes left open to the International Telecommunication Union. At this state of international development, only the World Trade Organization has the ability to place sanctions against national governments, including the right to impose fines. Thus RF geo-location satellite networks can more clearly identify infractions, but they do not offer a regulatory solution if national governments choose not to cooperate or are the source of the jamming operations themselves.

Another interesting area of possible application of new RF geo-location services might well be in the area of “crimes against humanity.” Already remote sensing satellites have been used in documentary evidence as to when villages have been burned or other acts of war or violence have taken place. The use of radio communications by those committing acts of terror or genocide might prove to be even more important tools to document horrendous acts of violence. The business model for how RF geo-location systems are used by governments is yet to be clarified. Will governments make an umbrella agreement for all types of applications? Such usages might be for such areas as RF spectrum interference detection and illegal use enforcement, national defense applications, criminal investigations and gathering of judicial evidence, drug enforcement, smuggling, etc. In theory there could be separate agreements with different types of governmental agencies and perhaps even at the national, state, regional, or local levels of government. Initially it seems likely that there will be umbrella agreements by national governments to receive all data for their country for all types of governmental functions and all levels of jurisdiction. In time these agreements may become more tailored. Such agreements would apply to governmental functions and not exclude other commercial applications in that country.

Another interesting application is for rescue operations. The cost of operations of various units around the world to detect emergency distress and indications of a plane crash or shipwreck is quite high. There are units installed on ships and aircraft known as emergency position-indicating radio beacon station (EPRIRBS) that are activated as emergency occurs. Today over 90% of the alerts are false alarms, yet a number of regional stations are staffed 24 h a day, 7 days a week to detect such alarms. It might be possible that RF geo-location satellites could largely automate such a system globally. This is but one of the many ways that such systems might be used to respond to emergencies and natural and man-made disasters. They could also be used to locate missing hikers or adventurers around the world or respond to a new type of global alarm system based on a newly designated alarm frequency. Again the issue of how such services fit into a commercial model of operation arises. These are just some of the many issues that arise with such a new global capability. When the laser was invented, its uses and utility were seen in a very narrow range of possibilities. Today there are many thousands of applications that were never dreamed of at the time. The same may prove true of the RF geo-location-type satellite. It may be in several decades there may be hundreds of applications developed that will prove to be of enormous importance to public safety, law enforcement, national defense, transportation, communications, health care, education, and a wide range of commerce.

One area that may develop as a particularly important new application could be in the area of cybersecurity. This may relate to aircraft and ground auto, bus, trucking, or train transportation safety. There is mounting concern on cyberattacks as there is more and more use of artificial intelligence in self-driving transport systems, in aircraft guidance and control systems, and in vital urban infrastructure, as well as in Internet of Things feedback systems. In this global environment, there may well be spurious commands and cyberattacks on these systems. These might come from terrorist and criminal organizations, and in some cases they might use identifiable RF-based attack frequencies. Thus, there may well be important opportunity to use space-based RF geo-location systems to identify the source of such criminal and terrorist cyberattacks and also, just as importantly, to provide proof of the origin of these assaults (Pellton and Singh 2018).

What is particularly compelling and interesting about the Hawkeye 360 small satellite enterprise is that all of the participants in this totally new service are a part of what is called the NewSpace industries or the Space 2.0 industries. Most of these companies are true start-ups or were truly so just a few years ago. Hawkeye 360 was organized in 2013–2014. Other Partners such as Deep Space Industries, Space Flight Industries of Canada, GOM Space, and even SpaceX the launching organization are all new enterprises. None of these organizations have a kinship to the long-established aerospace companies that grew out of the long-term military industrial complex that dates back to the World War eras. None of these enterprises bear any resemblance to the Lockheed Martin, Boeing Aerospace, or Northrop Grumman stalwarts of the traditional aerospace entities.

The remarkable thing about the new Hawkeye 360 small satellite system is not only what these RRF geo-location devices can do but that the spacecraft are only 15 kg in mass and that three of the initial “trio” launched in December 2018 were essentially an ancillary aspect of the overall Falcon 9 launch.

The remarkable technical and nuanced design of the The quite unsual thing about the Hawkeye 360 satellites are their nuanced and ‘sophisticated’ design that can provide a precise geolocation for a huge range of frequency spectrum uses on a global basis. Further, these are not two ton satellites that required 4 or 5 years to design and build. Rather they were designed, constructed, flight qualified, and launched within an 18 month schedule. If Hawkeye 360 is able to deploy its full

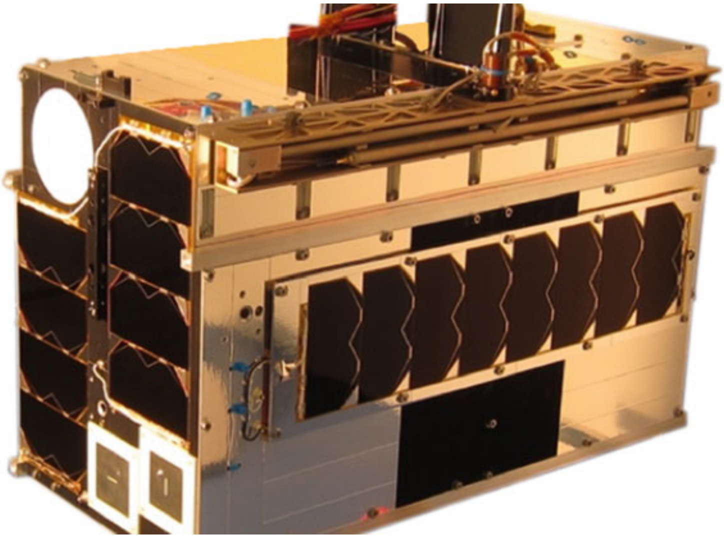

Fig. 2 Close-up of the Hawkeye 360 spacecraft. (Graphic courtesy of Space Flight Laboratories)

network and find sufficient customers to create a paying commercial and governmental group of customers, it will not only be a testament to finding and exploiting an entirely new market, but it will also be based on finding the right new technology and small satellite ingenuity to design, build, and launch this capability in a small satellite with a mass of only 15 kg (see Fig. 2).

5 The Hawkeye 360 System's Desire to Provide Rapid Data Distribution

Jamming, as well as various forms of RF interference, is something that service providers want to respond to with a sense of great urgency. In many cases such as broadcasting or most telecommunications services or downloads of remote sensing or Earth observation data, disruption of service can result in loss of revenues or even discontinuation of service and permanent loss of customers.

One possibility would be to make an arrangement for a commercial relay of the data from the "trios" of Hawkeye 360 satellite so that there could be a near real-time download of the day. This approach has the advantage of not necessarily making landing licensing arrangements with the countries where the data would be downloaded and be able to provide data for analysis by customers on a much more rapid basis.

One option that has been considered is the signing up with the new Audacy data relay satellite network for instant download of acquired frequency use data. This network is designed to download data instantly to ground stations located strategically around the globe. This system was conceived as being able to provide data relay service at a variety of data speeds from medium to quite broadband rates. Thus such a data relay system can support many types of satellite applications including remote sensing and analytics, frequency monitoring (i.e., RF geo-location), IoT services, meteorological services, or in fact any satellite services company that needs to move data on a near real-time basis. Increasingly there will be a need by many satellite operators to avoid storing data that can be downloaded only when passing over a suitably located ground station (https://www.spaceitbridge.com/new-space-startups-hawkeye-360-audacy-turn-up-partner-programs.htm). These arrangements, of course, will depend on Audacy being able to complete their financing and the full deployment of their proposed commercial data network. It remains a challenge for such a start-up venture to create a sufficient revenue stream to support the substantial capital investment that this network will require. Other arrangements might be made with other systems that can provide satellite data relay services.

6 Conclusions

The field of satellite applications has for quite a few years focused on three primary areas. These are satellite communications, remote sensing/Earth observation/meteorological satellites, and global navigational satellite services (GNSS) or precise navigation and timing (PNT) services. These are now well-established fields of satellite applications, and their commercially related services generate over $125 billion (US) in revenues. The new cost-efficiencies of small satellite constellations are now leading to new satellite applications that generate commercial revenues in new sectors.

One of the more promising new areas is that of RF geo-location services that is being pioneered by the Hawkeye 360 company that has partnered with the University of Toronto Space Flight Laboratories, Deep Space Industries, and GomSpace to create a new small satellite constellation that is expected to grow ultimately to a network of 30 15 kg small satellites configured into 10 “trios” or 3-each satellite clusters. Each three-satellite cluster is to be precisely configured together so that triangulation measurement processes can detect the geo-location of radio-frequency emissions over a wide range of frequencies. The application of this new type of satellite sensing capability is expected to give rise to a wide range of new commercial services and revenues.

The Hawkeye 360 constellation has determined that a particular value-added capability will be critical to its ability to sell its RF geo-location data much more effectively if its data can be provided to its commercial customers in as close to “near real time” as possible. Thus it has made pending arrangements with the Audacy commercial data relay system – positioned in a 14,000 km MEO orbit – to instantly download its data via this system to a worldwide system of three antennas established by GomSpace so that the data can be fed to its commercial users on a global basis as quickly as possible.

This new and currently unique commercial satellite service that is augmented by the Audacy instantaneous download capability makes this Hawkeye 360 network unique in the service capability that it provides. Today Hawkeye 360 is in the early stages of deploying its 18-satellite constellation of 6 “trios” of triangulating satellites. It is just beginning to operate globally and establish a number of commercial customers that are seeking a wide range of RF usage information. If this system of RF geo-location satellite services is commercially successful, it is likely that there will be other satellite systems that seek to offer competitive commercial services that are alike in their capabilities – including a near-instantaneous download service of RF usage with designation of exact location.

Satellite-based data relay systems that relay data have been around for some four decades starting with the NASA Tracking and Data Relay Satellite System (TDRSS) and then followed by the European Space Agency (ESA) and JAXA. Today commercially based data relay systems such as Audacy, Theia, and other such data relay and data services companies are starting to develop that are intended to operate as commercial enterprises rather than as governmental space agency operations.

Defense- and Security-Related Services

Security Concerns Related to Smallsats, Space Situational Awareness (SSA), and Space Traffic Management (STM)

Joseph N. Pelton

Contents

Abstract

The strategic uses of outer space are today quite diverse and continue to grow in scope (i.e., diversity of defense-related applications) and scale (i.e., size of operations and funded activities).

These strategic activities in space include: (i) tracking capabilities on the ground and by satellite of all trackable space objects in Earth orbit and the ability to track all new launches into space including missiles (i.e., space situational awareness capabilities); (ii) deployment and operation of space precise navigation and timing systems that can be used for targeting and deployment of weapons systems as well as space communications and meteorological systems to meet national defense operations; (iii) deploying and operation of space systems that can detect explosion of nuclear weapons systems; (iv) procedures, limitations, and operational standards

related to rendezvous and proximity operations (RPO) and protections against attacks on strategic assets in orbit; and (v) conducting research on new space systems and technology of possible use in future defense-related systems such as on-orbit servicing, space debris removal or repurposing, lower cost launching systems, new data monitoring capabilities and facility optimization and inventory operations via satellite-IoT messaging, etc.

Many of these space systems and technology involve the deployment and use of what might be considered conventional space systems, but in a number of instances, this might also require the development of small satellite constellations, the use of hosted payloads, or concerns about orbital debris that could result from small satellite constellations. Such requirements are components of space security planning and implementation processes. This chapter, in particular, explores the issues of security-related space situational awareness as well as planning for future space traffic management systems, particularly as this relates to small satellite systems and in some cases hosted payload systems.

Today, many countries around the world with active space programs and space security activities are concerned with improved space situational awareness activities and are planning for future space traffic management systems. There are activities in these areas underway in China, Europe, India, Japan, Russia, as well as several other countries with evolving space programs. Nevertheless, for several historical reasons such as the United States' major role in conducting space situational awareness operations and sharing this data with allies, this is an area where the United States' activities have largely dominated, particularly since the end of the so-called "Cold War."

This situation has been further shaped by the 2018 activities of the United States to issue publicly the U.S. Space Policy Directive-3. This is not to say that there have not been increasing activities being planned or implemented in such areas as noted above. Further, the UN Committee on the Peaceful Uses of Outer Space has had an active Working Group on the Long-Term Sustainability of Outer Space Activities (LTSOSA) that developed and received approval of 21 new guidelines that in a number of instances touch on areas related to space situational awareness (SSA) and issues that concern space traffic management (STM).

This chapter seeks to address current concerns that come from the deployment of many new large-scale satellite constellations in Low Earth Orbit (LEO) and polar orbit and how these changes will impact the need for improved space situational awareness (SSA) capabilities and enhanced means of space traffic management (STM) in the years ahead. It notes the ways that commercial satellite systems and governmental and security-related satellite networks are interrelated and how this might complicate the way forward to safe space operations and could also lead to heightened concerns with orbital space debris.

1 Introduction

During the cold war era where the rivalry between the United States and the USSR was at its highest levels, there was concern about a possible nuclear attack by intercontinental missiles by these adversaries. There were radar systems installed by both countries to detect missile launches so as to allow an instantaneous counter initiative. This set of countervailing threats created great concern over possible preemptive nuclear attacks. The idea of mutually assured destruction (MAD) was aimed at creating a dynamic strategic balance whereby the opponent would know that any such attack would be followed by an automatic strike on the attacking country and would kill the citizenry of the attacking country in a devastating way (Wohlstetter and Kahn 2010).

Policy strategist Kahn noted that unless the mutual assured destruction was known to in place, then first strike approach by a nuclear power would possibly entertained.

He wrote in *On Thermonuclear War*: “In most postures that do not involve automatic mutual annihilation there will be an advantage in striking first.”(Kahn 1960).

The capability to detect missile launches with radar systems such as the Defense Early Warning (DEW) line have increased in capability and function over time and more and more satellites were launched into orbit and the function known as space situational awareness increased to not only detect possible missile attacks, but also to include the ability to track satellites in orbit, and to allow satellite or space facility to maneuver to avoid collisions. The U.S. Joint Space Operations Center (JSpOC), now a part of the so-called “Space Force”, is today becomes fully functional. This multibillion dollar facility that deploys Gallium Nitride S-band radar technology is operated by the U.S. Air Force. This sophisticated radar system located in the Marshall Islands in Micronesia was built under contract by Lockheed Martin. It will eventually be able to track up to 500,000 orbiting space objects and detect all missile launches with greater precision (Space Fence: How to keep space safe. 2019). (See Fig. 1).

A complementary S-band radar facility that could possibly be built in Australia is also under consideration (Pelton 2013).

The ability to track satellites to support strategic defense systems and to prevent possible collisions of satellites in orbit continues to increase in sophistication and precision. One key development is the creation of the Space Data Association that is a consortium of satellite operators that creates a means of sharing data among satellite operators with regard to possible conjunctions that might occur between various satellite systems. This Space Data Association is currently largely constituted by operators of GEO satellite networks but its membership could be expanded to include operators of small satellite constellations. Also there are a number of

Fig. 1 The S-band Space Fence to provide precision space situational awareness. (Graphic from the Global Commons)

nationally funded initiatives to undertake satellite tracking operations. Optical tracking capabilities are being installed at various locations such as in Germany, Australia, and elsewhere.

Another key development with regard to space situational awareness (SSA) is that a number of private contractors that have started to provide independent tracking capabilities of satellites and space debris. These private contractors include: Analytic Graphics Inc. (AGI), ExoAnalytics, Rincon, Lockheed Martin, LeoLabs, Boeing, Schafer Corp., and Applied Defense. Most of these are radar-based capabilities, but some such as ExoAnalytics are deploying telescopes with individual observers under contract now carrying out tracking operations at many locations around the world (Weeden 2016).

2 Separation of Commercial and Defense-Related Space Situational Awareness and Space Traffic Management Activities

There has been in the last few years increasing concern and discussion about whether there should be a separation of the tasks related to space situational awareness between commercial satellite networks and defense and strategic space operations? This issue that began to first be discussed seriously around 2016 was directly addressed in the United States when the Space Policy Directive-3 was issued. This document provided specific guidance on a number of points but in particular sought to address the respective roles of governmental agencies in providing SSA and STM services in support of commercial space activities versus defense-related missions and missile defense.

Thus Space Policy Directive-3 explicitly stated the need for a change in space policy in light of many new and growing "NewSpace" commercial activities, including the increased launch of small satellite constellations. It noted the problem as follows:

"The future space operating environment will also be shaped by a significant increase in the volume and diversity of commercial activity in space. Emerging commercial ventures such as satellite servicing, debris removal, in-space manufacturing, and tourism, as well as new technologies enabling small satellites and very large constellations of satellites, are increasingly outpacing efforts to develop and implement government policies and processes to address these new activities."(Space policy Directive-3 2018).

The result of this concern was that there should be additional steps taken to achieve a pre-launch certification of all space missions to reduce the possibility of creating additional space debris. It was also stated that a new process to undertake SSA and STM capability with regard to all of this new commercial space activities.

The US Government's Department of Commerce was charged with developing, in cooperation with the U.S. Department of Defense, a new capability to undertake "basic" SSA and STM activities with regard to the growing number of commercial space activities and especially small satellite constellations. The U.S. Department of Defense would continue to monitor space objects and launches and maintain an authoritative catalog of space objects from a national security of perspective. This new US national space traffic management activity and the organizations having responsibility for these space monitoring responsibilities was stated as follows:

(i) "The Secretaries of Defense and Commerce, in coordination with the Secretaries of State and Transportation, the NASA Administrator, and the Director of National Intelligence, should cooperatively develop a plan for providing basic SSA data and basic STM services either directly or through a partnership with industry or academia, consistent with the guidelines of sections 5(a)(ii) and 5(b)(ii) of this memorandum.

(ii) The Secretary of Defense shall maintain the authoritative catalog of space objects." (https://www.whitehouse.gov/presidential-actions/space-policy-directive-3-national-space-traffic-management-policy/ Section 6 d (i) and (ii).).

This U.S. Space Police Directive-3 provides a number of guidelines and spells out processes that are to be carried out with regard to SSA and STM under the US space program and its over sight and licensing of commercial satellite activities. It indeed carefully defines the nature and regulatory aspects of these activities from a commercial and defense-related perspective. Since as of 2019 no other nation has undertaken to define such guidelines in such detail, the full text of this Space Policy Directive-3 has been provided as an annex to this chapter.

A further reason as to why the full text has been provided below is because it has also been suggested that these regulatory procedures, as spelled out in the U.S. Space Policy Directive-3, could serve as a blueprint for what other countries might undertake with regard to their space activities in terms of spelling out pre-launch due diligence procedures to be carried out in order to better prevent the creation of space debris. It also better defined the meaning and scope of SSA and STM activities. In essence, it served to anticipate the coming issues related to expanded commercial space activities and the need for more explicit regulatory processes that are likely to be required as various types of commercial space activities, especially in the form of large constellations of small satellites, expand in the future. In short, it served to define what steps need to be taken in order to prevent or minimize the collision of space objectives and also lessen the opportunity for frequency interference (Pelton 2019).

As useful as these new space policies in the arena of SSA and STM, there remain any unresolved and key questions. These questions include:

Do we need new standards of safety operation or space traffic management in order to deploy and operate all of the large-scale satellite constellations in Low Earth orbit more safety? This becomes more and more urgent as the number of satellites and small satellite constellations continues to grow in number. There are now over 20,000 small satellites proposed for deployment, largely in LEO, and there seems to be a critical mass proposed for the altitudes between 700 and 1200 km (Muelhaupt et al. 2019).

There are subsidiary questions such as performance and safety standards for AI controls to network controls to prevent collisions, automatic end of life de-orbit, or other space traffic management regulation to preserve the safety of all constellations. Given that there are currently at total of some 1500 operational satellites in all types of Earth orbits, the changes in density of satellite deployments suggests that there are urgent answers needed to these questions. Some fear that a rash of satellite collisions in LEO orbit could serve to render access to space nearly impossible. Such a runaway build up of space debris would be the ultimate consequences of what is known as the Kessler Syndrome.

3 Hosted Payloads to Provide Space Situational Awareness to Detect Nuclear Explosions

The typical definition of space situational awareness includes all of the ground- and space-based equipment that is used to monitor the location of space objects or launched rockets primarily to detect if a launch represents a threat from a missile or if there is a threat of space objects colliding and creating dangerous orbit space debris. Yet another definition relates to monitoring devices in space that are able to detect a nuclear detonation. Today, there are satellites in orbit designed to detect the possibility of a space collision, but there are also devices designed to detect possible nuclear denotations. They also can monitor the impact of asteroids and meteors in order to more accurately determine the threat level posed by near-Earth objects.

The nuclear detection of detonation sensors are not separate satellites, but rather small hosted payloads (See Fig. 2).

The ability to use space-based sensors that can detect accurately nuclear explosion sensors are considered important both to monitor compliance with the Limited Test Ban Treaty (TBT) and the Threshold Test Ban Treaty (TTBT),

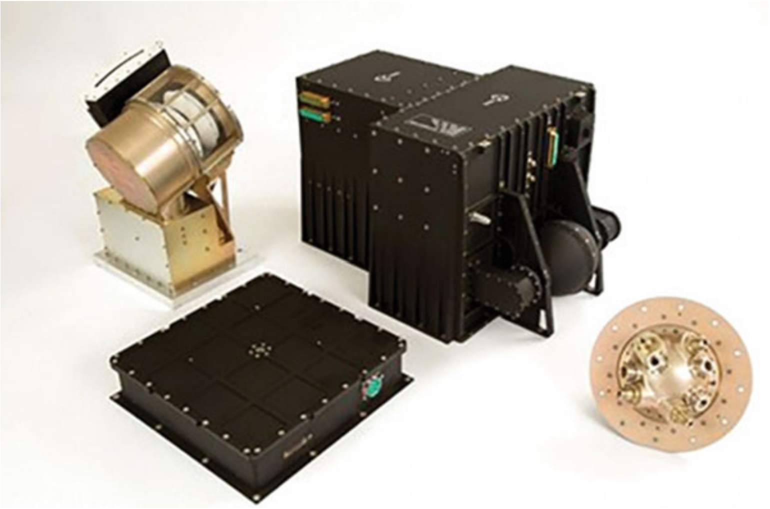

Fig. 2 Components of the hosted payload for space-based nuclear detonation detection. (Graphic courtesy of the U.S. Government)

and simply to detect any nation or entity that might detonate a nuclear device. In the United States, it is the National Nuclear Detection Administration that is housed at the Sandia and Los Alamos National Laboratories that are responsible for the design, manufacture, and testing of sensors to help enforce these test ban treaties. A responsibility that they have carried out for essentially a half century since the first of these treaties came into force. This space based nuclear test ban enforcement was accomplished with the launch of 12 dedicated Vela satellites starting back in 1963. These early satellites could only monitor nuclear test above ground on in space, but the Vela satellites were replaced with sensors located in hosted payloads that could detect nuclear explosions whether below ground, on the surface, or in space. These were launched on-board GPS satellites or other US satellites capable of including these sensors.

The most recently sensors are known as Global Burst Detectors (GBDs) and are primarily deployed as hosted payloads on GPS satellites. This system of on-board sensors are known as Space and Atmospheric Burst Reporting System (SABRS). The second generation of SARRS payloads began to be launched on GPS satellites in 1918 and have continued in 2019. Yet another payload known as SENSER that is intended to increase the performance of future GBD packages is also to be launched shortly. Some of the SBD payloads will be launched on Air Force satellites including the STPSat-6 (National Nuclear Detection Administration 2018).

While the Air Force satellites using to help track orbit space debris are large-scale satellites, the SABRS system is essentially a smallsat program deployed as hosted payloads. Figure 3 is an Air Force satellite that is designed to assist with the precise tracking of orbital space debris.

Fig. 3 Air Force satellite designed to assist with tracking of orbital space debris and missile launches. (Graphic courtesy of the U.S. Air Force)

The concern about the possibility of the launch of some 20,000 satellites being deployed into over a dozen of large-scale constellations is thus the primary small satellite issue by defense agencies and ministries. If projections of possible collisions that might occur both during the deployment or removal of the small satellites in these diverse large constellations, as made by the Aerospace Corporation, suggest that may defense space systems could be placed at risk (Muelhaupt et al., op cit.). Nevertheless, there are a number of possible applications of small satellites for defense-related applications. This thus creates a dilemma in that deployment of small satellites for strategic applications could complicate debris concern. Nevertheless, several different smallsat projects are under consideration.

4 Smallsat Projects by Defense Agencies

These smallsat applications for defense-related purpose range from experimental demonstration of technology for smallsats mission to test sensors for weather satellites for deployment in Low Earth Orbit (LEO), or orbital measurement experiments such as the Armadillo project. This is a three-unit project that was designed to measure the space debris environment in LEO at the submillimeter dust particle level. This project is key to the U.S. military's understanding of the characteristics of

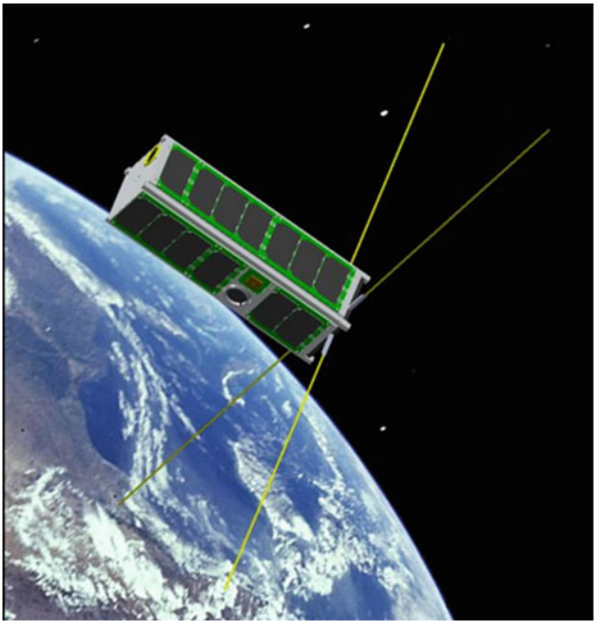

Fig. 4 The Armadillo 3 Unit Cubesat Submillimeter Debris Measurement Project. (Graphic courtesy of the U.S. Air Force)

the space debris at the smallest level and to understand its impact on satellites and to calibrate the SSA environment at the submillimeter debris conditions (Fig. 4).

Several countries had undertaken smallsat projects to test active debris removal experiments to cope with the rising amount of orbital debris, especially in Low Earth Orbit (LEO). These projects have included Switzerland's (Clean SpaceOne), Germany's (DEOS project), U.S. (Darpa's Orbital Express), and U.K./European Union (Remove Debris) (Pelton 2015).

The U.S. Defense Advanced Projects Research Agency (DARPA) completed a study of orbital debris risk known as "The Catcher's Mitt" in 2011 that assessed the risks that orbital debris presented to defense satellite networks. This intensive effort studied the risk level going forward in various orbits as then projected but that profile of the future has now changed and some projections of expected orbital collision such as by the European Space Agency (ESA) now concludes that a major accident will occur every 5 years (See Fig. 5).

It concluded that the space situational awareness and space traffic management, as now being implemented seemed adequate, that the problem of orbital space debris was considered "manageable." This DARPA study also concluded that an viable active debris removal capability that is capable of addressing the most severe risk factors such as the Envisat large-scale satellite stranded in LEO was also needed. The situation assessment, however, was based on the conditions that existed in 2011. Today, the environment has changed and the number of small satellites to be launched has increased exponentially (https://www.space.com/11657-space-junk-orbital-debris-cleanup-darpa.html).

Fig. 5 Simulated collision of a satellite collision in orbit. (Graphic courtesy of the European Space Agency)

There are also operational small satellite constellations also currently deployed such as the Mobile Users Operational Satellite system. This smallsat network provides key mobile satellite services for the U.S. defense network and provides prime mobile services and replaces many of the services that were previously provided by the Iridium and Globalstar system on a dual use basis.

5 Conclusion

The smallsat revolution that has come with new ways of designing and manufacturing satellites faster, at less cost, and new launch options that makes the deployment of LEO constellations much more attractive. This new wave of small satellite constellations has exploited the new capabilities that have come from the use of miniaturized components and use of new launch options.

These trends have led to a sharp rise in the number of smallsats that are planned to be launched in the next 5 years. Further, these networks will need to be resupplied on a time scale as short as 3 years and typically within 5–8 years. Thus there are a huge number of satellites planned to be launched on an intensive launch schedule, and if these networks are successful, this trend will follow into the foreseeable future. This trend seems to portend a strategic issue related to orbital space debris and critical buildup of orbital congestion in the LEO altitudes largely between 700 and 1200 km with a peaking around 900 km.

This future trend line suggests that there is a mounting strategic concern about the adequacy of space situational awareness and preliminary attempts at space traffic management. The UN guidelines for debris removal of deorbiting of space craft within 25 years of end of life no longer seem to be adequate to this new orbital environment. Many operators of small satellite constellations have suggested new guidelines such as removal within 1 year with some commercial operators now even suggesting practices that would remove defunct satellites within days. Defense agencies and ministries as well as commercial system operators are moving in a new direction to better cope with orbital debris issues. This is not only to be “better citizens” in the space domain, but because they understand that unless such steps are taken, the safe operation of constellations, particularly in LEO, will be increasingly at risk for all.

There are thus some conflicting values and interest now in play. On one hand, there are a number of defense-related operations best conducted in LEO. These include such activities as mobile communications satellite networks, meteorological network coverage, and even surveillance systems that have advantages when operated in LEO and polar orbits. On the other hand, it is important that SSA and STM capabilities be improved to cope with possible satellite conjunction that could lead to catastrophic collisions that endanger all future space safety. Billions of dollars of commercial, governmental, and military assets could be placed at risk.

The assessment in 2011 by the U.S. DARPA “Catcher Mitt” study that concluded that space debris concern and safe strategic space operations were “manageable” have seemingly begun to alter to a much higher level of concern. Risk assessment studies by the Aerospace Corporation have shown heightened risk of collisions when large-scale constellations are first deployed and also when removed from orbit. The current provisions of the U.N. Liability Convention does not create incentive to remove debris from orbit quickly.

The one specific step forward to address these increased orbital debris concerns has been the U.S. Space Policy Directive-3 that seeks to increase US capabilities for space situational awareness and to initiate certain enhanced steps for space traffic management. These new initiatives are to improve capabilities for both commercial systems on one side and defense and governmentally related satellite networks on the other.

It seems that other countries, and especially those countries with space security-related programs, will begin to move forward to increase their capabilities and regulatory controls with orbital debris, SSA, and STM-related measures. The French Space Operations Act was intended to be one such step forward, but its enforcement of the 25-year debris removal guideline, now appears somewhat dated in light of the very large number of satellites now planned to be deployed in the next few years.

It currently seems more likely that national laws and guidelines as well as national initiative to increase SSA and STM capabilities will be accomplished first rather than any new international guidelines concerning these issues. The U.N. Guidelines on Debris Removal required over 15 years to be discussed, agreed, and adopted. The new guidelines related to the longer term sustainability of outer space activities that were discussed and agreed within the UN Committee on the Peaceful Uses of Outer Space (COPUOS) were useful, but these remain well short of the needed steps necessary to allow any widely agreed approach toward some sort of international space traffic management system, or even an open world system to carry out effective space situational awareness (SSA) procedures or processes.

Finally, the types of steps outlined in the U.S. Space Policy Directive-3 on National Space Traffic Management Policy, as provided below, may possibly prove helpful to other countries in defining their own priorities and national aims as they amend and strengthen their efforts related to space situational awareness (SSA), space traffic management (STM), and safe strategic access to space and perhaps establish new guidelines for removal of defunct space objects from orbit in a more accelerated manner.

Annex

U.S. Space Policy Directive-3, National Space Traffic Management Policy

Adopted June 18, 2018

SUBJECT: National Space Traffic Management Policy

Section 1. Policy. For decades, the United States has effectively reaped the benefits of operating in space to enhance our national security, civil, and commercial sectors. Our society now depends on space technologies and space-based capabilities for communications, navigation, weather forecasting, and much more. Given the significance of space activities, the United States considers the continued unfettered access to and freedom to operate in space of vital interest to advance the security, economic prosperity, and scientific knowledge of the Nation.

Today, space is becoming increasingly congested and contested, and that trend presents challenges for the safety, stability, and sustainability of U.S. space operations. Already, the Department of Defense (DoD) tracks over 20,000 objects in space, and that number will increase dramatically as new, more capable sensors come online and are able to detect smaller objects. DoD publishes a catalog of space objects and makes notifications of potential conjunctions (that is, two or more objects coming together at the same or nearly the same point in time and space). As the number of space objects increases, however, this limited traffic management activity and architecture will become inadequate. At the same time, the contested nature of space is increasing the demand for DoD focus on protecting and defending U.S. space assets and interests.

The future space operating environment will also be shaped by a significant increase in the volume and diversity of commercial activity in space. Emerging commercial ventures such as satellite servicing, debris removal, in-space manufacturing, and tourism, as well as new technologies enabling small satellites and very large constellations of satellites, are increasingly outpacing efforts to develop and implement government policies and processes to address these new activities.

To maintain U.S. leadership in space, we must develop a new approach to space traffic management (STM) that addresses current and future operational risks. This new approach must set priorities for space situational awareness (SSA) and STM innovation in science and technology (S&T), incorporate national security considerations, encourage growth of the U.S. commercial space sector, establish an updated STM architecture, and promote space safety standards and best practices across the international community.

The United States recognizes that spaceflight safety is a global challenge and will continue to encourage safe and responsible behavior in space while emphasizing the need for international transparency and STM data sharing. Through this national policy for STM and other national space strategies and policies, the United States will enhance safety and ensure continued leadership, preeminence, and freedom of action in space.

Sec. 2. Definitions. For the purposes of this memorandum, the following definitions shall apply:

(a) Space Situational Awareness shall mean the knowledge and characterization of space objects and their operational environment to support safe, stable, and sustainable space activities.
(b) Space Traffic Management shall mean the planning, coordination, and on-orbit synchronization of activities to enhance the safety, stability, and sustainability of operations in the space environment.
(c) Orbital debris, or space debris, shall mean any human-made space object orbiting Earth that no longer serves any useful purpose.

Sec. 3. Principles. The United States recognizes, and encourages other nations to recognize, the following principles:

(a) Safety, stability, and operational sustainability are foundational to space activities, including commercial, civil, and national security activities. It is a shared interest and responsibility of all spacefaring nations to create the conditions for a safe, stable, and operationally sustainable space environment.
(b) Timely and actionable SSA data and STM services are essential to space activities. Consistent with national security constraints, basic U.S. Government-derived SSA data and basic STM services should be available free of direct user fees.
(c) Orbital debris presents a growing threat to space operations. Debris mitigation guidelines, standards, and policies should be revised periodically, enforced domestically, and adopted internationally to mitigate the operational effects of orbital debris.
(d) A STM framework consisting of best practices, technical guidelines, safety standards, behavioral norms, pre-launch risk assessments, and on-orbit collision avoidance services is essential to preserve the space operational environment.

Sec. 4. Goals. Consistent with the principles listed in section 3 of this memorandum, the United States should continue to lead the world in creating the conditions for a safe, stable, and operationally sustainable space environment. Toward this end, executive departments and agencies (agencies) shall pursue the following goals as required in section 6 of this memorandum:

(a) Advance SSA and STM Science and Technology. The United States should continue to engage in and enable S&T research and development to support the practical applications of SSA and STM. These activities include improving fundamental knowledge of the space environment, such as the characterization of small debris, advancing the S&T of critical SSA inputs such as observational data, algorithms, and models necessary to improve SSA capabilities, and developing new hardware and software to support data processing and observations.

(b) Mitigate the effect of orbital debris on space activities. The volume and location of orbital debris are growing threats to space activities. It is in the interest of all to minimize new debris and mitigate effects of existing debris. This fact, along with increasing numbers of active satellites, highlights the need to update existing orbital debris mitigation guidelines and practices to enable more efficient and effective compliance, and establish standards that can be adopted internationally. These trends also highlight the need to establish satellite safety design guidelines and best practices.

(c) Encourage and facilitate U.S. commercial leadership in S&T, SSA, and STM. Fostering continued growth and innovation in the U.S. commercial space sector, which includes S&T, SSA, and STM activities, is in the national interest of the United States. To achieve this goal, the U.S. Government should streamline processes and reduce regulatory burdens that could inhibit commercial sector growth and innovation, enabling the U.S. commercial sector to continue to lead the world in STM-related technologies, goods, data, and services on the international market.

(d) Provide U.S. Government-supported basic SSA data and basic STM services to the public. The United States should continue to make available basic SSA data and basic STM services (including conjunction and reentry notifications) free of direct user fees while supporting new opportunities for U.S. commercial and non-profit SSA data and STM services.

(e) Improve SSA data interoperability and enable greater SSA data sharing. SSA data must be timely and accurate. It is in the national interest of the United States to improve SSA data interoperability and enable greater SSA data sharing among all space operators, consistent with national security constraints. The United States should seek to lead the world in the development of improved SSA data standards and information sharing.

(f) Develop STM standards and best practices. As the leader in space, the United States supports the development of operational standards and best practices to promote safe and responsible behavior in space. A critical first step in carrying out that goal is to develop U.S.-led minimum safety standards and best practices to coordinate space traffic. U.S. regulatory agencies should, as appropriate, adopt these standards and best practices in domestic regulatory frameworks and use them to inform and help shape international consensus practices and standards.

(g) Prevent unintentional radio frequency (RF) interference. Growing orbital congestion is increasing the risk to U.S. space assets from unintentional RF interference. The United States should continue to improve policies, processes, and technologies for spectrum use (including allocations and licensing) to address these challenges and ensure appropriate spectrum use for current and future operations.

(h) Improve the U.S. domestic space object registry. Transparency and data sharing are essential to safe, stable, and sustainable space operations. Consistent with national security constraints, the United States should streamline the interagency process to ensure accurate and timely registration submissions to the United Nations (UN), in accordance with our international obligations under the Convention on Registration of Objects Launched into Outer Space.

(i) Develop policies and regulations for future U.S. orbital operations. Increasing congestion in key orbits and maneuver-based missions such as servicing, survey, and assembly will drive the need for policy development for national security, civil, and commercial sector space activities. Consistent with U.S. law and international obligations, the United States should regularly assess existing guidelines for non-government orbital activities, and maintain a timely and responsive regulatory environment for licensing these activities.

Sec. 5. Guidelines. In pursuit of the principles and goals of this policy, agencies should observe the following guidelines:

(a) Managing the Integrity of the Space Operating Environment.
    (i) Improving SSA coverage and accuracy. Timely, accurate, and actionable data are essential for effective SSA and STM. The United States should seek to minimize deficiencies in SSA capability, particularly coverage in regions with limited sensor availability and sensitivity in detection of small debris, through SSA data sharing, the purchase of SSA data, or the provision of new sensors.

New U.S. sensors are expected to reveal a substantially greater volume of debris and improve our understanding of space object size distributions in various regions of space. However, very small debris may not be sufficiently tracked to enable or justify actionable collision avoidance decisions. As a result, close conjunctions and even collisions with unknown objects are possible, and satellite operators often lack sufficient insight to assess their level of risk when making maneuvering decisions. The United States should develop better tracking capabilities, and new means to catalog such debris, and establish a quality threshold for actionable collision avoidance warning to minimize false alarms.

Through both Government and commercial sector S&T investment, the United States should advance concepts and capabilities to improve SSA in support of debris mitigation and collision avoidance decisions.

(ii) Establishing an Open Architecture SSA Data Repository. Accurate and timely tracking of objects orbiting Earth is essential to preserving the safety of space activities for all. Consistent with section 2274 of title 10, United States Code, a basic level of SSA data in the form of the publicly releasable portion of the DoD catalog is and should continue to be provided free of direct user fees. As additional sources of space tracking data become available, the United States has the opportunity to incorporate civil, commercial, international, and other available data to allow users to enhance and refine this service. To facilitate greater data sharing with satellite operators and enable the commercial development of enhanced space safety services, the United States must develop the standards and protocols for creation of an open architecture data repository. The essential features of this repository would include:

- Data integrity measures to ensure data accuracy and availability;
- Data standards to ensure sufficient quality from diverse sources;
- Measures to safeguard proprietary or sensitive data, including national security information;
- The inclusion of satellite owner-operator ephemerides to inform orbital location and planned maneuvers; and
- Standardized formats to enable development of applications to leverage the data.

To facilitate this enhanced data sharing, and in recognition of the need for DoD to focus on maintaining access to and freedom of action in space, a civil agency should, consistent with applicable law, be responsible for the publicly releasable portion of the DoD catalog and for administering an open architecture data repository. The Department of Commerce should be that civil agency.

(iii) Mitigating Orbital Debris. It is in the interest of all space operators to minimize the creation of new orbital debris. Rapid international expansion of space operations and greater diversity of missions have rendered the current U.S. Government Orbital Debris Mitigation Standard Practices (ODMSP) inadequate to control the growth of orbital debris. These standard practices should be updated to address current and future space operating environments.

The United States should develop a new protocol of standard practices to set broader expectations of safe space operations in the 21st century. This protocol should begin with updated ODMSP, but also incorporate sections to address operating practices for large constellations, rendezvous and proximity operations, small satellites, and other classes of space operations. These overarching practices will provide an avenue to promote efficient and effective space safety practices with U.S. industry and internationally.

The United States should pursue active debris removal as a necessary long-term approach to ensure the safety of flight operations in key orbital regimes. This effort should not detract from continuing to advance international protocols for debris mitigation associated with current programs.

(b) Operating in a Congested Space Environment.
   (i) Minimum Safety Standards and Best Practices. The creation of minimum standards for safe operation and debris mitigation derived in part from the U. S. Government ODMSP, but incorporating other standards and best practices, will best ensure the safe operation of U.S. space activities. These safety guidelines should consider maneuverability, tracking, reliability, and disposal.

The United States should eventually incorporate appropriate standards and best practices into Federal law and regulation through appropriate rulemaking or licensing actions. These guidelines should encompass protocols for all stages of satellite operation from design through end-of-life.

Satellite and constellation owners should participate in a pre-launch certification process that should, at a minimum, consider the following factors:

- Coordination of orbit utilization to prevent conjunctions;
- Constellation owner-operators' management of self-conjunctions;
- Owner-operator notification of planned maneuvers and sharing of satellite orbital location data;
- On-orbit tracking aids, including beacons or sensing enhancements, if such systems are needed;
- Encryption of satellite command and control links and data protection measures for ground site operations;
- Appropriate minimum reliability based on type of mission and phase of operations;
- Effect on the national security or foreign policy interests of the United States, or international obligations; and
- Self-disposal upon the conclusion of operational lifetime, or owner-operator provision for disposal using active debris removal methods.

(ii) On-Orbit Collision Avoidance Support Service. Timely warning of potential collisions is essential to preserving the safety of space activities for all. Basic collision avoidance information services are and should continue to be provided free of direct user fees. The imminent activation of more sensitive tracking sensors is expected to reveal a significantly greater population of the existing orbital debris background as well as provide an improved ability to track currently catalogued objects. Current and future satellites, including large constellations of satellites, will operate in a debris environment much denser than presently tracked. Preventing on-orbit collisions in this environment requires an information service that shares catalog data, predicts close approaches, and provides actionable warnings to satellite operators. The service should provide data to allow operators to assess proposed maneuvers to reduce risk. To provide on-orbit collision avoidance, the United States should:
   - Provide services based on a continuously updated catalog of satellite tracking data;

- Utilize automated processes for collision avoidance;
- Provide actionable and timely conjunction assessments; and
- Provide data to operators to enable assessment of maneuver plans.

To ensure safe coordination of space traffic in this future operating environment, and in recognition of the need for DoD to focus on maintaining access to and freedom of action in space, a civil agency should be the focal point for this collision avoidance support service. The Department of Commerce should be that civil agency.

(c) Strategies for Space Traffic Management in a Global Context.
  (i) Protocols to Prevent Orbital Conjunctions. As increased satellite operations make lower Earth orbits more congested, the United States should develop a set of standard techniques for mitigating the collision risk of increasingly congested orbits, particularly for large constellations. Appropriate methods, which may include licensing assigned volumes for constellation operation and establishing processes for satellites passing through the volumes, are needed.

The United States should explore strategies that will lead to the establishment of common global best practices, including:

- A common process addressing the volume of space used by a large constellation, particularly in close proximity to an existing constellation;
- A common process by which individual spacecraft may transit volumes used by existing satellites or constellations; and
- A set of best practices for the owner-operators of utilized volumes to minimize the long-term effects of constellation operations on the space environment (including the proper disposal of satellites, reliability standards, and effective collision avoidance).

(ii) Radio Frequency Spectrum and Interference Protection. Space traffic and RF spectrum use have traditionally been independently managed processes. Increased congestion in key orbital regimes creates a need for improved and increasingly dynamic methods to coordinate activities in both the physical and spectral domains, and may introduce new interdependencies. U.S. Government efforts in STM should address the following spectrum management considerations:

  - Where appropriate, verify consistency between policy and existing national and international regulations and goals regarding global access to, and operation in, the RF spectrum for space services;
  - Investigate the advantages of addressing spectrum in conjunction with the development of STM systems, standards, and best practices;
  - Promote flexible spectrum use and investigate emerging technologies for potential use by space systems; and

- Ensure spectrum-dependent STM components, such as inter-satellite safety communications and active debris removal systems, can successfully access the required spectrum necessary to their missions.

(iii) Global Engagement. In its role as a major spacefaring nation, the United States should continue to develop and promote a range of norms of behavior, best practices, and standards for safe operations in space to minimize the space debris environment and promote data sharing and coordination of space activities. It is essential that other spacefaring nations also adopt best practices for the common good of all spacefaring states. The United States should encourage the adoption of new norms of behavior and best practices for space operations by the international community through bilateral and multilateral discussions with other spacefaring nations, and through U.S. participation in various organizations such as the Inter-Agency Space Debris Coordination Committee, International Standards Organization, Consultative Committee for Space Data Systems, and UN Committee on the Peaceful Uses of Outer Space.

Sec. 6. Roles and Responsibilities. In furtherance of the goals described in section 4 and the guidelines described in section 5 of this memorandum, agencies shall carry out the following roles and responsibilities:

(a) Advance SSA and STM S&T. Members of the National Space Council, or their delegees, shall coordinate, prioritize, and advocate for S&T, SSA, and STM, as appropriate, as it relates to their respective missions. They should seek opportunities to engage with the commercial sector and academia in pursuit of this goal.

(b) Mitigate the Effect of Orbital Debris on Space Activities.

  (i) The Administrator of the National Aeronautics and Space Administration (NASA Administrator), in coordination with the Secretaries of State, Defense, Commerce, and Transportation, and the Director of National Intelligence, and in consultation with the Chairman of the Federal Communications Commission (FCC), shall lead efforts to update the U.S. Orbital Debris Mitigation Standard Practices and establish new guidelines for satellite design and operation, as appropriate and consistent with applicable law.

  (ii) The Secretaries of Commerce and Transportation, in consultation with the Chairman of the FCC, will assess the suitability of incorporating these updated standards and best practices into their respective licensing processes, as appropriate and consistent with applicable law.

(c) Encourage and Facilitate U.S. Commercial Leadership in S&T, SSA, and STM. The Secretary of Commerce, in coordination with the Secretaries of Defense and Transportation, and the NASA Administrator, shall lead efforts to encourage and facilitate continued U.S. commercial leadership in SSA, STM, and related S&T.

(d) Provide U.S. Government-Derived Basic SSA Data and Basic STM Services to the Public.

  (i) The Secretaries of Defense and Commerce, in coordination with the Secretaries of State and Transportation, the NASA Administrator, and the

Director of National Intelligence, should cooperatively develop a plan for providing basic SSA data and basic STM services either directly or through a partnership with industry or academia, consistent with the guidelines of sections 5(a)(ii) and 5(b)(ii) of this memorandum.

  (ii) The Secretary of Defense shall maintain the authoritative catalog of space objects.

  (iii) The Secretaries of Defense and Commerce shall assess whether statutory and regulatory changes are necessary to effect the plan developed under subsection (d)(i) of this section, and shall pursue such changes, along with any other needed changes, as appropriate.

(e) Improve SSA Data Interoperability and Enable Greater SSA Data Sharing.

  (i) The Secretary of Commerce, in coordination with the Secretaries of State, Defense, and Transportation, the NASA Administrator, and the Director of National Intelligence, shall develop standards and protocols for creation of an open architecture data repository to improve SSA data interoperability and enable greater SSA data sharing.

  (ii) The Secretary of Commerce shall develop options, either in-house or through partnerships with industry or academia, assessing both the technical and economic feasibility of establishing such a repository.

  (iii) The Secretary of Defense shall ensure that release of data regarding national security activities to any person or entity with access to the repository is consistent with national security interests.

(f) Develop Space Traffic Standards and Best Practices. The Secretaries of Defense, Commerce, and Transportation, in coordination with the Secretary of State, the NASA Administrator, and the Director of National Intelligence, and in consultation with the Chairman of the FCC, shall develop space traffic standards and best practices, including technical guidelines, minimum safety standards, behavioral norms, and orbital conjunction prevention protocols related to pre-launch risk assessment and on-orbit collision avoidance support services.

(g) Prevent Unintentional Radio Frequency Interference. The Secretaries of Commerce and Transportation, in coordination with the Secretaries of State and Defense, the NASA Administrator, and the Director of National Intelligence, and in consultation with the Chairman of the FCC, shall coordinate to mitigate the risk of harmful interference and promptly address any harmful interference that may occur.

(h) Improve the U.S. Domestic Space Object Registry. The Secretary of State, in coordination with the Secretaries of Defense, Commerce, and Transportation, the NASA Administrator, and the Director of National Intelligence, and in consultation with the Chairman of the FCC, shall lead U.S. Government efforts on international engagement related to international transparency and space object registry on SSA and STM issues.

(i) Develop Policies and Regulations for Future U.S. Orbital Operations. The Secretaries of Defense, Commerce, and Transportation, in coordination with the Secretary of State, the NASA Administrator, and the Director of National Intelligence, shall regularly evaluate emerging trends in space missions to recommend revisions, as appropriate and necessary, to existing SSA and STM policies and regulations.

Sec. 7. General Provisions.

(a) Nothing in this memorandum shall be construed to impair or otherwise affect:
  (i) the authority granted by law to an executive department or agency, or the head thereof; or
  (ii) the functions of the Director of the Office of Management and Budget relating to budgetary, administrative, or legislative proposals.

(b) This memorandum shall be implemented consistent with applicable law and subject to the availability of appropriations.

(c) This memorandum is not intended to, and does not, create any right or benefit, substantive or procedural, enforceable at law or in equity by any party against the United States, its departments, agencies, or entities, its officers, employees, or agents, or any other person.

(d) The Secretary of Commerce is authorized and directed to publish this memorandum in the Federal Register.

Small Satellites, Safety Challenges, and Reforms Related to Strategic Space Defense Systems

Theresa Hitchens

Contents

Abstract

The question of how to manage and cope with increasing congestion in orbit in order to maintain safe and secure space operations has now come to the fore. This is the case in the USA, where policymakers and industry are involved in efforts to revamp current laws governing space activities, as well as in international fora where normative discussions are the dominant approach.

The increased salience of space traffic management (STM) has been largely driven by the growing commercial interest in the deployment of small satellites in mega-constellations, which inevitably will increase space congestion and challenge space safety. The increase in very small satellites in low Earth Orbit (LEO) makes space situational awareness more difficult. Complicating the picture is the advent of spacecraft capable of rendezvous and proximity operations (RPO) – operations that hold vast promise but also carry great risks.

Thus, the creation of a STM regime, including new safety standards related to removal of space debris from orbit, is becoming more urgent.

Unfortunately, ensuring space safety and assuaging national security concerns about protecting military space capabilities are in some ways contradictory. Safety and security often require opposing strategies; national versus international control often require opposing approaches. The US military and other

1 Introduction

The subject of space safety, space situational awareness of space objects and orbital space debris, and current rising concern about the deployment of a large number of mega-constellation is a subject of importance. It is of particular concern to those defense agencies charged with space security issues and defense and monitoring of space assets.

This article with brief updates and some editorial amendments previously appeared in the *Journal of Space Safety Engineering* (2019). It is licensed to the publisher to be printed in the *Handbook of Small Satellites* by the author, who continues to hold the copyright. It is published here under its new title and with amended text.

The number of working satellites in orbit is expected to skyrocket from the current level of more than 2000 to at least 10,000 within the next decade, and if all proposed launches are actually accomplished, the number could top 20,000. Many of these new satellites will be part of "mega-constellations" that will often number in the hundreds or even thousands (see Table 1).

Increased congestion inherently leads to increased risks, both of collisions and of radio-frequency interference. Further, new activities – such as remote proximity operations (RPO) that involve numerous maneuvers by spacecraft – also are likely to increase collision risks if not properly monitored and controlled. Complicating this picture is the fact that satellites are increasingly being operated by newcomers with less experience. There are at least some 90 governments and entities now owning and operating spacecraft including universities and nongovernmental organizations (NGOs). Unfortunately, neither the technology for monitoring all of this activity and allowing operators to ensure safe operations nor the regulatory mechanisms for controlling dangerous activities is currently adequate to face this new environment.

Table 1 Compendium of satellites in orbit or filed for launch in constellations

Country	Constellation	No. of sats	Radio-frequency bands
Argentina	Satellogic NuSat	300	Remote sensing
Australia	Fleet	100	Remote sensing
Canada	CANPOL-2	72	LEO and highly elliptical Earth orbit in VHF-, UHF-, X-, Ka-bands
Canada	Telesat constellation	117 sats plus spares	LEO in Ka-band
Canada	CONSTELLATION	Nearly 800 sats	LEO in Ka-band
France	Thales Group's MCSat	Between 800 and 4000	LEO, MEO, and HEO orbit Ku- and Ka-bands
China	CommSat	800	Ka-band
China	Lucky Star	156	Remote sensing
China	Hongyan	32	Remote sensing
China	Xinwei	32	Remote sensing
Liechtenstein	3ECOM-1	264	Ku- and Ka-bands
South Korea	Samsung	4500	Ka-band
Norway	ASK-1	10	Highly elliptical Earth orbit in X-, Ku-, and Ka-bands
UK	L5 (OneWeb)	650-750-1200-4000	Ku- and Ka-bands
USA	Boeing	1396–2956	V-band in 1200 km orbit
USA	SpaceX (Starlink)	4500 plus	Ku-Ka band
USA	SpaceX (V-band)	7500 plus	V-band
USA	Athena-Facebook	Details pending but of a large size	Ka-band
USA	Karousel MEO	20 MEO satellites	Ka-band
USA	Kuiper-Amazon	3236	Ka-band in three orbital tiers
USA	O3b mPower MEO	24	Ka-band
USA	Capella	48	Radar remote sensing
USA	Planet (Doves, Terra Bella, et al.)	300 plus	Active optical remote sensing
USA	Orbcomm	31	Active messaging (L-band)
USA	Iridium	72 plus spares	Active mobile satphone
USA	Globalstar	40 plus spare	Active mobile satphone

Note: This chart is not comprehensive, but of indicative of the many satellite constellations, mostly in low Earth orbit (LEO) either operational or filed for deployment (compiled from several sources)

In the USA, as in several other spacefaring countries such as France and Russia, the responsibility for monitoring on-orbit activity – the critical foundation for any future space traffic management (STM) regime, at either the national or international level – has been vested in the military. Only the USA, however, has a comprehensive system for "space situational awareness (SSA)" that includes maintenance of a "catalog" of space objects including active satellites and debris, conducting conjunction assessments, and providing collision warning/alert messages to spacecraft owner/operators around the world. The major civilian effort in this area, known as the Space Data Association, has a much lesser capability in this regard, and its efforts are currently focused on larger satellites in the geosynchronous Earth orbit (GEO) and not small satellites in low Earth orbit (LEO).

As of today, the 18th Space Control Squadron (18th SPCS), under the 14th Air Force at Vandenberg AFB in California, is tasked with promoting the responsible use of space, advancing spaceflight safety, and sharing of SSA data. Further, US Strategic Command (STRATCOM) has instituted SSA data sharing agreements with at least 16 nations to date and more than 70 commercial space operators (US Strategic Command 2018a). These agreements involve different "levels" of data sharing, with STRATCOM providing more precise data to closely allied governments such as those in the Five Eyes intelligence sharing network (Australia, Canada, New Zealand, and the UK).

This SSA architecture is enabled by the Space Surveillance Network (SSN) of ground- and space-based sensors (including optical telescopes and ground-based radar), also primarily owned and operated by STRATCOM, and until last year managed by the Joint Space Operations Center (JSpOC). In July 2018, US Strategic Command created the Combined Space Operations Center (CSpOC) at Vandenberg AFB to replace the JSpOC and to assume "operational command and control of space forces" (US Strategic Command 2018b). Reportedly this change was "designed to enhance coordination and cooperation between the USA and its allies in safeguarding the space domain" and to "provide input to develop and improve the ability to rapidly detect, warn, characterize, attribute, and defend against disturbances to space systems." Further, CSpOC missions include "missile warning; positioning, navigation, and timing; optimization and restoration of military satellite communications; theater battlespace awareness using overhead persistent infrared; environmental monitoring; theater support fires; defensive space situational awareness and space defense" (US Strategic Command 2018a, b). With the stand-up of the new US Space Command on Aug 2, 2019 responsibility for the mission has shifted from STRATCOM to Space Command – although the actual day-to-day operations remain the same.

It is important to understand that the primary mission of the US SSN Network and the SSA architecture is *not, and has never been,* to assure on-orbit safety or assist foreign/commercial satellite operators. Rather, the mission is to develop an "operational picture" that provides the technical foundation for the protection and defense of Defense Department and US Intelligence Community spacecraft. For this reason, the USA on June 18, 2018, signed Space Policy Directive-3 (SPD-3) on space traffic management (STM) Policy that outlines US policy and future governance of US space activities, including oversight of commercial actors (The White House 2018). The policy would see the Commerce Department becoming the linchpin agency in undertaking most related SSA/STM activities, shifting responsibility for providing SSA data and collision warning to commercial, civil, and non-US government operators from the military – in order for the Defense Department to "focus on protecting and defending US space assets and interests." This change, however, will require the approval of Congress – which has yet to take up the issue.

The change also raises a series of questions for Pentagon leadership and the US government about how military SSA activities will integrate with a future civil STM regulatory regime, as well as how both of these overlapping sets of activities will interact with other spacefaring nations/operators at the international level. Unfortunately, US decision-makers will face a number of security dilemmas about the future use of space that will not be easily resolved.

2 Space Situational Awareness: Safety Versus Secrecy

Perhaps the most fundamental of these questions is to what extent will the US government prioritize the military mission of SSA – which is considered a subfunction of "space control" designed to deter and defeat adversary space and counterspace abilities – versus the space safety and sustainability of the space environment? Unfortunately, these two SSA goals are in many ways inherently contradictory and create a classic security dilemma for Pentagon leaders.

For example, the US military does not include many of its national security satellites, especially classified Intelligence Community satellites, in the US space object catalog; nor does it routinely inform operators when one of those satellites becomes dysfunctional, even when it might put other operators at risk, as was the case with the DSP 23 missile warning satellite that malfunctioned in 2008 (Shalal-Esa 2008). Further, the USA does not require operators, whether commercial, civil, or especially military/Intelligence Community, to register and report satellite maneuvers. This lack of transparency actively undercuts the safety of other operators – especially those who do not have indigenous technical capabilities to maintain their own SSA system. And, sadly, if any space operator is essentially "flying blind," all space operators are put at risk, including the US military itself.

Another problem is that space object data shared publicly via the *Space.track* website does not include precise-enough data (or margins of error) for commercial operators to distinguish between a real possibility of collision and a false alarm, even though the 18th SPCS has higher-precision data. This is why, in 2009, a number of commercial space operators created the Space Data Association to share their own data about their satellite operations in order to better avoid interference (Space Data Association n.d.). "We discovered that the majority of conjunctions, or close approaches, were missed by the Joint Space Operations Center, and the majority of conjunction summary messages that went out advising us of close approaches were wrong," Richard DalBello, then vice president of Intelsat General for legal and governmental affairs, told a Feb 23, 2012, conference audience (Morring 2012).

According to US officials involved in the transition, DoD will continue to maintain the US Government's "authoritative catalog" of space objects and will continue to engage in military-to-military SSA data sharing and STM information exchange. DoD will continue to operate the SSN sensors for its military missions and to provide the Department of Commerce with SSA data. What data is shared with Commerce and at what level of precision remains to be seen – that is, will raw observational data be provided at higher levels of accuracy than the so-called two line elements currently publicly shared via the *Space.track.org* website or only information about potential conjunctions. If the latter, will margin of error calculations be provided?

Another question yet to be resolved is whether or not the Pentagon will have the authority to prevent Commerce from sharing data with better accuracy than that up to now provided by DoD. This is a critical issue, as currently Commerce is trying to figure out how to integrate the use of new sources of observational data – such as that being provided on the commercial marketplace by companies such as Analytical Graphics Inc. and data generated by foreign sensor suites – into the future civil SSA system precisely so as to be able to provide more accurate collision warnings. Kevin O'Connell, the head of the Commerce Department's Office of Space Commerce, speaking at a Nov 14, 2018 workshop sponsored by the University of Maryland's Center for Orbital Debris Research and Education (CODER), said that one major part of the office's responsibilities "will be to create an open architecture data repository that starts with the DoD catalog and enables a host of innovative capabilities and data sets provided by industry, academia, our allies, and partners." He added, "The repository is likely to be a very important source of innovation. Already within our early discussions, we hope to draw on state-of-the-art data management and data sharing capabilities, such as those that are available within cloud computing, and also allow for experimentation as new data sources and algorithms become available. There are important policy and technical questions about data fusion, but we will strive to create maximum opportunities for exploration, curation, and collaboration."

However, DoD may be reluctant to see foreign countries, especially those countries the Pentagon views as potential future adversaries, being given access to highly accurate satellite positioning data – especially about US satellites that DoD relies on for its own missions, which include many commercial communications satellites. This is because DoD sees SSA capabilities as part of the "space control" mission that includes offensive and defensive measures to ensure freedom of action in space.

Joint Doctrine 3–14 on Space Operations defines space control as follows: "Space control employs OSC [offensive space control] and defensive space control (DSC) operations to ensure freedom of action in space and, when directed, defeat efforts to interfere with or attack US or allied space systems. Space control plans and capabilities use a broad range of response options to provide continued, sustainable use of space. Space control contributes to space deterrence by employing a variety of measures to assure the use of space, attribute enemy attacks, and consistent with the right to self-defense, target threat space capabilities" (Office of the Joint Chiefs of Staff 2018).

It defines SSA as follows: "Situational awareness is fundamental to conducting space operations. SSA is the requisite foundational, current, and predictive knowledge and characterization of space objects and the OE upon which space operations depend including physical, virtual, information and human dimensions – as well as all factors, activities, and events of all entities conducting, or preparing to conduct, space operations. Space surveillance assets include a mix of space-based and earth-based sensors. SSA is dependent on integrating space surveillance, collection, and processing; environmental monitoring; status of US and cooperative satellite systems; understanding of US and multinational space readiness; and analysis of the space domain. SSA must incorporate understanding of the space capabilities and intent of those that pose a threat to our space operations and space capabilities" (Office of the Joint Chiefs of Staff 2018).

US Air Force doctrine further states that SSA "is foundational and fundamental to the conduct of all space operations functions and is especially critical to the effective conduct of counterspace operations" (Curtis Lemay Center for Doctrine, Development and Education, US Air Force 2018a, b). Counterspace operations include actions both to protect US space assets (i.e., "defensive counterspace") and to "deceive, disrupt, deny, degrade or destroy" adversary space systems (i.e., "offensive counterspace" (Curtis Lemay Center for Doctrine, Development and Education, US Air Force 2018a, b).

Thus, the US military also sees the SSA capabilities of other countries as part of their counterspace capabilities. A new report by the Defense Intelligence Agency, "Challenges to Security in Space," cites the SSA capabilities of both Russia and China as part of their counterspace capabilities noting that they could be used for targeting US systems (Defense Intelligence Agency 2019). Both China and Russia are developing a number of technologies that could enable ASAT systems, the DIA study finds, stating: "Both states are developing jamming and cyberspace capabilities, directed energy weapons, on-orbit capabilities, and ground-based antisatellite missiles that can achieve a range of reversible to nonreversible effects." It also states that China is considering the benefits of attacking US early warning satellites during a conflict, because those satellites are also being used to guide US missile defense interceptors to their targets. Therefore, it is obvious that there might be reluctance on the part of the US military and Intelligence Community to providing on-orbit data that might make targeting US satellites easier.

A related question is when DoD will be able to upgrade the software used for SSA tasks, including allowing the system to integrate sensor data from non-DoD owned telescopes and radar as well as orbital positioning data provided by outside operators. After years of cost overruns, delays, and requirements revamps, DoD in effect canceled the long-running Joint Space Operations Center (JSpOC) Mission System (JMS) program that was designed to upgrade current SSA data-crunching capabilities. The three-phased, $1 billion-plus initiative was aimed at upgrading hardware and software for space surveillance, collision avoidance, and launch support and enabling the generation of more precise and timely orbital information (International Defence, Security and Technology 2019). The new system was supposed to be able to integrate the massive amount of sensor data generated from the Space Fence ground-based radar system. The final increment, JMS 3, was supposed to transform the entire system into a battle management system, as well as allow the integration of orbital data provided by commercial industry and allied governments.

However, the Pentagon in early 2018 halted JMS 3, splitting the requirements into two pieces to be managed separately by the CSpOC and the National Space Defense Center (which coordinates with the National Reconnaissance Office) and renaming the whole effort the Enterprise Space Battle Management Command and

Control (ESBMC2) program (Clark 2018). Whereas the JMS 2, still in development, is focused on space safety, the ESBMC2 effort is squarely aimed at warfighting. EMSBMC2 is being designed as “a more dynamic, warfighting C2 system that was based on an open architecture systems with defined message standards, enabling us to rapidly on-board planning and tasking software applications,” according to the Air Force (Clark 2018). It also is aimed at “unity of effort” with NRO. While the overhaul of the Air Force SSA C2 and data management architecture revives hope for improving military SSA capabilities, there remain many questions about how (and even if) data will be passed from the National Space Defense Center and the CSpOC and how the ESBMC2 system will validate and integrate non-DoD generated data.

The fundamental view from DoD is that SSA is a warfighting tool. Therefore, there is a predilection toward secrecy, both about US space assets and about the accuracy of information (and the sources and methods by which it has been gathered) the USA has regarding the assets of other nations. However, secrecy about the space environment, including spacecraft and their movements, actively undercuts safety of operations. If the USA takes a too stringent hold on data release – that is, if national security concerns prevent sharing the best SSA data that is gathered – it will detract from safety and sustainability of the space environment for all. And, sadly, if any space operator is essentially “flying blind,” all space operators are put at risk, including the US military itself.

What is most critical with regard to all of the above questions and issues is the new space environment that is now anticipated. There are now many thousands of new space launches anticipated. Many new LEO and MEO constellations are either in active planning or being initially deployed, including OneWeb, the SpaceX Starlink and V-Sat networks, Athena, Kuiper, MCSat (by Thales Alenia), Telesat, Constellation, Theia, Planet, Spire, O3B, O3B mPower, and dozens more of these networks largely clustered between 700 and 1200 km altitudes with a critical concentration around 900 km.

3 National Versus International Approach; Restrictions Versus Freedom of Action

The nascent US approach to STM, as embodied in SPD-3, is also somewhat self-contradictory in that it is aimed at promoting US industry and bolstering US freedom of action in space while simultaneously calling on other countries to take up a similar approach.

The current effort as outlined in US Space Policy Directive-3 is attempting to establish a loose regulatory structure for US space activities that empowers the US commercial space industry to take a predominate position in the international market, as well as to provide the US strategic space program with innovative capabilities. SPD-3 acknowledges the need for a more robust structure for oversight of US space operators, especially for new types of space activities such as rendezvous and proximity operations (RPO) and active debris removal. SPD-3 states: “To maintain US leadership in space, we must develop a new approach to space traffic management (STM) that addresses current and future operational risks. This new approach must set priorities for space situational awareness (SSA) and STM innovation in science and technology (S&T), incorporate national security considerations, encourage growth of the US commercial space sector, establish an updated STM architecture, and promote space safety standards and best practices across the international community" (The White House 2018).

According to US officials, the administration intends to go its own way to develop a national STM regime based on industry-designed best practices and then attempt to convince other countries to adopt a similar approach. SPD-3 states: "The United States recognizes that spaceflight safety is a global challenge and will continue to encourage safe and responsible behavior in space while emphasizing the need for international transparency and STM data sharing. Through this national policy for STM and other national space strategies and policies, the United States will enhance safety and ensure continued leadership, preeminence, and freedom of action in space."

In an interview with *SpaceWatch Global* on Dec 2, 2018, Dr. Scott Pace, Executive Secretary of the US National Space Council, indicated that the USA will forge ahead on setting rules for new types of space activities apparently with limited consultation with allies or other space faring nations. He said that the US government is moving quickly to provide "mission assurance" authority for on-orbit activities by US space companies to the Commerce Department, including licensing procedures for "satellite servicing, bases on the lunar surface, and space stations." Asked about the administration's international approach, Pace said: "We don't know that we really need anything new" because the 1967 Outer Space Treaty is "fairly permissive" (Space Watch Global 2018).

However, given that the goal of SPD-3 seems to be to promote US industry and US freedom of action in space, what incentives will other nations have to go along? Indeed, there is already some evidence US allies in Europe are growing uncomfortable with the US space initiatives seeming lack of consideration for allied interests and concerns. At a November 2018 conference sponsored by the Institut français des relations internationales (IFRI), a number of European officials expressed unease with the US space initiatives commercial space policies. François Raffenne, strategic planning and analysis manager for ArianeGroup, told the conference that the USA is not listening to European views on vital questions for the future of the space environment, such as "What is space deterrence?" "What is 'victory' in space?" and "What is the difference between a civil and military space asset?" He said that there is a "need for regulations to follow, and that right now the USA is the only actor able to articulate those regulations." But, he cautioned, Washington is doing so "in support of national objectives; in support of US space dominance by civilian, military and commercial goals." He explained that the US space initiatives as outline in SPD-3 "will have implications that will dictate rules of the road; the question is how Europe will respond to the US lead" – warning that Europe has its own interests to look out for (Author's notes from attending the conference).

Further, the Trump administration has backed away from international efforts to develop best practices for space operations under the auspices of the United Nations at the Committee for the Peaceful Uses of Outer Space (COPUOS). According to State Department officials, rather than supporting new discussions to expand upon the set of 21 guidelines developed by the Scientific and Technical Subcommittee's Working Group on the Long-Term Sustainability of Outer Space and approved by the Committee in June 2018, the USA intends to focus on national implementation. And while the COPUOS Legal Subcommittee has had an annual agenda item on STM since 2015, the USA and the Russian positions have been that it is too early to seek a legally binding international accord on STM, as there is not yet an agreed multilateral understanding of the necessary parameters of such a regime. The US government also has argued during Legal Subcommittee meetings that the Scientific and Technical Subcommittee should first look at what technical approaches are even feasible to create such a regime.

An STM regime followed only by one or a handful of nations would do little to create a safer space environment. Worse yet would be a situation where the rules governing safe practices on orbit differ widely from country to country, as it would drive commercial industry to seek the locale with the least restrictive rules – as already a serious problem regarding the shipping industry where "flags of convenience" are common so as to minimize the need to comply with environmental safety and health regulations. As an example of how such problems could manifest, US firm Swarm Technologies in January 2018 managed to launch four very small satellites, called SpaceBEEs, on an Indian government Polar Satellite Launch Vehicle after having been denied a US launch license by the Federal Communications Commission because of safety concerns (Henry 2018). This violation of US licensing law was made possible because neither the company, Spaceflight, that arranged for the SpaceBEEs ride share on the Indian rocket nor the Indian government required Swarm to provide evidence of a license. Spaceflight, a US company, has now changed its operating procedures to require proof (Grush 2018), though there is no evidence that the Indian government has done the same.

The need for an international approach is recognized in SPD-3, yet the document also states that the end goal is US "freedom of action" in space – a goal enshrined in US national security space policy. The US military long has been wary of any international treaty or effort that would seek to restrict in any way its future actions in space. For the past several decades, the military's dim view of any new international legal mechanisms for governing space has been reflected in the long-standing US preference for voluntary measures, such as best-practice guidelines.

Of course, if any future international architecture for STM is primarily voluntary, and based on individual state practice, the Pentagon can always count of being exempted from any rules it finds too constricting since it can fall back on the provision in international law to have the right to self-defense.

An example is the case of US military adherence to the Space Debris Guidelines of the Committee on the Peaceful Uses of Outer Space endorsed by the UN General Assembly in 2007. Those guidelines actually were based on US government debris mitigation practices formulated by NASA, and most if not all are already incorporated into US government licensing rules for space launches. DoD Directive

3100.10, Space Policy, states that the “DoD will promote the responsible, peaceful, and safe use of space, including following the US Government Orbital Debris Mitigation Standard Practice (ODMSP)” (US Department of Defense 2016).

However, ODMSP allows for a waiver of the practices if approved by the “head of the sponsoring department or agency” (Sims and Braun 2017). The Air Force, which is responsible for most military satellite acquisitions, lays out the process for obtaining waivers in Air Force Instruction 91–217, “Space Safety and Mishap Prevention Program,” that includes review by the program safety officer, the Office of the Air Force Secretary, and the Secretary of Defense (Office of the Secretary of the Air Force 2017). DoD practice, according to Pentagon officials, has been that waivers are granted if compliance would result in significant increases in cost or place onerous constraints on important military missions. In the not-too-distant past, waivers for DoD space missions were easily obtained and quite common, according to Pentagon officials involved. The Obama administration, however, cracked down on the practice, so it is increasingly difficult for DoD satellite program managers to obtain them.

In addition, there is no explicit prohibition in US National Space Policy, DoD policies, or US military doctrine on the use of debris-creating antisatellite (ASAT) weapons. In fact, the Pentagon’s policies and doctrine allow for space control and counterspace operations that destroy adversary space and counterspace systems (as noted above). And while US military leaders, including Gen. John Hyten, newly appointed vice chairman of the Joint Chiefs of Staff, and former head of both US Strategic Command and Air Force Space Command, have been vocal about their disregard for debris-creating ASATs, the US government has up to now opposed any effort toward negotiation of a treaty to ban such weapons.

It should be obvious that if the USA can insert compliance waivers into its implementation of voluntary rules and guidelines for space activities, other nations could do the same. It should be similarly obvious that if all nations decide to exempt their military space forces and activities from compliance with any future national or international STM guidelines, the space environment likely will continue to be put at serious risk. Due to the laws of physics prevailing in outer space, the actions of any single space operator have the potential to affect all other operators – and no one can escape the laws of physics. Any STM regime would by necessity include some restrictions on certain types of activities and constrictions on how activities are undertaken; an international STM regime – especially if legally binding – would inherently restrict US freedom of action in outer space. Thus, the US military will need to be ready to accept some restrictions on its freedom of action for a STM regime to be developed, both at the US national level and the international level.

4 Conclusion

The US government and its military have a large stake in ensuring safety of space operations. This would seem to imply the need to support the development of future US and international STM regimes. However, such a position faces a number of dilemmas as STM governance processes unfold. There will be trade-offs to be made between secrecy and transparency, and between a controllable national regime and an international regime less in the control of the US government. There will be a dilemma of choosing between a closed-loop warfighting posture and an open, multi-stakeholder architecture for safety.

However, the skyrocketing population of small satellites coupled with the technological shortcomings in the current American SSA capabilities will force the US government and other space security actors to focus more clearly on these issues in the immediate future. In a positive sign, the US government since 2015 has been seriously investing in improved space situational awareness (SSA). In fact, a Government Accountability Office study in 2015 was able to track $6 billion in planned spending in this area through FY2020 (Government Accountability Office 2015).

However, the US military has yet to puzzle out how it intends to interact with the new civilian STM architecture envisioned by SPD-3. Because SPACECOM (like STRATCOM before it) has not yet resolved its serious software problems, the job of coordinating between the civil agency and the Pentagon will be extremely complicated. This will require both technical and organizational solutions as well as goodwill on both sides. Fortunately, at this time, there seems to be a good working rapport between current activities in the US Department of Commerce and DoD, with regular information changes ongoing.

The shift in responsibility for SSA and STM from the military to the Commerce Department further requires congressional approval and oversight. Unfortunately, lawmakers seem to still be divided on which civilian department should be made responsible for the new civilian body and processes. Some within the Congress believe the role of a civilian STM agency should not be given to the Commerce Department as laid out in SPD-3, but rather to the Transportation Department under the management of the Federal Aviation Administration (FAA), which has had long experience in handling space safety oversight for launch and reentry of space vehicles. This divide has meant limited progress can be made in developing STM approaches to the various issues at hand, including SSA data sharing and regulations for new types of space activities such as on-orbit servicing and mega-constellation operations. Meanwhile thousands of small satellites (i.e., nanosats, microsats, and minisats) for mega-constellations may be deployed before these issues are resolved.

Time, however, is of the essence. Space security officials in the USA and other space faring nations must face the challenges of SSA and STM now and not succumb to bureaucratic inertia. The commercial industry, both here and abroad, is surging relentlessly forward in development of new capabilities and launching small satellites at unprecedented rates. While Congress is currently deadlocked on granting legislative authority for the new civilian STM agency, that deadlock will not last forever, and there are a number of technical issues that can be hashed out in the meantime. Therefore, there is a role for industry and academia to play in setting the stage for a future regime by developing best-practice concepts both at the technical and operational level.

Finally, Washington needs to be aware that the international community is becoming increasingly unwilling to wait for, and follow, the USA lead on seeking international solutions to the ever-increasing congestion in space. As the US

National Space Council moves forward with the sweeping reorganization of space enterprise, there will be a need for new focus and coordinated effort to find solutions to the SSA/STM challenges that *include* cooperation and coordination with international partners.

Abstract

There are both positive and negative national security implications associated with the deployment of small satellite constellations, particularly those destined to be mega-constellations. This chapter attempts to discuss both sides, benefits, and risks, aimed to enable the reader to decide whether they are optimistic or pessimistic, or indeed cautiously ambivalent about small satellite constellations. In this context, this chapter first provides definitions for national security (taking into account personal and financial security), small satellites, and constellations. Its subsequent two sections deliberate about various potential positive and negative implications for national security of small satellite constellations in more detail. On the positive side, the analytical focus is on the capability enabling functions of small satellites, their antisatellite (ASAT) capability, as well as their ability to upgrade, enhance resilience of and reconstitute space system functionality. On the negative side, the chapter examines such national security-related risks as increased orbital congestion, frequency overcrowding, and the danger to people, property, and environment. The penultimate section deals with the issue of managing the risks, with particular consideration of the concept of *responsible use*, considering observability, maneuverability, communication and controllability, the ability of small satellites to operate safely, regulation, legality and ethical constraints, as well as liability. The chapter concludes with a brief summary and the authors' view on how progress might be made in a way that embraces small satellite constellations responsibly, to optimize their benefits, while protecting global security concerns.

1 Introduction

> There is nothing more difficult to take in hand, more perilous to conduct, or more uncertain in its success, than to take the lead in the introduction of a new order of things. Because the innovator has for enemies all those who have done well under the old conditions, and lukewarm defenders in those who may do well under the new. (Machiavelli)

With the potentially exponential increase in small satellites, particularly those destined for mega-constellations, the world faces something of a dilemma – is this a good or bad development for national security? For the small satellite constellation advocates there is no doubt, they present an outstanding opportunity for the global community to access commercially competitive space products and services at a fraction of the historic costs, with the potential to enhance national (and personal) security. However, for those troubled by national security threats and issues, the burgeoning capabilities, combined with the sheer numbers of miniaturized orbital assets, and the ever-reducing cost of entry into this developing marketplace, the emergence of small satellite constellations is probably mildly alarming. Which view is right? They both are!

Of course, this is not a simple debate (good vs. bad), and the intellectual argument is somewhat skewed by the perspective one takes. Organizations committed to creating businesses associated with small satellite constellations will argue the very significant benefits to mankind of the low cost (or free) access to their services and products. For example, OneWeb's vision, "Internet access everywhere, for everyone" (OneWeb n.d.), is difficult to critique negatively, particularly as it resonates so eloquently with the values of freedom held dear by much of the global community. Depending on one's definition of national security, this type of capability could be seen as enhanced resilience beneficial to society and, therefore, national security. However, some states may view the vision with some concern, perhaps seeing it as a challenge to the systems that underpin the way their societies currently function. Similarly, nations that are the prime beneficiary of a constellation's products or services for national security purposes will doubtless argue for the benefits the capabilities offer and their right to exploit them; their adversaries might take a different view. Unsurprisingly for space, the debate will most likely gravitate to one of responsible use, which again is skewed by perspective.

This chapter attempts to offer both views, for and against, with the aim of enabling the reader to decide whether they are optimistic or pessimistic, or indeed cautiously ambivalent about small satellite constellations. The chapter covers:

- *Definitions*. To create the context, the chapter begins by defining national security, small satellites, and constellations. This section also provides a brief history of small satellites.

To consider whether and how a nation's security could be enhanced or degraded by small satellite constellations, the chapter turns to:

- *National Security Enhancements*. This section examines the potentially positive contribution of the emerging capabilities, examining inter alia: the capability enabling functions of small satellites; antisatellite (ASAT) capability; and the ability to upgrade or enhance resilience of Space system functionality.
- *National Security Risks*. The next section covers the potential risks to national security: orbital congestion; frequency overcrowding; the danger to people, property, and environment; the re-entry risk, the maneuver risk, the dangers of ride-sharing and piggyback launches; and attacks by microsatellites.
- *Managing the Risks*. The penultimate section deals with the issue of managing the risks, covering observability; maneuverability; communication and controllability; the ability of small satellites to operate safely; regulation; liability; legality; and, ethical constraints.

- *Conclusion.* The chapter concludes with a brief summary and the authors' view on how we might progress in a way that embraces small satellite constellations responsibly, to optimize their benefits, while protecting global security concerns.

It is important to state that the legality of the activities small satellites may undertake is not considered in the positive and negative contribution sections.

2 Definitions

2.1 National Security

There are numerous definitions of national security and the concept has, over the last six decades, morphed from that of repelling unwanted influences (normally using the military), to maintaining freedoms, prosperity, self-determination, and wellbeing (normally through use of all instruments of power).

Collins Dictionary defines national security as "A country's national security is its ability to protect itself from the threat of violence or attack" (Collins n.d.). The problem with this definition is that it does not address the subtlety of the threat of erosion of societal wellbeing due to the loss or erosion of services; this is important when we consider space and satellite capabilities. As the 2015 UK National Security Strategy points out, "Economic security goes hand-in-hand with national security" (HM Government 2015), making the clear link between national security and society's ability to function. When considering the benefits and risks of small satellite constellations, while violence and attack are relevant, taking this view only would lead to a myopic perspective of the issues. Therefore, to situate the following analysis in a broader context, it is preferable to adopt Charles Maier's definition of national security (as presented in his unpublished paper for the MacArthur Fellowship Program, Social Science Research Council, 12 June 1990):

> A capacity to control those domestic and foreign conditions that the public opinion of a given community believes necessary to enjoy its own self-determination or autonomy, prosperity and wellbeing.

This definition encompasses the societal aspects of national security, and by implication issues such as security of a nation, individual, and way of life, and the importance of assured (critical) services. For the purposes of this chapter those small satellite constellation capabilities that enable these elements are considered positive and those that degrade or deny the elements are negative.

2.2 Small Satellites

There is no universally accepted definition of small satellites; accordingly, most commentators use their attributes to differentiate small satellites from large(r)

Table 1 Classification of small satellites

Class	Mass (kg)
Mini-satellites	100–180
Micro-satellites	10–100
Nano-satellites	1–10
Pico-satellites	0.01–1
Femto-satellites	0.001–0.01

Table 2 Classification of small satellites

Class	Mass (kg)
Small satellite	500–1000
Mini-satellites	100–500
Micro-satellites	10–100
Nano-satellites	1–10
Pico-satellites	0.1–1
Femto-satellites	<0.1

satellites. Overall, small satellites, in comparison to large(r) satellites often have the following characteristics (Marshall 2008):

- Low cost ($50– $100 million)
- Fast turnaround (12–36 months from authority to proceed to launch)
- Use of latest technology
- More than one satellite per launch or use of small affordable launch vehicles
- Use of off-the-shelf technologies wherever possible (both commercial and other)
- Higher risk
- Less complexity
- Less durability
- Less orbital time
- Lower satellite and launch costs
- Speedier deployment rates

These attributes do not always stand up to scrutiny as differentiators, so the more common categorization of small satellites is by mass or size. Elizabeth Mabrouk (2017) described the following classes of small satellite (Table 1):

Sir Martin Sweeting, in his paper "*Modern Small Satellites–Changing the Economics of Space*" (Sweeting 2018, pp. 343–344), used similar but not exactly the same mass numbers for the different classes, and includes the specific class for "small satellite" (Table 2):

A 2017 International Institute of Astronautics (IAA) report (Cho and Graziani 2017) accords with Martin Sweeting's view, albeit combining the small and mini-satellite classes into one 100–1000 kg mini-satellite class. These differing views serve to highlight the lack of a common definition of small satellites, and as

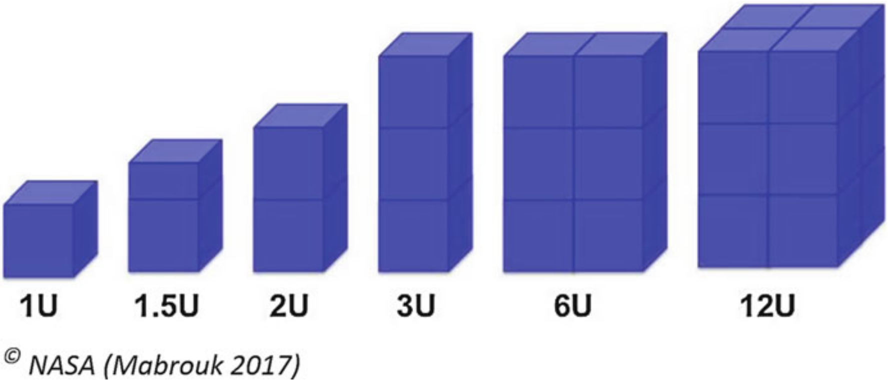

Fig. 1 CubeSat units. (© NASA (Mabrouk 2017))

Finkleman (2013) highlights, the mass discriminant belies size, orientation, maneuverability, and other discriminating attributes. The choice of orbital architectures for small satellites by any definition must consider these other characteristics. However, the *cursor* must be set somewhere, so for purposes of this chapter small satellites are those with a mass of <1000 kg.

2.3 CubeSats

It is worth a brief word on CubeSats, as many of the aspiring constellation providers are turning to this class of satellite. “CubeSats” are a class of nanosatellites that use a standard size and form factor. The standard CubeSat size is “one unit” or “1 U” measuring 10 × 10 × 10 cms, and is extendable to larger sizes, e.g. 1.5, 2, 3, 6, and even 12 U. CubeSats now provide a cost effective platform for science investigations, new technology demonstrations and advanced mission concepts using constellations, swarms disaggregated systems (Mabrouk 2017). The image below (Fig. 1) shows how these “units” can be aggregated to provide different sized nano-satellites.

2.4 Constellations

“A satellite constellation [...] is a system of satellites that work together to achieve a single purpose.” In line with this definition offered by Rouse and Haughn (2017), a constellation could be a relatively small number of satellites operating to provide a service (e.g., the GPS constellation). However, this chapter will consider small satellites forming large-scale constellations (mega-constellations), which are primarily planned for Low Earth Orbit (LEO); these are generally perceived to offer the following capabilities:

- Continuous, multipoint data gathering
- Fast download and upload speed
- A global imaging capability and capacity
- Modularity – the use of standardized units allowing flexibility such that satellites can cover the operations of other satellites
- Networked – the use of satellites that work together in a network to disperse the system capabilities
- Redundancy – the use of more satellites than are minimally required for the provision of the capability

As such, these capabilities offer significant commercial opportunities for the constellation suppliers, specifically as the cost of (equivalent to traditional space-based) service provision promises to be materially reduced.

Making a constellation of satellites work has very specific challenges:

- *Mission Design*. Constellations may have three forms of "control" – controlled satellites where some degree of propulsion maneuver is possible; uncontrolled swarms of satellites with no form of propulsion, and something between the two utilizing a slave/master approach. All of these approaches have weaknesses, covered in the vulnerabilities section below.
- *Critical Mass*. The mission architecture will define the coverage provided by the constellation, but whatever the architecture is, there will be a critical mass of satellites required to provide the coverage required.
- *More Satellites, More Risk*. If all the planned constellations are realized, the total number of operational satellites in orbit would quadruple, exacerbating the risk of catastrophic and cascading satellite collisions (Grush 2018). As constellations grow in size, they can no longer be considered in isolation and potential coupling with the background satellite population will become an increasing issue.

2.5 Constellation Vulnerabilities

- *Cyber*. The need to communicate with the ground may create the ability for a third party to intervene in operations making the satellite and potentially the constellation vulnerable to cyber-attack.
- *Vulnerability in Design*. Constellations made up of similar components have increased potential for systemic failure, due to common design elements.
- *Jamming and Spoofing*. Jamming or spoofing a subset of constellation could impact the integrity of the system as a whole.

2.6 Small Satellites and NewSpace – The Rise of CubeSats

The phrase NewSpace is used to imply a different approach and ethos to more established methods and business models associated with new entrants to the space

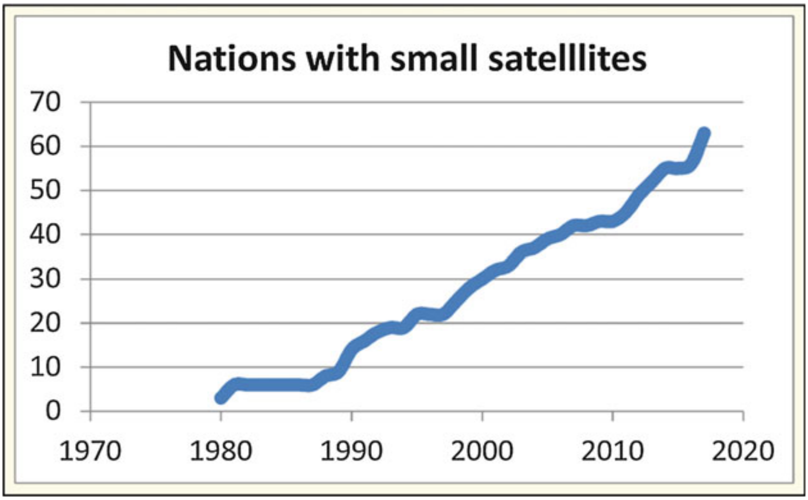

Fig. 2 The rise of nations with small satellites. (Sweeting 2018, p. 353)

sector and characterized by agility, entrepreneurship, and exploitation of off-the-shelf technologies (Sweeting 2018).

CubeSats have contributed to the NewSpace dynamic and the progressive evolution of the small satellite market. Affordability of design, manufacture, launch, and operation has dramatically increased the number of *space-faring* nations (as shown in Fig. 2 below), mainly for education and technology demonstration purposes. Advances in related R&D (e.g., components and sub-systems miniaturization) have also sparked a growing interest in civil, military, and commercial applications for CubeSats (ESPI 2018).

The growth of use of CubeSats is set to increase significantly with the large number of proposed CubeSat constellations (Fig. 2). With limited size and weight, CubeSats cannot match the capabilities of larger traditional satellites. For example, large optics are not feasible, and uncertainty exists with the reliance on yet to be proven launch vehicles, which may limit military use. However, constellations offer applications and services that could challenge some traditional satellite capabilities (ESPI 2018).

2.7 National Security Implications

It is perhaps unsurprising that there are both positive and negative security implications associated with the deployment of small satellite constellations, particularly those destined to be mega-constellations. The next two sections cover the positive and negative influences on national security respectively. These will be examined through the lens of the potential capabilities the constellations might provide and from the perspective of what constellations can do for a nation. This narrative does not comment on the potential *second order* impact on national security of a state resulting from an increased capability, i.e., it could be argued that for some nation's, an increased military (particularly hostile) capability could serve to decrease a nation's security as it may be perceived to be more threatening.

3 The Positive National Security Implications

3.1 Enhancement of Security-Oriented Applications

The applications or services potentially provided by small satellite constellations may not be new or indeed novel, but their availability and cost could be transformational for national security, particularly for nations that have not previously had access to capabilities. Even those nations that have previously enjoyed access to capabilities provided by their own or allies' government-owned satellite assets may find the offering from the commercial sector cost-effective and compelling.

As suggested by Larsen (2017, pp. 302–303) and Marshall (2008, pp. 154–157, 166–178), small satellite mega-constellations with remote sensing, communications, broadcasting, or navigation capabilities can offer functions that have potential to enhance a nation's security. Some notable functions are:

- *Intelligence*. A small remote sensing satellite mega-constellation positioned throughout LEO and the Medium Earth Orbit has the potential to provide a global optical and radar reconnaissance capability, with continuous or near-continuous coverage. This offers a nation an intelligence gathering capability that can, in some cases, dramatically improve a state's ability to monitor an adversary's activities and to improve their early warning potential against military build-up, maneuvers, activities, and even long-range ballistic missile strikes. The latter becomes increasingly relevant as more and more actors engage in the development long-range ballistic missile capability.

  This *intelligence* has broader security applications too. The ability to access what is happening on the ground with near-continuous coverage offers real benefits for disaster monitoring, planning and relief, enhancing a nation's resilience, an important aspect of the wider national security.
- *SIGINT*. A small satellite mega-constellation in various orbits offer nations a signals intelligence (SIGINT) capability that for some could be a significant enhancement of their ability to gather intelligence. As above, SIGINT provides a state and its military the potential to monitor an adversary's command and control networks and gain an insight into military or government activities.
- *Bandwidth*. A military communications and broadcasting small satellite mega-constellation in LEO and Geostationary Orbit (GEO) will increase demand for satellite communications bandwidth, with impact on spectrum availability for other uses.
- *Navigation*. Although this may be more in the realms of future capability, a small satellite mega-constellation may well provide navigation services, which

complement those provided by large satellite assets in GEO. This has the potential to enhance military navigation capability and provide a much-needed resilience to the loss of GNSS services. In addition to enhancing resilience and robustness of those capabilities that are reliant on space-based navigation products, such services can support a nation's ability to effectively employ modern precision-guided munitions; for some nations this could be transformational.

- *Timing*. Again, more in the future than today, but a small satellite mega-constellation may have the ability to provide a timing signal of sufficient quality to enable time-reliant systems to operate. In addition to the resilience this may provide for military capability, it also offers to mitigate the loss of timing and therefore provide resilience to the critical national infrastructure sectors' that have a reliance on timing to function.

3.2 Provision of Antisatellite (ASAT) Capability

Notwithstanding the unacceptability or legality of such a capability, it is technically possible for an appropriately enabled small satellite mega-constellation to perform as an ASAT weapon system for the purpose of neutralizing (perhaps temporarily) the functionality of an adversary's national security-oriented space system in times of conflict. This is clearly contentious and there are risks associated with ASAT activities, not least the potential for a direct or indirect response that could be deleterious to the attacking nation's own national security. There is also the significant risk of debris of the ASAT action because of its kinetic nature, again raising the potential of an escalation of retaliatory action if other nations perceive a threat to their national security. Ultimately, this can jeopardize the stable use of outer space or at least of certain orbits for any activity, including for the application of small satellite mega-constellations to advance states' national security, including personal security.

Drawing on the work of Baines (2004), Harrison et al. (2019, pp. 3–7) and Marshall (2008, pp. 160–162, 180–192), a small satellite mega-constellation can technically be configured as an ASAT weapon system, to employ a range of attack mechanisms.

- *Kinetic – Direct Impact Attack*. With an on-board propulsion system, a small satellite can be maneuvered to a conjunction with an adversary's satellite, with the intention of neutralizing or degrading a national security-oriented space capability in times of conflict. This effect could also be achieved by "nudging" another satellite to cause it to tumble. It is also possible for the attacking satellite to deploy pellets, specifically creating a targeted debris field with the intention of impacting and degrading an adversary's system.
- *Kinetic – Proximity Attack – Explosion*. A small satellite with on-board propulsion system combined with an explosive mechanism can be maneuvered to close

proximity of another satellite asset, and the charge initiated to damage the latter in times of conflict.

- *Kinetic – Proximity Attack – Capture*. A small satellite with on-board propulsion system combined with a method of capturing another orbital object, e.g., via a net or harpoon (University of Surrey 2018), and an explosive mechanism, can be maneuvered to close proximity to another satellite asset, and the charge initiated to damage the latter in times of conflict.
- *Data Disruption*. An ability to move close to another satellite with on-board propulsion and a payload with a spoofing or jamming capability could render the target satellite unusable or deny its product to an adversary. Similarly, an electronic or cyber-attack system could corrupt data on the platform degrading its systems. Satellite-based laser systems could also be employed to *dazzle* sensors, again eroding the data the sensors can both receive and manipulate.

As indicated above, it is reasonable to assume that a state's development and deployment of a small satellite mega-constellation aimed to advance its national security could be perceived by other states as a move that weakens their respective political and national security. This may lead to proliferation of these capabilities as states seek to develop and deploy better ASAT weapon systems capable of neutralizing the functionality of adversary's small satellite mega-constellation. Naturally, the application of any kind of ASAT weapon system is likely to escalate tension and perhaps result in conflict where otherwise it would not have occurred. Debris resulting from ASAT operations will jeopardize the stable use of outer space or some orbits.

3.3 Rapid Upgrade Potential

Given the anticipated life cycle of constellation-based small satellites – according to Larsen (2017, p. 279), as little as 9–18 months – there is significant potential to upgrade the security related capabilities in response to a changing threat, thus creating a form of small satellite capability *race*. With Marshall's deliberations in mind (Marshall 2008, p. 166), this is likely to be significantly more cost-effective than reliance on larger satellites remaining at the *cutting edge* (although advances in configurable software and on orbit manufacturing could challenge this hypothesis). It is the nature of small satellite constellations that there is a continuous replenishment requirement as satellites reach the end of their mission and deorbit. It is advantageous that these new small satellites can be built with a more recent generation of technology, thus upgrading the technological standard of their respective space system. Related to this is the fact that the necessary frequent replenishment missions permit operators to accept more risk in testing technology with a potentially lower readiness level, as well as to enjoy faster learning cycles in technological development.

3.4 Enhanced Resilience of Space Systems

As distinct from larger satellites, security-oriented small satellites have some features that make them innately resilient to certain types of ASAT attack. As societies (and military) reliance on many space-based products increases, the prospect of assured capability is extremely important to national security.

Leaning on related previous discussions (Baines 2004, pp. 150–152, 167–170; Larsen 2017, p. 303; Marshall 2008, pp. 166–182; Querejazu and Randazzese 2017, pp. 5–6), some of these features arguably are:

- *Small Size*. The smaller the satellites, the harder they become for an adversary to target them individually with physical ASAT weapons. Size also contributes to their individual resilience to space debris, as they are less likely to be impacted in random collisions. However, by contrast, for constellations, the large number of small satellites also makes it *more* probable that space debris hits one of them at some point – that said, the innate resilience of sheers numbers in mega-constellations is likely serve to mitigate this threat.
- *Number and Orbital Dispersion*. A constellation can comprise tens, hundreds, or even thousands of satellites situated in one or more orbits. As such, achieving a successful attack against a variety of small satellites will be extremely challenging for an adversary. Similarly, a large number of satellites potentially throughout different orbital locations make environmental events in space such as solar flares less of a threat to their collective capability. A few specific attributes can influence the difficulty an adversary would have to target and degrade a mega-constellation, and the innate resilience the system has to environmental threats:
  - The large number of satellites in the constellation, and potentially small number in particular orbital planes.
  - The distribution of different payloads among the satellites and orbits, providing a degree of system modularity. This presents the adversary with a challenge – which small satellites in the constellation do they target.
  - The satellites' potential to perform their tasks collectively and individually, presenting an adversary with a similar challenge to above – how to target effectively.
  - Satellite-to-satellite link or networking capability and multiple space-ground links or hops, which deliver innate resilience and redundancy.
- *Potential to Deploy Decoys*. Hiding decoy satellites in the constellation to increase the overall space system resilience against ASAT weapon attacks is a viable option, again challenging adversaries to determine which satellites to target.

3.5 Reconstitution of Space System Functionality

Assuming the worst where an adversary has successfully degraded a mega-constellation or its capability, the ability to cost-effectively reconstitute the system will significantly enhance a state's national security, especially when compared with the challenge associated with reconstituting larger satellite capabilities. As, mentioned in previous writings related to this topic (Baines 2004, pp. 150–152, 167–170; Larsen 2017, p. 303; Marshall 2008, pp. 179–182; Querejazu and Randazzese 2017, pp. 5–6), the attributes and characteristics of mega-constellations provide opportunity to reconstitute the system and capability comparatively rapidly. In particular:

- *Launch*. Their small size and weight means that multiple small satellites can be launched together and with a relatively low price tag. Many commercial and state launch services for small satellites are under development, offering a state more options to launch them rapidly and responsively. This also enables a state to build on-demand infrastructure and to store large quantities of spare satellites at relatively low cost. Small satellites might be launched as secondary payloads to large(r) satellites.
- *Speed of Development and COTS*. Small satellites are associated with fast, low-cost development and production cycles, due to the use of modular design and commercial off-the-shelf (COTS) products.

Notably, a potential beneficial secondary effect of a high space system resilience and reconstitution ability against ASAT weapon attacks is that it can dissuade or deter an adversary from carrying out such an attack in the first place.

4 The Negative National Security Implications

4.1 Increased Orbital Congestion

The deployment of mega-constellations in one or more similar orbits can lead to orbital congestion, potentially impairing or preventing the safe operation of security-oriented space objects in the orbits. There is also potential that congested orbits become progressively difficult to cross. Drawing on some related deliberations by ESPI (2018), Finkleman (2013), Greco (2019, pp. 105–106), Larsen (2017, pp. 277, 279–280, 289–290, 296–302), Marshall (2008, p. 178), and Shaw and Rosher (2016, pp. 319–321, 325–327), several notable attributes of small satellite mega-constellations, including with regard to operators, that affect this are:

- *Number of Small Satellites*. The deployment of small satellite mega-constellations comprising tens, hundreds, or even thousands of satellites positioned in one or more orbits can overcrowd the orbits and increase the risk of collision. Reportedly (Sweeting 2018, p. 356), the proposed small satellite mega-constellations (as of around early 2018) shall encompass nearly 25,000 small satellites, with ca. 23,000 for communications, 1500 for EO, and 800 for various services. Any such collision will lead to an increase in space debris, exacerbating the core problem. Although statistically unlikely, even with mega-constellations on orbit, an exponential increase in space debris could catalyze the so-called Kessler syndrome, where a chain reaction of conjunctions could render some orbits unusable.

- *Default Rate and Mission Life of Small Satellites*. Small satellites linked to mega-constellations still seem to have a rather problematic default rate, suggesting reliability may be an issue. For example (O'Callaghan 2019), SpaceX's first 60 small satellites launched as part of its "Starlink" small satellite mega-constellation project suffered a 5% failure rate (3 out of the 60 satellites did not work). Considering that Starlink shall consist of around 12,000 satellites at altitudes from 550 to 1100 km by the early 2020s, such a failure rate would result in around 600 inoperable satellites in these orbits just from this project. Furthermore, the mission life of small satellites can be short in some cases – according to Larsen (2017, p. 279), as little as 9–18 months, and not all of them might be successfully deorbited. Each of these factors can increase the amount of space debris in certain orbits, with the related consequences outlined under the previous point. This problem is compounded by the potential frequency of replenishment launches, necessary to maintain the constellation, that may also leave further space debris in the form of launcher components.
- *Lack of Public Registration of Small Satellites*. In the past, states have sometimes failed to register and to update the registration information of space objects for which they bear responsibility under international law, in the dedicated and publicly accessible United Nations Register of Objects Launched into Outer Space (UNOOSA n.d.), and their respective national registers. In the case of the UN registry, the information would include (Convention on Registration of Objects Launched into Outer Space, art. IV):
  (a) Name of launching State or States
  (b) An appropriate designator of the space object or its registration number
  (c) Date and territory or location of launch
  (d) Basic orbital parameters, including:
      (i) Nodal period
      (ii) Inclination
      (iii) Apogee
      (iv) Perigee
  (e) General function of the Space object

  Arguably, states' negligence to publicly register and frequently update the registration information of (mega-)constellation-forming small satellites for which they are internationally responsible can increase the collision risk in the constellation's orbit(s). Operators with space objects in the constellation's orbit(s) may lack important official information to properly predict, prepare for, and respond to potential conjunctions. Even the identification of the (mega-)constellation-forming small satellites' actual operators might prove challenging.
- *Insufficient Tracking Capabilities and "Stealth" Satellites*. There is no guarantee that an operator of space objects outside of mega-constellations has access to Space Situational Awareness (SSA) capabilities that allow sufficient tracking of small satellite mega-constellations. Similarly, there is no guarantee that an operator of a mega-constellation has access to SSA capabilities that allow for tracking

others' space objects, especially small satellites in other mega-constellations. Additionally, some satellites might be designed to have a minimal radar cross section and reduced emissions signature, specifically to better protect them from an adversary's ASAT capabilities. Thus, the deployment of one or more small satellite mega-constellations can create a situation in which some operators of space objects are unable to ensure safe navigation in the constellations' orbit(s), increasing the respective collision risk.

- *Maneuverability.* Small satellites often have no or only a limited onboard propulsion system. In the case of mega-constellations, such a technical restriction can increase the collision risk as the satellites are unable to maneuver away from a conjunction. Furthermore, constellation operators will have difficulty actively de-orbiting satellites at the end of their mission to avoid having them become space debris. A rule of thumb is that the higher the orbit of a satellite, the longer it will take to de-orbit without intervention.

4.2 Overcrowded Radio Frequencies

Building on discussions by Larsen (2017, pp. 283–287) and Shaw and Rosher (2016, pp. 313–314, 317, 321–324), operators are likely to want to use similar radio frequencies to communicate with their constellations, which over time will become a limited resource, and are subject to heavy international (mainly through the International Telecommunication Union) and national level regulation. As such, the deployment of various small satellite constellations in one or more similar orbits can lead to (localized) overcrowding of such radio frequencies. This overcrowding may lead to the degradation or denial of security-oriented capabilities. Moreover, it can make operators' interference-free communication with and thus safe control of their space objects difficult, with a consequential increase in the collision risk.

Adherence to the international spectrum regime of the ITU has a further security implication. Use of radio frequencies outside the agreed international regulatory regime can create intergovernmental discord that can grow into an intergovernmental conflict, possibly diminishing states' national security.

4.3 Danger to People, Property, and the Environment

Somewhat drawing on thoughts provided in Shaw and Rosher (2016, pp. 320, 326–327) and Staff Writers (2015), the deployment of mega-constellations has the potential to marginally increase the danger to people on Earth (injury), people's property (damage), and the environment (pollution).

Each of the many launches has the potential to fail and to distribute hazardous material, which could result in injury, property damage, or environmental pollution.

Additionally, every launch emits potentially harmful and CO_2 increasing pollutants into the atmosphere.

De-orbiting and burning up of the many launcher parts and short-lived small satellites in the atmosphere can be considered a form of pollution. Parts that do not burn up have potential to injure people, cause property damage, and pollute the environment otherwise. Naturally, the higher the number of launches and small satellites per constellation, the higher the risk to people, property and the environment.

5 Managing the Issues

As stated previously, in many respects what is a positive for the national security of one nation is very likely to be negative for another. Therefore, in terms of managing the issues around mega-constellations, the approaches taken are less focused on enhancing the positives or minimizing the negatives; they are centered on the concept of the *responsible use of space*, i.e., promoting what would generally be perceived as reasonable behavior.

There are potentially significant strategic, legal, or standards-based approaches (e.g., no-go zones, or driving behavior through an internationally agreed view of the asset and liability obligations) that may have a role in the future. Indeed, there is some guidance already in place, which is pertinent to small satellite mega-constellations; the text below comes from ISO/CDC/20991 (as cited in: Cho and Graziani 2017, p. 31):

> This standard describes minimum requirements for small spacecraft.
>
> Small spacecraft may employ untraditional spacecraft development and management philosophy. These spacecraft projects are usually budget-limited or mass-limited, which makes a single (exclusive) launch unaffordable.
>
> The scope of this standard encompasses different categories of small spacecraft, so-called mini-, micro-, nano-, pico-, and femto-, as well as CubeSat spacecraft. Therefore, for the sake of convenience, the term “small spacecraft” is used throughout this document as a generic term. Regardless of the development philosophy, there are minimum requirements every spacecraft shall comply with. This standard explicitly states those requirements and also refers to existing applicable standards. In that sense, this standard serves as the top standard to cover the minimum requirements for various stages of small spacecraft system life-cycle with emphasis on design, launch, deployment, operation, and disposal phases. In this way, (1) safety, (2) harmlessness to co-passengers and launcher, and (3) debris mitigation are all assured.
>
> This standard is addressed to small spacecraft developers, as well as dispenser providers and the launch operators.

Verification was added to address the issue on how the requirements described above should be verified. ISO/CDC/20991, provides (as cited in: Cho and Graziani 2017, p. 33):

> 6 Verification
>
> Verification of compliance with requirements listed below shall be documented with sufficient precision and quality to allow review and approval by the appropriate authority.
>
> - Safety (5.2)
> - Main payload, adjacent payload(s), and launcher harmlessness (5.3)

- Debris mitigation (5.4)
- Use of radio frequencies (5.5)
- Testing related to safety, debris mitigation, and harmlessness to co-passengers and launcher (5.7)
- CubeSat (5.8)

The documentation regarding these verifications may be required by the launch operator to guarantee harmlessness to the main passenger or the co-passengers of the flight.

However, international space law and protocols are notoriously slow to implement, and the *problem* is here now. Therefore, a more tactical approach to mitigating the risks associated with mega-constellations is needed.

There are a number of technical solutions that can be implemented as characteristic of responsible use:

5.1 Situational Awareness

The ability to determine the location of a satellite at any time is critical to the safe operation of small satellite constellations, as with any space object. In the case of small satellite constellations that have limited or no maneuverability, the choice of orbit architecture has to balance the cumulative time a satellite can be observed by limited ground-based sensors and the area of the Earth it can cover over time. This balance will determine the optimal inclination and apogee of the orbit chosen.

Observation of the satellites by radio telescopes could be more ubiquitous as they will inevitably have radio frequency signatures from both electronic devices on-board and communication transmissions. These can provide highly accurate orbit observations (Finkleman 2013).

5.2 Collision Risk: Maneuverability

The ability to maneuver a satellite, combined with accurate situational awareness, will obviously reduce the risk of conjunctions. Such capability would require either propulsion or the use of aerodynamic characteristics. The mass limitations of many small satellites, such as small CubeSats, will not allow storage of chemical propellant on-board. A better alternative is electronic propulsion, but its use is limited by the lengthy period of continuous thrust that may be required. Such thrust is necessitated by the few hours within which satellite trajectories can be estimated.

There are other possible alternatives, such as catalysis of gas or fluid into high-pressured gaseous propellant, but these also add mass to the satellite. All these possibilities for maneuver are only really effective for small orbital or attitude corrections and not for conjunction avoidance (Finkleman 2013, p. 2).

5.3 Re-entry Risk

Spacecraft and launcher upper stages in LEO will deorbit naturally by orbital decay by the operation of drag and gravity at random and by uncontrolled re-entry.

They can also be deorbited in a controlled re-entry to a known location, using on-board propellant. A controlled re-entry would also require reliable on-board computer, attitude control, and other subsystems, which add to the cost of the space object.

To achieve the less costly uncontrolled re-entry within 25 years, as stipulated in current debris mitigation guidelines, the orbital perigee is lowered to an altitude that increases atmospheric drag. The re-entry location of an uncontrolled space object, necessarily at a shallow angle, can at best be predicted within a margin of ±2,740 km, due in part to uncertainty of atmospheric density at the time of re-entry.

In the absence of agreed international norms on risks posed by re-entry of space debris, there are varying national thresholds stipulated by some countries, but by no means all space active countries. For example, French law prohibits uncontrolled re-entries from January 2020. The USA has no proposal to change its existing acceptable risk threshold defined by NASA in 1997 of 1 in 10,000 per re-entry.

Although the re-entry risk associated with the light satellites in mega-constellation is small and would meet the US threshold. However, the increasing number of launches for the predicted mega-satellite constellations will result in a growing population of dead satellites and launch upper stages that would lead to many daily re-entries. These would escalate the risk of damage and injury on the ground, at sea and to flying aircraft, unless uncontrolled re-entry is banned or acceptable risk thresholds are internationally agreed and enforced. (Staff Writers 2015)

5.4 Regulatory, Legal, and Ethical Constraints

The growing capability and maneuverability of CubeSats in particular pose security, policy, and regulatory challenges for governments responsible for their authorization and supervision. The balance has to be struck between ensuring and managing security associated with the current and foreseen growth of the CubeSat market and mega-constellations while not unduly hampering the NewSpace market dynamic. The approaches, regulations, standards, and guidelines will inevitably be at the national level, although they need to be internationally harmonized to develop a shared framework (ESPI 2018, p. 2).

It has been argued that small satellite constellations do not and cannot meet current regulatory requirements, let alone as they might evolve and regulations develop. In addition there are a number of ethical and technical guidelines relating to satellites, without differentiating between small and large satellites. Clearly these will have to be refined and developed to be effective (Finkleman 2013, p. 5).

There can be little doubt that some international solution is needed to regulatory, legal, and ethical issues surrounding small satellites and mega-constellations. As mentioned previously, there is a critical balance to be struck, between making the activities safe for all and promoting the markets that will inevitably grow with the capabilities.

5.5 Liability Considerations

An indirect threat to a state's national security is its international liability (e.g., fault liability in orbit, and absolute liability on Earth) to damage caused by small satellite mega-constellations for which it bears liability under international law. Importantly, even if the constellation is operated by a private entity, the state bears the liability. The need for an understanding of the responsible use of these capabilities is paramount and could be exercised through a robust regulatory and licensing regime. However, what is acceptable *responsible* behavior for one nation may not be the same for another, so once again there is need for international norms.

An operator's mishandling of a mega-constellation can potentially wreak havoc to foreign operators' space objects in the same orbit(s). This can expose the state liable for the constellation to catastrophic losses and thus strain its financial stability, which in turn can affect its national security. Also, if the liable state is unwilling to pay up for any of the above, there is the potential for an international conflict.

6 Conclusion

The world does indeed face a dilemma with the emergence and proliferation of small satellite mega-constellations. The potential benefits to national security are very significant, particularly for those nations for whom the access to cost-effective space capability is new. But even for the traditional space-faring nations, there are very considerable national security advantages associated with the exploitation of small satellite mega-constellations. These include: intelligence, SIGINT, bandwidth, navigation, timing, ASAT, the ability to rapidly upgrade and reconstitute space capabilities or enhance the resilience of space systems. These are all potentially significant national security positives, for some nations, transformational.

But all these potential benefits come with some risks to national security: potentially increased orbital congestion, overcrowded radio frequencies, and the danger to people, property, and the environment.

It is fair to say that one nation's benefit could well be another nation's threat or risk, so the dynamic of the impact of small satellite mega-constellations on national security is not straight forward. It is clear that to optimize the benefits and mitigate the risks, both must be managed, ideally internationally. It is likely that any legal or regulatory approach at the international level could well take considerable time to agree and implement, which points to national solutions in the short-term, perhaps based on the concept of *responsible use of space*.

While this chapter is intended to provide some food for thought, it would be odd not to offer some concluding remark. Small satellite mega-constellations are here now, and the subsector is only destined to grow. Are they a good thing? They do offer much, particularly in the realms of national security in its widest sense. However, it is necessary to exercise caution, if only to ensure that the commercial opportunities can be realized, and the potential benefits to national security are delivered.

Small Satellites, Hosted Payloads, Dual Use, and Strategic Space Services

Joseph N. Pelton

Contents

Abstract

The concept of dual use of and hosted payloads on commercial satellites for strategic or defense-related service requirements developed relatively early in space age. The Intelsat II satellite was deployed for the prime purpose of meeting NASA tracking, telemetry, and command needs associated with the Project Gemini mission in the late 1960s. The Marisat program in the 1970s, as funded by the US Navy, was perhaps the first instance of a hosted payload where a satellite deployed both commercial and defense related payloads at the same time. The design and deployment of small commercial satellites in low Earth orbit (LEO) by Iridium, Globalstar, and Orbcomm were strongly supported by military

programs that saw the opportunity to use small satellite constellations to meet strategic communications needs of remotely deployed personnel. Indeed there have been ongoing instances where commercial satellites, small, medium, and large, as well as hosted payloads, have been employed in a dual use mode to meet defense-related needs and strategic governmental purposes. This has been true in past decades and seems likely to continue for the future.

This chapter reviews some of the history associated with the use of small satellites and hosted-payload systems to meet strategic needs both via dedicated and dual use systems. These needs have included: (i) tactical, strategic, and routine telecommunications and networking services; (ii) support for tracking, telemetry, and command; (iii) remote sensing and surveillance; (iv) weather monitoring and real-time updates on both Earth and space weather conditions; (v) monitoring services related to aircraft safety and aircraft operations; and (vi) registering instances of nuclear device testing.

Going forward strategic use of space might be in some senses reimagined. Strategic analyses have noted that some of the challenges of the future may relate to shortages of strategic resources such as water, depletion of aquifers, or other consequences of climate change. Thus, deployment of satellites for future strategic needs might be associated with monitoring climate change, international peacekeeping or international law enforcement associated with resource shortages, etc. As global population and urbanization grows, desertification and water shortages, and concerns with illegal migration or international law enforcement increase over time, there may be new missions for space system usage in a broader definition of military and defense activities. These aspects will also be briefly discussed in this chapter.

Financial oversight organizations have consistently suggested that cost savings can be achieved by using commercial networks on a "dual use" basis to meet many of the needs of defense-related organizations and that this has seemed to be particularly true with regard to the use of small satellite systems and in the case of hosted-payload or "piggyback" systems where particular economies are possible.

This chapter seeks to review the past history of instances where dedicated or dual use small satellites or hosted payloads have been used to meet security and defense-related service needs and also to explore the future trends with regard to the more effective ways to use smallsats and hosted payloads to meet security needs in coming years. These future opportunities will be assessed in terms of costs and possible cost reductions, ability to respond quickly to service needs, and reliability and resilience of the space-based services that are needed.

1 Introduction

There has been a long-term cooperative relationship between security and defense-related agencies and high-tech companies. This relationship was strengthened when the "aerospace and defense industries" worked closely with military units to develop new aircraft, weapon systems, and the atomic bomb. The significance of the so-called military-industrial complex was emphasized by President Eisenhower as he left office in 1961. In his famous farewell address President Eisenhower said: "...We have been compelled to create a permanent armaments industry of vast proportions. This conjunction of an immense military establishment and a large arms industry is new to the American experience." He noted that this partnership, born of World War II challenge, was a great new capability but also a strong new alliance that must also be seen as a cause of potential concern. He noted that this capability could produce new capabilities that could be used for peace but also for warlike aggression alike (President Dwight D. Eisenhower's Farewell Address 1961).

In early 1960s, the space race between the United States and the Soviet Union had become an issue of prime strategic focus. The development of missile weapons systems and civilian space programs were seen as closely allied enterprises. The objective set by President Kennedy of the United States to send and return an astronaut to the Moon by the end of the decade was set in the strategic context of a "Cold War" contest between the United States and the USSR (Logsdon 1970). Likewise the initiative to create a global satellite system as also called for by President Kennedy in early 1961 in a speech to the United Nation was an effort to use space applications as yet another way to showcase US technology in the space applications domain (Pelton 1974).

The US military sought to deploy satellite technology to provide secure global telecommunications with the deployment of the Initial Defense Satellite Communications System (IDSCS) in 1965 as a small satellite constellation low Earth orbit (LEO) with random spacing. This type of system, however, was not continued when the Syncom 2 and 3 satellites followed by Intelsat I (i.e., Early Bird) showed in a convincing manner that GEO systems were sustainable and operational viable.

The shift to GEO systems and increasingly larger and complex satellites in general was adopted not only by the US military systems but also by other charged with security responsibilities in Europe, India, China, Canada, Japan, and the USSR/Russia. This did not mean that interest in smaller satellites was dropped. Further, military and security-monitoring organizations also recognized that the concept of hosted payloads on satellites of all sizes opened up another option. Hosted payloads could be used to test new technologies and system capabilities or to create a complete new capability if deployed on a global constellation.

These various ways that have been employed to use small satellites or hosted payloads are reviewed below. These instances are now quite numerous and going forward are likely to increase in number. The US General Accounting Office published a report with regard to the placing of hosted payloads on commercial satellites since 2009 and included several planned through 2022. Its independent conclusion with regard to this approach in the case of the US military was as follows: "The GAO and others have found that using commercial satellites to host government sensors or communications packages – called payloads – may be one way DOD can achieve on-orbit capability faster and more affordably. Using hosted payloads may also help facilitate a proliferation of payloads on orbit, making it more difficult for an adversary to defeat a capability. . .DOD estimates that it has achieved cost savings of several hundred million dollars from using commercially hosted payloads to date, and expects to realize additional savings and deliver faster capabilities on orbit from planned missions" (U.S. Governmental Accounting Office 2018).

Cost savings are not restricted just to "hosted payload" systems. The development and use of dedicated small satellite projects – both as specific missions and larger-scale constellations –can also provide cost economies to security-focused activities. Of the six applications listed in the abstract and perhaps more, the use of small satellite systems can help to lower costs. These cost savings can come from: (i) new designs such as using miniaturized components, (ii) new construction techniques (i. e., additive manufacturing), (iii) use of standardized and sometimes off-the-shelf components, (iv) use of new launch technology (i.e., reusable first stage launchers), or (v) use of new digital or smart software that allows smaller spacecraft to accomplish new functions or services such as video streaming; improved synthetic aperture radar sensing; or three-dimensional terrain mapping.

2 Transition from GEO-Based Satellites for Defense and Security-Related Services to Smallsats

For many years one of the larger applications for dual use of larger-scale GEO satellites, at least in terms of revenues, was for television entertainment distribution. Most of such video distribution activities were not strategic in nature. These satellite telecommunications that relay functions for defense agencies have included such activities as distribution of sports and entertainment television and radio programming, or personal communications between troops and family. Yet such activities were still clearly in support of defense-related missions such as overseas deployment of troops and troop morale. In the future it is possible that some of the new large-scale networking constellations, and projects such as the Karousel elliptical orbital system, that seek to provide video streaming might meet such security or defense-related service needs on a 'dual use' basis.

The existing ground system configurations, however, may well serve as a key reason as to why these video-related services might largely remain the preserve of large-scale geosynchronous satellites for a number of years to come. In a number of cases it will be the cost and configuration of ground systems that will dictate which types of satellites provide which types of services for a number of years to come. In general, the cost of flat panel antennas with electronic beam forming and the rate at which the cost of these systems fall will be a strong factor of small satellite constellation success in many markets – commercial, governmental, and defense-related alike.

3 Security and Defense-Forces Deployment of Hosted Payload Small Satellite Programs

There are a number of instances where US DOD defense-related projects have gone forward or are now in planning or active construction. These projects have served to a test of key new space technology concepts. On November 23, 2009, the IRIS (Internet Routing in Space), as designed and fabricated by CISCO Systems, was launched on-board the Intelsat 14 satellite. This piggyback mission was to test the feasibility of high-speed on-board processing and routing of signals in space. This successful test led to the conclusion that the ground segment for DOD telecommunications and networking satellite networks could be simplified and thus deployed at much less cost without losing network capability (Brinton 2009) (Fig. 1).

Perhaps the other end of a hosted payload-type project for defense purposes from the IRIS one-off technology feasibility test is the DOD REACH system. This is the Responsive Environmental Assessment Commercially Hosted (REACH) program that involves the installing of over 30 dosimeter instruments on a number of different

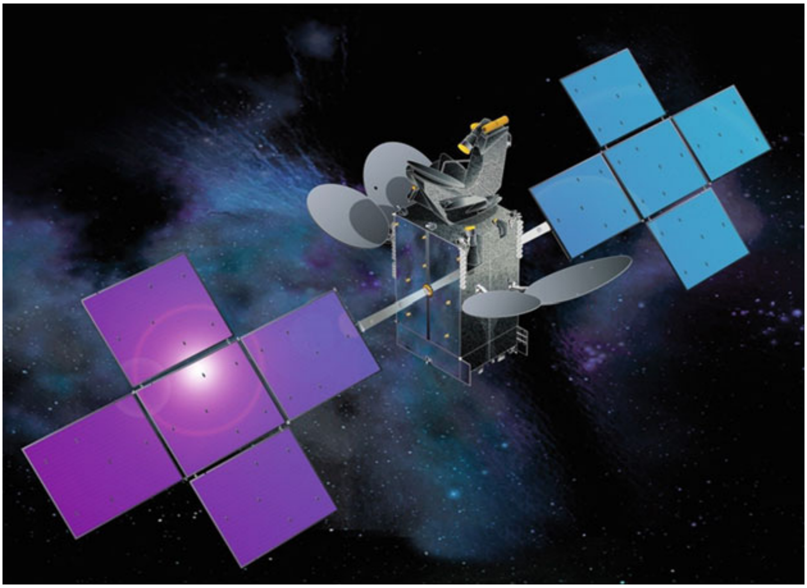

Fig. 1 The Intelsat 14 satellite with hosted payload IRIS router aboard (see gold and black units). (Graphic courtesy of Intelsat)

commercial satellites to create a systematic monitoring of space radiation. These instruments that were inserted in a number of different commercially deployed LEO satellites each had two dosimeters of differing sensitivities to detect radiation from space weather or from a nuclear explosion that released radiation.

This configuration was not to test a new technology, but rather an operational system to detect radiation from a global perspective. This system was designed to detect radiation from a coronal mass ejection from the sun, a nuclear explosion, or even cosmic radiation (Mazur et al. 2017).

Independent assessment of the implementation of the REACH program on-board commercial systems rather than as stand-alone networks found that it was deployed at an estimated cost savings of $230 million. The additional finding was that the system was able to be deployed in a more rapid manner due to the use of a variety of LEO-deployed commercial satellites to carry these REACH instruments. Although it was not a part of this assessment, it is also clear that the use of piggy-backed instruments, rather than deploying them as free flyers, also reduced the space debris concerns when these instruments reached their end of life (U.S. Governmental Accounting Office 2018).

Yet another payload arrangement has been used in the GEO-based MUOS network for mobile communications deployed by the US Navy for naval and other DOD net-centric mobile operations. In this case there is a UHF-legacy package that flies on the MUOS satellites. The MUOS system has 16 times greater throughput capability than the original UHF satellite system and will eventually replace the UHF Satellites. These MUOS satellite carry a small “legacy” payload that will provide UHF telecom service until the old narrow band UHF SATCOM system is entirely phased out (U.S. Navy Program Executive Office 2016).

4 Dedicated Small Satellite Programs for Defense and Security-Related Programs

Clearly the US DOD is still heavily focused on large GEO networks. Although it has supplemented its mobile capabilities through dual use of the Iridium and Globalstar systems, its legacy, SATCOM UHF and MUOS (Mobile User Objective System), is based on GEOS networks with large deployable multi-beam antennas.

Although the US Department of Defense has been funding in the last few years, i. e., since 2017, commercial efforts to develop small launcher capabilities, it has been slow to develop specific programs for dedicated small satellite networks. There have been few dedicated smallsat projects undertaken or even started. Instead, there have only been the hosted payload projects such as the REACH network, and the legacy UHF payloads on the MUOS satellites.

In the US 2019 budget there was a new line item that includes $47.6 million procurement funding line for the procurement of smaller capacity launchers that can lift up to a capacity of 3636 kg (or up to 8000 pounds). This is for the so-called Rocket Systems Launch Program and would cover both LEO up to GEO launches.

Fig. 2 The Vector Smallsat Launcher designed for rapid deployment from flexible launch locations. (Graphic courtesy of Vector Launch, Inc.)

Presumably this would be for rapid deployment capabilities and for a variety of small satellite launch requirements (Erwin 2018a).

Under the DOD small launch vehicle program the idea has been to fund perhaps two launcher programs. This is a difficult activity to decide since there are now on the order of 150 small launcher development programs vying for support. There are several front runners such as Vector, Virgin Orbit, and Rocket Labs who have been mentioned as lead candidates. The truly unsolved mystery is what payloads are to be launched and whether these will be for LEO constellations or GEO-based missions – or perhaps both (Hitchens 2019) (Fig. 2).

The US Defense Advanced Research Projects Agency (DARPA), however, has an active R&D effort known as “Blackjack.” The purpose of this program would be to create a series of “interchangeable payloads.” The apparent objective under the R&D program would be to develop a series of “commodity-like” set of different payloads that would be capable of being “plugged into” a common bus. The process has been likened to developing common payloads which could be “snapped” into a common satellite bus very much like “Lego” units. This would eliminate the need to create different small satellite buses over and over again. There have been reports that the Air Force might seek to transfer the findings from the Blackjack R&D into actually implementation. This US Air Force project is currently called CASINO (Commercially Augmented Space Inter Networked Operation). The funding for this program is currently not authorized by Congress (Paul “Rusty” Thomas 2019).

In 2018 the US Army Space and Missile Defense Command (SMDC) took two actions on the small satellite front. On the one hand, they cancelled the Kestrel Eye small satellite experiment. This was a $2 million project which had been ongoing for a couple of years. Its objective had been to test the feasibility of a dedicated network of LEO smallsats that would be able to provide tactical communications to ground troops. There was no explicit reason provided for the cancellation of this test program.

The Army Command however in close proximity announced that they had selected Dynetics as the contractor that would be developing two new small satellites for a classified program known as Gunsmoke-L. The purpose of this $.3 million project was to develop two small tactical spacecraft that would operate in low Earth orbit for at least 2 years and would be used to support tactical operations of the Army in an unspecified manner (Erwin 2018b).

There are many unknowns at this point in terms of small satellite launcher firms that will play a leading role, the types of satellites, missions, and orbits that will be pursued in the new US space initiatives that have been announced under new initiatives that have been various described as a "US Space Force" or new "US Space Command" or "SPACECOM" which has been described as a new capability "to defend America's vital interests in space." This so-called Space Command – one of 11 specific commands – would presumably take the place of the so-called Space Force that had originally been backed by President Trump. Until the mission, objectives, and strategies of the US SPACECOM are better defined, the plan for expanded use of dedicated smallsats and expanded use of lower cost and smaller cost launchers of small satellites will likely remain somewhat nebulous (Howell 2019).

Further this uncertainty will also likely impact the future planning and space security programs of other space powers such as China, Russia, Japan, Europe, and other countries such as Israel, Iran, and North Korea. The uncertainty created by the US efforts in the arena of space security and space defense was one of the top areas of discussion and concern at the European Space Policy Institute's annual conference in Vienna, Austria.

There has been a broadly based international effort to define a common global terminology with regard to space security matters and military uses of outer space that began in May 2016 known as Milamos. This effort was undertaken to create a "Manual on International Law Applicable to the Military uses of Outer Space (Milamos)" and especially issues related to possible space hostilities. The purpose of this project is as follows: "Such a manual will clarify the limitations international law places on the threat or use of force in outer space. It aims to look at how, against the backdrop of rapidly developing technologies and applications, what military uses and objects are considered lawful or outrightly prohibited in outer space" (Manual on International Law Applicable to the uses of Outer Space (MILAMOS) 2016a). This effort is financially backed by the Canadian Government and involving space lawyers from a wide range of universities around the world. Participating institutions are McGill University, St. Thomas University, the University of Cologne, Beijing Institute of Technology, St. Petersburg State University, Institute of Defense Studies and Analysis, Western Sydney University, and the Secure World Foundation (Manual on International Law Applicable to the uses of Outer Space (MILAMOS) 2016b).

This effort is known as the Milamos project and it has tried to confirm the peaceful uses of outer space patterns under existing international law and international treaties and conventions that have been approved by the international community of nations ever since the "Declaration of Legal Principles Governing the Activities of States in the Exploration and Use of Outer Space," which had been adopted by the General Assembly in its resolution 1962 (XVIII) in 1963. This was followed by the adoption and entry into effect of the Outer Space Treaty of 1967 known formally as the "Treaty on Principles Governing the Activities of States in the Exploration and Use of Outer Space, including the Moon and Other Celestial Bodies" (UN Office of Outer Space Affairs 1967).

It is still too early to know the practical effects of new initiatives in military space. The new US Strategic Command for Space appears to suggest that there will be a more confrontation environment. On the other hand, the international Milamos effort to create a new international manual to address international law provisions and terminology seeks to minimize confrontation and spell out more clearly what the "rules of road" for outer space, especially in Earth orbit, actually are today.

5 Fast Deployment Concepts

The idea of being able to deploy special capability to provide telecommunications and networking capacity to a particular area where hostilities might occur over land or littoral locations has been suggested as a need that might occur when a war or armed confrontation breaks out where limited communications or other services are in very short supply. The original context was that a GEO satellite might be ready to be quickly deployed on a separate launch operation on demand and with minimal delay.

The development of new small satellite technology and rapid availability of small satellite launchers that can be quickly be configured for virtually instance deployment has advanced the feasibility of such a concept. Other requirements for radiation detection instrumentation, surveillance systems, or other applications could be designed as rapid deployment space systems. The problem is that most rapid deployment systems would make sense as GEO-sat systems because these systems provide coverage of up to 40% of the Earth's surface, while LEO and MEO systems require a good sized configuration to provide wide area coverage.

The development of new smaller launch vehicles that can be quickly deployed and virtually instantly launched would seem to be the major advancement in this area. It is still not clear how significant this type of capability might be and when this type of rapid deployment capability might actually be used to respond to future strategic needs.

6 Use of Commercial Small Satellite Programs for Dual Use Services

The history of space applications and services in the domain of military defense and national and regional security systems suggests that the military and defense-related aspects of outer space have continued to expand. Strategic concerns about the space domain are expanding due to new technology and applications related to system systems. A part of the concern and strategic “confusion” arises from the expansion of “dual use” applications of commercial systems and a rising number of hosted payloads wherein military and defense-related capability are added to civil governmental or commercial space systems.

There is currently a significant use of commercial mobile communications as a backup, supplement, or even primary mode of mobile communications to support military purposes. Thus the Inmarsat system is used for mobile communications on the move as well as service to Inmarsat I phones in support of strategic mobile services in Europe. The Globalstar OG2 and Iridium Next LEO-based networks are still heavily relied on for various forms of voice and data communications by US defense networks even though the deployment of the MUOS system has lessened these requirements to some extent. The latest generations of these satellites are now at the upper limits of what can be considered to be minisatellites. Further the Aireon system on the Iridium Next is also of assistance in military air navigation capabilities as well (see Fig. 3).

Even the Thuraya GEO-system for mobile satellite services is relied on by some defense units. The Inmarsat and Thuraya commercial systems can provide higher data rate services, but the Globalstar and Iridium services can provide mobile voice and data services with greater reliability at the higher latitude regions of the world.

The other key dual use issues as posed by small satellite constellations in terms of strategic and defense related applications are the large number of new Mega-Leo systems now being deployed or planned for launch within the next 5 years. These present both potential opportunities and potential concerns. Many dozens of new these new systems are being deployed for broadband communications and networking, for optical and radar remote sensing, and some totally new uses such as

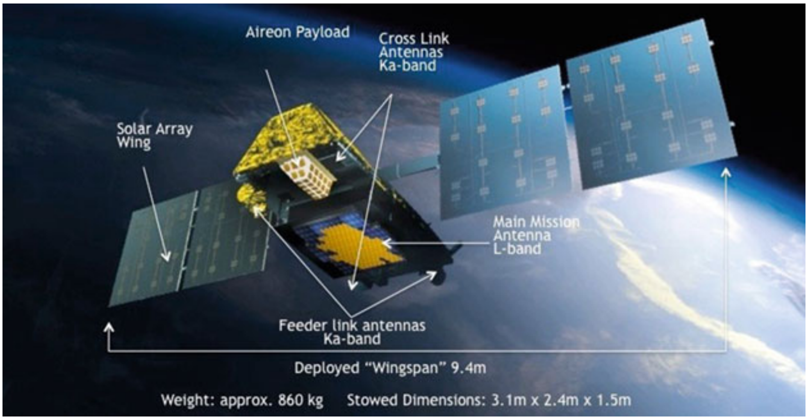

Fig. 3 The Iridium next generation of mobile satellites is still used to provide dual use military mobile communications to several nations. (Graphic courtesy of Iridium)

commercial data relay from LEO to GEO satellite or MEO satellites or RF Geolocation. It is entirely possible that defense and military applications will be found for many of these new networks. The deployment of so many of these satellites, however, also poses risks of satellite collisions and thus danger to military satellite networks.

Many of these new LEO-based systems will provide greatly expanded coverage and remote area services that are not available with existing GEO networks. The ability of the broadband Mega-LEO networking satellite systems to provide interconnection via low-cost Wi-Fi networking services in rural and remote area might offer dual use capabilities that might prove of significant value to future defense-related needs.

There are also clear value that the data relay and machine-to-machine (M2M0) commercial systems can provide for dual use in such areas as automatic identification services (AIS), for Internet of Things (IoTs) data relay, and other forms of data relay associated with mobile platforms, vehicles, and ships. Systems like Orbcomm, Spire, exactEarth, and others offer AIC, M2M, and IoT data and more that will likely find a variety of dual use applications. Some of the new systems such as exactEarth provide significant economies for vital data that can pay for the service simply by such measures as fuel savings for ships that can be steered much more efficiently from port to port or avoidance of dangerous storms at sea (see Fig. 4).

The ability of some of these systems, particularly those operating MEO systems that might provide new dual use options for offering video streaming service needs, could also offer new options for providing sports and video entertainment to overseas troops or other dual use needs such as support for UAV systems carrying out remote surveillance service needs. In short, these new LEO and MEO system potentially offer many dual use opportunities and new cost efficiencies.

Fig. 4 There are dual use opportunities from smallsat systems like the exactEarth small satellites as pictured below. (Graphic courtesy of exactEarth)

7 Extremely Small Satellites for Strategic or Defense-Related Needs

Most of the dual use applications of commercial small satellite systems that have been discussed above are geared to wide area coverages on a regional or global basis, since satellite altitudes offer the advantage of wide coverage as one of their prime advantages. There are however other types of applications that can be pursued in the case of the very smallest of satellites such as femtosats, chipsats, picosat, pocketqubes, and cubesats. In the case of field effects such as radiation or changes to the Earth's magnetosphere, coronal mass ejection storms hitting the Earth's atmosphere, it might be very useful to have a cluster of something like chipsats, femtosats, etc., to fly into an area in proximity to a mother ship. This could allow a group of these smallest of satellites to collect data and to report data back to a central satellite that can relay data back to Earth.

There are also conceptual studies of creating a virtual antenna system that is created by a large collection of picosat electronic units that can be combined together to create a large-scale "virtual electronic" transmitting and receiving system. This type of architecture might allow the creation in space of new types of antennas that are no longer "dishes" or even solid structures but simply a cluster that is shaped by electromagnetic forces. This might be used for interplanetary communications or other future scientific or strategic purposes (Iida et al. 2003).

8 The Smallsat Advantage for Defense and Security Services

The expansion of the military and defense establishment into the small satellite has understandably been a slow, cautious, and deliberate process. The first steps have been through the installation of hosted payloads on to commercial platforms, the use of small satellite projects to test new technology and to carry out experimental projects, and to exploit commercial small satellite via dual use applications starting with mobile satellite services. This experience has been generally favorable.

Independent assessments of these uses of small satellite systems, technologies, hosted payloads, and experimental projects have suggested that reduced costs have been achieved, program objectives were effectively met, and projects were generally advanced over being carried out through dedicated defense, military, or especially designed security systems.

The current conditions seem to indicate that the next step appears to be to move into dedicated small satellite constellations. The DARPA Blackjack, the Army Casino initiative, and the Gunsmoke-L initiatives will likely help to define new dedicated projects and full-fledged constellations. This does not mean a rapid shift away from large-scale GEO-based systems and MEO-based networks such as the Global Positioning System (GPS). Rather it suggests a more balanced and agile combination of types and sizes of satellite systems. In general, it seems likely that European defense initiatives will build on the experience gained by Air Bus and

Thales Alenia in building a significant number of LEO-based systems to meet future strategic and military systems with a reliance on dual use systems as well.

9 Space Satellite Constellations to Meet Strategic Space Concerns of the Future

The military, defense, and strategic uses of outer space are often used interchangeably to refer to space systems for national and regional defense. These systems might be used to support surveillance, telecommunications, networking, or broadcasting services of a tactical or operational basis, weather monitoring, navigation, targeting or guidance, monitoring the skies for enemy attack, or assessing radiation or other signs of the use of weapons of mass destruction. There have been studies of future trends that suggest that in future the results of climate change, particularly water shortages, desertification, and resulting patterns of migration could become strategic and national defense-related issues.

The ability of satellites today to support positive developments such as the meeting of the UN Sustainable Development Goals (SDGs) may tomorrow also be used strategically to monitor scarce resources, or to monitor key aspects of climate change in a strategic sense of the word. Strategies that can be used today to cope with climate change in a sustainable way might become increasingly important. Small satellite constellations equipped for Earth observation, data analytics, water conservation, and sustainable urban planning and operated as commercial or civil governmental space agency operations may become increasingly important in a strategic sense in coming decades.

10 Conclusion

The future of military and defense-related satellite systems is at strategic point where a number of key decisions will need to be made. These decisions will largely hinge on whether to continue to focus primarily on a space infrastructure investment program that is concentrated on large, sophisticated GEO-based systems for telecommunications, networking, surveillance, and meteorological systems and high MEO GPS systems or to diversify more into the accelerated use of various forms of small satellite systems.

Part X

Key New Uses of Smallsats to Meet Social and Economic Needs

Small Satellites and New Global Opportunities in Education and Health Care

Joseph N. Pelton

Contents

Abstract

The advent of satellite communications has opened new doors to health and education services around the world. This has been true from the very earliest day of the space age – particularly in rural and remote areas of the world but also all across the world. As satellite communications system became more powerful and capable, this enabled the use of smaller and less costly ground antenna systems that required much less power. This extended the global footprint of where satellite services – including those for tele-education and tele-health services – could be delivered.

This expanded ability to deliver satellite services, even into rural and remote areas, enabled the creation of satellite-based health care and schooling in many areas of the world where such services were limited or even totally lacking. The latest evolution in the satellite industry now involves innovations in the field of

small satellite systems. One of the objectives for these small satellite constellations is for them to be designed, built, tested, and deployed at significantly lower cost.

A further objective is to operate such low Earth orbit constellation with minimal transmission delay and thus optimize them to provide Internet-based services to rural and remote areas, perhaps more efficiently than GEO-based satellite networks. Such new abilities to offer broadband Internet-based services with minimal transmission delay are thought to allow new options. Prime among these options are a wide variety of new satellite-based health and education services that opens the door to such offerings being much more widely. Indeed the aspiration is to provide expanded services to billions of now unserved or underserved populations – especially in Africa, South and Central America, Asia, and the South Pacific – and perhaps even expand rural and remote populations in economically developed countries wherever they might live. There is a long history, now longer than over 40 years, of using satellites to provide rural and remote health and educational services. This article will review some of this history and explore the potential of new large-scale low Earth orbit satellite networks being equipped to extend these tele-education and tele-health services even further.

Broadband services · Digital divide · Flat panel antennas · Internet service provider · Geosynchronous Earth orbit (GEO) · Low Earth orbit (LEO) · Medium Earth orbit (MEO) · Photovoltaic · Small satellite constellations · Solar power and battery systems · Tele-education · Tele-health · Virtual private networks (VPNs) · Wi-Fi systems · Wide area networks

1 Introduction

The great advantage of satellite communication technology has always been its ability to provide very broad coverage of the world and especially to connect to rural, remote, and island areas. The initial geosynchronous Earth orbit (GEO)-based satellite systems, from the first, were well suited first to providing television distribution services and coverage to remote areas. As satellite technology and systems became more powerful and capable, these networks also became enabled to provide direct broadcast television and broadcast radio service. Although the commercial market for broadband GEO satellites has been largely supported by the demand for entertainment, news, and sports-related services, there has been, in parallel, a significant use of these satellites for health, education, and training purposes. With the birth and expansion of Internet-based services, however, there has been a shift toward the use of interactive health and education services via networked services, especially via the Internet, that have often used terrestrial cable and wireless services. In a number of cases, this has led to a transition off of satellite networks and on to Internet-based or networked streaming services.

GEO satellites have sought to respond to the challenge of providing streamed network services and multi-casting-based operation. These attempts to optimize GEO satellite systems to offer networked services have included “spoofing” and new standards to compensate for transmission delays and the creation of virtual private networks. This has, in particular, led to the development of so-called Internet Protocol over Satellite (IPoS) standards. These have included IA Standard 1008, IPoS, November 2003, and TSI Standard TS 102354, TSS-B, January 2005. These standards for providing IPoS via GEO orbit satellites have allowed the following adjustments to occur for more efficient provision of networked services (Hughes Network Systems (HNS) briefing at Intelsat Headquarters):

- Increase window size so that latency is not confused with system congestion and thus force a resort to slow recovery.
- Provide “spoofing” so that each transmission leg is optimized.
- Operate under the IETF-recommended “DiffServ” mode of operation with per-hop behavior (PHB) optimization.
- Flags are generated so that new headers can be correctly read.
- Cope with IP Sec (Internet Protocol Security) processes in virtual private networks (VPNs).

Despire these efforts to GEO satellites for networked services, limitations still remain. This is a particular problem where the flow of data is not highly assymetrical and especially where there is continuing flow of information in both directions and at higher data rates. Indeed in many cases, GEO satellite systems operations in rural and remote areas have been designed to broadcast broadband services on the downlink and then use terrestrial networks for narrower-band return link services.

But the newer MEO and LEO satellite constellations that have been deployed, starting with Iridium and Globalstar, and more recently with the O3b medium Earth orbit (MEO) constellation, have been optimized for networking services. It is the aspiration of the new LEO-based constellation such as OneWeb and a number of other large constellations of small satellites to be better equipped to provide networked services and especially to support Internet-based services. Nevertheless GEO-based systems such as Intelsat, ViaSat, EchoStar/HNS Jupiter services, etc. continue to offer a range of networked services in both developed and developing regions of the world using the optimized standards noted above.

What is indisputable is that these new LEO and MEO systems are much closer to Earth and have much lesser transmission delay. Thus, in some ways, these constellations are better suited to data networking. In fact, in some of the lowest altitude of these systems, such as Starlink by SpaceX, transmission latency is equivalent to or better than terrestrial fiber-optic networks. These systems are thus well suited to providing broadband interactive services to support the latest forms of networked health and educational services designed explicitly to operate via the Internet.

In light of the already rich history of satellite-based tele-education and tele-health services via GEO satellites, there are high hopes with regard to the future use of small satellite constellations in this way. The aspiration is to use these new LEO constellations to provide the newest and latest forms of streaming and networked services for health and education purposes. It may well be that it is really not the technical and operational capabilities that are the main issue but rather financial, social, and regulatory issues that might represent the largest obstacles to this expanded usage.

Nevertheless this article will examine the degree to which LEO and MEO constellations are well suited to provide extended technical and service capabilities via networked delivery systems hosted on the Internet. It will explore the unmet needs of the estimated three and half billion people who now have limited or no access to the Internet.

This in turn results in limited access to health, education, and training services in their remote or isolated communities since so much of these resources are now only accessible via the Internet. It is some of the largest providers of access to the Internet globally who are pushing to extend Internet access to the billions of unserved peoples. Thus these backers are companies like Google, Amazon, and Facebook as well as banking institutions, broadcasters, and a wide range of other commercial enterprises who operate primarily via networked services. Yet, beyond these commercial interests, there are others who see the opportunities for providing vital social and civic services in a more effective and cost-efficient manner ("Broadband for the Next Billion" n.d.).

This extension of the digital network via LEO constellations to serve all the 7.8 billion habitants of the planet will help to reduce the "digital divide." It extends a whole new range of education, training, and health services to underserved regions of Africa, Asia, Central and South America, and the South Pacific.

The expanded capacity that these smallsat constellations provide is some sense being deployed at a critical time to meet growing unmet needed in education and health care. Some estimates suggest that the billions of students to be educated within the next three decades are equivalent to all the students up to this point in history. These estimates are based on the growth of global population, the rise of so-called megacities, and the extension of education and health-care services to an expanding range of people that will come with expanded communications and networking. These projections are based on estimates of nine billion people on Earth by 2050. The astonishing growth of world population is shown in Fig. 1.

The requirements of these various services are different in many ways, and thus health-care-based services, educational services, and training services will be broken down to examine what some of the technical differences that apply. This analysis will also explore some of the practical and operational service requirements that will need to be met to serve the needs of these underserved populations.

2 Historical Background

The use of satellite transmission to support medical and health systems, education, and training links back to the first commercial satellite services. One of the early television satellite broadcasts featured Dr. Michael Debakey, while performing a heart transplant in South Africa, sharing his procedures with doctors in the United States and Europe (Pelton and Alper 1986). The world's first truly global television

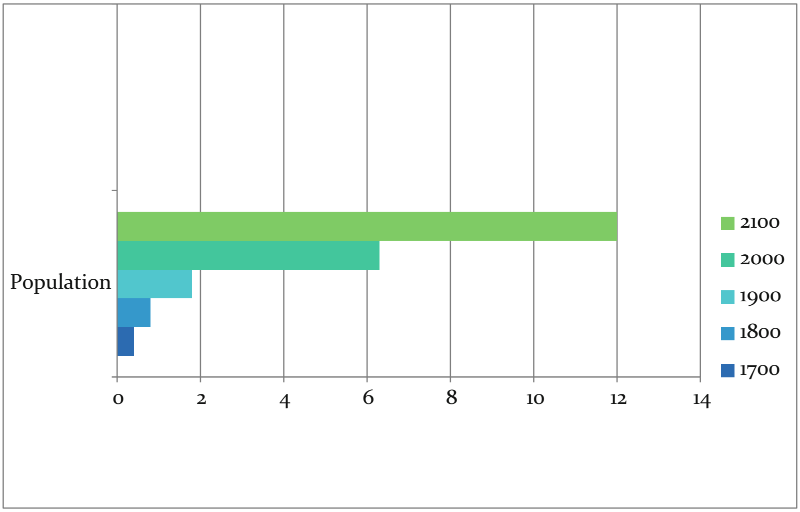

Fig. 1 The growth of human population since 1700 and projections through 2100. (Graphic prepared by Dr. Joseph N. Pelton. All Rights Reserved. Licensed for use by Author)

broadcast via Intelsat III satellites over the Atlantic, Indian, and Pacific Oceans was the coverage of the first landing of astronauts on the Moon in July 1969 a half century ago. This was not only a news event, but it was also a global educational event. Three Intelsat III satellites provided a worldwide "live" audience of over 500 million people an understanding of the technology that was involved and knowledge of how an Intelsat satellite had been moved from the Pacific Ocean to the Indian Ocean a little over a week before to create a truly global satellite network (Teitel n.d.) (See Fig. 2).

In the 1970s the Intelsat system began to provide not only international services, but it also began to lease transponders to countries to allow them to create national satellite networks beginning with Algeria in Africa. This network in Algeria connected with live telephone, data, and television services over a dozen regional capitals with telephone and data services during the day and television programming after 5:00 pm. This television service included news, entertainment, and educational programming. The harsh Saharan desert conditions had not allowed this type of telecommunications services using terrestrial connections. This new system allowed the transmission of educational television and public health messages. After the Algerian domestic network was established, over 70 domestic satellite systems were established around the world (Joseph 1986).

On the occasion of Intelsat's 20th anniversary, it was agreed to create what was known as Project SHARE. In this case SHARE stood for Satellite Health and Rural Education. An international advisory committee was established, and a joint cooperative agreement was established between Intelsat and the International Institute for Communication (IIC) in London that was signed to help administer the program. Under this program over 50 different programs were carried out to use Intelsat satellites, free of charge, to provide national or international television projects for

Fig. 2 Neil Armstrong descending from the Lunar Excursion Module Eagle 1 in July 1969. (Image courtesy of NASA)

educational and/or health-related programs. One of these projects included creating a Chinese National Educational Television University in 1985, 1986, and 1987. This project started with dozens of small terminals deployed in rural areas that were connected to an Intelsat satellite to provide educational and health-related programming (See Fig. 2). The programming for this network was developed by Central China Television and the Ministry of Education. When this system was transferred to a domestic ChinaSat network, this program ultimately grew to 90,000 very small aperture terminals serving 10 million students (Pelton and Marshall 2019) (see Fig. 3).

In another project there was a televised program of the world's leading doctors with expert knowledge of AIDS that was shared with 60,000 doctors and medical caregivers in Africa, Europe, North America, and South and Central America to advise this large audience the latest in research knowledge about this disease, its prevention, and treatment. And the Intelsat Project SHARE activity was just one of many such programs.

In India there were experiments with NASA's ATS-6 satellite that were successful in delivering educational and health-related programming to rural and remote communities. This led to the current INSAT educational satellite program that is delivering health and educational services to over one million students. In addition to the satellite programs in China and India, there are dozens of other programs. The Indonesia satellite program with Indosat was one of the earliest and was innovative in that it combined commercial service sites for oil, mining, or other industrial activities with earth station connections to serve education, health, and community needs (Satellite Television in Indonesia n.d.). Other significant programs can be

Fig. 3 The distribution of satellite TVRO terminals for Project SHARE tests sponsored by Intelsat. (Graphic courtesy of Joseph N. Pelton, Director of Project SHARE)

found in Mexico with Satmex, Nigeria, Malaysia, Brazil, The University of the South Pacific, the University of the Caribbean, Canada, and the United States plus a number of programs transmitted via the Arabsat network that supports services in a number of Middle Eastern countries programs.

In the last few decades, there have been many innovations in satellite-delivered public education at the primary and secondary levels, in college degree programs, as well as in medical tests and diagnosis and clinical treatments from remote locations. These programs have been carried out via telephone lines, coaxial cable and fiber connections, wide area networks, microwave relays, and satellite connections. Virtually all of these satellite-delivered services to date have been carried out through GEO-based satellite networks – global, regional, or national. The satellite systems are well equipped to deliver broadband video, but the return channel service for interactive services, from remote areas, has been a limitation. The various efforts to create interactive tele-education and tele-health services that operate via the Internet or digital networking systems have been the limiting factor that LEO constellations seek to address. These new networks, some with plans for thousands of satellites in low Earth orbit (LEO), are designed to operate with minimal delays that are comparable in end-to-end speeds of fiber or coaxial cable systems. The speeds of these small satellites which travel hundreds of kilometers rather than tens of thousands of kilometers do not have a problem with delay that can be confused with system congestion and trigger recovery processes.

3 Enabling Technology

The advantage of GEO, or Clarke orbit, satellites was in not requiring ground antenna systems that tracked the satellite as this type of satellite appeared to hover above continuously in the sky. This was a large advantage as satellite ground systems from tens to hundreds, to thousands, to literally millions of very small aperture terminals. This technical capability was first demonstrated by the experimental Syncom satellites in 1963 and 1964 and then the Early Bird satellites in 1965. As spot beams were added to allow more frequency reuse and greater power concentration this advantage further increased. This was because there was not a need to switch connections from beam to beam with a ground tracking antenna. In the case of LEO and MEO constenllations much more frequent switching was required between spot beams with a greater risk of a dropped connection.

It was only in the age of the Internet and the age of fiber-optic cable systems that supported very high broadband transmission rates at very low cost and low latency transmission that transmission delay of GEO-based satellites became of major concern. Some even began to claim that satellites for telecommunications services in the age of fiber networks were obsolete.

The ultimate success of the Iridium and Globalstar mobile satellite systems was key. These systems could not only work to handheld transceivers but they eventually proved capable of successul switching from beam to beam about once a minute and from satellite to satellite every 6 to 7 minutes. This proved that low latency LEO constellations could be viable for mobile voice service. It was improvment in digital communications and integrated circuits, especially application-specific integrated circuits (ASIC), that was key to creating viable ground terminals that could work technically and not be hugely expensive.

The next step forward that has been key to finding a technical solution to ground systems that could follow the fast-moving satellites in low Earth orbit (LEO) constellations is what are called flat panel antennas or electronically tracking antennas that can be manufactured at relatively low cost. It is actually the revolution in ground segment technology as much as improved small satellite design and manufacture that completes the technological breakthroughs to make large-scale satellite constellations viable in their operations both in the skies and on the ground. If these ground antennas for users were to be hugely expensive, the whole financial viability of such networks would not work for all sorts of networked services and especially not for educational, training, or health-based services.

Thus a combination of need to provide low latency data networking services to unserved or underserved portions of the world and new satellite systems technologies that have given birth to new telecommunications services in area of the world that have been described as suffering from the “digital divide.”

The enabling technologies on the ground are (i) flat panel antennas that can provide rapid electronic tracking of LEO satellites; (ii) new ways to provide low-cost sustainable power to remote areas (e.g., solar, wind, battery systems, etc.); (iii) new community-based ground systems to interconnect satellite ground systems with Wi-Fi and Wi-Max connections to cell phones and computers; and

(iv) even installations at schools, universities, hospitals, and medical clinics that can allow hybrid ground systems that can work to GEO, MEO, and LEO satellite systems as well as localized Wi-Fi coverage.

The enabling technologies that have come in the sphere of space systems design efficiencies include (i) the ability to produce on a mass production basis many small satellites and to do so with a high level of reliability and manufacturing quality, including use of additive manufacturing techniques; (ii) the use of miniaturized components, phased array antennas, power systems, and other design features to shrink the mass and volume of new satellites design; (iii) new reduced-cost launchers and rocket motors produced by 3D printing, including reusable first-stage rockets plus the ability to launch many small satellites on a single combined launch; and (iv) new sparing concepts that simply provide for replacement of failed satellites rather spending large amounts of time and money on reliability testing to highly exacting levels when networks consist of only a few very large and expensive GEO satellites.

4 Use of Large-Scale Constellation for Educational Services

The easiest and most cost-efficient way to utilize the new small satellite constellations for vital community services is in the area of training and education. The ubiquity of instructional materials, in a wide range of languages, available on the Internet just keeps growing. Most educational programs do not require a particular level of image resolution, and in some cases experiments have shown that even radio- or audio-based educational programming can be quite successful.

Today’s online educational systems such as computer labs for instruction in foreign languages, science, mathematics, and engineering are often available free or at low-cost licensing fees. Nevertheless there are problems of language and cultural sensitivities. The number one lesson learned from the Project SHARE activities was that when educational programs were locally produced within a country in native languages and with native teachers, the programs had a good chance of being sustained over time. It was equally true that instructional programs which were imported from one country to another by outside teachers and the teachers were not communicating in a native language, then these programs did not sustain themselves (Project SHARE Report, Intelsat, Washington, D.C. 1986). The same experience was found to be true in the case of other programs such as the NASA ATS-6 educational broadcasts in India versus the Edusat programs produced for the INSAT educational broadcast programs, the Indosat program in Indonesia, etc.

Another key finding is that on-site instructors are needed to supplement tele-educational programs delivered by satellite or Internet access. There is the case of health programming about house flies that was provided to Indian school children in the ATS-6 experiments. One of the early satellite television broadcasts to Indian village was a health program that discussed how flies could spread disease. The local instructors who talked to the villagers after seeing the health instruction were surprised with the responses and the lack of understanding of what they had seen. The villagers noted that it was interesting, but fortunately their town was not infested with these gigantic flying vermin. They had not understood that they had seen extreme close-ups that almost completely filled the television screen. The villagers thought the flies were a thousand times larger than they actually were. They did not recognize that these were indeed the same flies that bred freely in their own homes.

Local instructors are needed to interpret new materials, clear up false impressions, and extend knowledge essential to complete actual learning. The lessons that television program can start to provide must be accompanied by interactive learning. It is the essence of learning to start with bodies of learning and information, but this must be completed by questions and answers between students and teachers. One-way broadcasts are the start of learning, but interactive intercourse and research challenges are needed to complete true understanding and ultimate wisdom.

Arthur C. Clarke, the father of satellite communications, and futurist of great renown, made a speech at UNESCO in Paris with regard to the International Programme for the Development of Communication (IPDC) at its inaugural session in the early 1980s (UNESCO n.d.). In this talk he explained the great potential of not only satellite communications for instruction but also the possibilities that could come with the integration of satellites, computer networks, and artificially intelligent software.

Thus he foresaw the power that low-cost and globally updatable computer systems could bring to instruction. After his talk reporters asked if he was suggesting that automated systems should prevail and that there were no longer a need for teachers. Clarke responded to say that there would always be a need for teachers and question and answer interaction between students and instructors. But then he added: "..perhaps a teacher who can easily be replaced by a machine might be indeed become expendable and he or she might consider another line of work."

Clarke in his presentation noted a possible future where an "electronic tutor" might contain a great body of information that could be easily updated by an electronic network as well as a global satellite system geared to meeting worldwide educational and training needs. He stressed his vision of updatable handheld "electronic tutors" might evolve in unexpected ways. He suggested that the personal educational devices he envisioned might have as much to do with the future business models of Mattel or Tyco than IBM. By this statement he meant that the cost of massively integrated chips was becoming so low that by the twenty-first century, terabytes of educational information might be stored on the equivalent of toys. The device he described in several ways is remarkably similar to the "smart software" we know today as SIRI and ALEXA. The deployment of low Earth orbit (LEO) constellations of small satellites that brings low-cost wireless access to the entire world and can enable easy access to the world's storehouse of knowledge could complete Clarke's vision some 40 years ago (Op cit: Joseph Pelton and Peter Marshall).

The problem with describing the educational, training and health capabilities that new LEO constellations might provide is the sheer number and diversity of systems that are currently planned to be deployed. Between 2020 and 2025, the satellite services research company has projected that somewhere upward of 7000 new small satellites in constellations will be deployed, and some even foresee that as many as 20,000 small satellites for telecommunications, networking, remote sensing, frequency monitoring, information gathering, technology verification, and scientific experimentation will be deployed (Northern Sky Research).

The educational and training applications and services are thus still largely being conceived, and the hardware and software are still being rolled on. The new satellite networks and ground equipment are the hardware that will enable tens of thousands if not hundreds of thousands of new educational opportunities. The software and instructional programs are the next round of innovation that is still largely yet to come. There are potentially some 3.5 billion people that will be able to access the Internet via these new systems, but the key word here is "potentially." There are a myriad of economic, regulatory, cultural, and even religious factors that will be involved in whether the educational and training potential are unlocked.

Those involved in the satellite communications industry tend to focus on the successful deployment of the satellites and the design and implementation of ground systems, but the hard part of most educational and training programs comes with what happens next. Are the flat panel antennas on the ground interconnected to Wi-Fi systems that allow connection to cell phones or local schools or universities or training centers?

The Arthur C. Clarke Foundation some 20 years sought funding to carry out a series of tests and demonstrations known as the Millennium Village. This program sought integrated programs to benefit rural and remote villages in developing countries. The concept was to create an integrated program that would combine health-care services, solar light and electricity, emergency warning services, and sufficient power to support electricity for computers in schools and training centers. Perhaps most critical it was designed also to support new tele-work opportunities and training for villagers to learn particular skills in order to add new jobs. These might be activities that they could perform directly in the village such as in education, health care, or production of new products. It would also be designed to help create new positions and training programs. This training might support either new industry or services for the local village or could be in the form of teleservices. These new opportunities might well be designed to support urban enterprises via computer networking or telecommunications on a full-time or part-time basis (Freling and Herzfeld 2001).

The theory was to design a comprehensive set of services, education and training programs, health-care opportunities, power and lighting, and new economic and teletraining activities that could over time repay the new capital investment that the Millennium Village program would envision. This program would have depended on VSAT transceivers connected to GEO satellites and solar power and light systems that would have perhaps been too expensive to break – even within a decade – and networked services would be limited by the transmission delays associated with GEO satellites.

There is a real prospect that today integrated services that integrate remote education and training systems with economic development, power and lighting,

Millennium Village Project Objectives-Evaluation Criteria

- Increase in jobs & training
- Increase in literacy & education
- Increase in health care & disaster warning
- Economic development
- Generation of new investment/capital
- Improved infrastructure (especially power & lighting)

Fig. 4 Programmatic goals for evaluation for the Millennium Village Project in 2001. (Graphic courtesy of the Arthur C. Clarke Foundation)

and other services might have a much better chance of financial viability due to lower cost and the benefit of optimized networking services. The objective was to carry out projects in different countries and carefully monitor outcomes and success and failures to see which aspects succeeded or failed after care evaluation. The idea of seeking an integrated set of objectives rather than looking at various objectives on a piecemeal basis was an important concept two decades ago, but it might be even more important today. The figure below includes the evaluation criteria that were considered to be of prime importance then. Today other criteria related to the environment and climate change and the UN Sustainable Development Goals might well be added (see Fig. 4).

5 Use of Large-Scale Constellations for Heath Services

There is often a tendency to lump together tele-services and networking systems for education, training, and health-care services. It should be noted that the approach used for satellite or other forms of tele-services for connecting remote communities with doctors, practicing nurses, clinics, and hospitals represents, for a number of reasons, a special case. These reasons include such factors as (i) legal liabilities that can and often do apply; (ii) the resolution and clarity of images associated with treatment and diagnosis that can make a significant difference between the right and wrong decision as to the medical treatment needed and indeed what the actual ailment might be; (iii) viewpoints and even linguistic nuances and misunderstandings that can lead to problems and concerns as to how a patient can be properly given a medical checkup and evaluation, treatment, and prescribed medicine; etc.

In the case of education and training, a teacher might give a bad lesson, but this will not create a lasting problem that cannot be overcome. If a medical practitioner cannot see the patient and his or her symptoms clearly, this can be a major problem.

If there are fuzzy or incomplete views of X-rays, sonogram images, unclear medical readings, or even slightly off colorations of skin tones, such as in the case say of jaundice, there can be long-term adverse health consequences through misdiagnosis or ordering of the wrong medical treatment. In short, in case of tele-medicine applications, higher resolution and higher levels of reliability and visual and audio accuracy are required.

The issue of legal liability in the provision of health and medical care is also of major concern, particularly in litigious countries. In this case the providers of satellite services for medical treatment, either the patient or the care provider, might charge that the quality or the reliability of the service was inadequate and led to a patient's collapse or even death. In the world of education or training, there are no life or death issues that would normally arise, but in the area of medical care and services, this is also a possible area of legal contention that could arise.

Finally there are cultural, social, religious, or even language issues that could become a problem that can affect those offering tele-health services via a satellite or telecommunications network. There are many cultural or language-based misunderstandings that can arise in the case of medical examination process. This can involve mishearing or not understanding of symptoms, or not understanding cultural standards of modesty, or limitations on acceptable treatment processes or medication. Clearly arrangements to have doctor and patient to be of the same sex, language, and cultural background are advisable, but the provider of the telecommunications or network service is often not able to control such factors. Nevertheless, the scheduler or administrative staff that make the initial arrangements may find themselves in the line of fire in a court of law even though they had no particular choice or say as to who the patient or caregiver might be in a particular instance where a transgression is alleged.

The bottom line is that education and training services, in contrast to tele-health and tele-medicine activities, are less demanding as to the quality or reliability of the service or exposure to liability. This does not mean that issues of quality or liability never arise in the case of training and educational services, but they are definitely much less likely to arise.

6 Cube Satellites for Innovative Educational and Health-Care-Related Uses in Rural and Remote Areas

The advent of cube satellite technology and systems design, which might be anything from a PocketQube to a six-unit CubeSat, provides a new wide-open opportunity for experimentation and new design concepts as to how truly small satellites might be used to aid the cause of education, training, health, or medical care. When satellite applications were thought of in terms of huge multi-ton GEO satellites the opportunities in terms of space services were limited to leasing capacity from large enterprises that could launch such large and expensive systems. Today there are a wide range of new ideas and experimental concepts as to how small satellite experiments and projects might be built and launched in the range of

$50,000 to $500,000 dollars. There are many innovative ideas as to how true small satellites might be used in such ways as:

(i) Tracking of urban growth patterns
(ii) Tracking and reporting of water levels and flows of lakes and rivers
(iii) A neighborhood by neighborhood alert systems that could precisely chart the spread of pandemics or major disease outbreaks
(iv) The detection and reporting of crop or forestry diseases
(v) The detection of schools of fish for local fishing industries
(vi) The monitoring of and reporting to environmental authorities of industrial or organic pollution patterns
(vii) Testing of the designs, effectiveness, and lifetimes of sensors, routers, solar cells, batteries, torque rods, passive deorbit systems for satellites at end of life, or hundreds of other purposes
(viii) Many other reasons and purposes that can now be accomplished at lesser cost and greater effectiveness in terms of coverage and timely response

The reduction of the cost of actual in-orbit activities can now be financed through a university, a medical clinic or hospital, or even crowd funding programs. These innovations have opened the door for students in colleges and universities or trainees and interns in hospitals to come up with experimental ideas or even possible new operational space systems in totally new ways and via start-up enterprises. The Spire Series of satellites began with a crowd-funded satellite.

Students can now not only learn about space sciences and engineering, but they can actually have the opportunity to design and arrange for the launch of small satellites. Space agencies have created opportunities for students and professors to design and build small sats to test new ideas.

NASA began its CubeSat program for land-grant colleges and university. Today the European Space Agency (ESA), the Japanese Space Agency (JAXA), and others have followed suit to encourage student innovation and expertise. Even corporations have sponsored such small satellite experimentation. The LifeSat program launched two small satellites that allowed world wide connectivity via just two low Earth orbit (LEO) cubesats. This project was sponsored by Japanese corporations. These two CubeSats allowed data relay services from remote clinics. This allowed doctors isolated from the Internet to request information from the latest medical journal and experts from all over the world and get a response within a few hours.

Another project, a not for profit activity called Volunteers in Technical Assistance (VITA), offered engineering and other expert advices in rural and remote areas via GEO satellites and CubeSat relays, primarily in South America, where reliable terrestrial communications were not available (Volunteers in Technical Assistance n.d.).

Thus there are ways to deploy small satellites, even one or two satellites at a time to provide connectivity to isolated areas that provide elements of training, education, access to information from the latest researchers, and even various forms of testing and certification. There is valuable experience with institutions such as the

University of the South Pacific, the University of the South Pacific, and others as to how to operate successful tele-education, tele-training, and even tele-health programs. This experience can be valuable in developing new LEO-based cubesat programs in terms of extension of services and more cost-effective programs.

In the case of the University of West Indies, the cost-effectiveness of satellite communications systems allowed this multi-island university program to be structurally reorganized. The University decided that different campuses would specialize expertise in various disciplines at different island locations. Thus one campus would focus on forestry, another would center their research on agricultural crops and horticulture, and so on. With the ability to tie all the campuses together via satellite networking, the entire regional university could act as an integrated and holistic facility that can avoid a high level of duplication of faculty by hiring on a duplicative basis many areas of research. These types of experiences and beneficial uses of communications to organize more efficiently can potentially represent beneficial examples that can be greatly expanded as new broadband LEO satellites services are deployed.

These early programs encountered difficulties and limitations due to the cost of ground systems, or limitations due to lack of bandwidth or latency in the case of computer-networked activities. This was due to such factors as GEO satellite delay, available bandwidth, high cost of transmission, or the limitations of machine-to-machine data relay that slowed down communications. In most cases, however, it was not the technical nor operational constraints that were the largest barriers to the use of satellites to provide rural and remote educational and health-care services. In fact it was largely limited financial resources, a lack of understanding the potential of tele-health and tele-educational services, and social, cultural, and regulatory constraints.

There are some of the satellite systems that have been designed to provide rural services such as the network that was designed to provide direct broadcast radio satellite services to Africa and South America and the Caribbean that sought to address these issues over a decade ago. There was, on one hand, a foundation established whose purpose was to provide health and education services that were a part of the overall development plan for this new satellite program. The system was designed, for instance, to provide during nighttime hours, when usage of the satellite transmissions was low, the ability to low-load short educational television programming, in lieu of radio broadcasting. One of the biggest barriers to the use of the AfriStar radio broadcasting satellite for its intended purposes was that governments in Africa placed a 100% tariff on the low-cost radio receivers so that instead of costing $50 (US) per receiver, the effective cost was $100 (US) per receiver. It is such aspects that are sometimes not anticipated in the rollout of educational or health-care delivery systems that can become a major barrier to the success of such programs.

7 Conclusion

It is clear that a number of new small satellite-based large-scale constellations are designed to operate in low Earth orbit. A number of these systems are described in some detail in this handbook of small satellites. They are variously described in terms of their technical characteristics, dates of deployment, operational parameters, etc. It is important to recognize that the ability of such new satellite networks to provide networked services and to provide global coverage does not constitute an immediate opportunity for significantly expanding the range of satellite-based tele-education and tele-health services.

The truth of the matter is that the transmission delivery is just the start of a long and difficult process. The ground systems for connecting to the users in rural and remote areas at a cost that is affordable are a huge obstacle to overcome. In many regions of the world, there is a lack of electrical power that is sufficient to operate the user devices. There can be tariffs applied to user devices that, in effect, double their cost to the students or patients that would seek to use new forms of satellite-based programming for training, education, or health care.

Small Satellites, Law Enforcement, and Combating Crime Against Humanity

Joseph N. Pelton and Amit Maitra

Contents

Abstract

The strategic uses of balloons, aircraft, and then satellites have been an established practice to carry out reconnaissance, remote sensing, monitoring, and intelligence both for military and law enforcement purposes starting several centuries ago. The use of satellites for this purpose started with the Corona spy satellite. Today reconnaissance satellites are used by a number of countries for strategic purposes. These spy satellites are typically large in mass and volume and highly sophisticated with very high spatial resolution. The small satellite revolution has shown that small satellites of much less cost and size can be used

for many new purposes that range from industrial espionage to surveillance for law enforcement purposes by a growing number of countries. Further remote sensing satellites with time-stamped imaging have also been used in international courts to provide visual images to document attacks against towns and villages that have been described as crimes against humanity and even genocide.

Small satellites have become able to offer a range of new capabilities. These new capabilities have included much more frequent temporal resolution – sometimes providing coverage more frequently than once a day. They have also been able to provide updated information at much lower cost and with augmented data analysis that have provided valuable to police, coast guard, United Nations peacekeepers, and others charged with law enforcement and border protection and even with protecting the world against crimes against humanity.

This chapter explores some of the ways that new small satellite constellations can be designed to carry out improved forms of law enforcement, strategic defense, and even new ways to combat crimes against humanity. These new capabilities can sometimes work with a variety of capabilities from cubesat systems, to microsats or minisats, to large-scale satellites or various types of high-altitude balloons or aircraft such as UAV, or other means, in order to provide a full range of surveillance and observation capabilities. The primary focus of this chapter is on satellite imaging. Nevertheless the opportunities now presented by small satellite constellations for law enforcement and related activities from zoning enforced up to combating crimes against humanity are numerous and still growing. Today such satellite and high-altitude platform capabilities include position tracking, RF-geolocation detection, artificial identification system (AIS) monitoring, and in the future perhaps monitoring of wireless messaging and conversations.

While small satellites in the area of law enforcement and other strategic services are not a unique capability, they can combine with other resources to provide valuable service capabilities for detection, monitoring, security planning, enforcement, and legal prosecution. These capabilities can include optical, infrared and new infrared imaging, radar, as well as augment the abilities for tracking and monitoring such as AIS, near real-time tracking and identification, and entirely new capabilities such as RF-geolocation.

This chapter describes some of the innovative ways that small satellite constellations can offer security officials, law enforcement officers, and even jurists useful information to undertake law enforcement, protection of the peace, and valuable information that can be used in court cases to help to prosecute crimes against humanity and international criminal cases such as drug smuggling, fishing and pollution violations, and illegal trafficking across national borders.

1 Introduction

Military organizations in the United States and the Soviet Union have used spy satellites such as the Corona spy satellites to carry out strategic surveillance starting some 60 years ago. Such satellites were very massive and expensive and in some cases have costs billions of dollars to design, build, and operate.

While governments are now still vigorously developing its next generation of spy satellites, the commercial spy satellite industry is selling slightly less detailed imagery to both public and private sectors. The most detailed commercial reconnaissance systems have resolutions that are as refined as 25–35 cm in spatial resolution. In some cases these high spatial resolution commercial satellite systems are restricted to shutter control for very sensitive military locations. It has been noted, however, that this use of shutter control over the territories of various countries, so these sites are obscured actually serves to identify exactly where sensitive military and security facilities are indeed located.

Images from these high-resolution satellites provide detailed pictures of cities, homes, cars, aircraft, and various equipment and weaponry. Coverage and access to satellite imagery has created new market opportunities across all domains, including agriculture, forestry, fishing, mining, urban planning, pollution detection and control, and a variety of law enforcement activities. Law enforcement and security analysts can use reconnaissance from spy satellite, aircraft, UAV, and drone imagery in a wide variety of actions. These might include damage assessment such as from a bomb or improvised explosive device, search for a dangerous criminal or escapee, and as security for a special venue such as a major sporting device or meeting of heads of state.

The advent of small satellite constellations has not really been a “game-changer” in terms of transforming the use of satellites for law enforcement and efforts to use imaging in such efforts to combat crimes against humanity, but it has definitely altered the economics and patterns of use in terms of frequency of updates of information and the economics of and cost effectiveness of such usages.

2 Historical Perspectives on Use of Surveillance-Sats in Law Enforcement and Related Purposes

There are many documented high profile cases where surveillance satellites have been used not only for law enforcement, but for recovery from terrorist attacks, preventive policing actions to provide for setting up site protection for a critical venue, or time stamped images employed to prosecute instances of war crimes and instances of alleged cases of crimes against humanity. Some key instances are noted below.

- In the September 11, 2001, attacks on the World Trade Center, essentially seven skyscraper buildings on top of a large subway system and surrounding lower-rise buildings were destroyed. Several government agencies were consulted and cooperated not only to assess the damage, but to consider how to best undertake recovery and assist with the planning a coordinated response regarding damaged infrastructure such as transportation systems, electrical grid, water and gas lines, etc. These agencies were able to compare satellite images of the impacted site and the damages incurred after the attack with images taken immediately before and after the attacks. NASA Landsat images as well as images taken by astronauts on the International Space Station (ISS) were also brought to bear. The images from spy reconnaissance satellites were likely the most useful in this regard. This allowed a sort of response teams to develop a sort of triage plan to see where there might be immediate threats and dangers to address in terms of possible loss of life, dangerous potential collapses, areas of greatest threat to such aspects as subway infrastructure, flooding, dangerous gas releases, and other vital information that could help with recovery, restoration, and identification of dangers to assist first responders and other personnel on the site.
- In the fall of 2002, there were a series of sniper attacks where unsuspecting victims were shot and killed. This ongoing terrorist activity essentially paralyzed the Washington, D.C., for many days. Pentagon officials, the National Security Agency (NSA), and the 14 members of the United States "intelligence community" were consulted as to whether they might be able to use classified surveillance imaging to help locate and apprehend the sniper. Pentagon officials decided against using satellites, and instead Defense Secretary Donald Rumsfeld approved a plan to dispatch sophisticated military surveillance aircraft with law enforcement personnel aboard to assist with this urgent search for what ultimately was found to be a two person operation undertaken by a marksman and a younger assistant. Spy satellites, if used, would have offered more detailed imagery of several kilometers around the site of an attack immediately after it occurred, thereby aiding in the identification of the vehicles in the vicinity. The more targeted data from higher altitude aircraft was considered to be the more appropriate search tool, and thus this approach was used instead (Korody 2004).
- The Secret Service, local police, and the Federal Bureau of Investigation (FBI) employed satellite imagery while providing information necessary to secure the venues of the 2002 Winter Olympics in Salt Lake City, Utah. It was later alleged by the American Civil Liberties Union (ACLU) and others that there had been widespread monitoring of the athletes and attendees by visual surveillance and cellphone monitoring of attendees, but this activity was never proven or admitted by US governmental officials (Marisa Payne 2017).
- There have also been suggestions that spy satellite imagery provided useful information to secure the Ronald Regan funeral procession in June 2004 and to provide a monitoring capability similar to that used to provide security support to the Winter Olympics in Salt Lake City, Utah (Satellite Imagery 2004).
- In a more recent instance, the US National Geospatial Intelligence Agency (NGA) has partnered with several non-governmental organizations concerned with

human rights abuse and crimes against humanity with a special focus on potential violations by North Korea. In this case, the Agency has supplied unprocessed imaging data and specialized computer applications designed for imaging analysis to partner NGOs. The objective was to allow these organizations to search for such things as possible mass graves or perhaps concentration camps. It is unclear from public sources whether this was exclusively satellite imaging or included any high-altitude aircraft imaging (McLaughlin 2018).

- One of the more frequent new uses of satellite imagery has been to detect, or to confirm, reports received of growing of crops such as marijuana or poppy seeds as part of drug enforcement programs. Such uses do not require sophisticated spy or reconnaissance satellites. Commercial satellite systems have sufficient resolution to detect the growing of illegal substances (Satellite imaging 2019).

The foregoing examples, of which there are many others, illustrate that when near real-time, high-resolution satellite surveillance, or satellites with high temporal resolution (i.e., quick return of coverage to the same site), is utilized over major population centers or other critical sites, the scope and efficiency of law enforcement can increase. Yet at the same time, there are also parallel concerns that abuse of such capabilities can lead to violation of personal liberties. These can include the right to personal privacy, the right to be protected against illegal searches, and other freedoms expected in a democratic society. This is a topic addressed later in this chapter.

The potential applications are broad and many. The uses could include establishing security perimeters and weaknesses in security operations. It can involve locating escaped criminals and fugitives from the law. It can also involve detection of smuggling operations, illegal fishing, or cutting of timber operations, various forms of zoning violations, or industrial-operated activities leading to various forms of polluting or even illegal diversions of water supplies from lakes or rivers. Analysis of various forms of surveillance information to determine patterns and suspicious activities can also lead to crime detection or even prevention.

3 Current Innovations Using Satellite Technology for Law Enforcement and Related Activities

The use of satellite imaging, sensing, signal detection, and illegal radio-frequency detection keeps increasing. New commercial systems and particularly use of new commercial small satellite constellations are adding to available capabilities at a rapid rate. Today there are radar and infrared imaging systems available. These are being combined with optical imaging. Radar and infrared satellites are effective in darkness and through cloud cover, thereby ensuring wide advantages for surveillance of suspected criminals. Indeed the creation of data fusion centers designed to combat terrorism are often equipped to be able to combine a large amount of geospatial data together. Many such fusion centers are able to draw on additional elements of information such as conversations or messaging on cell phones, wiretap information, and other types of entirely new types of information such as illegal use of radio frequencies. This type of information can be provided from RF-geolocation satellite systems such as the new Hawkeye 360 small satellite constellation.

Conventional commercial satellites such as Spot Image and GeoEye, for instance, have been used for local code enforcements as noted in these examples below.

- State law enforcement agencies use satellite imagery to investigate violations of zoning and environmental regulations. A case in point is the Arizona Department of Water Resources, which has used satellite imagery from a French Spot Image satellite to find violations of irrigation permits. In another instance, satellite imagery has been helpful in discovering unreported and illegal timber harvesting (Korody 2004).
- North Carolina jurisdictions are using satellite remote sensing "to find unreported building activities, agricultural development and other property improvements that would raise property-tax assessments." Remote sensing from small satellite constellations are now being used to detect code violations such as building without official permit violations such as the building of small backyard porches or other more serious violations. Another instance was that of a farmer being fined for violation of water permits and illegal diversion of water based on satellite imaging (Korody 2004).

The future of law enforcement through the use of space remote sensing does not have to depend on super high spatial resolution governmental spy satellites, nor even very large and sophisticated commercial remote sensing satellites. There are many law enforcement and detection functions that may be possible by means of small satellite constellations.

Going forward, small satellite constellations that operate at low cost with quicker return to a particular site or new capabilities such as RF-geolocation, artificial identification systems (AIS), and more sophisticated data analytics might be able to offer new capabilities for law enforcement or related services. The extent to which these capabilities might be used in the future is just beginning to be explored.

The Planet Dove, Terra Bella, and other higher-resolution small satellite constellation can combine to provide a combination of capabilities. The Planet Dove constellation has high temporal resolution with its larger-scale 3-unit cubesats to provide quick updates. Its higher-resolution systems such as its Terra Bella satellites can provide relatively clear and precise images. This combination of system data and increasingly sophisticated data analytics is provided to Google under the contractual arrangements under which Planet Labs acquired Terra Bella from Google and became simply "Planet." Figure 1 below from Google Earth shows the Chinese hidden camps in the desert used for detainees. These images were first developed via the Sentinel imaging satellite that was developed by the European Space Agency and had a mass of measuring around 2 mt. But today these images of isolated spots of interest can be quickly updated via the Planet small satellite constellations or other small satellite systems. Other small satellite systems using radar sensing such as ICEYE and Capella can become particularly adept at detecting metal structure in remote locations.

A satellite swung over the rolling deserts and oasis cities of China's vast far west on 12 July 2015. The images it captured that day just showed a patch of empty, untouched, ashen-grey sand - an unlikely place for an investigation into one of the most pressing human rights concerns of our age.

Rapid development in the high desert has occurred since July 2015 as detention camps have expanded over the site.

- Satellite photos taken of that same piece of desert on 22 April 2018 and again in October 2018 show how quickly the site has been developed. .
- Dabancheng, as seen in Sentinel images in October 2018, shows an enclosed area with a 2km-long exterior wall punctuated by 16 guard towers.

Fig. 1 Images taken by the Sentinel remote sensing satellite designed ESA provide images of China's camps being built in Dabancheng. (Graphic courtesy of Google Earth)

4 Potential Uses of Small Satellites for Law Enforcement

The potential for the future are broad and of significant impact. Currently the vast ocean areas that cover some 75% of planet Earth are today almost impossible to police effectively. Illegal, unreported, and unregulated fishing adversely impacts the profit margin of legal fishing. It is estimated that illegal, unreported, and unregulated fishing amounts to 26 million tons of fish each year. This is estimated, as calculated based on global profits, to represent an amount that is a quarter of that derived from legitimate and authorized fishing operations. Illegal fishing fleets that are now operating represent what amount to a multi-billion-dollar criminal activity. This actually harms legitimate fishermen. Unauthorized fishing is even more harmful in terms of the environmental damage that is created over time by overfishing. Increasing new surveillance capabilities now being deployed in terms of small satellite constellations that are now available in low-Earth orbit, policing has now become possible at a reasonable cost. Black market operations can be spotted and illegal fishermen brought to justice (Hambling 2019).

Commercial small satellite startups known as Capella, from the United States and another from Finland called ICEYE are both equipped with radar sensors. Since radar sensor receives a sharp reflection from metal, both of these systems are excellent for detecting ships and boats at sea (Fig. 2). Even with relatively low resolution, these satellites are able to distinguish ships from fishing boats, and with the correct data analysis they can determine which fishing boats are operating in legitimate fishing waters or not. Also since radar operates during the day and night, these systems are capable of finding fishing boats that violate fishing waters

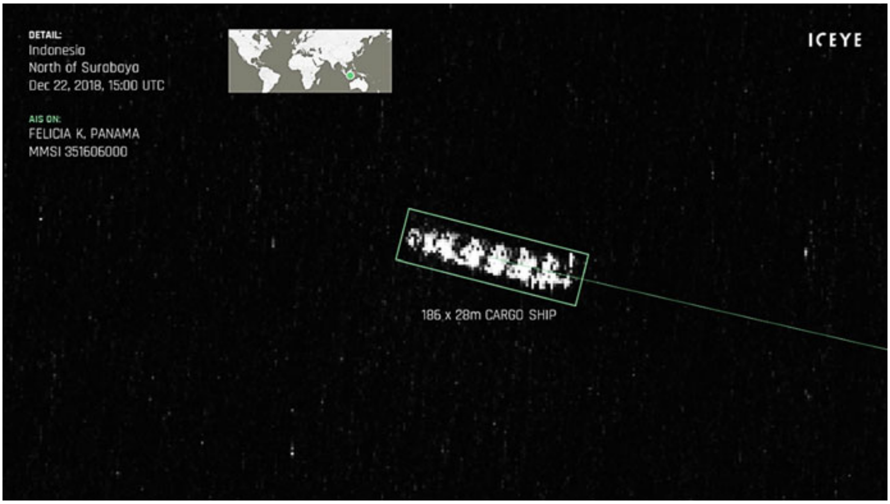

Fig. 2 A cargo ship identified by an ICEYE satellite at a location North of Surabaya, Indonesia, on December 22, 2018, 15:00 UTC. (Graphic courtesy of ESA and ICEYE) (ICEYE and Spire joins 2019)

24 h a day and especially to spot those that use the cover of night to go into prohibited waters.

Further the small satellite system known as SPIRE has also joined with ICEYE in the small satellite systems that are working to detect illegal fishing in cooperation with the European Space Agency. SPIRE is equipped with the ability to track and locate ships (and vehicles as well) that emit an automatic identification systems (AIS) signal. Currently there are about a dozen of small satellite constellations equipped with this capability in operation or proposed for service. When ships detected by ICEYE at sea do not link up with an AIS signal detected by SPIRE, then this ship becomes a “dark ship” and is presumed to be carrying out an illegal function such as smuggling, illegal fishing, or some other covert activity. In other cases an active AIS signal indicates it is at a location where it should not be traversing or fishing.

The partnership between ESA, ICEYE, and SPIRE is not just restricted to locating illegal fishing, detecting pollution, or illegal activities such as smuggling, but a number of positive environmental and other useful activities. The focus of these joint activities have been characterized as follows: “Challenging issues such as natural disaster response and climate change research, oil spill and illegal fishing detection all require repeated and timely imaging, regardless of the weather conditions or time of day. This shared effort to gain vast SAR imaging capabilities from new technological developments impacts the whole Earth observation industry and its end users.” Indeed the original prime mission of ICEYE was to observe ice cover and identify and monitor dangerous icebergs (ICEYE and European Space Agency 2019).

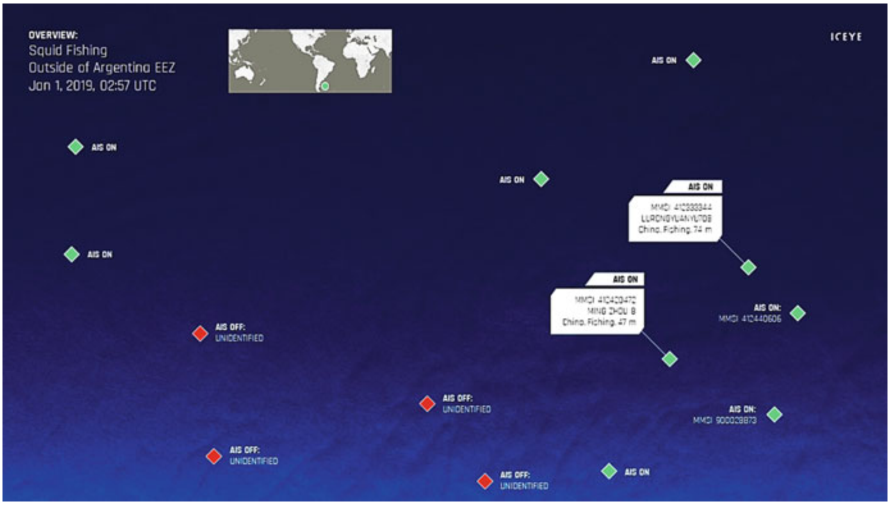

Fig. 3 Squid fishing near Exclusive Economic Zone (EEZ), Argentina. (Graphic courtesy of ICEYE)

In some cases the process works not as active detection of illegal activity but rather as a warning or alerting system that allows a ship to be alerted that it is close to or near a restricted area for fishing or secure area zone. In Fig. 3 AIS location signals are used to alert two Chinese ships that they are nearing an Argentine Exclusive Economic Zone. There is the further issue in this case of a “dark ship” whose AIS signal is not active.

5 Does Use of Satellite Imaging, GNSS Tracking, and RF-Geolocation Detection of Artificial Identification System Monitoring Constitute “Illegal Search”?

Clearly new small satellite constellations are creating a variety of new law enforcement capabilities. These can be used in dozens of ways to help law enforcement at the domestic level or on the high seas. These tools can be used as a warning system, as a detection or monitoring system, or even as a form of search and article of prosecution. The farmer who diverted the water and the person that builds a back porch or adds on to the back of their house and does not report it to tax authorities would in the past not be fined or have their home reassessed without a search and someone coming to a property to verify an infraction. In the world of satellite imaging, AIS signals, RF-geolocation, and other data analytic tools, the abilities of law enforcement and even exhibits for criminal prosecution are available simply as data readouts.

The law of what constitutes a legal search anymore is no longer clear. A judge does not have to sign a search warrant for every image taken by a satellite in orbit or a high-altitude platform hovering at 20 km overhead.

There is an ever-growing ability of satellites to operate as a hidden yet increasingly constant surveillance tool operating overhead. Satellites and high-altitude platforms can now observe individuals and activities with ever higher levels of spatial resolution. These tools are now increasingly being used to meet the needs of law enforcement agencies. In the days of terrorist attacks such as those that have occurred in Paris, London, Bali, and most sensationally New York City and Washington, D.C., in the so-called 9/11 attacks, public opinion tends to favor heighted secured and more surveillance tools in the name of safety and anti-terrorist protections.

At the same time, this ability pushes the limits of constitutional protections. It is not clear as what today's reasonable expectations should be within a free and democratic society. What are today's reasonable privacy expectations? What is an invasive and illegal search of one's person or property in the twenty-first century? It is not just a matter of satellites or high-altitude platforms armed with sensors, imaging devices, and other tools of cover observation. There are close circuit cameras, recording devices, and security systems almost everywhere in today's urban settings.

Controlling crime, combating terrorism, and maintaining public order is necessary within a free country. These requirements lead to implementation of reasonable limitations on some civil liberties. A free society can be held hostage to excessive crime and an atmosphere of violence. For example, in today's turbulent environment, individuals are not allowed to enter an airport terminal unless they agree to a search of their persons and items they carry. The concerns of air travelers to be free from acts of terrorism outweigh individual freedom of unrestricted access to a public airport terminal. Nevertheless judicial systems to protect an individual's right not to be subject to unreasonable search and their right to privacy remain important to a free society. Methods to check technological intrusions into one's personal life and not to allow unrestricted observation and digital snooping will become ever more important in the time ahead.

No discussion on how law enforcement embraces new technology that collects evidence of a crime is complete without reference to privacy concerns regarding the use of surveillance satellites that observe individuals and their activities and movements. The new technologies that law enforcement uses include Global Positioning System (GPS) tracking devices, radar, night vision, thermal imagers, and other sensors. As these devices and sensors are integrated together, then surveillance satellite technology becomes just another tool to be used. As technology advances and imagery becomes more readily available to law enforcement, the use of surveillance satellites will increase in a wide variety of law enforcement actions. While new surveillance power strengthens law enforcement's operational efficiency, legal questions that mostly center on whether use of the technology infringes on the privacy interests of individuals also must be addressed.

In the United States the Fourth Bill of Rights provides protection against "unreasonable searches" and unfortunately there is nowhere in the Bill of Rights a right to privacy defined. The US Supreme Court has moved back and forth in defining what unreasonable searches constitute. They have often found in favor of individuals being unreasonably searched by police, particularly within the home, but have not been so protective when it comes to technology. In the case involving a helicopter flying over a back yard, the US Supreme Court ruled that the Fourth Amendment did not provide such protection. It is on this basis that satellite surveillance seems to have a wide area of discriminatory powers (Florida v. Riley 1989).

6 Conclusion

The ability of small satellite constellations to provide a greater ability to provide new tools for law enforcement and anti-terror methods and even provide evidence in cases combatting crimes against humanity seems likely to continue to increase in years to come. These small satellites will likely become for refined in terms of law enforcement capabilities for many reasons. These include improved and higher-resolution sensor technology, lower launch costs, faster digital processing capabilities, and new software applications to conduct image processing at faster speeds. These and other technological efficiencies born of the "NewSpace" revolution seem to hold out the prospect of increasingly sophisticated surveillance capabilities. Part of this enhanced capability will come with integration of various capabilities.

Today small satellite constellations plus high-altitude platforms and stratospheric systems seem to hold a number of key new tools for law enforcement and related capabilities. Thus there are small satellites that have reasonably high spatial and temporal resolution with optical, infrared, and radar-based sensors. These can be linked through digital processing systems and so-called "fusion analysis" centers to create integrated surveillance and data analytics to produce holistic results. Thus small satellites with automatic identification systems (AIS) signal collections can put together data from small satellite radar systems to identify "dark ships" across the world's oceans. The many small satellites involved in the Capella and ICEYE radar systems can link together with the SPIRE data analytics to help identify smugglers and illegal fishing boats.

This is but one example of the new sensing and imaging capabilities that can link to data analytics to support law enforcement. There are today scores of newly deployed or planned small satellites with remote sensing and surveillance capabilities (optical, infrared and near infrared, radar, etc.), with capabilities for AIS signal, RF-Geolocation, data relay, etc. These sensing capabilites can also be linked to Global Navigation Satellite Systems (GNSS), meteorological, and commercial data bases to assist in detecting criminal activity, protect against data breaches, providing warnings against physical or cyber intrusions and more. There are also satellites that can relay Internet of Things signals from activated units that will in many cases be related to security related information such as whether a door has been opened or a circuit activated that should not have occurred.

The addition of all these capabilities related to small satellite system opens a wide range of new capabilities to fight criminal behavior, stop terrorist attacks, and help combat crimes against humanity. There is a downside of this progress. The automation of so many of these functions also creates new vulnerabilities that cybercriminal or cyberterrorists may also find to exploit. Further as noted above, these high-tech tools can also be invasive. This means that all of these new capabilities can also reduce an individual's sense of privacy and subject citizens to more circumstances where unreasonable and unwarranted searches can be made by sensors that may be on the ground or in the sky. It is the job of technologists and legislators to try to find a middle way between protection of citizen's safety against criminal attack and preservation of a citizen's right to privacy and unreasonable and unwarranted search.

Abstract

This chapter will present the historical, current, and future status of the use of space technologies, including the new generation of small satellite constellations, for precision agriculture and forestry. Human population growth and urbanization, along with environmental issues and climate change, will continue to put pressure on our global agriculture and forestry resources. New and improved methods of feeding the world's growing population, while at the same time protecting our finite natural resources, will be needed and must be developed now if they are to meet the coming demands. This chapter will consider the benefits and challenges of this emerging new technology and how the small satellite revolution will impact this important capability.

Keywords

Precision agriculture · Precision forestry · Global population growth · Remote sensing · GIS · GPS · Decision support system (DSS) · Climate change · Hyperspectral

1 Introduction

1.1 Historical Context, the Origins of Agriculture

For the majority of human history, we were hunter-gatherers, living in small bands, constantly roving across the landscape. The first agricultural revolution occurred independently around the planet, with the domestication of plants and animals for crops and food happening in the Middle East, Asia, and the Americas between 11,000 and 8000 years ago in many independent locations (Tauger 2008). This may well have been enabled by the end of the last Ice Age, which occurred around 13,000 years ago. The domestication of plants and animals allowed for a sedentary lifestyle and larger communities, and surpluses led to more complex social structures and more stratified societies, including social complexity and the emergence of elites. Agriculture soon became the norm around the world, and people settled into stable agricultural production systems that were focused both on centralized production in places like China and Mexico, as well as on small farms, and local production sufficient to meet local needs. In the Middle East, large-scale agriculture was well established in the "fertile crescent" of Mesopotamia and in Egypt by 10,000 years ago, with a wide variety of crops and domesticated animals being managed (Janick 2002). Human population around the world increased, and complex societies developed with specialized occupations beyond farmers (Fig. 1).

2 The Second Agricultural Revolution

The second agricultural revolution occurred during the Industrial Revolution in the eighteenth and nineteenth centuries. The development of the steam engine, railroads, mechanical seed presses, automated threshers and reapers, and other developments provided a massive improvement in the productivity of agriculture. This, in part, enabled the Industrial Revolution by providing a growing urban labor pool, as many workers were no longer needed on the farms. Innovations, such as the horse-drawn seed press, mechanical cotton gin, improved plows, the mass adoption of new crops such as the potato and corn (both American imports), and improved crop rotation methods and nitrogen-fixing plants, all led to significantly increased agricultural output in Western Europe and North America (Mingay 1977). Similar advances were made in animal husbandry, with many new breeds of cattle, pigs, and horses being introduced. Agricultural markets became national and even international, and people no longer had to grow all they needed themselves. People began buying and selling their produce on the open market, often at a national scale, and money overtook the barter of goods. This significant increase in agricultural productivity laid the

Industrial Statistics.

We are indebted to S. W. Huse & Co., publishers of *Vox Populi*, for the following industrial statistics of Lowell, Mass :—

The Middlesex Company make use, annually, of 2,000,000 teasels, 2,000,000 lbs. fine wool, 50,000 lbs. glue, $30,000 worth of dye stuffs, and $13,000 worth of soap.

In addition to the above, the Merrimack Manufacturing Co. use 1,000,000 lbs. of madder, 380,000 copperas, 60,000 alum, 50,000 sumac, 40,000 soap, and 45,000 indigo, per annum.

The Lowell Bleachery uses 40,000 lbs. indigo, and $30,000 worth of other dyeing materials, per year.

The population of Lowell in 1828 was 3,532. In 1840 it was 20,796. In 1850 it was 33,385. Increase in ten years, 12,289. Population of Lowell in 1855, 37,553.

The Lowell Machine Shop, located among the above mills, can furnish machinery complete for a mill of 6,000 spindles in three

foundation for much of modern life, with fewer and fewer people working the land and with smaller and smaller amounts of the land devoted to agricultural production. Even so, today, some 1/3 of the population of the Earth is involved in agriculture, with many of them surviving on subsistence farming. Many of these are the poorest among us (Fig. 2).

3 The Third Agricultural Revolution

We stand on the cusp of a third global agricultural revolution, the precision agricultural revolution, a revolution that is going to be much needed and which holds tremendous promise to meet the growing needs of our future population and changing climate, but which also holds many unanswered questions. What is driving all this? There are three major forces that are shaping our global future need for new methods of producing food.

3.1 Human Population and Urbanization Growth and the Need for Improved Agricultural and Forest Productivity

According to the United Nations, there are currently over 7.3 billion people living on the Earth, and this is projected to increase to over 9.7 billion by 2050, as shown in the figure below (UN 2019). Some estimates are that we will require 70% more food by then. Our current agricultural production capability will require a massive increase in order to meet this demand. Either millions of hectares of new land will have to be brought into agricultural production, or we must find significant increases in agricultural productivity (Fig. 3).

4 Urbanization

A second related component of our future food requirements is the increase in urbanization and the development of megacities containing many tens of millions of people each (United Nations 2018). Again, according to the UN, for the first time in human history, more people now live in urban areas than rural locations in our world. In 1950, 30% of the global population was urban, but by 2018, it was 55%, and by 2050, it is projected that 68% of us will be urban dwellers. And 90% of this

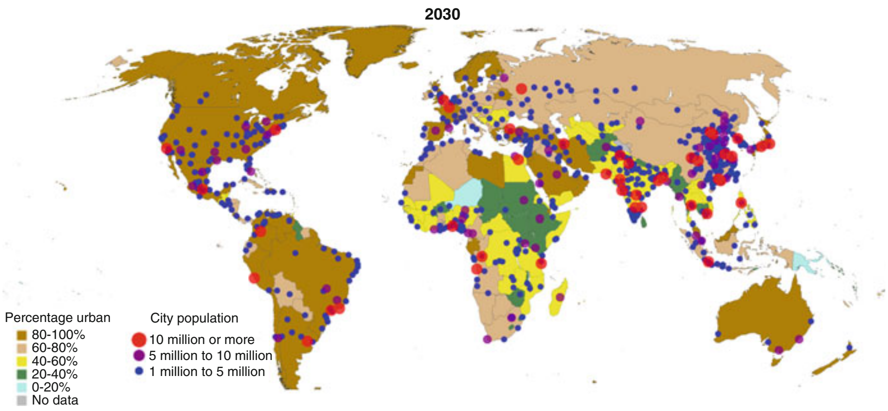

Fig. 4 Urban agglomerations by 2030. The large red circles will have a population of over ten million persons. Blue dots are between one and ten million. (Image courtesy United Nations https://population.un.org/wup/Maps/)

urban growth will be occurring in the developing regions of Asia and Africa. China, India, and Nigeria alone will provide 35% of this new urban population. India alone will add over 400 million new urban residents by 2050. Today, we have some 33 megacities with over ten million residents each, but by 2030, there will be an estimated 43 megacities, with most of these being located in the developing world. These new megacities will remove much of the productive agricultural lands which currently border these locations, so there will be an associated reduction in agricultural productivity in the immediate vicinity of these large urban growth zones (Fig. 4).

5 Global Climate Change

Lastly, we must consider the role that climate change will play in all this. There is a strong scientific consensus that global warming and climate change are real and are beginning to play an increasing role in changing our environment, and this includes agriculture. A recent analysis from the National Academy of Sciences of the United States shows that each 1 °C rise in global mean temperature would, on average, reduce global yields of wheat by 6.0%, rice by 3.2%, maize by 7.4%, and soybean by 3.1%. These four foods provide some 75% of global nutrition (Zhao et.al 2017). These amounts will vary spatially around the world. For example, wheat reduction will be more severe in India and Russia than in North America, but all will see reductions (Fig. 5).

These three powerful forces, population increase, urbanization, and climate change, will drive a profound global change in how the world gets fed. This also brings new meaning to the importance of the concept of sustainable development. How the developing nations in Asia and Africa will be able to support this

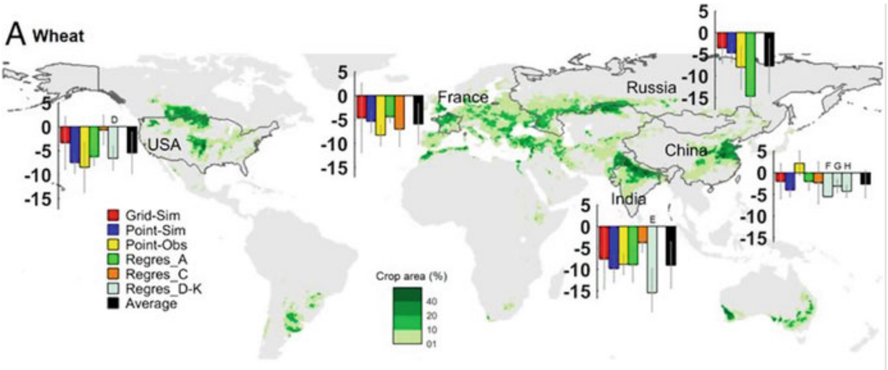

Fig. 5 Possible reduction in global wheat production with a 1 °C rise in global temperature average, according to several models. (Image courtesy National Academy of Sciences of the United States https://www.pnas.org/content/114/35/9326)

population and urban growth in societal, economic, and environmental terms is unclear, but the one thing that is certain is that these millions of new urbanites will need to be fed, and the environmental impacts of these processes must be understood and managed now. At this point, we do not have the agricultural capacity to feed all of these new people, and so new and more efficient means of agricultural production must be developed. This is the context within which precision agriculture must be viewed.

6 Initial Efforts in Large Area Agriculture Monitoring

There have been several very interesting and relatively successful attempts to harness advanced technologies for agriculture that have laid the foundation for precision agriculture. The US Department of Agriculture (USDA) had been using aerial photography since the 1930s to assess agricultural production in the United States. As soon as the Space Age began, there were discussions about how satellites and space remote sensing could be applied to improve this regional agricultural monitoring and forecasting, both domestically and abroad. The first major attempt was the LACIE (Large Area Crop Inventory Experiment) project. This was a 3-year, joint activity of NASA, NOAA (National Oceanographic and Atmospheric Administration), and the US Department of Agriculture (USDA). It took place in 1974 through 1977, which was very early in the first era of civil remote sensing with the Landsat 1 data (originally the ERTS (Earth Resources Technology Satellite)), launched on July 23, 1972. The goal was to determine if Landsat data, combined with weather satellite and other information, could remotely assess continental-scale wheat production with a precision that would be useful for the USDA and other government agencies. The goal was to determine regional and continental wheat production estimates that would be within 90% of the actual yield 9 years out of 10.

Fig. 6 The LACIE project logo. (Image courtesy NASA)

This was actually achieved in the third and final year of the project covering the 1976–1977 growing season in Russia, the primary target of the program (Fig. 6).

Understanding the success or failure of the Russian wheat crop was considered to be a national security issue for the US government, as a major crop failure could be a source of global economic and security instability. The overall method utilized is shown in the graphic below. Landsat satellites acquired imagery over vast areas of Russia and North America (as a control that could be field checked) during the wheat growing seasons, and the data were telemetered down to the ground and processed into different classes of vegetation, including wheat. These data were stored and analyzed by agricultural and imagery specialists, along with NOAA weather satellite data, various ground and textual data, and other sources of information, all to generate the final crop estimation figures, which were then compared with actual results after the growing season was over (Fig. 7).

The method was revised and improved over the three growing seasons of the project, and by the third season, the estimates were surprisingly robust. The Soviet government predicted wheat production in 1977 of 213.3 million tons, which would have been a 13% increase over the 1971–1976 yield averages. The LACIE estimate was for 91.4 million tons, and the actual yield, determined from records made available after the fall of the Soviet Union, showed an actual harvest of some 92 million tons of wheat, within 1% of the LACIE estimated value (Erickson, 1984). This was a very ambitious program using very early 80-m and 6-bit remote sensing imagery and using very primitive (by today's standards) image processing and analysis capabilities. The results showed that the global monitoring of food and fiber production using satellite remote sensing and ancillary data was, indeed, possible (Fig. 8).

The success of the LACIE project led to a follow-on activity named AgRISTARS, also a joint NASA, NOAA, and USDA effort, along with the Department of the Interior and the Agency for International Development (NASA 1982). This program began in 1978, and was a 6-year program to further determine the application of advanced space remote sensing, weather satellite data, computing, numerical modeling, and other approaches to provide the USDA with global crop forecasting, analysis, and other capabilities. There were a total of seven technical aspects, plural to plural:

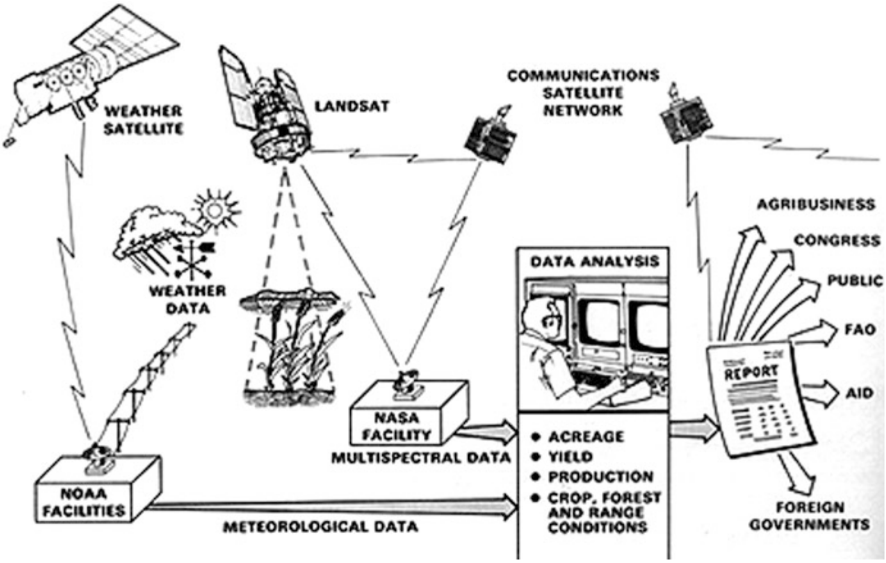

Fig. 7 LACIE experiment design. (Image courtesy NASA. https://www-legacy.dge.carnegiescience.edu/SCOPE/SCOPE_23/SCOPE_23_4.4_chapter8_191-217.pdf)

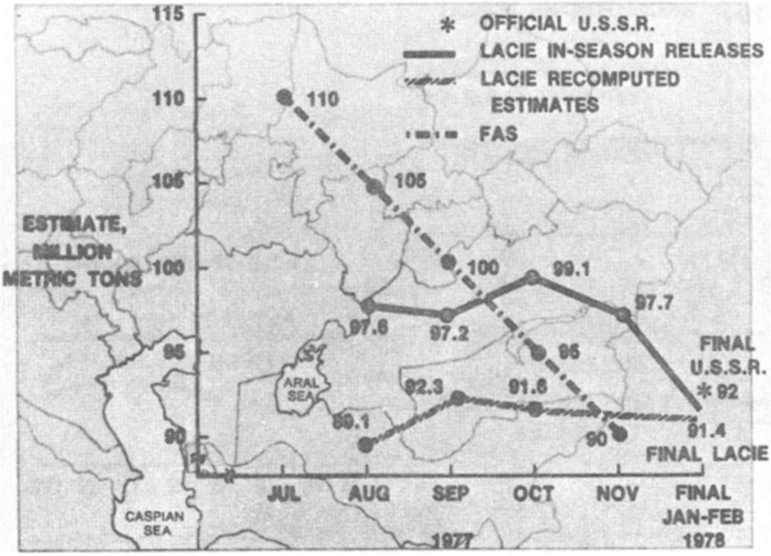

Fig. 8 LACIE results for 1977 Soviet wheat crop. The estimate was within 1% of the actual final amount. (Image courtesy NASA https://www.legacy.dge.carnegiescience.edu/SCOPE/SCOPE_23/SCOPE_23_4.4_chapter8_191-217.pdf)

- Early warning of change affecting production and quality of commodities and renewable resources
- Commodity production forecasts
- Land use classification and measurement
- Renewable resources inventory and assessment
- Land productivity estimates
- Conservation practices assessment
- Pollution detection and impact evaluation

AgRISTARS prepared for the use of the new generation of 30-meter Landsat Thematic Mapper satellites, first launched in 1982, which provided vastly improved 30-m spatial resolution and 8-bit data, along with new NOAA satellite data and improved modeling and analysis techniques. Additional crops like corn and soybeans were analyzed, as were forested areas, and the program was quite successful (Caudill and Hatch NASA, n.d.).

The success of LACIE and AgRISTARS projects demonstrated the effectiveness of this approach, and there have been several follow-on capabilities, as shown in Fig. 9, which is an operational dataset produced by the USDA National Agricultural Statistics Service. The USDA Foreign Agricultural Service (http://fas.usda.gov), to this day, prepares global and regional strategic crop forecasts for the US government on a recurring basis as an input into its national security and economic monitoring activities (Fig. 10).

The United Nations Food and Agriculture Organization (UN FAO) is the UN organization responsible for monitoring global agriculture, forestry, and fisheries and defeating hunger. Its Latin motto “Fiat Panis” means “Let there be bread.” FAO collects a wide range of statistics and operates a database called AMIS (Agricultural Market Information System). This program began in 2011 and is a G20 program

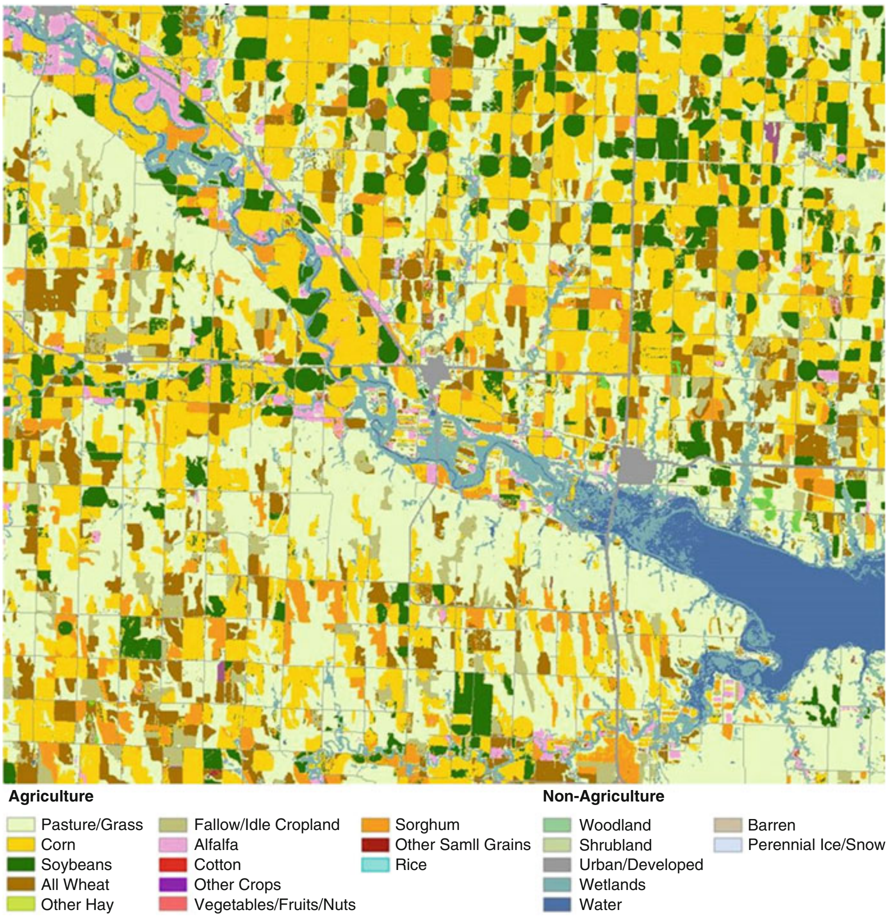

Fig. 10 A production USDA satellite image vegetation classification. (Image courtesy USDA National Agricultural Statistics Service)

designed to accurately forecast the global, short-term market outlook for wheat, rice, maize, and soybeans on a monthly basis (UN FAO 2013). Also launched at the same time was the GEOGLAM (Group on Earth Observations Global Agricultural Monitoring Initiative). The purpose is to "strengthen global agricultural monitoring by improving the use of remote sensing tools for crop production projections and weather forecasting by providing coordinated Earth observations from satellites and integrating them with ground-based and other in-situ measurements" (GEOGLAM 2019).

Both of these UN initiatives also serve to support the 2030 Agenda for Sustainable Development and its 17 Sustainable Development Goals. These goals include eliminating poverty and hunger, sustaining our natural resources, and responding to

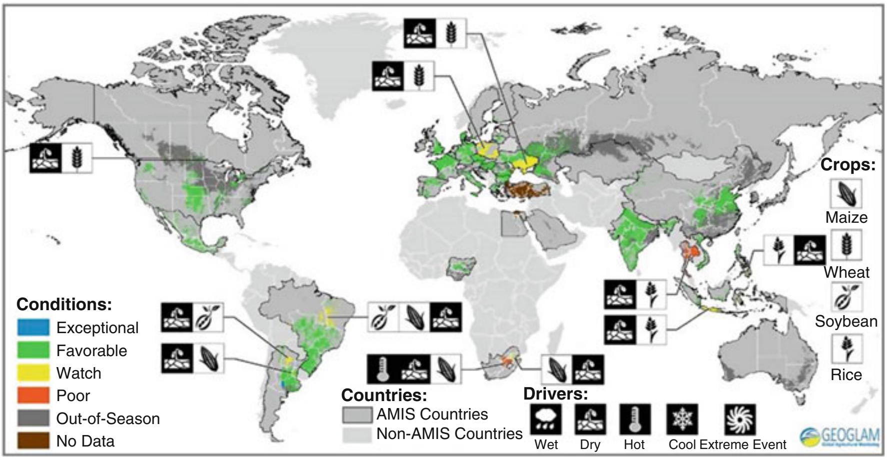

Fig. 11 A GEOGLAM product, showing global crop conditions and drivers for February 28, 2016. (Image courtesy USDA. http://www.geoglam.org/index.php/en/global-regional-systems-en/crop-monitor-for-amis)

climate change. Advanced technologies clearly play a role in this ambitious and difficult process (Fig. 11).

Today, in addition to the USDA in the United States, many nations around the world conduct their own crop forecasts. As just one example, in India the Mahalanobis National Crop Forecasting Centre has a staff of 20 and an annual budget of some US$1.5 million. They produce the FASAL (Forecasting Agricultural output using Space, Agro-meteorology and Land-based observations) program, producing crop forecasts at district and national levels for nine major crops, including jute, kharif rice, sugarcane, cotton, rapeseed and mustard, rabi sorghum, wheat, rabi pulses, and rabi rice (Mahalanobis National Crop Forecasting Center 2019). An excellent review of several national agricultural monitoring systems is available online from the UN FAO (UN FAO 2016).

In addition to these, and other governmental activities around the world, several major agribusiness interests such as Nestle, General Mills, and other international agribusinesses, as well as commodities exchanges and other financial trading institutions, also have crop estimation capabilities, either in-house or contracted, to look at the changing status of strategic commodities and their financial implications (Fig. 12).

6.1 Moving from Monitoring to Managing Agricultural Production

These continental and national-scale agricultural monitoring programs primarily record what is being produced or what *has* been produced, but what has been lacking

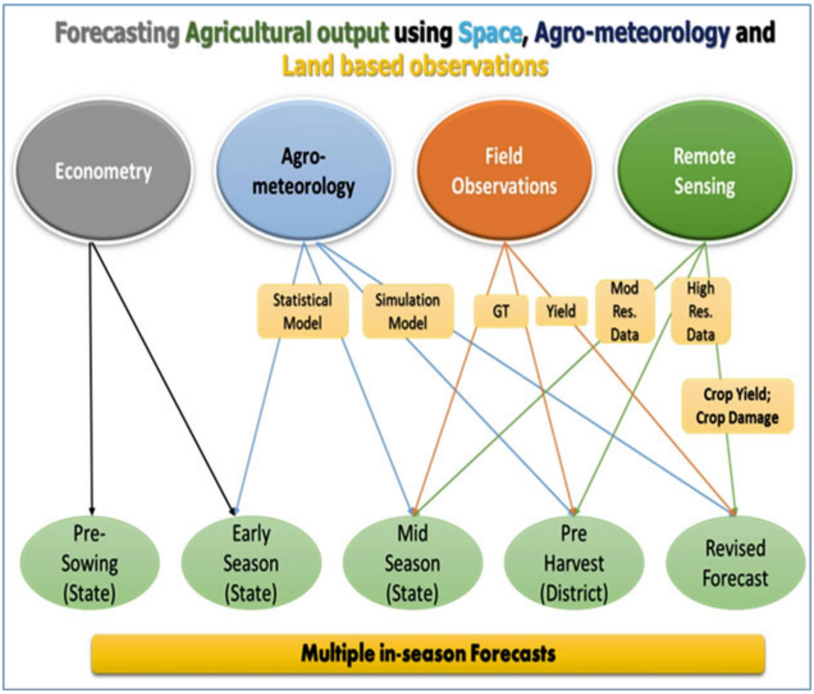

Fig. 12 Indian FASAL agricultural forecasting method. (Image Courtesy Indian Ministry of Agriculture and Farmers Welfare. https://www.ncfc.gov.in/about_fasal.html)

is local data to *drive* significant improvements in agricultural production. This is the promise of the third agricultural revolution, precision agriculture.

Scale is a vital aspect in the application of advanced technologies to the agriculture and forestry domains. The figure below shows a representation of agricultural scales, players, and issues (Fig. 13).

It is clear that agriculture operates on many different scales, from individual fields to global production, with many different commercial and governmental players, and complex issues of production, monitoring, and management that also vary widely around the world. Farming in North America is largely a multimillion dollar per year agribusiness, conducted on a vast scale and involving millions of dollars per operator. In much of the world, agriculture is still a very local activity driven by basic subsistence needs.

7 Current Precision Agriculture Systems

Technologies across the board have improved significantly since these modeling and forecasting capabilities were put in place. The next major development was the concept of precision agriculture as an integrated system for managing and improving

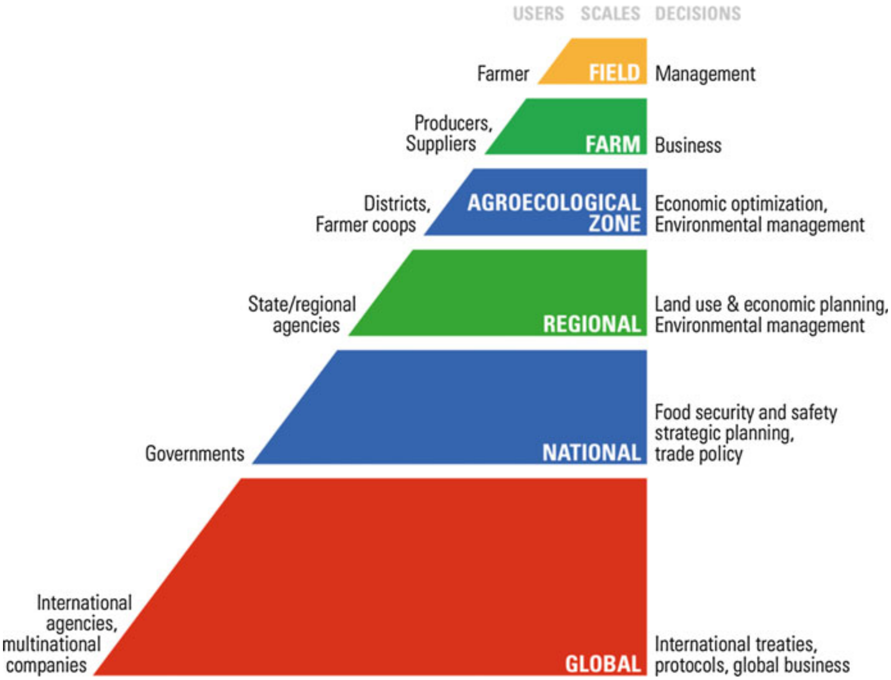

Fig. 13 The scales and players in agricultural forecasting. (Image courtesy UN FAO http://gsars.org/wp-content/uploads/2016/03/AMIS_CYF-Methodological-and-Institutional-Aspects_0303-web.pdf)

agricultural production, as opposed to large area crop monitoring that simply tracks what is being produced. The goal here is to actually *improve* the production process on a local level with improved yields and decreased cost and environmental impact.

So what exactly is precision agriculture? It has several names, including smart farming, satellite farming, and site-specific agriculture. I like calling it "bytes for bites," but they all refer to the concept of an integrated and real-time technology-based crop management system that monitors and shapes the crop throughout the entire growth cycle from pre-planting through harvest and distribution. In such a system, the detailed particulars of the crop fields, in relation to historical crop productivity, soils, slope, fertility, moisture, and other factors, are entered into a geographic information system (GIS) with data down to the square meter or less for each field. Satellite navigation and GPS are key aspects of such a system, and robotic tractors are now routinely able to drive the exact same route with sensors that can record various parameters, with the farming only monitoring the vehicle from the cabin in air-conditioned comfort. Another key part of the system is the VRS mechanism, or variable rate system. This allows the computers on the field tractor, based on the historical, current, and projected data, to distribute seed, water, fertilizer, herbicides, and pesticides on the field square meter by square meter, instead of simply putting out equal amounts of these, regardless of the particular field needs or conditions on the ground. And the system knows what the field characteristics are, what has been distributed, how the crops are doing, what is needed next, and when to harvest, all with quantitative precision. Remote sensing, from both satellites, aircraft, and now from drones, provides the real-time crop status and growth history, as well as soil moisture and crop stress from drought or disease. These data and in situ measurements from the fields and GPS tractors are fed wirelessly and automatically into the GIS system for analysis and determination of future activities. A decision support system (DSS) approach is often used, where specific rules are defined in the crop management software that trigger actions to produce the maximum crop yield for the minimum financial cost. Numerical modeling and even daily agricultural futures and estimated crop prices vs. total expenses provide daily estimated crop yield in terms of total amounts and also in dollars per acre (in the United States).

The benefits of this approach are clear, and major production systems are in operation today in North America, Australia, Argentina, and Brazil that demonstrate up to 30–50% decrease in cost and in the required application of fertilizers and pesticides, with equally significant increased yields. The environmental benefits of reduced water use and fertilizer and pesticide application are also important benefits of the precision agriculture approach.

The initial research and development was conducted in the United States, and early prototype systems were developed in the United States, Canada, Australia, and Brazil. There were relatively simple at first but have grown in complexity and sophistication. There was less initial interest in Europe, where agricultural scales are on a much smaller size and where governmental crop subsidies and policies were key economic factors in agricultural decision-making. But inroads in the UK and then France were made. There was, and still is, much less involvement in Asia and Africa, where the high initial cost and technical requirements make such approaches less interesting. There is tremendous potential in China and India, but these have not yet been realized.

7.1 Current Status

Precision agriculture has matured to where, for certain classes of large-scale agriculture in the developed world, it can be implemented with off-the-shelf technologies and equipment and which will provide measurable benefits. Farming operations can purchase their own systems or can contract with companies which provide a contract service. The growth potential is huge. A recent 2018 market report by Zion Market Research states that the global precision agriculture market is currently values at around US$5 billion and is expected to grow to over US$15 billion by 2025, a 13% increase (Zion Market Research 2018). Another market forecast by Grand View Research, Inc. projects a global market of over US$43 billion by the same 2025 date (Hexa Reports 2019), driven by its increasing visibility and potential for efficiencies and reduced waste. This report states that the Asia-Pacific region is poised for significant growth led by China, South Korea, and Japan, which all share an advanced level of technical capability. Japan and South Korea also share a drastic need for improved agricultural production on very limited available land areas.

8 John Deere: Nothing Computes Like a Deere

The John Deere tractor company of the United States has established itself as a world leader in precision agriculture. Starting his business in 1804, John Deere was a blacksmith who introduced a steel self-scouring plow, which he introduced in 1837. This was much more appropriate for American needs, and was quickly adopted, making the company a leading provider of agricultural equipment to this day. As early as 1997, John Deere offered GPS receivers and computers as options for their many tractors. These early activities have grown to where they are deeply involved in not only GPS and computer-aided tractors and variable rate distribution systems. They purchased the NavCom GPS company in the 1990s and partnered with NASA's JPL in 2004 to be able to provide highly accurate GPS data (down to a few centimeters or 1 inch) to their autonomous GPS-equipped tractors in fields around the world. In 2017 they purchased Blue River Technology, an early artificial intelligence computer vision, and robotics start-up from Silicon Valley to continue their development of advanced smart farming systems (Fig. 14) (Gagliordi 2018).

According to John Deere, today some 1/3 of croplands in the United States are farmed using GPS-guided precision agriculture tractors, along with half of the crop areas in Europe and South America, and a surprising 90% of farmlands in Australia (Anderson, G 2018). (N.B. I find the 50% number for Europe to be quite high and believe it to be significantly lower).

Precision agriculture has arrived, and there are many other players. L3Harris Technologies is very involved, and major international agribusiness such as Monsanto and several others are as well. The European Union has become a major supporter of smart farming, seeing this as a means to support the continuation of agriculture in Europe, while providing environmental benefits and reducing agriculture-related pollution European Commission (2019).

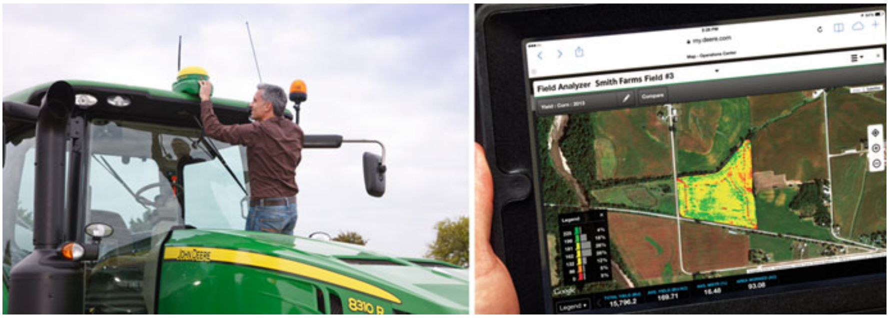

Fig. 14 A John Deere smart tractor and computer display. (Images courtesy NASA and John Deere https://www.nasa.gov/sites/default/files/thumbnails/image/spinoff_johndeere2.jpg)

8.1 Expanding the Precision Agriculture Model Beyond the Major Field Crops in the Developed World

Precision agriculture will not be limited to traditional crops like wheat and corn. Prototype projects have been conducted for fruit orchards, nut trees, and vines as well. There are similar approaches that are being developed for livestock using smart RFID sensors and automated feed and water distribution devices, ventilation and cooling, and "smart stalls" that weigh the animals and "smart collars" that monitor animal health. Similar systems are being developed for precision aquaculture, again consisting of in situ monitoring devices, DSS software, and automated water quality and feed dispensing systems. There are even prototypes for precision beekeeping systems. These systems have demonstrated the benefits, but, at present, precision agriculture is more suited to very large area mono-cropping in the developed world, where massive fields, up to 1000 hectares each, are managed using enormous and complex tractors costing millions of dollars and where high-speed Internet and computing is the norm. But there are currently relatively small agricultural businesses that are finding increases in efficiencies and profit using these systems.

9 Precision Forestry

Forestry is a very interesting and different industry, but which also has great promise regarding precision forestry technologies. There are currently some 300 million hectares of plantation forests in the world and an additional 900 million hectares of natural forests used for wood resource extraction. The value of this industrial forest is over US$200 billion, and wood remains the primary source of heating and cooking in the poorer regions of our world Choudhy, H. (2018). The world's forests also provide important environmental, recreational, animal habitat, and carbon sequestration benefits. The same basic concepts of precision agriculture can be applied to forestry, but there are also major differences and impediments. These include the fact that many forests are relatively unmanaged, are owned by governments, and are in remote and inaccessible terrain. Other forests are basically agricultural monocrops, but with a time frame of ~50 years per crop. Forestry is, like agriculture, a very conservative industry, little changes since the first scientific forest management concepts were developed in Germany in the nineteenth century, but this is all changing. Sweden has pioneered highly automated forest extraction systems that significantly increase the efficiency, safety, and speed of timber removal, and this has been widely adopted and has opened the industry to new and innovative techniques. A second recent innovation is the introduction of airborne LiDAR remote sensing, which is extremely useful for efficiently measuring large areas of timber resources (Fig. 15).

Today, forest management companies are beginning to consider the benefits of the precision agriculture model for forestry. The potential benefits of reduced costs and increased production are attractive, especially in regions of the world like Western Europe and parts of Asia where forest lands are limited. Deforestation

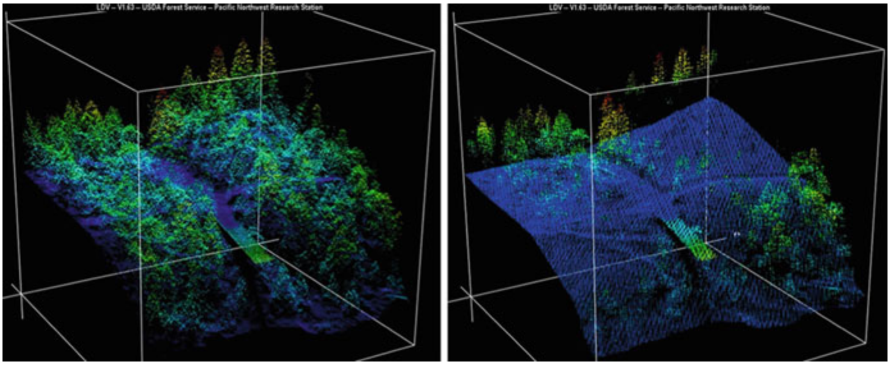

Fig. 15 Before and after airborne LiDAR images of the 2014 King fire region in El Dorado National Forest, California. (Image courtesy NASA JPL. https://www.jpl.nasa.gov/spaceimages/details.php?id=PIA19360)

and climate change impacts will also be increasingly important factors affecting where and how forest resources are available.

10 The Present Becomes the Future

This is the current status of these integrated tools, but the future, the very near future, will be very different and potentially quite amazing.

In my recent book on disruptive technologies and innovations and the new commercial space revolution, I discuss the synergy of many new IT and space technologies, driven by a new generation of space entrepreneurs, which will drive the next revolution in space applications here on Earth (Madry 2019). We are quickly approaching a new world where the integration of powerful new technologies and innovative and disruptive "Silicon Valley" entrepreneurial space ideas is fundamentally altering how we do space and what that means here on Earth.

What we are seeing is the development of an integrated and synergistic combination of enabling technologies that will soon revolutionize many activities here on Earth. These include, but are not limited to, satellite positioning, navigation, and timing (PNT), geographic information systems (GIS), airborne and satellite remote sensing, aerial drones, vast networks of in situ measurement devices, robotics and automation, big big data, cloud computing, the Internet of Things (IoT), artificial intelligence (AI) and machine learning, decision support systems (DSS), computer vision, 5G wireless Internet, machine-to-machine communications, nanotechnologies, advanced genetics and genetically modified organisms, miniature biological sensors, and much more.

The implications for agriculture are clear. Detailed and local soil, moisture, and weather models could provide input into which places to plant which crops. With global climate change, this could allow proactive restructuring of where which crops are planted to match the best field conditions with changing crop market values and changing needs. Making sure that each seed is put in exactly the right place and depth, with the right soil conditions and moisture content to allow each individual plant the best chance for maximum growth at minimum cost, is within the realm of reality and then tracking and nurturing that plant all the way through to harvest. Let us look at just a few examples of some of these new capabilities and how they will soon impact global agriculture and forestry.

11 Big Data and the Internet of Things

Agriculture, at every level, is an extremely complex and inefficient system of systems. We tend to focus on the crops in the fields and the process of growing and harvesting, but agriculture takes much more than this to bring food to the table. Big data and the Internet of Things have great potential to improve efficiency at all levels of the agricultural cycle. This includes the distribution of just the right type and amount of seeds and materials to the farm; fuel management; management of water, fertilizer, herbicides, and pesticides; and the entire distribution system of the harvested crops to storage, market, wholesalers, food processers, and, ultimately, the end users. Agricultural fleet management, from harvest to delivery to your local grocery store, could also be significantly improved, reducing fuel use and pollution and eliminating produce spoilage. An amazing 1/3 of all food produced globally today is lost, ruined, or wasted, according to McKinsey & Company (Mangin, C. 2016). This is an equally amazing $940 billion economic loss per year, and no other comparable global activity comes close to this level of inefficiency, not to mention that almost 800 million people on Earth, 1 out of every 9 of us, go hungry each day. It therefore also has some of the greatest potential to be easily reduced using emerging big data, data analytics, and IoT systems. Tools like RFID and cloud computing could also significantly improve global agricultural production and supply chain management, solely through decreasing the vast amount of inefficiencies, theft, waste, and loss.

12 Big Weather

Improved weather forecasting can also play a major role in better crop management, through the reduction of the use of irrigation and potential crop damage such as hail, severe winds, or other severe weather. No less than IBM has developed a new precise weather forecasting system that they call Deep Thunder, which can feed data into improved models and production management systems. Based on the IBM Thomas J. Watson Research Center in New York, this program uses IBM's supercomputing power and data to develop new detailed weather models. These are based, in part, on over 200,000 Weather Underground personal weather stations and smartphones in a powerful example of crowd sourcing and citizen science, in addition to other sources including weather satellite data. It creates 24–48-h weather forecasts at 1–2-km resolution. The future potential is for accurate forecasts down to the square meter.

This concept could lead to more precise timing of planting, harvesting, irrigation, and mitigating potential damaging events such as severe winds or citrus freezes. IBM estimates that crop losses from severe weather events alone could be cut by 25% using this system (IBM 2019).

12.1 The Next Revolution: The New Mega LEO Satellite Constellations

Most precision agriculture systems today are stand-alone. Many are based on a single computer or local system, one GPS tractor, and are used to manage a single agricultural operation. The current limitations, including the lack of high-speed wireless bandwidth, particularly in the developing world, significantly limits the broad utilization of this technology, but this is soon about to change. This is because we will soon be able to add to this list of technologies the several new mega LEO satellite constellations that will provide seamless and low-cost telecommunications and remote sensing across the globe. Each of these technologies discussed briefly above is a stand-alone technology, but it is the synergy of these that will bring the powerful benefits of precision agriculture. Much of this synergy depends on the ability to pass large amounts of data seamlessly between different data monitoring, acquisition, and analysis systems and sensors in the fields and on the tractors and from satellites in space to the ground.

12.2 The Coming Mega LEO Revolution

A new generation of LEO remote sensing satellites is also an important part of the precision agriculture revolution. Led by Planet (formerly Planet Labs), there is a new generation of civil remote sensing satellites that are smaller and which can provide daily or even hourly image acquisition of the entire planet, an important component of detailed agricultural monitoring (Fig. 16).

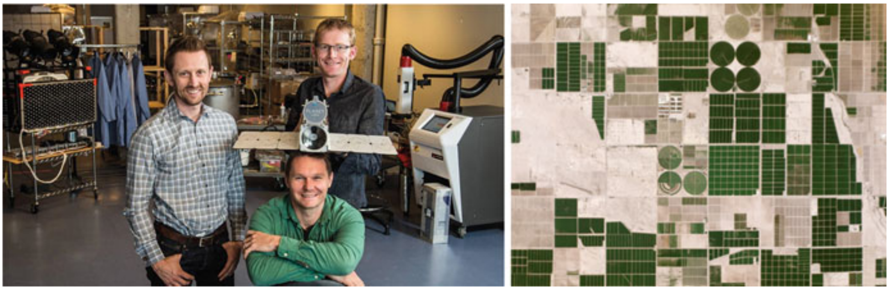

Fig. 16 (**a**) Planet “dove” satellite (and designers), a 3-U CubeSat remote sensing design. (Image courtesy Planet, Inc. https://www.sciencemag.org/news/2015/04/feature-how-tiny-satellites-spawned-silicon-valley-will-monitor-changing-earth). (**b**) A Planet satellite image of agricultural fields. (Image courtesy Planet, Inc. https://www.planet.com/pulse/planet-labs-strikes-agreement-with-wilbur-ellis-to-enhance-agverdict-data-tool/)

Planet has announced strategic partnerships with two major precision agriculture providers. In 2015 they announced a partnership with Wilbur-Ellis, to provide imagery for their AgVerdict data product (Alban 2015), and also with Farmers Edge, another major precision agriculture service company, to provide imagery to their products and services (Grassi 2017).

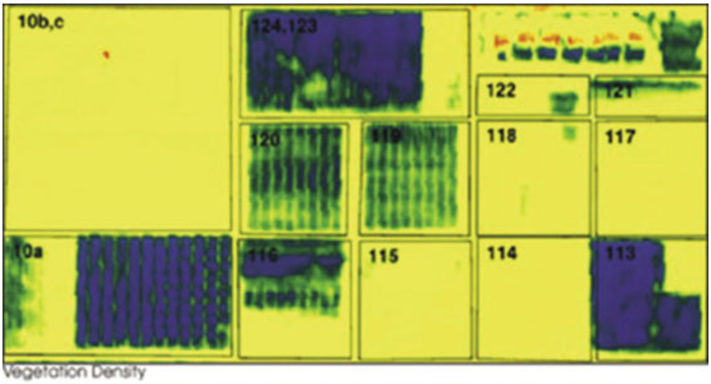
There are other LEO remote sensing systems active and in development, including hyperspectral systems, which can significantly improve agricultural classification. Also now available are a new generation of high-resolution RADAR satellites, which are particularly useful in agricultural areas with persistent cloud cover.

Urthecast (urthecast.com) currently offers 75-cm pan-sharpened imagery as well as their OptiSAR RADAR constellation. This system has 16 satellites in two orbital planes, and combines multispectral optical and SAR RADAR satellites flying in tandem, providing 1-m imagery and .5-m RADAR on a daily (or more frequent) basis. No matter what the weather is on the ground, data can be acquired, and the fusion of optical and RADAR data provides added detail.

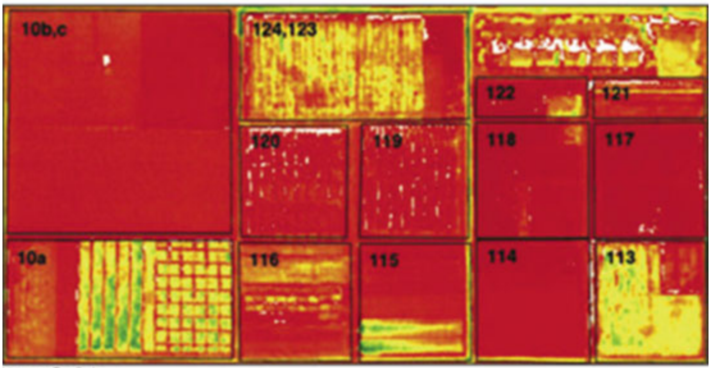
And a new generation of hyperspectral imaging satellites is in development and already in orbit. These systems sample the electromagnetic spectrum in hundreds or thousands of slices, providing much more information for precision agriculture, but they also require more sophisticated satellites, plus more data transmission, and data processing. Recent increases in data processing and lower data storage costs will mitigate these in the future. In the private sector, San Francisco-based HyperSat LLC has raised $85 million to launch two hyperspectral satellites in 2020: NorthStar from Canada plans a 40-satellite constellation and has over $80 million in financing, including funding from the Canadian government, and Brazilian company Satellogic has raised $27 million and has launched three satellites so far. Constant satellite imaging of the Earth is now a reality, and this is a powerful part of the precision agriculture future. Ultimately, it will be the combination of all of these systems, as well as airborne and drone systems, that will provide increased crop classification, as well as improved drought and stress monitoring for input into the precision agriculture management process (Fig. 17).

12.3 The New Broadband LEO Systems

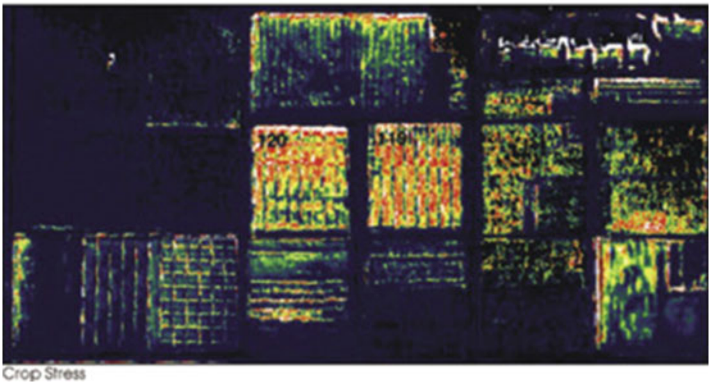
But the real LEO revolution is the coming wideband telecommunications constellations that are currently in development. There are several proposed mega-low Earth orbit (LEO) satellite telecommunications systems coming soon. All of these share a general architecture and goal: to provide high-speed and low-cost, wideband Internet connectivity worldwide. The benefit of LEO constellations for telecommunications and broadband Internet services is the low signal latency. Being only a few hundred km above the Earth, these systems have a very low signal delay, as opposed to the traditional GEO orbit at 35,786 km (22,236 mi), which can have a signal delay of some 540 milliseconds (~1/2 s) round trip. The downside of LEO constellations is that they require many more satellites to provide global coverage, due to the small footprint on the ground at that lower altitude. One GOES telecom satellite can cover nearly 1/3 of the planet, where it takes several hundred satellites to provide global



Vegetation Density



Water Deficit



Crop Stress

Fig. 17 NASA hyperspectral image showing vegetation density, top; water deficit, middle; and crop stress, bottom. Using algorithms and techniques, it developed with funding from Goddard Space Flight Center. This image was developed by the NASA Goddard Space Flight Center for the precision agriculture firm GeoVisual Analytics to let them learn more about their customer's crops, including predicted yields. (Image courtesy NASA. https://spinoff.nasa.gov/Spinoff2017/ee_8.html) coverage from LEO. This means you must build, launch, and operate a much larger number of satellites, but they can also be smaller and less complex than the very large, and very expensive, traditional GEO telecom satellites, and new lower-cost launch systems like the SpaceX Falcon 9 significantly reduce the cost of launch. One added complexity of these is that the satellites come into and leave the view of any place on the planet quite quickly, so satellite-to-satellite optical laser links are required to maintain the connection between any two places on the Earth. While this adds complexity, the speed of light in the vacuum of space is actually faster than through terrestrial fiber optic lines, so the speed of a LEO space Internet connection will be, at least theoretically, faster than today's systems. The satellites also must be replaced more frequently due to the atmospheric drag at lower altitudes. But the benefit will be truly global broadband Internet services. It must be remembered that only some 20% of the world today has high-speed cell service. The change will be revolutionary. So who are the new entrants?

OneWeb, which is obtaining new financing from the U.K., is now seeking to move on from its bankruptcy so it can deploy its large LEO constellation. Airbus, which is the manufacturer of the satellites as well as an investor in OneWeb, has built a low-cost mass production plant in Florida in the U.S. where the smallsats are being constructed. The deployment schedule for these satellites has been disrupted by the bankruptcy and will be delayed beyond the 2021 deployment date.

Elon Musk's SpaceX is developing the Starlink constellation, which will consist of some 12,000 (!) LEO satellites in several different orbits. Two prototypes are already in orbit for testing, and in May of 2019, the first 60 operational satellites were launched, on a single previously flown SpaceX Falcon 9, of course. The total cost of the system is estimated to eventually be some $10 billion. Often overlooked is the significant ground infrastructure that these will require. SpaceX Services, Inc. filed an application with the US Federal Communications Commission for the licensing for up to one million fixed satellite Earth stations, which would be the user terminals for the system. This system is designed, in part, to provide commercial funding for Musk's Mars exploration activities. He has received a $1 billion investment by Google and Fidelity to build out the system.

Kuiper Systems, a wholly owned subsidiary of the Jeff Bezos-led Amazon, filed documents requesting permission to launch a 3236-satellite constellation. The system would place the satellites into 98 orbital planes at altitudes of 590 to 630 km, including 784 satellites at an altitude of 590 km, 1296 satellites at a height of 610 km, and 1156 satellites in 630-kilometer orbits. The goal, again, is global broadband Internet service direct to end customers.

The Canadian company Telesat is creating a 300-satellite LEO constellation for Internet services, which should be capable of offering service throughout Canada by 2022 and globally by 2023. This system has received US$60 million from the Canadian government (Henry 2019).

Fig. 18 Canadian Telesat LEO satellite. (Image courtesy Telesat)

Thales Alenia Space and LeoSat of Luxembourg have also announced plans for a similar satellite broadband system, with 108 LEO satellites in 1400-km polar orbits that will be more focused on governmental and large corporate customers (Fig. 18).

Finally, technology giant Samsung has announced a plan to develop a 4600-satellite constellation, designed to provide up to 200 Gb per month directly to up to 5 billion of the Earth's people, but they have not yet made a final commitment (Khan 2019).

These systems, even if all are not built, and probably will not all survive in the open marketplace, will create a new and integrated digital world, including a global Internet of Things. But by far the greatest difference is the new generation of commercial space entrepreneurs who see IT and space as a launch pad to new commercial and humanitarian capabilities that exceed our current mindset. We are rapidly approaching a very different and challenging global context regarding food and agriculture, one that also brings a hopeful and possibly revolutionary technological environment that could make a real impact. But where do we go from here?

13 Discussion

Some conclusions and recommendations for the further implementation of precision agriculture are appropriate here, as a guide for consideration of adoption of precision agriculture more broadly in the developed world and also in the developing world nations of Asia and Africa. A European Union focus group in 2015 on the mainstreaming of precision agriculture in Europe made several important conclusions and recommendations that are relevant to this question (European Commission 2019). A liberal paraphrasing of some of these conclusions includes the following important points:

1. Farmers must be actively involved in the development of these tools.
2. Skilled advisors will be important to successfully bring these tools to farmers.
3. Potential economic benefits are hard to measure and must be clearly and convincingly demonstrated.
4. Small and medium farms need reduced up-front investment and lower risk before they can consider adoption.
5. Technical progress must continue, and costs must continue to come down.
6. Shared data is an issue for farmers.
7. More research is needed on applying these rapidly advancing technologies to small and medium farms.

Recommendations included:

1. Development should focus on practical farming problems and not on technology.
2. Multi-actor collaboratives are needed to address the complexity of the problems, and teams need to be formed consisting of farmers, technologists, and others.
3. Analytic support tools and training tools are needed.
4. DSS models and related tools are needed to help farmers determine if this will work for them before they invest.
5. Up-front and total cost and ease of use are important.
6. New business models for data management are needed.

These general conclusions and recommendations can be more broadly applied regarding the appropriateness of advancing these technologies around the world. Clearly, in Asia, Africa, and poor nations around the world, there will be very different contexts regarding the introduction of precision agriculture. But the general conclusions and recommendations listed above serve as a good guideline for consideration.

Clearly, farmers must be involved in the development of these tools if they are going to be successfully implemented. This goes for other key players as well, including the financial institutions that traditionally finance the annual up-front costs of farmers for seed, etc. This brings up the issue of technology push vs. user pull. We are very good at developing new technologies, which we push out to potential users, often without success. This approach is unlikely to succeed in such a very traditional and non-tech industry such as agriculture. Precision agriculture is certainly a technology push approach, and we need to find additional ways to bring the farmers and agricultural interests more into a user pull mode, where they work with precision agriculture interests to develop tools that they actually need and want to adopt and actually *can* adopt. A key component of this will be developing credible case studies that demonstrate the benefits of these systems to a variety of use cases, crops, scales, and geographic locations. The up-front costs required of such technologies need to be reduced, and the level of technological sophistication required by farmers needs to reduced significantly. Training opportunities for potential users must be developed that are realistic and made widely available. Ultimately, new business models for farmers are going to need to be developed that are relevant to the cultural, social, political, and economic realities of farmers who are not accustomed to this new way of integrating advanced technologies into their farming operations.

There are already several innovative and culturally and technologically appropriate activities already occurring. For example, in Kenya, a platform for connecting agricultural producers and purchasers has been established called Sokopepe (https://sokopepe.co.ke), that links small farmers to bulk purchasers. They also have an information system providing small farmers access to data, market information, weather, and more, all using the prevalent SMS systems found throughout Africa. Another similar tool there using SMS is called MFarm (https://www.mfarm.co.ke). This provides current commodity prices for different regions and connects small farm operators with buyers in ways that have traditionally been impossible for them. Previously, small producers were never aware of the different prices buyers were offering, and they would simply sell to the nearest market. Now they can find the best prices for their products in their region, and get connected with wholesale buyers directly, all through SMS. There will be many developed vs. undeveloped world issues this all plays out. There will not be a one-size-fits-all version of precision agriculture.

All of this will raise many new and complex legal and policy issues. There is already a strong reluctance of farmers to release data on their operational efficiencies to banks and governments, for obvious reasons. Who will own all of this very detailed data? Who has access? Who is liable if mistakes are made due to incorrect data? How vulnerable would these systems be to hacking by criminals, non-state actors, terrorists, or hostile nations?

Closely related to the legal issues are the myriad national and international policy issues that will involve the intellectual property, copyright, and digital data issues that will be raised. Who will benefit from these decisions? Will it be only the large international agribusiness? Will the interests of small and medium farmers and producers be protected? Policy and legal decisions always trail behind technology developments, especially today, and so policy-maker and lawmakers are always playing catch up.

Food safety is another important aspect of the global agriculture equation that could be impacted by this new generation of agricultural technologies. Creating a digital data chain that allows the consumer or government agency to track a food product all the way back through the production and distribution chain to the producer could revolutionize food safety management and the response to outbreaks of food-borne diseases or food terrorism, which is, sadly, a growing concern.

Another key concern moving forward is the potential dependency upon these complex and computer-based technologies for our global food supply. In traditional agriculture, the individual farms and farmers are highly independent and not dependent upon outside factors. An integrated global precision agriculture system brings the promise of increased yields and efficiencies, but what do we do when the system goes down, whether if from accident, mistake, or intentional attack? The potential dangers of this are evident. Complex systems that can fail will fail.

And these systems do not come for free. Million dollar GPS tractors are not likely any time soon in most African contexts. Any increases in productivity must also pay for all of the cool tech that will be required and the satellite builders, tech developers, and systems administrators that will have to be paid. Agricultural labor is among the cheapest in the world, hyperspectral satellite data analysts and satellite constellation controllers are not. Automation of much of the data processing flow will be vital if precision agriculture will be able to succeed in the developing world.

14 Final Conclusions

Global population growth, urbanization, and climate change will bring unrivalled pressures upon the global food supply system, and new efficiencies and capabilities will be required sooner than many believe. Precision agriculture will soon bring powerful new capabilities to a world that will see tremendous new food and fiber needs, but there are significant technical and cultural challenges.

While these new technologies, including the upcoming new generation of mega LEO satellite constellations, will bring low-cost and high bandwidth data around the world for the first time, their broad adoption in agriculture is far from certain. These new capabilities, combined with the new persistent remote sensing systems and allied GNSS and other technologies, could bring a new revolution in agriculture. But agriculture is the world's most traditional sector, and how it is willing or able to adapt to these radical changes will be interesting to watch. Our dinner may well depend upon it.

Small Satellite Systems to Manage Global Resources, Energy Systems, Transportation, and Key Assets More Efficiently

Scott Madry and Joseph N. Pelton

Contents

Abstract

The UN Committee on the Peaceful Uses of Outer Space and its Working Group on the Long-Term Sustainability of Outer Space Activities (LTSOSA) have sought to develop recommendations that could help allow humans to continue to access space for the longer term on a sustainable basis. The United Nations General Assembly has also approved a series of 17 sustainable development goals to assist nations to create clearly defined aims to improve the human condition for the longer term by means of well-defined objectives. These include goals to improve the atmosphere, the land, water, energy systems, transportation,

https://doi.org/10.1007/978-3-030-36308-6_57

and more. These various efforts of UN COPUOS and the UN General Assembly are described elsewhere in this chapter.

This chapter, however, is not about attaining these various clearly set goals and recommended actions. Rather it is about the opposite side of the coin. Thus it specifically addresses how small satellite projects and activities can provide capabilities to improve performance in many areas and also to aid new monitoring and enforcement capabilities. The areas of monitoring and enforcement can be as wide as new zoning and planning systems, a strengthening of environmental protection practices, or various forms of law enforcement and national defense. These new tools can help to assist nations, in both developed and developing economies, to exploit new and cost-affordable small satellite capabilities to make many industrial, corporate, or business more efficient on one hand or to prevent harmful practices related to the air, land, and sea environment.

The monitoring of certain key resources such as fish or fresh water or key natural resources might serve a key function of monitoring the "health of our planet" as a sustainer of life, especially human life. In short small satellites that monitor and keep track of our supplies of drinking water and nourishment and help protect vital resources could serve the function of a canary in a coal mine of letting us know when the dangers of overconsumption have reached perilous levels.

This can also be stated in a more positive and proactive way. Our new cost-effective "eyes in the skies" can be translated into finding new ways to manage resources such as fishing grounds, water, forests, natural resource mining, and other finite materials that need better management and systematic recycling. These new satellite tools can assist with longer-term goal setting to meet the needs of future generations. Such efforts may need deployment and use of not only small satellite networks but new regulatory processes, laws, or best practices that can be established on a global basis and consistently followed around the world.

This chapter seeks to address the use of small satellites to address areas of water, energy, transportation, and environmental concerns, as well as the use of satellites to help provide oversight and enforcement processes in these and related sectors. These sectors of regulatory concern include such areas as fishing, mining, packaging, and even recycling practices. Ultimately, addressing these issues involves more than efficiency of global operations and economic success but sustainability of humans and all the life forms on Earth over the longer term. Thus it is now recognized that one must produce energy for use by consumers and industry but do so in a sustainable way. The same is applied to transportation systems, mining, food production, and so on. The prudent use and supply of potable water may prove to be one of the greatest challenges of the coming decades.

Thus the topics that will be considered are addressed not simply in terms of economic output but in other ways that include possible enforcement practices, environmental concerns, and perhaps ways to create new incentives for positive behavior by citizens and businesses.

The special emphasis will be on how small satellites and related ground systems and data analytics might be combined together and used in a constructive

way to achieve required results around the world to preserve the resources needed for future generations. In some ways, this chapter closely correlates to the chapter on small satellites, resource management, and "smart farming" and "smart forest management." The discussion of "smart farming" and "smart forestry management" is geared to see how constructive use of new satellite technology and systems can increase productivity and multiply output; yet here too, there may well be a need to develop improved standards and environmental enforcement measures to achieve overall desired results.

1 Introduction

There are increasing concerns that humans are overconsuming a wide range of resources. As there are more people, more urbanization, and more consumption of energy, food, fish and water, metals, wood, petroleum, and hydrocarbon fuels, there is also more pollution. These patterns of overconsumption and a lack of recycling are sometimes referred to as "non-sustainable" economic practices. The lack of a positive circular economy where resources are reclaimed rather than consumed is quite negative, in the longer term, for both developed and developing economies. Population growth compounds these overconsumption patterns.

These negative results can be seen in many ways that include climate change; shortages of potable water and, over time, food and fish; the dying off of many species of animals and plant life; and systematic flooding of coastal areas.

Geologists have informed us that we have now entered the Anthropocene Age, where humans are the major shaper of change in our world today. A recent UN report documents the accelerated rate at which more and more species are dying out under human influence (Fears 2019). All of the trends raise serious concerns. One of these negative consequences is that the future needs of generations yet to come are increasingly at risk.

These are not self-correcting issues. But issues as large in scope, magnitude, and timescale that have been called by ecologist and English professor Tim Morton "hyperobjects" are difficult for people to cope with in any sense of competence. Unless we are hit over the head by a catastrophic event, we are slow to take any corrective action. So far most of the human response to the ongoing climate crisis has been more like putting a band aid rather than applying a tourniquet.

Although some economically developed nations have reached zero population growth, some of the largest nations in the world such as India, Nigeria, Indonesia, and Brazil and many Middle Eastern countries have substantial population growth rates. The current global population rate may bring human levels to as much as 12 billion by 2100. Population growth rates as they are occurring today more than offset “green initiatives” such as electric cars or solar or wind energy systems. Population growth is largely outstripping global supplies of food, fish, and especially water.

Of all the scarce resources on Earth, fresh or potable water is now the most critical. If one starts with all the world’s water, this seems to be far from true. There is a total of 35 million cubic kilometers of all types of water. Of this amount only 2.5% of the total represents fresh water. And of this supply, at least 70% is not accessible either because it is frozen in the polar ice caps, permanent snow cover, or it is buried deep in crater lakes. Thus today humans, animals, and all vegetation can get access to about 200,000 cubic kilometers of fresh water. The following graphic prepared by the Sierra Club dramatically shows the limited supply of water compared to the total volume of Earth (see Fig. 1).

Further, the fresh water available is far from evenly distributed. Studies undertaken by the UN Food and Agricultural Organization have estimated that by 2025, 1.8 billion people will be living in areas where access to potable water will be limited or extremely scarce (Ruz 2011).

Of all the functions that small satellite constellations will carry out, providing inventories of water, water shortages, and information about such things as water leakages and information about underground water aquifers may well prove to be the most vital function.

The good news is that small satellite constellations that are combined with data analytics could begin to provide useful and actionable information to national

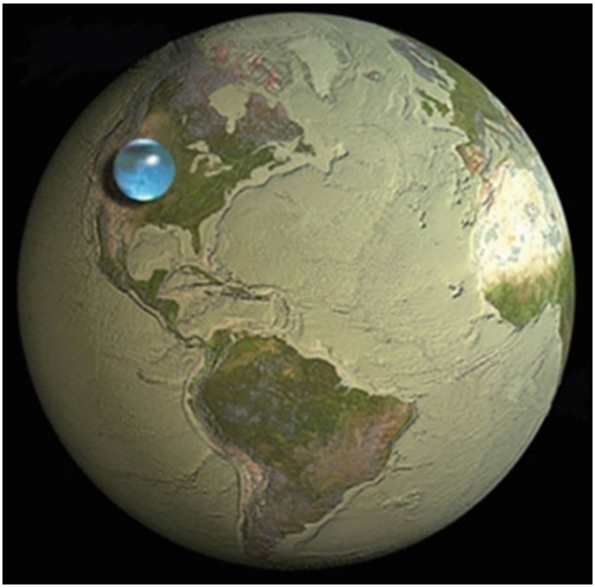

Fig. 1 Graphic showing the limited supply of water compared to Earth’s volume. (Graphic courtesy of the Sierra Club)

planners and regulators around the world and many types of resources including food, fish, and water. Remote sensing satellite constellations could chart the global supply and demand patterns of any types of resources with new precision.

The data analytics could produce growth trends in consumption rates of food, fish, water, and energy; car, truck, and bus miles driven; desertification; loss of arable land; loss of wet lands; and even presence or extinction of endangered species. The analysis that follows can start to document what existing sensing data is already telling us about key consumption patterns. The question that remains is whether there will be systematic attempts to get more fine grain data that could be used by regulators. Small satellites, particularly in remote sensing, could be used in such areas as pollution oversight and regulation, taxation policy to create new incentives and disincentives, and so on.

2 The Use of Small Satellite Consortiums as a Source of Regulatory Control and Incentive

The first question is whether small satellite-collected data can and will be effectively linked to new regulatory controls and/or tax incentives, and if so, will these new processes be embraced and used in national, regional, or even other forms of global planning to reduce pollution and make industrial and consumer practices “greener.”

The new small satellite consortia such as Planet and Spire and other new remote sensing satellite systems around the world will be able to generate not only a prodigious amount of information but with a return rate measured in hours – not days or weeks. The key is whether governments, nongovernmental organizations, and environmental groups join forces to make this data actionable.

If the right incentives – and penalties – are devised and enforced, this new satellite-based information can encourage and bring into being “circular economies” around the world. A circular economy is one that uses renewable energy rather than disposable energy. A circular economy is one that that is focused on reusing metals and chemicals and consuming food that grows in fields rather than depending on livestock. In short, a “circular” economy is the reverse of a “disposable” economy that eats up its resources rather than recycles them.

The new and rather precise tools that collect information about all forms of consumption several times daily are a very powerful mechanism that can be used to rein in the worse forms of abuses in terms of pollution, overconsumption, and lax practices with regard to recycling, overfishing, and wastage of water, food, and metals and also help to limit the use of dirty fuels. Alternatively there could be new incentives created to eat less meat and consume more environmentally friendly foods, use less water, use greener energy, and generally pursue more environmentally benign patterns of behavior. The use of more incentives such as lower taxes or rebates on green resources could be a powerful tool for conservation, if consumers are willing to “buy into a monitoring system” that provides a degree of tracking of their consumption habits.

The new “eyes in the skies” tools can do more than monitoring pollution or overconsumption patterns. These tools can be used in many other ways. This might be used to help develop better transportation and distribution processes and aid in the improvement of weather data and agricultural processes and hydroponic farming techniques. Essentially the key is to link up global patterns of consumption and environmental changes with important new processes. This might be the restocking of fishing areas, the monitoring of mining, or the recycling processes or other uses of big data analysis to see where progress is being made and where overconsumption or disposable economic practices are increasing.

The key is really not small satellite constellations and their data gathering but big data analytics and the creation of new tools to allow critical data to be acquired in a systematic basis. There are ways to encourage and incentivize a range of “green” practices, “circular” economic practices, zero-growth population practices, etc., and these can, of course, also be linked to penalties for abuses linked to overconsumption.

It might reasonably be observed that a good deal of data is already available, yet despite this information, a number of environmentally destructive and counterproductive behaviors by consumers, industrial producers, and governmental legislators and regulators still continue. This is a valid and quite significant point to address.

One might hope that if the data can be applied to the day-to-day practices of individual consumers, so that they could actually “see” how their particular behaviors are creating unacceptable levels of overuse, people could see in near real time how their patterns of consumption or unintentional polluting activities might be reformed by new patterns of consumption, and they might indeed be motivated to change.

If people – or companies or governments – could almost instantly see where their consumption patterns, when compared to others in their town, city, state, region, or country, were out of step, then they have a much greater chance of changing their consumption practices.

If the data analytics, linked to high-performance but low-cost small satellite sensing networks, can show people their excessive consumption actions, and what simple changes could make a difference, there can be potential for both better understanding and eventual reform of their practices.

It is quite possible for many people to be unaware of when they are needlessly consuming too much water, using too much energy, eating too many calories, polluting the air too much, etc.

The key to change is a clear and viable offering of reasonable and cost-effective alternatives. These options will often need to be tied to various penalties and incentives that complete the picture. The appeal to people to save resources for their grandchildren and great grandchildren is fine, but alternatives must show a reasonable way forward. Most people will start to reform if they can, for instance, find ways to use less water than before, save money as well as water, and make available to others a resource that they desperately need. The most important change will perhaps be “institutional change.” This might be new laws and penalties to create limitations with teeth against significant new developments in deserts where water is already in short supply.

There are impressive projects such as undertaken by Dr. Jerome Glenn that monitor many key patterns of consumptions and chart key trends, but this data is provided as macro-data to corporate, government, and defense-related officials. It is meaningless to individuals if they cannot see the impact of their everyday practices in terms of what it means for their family versus the families in other towns, cities, or nations. If they could see in ways that they could readily understand what their “standard of living” means to others in the world or subtracts from the heritage of their grandchildren, it becomes a more powerful story. If they could also see the ways that they could pollute less, consume less water, and waste less energy, progress might well be made. The key might well not be the new small satellite constellations that produce new data every 4–6 h but the data analytics that can show the implications in near real time of what their patterns of consumption, pollution, or waste actually mean to others that are denied resources that are being wasted without much thought of their larger implications. Much indifference is likely born of a lack of understanding as to what the implications of their action really entail.

At least a substantial number of people would respond to the actual knowledge that in the last 12 h, they had used four times more water, ate twice the amount of food, used three times more energy, or created one and half time waste than a counterpart in say rural Portugal. Especially if they could understand how they might re-equip their house, plan their water and food consumption differently, or use a different type of car or solar or wind source to be environmentally more friendly, at least the hope would be that many would use that new information in a constructive ways if they were consistently made aware of their consumption patterns. Such a localized and personalized reporting system on consumption is, of course, not a panacea. Some people would be indifferent to such information, but they might respond to thought leaders or seek to conform if their neighbors began to behave differently and they began to stand out overtly as being outside the norm. In some cases, parents might refuse to adapt, but their children would see the social, cultural, and moral value of change. Let’s explore some of the data that is now available at least at the macro-level, even though it is not broken down to the level of towns, neighborhoods, and households.

3 Food, Fishing, and Water

The following profile of global food consumption is broken down on a calorie consumption basis. It shows the differences in diet around the world and also shows an upward trend in calories in all regions of the world (Global and Regional Food Consumption Patterns and Trends 2019) (see Table 1).

The question is: Is this consistent growth in food and calorie consumption actually a positive trend line when seen against the longer-term needs of the planet? If one projects the population of the world which is now around 7.8 billion, which could reach 12 billion by the end of the twenty-first century, and food consumption of humans averaged some 3000 calories per day, that would total 36 trillion calories of food each day or 1.3 quadrillion calories per year. This, of course, does not take

Table 1 Daily food consumption measured in calories for regions of the world

Region	1964–1966	1974–1976	1984–1986	1997–1999	2015	2030
World	2358	2435	2655	2803	2940	3050
Developing countries	2054	2152	2450	2681	2850	2980
Near East and North Africa	2290	2591	2953	3006	3090	3170
Sub-Saharan Africa (but not South Africa)	2058	2079	2057	2195	2360	2540
Latin America and Caribbean	2393	2546	2689	2824	2980	3140
East Asia	1957	2105	2559	2921	3060	3190
South Asia	2017	1986	2205	2403	2700	2900
Industrialized countries	2947	3065	3206	3380	3440	3500

These statistics and projection for 2030 come from the UN Food and Agricultural Organization

into account food for horses, cattle, dogs, cats, and all the other animals that inhabit Earth. In many ways, this path forward for an Earth of finite resources is quite troubling in terms of potable water supply where nearly a billion people have an inadequate supply today. And for the longer term, this will also translate into an inadequate food supply. Already there are lists being developed of many resources especially metals that are becoming scarce.

In 1800, there were only 800 million people on our planet. In 1900, there were 1.8 billion. Today there are 7.8 billion, and in 2100 there will be perhaps 12 billion. It is reasonable to project that this time, there will be shortages at many levels. Some of these key areas are most likely to be potable water, food, fish, and cost-effective and clean energy supplies, as well as major gaps in education and healthcare systems, sufficient transportation systems, and certainly many minerals, metals, and other natural resources (Pelton 2019).

The average of calorie consumption for a country or region does not reveal the variation in calorie intake. There are charts that show that for certain regions and countries, the disparity of calorie intake is quite high. Indeed studies have shown that in many countries such as China, Mongolia, and other parts of Asia, plus over a dozen countries in Africa, there is a wide variance as to the daily caloric intake between the wealthy and poor. In some cases there are truly dramatic differences (Roser and Ritchie 2019).

The bottom line is that there is a significant likelihood of food shortages coming in future decades, and so the supplies and areas of shortages need to be carefully monitored. Some of this gap will come from population growth, and other aspects may come from a higher standard of living and more food intake. One area that is not always carefully considered is the consequences of climate change and more crop loss due to violent storms such as floods, hurricanes, typhoons, and tornados that can wipe out many crops. On top of this, climate change conditions that will lead to droughts in some areas and flooding in others will create areas with intense shortages and major changes in food production areas requiring changes in infrastructure and land use. The biggest single factor may be the lack of water. Cape Town, South Africa, faced a near-zero hour water supply crisis in 2018, where there simply would not be drinking water available to millions of people in a major urban area. In many areas of the world, access to water will lead to limited crop production, desertification, or even famine in the decades ahead.

The problem of water supply is clearly increasing as shown by the imaging from space documenting the "desertification" of our planet. The key statistics are not encouraging. This is a quote from a recent article in The Guardian newspaper in the UK: "Currently, 844 million people – about one in nine of the planet's population – lack access to clean, affordable water within half an hour of their homes, and every year nearly 300,000 children under five die of diarrhea, linked to dirty water and poor sanitation" (Harvey 2018).

Remote sensing satellites can show not only the immediate status of the world, but analytics can show the annual cycle of rainfall, the cycle of vegetation, and the longer-term movements toward desertification. Figure 2 shows the spread of the Saharan desert that has forced residents of the region to relocate in search of consistent access to water supplies.

And the problem of access to potable water is getting worse. The NASA Gravity Recovery and Climate Experiment (GRACE) satellite project has mapped nearly 20 hotspots over a period of 15 years. These hotspots are specific areas where water resources are drying up and underground aquifers are becoming saltier and depleted of water. These include areas in China, India, the Middle East, and even California in the USA. The data from the GRACE satellite observations have confirmed the predicted likely outcome when the GRACE satellite was launched. The data show that areas prone to drought are indeed drying up, including major key aquifers, and

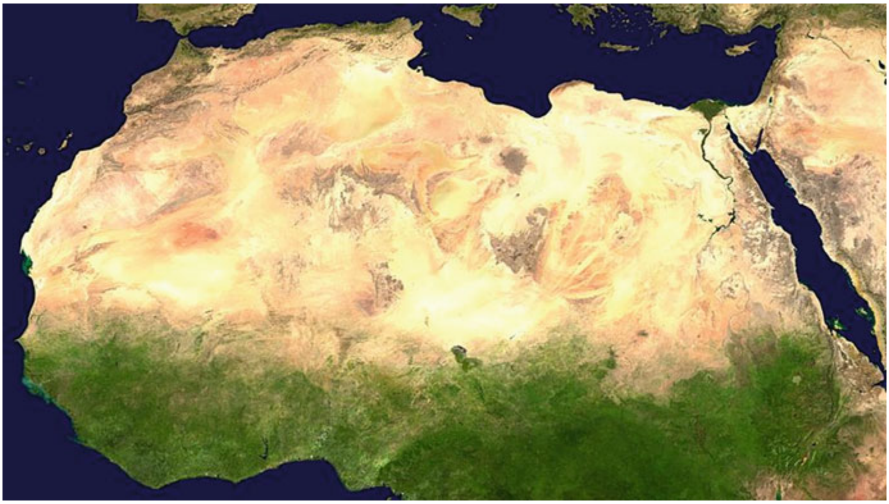

Fig. 2 Imaging from space that shows the southward growth of the Sahara Desert. (Graphic courtesy of NASA)

Table 2 Key applications of smallsat constellations for fishing, food, and water conservation

Small satellite constellation-based services for fishing, food, and water conservation
Global monitoring of aquifers that are being depleted or becoming polluted with salt
Measurement of levels for lakes, rivers, and reservoirs and analysis of why changes are occurring
Development of new systems to measure loss of vital habitats and systematic ways to monitor the loss of species in both the animal and plant worlds
Detection of faults in dams, leaks in pipelines, and other water wastage
Detection of schools of fish and changes in patterns in schools of fish
Measurement of productivity of crop fields and detection of crop diseases
Support to "smart farming" by new ability to apply water and fertilizers in a targeted manner
Better ways for ordering fertilizers and supplies and arranging delivering at lower cost
Ability to monitor markets and finding the best time and location to bring crops to market
Ability to take remote training courses in water management, agricultural production, and water conservation

areas that are already wet are typically getting wetter. The drying up of these major aquifers may represent the biggest challenge of all (NASA Gravity Recovery and Climate Experiment 2019).

Currently, about 65% of the total fish food supply is obtained from fishing in marine and inland waters, while the remaining one third is derived from so-called aqua-farming. During the last years of the twentieth century, total production from both inland and marine capture fisheries has reached a peak of about 10 kg per capita. Increases of productivity in fishing for the last 20 years have come from aqua-farming. This is particularly the case for the highest value fish.

There is considerable evidence that new small satellite constellations for networking, remote sensing, etc. can make significant contributions to fishing, food production, water conservation, and detection of sources of desertification and depletion of aquifers around the world. The applications indicated in Table 2 are just some ways that these new systems can increase productivity, sales, and profits and detect problems in these areas. The improved use of these systems will in time greatly expand, particularly as hyper-spectral analytics and other new ways to use these space tools evolve.

Clearly there is growing evidence that there is a correlation between human activities and the loss of more and more species as has been reported in the recent UN report. This disturbing report has indicated how the spread of people across the world is threatening all sorts of biota on land and in the sea (Leahy 2019). The UN report has warned that as many as a million species are now at risk (see Fig. 3).

4 Smallsats and New Trends in Energy Systems, Climate Change, Tele-services, and Transportation

The world has depended on some form of hydrocarbon fuels for a very long time. This was first wood, then coal, and now natural gas and oil. The human population keeps growing and has now nearly reached 8 billion and is headed to perhaps

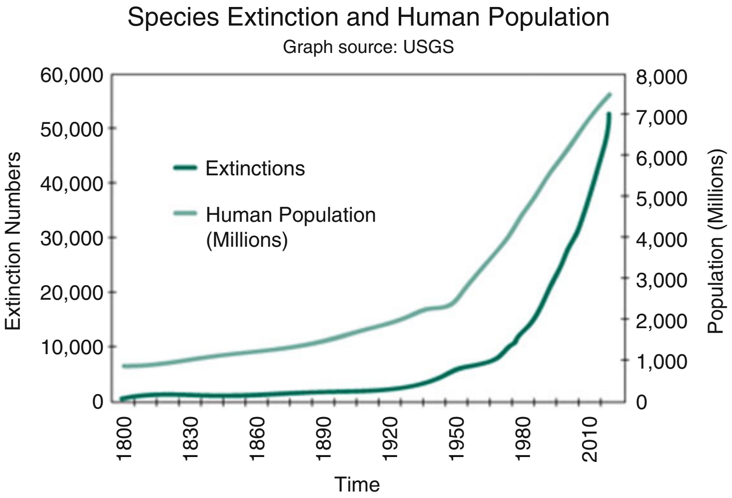

Fig. 3 Plotting of human growth versus rising number of species extinctions. (Graphic courtesy of the US Geospatial Services)

Table 3 Some of the world's largest CO_2 producers. (Source of information: "Our World in Data")

Country	% of world population	% of CO_2 production	Ratio
China	18.64%	29.25%	1.56
India	17.8%	6.69%	0.37
U.S.	4.36%	17.8%	4.08
Indonesia	3.51%	1.35%	0.38
Russia	1.96%	4.82%	2.46
Japan	1.73%	3.55%	2.04
Mexico	1.71%	1.38%	0.80
Germany	1.11%	2.28%	2.05
Iran	1.08%	1.85%	1.70
South Korea	0.69%	1.71%	2.475

12 billion. Today the increase in fuels used in transportation systems, aircraft, buses, trucks, and automobiles is still largely fueled by petroleum products, and this is no longer sustainable.

Table 3 shows the countries of the world that largely represent the biggest uses of hydrocarbon fuels producing the greatest amount of CO_2 pollution. The table displays each of country's size as a percentage of the world population and percentage of the world's CO_2 production that they release into the atmosphere – again as a percentage of the total human-based production. In these metrics, China is the biggest carbon polluter in terms of total production, but the USA is the biggest carbon polluter in terms of it relative population size.

The USA currently produces over four times the amount of pollution it might be expected to produce simply based on the number of its inhabitants. At this time just four countries, namely, China, the USA, India, and Russia, produce almost 60% of the world's greenhouse gas (GHG) pollution. Most developing countries produce proportionately less pollution today. However, the increasing level of industrialization and mechanization of agriculture across the globe is increasing greenhouse gas emission across the world economy. This increase is occurring due to population growth and industrialization. The increase in GHGs continues to occur despite the Paris Accord and other such efforts. The relentless rise of the average global temperature continues to rise despite the efforts to transfer energy use and transportation systems to cleaner systems based on solar, wind, and other green and recyclable energy systems that limit pollution (CO2 Emissions).

The new small satellite networks, and their associated data analytics, can help to accelerate the transition to "green" energy sources in a variety of ways. The large constellations for telecommunications and network streaming services can aid the development and operation of tele-health and tele-education programs to rural and remote areas. The first of these new networking-oriented systems for unserved or underserved parts of the world was the MEO orbit system known as O3b. This name refers to the "other three billion" people of the world. This name was devised by founder Greg Wyler, who chose this name well. It was his intent to create a new system that could bring connectivity to the three billion plus people who today live in locations that are largely without effective or low-cost connection to the Internet, the World Wide Web, or telephonic services.

Unfortunately such connectivity is becoming critical. Low-cost and effective connection to the Internet and electronic digital communications is becoming more and more essential to meeting a variety of needs in the modern world. Even remote farmers need to be able to find the best price to buy and deliver fertilizer and know where and when to sell their crops. Indigenous peoples are today finding a need for communications to receive medical care and sell their products and wares to others.

Essentially, the transformation that is increasingly occurring in the world of eight billion people is to substitute telecommunications, broadcasting, and networking for physical transportation. It is always easier and more cost-effective to transport electrons than people. Commuting to and from work each day consumes a good deal of energy, increases pollution, and can consume 1–2 h or more. It requires the building and maintaining of streets, highways, bridges, and tunnels. People that can be remotely trained to perform new jobs and then tele-commute to work can save energy, reduce pollution, eliminate the time lost in daily transit to and from work, and reduce the high costs of transportation. This concept of tele-work has largely been applied to industrialized nations, but today it can be effectively applied not only to national labor markets, but one can also see "electronic immigrants" performing service jobs remotely from one country to another.

Increasingly, activities such as accounting and editing of books, magazines, and even newspapers as well as tele-marketing and other tele-services have been shifted to countries as diverse as India, Jamaica, and Ireland. Even within a country, telework services can be moved from urban areas to rural areas via tele-work systems. The new small satellite-based networking systems provide greatly expanded new links to rural and remote areas. If established in effective ways, this can allow new pools of workers to be trained to carry out a wide range of tasks.

If the small satellites networks are efficiently set up to provide tele-health, tele-education, and then professional tele-training services, a huge new pool of workers can be trained to perform a wide range of new services at reduced salaries. These workers can fill in labor shortages in the service sector. There are people in Barbados and Jamaica that were trained to perform parts inventories for US airlines. The back offices of banks in New York and California have tele-workers in Ireland doing the back-office operations.

Forty years ago the cost of long-distance and especially overseas communications was 10–50 times the hourly rate of many workers. Today the ratio has almost reversed. The super low cost of small satellite constellations for networking services might be as low as $0.01 an hour to $0.10 an hour. This inversion in the cost of broadband communications with respect to workers' salaries, even in developing countries, opens the door to new forms of tele-work within countries and even on a global basis (Iida et al. 2003).

The bottom line is that the new networking small satellite constellations that will cover the globe will not only bring the Internet and broadband fifth-generation (5G) cellular services to the world, but it might ultimately serve to bring more than a billion new tele-services workers into the global economy. This could, in time (i.e., perhaps over the next 20 years), have almost revolutionary impact on global education, the provision of health care services, and the salary structure for companies that are heavily invested in tele-services (e.g., banking, insurance, transportation and airline and hotel bookings, bookkeeping, editing, inventory control, etc.).

Of course small satellites for remote sensing, Earth observation, and data analytics could impact transportation, energy, and patterns of transportation systems usage in new ways as well. This can be in many diverse ways. One might be able to use these systems and data analytics to do many things differently. This could be as diverse as prospecting for new sources of oil and natural gas to planning new roadway systems or train tracks in difficult areas such as mountain ranges, dessert areas, jungles, or wetlands. These small satellite systems could be used in planning new pipelines or restoring old ones or planning high-voltage electrical transmission systems. Certainly these systems could be used to improve the energy efficiencies of buildings by measuring their release of heat, or they could be used to detect noxious gas emissions.

The key in this regard is to design these systems and the analytics processing and algorithms to be able to accomplish more effective management on one hand and governmental regulatory oversight and enforcement processes on the other. The advent of some new capabilities such as driverless cars, improved "smart" electrical grids, and other oversight of transportation and energy systems safety, especially in the area of cybersecurity, opens up new areas of opportunity to implement new capabilities for efficiency and better regulatory oversight and safety measures. We must also consider that unscrupulous business interests might use the same technologies to accelerate their improper or illegal fishing or mineral extraction for short-term financial gain. This is why enforcement use of this information will become more and more important.

There are clearly a large number of ways that new small satellite constellations can open up doors to better manage energy systems and transportation systems,

Table 4 Improving systems to manage energy, transport, and tele-services and limit pollution

Using smallsats to better manage resources for energy, transport, pollution, and tele-services
Policing of release and excess generation of greenhouse and noxious gasses (GHGs)
Monitoring of wasted heat at power generation stations
Optimizing traffic planning and urban planning to relieve congestion
Replacing daily commuting with tele-workers
Tele-training of remote workers for tele-services jobs
Redesigning and optimizing buildings to be more energy-efficient
Improved design of new roadways and train tracks in remote and isolated areas
Improve efficiency of government services using broadband cellular services
Use of monitors to improve traffic flows and customs inspections

exploit new types of tele-services, and provide better oversight of pollution and climate change mitigation procedures. Some of these new opportunities as discussed above are summarized in Table 4.

5 Natural Resources

The intensive mining of metals and rare-earth materials is now starting to lead to shortages and listing of resources that are now considered scarce. There is a growing number of common metals that are becoming much more difficult to find such as gold, platinum, zinc, lithium, and copper, as well as many rare-earth metals such as selenium, hafnium, gallium, and indium. Although metals can be recycled, there will at least be price increases unless new reserves are found. There are even several "space mining companies" who have suggested that new valuable metals can be found in outer space. These companies are known by such names as Planetary Resources Inc., Moon Express, and Deep Space Industries. Some have indicated that they will be seeking out asteroids that are quite high in platinum that might be worth many billions of dollars. In fact, many of these enterprises have indicated that their first objectives are actually the so-called volatiles such as water. This is because, in space, water, by containing both hydrogen and oxygen, constitutes the equivalent of rocket fuel that is quite expensive to lift into orbit.

The various types of new smallsats for remote sensing and Earth observation are important tools for the exploration and discovery and even the ultimate exploitation of mining of resources. Radar sensors, infrared sensors, and multispectral and hyperspectral sensors all can be used in a variety of ways to identify geological clues as to what resources might be hidden below the ground or even at modest depths of the ocean.

The new space satellites for networking and broadband cellphone connectivity can provide vital services once a resource is discovered. Remote mining operations need connectivity to carry out operations in isolated areas. The ordering of equipment, the scheduling and arrangements for shipments in and out, and all sorts of telecommunications, streaming, and networking services are needed to sustain the staffing, food and supplies, and accounting and management of a remote mining operation. There is also the need to have reliable remote communications from networking satellites and other regulatory or government functions such as oversight, safety inspections, permitting, and zoning.

6 Conclusion

The difficulty in attaining clear-cut understanding of the potential applications and effective uses of the new constellations of small satellites is that so many of these are still only proposed, licensed, or in production, but not actually deployed in orbit. Many of the indicated applications will indeed prove to be important and will benefit those in unserved areas of the world as now envisioned. In truth, forecasting the benefits of large-scale smallsat networks for networking, remote sensing, and data analytics at this time is challenging. Forecasting the prime usages is somewhat like projecting the benefits of the Internet at the time experiments were being conducted via the so-called Arpanet that preceded the actual Internet global data network. Many of the benefits discussed in this chapter will be proved as these networks are fully deployed, but new and unanticipated applications will evolve over time.

If one were to define all the needs of the so-called "Global South" countries of the world that exist today, there can be reasonable prospects that these new smallsat networks will provide substantial assistance in some ways to virtually all these unmet requirements. The question is whether they do so in the ways that are currently anticipated and explained above or in a new and totally unexpected manner.

Clearly, key areas of concerns related to food, fishing, water, energy systems, transport, pollution and climate change, training, and remote tele-services and obtaining key natural resources will benefit from the new small satellite constellations and in important ways that we cannot yet see.

The tendency to view these new systems solely in terms of the satellite hardware is largely a tactical mistake for at least two reasons. First it is likely to be new and innovative software that truly unlocks the practical use of using these systems. It is the software and computer-based analytics that will be the key aspect of how these small satellite systems will achieve future success. In truth, it will be the interface with users that will allow these networks to unlock future problem-solving, market successes or failure, and beneficial results. As Clive Thompson, a contributing editor to Wired Magazine, has recently stated: "Spreading the creation of software…. doesn't just expand economic opportunity, it also encourages other ideas." This may be one of the essential ideas to the longer-term success of small satellite constellations. It is the software rather than the hardware that will ultimately triumph (Thompson 2019).

Secondly, the ground systems are also crucial. It will be the flat-panel antennas, electronic tracking of the fast-moving satellites, and the seamless connection to 5G cellular systems, to the Wi-Fi networks, and to mobile networked multiple-input/

multiple-output (MIMO) antennas that are crucial. These ground systems and their interface to actual users will be the true key to the ultimate success of these satellite networks in the day-to-day marketplace where consumers, businesses, and government agents work.

Small Satellites and Governmental Role in Development of New Technology, Services, and Markets

Joseph N. Pelton and Eric Dahlstrom

Contents

Abstract

The evolution of new technology from research laboratory to prototypes and then commercial mass production has shown a fairly consistent pattern of development through at least the eighteenth, nineteenth, twentieth, and now the twenty-first centuries. New ideas have first been developed by inventors or in research

laboratories. Patents are filed that protect the original inventor but also establish a framework for further development and improvements.

Often the next step is to produce various prototypes that gradually increase the practical capabilities of the new invention, service, or product. These early evolutionary stages help to increase performance and reliability of the new invention. This can also lead to additional developments, new formats, or designs. This can lead to additional patents and production processes which can allow the new product to be manufactured with increased speed and reliability and thus converted from the original prototype to a mature product for a mass-produced marketplace. This evolutionary development process has been true, in varying degrees for steamboats and locomotives, for automobiles, for aircraft, for submarines, for various types of guns and munitions, for telecommunications and networking systems, for radio and televisions, for computers and cell phones, and for a wide array of other inventions and new products consumed by civilians.

New products related to military defense and related strategic systems such as for weapon systems, avionics, aviation, telecommunications, computers, and artificial intelligence have particularly seen a high level of governmental research and development involvement in the front end of the research and development to move inventions, to prototypes, to improved prototypes, to initial manufactured products or system, and ultimately to refined systems.

Further governments often represent and provide the initial market for a new technology as well. In the case of space systems, governments and military ministries were among the first users of satellites for communications, remote sensing, Earth observation and meteorological monitoring, and GNSS and precise navigation and timing services. In short, in the field of space systems and applications, it has typically been military-related research and governmental spending that has had the predominate role in defining new space technologies and systems and guided their development. This has been true, especially in the USA, Europe, and largely countries of the OECD for a half century. This chapter addresses how "new space" and the small satellite industry has for the first time since World War II redefined the future direction of the space industry. In this new space environment, the new paradigms are being developed not by the key players in the so-called "military-industrial" complex but rather by start-ups, "Silicon Valley"-type entrepreneurial thinking, and even projects pushed by Google, Amazon, and Facebook and entrepreneurs such as Elon Musk, Jeff Bezos, etc. This chapter explains how the small satellite revolution and its overall development in terms of new types of launch vehicles, new types of satellite and ground systems design, and new types of space services also represent a shift in the development of space enterprise and services in the twenty-first century. Governments have not led the way but are now supporting this new technology but using it in their own missions and purchasing new types of space services supplied by new small satellite start-ups.

1 Introduction

In the new industrial age, represented by the post-World War II era, governmental research labs have often done a good deal of the "heavy lifting" that is required for expensive and difficult initial investigations of new high technology. These basic and applied research efforts have led to key inventions and have often underwritten much of the cost of demanding development work. This applied research can convert early ideas and prototypes into actual products that can be mass produced. This process of invention, prototyping, and then mass production can be a demanding and expensive process. The evolutionary process or development cycle where governmental research and development efforts are typically involved can last years or even a decade or two.

The time from the first invention to the time when actual mass production of a new product or provision of a service, in some cases, can be long indeed. Yet in most economies that operate on a capitalist basis, wherein private enterprises produce virtually all products and services and governments let free enterprise predominates most production, this transition almost always occurs. Thus the front-end transition from R&D to production and phased out of government involvement typically occurs within a decade and seldom requires as much as two decades for the government's role to phase out.

This transition from governmental research involvement to high-technology companies ultimately taking over production has been the case in such areas as aviation, aerospace systems, advanced telecommunications, artificial intelligence, robotics, computer systems, and even munitions and explosives. The idea has been that free enterprise industry within a competitive market can, in the longer run, produce products for both defense and consumer markets more efficiently. This transfer of even high-technology products from governmental research labs to commercial mass production has been the most common approach for capitalist economies around the world. It can also be seen that the longer this hand-over process lasts, the greater influence of the governmental/military influence on the technology and the larger the impact on products for the markets produced. This has seemed to be the case with the development of space technology and space-related markets. But the pattern of development as related to small satellites has been quite different. It has largely been the case that governmental and defense agencies have followed the efforts that have come out of university-based start-ups that have led the way. Large and sophisticated space projects have been dominated by large and established aerospace companies and governmental and defense agencies, while totally new space enterprises have led the “newSpace” revolution.

This chapter discusses the development of new space technologies and the exceptional case of government and military laboratories and agencies playing a role of direct involvement for a much longer period of time. However, today, new business models and technological innovation from the world of networking and computers are disrupting the aerospace industry and driving the market and the technology in new directions.

In short, the longer-term impetus from governments and established aerospace companies in the direction of “bigger and more complex” for commercial space systems is now being challenged. This is no longer accepted by “New Space” entrepreneurs as the best path forward. Today the civil space agencies and defense ministries have recognized the potential of small satellite technology and systems. What was once an effort to encourage student research and recruit new talent into the space industry today has now transformed into a recognition that smallsat systems can be a mainstream effort. Increasingly governmental and defense agencies are embracing the “smallsat” paradigm as a mainstream approach to more cost-effective space research and expansion of space application opportunities.

What this chapter explores is how the small satellite industry and the development of new types of reusable launch systems, etc. represents a departure from past patterns of how the field of space has developed. These new entrepreneurial directions have not grown out of governmental research programs nor from the initiatives of established aerospace companies. These new directions lately seem to arise from entirely new types of entrepreneurial thinking and technological innovation that have occurred largely in the last 20 years and especially the last 10 years.

Governments and especially governmental space agencies and military ministries have been slower to accept the transfer of their prime responsibility to industry in the space field. Instead governments and defense ministries have pursued a joint program of shared development with an emphasis on large-scale projects. There has been continuing efforts to retain governmental leadership for large-scale space systems such as space platforms and sophisticated space weapon systems. Further in the case of such activities as space communications, Earth observation, and precision navigation and timing (PNT) satellites (also known as Global Navigation Satellite Systems (GNSS)), the path forward has largely been led and predominated by a coalition of governmental and defense agencies in cooperation with large and established aerospace companies. The mainstream approach for these space systems and applications has been in the direction of “bigger, better, and more complex.”

The governmental designs and processes have guided the direction of technological in these areas to a very large extent – for governmental, defense, and even related commercial systems. Aerospace industries have found that following the lead of military and governmental civil space agencies in this direction was a highly beneficial direction to proceed in terms of large-scale contracts.

What this chapter explores is how the small satellite industry and the development of new types of reusable launch systems have not grown out of governmental research programs but largely out of entirely new types of entrepreneurial thinking and technological innovation.

Especially new “smallsat” initiatives have emerged from true entrepreneurial innovation. These new directions have come out of university laboratories and start-up companies often arising from the computer and networking industries. In this new “Silicon Valley-type” thinking, satellites and launch vehicles can be much smaller and start-up costs much smaller. The old assumptions about how to design, build, launch, and operate a satellite have suddenly changed. With these changes, the types of markets to be served and how to best serve new clients also have altered greatly as well. In short, “small satellites” are a part of a major paradigm shift affecting many aspects of the commercial space industry that spreads across a wide range of areas.

“New Space” or “Space 2.0” thus represents a new space revolution created by entrepreneurs and start-up companies. They have shown the logic of pursuing new technology, new methods of production, new types of satellites and constellation design, new types of ground systems, new types of launch vehicles, and the development many new types of space services and analytics. This “revolution” has opened a whole new set of questions as to what satellites are supposed to do, who can design and sell commercial space systems and services, and even who are the customers for these new offerings.

Indeed, most of the leadership in the development of these new technologies have come from young minds and young firms. Out-of-the box thinking has led to the creation of new high-tech markets. The established and large aerospace companies have largely been the followers. Only recently have the major aerospace organizations and the space agencies such as NASA, ESA, and others such as DARPA joined in to develop and exploit this new technology and stimulate this new market. The lesson now seems to be clearly learned, and established aerospace companies, governmental space agencies, and defense ministries have learned to embrace “smallsat” systems and technology as a mainstream approach for both research and operational systems. The convergence has now been complete. ESA, NASA, JAXA, the European Union, and others have now embraced the potential of smallsats as have defense-related space programs. The background surrounding this unusual pattern of technological development, and the new ways that governmental and defense space agencies are seeking to employ smallsat technology and systems represents the main purpose of this article.

2 Historical Background

The so-called military-industrial complex was largely born of World War II. This merging together of governmental research establishments and large and sophisticated high-tech munitions, aerospace, and computer companies gave birth to atomic weapons, fighter jets and bombers, high-speed computers, and subsequently the Internet.

Today governmental research labs and governmental science and technology ministries are funding the development of applications for life and medical sciences, cloning, artificial intelligence, and robotics. There also continues to be large investment at least within military ministries and agencies in developing more and more sophisticated new space systems. This is focused, however, on big and sophisticated space systems such as sophisticated military missile systems, larger and more complex launch systems, space stations, and even space colonies.

This “in synch” governmental, military, and commercial development continued for decades along the line that has sometimes been called “technology inversion.” Thus this approach supported the development of larger launchers, more powerful and higher gain satellites which in turn allowed ground systems to be simpler, smaller in size, and less costly. Under this approach one can install very small dish antennas which are low in cost and easier operate.

The principle of larger and more and more capable satellites which giant rockets were capable of lifting to geosynchronous orbit worked very well for communications and broadcasting satellites. Thus the needs of military systems for large and capable missiles also worked well to meet the perceived needs of commercial space applications, especially for the largest market of satellite communications including fixed, broadcast, and mobile services. This cooperative and supportive relationship was further reinforced by the so-called dual use of commercial satellite networks to meet the needs of not only commercial markets but of military services for non-tactical communications.

The graphic in Fig. 1 shows the usual pattern of new high technology development. In many cases governmental R&D supported the upfront development that typically then transitioned rather quickly into largely independent commercial mass production.

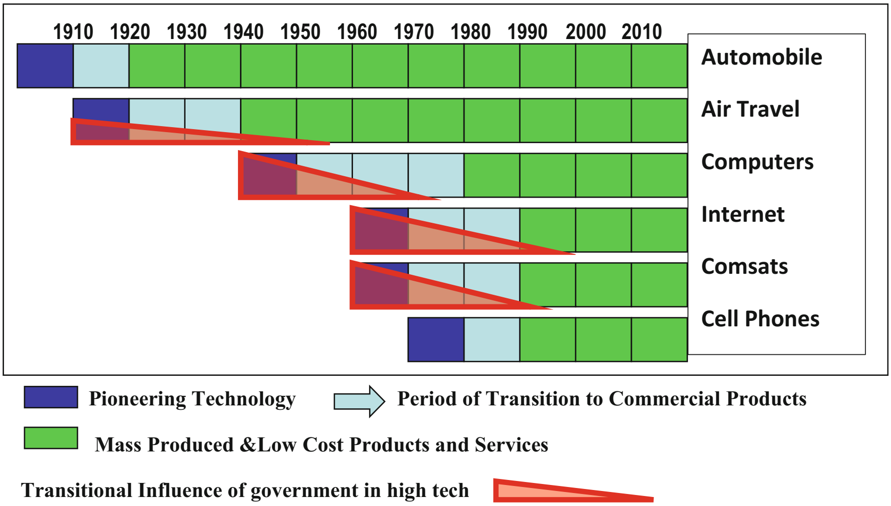

Fig. 1 Governmental influence on new technology, systems, and markets. (Graphic courtesy of Eric Dahlstrom)

But space systems have largely been different. For nearly a half century, there has been an ongoing symbiotic relationship that has sustained itself. The aerospace and electronics companies represented by Airbus/EADS, Thales Alenia, McDonald Detwiler, Boeing, Northrop Grumman, Lockheed Martin, Raytheon, and many others have been extremely closely knit together with governmental space and military activities.

The space industry and the role played by government have clearly been different from the role played by governmental research agencies and the industries depicted in Fig. 1. Even in the case of the cell phone industry, governmental technologies and regulatory officials played a key role in terms of establishing a process to allocate spectrum that could be used to provide expanded mobile communication services. In this case the assistance was largely focused on providing a regulatory framework for reallocation of spectrum, rather than aiding in the development of the new multiplexing and encoding systems.

One of the key factors to the ongoing relationship between governmental and military entities and the mainstream aerospace industry is that many of the products produced and those required by the military have remained so parallel since the end of World War II. Also the leadership pool for the military and the aerospace industry has frequently overlapped for many decades as well. The parallels in the technology development and the perceived market and service requirements have continued to align closely for at least a half century.

But starting around 2010, there was a disruption that for the first time saw the technology and commercial aerospace trends and market patterns start to diverge from those of the governmental and military worlds. These new technology and market trends largely did not come from the aerospace industry but emerged from the pool of entrepreneurs in Silicon Valley, university research labs, and the world of the Internet and networking. Instead of a continuation of space systems, satellites, and launch vehicles, continuing to grow bigger and bigger and more complex, the new thrust was toward smaller and in some cases away from complexity as well.

The “NewSpace” industry revolution and the emergence of the small satellite market had started to unfold. The new business paradigms that emerged from the new start-ups and new initiatives such as the “XPrize competition” directly challenged the conventional wisdom and the thinking of conventional aerospace companies, established satellite service providers, and most military and civil space agencies about the future of space activities.

3 Evolution of Small Satellites and New Commercial Launch Systems Markets and Governmental Support

This “NewSpace” revolution largely first occurred in the area on remote sensing markets, although it could be argued that the various new space initiatives that began in the 1990s such as Iridium, Globalstar, ICO, Orbcomm, and Teledesic were a key part of the new thinking about smallsats and commercial services from LEO constellations.

Yet it was the true entrepreneurial initiatives that came from such organizations like Planet Labs, SkyBox, and Spire which were entirely new start-ups that signaled that this was the start of something quite new and different. These new entrepreneurial initiatives emerged based on entirely new business models and technological approaches. This was in part led by key advances related to the miniaturization of sensors. These start-up organizations demonstrated that they could deploy much lower-cost spacecraft – as small as 3-unit cubesats – to provide commercial quality services. These smallsats could, of course, also be launched at much less expense. These new "outside-the-box" thinkers thought in terms of deploying many more spacecraft to provide updated information and global coverage more quickly. They also emphasized data analytics and new ways to manufacture spacecraft more quickly and at less cost. They created different approaches to testing and developed new ways of updating their designs and engineering models much more rapidly.

The "NewSpace" entities focused on the deployment of many more small satellites in lower Earth orbit constellations. This in turn led to a different approach to sparing and restoration of service planning and practices. In many ways these new enterprises gave birth to thought processes and business concepts that were much more akin with the computer industry and the types of innovation that came from Silicon Valley. Indeed many of these new initiatives came out of this area or from university student design exercises. Much of the approach and culture was indeed "foreign" to the aerospace and defense industries and governmental satellite networks that had grown out of the so-called World War II military-industrial complex.

Today governmental civil and defense space organizations and research institutes are seeking to find ways to use these new capabilities to respond to their needs. This was a new type of situation quite different from the historical patterns of the past. Instead of these governmental and defense entities developing and driving these smallsat constellations, they were suddenly placed in the mode of responding to innovations arising from these new commercial satellite networks.

The governmental response tended in three prime directions. One was to explore ways to use smallsats to carry out research in a more efficient way in terms of both time and money. The second way was to use these new networks to carry out ongoing missions and increase the market use of these new commercial networks. The third way was to embrace small satellite technology and constellation to design and deploy small satellite constellations to meet government or defense requirements.

4 Use of Government and Defense Smallsats for the Pursuit of Research Activities

NASA, ESA, and the US Air Force are just some of the governmental agencies that have found that smallsats could be used to pursue key space science and applied research objectives. They have found that projects at the microsat, nanosat, and picosat level could produce solid and useful research results and do so while saving on the cost of the spacecraft and the cost of the launch. This has happened in a variety of ways. The US Air Force, for instance, has funded a University Nanosat Program, it has used hosted payloads to undertake research projects, and it has contracted with commercial aerospace companies to build small satellites for both space research scientific missions as well as to undertake proof of concept for new operational systems.

The University Nanosat Program began with the 2004 launch of the 3-CornerSat (a project of Arizona State University, New Mexico State University, and the University of Colorado (Boulder)). This microsat-type experiment was a sophisticated test, and demonstration of stereoscopic imaging, distributed operations, and virtual formation flying operations and communications was the first in a series that continues today. This program is funded under the US Air Force Office of Scientific Research (AFOSR), and it operated from the Air Force Research Laboratory (AFRL) through its Space Vehicles Directorate (RV) (Fig. 2).

Subsequent projects have included the Fastrac microsat project built by students at the University of Texas (Austin) and launched in 2010. This project had the goal of demonstrating autonomous high-precision real-time relative navigation using innovative GPS technologies (Fig. 3).

Subsequent spacecraft developed under the US Air Force UNP included the launch of four more projects in 2013 with research spacecraft projects from Cornell University and the University of Colorado (Boulder) and from the University of Hawaii and two spacecraft from the University of St. Louis. There was another launch of a project from the University of St. Louis in 2015. Another smallsat experiment was developed by the University of Florida in 2018 and launched. For more university spacecraft were launched in this program in 2019 with at least six more scheduled for launch.

Fig. 2 The 3-Corner smallsat experiment was the first in the University Nanosat Program (UNP). (Graphic courtesy of the US Air Force)

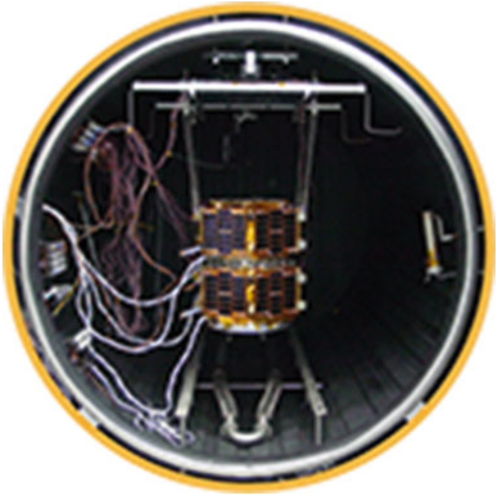

Fig. 3 The Fastrac project out the University of Texas (Austin) in 2010. (Graphic courtesy of the US Air Force)

The US Air Force explains that this program is not only to carry out serious research projects but also to train young people to design, build, and operate small satellites for the future. In the first few years, only two small satellites were launched, but since 2013 over 15 of these sophisticated research satellites have been launched or committed to be launched shortly (University Nanosat Program 2019).

The Air Force has also addressed new ways that it would undertake mainline research and development for their next generation of satellite systems. In particular it decided to commission the construction of two 3-unit cubesats to test sensors and GPS position determination to be used in its next generation of meteorological satellites. It contracted with Boeing to build two SENSE nanosatellites. These small satellites had a mass of only 4 kg and measured 30 × 10 × 10 cm in size. These two experimental and proof-of-concept satellites were launched on the ORS-3 mission in 2013 (Sondecker et al. 2012).

These SENSE smallsats were designed to collect and transmit weather data, but its software for transmitting this data did not work properly, and Boeing had to be given a supplemental contract of $400,000 to correct the software problem (Gross 2015).

Each of these SENSE nanosats contained a sensor and GPS receiver. These SENSE nanosats were designed to gather data that could be combined to make accurate weather predictions and to do so with greater accuracy. These smallsats had miniature S-band transceiver to downlink data at one megabit per second. The hope was to find a low-cost way to test new technology before it is included in operation weather satellites with new types of sensors and more sophisticated locational accuracy (see Fig. 4).

ESA and NASA, among other civil space agencies as well as the US Defense Advanced Research Projects Agency (DARPA), have also carried out a number of smallsat research projects in the past decade.

European Space Agency: ESA has set up a "CubeSat Systems Unit" to develop and expand European competency to create smallsats for high-quality research.

Fig. 4 The 3-unit cube satellite SENSE experimental project for US Air Force. (Graphic courtesy of the US Air Force)

Under this program, there are active programs to test rendezvous and docking and to explore near-Earth asteroids. During 2018 there was a successful ESA-funded CubeSat GomX-4B project. This smallsat tested precision micro-propulsion controls and intersatellite radio links for rapid data relay that could be used on research satellites as well as commercial telecommunications satellites. There were three ESA cubesat mission in 2019 for technology verification related to taking measures related to atmospheric reentry measurements, another for ozone monitoring and yet another for solar radiation studies. In addition there are a range of other small satellite projects that are under development by other ESA directorates. The economics that perhaps a dozen cubesat or smallsat missions can be conducted for the cost of one large spacecraft mission has been a powerful force to support the development of these type missions (Space Daily 2019).

European Union and a Consortium of Research Partners: One of the more innovative small satellite research projects has been the RemoveDEBRIS project undertaken by the European Union; the Surrey Space Center; Surrey Space Technology Ltd. (SSTL); Airbus Defence and Space (Germany, UK, and France/Toulouse); Airbus Safran Launchers (France); ISIS (Netherlands); CSEM (Switzerland, Inria (France)); and Stellenbosch University (South Africa). This 100 kg smallsat project was launched on a Falcon 9 to reach the International Space Station (ISS). It was then deployed into space by the NanoRacks' new Kaber system now operational on the International Space Station.

This innovative small satellite project was designed to test a number of methods for removing space debris from orbit (Remove Debris 2019). Rather than attempting to engage in actual active debris removal (ADR) the experiment with a simulation of such an activity with tests of capturing a small satellite with a net, a harpooning of a derelict satellite, active test of a laser ranging instrument, and effectiveness of a passive dragsail device designed to increase atmospheric drag. There were also two research cubesats aboard. The complex series of experiments were all compressed into a single 100 kg smallsat that was deployed by the Kaber deployment system operated by NanoRacks in 2018 (Clark 2018) (Fig. 5).

Fig. 5 The RemoveDEBRIS small satellite in orbit. (Graphic Courtesy of Surrey Space Centre)

NASA Space Satellite Research Program: NASA now has a very active smallsat research program underway. It has selected, via its Solar System Exploration Research Virtual Institute (SSERVI), ten small satellite missions for solar and planetary research. These missions which are a part of its planetary deep space studies program vary in size from cubesats up to 180 kg (400 pounds) in size. NASA's Jim Green, now Chief Scientist, in announcing these ten projects said: "These small but mighty satellites have the potential to enable transformational science. They will provide valuable information to assist in planning future Announcements of Opportunity, and to guide NASA's development of small spacecraft technologies for deep space science investigation." (NASA Selects Cubesat, Smallsat Mission Concept Studies 2011).

There are many other small satellite research projects now underway around the world that are being pursued by JAXA, ISRO, Roscosmos, the Chinese National Space Agency, and the US Defense Advanced Research Projects Agency (DARPA) and by smaller space agencies such as in Brazil, Swiss space research institutes, etc. Many of these efforts are discussed elsewhere in this handbook. The main point being made here is that hundreds of small satellite research projects are underway as mainstream research and technology demonstration activities by all the space agencies around the world as well as by defense space agencies. These activities have now become mainstream and are no longer mere student cubesat exercises.

5 Governments as Clients for Smallsat Constellations

There are governmental activities involving smallsats that go beyond research projects and demonstration of new technologies. Governments find many of the new operational small satellite programs to be a viable and cost-effective ways to contract for ongoing services. Below are just some of the examples of how governmental entities are using operational smallsat systems as a way of obtaining ongoing services. These various functions are in such areas as law enforcement, coastal monitoring, aircraft and shipping safety, agricultural and forestry monitoring, and various forms of economic development. These uses of commercial systems are already sufficiently prevalent that an exhaustive listing is really not possible. The examples cited below are noteworthy because of their originality and unique new capabilities.

6 Governments as Clients for Smallsat Constellations

There are many reasons why governments, law enforcement agencies, agricultural or forestry officials, or transportation or other safety personnel might find new smallsat constellation services to be of critical importance. Here are a few case studies.

6.1 New Zealand and Hawkeye 360 Smallsat Constellation

The Hawkeye 360 smallsat constellation provides a new type of radio-frequency (RF) geolocation service. This is accomplished by using a smallsat constellation to triangulate the exact location of all RF spectra use around the globe. The technical functioning of this smallsat constellation is described more fully elsewhere in this handbook (Wrne 2019).

The interesting aspect of this smallsat constellation is that governments such as that of New Zealand have signed a contract to obtain data from this system for law enforcement to seek to identify those that might engage in illegal fishing, smuggling, unauthorized entry, or other activities that might utilize unauthorized radio communications, especially for illicit purposes. This is a new way of undertaking law enforcement that could not otherwise be provided for a low-cost annualized fee.

6.2 Governmental Needs and Smallsats Providing Internet of Things and Automatic Identification System

There are a number of smallsat systems that are now providing or planning to provide shortly automatic identification system (AIS) plus machine-to-machine (M2M) data services. The growing demand for data relay system is now being driven by the demand for Internet of Things (IoT) data relay from remote areas. These smallsat constellation systems, planned or operational, include such networks as the Else Constellation, the Eutelsat LEO Objects (ELO), Kepler, Kineis (to replace the Argo network), Orbcomm, and Spire. Again these networks and their service offering are described in other sections of this handbook. The services provided by these smallsat networks are supported by many commercial clients, but governmental support and use of these networks are extensive and growing in number and volume of use (The Economist 2019).

6.3 New Smallsat Constellations and Their Support of New and Expanded Governmental Needs

And the future synergies between governmental requirements and large-scale LEO constellations will continue to unfold and expand in future years. The ability of the many new constellations designed to provide broadband telecommunications and networking services, remote sensing, and data analytics will produce new and expanded support to a wide range of governmental services in coming years. The dual use of these systems for commercial and governmental services (including those for defense agencies) can be expected to expand and grow. These networks will be able to provide broadband services by governments to rural and remote areas. These will include educational, healthcare, agricultural, forestry, and mining-related technical support services, economic development support, and many other governmental services.

7 Conclusion

The very first satellites that were launched in the late 1950s and 1960 were small satellites. But the mainstream development in the years that followed was to design and produce larger and larger satellites and launch vehicles to support more and more ambitious space services and programs. Many of these developments were closely allied with the needs of defined military- and defense-related services and the established aerospace companies that supported these efforts.

When the “smallsat” and “cubesat” efforts began along with miniaturization of digital processors and sensors, it was largely seen as an educational and training exercise for university students to learn about satellite technology and get some experience with satellite technology and design processes. The mainline focus by governmental and defense-related agencies, mainline large aerospace companies, and many commercial space services continued to be on large satellites, largely in GEO orbit and some MEO and polar orbit systems such as for GNSS and remote sensing. Smallsats were seen as largely as a cross between hobbist activities and training, such as the project of the ham operators volunteers that built the OSCAR satellites.

But innovative university students and faculty plus entrepreneurs with start-up ventures designed and managed to get funding for new commercial smallsat ventures. Activities in the smallsat field and the growing “NewSpace” arena began to become more real and commercially serious. New “smallsat” space systems and ventures such as Spire, Planet Labs, and Skybox, emerged. The bankruptcy associated with Iridium, Globalstar, ICO, and Orbcomm were overcome, and the viability of these systems began to become clear.

The result has been a resurgence in the design, manufacture, and deployment of smallsat constellations. Many things have supported this development such as new lower-cost commercial launch systems, new ground stations with electronic tracking capability, improvement in miniaturized components and digital processors, new levels of support and financing from the computer and networking world, and new approaches to the manufacturing of small satellites and how they are tested, deployed, and operated as well as new approaches to the sparing philosophy used in large-scale networks.

Today everybody – established aerospace corporations, civil space agencies and defense agencies, launch service providers, and service providers for networking, remote sensing, and other services – are taking "smallsats" seriously. The backers of many of these systems are in a number of cases coming from new sources. Organizations such as Google, Amazon.com, Facebook, and others from the world the Internet and Silicon Valley are seeing the value-added aspect of small satellite systems. It seems almost overnight the world of "NewSpace" has exploded to bring new vitality and interest to the field of space technology, systems, and services. What has started as largely a US phenomenon has exploded worldwide. The accessibility of smallsat technology and capital financing has fueled this interest. Governmental space agencies that 20 years ago saw small satellites as a sideline have increasingly embraced the use of this new technology and have sought to utilize it in new and an expanding range of ways. They continue to fund and support ways for students and universities to use this technology and bring innovations to the space field. They are developing programs and missions to accomplish research, technology demonstration, and operational programs. And they are beginning to buy new and important space services from the growing number of commercial service providers that are developing and deploying smallsat networks.

Smalls Satellites and the 17 United Nations Sustainable Development Goals

Joseph N. Pelton

Contents

Abstract

The United Nations General Assembly at the time of the new millennium approved a set of developmental goals known as the millennium goals that were to be strived to be accomplished by 2015. Although progress was made toward those goals on a global basis, there remained a great deal more to be accomplished. In 2015, a new set of expanded goals were approved known as the sustainable development goals. These new objectives were set to be accomplished by 2030.

There are many ways that satellite technology and various types of space applications can be applied to reaching the 17 United Nations Sustainable Development Goals (SDGs). This is especially true with regard to small satellite

technology and services. "Smallsats" can contribute to the accomplishment of those goals in many ways. This is because "smallsats" can reduce significantly the cost of deploying and operating satellites as well as reducing launch costs. The use of off-the-shelf components can in many ways make "smallsat" technology more accessible to developing countries. The UN COPUOS has also established a working group on "Space 2030"agenda that will seek to define and develop space capabilities, including small satellite systems and applications, that can further the UN Sustainable Development Goals. This process will start in 2020 and will continue to report on progress achieved.

The following chapter discusses the various ways that small satellites, individually and in constellations, can be employed to work toward achieving these 17 UN Sustainable Development Goals.

1 Introduction

For many years, the activities of the space-faring nations such as the United States, the USSR/Russia, China, Japan, Canada, the European Space Agency, and India have been seen as very expensive and highly technological undertakings that were primarily focused on exploring the outer space and developing high-technology rocketry. These activities, such as sending astronauts to the Moon, or sending research probes to the Sun, Venus, Mars, or other planets, or deploying space stations in orbits, were correctly seen as scientific missions that had little to do with the social and economic needs of the average citizens and virtually nothing to do with the needs of the developing world.

What is not as widely reported is that for the past 50 years, there have been important developments in the field of applications satellites that are increasingly providing vital services that are critical to humans across the globe. These application satellites are responsible across the globe for communications, broadcasting, networking, remote sensing, navigation, position location, smart agriculture, fishing, forestry, forest fire prevention, law enforcement, mapping, weather forecasting and storm alerts, national defense, and much more. This chapter seeks to explore the many ways that satellite applications, and especially small satellites and smallsat constellations, are now, and even more so in the future, providing a wide range of vital services that will be critical to progress against the United Nations 17 Goals for Sustainable Development for 2030.

At the 2017 Manfred Lachs Conference at the McGill University Air and Space Law Institute, the attendees from all over the world sought to identify and assess how space applications could contribute to meeting the United Nation's Sustainable Development Goals for 2030. (Summary Report of the Working Group of the "Space 2030" Agenda of the Committee on the Peaceful Uses of Outer Space A/ AC/C 195/C.1 WG 2030/2019/L.1.) At the end of this section, in Table 3 there is a chart prepared by the author, which seeks to identify by specific type of satellite services the various ways that can be utilized by satellites, including small satellite systems, to support these 17 goals or which might be able to assist in achieving these goals in the future.

The following analysis seeks to indicate the ways that small satellite systems might be particularly able to provide new or expanded capabilities to meet specific UN sustainable development goals.

2 Historical Use of Satellites for Education and Healthcare Services

The idea of using satellites to bring educational and health-related services to areas of the world where such services are greatly lacking is certainly not a new idea. Arthur C. Clarke envisioned that satellites could be used to provide low-cost and global communications to the world when he first wrote of this technology even back in 1945. NASA's early experimental satellite program known as the Applications Technology Satellite series sought not only to develop the technology but to test out new applications in rural and remote areas. The ATS-6 satellite was the first application to have an unfurlable antenna. This high-gain antenna was tested first in Appalachia and then in rural India's SITE experiments to provide remote educational and health services in the 1970s (NASA – ATS; see Fig. 1).

These experiments subsequently led to Indian Space Research Organization's INSAT program to provide rural education to villages in rural India. This program today provides education and health services to over a million students using tele-education-based systems. In the mid-1980s, the Intelsat satellite system started a Project SHARE initiative. In this case SHARE stood for Satellite Health and Rural Education. In order to carry out the international Project SHARE activity, a partnership was created with the International Institute for Communications (IIC), the Education Secretary of the British Broadcasting Corporation was recruited to help in the design and execution of projects, and an international advisory council was formed. These international partners from over a dozen countries helped to make the Project SHARE initiative a success.

Ultimately some 70 international projects were approved to test satellite-based educational and health services. These projects, in terms of time scale, ranged up to the large-scale multiyear Chinese satellite TV initiative with extensive television programming developed by the Chinese Department of Education and China Central Television. They also involved "one-off" events such as "The Day of Six Billion" television show that reached some 140 different countries and nearly one

Fig. 1 The NASA applications technology Satellite-6 with its antenna unfurled that carried out educational experiments in India and Appalachia in the 1970s. (Photo courtesy of NASA)

hundred countries provided programming for this event that was organized by CNN.

This Chinese satellite television educational and health distribution programming started with only a few dozen remote TV receive-only (TVRO) terminals but was eventually operationalized on Chinese domestic coverage satellites (Chinasats) and expanded to provide educational and health education programming that was provided to many thousands, and eventually as many, ten million students. This ambitious Chinese initiative was designed to extend a remote television instructional system to eventually cover the most remote parts of China. There were also projects that involved experiments involving the University of the South Pacific and the University of the Caribbean plus many scores of other projects around the world. Many of these programs were designed to provide educational programming directly to remotely located students. Others such as the ambitious program organized by the Miami Children’s Hospital organized a tutorial by some of the world’s leading experts on the AIDS pandemic to be distributed over all of South and Central America, North America, Europe, the Middle East, and Africa for an audience of over 65,000 doctors, nurses, and healthcare providers. This multi-continent event involved three interconnected Intelsat satellites (Report on Project Share, Intelsat, Washington, D.C. 1987).

3 Small Satellites for Communications and Networking

A great number of small satellite constellations are now licensed to be deployed in the next few years to provide expanded communications and networking services, and especially this is the case for underserved regions of the world in developing economies. Three founders of the so-called OneWeb small satellite constellation left Google to start the WorldVu company that became OneWeb. These entrepreneurs were Greg Wyler, Brian Holz, and David Bettinger. Greg Wyler had also previously started a medium earth orbit (MEO) satellite system known as O3b (short for Other Three Billion – or the residents of the equatorial regions of the global that were underserved for communications and networking) (History, One Web Satellite Network https://en.wikipedia.org/wiki/OneWeb_satellite_constellation#History (last accessed Feb. 4, 2019)).

Greg Wyler had first planned to provide new telecommunications and networking capability in rural Africa using fiber-optic networks in underserved countries, but none of the business models worked. He first organized and got backing for his O3b medium earth orbit (MEO) in partnership with the SES satellite system of Luxembourg. The success of the 16-satellite MEO system led him to found WorldVu with his two partners from Google. This led him to come up with the design of a 900-satellite low earth orbit (LEO) network that would blanket the world but provide particular coverage of Africa, South and Central America, and Asia with very low latency (or transmission delay). This design was optimized so that it would be possible to provide cellular phone or Internet services in most underserved regions of the world. As of December 2018, however, OneWeb has scaled down the size of its initial constellations from 900 to 600 (Henry 2018).

In discussions with Greg Wyler during the Arthur C. Clarke award ceremonies, he explained that he wanted to bring broadband services to underserved countries at low cost and with minimal delay that is important both to cellular services and Internet connection. He also explained that he saw advantage in non-GEO satellite systems because of the much-reduced path loss and thus higher effective power levels from smaller satellites. The other advantages were much-reduced latency or transmission delay, the reduced gain needed for ground systems, and the lower production costs and launch costs for small satellites. His first approach was the simpler and lower-cost MEO system that he called O3b. When this MEO system deployed along the equator that consisted of 4 satellites, then 8, then 12, and eventually 16 (although only 13 are now operational) proved financially viable, he sold out his interest to SES that took over full ownership of the O3b and focused on a truly large-scale LEO satellite system. This started out as WorldVu and then transitioned to the pioneering OneWeb small satellite network.

Most entrepreneurs are focused on making money, but Greg Wyler is an unusual businessman, who has put social objectives ahead of his financial goals. He has let that drive to come up with unusual schemes to make his OneWeb system viable. One of his key objectives has been to make his suppliers of both the satellites and the launch services also key financial investors. Thus Airbus and Arianespace are both suppliers and investors. The enthusiasm for the OneWeb system by Wyler to meet social goals is hard to miss. In conversations with him and in other public statements, he has confirmed his belief that OneWeb can at least help to reduce poverty (Goal 1), improve farming efficiency and thus reduce hunger (Goal 2), improve health services and education via tele-services (Goals 3 and 4), and support economic growth and industry innovation (Goals 8 and 9). The argument could be made that if more effective, higher-quality, and lower-cost education and health services can be achieved via more extensive and lower-cost communications and networking, this will ultimately increase prosperity and knowledge and aid in the achievement of all 17 UN Goals.

Nor is the OneWeb small satellite system unique. Indeed, most of the pending or proposed small satellite systems around the world will offer the possibility of lower-cost, lower-latency, and perhaps higher-power access to mobile communications and Internet connectivity. In short, many of the proposed smallsat networks will provide potential aid toward meeting at least several of the UN Sustainable Development Goals. The Geeks Without Frontiers is a nongovernmental organization that has been established to leverage the new infrastructure that smallsat constellations offer to bring broadband connectivity to the developing parts of the world through their "Community Connect" project. This NGO is currently sponsored by EMEA Satellite Operators Association (ESOA), the Arthur C. Clarke Foundation, the Asia-Pacific Satellite Communications Council (APSCC), Telesat, Intelsat, the Space and Satellite Professionals International (SSPI), the International Space University (ISU), the International Institute of Space Commerce (IISC), the Danish Telecom Industry Association, the Satellite Industry Association, and the American Institute of Aeronautics and Astronautics (AIAA) (Community Connect).

GEEKS' co-founder Michael Potter has explained the mission to bring broadband communications to the developing world in the following manner: "The Community Connect vision is to enable 100% availability of broadband communications services everywhere, providing businesses, governments, hospitals, schools, NGOS, individuals and others with access to broadband services, wherever they are located. This will help to bring the educational, healthcare, social, economic and e-government benefits to communities everywhere and facilitate and accelerate the achievement of the UN's Sustainable Development Goals (SDGs)" (Geeks Without Frontiers Releases Its 'Community Connect' Global Broadband Initiative at the Geeks "Connectivity is the Revolution!" Thought Leadership Forum, October 19, 2017 https://globenewswire.com/news-release/2017/10/19/1150375/0/en/Geeks-Without-Frontiers-Releases-Its-Community-Connect-Global-Broadband-Initiative-at-the-Geeks-Connectivity-is-the-Revolution-Thought-Leadership-Forum.html).

The initial role out of this project is to provide broadband connectivity to some 80 communities using satellite technology to demonstrate the fundamental approach. The stated plan is to use this initial beta test as the best way to prove the viability of the plans. Certainly an actual test with actual communities and actual users appears a wise way to prove the strengths and weaknesses of this rural networking plan before it is scaled up for a much larger-scale implementation. This seems wise for several reasons that include (i) understanding practical problems of rural users (this might include based on other rural projects an identified need to train new users how to use telephones and computers to access these networks or access to reliable and continuous local power at modest cost); (ii) proving the soundness of the concept and levels of use to potential investors in larger-scale projects; (iii) understanding the problems and issues involved with ground segment facilities to access the new satellite facilities; and (iv) testing practical aspects such as the billing and collection of fees associated with these new digital satellite and wireless networks.

Fig. 2 The Broadband for the Next Billion campaign foresees use of smallsats and fiber-optic networks

Although this Community Connect initiative is not exclusively tied to satellite technology, its business plan is generally based on use of new satellites being deployed to provide network connectivity for developing countries such as O3b, OneWeb, and other small satellite constellations now planned. Certainly these new "smallsat" constellations currently appear to be one of the prime ways for current goals and objectives of the "Geeks Without Frontiers" and their "Community Connect" and "Humanity Connect" projects to be accomplished. One of the elements of the overall program known as "Dig Once" does indeed include plans to use fiber-optic networks as part of the overall telecommunications development plan and is indeed seen as an element in the "Geeks Without Frontiers" strategic plan to create their ambitious ultimate goals of "Broadband for the Next Billion" campaign (see Fig. 2).

The "Geeks" may find in their current beta trials with the 80 trial communities that there is an additional need to create more Wi-Fi hotspots or other terrestrial wireless systems to supplement the satellite architecture. Likewise they may find that they need to develop improved and lower-cost earth station facilities capable of tracking LEO smallsats and which can also be acquired at lower cost and with reduced tariffs.

In the past many satellite projects for rural services have concentrated on the space segment and found that the problems actually focused on such issues as earth station costs and related tariffs, access to power at the local level, or other "last mile services" issues (Geeks Without Frontiers Launches 'Humanity Connect!' To Empower Displaced Persons Through Connectivity-Driven Solutions for Disaster Preparedness and Refugee Relief https://globenewswire.com/news-release/2018/08/20/1553736/0/

en/Geeks-Without-Frontiers-Launches-HumanityConnect-To-Empower-Displaced-Persons-Through-Connectivity-Driven-Solutions-for-Disaster-Preparedness-and-Refugee-Relief.html (Last accessed Feb. 6, 2019)).

The "Connect Humanity" initiative by the "Geeks Without Frontiers" is a most commendable initiative, but it will face many challenges that have been faced by a number of past initiatives that have sought to address the issue of rural telecom and networking access.

In the 1980s, there was the Afrosat initiative boosted by the International Telecommunication Union (ITU) that envisioned a high-power satellite optimized to work to 3 m earth station to provide rural services for the entire African continent. This system never came into being for a variety of reasons. These included political differences among the African nations, differences between Intelsat, the ITU, European countries with interests in Africa, plus the high cost of acquiring very small aperture antennas and installing them with the necessary power supplies and maintenance and repair staff.

On top of these problems, there were difficulties presented by the tariffs on these ground systems by the African nations for imported equipment that might be in the 50% to 100% level. There were in many instances in many African nations a lack of skills, training, and access to telephones or telecommunications facilities such as telex or fax machines that might be easily used by rural populations in villages across Africa.

Over a decade later, the Afristar radio services satellite was deployed to offer radio broadcast channels for the entire African continent in 1998. This direct audio broadcasting satellite provided the opportunity for commercial and educational and health-related radio channels and even nighttime downloads of video educational programming. There were many reasons why this effort, in its original commercial form, failed commercially. One of the prime reasons was that the low-cost satellite radio receivers that were then available at $50 apiece attracted a 100% tariff (Afristar).

In other rural development projects around the world, new telecommunications facilities were installed, but usage remained very low. When studies were made, it was found that one of the reasons for initial low usage was that no one had taught villagers how to dial telephones or to find telephone numbers. The bottom line conclusion is that extending telephone and digital networking capabilities into rural and underserved areas is more than just a matter of extending networks, but that there are other key elements that must be addressed as well.

Training as to how to use such networks, access to telephones, computers, radios, or fax machines, tariff-related issues, and educational, health, and governmental services programs that teach remote users the value of using such rural networks, must be a part of the overall implementation program. Other aspects such as computer software that is available in locally used languages can also be key. Many of these of the studies of telecommunications development in rural and remote areas show similar results. These studies show that the economic multiplier effect of such infrastructure development can be high as in four to one or even higher but that training in the effective use and applications of such systems is critical to achieving successful use of such systems. Instructions in local languages and educational and health-related programming that is adapted to local culture, customs, and language can be critical to success (Pelton 1987; http://glovis.usgs.gov; https://neo.sci.gsfc.nasa.gov/; http://arthexplorer.usgs.gov; http://cophub.copernicus.eu; http://search.earthdata.nasa.gov; www.class.noaa.gov; http://coast.noaa.gov/digitalcoast; www.ipums.org/IPUMSTerra.shtml; http://lance.modaps.eosdis.nasa.gov; http://earthdata.nasa.gov/lance; https://vito.be/en).

4 Mobile Satellite Service Satellites Vs. New Small Satellite Constellations for Rural Services

There are several small satellite networks that have been deployed, beginning in 1997 and 1998, that were designed to provide mobile satellite services. These included Iridium and Globalstar that deployed smaller satellites in low earth orbit (LEO) constellations. Also there were Thuraya and Inmarsat I-Phone service that utilized larger satellites in GEO orbits. These various systems provided truly global coverage including equatorial regions of the world and could thus service to rural and remote areas.

The problems that arose for these networks in providing rural service to most remote communities were severalfold. The consumer handsets were costly and priced well above $1000 dollars (US). The usage charges were high and beyond the means of most low-income residents in these remote areas with rates around $0.50 to $1.00 a minute. Further there were other practical problems such as access to electrical power for the satellite phone chargers or no place to purchase these expensive phones or laptop-size consumer terminals. Further these satellite phones were typically subject to high tariffs that steepened the cost even more. The Iridium and Globalstar LEO smallsat constellations were engineered to provide telephony-type services for higher-end users and provided only very low data rates. Thus these smallsat networks were not really adequate to provide Internet access-type services.

Although attempts were made to create remote stations that were in essence village pay phones, these did not prove to be commercially viable. Thus in remote areas, smallsat constellations for mobile satellite services were essentially used by military personnel, representatives of multinational organizations, and aid relief workers for nongovernmental organizations.

The second-generation satellite constellations for Globalstar and Iridium (Iridium Next) are actually larger than what most would classify as “smallsats” and remain geared to the needs of the military and multinational users traveling to remote areas rather than the indigenous population. The challenge is to find the suitable architecture for the satellites and the user terminals and perhaps intermediate distribution Wi-Fi systems that can allow villagers to use simple low-cost cell phones to access the new generation of LEO satellite constellations and to do so via access fees that are consistent with the incomes of the users in remote villages. In some cases GEO satellites working to and from low-cost VSATs and then Wi-Fi networks may be able to provide economical services. The problem of transmission delay or "latency," however, remains as a problem for Internet- or data-based services.

5 Remote Sensing Satellite Services Helping to Achieve UN Sustainable Development Goals

The field of remote sensing via satellites has been perhaps the most adept at achieving success in providing assistance in meeting a number of goals of the UN for sustainable development. The uses of remote sensing keep expanding as the range of sensing technologies and applications continue to expand on one hand and have become more affordable and available on the other. Small satellite systems that are now in the cubesat range such as Planet and Spire, in particular, are supplementing and expanding the remote sensing that was previously carried out by much larger and expensive Earth observation satellites (see Fig. 3).

The uses of small satellites to accomplish the UN Sustainable Goals can be found in virtually all of the 17 goal areas. Nevertheless, there are 11 out of the 17 goal areas as noted below where remote sensing and Earth observation satellites make substantial contributions to the UN objectives. Indeed many of these goal areas cannot be addressed accurately and synoptically without these technologies (Table 1).

The technology involved with the design, manufacture, and deployment of smallsats for remote sensing and Earth observation continues to allow these spacecraft to become more capable of whole shrinking in volume and mass. Satellites such as "Doves" by Planet and cubesats by Spire continue to improve. Recently it was confirmed that cubesats can not only provide high-quality sensing but that three to six unit cubesats are capable of hyperspectral imaging. Hyperspectral sensing across many bands can much more accurately allow the detection of specific diseases in

Fig. 3 A 3-unit cubesat by Planet imaging the Earth

Table 1 Ways that remote sensing satellites can assist in achieving UN goals (Source: Author compilation)

UN sustainable development goals where "smallsat" remote sensing can be most impactful	
UN goal	Positive impact area
SCG 1: No poverty	Improved farming productivity, economic growth
SDG 2: Zero hunger	Smart farming, disease spotting, and agricultural productivity
SDG 3: Good health	Better crops, improved pollution monitoring
SDG 6: Clean water	Monitoring of water pollution, more efficient farming, mining, forestry
SDG 7: Clean energy	Solar research, wind current research
SDG 8: Economic growth	More efficient farming, fishing, and forestry, new clean energy industry and jobs
SDG 11: Sustainable communities	Earth observation to monitor human growth, urbanization, pollution, etc.
SDG 12: Responsible consumption/production	Monitoring of industrial plant-generated pollution, fish and wildlife population monitoring
SDG 13: Climate action	Constant monitoring of weather, climatic changes, ice cap sizes, thermal changes, desertification, clean water supplies, etc.
SDG 14: Life below water	Continuous survey of oceans and polar regions, ocean pollution, thermal changes, hurricanes, monsoons, thunder storms
SDG 15: Life on land	Remote sensing of entire land areas, farms and forests, aridity, sensing of changes to clean water supplies, snow fall, crop yields, weather, heat, etc.

The 11 goal areas noted above are areas where remote sensing satellites are making prime contributions. Satellite telecommunications, networking, Earth observation, and precise navigation and timing satellites can, of course, be used to support many of the UN SDGs as well

crops and accurately assess which nutrients might be missing in specific farming areas. In short smallsats that can carry out hyperspectral sensing or even carry out active radar sensing with clusters of spacecraft as small as 500 kg suggest that smallsats are not only highly capable but are increasingly able to perform tasks once reserved for much larger spacecraft.

The key to the future is not only proving that smallsats can conduct remote sensing and Earth observation with sufficient resolution and sophistication to prove useful. Perhaps the most important key lies with the idea that processed satellite data can be made widely available to users around the world on an ever more rapid basis. Below is a guide to satellite-based remote sensing that can be accessed via the Internet after the user gains access via a proper registration procedure. Today many of these data bases as operated by NASA, the European Space Agency, and other providers have data that derives from very large-scale and highly capable satellites. But the future seems likely to be more and more driven by highly capable smallsats that can duplicate the capabilities of satellites that might have weighed several tons, but are now being replaced by satellites that only have the mass of a few kilograms. (See Table 2 for a listing of websites providing access to remote sensing and Earth observation data.)

Table 2 Free web sites to support remote sensing services

Key free web sites providing information about remote sensing via satellite	
Description of web site	Web site URL
GloVis: The US Geospatial Service Global Visualization Viewer. This provides a search and order tool for information about the US Earth observation data. Registration is required in order to use this data base	http://glovis.usgs.gov
NASA Earth Observatory (NEO): This NASA web site allows access to more than 50 datasets on atmosphere, land, ocean, energy, environment, and other additional information. This website requires registration in order to use it	https://neo.sci.gsfc.nasa.gov/
USGS Earth Explorer: This site is perhaps the most comprehensive website that provides free access to data from many different US sources, including both aerial and satellite-based sensing. This web site requires registration	http://arthexplorer.usgs.gov
Copernicus Open Access Hub: This site provides free and open access to data from the Sentinel 1, 2, and 3 satellites as well as process and specifically derived user products. This web site requires registration to use it	http://cophub.copernicus.eu
NASA Earth data: Earthdata search, as of January 1, 2018, became the primary means for searching and discovering NASA Earth observing data. The Reverb data search and the discovery system that NASA Earthdata replaces are no longer operational. Registration is required to use this database	http://search.earthdata.nasa.gov
NOAA (National Oceanic and Atmospheric Administration) CLASS: This website stands for the Comprehensive Large Array-data Stewardship System. The CLASS website provides data from the US Department of Defense (DoD), Polar-orbiting Operational Environmental Satellite (POES), Environmental Satellite (GOES), and other sources. Registration is required in order to use this database	www.class.noaa.gov
NOAA Digital Coast: This database is focused on data from coastal regions. Data is organized by infrared, radar, and true color composites that can be downloaded. Registration is required in order to use this data base	http://coast.noaa.gov/digitalcoast
IPUMS Terra: This database is operated by Integrated Population and Environmental Data. This organization integrates population census data from around the world with global environmental data. Also see a web site known as Terraclip. Registration is required	www.ipums.org/IPUMSTerra.shtml
The Land, Atmosphere Near real-time Capability for EOS (LANCE): This web site is a component of NASA's Earth Observing System Data and Information System (EOSDIS). Registration is required	http://lance.modaps.eosdis.nasa.gov http://earthdata.nasa.gov/lance
VITO Vision: This website is operated by the Flemish Research Center. VITO stands for Vision on Technology for a Better World. This website provides information about various broad areas of vegetation from such sources as PROBA-V, SPOT-Vegetation, and METOP. Registration is required	https://vito.be/en

This listing of the ten internet websites that, with registration, provides a great amount of free Earth observation. It was prepared by Scott Madry with assistance by Joseph N. Pelton. It is licensed for this publication. All rights reserved

6 Other Small Satellites Providing Support to Achieving UN Sustainable Development Goals

The satellite services that provide the greatest level of support to achieving the UN Sustainable Development Goals (SDGs) are clearly those related to distributing information related to health and education, providing interactive telecommunications and networking, as well as Earth observation, meteorological, and remote sensing applications. The flexibility that “smallsat” technology and systems offers worldwide and especially for developing economies continues to be examined and new applications and services developed.

Cubesats and even smaller nanosats and femtosats can be used to test new sensors, components, or instruments that can provide valuable proof of concept for experimenters and even student projects around the world. Scientific experiments by researchers in developing economies can now become much more affordable. The tiny processors that now weigh only a gram or two have many times the processing speeds of computers that were quite large and massive several decades ago. This miniaturization of processing power and high-quality sensors can unlock many new capabilities for scientific and engineering programs around the globe.

And exactly what is a “smallsat” continues to be posed around the world? Its definition actually continues to evolve as new capabilities become possible. Another element that keeps evolving is in the arena of “smallsats” is, in fact, hosted payloads. Initially the idea of hosted payloads involved putting a small experimental payload on a large satellite. Intelsat in partnership with Cisco placed an experimental router on one of its large Intelsat 18 satellites for instance. Now a large satellite might fly over a dozen small experiments or proof of concept as part of a mission. The latest iteration of what a hosted payload might mean includes the idea of placing a whole “small sat” constellation onboard a larger constellation. The Iridium Next generation is now almost fully deployed. Onboard this constellation is riding the Aireon packages for precise airline navigation, or more precisely a global air traffic surveillance system for air safety.

This Aireon system as deployed on the larger Iridium satellite provides a space-based Automatic Dependent Surveillance-Broadcast (ADS-B) network. This is an air traffic surveillance technology that relies on aircraft broadcasting their identity, a precise Global Positioning System (GPS) position for each aircraft in the sky every half a second, plus other information derived from the aircraft’s onboard system. This system will be used by Air Traffic Controllers (ATCs) to identify and separate aircraft in real-time. Space-based ADS-B extends the same ADS-B technology currently received on ground-based receivers to space and provides much more extensive global coverage.

This system can be used to enhance air safety and track hijacked planes and could be extended to ships at sea and other vehicular transport systems. This type of hosted payload approach could be used in a variety of ways by others to create other types of global services such as to monitor air and ocean pollution, etc. This approach not only saves costs, launches, and orbital debris but also could be seen as a way to reduce congestions of space.

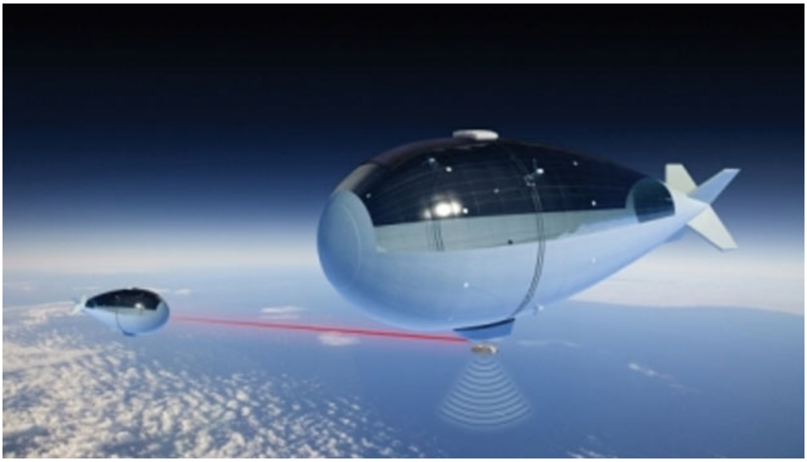

Fig. 4 HAPs can assist with UN SDGs related to health, education, and land and sea pollution and more. (Graphic courtesy of Thales)

Another area where innovation may be coming in future years is to have smallsat payloads at lower altitudes that are not satellites at all. These are, in fact, high altitude platform systems (HAPS). The advantage that a satellite provides is wide-area coverage. A HAPS at an altitude of 21 km or 12.5 miles provides complete coverage for island countries such Jamaica or Aruba, and it offers much less path loss or latency for communications or television broadcasting. Companies such as Thales Alenia Space are now offering services via what it calls “Stratobus,” and this technology could be used to provide telecommunications, networking, Earth observation, or remote sensing services to a number of counties in future years that are very much akin to those noted above for communications or remote sensing satellites (see Fig. 4).

7 Analysis of Space Systems Potential to Meet UN Sustainable Development Goals

The potential of space systems of all types and dimensions to meet the UN Sustainable Development Goals for 2030 is considerable as summarized in Table 3. A fuller explanation of the UN Goals for 2030 is presented in fuller details in Part 14 of this Handbook.

8 Conclusion

The UN Sustainable Development Goals are quite ambitious. The details of the goals are provided in chapter ▶ “UN Sustainable Development Goals for 2030.” Unfortunately the measured progress to date against these 17 objectives indicates that few

Table 3 Key areas where small satellite systems can help achieve UN sustainable development goals

Space-based services that aid UN goals for sustainable development
Prepared by Joseph N. Pelton for the Manfred Lachs conference in Montreal in 2017 in preparation
For the UNISPACE + 50 conference in 2018

Goal	Telecom and networking sats and HAPs	Broadcasting sats and HAPs	Remote sensing sats	Meteorological sats	Navigation and timing sat	Solar power sats
No poverty (Goal 1)	New jobs via telework, opportunity for remote services, training in remote villages	Broad distribution of information on birth control, nutrition, vaccines, etc.	Improved information to support fishing, farming, forestry, mining, etc.	Reduced losses of crops, housing, infrastructure	Improved farming and fishing via precision geolocation	*In future* Lower-cost clean energy to rural and remote locations
Zero hunger (Goal 2)	More efficient agricultural and fishing markets	Broad distribution of information on nutrition and birth control	More productive farming and lower-cost food	Less crop loss due to storms, flooding, typhoon, hurricanes	Improved farming and fishing via precision geolocation	TBD
Good health and well-being (Goal 3)	Tele-health and remote medical service	Broad distribution of information on birth control, nutrition, vaccines, etc.	Detection of crop or tree disease	Detection of solar flares and ozone holes	Ability to precisely track spread of disease and pandemics	TBD
Quality education (Goal 4)	Quality tele-education programs, remote testing programs	Educational radio and television, access to global news	TBD	Less destruction of schools and educational infrastructure	Cost savings on school transportation	*In future* Clean energy to remote locations for tele-education
Gender equality (Goal 5)	Tele-educational programming	Global news and TV broadcasts	TBD	TBD	TBD	TBD

(continued)

Table 3 (continued)

Space-based services that aid UN goals for sustainable development
Prepared by Joseph N. Pelton for the Manfred Lachs conference in Montreal in 2017 in preparation
For the UNISPACE + 50 conference in 2018

Goal	Telecom and networking sats and HAPs	Broadcasting sats and HAPs	Remote sensing sats	Meteorological sats	Navigation and timing sat	Solar power sats
Clean water (Goal 6)	Tele-education on water purification and sanitation	Broadcasts on water purification sanitation	Detection of polluted water. Passable road access info for water trucks after disasters	Better protection of water reservoirs against storms	Locate polluted waters, storms with acid rain, etc.	TBD
Affordable and clean energy (Goal 7)	Tele-education, internet access to create solar, wind, tidal, geothermal energy systems	Broadcasts on energy savings and building clean energy systems	Aid in finding good locations for wind farms, geothermal energy, and tidal energy	Aid in finding good locations for wind farms, geothermal energy, and tidal energy	Assist in location of renewable energy systems	*In future* Lower-cost clean energy to cities and rural and remote locations
Decent work and economic growth (Goal 8)	Telework, village training, tele-banking, tele-services	Open univ. training	Aid to more productive mining, fishing, farming, forestry, and transport	Support to new construction and design of infrastructure related to climate change	Support to new construction and design of transportation systems	In future Lower-cost clean energy to cities and rural and remote locations
Industry, innovation, and infrastructure (Goal 9)	Tele-education, internet-based innovation, internet-based technology incubators, protective security for infrastructure	Educational radio and television, access to global news	Aid to more productive mining, fishing, farming, forestry, and transport	Support to new construction and design of infrastructure related to climate change	Support to new construction and design of transportation systems	*In future* Lower-cost clean energy to cities and rural and remote locations

Reduced inequalities (Goal 10)	Tele-education, internet-based learning and data bases	Educational radio and television, access to global news	TBD	TBD	TBD	TBD
Sustainable cities and communities (Goal 11)	Substitution of tele-services for physical transportation, telework reduced transportation and cleans environment	Educational radio and television, access to global news	Key topographic information for transportation, water, and sewer planning	Key info related to protection of city infrastructure from violent storms	Improved traffic and transportation control	*In future* Lower-cost clean energy to cities and rural and remote locations
Responsible consumption and production (Goal 12)	Tele-education, tele-services, services can be provided worldwide	Broadcasts on telework, conservation, on energy savings and building clean energy systems	Monitor hazardous waste locations, atmospheric pollution, oil spills, garbage scows, etc.	Note changes in weather and climate due to industrial activities	Accurately pinpoint sources of pollution	*In future* Lower-cost clean energy to cities and rural and remote locations
Climate action (Goal 13)	Tele-education, telework, sat services, services can be provided worldwide	Broadcasts on telework, conservation, on energy savings and building clean energy systems	Track ice-cap and glacier melting, measure ocean temperature, atmospheric temperatures	Track changes in atmospheric temps, intensity of storms, solar activity	Pinpoint location of atmospheric and oceanic sensors	*In future* Lower-cost clean energy to cities and rural and remote locations
Life below water (Goal 14)	Tele-education, global internet access. Track location of endangered species	Sat broadcast TV and radio can strengthen education, civic activism, and knowledge of law	Detection of water and ocean pollution, coral bleaching, fish depletion, etc.	Track Ocean storms and hurricane	Exact location of sensor and ocean buoys	TBD
Life on land (Goal 15)	Tele-education, global internet access. Track location of endangered species	Sat broadcast TV and radio can strengthen education, civic activism, and knowledge of environmental law	Used to track animals and endangered species	Monitor violent storms and provide flood and high wind warnings	Exact location information re earthquakes, volcanos, rescue ops	TBD

Table 3 (continued)

Space-based services that aid UN goals for sustainable development
Prepared by Joseph N. Pelton for the Manfred Lachs conference in Montreal in 2017 in preparation
For the UNISPACE + 50 conference in 2018

Goal	Telecom and networking sats and HAPs	Broadcasting sats and HAPs	Remote sensing sats	Meteorological sats	Navigation and timing sat	Solar power sats
Peace, justice, and strong institutions (Goal 16)	Low-cost sat telecom and internet access can strengthen education, civic activism, and knowledge of law	Sat broadcast TV and radio can strengthen education, civic activism, and knowledge of law	Time-stamped remote sensing data has been used to prosecute crimes against humanity			TBD
Partnerships for the goals (Goal 17)	Satellite manufacturers and service providers can help promote telework, tele-education, tele-health	Satellite manufacturers and sat broadcasters can help promote telework, tele-education, tele-health				TBD

Prepared and copyrighted by Joseph N. Pelton, All rights reserved. Printed with the permission of the author of the quantitatively defined aims will be achieved by 2030. Nevertheless many of the pathways forward to achieve these demanding goals, in numerous cases, will depend heavily on space-based systems. Furthermore, achievement of these goals in areas related to healthcare, education, reduced poverty and hunger, economic development, environmental protection, etc. will likely be heavily dependent on small satellite technology in particular.

Yet, small satellite technology is not a panacea. In fact, if the orbital space debris removal problem is not resolved soon, then very large-scale LEO constellations could create serious "space pollution" problems that could limit future safe access to space. The accelerated launch schedule required to orbit as many as 20,000 new satellites in a span of over only a few years carries with it very serious environmental concerns. Thus it is a difficult balancing act to note the many benefits that small satellite systems can bring to meet the longer-term objectives of the UN Sustainable Development Goals for 2030 against the hazards of potential increases in orbital space debris.

more precise tracking of aircraft on an entirely global basis. This chapter describes how the hosted payload system, known as Aerion, is now deployed on the Iridium NEXT System. This innovation is just one of the ways that small satellite constellations and host payloads on these systems can provide new capability in such important ways as air safety and air traffic management. Aerion is just one example. More new companies to provide ADS-B services will develop in time. Other small satellite demonstrations of ADS-B such as the CAN-X7 are now launched, and GomSpace has a small satellite designed to carry out ADS-B services. New and improved ADS-B capabilities will continue to develop, and it seems likely that these will evolve using advanced small satellite design concepts.

This chapter will trace the history of development of what is formally called automatic dependent surveillance-broadcast (ADS-B). In particular it will explore the use of small satellite systems and hosted payload technology to prove this vital new service and to implement a fully functional program around the world. This new approach to air navigation and exact location of aircraft in the sky will be predominately using small satellite technology and systems for reasons explained in this presentation. This new technology can in time change the entire concept of air traffic management (ATM) and enhance air safety.

1 Introduction

For reason of economy and pervasiveness of comprehensive global coverage, the use of small satellites will play a critical role in accomplishing the deployment of this new air navigation and safety program.

This chapter will also describe how small satellites are no longer just used for experimental projects and proof of concept but can increasingly serve a key and useful purpose in the deployment of critical and fully operational systems in the world. The uses of small satellites for such purposes as telecommunications, networking, and remote sensing have been demonstrated and are now being widely accepted, but new applications as RF geolocation, aircraft navigation and air safety, and other new applications are just starting to be realized.

2 Background

The growth of aviation, especially commercial aviation, has been phenomenal in the last century. The Paris Convention was signed in October 1919 and is formally known as the Convention Relating to Regulation of Aerial Navigation. This was the first attempt at regulating the growth and safety of civil air traffic on a global basis. On this occasion, 26 countries which represented the predominant number of countries operating ongoing aerial operations at the time signed on this convention. As part of this process, they endorsed the idea that each nation would assume exclusive control over the airspace above their own territory. The convention sought to address in a comprehensive matter administrative, organizational, and operational aspects of civil aviation and established processes that would apply to private air travel as well. This convention provided the broad areas of control of civil aviation for the next 25 years (Convention Relating to the Regulation of Aerial Navigation 2019).

This was followed by the Chicago Convention of 1944. This key and comprehensive air safety and navigation convention for civil aviation remains in effect until this day. It is one of the most significant conventions ever achieving international agreement and has perhaps served a large number of lives through improved aviation navigation and safety (Convention on International Civil Aviation – Document 7300 2019).

It was this convention that finally led to the formation of the International Civil Aviation Organization (ICAO) that coordinates international approaches to air traffic management and aeronautical navigation and safety. This specialized agency of the United Nations, which is headquartered in Montreal, Canada, coordinates and helps to improve civil aviation safety, navigation, and air traffic management standards (ICAO 2019).

The preamble of Chicago Convention of 1944 states:

> WHEREAS the future development of in international civil Aviation can greatly help to create and preserve friendship and understanding among the nations and peoples of the world, yet its abuse can become a threat to the general security; and
>
> WHEREAS it is desirable to avoid friction and to promote that cooperation between nations and peoples upon which the peace of the world depends;
>
> THEREFORE, the undersigned governments having agreed on certain principles and arrangements in order that international civil aviation may be developed in a safe and orderly manner and that international air transport services may be established on the basis of equality of opportunity and operated soundly and economically. (See Convention on International Civil Aviation above.)

It has been these principles that have guided the actions of the ICAO staff and leadership to seek to enhance international cooperation through improved standards, processes, and equipment to enrich civil aviation safety and navigation.

3 ICAO and Air Traffic Management (ATM)

The seamless growth of commercial aviation can truly be attributed to the work done by ICAO. Since the formation of ICAO, air traffic has increased from a few commercial aircrafts to the present day of flying many billions of international passengers each year. Air safety has been increased via the Standards and Recommended Practices and other guidance material produced by ICAO. These standards that are now followed by all commercial airlines and private operators have truly allowed civil aviation to be transformed into the safest form of travel. This has been brought about not only by regulatory standards and actions by ICAO but also the innovation that has taken place in aircraft design and manufacturing plus all allied subjects related to safety including navigation.

However, air traffic management (ATM) today is becoming increasingly challenged with the limitations of existing navigational and positioning technology. The radars used today were developed in the twentieth century and involved designs that were used extensively in the Second World War. They still remain the most popular technology for aviation traffic management. Important improvements in radar-based technology have come over the years. These have included instrument landing systems, rotating radars, Doppler positioning systems, secondary radars, and airborne collision avoidance/transportation collision avoidance systems (ACAS/TCAS). The advent of global navigation satellite services (GNSS) which is also known as precision, navigation, and timing (PNT) service has moved to a different type of approach. The latest innovation known as automatic dependent surveillance-broadcast (ADS-B). ADS-B represents an important innovative technology in air traffic management (ATM). The US Federal Aviation Administration (FAA) has made it compulsory for all aircrafts flying in US airspace to have ADS-B instruments installed in the aircraft by 2020. It is likely that ADS-B equipment will be installed in all civil aircraft around the world in the coming years.

The ICAO Council President has stated at the global CANSO Conference in 2018: “Today’s incredibly rapid rate of technological progress is now forcing us to acknowledge that a revolution is underway, with Unmanned Autonomous Systems (UAS) navigating residential and urban environments for a wide range of purposes at one end of the spectrum, and high-altitude balloons, RPAS, and super- or hypersonic aircraft jetting across the stratosphere at the other. . .Airspace design and management would be changing dramatically in the years ahead as more and more aircraft enter into service which fly higher, lower, faster, and much slower than those we manage today.”(ICAO Council President Dr. Olumuyiwa Benard Aliu speaking at CANSO’s Sixth World Air Traffic Management (ATM) Congress in Madrid, Spain, on March 2018).

To handle this dramatic growth, air traffic management must shift to deliver a more scalable model. This must be a digital system that can monitor and manage this increased level and diversity of activity. That system is what is now being called *unmanned traffic management*, or UTM. The UTM team at Airbus, for instance, has spent months executing research and tests to determine its recommendations on the best approach for a future UTM. Other aircraft manufacturers around the world are conducting similar research.

Further, the ICAO Council President has also drawn attention to the fact that new space-based automatic dependent surveillance-broadcast (ADS-B) technology should eventually serve as a truly global aircraft positioning solution, redefining how seamlessly modern ATM will function and deliver important efficiency and emission reduction advantages.

"We do not yet have a global ADS-B mandate, however by 2020 a number of States and regions will be ADS-B capable and many commercial aircraft will be equipped with suitable transponders"(Ibid). He went on to say that this new capability will be needed as (ADS-B) technology eventually serves as a truly global aircraft positioning solution. This new capability will redefine how seamlessly modern air traffic management (ATM) will function and deliver important efficiency and emission reduction advantages (Sixth World Air Traffic Management Conference CANSO Conference, March 2018).

4 Air Surveillance Over High Seas and ICAO's Responsibility

While the issue of improving air surveillance for aviation was taking place, the new GNSS-based technology made available by ADS-B services had been discovered. This technology could be applied to meeting needs of gaps in coverage over the high seas.

Under Chicago Convention, Article 12, Rules of the Air, states:

> Each Contracting State undertakes to adopt measures to insure that every aircraft flying over or manoeuvring within its territory and that every aircraft carrying its nationality mark, wherever such aircraft may be, shall comply with the rules and regulations relating to the flight and manoeuvring of aircraft there in force. Each Contracting State undertakes to keep its own regulations in these respects uniform, to the greatest possible extent, with those established from time to time under this Convention. Over the high seas, the rules in force shall be those established under this Convention. Each Contracting State undertakes to insure the – prosecution of all persons violating the regulations applicable.

In light of this, responsibility for surveillance over high seas as such falls on ICAO. ICAO has divided the airspace over the high seas into flight information regions (FIRs) and as needed has allotted responsibility to adjoining countries for implementation without giving any rights.

5 ICAO: Every Minute Tracking Signal Device Development Needed

On March 8, 2016, the ICAO Council adopted new provisions aimed at preventing the loss of commercial aircraft experiencing distress in remote locations. In this regard, ICAO announced new amendments to Annex 6 of the Chicago Convention (*Operation of Aircraft*) which were to take effect between then and 2021. These changes related primarily to the requirement for aircraft to carry autonomous distress tracking devices which can autonomously transmit location information at least once every minute in distress circumstances. Some other issues were also listed. These included the requirement for aircraft to be equipped with a means to have flight recorder data recovered and made available in a timely manner and extending the duration of cockpit voice recordings to 25 h so that they cover all phases of flight for all types of operations (Montréal, March 8, 2016, press release: ICAO).

These developments are consistent with the findings and recommendations of the multidisciplinary ad hoc working group ICAO formed after Malaysia Airlines MH370 went missing on May 2014. Dr. Olumuyiwa Bernard Aliu, ICAO Council President, explained at the time the importance of these changes. "They directly support the concept of operations for the Global Aeronautical Distress and Safety System (GADSS) which was proposed by ICAO at that time, and will now greatly contribute to aviation's ability to ensure that similar disappearances never occur again" (States Make Further Progress through ICAO to Help Avoid Recurrence of MH370-Type Disappearances March 8, 2016: Speech of Dr. Olumuyiwa Benard Aliu, ICAO Council President.icao.int).

The provisions relating to 1-minute distress tracking are performance-based, meaning that airlines and aircraft manufacturers may consider all available and emerging technologies which can deliver the 1-minute location tracking requirement specified.

The new flight recorder data recovery provisions are also performance-based. This means that related technology solutions may or may not entail the need for deployable flight recorders. Taken together, these new provisions will ensure that, in the case of an accident, the location of the site will be known immediately to within six nautical miles and that investigators will be able to access the aircraft's flight recorder data promptly and reliably. They will also contribute to greatly improve more cost-effective search and rescue operations.

6 ADS-B

By September 2014, ICAO published an ADS-B Implementation and Operation Guidance Document and by July 2018 it published an ADS-B Implementation and Operations Guidance Document (CNS SG/22 Appendix K to the Report 2018).

7 What Is ADS-B

ADS-B, in brief, is a GNSS/GPS-based technology. ADS-B provides many benefits to both pilots and air traffic control that improve both the safety and efficiency of flight. The prime advantages are listed below:

1. The pilot – When using an "ADS-B In" system, a pilot is able to view traffic information about surrounding aircraft if those aircrafts also are equipped with "ADS-B Out" capability. This information includes altitude, heading, speed, and distance to aircraft. (In addition to receiving position reports from ADS-B out participants, it can provide position reports on non-ADS-B out-equipped aircraft if suitable ground equipment and ground radar exist.)

2. Weather – Aircraft equipped with universal access transceiver (UAT) ADS-B In technology will be able to receive weather reports and weather radar through flight information service-broadcast (FIS-B).
3. Flight information – Flight information service-broadcast (FIS-B) also transmits readable flight information such as temporary flight restrictions (TFRs) and NOTAMs to aircraft equipped with UAT.
4. Expense – ADS-B ground stations are significantly cheaper to install and operate compared to primary and secondary radar systems used by ATC for aircraft separation and control.

In the USA, unlike some alternative in-flight weather services currently being offered commercially, there will be no subscription fees to use ADS-B services or its various benefits. The aircraft owner will pay for the equipment and installation, while the Federal Aviation Administration (FAA) will pay for administering and broadcasting all the services related to the technology.

The ADS-B system is comprised of multiple parts, including ground stations and aircraft installed equipment (Adam Krumbein: Introduction to ADS-B Technology for Enhanced Aviation Tracking and Safety: SWA southwestantennas.com dated Nov. 21, 2016).

Under the requirements for the NextGen air traffic system, all aircraft which fly within US airspace will be required to transmit “ADS-B Out” information to ADS-B ground stations and other ADS-B equipped aircraft by 2020. This information includes aircraft identification, altitude, speed, and velocity. The ADS-B equipment package installed on the plane includes a GPS unit for providing location information, processing hardware, and antennas for transmitting and receiving the ADS-B signals. “ADS-B In,” on the other hand, means “ADS-B In” is the receiver part of the system. “ADS-B In” equipment allows aircraft, when equipped properly, to receive and interpret other participating aircraft’s “ADS-B Out” data on a computer screen or an electronic flight bag in the cockpit.

As the aircraft flies over individual ADS-B receiver ground stations, these pick up the “ADS-B information broadcast by each aircraft, which can then be used by air traffic controllers as a supplement to radar-based tracking.

Airspace safety should improve with ADS-B by giving pilots and air traffic controllers additional information about exactly where each aircraft is in the system, helping to prevent midair collisions or close calls during takeoff and landing. Existing flight corridors over land will be able to safely handle an increasing number of daily flights with ADS-B, adding accuracy and redundancy to the existing airline tracking systems. The addition of a global satellite system coverage will greatly expand the abilities for all aircraft to connect to the ADS-B system.

8 Acceptance of ADS-B by ICAO and Other Governments

As early as 2003 at the 11th ICAO Air Navigation Conference it was recommended that States recognize ADS-B as an enabler of the global ATM concept bringing substantial safety and capacity benefits. It also supported the cost-effective early implementation of this new capability. They urged ongoing effort to ensure that it would be harmonized and made compatible and interoperable with operational procedures, data linking, and ATM applications (ADS-B Implementation and Operations Guidance Document: Introduction CNS SG/22 Appendix K to the Report (2018)).

ADS-B is, therefore, a new surveillance technology designed to help modernize the air transportation system. It provides foundational technology for improvements related to **NextGen** (Next Generation Air Transportation System) and **SESAR** (Single European Sky ATM (Air Traffic Management) Research Program). NextGen refers to the effort of the US FAA (Federal Aviation Administration) to transform the ATC (air traffic control) system to support a larger volume of airplanes more efficiently. SESAR is a similar effort in Europe in which EC (European Commission) and EUROCONTROL are its founding members.

For NextGen and SESAR, ADS-B is one of the most important underlying technologies in the plan to transform ATC from the current radar-based surveillance to satellite-based GPS (Global Positioning System) surveillance. In addition, the FAA states that ADS-B will serve as the cornerstone for this transformation, bringing the precision and reliability of satellite-based surveillance to the nation's skies (eoPortal Directory ADS-B 2019).

Modern Mode-S transponders on board of aircraft transmit the flight position and other information by so-called extended squitter messages (1090ES) on the 1090 MHz SSR-Mode-S downlink frequency (ADS-B Out). In the future, radar systems will be complemented or even replaced by less costly ADS-B ground stations, which will be integrated in the existing surveillance infrastructure. The European ADS-B Implementing Rule requires that new aircraft heavier than 5700 kg or faster than 250 knots will be equipped with "ADS-B Out" from 2015 onward when flying IFR (instrument flight rules), and for already operational aircraft, a retrofit was made mandatory from end of 2017 on. In 2020, ADS-B surveillance shall become operational.

Yet there remains a key issue with ADS-B coverage for long-distance and overseas flights. In these instances, usefulness of radars and even ADS-B is limited as these technologies depend upon ground-based stations. Thus with only ground-based stations, ADS-B is therefore unable to provide coverage over oceans which, in fact, is 70% of the airspace. Further, there is also the issue of difficult terrains like polar regions or high mountains where ground stations cannot be installed. Therefore, shifting from radars to GNSS-based technology like ADS-B offers much greater quality of air traffic management over land surface. This service needs to be extended to satellites to provide truly global coverage.

9 The Case of Missing MH370 Flight Over High Seas

Perhaps the defining moment for the global adoption of ADS-B was the case of flight MH370 which has now become infamous as the flight which took off from Kuala Lumpur to Beijing and became untraceable. The flight disappearance of MH370 in

2014 was truly a momentous moment for the aviation industry comparable even to hijacking of civil domestic aircrafts from Boston airport in the USA in 2011 and thereafter suicidal attack on various iconic buildings including the twin towers of the World Trade Center in New York in 2001. While the incident of 2001 led to security awareness in commercial aviation, the disappearance of MH370 over the South China Sea was an eye opener for safety of civil aviation and in particular surveillance of aircrafts over high seas.

Shortly after the disappearance of Malaysia Airlines flight MH370, a special Multidisciplinary Meeting on Global Flight Tracking (MMGFT) was convened at the ICAO Headquarters in Montréal, Canada, to propose recommendations for future actions. One of the main decisions taken was the need for operators to pursue global tracking of airline flights at a faster pace.

10 Shortcomings of ADS-B

So, while ADS-B as a technology has gained great advantage and acceptance over traditional secondary radar as it gives its location, speed, direction, etc., it still suffers from a major flaw. This is because it needs ground stations to reflect the messages which come from aircrafts which makes its coverage over high seas impossible via ground stations. The shortcomings of the old radar system of air navigation and the newly emerging technology of ADS-B had a clear common denominator. This was the inability of either of these systems to provide surveillance and navigation over high seas or difficult terrains like polar regions where ground stations cannot be installed. This is where the use of small satellites to provide ADS-B connectivity enters the picture as the solution.

11 Use of Small Satellite Constellations to Provide Global Safety to Aviation: ADS-B Over Satellites

Perhaps the greatest shortcoming of existing technology for air navigation surveillance (ANS) using radar is the absence of air surveillance over high seas, polar regions, as well as difficult terrains which are quite challenging. The missing MH370 flight in 2014 over high seas was a challenge to ICAO and the aviation community. While the lack of air surveillance over high seas and polar regions had started bothering aviation experts, it was fortuitous that a year earlier in 2013 the German Space Agency DLR had started experimenting on the same subject. DLR had already by 2013 experimented with a hosted payload on a European Space Agency's satellite PROBA-V′ on May 23, 2013, to test whether ADS-B can work from satellites instead of ground stations. On switching on for the first time, it recorded over 12,000 ADS-B messages within 2 hours at an altitude of 820 km (ADS-B over Satellite – first aircraft tracking from space, June 13, 2013, DLR News).

DLR's experiment proved that signals even from a height of about 800 km would be comparable to signals from ground stations. The advantage would, of course, be that the satellites could cover the entire oceanic air space as well as the polar regions and areas where ground stations cannot be installed. The satellites would, however, have be a constellation to cover the entire globe because the signals only had a range of 800 km and thus would be too weak for MEO- or GEO-based satellites to capture.

The DLR experiment of "ADS-B over Satellite" proved successful and was the successful proof of concept needed to move to the next stage. "Worldwide, this is the first experiment ever of this kind – and now we have evidence that this concept works," says DLR Project Manager Toni Delovski. The project team detected over 100 aircrafts during the first pass over the British Isles, East Asia, and Australia when the receiver was switched on. "For some aircraft, we were able to determine multiple positions over time, which allowed us to reconstruct their flight paths"("ADS-B over Satellites: The World's Fastest ADS-B receiver in Space"; T. Delovski, K. Warner, T. Raw like, J. Benrens, J. Bredemeyers, RWendel. DLR-Institute of Space Systems, Robert-Hooke Str7, 28359 Bremen Germany; Toni.delovski@dlr.de).

ADS-B signals are broadcast by aircraft every second; they include aircraft position and velocity information. Currently ADS-B equipment is being introduced on aircraft as a supplementary data source to the ground-based radar to monitor air traffic. The problem with radar is that its coverage is restricted. Once out of the range of terrestrial radar stations, the continuous air traffic surveillance stops. "For example, aircraft travelling from Europe to Brazil disappear from the radar over the Atlantic and will only be detected again by terrestrial radar shortly before reaching South America," explains Delovski (Ibid).

There is currently no continuous air traffic surveillance by terrestrial radar over oceanic airspace or in regions with limited air traffic surveillance infrastructure. But tracking from space could close this gap. ADS-B over Satellite was a joint project of the DLR Institute of Space Systems and the DLR Institute of Flight Guidance, in cooperation with the Luxembourg partner SES Techcom Services (Convention Relating to the Regulation of Aerial Navigation 2019).

12 PROBA-V Test Results and Considerations

The ADS-B receiver test results were limited by the fact that this was the first onboard satellite experiment of its kind, receiving 1090ES ADS-B squitter signals that were being transmitted from aircraft. Therefore, the experimenter could not build on experiences or any previous evaluation results. The assessment could not be completely definitive of the achieved results when one takes into account the constraints under which this experiment was conducted, due to limitations in cost and time as limited power and geometric coverage areas.

The reception of 1090 extended squitter ADS-B messages on board of the PROBA-V satellite was mainly affected by the following issues, which may lead to a loss of ADS-B information:

- RF signal loss due to the low signal level resulting from the distance between the receiving satellite at an altitude of approximately 820 km and the transmitting aircraft at an altitude that varied between 0 and 12 km.
- RF signal loss due to the shapes of the satellite antenna vertical radiation pattern and the aircraft antenna vertical radiation pattern.
- Corruption of messages by garbling, when several messages arrive at the ADS-B antenna onboard of the satellite and, at the same time, due to overlap and thus cannot be decoded by the ADS-B receiver.
- The ADS-B receiver on board of PROBA-V is a hosted payload, while the main mission is the vegetation scanner. So the antenna mounting position was a compromise in order not to disturb the main mission and the other payloads
- Speed of the satellite of about 27,000 km/h, which leads to a limited time of observation for each detected aircraft of about 3 min maximum (ADS-B over Satellite Global Air Traffic Surveillance for Space: Conference Paper 2014: http://www.researchgate.net/publication/286240589).

13 Hosted Payload and ADS-B Over Satellite

One of the most interesting aspects of this experiment was that the in-orbit test of ADS-B over Satellite using a hosted payload and the finding that this service does not necessarily require independent satellites. The ADS-B instrument is light and can be hosted as a payload on any satellite or for that matter even on a high rising balloon. The quality of antenna and receiver sets does become critical in terms of requiring to be posted on a free-flying satellite.

14 Automatic Dependent Surveillance-Broadcast (ADS-B) Over Satellites

Automatic dependent surveillance-broadcast (**ADS-B**) **over satellite** is a surveillance technology in which an aircraft determines its position via satellite-based navigation without the help of ground-based equipment. The aircraft also periodically broadcasts the signals, enabling it to be tracked, and various information as to location, speed, and bearing to be relayed to the satellite coverage. This allows the information to be ultimately received by the air traffic control without ground stations, and no interrogation signal is needed from the ground. It can also be received by other aircraft to provide situation awareness so that the pilot can be fully aware of other objects in the sky around him if they are equipped with ASD-B equipment.

ADS-B is “automatic” in that it requires no pilot or external input. It is “dependent” in that it depends on data from the aircraft’s navigation system. Further, this information as to speed and position heading is sent regardless of the action of the pilot or the functioning of the engine. It can, therefore, be put on a pilotless aircraft or unmanned autonomous vehicle (UAV) or even a balloon or drone. ADS-B is therefore a possible replacement of a secondary radar. However, a primary radar is different in function as it detects an unknown object in the sky, while ADS-B has no detection capability and is not a substitute for primary radar.

15 Advantage of ADS-B Over Satellites Over Normal ADS-B

There are several advantages of ADS-B over Satellites compared to ground station ADS-B.

The most obvious advantage is, of course, that ADS-B operates seamlessly over the high seas and polar regions. What is not so obvious is that it also covers certain land areas where it is difficult to put up ground stations like forests or mountains or large lakes. Some countries that are also not equipped to operate ADS-B ground stations can also benefit from it.

There are also other advantages such as:

- Search and rescue operations over high seas and areas out of range of ground stations become trackable via its ADS-B signals. This feature could have been used in the case of MH370.
- New air routes over high seas can be formed which will be more direct and save money for airlines.
- Another advantage of ADS-B over Satellites is that it will save energy and, therefore, fuel burn and lower greenhouse gas emissions.
- The satellites to be used can be small and deployed in low Earth orbit and even be designed as hosted payloads. This can make them lower in cost.

Today, there are other in-orbit tests underway. Canada has launched its CAN-X7 test satellite to experiment with ADS-B service. The small satellite designer and manufacturer GomSpace has developed a design for an ADS-B system.

Perhaps the most significant and first commercial venture has already started under the name of Aireon. This company is pioneering the commercial offering of an ADS-B service for air traffic management (ATM).

Aireon is backed by NAV CANADA, the Canadian Government Air Navigation Agency, with support beginning in 2014. Aireon LLC is a joint venture between NAV CANADA, IAA (Irish Aviation Authority), ENAV (Ente Nazionale per l'Assistenza al Volo, Italy), NAVIAR (Navigation Via Air, Denmark), and Iridium, which is hosting the Aireon payload on board the Iridium NEXT LEO constellation of 66 operational satellites. This Aireon system, now fully deployed, is actively providing a global system for tracking and monitoring aircraft anywhere in the world by using spaceborne ADS-B receivers.

Aireon is pioneering what many would characterize as next-generation aviation surveillance system. These are deploying the latest ABS-B technologies that were formally ground-based and, for the first time ever, are now operating globally. The objective of the Aireon hosted payload packages is to significantly improve efficiency, enhance safety, reduce emissions, and provide cost-savings benefits to all stakeholders interested in aviation safety and navigational efficiency. Space-based ADS-B surveillance covers oceanic, polar, and remote regions and can also augment, or in some case replace, existing ground-based systems.

In this effort, Aireon is working in partnership with leading air navigation service providers (ANSP) from around the world, like NAV CANADA, the Irish Aviation Authority (IAA), ENAV, NATS, and NAVIAR, plus others that will be recruited to join this network initiative. Iridium Communications Inc. that operates the Iridium NEXT satellite network for global voice communications and hosts the Aireon packages is also a partner.

Iridium Communications Inc. (formerly Iridium Satellite LLC) is a publicly traded US company. Iridium operates a constellation, a system of 141 active satellites used for worldwide voice and data communication from handheld satellite phones and other transceiver units. This is a combination of first- and second-generation satellites. The Aireon payloads are only on the 66 Iridium NEXT satellites.

The current Iridium network covers the whole Earth, including poles, oceans, and airways, with 95 satellites, with the remaining 46 acting as active backups. With the help of "Iridium NEXT," Aireon is hosting its specially developed receivers and is providing a global, real-time, space-based air traffic surveillance system, available to all aviation stakeholders. Aireon's space-based global surveillance system is thus the first globally deployed automatic dependent surveillance-broadcast (ADS-B) service. Instead of utilizing traditional radio receiver towers on the ground, Aireon has redesigned them into flexible and highly effective space-grade receivers. This allows for 100 percent global surveillance using the same ADS-B signal that aircraft already transmit. Iridium NEXT's low-latency, 66 cross-linked low Earth orbit (LEO) satellites meet the technical demands of global air traffic surveillance and tracking (Aireon 2019).

Iridium Communications Inc. is, therefore, a major partner of Aireon and has launched under its "NextGen" scheme 66 satellites of about 860 kg in mass. Each includes the ADS-B package. The network is deployed at a height of 780 km above the Earth. Of these, 60 satellites will provide the ADS-B services, while 6 will be in-orbit spares ready for providing service if one of the other packages should fail. Iridium NEXT's low-latency, 66 low Earth orbit (LEO) satellites are well suited in altitude, power, and coverage to meet the technical demands of global air traffic surveillance and tracking.

A "hosted payload" is the term now commonly used in the space industry to describe packages that are "piggybacking" on a larger and more powerful satellite. Such a module can be attached to a commercial satellite with communications circuitry that operates independently of the main spacecraft but which may share the satellite's power supply and even their transponders for transmission of communications signals. The concept has been also been referred to as "hitchhiking" in addition to "piggybacking."

Iridium NEXT is hosting the Aireon system and is currently the only commercial satellite constellation with the global coverage capability and universal reach to enable global air traffic surveillance due to its polar orbital configuration. The Globalstar mobile satellite communications network has service only up to 55°

latitude north and south and thus does not cover the polar regions. It also does not have inter-satellite links to allow transfer of data to reach ground control facilities. The polar orbiting configuration provides complete global coverage and inter-satellite relays. With these combined features, it could potentially eliminate the need for ground stations. Ground-based redundancy helps to make the total system more resilient.

ADS-B information broadcast from the aircraft will be received by a hosted payload (AHP), which transfers aircraft data from satellite to satellite via cross links down to Aireon's ground-based Teleport Network (TPN) and Aireon Processing and Distribution (APD) system. With the assistance of a partner, Harris Corporation, the APD decodes and verifies the data and delivers the data to the appropriate stakeholder facilities that have subscribed to the Aireon service.

16 The Aircraft Antenna for ADS-B Service

In order to ensure reliable satellite reception, an A1 class transmitter and top mount aircraft antenna (commonly found on most commercial aircraft and private jets) is required due to the space-based nature of Aireon's receivers. Aircraft with a traffic alert and collision avoidance system (TCAS) to help prevent midair collisions are typically equipped with both top and bottom mount antennas (see Fig. 1).

Fig. 1 Operational configuration between aircraft and Aireon packages. (Graphic courtesy of NAV Canada)

A paper titled “Low-Earth orbit satellite constellation for ADS-B based in-flight aircraft tracking” by Thien H. Nguye, Naomi Tsafnat, Ediz Cetin, Barnaby Osborn, and Thomas F Dixon (Nguyen et al. 2019) presents a parametric study that seeks to define an optimum design for a custom ADS-B satellite constellation.

The number of satellites, inclination, and altitudes of each satellite were varied to examine their effect on coverage. The aim was to design an alternative low-cost satellite constellation providing equal or better ADS-B coverage than that provided by ground stations/antennae. To evaluate the ability of a constellation of LEO satellites to provide ADS-B coverage in the absence of land-based ADS-B receivers, popular flights over the Atlantic and Pacific Oceans were simulated.

Thus, different satellite constellations were simulated and the link-budget data for each test case was analyzed. For the purpose of parametric analysis, three flight path possibilities were defined, and one flight from each modeled flight path was used for the optimization analysis.

The results from this simulation show that if there had been only 18 satellites in a constellation, they would have provided coverage to almost continually track the MH370 during its flight. Had the ADS-B transponder remained operational during the flight, the probable crash and debris locations area would have been quite small for the search. The parametric study suggests that a larger number of satellites at higher altitude provide more reliable ADS-B coverage for the transoceanic flights of interest. Geometrically, a 60° inclination was the most coincident with the flight paths of interest and provided the most optimal coverage of the inclinations tested. This was only a theoretical analysis, and other factors such as coincidence with an actual constellation, such as Iridium, might prove to be a more important consideration.

17 Aireon Results to Date

The Aireon experience: The use of small satellites in Leo for air traffic surveillance and management is yet another important use of small satellites.

In terms of the performance results, the performance was in many ways better than expected. Of the 113 million ADS-B reports received on April 2019, all arrived within the target 8-second update rate, with some as low as 3–4 s. The average time it took for those position reports to reach a controller was just 0.17 s against a target of 2 seconds. This shows the quality of real-time information given the journey that data makes from the aircraft, through Aireon’s satellite network and Iridium inter-satellite, and then to its ground station before reaching the ATM system.

Further, this data is now being used for allowing low-latency, real-time surveillance, thereby reducing the distance between aircrafts. This capability offers airlines that were previously assigned fixed speeds and heights the opportunity to take advantage of more flexible flight paths and optimum trajectories, that is, reducing fuel use and greenhouse gas emissions and helping them maintain their operating schedules (https://nats.aero/blog/2019/06/operational-trial-of-aireon-service-shows-potential-for-big-benefits/14 June 2019).

18 Conclusion

The European Aviation Safety Agency has certified Aireon as a new air navigation service provider (ANSP) for its space-based ADS-B surveillance, the first of its kind certification ever issued by the civil aviation regulator.

The FAA has engaged the Harris Corporation to interconnect space-based ADS-B to FAA infrastructure in support of advanced surveillance enhanced procedural separation (ASEPS). Further, is has sought further trials and information so as to achieve the following:

- Added independent validation with time difference of arrival.
- Flight test the service capability.
- Perform continuous monitoring
- Update interval (UI) result from FAA flight test is 8.05 s for oceanic holding pattern.
- Space-based ADS-B routing to any service delivery point within the FAA network connecting to ATOP/MEARTS/ERAM to be considered equivalent to ground-based ADS-B.

The Airports Authority of India has signed a memorandum of understanding (MoU) with Aireon for implementation of space-based automatic dependent surveillance-broadcast (ADS-B) data services for the oceanic regions of the Indian flight information regions (FIRs):

- Aireon has signed data service agreements (DSAs) with 11 aviation organizations, making up 28 countries. These include NAV CANADA, NATS, ENAV, IAA, NAVIAR, DC-ANSP (Curacao), Air Traffic Navigational Services Co. Ltd (South Africa), the Civil Aviation Authority of Singapore, Seychelles Civil Aviation Authority, ISAVIA (Iceland) and Aerial Navigation Safety in Africa and Madagascar (ASECNA – Western Africa and Madagascar).
- In reference to other aviation stakeholders, Aireon and FlightAware have announced a partnership on September 2016. Together, they created a product called GlobalBeacon. GlobalBeacon is a first of its kind product and a turnkey solution for airlines to be in compliance with the International Civil Aviation Organization's (ICAO) Global Aeronautical Distress Safety System (GADSS). This controls Global Beacon system that enables airlines of all sizes to proactively position themselves to respond in the event of an emergency.

Small satellites and the early operational experience of the Aireon hosted payload on the Iridium NEXT satellite have shown the way forward – both for the ICAO and National Aeronautical Service Providers. Thus, it has been shown that ADS-B over Satellite provides reliable information on aircraft location with precision and a new level of accuracy. Many believe that ADS-B services offered by small satellites can provide the answer to the lack of accurate aeronautical navigational and positioning services in many areas of the globe. There have previously been areas where there has been limited or no positional surveillance over the high seas, polar regions, and some difficult terrains. This new technology supplied via the use of small satellites in a global constellation appears to represent a game changer and an important new small satellite application of significance.

There is value beyond its critical new safety and navigational accuracy service. There is also the additional opportunity to help with better and tighter flight management. This can help to save fuel and limit greenhouse gas emissions. This can also, perhaps, reduce or eliminate future dependence on the Second World War Technology of outdated radar technology for CNS/ATM. In some cases, outdated ground equipment can be replaced and phased out of service. The longer term question remains with regard to the resilience of these systems and to what degree is there a need for greater redundancy of such systems. Operational experiene will verify the longer-term ability of such systems to avoid major outages and help address concerns such as solar storms or other possible sources of system failure.

Small Satellites and Risk management, Insurance, and Liability Issues

Chris Kunstadter

Contents

Abstract

Space insurance is the financial protection and risk-sharing regime that protects those involved in space activity from loss of assets, business interruption, and third-party liability for bodily injury and property damage. The first space insurance policy was written in 1965, to protect COMSAT, the US signatory to INTELSAT, from liability arising from their involvement in deployment of the earliest INTELSAT satellites. Since then, space insurance has expanded to become a critical resource that enables innovation and investment in space activity, as well as unlocking the economic potential and providing an economic safety net for the risks associated with space activity.

1 Introduction

Risk can be defined as the intentional interaction with uncertainty. The risk management process involves identification of the perils faced; assessment of the hazard – or impact – of those perils; and treatment of the consequences. Treatment options include avoidance (don't do the risky thing), reduction (incorporate protection from perils), retention (acceptance of the risks), and sharing (e.g., insurance). Risk has many aspects. Table 1 diagrams the many key dimensions of risk.

Three principles of insurance play a significant role in space insurance:

- Pooling: "Losses of the few are paid by the many." Unlike automobile insurance, where millions of drivers pay insurance premiums to cover the losses of those few who have accidents, the small number of launches and satellites results in potential volatility, as a single loss can wipe out an entire year's space insurance premium.
- Fortuity: "Losses must be unanticipated." When a failure occurs, the cause tends to be a random "escape" resulting from errors in design, workmanship, or process. The intense scrutiny that space programs receive is designed to eliminate those risks that can be foreseen or anticipated.
- Indemnification: "Claims are paid for the actual loss sustained." Insurance not being a source of profit, claims reimburse the insured party for the actual financial loss sustained, e.g., the asset value, loss of income, or payments for liability to third parties.

2 Space Insurance

Space insurance provides coverage for satellite owners, operators, users, manufacturers, launch service providers, and other space operators during launch, initial operations, and on-orbit operations, through the life of a satellite or payload.

Table 1 Key elements of risk critical to the space insurance enterprise

Key elements of risk	
Definition	Risk is the intentional interaction with uncertainty
Risk management process has three stages	Identification → assessment → treatment
Treatment options	Avoidance, reduction, retention, and transfer (insurance)
Principles of insurance considers these three aspects	Pooling, fortuity, indemnification

In addition, ancillary coverage is available for pre-launch risks (e.g., assembly, integration, testing, transportation, pre-launch processing), end-of-life deorbiting and reentry, financial consequences (e.g., political risks and credit risks), and other risks. Space insurance includes virtually all technical risk from launch onward, and covers all risks, with few exclusions. The cost of space insurance is typically the third largest cost for a space program, after the satellite and the launch services.

The global insurance market generates about $4 trillion of premium each year – it is a major contributor to the financial economy. While space insurance has traditionally contributed only $400 million to $1 billion of annual premium into the insurance market (i.e., 0.01–0.025% of the global insurance premium), losses in space insurance are often dramatic and highly publicized. Thus, insurance company managements pay close attention to this low-frequency/high-severity corner of the market.

The first space insurance policy was written in 1965, to protect COMSAT, the US signatory to INTELSAT, from liability arising from their involvement in deployment of the earliest INTELSAT satellites. Since then, space insurance has expanded to become a tool that enables innovation and investment in space activity, as well as unlocking the economic potential and providing an economic safety net for the risks associated with space activity.

Unique challenges drive the cost and terms of space insurance:

- Rapidly evolving technologies, smaller satellites, new launch vehicles, satellite constellations, custom-built satellites, generic anomalies, and the space environment are key technical issues that differentiate space insurance from other lines of insurance.
- The small number of launches and satellites drive a large variance in annual results, while the low frequency and high severity of losses drive potential volatility of in those results. Furthermore, the large range of insured values – from a $50,000 CubeSat to an $800 million launch of two large satellites – drive capital requirements that generate stiff competition among the insurance companies engaged in space insurance.
- The short "tail" (i.e., if a launch fails, it will occur in the first minutes or hours of when the insurance attaches), high cash flow (i.e., premium for a launch is paid prior to the launch), and uncorrelated risks (losses in space insurance do not overlap with losses in other lines of insurance) make space insurance attractive to insurance companies, increasing competition.

3 Insurance Coverages

Space insurance coverages for asset protection represent the vast majority of space insurance premium. Business interruption, liability, and ancillary coverages contribute less than 5% of the total annual premium. Nonetheless, as commercial human spaceflight emerges, insurance for this new market will grow quickly.

Coverage for asset protection is generally viewed as three separate phases – launch vehicle flight (from launch to separation of the satellite in orbit), initial

Table 2 Phases of space insurance coverage

Phase	Insurance coverage	Duration
Launch vehicle flight	Launch vehicle flight only: Covers launch vehicle flight phase, from	The launch flight only can be combined with post-separation into a launch plus one year policy
Post-separation (initial operations)	Post-separation: Covers initial operations phase (orbit raising, deployments, testing) and in-orbit	Post-separation can be covered in a Launch-Plus One Year Policy
In-orbit life	In-orbit: Covers in-orbit life for one year at a time. Renewed annually based on satellite health.	

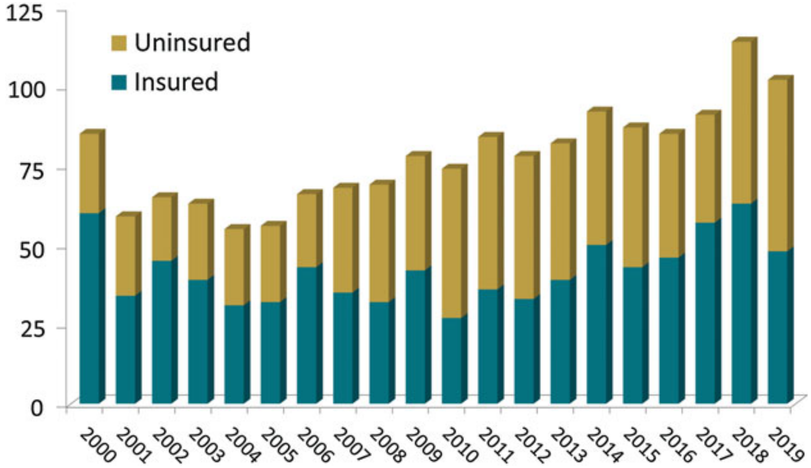

Fig. 1 Insured versus uninsured launch coverage since 2000. (Graphic courtesy of AXA-XL)

operations (post-separation activities such as orbit raising and testing), and in-orbit operations (ongoing mission operations through the life of the satellite) (see Table 2).

While policies can be written for any one or a combination of these periods, the most common policies are "launch plus one year" (i.e., launch vehicle flight, initial operations, and in-orbit operations through one year from launch) and "in-orbit" (i.e., covering mission operations on an annual basis, renewed each year based on health review from the end of the launch plus one year policy).

Coverage is typically procured by the satellite owner/operator, though any party with a financial interest can protect their exposure with insurance. The pattern of coverage or "self-insurance" has varied over time since the practice of launch insurance started in 1965. Figure 1 shows the variation in the market since 2000 (see Fig. 1). Many government launches are uninsured.

Some launch service providers may provide a "launch risk guarantee" (LRG) which will provide the satellite owner with a free relaunch or refund in the event of a launch vehicle failure that results in loss of the satellite. The LRG does not cover the value of the satellite, so the owner will need to buy “wrap-around” coverage for the satellite during launch vehicle flight.

Under satellite procurement contracts, some satellite owners will withhold a portion of the contract value to be earned by the manufacturer over the satellite’s life, based on successful performance. These contract “incentives” or “warranty payback” payments can, likewise, be insured by the satellite manufacturer.

Some insurance policies, such as homeowners insurance, cover only specific “named perils,” such as fire, windstorm, burglary, etc. Space insurance policies, as well as some other commercial lines of insurance, are written as “all-risks” policies – any loss is covered, no matter what the cause, unless it is explicitly excluded. Space insurance policies typically exclude war and terrorism, as well as several other intentional acts. Any cause that is not excluded is covered, whether design, workmanship, environmental (e.g., solar activity, micrometeoroids, space debris), or other causes.

4 Underwriting Process

The process of underwriting space risks involves understanding and analyzing complex technologies and long-term business plans. As such, insurance companies constantly track the space industry to review and anticipate developments in applications and markets. When a new program is ready to be insured, the client (e.g., the satellite owner/operator) will contract with an insurance broker to act as their agent in approaching the insurance market (the 30–35 insurance companies around the world who have the appetite to write space insurance). The broker’s role includes shepherding the client through the process of briefing the insurance market, designing the insurance coverage to ensure it is tailored to the specific technical and business needs of the client, negotiating the policy wording and pricing with the market, and, in the event of a loss, helping ensure that the claim is settled in a timely manner.

The underwriter assesses the risk, negotiates the terms and conditions of the insurance policy, and determines the appropriate premium to charge for the risk provided. The process can be quick or extended. An in-orbit renewal on a healthy satellite can be done in 1 day, while a complex launch insurance program on a constellation may take up to a year to finalize.

Underwriting criteria are the basis of the coverage design and risk analysis and include:

- Design: mission requirements, concept of operations (CONOPS), mission timeline, operating environment, system architecture, subsystem design, redundancy, margins, budgets, new technologies, unit-level qualification status and flight heritage, assembly, integration, and test flow
- Experience: operator experience, manufacturer experience, launch provider experience, anomaly resolution (ground and flight, investigation process, anomaly attribution, root cause, corrective action, cross-program issues)

- Contracts: spacecraft purchase agreement, launch services agreement, performance specifications, interface control document (ICD), qualification and test plan
- Commercial: business plan, contractual obligations, exposure analysis, asset valuation, loss calculation, insurance policy terms and conditions
- Pricing: statistical analysis, historical failure rates, quantification of potential loss scenarios, loss frequency vs. severity, insurance market conditions

5 Market Dynamics

Launch activity has increased dramatically in the past 15 years, from a low of 55 launches to orbit in 2004 to 114 launches in 2018. Likewise, the number of satellites launched has increased from 77 in 2004 to 520 in 2019. This increase is directly tied to the commercialization and globalization of space activity and has created both opportunities and threats to the space insurance market.

In 2018, 60% of launches carried some insurance, up from 36% in 2010. From 2014 through 2018, over 800 satellites were insured during launch, more than in the two decades prior to that, combined. 85% of the satellites insured during launch between 2014 and 2018 were small satellites. Only 120 were large GEO communications satellites that have traditionally generated most of the premium in space insurance. The smaller satellites generally carry low amounts of insurance. Even when 100 or more of these small satellites are carried on a single launch, the total amount of insurance on the launch is still well below the insured value of a launch carrying one or two large GEO satellites.

The relative insurance coverage of GEO satellites and LEO SmallSats is shown in Fig. 2. Clearly launch insurance coverage for GEO continues to outweigh that of LEO satellites, but coverage for LEO systems represents the area of largest growth, while coverage for GEO systems is now relatively stable (see Fig. 2).

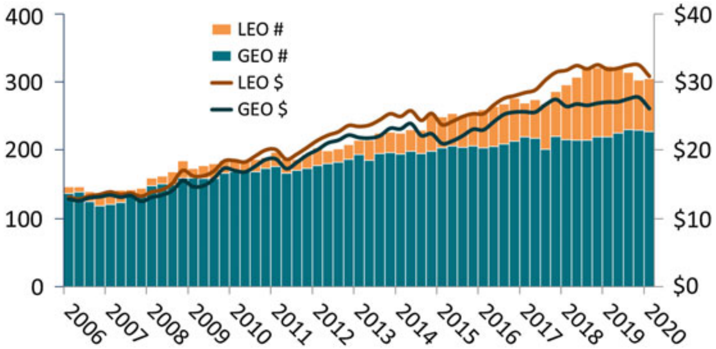

Fig. 2 The relative space insurance coverage for GEO and LEO satellite systems globally. (Graphic courtesy of AXA-XL)

Clearly the type of satellites in terms of their orbits, size, and value are changing rapidly in the global marketplace. These changes in the numbers and types of satellites being launched are in turn changing the nature and coverage profile of the global launch insurance market (see Fig. 3).

Insurance companies allocate their capital to space insurance based on the maximum amount that could be lost in any one accident. This would typically be on any one launch or on any one satellite in orbit. To accommodate the insurance needs of a large GEO launch which may carry two or more large satellites, the insurance market has provided up to $800 million of capacity to cover the value of the satellite(s) and launch. Capital is allocated by insurance companies with the expectation that it will generate premiums sufficient to cover the losses expected to occur in a year.

As the price of insurance is directly correlated with the available market capital, the excess of capital for smaller risks had pushed insurance premiums to their lowest levels in history by mid-2019. This is simple supply and demand – as long as market capital (along with its requirements for a return on investment) remained high, insurance pricing stayed low. With the significant insurance claims in space activity in 2019, some insurance companies curtailed their space insurance lines of business, either withdrawing completely, imposing severe restrictions, or decreasing their capital allocation. As a result, the $800 million of capital available to insure the largest risks has been reduced to around $650 million, and the number of insurance companies who offer space insurance coverage has decreased from 40–45 to 30–35.

Meanwhile, the increasing number of low-value launches and satellites means that the insurance companies in the space insurance market are competing for every risk, whether large (e.g., the $800 million launch) or small (e.g., a single $50,000 CubeSat). An individual insurance company rarely provides more than $50 million

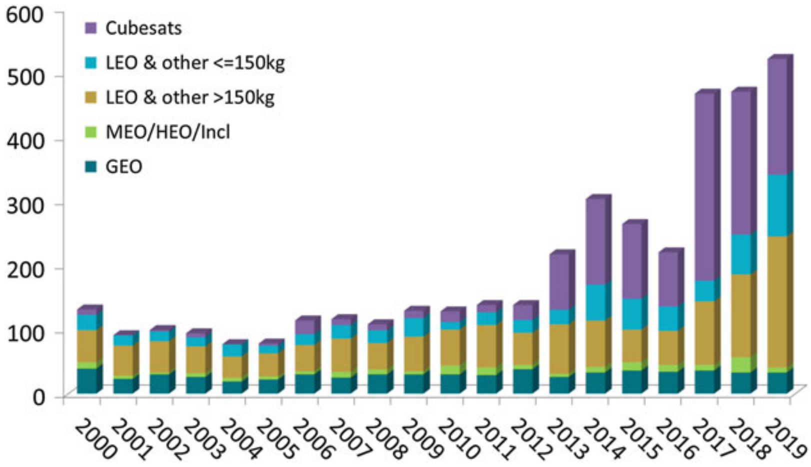

Fig. 3 Changes in the types of satellites being launch by orbit and size shown from 2000 to 2019. (Graphic courtesy of AXA-XL)

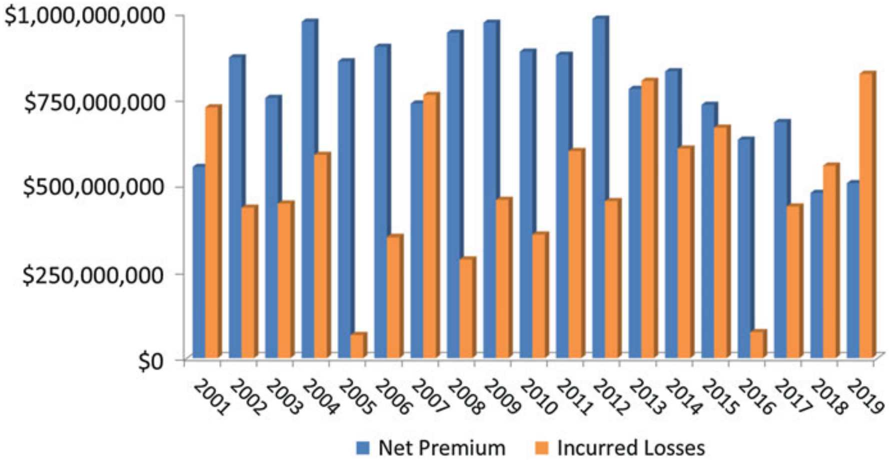

Fig. 4 Market annual premiums and claims. (Graphic courtesy of AXA-XL)

to $75 million per risk (e.g., per satellite or per launch), and some provide only $1 million per risk. As a result, a large insurance placement will be provided by a number of insurance companies. A specialized insurance broker, as an agent of the client (e.g., satellite owner), will work with the whole space insurance market to get the required capacity for a risk, whether large or small.

In 2018 and 2019, six major insured losses, as well as eight smaller losses, accounted for over $1.38 billion in space insurance claims. This level of claims was offset by only $980 million in premium, for a loss ratio (claims/premium) of over 140%. Insurance companies generally require a loss ratio on volatile lines of business of 50% to 70%. This "insurance cycle," where a soft market hardened, last occurred in the early 2000s, following a number of large space insurance losses as well as the insurance losses following the terror attacks of 9–11. Figure 3 shows the worldwide trend of net premiums paid versus incurred losses. The worldwide claims for 2019 represent the first time since 2001 where claims were very substantially larger than the incoming premium payments (see Fig. 4) (Williams and Walsh 2016).

6 New Technologies

Space insurers track space activity such as launch vehicle and satellite successes and failures. New technologies, such as the introduction of new launch vehicles and new satellite technologies, present challenges for insurers. Newly developed launch vehicles have historically experienced failure 25% of the time on their first launches and the same failure rate on their second launches. The learning curve typically

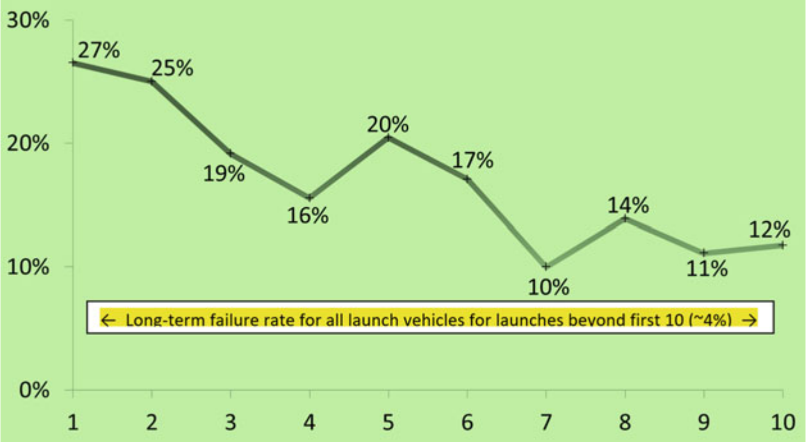

Fig. 5 Launch vehicle failure rates for first ten launches of a new launch vehicle. (Graphic courtesy of AXA-XL)

develops to a baseline failure rate after 6 to 12 launches, with the long-term cumulative launch failure rate being around 4–5% (see Fig. 5).

Likewise, new satellite technologies present challenges. Since 2000, the average mass of geostationary (GEO) communications satellites has increased by 33%, while the average payload power has increased by 100%. This increase in "energy density" of satellites is brought about by miniaturization of components and process improvements in manufacturing. Nonetheless, this increase in energy density has resulted in more satellite anomalies occurring within the electrical power system. Fully half of the anomalies on GEO satellites that resulted in loss of capability have come from the electrical power system. The cause of failure in satellites based on statistics for GEO satellites since the year 2000 can be broken down among various failure modes as follows: (a) batteries and electrical systems, 55% (these include battery cell failures, electrical harnesses, circuitry, mechanical aspects of electrical systems such as switches, etc.); (b) chemical and electrical propulsion systems, 18%; (c) other bus component failures, 16%; and (d) failure of payloads, 11%. This indicates that 89% of the failures relate to the spacecraft bus and only 11% are due to the payload and its instruments and functional units (AXA-XL, Causes of Losses, Feb 9, 2020).

With the growth of commercial satellite constellations and production-line manufacturing of satellites, the phenomenon of "generic anomalies" has arisen. Generic (or systemic) anomalies occur when a fault (either design, workmanship, or piece part) is introduced into a number of satellites, but not discovered until those satellites have been launched. In such a case, numerous similar on-orbit failures may be encountered, resulting in large space insurance claims. To avoid this, satellite operators will typically launch a small number of satellites to test them before deploying the full constellation.

7 Space Sustainability

Space insurance companies have taken active roles in promoting space sustainability and responsible space activity. Insurers have incentivized operators, manufacturers, launch service providers, governments, and institutions to implement technologies, processes, and operations that minimize risk to the space environment. Such "best practices" include improving Space Situational Awareness (SSA), introducing space traffic management (STM), and supporting on-orbit servicing (OOS). Specific types of OOS that can benefit space insurers include on-orbit inspection, repair, and refueling. As an example, over 80 GEO satellites launched since 2000 that have had significant anomalies would have benefitted directly from OOS, whether re-orbiting/deorbiting, inspection, repair, or life extension. This is in addition to a number of satellites that reached the end of their operational life and were unable to be satisfactorily re-orbited out of the heavily trafficked GEO belt.

Over 50 organizations (e.g., industry groups, advocacy organizations, governments, institutions, and satellite and launch operators) are working to develop efforts in responsible space activity. While not all efforts are coordinated, and some have opposing agendas, the development of guidelines, standards, regulations, and even rating systems will pressure all space actors to design and operate with sustainability as a core principle.

Specific technologies that can aid in Space Situational Awareness (SSA) include beacons for tracking, propulsion for orbital maneuvering, and even cameras for self-inspection. All of these technologies reduce the risk of collision and debris generation in space.

8 Conclusion

Space insurance is an enabler of innovation and investment. Financing of space activity requires large capital investments, and investors rely on insurance to protect them from catastrophic losses. Space insurance companies have adapted to the changing technical, commercial, and policy environments to continuously develop new types of insurance coverages and to lead efforts to maintain a healthy and sustainable space environment.

Small Satellites and Planetary Defense Initiatives

Joseph N. Pelton

Contents

Abstract

The issue of cosmic hazards and planetary defense is often associated with coping with asteroids impacting Earth and missions going into space to set off nuclear weapons in a last ditch effort to save the world as popularized in movies. There are many initiatives that can be undertaken to address cosmic hazards such as asteroids, coronal mass ejections from the Sun, and other similar threats. Many of these threats might well be addressed through small satellite initiatives. This chapter seeks to identify several types of cosmic hazards and small satellite-related initiatives that might be able to address such threats to people and global infrastructure that might be addressed via small satellite programs. This includes some projects that have already been tested in space as well as possible initiatives that are still being considered at a conceptual or design engineering level. The main thrust of this chapter is to highlight ways in which small satellite activities might be able to provide useful protective capabilities for planet Earth if these activities can be initiated at an early stage and various types of threats detected

1 Introduction

The space age has unlocked a great deal of new scientific information about the characteristics of the Earth, the solar system, and nature of the cosmos. There is today a much greater understanding of the Earth’s vulnerabilities from potentially hazardous asteroids and comets as well as the dangers from space weather and solar eruptions. As the number of humans has increased, as urban centers have expanded so that nearly 55% of the world’s population now live in cities, and as humans are more dependent on modern infrastructure, vulnerabilities have expanded exponentially. Two of the greatest dangers come from potentially hazardous asteroids and comets and from solar eruptions, known as coronal mass ejections.

Geologists have now declared that humans now live in a new geological age known as the Anthropocene Age. The prime shaper of the world’s geology is human activity. The lesser known fact is that urbanization, modern human lifestyles and employment, and dependence on key infrastructure have made humans much more vulnerable to natural disasters – prime of these vulnerabilities are pandemics, infrastructure failures, and natural and human-caused disasters. Among these disasters that could give rise to mass-destruction events are very large cosmic objects impacting Earth (i.e., potentially hazardous asteroids and comets) and solar events called coronal mass ejections. This chapter addresses these two cosmic hazards in some details and address ways that small satellite technology might be deployed to help avoid truly devastating loses from cosmic hazards. In short this chapter addresses how new types of small satellite missions could represent a viable means of addressing a new strategy of planetary defense.

2 Asteroid Threat Assessment

A precise threat assessment of the likelihood of a major asteroid hitting Earth is not an exact science. We know that there are a significant number of asteroids that are known as Near Earth Objects (NEOs). The following chart represents a current

Table 1 Estimated threat levels for different sizes of asteroids

Ground impact	Probability/year	Diameter	Blast radius	Deaths	Ground damage	Interval within lunar orbit (i.e., within 400,000 km)
5 megaton asteroid impact	$1.67E^{-03}$	44 m	About 20 km	About 200	About 1200 km^2	1/20 years
100 megaton asteroid impact	$1.00E^{-04}$	120 m	About 60 km	About 19,500	About 10,000 km^2	1/80 years
1000 gigaton asteroid impact	$2.00E^{-06}$	3 km	About 500 km	Unknown	About 800,000 km^2	1/600 years

Note: The above estimates as to likelihood of occurrence of various sizes of asteroid strikes should only be considered rough order of magnitude figures. The actual results would be expected to vary significantly depending on actual point of contact and many other factors such as proximity to inhabited areas, air-burst or land or water impact, etc.

projection of various sizes of Near Earth Objects in terms of their mass, their probability of impacting Earth, their blast radius and ground damage area, and possible fatalities (see Table 1) (Pelton, Space Security 2019).

This is all based on known probabilities and the latest data. The results are acquired data from sensors located on the NAVSTAR satellites that constitute the Global Positioning Satellite (GPS) system and other U.S. governmental satellites. These sensors are placed on these satellites in order to detect nuclear explosions, but they can also detect asteroid and larger bolide impacts. The data from these sensors have documented the fact that impacts are at least three times – and perhaps as much as ten times – more common than previous thought. This assessment of greater likelihood was provided by former Astronaut Ed Lu, Head of the B612 Foundation that has as its main mission the detection of and assessment of threat levels associated with asteroid strikes on Earth (Blast Sensors, April 4, 2014).

Another way of assessing asteroid threat is based on the energy released from actual impacts and the creation of a graphic that connects the data collected from the aftermath of actual events. Figure 1 shows the estimated energy release from three different strikes. These range from the smallest in the form of the Chelyabinsk strike in 2013, up to the much more devastating Tunguska impact in 1908 in the early days of the twentieth century, and finally to the so-called Chicxulub catastrophic event that occurred over 75 million years ago along the coast of Mexico that wiped out the dinosaurs and led to the K-T mass extinction. This chart shows that the Chelyabinsk event released the equivalent of 75,000 tons of TNT. The Tunguska event which involved the equivalent of a 40 m asteroid involved an event equivalent to an 8 megaton atomic bomb. Finally the true mass extinction event has been calculated

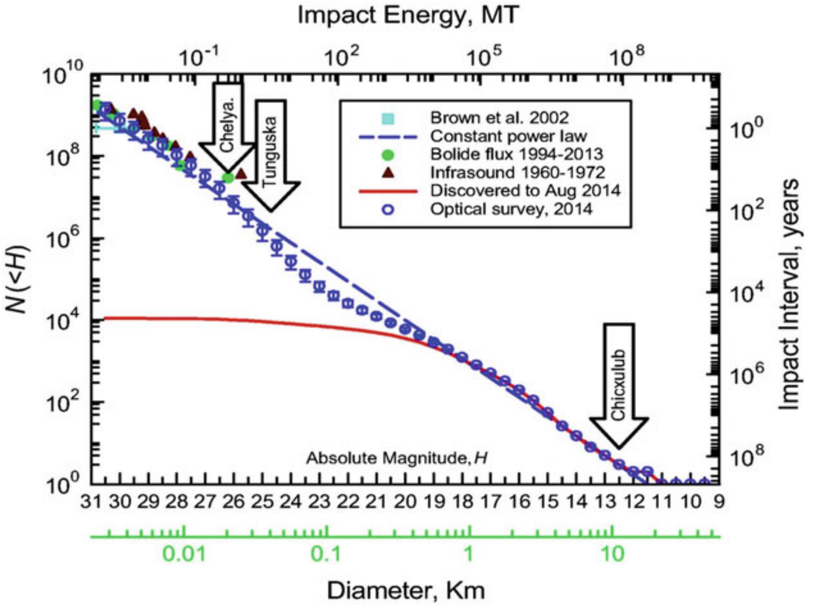

Fig. 1 The estimate energy release from various meteor and asteroid strikes on Earth. (Graphic courtesy of Jet Propulsion Labs/NASA)

to have involved an energy release equivalent to a 100 million megaton nuclear weapon (see Fig. 1). The problem with the current process of seeking to identify potentially hazardous asteroids as undertaken by NASA is that the official practice is to chart all such objects that are 140 m and larger in diameter. Yet the Tunguska event that released the equivalent of an 8 megaton atomic weapon destroyed the area equivalent to the San Francisco Bay Area.

This means that Tunguska-sized bolides are true city-killers but that the NASA search process is only looking for asteroids that could wipe out an area equivalent of the State of New York. The B612 Foundation has called for the development of infrared space telescope that could track Near Earth Objects (NEOs) and particularly potentially hazardous asteroids (PHAs) down to a size of 35 m. Estimates are that there are more asteroids of this size than the metric of estimated asteroids that are 140 m in diameter. Indeed there are estimated to be at least an order of magnitude more of potentially hazardous asteroids that are of the 35 m size compared to those over 140 m (Pelton, Introduction to the Handbook 2015).

The inventory of Near Earth Objects (NEOs) as conducted by NASA has now identified some 10,000 asteroids that are registered with the Minor Planet Center and the International Asteroid Warning Network (IAWN). The United Nations Committee on the Peaceful Uses of Outer Space and the General Assembly have increasingly recognized the significance of a major asteroid or comet hit on a world with ever-increasing human population and increasing urbanization. They approved the creation of the global initiative to create an

International Asteroid Warning Network (IAWN) and perhaps even more importantly the creation of a Space Missions Planning Advisory Group (SMPAG). These units, although endorsed by the United Nations General Assembly, are composed of independent scientific personnel. The SMPAG would recommend a global response in the event that a major potential strike by an asteroid or comet on planet Earth were identified as a major threat (Near Earth Objects Status, Feb. 2017).

The discussions of options that might be used against incoming potentially hazardous asteroids or comets have typically focused on what can be done to avert a catastrophe in the context of a short-term threat. These options involve the use of massive amounts of information that might be associated with a nuclear blast detonated on the incoming object in space, the use of very high level directed energy beams that are considered space weaponry, projectiles launched by a rail gun system, engineering a collision between the PHA and an asteroid placed in lunar orbit as a defensive system, or other techniques involving a great surge of energy. Clearly if incoming asteroids of great size were to be discovered just before impact is to occur, only a very high energy diversion would be necessary. Something as large as a 5-km-diameter asteroid that caused the K-T mass extinction would be very hard to divert indeed without many months if not years of warning (see Fig. 2).

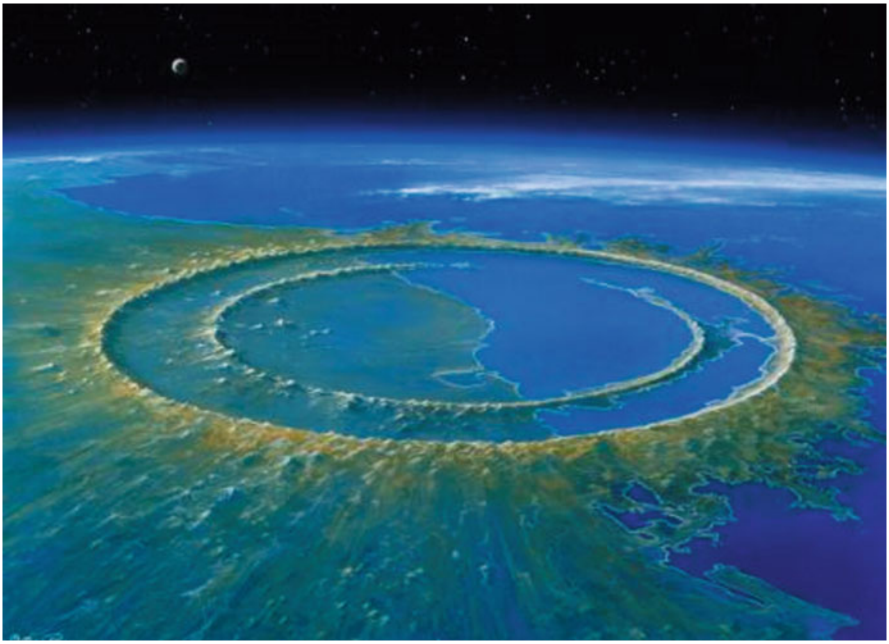

Fig. 2 Crater from the Chicxulub asteroid that was estimated to be 5 km in diameter. (Graphic courtesy of NASA)

3 Small Satellites and the "Laser Bees" Approach to Diverting Asteroid Orbits

There are ongoing efforts to create new capabilities to track potentially hazardous asteroids with greater precision so that dangerous NEOs could be identified years in advance so that missions to divert these objects to new, much less dangerous orbits might well advance. The trick is to accomplish the diversion with only minor energy thrust or velocity deltas sustained over a long period of time. The B612 Foundation has been dedicated to create new infrared space telescope to detect much smaller potentially hazardous asteroids (PHAs) and a much greater inventory of these dangerous Near Earth Objects (NEOs), but unfortunately has not obtained the funding to do so.

The Planetary Society has on the other hand pursued new concepts and design constructs that could create small orbital diversions to avert asteroids hitting Earth if there are years of advance warning. This project started out on the basis of what was called "mirror bees." The idea was to create a series of small satellites with mirrors on them to flex sunlight that would heat the asteroid and help to divert its path. After conceptual evaluation, the new idea was developed to replace mirrors with lasers that could heat the asteroid sufficiently to create small jets of materials ejected from the asteroid to create thrust that could divert the asteroid's orbit over time.

This newly dubbed "Laser Bees" project that would deploy a swarm of small satellites has been described in the following manner:

> "This technique involves many small spacecraft – each carrying a laser – swarming around a near-Earth asteroid. The spacecraft could precisely focus their powerful lasers pumped by sunlight onto a tiny spot on the asteroid, vaporizing the rock and metal, and creating a jet plume of super-heated gases and debris. The asteroid would become the fuel for its own rocket – and slowly, the asteroid would move into a new trajectory." (What is a 'Laser Bee'? 2019)

This idea when compared to that of using a nuclear weapon to blow an asteroid apart and into a new orbit has the advantage of involving a much lower cost since the rocket carrying the nuclear weapons would be much larger, particularly if manned by astronauts to place and activate the nuclear explosion. From a safety viewpoint, the new orbit would be controlled and would not create the risk that parts of the asteroid blown apart might still hit Earth. Finally agreement on the deployment of a swarm of "Laser Bees" would be much less controversial and would not be considered a "space weapon," or launching a nuclear weapon into space (Bruce Betts, What are Laser Bee Projects 2013; Fig. 3).

There was an intended NASA Asteroid Redirect Mission planned for 2025 that was canceled by the President Trump Administration in late 2017. The intent of this mission was to develop a robotic spacecraft with a large robotic arm. This mission, known as Asteroid Redirect Mission (ARM), was canceled by means of White House Space Policy Directive-1 on Dec. 11, 2017, that refocused efforts on sending crewed missions to the Moon and then to Mars. The key elements of this mission would have been to visit a large Near Earth Asteroid, not yet identified, with the purpose to collect a multi-ton boulder from its surface by means of a robotic arm. It

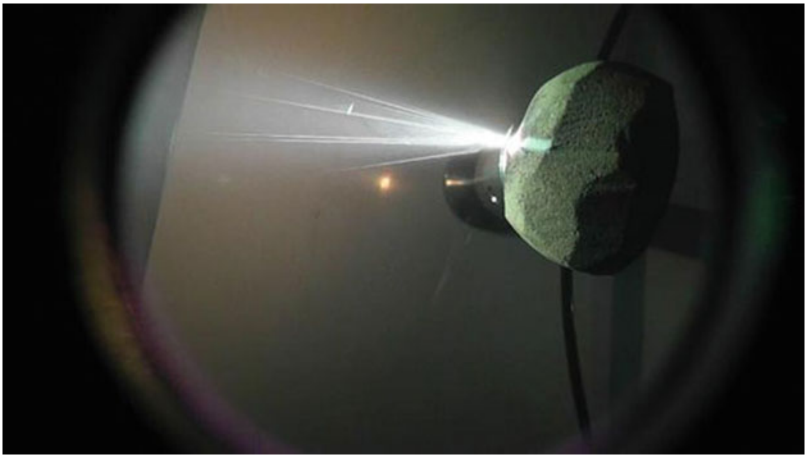

Fig. 3 A laser ablating a sandstone rock in a lab in Scotland to create a jet stream. (Graphic courtesy of the Planetary Society)

was also intended to test the concept of solar-electric propulsion (Asteroid Redirect Mission 2019).

The most sensational aspect of the mission would have been to redirect the boulder into a stable orbit around the moon, known as a distant retrograde orbit, where astronauts could have explored it and also returned to Earth with samples. Elements of this mission still remain under study. Any mission of this kind, if re-established, would also include an experiment with perhaps five or six cubesat size satellites equipped as “Laser Bees” that would be able to experiment with redirecting the asteroid at the mission’s end (NASA’s Asteroid Redirect Mission Cancelled Dec. 11, 2017).

The laboratory tests that have been carried out in Scotland under funding from the Planetary Society of “Laser Bees” as an approach to the redirection of asteroids have produced encouraging results that this approach, given enough advanced warning, could be nearly as effective as high-powered nuclear energy release. This is due to three reasons: (i) the laser-heated materials from the asteroid are providing the propulsive fuel rather the need to bring fuel along with the mission; (ii) the asteroid’s mass lessens over time and thus accelerates more rapidly; and (iii) the power for the lasers is to be supplied by solar energy that was not provided on board the small satellite itself. Thus Newtonian physics, itself, supplies three sources of mission efficiency, and over a year’s time this could significantly alter an asteroid’s orbital parameters. Thus it is hoped that any renewed asteroid redirect mission would include “Laser Bee” experiments at 1% to 2% add-on to the total mass of the overall project. Again it may turn out that small satellite technology with something like 3 unit to 6 unit cubesatellites might provide a powerful longer-term means to redirect a potentially hazardous asteroid.

There is, as is almost always the case, more than just new technology development involved here. There is also a matter of space policy and regulation. The idea that one might just reposition and asteroid’s orbit, or perhaps even place a repositioned asteroid or a boulder snipped off of an asteroid into a “distant retrograde orbit” around the Moon, is a matter of unsettled international law. There are elements of space law that address staking a claim of sovereignty over celestial objects, but there is no established space law about who might have the right to move celestial objects about in their orbit or place them in new orbits around the Earth or Moon. Again this is new territory that envisions new technological capabilities that were not anticipated when the Outer Space Treaty and its subsidiary international agreements were negotiated and agreed. It would seem that the Space Mission Planning Advisory Group (SMPAG) might at least be consulted about any such asteroid redirect mission and their expert advice be sought before such missions are contemplated and executed (Space Mission Planning... 2019).

For the longer term some form of national and international guidelines or perhaps even a treaty agreement should be developed in this area. Perhaps this might be done in conjunction with agreements worked out for space operations and rendezvous and proximity operations.

4 Small Satellites and Protection of Earth and Mars Against Coronal Mass Ejections (CMEs)

The other key areas where small satellites might play a key role in protecting Earth against a major space hazard might well be in the area of dangerous solar storm events. This would be, in particular, in the case of a catastrophic coronal mass ejection that has a devastating impact on vital global infrastructure on which billions of people depend. Fortunately Earth has an iron core and a natural protective shielding in the form of a geo-electromagnetic field that surrounds this small six sextillion ton planet. Mars, for instance, is not so fortunate. Mars’ lack of an electromagnetic shield is why it has such a minimal atmosphere. The solar wind and coronal mass ejections are stripping away its atmosphere relentlessly year after year.

There are a number of different types of solar occurrences that impact life on Earth. First of all the Earth is totally dependent on the Sun for energy. The Sun is the basis of all energy used in our world today. Oil, natural gas, trees and vegetation, wind, and any other energy source that is used today are all merely stored energy that initially came from the Sun. Without the Sun Earth and all life forms would die. Fortunately the Sun provides more energy than human’s use by a huge margin and will do so for eons to come. But not all solar energy is beneficial. Solar flares of radiation in the ultraviolet range, X-rays, and above can be dangerous. Without the Earth’s ozone layer, there would be much greater problems with cancer and genetic mutation.

About half the time where solar flares of radiation occur, there is another phenomenon known as coronal mass ejections (CMEs) that involve the spewing of many quadrillions of ions out into space. This is actual mass that travels at millions of kilometers/hour. The magnitude of the mass ejections varies greatly in terms of the

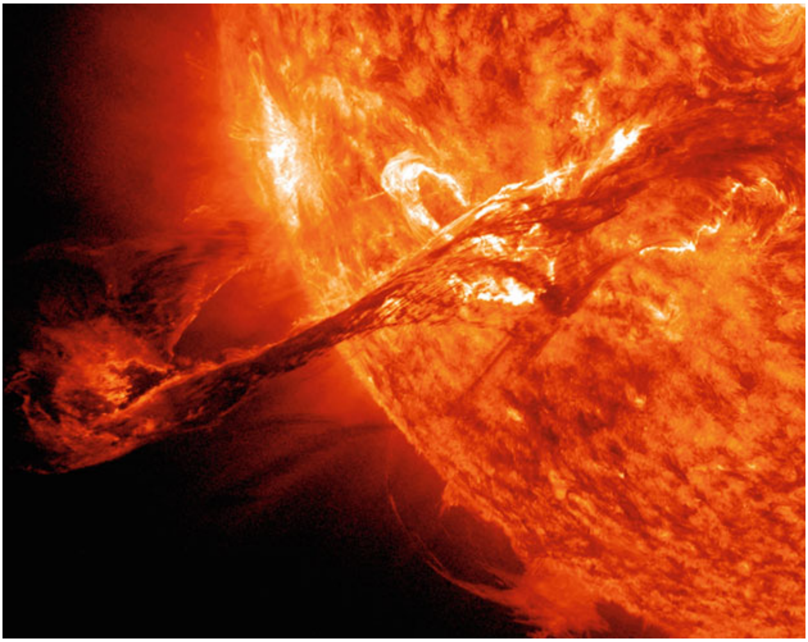

Fig. 4 Massive solar coronal mass ejection event of 2012 narrowly missed Earth. (Graphic courtesy of NASA)

number of ions released and their velocity that determines their destructive force. Fortunately most of these ejections miss Earth and thus go harmlessly into outer space. The ion ejection captured on a NASA solar observation satellite was hundreds of thousands of meters long (see Fig. 4). This ejection occurred in 2013; however, it narrowly missed Earth, and thus its very deadly stream of particles was not able to burn up transformers in electrical grids, SCADA controls on pipelines, disable telecommunications networks, perhaps destroy satellites, and bring the synchronization of the Internet to a halt (see Fig. 4).

The biggest of these solar events seems to occur about once in a hundred and fifty years. The so-called Carrington Event of 1859 occurred at the very start of the electrical age. When this massive CME event occurred, telegraph offices caught on fire as paper ignited. The so-called Northern lights came down to Cuba and Hawaii and lit up the skies. There are Chinese records of a similar solar event that occurred very early in the eighteenth century. In the eighteenth and nineteenth centuries, this type of event had little lasting impact on society. But today electrical grids, the Internet, vital communications networks, and vital satellites might be lost. The residual or collateral results could be trillions of dollars of economic losses, and a huge number of people might lose their jobs, starve to death, or otherwise suffer from such an event today. One study carried out by Lloyds of London has projected a loss of over 2 trillion dollars associated with the loss of the North American electrical grid with a hit similar to the Carrington Event (Solar Storm 2013).

And these events actually occur rather frequently at a lower level. The Montreal event of 1989 took out much of the power grid from Chicago to Montreal when this CME event occurred. The Halloween event in Scandinavia early in the twenty-first century knocked out power in a wide region as well. The Sun goes through an 11 year cycle from solar minimum to solar max. During the period of solar max, there can be as many as 15 coronal mass ejections in a week. The growing concern is that Earth, based on probabilities, is overdue for a Carrington Event-type hit by a very high-powered CME.

And there is now a serious further concern. This is that the Earth's magnetic poles are shifting from North to South. At this point it seems that magnetic North has moved down to Siberia, while magnetic South has moved up toward Australia. As the magnetic shift occurs as it has happened many dozens of times throughout Earth's history, the magnetic field that is manifested in the Van Allen belts will begin to break up in very odd ways. Some computer modeling has suggested that the protective shielding of the Earth's electromagnetic field will lose much of its effectiveness. One model that is shown in Fig. 5 suggests that the effectiveness of the natural shielding will be reduced down to only 15% of its current levels. This is to say that its protective shielding might be some seven times less than it is today (see Fig. 5).

The loss of vital infrastructure such as electrical grids, transformers, telecommunications networks, SCADA controls for traffic signals, pipelines for natural gas, petroleum, water and sewage, satellites, and more could be devastating to the global economy, and the collateral loss of life could mount into millions. It could be that the most vital space infrastructure of all time might well be the design and

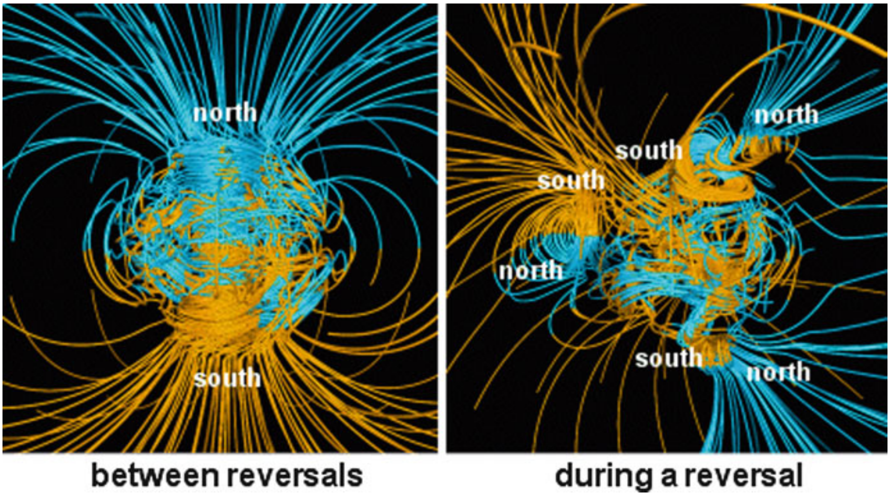

Fig. 5 The projected impact on the Earth's electromagnetic field shielding that will occur during magnetic polar shift. (Graphic courtesy of Global Commons)

implementation of satellites to form an artificial electromagnetic shield to protect Earth against a massive coronal mass ejection.

To date none of the world's space agencies have accepted the strategic mandate of making planetary defense a top priority. Today many space agencies are involved in relevant areas of research. These activities include seeking to create an inventory of Near Earth Objects and especially potentially hazardous asteroids, to examine technologies that could redirect asteroids, and to better understand solar flares, coronal mass ejections, and the Earth's electromagnetic shielding. Nevertheless they have not actively set planetary defense as a top strategic priority. They have not created units that might actively design and deploy systems that might protect Earth against asteroids or an extremely powerful coronal mass ejection.

The time has come to recognize that planetary defense is both technically possible and should be actively undertaken as a top priority for space agencies cooperating together. There have been some initial thoughts about how this might be done. Some of the first thoughts have focused on the creation of a very large shield system that would be deployed at Lagrangian Point 1. This is the point where the gravitation fields of the Sun and the Earth essentially are equal, and thus a satellite could be positioned there with very little stabilization force. This location and the gravitational effects that cancel one another out are shown in Fig. 6.

The problem that has arisen has been that of a "tailing" effect where the blast of ions is initially stopped but that the ions would then swirl around the field and then continue to hit Earth with great force.

The alternative idea of not creating a single electromagnetic field to block the flow of ion thus arises. The alternative would be to create a matrix of smaller satellites with lower levels of magnetic field strength that would be more like a sieve. This would allow some of the ions to come through but others to be diverted so that they would miss Earth. This might be built in tiers so that if the first wave of ions were not stopped then the second layer might provide a slowing or diversion of

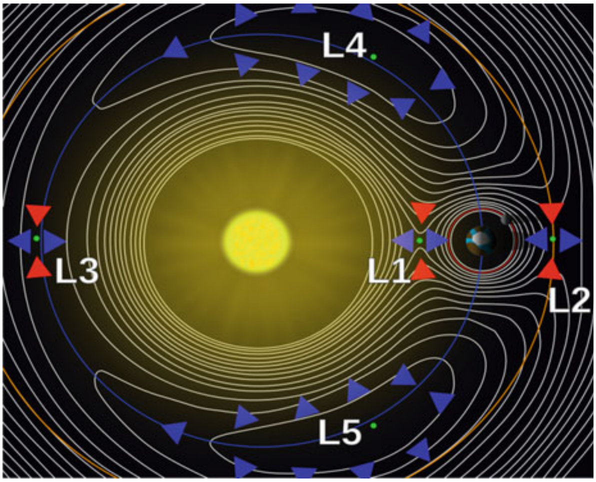

Fig. 6 The Lagrangian points of gravitational stabilization and location L1 for a CME shield. (Graphic courtesy of the global internet commons)

the ions. The key issue is whether a large matrix of small satellites could be designed with inflatable materials that could hold a charge as high as one Tesla that could be smaller in mass and lower in cost to provide an effective electromagnetic shield for Earth and deployed at a reasonable cost.

Another intriguing question is whether the existing electrical grid system operators of the world (both governmental and commercial) can be organized to contribute sufficient monies toward such an on-going protective shielding project. This would require sufficient monies to sustain the design, building, deployment, and on-going operation of such a matrix of small satellite units. Today no one knows clearly what design of such a protective matrix of small satellites would be needed to help to protect Earth from a future lethal torrent of CME ions that can be expected to come toward Earth with catastrophic effect in coming years.

The first step would be to seek to test the magnetic blocking capability against high speed ions provided by a single small satellite designed for this purpose. Or perhaps to test a cluster of three or four small satellites. A key question would be to test whether a distributed matrix of small satellites would be more effective and less costly than a single very large magnetic field satellite. A subsidiary question is whether such a matrix of small satellites could be also designed so as to modulate solar radiation so as to forestall climate change effects until greenhouse gas emissions might be greatly reduced or other longer-term solutions might be found.

One further aspect of an electromagnetic space shield has now occurred. This is the idea that such a shielding system could also be applied to Mars. Mars has no natural electromagnetic shielding because it has no iron core. As there is warming on Mars and frozen ice on the Red Planet released as water and water vapor, this too will be stripped away by the solar wind. If it were possible to create a solar shield for Earth, it would be much easier to contemplate doing it for Mars. Mars is much further away from the Sun and it is also much smaller than the Earth. Thus NASA chief scientist James Green has suggested that a solar shield for Mars could be much smaller in size with less electromagnetic field force (Green et al. 2017). This is just one of the ideas that have derived from the original concept of creating a solar shield and first designated by the author as a LAPSE (Lagrangian Protector against Solar Ejections) (Pelton and Green 2017).

5 Conclusion

The world of small satellites today is focused on such uses as education, training, technology verification, and practical space applications such as telecommunications, remote sensing, meteorological and climate change monitoring, space navigation, RF geolocation, real-time data relay, and other practical applications. Increasingly it has been recognized that small satellites can play a key role in scientific space investigations and deep space exploration. Small satellites have been used to measure changes in the Earth's electro-magnetosphere and to probe the Sun's characteristics and other deep space phenomena. This chapter suggests that small satellites could be used in efforts to divert threats from potentially hazardous asteroids through the use of so-called Laser Bees and might be used in a matrix of smallsats to create an artificial magnetic shield described by the author as Lagrangian Protector against Solar Ejections (LAPSE).

Current Innovative Small Satellite Projects

Planet's Dove Satellite Constellation

Mike Safyan

Contents

Abstract

Planet Labs Inc. ("Planet") designs, builds, and operates the world's largest fleet of remote sensing satellites and sells the imagery data and derived products to a wide variety of government, commercial, academic, and nonprofit customers. Planet utilizes an Agile Aerospace approach to take advantage of improvements in commercial-off-the-shelf technologies, increased access to launch opportunities for small satellites, and readily scalable cloud-based IT infrastructure. This chapter describes the development of the Flock constellation, Planet's medium resolution fleet comprised of Dove satellites, and the surrounding infrastructure required to operate this innovative system.

1 Introduction

In 2010, Planet Labs Inc. or “Planet” (known as “Cosmogia” at the time) was founded by former NASA scientists and engineers Chris Boshuizen, Robbie Schingler, and Will Marshall. The plan for the company was to build and operate a large fleet of small satellites capable of imaging the entire Earth’s landmass every day. Although space-based remote sensing systems had been flying for decades and a number of commercial satellite imagery companies were already in operation, nobody had previously attempted to build and deploy a large enough fleet to be able to achieve those levels of global coverage and timeliness of revisit. The co-founders took advantage of a handful of emerging technological trends while simultaneously identifying a commercial need in the market and available venture capital (VC) funding to finance the endeavor.

2 Planet’s Dove Satellite Constellation

2.1 Emerging Trends

At the time of Planet’s founding, several trends were emerging to create the perfect conditions for a new approach to satellite systems. The three major trends were (1) advances in commercial electronics, (2) the Cubesat standard and increased access to launch, and (3) cloud storage and computing.

Advances in the commercial electronics industry were making consumer electronics more and more powerful while continuing to shrink the size and power requirements of those devices. Even in 2010, smartphones already carried most of the systems needed for a satellite including a fast processor, large data storage, efficient batteries, a variety of attitude sensors, radios for communication, GPS, and a camera system. Planet’s founders had demonstrated as much while at NASA Ames with the “PhoneSat” project.

PhoneSat was a 1 kg satellite with an Android smartphone as the “brains” of the satellite. The PhoneSat satellites successfully demonstrated basic telemetry communication and transmission of low-resolution Earth imagery captured by the phone’s camera from space (Marshall et al. 2011). Although there were several challenges encountered in modifying a smartphone to behave as a satellite, the early PhoneSat missions were intended as proof of concepts. Commercial electronics, which in some cases were more advanced than their space-grade alternatives, could indeed be used in space within certain mission parameters. Going forward, it wasn’t necessary to use an actual smartphone on a satellite to take advantage of those benefits. Instead, a revolution was emerging from the act of utilizing the technologies, components, and fabrication techniques coming from the commercial electronics industry to custom-build satellites.

When the Cubesat became a commonly accepted satellite standard, it significantly lowered the barrier to entry for small satellite missions. At that time, most Cubesats were being built and operated by university teams and research institutes, but the principles of constraining a satellite design to fit within a standardized launch envelope equally applied to a commercial satellite. By conforming to the Cubesat specification, a standardized launch adapter and deployment system could be used, greatly simplifying the coordination requirements between satellite operators and launch providers. Standard Cubesat deployer systems also allowed for the number of Cubesats on a given launch to easily scale up or down depending on the launch capacity available. One Cubesat could be easily swapped for another within minimal impact to the launch provider. This helped enable a growing number of "piggyback" launch opportunities that easily allowed Cubesat customers to ride along on larger rockets going to Low Earth Orbit (LEO). And because Cubesats are so small, a large number of them could be launched either on a single rocket or across multiple rockets, but at a fraction of the total cost of a typical, large satellite mission.

And finally, the **growth of cloud computing and storage services** from companies like Amazon and Google revolutionized data management. Even small satellites are capable of generating massive amounts of data (think of how quickly a smartphone would run out of storage if it took a picture every second for 3 years). Storing and processing the data requires a significant amount of IT infrastructure. Cloud services eliminate the need for companies to build the infrastructure themselves and allow for that capacity to seamlessly scale at an efficient price point.

Taking into account the above trends, the co-founders wrote out a list of all the possible missions that could be enabled by this novel architecture – which is composed of many low-cost, small satellites that benefit from advancements in commercial electronics. The list was quickly narrowed to missions that had clear commercial value, and finally a remote sensing mission was identified as the optimum balance of feasibility, uniqueness of capability, and significant market potential.

2.2 The Remote Sensing Market

Satellite remote sensing systems can be categorized by a handful of key characteristics (Satellite Imaging Corporation 2017):

1. *Spatial Resolution*: The pixel size of the smallest feature able to be resolved in an image.
2. *Temporal Resolution*, or *Frequency of Revisit*: How often a satellite system can image a specific point on the Earth.

3. *Coverage*: How much of the Earth's surface is captured by the satellite system over a given duration.
4. *Spectral Bands*: The portion of the electromagnetic spectrum that the satellite system is remotely sensing.
5. *Spectral Resolution*: The number of spectral bands captured by the satellite system and the quality of spectral information being captured.
6. *Radiometric Resolution*: The amount of detail expressed in each pixel, also known as bit depth.

Two basic types of optical remote sensing satellites were flying at the time: (1) *high spatial resolution*, *low coverage* and (2) *low spatial resolution*, *high coverage*.

In the first category, commercial companies such as DigitalGlobe and Airbus were flying satellites with very high-resolution systems (<50 cm per pixel). Spatial resolution is directly related to the size of the satellite's telescope, and thus a high-resolution satellite is usually the size of a small school bus. These satellites might have a mass of several thousands of kilograms, which directly impacts the cost and complexity of the system. The size of the satellite also greatly impacts the launch cost, which roughly scales on a per kilogram basis. The result of such high-cost, complex systems is that a company can only afford to launch and operate at most a handful of very high-resolution satellites at any given time.

These very high-resolution satellites are operated in a "tasking" or "point and shoot" mode, and the Area of Interest (AOI) must be determined ahead of time. Using off-nadir imaging, a very high-resolution satellite system may be able to capture the same AOI multiple times within quick succession, but that comes at the expense of being unable to image other targets. A useful analogy is to think of these systems as if they were capturing imagery through a soda straw; certain locations will be imaged in great detail, but most of the Earth's surface will be missed. It can be said that such systems optimize for *spatial resolution* at the expense of *coverage* and *temporal resolution* (on a global scale).

In the second category, the joint NASA-USGS Landsat mission is considered. For example, Landsat 8 is operated in "monitoring" mode (as opposed to "tasking") with a very large Field of View (FOV), periodically sweeping its imager across the entire Earth's surface. Landsat 8 images the same point on the Earth's surface approximately once every 16 days and captures a total of 11 spectral bands, with visible imagery at 30 m per pixel. It can be said that such a system optimizes for *coverage*, *spectral bands*, and *spectral resolution* at the expense of *spatial* and *temporal resolution*. A further challenge is that optical satellites cannot see through clouds, so it may take several months to get a cloud-free image of an area since the satellite is passing overhead so infrequently.

Taking the above into account, Planet's co-founders recognized a gap in the remote sensing market. A system optimized for *temporal resolution* and *global coverage*, with adequate *spatial resolution* and *spectral bands*, would provide a highly differentiated product with substantial commercial value. With this knowledge in hand, the co-founders were able to round up a group of investors to help fund the early stages of the company (Fig. 1).

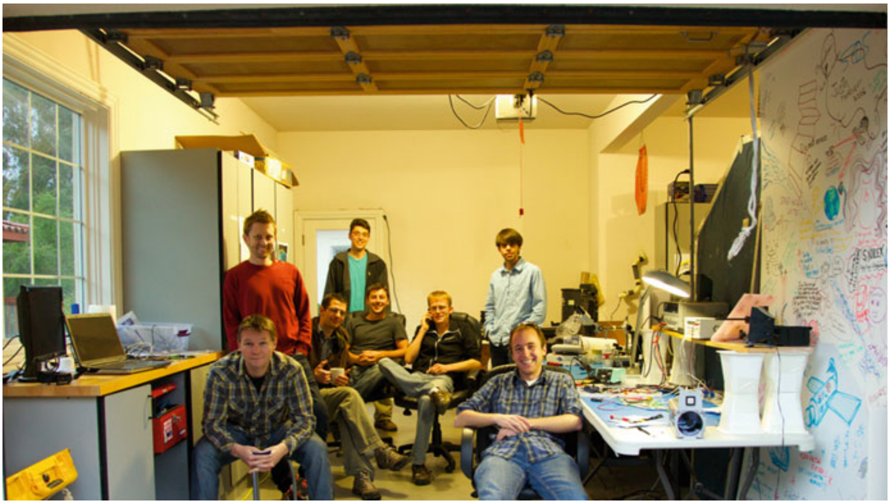

Fig. 1 Planet's founding team (known as "Cosmogia" at the time) posing with the first Dove prototype in the Cupertino garage. (Image © 2011 Planet Labs Inc., licensed for one-time publication)

Rather than show up to investor meetings with slick PowerPoint presentations, the founders would carry around the Dove prototype in a Pelican case and show with real hardware how much progress had already been made on a shoestring budget. Being based in Silicon Valley meant that there were many risk-tolerant funding sources available, so the co-founders were able to be more selective with the types of VCs they wanted to work with. Planet's co-founders wanted to make sure their investors understood the nuances of building a space company and were aligned with Planet's mission to do good in the world with Earth Observation data. Investors like DFJ (now "Threshold"), who invested early in SpaceX; Capricorn, a fund focused on social impact and sustainability; and Yuri Milner, an early investor in Facebook and a space enthusiast were some of the early investors that provided the capital to get the company off the ground.

The co-founders and investors agreed that the traditional approach of using small numbers of large, expensive satellites would be unfit for the job. Planet's first reference mission, dubbed "Mission 1," would be to launch and operate 100+ medium resolution satellites into a morning-crossing Sun-Synchronous Orbit (SSO) in order to image the Earth's landmass every day. To achieve this, a different approach to satellite design would be required.

2.3 Early Dove Satellite Design

The Cubesat specification defines a "U" as a $10 \times 10 \times 10\ \text{cm}^3$, and at that time 3U Cubesat deployers (accommodating $10 \times 10 \times 30$ cm satellites) were the most common deployer sizes being flown. The Planet team identified the biggest telescope

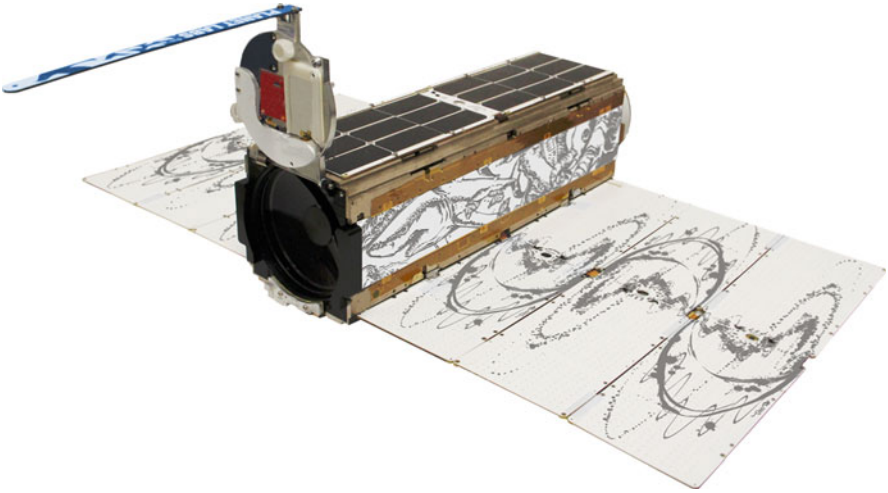

Fig. 2 Planet's Dove satellite in flight configuration with antenna flap and solar panels deployed. (Image © 2015 Planet Labs Inc., licensed for one-time publication)

that would easily fit within a 3U and began to design the satellite around that. In fact, Planet's earliest satellite models used a Questar telescope, originally designed for backyard amateur astronomy, which neatly fit within the 3U envelope and was readily available at the local hobby shop. Such a telescope would produce imagery at 3–5 m per pixel when matched with an appropriately sized camera sensor and flown at altitudes between 300 and 500 km. The 3U envelope also had enough volume to support the required focal length of the imaging system and all the supporting avionics. And finally, the Planet team wanted to give the satellite a name that conveyed the intended peace-bringing nature of the mission, and thus the "Dove" satellite was born (Fig. 2).

The total mass of the Dove satellite was approximately 5 kg and also featured a small, cylindrical compartment in the rear (sometimes referred to as the "tuna can") to house the camera sensor, which took advantage of the available volume inside the pusher spring of the Cubesat deployer. Although the Dove did not strictly adhere to the official Cubesat standard (the "tuna can" and a handful of other minor modifications were outside the official Cubesat specification), it was close enough to a 3U to make no difference to a launch provider. Each Dove satellite also featured artistic designs or inspirational quotes wherever there was spare surface area. It was Planet's way of showing that not only did the satellites have immense commercial value; they could also be fun and inspirational as well.

The first Dove prototype was built in a garage in Cupertino, California, where the company was founded. The idea was to keep the system as simple as possible, utilizing commercial-off-the-shelf components or custom-ordered elements that could easily be manufactured at scale. Aerospace suppliers were typically avoided as they often could not meet the size, cost, performance, order quantity, or turnaround time requirements. In fact, the only aerospace-grade component currently used on the Dove satellites is the solar cells. Due to the small size of the satellite, high-efficiency aerospace solar cells are required to meet the mission's power requirements, while all other components on the satellite are either off-the-shelf or custom-designed.

At the outset, the Planet team did not have sophisticated test facilities available, so they improvised as needed. To test the imaging system, engineers pointed the telescope from the Cupertino garage across a clear line of sight to a mountaintop observatory approximately 20 miles away to verify the focus and camera settings. The first "clean room" Planet ever built was a modified greenhouse tent purchased at a local hardware store, dubbed the "clean enough room."

Rather than build the perfect satellite from the outset, Planet borrowed Silicon Valley's approach to iterative software design and developed what is now called Agile Aerospace, a philosophy of spacecraft design that supports building the best satellite with what's available at the time, learning from that process to see what failed or what could be improved, and then immediately building the next iteration with those lessons learned. This was a capabilities-driven approach, rather than a requirements-driven one.

Because launch schedules were unpredictable, Planet would often take advantage of launch delays as an opportunity to advance the satellite design. It made no material difference to the launch provider since the satellite still maintained adherence to the Cubesat deployer, and Planet always ended up launching the latest technologies. With the satellite components being relatively low-cost and easily available at scale, each engineer could have a satellite (or satellite subsystem) sitting right on their desk, greatly parallelizing development. A new generation or "build" of the Dove satellite was produced roughly every 3–6 months.

As a further effort to keep the satellite system simple, the Dove satellites do not have onboard propulsion but rather use a technique called "differential drag" for limited orbital maneuvering. At the lower altitudes where the Doves operate, there is enough atmosphere to impart an appreciable drag force on the satellite. This drag force varies depending on the surface area of the satellite that is presented towards the velocity vector, and when the Dove's solar panels are fully deployed, there is an approximately 10:1 difference in surface area depending on if the satellite is oriented to fly at maximum drag ("face-on") or minimum drag ("edge-on"). When properly orchestrated, the varying attitude states give the satellites some limited maneuvering capability. Using differential drag techniques enables the initial phasing of the satellites so that they can be equally spaced around an orbit after launch, and differential drag is also used to maintain the relative phasing of the satellites over time as their orbits naturally drift and decay, all without the need for a propulsion system (Foster et al. 2018) (Fig. 3).

Unlike traditional satellite systems with lifetimes upwards of 15 years, the expected Dove satellite lifetime is between 2 and 3 years, usually limited by the long-term survivability of the onboard commercial electronics in the high radiation

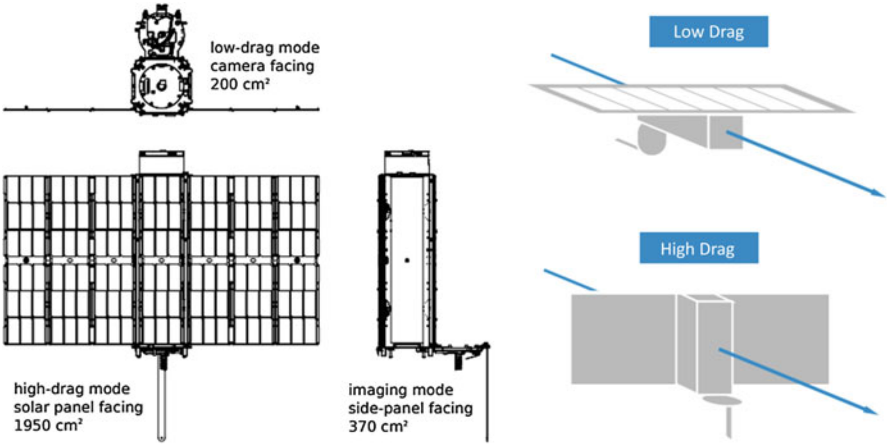

Fig. 3 Various drag orientations for the Dove satellite that enable differential drag maneuvering. (Image © 2018 Planet Labs Inc., licensed for one-time publication)

environment of LEO. Planet launches enough Doves such that if a percentage of the satellites fail, the system in aggregate is unaffected. This approach of shorter lifetime coupled with failure tolerance at the constellation level comes with several advantages:

1. **Planet is always flying the latest and greatest technologies**. Continued advancements in commercial electronics, such as faster processors and better camera sensors or more efficient batteries, are readily folded into the Dove satellite design as they become available. Planet avoids the need for radiation-hardened parts, which are typically bulkier and more expensive compared to their commercial counterparts.
2. **Planet is able to react to the market**. Customer feedback and industry trends can be quickly accounted for in subsequent generations of the satellite design.
3. **Many of the subsystems need only to be single-string**. While some of the critical subsystems such as communications and attitude control do have onboard redundancy, a majority of the Dove satellite systems are single-string, keeping the mass of the satellite low and reducing complexity. Redundancy is accounted for across the entire fleet with the numbers of satellites being flown, rather than focusing on the performance of any single satellite. It was found to be much easier to account for spare satellites rather than attempt to achieve an additional decimal place of reliability on each satellite.

Shorter lifetime of the satellites also comes with some disadvantages, such as the recurring need for constellation replenishment (and associated launch costs), but the simplicity of the approach and the aforementioned advantages greatly outweigh the disadvantages and still cost significantly less than the traditional satellite approach.

2.4 Doves 1–4

The first launch contract Planet ever signed was via Spaceflight Industries for the launch of one Cubesat, Dove 1, on the maiden flight of the Antares rocket (which was called Taurus II at the time). When the contract was signed, the launch was scheduled for December 2011 and would carry a Cygnus mass dummy as the primary payload. Although launch schedules are notorious for delays, maiden flights can be particularly egregious, and month after month the Antares launch date kept slipping. The team used the additional time to improve the satellite design, and Planet signed a second launch contract via Spaceflight for Dove 2 to launch on a Soyuz as a follow on to Antares. If all went to plan, Dove 1 was to launch sometime in 2012, giving enough time for those learnings to be folded into Dove 2, which was to be launched about a year later. The thinking was that at the very least, having two launch contracts on two separate launch vehicles would mitigate schedule risk and launch failure risk, especially recognizing that the maiden flight of a rocket also has a higher-than-average risk of failure. As luck would have it, Dove 1 and Dove 2 ultimately launched 2 days apart.

When time came to deliver the satellites for each respective launch, the Planet team was faced with two very different scenarios. On the one hand, the Antares rocket had a statistically higher likelihood of failure, and even if it was successful, the drop-off altitude was very low (approximately 250 km altitude), allowing for only a week of operations before the Dove orbit would decay due to drag and the satellite would burn up in the atmosphere. On the other hand, the Soyuz rocket was one of the world's most reliable launchers and would drop off the Dove at a much higher altitude (approximately 575 km), giving the satellite several years of orbital lifetime and plenty of time for the Mission Operations team to run through its mission objectives. Planet also had two satellite types ready to be launched at the time: a Build 4 Dove, which was thoroughly tested and considered a stable design but also carrying lower-performing subsystems, and a Build 6 Dove, which was newly released with higher-performing subsystems but had not undergone as much long-term testing and was considered experimental. The team decided to match risk with risk, and so the stable Build 4 design was assigned to the low-risk Soyuz launch (Dove 2), and the experimental Build 6 design was assigned to the high-risk Antares launch (Dove 1).

Dove 2 successfully launched on April 19, 2013, and Dove 1 successfully launched 2 days later on April 21, 2013. Due to the extremely low drop-off altitude of Dove 1, the Mission Operations team worked around the clock for a week straight to commission the satellite and run through its test objectives, which were to turn the satellite on, gather some basic telemetry, schedule a series of camera activities, and download at least one image over the X-band radio. To further complicate matters, Planet only had one X-band capable ground station available at the time located in Chilbolton, UK, meaning there were only a handful of opportunities to get things right before the satellite permanently deorbited. The Mission Operations team's tireless efforts paid off and Dove 1 was able to capture and downlink an image of a forested field just outside of Portland, Oregon. This was an incredibly important milestone for the company. Despite extensive development on the ground, Planet's approach had thrown out most of the aerospace industry's playbook in building the satellite, so the outcome of the mission was uncertain until the last moment. After seeing that first clear image from Dove 1 finally appears on the ground, the team deemed Dove 1 a resounding success. This gave Planet confidence in the viability of the Dove design, which helped enable further rounds of fundraising for the company. Six days after launch, Dove 1 deorbited, and the Mission Operations team turned its full attention to Dove 2, which was also able to successfully capture and download several clear images over its slower S-band radio system. Dove 2 also gave the Mission Operations team experience with more sustained operations and was better able to test the in-house built UHF radio and attitude control system.

The launch of Dove 3 and Dove 4 followed shortly after, successfully launching on a Dnepr rocket on November 21, 2013. Dove 3 and Dove 4 were both Build 7 versions, but Dove 3 was housed inside an ISISpace ISIPOD deployer (same as Dove 1 and Dove 2), while Dove 4 was housed inside the UniSat-5 satellite. Dove 3 would be immediately deployed once the Dnepr reached orbit, whereas UniSat-5 would wait several days after it was released from the upper stage until deploying Dove 4. Dove 3 deployed without issue, but unfortunately UniSat-5 suffered an in-orbit anomaly and was unable to deploy Dove 4. Planet's risk mitigation strategy of utilizing two different deployment systems on a single launch resulted in at least one satellite being deployed, and Dove 3 was able to successfully complete its mission. At the time of writing, UniSat-5 remains nonoperational in orbit with Dove 4 trapped inside.

2.5 Flock Launches

Following the successes of the early Dove missions, the next phase of building up to Planet's Mission 1 was to launch Planet's first fleet, or "Flock," of Dove satellites to prove Planet's ability to operate a constellation. Planet's manufacturing capability underwent a major upgrade, and many of the improvements between the subsequent Dove builds were focused on ease of manufacturing and ease of testing, in addition to improving the performance of the various subsystems, so that the satellites could be more easily manufactured at scale. Planet's manufacturing output grew from several days to build the first prototypes to about a dozen satellites per week and now stands at over two dozen per week, fully environmentally tested and ready for launch (Fig. 4).

In addition, each time a batch of satellites needs to be delivered for an upcoming launch, the manufacturing team would "overbuild" by a certain number of satellites to allow margin for error. For example, if 20 Dove satellites were scheduled for launch, 25 satellites would be built and tested. If any of those satellites experienced issues during the assembly or testing phase, those satellites would be "red-tagged" and set aside for future investigation. Since Planet is usually launching as a secondary payload, the team does not have the ability to delay a launch for production issues, so the strategy of "overbuilding" always guarantees a minimum number of

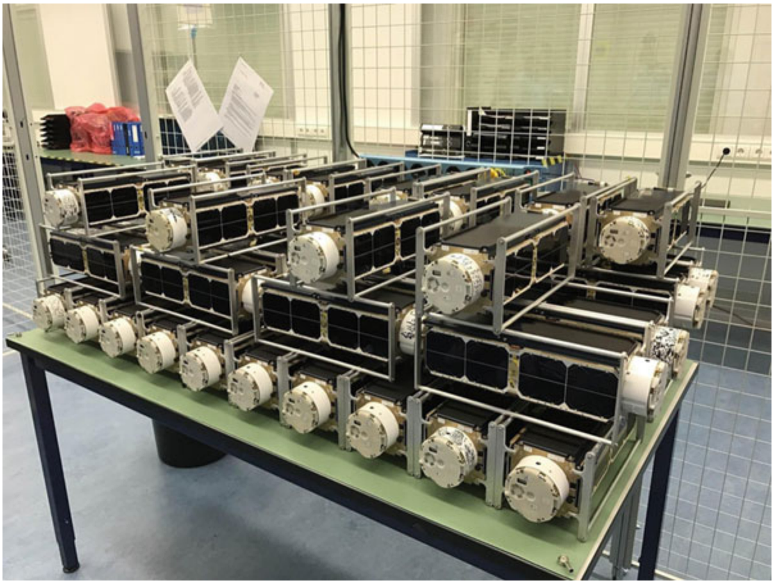

Fig. 4 A flock of Dove satellites ready for launch. (Image © 2017 Planet Labs Inc., licensed for one-time publication)

satellites ready for each launch. During the lulls in between manufacturing runs, the manufacturing team can take time investigating any issues discovered on the satellites left behind and will either keep those satellites as ground spares or scrap them for parts for future builds.

Flock 1, comprised of 28 Dove satellites, was launched on January 9, 2014, as cargo inside the Cygnus capsule to the International Space Station (ISS) on an Antares rocket and deployed into orbit 45 days later through an ISS airlock. Planet's Agile Aerospace approach required many iterations to refine the satellite design over time, and launching via the ISS had several advantages. There was a steady cadence of cargo launch opportunities to the ISS (roughly every 3–6 months, aligning with Planet's design iteration cadence), the low deployment altitude of approximately 400 km resulted in slighter better imaging resolution, and the launch environment was relatively benign due to the satellites being snugly packed inside of cargo bags. The low deployment altitude also meant that the satellites naturally deorbited after about a year of operations, making it a "self-cleaning" orbit.

After a series of successful ISS launches, on October 28, 2014, Planet suffered its first launch failure when the Antares rocket, carrying 26 Dove satellites bound for the ISS, experienced a catastrophic breakup only a few seconds after lifting off the pad. For most companies, the loss of 26 satellites would be equally catastrophic, but Planet's Agile Aerospace approach kicked into high gear, and it only took 9 days after the Antares failure for the manufacturing team to produce two additional Dove satellites and deliver them for launch integration on the next available launch. Those two satellites were launched on a Falcon 9 ISS cargo mission less than 3 months later on January 10, 2015, demonstrating just how quickly both NASA and Planet could recover from a launch failure. The Antares rocket was completely destroyed, but because those Dove satellites were housed inside of their deployers, which were further protected from the blast by being inside the Cygnus cargo module, almost a dozen Dove satellites survived the Antares failure and were later recovered near the site of the accident. Those surviving Doves now sit as proud museum pieces in Planet's headquarters in San Francisco.

Although ISS launches were frequent and dependable, the delivery timelines on ISS launches were often 60 days or more before launch, as opposed to the typical 30-day delivery timeline on direct launch opportunities. In addition, once the cargo reached the ISS, astronaut time had to be allocated to unpack the cargo bags and load the Cubesat deployers onto the deployment pallet. Cubesat deployments had to compete for airlock access with other ISS experiments and activities, and finally, visiting vehicles such as the Soyuz, Cygnus, or Dragon had to be clear of the ISS before Cubesat deployments could be initiated. NanoRacks, Planet's ISS partner, advocated as best they could with NASA and the partner space agencies for crew and airlock resources, but in many cases it took several months after Planet's satellites reached the ISS before they could be deployed. These delays greatly hindered Planet's Agile Aerospace design loops, but the ISS was the most reliable and consistent path to orbit at that time. In fact, of the 144 Dove satellites launched in 2014 and 2015 across 9 launches, 133 of the Doves were sent to the ISS, and only 11 of them were sent to the Mission 1 reference orbit of SSO. There simply weren't very many SSO launch opportunities available during that time, so Planet mostly made do with the ISS.

Sun Synchronous Orbit (SSO) is ideal for optical imaging satellites. The near-polar inclination allows satellites to see the entire Earth's landmass, and with respect to the sun, the orbit processes in such a way that the satellites consistently cross overhead at the same local time of day. This creates consistent shadow angles in the imagery, greatly easing the task of automated imagery analysis algorithms, and makes it easier to compare imagery from one day to another. The ISS orbit, on the other hand, is at 51° inclination. The non-SSO inclination of the ISS orbit means that the satellites only see $\pm 51^\circ$ latitude on the Earth's surface. It also means that the effective local time of day when the satellite crosses overhead drifts over time, resulting in "blackout" periods when the satellites don't have the right illumination conditions to successfully capture imagery.

After 2015 the launch market began responding to the growing demand from small satellite companies like Planet and offered more opportunities to SSO. Even more critically, in 2016 the US Government began to allow commercial US companies to launch on Indian rockets, which were regularly flying to SSO. Planet was able to transition from its R&D phase utilizing ISS launches to the company's operational phase with its fleet in SSO. The Polar Satellite Launch Vehicle (PSLV) turned out to be a critical launch vehicle for Planet. Between Soyuz and PSLV launches in 2016 and 2017, Planet launched an additional 148 Dove satellites to 500 km SSO, providing enough actively imaging satellites in orbit to achieve Mission 1 imaging the entire Earth's landmass every day.

2.6 Flock Operations

Flock operations are intentionally simple to keep the satellite fleet manageable. In nominal operations, each Dove satellite runs on an automated schedule capturing nadir-oriented imagery at a regular interval while in daylight. The imagery and telemetry data are stored onboard until downlinked to a ground station, and then the process repeats. The Mission Operations team at Planet is small but mighty; the number of Dove satellites flying greatly exceeds the number of satellite operators.

Mission Operations primarily focuses on improving automated operations and responding to anomalies, rather than having humans actively track every activity on each satellite. The team is split between Planet's US headquarters in San Francisco, California, and Planet's European headquarters in Berlin, Germany. Operators can also log in to the Mission Operations system via a secure, remote VPN, allowing operators to perform satellite tasks from home if needed. Most days, each team is able to maintain a "9 to 5" workday, with the differing time zones between California and Germany helping to spread the workload. If a Dove satellite experiences an anomaly during off hours, the Mission Operations team is usually able to wait until working hours to address the issue given that there are enough active satellites operating in Planet's fleet to withstand temporary individual outages (Demir et al. 2018) (Fig. 5).

The Dove onboard software is regularly updated for performance improvements and bug fixes. The software is first deployed to a ground spare satellite and tested extensively and then uploaded to a small handful of on-orbit Doves for further testing before being deployed to the entire fleet. Maintaining version control over the various Dove builds flying in orbit with different hardware builds, hardware states, and software versions can be a challenge, but the benefits of continuous improvement of the satellites outweigh the costs.

2.7 Ground Station Network

Planet's ground station network is comprised of about a dozen sites around the world and is a hybrid model of leased antennas and Planet-owned antennas. Because of the sheer number of satellites operating in orbit, the ground station antennas are active for most of the day, and many of the ground station sites have several antennas in a single location to account for when several Dove satellites are in view. Planet takes a similar approach to its Mission Operations strategy and runs the ground station network in a highly automated, hands-off fashion. The ground stations are unmanned during operations and monitored remotely, which again is overseen by a very lean team.

The ground network uses two communications paths to establish contact with the Dove satellites: low-speed Telemetry, Tracking and Control (TT&C) over UHF and high-speed communications over S-band (uplink) and X-band (downlink). The UHF ground systems utilize broad-beam Yagi-Uda antennas, and the S-band/X-band

Fig. 5 A Planet Mission Operations operator commanding satellites from her laptop with a Dove model in the forefront. (Image © 2018 Planet Labs Inc., licensed for one-time publication)

system uses parabolic dish antennas typically 5–7 m in diameter, although a handful of Planet's ground stations have antennas with all three frequency capabilities combined into a single parabolic dish.

The UHF system is especially important during the satellite commissioning phase right after launch when the Doves are traveling in a cluster and might easily be mixed up from the ground. Planet's UHF Low-Speed Transceiver (LST) radio is used both on the Dove satellite and on the ground station and has the ability to quickly establish communications, identify which Dove satellite is which, and even refine satellite positioning estimates using radio ranging. Planet has a 100% success rate in contacting every Dove satellite ever deployed over the UHF LST radio, usually within a timespan of a handful of orbits. The smallsat community has historically struggled with post-launch satellite tagging, tracking, and communications, especially on large cluster launches, which is why Planet open-sourced a version of its LST radio called the OpenLST for other satellite missions to take advantage of.

The S-band/X-band radio system was also designed in house and utilizes the DVB-S2 communications protocol to achieve amazing downlink rates. The latest generation of the Dove satellite can downlink imagery data at speeds better than 1 Gbps over X-band by using advanced DVB-S2 modulation and coding, improvements in the satellite antenna, and dual-polarization transmissions.

2.8 Space Stewardship

Orbital debris mitigation and responsible space stewardship is a top concern for Planet, especially considering the numbers of satellites in Planet's fleet. (At the time of this chapter's writing, over 350 Planet satellites have been successfully launched and deployed into orbit.) Planet was the first company to launch in such large numbers, and the company wanted to make sure it was being a good space stewards and leading by example. Planet developed the following principles to abide by:

1. No intentional junk: Never intentionally release any debris, including during deployment of actuated systems (e.g., the Dove's fold-out solar arrays).
2. Launch low: Planet aims to launch the Dove satellites between 400 and 600 km in altitude, with a target orbit of 500 km. This has dual benefit: the satellites will naturally decay from orbit well within the 25-year deorbit guideline (in most cases the deorbit lifetime is 5 years or less), and the Doves also avoid the most congested region of LEO between 700 and 1000 km, thus reducing the risk of collision with other space objects.
3. Share data: Planet openly publishes its most up-to-date satellite positioning data so that other satellite operators can more accurately assess any potential conjunctions. Many of the conjunction warnings issued to satellite operators turn out to be false positives due to the large uncertainties in the propagated estimates of satellite positions. By using the Dove's UHF transceiver for radio ranging along with the onboard GPS, Planet can provide more accurate position data to other satellite operators and help filter out false positives.

Although Planet currently operates the world's largest satellite fleet, those numbers will likely soon be eclipsed by the communications "megaconstellations" being developed by SpaceX, OneWeb, and others. Regardless, Planet is committed to continuing to advocate for responsible space operations, especially as the space environment evolves over time.

2.9 Current Status

In addition to the Flock constellation, Planet also owns and operates two other satellite fleets: the five RapidEye satellites, which produce medium-resolution imagery of similar quality to the Doves, and the constellation of SkySat satellites, which produce sub-meter, high-resolution imagery and HD video. The RapidEye satellites are expected to be retired in 2020 as they have been operating since 2008, and equivalent imagery capabilities are being produced by the latest generation of the Dove satellites. The SkySats, on the other hand, have an expected lifetime of several years to come. The SkySats, in combination with the Flock fleet, produce a combined dataset not available anywhere else at such scale.

After the milestone Flock launches in 2017 and the acquisition of the SkySat satellites that same year, Planet transitioned from a space-focused company to a product-oriented company. The company's primary focus is on developing Planet's imagery platform, easing the integration of Planet's imagery to other existing platforms and workflows, and enabling the development of imagery analytics to automatically extract features and insights such as automated road and building detection from the raw imagery. Planet's imagery is already being adopted on a global scale by a variety of different users, including government agencies, agricultural and forestry industries, environmental nonprofits, prominent media outlets, and academia. The user base continues to steadily grow as industries not typically used to relying on remote sensing data begin adopting Planet's unique dataset.

In parallel with Planet's imagery product developments, the company's space efforts are also steadily advancing. Planet recently announced the SuperDove platform, the next-generation Dove-series satellite that will feature a total of eight spectral bands in the visible and infrared spectrum and improved performance across multiple subsystems. In addition, improvements are being made to Planet's high-resolution platforms as the company continues to push the boundaries of what can be done with large networks of small satellites. Planet's ultimate goal of using space to help life on Earth by providing best-in-class imagery capabilities remains the company's top priority, with many more exciting developments expected in the future.

3 Conclusion

In the span of less than a decade, Planet went from a handful of engineers tinkering in a Silicon Valley garage to a company that operates the world's largest fleet of remote sensing satellites producing a dataset that is unmatched in its global coverage and frequency of revisit. Utilizing the Cubesat standard, commercial off-the-shelf-components, and cloud computing and storage services, the company took a radical new approach to satellite design, manufacturing, and operations. Planet has now set its focus on developing more powerful imagery analytics tools and the commercial adoption of its imagery data across a variety of industries and markets while still pushing forwards its space-based capabilities to remain at the forefront of the remote sensing industry.

Contents

Abstract

The advances of the NewSpace movement have acted as a wellspring for the field of entrepreneurial space. Made possible by these developments, Toronto-based Kepler Communications is working to lay down the telecommunications infrastructure of the next century by using its low Earth orbit (LEO) constellation as a cellular network for spaceborne assets. Kepler emphasizes taking small steps toward its goal, using its LEO network first to deliver Earth-based services to the global VSAT market and to the burgeoning industrial IoT ecosphere. With careful observance of historical lessons, Kepler has developed a robust business strategy to navigate the minefield of private space. With its plan in hand and a laundry list of bleeding-edge technological innovations, Kepler is placing one foot in front of the other on its path to build what it calls the "Internet in Space."

1 Introduction

Kepler Communications was founded in 2015 by a group of University of Toronto graduates with the mission to build the space infrastructure for the next century. In doing so, it joins a long legacy of people to pursue lofty goals in space – many of whom have stumbled along the path. Their activities can provide the basis for understanding Kepler's emergence, as well as its early success. To be clear, a small, private company like Kepler could not have existed for most of space development history. Space has traditionally been an arena that only the largest, most advanced economies could ever hope to step into. Fortunately for Kepler, much has changed.

The beginning of the satellite communications industry is often attributed to the visionary author Arthur C. Clarke who, for an article in *Wireless World*, described that relay satellites could be used for distributing television programs in a 24-h orbit (Clarke 1945). Some 13 years later in 1958, the USA launched the world's first purpose-built communications satellite SCORE (Signal Communications by Orbiting Relay Equipment) (Smithsonian 2019a). SCORE was primarily built as a response by the USA to the Soviet launch of Sputnik 1 and 2. It survived in orbit for only a few months, with its most well-known achievement being a broadcast of a Christmas message from President Eisenhower. Both US and Soviet endeavors highlight the enormous feat of space access, which had been closely held within government superpowers.

Kepler's first true predecessors were Telstar 1 and 2, a set of commercial telecommunications satellites launched in 1962 through a multinational private-public consortium comprised of AT&T, Bell Telephone, NASA, the British General Post Office, and the French National Post, Telegraph, and Telecom Office (today, commonly known as the company Orange) (Smithsonian 2019b). The technology aboard each of the Telstar satellites was primitive relative to today. Firstly, each satellite was spin stabilized, meaning it was constantly rotating. This invoked the need for low-gain, omnidirectional antennas, limiting the bandwidth that could be supported. The technology at the time meant that enormous facilities such as the Andover Earth Station (a 177-foot horn antenna housed in the equivalent of a 14-story building) needed to be built to receive Telstar's faint signals (Maine 2019).

Like Kepler's own network, these satellites were launched into a non-geostationary orbit, which meant that the signals could only be received and transmitted intermittently from the ground as the satellite passed overhead. Nevertheless, Telstar enabled the world's first transatlantic television feed, a remarkable feat for the time.

Its use marked a shift toward the commercial use of space, away from government-exclusive activity. Although some parts of the world saw this restriction persists for decades (e.g., China), the seeds of early space commerce had been planted in North America and Europe.

Kepler's family tree started to grow. As Telstar and other early satellite systems such as Relay and Syncom were operating successfully in space, commercial satellite communications companies began to form. The Communications Satellite Corporation (COMSAT) was formed in 1963 as a result of the Congressional signing of the Communications Satellite Act of 1962, thus becoming the first government-initiated satellite communications company (COMSAT 2019). COMSAT then formed the International Telecommunications Satellite Consortium (now known as Intelsat) and in 1965 formally kicked off the global satellite communications industry with the launch of Intelsat I (nicknamed Early Bird). National governments around the world soon began to take notice of the benefits of satellite communications. In 1969, the Canadian government formed the Crown Corporation Telesat, which then went on to launch the world's first domestic satellite in 1972, called "Anik" (Telesat 2019). In 1977, 17 European countries set up the European Telecommunications Satellite Operator (now known as Eutelsat) (Eutelsat 2019). In 1979, 28 countries within the International Maritime Organization (IMO) established the International Maritime Satellite Organization (now known as Inmarsat) (Inmarsat 2019). SES (Société Européenne des Satellites*)* was established in 1985 by the Luxembourg government (SES 2019), and Thuraya was established by the United Arab Emirates (UAE) government in 1977 (Thuraya 2019).

All of these companies had been initiated in some way by a government-led initiative. Government support had been instrumental in these early years because of the inherent risks associated with building, launching, and operating satellites, as well as the national need in providing these communication services. But as time passed, many of them returned to private sector ownership. Telesat was the first to make this transition, being sold by the Canadian federal government to Bell Canada in 1998. Inmarsat followed suit in 1999, when the company was privatized. Both Intelsat and Eutelsat were then privatized in 2001. SES today maintains the Luxembourg government as a major shareholder, and Thuraya is now owned by Yahsat.

As technical risks were gradually mitigated and the needs for connectivity began to take shape, the late 1980s into the 1990s saw a wave of the first truly private initiatives. These new ventures represent Kepler's closest historical relatives and included Teledesic, Skybridge, ICO Global Communications, Iridium, Globalstar, and Orbcomm. Teledesic was certainly one of the most well-known ventures at the time. The company was conceived in 1990 by cellular industry pioneer Craig McCaw. Its original plan called for a constellation of 840 satellites to be deployed in LEO at 700 km altitude. Over time, the plan was scaled back to 300 satellites at 1400 km and then to 30 satellites in a higher medium Earth orbit. Nevertheless, the company was able to attract impressive investors, including Bill Gates, Saudi Prince Al-Waleed bin Talal, Boeing, and the Abu Dhabi Investment Co. (Chan 2002). Another well-known private initiative was Iridium, designed to provide global cellular services. Its constellation was initially envisioned in the late 1980s, and design effort began in earnest in the 1990s, financed by Motorola. Its primary objective was to target the mobile phone market for international business travelers. Iridium progressively launched its 66-satellite constellation between 1997 and 2002, with all satellites needed to be operable before commercial services could begin (Bloom 2016).

Each of the other ventures – Skybridge, ICO, Globalstar, and Orbcomm – had their own unique history, but all of the private initiatives would later find themselves in the same place, declaring bankruptcy. Teledesic, Skybridge, and ICO folded before being able to offer any commercial services. Iridium, Globalstar, and Orbcomm got their constellations off the ground first before conceding the same. The latter constellations specifically were able to later emerge from bankruptcy by either restructuring their debt or being acquired in an asset sale. Their fates did not bode well for the hopes of private space industry.

At this point, history had clearly indicated that the only successful satellite communications companies had either relied on governmental support or had been purchased out of bankruptcy for a fraction of their invested value. This begged the question, would private space companies ever be able to survive on their own? How might they do it? Early on, Kepler took the opportunity to learn from these stories, hoping to use them to navigate the treacherous road to private space independence. And although the world of space remains as harsh as it ever was, fresh water has slowly trickled into the landscape, bringing with it the possibility of life. The NewSpace movement of the mid-to-late 2000s bore a number of innovative developments that have allowed capital-limited groups to start placing and proving inexpensive products in space.

One of the great nucleators of this NewSpace movement was the CubeSat standard, developed as an attempt to simplify the construction of satellites and reduce their overall cost through standardization. Kepler's satellites use this very standard. The satellites of old were always built to-order, designed, and assembled by teams of highly specialized engineers with extreme material and construction standards. CubeSats are made up of multiples of $10 \times 10 \times 10$ cm "units," and their fixed design allows manufacturers to optimize their essential parts (like batteries, solar panels, and antennas) such that they can be sold as commercial-off-the-shelf components. These can then be purchased by any up-and-coming university or NewSpace satellite startup. In conjunction with the optimizations and cost reductions provided by the CubeSat standard, the miniaturization of many payload technologies progressed in parallel, often developed as the primary focus of these startups and universities. Kepler was one such group, and its goal of building an advanced telecommunication network led it to channel its efforts into developing the cornerstone technology it would need for its mission – a custom software-defined radio (SDR).

Kepler's SDR payload was built in accordance with the CubeSat specifications, allowing it to leverage available commercial-off-the-shelf products for the rest of the spacecraft and save costs. Furthermore, the development of a standard form factor also brought with it a reduction in launch complexities. Launch providers suddenly were working with an industry-shared specification that let them easily incorporate disparate satellites onto their rockets. This allowed them to aggregate multiple customers on the same vehicle, dramatically reducing the cost of launch to space. The days where a single rocket was built to launch a single satellite were over. This further acted to renew government interest in commercial space, penning new legislation and regulations to provide a catalyst for the growth of NewSpace companies. All of these factors have allowed low-capital upstarts like Kepler to not only build and launch their own satellites, but to do so in as short time as 12 months! Kepler and companies like it and were suddenly free to dream of a compelling future in space, and now they had the tools to achieve it.

2 Kepler's Approach to Internet in Space

From the building of the aqueducts that powered the Roman Empire, to the development of railroads that helped settle the western frontier, and to the construction of the cell towers that underpin our digital ecosystem, the initial laying of infrastructure is essential for the building of economies. This was the strongly held belief at the root of Kepler's foundation. Drawing parallels to these forms of essential infrastructure, it was clear that for humanity to sustainably expand into space there needed to be a new form of development – an underlying vision that united Kepler's founding team.

In pursuit of this vision, Kepler focused on the increased usage of low Earth orbit (LEO) and the ever-growing demand for spaceborne data. Recognizing the deficiencies in existing satellite communications infrastructure, Kepler set out to design a network of small satellites in LEO that would operate much like network routers, but in space. These routers would form the backbone of a space-based Internet infrastructure, moving data in both directions between assets operating in LEO to Earth and beyond.

Kepler then patented an initial architecture for its eventual space network, one designed to be particularly useful in solving the connectivity problems of LEO spacecraft. When fully deployed, Kepler's network will comprise of a constellation of 140 satellites working in concert, spread equally among 7 different orbital planes. Each of the planes was set up in what is called a Sun-synchronous orbit, which is precisely calculated such that satellites will pass over the same parts of Earth at the same time each day. Furthermore, the constellation would carry on-orbit spares (designed to quickly replace active satellites that might fail) and could provide the capacity to support a broad array of data streams not only for customers in space but also for those on Earth. But such a large network of spacecraft and a diverse array of services brought with it unique challenges. For one, unlike more traditional geostationary satellites (which can retain sight to a single teleport year-round), Kepler's constellation would need to be supported by a geographically dispersed ground station network spanning multiple continents. Further, Kepler's constellation would be too big to monitor with human eyes alone. It would need to develop autonomous software systems that could manage satellite health and orbital collision avoidance on their own.

Such a large-scale network plan required new forms of thinking at the company level to ensure risk tolerance procedures and good aerospace practices were properly adapted. Both spacecraft design principles and company-wide operations carry a higher degree of risk tolerance to achieve the desired timelines where redundancy is sought in number of satellites. Every 3 to 5 years, Kepler will upgrade its network of satellites, bringing the latest advancements to space and mimicking the pace at which modern terrestrial wireless infrastructure is upgraded.

At the time of Kepler's founding, early indicators suggested that the need for in-space connectivity was not so distant. Satellite launches were growing at 30% year-on-year. Barriers to space access had been readily declining from regulation to technology, ultimately leading to a proliferation of NewSpace companies. These businesses were poised to capitalize on renewed space access and provide services including de-orbiting, maintenance, Earth observation, and manufacturing. Despite the excitement within the space industry, Kepler recognized that in-space connectivity was a new product in a new market, and it would be years before adoption would take shape. This ignited the thinking on how to establish the envisioned constellation of satellites that could serve as the future of in-space connectivity.

3 How to Build the Internet in Space

The exploitation of space has always been a harsh and trying arena. Even the well-funded Big LEO projects of the 1990s failed to survive its punishing environment. An awareness of this has been embedded in Kepler's business philosophy since its infancy. If Kepler was to succeed, it would have to draw from all of the lessons of the past.

One of the most crucial lessons came from looking at companies that had misunderstood their opening market. For example, Iridium had based their product development strategy on one such market – the international business traveler – which never materialized. The company's fall was tied to its inability to compete with the ever-growing terrestrial cellular providers of the time. When the service went live in the early 2000s, their handsets cost $2000 and airtime was $2–4 per minute – orders of magnitude higher than the cost of cellular. The number of Iridium subscribers after their first year selling service was 10,000, a far cry from the 500,000 that all the development plans had designed to serve (Bloom 2016).

A similar market misreading was done by Webvan, the online home grocery delivery service and darling of the dot-com era. At its height, Webvan appeared as an exemplar company, seemingly executing its business plans with flawless efficacy. They invested in delivery trucks, built a state-of-the-art warehouse with automated sorting, employed a seasoned CEO with savvy investors, received great reviews from early customers, and generated promising early revenue. The company raised nearly $800 M USD across a number of private rounds and their IPO in November 1999. But like Iridium, they overestimated the readiness of their market. Shortly after first product shipment, they were selling 2000 orders per day, a mere quarter of what the initial business plan had called for. Their entire product development, infrastructure, and staffing rollout had been built around an assumption of 8000 daily orders! Fundamentally, both Iridium and Webvan fell victim to premature scaling. They ramped up all of their costs (marketing, sales, facilities, recruiting, production, etc.) to support a planned revenue model that never materialized to their expectations. When this happens, burn rate increases without revenue in-tandem, and companies enter into a downward spiral.

Webvan, Iridium, and many other ventures that have failed this way (read Segway, Apple Newton) employed a similar product-focused, "build it and they will come" business strategy, and each of them was struck by its Achilles heel. They went through the motions to envision, pitch, develop, and produce their project before they ever tested the target market. This approach leaves market engagement as the last step that the business performs in the product development cycle. As history shows, it can have fatal consequences.

In contrast, Kepler employed what might be called a "customer-focused" strategy, one that puts market testing earlier in the development cycle. In this way, customer feedback is often directly incorporated into the conceptual stage of the product itself. The essence of this method is to *first recognize the problem and then devise the solution*. To mitigate risk the progression of the product should proceed gradually, beginning with the recognition of smaller, manageable customer problems that can be solved in the near term.

Frankly, startups do not have the resources to develop a product for mainstream or mass-market customers with many requirements and high standards. It is much better to start with a smaller customer subset wrestling with a very specific problem. This way, early product generations can be validated in market *at the same time* that they are being designed. Only after the solution is demonstrated to be viable should the company seek to find a broader customer base. These activities act to slowly pour the foundation for the business. After the concrete has settled, focus can shift to increasing spending on things like infrastructure costs, improved reliability, and product robustness.

Critically, small satellites are uniquely suitable to this *customer-focused* strategy, especially in comparison to larger satellites. First, their development cycles and costs are substantially less. A nanosatellite can be designed and constructed in 1 year, whereas a new, large geostationary satellite will require 5 to 10. Second, a design pivot for a nanosatellite might cost the developers months of effort; for a large GEO, this can potentially cost years. These things make it far easier for nanosatellites to test new market hypotheses. If first service requires a \$100 M investment (as is the case for large satellites), then it is imperative that your market hypothesis is correct. Such undertakings are not risk tolerant. But if first service merely requires a \$1 M investment to deploy (as is often the case for small satellites), then it is possible to make a few changes to your business plan without incurring fatal setbacks. The value of this ability to dynamically test risky markets cannot be understated. It is a potent tool that, when combined with the wave of technological advancements being made in the small satellite industry, might be enough to give private companies the energy they need to survive in space. First, Kepler would have to solve its own technical challenges.

4 New Problems Demand New Solutions

Ultimately, Kepler recognized that new technology would be needed to make its constellation a commercially viable platform. Over time, it could progressively add new capabilities to its satellites, thereby paving the way for new types of devices to join the network. Each of these successive service offerings could act as a stepping stone to the next, allowing Kepler to iterate on the technologies that would be useful for its final in-space connectivity vision. Further, each of them would raise unique challenges, some of which have never before been explored by industry, government, or academia. And so without knowing either the market need or the timeline in which it could be realized, Kepler's early years of work focused on solving problems that were certain to be required for the build out of this infrastructure.

It was recognized early on that key to any large-scale data infrastructure is a central processing node that can manage and carry traffic throughout the network. This line of thinking (combined with an exhaustive survey of available technologies in the market) provided the impetus for building Kepler's core payload – a proprietary SDR and high-gain antenna. This focus on payload development allowed Kepler to differentiate its business from others and take full advantage of the recent NewSpace trends, including commoditized satellite components and plummeting launch costs.

When evaluating desirable payload characteristics, Kepler came across the need to select its operational frequency band. Fortunately, Kepler's early development was done in Seattle, home of the infamous Teledesic-failed satellite venture and a myriad of technical talent that had been through similar experiences. This access allowed Kepler's founders to attain a clear understanding of how the International Telecommunications Union (ITU) regulations had been changed as a result of Teledesic's efforts and the availability of Ku-spectrum for non-geostationary high-bandwidth data services. Understanding the history and justifications for how this scarce, complicated resource was allocated became essential for Kepler to obtain coveted access to the Ku-band and provided clear guidance on how to further develop its network. Kepler prioritized this effort early on, quickly filing its system characteristics with the ITU and applying for Ku-band licenses in Canada, Europe, and the USA.

Kepler's first two prototype satellites (named KIPP and CASE after the companion robots in Christopher Nolan's *Interstellar*) were launched in January and November of 2018, respectively. They host Kepler's first iterations of its high-gain Ku-band passive array antenna and custom SDR. When launched, these satellites were the first commercial telecommunication satellites in LEO to operate in Ku-band. In alignment with its *customer-focused* strategy, Kepler opened its network to the first type of customer – the remote VSAT market. As a niche market consisting primarily of a small number of high-value enterprises, Kepler was immediately able to offer useful, high-throughput services with KIPP and CASE.

5 High-Throughput Service

This high-throughput offering in Ku-band was eventually named the *Global Data Service* (GDS). To begin customer validation, Kepler started by identifying niche markets that could benefit from its offering and that were underserved by incumbent networks.

As it happens, sun-synchronous LEO networks are uniquely suited to provide connectivity to the poles, which themselves are utterly underserviced by terrestrial networks. This is primarily because the population density is so low – a killer for economies of scale. The simple solution: lower the cost of the orbital infrastructure. Kepler was able to loft KIPP and CASE into orbit with only a seed funding of US $5 M, a 12-month timeline, and a team of around ten. These satellites are capable of *moving tens of GBs per month* for customers above the 60th parallel. In particular, GDS offers store-and-forward (i.e., non-real time) connectivity at reduced cost, which remains useful for data-heavy demands from remote polar vehicles/facilities. A critical customer base is in maritime, including scientific, industrial, and shipping vessels operating in and around the Arctic. Earnings from GDS are then reinvested into the R&D necessary to allow Kepler's follow-on services to be developed.

To deliver GDS successfully, Kepler's high-gain antenna needed to support plenty of bandwidth and still fit on a 3U CubeSat bus. Part of the reason why Ku-band was selected as its operational frequency was because it had just the right balance that was needed. The narrow beamwidth achieved by the 3U-size Ku-band antenna was enough to make full use of the state-of-the-art pointing capabilities available for CubeSats at the time (controlled pointing to within $<5°$). In addition, Ku-band had sufficient bandwidth available under international regulations to enable the data rates that the business model demanded. With the antenna specifications selected, Kepler searched for a commercially available SDR to perform the necessary digital signal processing. Its search turned up empty, finding zero available Ku-band SDRs available to the CubeSat component market. If Kepler was to move forward, it would need to build its Ku-band SDR from scratch.

Kepler's custom SDR is powered by a special chip known as a field-programmable gate array (FPGA), a clever bit of engineering wizardry first developed in the 1980s that can *efficiently simulate discrete hardware components*. Unlike your granddad's radio (which would have built using a concoction of mixers, filters, amplifiers, modulators, and other separate components), an FPGA-powered SDR can simulate the effects of many such subcomponents to produce a *virtual* radio that can operate nearly as efficiently as the real thing. Critically, SDRs allow radio operators to change their center frequencies, bandwidths, modulation types, bit rates, and output powers dynamically via sensing, autonomously via schedule, or manually via telecommand (useful when trying to avoid interference with other systems). SDRs can also support certain advanced interference mitigation methods, such as "cognitive" radio, where a network of SDRs can dynamically communicate with each other to collectively determine the optimal use of a shared frequency and minimize overall spectrum use and therefore interference. Further, FPGAs can be reprogrammed on the fly, effectively “shape shifting” their virtual component layouts. This ability allows Kepler to keep its satellites up to date merely by patching their software throughout the entirety of their orbital lifetimes. KIPP was the first commercial Ku-band CubeSat system placed in orbit globally, and its specialty characteristics have allowed it to set the CubeSat uplink speed record, demonstrating ~150 Mbps with theoretical capability as high as 300 Mbps. Further still, the SDR is capable of operating using instantaneous channel bandwidths anywhere between 1 kHz and 250 MHz, a feat that analog radios would be hard pressed to replicate.

At the end of the day, KIPP and CASE were important proving grounds for Kepler as a company. They enabled Kepler to field-test and mature its core antenna and radio technology, build out its gateway network, develop compatibility with existing Ku-band user terminals, secure and bring into use the spectrum necessary for operation, and generate early revenue – an immensely powerful milestone for a startup in its infancy. The next step would be to extend the reach of Kepler’s network into the world of small data. The 2010s had seen great excitement for the mass deployment of the “Internet of Things” (IoT), and many of these small, portable devices could be ideally served by satellites in LEO.

6 Low-Throughput Service

In combination with the high-throughput capabilities in Ku-band, the expansion into IoT would mean Kepler’s network might one day reliably provide connectivity services for devices demanding anywhere between 10 kB/month and 500 GB/month. Meanwhile, IoT market growth predictions dwell in the stratosphere, with expectations that related technology spending will increase from the US $151B spent in 2018 to over US $1.5 T in 2025 (Leuth 2018).

A number of other NewSpace companies are aiming to get into the IoT market, but most of them are constraining their targetable devices to narrow specifications. To capture a broader share of the satellite-accessible market and to differentiate from competitors, Kepler’s plan for IoT is to support a swath of low- and medium-data rate applications. This is a technical challenge to be sure, but unlike many other NewSpace IoT companies, Kepler is working to greatly optimize its fixed costs by vertically integrating the ground and satellite sides of its network. To that end, all production-class satellites (i.e., non-prototype) are to be designed, assembled, tested, and staged for deployment in-house at Kepler’s Toronto HQ. All aspects of satellite design from power generation, onboard software, thermal management, and payload operations are managed by a team that effectively works on a single floor. This control is mirrored for Kepler’s user terminals. Kepler has designed its GDS customer modem from the bottom up; and it builds, assembles, and tests each finished product in-house. Powering the GDS modems is a derivative of the same custom SDR technology used on its satellites, a shortcut that saved substantial amounts of non-recoverable engineering time on their design. Lastly, Kepler fields its own technicians to install its GDS user terminals on-site. This level of control begets an enormous amount of flexibility, allowing Kepler to cohesively optimize all aspects of its service from launch to customer product. This approach will be extended to the development of a similar user terminal for IoT. In this case, the terminal will be a small transceiver module capable of direct-to-satellite communication.

These kinds of connectivity modules are useful when attached to sensors and trackers that operate in remote areas or over disparate cellular networks. Examples include animal trackers, whose subjects' migration patterns often lead them away from cell coverage, or rail/marine shipping container monitors that frequently cross borders and travel through poorly connected areas. Such devices are often designed to operate on a single battery charge. To be economical, they must be low cost, use little bandwidth, and be capable of operating for 3–5 years without maintenance, thus requiring low-power transceivers as well. Further, communications must be bidirectional, so that they can receive commands and updates from Kepler's network operations center. Kepler's IoT module has been designed to fit precisely these customer requirements. To handle the simultaneous traffic of thousands of co-located devices, ground and space devices employ an advanced spread-spectrum code division multiple-access scheme. The nature of these IoT devices mean that under international regulations that are categorized as *mobile*. This classification carries some regulatory implications, one of which is that Ku-band cannot be used to service them. Instead, frequencies are available in VHF, L-band, and S-band, requiring Kepler to develop a completely new antenna system.

Lessons learned from the development of the IoT module will further inform the rest of the development of Kepler's network in space. Advances in low-power hardware and communication protocols can be directly extended to Kepler's satellites, where every milliwatt counts. The multi-access scheme developed to manage transmissions from thousands of IoT modules at once can inform Kepler's approach to intersatellite links. Tapping into new revenue streams allows the funding of subsequent waves of satellite deployment.

Because "IoT" is a broad term that encompasses everything from simple thermometers to fully networked cars, device connectivity demands will vary. Thinking back to the location tracker application, such devices need only transmit their location data – a few bytes at most at a time. In contrast, a network of environmental sensors may need to transmit tens to hundreds of kBs. It is important that connectivity options capable of supporting this wide variety are available to customers. Many NewSpace IoT entrants have tailored their technology to focus on one type or the other, but Kepler's ability to leverage both high- and low-throughput data streams will allow its network to support the full breadth of terminal types that span the consumer landscape (Table 1).

Never before has a commercial satellite service been able to offer this level of flexibility. Each technology borrows from the others, mitigating risk and saving R&D expense. The ability to include increasingly diverse devices on its network allows Kepler to build its business gradually, paving the way to the stability that evaded Big LEO. After the foundation is laid, Kepler can pivot to deliver its final aspiration: laying the groundwork for the Internet in Space.

Table 1 Breakdown of consumer business models

Name	Monthly data rate	Cost of deployment	Description
IoT service	~10 kB	<$100	Small, independent remote devices
Small aggregator	100 kB–1 MB	$1000	To support local networks of ~10 devices
Large aggregator	1–100 MB	$5000	To support local networks of ~1000 devices
GDS	1–1000 GB	$30,000	VSAT backhaul

7 The Internet in Space

It has been over six decades since Sputnik first broke the barrier of orbit, but the commercial in-space economy has yet to emerge from gestation. Recently, the launch industry has seen incredible progress with SpaceX pioneering the advent of reusable launch vehicles and paving the way for others to follow. With every dollar that costs-per-kilogram to orbit plummet, the door to the final frontier opens a little wider. Within two decades, non-geostationary orbit will see a flurry of new activity made possible by cheap, ubiquitous access, and Kepler hopes to co-host the welcoming party. All major historical industrial developments are preceded by the laying of infrastructure. Where launch providers lay the tracks, Kepler hopes to raise the towers that bring our connected world beyond.

Visions aside, few outside the space industry are aware that objects in orbit are already plagued with connectivity challenges. In fact, non-geostationary satellites all suffer from one main issue commonly referred to as the *downlink problem*. Simply put, you cannot communicate with a satellite that you cannot see, and non-geostationary satellites are by their nature not always visible. Therefore, you cannot communicate with a non-geostationary satellite unless you have a ground station that can see it at any given time. This problem has dogged satellite operators since the space race, and the simplest way to solve it is to use an intersatellite relay. Such relays handle satellite traffic using the same principle that cell towers do with mobile signals. For Kepler, this task will be the final function of its orbital network.

An excellent example of the downlink problem can be observed in the current business of Earth observation satellites. These suffer from an embarrassment of riches – there is simply too much imagery data being collected for the supporting communications infrastructure to handle. The reality of getting your data back from space is operationally complex, expensive, and oftentimes the bottleneck that restricts a system's capabilities. LEO satellites, like those used for Earth observation, must send their wealth of imagery data back to Earth by contacting a "ground station" whenever they are in sight. Even when leveraging established ground networks, opportunities to send information to an Earth-based station are typically available for less than 40% of the day. With such limited access time, operators can find themselves generating more information than they could ever hope to send back to Earth! In these cases, they are forced to throw away valuable excess data and, in doing so, miss the business opportunities it could have served. Further, this problem of intermittent connectivity, by its very nature, prevents real-time communications between LEO satellites and users on the ground.

Historically, when an entity commissioned a space program, they would also be responsible for developing their own ground stations to "downlink" their information. By analogy, imagine the expense if every mobile phone user in the world had to purchase their own cell towers and operate their own network just to communicate. The individual buildup of this infrastructure may have been a viable solution in the past, but the market landscape of today has greater demands. The lack of a scalable communications system for LEO satellites limits the commercial use of hardware that has already been launched, and as the number of satellites in LEO grows, this acute communications problem will only become more pronounced.

Some companies today are building and operating ground station networks as a service – eliminating the need for customers to build their own facilities. One approach is to aggregate the unused capacity of existing satellite ground systems around the world and make them available to network subscribers. This would allow the owners of those grounds stations to maximize traffic on their networks. Others are building their own ground station infrastructure outright and selling the capacity to customers directly. But even with expansive commercial ground networks, achieving constant visibility is a momentous challenge, requiring dedicated antenna systems to be installed across the entire globe, including the oceans.

Until the Space Shuttle era, governments had largely been forced to accept this problem. Alongside the building of the International Space Station (ISS) and the Space Shuttle, the USA deployed a national space network to solve the communications problem. Investing nearly $5 billion, they launched 13 geostationary satellites that would relay traffic between customer satellites and a visible ground station, allowing them to maintain an always-on connectivity. This system, called TDRSS (Tracking and Data Relay Satellite System, pronounced *tee-driss*), is now more than 20 years old and costs $100 M/yr to maintain. With no line of sight to renew the system, other initiatives have been proposed, such as Europe's EDRS (you guessed it, the European Data Relay System). However, where TDRSS uses radio signals to communicate, EDRS plans to use lasers to transmit data at significantly greater speeds. This presents its own set of challenges, requiring satellites hoping to connect to the system to carry onboard a power-hungry 160 W, 60 kg terminal, which alone is almost 12 times the entire mass of KIPP! Furthermore, TDRSS and EDRS are government infrastructure and as such are burdened with red tape. This is made apparent by the fact that TDRSS users must both fall in line with the priority queue for government users and be approved through a formal process to get access to the service. Once granted, the astronomical cost of connecting satellites sits at a whopping $136 *per minute*.

As Kepler's constellation grows, it will tackle the downlink problem by using its own constellation as a giant relay. Each satellite will act as a mesh node, forming connections with adjacent Kepler satellites to connect orbital customers to the ground in real time. Together, the satellite nodes will form an interconnected network capable of relaying low-power transmissions from nearby spacecraft. These intersatellite links (ISLs) however come with their own technical challenges. One of the largest problems with orbital communication is dealing with "Doppler shift," a phenomenon that causes the frequency of radio waves transmitted between two moving objects to change in proportion to their relative positions (this effect is made particularly strong at orbital velocities). It is the same phenomenon that causes sound waves emanating from a car to change pitch as it passes you on the road. Kepler's satellites travel at over 7 km/s, and attempting to send and receive signals to customer satellites moving at similar speeds in different directions can result in some very distorted radio waves indeed. Kepler has patented its proprietary network architecture that deals with this complex issue. Today, it already operates software on KIPP that manages Doppler shift. This works by tracking the drift in its transmission center frequency as seen from a stationary receiver on the ground. Successive iterations of this functionality will be necessary for establishing reliable ISLs.

Another striking problem is determining the best path that information should take when traveling between satellite nodes. Kepler has devised an algorithm to solve this issue that routes data packets along a node pathway to the closest available ground station in the shortest amount of time. Before all 140 satellites are deployed, however, there may not always be a direct pathway available at any given moment. In the meantime, the network supports delay-tolerant transfer (packets are stored temporarily before being transmitted at the next available opportunity).

Kepler's constellation is to be deployed gradually in several phases. The first includes its *Interstellar*-themed prototype satellites. Its first production-class systems will launch shortly thereafter, beginning with a batch of approximately 16 satellites that will deliver commercial Earth-based connectivity services while also testing future on-orbit technologies. The subsequent generation will sport 50 new satellites, followed thereafter by the full 140-satellite deployment that will come equipped with all of the technologies it needs to support the Internet in Space.

Space is the new commercial frontier. The recent "entrepreneurial space race" has brought with it unprecedented levels of access and opportunity. Upstarts are constantly imagining new uses for the benefits that spacecraft in LEO and beyond can provide. By building a communication network in accommodation of this exciting new economy, Kepler is continually making new discoveries and deriving valuable insights on the promising new world of private space.

8 Conclusion

The satellite communications industry at large has seen widespread transformation over its 60-year lifetime. In the time of Sputnik, space was tightly controlled by government agencies; today it is increasingly dominated by commercial activity. As technology and regulation become more accessible, space networks will continue to transition away from government-led initiatives into private enterprise. Standardization has been the largest catalyst to improving space access in the last two decades, not only for well-funded government organizations but also for entrepreneurs. The dramatic advancements in launch cost and commercial-off-the-shelf components mean that the cost of building a satellite communications business today is equivalent to that of a software-as-a-service company. This, along with new developments in SDR technology and reduced barriers to space, is what has ultimately made Kepler's existence possible.

Kepler's vision is rooted in a long-term view of the needs of this emergent commercial space sector. History has shown that the greatest industrial and economic developments of the past were first preceded by the laying of critical infrastructure. Its aspiration to build the Internet in Space was directly informed by these patterns. Kepler holds the founding belief that the establishment of ubiquitous space connectivity will be required to sustain this nascent, future economy. With this in mind, Kepler has formulated the design of an orbital network of 140 satellites with the line-of-sight to support the communication needs of the future, from Earth to LEO and beyond. Its network was specifically designed for gradual scalability. By incrementally providing services to Earth-based markets, it can navigate many of the revenue pitfalls faced by prior satellite communications businesses. Starting with a high-throughput service to the remote VSAT market in Ku-band, Kepler uses its own proprietary SDR technology to move large quantities of data for users that are otherwise underserved/unserved today. As the number of spacecraft in orbit increases, the network can continually both increase capacity and provide better revisit times for its terrestrial users. Further, its orbital architecture naturally lends itself to support the globally expanding market of remote IoT devices, especially where their terrestrial connectivity is bogged with regulatory restrictions, patchy infrastructure, or cross-border incompatibility. In the long term, this service diversity provides Kepler the ability to overcome challenging market adoption timelines and sustainably grow its business.

With the limited capital expenditure required to set up the network and the ability to refresh its spacecraft technology on a rolling 3–5-year basis, Kepler is well-poised to rapidly advance the state of satellite communications. This progress will be actualized by the variety of technological upgrades added to its network over time, including the pioneering of intersatellite optical communications, to the substantial increase of on-orbit processing capabilities. Each of these technologies will be introduced incrementally to the network and immediately tested in-market, each helping to pave the way to the Internet in Space.

The OneWeb Satellite System

Yvon Henri

Contents

Abstract

The majority of the world still does not have access to the Internet, and this "digital divide" is not only an issue in developing countries. Unconnected populations exist in every country, and it is important to find ways to provide universal access to the Internet. Furthermore, the demand for connectivity (Internet and data) is growing exponentially, and existing terrestrial solutions likely will be insufficient. OneWeb is building the world's first global communications network in space to deliver high-throughput, high-speed services capable of connecting everywhere to everyone with new satellite technology and meaningful

solutions with low latency. OneWeb, by launching the first large-scale mass-produced constellation of satellites in low Earth orbit at 1,200 km altitude, is committed to the sustainable values that will shape the world to help bridge the digital divides that exist so nobody gets left behind.

This large OneWeb constellation of about 650 satellites was scaled down to 288 satellites to restructure its capital financing in 2019, but after having launched 74 satellites it filed for bankruptcy in May 2020. New financing as of July 2020, to be provided by the UK Government and by the Indian mobile network operator Bharti Global, of $1 billion, will apparently allow this system to recover from bankruptcy and still be deployed. The 2021 start of service date mentioned in this article has been delayed due to the bankruptcy.

1 Introduction: Internet Access Everywhere, for Everyone

Almost half the entire human population is not yet connected to the Internet and when connected the access is limited, both in developing and developed countries. At the same time, the global demand for data, especially mobile data, is growing exponentially, and terrestrial solutions alone cannot keep up. Indeed, new applications will drive continued consumption growth – autonomous cars, virtual reality, and artificial intelligence. Today aviation and maritime mobility are also hampered by the lack of connectivity in the skies and at sea – many areas still underserved, indeed:

- Forty-eight percent of the world's population is not connected to the Internet (ITU's Measuring the Information Society Report 2018). Terrestrial solutions cannot reach everybody economically.
- Growth rate of people connecting for the first time has slowed (M-Lab 2019). The gap in society of digital haves and have-nots is widening.
- Expected increase in IoT connected devices from 8 billion in 2017 to 13 billion in 2020 (GSMA Intelligence Global IoT Connections 2019). High demand for existing connectivity to be faster.
- Seventy-six percent of enterprises looking to cloud applications and platforms to accelerate IT service delivery (IDG Cloud Computing Study 2019). Prioritization of public cloud is happening fast.

2 New Satellite Technology Can Meet the Increasing Data Demand

Only space-based infrastructure can ever provide true geographic ubiquitous coverage of the world. The satellite industry has gone through game-changing transformation in the last decade, not only creating high-throughput satellites for use at the traditional geostationary satellite orbit but, more importantly, developing non-geostationary satellite systems (NGSOs) that are much closer to Earth, thus cutting the latency (delay) in communication to a tenth of what it used to be. With latencies of under 150 ms, these NGSOs are designed to revolutionize wireless broadband coverage for the entire world.

OneWeb's high-speed, low-latency, and global solution are well-positioned to win in these markets.

3 OneWeb's Mission: To Provide Global Satellite Internet Coverage

OneWeb is building the world's first global communications network in space to bring unparalleled high-quality broadband access, low latency, redundancy, security, ubiquity, and opportunity to everyone by:

- Launching roughly 650 mass-produced satellites into the first mass-produced low Earth orbit constellation at 1,200 km altitude
- Initiating seamless global coverage, with customer demonstrations in late 2020 and launch of commercial services in late 2021
- Serving fixed and mobility markets including maritime, aviation, enterprise, cellular backhaul, land mobility, government-civilian, military and humanitarian, and consumer broadband sectors
- Building sustainable practices and environmental stewardship into the business model

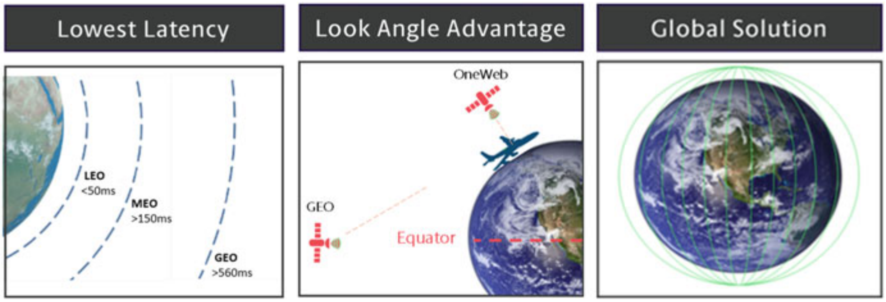

Fig. 1 OneWeb value proposition (graphic courtesy of OneWeb)

To provide global availability, high performance, and low latency (under 50 ms), OneWeb has partnerships to provide low-cost, easily manufactured satellites (with Airbus) and strong partners who are leaders in their respective fields (such as Qualcomm, Softbank, Coca-Cola, Hughes, Grupo Salinas, and Intelsat).

4 OneWeb Value Proposition

Low Latency: OneWeb's network is 30 times closer to Earth than traditional satellite systems, providing services on par with or faster than optic fiber or cable. Most of today's in-demand applications require low latency.

Global Coverage: OneWeb's polar orbiting satellites are designed to logically interlock, creating a coverage footprint over the entire planet. Global coverage means connectivity everywhere: land, sea, or air and even over the poles.

Applications: Machines do not care about latency, but people do. OneWeb's combination of high speed and low latency enables everybody to use all the interactive applications while unlocking totally new applications (Fig. 1).

5 OneWeb System Architecture

The OneWeb satellite system will consist of an initial constellation of 650 or more operational low Earth orbit (LEO) satellites with circular orbits at an altitude of 1,200 km inclined to polar in 12 orbital planes spaced around the equator, with 49 or more satellites evenly spaced in each orbital plane (650 satellite constellation: 588 satellites in service + spares at the beginning). The constellation is scalable as demand increases (Fig. 2).

The system performance with global coverage will provide:

- Terminal download speeds up to 195 Mbps
- $>$ 99.7% availability
- End-to-end latency ideal for real-time applications such as cloud gaming

Fig. 2 OneWeb global coverage (Graphic courtesy of One Web)

- 16-beam "Venetian Blind" pattern per satellite
- Beams are 1,600 km in longitude and 65 km in latitude
- Wi-Fi/2G/3G/LTE/4G/5G experiences

operating in full compliance with the United Nations' International Telecommunications Union (ITU) regulations in:

- User links in Ku-band (10.7–12.75 GHz and 14.0–14.5 GHz)
- Gateway links in Ka-band (17.8–18.6 GHz, 18.8–19.3 GHz, 27.6–29.1 GHz, and 29.5–30 GHz) (Fig. 3)

6 OneWeb Organization and Network Infrastructure

OneWeb headquarters are located in London, UK, along with one of two satellite operation centers (SOCs); the other SOC is in Virginia, USA. There are also ground stations positioned around the world for monitoring and controlling the satellites. Initial locations include Norway, Canada, and Sicily. More than 40 ground stations (satellite network portals/gateways) will be responsible for monitoring the entire OneWeb constellation once it is fully launched. OneWeb will be tracking the positions of each satellite constantly, using automated processes to efficiently manage complex tasks, as well as to predict any potential interference.

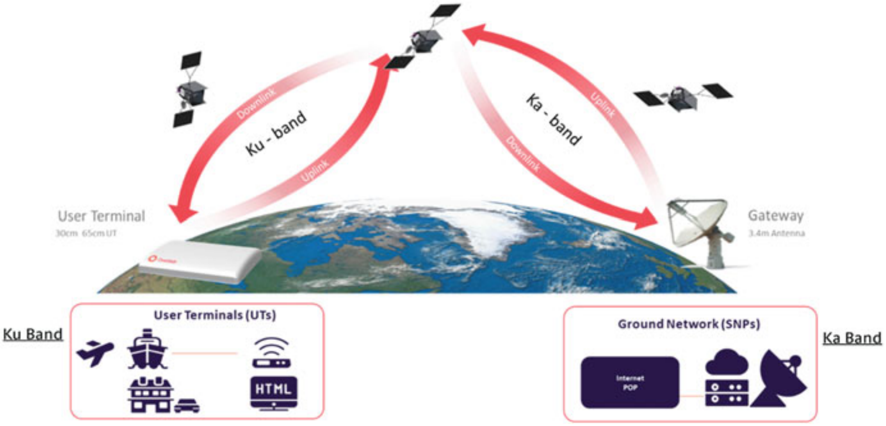

Fig. 3 OneWeb architecture (Graphic courtesy of One Web)

The network infrastructure is deployed in three layers:

- Network data center (NDC): the NDCs will be deployed in key global locations. The data centers will host the authentication, authorization, policy, and user terminal databases.
- Point of presence (PoP): the PoP will connect the OneWeb network to the Internet. PoP will be deployed at key Internet peering points.
- Satellite network portal (SNP): SNPs are the ground stations, deployed to maintain connectivity to the LEO satellites. SNPs are mostly in remote locations that allow large antenna farm arrays. Each site requires between 7 and 30 full motion antennas (16 on average) with 3.5 m Ka-band, circular polarization feed, 2.5 GHz bandwidth, and 2 polarizations (Fig. 4).

The first batch of six satellites was successfully launched on February 27, 2019; a massive launch campaign is on track and has begun with the successfull launch of 34 satellites on February 7, 2020 and with continuing monthly launches of more than 30 satellites per launch with Soyuz (Arianespace) over the next 2 years; commercial service is expected to be launched at the end of 2021.

7 OneWeb User Terminals

The OneWeb user terminal (UT) consists of a satellite antenna, a receiver, and a customer network exchange (CNX) unit, easily deployable and cost-effective intended to be located outdoors in view of the satellites and directly on customer locations. The CNX connects the UT to the customer's network which in turn connects to end-user devices including laptops, smartphones, sensors, and more. These terminals will have fixed antennas that employ phased array antenna technologies or steerable dish antennas to track the moving OneWeb satellites. For security

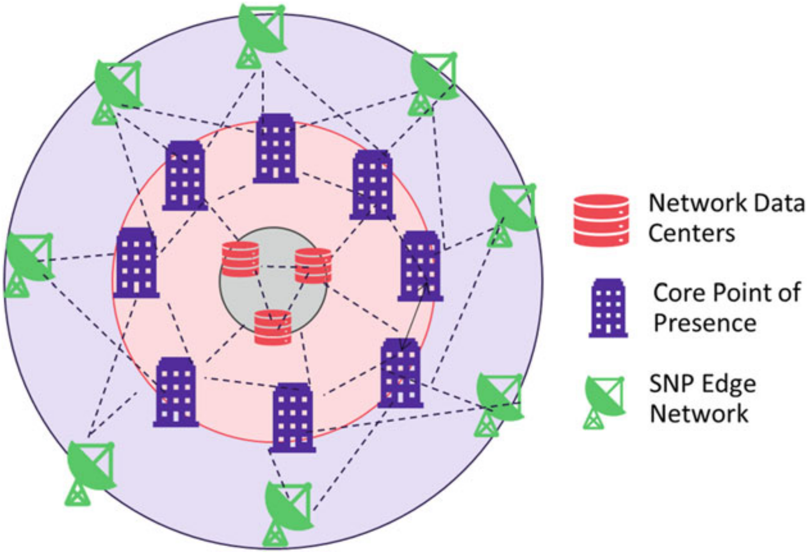

Fig. 4 Network infrastructure (graphic courtesy of OneWeb)

Fig. 5 User terminals (Graphic courtesy of OneWeb)

reason, user terminals on ground are installed at fixed locations, and they are GPS locked; meaning that once installed, it will only work at the installed location. If the location changes, the user terminals will be deactivated.

OneWeb is working with leading vendors to provide a portfolio of high-performance UTs that can be easily self-installed and which will be customized for specific applications within the aviation, maritime, enterprise, cellular backhaul, government, and consumer broadband sectors (Fig. 5).

8 OneWeb Satellites

OneWeb Satellites – a joint venture of OneWeb and Airbus – has found a way to change the economics of space with the opening in July 2019 of the world's first high-volume, high-speed, advanced satellite production facility in Florida (USA).

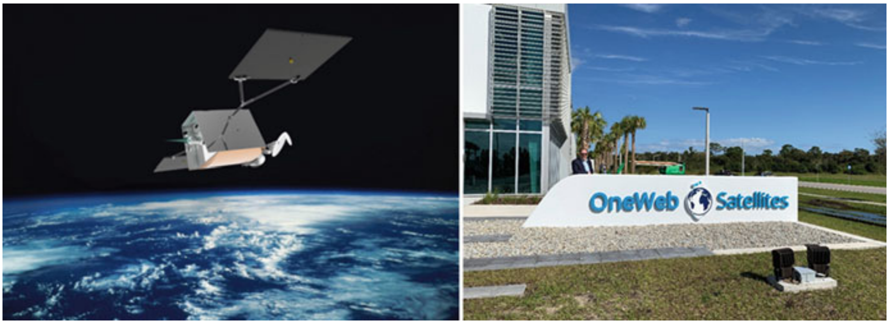

Fig. 6 Satellite and satellite factory (Graphics courtesy of OneWeb)

The factory is designed to produce small, highly efficient satellites at a rate of two per day, at approximately 1/50th of the cost of a traditional manufacturer. The total spacecraft mass is about 150 kg, payload mass about 60 kg with electric propulsion (Xenon HET). The design life of the first satellites to be launched will be greater than 7 years in a 500 km orbit and greater than 5 years in a 1,200 km orbit.

Historically, satellites are individually custom built, costing tens of millions of dollars to build, and it takes more than a year to produce a single one. The OneWeb Satellites facility is the first to employ industrial-scale mass production techniques for satellites, enabling dramatically reduced costs and production times that can deliver one satellite per production shift or two a day, making space technology far more accessible (Fig. 6).

9 OneWeb Market Sector

OneWeb's satellites will provide global connectivity and networking solutions that can influence and enable digital transformations that will change society, industry, and global enterprise.

9.1 Maritime

OneWeb is powering the digital transformation of vessels at sea by providing networking solutions tailored to any need, at any level, replacing one-size-fits-all connectivity with a full spectrum of tailored, customizable broadband channels. The high-throughput, low-latency global network is delivering unprecedented flexibility, lowering the barriers to high-quality maritime connectivity, minimizing environmental impact, and enabling the fleets of the future on all world routes, including the Arctic ones.

9.2 Aviation

OneWeb's vision-led global communications network provides Internet access everywhere, creating new use cases and opportunities for both business and commercial aviation. Business jet passengers consider high-performance bandwidth, speed, and coverage area of onboard connectivity essential for inflight office and travel time. Commercial airlines want to provide ever-improving service quality and incremental value to reflect loyalty. Passengers boarding commercial airlines with mobile devices switched on want a reliable, safe, fiber-like Internet experience in the sky for seamless and uninterrupted access to their emails, social media networks, online games, or applications.

9.3 Enterprise

Enterprise information systems and business functions that once were relatively constant are becoming more agile as organizations turn to more dynamic, digitally powered, cloud-enabled applications to accelerate their IT delivery. OneWeb's connectivity will enable this digitalization process within the enterprise sector, streamlining ISP solutions with low-latency, secure fiber-like connectivity everywhere that offers a competitive advantage, more intelligent interactions, a more skilled and connected future workforce, and operational capability across a wider geographical region.

9.4 Government

OneWeb's global communications network will deliver the levels of reliable and secure throughput that government applications require. The high speed and low latency create new use cases that will enhance decision-making and security to connect those who protect. These include breakthroughs in the commercial mobile communications sector such as increased GPS capability, improved persistent FMV (full-motion video) relay for unmanned aircraft systems, and increased reliance on mobile ad hoc networks. OneWeb's global network also creates new solutions for civil government applications such as border forces, maritime security, disaster management and recovery, and government-funded nonprofit social initiatives in areas such as education.

10 Responsible Space

OneWeb is the only LEO satellite communications company to embed sustainable practices into all corners of its operation, across company culture, production lines, launch processes, and orbit. The term Responsible Space describes practices that drive sustainability within the space industry, to minimize harm and build operations that work for everyone.

OneWeb uses the term Responsible Space to describe a far-reaching framework of principles and best practices on which the company, and other space industry participants, can build a shared commitment to sustainability in space. The fundamental premise is that space is a shared, natural resource which, if used responsibly, can help transform the way people live, work, and interact. Responsible Space also builds on and strengthens work already being done within the broader space community to address this important issue. OneWeb applies the principles and values of Responsible Space into all areas of the business, into design and operational practices, technological innovation, and collaborative partnerships. In this regard, OneWeb announced in December 2019 that a low-cost, advanced grappling fixture shall be installed across the OneWeb constellation that can support a variety of capture techniques for satellite servicing and disposal.

"OneWeb's Responsible Space framework informs who we are and where we are going as a company. With OneWeb's monthly satellite launch campaign beginning at the beginning of 2020 and commercial services starting in 2021, we are committed to seeing the continued advancement and discussion of the issues at stake for the Space community" (Adrian Steckel 2019).

11 Conclusion

The OneWeb satellite constellation is in many ways a game-changing space-based network building the world's first global communications network in space to deliver high-throughput, high-speed services capable of connecting everywhere, to everyone, for low-cost, low-latency access to the Internet. Many of the unique aspects of the architecture, responsible space practices, and aspirations for this new large-scale low Earth orbit (LEO) constellation that is currently being deployed are summarized and described in this chapter.

The Spire Small Satellite Network

Jeroen Cappaert

Contents

Abstract

This chapter provides a detailed description of the Spire small satellite network from a technical, services, financial and network perspective. It first describes how the Lemur-1 cubesat demonstrated the feasibility of this innovative new system that led to deployment of the Lemur-2 network and the current deployment of a global network of over 80 three-unit small satellites. It also explains how it has evolved through the raising of capital through venture capital rounds of financing.

It describes Spire's complex, diverse, and growing range of services and data analytics as they have evolved to date. These various services include: (i) a range of maritime Domain awareness products; (ii) a variety of critical weather and

1 Introduction

Spire is a data and analytics company that collects data from space to solve problems on Earth. Owning and operating one of the largest satellite constellations in the world, Spire identifies, tracks, and predicts the movement of the world's resources and weather systems so that businesses and governments can make smart decisions (e.g., see Fig. 1 for an example data set).

Spire offers a suite of RF sensing products, including AIS-based maritime data and associated predictive analytics products, ADS-B aviation data, and radio occultation-derived weather, atmospheric and ionospheric data. The company operates an expanding constellation of 84 nanosatellites and 31 ground stations. Spire's space operations, data processing, and distribution network are born in the cloud and dynamically scalable.

In addition to RF collection capabilities, Spire offers a space-as-a-service product suite, Orbital Services. This program allows customers to either integrate third-party sensors as hosted payloads or develop custom payloads, leveraging Spire's high-frequency launch schedule and infrastructure to deploy satellites on orbit within 6–9 months of project kick off.

2 Brief History

Spire Global Inc. (previously known as NanoSatisfi Inc.) was founded in 2012 in the USA and opened an office in San Francisco. Spire started work on its first 1U CubeSat satellites, named "ArduSat," which were partially co-funded through the crowdfunding platform KickStarter and had mainly educational applications. The first ArduSats were launched in August 2013 as one of the first Cubesat deployments from the International Space Station (see Fig. 2) and the first commercial satellite

Fig. 1 Example Spire dataset, AIS + ADS-B. (Graphic courtesy of Spire, ©Spire Global)

deployment. ArduSat and the educational applications were later spun out to focus solely on educational technology.

After successful launch and operation of the ArduSat technology demonstrators, Spire built and launched a 3U CubeSat technology demonstrator, LEMUR1, in 2014 as a precursor to its production satellite series, LEMUR2. LEMUR1 had early versions of Spire's AIS and GNSS payloads on-board and validated critical technology elements needed for further production satellites. In the meantime, Spire also opened offices in Singapore and Glasgow, UK.

In 2015, the first LEMUR2 satellites were launched, which kicked off the build-out of the LEMUR2 constellation. As the constellation reached critical mass and more capabilities were added, such as ADS-B in July 2018, data and analytics products were rolled out in the various markets Spire operates in. Spire has since been providing data and services to a large swath of customers, including many commercial entities, NGOs, and government partners (e.g., NGA, NASA, NOAA, ESA, UKMet Office). Since then, Spire has opened further offices in Boulder, CO, Luxembourg, and Washington DC.

Spire has raised multiple rounds of venture funding since its inception from top-tier financial and institutional investors such as BVP, RRE, Promus, Qualcomm, Luxembourg Future Fund, Mitsui, Itochu, GPO, and many others.

3 Business Overview

3.1 Strategic Direction

All of the products that Spire has developed or is developing follow the three strategic pillars the founders have set out from the beginning:

Fig. 2 ArduSat Satellites being deployed from ISS. (Credit: NASA)

- **Use of Software-Defined Technology**: Spire truly believes software is eating the world and collects data with sensors that are programmable and re-programmable in orbit. It is applying Moore's Law to space, making sure Spire's sensors are as up to date as the latest cellphone.
- **Focus on global and timely coverage**: Spire collects data where no one else can, capturing radio frequencies in remote and inaccessible locations where ground-based receivers cannot reach. Whether it is AIS, ADS-B, GNSS-RO, Total Electron Content (TEC), or other types of measurement – Spire monitors signals that can only provide value being detected en masse from space.
- **Quantity over size**: Spire collects data where the number – not the size – of sensors matters most. Each LEMUR satellite can hold multiple sensors in one 3U bus. By using many satellites and payloads rather than just a few, data is updated more often and delivered to the customer in a more timely fashion. Spire makes physics work in its favor.

3.2 Businesses

Spire currently has five main business lines (see Fig. 3):

- **SENSE:** Spire SENSE provides maritime Domain awareness products.
- **STRATOS**: Spire STRATOS provides critical weather and space weather data and products
- **AIRSAFE**: Spire AIRSAFE provides air traffic data for
- **GVM/Weather**: Spire GVM provides innovative global weather prediction fueled by its data
- **CUSTOM/Orbital Services**: Spire Orbital Services provides the opportunity for others to take advantage of the infrastructure Spire's built over the years and get payloads operating in space rapidly.

The business lines are explained in more detail below.

3.2.1 SENSE: Maritime

Spire Maritime uses satellite AIS data and sophisticated APIs to provide maritime awareness solutions for vessel tracking, ship monitoring, and for viewing historic AIS data and predicted positions.

Spire has one of the largest satellite constellations in the world. Spire Sense Cloud gives you access to this industry-leading AIS data. The Standard and Premium APIs let you access AIS data that has been cleansed: data where the noise and redundancies have been removed. For advanced analytics and planning, the cleansed data is much better than the raw AIS feed, which can be full of errors.

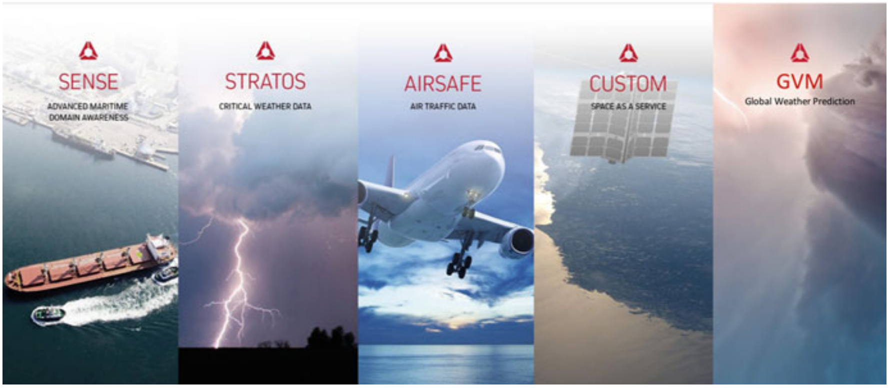

Fig. 3 Spire business lines. (Graphic courtesy of Spire, ©Spire Global)

Spire maritime is pioneering entirely new technologies that are already changing the way maritime data is collected and analyzed. Some examples of Spire Maritime's research and development projects:

- **Predictive analytics**: forecasting ship locations and routing. This is unique, first-in-market technology and is constantly improving.
- **Decollisioning**: Separating AIS signals in high-traffic zones directly from space, improving speed and allowing for more real-time analysis.
- **Weather integration**: Spire's Stratos Cloud is pioneering next-generation weather observation. Fused with Sense Cloud, weather data can increase fuel efficiency and routing among other benefits. Spire maritime also aids the National Oceanic & Atmospheric Administration (NOAA) with their research.

Each of Spire's satellites hosts satellite-based automatic identification system (AIS) receivers (S-AIS) that capture both Class A and B transponder messages, working to ensure global coverage. Spire's geographical focus is on areas generally 50 miles or greater from shorelines, areas outside the range of traditional existing Terrestrial AIS (T-AIS) receiver towers. Spire focuses collection over open ocean and polar regions – areas that are impossible to cover without S-AIS capability – and enhances their S-AIS data with third-party T-AIS data.

3.2.2 STRATOS: Weather Data

The Spire Stratos sensor, which uses signals from global navigation satellites, gathers data about our atmosphere, ionosphere, ground, oceans, and magnetic fields.

GNSS-RO harnesses the power of global navigation systems to capture weather data. As Spire's LEMUR satellites orbit the Earth, they pick up signals from GPS satellites rising and falling on the horizon. These signals, which scrape through the atmosphere, are bent by the moisture that they encounter. Once analyzed, the bent signals tell us a great deal about the temperature, pressure, and humidity of the air on our planet.

Spire is the only commercial entity in the world with the expertise to process raw radio occultation data into measurements to be placed into weather forecasts. Each profile is collected with a Spire satellite and analyzed using Spire's cloud-based processing system. The system is able to scale from thousands to hundreds of thousands of profiles processed per day.

Spire's GNSS receivers continuously track multiple dual-frequency GNSS satellite signals to increase accuracy of their data. Spire tracks all major GNSS constellations, with a 50 Hz frequency of collection. The neutral atmospheric data collected through GNSS-RO has been validated by multiple trusted third parties to be as good or better than that produced by NOAA's COSMIC 1 system, the golden standard in radio occultation.

Spire's GNSS-RO sensor-equipped satellites collect 256 evenly distributed slices of atmospheric data per occultation, measuring from the ground to an altitude of 80 km. In whole, the constellation produces 5000 profiles per day at the time of writing and is still increasing production levels rapidly, collecting both rising and setting occultations.

Spire computes its atmospheric and weather measurements leveraging RO observables including GNSS signal excess phases, bending angles, refractivity profiles, as well as dry and wet temperature and pressure measurements. RO data is collected from antennas in the velocity and antivelocity direction, resulting in a vertical sounding resolution of about 100 m, along-track resolution of about 200 km, across-track resolution of about1 km, and an accuracy of about 0.5 km.

In addition to RO data, Spire collects TEC observations. Spire estimates its ionospheric data to determine TEC to a level comparable to that of COSMIC. The spatial resolution of the associated ionospheric data is estimated to be at about 10 km.

Spire is currently developing a GNSS-Reflectometry (GNSS-R) product that will be supported by two satellites and incorporated into its suite of STRATOS weather products by 2020, as part of a collaboration with the European Space Agency. Through GNSS-R, Spire's satellites will be able to capture and measure GNSS signals that have been reflected off the Earth's surface.

Over oceanic regions, GNSS-R data will provide estimates of sea surface roughness (mean square slope), sea surface wind speed, sea surface heights (altimetry), and sea surface ice extent maps. Over land surfaces, GNSS-R data will provide soil moisture estimates, as well as flood inundation/wetlands extent maps.

3.2.3 AIRSAFE: Aviation

Spire Aviation provides precise position data over land and fills gaps in remote areas of the world that are out of reach of existing ADS-B data collection.

The positional data is enhanced with flight schedule information, aircraft information, and more. With large volumes of position reports every day from over land and sea, Spire Aviation is solving the needs of industries in Aviation and Logistics. Spire's satellites are positioned in areas lacking traditional radar coverage such as over open-ocean, polar regions, and data deserts.

As of July 2018, every new LEMUR satellite is equipped with this capability. Spire is currently working towards growing its ADS-B capable fleet to provide global coverage and performance complying with international regulations.

Spire currently captures four million ADS-B messages from 40,000 aircraft daily but estimates 30 to 40 million per day at FOC. Captured data includes Aircraft Identification (ICAO Address), callsign, speed over ground, vertical rate, latitude and longitude coordinates, barometric altitude and/or GNSS height, aircraft status/operational status/target state, and emergency status.

3.2.4 Weather Prediction

Spire also offers an analytic product referred to as the Spire Operational Forecast (SOF). This is Spire's own global Numerical Weather Prediction (NWP) product which processes its current weather observation data with computer models to form a weather forecast and provide weather prediction alerts. This NWP uses Spire's own proprietary models and input from other global weather models to create an optimized prediction called the SOF. SOF has been specifically developed to meet the needs of commercial and government clients. Spire plans to initially address the weather forecasting requirements of underserved geographic regions and developing nations.

In addition to incorporating Spire's own GNSS-RO data, SOF also incorporates third-party data from NOAA and ECMWF including wave height, sea surface temperature, ocean currents, and sea ice. The model collectively offers the following outputs: surface temperature and winds, accumulated precipitation, cloud cover, land surface temperature and moisture, as well as wind, temperature, and humidity throughout the troposphere and lower stratosphere.

Spire weather forecasts are provided to end users through a set of APIs aimed at allowing the customer to download and manipulate the data on their systems.

3.2.5 CUSTOM/Orbital Services: Space as a Service

Spire works with businesses and government to co-create and deploy customizable data collection satellites within just 6 months. This provides secure, near real-time data from custom payloads fitted to a customer's needs. Spire launches on average every 6–8 weeks and the satellites are built at a rate of up to two per week.

Spire is working with the ESA to demonstrate the power of Space Mission Providers (SMP). As part of the program, Spire is engaging in several demonstration missions that show how Space as a Service can put new payloads in space quickly and at an incredibly reasonable cost.

Spire builds both its own LEMUR satellites, as well as customizable satellites for customers at its facility in Glasgow, United Kingdom. As a supplement to this capability, Spire also offers integration of third-party RF sensors as hosted payloads on its own LEMURs.

Due to Spire's consistent launch schedule and build rate, it can quickly iterate on and deploy satellite capabilities for its customers. Specifically, Spire reports it can deploy a custom satellite within 6–9 months.

4 LEMUR2 Constellation

Spire's constellation consists of 3U LEMUR2 Cubesats. At the time of writing, 84 LEMUR2 platforms are in operations, with a total of over 100 satellites built and launched across over 20 launch campaigns. Twelve satellites have naturally deorbited, and ten were lost in a launch failure in November 2017.

Additional satellites have been shipped to various launch providers, are awaiting launch, or are in the build stages, for a total of about more than 120 LEMUR2 satellites built by Spire's team.

The first LEMUR2 satellites were launched in September 2015 and the most recent ones were deployed in July 2019 (at the time of writing). Seven more launches are manifested in the near future. The Spire constellation has taken advantage of a large number of launch opportunities over the years, working with most of the

industry's launch brokers and launch service providers. A comprehensive launch history is listed in Table 1.

Due to the constellation being built mostly using rideshare launches, the satellites over a heterogeneous set of LEO orbits, between 400 and 600 km in altitude (see Fig. 4), and between equatorial and SSO inclinations, to form a nearly global coverage pattern (see Fig. 5).

This yields a constellation with excellent revisit time and data latency (e.g., average revisit time over 24 h shown in Fig. 6). Orbit spacing is managed using differential drag techniques.

5 Satellite Engineering and Manufacturing

5.1 LEMUR2 Satellite

Spire's LEMUR2 satellites are flexible multisensor platforms built to operate a variety of in-house and hosted payloads. As mentioned above, Spire currently also commercializes this platform through a "Space-as-a-Service" offering with aerospace and defense customers.

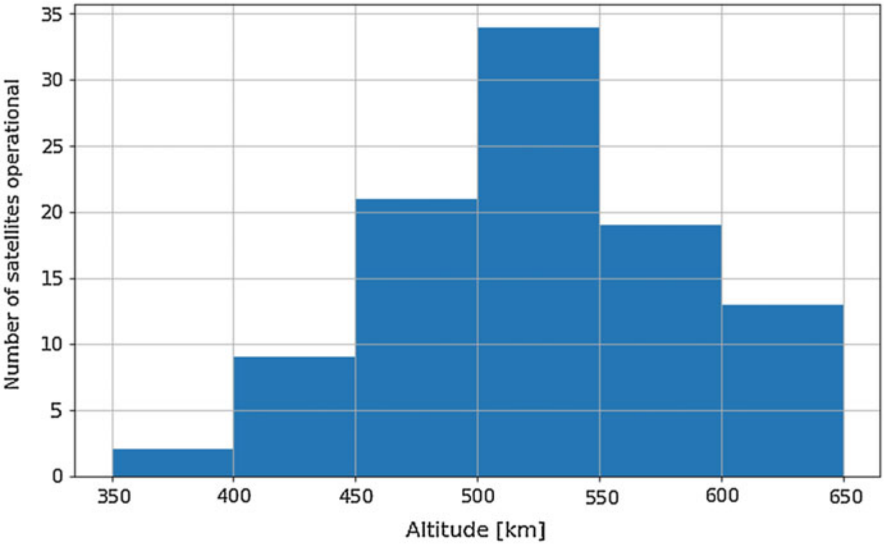

Fig. 4 Current LEMUR2 altitude distribution. (Graphic courtesy of Spire, ©Spire Global)

Spire designs, builds, and tests all of its satellites in-house at its Glasgow offices. The company uses adapted COTS electronics to ensure access to the latest technologies, increase iteration speed, and reduce cost. The satellites are placed in low-Earth orbit and are scheduled to be retired and replaced every 2–3 years. Spire adheres to internationally recognized guidelines for disposal of old satellites.

The satellites are multisensor and carry multiple payloads per vehicle. Spire's production satellite carries all three of its main payloads: AIS, ADS-B, and GNSS sensing. Spire also launches other versions of satellites with more experimental payloads, or to demonstrate critical new technologies, such as a set of satellites with GNSS reflections (GNSS-R) technology, or satellites with a GPU-based parallel computing payload on-board.

The LEMUR2 platform (Fig. 7) is a 3U cubesat, with multiple deployable antennas and solar arrays. LEMUR2s operate on UHF, S-band X-band frequencies. Spire has built over 20 versions of its platform, through four major generations.

As a perk in Spire, employees are each allowed to name one LEMUR2 satellite, which sometimes results in satellite names with interesting stories connected to them, such as "LEMUR-2-CUBECHEESE," "LEMUR-2-SPIREMINIONS," or "LEMUR-2-BROWNCOW."

5.2 Systems Engineering Approach

Spire borrows heavily from agile software methodologies in the ways it thinks about satellite iterations and system engineering. It is a more cyclical and iterative model than is usual in the aerospace industry (see Fig. 8).

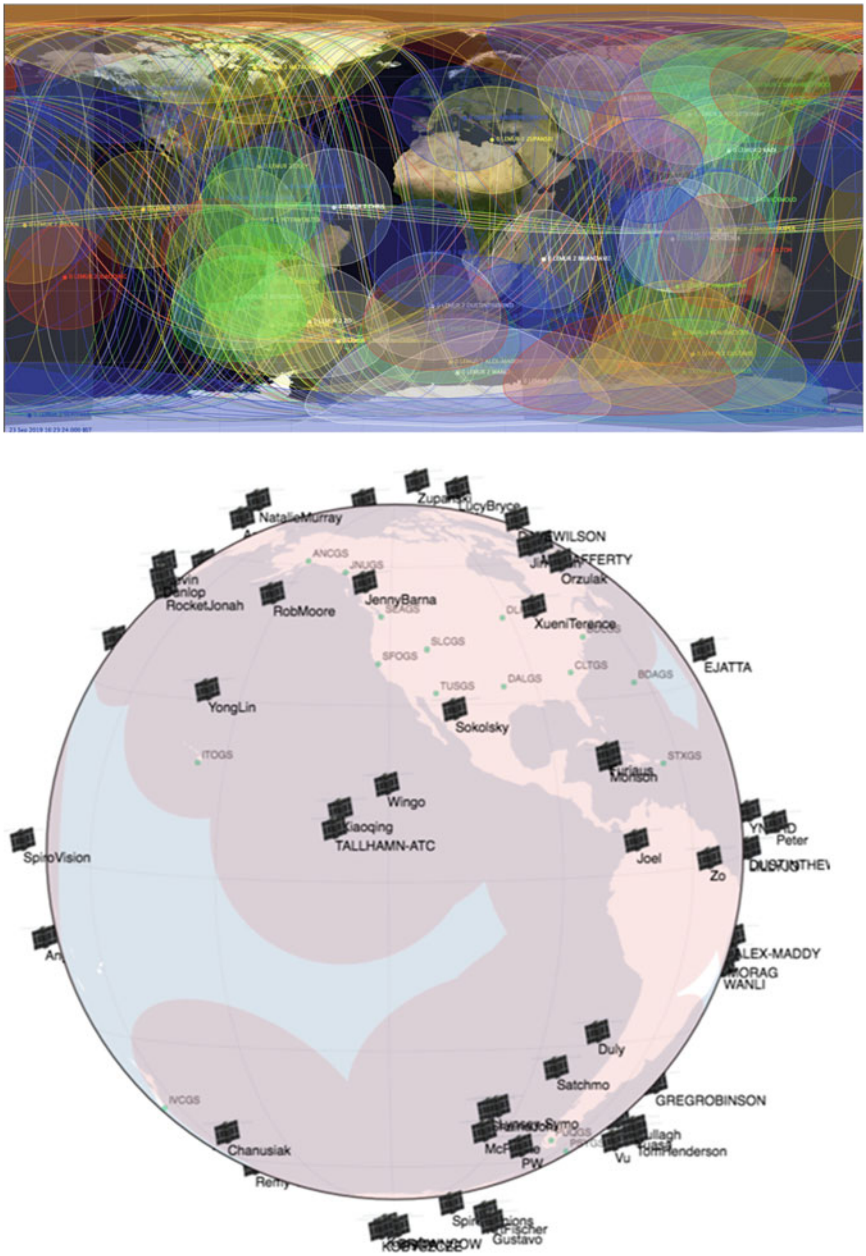

Fig. 5 Current LEMUR2 constellation overview. (Graphic courtesy of Spire, ©Spire Global)

Spire engineering is not afraid to try something new and keeps only as long as it helps to achieve the goals. If something's working, it stays. If it is not working, or not providing progress, the process should be cut out – to not hold on to something just

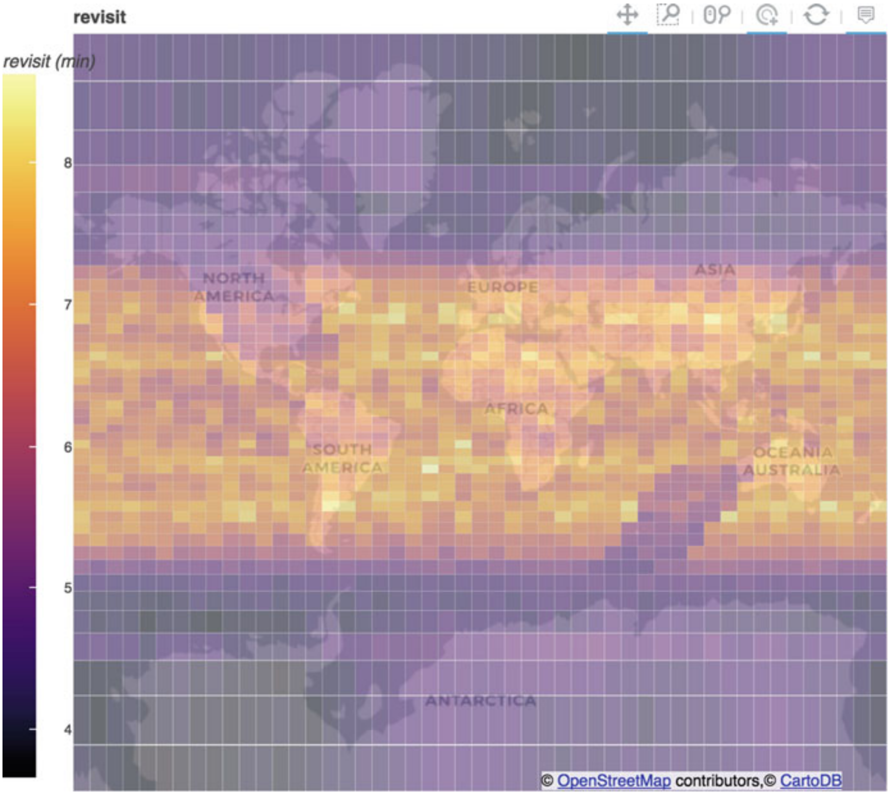

Fig. 6 Example revisit time distribution for LEMUR2 constellation. (Graphic courtesy of Spire, ©Spire Global)

because it has been done in a certain way for a long time. There is nothing sacred about the process itself, only what the process lets us accomplish.

As new feature ideas enter the satellite pipeline following a customer request or need, or following engineering-driven improvements, a standard scope of work is prepared and the systems engineering process is kicked off for the new version of satellite.

At the mission level, the inputs to the process are the mission requirements and objectives. High-level trade-offs are done to determine mission feasibility and overall scope of change to the LEMUR satellite platform. This includes verifying the design budgets (i.e., mass and volume budget, RF budgets, power budget, data budget), any necessary constellation analysis or simulation, high level subsystem trade-offs, and cost and timeline trade-off evaluation. Based on the output of these trade-offs, a high-level feature list is compiled for the satellite system level. If any requirements need to be placed on any of the ground systems (e.g., operations, ground stations), those are identified at this stage as well.

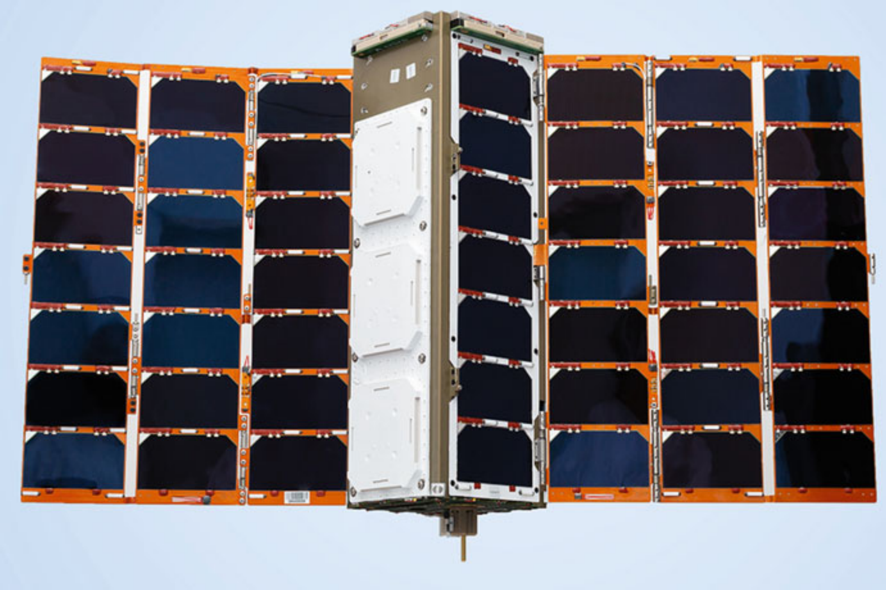

Fig. 7 Spire LEMUR2 satellite. (Graphic courtesy of Spire, ©Spire Global)

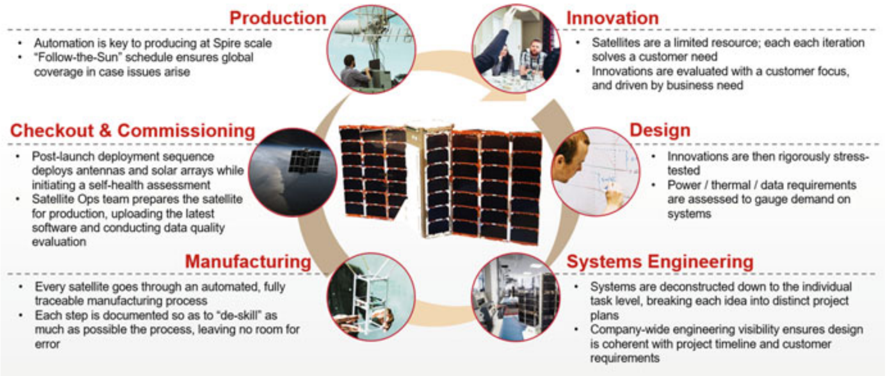

Innovation

- Satellites are a limited resource; each each iteration solves a customer need
- Innovations are evaluated with a customer focus, and driven by business need

Design

- Innovations are then rigorously stress-tested
- Power / thermal / data requirements are assessed to gauge demand on systems

Systems Engineering

- Systems are deconstructed down to the individual task level, breaking each idea into distinct project plans
- Company-wide engineering visibility ensures design is coherent with project timeline and customer requirements

Manufacturing

- Every satellite goes through an automated, fully traceable manufacturing process
- Each step is documented so as to "de-skill" as much as possible the process, leaving no room for error

Checkout & Commissioning

- Post-launch deployment sequence deploys antennas and solar arrays while initiating a self-health assessment
- Satellite Ops team prepares the satellite for production, uploading the latest software and conducting data quality evaluation

Production

- Automation is key to producing at Spire scale
- "Follow-the-Sun" schedule ensures global coverage in case issues arise

Fig. 8 Systems engineering approach. (Graphic courtesy of Spire, ©Spire Global)

Once the mission requirements are translated into the system level in the form of a high-level satellite feature list and a set of budgets, the satellite deep-dive review is held with the satellite design team. The output of this review is a detailed requirements list for all satellite subsystems and a list of actions for the system level design. The satellite qualification plan is put together at this stage, as well as the subsystem qualification plans.

Based on the detailed design requirements, the necessary subsystems are (re) designed and go through thorough design reviews. The subsystems all have individual qualification plans that are defined based on the overall satellite qualification plan and the subsystem requirements. Subsystem prototype hardware is acquired and put through the qualification plan.

Then, based on the qualification test report, a go/no-go decision is made to either make alterations to the subsystem design or proceed to acquire flight hardware for the design. In the subsystem qualification stage, all the documentation and test hardware and software needed to hand off the designs to the satellite manufacturing team is completed.

Once all subsystem qualification tests have passed and the necessary prototype hardware is in house, a qualification model (QM) is built. The QM is a full equivalent of what will later be the flight model (FM). The qualification model serves two purposes: it will be used for integrated testing against the satellite qualification plan, and after passing the satellite qualification review the QM will remain on the ground as the representative ground test platform for that satellite revision. At that point the QM is handed over to the satellite operations team.

After the qualification tests have passed, the designs are handed off to the manufacturing team and flight hardware can then be acquired by the supply chain team as necessary for the satellite builds. Each satellite goes through functional and environmental acceptance testing before delivery. At the end of the test campaign, a Certificate of Compliance (CoC) is produced that is signed off by the satellite design team, the manufacturing team, and the satellite operations mission director.

Based on the CoC, a mission readiness review is held before deployment to ensure the satellite operations team is ready to put the satellite into production. The output is a list of action items to prepare the ground systems and satellite operations teams. After initial checkout and commissioning, satellite operations produce a postdeployment checkout report, which indicates the performance of the satellite in orbit and describes any issues found against the checkout procedures.

5.3 Manufacturing and Vertical Integration

Spire does all of its satellite systems design, subsystem design, and satellite manufacturing in-house (e.g., see Fig. 9). Early on, Spire's identified that one of the keys to success in building out a rapidly changing production constellation was owning a much of the supply chain as possible.

Owning almost all of the steps in the satellite value chain has yielded three main benefits:

- **Speed:** Vertical integration enables a higher speed for various reasons: systems knowledge resides in-house allowing faster iteration and issue resolution, test facilities do not need to be booked weeks in advance with no transport required, etc.
- **Reliability:** Insight in all the design aspects and details guarantees the ability to address issues that arise on any level of the design. This enables the ability to guarantee the reliability of the spacecraft to the desired level. For example, the

Fig. 9 LEMUR2 satellites in the Spire cleanroom. (Graphic courtesy of Spire, ©Spire Global)

exact batch of chips assembled onto a printed circuit assembly, or the exact piece of software running on a critical system is always known. While high levels of reliability can eventually be targeted, the immediate benefit is in repeatability and traceability.

- **Control:** This enables faster iteration on all aspects of the chain, across hardware and software, allows fast scaling, and bolsters innovation. It enables the ability to build and include new features very quickly.

The combination of these factors results in the fastest path to high-quality satellites with the lowest amount of risk possible.

While not the main driver, cost is also drastically reduced due to vertical integration. Spire still works with selected vendors and partners, but ensures there is a relationship that is mutually beneficial and often exceeds just a vendor-buyer relationship.

In addition, bringing AIT facilities in house has further sped up the manufacturing cycle, to the point where it is possible to build and test satellites in just a few days (see Fig. 10).

Spire has access to vibration testing, thermal (vacuum) testing, solar testing, magnetic testing, and RF/EMC testing in-house (e.g., see Fig. 11).

To keep track of all the design and manufacturing flows, Spire has developed a comprehensive software suite that allows us to not only track all designs and

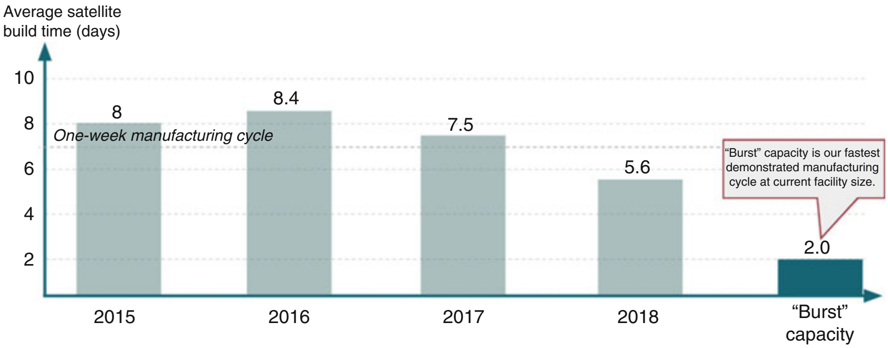

Fig. 10 Spire's build cadence over the years. (Graphic courtesy of Spire, ©Spire Global)

Fig. 11 A Spire technician manipulates a LEMUR2 satellite in Spire's EMC chamber. (Graphic courtesy of Spire, ©Spire Global)

processes but also to ensure all documentation needed to produce satellites is present.

The "Spire Requirement Planning" (SRP) tool (screenshot shown in Fig. 12) provides us with features commonly found in PLM, ERP, and MRP systems, allowing us to effectively bring all design data, supply chain and finance data, and manufacturing data together in the same place.

Design data is kept in the system for all items that are present on the satellite's Bill of Materials (BOM). Detailed design information is made available for the different types of designs (e.g., schematics, mechanical drawings). When new designs are entered in the system, all information for the design items is gradually populated throughout the design cycle, until everything is present, at which point it can be handed over to supply chain to order components and to manufacture satellites. Once hardware is built, it is also tracked in this system, along with all performance and test

data, such that later when satellites are in orbit, there is complete traceability to the subsystem and component level. This is data often used in debugging on-orbit issues or anomalies.

6 Ground Systems

6.1 Ground Stations

Since its founding, Spire has also owned the ground system element of the space data chain. To fully enable flexibility in acquiring data and operating the constellation, control of the ground station network was necessary from day one.

For a constellation operator, it is paramount to have access to every opportunity for a groundstation contact, regardless of whether it is eventually used or not. For us, having the flexibility to schedule (or not) a ground station to optimize constellation contact time is important and would be much harder with only limited windows of opportunity at certain stations, or having to schedule windows well in advance. As a

Fig. 13 Spire Groundstation Network. (Graphic courtesy of Spire, ©Spire Global)

side benefit, it also results in a lower cost given due to only having to guarantee compatibility with Spire's constellation.

Starting with a single groundstation site in San Francisco in 2012, the network has expanded to over 30 sites across the world, with hardware deployed to all 7 continents (current coverage illustrated in Fig. 13).

The network consists of a combination of UHF, S-band, and X-band groundstations (some examples in Fig. 14).

The groundstations operate in bent-pipe mode, which means that no data is ever left un-encrypted on a groundstation. The groundstations are deployed, maintained, and monitored by Spire's own field team. A similar iterative approach to groundstation design as utilized by the spacecraft team is used by the groundstations team.

In addition to the Spire-run groundstations, surge-support ground stations from partner groundstation networks are also used if needed.

6.2 Constellation Management

Operating a large cubesat constellation comes with a few challenges:

- The iterative design approach yields a heterogeneous constellation, where every launched batch might at best have slight hardware differences and at most completely different payloads.
- As satellite software is often updated, various satellites will run different versions of software, even within a single launch batch.
- Each satellite usually develops its own "personality," given the specific hardware it has on board
- Operational priorities can shift based on customer demand.

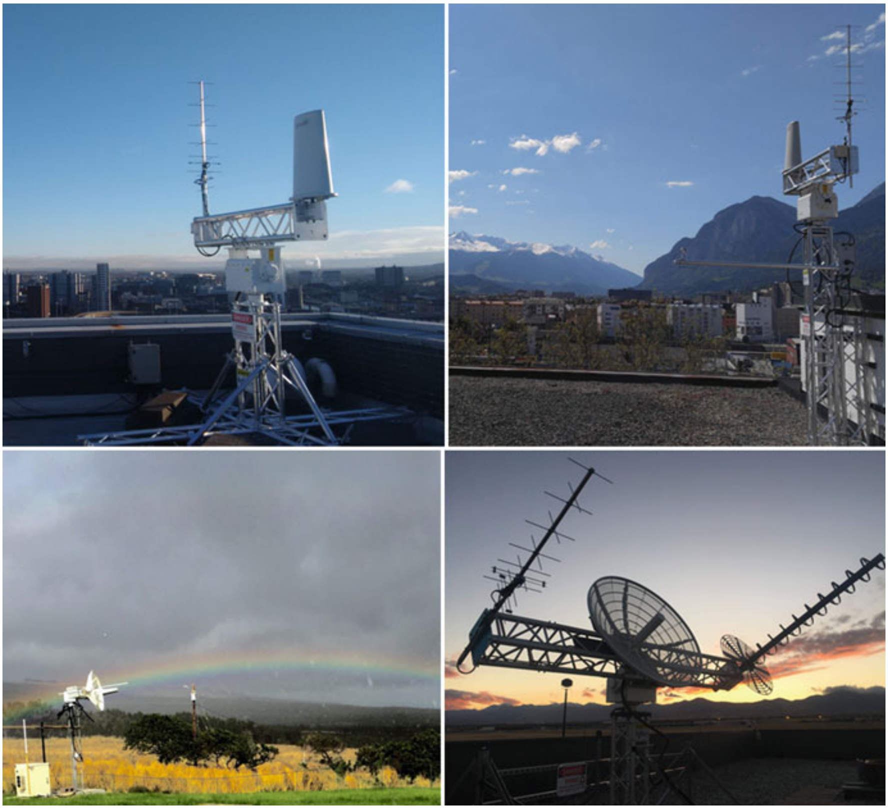

Fig. 14 Spire Groundstation Examples. (Graphic courtesy of Spire, ©Spire Global)

Additionally, all of the above issues are also present for groundstations.

So to be able to operate efficiently a number of backend systems are required.

6.2.1 Per-satellite Configuration

As indicated above, each satellite usually ends up having a unique personality, resulting in the need for a per-satellite configuration database. This database keeps track of things like satellite frequency configuration and licensing jurisdiction, status of subsystems, status of watchdogs, timestamps of the last time maintenance procedures were executed, software interface version, ADCS control mode, telemetry alerting limits, etc. Whenever missions are scheduled and executed, the satellite configuration database is used to determine how to interact with a specific satellite and what software interfaces to use.

In addition, the database also contains groundstation characteristics, so the scheduler (see below) knows which satellites are compatible with which groundstations.

6.2.2 Scheduling, Automation, and Data Management

Managing a few satellites can be done by hand by a team of operators. Managing 20 satellites can be done with a little bit of scripting and simple automation. Managing more than 50 satellites requires a completely different level of automation. Satellites can no longer be thought of as individual assets, but rather the constellation has to be considered as a whole. Assets need to be continually optimized to provide maximum product value.

Two major software systems support this. In space, satellites run a suite of automation software. This software knows for each task that the satellite has to perform the actions it has to take on-board to complete this task and present the resulting data over the next groundstation contract. On the ground, a central scheduler optimizes the schedule for satellite/groundstation contacts as well as for payload operation windows. As the schedule gets synchronized to the constellation, satellites capture the data they are instructed to collect and downlink it as they pass over groundstations (either self-initiated or initiated by uplink commands). As time progresses, based on feedback from the constellation on how captures are being executed, the schedules can be adapted to optimize for customer value. If no major issues arise, no human interaction is required for this system to run and deliver data to APIs.

After the data is downlinked, it is pushed to a downstream processing or analytics system based on the data type, after which it is made available in a customer facing APIs.

6.2.3 Incident Management

Given the level of automation present, the main job of the satellite operations team is not to directly command or task the satellites, but rather to monitor the constellation for any anomalies that might occur, and manage those appropriately. To be able to do this effectively, an incident management system is required, that can link back to operational data, on-ground test results, and any other information that can help resolve the issues at hand. The satellite operations team can then feed this information back to the satellite engineering team as new satellite versions are being developed.

7 Conclusion

Spire's multisensor CubeSat constellation approach has enabled it to quickly build out a suite of diverse and high-quality data and analytics products. Fueled by vertical integration and constant iteration and innovation, it is able to improve data volumes and quality. Turning a proof of concept into a large-scale reliable production system requires a lot of systems and work behind the scenes, which Spire has built over the past 7 years. With all of this in place, Spire is now in the middle of commercializing its product suites and attacking new markets.

An Overview of Small Satellite Initiatives in Brazil

Rodrigo Leonardi and Adriana Elysa Alimandro Corrêa

Contents

Abstract

This chapter presents an overview of past and ongoing small satellite-related initiatives in Brazil and discusses the importance of these initiatives on several fronts such as education, training, research, science, applications, and business opportunities in the context of the Brazilian space sector. For this purpose, a brief history of early initiatives in the 1990s is provided together with a description of recent national small satellite projects, from mini down to pico-space objects, and an examination of synergies with other space activities in Brazil. This compilation of the major facts about the use of small satellites in Brazil is a helpful contribution for professionals interested in space activities in the country and in South America.

1 Introduction

Early studies and efforts to develop small satellites in Brazil can be traced back to COBAE, which was a commission, created in 1971, with the purpose of providing advice for the Brazilian government about the development of space activities in the country. COBAE activities were important to enable the very first satellite developed entirely in Brazil – more specifically at the Brazilian National Institute for Space Research (Portuguese: *Instituto Nacional de Pesquisas Espaciais*; INPE) – named SCD-1, a small satellite with a mass of 115 kg, that was launched into space by a Pegasus rocket in 1993 with the mission of receiving and retransmitting environmental data, from ground and ocean automatic data collection platforms, to tracking ground stations.

But the very first Brazilian small satellite launched into space was actually an initiative of one single individual. The small satellite Dove-OSCAR 17 was a Brazilian educational and an amateur radio satellite developed by Mr. Júnior Torres de Castro, an engineer from the state of São Paulo, using resources of his own. Dove-OSCAR 17 had a mass of about 13 kg and was launched in 1990 by an Ariane 4 launch vehicle as a piggyback of the French satellite Spot 2. It carried on-board a Digital Orbiting Voice Encoder designed to transmit synthesized voice messages and telemetry data. Although it was proposed and executed by a Brazilian engineer, the project took place at AMSAT Labs, Colorado, USA. Nonetheless, it is considered a Brazilian space object indeed by the United Nations Office for Outer Space Affairs.

These two small satellite projects, SCD-1 and Dove-OSCAR 17, followed very different paths and approaches to fulfill their missions. SCD-1 was a government planned and executed mission using national engineering and resources – what one would refer these days as the traditional approach – while Dove-OSCAR 17 was a bottom-up mission of opportunity with enormous support from international partners and with some elements of what one would refer these days as lean approach. But both were definitely pioneers of the small satellite category in Brazil and, back then, very innovative projects. And after them, Brazil embarked on other space projects, although did not maintain a constant flow of small satellite missions, as can be seen in Table 1 that displays a timeline of Brazilian space objects, under 500 kg, launched into space.

Meanwhile, Brazil established its space agency in 1994, and, since then, the Brazilian Space Agency (Portuguese: *Agência Espacial Brasileira*; AEB) is the civilian entity responsible for the country's space policy and program. Besides, in the aftermath of the tragical Alcântara VLS Brazilian launch vehicle accident in 2003, Brazil actually prioritized medium (e.g., China-Brazil Earth Resources

Satellite CBERS) and large (e.g., Geostationary Defense and Strategic Communications Satellite SGDC) space objects initiatives. But, recently, after more than a decade without expressive results on space objects under 500 kg, there is again a small satellite trend gaining visibility and importance in the Brazilian space sector. This chapter offers a compilation of the major facts about the use of small satellites in Brazil as a helpful contribution for professionals interested in space activities in the country and in South America.

The chapter is organized as follows. Section "Multi Mission Platform" contains a description of the basic elements of the Brazilian Multi Mission Platform for mini satellites. Section "Amazonia-1" presents the satellite Amazonia-1, scheduled for launch in 2020, and the associated technological challenges and gains. Section "Brazilian Nanosatellites" summarizes the current scenario of nanosatellites in Brazil. Section "Launch Vehicle for Small Satellites" reports some Brazilian initiatives that aim to provide access to space for small satellites. Section "Educational Initiatives" provides comments on the importance of small satellites for science and technology education. Lastly, section "Conclusions" offers a view of future opportunities and conclusions.

2 Multi Mission Platform

The Multi Mission Platform (MMP) is a generic platform for mini satellites developed in Brazil (e.g., (INPE)). Its service module – a satellite mounting platform with a mass of 250 kg – provides all necessary resources to support the operation, in orbit, for payloads up to 280 kg. The project is a joint effort of INPE and AEB, and it is one of the most important initiatives Brazil has carried out in the field of small satellites. Its propulsion, solar generator, thermal control, and mechanical structure subsystems were completely developed and manufactured in Brazil. The attitude and orbit control and on-board supervision subsystem were developed in cooperation with Argentina, and the power supply was designed in Brazil using hardware available in the international market. One of the main drivers of the MPP project is to allow the reduction of costs and development time of small satellites that adopt its service module as a reliable solution for their mission (the MMP serves primarily as a platform for small objects, but it is also suitable for satellites with a mass slightly above 500 kg). The MMP is planned to be qualified in space through the Amazonia-1 mission. Additionally, INPE and AEB have already carried out conceptual studies for future uses of the MMP such as Synthetic-Aperture Radar (SAR) applications and Ocean monitoring. The MMP is a project with considerable participation of Brazilian space companies. Figure 1 displays a schematic view of the MMP.

3 Amazonia-1

The Amazonia-1 is the first Earth Observation satellite based on the MMP, and it was designed, integrated, and tested in Brazilian facilities (e.g., (INPE da Silva et al. 2014; Chagas and Lopes 2014)). INPE and AEB are working together to ensure success of this Sun synchronous (polar) orbiting satellite that aims to generate images over the Brazilian territory in order to observe and monitor the Amazon rainforest, especially deforestation in the region, as well as the diversified agriculture throughout the country with a high revisiting rate – 5 days – working in synergy with existing environmental INPE programs and Amazon deforestation databases such as PRODES and DETER. In addition, it is expected that Amazonia-1 data would be useful as well for monitoring coastal zones, reservoirs, forests, and disasters.

For this purpose, it carries on-board a wide-view optical imager capable of observing a range swath of approximately 850 km with 60 m resolution in four spectral bands – visible and near-infrared. The high revisiting rate is extremely valuable in applications for deforestation monitoring and alert in the Amazon, as it increases the likelihood of capturing useful images in the face of cloud cover in the region. The Amazonia-1 satellite consists of two independent modules: a service module, which is the MMP, and a payload module, which houses imaging cameras and equipment for recording and transmitting image data. The MMP has the purpose of bringing together in a single platform all the equipment that performs functions necessary for the maintenance of a satellite – pointing, power generation, thermal control, data management, and communication service.

The Amazonia-1 satellite is a very important milestone for the Brazilian space sector, and it is scheduled for launch in 2020 on a PSLV launcher. Figure 2 shows the Amazonia-1 through AIT at INPE and some subsystems developed and

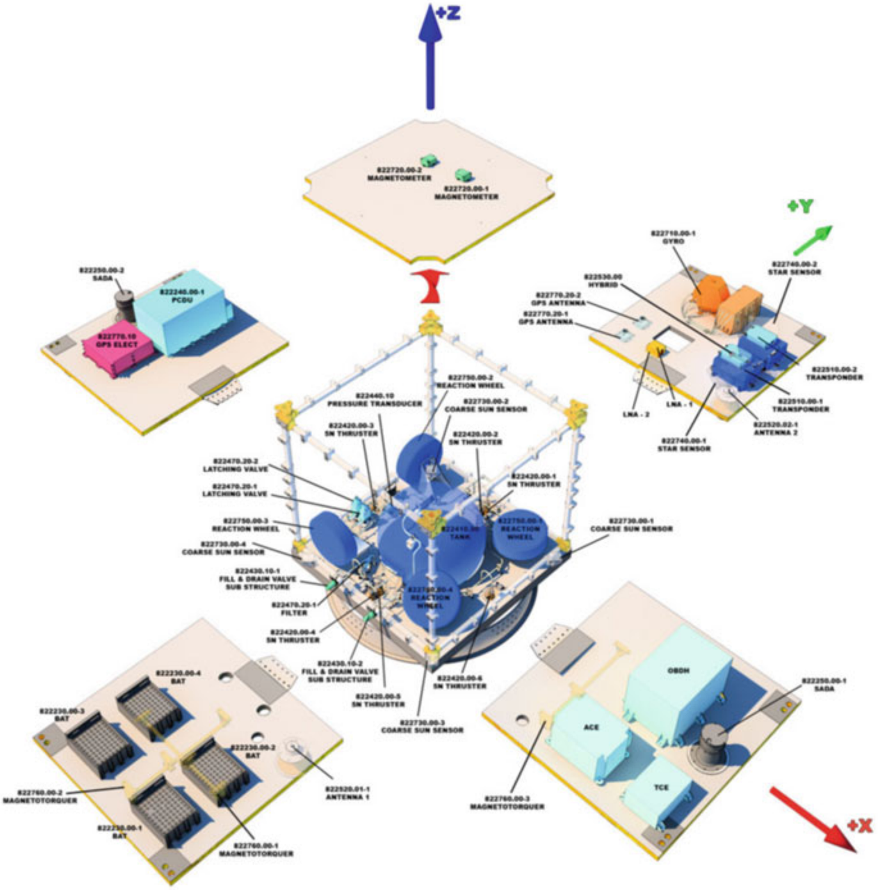

Fig. 1 Schematic view of the Multi Mission Platform embedded in a Cartesian coordinate system. On top (+Z), two magnetometers are positioned as part of the Attitude Control and Board Supervision Subsystem – ACDH. The ACDH also contains the On Board Data Handling (OBDH) computer (+X), the Attitude and Orbit Control System (AOCS) computer, propulsion control electronics (−Z), Sun sensors (−Z), star sensors (+Y), gyros (+Y), reaction wheels (−Z), magnetorquer (+X and Y), GPS receivers (−X), and on-board control and control systems software, embedded in their computers. The propulsion subsystem is positioned at the bottom (−Z) and contains thrusters, valves, filters, propellant tank, pressure transducer, and pipe assembly. On the +Y side also are positioned the antennas, part of the telemetry and remote control subsystem (TT&C), and the transponders. On the Y side are positioned other antenna and the batteries, part of the power supply subsystem. The power supply subsystem also contains the power distribution and conditioning unit (PCDU), positioned at -X side, and the solar generator drive group (SADE and SADA), at X and + X sides. During the nominal operation mode, the -Y face would be always pointed to Earth. In emergency mode, the satellite attitude control would point -Z facing the Sun, in order to warm up the propulsion subsystem elements, and two rotations per orbit would be imposed around the Z axis, in order to distribute external heat loads equally on the lateral panels. (Courtesy image from INPE)

The solar generator subsystem of the MMP fully developed and manufactured in Brazil. *Bottom center and right*. Components of the MMP attitude and orbit control and on-board supervision subsystem developed in cooperation with Argentina. (Courtesy images from INPE)

manufactured in Brazil and in South America. This important mission is driven by Earth Observation demands and an agenda that places national industry participation and national capacity building in strategic technologies among the central objectives of the Brazilian Space Program. About 60% of the budget resources destined to the development of the Amazonia-1 satellite were destined to contracts signed by the national industry for the development and manufacture of subsystems and equipment. More specifically, the following equipment/subsystems were developed by Brazilian companies: service and payload module structure (Cenic Engenharia), solar generator (Orbital Engenharia), propulsion (Fibraforte), WFI Camera (Equatorial & Opto), X-band antenna and remote terminal unit (Omnisys Engenharia), digital data recorder (Equatorial Sistemas), and DC/DC (AEL Sistemas). The main technological gains for the Brazilian space program resulting from the Amazonia-1 mission are:

- The qualification of the MMP as a space system, improving reliability and significant reductions in schedules and costs for the development of future satellite missions based on this platform.
- Consolidation of the knowledge in Brazil of the complete cycle of development of stabilized satellites in three axes, also gaining maturity in the activities of integration and satellite tests.
- Development of the propulsion of the attitude and orbit control subsystem in the national industry, although using parts acquired abroad.
- Development in the national industry of the opening mechanisms of the solar panel.

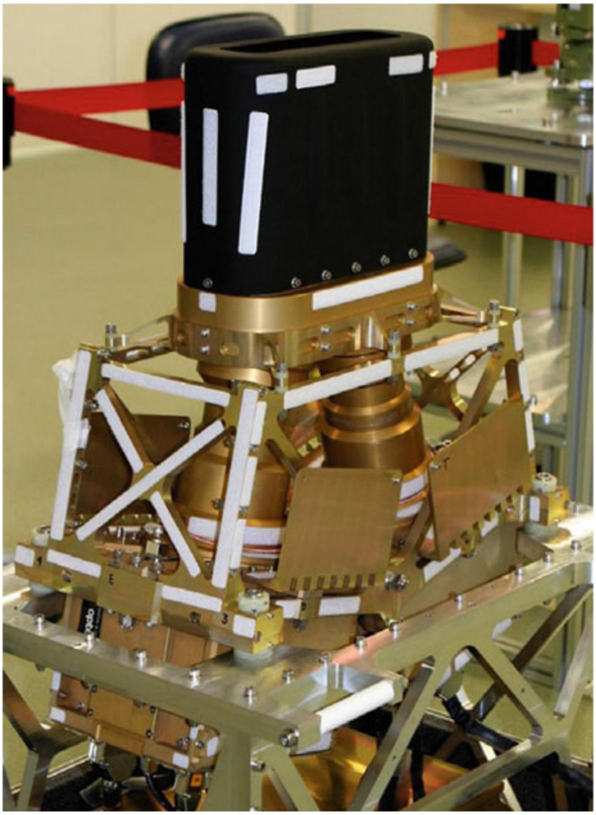

Fig. 3 Wide Field Imager (WFI) Camera developed in Brazil. (Courtesy image from INPE)

- Country capacity to carry out Launch and Early Orbit Phase (LEOP).
- Reliability, as future missions will benefit from project maturity.

Together with the satellite itself, the payload subsystem was also developed and manufactured in Brazil. The Amazonia-1 imager is a Wide Field Imager (WFI) Camera developed and used in the CBERS Program, therefore, an equipment already with flight heritage. The design, assembly, integration, and testing of signal processing electronics and mechanical and thermal design, assembly, integration, and testing of the camera were all performed in Brazil. Figure 3 shows the Amazonia-1 WFI payload camera.

4 Brazilian Nanosatellites

Nanosatellites represent an important technology trend of the global space segment and – in this satellite category – CubeSats are a good tracer of the growing demand for small satellite space applications and solutions. These platforms are being used for several space applications, such as education, Earth remote sensing, science, and defense as well described and analyzed in (Villela et al. 2019).

More than a thousand CubeSats have been launched over the past two decades. And, until the end of 2019, 16 CubeSats assembled in South America – 5 of them in Brazil – have been launched into space. Brazilian universities are playing an important role in proposing and developing CubeSats in Brazil. The NanoSatC-Br1 was the first Brazilian CubeSat launched into space. It was a 1U CubeSat proposed for studying the South American Magnetic Anomaly (Schuch et al. 2019). It was followed by Aesp-14, a 1U CubeSat for testing subsystems developed in Brazil (Bürguer et al. 2014); Serpens, a 3U educational CubeSat for research university experiments (Ishioka et al. 2016); Itasat, a 6U CubeSat designed to serve as a platform for future missions as well as testing Brazilian experiments, a transponder, a GPS receiver, and a radio amateur communication device (Shibuya Sato et al. 2019); and FloripaSat, a CubeSat carrying an ITAR-free FPGA, and a single-event upset counter (Slongo et al. 2019). All these projects share the common goals of capacity building, hands-on training, and Research and Development (R&D) under university leadership. All these objects were sponsored by AEB. And the latest object in this timeline, FloripaSat, had the opportunity of being launched as a piggyback of another Brazilian satellite, the CBERS-4A – a remote sensing space object with a mass of 1980 kg – in a classic example of when the AIT activities of a CubeSat have to be synchronized with the project schedule of a much larger satellite. An illustration displaying some Brazilian CubeSats and their respective payloads is shown in Fig. 4.

And other missions are already in the pipeline getting ready for launch. The NanoSatC-Br2 is a Brazilian 2U CubeSat envisaged for studying the Earth's magnetic field. Sport is a NASA-AEB-INPE-ITA – Technological Institute of Aeronautics (Portuguese: *Instituto Tecnológico e Aeronáutica*; ITA) – joint science 6U CubeSat mission targeting space weather, more specifically, to study the preconditions leading to equatorial plasma bubbles and scintillation in the ionosphere that disrupt radio communication systems, satellite technologies, and Global Positioning System (GPS) signals (Loures da Costa et al. 2018). The United States provides the science instruments and launch, Brazil provides the spacecraft (a legacy from the Itasat mission) and the operations, and the scientific data analysis is jointly done by Brazilian and North American scientists. The Sport mission is a prime example where a nanosatellite proves to be an excellent framework for engaging in international collaboration.

Despite the fact that the number of CubeSat-based space missions in Brazil is still modest, there has been an increase of initiatives resulting in a scenario where Brazilian CubeSat missions are going beyond the goals of R&D and aim to deliver quality data for science and services. In the proceedings of the Brazilian Aerospace Congress held in 2019 (Anais 2019), there are several proposals for CubeSat-based missions and nanosatellites associated technology: Raiosat is an INPE 3U CubeSat mission aiming to detect and study lightning flashes; NanoMirax is an INPE initiative, in partnership with a Brazilian startup, to detect cosmic explosions in X-ray with a CubeSat platform; and Conasat is an INPE proposal for putting in place

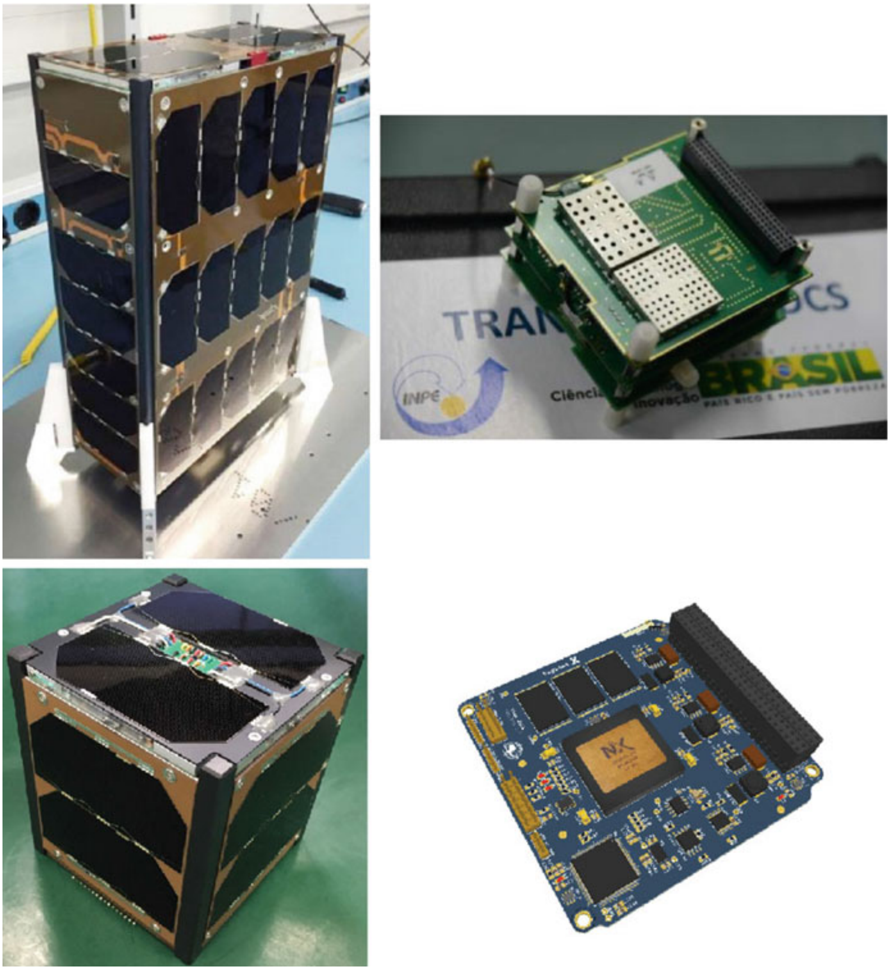

Fig. 4 Latest Brazilian CubeSats launched into space as displayed in Table 1. *Top row.* A picture of the 6U Itasat protoflight model and one of the payloads, a Data Collection Transponder. *Bottom row.* A picture of FloripaSat and one of the payloads, a board for testing an ITAR-free FPGA. (Courtesy images from ITA, INPE, and UFSC)

a CubeSat constellation for environmental monitoring. Furthermore, a few other missions are being proposed by different Brazilian stakeholders, for instance, Garatéa-L is a private enterprise to send a CubeSat to the Moon; Alfa Crux is an university initiative to establish a CubeSat constellation to provide communication links in regions of difficult access; and Brisa is a CubeSat proposal, from a Brazilian think-tank organization, for SWIR applications. Although a complete list of proposals being discussed in the Brazilian community is beyond the scope of this overview, it can surely state that these missions are a driver for further small satellite-related research and development. Just browsing (Anais 2019), one would find ongoing research in Brazil on nanosat as, for example, battery and solar panels, UHF and S-Band antennas, space tethers, transponders, and payloads.

A survey carried out for the United Nations/Brazil Symposium on Basic Space Technology (Creating Novel Opportunities with Small Satellite Space Missions, Natal 2018), co-organized by the United Nations Office for Outer Space Affairs and the Government of Brazil, identified a Brazilian network of 253 colleagues contributing to the field of nanosatellites. Half of them held a PhD, 24% held a MSc, 23% were grad students, and 3% were high school students. This statistic clearly shows that students are a significant part and a driving force in the Brazilian nanosatellite community.

In parallel, the Brazilian industry is also investing efforts to explore nano-platforms for offering their services and products. For instance, the Vcub is the first CubeSat proposed, designed, and developed by a Brazilian company, Visiona, a joint venture between Embraer and Telebrás, in search of a sustainable business model, precision agriculture, for instance, based on nanosatellites. Some other Brazilian companies (e.g., Criar Space Systems) and startups (e.g., Cron *Sistemas e Tecnologias* Ltda) are also taking a chance in the nanosatellite segment.

5 Launch Vehicle for Small Satellites

Brazil has a long and successful tradition with sounding rockets (e.g., VSB-30). But the country has not yet developed a national launch vehicle for inserting space objects into a stable orbit. This is in part a fallout of the Alcântara – Maranhão State – accident in 2003, when an explosion, caused by the accidental ignition of 1 of the 4 engines of the Brazilian rocket VLS, conceived for inserting small satellites into orbit, caused the tragical death of 21 people, together with the loss of the rocket, 2 small satellites, and the surrounding infrastructure, and resulting in a setback to the plans of a Brazilian launcher. Subsequently, a launch vehicle cooperation between Brazil and Ukraine did not deliver results as expected, turning it into a complicated situation to deal with. But Brazil efforts of developing a national launcher continues.

Nowadays, the Brazilian Aeronautics and Space Institute (Portuguese: *Instituto de Aeronáutica e Espaço*; IAE) is developing a Microsatellite Launch Vehicle named VLM. In order to achieve this objective, Brazil has developed and qualified a solid rocket motor, named S-44, with a performance of about 38kN of average thrust and 277 s of vacuum specific impulse, and is qualifying a solid rocket engine, named S-50, designed to have about 440kN of average thrust and 266 s of sea level specific impulse. Considering the current status of development of the S-50 solid rocket motor, some concepts for a Brazilian launch vehicle configuration to deliver small satellites to low-Earth orbit – from the Alcântara Launch Center, Brazil – would be capable of sending payloads in the range of 350–750 kg in a variety of orbit inclinations, as described in details in (da Cas et al. 2019). If Brazil succeeds in this endeavor, the strategic importance of small satellites for the Brazilian space program would be greater than ever.

Similar to what happens to nanosatellites, new stakeholders are also taking a chance in the launch vehicle segment. For instance, the Acrux Aerospace Technologies is a Brazilian startup proposing a rocket for small satellites.

Additionally, Brazil and the United States have celebrated in 2019 a technology safeguards agreement (TSA) in order to allow commercial launch activities from the Alcântara Launch Center. There is expectation that with this TSA in place, Brazil would play a part in the launch market, including offers of access to space for small satellites.

6 Educational Initiatives

Small satellites are an excellent venue for promoting space science and technology education, and AEB has been exploring them to conduct STEM activities, organize workshops and events, as well as continuously promote human capacity building for national space activities.

In 2017, AEB inaugurated in Natal, a space camp named CVT-E – Space Technological Vocational Center (Portuguese: *Centro Vocacional Tecnológico Espacial*; CVT-E) – located in the *Barreira do Inferno* Launch Center (Portuguese: *Centro de Lançamento da Barreira do Inferno*; CLBI) (Goncalves and Gurgel Veras 2016). The CVT-E has proven to be an important vector for educational social inclusion through space science and STEAM activities. Through hands-on activities based on interdisciplinary core principles, students have the opportunity to learn about the importance of space activities for the country and the world. In addition, they can know a little about the last projects developed in the space area and about what are the first steps to specialize in this area in the future. Some activities performed at CVT-E are rover workshops, CanSat (development, assembly, testing, clean room, operation, etc.), planetary sessions, and studies about space transportation, launch centers, astronomy, astronautics, and other relevant subjects. Over 3000 elementary and high school students have attended the CVT-E experience throughout 2018 and 2019. An example of an educational outcome of this center, a CanSat kit developed by CVT-E students, was presented at the second International Academy of Astronautics Latin American Symposium on Small Satellites (Guedes et al. 2019).

Another important educational initiative is a picosatellite developed by students from the Tancredo de Almeida Neves public school in Ubatuba, São Paulo, with technological support from INPE. The project has seen encouraging results toward promoting students interest in engineering, science, and technology, especially in Aerospace Engineering, by the assembly, integration, testing, coding, and launch of a picosatellite. This also promotes teamwork among different levels of education because some activities are being developed by elementary school students, others are planned for technical students, and some are even within the scope of grad students. The project has received recognition from the national and international scientific community. Tancredo-1 is the first picosatellite of the UbatubaSat project, and it is a compact tube-shaped picosatellite with a mass of less than 0.6 kg based on

TubeSat kit from Interorbital Systems (IOS). It was successfully launched in 2016 toward the Japanese Kibo module of ISS – International Space Station. Once at Kibo, deployment and final ejection were performed in January 2017 followed by ground operations. The picosat carries an educational voice recorder and an experimental Langmuir probe from INPE's Ionosphere research group on Plasma Bubbles (Tikami et al. 2017). The UbatubaSat project is already preparing a second object named Tancredo-2.

It is also worth mentioning that the Amazonia-1 has been providing hands-on learning toward fostering qualified professionals. Since 2016, about 130 professionals have had an opportunity to get involved in activities of integration and testing, space project management, and product assurance, through satellites being integrated at INPE.

7 Conclusions

The miniaturization of space devices is changing in profound ways how space activities are approached and conducted worldwide, and the Brazilian space sector is no exception. A case in point of size reduction is clearly seen when we track the evolution of transponders for a long and continuous Brazilian demand for environmental data collected with space systems. In order to attend this demand, the SCD-1 carried an analog transponder of 3.8 kg mass needed for fulfilling its mission of collecting data from platforms distributed over the Brazilian territory. Twenty-five years later, Itasat embarked a digital transponder of just 0.3 kg, developed by INPE, for the same task. More recently, INPE has developed another digital transponder, named Environmental Data Collector, of just about 75 g, for the exact same task onboard the Conasat mission. A small payload getting even smaller. A reduction in mass of 98% with respect to the very first device for targeting the same objective.

AEB is exploring synergies between small and large satellites. The SGDC – a more than 5 tonne satellite – has provided spin-offs through a transfer of technology from France to Brazil that allowed six Brazilian companies, AEL Sistemas, Cenic Engenharia, Equatorial Sistemas, Fibraforte, Opto Space & Defense, and Orbital Engenharia, to improve and advance industry know-how on satellite-related technology such as panels for optical instruments, propulsion system for attitude control, thermal interface material and control systems, solar panels, electric power, on-board systems, and optical instruments for Earth Observation. This transfer of technology is an investment and an asset for future small satellite missions, in a moment when there is growing demand in Brazil for small satellites, and a handful of future Brazilian space missions is prospecting the use of small platforms – Equars (space weather), Carponis (remote sensing), Lessonia (SAR), and Atticora (communications).

AEB has put in place a set of initiatives – from general-to-specific with an end-to-end approach – to promote small satellites, starting with space science activities toward middle/high school students and teachers (e.g., CVT-E); space research toward university professors and students (e.g., CubeSats); and hands-on learning in Brazilian space projects toward fostering qualified professionals (e.g., Amazonia-1).

This chapter has provided an overview of past and ongoing small satellite-related initiatives in Brazil. As discussed through the chapter, there is growing demand in Brazil for small satellites, especially those that attend qualified demands. Small satellites have also plenty to offer in terms of continuous human resources training. New stakeholders (universities, industry, startups, think-tank) are contributing to the advancement of the field (services, applications, innovation), as well as promoting international partnerships. Last but not least, small satellites are an important driver for a Brazilian launch vehicle development effort.

Abstract

The RemoveDEBRIS mission has been the first mission to successfully demonstrate, in-orbit, a series of technologies that can be used for the active removal of space debris. The mission started late in 2014 and was sponsored by a grant from the EC that saw a consortium led by the Surrey Space Centre to develop the mission, from concept to in-orbit demonstrations, that terminated in March 2019. Technologies for the capture of large space debris, like a net and a harpoon, have been successfully tested together with hardware and software to retrieve data on noncooperative target debris kinematics from observations carried out with on board cameras. The final demonstration consisted of the deployment of a drag-sail to increase the drag of the satellite to accelerate its demise.

1 Introduction

Over 60 years of activities in space have produced great benefits for the world population, from the SatNavs in cars, to satellite communications/broadcasting, as well as weather forecasting, environment monitoring, and the list could go on. There are literally hundreds of devices for everyday use and applications that rely on satellite technologies. When the satellites that deliver these services reach the end of their life and stop working, they are normally left in-orbit. In 2018 there were almost 3000 dead satellites still in-orbit, not to mention the final stages of the rockets that were used to put satellites into orbit, as well as fairings and other hardware. In addition to intact objects, there are also millions of fragments that have been produced by the degradation of these bodies from flakes of protective materials to shrapnel produced by explosions and collisions (Bonnal and McKnight 2017). Altogether, a mass of over 8000 tons of debris is currently orbiting the planet, posing as a threat for operative satellites.

Activities in space have not yet triggered the nightmare scenario known as the Kessler syndrome (named after the scientist who first investigated this phenomenon (Kessler and Cour-Palais 1978)) which is when fragments formed by a collision hit other objects producing further collisions creating new fragments that will hit other objects. This would result in a cascade effect that grows exponentially which would rapidly increase the density of objects to the point of making particular orbits unusable. Furthermore, the space sector cannot be complacent and simply continue to put more satellites in-orbit ignoring this problem, as collisions with space debris have already occurred (see for example (Wang 2010)). Almost routinely, the ISS and other satellites have to perform maneuvers to avoid being hit by other orbiting objects. There are guidelines to try to mitigate the growth of the debris population (Inter-Agency Space Debris Coordination Committee 2007) – these have been produced by the Inter-Agency Space Debris Coordination Committee (IADC), which is an international forum of governmental bodies (e.g., national Space Agencies), for the coordination of activities related to the issues of man-made and natural debris in space. Some Agencies and government bodies have adopted these guidelines and complemented them with further regulations. Perhaps the most quoted guideline is that satellites should be de-orbited, or re-orbited (putting them in a graveyard orbit) within 25 years from their launch. However, although these guidelines have been in place for some time, they are just "guidelines" and not enforceable regulations. Various countries, for example, have tested ground-launched anti-satellite missiles, hitting their satellite target in-orbit producing step increases in the space debris population. Hence, for a variety of reasons, from political to technological, to constrain the growth of the space debris population has proven to be challenging. There is consensus among the experts in the field that to stabilize the debris population, in view of the growing number of launches, the active removal of some debris from some of the most utilized orbits is necessary (https://ntrs.nasa.gov/archive/nasa/casi.ntrs.nasa.gov/20100017146.pdf; Liou and Johnson 2009), although the quantification of the benefits strongly depends on the modeling assumptions (White and Lewis 2013).

Various researchers and organizations have investigated the field of Active Debris Removal (ADR) (White and Lewis 2014a; Bonnal et al. 2013), and various methods have been proposed to address this issue (Shan et al. 2016; White and Lewis 2014b),

The European Space Agency has probably been the most active international participant in the space sector that is addressing this issue with its Clean Space Initiative (Innocenti 2016; https://www.esa.int/Our_Activities/Space_Safety/Clean_Space/The_Challenge). This is articulated in the area of EcoDesign (embedding environmental sustainability within space mission design), CleanSat (developing technologies to prevent the creation of future debris), and in-orbit servicing/ADR (removing spacecraft from orbit and demonstrating in-orbit servicing of spacecraft) to embrace all the relevant domains. The French space agency (CNES) has also been very active and has funded studies including OTV that takes into account different ADR mission scenarios (Pisseloup et al. 2013). Similarly the UK Space Agency has funded studies and issued guidelines applicable to UK crafts. The German Space Agency (DLR)'s DEOS (Deutsche Orbital Servicing Mission) aimed to progress towards ADR, designing a system for rendezvous with a noncooperative and tumbling spacecraft by using a robotic manipulator system incorporated within a servicing satellite (Reintsema et al. 2011).

In the industrial sector, Airbus focused on the capture technologies including a robotic arm, a net (Astrium Space Transportation 2003) and harpoon demonstrators (Pisseloup et al. 2016), as more cost effective capture technologies. Aviospace has also recently participated in some ADR studies such as their capture and de-orbiting technologies (CADET) studies (Chiesa et al. 2016) as well as the Heavy Active Debris Removal (HADR) (Bicocca 2014). The company D-Orbit has proposed solid rocket de-orbitation for the S-SAT mission (Antonetti 2016) and other methods have been proposed, for example, Ion-beam Shepherd, Gecko adhesives, and polyurethane foam

(Merino et al. 2011; Parness 2015; Trentlage and Stoll 2015), just to name some of the most relevant proposals. A very popular de-orbiting system has been dragsails, which attracted significant research attention and has already produced working devices (Hobbs et al. 2013; Kingston et al. 2015; Underwood et al. 2019).

It is acknowledged that for any new proposed space technology, in-orbit demonstration is a significant stepping stone to de-risk the final implementation. The RemoveDEBRIS, mission discussed in this chapter and other publications (Forshaw et al. 2016, 2017a, b; Taylor et al. 2018), has been the first mission to perform successfully in-orbit demonstrations of a series of technologies for ADR thus de-risking their future industrial implementation.

2 Mission Overview

The purpose of the mission was to perform in-orbit demonstrations of technologies for the active removal of large space debris. These are typically old satellites which were no longer working, upper rocket stages, and large fairings. More specifically, the technologies that were tested were: two technologies (a Net and a Harpoon) for the capture of the debris: a technology for the observation of a debris (a LiDAR camera & software) in order to automatically determine parameters such as distance, spinning rates, which would be essential during the rendezvous and debris capture, and finally a technology for the de-orbiting at the end of life, the Dragsail.

The need to perform in-orbit demonstrations stems from the impossibility to perform fully representative tests on the ground, and the need to increase TRL of the devices, reducing development risks before embarking in a real industrial ADR mission.

As seen in the infographic of the mission shown in Fig. 1, the satellite was put into orbit in two stages. Firstly it was taken to the International Space Station during one of the Space X periodic resupply missions and secondly, from the ISS, using the airlock in the Japanese module, the satellite was transferred outside the ISS and released in-orbit by the ISS robotic arm.

The actual RemoveDebirs mission was then performed, and in terms of hardware this consisted of a mini satellite platform (mothercraft) of approximately 100 kg mass that hosted the payloads performing the demonstrations. Once in-orbit, the platform released two 2 U cubesats that acted as space debris, targets for the Net capture and VBN technology demonstration. The Harpoon functioning was demonstrated by firing the Harpoon from the mothercraft at a target (the size of a table tennis bat), which was held at the end of a deployable boom at a distance of about 1.5 m from the platform.

Finally, the dragsail was supposed to be deployed from the mothercraft, and this consisted of an inflatable 1 m long mast supporting a mechanism that deploys radially four booms, that extending, unfurl 4 quadrants of sail. Once fully deployed, the sails form a square of approximately 3 × 3 m, with the deployable booms as diagonals. The inflatable mast holds the assembly from the center, at 1 m distance from the mothercraft (see Fig. 1). As the craft is in a Low Earth Orbit, the residual

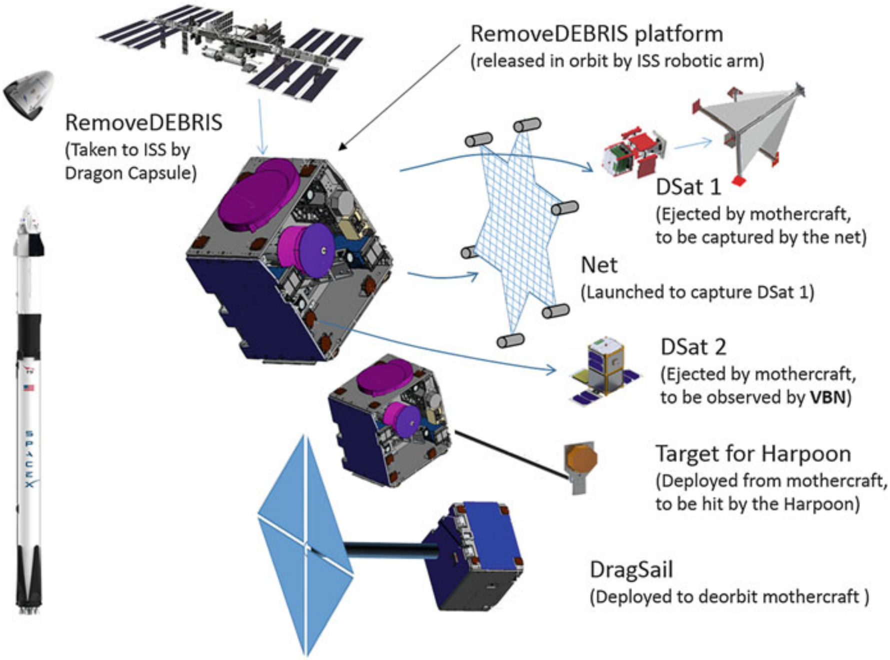

Fig. 1 Infographic of the RemoveDebris Mission

atmosphere allows the sail to produce drag that slows down the satellite, significantly accelerating the de-orbiting process.

2.1 Mission Team

The mission, whose design started in 2014, was performed by the team described in Table 1, led by the Surrey Space Centre at the University of Surrey. The overall cost of the mission was approximately 15 M euros. This was supported by a grant from the European Commission, part of its Framework Severn research funding round, and provided a 7 M euro contribution to the cost of the project, with the remainder self-sponsored by the partners.

2.2 Launch and Early Orbit Phase

At the end of the Assembly Integration and Testing activities, carried out in the SSTL cleanroom in Guildford, UK, the satellite, appropriately packaged (with protective panels, in a foam clamshell that was contained in a box which was finally put in the transportation case), was shipped to Cape Canaveral for launch. Once at the launch site, the external transportation/casing was removed, leaving the craft with its

protective panels in the protective foam clamshell. In this configuration, the craft was put in the cargo transfer bag and finally into the Dragon capsule.

The launch, on the 2 April 2018, was nominal, with the Dragon capsule propelled into orbit by the SpaceX Falcon 9 Rocket and the craft arrived at the ISS 2 days later as planned. The craft was then kept stored until mid-June, waiting for its scheduled time slot for unpacking and deployment into orbit. The unpacking consisted of removing the foam shell casing and protective panels, and the craft then was mounted on the sliding table in the Japanese module airlock. No other servicing operations were required form the ISS crew to make the craft operational. Once on the external side of the airlock, the craft was handled by the ISS robotic arm equipped with the NanoRacks Kaber Microsat Deployer, and released in orbit on the 20th of June 2018. Figure 2 shows the craft a few minutes after its release from the ISS.

The craft was released completely switched off in compliance with the ISS safety requirement, and contact was made during the first pass after power up, over the SSTL ground station in Guildford, UK.

The telemetry showed that the spacecraft was performing nominally, for example, Battery was fully charged, and temperatures as expected and commissioning progressed with switching on the spacecraft On Board Computer. Next, the craft was de-tumbled from the slow initial angular rate and brought to a controlled attitude state. Attitude and Orbital Control System commissioning progressed until the platform was in a coarse Nadir pointing mode.

All other platform checks, to verify health and functioning of the key modules not already checked were successfully performed.

The spacecraft then performed a series of maneuvers to verify its performance against the requirements for the various demonstrations.

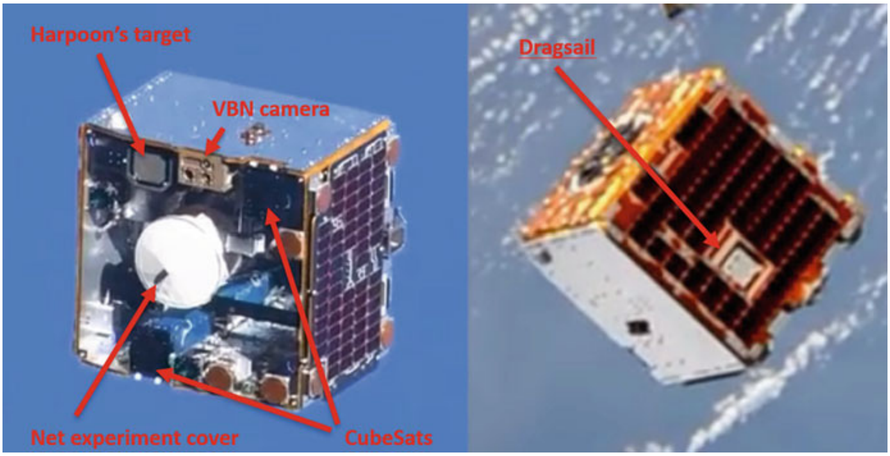

Fig. 2 RemoveDebris in flight, pictures taken from ISS

The final phase was the calibration and characterization of the cameras and VBN were tested over a range of exposures and frame rates which were planned for use on the experimental demonstrations and related parameters were adjusted.

By mid-September, the craft was ready to start the demonstrations with the Net capture scheduled as the first experiment. This was to be followed by the VBN demonstration, Harpoon firing and finally de-orbit sail deployment, with the series of experiments planning to take approximately 6 months.

3 Net Capture Technology Development and Demonstration

The first demonstration planned, was the Net capture. For this demonstration, the first cubesat had to be released form the mothercraft and while this slowly drifted away (planned separation speed 5 cm/s) and reached an appropriate distance (approx. 7 m), the Net had to be launched from the mothercraft to capture the cubesat. After the cubesat release from the mothercraft, and before this is captured by the Net, the cubesat deploys some inflatable structures to increase its original size (from the 10 × 10 × 20 cm dimension of a 2 U CubeSat, to approximately 1 m side length pyramid structure (see Fig. 3)). This is in order to be more representative of the size of a larger space debris and produce a situation more representative of the Net capture dynamics. The Net is held in a container/canister (see Fig. 4), and is deployed by launching 6 masses simultaneously, that are attached along the perimeter of the Net. The masses are cylindrical, with a push off spring at the base, and contained in 6 barrels located on the internal wall of the canister (see Fig. 4). A lid closes the canister pushing the masses down their barrels, compressing their push off spring. Once the lid of the canister is ejected, the masses are pushed out by their springs along trajectories that funnel out from the

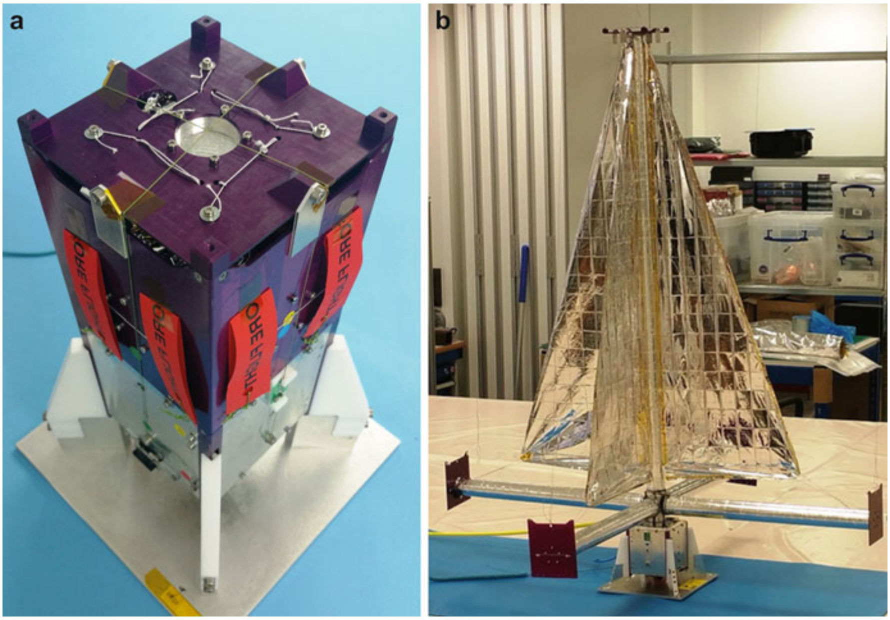

Fig. 3 Debrisat 1 (**a**) stowed configuration (**b**) deployed configuration

longitudinal axes of the canister in order to drag the net out from the central volume of the container, progressively stretching it open (see Fig. 5). During its deployment, initially the net will take the shape of a six-pointed star with each of the masses pulling one of the vertices of the "star," and eventually when fully deployed, the perimeter of the net should take approximately a hexagonal shape with vertices on a 5 m diameter circle. Once the target has been captured, the masses are naturally pulled towards the longitudinal axis by the Net, and each of the masses draws a string that runs along the perimeter of the net in order to close it, like a drawstring bag. The closure of the net is performed to ensure the retention of the target, as otherwise, after the initial capture, the net might open up and release the target. The activation of the drawstring is commanded by a timer, and the whole demonstration was planned to be filmed by two supervision cameras, starting recording just before the release of the target cubesat.

The design of the hardware has been supported by extensive experimental test campaigns, as both, the target cubesat and the Net launching device, have complex dynamics. For example, the cubesat presents the challenge of the inflatable booms that deploy the sail quadrants, and whose inflation/deployment is almost chaotic, and similarly the deployment of the net, from tightly packed in the container to fully open is difficult to model mathematically with good reliability. Even the cubesat deployer required significant testing to verify the very low ejection speed that was required.

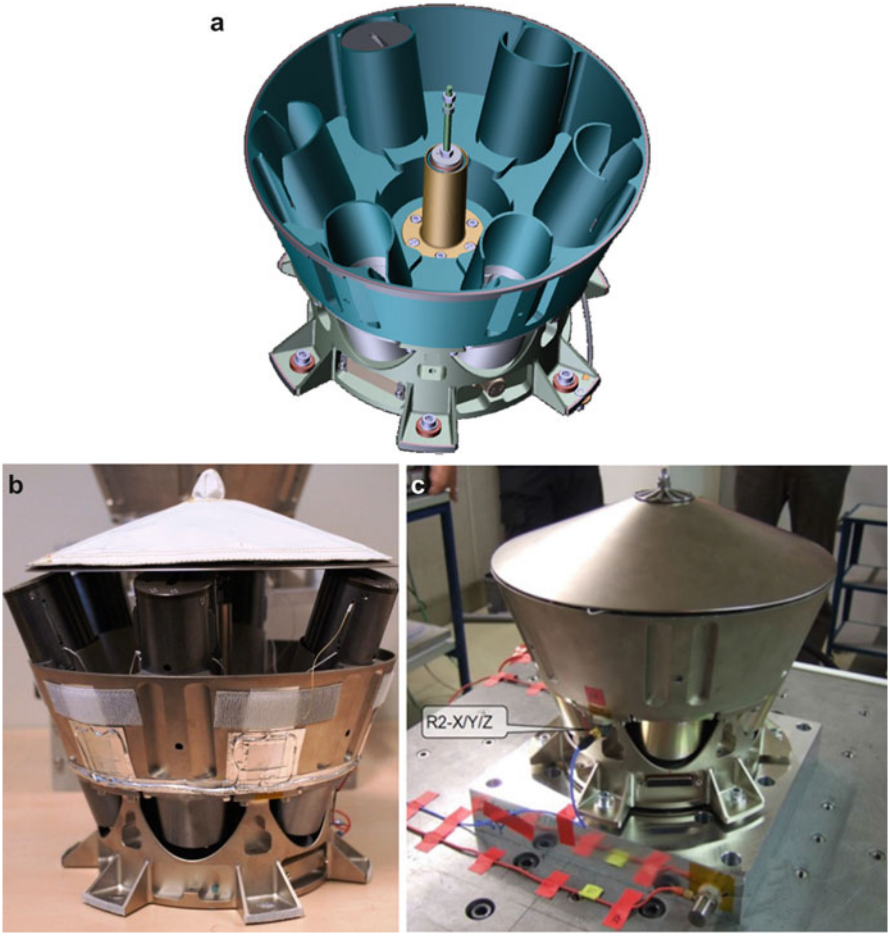

Fig. 4 Net capture device (**a**) CAD model of the container, (**b**) hardware, container with masses partially inserted in the barrel, and lid resting on the masses (**c**) container closed and ready for vibration testing

3.1 Hardware Ground Testing

The functioning of the net device was verified during ground test of increasing complexity. From simple packing and unpacking tests with people pulling the corners of the net out of the container to make sure that there were no snags during deployment, to functional tests in zero-g and vacuum in the drop tower (these tests only allowed us to verify the first second of the net deployment process), to tests during parabolic flights, to verify the closure of the net. Although these tests could give confidence in particular aspects of the design, none of the tests could verify the whole capture of a free floating non-cooperative target in space, with hardware that was similar to what would be required to capture a real piece of large space debris.

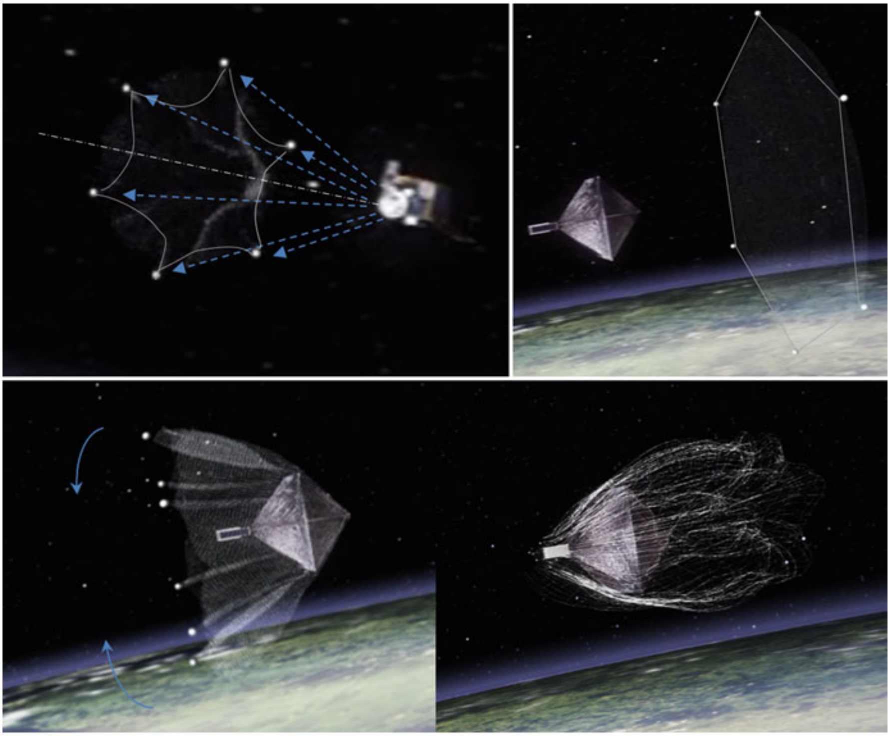

Fig. 5 Sequence from video animation of the Net ejection and DSAT#1 capture

Hence, the in-orbit demonstration was necessary to give full confidence in the design and reduce the risk of the further scaling up that will be necessary to utilize this technology in real ADR missions to capture an object a few meters in size.

Concerning the target cubesat, a significant test campaign was carried out to consolidate its design. From the initial baseline that included a 6 boom deployable structure as shown in Fig. 6, which gave substantial challenges in terms of its capability to withstand a harsh vibration environment, the design evolved into a 5 boom configuration visible in Fig. 3. The inflation is driven by two Cool Gas Generators; however, during most of the testing activities, to allow several repetitions and limit cost, compressed air was used.

The main challenge for the cubesat deployer used to eject the cubesats from the platform was to achieve a very low ejection speed, as in a realistic scenario there would be a very low relative speed between a debris and the spacecraft that is capturing it. This was achieved by implementing a two-stage deployer system illustrated in Fig. 7. The first stage pushes the cubesat out if its container using a typical large compression spring system that at the end of its run keeps the push plate flush at the opening of the container, with the base of the cubesat retained by the push plate. The second stage is the cubesat release system. This separates the

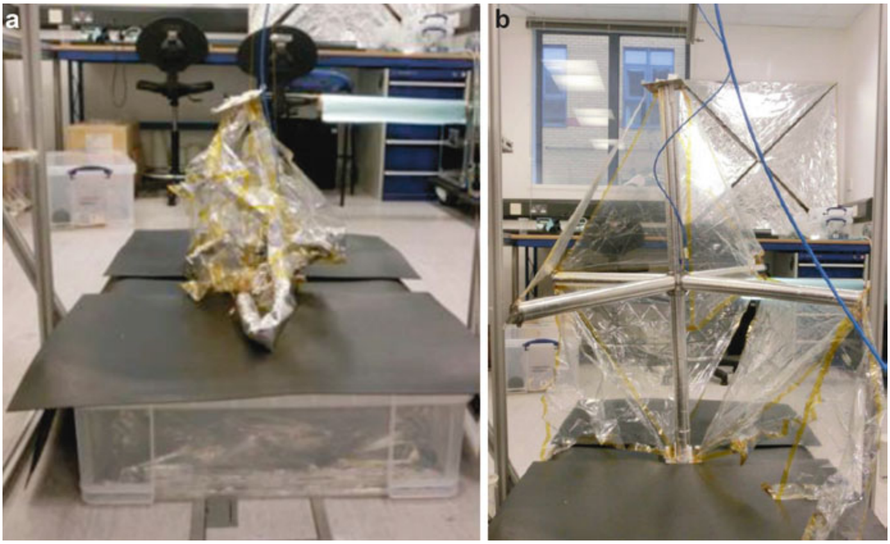

Fig. 6 6-DSat inflation testes, 6-boom configuration (**a**) during inflation (**b**) fully inflated

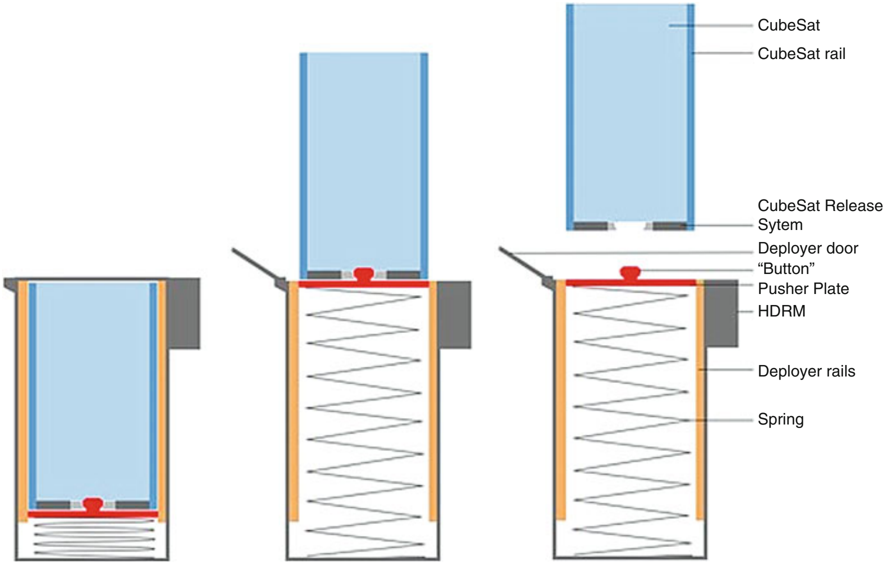

Fig. 7 Schematic of the CubeSat Ejection system

cubesats and gently pushes it away using low stiffness springs. The performance of this mechanism was verified in the lab using a long pendulum system for gravity compensation and a high speed camera to measure the release speed of the cubesat (see Fig. 8).

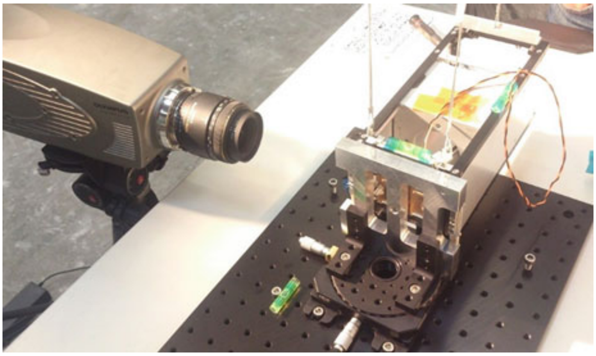

Fig. 8 Deployer and CRS: Detail of the Velocity Testing Setup. 2 U CubeSat suspended on pendulum and high speed camera

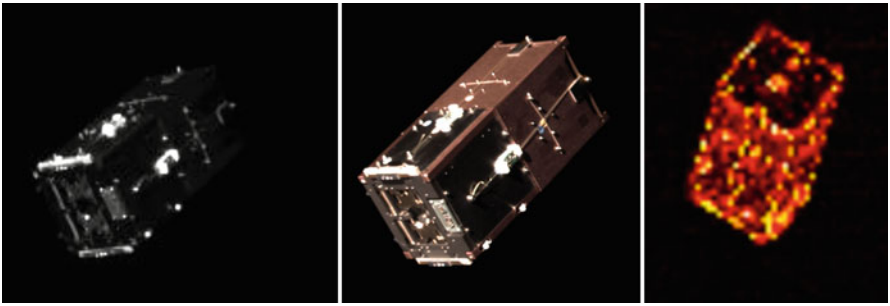

Fig. 9 Standard supervision camera, VBN digital camera, VBN Lidar camera

3.2 In-Orbit Demonstration

The in-orbit demonstration (16th of September 2018) was filmed by the two supervision cameras on the platform as planned. In addition, it was decided to use this opportunity to test also the functioning of the VBN cameras (i.e., a digital camera and a Lidar system that will be further discussed in the next section), and therefore, the demonstration was filmed by a total of 4 cameras. The type of imagery is visible in Fig. 9.

From the imagery, it is possible to see the cubesat drifting away from the mothercraft at a velocity slightly higher than planned (approximately 7.5 cm/s) and then inflating two of the four inflatable booms making the base of the pyramid (see Figs. 3 and 14). The inflation of the longitudinal boom is also visible, as the net captures the cubesat (see Fig. 15).

As the booms inflated, the cubesat started spinning, and this was most likely due to a gas leak from the two booms not correctly inflating, acting as a thruster and generating a moment to the cubesat. As the net was travelling towards its target (Fig. 15), pulled by the 6 throw masses, it assumed the shape of a 6 point star (each point pulled by one of the masses). However, the central area of the net remained

Fig. 10 DSAT#1 with lateral inflatable booms deployed

slightly tangled together preventing a full stretch of the mesh. It is estimated that the net opened to approximately 4 m diameter and then hit the spinning target wrapping itself around it. The capture itself happened at a distance of approximately 11 m, and the distance was estimated from the knowledge of the camera field of view and the size of the target. As the Net wrapped itself around the target, the imagery did not allow us to determine whether the drawstring mechanism worked properly. Although it was clear that the net achieved its main purpose (i.e., to capture the target). From the way it tangled itself around the cubesat and its deployable structures, it is very unlikely that, later on, the cubesat could unwrap itself and escape from the net. All the telemetry (Two Line Elements), from the moment of the capture to the complete de-orbiting of the cubesat (2nd of March 2019) enveloped by the net, is consistent with a single object.

In a real operational scenario, the net would be tethered to the motehrcraft, so that after the capture of a debris the mothercraft can tow it down and de-orbit together. However, this would require the mothercraft to have a very capable propulsion system and sophisticated AOCS which would significant impact on the mission budget, and this was considered to be beyond the scope of this demonstration.

Besides propulsion, to deploy this technology on an industrial scale to capture real large space debris, the technology will need scaling up, but there is nothing in the current design that could prevent an increase in size to enable capture of debris that could have dimensions of a few meters (Figs. 10 and 11).

4 Vision Based Navigation

The second demonstration to be carried out tested the performance of two cameras for VBN and related software. The two cameras were a standard high quality digital camera and a flash imaging LiDAR system, whereby the target is illuminated by flashes of laser whose reflections are captured by a sensor, enabling the measurement of the distance of the target.

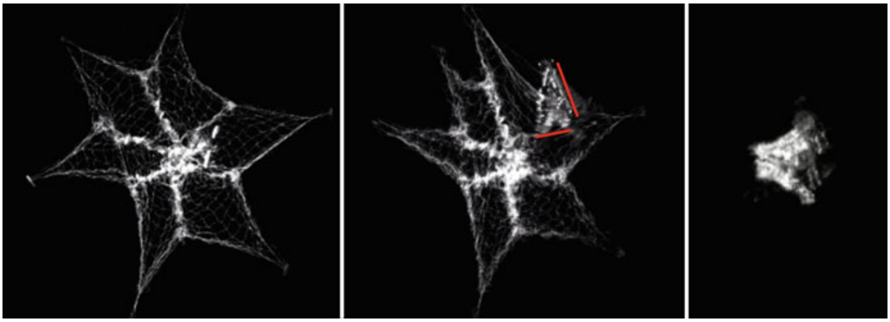

Fig. 11 Left – before the capture, two lateral booms visible. Center – Moment of the Net capture of DSAT#1, one of the satellite sails is shown, between the lateral and longitudinal booms –Right – after the capture, DSAT#1 tangled in the net

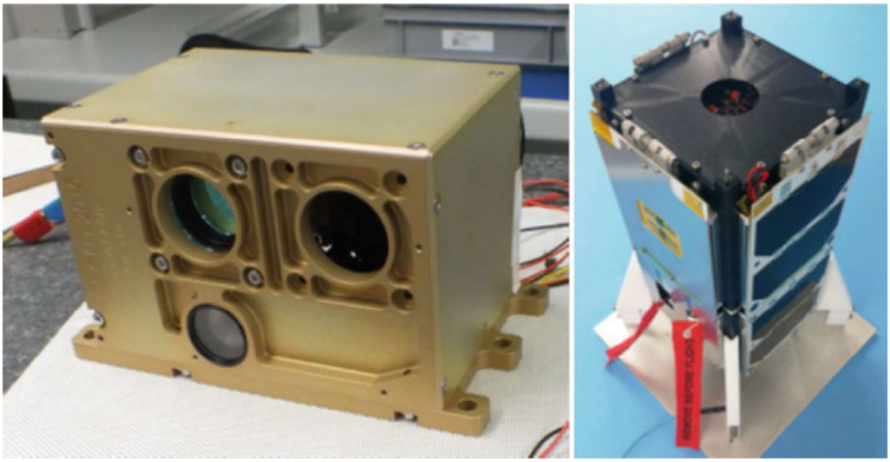

Fig. 12 Left: Vision Based Navigation payload, Right: DS-2 target in deployed state

The purpose of this demonstration was to test the hardware and to assess the state-of-the-art of Image Processing (IP) and navigation algorithms based on real flight data.

The device is shown in Fig. 12, together with the cubesat that was released by the mothercraft in order to be observed by the two cameras. The imagery from the cameras enables the reconstruction of the object and its dynamics (shape, distance, and spinning rate) that can be used for rendezvous algorithms for relative navigation.

4.1 In-Orbit Demonstration

The cubesat target for the VBN was released by the mothercraft on the 28th of October 2018, pushed away with a velocity of 2 cm/s, released by the same type of

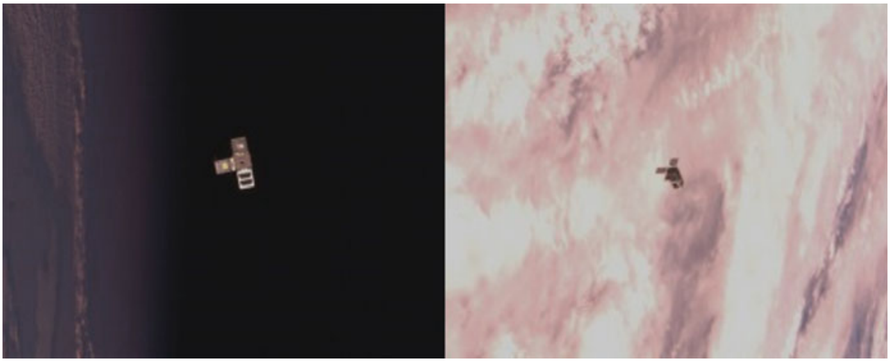

Fig. 13 DSAT#2 with different backgrounds

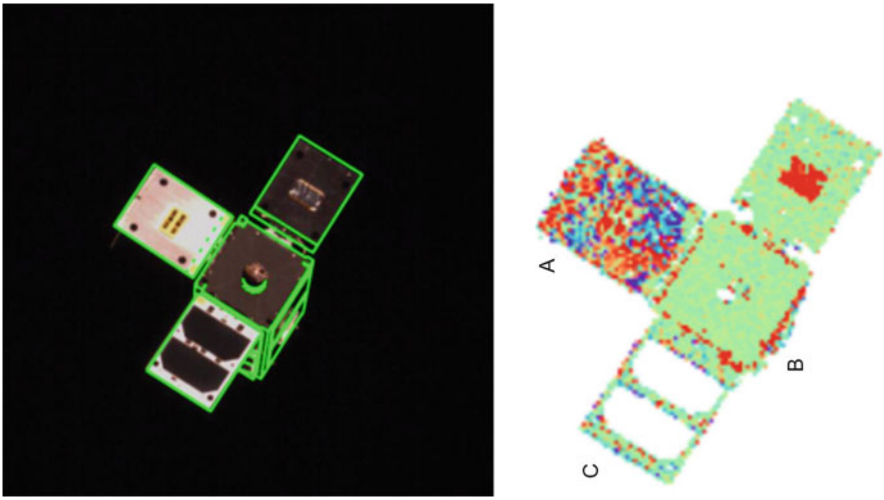

Fig. 14 Left: View of DSAT#2 with shape contours, Right: image from LiDAR camera

separation mechanism as that used for the first cubesat but with lower push off spring energy.

One of the challenges addressed by this experiment was to recognize the target independently from the background (see Fig. 13), and this demonstration provided a wealth of real data to assess the performances and robustness of the VBN algorithms. If a model of the geometry of the object being observed is available (e.g., a CAD model), the software can combine it with the sensor's measurements and improve the overall estimation of the kinematic of the object and its visualization (see Fig. 14). If other physical data of the target is available (i.e., inertia matrix), the estimation can be further improved including the equation governing the dynamics of the object in the algorithm.

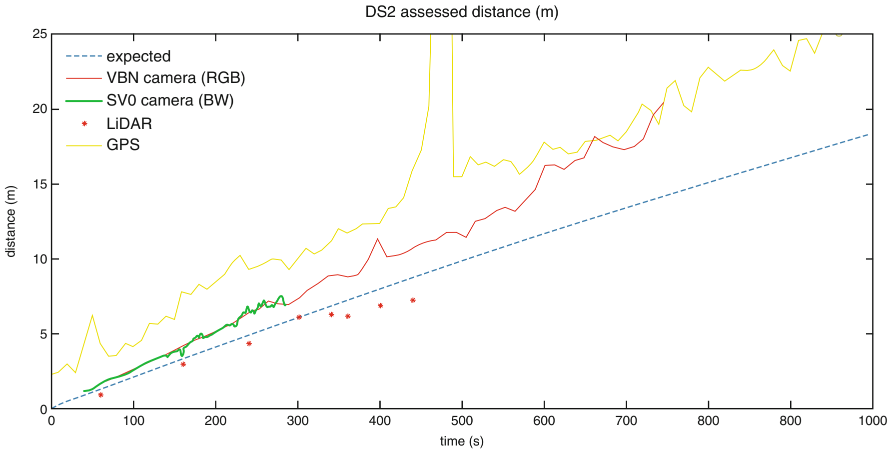

Fig. 15 Comparison of distance measurements using different systems

In this experiment, the measurements obtained by the Lidar system (target distance and spinning rates) were compared with the information obtained by the GPS on board the CubeSat, which were transmitted to the mothercraft via an inter satellite link.

Figure 15 shows a comparison of the measurements of the relative distance between mothercraft and cubesat, using raw data from the various sensors while the target was tumbling and also the background was changing, therefore varying the level of noise during the experiment. As knowledge of the physical characteristics of the target can improve significantly the estimation, further work in this direction is currently being carried out.

Downloading all the data from the experiment took a few weeks, as the videos were very large files and contact to download the data could only be made for a few minutes every day when the satellite was passing in view of the ground station in Guildford.

5 Harpoon

The next experiment to be performed was the Harpoon capture, and this was executed the 8th of February 2019. The demonstration starts activating the frangibolt that retained the target pressed against the mating structure of the chassis Harpoon Target Assembly (Aglietti et al. 2018) (see Fig. 16). After the target has been freed, the deployable boom that supports it starts to uncoil/deploy moving the target to a position 1.5 m away, in front of the harpoon firing device (Fig. 17).

The deployment of the target is recorded on video by the mothercraft supervision camera. Once the video has been downloaded and reviewed to confirm that the target is correctly deployed, the harpoon can be fired. Before firing the harpoon its safety

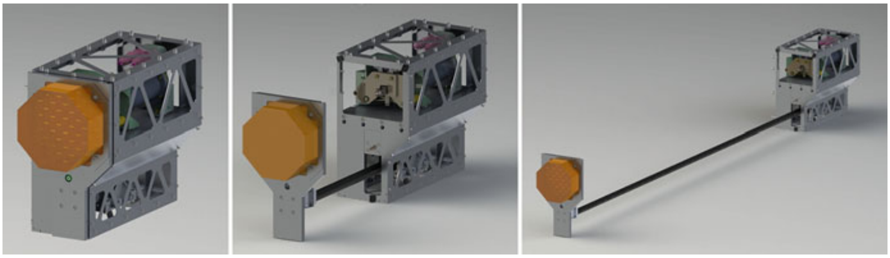

Fig. 16 Harpoon Target Assembly. Left – stowed configuration, the target is held against the chassis of the device by a frangibolt. Center – Once free, the target is moved into position by the deployable boom. Right – device fully deployed with target in its final position

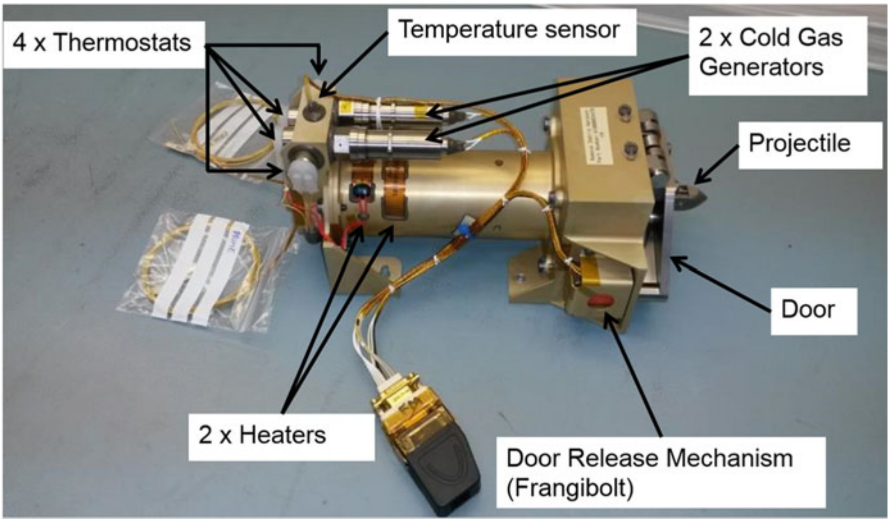

Fig. 17 Harpoon firing device

door, kept closed by two frangibolts, has to be opened to free the harpoon/bullet. The harpoon is launched using compressed gas produced by two Cool Gas Generators, and it is tethered to the mothercraft using a line whose length is significantly longer than the harpoon distance (see Fig. 18). A total of 27 harpoon firing tests were conducted to verify various aspects of the design and in particular the behavior and strength of the tether system, as it was mandatory to demonstrate the capability to retain the harpoon under any conditions (including missing the target). Early in the program, considerable attention was also given to the design of the tip of the harpoon and the barbs, with various design iterations, shown in Fig. 19, to improve its capability to imbed itself and lock on the target (Fig. 20).

The target, roughly the size of a table-tennis bat, includes an aluminum honeycomb panel of contraction representative of an old satellite structure that has to be struck by the harpoon.

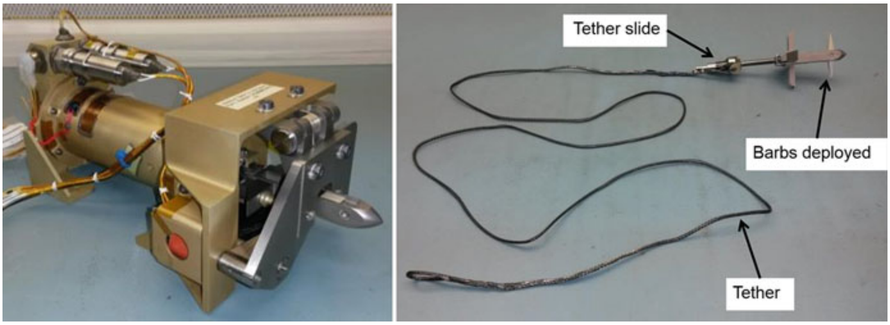

Fig. 18 Harpoon firing device, projectile, and tether

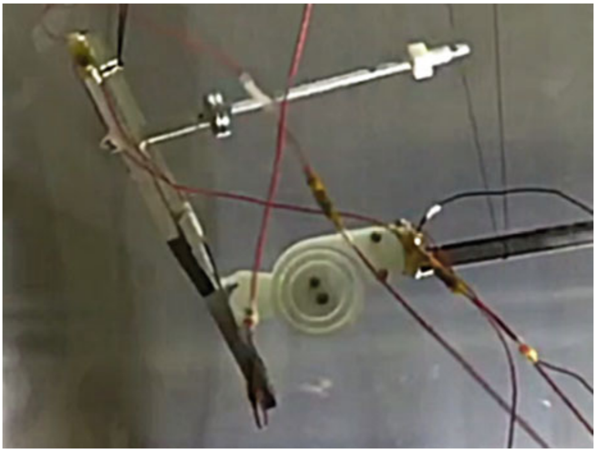
Fig. 19 Harpoon tip and barbs design iteration

Fig. 20 Harpoon target support implementing "shock absorber"



The deployable boom that supports the target is a lightweight CFRP with a U cross section and a series of holes along its length that engage a gear used for the deployment the boom.

During ground testing it became apparent that the high energy of shock of the harpoon hitting the target was sufficient to snap the target off the boom. Consideration was given to include a system, similar to a clock spring to reduce the amplitude of the mechanical shock upon the harpoon impact, and related stress on the structure. However, as after the impact the harpoon would effectively retain the target, the possibility of the target breaking off the boom was not deemed a particular concern and therefore the shock absorber was not implemented in the flight model.

5.1 Harpoon In-Orbit Demonstration

After the boom was deployed, the imagery was downloaded and examined to verify the status of the system before proceeding with the demonstration. This showed a significant oscillation of the target (see Fig. 21) with rotations of up to +/−17 deg and translations of the target central area of a few centimeters. This was due to the fact that the target was supported in a cantilevered configuration by a boom with relatively low stiffness and damping. Excited by the microvibrations generated by the equipment on board the platform, the system resonated, producing large oscillations of the target. As the main source of the platform microvibration was the actuators of the attitude control system, the issue was resolved performing the

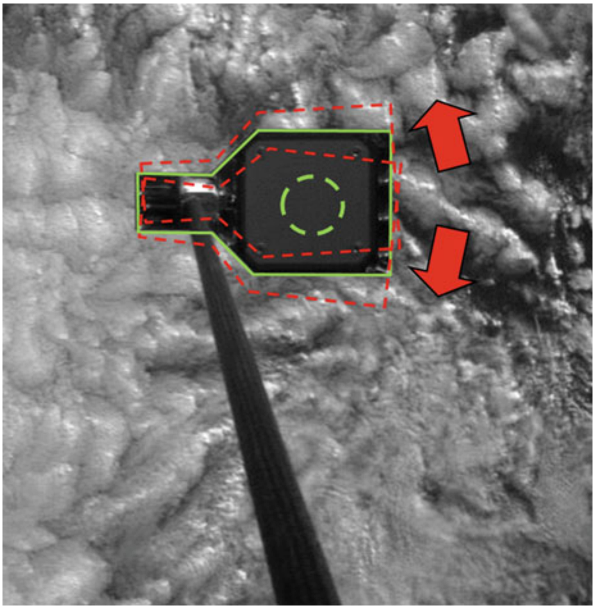


Fig. 21 Target deployed at the end of the boom, in green the nominal position and in red the positions at the extreme of the oscillations whose direction is indicated by the red arrows

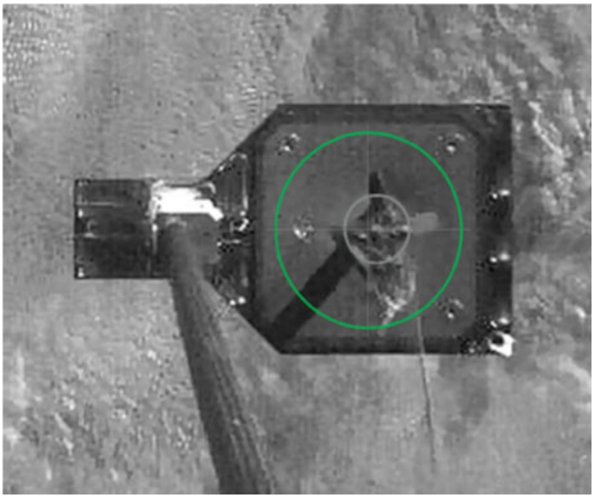

Fig. 22 Harpoon imbedded in the target

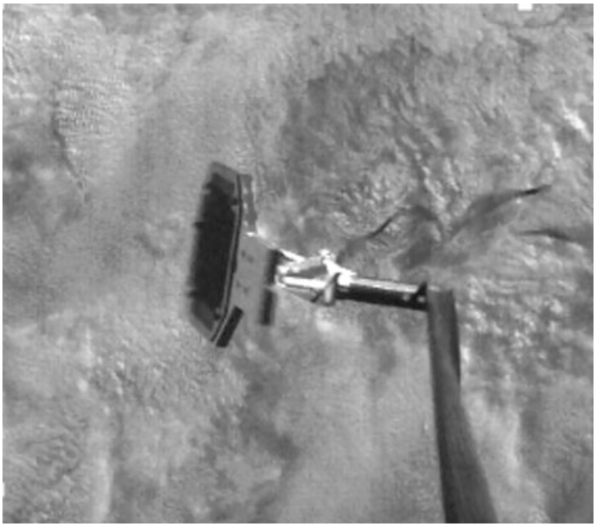

Fig. 23 Target snapping off the end of the boom

experiment in a mode of operation where the actions of the attitude control system had been minimized.

In this new mode of operation, it was verified that the target was stable, and it was possible to fire the harpoon. As visible in Fig. 22, the dart hit the target in the center and due to the mechanical shock the target snapped off the boom (Fig. 23), and floated away tethered to the mothercraft via the harpoon tether. After some time floating around the platform, the target retained by the harpoon tether wrapped itself around the boom (Fig. 24).

Fig. 24 Target retained by harpoon tether wrapped around the boom

6 Dragsail and De-orbiting

The final phase of the mission consisted of an accelerated de-orbiting of the craft, triggered by the deployment of a drag-sail. The concept of operation of this device is that deploying a sail like that shown in Fig. 25 in low earth orbit, where there is still some residual atmosphere, increases the drag, reducing the velocity of the satellite, so it de-orbits more quickly. The graphs in Fig. 26 show the improvement in the de-orbiting time which can be produced by this kind of system. In this case, the prediction showed that deploying the sail could have reduced the de-orbiting time to approximately 10% of its natural de-orbiting time.

The initial configuration of the craft had all the experiments mounted on the same side of the satellite in order to be monitored by the surveillance cameras. However, as the dragsail was the last device to be operated, possible malfunctions of the previous experiments (e.g., incapability to retract the boom supporting the harpoon target after its demonstration) would have impeded its deployment. In one of the last design iterations, to avoid any possible interference with the previous demonstrations, it was therefore decided to mount the dragsail on the opposite side of the satellite (see Fig. 2). Unfortunately, this did not allow us to video the operation of the dragsail, and successful deployment would have been confirmed mainly by the more rapid de-orbiting of the craft. Other indicators, such as changes/reduction in power generated by the solar panels due to shadowing of the sails, changes in telemetry

Fig. 25 Drag-sail system

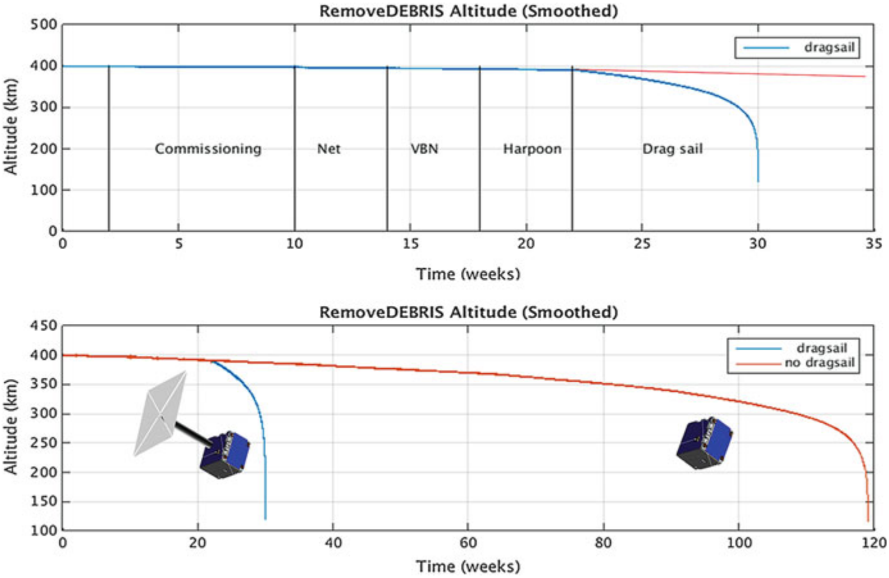

Fig. 26 RemoveDebris de-orbiting performance prediction with and without dragsail

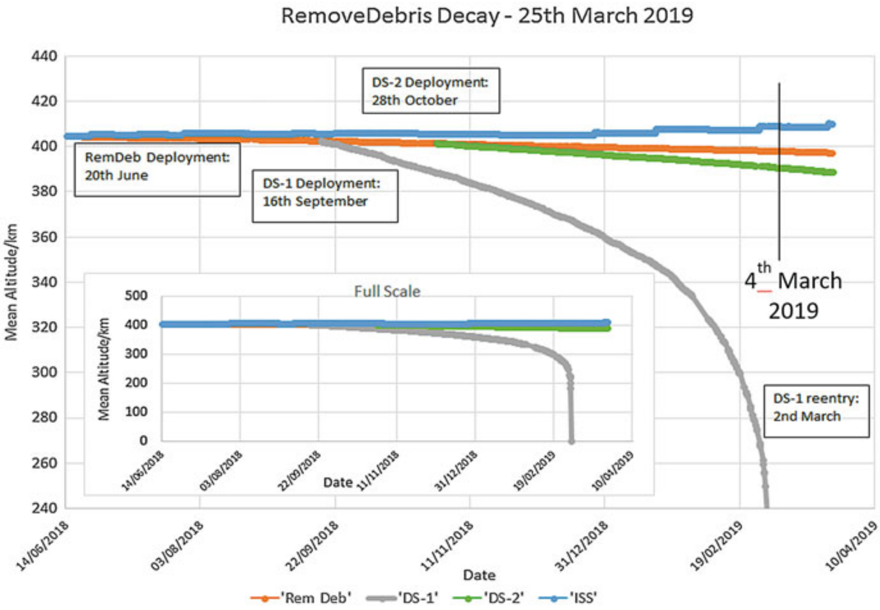

Fig. 27 Decay of the various RemoveDEBRIS objects

from the sun sensor, and observation from the ground (significant increase in brightness of the object), would have confirmed the successful deployment.

A command to deploy the dragsail was given the 4 March 2019. In the following days, some changes in the brightness of the object were reported, but no significant changes in the de-orbiting trajectory or in any of the other indicators could be detected. Figure 27 shows the altitude of the mothercraft, which is naturally de-orbiting (expected time for complete de-orbit is approximately 2.5 years), but no significant change occurred from the 4th of March. Note that the first cubesat, wrapped in the net, de-orbited in less than 6 months and the second cubesat is also de-orbiting at a faster rate than the mothercraft.

At this stage it has not been possible to confirm the nature of the anomaly in the operation of the dragsail, although most of the data is consistent with an issue with the deployment of the inflatable mast that supported the sails. However, the lesson learned in the development of the RemoveDebris drag-sail has been put into practice in the development of two new dragsails that have been supplied to the Space Flight Industries for their the SSO-A mission, and all the telemetry available for that mission has confirmed a successful deployment.

As the purpose of the RemoveDebris demonstrations was to pave the way to industrial exploitation of the various technologies that were tested, the dragsail experiment also fulfilled its purpose (Fig. 28).

Fig. 28 Ground testing of the DragSail for the SSO-A mission

7 Conclusion

The RemoveDebris mission has been the first successful in-orbit demonstration of a series of technologies for ADR.

Both the Net and Harpoon have been proven viable methods to capture large space debris. Indeed these devices will need scaling up, possibly up to one order of magnitude in terms of the size of the hardware, in order to be used in a real industrial scenario, for example, to capture large defunct satellites. However, none of the technologies implemented in the systems have features that would prevent their increase in size.

The VBN demonstration, besides verifying the functioning of the hardware and software, collected a wealth of data that will be useful for years to come.

The development of the dragsail and the anomaly in its operation, although disappointing at the time, has provided important lessons that have enabled the successful manufacturing and operation of a new generation of drag-sails. Most importantly the use of inflatable structures in space still poses significant challenges, and alternative solutions seem to deliver higher reliability. In the case discussed in this chapter, also the need for extensive testing, implementing a higher level of quality control in the whole MAIT process, has certainly contributed to achieving success in the new generation of drag-sails.

Once again, this project reconfirmed that the systems that underwent extensive ground testing performed better than those that relied on a small number of tests.

Overall, from a programmatic perspective, one important lesson learned was that in case of launches via the ISS, an earlier engagement with the ISS safety review process is very beneficial. In-fact in comparison to standard launches, where the craft is put directly in orbit, transiting through the ISS requires a higher level of safety. This is relatively easy to implement directly in the design if this is done at an early stage, rather than having to add modifications or carry out further unscheduled test activities to achieve compliance.

Still from a programmatic perspective, another peculiarity of the project was the "loose" contractual control of the interfaces between partners. This derived from the fact that the whole project was set up as a research collaboration between members of a consortium led by the SSC (the consortium coordinator) and with responsibilities described at top level in a research proposal subsequent description of work. Such consortium configuration was rather different from the typical contractual arrangement used to deliver space missions (e.g., a satellite development would normally be led by a Prime Contractor which leads a group of Subcontractors with responsibilities that are specified in detail in their subcontracts). While on one hand this enabled flexibility in the interfaces to optimize, from a technical perspective, the interface, and distribution of the work, it created some challenges from a project management perspective. The key for the successful delivery of this kind of project was to maintain top level alignments of the overall objectives and the partners' willingness to absorb some extra (unscheduled) work deriving from adjustments of the interfaces.

Besides its technical success, this project attracted significant media attention, which was welcome, as it raised the awareness of the issue of the space debris in the general public.

Abstract

This chapter discusses small spacecraft technologies and trends, e.g., propulsion systems, additive manufacturing, AI, standardization, launch solutions, miniaturization, and high-level design systems behind smallsat market growth, as well as forecasts related to the manufacture and launch of small satellites over 2019–2028.

Keywords

Small satellite · CubeSat · Smallsat · Satellite market · Satellite technology · Launch · Earth observation · Communications · Constellations · Small satellite market · Micro-launcher · Launch broker · Applications

1 Introduction

The exponential advancement of capability for small systems of all types is transforming the satellite industry in very powerful ways. In 2018, two tiny National Aeronautics and Space Administration (NASA) CubeSats, MarCO A and B, affectionately known to their controllers as Wall-E and Eve, accompanied NASA’s InSight mission to Mars and relayed photos of Mars and diagnostic data back to Earth from the entry, descent, and landing (EDL) of the primary spacecraft via the Mars Reconnaissance Orbiter (MRO), becoming the first CubeSats active in deep space (i.e., beyond Earth orbit). This begins the era of “bring your own communications relay” to science missions and is a considerable evolution in terms of value compared to previous missions, which required large/heavy/costly systems. The spacecraft, despite being the size of a shoe box, navigated to Mars independently of the main spacecraft, and their phased array X-band antennas and associated processing systems accomplished the relay flawlessly.

Many of these innovations are starting to arise beyond traditional places such as the US Space Coast and Pasadena, coming from new centers for small spacecraft development ranging from Glasgow, Scotland, where over 130 space companies are now located, to Adelaide, Australia's new Space Precinct (South Australia estimates over 80 space companies which now call it home), and to hundreds of universities across the world which may for the first time develop space hardware thanks to the low-cost CubeSat form factor.

In more common near-Earth communications applications, three Sky and Space Global CubeSats (10 × 10 × 30 cm) in 2017 successfully relayed 56 Kbps sessions/phone calls across Africa, a technology milestone. Future launches to bring the constellation to 200 satellites have been intended to be via air launch, on Virgin Orbit's LauncherOne, but funding appears uncertain at this point, putting the project at risk. This is just the very tip of the iceberg: far more massive constellations are now planned by several industry stakeholders, such as OneWeb (~650 smallsats), Elon Musk's SpaceX (up to tens of thousands of smallsats according to its various filings), and Jeff Bezos' Project Kuiper (3,236 satellites), raising hopes for inexpensive global internet but also raising concerns for astronomy observations and orbital debris mitigation, due to the significant risk increase in terms of orbital collisions.

In this chapter the technologies supporting small satellite market growth by enabling more and more capabilities within the smallsat form factor are discussed, capabilities which previously were only feasible on large, heavy, and expensive spacecraft with costs often valued in hundreds of millions to a billion dollars. The second part measures, breaks down, and analyzes smallsat industry growth over 2009–2018 and provides a market forecast and insights into market developments expected over 2019–2028. This exhaustive market analysis (all regions, all orbits, all operators and operator types, all launch service providers, all mass categories, etc.) covers all major satellite applications, from telecommunications in broadband and narrowband to provide worldwide connectivity services to Earth observation for civilian (climate change monitoring, resources management, agriculture, forestry, etc.) and military purposes, as well as navigation satellites, security satellites, technology demonstration spacecraft, science and space exploration missions, and many other types of small satellites, with various applications.

2 Small Satellite Technologies Driving Growth

Several advances in technology in particular have been responsible for the dramatic increase in small satellite capabilities and market expansion, ranging from the miniaturization of chips and propulsion systems to miniaturization of payloads, the advent of electric propulsion, more standardization and the availability of affordable commercial off-the-shelf (COTS) components lowering hardware costs, an evolving ground segment ecosystem, as well as a broader range of access to space solutions coming online (at both ends of the mass spectrum, from the launch of hundreds of satellites on heavy launchers to dedicated launches of a few kilograms of satellites) and reducing the launch bottleneck, facilitating and/or reducing the cost of access to space. The advent of AI and flat panel antennas are also playing a key role by greatly facilitating smallsat constellation operations and orbital coordination, driving important growth in telecom and Earth observation smallsats to be launched.

Miniaturization and technology improvements offer smallsat customers the choice between increasingly lighter satellites (at equivalent performance) and more capable but heavier satellites, due to the addition of improved capabilities (lifetime, propulsion, payload, etc.). Thanks to these improvements, CubeSats are now capable of delivering operational services, while, in the heaviest mass category, 250–500 kg satellites can now perform better than some >500 kg non-smallsat satellites.

These technological advancements translate into a rapidly growing number of small satellites. The space industry is on the verge of significant expansion and is undergoing profound changes both on technological and business terms, as dozens of new entrants and established stakeholders alike prepare for the 2020s. The smallsat industry is gearing up for significant expansion in terms of capabilities and demand, with the number of satellites to be launched growing sixfold over 2019–2028, compared to the previous decade. The next 10 years of the smallsat market will be defined primarily by the rollout of multiple constellations, which are estimated to account for 83% of smallsats, mainly for commercial operators (Fig. 1).

Much of the funding financing this technological progress and advancement stems from a boom in private investment in space start-ups. Over 400 start-ups have been funded with over $18 billion from over 500 venture funds since 2009, when SpaceX had its first successful launch, and this trend is accelerating (Fig. 2).

2.1 Capability Growth and Manufacturing: Launch Costs Decline

Capability of ICs of course has increased to where a watch has many times the power of a 1980s mainframe computer (device counts per CPU rising from 1000 in 1970 to circa 50 Bn in 2018), and though they are susceptible to gamma rays and other radiation damage on orbit, they are now so small, light, and power-conserving that multiple fail-over backups are feasible in a tiny package. Onboard processing can drastically reduce the amount of data to transmit on the downlink for Earth observation systems, while on-orbit intelligence can also adapt missions to new requirements once launched. This capability increase of roughly 50 million times from the days of the design of Voyager of course does not apply to all onboard systems, but many have come down dramatically due to their reliance on electronics.

Launch prices are key to this also and launch costs to Sun-synchronous orbit (SSO) range from $5,000/kg to ~$60,000/kg. The dispersion in launch prices reflects the differences between launch vehicles in terms of launch capacity (performance – kg to orbit – and launch rate); production and operation costs (as a result of differences in hardware, labor cost, and currency valuations); and versatility (i.e., the ability to accommodate and launch multiple payloads of various masses and volumes). However, prices advertised by providers and per kilo prices are not representative of invoiced prices, which are usually higher than advertised. This is because specific prices are calculated on the assumption that a launcher launches at full capacity (100% fill rate), an extremely rare scenario. Partially filled vehicles thus mean higher specific prices.

For now, launch competition remains driven by price with other factors such as on-time launch and injection precision as secondary considerations. Falcon 9 is the only launcher with a specific price as low as 5,000$/kg but for an entire Falcon 9, until in 2019 a new set of rideshare to SSO opportunities as early as 2021 was announced, starting at 5,000$/kg. The service aims to leverage first stage reutilization to provide yearly rideshare opportunities. Another launcher, India's Polar Satellite Launch Vehicle (PSLV), is also widely seen to be one of the most available and cost-effective. The Indian Space Research Organisation (ISRO) charged between 28,000$/kg and 38,000$/kg for 3 U CubeSats in 2018 and between 12,000$/kg and 16,000$/kg for heavier smallsats. Its Small Satellite Launch Vehicle (SSLV) is a new dedicated micro-launcher scheduled for a 2020 maiden flight and is expected to reduce price as low as 7,000$/kg and capture significant market shares. It theoretically combines the flexibility and reactivity of micro-launchers with the lower cost of a rideshare on a larger vehicle. The other small vehicles in development are by design more expensive than heavier solutions but allow for a shorter time to orbit. Prices from Rocket Lab, Virgin Orbit, and Firefly all have increased in recent years, ranging from 24,000 to 50,000$/kg. With a need to generate revenues and limited dedicated launch options available, prices are expected to stay at the current levels before increased global competition leads to lower prices. Moreover, the arrival of Chinese start-ups with competitive prices (e.g., 10,000$/kg for Kuaizhou-11) will push for mass production and high launch rates, eventually putting pressure on prices. The pricing of launch brokers comes at a premium as they act as a one-stop shop, giving access to multiple launch solutions, but they provide effective solutions for many players and improve utilization of launchers. Spaceflight Services, the only launcher broker with public prices, charges regardless of the launcher used, from $26,000 (for a 300 kg satellite) to 35,000$/kg (for a 50 kg satellite).

Cost declines driven by the availability of COTS components (for both hardware and software) and mass reduction for spacecraft which retain the same level of capabilities are also driving growth in value per dollar for small satellites. Combined, these trends show a dramatically rising value per dollar spent on spacecraft and launch to date, and these are expected to accelerate. This drives an increasingly robust market for small spacecraft and their services.

2.2 Propulsion Systems, Including the Electric Propulsion Paradigm Change

The small size and mass of CubeSats present challenges for adding propulsion, and most often they are so far launched without it. For missions in which rapid time to orbit and/or a maneuvering capability is required, standard chemical thrusters or solid propellant motors are often the best choices for larger spacecraft. However, many smallsats are too small for chemical propulsion systems, which are expensive in terms of volume, mass, and cost, in addition to the increased complexity of the small satellite. Therefore, given the volume, complexity, and cost of chemical propulsion systems, many smallsats did not have any propulsion capability in the past. Adding electric propulsion (EP) significantly improves the potential of the smallsat form factor, by enabling propulsive capabilities and autonomous maneuvers, which previously were limited to the largest smallsats and came at a high cost. In addition, most CubeSats share launch vehicles: this often subjects them to rules against the use of propellants such as hydrazine, or pressurized tanks in general. In consequence, today the majority of smallsats either tends toward electric propulsive capabilities or no propulsion, as the mass and cost of chemical propulsion remains prohibitive for most smallsats. Only smallsats in heavier mass categories may opt for a chemical propulsion system, often based on hydrazine. Green monopropellants are being developed as potential replacements to hydrazine, which is highly toxic.

The propulsive mass efficiency of propulsion systems is defined by their specific impulse (ISP). While chemical propulsion systems have specific impulse (ISP; a measure of fuel effectiveness), in the 250 s range, electric propulsion can reach ISPs of 4000 s and above, allowing a spacecraft to go much further per kg of propellant. The transition in larger satellites to electric propulsion, generally using Xenon or Krypton fuel ionized in a magnetic field and accelerated out the back of Hall-effect thrusters at very high speeds (typically up to 80 km/s), is only just reaching CubeSat-sized smallsats. In large spacecraft such thrusters can turn 1.35–10 kW of input power into thrust of 40–600 millinewtons for up to 8,000 s specific impulse at efficiency in the range of 45–60% (Choueiri 2009).

Today, smallsats can benefit from a growing range of propulsion types, currently available on the market or at various stages of development, from early research to the in-orbit validation of prototypes. Examples include cold gas thrusters, with an ISP around 80 s, solid fuel motors with an ISP around 210 s, water propulsion with ISP around 175 s, plasma (water) propulsion with ISP up to 750 s, and electric propulsion with ISP up to 6000 s. Bradford Space's ECAPS company developed a range of high performance green propellant (HPGP)-based thrusters enabling a 6% increase in ISP compared to hydrazine propellants (in addition to toxicity reduction), which have been adopted by a wide array of smallsat operators. Green propulsion systems using fewer toxic propellants from Ball Aerospace will also be tested on NASA'S Green Propellant Infusion Mission (GPIM).

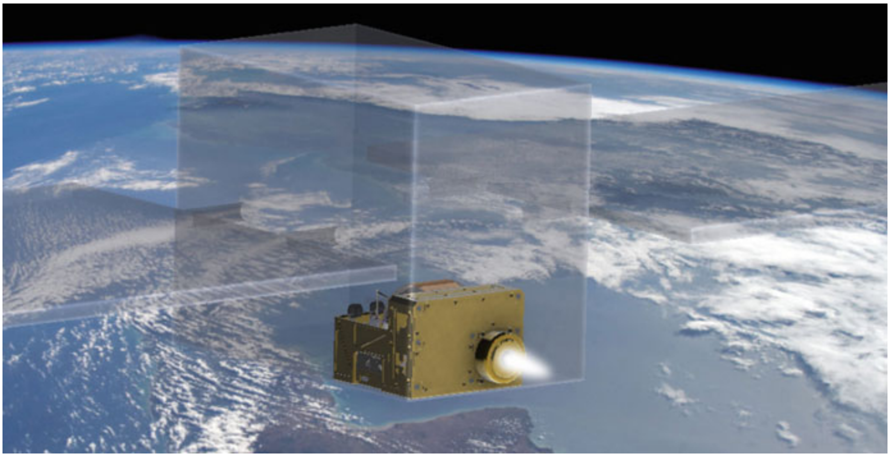

Fig. 3 Artist rendering of CubeSat radio frequency electric propulsion system. (Image: © Phase Four, 27 June 2019, All rights reserved to Phase Four; this figure is licensed to Springer to publish in the Handbook of Small Satellites)

Electric propulsion (EP) features many different subcategories undergoing parallel development, with a wide range of new entrants, many of which are spun-off from academia. Among the various types of electric propulsion are resistojets, electrosprays, ion engines, pulsed plasma thrusters, and Hall-effect and RF thrusters. Electric solid-state propellants also are under development to control ignition and extinguishment voltage. Hall-effect thrusters, for example, are under development by Accion, Phase Four (USA, shown in Fig. 3 below), ThrustMe (France), Clyde Space (UK), and Neumann Space (Australia), among others, most of which are targeting in-orbit demonstration within the year. Neumann Space aims for a 10 K second specific impulse ion thruster which can use a variety of fuels, and in 2019 Phase Four unveiled Maxwell, a CubeSat radio frequency plasma thruster capable of delivering up to 10 mN of thrust and up to 1,400 s of specific impulse, with total impulse of up to 14,000 newton-seconds. It is intended for satellites of 20–500 kg with 300–500 W power budgets.

The main impact of EP on satellite operations is an improved time to orbit as well as an optimized satellite lifetime. For geostationary Earth orbit (GEO) missions, the trade-off is often a slower orbit raise compared to chemical propulsion (4 months vs 1 week), which means delayed revenue generation, in exchange for a smaller, less costly satellite of equal capability (as the fuel mass saved can be replaced by either additional payload mass or significant savings on launch costs). However, when considering EP for low Earth orbit/Sun-synchronous orbit (LEO/SSO) operations, there are many variables to consider. Smallsats launched via ridesharing tend to be released as secondary payloads into the orbit of the main payload. While this is the least expensive access to space option for smallsats, it is also the least practical. EP thus enables them to perform orbital maneuvers such as orbit raising, plane changes (i.e., modifying the inclination of an orbital plane, effectively accessing another orbital plane), and constellation phasing (i.e., spreading the satellites along an orbital plane), allowing the satellites to autonomously reach their final orbit.

Considering that satellites in LEO have relatively short lives, some satellite operators take this to the extreme and forgo propulsion altogether (e.g., Planet, Spire). If low enough, satellite phasing can be achieved by altering the orientation and drag profile of each satellite (or its solar panels) thus modifying the orbit without propulsion. In 2019, the use of EP for attitude control of a smallsat was demonstrated by Morpheus Space, which flew NanoFEEP thrusters on the UWE-4 technology demonstration 1 U CubeSat.

In 2019, the Federal Communications Commission (FCC) released new regulations meant to streamline licensing procedures for small satellites. However, only satellites up to 180 kg, within a limit of 10 satellites (i.e., constellations under 10 spacecraft) and with 6 years of orbital lifetime, would be eligible for this fast-track licensing regime. Application fees would be reduced from \$450 k to \$30 k for eligible satellites. The applicant would have to prove that he mitigates the risk of creating new space debris. If the orbit is above 600 km, a propulsion system is required to ensure a secure end-of-life removal and to enable collision avoidance maneuvers. Satellites would also be required to carry a telemetry marker so that ground teams are able to distinguish it from other satellites. This specific regime does not apply to mega-constellations or to CubeSats with a 1 U form factor.

2.3 Standardization and Commercial Off-the-Shelf (COTS) Hardware Lowering Costs

Standardization is now a strong growth factor for smallsats. In the past, initial missions used to be one-off custom efforts. With a focus on rapid and low-cost development, standardization facilitates compatibility and interoperability and removes the obstacles related to legacy technology by allowing the simultaneous use of upgraded components and software.

Standardization is even more critical at subsystem level than for the satellite itself. The 1 U CubeSat standard (10 × 10 × 10 cm) established in 1999 aimed to facilitate design and manufacturing by research institutions using non-space-graded hardware. It was later adopted by commercial operators for operational services. The CubeSat form factor is so far the only standardized platform bringing agility to launch services with their ability to swap launchers on short notice thanks to CubeSat dispensers, booked by launch brokers who buy unused capacity from launch providers.

Seeking to replicate the success of the CubeSat form factor, the Aerospace Corporation proposed another launch standard, Launch-U, in August 2018. This standard for larger smallsats (45 × 45 × 60 cm; 60–80 kg), if adopted by the industry, would provide the same platform agility as the CubeSat form factor. One Launch-U equals roughly 96 units. Rocket Lab's Electron and Virgin Orbit's LauncherOne would, for example, be capable of hosting up to two and seven Launch-U's under their fairings, respectively.

In heavier mass categories, platform diversity is driven by mission diversity. Several platforms are compatible with the Evolved Expendable Launch Vehicle (EELV) Secondary Payload Adapter (ESPA) ring payload adapter enabling piggyback launch options. No other comprehensive initiatives have yet materialized in a single format. Further initiatives envision satlets, or easily stackable modular spacecraft that can be connected depending on mission requirements, with the involvement of the Defense Advanced Research Projects Agency (DARPA) and NovaWurks.

The multiplication of dedicated suppliers was key to the development of the industry. Commercial off-the-shelf (COTS) hardware, miniaturization, electronics integration, and sometimes non-space-graded components allow reasonably similar performance at smaller size and lower cost. Low development costs and short manufacturing times are key advantages of smallsats, in addition to large-scale manufacturing economies of scale and continuous iteration in product development. CubeSat platforms are now a commodity allowing operators to focus on the design of their payload or on their business of selling satellite services. Online procurement is now common to build CubeSats. Smallsat manufacturers are positioning themselves as “one-stop shop” suppliers, offering simulators and payload development tools in addition to satellite platforms plus turnkey services (testing, regulatory compliance, insurance, launch procurement, ground control).

Larger small satellite platforms have yet to become truly recurring products, and modifications are often needed to adapt to each mission’s requirements. Regarding mechanisms, the development of microelectromechanical systems (MEMS) helps with the miniaturization of some subsystems, enabling them to fit into smaller form factors. Oxford Space Systems, for example, develops deployable antennas and solar panels, stored energy hinges, and extendable booms. This also allows avoiding the use of pyrotechnic devices wherever possible, due to their potential hazards, so other release mechanisms such as springs or sophisticated MEMS are used. In 2019, NSLComm launched a constellation prototype designed to test its deployable antenna reflector using built-in shape memory polymers, which could result in throughputs as high as 1 Gbps; an impressive feat for a 6 U Ka-band CubeSat.

2.4 Directed Beam Telecoms for Small Satellite Systems

Directed beam flat panel array antennas and associated processing systems both on the spacecraft and on ground terminals are expected to soon have a major impact on small satellite and ground segment capabilities. As small satellites tend to be in low Earth orbit, tracking antennas on user terminals are required to keep one or more spacecraft in the receive beam of the terminal. Medium Earth orbit systems like O3B also require tracking, and early commercial terminals are so far primarily using physically moving dishes, but flat panel phased arrays are currently being developed by many stakeholders seeking to profit from the important forecasted markets for flat panel antennas.

The flat panel antenna system used onboard MarCO A and B is still beyond the budget of most CubeSat builders, but flat panel phased array antennas on satellite terminals with associated processing to track LEO orbiting CubeSats appear to be incoming, to be followed by commercial flat panels orbiting on smallsats themselves (thereby eventually able to create multiple beams toward ground terminals).

In support of developing economical CubeSat-flown flat panel arrays, NASA/JPL has proposed the Integrated Solar Array and Reflectarray Antenna (ISARA) mission. It is intended to test the integration of a flat reflector into the solar array used to power a CubeSat, thereby raising data rates from the 9.6Kbps now typical in CubeSat links using high frequency band radio (3–30 MHz) to over 100 Mbps at Ka band (26.5–40 GHz, further discussed below), without adding the size and mass of a separate flat panel array antenna to the spacecraft (JPL CubeSat).

On the user terminal end of CubeSat space segment communications, Kymeta Corp. of the USA began shipping its metamaterial electronically steered flat panel antennas to customers in 2017, although for now these are intended mostly for systems using larger satellites and come at a high cost per unit. The ground terminals are thus mostly reserved for yachts, commercial ships, tractors, and first responder vehicles. ThinKom Solutions, also in the USA, also produces commercial phased array antennas for aircraft and motor vehicles that are expected to work with future low and medium Earth orbit constellations. Meanwhile, Phasor is testing low-profile electronically steered broadband antennas for buses, ships/yachts, and aircraft. Many more products are coming, including entries from Isotropic Systems, Alcan Systems, C-Com Satellite Systems, SatixFy, AvL Technologies, Ball Aerospace, Rockwell Collins, and Viasat (SpaceNews 2018).

2.5 Use of Additional Spectrum Bands by Small Satellites

Spectrum represents one of the top requirements for all satellite operators, and CubeSat systems tend to be able to afford less while needing more than traditional systems. Traditional communications satellites in geosynchronous Earth orbits (GEO) have historically used C band at 4–8 GHz, now coming into use also for 5G mobile, Ku band at 12–18 GHz, and recently Ka band at 26.5–40 GHz for their space segments to fixed terminals. Ku and Ka are named for being under and above the 22.24 GHz water vapor resonance which absorbs radio waves strongly. For mobile satellite services, the prized lower spectrum bands include L Band at 1-2GHz in mixed mobile and fixed use and S band at 2–4 GHz (though portions of both bands are reserved for terrestrial mobile communications).

The use of Ku and Ka band by LEO smallsats is relatively new and was allegedly inaugurated by two Canadian companies, Telesat and Kepler Communications in 2017 and 2018, respectively (however, OneWeb and SpaceX claim they were first for primacy rights on spectrum, which are given on a “first come first served” basis at the FCC). Further applications for these bands have been made by more than eight other LEO operators.

Some large new constellations are using a wide variety of bands outside of the mainstream, such as China's Galaxy Space launch of a Q/V band prototype for a potential future constellation in 2020, and some systems are using newly efficient algorithms to separate thousands of terminals' signals from one another in a very narrow bandwidth. An example of the latter is Australia's Myriota, whose constellation of polar orbit nanosatellites will use a tiny sliver of L band to collect data from terrestrial Narrowband Internet of Things (NB-IoT – a primary terrestrial IoT standard) environmental sensors outside of mobile network coverage. Limited to 24 bytes every 4 h in one direction only, no panoramas of the bush are feasible, but very inexpensive sensor data collection is, such as whether cattle have enough water in a given spot. This is a truly tiny sliver of usage compared with the "Internet Everywhere" constellations discussed below, and supports very small terminals with very long battery lives by comparison, as well as economizing on spectrum.

2.6 Militaries Across the World Show Substantial Interest in Smallsat Constellations

Whether through hardware failure, debris impacts, or aggressive external action, the premature loss of a satellite has extensive repercussions, due to its replacement cost and to the loss of significant projected benefits/revenues during its expected lifetime. Smallsat constellations, on the other hand, are designed with redundancy and resilience at heart. When the size of the constellation is sufficiently large, the loss of even a handful of satellites may have little to no impact on the final service offered to end users. Additionally, ground spares can be launched much more easily and rapidly than for larger satellites, and many constellations plan in-orbit spares for maximum reactivity, i.e., satellites "standing by" in case of failures and ready to provide a service. The US military, for example, is more and more involved in the smallsat industry, as low-cost, expendable, and distributed assets such as smallsat constellations are far more resistant to enemy action and a strong advantage in any conflict.

Defense agencies have supported smallsats since the 2000s but have been reluctant to use them beyond in-orbit demonstration. Increased threats in the space environment, coupled with budgetary realities and the flexibility and resiliency of smallsats, make small satellite ventures inherently well positioned to meet those needs. The Blackjack program, led by the DARPA in collaboration with the Rapid Capabilities Office, is an architecture demonstration intending to show the utility of global LEO constellations and mesh networks of lower size, weight, and cost based on commercial smallsat platforms to the military. In the meantime, Viasat was awarded a demonstration contract for a tactical LEO comms demonstrator using Link 16, a NATO communication protocol. The newly created Space Development Agency released in 2019 an RFI for agile and responsive architectures aiming to leverage industry solutions.

The world's military organizations are also suddenly interested in the development and launch of LEO constellations, both for telecommunications (global coverage, low latency, resiliency) and Earth observation (surveillance, monitoring of enemy activity and conflict zones, border security, etc.). Part of the rationale for this is the capability to detect the ionized exhaust trails of hypersonic cruise missiles while remaining difficult for anti-satellite (ASAT) weapons to take out, unlike large single spacecraft which are vulnerable to ASAT weapons. Russia claims to have flown a hypersonic cruise missile, the Avangard, from the stratosphere over the Ural Mountains in Eastern Russia to hit a target on Kamchatka Peninsula on its Pacific coast 6,000 km away, at Mach 27, a speed very close the Space Shuttle's reentry velocity. This was launched by a rocket and thus would have been visible initially to existing anti-ICBM systems but would have become effectively invisible during its cruise phase, in which it reportedly remained fully maneuverable. Another Russian hypersonic cruise weapon, Kinzhal, is reported capable of Mach 10 under its own power, with no rocket boost phase, and hence would be invisible to current detection satellites. Russia claims operational deployment of its initial hypersonic systems. China also tested its Xingkong-2 "Waverider" hypersonic cruise missile in 2018. This weapon also reportedly demonstrated full maneuverability through the stratosphere at Mach 6, described by the China Academy of Aerospace Aerodynamics as able to "break through any current generation anti-missile defense system," hence the development priority for new smallsat-based defense systems.

In light of these announcements, the USA and its allies have raised focus on catching up and begun greater financing of this effort, with the USA reportedly allocating circa US$1B per year to it. France and Japan also are joining the race, France to launch hypersonic weapons in 2022 and Japan in 2026 (per the U.S. Congressional Research Service, 2019). Hypersonic vehicles also experience ionization envelopes, essentially like the impenetrable ones enveloping the Space Shuttle on its reentry as their speeds approach Mach 17. This makes communicating with these weapons challenging, and new satellite systems may facilitate circumventing this problem also.

The race to be able to detect and deflect these weapons is on for real now, undoubtedly funded in most countries capable of developing them. Detection of hypersonic weapons' flight paths and intended targets, as well as communicating with anti-hypersonic missile systems which will be built to respond, requires satellite systems, and the advent of anti-satellite weapons tested successfully by the USA, Russia, China, and India up the ante on required resilience of such systems. Likely responses will therefore entail large LEO constellations, a step function in military demand for such systems.

The USA, for example, considers launching hundreds of small satellites with sensors capable of tracking heat sources an order of magnitude cooler than rocket boosters, making them hard to take out by deploying many of them. The satellites would also be used to help guide US hypersonic weapons. The full Hypersonic and Ballistic Tracking Space Sensor network could be up and running by 2030 (Stone 2020a) (Fig. 4).

Pentagon's New Space Agency Seeks $10.6 Billion Over Five Years Bloomberg, 4 Oct 2019

The US launched its Space Command and Pentagon Space Development Agency in 2019, and France announced it is arming its new satellites.

This raised serious fears of Kessler Syndrome from cascading Orbital Debris impacts.

More additional countries are expected establish or expand military forces in space in 2020

Space Development Agency Head Fred Kennedy Presentation, April 9, 2019

2.7 Small Spacecraft Onboard Processing via AI and Machine Learning

James Lovelock, at 100 years old, in his recent book *Novacene*, postulates a rapid evolution to a benevolent AI/Human stewardship of our planet. He notes: "The sea bird, with its graceful flight, took more than 50M years to evolve from its lizard ancestors. Compare this with the evolution of today's airliners from the string-bag airplanes that flew a mere 100 years ago. Such intelligent, intentional selection appears to be a million times faster than natural selection. By moving beyond natural selection, we have already enrolled as sorcerers' apprentices.[10]" His prediction may be considered to be reflected, among many places, in AI for small Earth observation spacecraft.

CubeSats and large data flows do not mix well, as high data rates require large communication systems to operate. Initial examples of AI in small satellites are therefore focused around drastically reducing the data stream required for remote sensing/Earth observation satellites. On the upcoming Federated Satellite System Catalunya (FSSCat) mission by the European Space Agency proposed by Spain's Universitat Politècnica de Catalunya, AI technology will fly on one of the two CubeSats (federated over a radio and optical intersatellite link) that make up the mission – the mission consists of two 6 U (i.e., 6 of the 1 U volume of 10 × 10 × 10 cm) CubeSats working together in support of the Copernicus Land and Marine Environment service. Sensors will include a Global Navigation Satellite

System (GNSS) reflectometer, an L-band radiometer, and a multispectral optical payload to measure soil moisture, ice extent, and ice thickness and to detect melting ponds over ice. One of these spacecraft, dubbed PhiSat, will have the ability to decide for itself which images are worth sending back to Earth for further analysis.

Raw data is generated in orbit and transmitted to Earth ground stations, after which it is processed and analyzed. Satellite throughput is limited by bandwidth, and ground stations as well as data centers are costly, particularly for new entrants, and often saturated. With terabytes of data being routinely generated, and much of it commercially unviable, the costs associated with data downlink, storage, and analysis can become too much to bear and an important barrier to entry. So far, few players have sought to address this inefficiency, which increases in direct relation with the increase in data generation.

Onboard processing reduces the amount of unused data while improving accuracy and pertinence of received data, as it allows satellites to perform initial autonomous data analysis in orbit. Only relevant data is downlinked back to Earth, reducing the need for storage, making data easier to find, and reducing the final cost per GB of data. Human interaction with the data is refocused onto decision-making rather than analysis.

This trend will lead to improvements in satellite design, ease strain on the value chain, reduce operating costs, and improve profitability. In 2018, the HyperScout CubeSat mission demonstrated this capability in orbit, and the OVERPaSS consortium, led by Earth-I and including Surrey Satellite Technology Ltd (SSTL), was founded to develop onboard data processing capabilities.

2.8 New Design and Manufacturing Methods

The processes used for initial design of small spacecraft and the constellations they will form are accelerating along with the rapid tailored fabrication and mass production of the satellites.

Increasingly, new high-level system design is being supported by modular, shared Digital Twin modelling generally referred to as concurrent design. A burgeoning example of this method is used by the Australian National Concurrent Design Facility of the University of New South Wales (UNSW) Canberra. In this system, modules of simulation code have been built around core spacecraft simulation software from France's National Centre for Space Studies (CNES). This has adapted the system to smaller missions and enabled a real-time high-level design process in which technology specialists use design elements for power/solar arrays, propulsion systems, launch weight and distribution of mass, thermal balance, communications link and spacecraft bus loadings, etc (Fig. 5).

Design beyond individual spacecraft, to the constellation level with orbital dynamics overlaid on link budgets; intersatellite communications and shared processing; Telemetry, Tracking, and Command; and traffic carrying links to Earth stations, is next up for this process. Other concurrent design facilities are used by

Fig. 5 Australian National Concurrent Design Facility at UNSW Canberra. (Image © UNSW Canberra. All rights reserved to UNSW Canberra; this figure is licensed to Springer to publish in the Handbook of Small Satellites)

major prime contractors and NASA (e.g., the Goddard Space Flight Center and Integrated Design Center for Concurrent Engineering).

2.9 Improved Access to Space Reducing the Launch Bottleneck

The market entry of SpaceX and Rocket Lab and the capacity to deploy CubeSats from the International Space Station (ISS) have greatly improved access to space for small satellites in recent years, combined with the launch of hundreds of smallsats of Indian and Russian launch vehicles. This is just the beginning. On the launch side, future developments include new and established players that seek to challenge SpaceX on the launch cost side, or by seeking to provide a different value proposition (e.g., a better time to orbit, premium services via dedicated launches, more flexibility, etc.). In 2019, SpaceX dramatically undercut its smallsat launch prices by offering lowest pricing in the industry, with regular rideshare opportunities into subsynchronous orbits for $5,000/kg of payload, a substantially lower price, competitive even with the cheapest Indian and Chinese launch solutions, starting in 2020/2021. Rising companies capable of challenging SpaceX to look forward to include Blue Origin with its New Glenn launch vehicle (with a massive performance to LEO and a 7-m fairing capable of launching hundreds of smallsats at once, in addition to partial reusability with first stage recoveries and reuse) and Relativity Space (which seeks to additively manufacture launch vehicles in a matter of weeks instead of months, at a very low cost; See Fig. 6). SpaceX itself is not staying idle

Fig. 6 Relativity Space Stargate Printer. (Image: © Relativity Space; All rights reserved to Relativity Space, this figure to be licensed to Springer to publish in the Handbook of Small Satellites)

and is trying to improve its own capabilities through the development of Starship, a very ambitious fully reusable and super heavy-lift launch vehicle which would be the largest launch vehicle operational, if SpaceX demonstrates its technical, financial, and legal feasibility. As it is fully reusable and expected to be capable of launching dozens, if not hundreds, of times, its marginal launch cost would be limited to refurbishment operations and refueling activities (which Elon Musk has said to be as low as $900 k), totaling about $2 million per flight (i.e., less than the cheapest and smallest launch vehicles, despite a massive payload capability). This is however uncertain/remains to be proven.

Other more exotic and “nonconventional,” low-TRL (technology readiness level) technologies are being introduced despite their lower credibility and higher risk, such as SpinLaunch, a start-up funded to develop a centrifugal force “space catapult,” succeeding at multiple major fund raisings despite a widespread skepticism about its technology.

Furthermore, online procurement is now common to build CubeSats, and smallsat manufacturers are positioning themselves as “one-stop shop” suppliers, offering simulators and payload development tools in addition to satellite platforms plus turnkey services (testing, regulatory compliance, insurance, launch procurement, ground control). Launch brokers and micro-launchers are now offering online booking systems to simplify procurement. With dozens of micro-launchers in development, smallsats are poised to benefit from more launch flexibility for reaching specific orbits and to reduce time to launch, at the cost of a premium in $/kg compared to a rideshare launch on a heavier vehicle. Micro-launchers aim to launch every couple of weeks or even days, although such responsiveness and launch rates have yet to be demonstrated (Figs. 7, 8 and 9).

2.10 Launch Brokers: A Middleman Business Model Providing Flexibility

Launch brokers optimize payloads across multiple launch systems and, in doing so, offering customers easier/cheaper and wider access to orbit. This service allows for

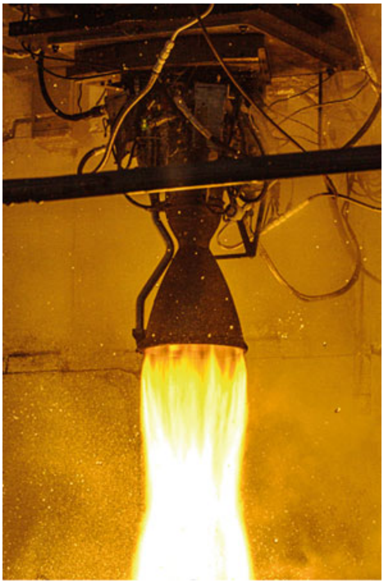

Fig. 7 Rocket Lab 3D printed Rutherford engine firing. (Image: © Rocket Lab; All rights reserved to Rocket Lab, this figure is licensed to Springer to publish in the Handbook of Small Satellites)

Fig. 8 SpaceX Starship. (Image: © SpaceX; All rights reserved to SpaceX, this figure is licensed to Springer to publish in the Handbook of Small Satellites)

significant cost savings for operators compared to buying an entire launch, which may be either unaffordable or impractical because their satellite weighs only a few kilograms. Aggregators offer a comprehensive service through aggregating and marketing excess payload space and assisting in integration and overall logistics. The logistical support of brokers for mission preparation and integration may also be essential for small operators not familiar with these activities. The business model of the launch brokers is complex: as they aggregate unused payload space on multiple launchers, they must accommodate the schedules of the launch provider, the primary

Fig. 9 Virgin Orbit LauncherOne/Cosmic Girl. (Image: © Virgin Orbit; All rights reserved to Virgin Orbit, this figure is licensed to Springer to publish in the Handbook of Small Satellites)

mission, and the secondary passengers. They also must include the margin of the launch provider into their costs. Launch brokers include Spaceflight Services and NanoRacks LLC in the USA, which democratized access to space via the ISS, as well as ISIS (Netherlands), Exolaunch (Germany/Russia), Precious Payload (USA), and Space BD (Japan), which has access to Japan's Kibo module on the ISS, and which early-on specialized in ISS launch, but is now branching out and has contracts as far away as Australia.

2.11 An Evolving Ground Segment Ecosystem

The ground segment is evolving to adapt to the growing smallsat market, in anticipation of significantly higher volumes of data expected to be downlinked in the coming years. Ground stations for data transmission and reception represent significant capex investments, especially for new entrants with less resources to expend. Due to the need for multiple stations to ensure global coverage, it can be too costly to implement for most emerging players. Companies such as RBC Signals, Spaceflight Networks, Infostellar, Leaf Space, and Amazon Web Services (AWS) propose access to their ground station networks with pay-as-you-go customized services ("space as a service"). Customers can adapt their contracts to their needs (e.g., continuous or sporadic data downloads). AWS's market entry is likely to disrupt other players, as the company will enable important synergies with its data storage and analytics capabilities. It seeks to operate a global network of Lockheed-built ground stations, starting with 12 locations and 8 publicly disclosed customers, including Capella Space, Spire, Maxar's DigitalGlobe, Myriota, D-Orbit, NSLComm, Open Cosmos, and Thales Alenia Space.

2.12 Resulting Mega Constellations

Advanced systems with greater bandwidth and very large numbers of satellites, enabled in part by the above technology advances, are now being proposed, developed, and launched in the case of the most advanced players (Starlink and OneWeb). Some are seeking to employ nontraditional bands, often for the first or nearly the first time. SpaceX's Starlink constellation, for example, intends to use Ku and Ka for early generations of satellites and is reportedly considering using V band and optical intersatellite links in later generations of satellites. Starlink will reportedly use phased array antennas at Ku and Ka bands on 260 Kg spacecraft initially at 550 km orbits, as well as on consumer ground terminals "with flat antennas the size of pizza boxes." Initial Starlink and OneWeb launches have lacked optical intersatellite links, but these are planned for in later generations. Due to the high cost of laser terminals (a very early stage technology), it is likely that SpaceX will try to internalize their design and production for more vertical integration and cost synergies. The satellites will use more traditional Hall-effect thrusters with Krypton fuel, cheaper than the Xenon in widespread use for electric spacecraft propulsion on larger spacecraft, and more traditional than other electric small spacecraft propulsion systems discussed here. This constellation has filed for licenses to grow from its existing 300 satellites (as of March 2020) to over 12,000, and possibly 42,000, but this remains highly unlikely due to the cost of manufacturing and launching the satellites. SpaceX itself has said that less than 2,000 satellites would be sufficient to start an operational service, and the high figures are likely to include several generations of replacement satellites, as their lifetime is limited to about 5 years.

Amazon's Kuiper constellation FCC application ("APPLICATION FOR AUTHORITY TO LAUNCH AND OPERATE A NON-GEOSTATIONARY SATELLITE ORBIT SYSTEM IN KA-BAND FREQUENCIES") describes a system of 3,236 satellites in 98 orbital planes, at altitudes between 366 and 391 miles, to serve "tens of millions of customers" with internet over Ka band (17.7–20.3 GHz, primarily for customer connections, and 27.5–30.0 GHz primarily for gateway connections). The system is intended to be sold through mobile network operators to reach customers outside their coverage areas. Initial targets mentioned in the FCC application include mobile services to aircraft (where initial trials have exceeded 600 Mbps), maritime vessels, land vehicles/first responders and fixed services to homes, schools, businesses, hospitals, and government agencies. The system will use software-defined networking (SDN) control and new technologies for spectrum sharing and control being developed by Amazon, building on its drone work.

One of the most mysterious constellation plans, most of which remain highly uncertain, is that of Facebook, which filed a small satellite experimental application in 2018 via its subsidiary PointView LLC. The project, as reported by IEEE and Wired, is to be called Project Athena, and early concepts imagine up to 1100 LEO satellites. Little information is available on the project, but Facebook and PointView LLC have been experimenting with optical laser links and with the exotic E-band (71–76 GHz for downlinks and 81–86 GHz for uplinks) which is said to be capable of 10 Gbps downlinks and 30 Gbps uplinks, a massive improvement over tradional alternatives. It however remains to be demonstrated, and the launch of its first Athena prototype has been delayed to 2020 due to the 2019 Vega launch failure. Facebook is probably waiting for demonstration results to take a go/no go decision for a constellation, particularly as it would be very late to market. It remains to be seen whether the technology works as expected and whether it makes economic sense.

Apple also has hired senior satellite executives and engineers and is thought to be at least tentatively considering a direct-to-handset service and/or seeks synergies with its autonomous vehicle business.

These and other main large planned constellations are summarized in Fig. 10 below. The list is not exhaustive and only includes some of the most credible players. Not all will be funded and launched.

3 Small Satellite Market Growth Patterns

A total of 1,470 smallsats was launched from 2009 to 2018, i.e., an average of about 147 units per year. Most of them (53%) were launched over 2015–2018, mainly for Planet and for academic purposes. The dominant smallsat applications were technology demonstration and Earth observation with proof-of-concept missions seeking to demonstrate platforms and payloads and the deployment of the first smallsat constellations. In the future, smallsats will continue to be used for Earth observation, however second to satellite communications, as several constellations will launch for broadband and narrowband communications.

Over the next 10 years (2019–2028), Euroconsult anticipates that about 8,600 smallsats will be launched, at an average of 835/year by 2023, growing to an average of 880/year by 2028. Euroconsult's 2019 forecast for the next 10 years increased by 22% over the 2018 estimates, highlighting the untapped demand potential for several applications in some regions of the world and new entrants such as Amazon's Project Kuiper constellation. The future smallsat market will be driven by the rollout of several constellations, mainly by commercial operators for broadband communications, Earth observation, and data collection services. Constellations are anticipated to account for 83% of the 8,600 smallsats to be launched. The constellation market is cyclical with strong year-to-year variations driven by their initial deployment in batches within a short period of time in order to begin services as early as possible, followed by waves of replacement satellites. The market for single-satellite missions (about 1,470 units) is more evenly distributed over time.

Most future smallsats (circa 70%) will be launched into LEO. Telecom constellations in LEO seek to enable wide or even global connectivity at lower latencies. Meanwhile, Sun-synchronous orbits (SSO) will be the main destination for most Earth observation satellites. Geostationary transfer orbits (GTO), not a traditional smallsat destination despite new small GEO satellite projects, are increasingly being used as an injection orbit for science/exploration missions beyond Earth orbit.

The smallsat market is going through significant expansion in terms of both capabilities and demand. While 2018 did not exceed 2017's record, the number of

satellites launched remained stable (322 compared to 330 in 2017), at a 93% increase from the 167 units average observed over 2014–2016. The past and current years are critical for the smallsat industry with the launch of the first operational satellites for telecom mega constellation ventures, and the maiden flights of several micro-launchers, with contrasted outcomes. Moreover, mass production facilities are becoming operational and are expected to further lower the manufacturing cost of smallsats.

In the last 2 years, numerous companies have developed satellite solutions, largely based on constellation projects, to deliver better services and reach out to new users. These solutions are supported by new ventures and entrepreneurs investing in the so-called "new space" or "adaptive space" environment. The objectives of the numerous low-cost constellations in development are to provide global, low-latency connectivity from a single system (telecom segment), high-frequency change detection (Earth observation segment), and low data rate/narrow-band data collection services from ground sensors such as remote devices and connected vehicles (information segment). The information segment is critical for the emerging Internet of Things (IoT) and Machine to Machine (M2M) communications sector, as well as for air and sea traffic monitoring systems including space-based automatic identification system (AIS – ship locations), automatic dependent surveillance – broadcast (ADS-B – aircraft anti-collision system), and radio frequency (RF) monitoring. The market is aided by advances in satellite systems miniaturization, permitted by new technologies in space and space-related sectors, particularly in computational technology and data analytics. As a result, smallsats are now providing operational services that were previously only achievable through heavier satellites.

The 1,470 smallsats that were launched between 2009 and 2018 have an estimated total market value of $12.6 billion (manufacturing and launch combined). The 8,588 smallsats that are due to be launched over 2019–2028 are valued at $42.8 billion, i.e., almost a quadrupling decade-to-decade. Market value is expected to grow more slowly relative to the number of smallsats, reflecting the growing penetration of low-cost smallsats for (Euroconsult 2019) CubeSats and nanosats below 50 kg of launch mass and (Investment in Space Startups 2009) large-scale constellations with a satellite cost of $1 to 1.5 million per unit. This is also representative of the expected decrease in the average cost per kg of smallsat expected in the coming decade, as more affordable platforms and payloads will be introduced on the market and increased competition driven by new entrants will lead launch service providers to lower their prices.

Smallsats <10 kg (mostly 3 U CubeSats) alone will only account for an estimated 2% of future total market value over 2019–2028, due to their low manufacturing and launch value compared to larger smallsats.

Satellite manufacturing is expected to represent 70% of the $42.8 billion future market, i.e., $30.1 billion, with the remaining 30% dedicated to launch services. Most of the smallsat manufacturing market value is placed with large or small integrators that are independent of the satellite operator. In-house manufacturing remains the rule for most satellites below <50 kg and for academic CubeSats;

however larger smallsats tend to favor outsourcing production to third-party integrators.

Three broadband mega constellation projects (SpaceX's Starlink, OneWeb, and Amazon's Project Kuiper) concentrate most of the demand, in terms of number of satellites, launch mass, and market value. However, they are not representative of the industry as a whole, which is highly diverse due to the variety of operators, start-ups, universities, and emerging countries accessing space for the first time, thanks to the growing affordability and capabilities of smallsats.

3.1 Launch

The 1,470 smallsats launched between 2009 and 2018 were not equally distributed among countries of the smallsats' operators and those of the launch services providers. Only 11 countries own autonomous access to space capabilities and have launched smallsats for their own needs but have also launched on behalf of 65 other countries as they export their launch services capabilities. However, countries with autonomous access to space are not always able to retain domestic demand, and local smallsat operators may procure a launch service abroad, if a better value proposition is found elsewhere. This happens when domestic supply is not available, not compatible with the mission, or not sufficiently affordable for the satellite operator (Fig. 11).

The concentration of dedicated micro-launchers under development in the USA is not a surprise but a consequence of inadequate launch supply in the USA as 35% of smallsats operated by US operators were launched by either India or Russia over 2009–2018. Upcoming dedicated launch suppliers are looking to capture this demand with attractive solutions and are lobbying the US government to prevent this demand drain from a regulatory point of view, claiming that they will soon be able to offer domestic access to space solutions for smallsats. For example, launching on India's PSLV is not forbidden to US operators, but it is frowned upon, and operators still need to solicit a waiver from the government. On the other hand, US smallsat operators emphasize their current needs to be launched as soon as possible, regardless of the launch provider's country of origin, as being prevented from launching, or a delayed launch may endanger their business (Fig. 12).

From 2009 to 2018, the small satellite launch market remained concentrated with four launch providers, representing 58% of the revenues. With $586 million, Arianespace dominated the market with its Vega and Soyuz launch vehicles. The French-based company is closely followed by SpaceX at $544 million, Chinese national launch provider China Great Wall Industry Corporation (CGWIC), which commercializes a wide range of launch vehicles and is in charge of deploying most Chinese small satellites ($491 million), and Northrop Grumman (which includes Orbital ATK since its acquisition) using former intercontinental ballistic missiles (ICBMs) Minotaur and Taurus, as well as Pegasus and Antares (International Space Station (ISS) cargo resupply mission), at $443 million.

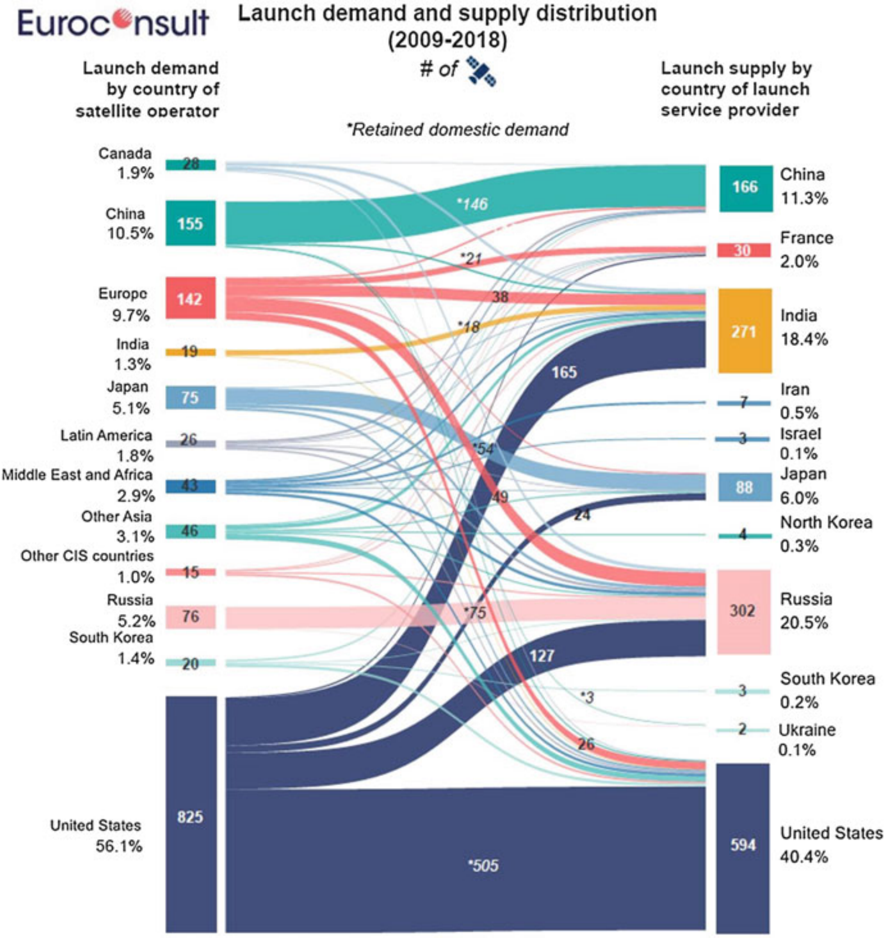

Fig. 11 Launch demand and supply distribution per country of satellite operator and launch provider for the 1,470 small satellite launched over 2009–2018. (Source: Euroconsult 2019; All rights reserved to Euroconsult, this figure is licensed to Springer to publish in the Handbook of Small Satellites)

The profiles of launch revenues were very different from one launch service provider to another. Arianespace has generated an average revenue of $33 million per launch with a total of 30 satellites over 10 years, mainly due the relatively high prices of dedicated Vega missions. In the meantime, SpaceX and Northrop generated on average $12 million and $23 million per launch, respectively, with a total of 163 and 210 satellites each, respectively, over 2009–2018, reflecting the average form factor difference between the providers, as they launched large numbers of low-mass CubeSats during ISS cargo flights.

An estimated $3.5 billion in revenues were generated by smallsat launches over 2009–2018, out of the $12.6 billion manufacturing and launch total market value.

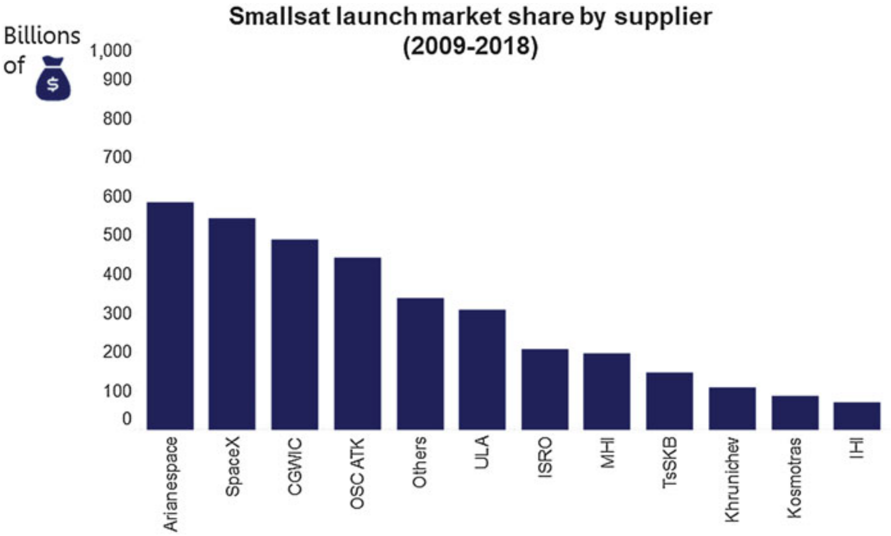

Fig. 12 Smallsat launch market share by launch service provider over 2009–2018. (Source: Euroconsult 2019; All rights reserved to Euroconsult, this figure is licensed to Springer to publish in the Handbook of Small Satellites)

Annual variations ranging from $206 to $864 million were experienced, depending on mission readiness and launch vehicle availability. Over 2019–2028, launch services are expected to generate $12.7 billion, a + 260% increase over 2009–2018. The expected growth in launch cadence and volume (from 1,470 to 8,858 smallsats to be launched), combined with anticipated long-term reductions in average access-to-space costs, are the leading launch market growth drivers.

Different trends affect the two ends of the mass spectrum: <10 kg smallsats will witness a slower average cost per kilo decrease from $45 k to $37 k (−18%) as a consequence of the higher specific prices of dedicated micro-launchers; average >250 kg smallsat launch costs will fall from $45 k to $8 k (−82%). This is a result of super heavy-lift capabilities arriving on the market, such as SpaceX's Falcon Heavy and Blue Origin's New Glenn, which are expected to leverage partial reusability and batch launches to cut prices.

Heavier (51–500 kg) smallsats generate more revenue, as they use more of a launcher's capacity, filling launch vehicles more quickly than lighter satellites. This mass category should generate $11.5 billion in launch value over 2019–2028, a + 281% increase over the previous decade, driven by the three communication mega constellations (Starlink, OneWeb, Kuiper). This mass category accounts for 91% of launch market value over 2019–2028. Mega constellations also affect targeted orbits for the >51 kg mass category, as communication smallsats destined for LEO account for much more mass and value than Earth observation smallsats to be launched into SSO (most of which are <50 kg, hence the stable value shares for that mass category). SSO's share is therefore expected to fall from 42% to 18% of the

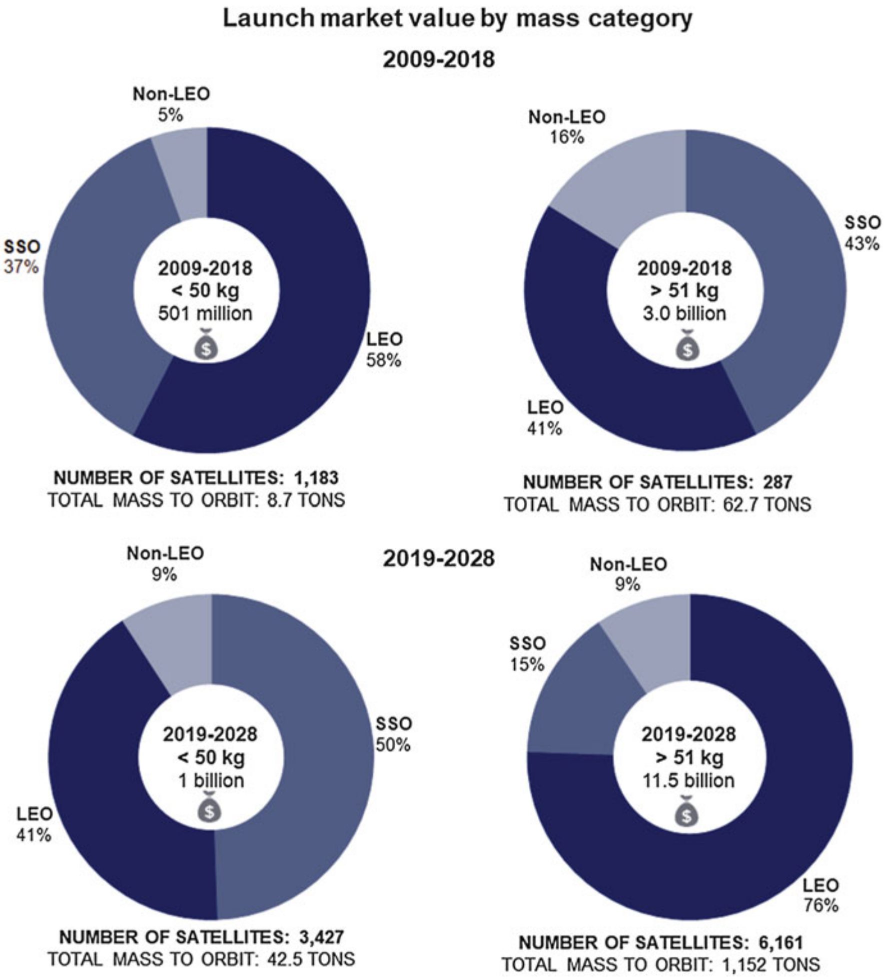

Fig. 13 Launch market value by smallsat mass category over 2009–2018 and 2019–2028. (Source: Euroconsult 2019; All rights reserved to Euroconsult, this figure is licensed to Springer to publish in the Handbook of Small Satellites)

$12.6 billion. Satellites with a launch mass <50 kg will generate $1.5 billion in launch revenues, accounting for only 9% of the 2019–2028 small satellite launch market. 50% of this will be generated by launches into SSO, while LEO is expected to account for 41% of the $1.5 billion in launch revenues (Fig. 13).

New, dedicated launch service providers are working on various systems to capture the growing small satellite market. Value propositions vary by solutions. Dedicated micro (<500 kg in LEO) and small launchers (<2 t in LEO) aim to provide affordable and responsive access to space by flying small satellites as their primary payload (as opposed to relying on ridesharing, etc.). With these new launch solutions, the price per kilogram may not be the only appropriate metric to compare

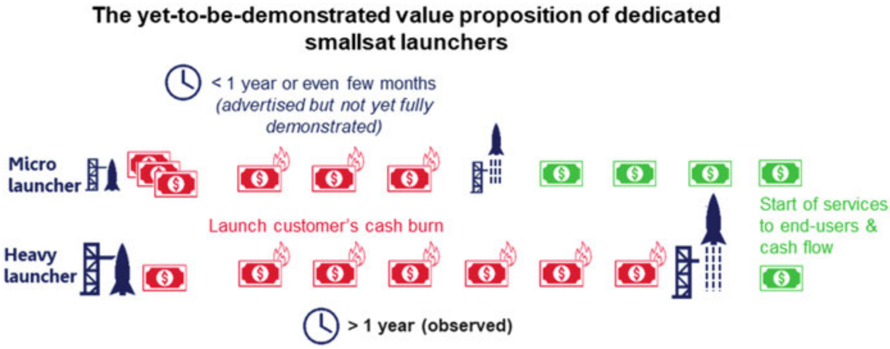

Fig. 14 A better time to orbit: the value proposition of dedicated micro-launchers. (Source: Euroconsult 2019; All rights reserved to Euroconsult, this figure is licensed to Springer to publish in the Handbook of Small Satellites)

vehicles, as these micro-launchers come with a premium in price in terms of $/kg of payload. With more vehicles becoming available, operators could be more selective, using different launch service KPIs to assess performance, such as time to orbit, launch schedule reliability, and services associated with payload integration as additional parameters in their decision-making. This could lead them to prefer dedicated solutions. Among these new suppliers, a few air-launch systems are under development, such as Virgin Orbit and Stratolaunch (which cancelled its plans to develop a micro-launcher in 2019). Air launch can increase the performance of the vehicle by up to 30%, enabling a wider range of launch azimuths and more flexibility as it can be operated from airports. However, existing carriers have a limited payload capacity and come at a relatively high price/kg (Fig. 14).

About 100 companies claim to develop dedicated launch systems as of 2019. Rocket Lab's Electron and iSpace's Hyperbola-1 excepted, both of which successfully reached orbit in 2018 and 2019, respectively, no privately funded small launcher has yet conducted successful orbital missions. Landspace and OneSpace both failed as they attempted to be the first orbital privately funded launcher in China in 2018 and 2019, respectively. The most advanced systems have already secured contracts, including multi-launch agreements, but this does not prevent business failures, as Vector had to put its activities on hold when a key investor stopped financing the company, before filing for bankruptcy in 2019. The status of dozens of projects is unclear, and several have been terminated since the early 2010s. It is likely that many more small launch ventures will fail to reach the market, considering the major barriers to entry (technical, financial, and legal). Even once operational, the sustainability and profitability of micro-launchers are questionable. Micro-launchers have higher costs/kg than larger launch vehicles. Their market acceptance still must be demonstrated beyond initial customers, and the economics of higher launch price vs. reduced cash burn while awaiting launch has yet to be validated.

For constellations, the deployments of hundreds of satellites into multiple orbital planes require the most cost- and time-effective launch solutions to reduce capital expenditures over time and start services as soon as possible to generate revenues.

This favors medium and heavy launchers for full-scale deployments of the constellations. The phasing of launch demand for constellations varies greatly depending on their life cycle and orbital architecture. Micro-launchers can contribute to proof-of-concept (i.e., the launch of prototypes and demonstrators) and limited replenishment (i.e., replacement satellites), or deployment into underserved orbits, provided their reliability and responsiveness are demonstrated. Kleos Space, for example, aims for a 37° inclination for higher revisit frequency on the most populated areas and therefore wishes to deploy its constellation through dedicated launchers, the only solution to cover such low inclinations.

3.2 Manufacturing

2019–2028 is expected to witness a large increase in supply from 1,470 satellites to 8,588 satellites. North America will continue to account for an important share of the supply with almost half (48%) of satellites (4,157) as it concentrates the manufacturing of three mega constellations (Starlink, OneWeb, and possibly Amazon will be manufactured in the USA) (Fig. 15).

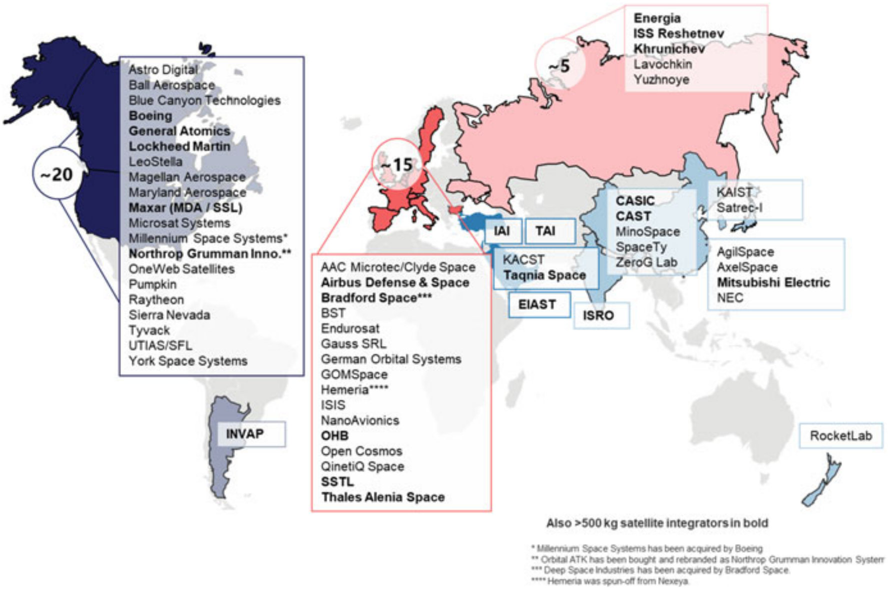

Fig. 15 Main small satellite integrators around the world. (Source: Euroconsult 2019; All rights reserved to Euroconsult, this figure is licensed to Springer to publish in the Handbook of Small Satellites. *Note: the map above does not include satellite integrators which have not launched a satellite into orbit to date and does not include in-house manufacturing. It is a list of the main satellite integrators that are commercializing their manufacturing capabilities. For example, SpaceX and Planet are not featured on the map despite being the two largest satellite operators as of early 2020, as they only manufacture satellites for themselves and do not seek to commercialize manufacturing services to third parties*)

Asia is expected to have a sizeable market share, with 17% of satellites over 2019–2028. Europe is expected to experience substantial growth in number of units (+204%) but will lose market share (from 17% to 9% in the next decade) as it is expected to grow more slowly than North America and Asia.

Satellites for which an integrator has not yet been selected, i.e., the open market, are expected to account for 24% of the 8,588 smallsats to be launched over 2019–2028. As such, each region's market share relative to other regions may grow if that region captures more of the open market than others. Satellites which are captive of their own manufacturing industries (e.g., government smallsats from countries with an established industry) are part of the respective regions of their governments.

Russia and Central Asia's share of smallsats to be launched is expected to decrease from 6% to 1%, although the region will see a marginal increase in number of satellites manufactured from 89 to 118 units in the next decade (Fig. 16).

At the satellite supply level, high fragmentation of the market is expected. Planet accounted for the largest single share (24%) of the manufacturing supply over 2009–2018 but only addressed its own needs as a vertically integrated company (Terra Bella excepted, sourced from SSL, formerly Space Systems Loral). Universities accounted for large shares of the supply with 27% of satellites being manufactured by an academic institution in the past decade. The remaining manufacturing supply was highly fragmented with no company owning more than 5% of the demand in terms of units. Circa 26% of the supply was addressed by about 268 organizations manufacturing up to three orders each. 23% of the supply was addressed by 57 companies manufacturing between 4 and 10 units. Following a merger between AAC Microtec and Clyde Space, the new company accounted for 5% of the past supply with about 70 units, mostly for Spire before it brought production in-house.

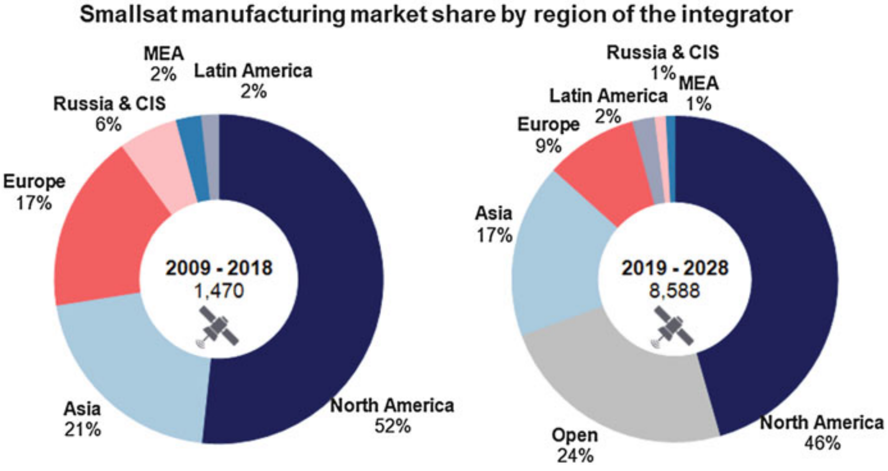

Fig. 16 Smallsat manufacturing market share (in units) by region of the integrator over 2009–2018 and 2019–2028. (Source: Euroconsult 2019; All rights reserved to Euroconsult, this figure is licensed to Springer to publish in the Handbook of Small Satellites)

This supply fragmentation here only considers supply at the satellite level. Since some of the companies are also providing subsystems and components, their market share is expected to be higher than figures presented here due to the associated additional revenue. This is the result of commoditization and standardization allowing satellite operators to combine hardware from various suppliers.

The smallsat manufacturing market, which was valued at $9 billion over the past decade, is set to grow by +232% to about $30 billion over the next 10 years, mainly driven by the multiplication of constellation projects from both commercial and government stakeholders. In countries where an established supply chain and integration capabilities exist, civil government and military demand are assumed to be captured by domestic industry, meaning that contracts are not open to foreign bidders. This is the case for the USA, Canada, Europe, China, India, Japan, Russia, South Korea, Israel, Iran, and North Korea, and it may soon be the case of Saudi Arabia and Qatar. On top of that, considering that Starlink and OneWeb already have identified integrators, only a small market value share (12%) remains commercially open. Furthermore, this 12% share of open market features Project Kuiper, which has yet to select a third-party integrator or prefer in-house production and which is not considered as captive to North American integrators.

Asia is expected to experience substantial growth over the next decade (+45%), second only to North America in market value. The next decade will see Asia account for 14% of the total manufacturing market value, compared to 32% for North America. This is a consequence of local manufacturers winning notable contracts from the government, such as the Hongyan and Xingyun constellations by the China Aerospace Science and Technology Corporation (CASC) and the China Aerospace Science and Industry Corporation (CASIC), respectively. North America is expected to grow by +182% from $3.4 billion to $9.5 billion due to its established industry base, mega constellations, and commercial new entrants in the USA and Canada.

Europe’s market share is expected to decrease from 15% to 7% over 2019–2028. Despite growth in absolute terms, driven by constellations such as Iceye, Astrocast, and Hiber, Europe will grow more slowly than Asia and North America and therefore account for a smaller market share relative to those markets. The manufacturing contracts from Russia are largely won by local primes to support government civil/defense missions (led by Russian Research and Production Enterprise Pan-Russian Research Institute for Electromechanics (FSUE NPP VNIIEM) and Information Satellite Systems Reshetnev (ISS Reshetnev)). Manufacturing market value is set to increase across Latin America, driven by the Satellogic constellation.

In addition to contracted manufacturing market shares and 12% open market, 30% of 2019–2028 manufacturing market value is captive to specific regions. The captive market mostly includes government-operated single-satellite missions and constellations from countries with an established manufacturing base, which are not open to be addressed by foreign manufacturers. This market remains to be competed for but only by local integrators (Fig. 17).

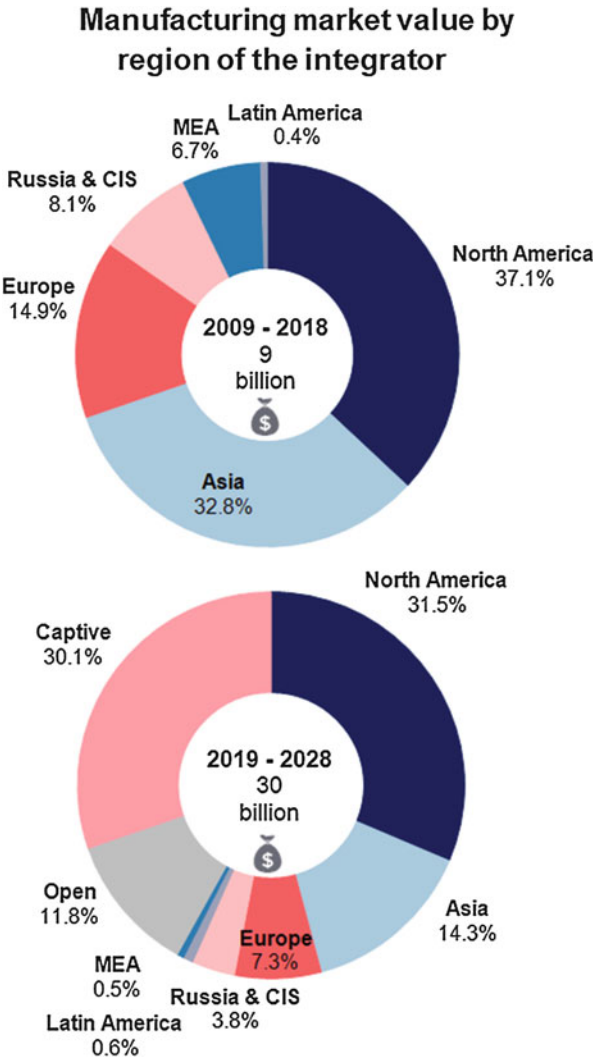

Fig. 17 Smallsat manufacturing market share (in value) by region of the integrator over 2009–2018 and 2019–2028. (Source: Euroconsult 2019; All rights reserved to Euroconsult, this figure is licensed to Springer to publish in the Handbook of Small Satellites)

4 Constraints to Manage and Upcoming Challenges

The market growth discussed here represents an integer multiple expansion of the number of spacecraft on orbit. This suggests managing the hazards, and downsides of this proliferation will be required to assure this proves feasible and desirable. Good practices and stewardship must be advocated for in order to ensure the sustainability of the space environment and prevent Earth orbit from becoming a new “wild west” and hypervelocity junkyard.

Looking forward, an important challenge for smallsat constellations will be the mitigation of their impact on the space environment. As for any specific environment back on Earth, conservation and sustainability measures should be implemented to ensure that future generations may benefit from the same opportunities. Without looking too far into the future, in-orbit failures or collisions could have dire consequences in orbits populated by hundreds of satellites, threatening entire constellations and their business models.

Licenses to launch around the world entail an increasing element of specific commitment to mitigating the rise of on-orbit debris, spawning technologies to support this. Systems are becoming multilevel, and many orbital altitudes will become occupied with large numbers of small spacecraft. Some of these higher orbital levels will push into the Van Allen radiation belts, bringing the spacecraft using them into the realm of charged particles confined there, including those arising from nuclear explosions on-orbit past and potential. This section explores these hazards and challenges, and means for their mitigation.

4.1 Orbital Debris Mitigation

Most smallsat systems discussed here operate as constellations and many without the propulsion systems required to perform collision avoidance maneuvers. Even smallsats equipped with propulsion do not necessarily have the sufficient delta-V generation capability to enable performing collision-avoidance maneuvers: this is generally the case of electric propulsion, which does not enable “last minute maneuvers” due to its low thrust. The numbers of such spacecraft expected to launch shortly will dwarf the total number of satellites currently on-orbit, so mitigating their potential to generate orbital debris is a high priority for system designers and governments.

As of today debris below 10 cm in diameter cannot be tracked. Researchers have been trying to raise awareness of the fact that often it is now actually not known what object is being tracked. This means that anything below 10 cm in diameter is essentially invisible and of significant risk to space operations. NASA/US Space Surveillance Network estimates, as shown in Fig. 18 below, that >20 K debris objects of 10 cm diameter or larger currently are in orbit. The estimated number rises to 0.5 million objects of 1 cm or larger and in excess of 100 million objects 1 mm or larger. To illustrate the power of small bits of debris, a 1-cm-aluminum sphere moving at a LEO typical 10 km/s carries the same impact as a 200 kg safe moving at 150 km/h (Fig. 18).

LeoLabs, a commercial Space Situational Awareness (SSA) company based in California, seeks to improve the industry’s understanding of the population of orbital objects, active satellites, and space debris combined. Currently, the company tracks >10,000 orbital objects 10 cm or larger using its existing two ground-based radars, in Texas and Alaska. With a new higher-frequency radar coming online in New Zealand, it expects to grow its database by a factor of 10 to 25 by being able to see objects down to 2 cm in diameter. In August 2019, LeoLabs unveiled a LeoTrack, a

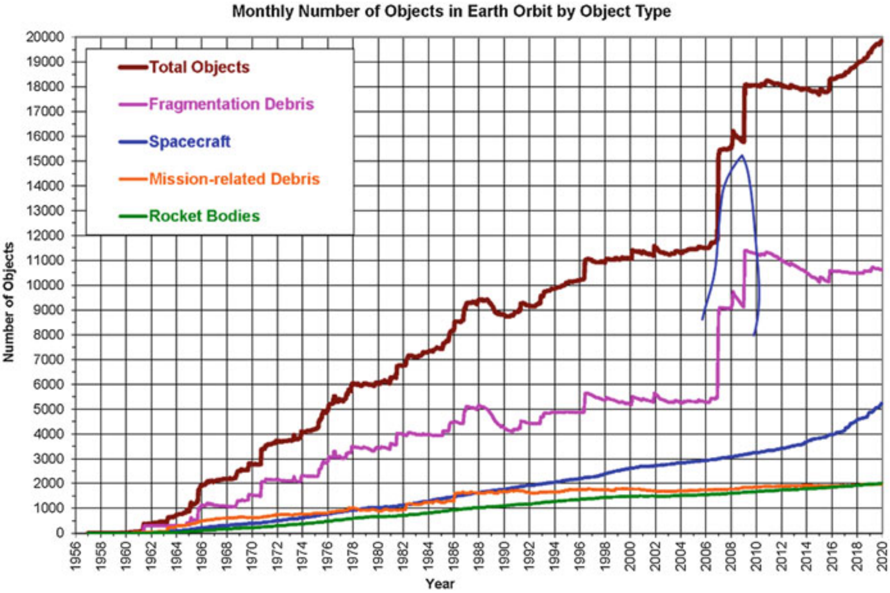

Fig. 18 Growth of orbital debris 1957–2020. (Image NASA. Source: J.-C. Liou, PhD, NASA Chief Scientist for Orbital Debris Personal Communication; not subject to copyright)

commercial satellite tracking service targeting small satellite operators. Sold via a monthly subscription at $2,500 per month per satellite (with possible discounts for large constellations), this software will provide several services such as smallsat tracking, orbital state vectors, predictive radar availability, scheduled passes, and visualization tools. LeoLabs expects to be able to identify satellite positions within a hundred meters, a factor of ten improvement compared to the current kilometer-level precision of the Joint Space Operations Center (JSPOC). Several smallsat players have already subscribed to the LeoTrack service, including BlackSky, Maxar Technologies, Planet, and Swarm Technologies (which is known for operating 0.25 U CubeSats which are harder to track).

As regulation by governments and agreements in the UN are tightening restrictions on Orbital Debris Risk Mitigation licensing requirements, companies building CubeSats are increasingly required to plan for deorbit mechanisms.

4.2 Radiation in Higher Orbits Could Present a Risk for Smallsats

Radiation from debris/missions poses its own hazards, including that from the 1962 US "Starfish" test of a ¼ megaton nuclear bomb in space, and similar tests by the Soviet Union, possibly soon to be joined by a North Korean high-altitude weapon test and perhaps others. High-energy electrons and other charged particles from these blasts killed the first communications satellite, Telstar, and a number of other spacecraft. A substantial proportion of these electrons are now known to be still trapped in the Van Allen radiation belt, as indicated by NASA's Van Allen probe missions (2012 to 2019). A military spacecraft is now in-orbit, and two more are planned for 2020, to take the first steps to analyze the potential for radiation belt remediation (RBR).

In 2019, the US Air Force launched the DSX dipole antenna, described as the largest robotic mission structure ever launched. It will transmit very low frequency (VLF) radio into the Van Allen belts to cause charged particles to deorbit, and will measure what is hoped will be particles falling out of orbit as a result. In 2020, a team from Los Alamos and NASA's Goddard Space Flight Center will launch a second experiment in VLF precipitation of charged particles. This suborbital mission will loft the Beam-Plasma Interactions Experiment, a miniature accelerator that would create its own high-energy electrons, would generate VLF waves, and cause precipitation of charged particles. Finally, a second suborbital mission will launch a few months later: The US Naval Research Laboratory plans to launch the Space Measurements of a Rocket-Released Turbulence mission. The mission will spread 1.5 kg of barium atoms. When ionized by sunlight, the barium becomes a moving plasma, emitting radio waves.

The missions should help validate effectiveness of these techniques and enable determination of which, if any, of these three approaches to RBR system is most feasible.

It is not known however, and won't be from these tests, what side effects might result from a wide deployment of such technologies. Energy released into the atmosphere could rival that of coronal mass ejections and impair communications and navigation. Some potential by-products could damage the ozone layer (e.g., oxides of nitrogen and hydrogen), so additional research would be needed before deployment (Stone 2020b). Most notably, low-cost smallsats built without space-graded, rad-hard components would be at risk.

4.3 Concerns for Astronomical Observations

Perhaps of little direct financial effect but with an important impact on public perception of the satellite industry, LEO constellations may cause interference with astronomical observations. Satellites in LEO are already visible to the naked eye, and the first generation of the Iridium constellation (66 satellites) was known for its "Iridium flares," i.e., a visible phenomenon caused by the reflective surfaces of satellites (which could be antennas, Synthetic Aperture Radar (SAR), or solar panels), reflecting sunlight toward Earth. Ranging up to −9.5 magnitude, some Iridium flares were so bright that they could be seen in the daytime and occasionally disturb astronomy observations. Iridium took these considerations into account for the design of its second generation, which does not flare. However, considering the thousands of constellation smallsats expected to be launched in the decade, light pollution has the potential to become an important issue if not considered.

Relatively simple changes such as changing the albedo to reduce satellite reflectivity may be sufficient to mitigate this risk. Following the first Starlink launch, SpaceX was

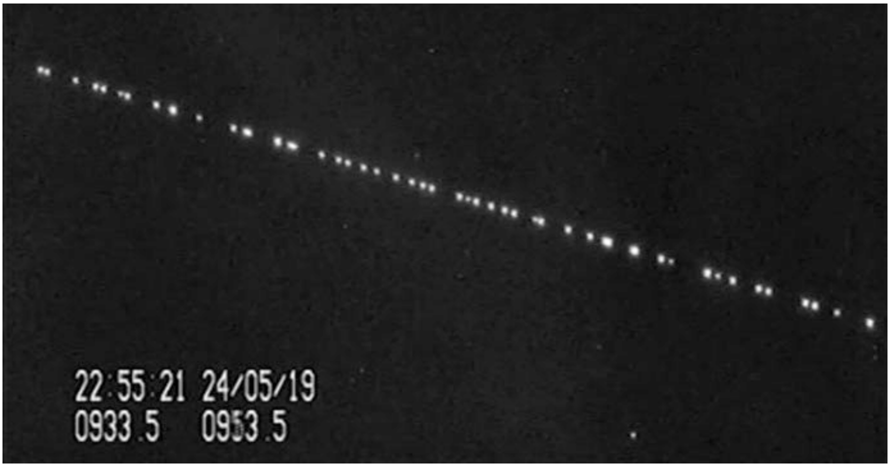

Fig. 19 Starlink satellites released from launcher. (Image © Marco Langbroek via SatTrackBlog; All rights reserved to Marco Langbroek, this figure is licensed to Springer to publish in the Handbook of Small Satellites)

highly criticized even before its satellites were raised to their operational orbits, and agreed to take steps to avoid this in the future, including launching darkened prototypes on subsequent launches to assess the difference from initial versions.

In 2019, PepsiCo explored the possibility of advertising from space using “orbital billboards” made of a constellation of highly reflective smallsats, due to be visible from the ground. It quickly backtracked due to public outcry and criticism. While there may not yet be any laws regulating the light pollution caused by LEO constellations, federal law in the USA does indeed prohibit the use of “obtrusive space advertising.” Similarly, the Humanity Star reflective payload launched by Rocket Lab in 2018 was largely seen as an “act of vandalism” on the night sky (Fig. 19).

Interference to radio astronomy is also a significant concern, with many constellation satellites radiating in bands in or close enough to those used for celestial observations that side lobes of the signals will likely interfere.

4.4 Satcom Constellations Need to Secure Landing Rights to Enable Commercialization

While successfully financing, manufacturing, and launching a satellite constellation qualifies as a major engineering feat, it is not sufficient to guarantee its commercial success, as the Iridium bankruptcy in the 1990s can attest. One of the main challenges for communications (broadband or narrowband) constellations will be to successfully secure landing rights (i.e., the authorization from the government or telecom regulating authorities to commercialize satellite capacity in a given country) in dozens of countries around the world. Negotiating with dozens of governments remains a challenge for most countries, let alone emerging space companies with no experience in dealing with foreign countries.

Securing partnerships with established satcom operators for capacity commercialization in foreign countries could be a way to mitigate this, and fast-track this critical negotiation phase. It would however negatively impact margins, as such an operator would take away a share of revenues in exchange for access to its existing network of distributors. This was part of the rationale behind the aborted merger between OneWeb and Intelsat.

Furthermore, geopolitics also play an important role, as access to the Chinese and Russian markets is far from guaranteed for US-based constellation operators and vice versa. OneWeb, for example, has repeatedly been denied access to the Russian market, due to fears of espionage and fears of losing control over the nation's communications from the Russian government.

4.5 Consumer Ground Segment Costs Drive Adoption Rates

Home antennas for GEO satellites are a simple matter and can be obtained for as little as $50. The cost of this piece of hardware is so low that it is often part of the subscription price of TV/Internet bundles. However, antennas for LEO broadband constellations face the difficult task of maintaining a link with rapidly moving targets in low orbits, seamlessly switching targets once a satellite is out of range.

Electronically steered flat panel antennas (FPA) are accepted to be the technological solution to this problem; however their cost remains prohibitive and does not permit the broadband constellation business case to succeed at current costs levels, as they remain unaffordable by the public despite improvements. A few years ago, consumer-grade antennas were estimated to cost ~$20 k per unit and have dropped to ~$1.5 k per unit today. Companies aim to bring this cost down to <$1 k, with some companies aiming for antennas as cheap as $300 to $500. Such prices however remain to be achieved.

This satcom-centered rationale also applies to Earth observation constellations but with the number of ground stations for data downlink rather than consumer terminals, which do not apply to Earth observation. The more important the amounts of data collected and the data downlink requirements, the more ground stations are required. The capex to establish a significant ground station network across the world quickly rises. One way to mitigate this is to work with ground station "as a service" providers, renting antennas on a "pay-as-you-go" model, favoring OpEx over CapEx.

4.6 Antenna Production and Distribution (Supply Side)

Consumer affordability is key if smallsat constellations are to reach their projected revenues and market adoption objectives, which will define success or failure. However, developing the ability to produce and deliver a sufficient number of antennas is just as serious an issue as the cost to produce them. Several million FPAs must be shipped over the future decade to keep up with projected market forecasts; however production of affordable antennas has yet to start. Companies are, reasonably enough, focusing on enabling mass production to leverage economies of scale.

Production and distribution of consumer-grade FPAs however is a chicken and egg problem, as market demand is required for mass production to begin and mass production at consumer-friendly costs requires an established and sustainable market demand. A new wave of FPA-focused venture capital and/or government financial backing could be required to bridge this gap; however uncertain ROIs mitigate the interest of investors.

Until then, business-/enterprise-grade antennas will remain the norm, with FPA companies already commercializing the more expensive antennas for ships, emergency response vehicles, and aircraft.

It may be that captive production such as that of SpaceX could solve this, given sufficient capital.

5 Conclusion

5.1 New Business Models and Smallsats as a Service (SSaaS)

From building hardware and integrating it into satellite operations, ground stations, and analytics, the smallsat ecosystem is maturing and evolving. More and more private companies are establishing niches and specializing, while others are moving into the “Smallsats as a Service” business model. For an entity looking to launch a payload into orbit, reactivity, lower costs, ease of operations, accessibility, and operational simplicity are in high demand. Whereas in the past it may have been difficult to find platform providers, launch providers, and even facilities for testing and qualification, these can now all be procured online. While not yet as simple as ordering hardware online, that point is quickly approaching. This increased accessibility benefits new entrants and organizations which are new to the space sector. The SSaaS business model removes complexity and barriers to entry, facilitating market entry for newcomers. Additionally, this new granularity offers a level of transparency over the value chain which improves the confidence of industry outsiders. SSaaS allows the customer to step out of the satellite value chain entirely and rely exclusively on managing its core business, whether that is data analytics, scientific research, or something else. The SSaaS customer can now have as much or as little input into the life cycle of its satellite as desired. While SSaaS may not always meet the needs of all customers (as in cases of specialized orbital and hardware requirements), it addresses the most common market needs in a clear fashion.

5.2 Turnkey Satellite Missions

More integrated value propositions are emerging as companies propose full solutions from system integration to data delivery, allowing their customers to concentrate effort on value added services. Examples of this include Tyvak, York Space Systems, and Open Cosmos. Open Cosmos provides a hardware mock-up of its satellite to its clients, so that they can build their payload into it. Once the payload is ready, it is quickly integrated into a real platform, and all other aspects of licensing and launch campaign management are then managed on behalf of the customer. Tyvak on the other hand actively seeks upstream companies outside of the space sector, to propose solutions and explore how its capabilities can meet their needs.

5.3 Increased Modularity and Standardization of Spacecraft "Blocks", i.e., Subsystems

One early indication of future directions for small satellites is the increasing modularity of small satellites which can be logically combined over robust intersatellite links while orbiting separately, or physically combined using a common bus, like electronic Lego. This subject has seen an increase in interest recently, starting with NovaWurks' "satlets" mentioned previously (NovaWurks was acquired by Saturn Satellite Networks in 2019), the generic name of its HISat spacecraft, which are modular "Lego-like" spacecraft elements capable of independently performing all satellite functions (i.e., propulsion, payload, power storage and generation, etc.). In theory, each of these elements is capable of operating as its own spacecraft and provides redundancy in case of failure, as every "satlet" is capable of taking over the functions of another "satlet" that has failed. To date, several prototypes have been deployed on various orbits for technology demonstration purposes. The US military has long been interested in this concept (NovaWurks was contracted as early as 2012 by DARPA to participate in its Phoenix project) due to its interest in redundant assets that are highly resilient in the face of failure or direct attack from an adversary. DARPA is supporting NovaWurks through the sponsoring technology demonstration missions, and operational agencies within the US government will surely become customers when the technology is more fully proven in orbit and made available commercially. The National Reconnaissance Office, which operates US surveillance satellites, is taking a similar approach, experimenting with small standardized systems to which engineers can attach instruments.

5.4 Hosted Payloads

Hosted payloads may also play a role, albeit a niche one, in the future. Launching a payload without a dedicated satellite is a tested means of getting to orbit with little hassle. In past offered by companies such as SES (formerly Société Européenne des Satellites) and Iridium, hosted payloads are being offered by new and established companies such as Loft Orbital and Spire. Spire provides "space as a service," allowing third-party payloads on the back of its own satellites. In 2019, it announced a deal with a defense contractor, KeyW Holding Corp, to host its reconnaissance payloads on its satellites. It previously offered to fly 20 payloads on its satellites within 12 months for €10 million. Loft Orbital offers "mission as a service," with a plug and play "condo" housing that is designed to receive parallel hosted payloads. It has announced partnerships with stakeholders all across the smallsat value chain.

5.5 Quantum Navigation Systems

New ultra-accurate/ultra-stable quantum inertial navigation systems seeking to offer positioning without the need for access to a Global Navigation Satellite System is also likely to be adopted by MilSat constellations once sufficiently miniaturized. (e. g., M Squared/Imperial College London's "Quantum Compass" system).

5.6 The Beginning of Deep Space Science and Exploration Smallsats

In science missions too, the success of the MarCO CubeSats has spurred mission planners to include more interplanetary CubeSats on missions to the outer solar system, starting with Europa. China's Chang'e 4 lunar landing on the far side of the Moon in the early 2019 was supported by Queqiao, a small satellite (425 kg) communications relay probe, to enable live connectivity with the far side. Exploration and science missions, traditionally burdened with high costs and long development times, are increasingly looking at smallsats to provide operational services at a fraction of the cost associated with space exploration in past decades, and the Queqiao and MarCO successes have demonstrated the smallsat form factor's great potential for science and exploration missions.

5.7 Bright Prospects Ahead for Small Satellites

A similar positive feeling is permeating the space industry, as space agencies, commercial stakeholders, and military entities alike realize the game-changing potential that smallsats are bringing to the space sector. Small spacecraft can indeed be said to be taking over the industry as of this writing. Furthermore, the cost reduction supported by smallsats means new entrants, previously hampered by the cost of developing and launching space assets, may enter the space sector, driving more synergies with other industries such as software and IT, electronics, power management, thermal and material sciences, etc. which will in turn enable further growth prospects in the future.

Abstract

The well-established terrestrial satellite applications markets have been generating revenues and producing very substantial earnings in the billions of dollars for many decades. These major markets include the telecommunications and broadcasting services: fixed satellite services, mobile satellite services, and broadcasting satellite services and the Earth observation/remote sensing/meteorological satellite services. Also very important to commercial customers is the global navigation satellite services (GNSS) also known as precision navigation and timing services. In the case of GNSS, at least in the United States where the actual satellite system is government-owned, most of the revenues come from the manufacture and sales of user equipment and services rather from operation of the satellite systems themselves.

There have been profitable businesses associated with the development and manufacturing of satellites. These include the manufacturing of satellites, ground antennas that support these various space-based applications, the launch services industry that launches these systems into orbit, and the space insurance industry that can safeguard companies against risks associated with the launch of the satellites, possible liability claims, and even the loss of revenue from satellites or from in-orbit failures.

The status and nature of these well-established space systems are currently in a state of upheaval and change. One of these changes in satellite telecommunications is that new quite efficient high-throughput satellites (HTS) are challenging less efficient satellites that operate at lower speeds and are much less cost-efficient. There is also rapid technological innovation of new more cost-efficient launcher systems, applications satellites, and ground systems that will increase the competitiveness of all commercial uses of space.

Major technological innovations and cost-reducing trends provide a stimulus to all sorts of space-based services. However, they also create a sense of confusion in understanding the economic and financial impacts that come from the so-called “NewSpace,” “Space 2.0,” and “small satellite” revolution. In actuality, not only are “small satellites” cheaper to manufacture and launch, but also the large geosynchronous high-throughput, high-efficiency satellites can, and are, being designed, built, and launched more efficiently as well in terms of net cost per rate of digital throughput for data, voice service, or video channels.

Current economic analyses have generally concluded that it is too early to measure the economic performance of small satellite constellations in relation to new high-efficiency geosynchronous satellite networks. Further the economics and design innovations are different for remote sensing satellites than satellites that are providing communications services, making any comparisons more difficult. And there are many risks in space systems that are different from terrestrial operations and need to be understood better. Despite these market analysis limitations, this chapter seeks to assess the relative economics of small satellite systems deployed in LEO and MEO orbits, versus the most efficient of GEO applications satellites.

1 Introduction

Regardless of which part of the commercial space industry is being analyzed today, they are all characterized by continuous and dramatic change. There are new satellite applications products and services, launcher options, types of ground systems, and antenna designs that are designed, manufactured, and sold incorporating technological innovation, manufacturing process changes, and speed of design and production. Much of these innovations are associated with the companies and entities involved in “NewSpace,” “Space 2.0,” and the world of small satellite innovation coupled with new launch vehicles providing access to low Earth orbits.

It should be clearly noted that there is nothing really “new” in “NewSpace”. All companies, whether new or traditional, have market and technology innovation and making a profit as prime motivators. All successful corporations must seek innovation to survive and to introduce new products and/or services to sustain themselves. In the United States, the government space agencies have relied on the private sector to manufacture most space equipment from beginning of the space era in the mid-1950s. Some of the more recent changes, however, are the aggressive initiatives of the government to stimulate private innovation and new entries from the computer, digital services, social media, investment banking and venture capital firms, and especially entrepreneurial start-ups.

However the rise of a multitude of new companies does not mean that the conventional space system manufacturers, service providers, and launch providers are going to fail in light of these changes (Rapp et al. 2015). They will face increasing competition. Indeed these industries are already quickly adapting to this new world of more rapid innovation. And the more traditional aerospace companies have adopted new practices that have come from rapid prototyping and new manufacturing techniques such as additive manufacturing and use of advanced analytics and artificial intelligence being used across the spectrum of the aerospace industry. These innovations are stimulated by continued public and private research and development as well as a growth in consumer demand.

The current small satellite revolution has also broken down some of the barriers to starting a new space enterprise. New types of initial capital formation such as small start-up funding through crowdsourcing and other Internet programs as well as large investments from wealthy individuals and venture capital companies have led to a renaissance in space industry innovation.

None of these providers of new funding guarantees any assurance of eventual economic success in the market place. The bottom line is that space enterprise is an attractive yet risky type of business that will be characterized by some significant new economic successes but can also lead to a significant rate of business failures. The SpaceX Ansari Prize contest from the early 1990s to 2004, which had the aim to create a viable space plane prototype, produced only one winner. Along the way there were close to two dozen start-up ventures that ultimately failed as ongoing business ventures. Today, challenges from both government and private initiatives have produced parallel results. What is important is that investors now view space as more than government missions and are willing to invest in space ventures. And, some government agencies themselves view space, particularly in low Earth orbit, as an opportunity for economic development and are providing significant incentives, both financial and regulatory, to these new private ventures. This has been particularly true in the United States, Luxembourg, New Zealand, the United Arab Emirates, France, and even somewhat unlikely locations such as China, Denmark, etc.

Over the past two decades, GEO system operators and space insurance companies have been developing a large storehouse of knowledge about how to deal with the unique aspects of risk and insurance coverage for space assets and applications. Newer companies that are operators of LEO small sat constellations do not have the same knowledge base and history. This creates new challenges for these companies, but in some cases it allows for more innovative concepts and new industrial and technology processes to flourish.

In summary, commercial space systems, particularly those in low Earth orbit, are rapidly evolving and changing. New associated challenges and risks are yet to be solved. During this transition phase, there will be winners and losers; neither can be easily predicted. But what is clear is that the role of private space actors is growing and the future rewards are likely to be very lucrative for those that survive and thrive matching the market demand for existing and new services to the regulatory, production, and global sales challenges that will be inevitable.

2 The Demand for New Space Products and Services

The rise of the large successful aerospace enterprise was stimulated in the United States by the post-World War II "Cold War." The result was a very large military-industrial development funded by the US government and built and operated in close association with private companies. The companies were therefore dependent on the multimillion dollar government contracts generated by defense-related demand. These organizations were awarded contracts to carry out research and to develop weapons systems and the underlying related technology that supported weapons systems. It should be noted that many scientific and engineering breakthroughs were created from that research that enabled mission success with improved manufacturing productivity, new materials, and new products and services for business and consumers.

Space capabilities were one direct objective of this government investment, and today's space capabilities are a legacy of the era of the 1950s and 1960s. Along with those space successes and terrestrial applications were the dominance in the industry of very large firms with close government connections on both the civil and security side.

Of course, this large government investment was the major source of market demand for space applications. Unlike normal consumer goods like food, clothing, housing, travel, etc., where the price of the product is the market signaling mechanism for economic choices, government purchase decisions are often made for other reasons such as security, defense, and social welfare. Normal economic models do not account very well to those non-price-based purchases, and other non-market factors such as the oligopolistic structure of the aerospace industry also separate traditional space supply and demand from most other free-market industries.

Many space applications are now transitioning from government purchases for government use to consumer purchases with the government buying services alongside at prices determined by market forces. As barriers and disincentives to these previously "closed" markets begin to deteriorate, the space sector and its commercialization will also begin to be more price-sensitive and more "mainstream" in terms of industrial organization. The real test is in the future and will be driven by more traditional capitalist decisions. An open question is whether and how fast the large traditional space companies can and will adjust to these changes.

It should be noted that the telecommunications market is the oldest commercial space service, dating back to the 1970s. It was then a heavily regulated industry and government space telecommunications satellites, although built and operated privately, were dominant. By the 1990s the trends were clear and slowly private, and competitive telecommunications satellites were permitted, and by the early 2000s, with the privatization of Intelsat, the transition was fully in progress. Today, it is a regulated market because of limited spectrum availability, but relatively open to price competition both domestically and internationally. No other space application is both as open and as lucrative as are telecommunication and direct radio and TV broadcasting.

New markets for telecommunications and other space services are developing and growing. How fast and how effective they will be is yet to be fully determined, but the prospects for a growing market are stimulating innovation and investment in space applications. It should also be noted that there is no real demand for launch vehicles themselves. That demand is fully dependent on how we find uses for space and therefore launch vehicles is the transportation artery for those uses rather than a "use" of space themselves.

No longer does one have to be a multibillion dollar aerospace industry such as Boeing, Lockheed Martin, Airbus, Thales Alenia, NEC, Mitsubishi, CAST of China, etc. to enter and prosper in the world of space hardware manufacturing, space application services, or space launch services. But, the barriers to entry remain relatively high, and the ultimate road to success remains difficult. Many new ventures falter if they cannot find or generate the demand for their products or services, or cannot generate enough progress to support a second or third round of equity funding. Sometimes they will be rescued by strategic mergers. Other ventures will find incentives to get started, but also within a year or two, the most likely outcome will be organizational breakdown, discontinued support from a start-up incubator, bankruptcy, or acquisition, Only a few will accomplish the long shot success of continued rounds of funding to finance the growth needed to reach financial viability. The road has been paved with numerous companies that no longer exist and with others that have been extremely successful.

3 The Demand for Money (Financing) for New Space Products and Services

The world of digital innovation that grew up in Silicon Valley and elsewhere led to increases in available capital for new enterprises. Venture capital firms and other investors worked with research universities, inventors, and others with bright ideas. Thus, coupled with the growth of the Internet and social media, a number of new financing mechanisms evolved such as crowdsourcing and Kickstarter, along with traditional funding from banks, investment houses, and friends and families. These were responsible for getting the new ventures off the ground sufficiently to later obtain larger rounds of subsequent financing.

The financial evolution and roadmap to true large-scale viability of the SPIRE system, in some ways, might be considered an ultimate roadmap that other start-up organizations might follow in years to come. The SPIRE constellation has now launched over 100 satellites into orbit and is providing data analytics to a growing range of customers (Howell 2019). It started small, but its ultimately leap forward came when it concluded a multibillion dollar 25-year contractual arrangement with the European Union/European Space Agency's Galileo system for predictive weather analysis and future space-based analytic services (Michael and CNBC News n.d.). (See Fig. 1 of a SPIRE cubesat.)

A key strategy has now emerged in terms of financing new small satellite constellations by raising capital funds through contractors that were willing to invest in the project. This has been particularly successful in the case of the One Web large-scale small satellite constellation. In lieu of payment, or at least in lieu of some portion of the payment, the suppliers have become investors and partial owners of the One Web system. Airbus, which is the main supplier of the satellites for the constellation, is a partial owner of the system. Although the One Web satellites with a mass of 150 kg are about a hundred times more massive than a SPIRE cubesat, they are nevertheless still considered to be "minisats." (See Fig. 2.)

Similar arrangements have been made with Arianespace and Virgin Galactic as launch service providers that also become capital investors in the new LEO constellation. Qualcomm, which is another indirect supplier, is another investor. Most striking of all is the investment in the new LEO system by GEO satellite operator Intelsat. (At one point Intelsat and One Web were to go a step beyond with a merger

Fig. 1 The latest generation of SPIRE cubesat shown next to an apple to demonstrate scale. (Graphic courtesy of SPIRE)

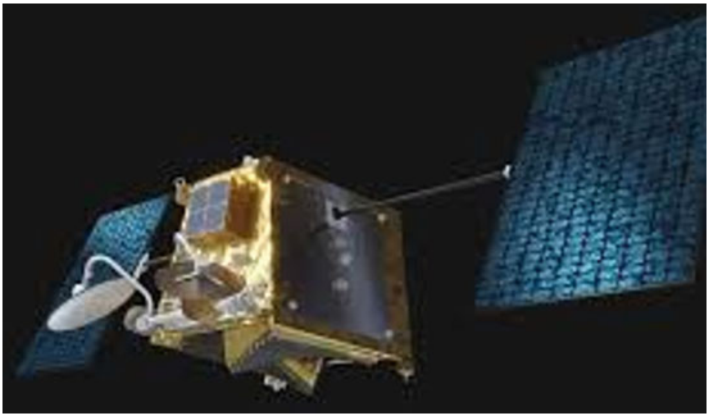

Fig. 2 One of 650 One Web satellites that will be in this LEO small sat constellation that may eventually expand to 4000. (Graphic courtesy of One Web)

of the two systems that would have been financed by SoftBank of Japan. These arrangements were never finalized.) Currently, three rounds of investments, which have been led by SoftBank of Japan, have raised $3.4 billion in investments. Of all the new large-scale constellations, this project has come closest to completing the full financing of their system as of July 2020. This financing would include the latest

$1 billion of new financing from the U.K. government and from the Indian mobile network operator Bharti Global that would lift the system from bankruptcy which was declared in May 2020. Thus this new OneWeb system will be the first of the new large-scale systems to be deployed and will be the first to deploy what can be described as a new 5G ready satellite network for global networking services (Henry 2019).

This type of financing arrangement, which is based on the supplier also becoming an investor, has the potential to be applied for much smaller scale small satellite constellations. At least in theory, this would be result in less costly manufacturing and launch costs for potentially cash-starved new entrants into the industry.

In concept such arrangements create incentives for all of the suppliers to work with extra zeal for the success of the new enterprise. A final dimension of such an arrangement is to have the bank that is providing the financing for the new system to likewise become an investor in the project. Indeed, in the case of One Web, it was the initial investment made by SoftBank that led to the other investments that followed.

In the case of an investment bank direct involvement in a new small satellite constellation, there are multiple options that might apply such as reduced financing rates, deferred loan repayments, or pledging future streams of revenues to the financial bank. The arrangements for the One Web supplier as investment arrangements are confidential, but the basic types of bartering arrangements are rather straightforward.

4 Risk and Financing

One possible concern is that a supplier that offers “bartered services” for an investment in a satellite system but continues to be a supplier to other competitive or potentially competitive satellite services could be subject to conflicts of interest charges, particularly if some unlikely misadventure should occur. For example, an organization such as Arianespace that offers launch services to a large number of satellite operators might make special contract arrangements against a liability claim. In any event all such suppliers should be well advised to set up entirely blocked lines of communications between the part of the organization that holds the investment in a company where they are supplying a service and the part that is actually delivering the satellite or the launch service. In theory these should be completely separate divisions.

The traditionally engineering GEO satellites for telecommunications such as those operated by Intelsat, Via Sat, Echostar/HNS, Telesat, and Eutelsat are today quite large, multi-ton spacecraft that may cost upward of a quarter of a billion dollars (US) each. Since it takes only a few of these satellites in order to serve the entire globe, in-orbit spares are also deployed to back up the operational capabilities. Although there might be incremental revenues derived from this type of spacecraft that provide these backup services that may be subject to interruptions from preemption options, this provision of in-orbit spares is quite expensive for GEO-based communications and broadcast satellite services. The same high expense applies to providing on-orbit spares for GEO-based Earth observation and meteorological satellites. In the case of full size remote sensing satellites in sun-synchronous orbit, the backup and resilience costs are not as high as for the larger GEO orbit satellites, but they are still quite substantial.

The very large-scale newer LEO orbit constellations for communications, networking, or remote sensing incur backup costs that are relatively modest. Constellations for mobile satellite communications such as Globalstar or Iridium could work around a single failure even with a LEO network of 50 to 70 satellites. This is particularly the case with Iridium that have inter-satellite links. In the case of very large networks of a 1000 or more, this problem should not prove to be an issue unless there were a major series of collisions that trigger multiple additional satellite conjunctions and a proliferation of space debris. In such a case, the problem then would become a much larger space environmental issue.

Unusual sunspot activities and actual coronal ejections of ions can be quite dangerous to satellites in orbit. Some areas of natural risks (e.g., high magnitude solar X-Class or above flares are easier for GEO systems to manage in comparison to MEO or LEO constellations. There are global warning systemsin place, and the timely and very quick powering down of GEO satellites coupled with the use of heavy-duty circuit breakers can be protective actions for a fleet of three to a dozen GEO satellites. Protective action for constellations with as many as 7500 satellites in a global constellation may be much more complicated. Further installation of heavy-duty switches and other types of radiation hardening measures may not be considered economically feasible in the design and engineering for constellations of small satellites.

The bottom line is that considerations related to risk, risk management, and insurance against loss of satellites as well as the consequent risk of lost revenues are considerably different for those engaged in GEO-based satellite services and those deploying large-scale small LEO satellite constellations. The management question is whether one engineers and protects against satellite failures and provides for in-orbit space for Geo-based systems or does a company simply provide a few more LEO satellites in a large constellation. The assumption is that there is a reasonable cycle of failures will be worked around until the next batch of small satellites goes up in a non-ending renewing cycle. Some of the largest constellations may well decide that self-insurance, either through GEO redundancy or through replacement small sats, will make the most sense for them rather than purchasing insurance policies that only provide a limited amount of guaranteed revenues, but not service.

Finally another thorny issue that will increase risk is becoming apparent. New small satellite constellations by ESA and NASA (ESA's Swarm satellite configuration of three small satellites and NASA's MMS configuration of four small satellites) have confirmed that the Earth's magnetic poles are shifting with magnetic North now slipping down to Siberia and magnetic South now moving up toward Australia (Swarm Mission Overview 2019). (See the ESA small satellite constellation pictured in Fig. 3.)

The Earth's magnetic poles currently hold into shape the so-called Van Allen belts of radiation. These belts of ionized particles actually protect Earth and especially LEO satellites from solar storms. As this newly discovered shift occurs, satellites,

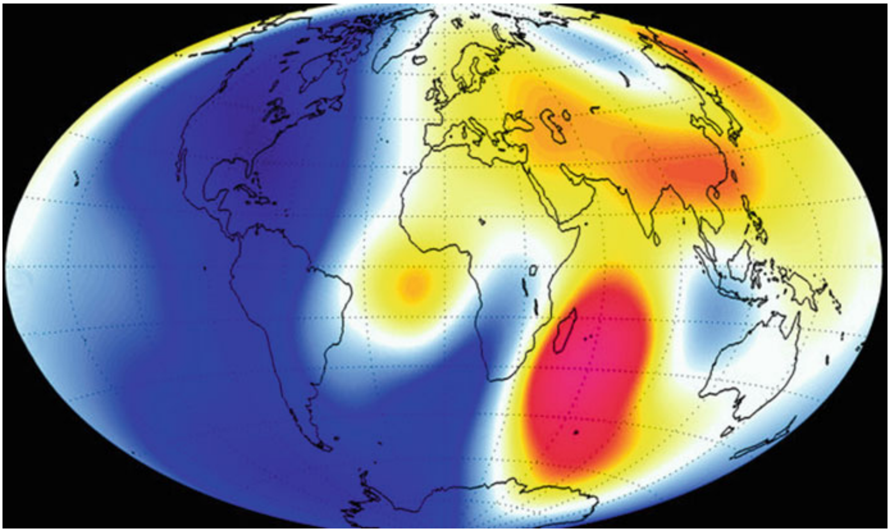

Fig. 3 The Earth's changing magnetosphere with the magnetic North pole moving down toward Siberia and magnetic South moving up toward South Africa (as depicted in red). (Graphic courtesy of ESA)

electronic grids, pipelines, and other infrastructure will be exposed to higher levels of risk. These are new risks that satellite engineers and insurance companies will need to take into account going forward.

5 The Supply Side: Innovation and New Technological Developments

The entrepreneurial innovations that are concentrated in California's Silicon Valley have been generated by people with a special drive focused on all types of new technological discoveries. Some are the result of university research, some are new businesses built on ideas nurtured in garages or maxed out credit cards, and some are attributed to larger companies expanding their R&D efforts. This has largely come from the computer, telecommunications, artificial intelligence, software, and Internet-based digital economy, although some have come from the world of bio-technology, medical research, or other sciences and applications.

There are today a number of new space ventures that got started by such innovative means. The SPIRE constellation discussed elsewhere in this handbook got started by raising funds for its first experimental test satellite via crowdsourcing. A well-crafted appeal made via the Internet allowed this fledging enterprise to launch its very first cubesat experimental prototype. This success led to a number of other rounds of investment that followed a more conventional path forward of seeking several rounds of investment by angel investors (https://www.SPIRE.com/en/SPIRE/about-SPIRE (Last accessed June 10, 2019)). (See Fig. 1 above.)

Nor is the successful bootstrapping upward of a start-up to financial viability in the case of SPIRE a unique story. The Skybox venture was started by four graduates from Stanford University that managed to get sufficient start-up capital to get their small refrigerator-sized 1 meter cube satellites to orbit before being bought out by Google. Planet Labs was started by graduates of the International Space University that based their efforts largely on the sweat equity of a number of college graduates from Silicon Valley. Today Planet, the owner of Planet Labs, Terra Bella, and other assets, is managing hundreds of remote sensing satellites in what is now a highly successful business (Schingler n.d.).

6 The Supply Side: Costs of Production

The manufacturing of satellites and space equipment has seen major improvements, both in quality, performance, and lower costs over time. Some of these improvements can be traced to moving up the "learning curve" as companies gain experience in production techniques. Some are traced to improved technology and components within the satellites. And, some are the result of taking advantage of scale economies and larger orders that are required for mega-constellations of small satellites, standardized components, and more experienced production workers. In addition, although the manufacturing of single-unit large R&D satellites often required by government specifications is more expensive since each satellite is unique, the design and components often use new breakthrough technological improvements that then spill over to the commercial satellite production arena, contributing also to more efficient production of all satellites.

One successful innovation often leads to a chain reaction generating many new ideas and innovations. One of the main components of the current patent and the intellectual property system is that the technical information behind the invention is recorded and available publically. Although the invention is protected from being copied for a specified period and royalties or licensing fees are paid to the holder of the intellectual property during this period of time, others can seek to extend the knowledge and create new ideas or devices that go beyond the original invention. Some of the entrepreneurs that have engaged in developing small satellite technologies that are now building and operating small satellite systems are downstream beneficiaries of these earlier inventions.

6.1 Life Cycle Cost Analyses

The manufacturing facilities for large satellites that are very capable but few in number do not lend itself to mass production techniques or to large-scale economies and consequent large per unit reductions in manufacturing costs. They are designed for long lifetimes of 15 years and beyond and do not need frequent replacement.

Further they do not generate a large demand for launches and launch services. With the possible near-term development of effective satellite servicing, their life may even be extended for a longer time if such developments prove cost-effective.

The advent of swarms of large constellations of low Earth orbit satellites competing with the large GEO satellites for similar terrestrial uses and services may also be advantageous to the mass production of cheap (on a relative basis) and lightweight satellites. One factory could conceivably produce thousands of these satellites at a rate that would take advantages of scale economies and, like the revolution in the manufacture of automobiles almost a hundred years ago, make these small units quite inexpensively. And, since they are small and light in weight, they also may be able to be launched on smaller and cheaper vehicles. Finally, they are easily replaceable, and there would be no need for many, if any, spares in orbit.

That sounds like a very attractive business life cycle plan compared to the current methods. And it is a different model for the industry. But, the conclusion that these new techniques are better and cheaper has not been proven and may not be realized. There are many reasons for this. First, there are still no operating systems of swarms of satellites in space that effectively “talk to each other” and operate as one “big” satellite. Second, for some applications such as remote sensing, they are incapable in design of having a large aperture and producing equivalently good Earth observations. Third, the large number of satellites may also increase space environment risks from difficulties of managing all the new “traffic” in space (Werner 2019).

On the manufacturing end, there are other questions for which there are as yet no answers. First, these satellites will use components and materials from all over the world. A guarantee of a continuous and constant supply chain to make them could easily be subject to large fluctuations from political, economic, and availability issues, not to mention export control issues. Any disruption of a supply chain can add large costs to manufacturing and selling these satellites competitively. Second, as these small satellites age, new ones need to be launched. There is no model at present for a smooth production line that will keep the production line active at a fairly constant basis over time. It is quite possible that the life cycle costs of a mega-constellation of small satellites could end up with profit points being less than those for the services provided by the legacy large GEO satellites.

Other questions are also unanswered. How many mega-constellations are needed (i.e., can a terrestrial market support)? What are their vulnerabilities? Is the business model solid? It appears that the cost and size of each small satellite is increasing due to the desire and ability to have each one do more and more complex tasks; will this trend continue and significantly increase the total investment and cost of the systems? It is too early to predict the outcomes. But the present time does require that these difficult questions be posed.

6.2 Hosted Payloads

The idea of hosted payloads has evolved and also contributed to economic advantages in the development of new satellites and services. Some of the operators of satellite systems had technology or components that they wished to deploy on future spacecraft that they would like to test in space. Thus they simply attached an experimental package to one of their current generation of spacecraft for verification testing. For example, Cisco Systems developed a new router that it wanted to test in space. They approached and got permission from Intelsat to put this as a test package on an Intelsat 9 spacecraft. The Inmarsat Express satellite, a multi-ton satellite in a more recent launch, contained over 30 experimental packages.

In short, the operator of satellite systems recognized that the residual margin between their satellite mass and the maximum lift capability of their launch rocket had value and offered launch opportunities in the form of a "hosted payload." The extent of these opportunities were recognized that led to the formation of a "Hosted Payload Alliance" that assisted in matching up those seeking a launch opportunity for a small payload with someone who was launching a larger spacecraft. This was, in part, the reason why the Inmarsat Express ended up with so many experimental packages included in this launch.

In the case of small satellite constellations, the opportunities for so-called piggyback launches expanded in a significant way. Instead of a one-off launch of a hosted payload attached to a single launch, the opportunity expanded to the possibility of a hosted payload that could fly on a fully deployed satellite network and could thus achieve in this manner a completely operational global system. The first to achieve such a complete global network is the Aireon hosted payload network that is deployed on all of the Iridium Next satellite system for mobile satellite communications. This Aireon package and antenna system is deployed on all 66 plus spare satellites in the second generation of the Iridium satellites that is now fully complete and functional. The Aireon package provides a broadcast beacon for this new space-based Automatic Dependent Surveillance-Broadcast (ADS-B) that is sent to all aircraft equipped with the new antenna system built by the Harris Corporation. In this case the Aireon service is a joint venture between Iridium and Harris (Aireon Technical Specification 2019). There are clear economic advances that come with the ability to combine two satellite missions together on a single spacecraft, especially if this can be done on a complete constellation of satellites. (See Fig. 4.)

6.3 Matching Supply and Demand

The communications satellite industry has learned long ago that matching system capacity supply in orbit to market demand is good for bottom line profitability. This means not only that additional satellites are launched when demand dictates but also that the use of the most efficient digital coding systems is a way to provide market demands in the most efficient ways. Ten years ago transmission efficiency rates of 1 bit per Hz to 2 bits per Hz were common. Today systems typically operate a efficiency rates of 4 bits per Hz to 6 bits per Hz. Satellite system that have gone from 1 bit per Hz to 6 bits per Hz can thus send six times as much information through the same satellite and thus increase efficiency up to six times.

Fig. 4 The Iridium Next 66 satellite LEO constellation as it was in deployment

Such coding efficiencies are not possible to maintain at all times. Coding efficiencies and greater dwell times may become necessary in high noise environments and particularly in conditions such as very high rain rates and associated rain attenuation. Efficient system design with the latest encoding systems can make satellite much more efficient.

Those that are planning to implement large-scale constellations need to consider the economic risks of deploying a very large number of broadband systems without the corresponding market demand being firmly in place. There is a clear logic to the decision by the One Web constellation to deploy only the first 600 satellites and leave until later to launch of the next 300 or so satellites until later. Likewise is seems reasonable to wait until this part of the system is responding to real market demand before seeking to move to the ultimately envisioned 4000 satellite network for the longer term.

The O3b medium Earth orbit constellation that preceded by 6 years the One Web network was also launched a new four satellites increment in April 2019. Thus it has gradually built this constellation in size up to 20 satellites in MEO constellation and incrementally responded to consumer demand (O3b Satellites Roar into Space 2019).

As the next stage of this evolutionary growth, SES has now contracted to create a new MEO constellation of seven satellites to be launched starting in 2021. This new constellation is known as the mPower network. This constellation will have a combined capability to create a total of 30,000 spot beams and attain a total system throughput capacity of 10 terabits/second. Thus it would have the throughput capacity equivalent to a very high capacity fiber optic network. These would no longer by “small satellites,” but there is the ability in the satellite field to scale up capability by deploying more and more satellites in a constellation or to scale up the size of the satellites to increase capacity. (See Fig. 12.5 for a representation of the SES mPower network.) (O3b mPower 2019).

It is the concern about matching in-orbit satellite capacity to established needs that gives particular concern to the proposed SpaceX system of over 4500 satellites followed by a network of over 7500 satellites. This now proposed volume of satellite launches gives concerns about oversupply of satellite capacity, the SES mPower network, and other proposed systems that are noted in the handbook that seem to create the likelihood of a satellite service provider global “price war.” The current spate of proposed filings of communication satellite networks in the mid to late 1990s brings back vivid recollections of past market over calculations as represented by the Teledesic, Iridium, Globalstar, Orbcomm, and ICO networks that experienced bankruptcies in the late 1990s. Finally it concerns about not only the deployment of so many satellites but also the issue of how to effectively deorbit these many satellites at end of life as well as to deploy replacement satellites, perhaps as quickly as on a 7-year cycle.

6.4 Shared Support Systems and Associated Risks

In this way power, tracking, telemetry and command, mission control staffing costs, and clearly launching costs can be efficiently shared. As long as both the primary satellite and hosted payload perform as expected and all launches are successful, then the joint project is also economically efficient. Even the end of life removal of the satellite and the hosted payload has efficiency as long as both the system and subsystem reach their intended lifetime and perhaps exceed it.

The downside can come, of course, if things should go wrong. Perhaps the classic problem would be if the power systems on the Iridium satellites developed a design flaw such that it could support the primary mission, but would not be able to provide power for the ADS-B safety surveillance subsystem. Clearly such types of problems should be considered carefully before such system-wide sharing of resources are pursued. Even in a partnership arrangement, legally binding language needs to spell out a series of “if-then” contingencies of things that might go wrong and how the problem would be addressed. In the case of the Iridium Next and Aireon partnership, there were serious delays due to problems with the Falcon 9 Launch services, but currently all systems are successfully deployed, and no major issues have emerged after the constellation was fully deployed. Of course in the future, other joint projects and hosted payloads may not be as successful.

7 Looking Ahead: Demand and Supply in the Future

The concept of hosted payloads is not the only spin-off idea that has come with the small satellite constellation and “NewSpace” revolution. Another idea that is getting serious attention today is the idea of deploying high-altitude platform systems (HAPS) or so form of stratospheric platform or long-endurance aircraft that might provide communications, remote sensing, fire detection, or other services for a particular area such as an island country.

There has even been serious consideration of a constellation of as many as 15 HAPS that would provide telecommunications and broadcasting coverage of all of Japan on a continuous basis. There have also been ideas that have included solar- and battery-powered HAPS, automated jet aircraft that could stay aloft for as long as 7 days, and even beamed energy systems that could power and keep in position a high-altitude craft. Instead of an orbited satellite, the application platform would be the equivalent of a GEO satellite, but instead of being up at 35,870 km, it would be stationed at about 20 or 21 km in altitude. This could provide high gain services for communications, broadcasting, fire detection, or remote sensing with very negligible path loss.

In this case there have been more than a half dozen initiatives that have been seriously proposed as well as so-called aerostat projects that have been pursued but none have as yet proved technically and financially viable.

Quite recently Facebook, which was providing funding for a HAPS projects to support networking services, pulled out of one such project. Currently Amazon which is now backing a small satellite constellation known as Athena was seriously considering attaching data relay united to high-altitude meteorological balloon that would drift around the equatorial region to support remote Internet access. This project was known as deploying "Loons." Perhaps one of the more serious initiatives at this stage is the Stratobus initiative by Thales Alenia. This is a fully prototyped system that would operate for long duration missions up to an altitude of perhaps 20–21 km. This kind of stratospheric operation that would fly up to the region sometimes call near-space, sub-space, or Protospace is addressed elsewhere in this handbook of small satellites.

There are also manufacturing risks that can have more severe consequences for space equipment than terrestrial equipment. For example, a satellite series that had used the same batch of computer chips that contained a contaminant that in time disabled the satellites. Fortunately this problem was discovered to affect only a limited number of satellites. If such a problem had involved contaminated chips installed in thousands of small satellites, the economic consequences could run into billions of dollars, and the losses in revenue for services not performed could likely bankrupt the service providers.

Thus while risks for small satellite constellations might be minimized, and providing spares is more easily done, there are some other high level engineering and reliability risks for small satellite constellations. This can occur if a key component in thousands of small satellites were found to be defective after the satellites are placed into orbit and the result could be the cause of a catastrophic failure. In the case of an automobile manufacturer, if there is a faulty component in large production run, the component can be replaced in a local dealership. In the case of thousands of satellites deployed in space, there would not be any easy answers.

In summary, new mass production systems that may be developed for large clusters of almost identical small satellites face many risks that are different from the mass production of terrestrial equipment. They may also face other economic risks and costs. It is not a foregone conclusion that the mass production of these satellites is any cheaper or less risky than producing large LEO or GEO satellites that currently serve markets that are similar to those projected for small satellite clusters.

8 Regulatory Concerns

When entities are first engaged in planning the deployment of a new satellite system for telecommunications, networking, remote sensing, or other such applications, the initial thoughts are typically focused on the space segment, i.e., all the efforts that are directed toward the design and manufacture of the satellites, intersystem coordination of satellite spectrum usage through the International Telecommunication Union (ITU) procedures, making arrangements for the launch services for deploying the satellites in orbit, and controlling the network in orbit.

Besides a good assessment of market conditions, often overlooked are regulatory procedures and national licensing and landing rights for the countries where the satellite services are to be marketed. One of the largest single factors that led to the bankruptcy of the Iridium mobile satellite system was a recognition of the costs and pricing implications for their services in the countries where there services were planned. In many countries, particularly developing countries with limited access to hard currencies, international telecommunications is a key source of supply of key overseas monetary resources.

The idea that an Iridium satellite, or a Globalstar or ICO satellite, might be able to have its own “country code” and thereby allow users in their country to avoid using national telecommunication carriers and share revenues with the country in question was considered a very big problem indeed. Country after country demanded that cost of a “landing license” to operate in their country was a share of the entity’s revenue stream. The initial projected costs for the Iridium international cellular voice service – as well as the other systems such as Globalstar and ICO – was well under a $1.00 a minute, but when the total costs of getting landing licenses; coordinating frequencies, taxes, or tariffs; sharing of revenues with local telecommunications companies and governments; and ground equipment were all added, the actual price was much greater ($3 to $10 a minute).

How the various new small satellite constellations relate to national regulatory bodies is thus a very important issue. Some systems are opting to download their remote sensing data via data relay systems. This can speed up their download capabilities to near real time and avoid issues such as tariff fees for ground equipment and perhaps other forms of taxation.

Satellite networks that are seeking to provide telecommunications and networking services have more limited options. In the case of local networking and Internet services, they might be able to make commercial arrangements with nationally based Internet service providers to upgrade their service capabilities. Different countries will have different regulatory practices and legal constraints. In the age of broadband IP-based streaming of movies and video services, radio programming, and voice over IP, these small satellite constellations that are seeking to provide networking services may still be required to obtaining “landing licensing” and may very well be subject to revenue sharing arrangements. The world of telecommunications, broadcasting, and networking is now almost completely intertwined. The argument that a “networking” system is not competing for telecommunications services, either locally within a country or for international services, is unlikely to be accepted by national telecommunications licensing authorities.

The economic effects that are associated with “NewSpace” enterprises are evident in many different ways. Launch costs for lightweight small payloads are much less, mainly driven by their size and capability to be launched not only on small launch vehicles but using excess capacity on large vehicles. Companies as diverse as SpaceX, Blue Origin, Rocket Labs, Virgin Galactic, and Vector have begun to revolutionize the launch industry by adding such capabilities as reusable first-stage rocket engines, vertical integration of their rocket production, new materials, lower cost ground or air launch operations, true small launchers geared to the small satellite markets, and more. These lower cost and more flexible launch operations have not only made it easier to launch for small satellite enterprises. The lower cost not only enabled the creation of new satellite constellations for established satellite applications, such as telecommunications, networking, and remote sensing, but also opened the door to new commercial space services.

One of these new types of networks is the Hawkeye 360 system that is now offering RF Geo-location services. This new cubesat constellation is now monitoring frequency use on a global scale and does so with a precise identification of the RF users and their location.

There were at least two firms that are intending to offer commercial data relay services to support remote sensing services and rapid data analytics. These two companies are Audacy and Theia. The Audacy effort though is currently seeking financial support to continue operations. Nor do the new satellite services offered by innovative small satellite ventures stop there. There are likely to be in the future a number of firms that will seek to offer on-orbit servicing and perhaps also active debris removal. Firms that have developed, or are seeking to develop such capabilities, include McDonald-Dettwiler (MDA), Orbit Fab, SSL, Northrop Grumman Innovation Systems, Vivasat, and Conesat (Pelton 2015).

However, there are still many problems to be resolved, particularly in the area related to on-orbit services (OOS) and satellites that engage in so-called rendezvous and proximity operations (RPO). There is the question of nation-state liability if such close approach operations in space should go wrong. The resultant accident could result in a significant amount of new debris, and major liability claims might be created against the launching state as well as civil claims against the on-orbit operator. National security aspects and diplomatic problems are also likely consequences. No regulatory system now addresses these issues, and a new liability regime may be needed for in-orbit activities.

9 The Reshaped World of Commercial Satellite Services and the NewSpace Launch Services Industry

The world of commercial space is continuing to be reshaped in almost every dimension. There has been a major reshaping of design processes, innovation, and manufacturing cycles for satellites, and in many cases the size and mass needed for the satellites to perform many of their missions have decreased in major ways.

Likewise the design and cost efficiency of launcher have also dramatically changed. There are many new start-up companies in the world of commercial space. There tends to be a whole new cost structure that relates to many aspects of space operations and services. These relate to not only "NewSpace" commercial operations, but the impact is increasingly broad in terms of military and governmental satellite activities and in terms of the business practices and operations of well-established aerospace corporations.

It is no longer governmental space agencies and military ministries that are dominating space-related procurements. The dominant role of the "military-industrial complex" where procurements, especially in the United States, Canada, Europe, Australia, and Japan, largely came from governmental or defense agencies and largely went to the largest and longest established space agencies is tending to change. Commercial organizations rather than governmental and defense agencies dominate procurements. Contracts are less likely to be cost-plus arrangements with specific design specifications. Instead contracts are likely to set performance standards and establish a fixed price and delivery schedule for space-based equipment and systems.

So-called NewSpace practices have rippled through government space agencies and defense agencies and large aerospace corporations. Space agencies are sponsoring commercial competitions. Defense and governmental agencies are commissioning small satellites for many projects. Large aerospace companies are acquiring innovative start-up companies. Boeing is building cubesats for the US Air Force. Air Bus has purchased Surrey Space Technology Ltd. and also building small satellites for One Web. Northrop Grumman has acquired Orbital ATK. But some of the scale start-ups such as Sierra Nevada, Planet, Via Sat, SpaceX, Blue Origin, and SPIRE have become truly major aerospace corporations. Everywhere there is change and innovative design, and new corporate practices will evolve from many sources.

10 International Trends in "NewSpace" Service Industries

Many people attribute the so-called "NewSpace" revolution to the growing world of computers and digital systems. The idea of seeking 50% or 100% improvements in efficiency, design, or process rather than a 5% or 10% improvement is clearly what "Silicon Valley" innovation has been all about as new generations of products or systems have forged ahead with remarkable speed. Moore's law of a doubling of performance every 18 months has characterized the world of digital innovation for decades, but now the aerospace world is seeking to innovate in this fast pace way as well, even as the digital improvements may be increasing at a slower pace now.

The source of this type of "NewSpace" thinking may have come in part from Silicon Valley, but it has certainly spread worldwide. The world of cubesats, commercial launch vehicle design, and new aerospace innovation is now global in scope. There are more than a dozen new Chinese commercial launch vehicle companies and space satellite designers and manufacturers. The many companies that are designing and manufacturing new launchers, small satellites, and new flat panel antennas and starting new space-based service companies may still be predominantly in the United States, but there are a growing number of these innovators that are located in scores of countries around the world. Canada is also a powerhouse of new initiatives. Innovations are coming from countries like India, China, Taiwan, Australia, New Zealand, Luxembourg, Russia, Ukraine, Spain, Denmark, Italy, the United Kingdom, South Africa, South Korea, the Malaysia, United Arab Emirates, Chile, Brazil, and many other sources as well.

11 Conclusion

The purpose of this chapter was not to compare and contrast conventional designers and operators of large GEO satellite networks with small satellite networks in MEO or LEO orbit in precise terms of economic efficiency or market viability. This is much too early in the deployment process for small sat LEO constellations to reach any definite conclusions. The nature of these competitive systems and the evolution of related technology in terms of satellite design, new ground equipment design, new market demand, and new launcher systems will sort themselves out in the coming decade. Successes and failures for both types of systems seem likely to occur.

It may become apparent that the number of new systems is much limited by the expected amount of new types of demand for space-based services fueled by broadband Internet to rural and remote areas, 5G backhaul, and M2M messaging services associated with interactive IoT units. It is also quite possible that new innovative land-based systems may also compete with space services. It is thus not possible to predict the longer-term future, but it is clear that there are economic factors that encourage new and more efficient space systems just as there will always be competition from innovative non-space systems.

This chapter instead was oriented toward examining the economic consequences and trends that are inherent in all markets where there is rapid rate of technological change. Clearly there is alteration in space business models that are being driven by all of the new LEO and MEO small satellite constellations that are now planned with perhaps up to 20,000 satellites now planned for deployment. Nor are all the forces of change entirely market or technology driven. The vulnerabilities that could come from orbital debris collisions, small satellite deployment or defunct satellite removal, or even a gigantic solar storm that disables a large number of these new types of satellites – either high-throughput satellites in GEO orbit or small satellites in LEO or MEO – could have huge economic and market impacts that could affect the viability of many companies providing commercial space services.

The practices of governmental agencies, defense ministries, start-ups, and conventional aerospace companies are all changing, both in the United States and across the world. This chapter has examined how the developments of the past decade have enabled the creation of new types of space services, especially in telecommunications, remote sensing, and Earth observation, but also have spurred innovation in all sectors of the space industry with these broader effects being seen on in the years and perhaps even decades in the future.

Abstract

This chapter will look at how various classes of new space and satellite projects which may have capital requirements that can go from as low as under a $1M up to well into the billions of dollars are now able to come to fruition leveraging novel financing models which are being constructed. It is clear that for "New Space" to mature and reach its fullest potential, mastering the ability to drive large-scale infrastructure level investment into the sector is required. The financing mechanisms change as one progresses to new support service companies or small satellite ventures operating at the cubesat level, to satellite constellations of larger and larger size, to very ambitious space projects involved with building the cislunar architecture and beyond which may take decades to realize. A smaller space business might start with family and friends financing, angel investors, or even crowdsourcing on the Internet via such sites as "Kickstarter." The next step involves venture capital financing that might end with an initial public offering (IPO) or merger/acquisition. Finally, there are very long-term and ambitious space ventures that may involve various forms of public-private international financing arrangements which have been used in the past for large collective projects which are now being framed and envisioned for new space applications. In this chapter, all these mechanisms will be explored with the greatest emphasis and most lengthy discussion related to demystifying the venture capital financing process for new space actors since this is perhaps one of the most common approaches used. Other mechanisms exist such as spin-offs from established corporations or equity-based loans, but these are not addressed in any detail because they are unusual mechanisms which are available to entrepreneurial projects and small satellite venture startups but not often used.

The goal in this chapter is to help the budding space entrepreneur make their case for the right investment type and to help them to propose a structure based on a better understanding of the different investment classes and vehicles. There is also some consideration of how to posture their enterprise based on the longer-term future at a time when space industries will represent a multitrillion dollar sector. When one thinks of some of the larger projects described later in this chapter, it is important to see them in historical perspective. Although the numbers presented here for long-term space infrastructure projects seem large, they need to be seen in light of other infrastructure projects such as the original US Interstate highway system which is estimated to have cost $500 billion (in 2008 dollars) and the upgrade costs alone for the emerging 5G network which are estimated to be $200B *per year*. It is clear that when the case is made properly, the investment dollars are available. Currently, NASA's FY 2020 budget was nearly $22.629B in order to address their very ambitious mandate, and the capital requirements for some of the larger new space infrastructure projects are way beyond the political will that exists to support the kinds of budget expansions that would be needed if all space-related fundings were to come from the government. What can thus be seen is that to really make financial room for truly innovative, capital-intensive, and longer-term new space projects, there is a need for a new transnational investment model whereby there can be a pooling of the resources of international partners, corporations, high-net-worth individuals and family supporters, and other forms of private equity (PE) along with venture investors. It is clear that these future projects will not only involve venture capital and governments, but there will be a need to involve more of the capital community, coordinated in a way that supports competition and innovation which will allow these new space enterprises to keep learning and improving. All of this needs to be done while respecting and abiding the laws set by each sovereign nation to address their own national security concerns arising from non-controlling investments involving foreign parties.

It is important to keep in mind that as far as the investment community is concerned, investing in space has the same business risks as many other fields of endeavor – execution, technology obsolesce, and regulatory risk plus an additional set of risks due to operating in the space environment which magnifies the difficulty of executing the business plan and getting a return to the investors who ultimately want to make money and will compare this investment opportunity to many others. Although space investors are often motivated by a highest set of principles involving mankind's advancement in space, one of the main challenges that the space entrepreneur faces is finding innovative ways of buying down risk to create a level playing field with other capital investment opportunities available to the investor.

Although successful space missions are hard, financing space missions can be harder because in addition to the high and uncertain capital needs and high-risk levels of any space venture, space entrepreneurs also face immature and uncertain markets in terms of price points and market behavior. It is hoped that this chapter helps to equip the space entrepreneur on this journey to bring forward concepts which will enable the continuing progress of humanity in space for the advancement of a sustainable prosperity for all humankind.

1 Introduction

The commercial exploration of space should be seen among the historically great projects that mankind has conceived and pursued over time. In most instances, success for these projects has been dependent on finding an appropriate means of financing. From the pyramids to the voyage of Columbus to the construction of the American railway network, Interstate highway system, and telecommunication network – each project has lived or died on finding the right means of financing. Often this has depended on whether there has been public or private financing or some combination thereof. Although space finance is rather new, the concept of venture capital investing to achieve new worlds and new opportunities is not. It is sometimes said that Queen Isabella of Spain was the first true venture capitalist (VC) by backing an entrepreneur named Christopher Columbus with capital in the form of money, ships, supplies, and crew to do something that most people at the time thought was insane and certain to fail. This investment was made in exchange for a portion of the to-be-earned profits of the voyage, but at the start, such a project was seen as unlikely to succeed yet with an asymmetric payoff compared to at the capital at risk.

The following quote concerning Columbus's quest for financing his mission portrays the insatiable appetite for exploration and difficult quest for achieving a truly challenging goal that fuels the entrepreneurial zeal of mankind:

> Columbus arrives as a supplicant at the court of Queen Isabella of Spain, hoping for cash and three tall ships. When the Queen asks him what he desires, he bows over her hand and murmurs, "Consummation." The Queen is offended. Columbus becomes known at Isabella's court for his colorful clothes and excessive drinking. The Queen plays with Columbus, permitting him familiarities, then banishing him to the stables and piggeries for forty days. "The search for money and patronage," Columbus says, "is not so different from the quest for love." . . ..He dreams that Isabella is herself having a dream, in which she sees that all the known world is hers, but that she will never be satisfied by the possession of the known. Isabella's heralds arrive and tell Columbus that she has summoned him for his voyage–she saw a vision, and it scared her. (The New Yorker, June 17, 1991, p. 32)

Another era of similar entrepreneurial zeal took place in the USA during the 1800s in the whaling industry when outfitting to go out for the hunt was very expensive and risky but highly profitable when successful. The New Bedford agents would raise a pool of capital from corporations and wealthy individuals (today's limited partners) to fund ship captains (entrepreneurs) to launch a whaling venture (startup company) in search of asymmetric returns that were heavily skewed to the top agents yet often plagued with failure. Similarly, in 1878, J.P. Morgan would act as a "venture capitalist" to Thomas Edison financing the Edison General Electric Company. Today, VCs do not exist by royal treasuries or monopolistic titans of industry but by the grace of sets of limited partners who invest their own funds into specific VC funds to maintain a diverse portfolio to produce good returns relative to a specific market index.

In this section, the objective is to present ideas that can accompany and empower the next generation of modern space entrepreneurs, or existing ones, looking to take their businesses to the next level while attempting to create a new space infrastructure for both public good and private profit. The focus is on the challenge of raising the amount of capital needed to develop "new space" architectures for projects such as small satellite constellations, new launcher systems and related sub-systems, or even cislunar architectures, infrastructure, and space settlements. Such undertakings are typically defined as the following along a certain magnitude of capital need and the associated timing to achieve breakeven and profitability:

1. **LEO/MEO/GEO Satellite Systems or Supporting Services** – These might be for remote sensing, communications and networking, data relay, RF geolocation, solar power satellite systems, science and technology demonstration, or other applications. They also might involve a subsidiary activity to develop new encoding software or to develop and manufacture key subsystem components. The range of funding in this regime can be as low as a million dollars for a supporting service or to create a new satellite service using PocketQube picosats. However, this could also represent the need for billions of dollars of capitalization for a visionary large LEO or MEO constellations or GEO-based infrastructure. This "New Space" market is alive and well today, and many such satellite systems are already deployed, in development, or on the drawing board with significant engagement at all phases of the financing life cycle. Typical time to viability and profitability: short (3–5 years) to medium term (10 years), depending on the scale of the project.
2. **New Launcher Systems** – This may be a new development of a small-scale launcher, or it might be a new larger-scale launcher by an established launch service provider. Other possibilities are to serve as a launch aggregator or in developing a small satellite dispenser. Typical time to viability and profitability: short (3 years) to medium term (10 years), depending on the scale of the project.
3. **New Venture to Manufacture Small Satellites or Subsystem Components** – The key is not only to be able to manufacture small satellites and components but do so efficiently with the latest technology for additive manufacturing, with properly skilled employees, and suitable facilities but also with the right ability to integrate and test these systems with a high degree of commercial success. Typical time to viability and profitability: short (2 years) to medium term (5 years), depending on the scale of the project.
4. **The Cislunar Infrastructure (CLI)** – The focus here is on getting to the Moon and the developing a cislunar (between the Earth and the Moon) infrastructure for satellite communication servicing, establishing propellant depots, manufacturing, lunar logistics, aquaculture, tourism/settlement, and space mining-related capabilities. Although there is some activity starting up in this area today, there is likely to be an acceleration and maturation of such efforts which has been estimated to be about 20 years out. The build out of the CLI will also serve as an initial stepping-stone to take humanity to Mars which is the ultimate goal for space settlement with very large capital needs.
5. **Moon Colonization and Exploitation** – Once humanity gets back to the Moon on a manned mission in the next 5 years or so, the focus is then going to shift to working and investing to stay sustainable and in supporting larger and larger populations. There will be the need for businesses that focus on mining, processing, settlement, and tourism. Once this is established, such base will immediately serve as a stepping-stone to Mars perhaps as soon as the 2050

time frame where larger and larger populations of planet Earth will be able to be supported. The need for a new capital infusion at a much larger level (i.e., over $50B) will be required before real progress is made in creating a sustainable ecosystem.

This is not an exhaustive list of new space ventures that might seek new capital financing, but it represents the dynamic range of relatively small levels of backing that might be needed to launch up to the truly large new space ventures that could require vast sums to succeed.

2 Valuation of New Space Markets

Space enthusiasts know that there will be a market for many of their ideas, but the key question is how big it might be and when it might come to fruition. The uncertainty in answering this question places a tremendous amount of market risk than more traditional deals that investors might come across. It is challenging at this early stage to predict the value of longer-term projects such as water on the Moon or on Mars or how one should price communication services from the Moon or Mars back to Earth.

Space is still very much the "Wild West" in many ways, but when the West was settled, property rights were recognized. However, international space law is still in a state of flux so staking a claim and defending it are not yet an established practice. As of this writing, no individual, corporation, or nation can own a piece of the Moon, Mars, or even an asteroid, so for many business plans, fundraising must be done in a risky environment without being able to show material collateral such as acquired property so new ways of raising money are required. Even Columbus could offer the promise of new lands conquered for the Queen in exchange for the risk in funding the mission. A new model is required which will replace property rights with things that still allow money to be raised. The bottom line is that investing in space is not like investing in the next great software company so neither can anyone expect the funding mechanism to be.

3 New Sources of Funding for New Space Ventures

Long-term space infrastructure projects require new sources of long-term and very patient capital committed to realizing the vision of building space infrastructure. Most venture capital (VC) or private equity (PE) firms expect a 3–7-year return on their high-tech projects. However, many space infrastructure projects may require 10–20 years to see sizable returns. The challenge to bringing these forward is not the technology or the political, corporate, or social will in the USA, other countries, companies, and individuals since all of this actually exists. What is needed is to develop the correct finance plans to fund these audacious businesses. Silicon Valley VC investing despite all its successes has generally created a world with relatively impatient investors with short investment horizons due to the quick returns that have been available in the software and internet markets. This is not mentioned to be critical but rather to identify that there have been relatively quick return opportunities presented in the world of digitalization, and this is not usually so in the world of space.

Venture investment firms have made many hundreds of investments in roughly the last 5 years in early-stage space-related entrepreneurial firms mostly from the USA and Silicon Valley but also Japan, the EU, UAE, India, and some others. These firms are typically raising rounds as low as $1M but usually no higher than around $50–100M. The pipeline is full of entrepreneurial firms with great dreams that have been funded in this manner. Yet what is required is an effective way to winnow down the many hundreds of aspirational projects to a smaller set of truly viable ventures that might be able to raise hundreds of millions or even billions of dollars needed to fully realize their dreams to deploy this new space infrastructure. In the next few years, there may be significant shakeout of companies that cannot make it to this next level of serious rounds of capitalization. There is a need for considerable consolidation through mergers and acquisitions (M&A) to get to the levels of scale which can attract the needed investors. It will take time and new forms of consolidation or acquisitions before it will be possible to get down to a smaller group of companies that have the capability to raise both capital and execute their business plans.

Although the venture firms have been very impactful, the future of new space ventures cannot really rely on them alone given their charter and their scale. There is a need to get to the billions of dollars per year scale that will be required to really enable the needs of capital financing associated with many larger new space infrastructure needs. One key method will be the private equity (PE) industry which does have the financial depth required. There is probably $1T in PE funds around the world, but today, there is not much interest among these fund managers to invest in new space because these markets are still seen as being very uncertain and unpredictable. PE firms like to have predictable markets in order to raise debt capital so they can leverage their investments, but because of the uncertainty in the space markets, we are not yet there so their pools of capital are still on the sidelines. Similarly, many traditional aerospace industry companies are making investments in commercial space partially to service their government customer (and this is likely to increase), but they can only do so only while keeping an eye on quarterly earnings so excessive long-term risk does not fit their model. Likewise, the debt markets, with trillions in capital, are also on the sidelines with the exception of a few such as SoftBank of Japan. In general, one cannot expect much money from this class of investor in the near term until there are businesses with assets that can be used as collateral. It must be noted that the space industry has had previous period of high-yield financing when the IPO window opened in the late 1990s and bankers raised $15B for commercial sat companies some of whom made it while others went bankrupt or consolidated.

A chapter on space financing cannot be written without mentioning the great deal of money which was invested in Iridium Generation I, Globalstar, Teledesic, and even Orbcomm. These failures and bankruptcies took away naive ideas of "build it in space and they will come." The ideas of building the infrastructure and waiting for the demand failed miserably, so it is very hard with investors to bring that model back. It is not just space projects that face this challenge, one can look at several other commercial terrestrial infrastructure projects (such as the Chunnel) which were not financed properly, hit hard times but eventually came back to viability. Although there is certainty that mankind's future in space is bright, a careful analysis of timing and financing is required to ensure that some of the errors of the past are not repeated. This will require new and innovative ways of building space infrastructure and especially new ways to find ways to fund it sensibly in a manner which can be shared with government, corporate, and private investments resulting in benefits going to both private industry and the public sector. Some of these domestic space projects, such as Iridium, Globalstar, and Orbcomm, eventually became successful and have become great assets for many years once demand caught up with the capability offered by the infrastructure. The same challenge will be true for new space infrastructure now planned or being envisioned.

The key to successful space entrepreneurship lies not only in having a solid idea for the delivery of a product or service but also in finding patient investors with the right long-term vision. Space agencies are funding a lot of technology development and demonstrations with program such as Commercial Lunar Payload Services (CLPS) for delivering science and technology payloads for NASA, including payload integration and operations, launching from Earth and landing on the surface of the Moon. They have a long-term vision but are underfunded compared to the total amount of capital needed. Unfortunately, governments in general are proven to be unreliable because each administration brings an altered set of priorities and initiatives, so some programs are cut, while new programs are created with each administration. A lot of the investment community will not even invest alongside the government because they have been burned so many times because of examples where funding for programs has been cancelled.

Although the government has not been a reliable long-term partner, this can change by creating new public private partnerships (P3s) that do work. A prime example of this is the ISS cargo delivery program created by NASA which shared the cost of the development by buying down the development risk with capital that was non-dilutive to the investors. The government did not sit on the boards and try to direct the execution of the business plan; instead they bought down about half of the cost of developing the infrastructure, and once this was proven and deployed, they gave a big multiyear contract to deliver to the space station. This guaranteed and quantified the demand at a fixed level for a fixed number of years. With these two things in place, they were able to create a vibrant and competitive delivery service that helps keep the ISS going, supports commercial crew, and helps fund SpaceX and Northrop Grumman Innovation Systems to build rockets to buy down the cost of commercial satellite launches. This has had tremendous effects throughout the industry starting with NASA designing a P3 structure that checked off all the boxes for investors.

There are other patient large pools of capital that can wait years for a positive return such as sovereign funds which have many billions of dollars to invest and are becoming increasingly interested in space to help modernize their country's economy by getting involved in new space projects. To date they have not yet made significant investments from these funds, but this is expected to change if they are able to invest in profitable small satellite constellations from which they might also consider investing in activities on the Moon or in going to Mars. There are also substantial funds within family offices and a small number of billionaire space enthusiasts backing Virgin, Blue Origin, Bigelow Aerospace, and SpaceX, but there are 100–1,000s of other businesses with large wealth owners that can be attracted into this sector if the right case is made. Right now, most private investors worldwide are more concerned with preserving family wealth rather than increasing it, so they must be approached as a way to build long-term wealth in their families. This is a sector that will be a huge part of the economy in 10–50 years, and the message is that they need to invest now, to avoid missing out because it will become a lot more expensive to invest later down the road. Space entrepreneurs must do a better job of explaining the proposition to this group and attracting capital. Governments could also continue to support space billionaire initiatives, as well as encourage startup entrepreneurs by helping to buy down risk.

The range of financing mechanisms for new space ventures is thus quite large with the possibilities running the gamut from (i) small startups backed by "family and friends," angel investors, and "Kickstarter" crowdsourcing (these are often efforts used for spin-offs from a university cubesat project); (ii) various types of venture capital-backed projects ranging from modest projects up to very large venture capital initiatives that ultimately lead to initial public offerings (IPOs) for new public corporations and major new space organizations; and (iii) public-private initiatives that might be used to create global consortia and might be the core of longer-term space initiatives associated with space stations, settlements, and space projects on the Moon or Mars or even things such as planetary defense mechanisms.

4 Financing Concepts for the Smallest of Space-Related Startups

The "new space" revolution and the development of cubesat technology and systems that can provide commercial services have led to a whole new school of thought. New companies such as Spire, PlanetIQ, exact Earth, Capella, ICEYE and many more have shown that space industries can start without a multibillion dollar capitalization. Even smaller firms can be started to create components for small satellites, develop software, or analyze information from small satellite constellations to provide "data analytics" to customers. Such space services or component manufacturers can start with even smaller capitalization.

The smallest levels of capitalization for entrepreneurial new space companies have come from three types of funding. The first is simply known as "families and friends." There is someone who develops a new design for a component, a new software for encoding or encrypting signals, or something else that can be brought to market for perhaps as little as a few hundred thousand or a million dollars.

The innovator develops a prototype or working model or demonstrates how the new software will work with sufficient skill that they can go to their family, friends, work colleagues, and college associates to offer them investment shares in a basic corporate structure that perhaps an attorney friend will draw up and file incorporation papers. There might even be a first round of $100,000 of funding and a second round of $500,000 to get the project off the ground. In many cases, the project may fail, and the family and friends may lose $10K or even $25K, but if the project succeeds, then all of the early investors can end up profiting from such a low key launch.

The second approach would be to seek “angel investors” to invest. Although investors can put their money into a venture capital fund and then let professionals find the best investment opportunity, they can also qualify based on their net worth and income to become investors in new startup corporations. This can be a high-risk type of investment, but it can payoff handsomely if a new space corporation truly succeeds. There are actually many options here, and there can be individuals who are knowledgeable in the space industry that can identify new projects of note which they can recommend to angel investors. These “intermediaries” serve a useful role that VC firms perform in a much more structured way. The venture capital route has been the key route for the computer and web-based companies, and it is now a viable route for space-related startups to get their financing.

The third and newest type of approach to new space ventures is through crowdsourcing. The most notable site in this regard is the Kickstarter site. It is through this process that Spire funded its first cubesat experimental launch. The successful launch of this first trial demonstration satellite let Spire proceed to a series of venture capital rounds of financing and then have an IPO and go public. This, however, is a rare success in moving from a Kickstarter-funded initiative and then move all the way to a public corporation with quite substantial assets.

5 Entrepreneurial Capital Financing in the Here and Now

These next sections are for entrepreneurs interested in applying venture capital to fuel their space dreams and to help create a global system of sustainable prosperity to create new jobs and continue the path of global economic growth. This practical path of financing is “here and now” for most space entrepreneurs to secure early funding to get a space venture off the ground. It is the aim to demystify how this crucial part of the startup ecosystem works specifically for the space industry vs software, biotech, or any of the others in vogue in Silicon Valley, New York, or beyond.

The first step is to take a quick look at the space VC startup life cycle from every angle including how VC decision makers decide where to invest and how best to approach VC firms. This chapter also seeks to supply some legal and financial details and where to seek help in forming and growing a space startup. This information can help to reframe the relationship between space startups and their investors. If properly followed, this can lead to a true partnership aimed at advancing the future of space progress which requires that new ideas can come to fruition to fuel the future from a wider range of entrepreneurs with the goal of helping to clarify the world of space VC so new entrants can succeed in it.

Overall, the perspective that is offered here is that barriers to entry to space entrepreneurship are being reduced everywhere thanks to the new space revolution, the rise of globalization, and the influx of new talent into every industry and sector. It needs to be recognized that venture-backed companies overall account for nearly half of the entire R&D budget for US public companies while making up a fifth of the total market capitalization of public companies while employing over 4M people in high-tech industries. In a growing number of countries in Europe, these numbers and ratios are not too greatly different. Yet new space needs more entrepreneurs engaged, and the following sections will identify the incentives and systems behind VC investment strategies in order to help space entrepreneurs navigate the maze of venture investors and to help decipher behaviors and explain why and how the system works.

Venture firms use a formula to determine how much money to allocate to different types of space investments, and the current reality is that the amount of resources invested in innovation, space, or otherwise is based on the percentage of assets that need to be invested according to a formula rather than the number of investable opportunities that exist. When too much money is chasing too few deals, prices rise rather than funding the kinds of organizations that are needed. There are currently not enough quality space startups that are wide-ranging enough to build the kinds of companies needed for rapid continued expansion of new space industries, so they are more high-quality talent constrained than capital constrained. Although each space startup is unique, together they all have the common purpose to shape a better world in which everyone is represented and served well by the companies and systems that are created. This path requires the participation of policy makers, academic, government officials everywhere, civic leaders in space startup hubs around the world who are already helping to democratize startups geographically, as well as people who work in corporate innovation who might want to look to VCs for inspiration on how to fund and grow space-related projects within their organizations.

6 The World of Venture Capitalism (VC)

In the world of VC, there are no authoritative formulas, but there are many nuances to the field of space investing with lots of different firms that invest at different stages, under different investment theses, with different portfolio constructions and with different return expectations. Also, space entrepreneurs have their own perspectives, and their ideas come with a unique set of opportunities and challenges and conditions to be navigated. The story of space venture capital is a subset of the story of space entrepreneurship, and the space entrepreneur needs to recognize that VCs raise funds from a broad range of limited partners (LPs) such as endowments, foundations, pension plans, family offices, and fund of funds which is then invested into great space entrepreneurs with breakthrough ideas. VCs invest along the spectrum from early stage where the startup is little more than an idea and a couple of people to growth-stage startups, where there is some decent revenue coming in and the focus is on effectively scaling the business. A space company generally leaves the venture ecosystem via initial public offering (IPO), a merger or acquisition, or bankruptcy and a wind down. A good VC/space entrepreneur relationship involves more than just writing a check, and a good firm will help identify talented employees and executives to bring into the company or existing companies that can serve as live customer test sites. They will work with the team throughout the company building life cycle over long periods of time and multiple investment rounds spanning 5–10 years or longer while often serving on the board and providing strategic advice, contacts, and whatever it takes to make the company successful.

Just as entrepreneurship is essential to the innovation in many national economies, the same is true with the emerging space economy. Successful venture-backed companies have had an outsized positive impact on the US economy and many other industrialized countries, and the same is hoped for with space ventures. In the USA, nearly half of all initial public offerings (IPOs) since the mid-1970s were venture-backed companies, while US-based VCs have invested over $100B in R&D and are responsible for creating over $4T in market capitalization or about two-thirds of the total market capitalization of public companies formed in the USA having a tremendous impact on the net jobs created. This is hard evidence that for the space economy to flourish and expand, there is a need for new ideas to flourish. In order for startups to succeed and expand, the key to this success will be for space entrepreneurs to be able to access capital and present their unique ideas to capital markets as democratically as possible.

All entrepreneurs need to ask themselves if they are ready for VC financing and if venture financing is right considering the benefits and risks of this source of capital and as to whether their space business is appropriate in scope and type to raise venture financing. Key questions to be addressed are whether the intended chunk of the space market size is big enough that the business, when it achieves scale, has a reasonable prospect of being a home run and whether the proposed new space business moves the needle for a venture capitalist in terms of the overall fund returns. One must also keep in mind how to manage the balance of economic and governance terms with a VC and the tradeoffs and the downstream implications when needing to raise subsequent capital and how the board, with VC representatives in place, will work effectively to achieve the long-term goals of the business.

Typically, space VCs have lots more experience in these dealings than space entrepreneurs, so there is a need to level the playing field to eliminate the information asymmetry that can affect what should be a long-term, sharing and reasonably equal relationship. Care should be taken that information asymmetry doesn't pollute the foundation of a relationship that should last 10 years or more. VCs are typically seeking investment opportunities with asymmetric upside payoff potential (and capped downside), so they are interested in seeking to build industry changing businesses.

It is key to be able to ask the right questions of space VCs throughout the process to make informed decisions about how best to proceed each step of the way. Right up front, the term sheet is a big part of the VC financing process and defines the economic and governance rules under which they will operate. Once funding is in hand, the founders will need to be able to operate within the economic and governance constraints that they agreed to with the assistance of the board of directors to help steer the ship under the various well-defined legal constraints. VCs will also look at exits and how money that comes into the company goes back to investors in the form of an initial public offering (IPO) or an acquisition or merger. Although timing isn't everything, it is something to consider. Bad timing can be a big reason why ideas that failed in one era become successful businesses decades later as market conditions change and business models that failed can become viable. One might ask why this is the time right for this space startup idea to come forward not and if there are already too many new space projects of a particular type being backed by VCs or if it might be too late to seek VC assistance. Things to consider carefully are:

(i) Whether the amount of capital required to start a space company has begun to decline to the point that they are in an investment class and size comparable to software startups.
(ii) How can a space startup leverage space incubators which are basically a startup school where cohorts or entrepreneurs go through a series of tutorials and mentorship sessions over a 3-month period to see what might come out the other end. This has educated a whole range of space and other entrepreneurs on the process of starting a company of which raising capital is an integral part thus cracking the code of the VC industry and illuminating entrepreneurs in the process of startup company formation and capital raising creating a true community of entrepreneurs which can share their knowledge and views on company building and their experiences working with VC firms tipping the balance of power in favor of the entrepreneur.
(iii) How to look to a space VC firm for more than a check. A good firm with space experience can help a CEO with tasks that include technical recruiting, executive recruiting, PR and marketing, sales and business development, corporate development and regulatory affairs, and the most important assistance might be to coach the CEO to be world class.

7 Space Venture Capital and How Is It Unique

If one looks at the five largest market capitalization companies today (Apple, Microsoft, Facebook, Google, Amazon), all of them were funded by venture capital, but also many successful non-technology businesses have been venture capital funded; how this success can be translated to the space community will be examined here. Venture capital is a source of funding for companies that are not otherwise good candidates to get funding from other, more traditional financial institutions such as banks which have traditionally been the lifeblood of new company formation. However, loans are not always the best form of financing for all companies because they are not part of the permanent capital structure of a company (which means that they must be paid back with interest). Whereas a loan is well suited for a business that will be generating near-term cash flow sufficient to pay the interest and principal, this model only works for the most established space companies in the most predictable markets. This is why equity in the form of financial investment in exchange for an ownership interest is permanent capital, and there is no set time frame over which it must be paid back. The equity holder is making an implicit bet at the time of investment that the value of the equity will grow commensurate with the financial progress of the business and that it can be sold at a profit at some future date. Founders are often faced with the decision of debt or equity, but if a space venture can generate near-term cash flow, or if it is possible to reduce investment in some area of the business to make available cash to pay interest and ultimately principal on the debt, then bank lending may be the best source of capital allowing company management to retain control of their business. However, almost all space-related startup businesses do not have a near-term ability to generate cash flow or do not want to have nonpermanent capital in the business, so they have to choose equity financing in exchange for giving up some portion of ownership to equity holders. Equity-based financing is often the better choice for businesses that are not generating near-term cash flow, are risky, or have long illiquidity periods. Many angel or seed early-stage investors often will invest in companies via convertible notes which have distinguishing characteristics that make them look more like equity where the initial investment looks like debt with an interest rate and a date by which the principal amount of the debt is expected to be repaid, but the conversion feature is the mechanism by which the investor can convert the debt into equity in lieu of getting the principal back. This conversion feature turns nonpermanent capital into permanent capital, and it often tied to an equity-based financing for the company.

8 How Might Early-Stage Space VCs Decide Where to Invest?

The investing world is dramatized on TV and in the media, but in reality, not many people are really in tune with what drives space VC decisions. The challenge is that for early-stage venture, investing raw data is hard to come by, and there is rarely a rearview mirror that accurately portrays the future space market in a predictable way. The entrepreneur needs to develop the skill of qualitative space market evaluation as well as quantitative ways to model the potential future returns of an investment. However, typically, there are not enough financial space metrics to meaningfully model future potential returns for a business that is speculating on a future market such as space applications. This is especially true in new area such as RF geolocation, solar power satellite systems, or on-orbit servicing. But in the experience of many VC firms, there are qualitative high-level factors that they use to evaluate the prospects for an investment which fall into three categories: people, product, and market.

A typical space startup is little more than a very small collection of individuals with an idea, so the quality of the people and team built around them is key. Since ideas are not necessarily proprietary, the ability of the team and particularly the founders to quickly establish their vision and market plan is key. It can be expected that the VC firm will seek to delve into the background of the founders and their team for clues of their effectiveness in executing their idea. So when putting a team together, it is important to have a good dynamics among the founders, so think long and hard about the quality of the people recruited and whether they will convince a VC that the assembled team has the right market unique stuff to carry out the vision in what will likely end up being a tight market for good ideas. Another big area of investigation for VCs focuses on the founder's leadership abilities to determine if the founder can create a compelling story around the mission to attract a great team as well as customers to buy the product and later-stage investors to help with growth stage.

An investor then examines if the space product or service will solve a fundamental need in the market such that customers will pay real money to purchase it. These new products need to be ~10X better or cheaper than current best in class to compel companies and consumers to adopt.

Lastly, market size is the third leg of the stool used to evaluate an early-stage space investment opportunity. What matters most to VCs is the ultimate size of the market opportunity that is being pursued. Big markets are good and leave lots of room for error, while small markets are bad. VCs fear getting the company right but never being in a market big enough or failing to invest in a company that does become the next behemoth. VCs are looking to invest in big market opportunities where fortunes can be won or lost based on their ability to understand the market size and think creatively about the role of that specific new technology can be employed in developing these new markets.

What's key is that as a space entrepreneur and consumer of VC dollars, one needs to be aware of the time constraints imposed where a VC will push for an exit to generate liquidity which is a function of how the company is doing and where the firm might be in its fund life cycle and how the rest of the companies in the fund are performing. A key factor to be aware of and to ask a potential VC partner is how old the fund is, where one is receiving capital from, and to find out where they are in their life cycle. If they are early in the fund, they should have less pressure to return capital putting less pressure on the startup business. If they are later in the fund cycle and haven't generated sufficient liquidity from other investments, the pressure for a more near-term exit could be much more intense.

9 Forming a New Space Startup

Great space company founders are innovative, brave, inspiring, and visionary, and their ideas can be groundbreaking and world changing. It is critical to get the company off on the right foot beginning with a visit to a lawyer's office to work out things like tax and governance to understand how to set up the business. There are several firms out there who have special practices and years of depth of experience in space, and it is possible to find many of them at some of the premier space conferences held around the country. Some law companies are equipped to provide legal services for equity or at least deferred compensation.

10 Raising Money from a VC

Although raising money from a VC is all the rage for many space startups, one should start by asking if venture capital is right for the company and, if the project is just starting, whether other mechanism such as family and friends, angel investor, or some form of crowdsourcing is perhaps the better answer. If the project has matured to the stage where VC financing is realistic, then the next question is the amount and valuation at which funding should be raised. If one does decide to go forward, the simple guide is to raise the highest valuation possible in order to give the startup as much runway to grow the business. The right time to raise capital is when it is available. But, if the ultimate size of the opportunity isn't big enough to create a stand-alone, self-sustaining business of sufficient scale (such as being a profitable, high-growth, several-hundred-million-dollar revenue business over 7–10 years which will support a capitalization of sever billion dollars), it may not be a candidate for venture financing because it does not have sufficient scale to move the needle on the fund's overall economics. The next step might be to think about taking a different approach to financing such as looking to smaller VC funds which will look to exit sooner through acquisitions or even considering banks for debt financing. Another big factor in determining whether VC is right is determining if one can live with sharing equity ownership, board control, and governance in a relationship that will last 8–10 years. If one decides to go ahead with VC financing, there is a need to set about to raise as much money as possible to safely achieve the key milestones to show de-risking. This will be key for next investors who will be convinced that they are willing to put new money into the company at a price that appropriately reflects the progress that has been made since the last round of financing. Most early-stage companies raise new capital every 12–24 months reflecting the time frame over which reasonable business progress can be made. The milestones that are set should match the funding that is raised with some margin of error built in if things do not go according to plan. Since it will not be possible to raise all of the money that is needed right up front, this practice of setting milestones will be critical to phasing fundraising and setting milestones. By spreading the capital raised, the startup retains the benefit of increases in the valuation as the company "de-risks" the opportunity and the VC can size their investments based on achievement of these milestones so that if the objectives laid out at the time of the first round are reached, the next investor will pay for that success in the form of a higher valuation. Also, having too much money can be the death knell for early-stage startups since lack of financial constraints actually limits the need for creativity and innovation and creates dangerous dynamics amount the team.

Finding the right valuation at each successive round of financing is key but difficult. If there is overvaluation at any stage, then this raises the stakes and makes it more difficult to be able to achieve an even higher valuation for the next round, while if the current valuation is high or low, it is likely to reach a point of balance over the successive rounds. Prevailing market conditions can also have an impact on the valuation of a startup from round to round. But one must avoid falling into the trap of raising too little money since this can leave a startup without the financial resources needed to be able to achieve the business goals required to safely raise the next round of financing above the current round's valuation. It should also be mentioned that creating a competitive environment around potential investors helps as well which means keeping valuation expectations attractive to a range of potential participants. Also, keep in mind that employees often judge the success of the business at least in part on the external measure of valuation in a financing round compared to other companies that have raised money recently whether or not they serve as relevant benchmarks. Keeping the valuation moving up and to the right is key – not raising or raising at a valuation lower than the last round are the last things to do.

11 The Art of the Space Startup Pitch

Angel or seed investors are upstream of a VC in that they are typically investing at an early stage in the company's development than might a traditional VC. Many VCs develop symbiotic relationships with angel and seed investors since VCs are interested in a curated pipeline of opportunities and angel or seed investors are looking to see additional capital attracted to their company. Law firms tend to be important avenues into venture firms and are often upstream of the VCs since lawyers are motivated to introduce their best startups clients to VCs to help drive more resources to their firms. It is useful to find creative ways to get to the VC by finding someone who knows someone who has some relation to a VC. A suggestion for the VC pitch is to "be natural" and believe in the idea that is being presented with strong commitment. Communicate the commitment and responsibility of bringing this new space product or service it to the world indicating the wonderful opportunity that is being offered to the sponsor to join in on this journey avoiding the mindset that the meeting is just about "raising money" to fund the entrepreneurial team. The mission is to communicate that here is a chance to change the world, and the honor of the visit and presentation is truly theirs, not the team making the presentation. The VC should see the confidence and value the fact that this unique team is presenting to them a unique and breakthrough concept.

12 The Content of the Pitch

VCs are incented by their limited partners (LPs) to produce outsized returns relative to the alternative uses for which the LPs might invest that capital, so they are expected to lockup their capital for 10 years or more to give the VC the time to realize those returns in the form of acquisitions or the IPO of portfolio companies. Most of what the VC returns will not yield much, but those few home runs that return

10–25 times or more of the capital invested will make or break the business, and the pitch to a VC is to provide a convincing case that this new space startup has the potential to be one of those outliers. There are many ways to structure a pitch, but one is Guy Kawasaki's 10/20/30 Rule of PowerPoint which says that a PowerPoint presentation should have ten slides, last no more than 20 min, and contain no font smaller than 30 points. This rule is applicable for any presentation to reach agreement, for example, raising capital, making a sale, forming a partnership, etc. Ten is the optimal number of slides in a PowerPoint presentation because a normal human being cannot comprehend more than ten concepts in a meeting, and venture capitalists are very normal humans. The ten topics that a venture capitalist cares about are:

1. Problem
2. The solution
3. Business model
4. Underlying magic/technology
5. Marketing and sales
6. Competition
7. Team
8. Projections and milestones
9. Status and timeline
10. Summary and call to action

Of these 10, the focus will be on the 5 pitch essentials which are market size, team, product, go-to- market, and next round planning.

12.1 Target Space Market Sizing

The primary job of this chapter is to show the potential size of the market that is being addressed after painting the picture to show the VC audience that if they invest in the company, and the business is successful in the market, then the business can be big enough to really drive an outsize return to the fund and will it materially allow the VC to accomplish the objectives of his fund. Sometimes it is not obvious how big a market for a new technology or service can be. Thus, one cannot always use the current models as a proxy for market size or make assumptions of what this unique idea could accomplish, and instead one will need to make the case for a much broader line of thinking by considering the effect of adjacent technologies as a way to scale the definition of market size and a way to foresee a much larger addressable market than what might be perceived right now. This may be the single most important exercise that the entire team needs to master. One can also look at the network effect of the new space business and think about the new milieu that is to be addressed. For example, considering that once launch costs drop and regulations are relieved, then the conditions are right for a new space business. Network effects do not exist in every case when addressing an existing market which might be quite large already. In this case, one needs to show how the new space service can address that market and explain the macro trends which are evolving in that market. There is a need to show a clear vision of how the market will develop, and one needs to illustrate as clearly as possible the position of the new space startup's product or service within the market that develops as a result of a new technology. There is a need to rigorously prove the basic assumptions that the space platform, product, or service will become dominant. For a VC firm to take this "one giant leap," they must be convinced that there is a real potential of there being a pot of gold at the end of this space rainbow.

12.2 The Team

The long and the short of it is that the composition and quality of the startup team matter. There is a need to answer the question of why the VC should back this particular team vs waiting for the next set of "space wantrepreneurs" who might pitch the same or similar idea. Ideas about new space products and services are a "dime a dozen," and it is execution which sets the winners apart from the pretenders. At early stages, there is not a lot for a VC to undertake in terms of "due diligence" because so much of the analysis is qualitative, but the team can be examined closely. The pitch needs to talk about the strengths of the CEO and the rest of the team to explain what makes this particular team uniquely qualified to win the space products or services market allowing the VC to learn about the unique set of skills. This chapter should discuss prior accomplishments or experiences relative to the current business that is being pitched and why past success supports the likelihood of success in the current venture. The entire team needs to show the full range of competence including a deep technical understanding of the problem to be solved, coupled with the knowledge of how best to develop the right regulatory, sales, and marketing strategy ("go-to-market") capabilities. This means to show that the team represents ideal founders to back in this space initiative with a short but convincing story as to why this unique team is the best fit to start this company in a competitive market. Doing this requires a combination of skills to tell stories in a compelling way to articulate a vision that is likely to lead employees, customers, and financiers to want to come along for the ride. Think about what skills and advantages the team uniquely possesses that will prove valuable to the ultimate development of the new space business. Once the VCs are convinced of the market scale and the market opportunity to be exploited, it is equally important to sell the team as competent to build the company with the overall competence to succeed. The CEO and key leader for the project must also be effectively sold as well, and there must be a clear explanation as to what makes that person a natural born leader, or learned technology leader, who will cause people to quit their jobs and come work for the startup and cause customers to be willing to buy the products or services, or cause business development partners to want to help to sell the new company's wares and penetrate new markets and cause funding partners to want to provide the capital to do these things. If the main presenter or members of the team are successful repeat entrepreneurs, this is a large help. If this is not the case, then it is important to explain other leadership-like opportunities that are indicative of an executive or charismatic CEO leader. Storytelling skills, that ability to captivate an audience and get them commit to a new enterprise, are a good indicator or potential success in an entrepreneur. True storytelling is a critical talent. Presenting a vision for the opportunity that will make people want to be a part of the company building process will require the same skills that will help to land VC financing partners.

12.3 Product

This chapter is where to present a clear product plan and the data from the market showing how this product is clearly better or cheaper than existing alternatives. It's expected that the product or service plan is likely to pivot in the actual market when there is the ability to test a real product offering against real market needs. A VC wants to be comfortable that the process of evaluating the market needs is robust enough to enable the company to adapt appropriately to changing market demands. This chart should walk them through the thought process, the rigor of the analysis, but also show the ability to adapt to the changing needs of the market while continuing to learn from the product development experience.

12.4 Go-to-Market

In this chapter, there is the critical need to show how the company will acquire customers and that the business model supports profitable customer acquisition. Even if the current funding round does not get meaningfully into the market, it's important to include this aspect in the pitch since it is foundational to the long-run viability of the business. Instead, address things like the plan to build a sales force and the average selling price of the product or services. There is a need to explain how customers will be acquired, i.e., through brand marketing, partnerships and alliances, online interest acquisition, etc. Even if there is not yet a robust financial model at this stage of development, there should at least be a framework that gives a VC a warm feeling and understanding that there is clear thinking around customer acquisition. Walk the VC through the "go-to-market" strategy to show them an understanding of the target audience. As an entrepreneur at an early stage of development, no one expects that all of the precise and correct answers have already been figured out, but there need to at least be theories grounded in reasonable assumptions against which one can apply real-world experience. A hallmark of startup companies is that they often "pivot" which is to change an aspect of the business and try again when the original product or go-to-market did not quite work out the way that was expected. A pivot can be minor or a wholesale change of direction. VCs understand that despite the best intentions, most business go through some set of pivots along the way whether small tweaks or almost complete restarts. At the time of the presentation to the VC, one is not expected to be clairvoyant. It is well-known that things will not materialize as initially forecast. The objective is to demonstrate to the VCs that the team constituting the startup knows in great detail the ins and outs of the space business in a way that shows depth of preparation and conviction. Present a thoughtful engaged discussion on how key conclusions were reached and also be willing to listen to the feedback and incorporate it into future thinking, as appropriate.

12.5 Planning for the Next Round of Fundraising

In the final part of the pitch to VCs, one should clearly articulate the milestones intended to be accomplished with the money to be raised in this round. A VC is likely projecting ahead to the next round of financing to gauge the level of market risk that they are taking by funding the project at this stage. Show that in this round, enough money is being raised to accomplish the milestones set out such that the next investor will be willing to invest new money at a substantially higher valuation (roughly 2X) than the current round. This kind of momentum will be well received by both the current investors and all employees. If the VC firm feels that at the time the milestones are presented there is too much risk, then it is likely for there to be a discussion about raising more capital at the current round. Another option would be to lower the valuation or find other ways to increase the confidence interval around forecasted progress. Every VC knows that they will not be the only investor through the course of the company's life cycle which is why VCs care about the achievability of the milestones that are being presented. They know that they don't want to be or can't be the only capital provider at the next round of financing. Thus they are trying to estimate the risk of the startup they are funding may get stranded at the next round. The bottom line is to convince a VC that the business has a chance to be one of those outsize winners that will make them look like heroes in front of their limited partners (LPs) whose money is, in fact, being invested.

13 Term Sheet Economics

After doing a great job in the pitch to the VC and receiving initial interest, the next step will be to review the term sheet. The term sheet is usually the place where the asymmetry between VCs and founders comes into play the most because VCs have been through the process many times as opposed to the founder who likely has not. The term sheet has two big elements to it – economics and governance. *Economics* includes information on the size of investment, valuation, anti-dilution treatment, liquidation preference, the size of the employee option pool, vesting options, and founder shares. *Governance* deals with who gets a say in what happens in the company. The following is a review of the salient points on the term sheet along with and a few pointers to help with this process.

Usually, the first item defined in the economics section of the term sheet is a description of preferred shares. A benefit of being a C corp is that one can have different classes of shareholders with different rights. A VC will typically purchase Series A preferred shares of the company which are distinct from common shares (which is what the founders and employees typically hold), and they are also different from potential future series of preferred stock (which will be labeled "Series B," "Series C,"etc.). The reason for creating a new class of stock is to give it "preferred" economic and governance rights relative to those enjoyed by the common shareholder.

The section on aggregate proceeds will describe how much will be invested for what percentage ownership of the company, and it will also specify that any debt outstanding in connection with this investment of notes which will convert into equity under the terms of this financing. Notes (i.e., debt) are senior to equity so if a VC invests, they do not want other monies to be ahead of them in the event of a potential liquidation. This forces all notes to convert into equity in this round ensuring that everyone is in the same position with respect to the distribution of proceeds in the event of an exit.

Convertible debt is often raised at the seed stage for cost and simplicity reasons allowing both the entrepreneur and the seed investor to defer (until the Series A) on the question of valuation at this early stage of company development. Standard convertible debt documentation is pretty simple and don't require much legal time and expense. In its most basic form, the debt converts into equity at the same price at which the Series A investors purchase equity and is referred to as an "uncapped" note meaning that the valuation at which the note converts is not restricted and will be determined based upon the Series A equity price – this is not generally sought after by investors because they are taking on additional early risk yet receiving the same reward and the Series A investor. Because of this, most convertible debt is "capped" to establish a ceiling on the maximum price at which debt will convert into equity and a conversion discount (with or without a cap), so the cap sets a valuation limit for the debt to convert to equity. A conversion discount simply provides the note holder with a fixed conversion discount relative to the established Series A financing valuation wherever it may end up, and typically, this is employed up to the point where the cap comes into bear. Convertible debt financings can have multiple rolling closings, whereas an equity financing typically has only one. One word of caution is to be very careful of how much debt is raised in this manner since the long-term consequences of the founders' percentage ownership at Series A can lead to a situation where one can end up with less control than thought. The key is to ensure that all interests concerned stay aligned with the company's success. Be mindful as an entrepreneur and founder of the constant tradeoff between raising the capital needed to grow the business and minimizing the dilution of the shareholdings owned by the founders and other employees and early investors who are along for the journey. Thus it is important to be clear on the impact of every VC dollar on the existing crew of people involved.

The term sheet also says important things about what the market is willing to pay for the investment. First is the "post-money" valuation which is the valuation of the company once the VC has invested their money. The "pre-money" valuation is the valuation before the investment is made. Pre-money + amount invested = post-money, so if an investor offers \$1M and the post-money is \$5M, then they own 20%. Post-money valuation has two key elements. Any shares that convert as a result of prior convertible debt have to be included in this valuation. Debt gets taken into account as part of the valuation the VC is willing to pay, and this often provides full accounting of how much dilution has been created. Valuation also includes employee option pool because when all shares are added up, they cannot exceed the post-money valuation

When performing valuation, the comparable company analysis method requires that other publicly traded comparable companies are found whose valuations and financial metrics are publicly known that resemble the space startup. The object is to establish a reasonable value by looking at how those companies are valued as a function of certain financial metrics such as multiples of revenue. This analysis is hard when applied to a space startup which is quite often unique, and the ability to forecast revenue is unpredictable or at least quite difficult.

Over the long run, the value of a space company equals the present value of future cash flows. Whatever annual cash a company can generate in the future, if one discounts that cash to present-day values, an investor should be willing to pay no more than the current value of that future cash stream. The problem with this for a new space company is that it requires that one build out a financial forecast for their company estimating annual cash flow into the future and then discounting that back to the present day using a "discount rate" which is a way of saying the opportunity cost for a company's investments. Of course, this analysis makes good sense for mature companies with predictable future results based on past financial performance, but for early-stage companies, particularly early-stage space companies, this is a huge challenge.

The predominant question is how does an early-stage space startup company determine its valuation? The answer is found in a simple conceptual analysis since for very early-stage companies, there are no real financial metrics with which to value a company. There is a need to ask what would need to happen for a certain level of valuation to be achieved and justified or what would have to go right with the business for that to happen? Is the market size big enough to support a company with a certain level of revenue and what are all of the things that could cause the company to fail and how does one assess the probability of each of those nodes on the decision tree toward success or failure? As startups get more mature and have financial statements that are more reliable, later-stage venture capital deals will adopt more traditional metrics such as looking what has to happen to receive a 10X ROI from a sale or for the company to trade at a certain metric over revenue.

It should be noted that the valuation of a company includes the unallocated employee option pool ownership which is not diluted by adding this later but should be sufficient to handle the expected employee hiring until the next round of financing. The CEO should generate a head count growth plan for the next 12–18 months and estimate how much stock is required to grant those planned hires while keeping the pool as small as possible so that the current rounds don't dilute the company while the VC firm will want it as large as possible, so future hires don't dilute them after they invest.

The term sheet will also address the unlikely event that the board decides to pay a dividend to preferred shareholders (investors)before common shareholders (founders and employees), and this section of the term sheet specifies the amount in order to prevent founders from "dividending" out money to themselves at the expense of the preferred shareholders. Thus, if founders want to pillage cash, they have to pay the VCs first.

The liquidation preference section specifies who gets their money back under certain circumstances called liquidation events (company is sold or wound down). Liquidation preferences can be structured as some factor of the original investment the investor received back first but no more. For most startups, they are never taken over 1x. However, when a company is at a later stage of investment, an investor may request more than a 1x preference since they are entering later into the growth cycle and their chance to grow to a point where its value is some greater multiple of the valuation paid in the financing round. "Nonparticipating" means that the investor gets a choice to take liquidation preferences or convert preferred shares into common shares and take the equity value of her percentage ownership of the company. "Participating" means that not only does the investor get their original investment back, but they can also convert shares into common and participate in any leftover proceeds as with any other shareholder.

Redemption rights address the fact that the whole idea of seeking investment is so that it can become permanent capital upon which the company can be built, so an early-stage space startup should not entertain discussion of redemption nor allow the investor to give back stock in order to get their money back. An investor looking to exercise their redemption rights would put the company in dire financial situation so it simply must be stipulated that the investment is not redeemable. Given that the whole idea of raising capital is to keep it permanently to build the company, redemption would allow an investor to give back their stock in exchange for getting their money back and most likely any redemption rights, if granted, would come into play at the worst time possible for the company. In fact, most state laws restrict the ability of investors to exercise their redemption rights if doing so would put the company in a dire financial situation, so the suggestion would be to keep things simple by just stating that the investment is not in fact redeemable.

A section on Conversion/Auto-Conversion addresses investors who obtained preferred shares and at some point may want to (or the founders may want them to) convert into common shares since preferred has so many more rights over common. Often to go public, the capital structure of the company is cleaned up to bring everyone to common stock. On the IPO, it is possible to have "dual class" stock with high voting class and lower voting class, but preferred shares need to go away at the time of IPO. VCs will want to be sure that an IPO is of sufficient size relative to their initial investment to ensure trading liquidity so they can sell their shares into the public market. An IPO conversion term indicates that the IPO will be of a certain minimum size to avoid a low-trading volume small-cap stock where any appreciable effort to sell shares would result in a deflation in stock pricing. Most companies sell between 10% and 20% of the company at IPO, and minimum IPO thresholds will increase with later financing rounds. Another variety of autoconvert is to put in place a specific price per share or ROI threshold to force conversion. In the case of a voluntary conversion, a vote of the majority of the preferred stock is another way to convert preferred into common.

The anti-dilution protection provides some element of safety in the event that the company raises money in a "down round" which is at a valuation below that at which an investor invested which is highly dilutive to everyone's ownership stake. A broad-based weighted average as an intermediate form of anti-dilution protection is often used, but a "full ratchet" protects the VC from getting diluted at all by a down round of financing, but the founders and employees will not have such protection and will be diluted on their end. The more VCs get anti-dilution protection, the more diluted common shareholders can get as well.

Lastly, the term sheet addresses voting rights where each share of both common and preferred has only one vote. Some companies will have different classes of shares with different voting rights when they go public but rarely if ever when they are still private. Founders like to have a high vote stock that applies to their shares only so they keep enough voting power to control any actions, and one could stipulate that founders have 10X the voting rights, but this has not been implemented, and some founders will ask investors to enter a "voting proxy" where their voting rights go to the founders.

14 Term Sheet Governance

Governance is an important topic in the term sheet because it basically defines who gets a say in what happens in the company. Board composition is critical since it will vote on major corporate actions such as raising money and choosing the CEO and M&A decisions. Protective provisions determine what corporate actions the preferred shareholders get to have a say in as these serve as checks to the CEO's ability to take corporate actions as well as understanding auto convert, drag along, and voting structure. The key role of the board of directors is the hiring and firing of the CEO and is typically composed of an odd number of people to avoid deadlock. Series A preferred will appoint one board member as well as the major investor in an early-stage financing. The "lead" investor drives the negotiation of the term sheet with the CEO and typically invests half of the total amount of the round and will likely be the board representative for that set of preferred investors. The **second** seat is reserved for the common shareholders and designated to be the CEO. Sometimes the founding CEO asks to have the board seat designated to them directly. This could lead to the founder remaining a board member even after being removed as CEO so it is probably best if a board seat remains with the founder as long as they remain CEO but that they lose the seat when the position is lost or resigned from. The **third** seat is reserved for an independent person not affiliated with the company as an investor or officer and must be approved by two other board directors.

The term sheet sets the rules for the vesting of both employees and founder shares where a standard approach is for 25% of employee stock to vest 1-year anniversary of their hire ("1-year cliff vest"), and the remaining 75% vests in equal monthly increments over the next 3 years. Double-trigger acceleration has two triggers to the founder getting their acceleration. The first trigger is the acquisition itself, and the second trigger is the founder getting terminated by the acquirer other than for cause or good reason. This allows the acquirer to retain the founder without having to worry about options automatically vesting. If the acquirer doesn't want to retain the founder, then it's fair for their shares to vest on an accelerated basis.

From signing the term sheet to closing the investment typically takes 2 weeks to a month. The "no-shop" is a 30-day period in which the company is tied up preventing the disclosure of the term sheet to other parties or to pursue a deal with somebody else. When negotiating a term sheet, the space CEO must be forward thinking about what might be agreed to in the current term sheet as it will have implications for subsequent financings.

15 The Art of the Exit

It is said that one should always enter any endeavor seeing the end in the beginning. After one has mastered the many struggles of creating a space startup, the point will arrive where it is key to think about options to transition or exit the investor ownership structure or business profitably. Venture- financed space companies typically exit through being acquired by another company or by going public and holding an initial public offering (IPO). Whereas the company itself enters a new chapter of its life as a public company, the early investors typically exit their ownership positions in the company after having grown the equity value of their initial investment and thus providing a return capital to their LPs.

16 Creating a New Space Corporation

It is interesting to note the ratio of acquisitions to initial public offerings (IPOs) today has gone down so that the overall market is now seeing about 80% of exits coming via acquisition, but before the dot-com adjustment that occurred around the year 2000, the ratio had been at 50%. Every space startup should be planned to be acquired from day 1 and every day after that by building business development partnerships with companies that might have existing sales channels into some of the markets that the company is planning to enter since these relationships can often lead to acquisition offers. What is key here is that in order to have the option to be acquired, the company needs to be intentionally nurturing these relationships and considering some key issues. Although price is an important consideration, often the acquirer will propose to exchange its shares for the shares of the acquired company, and such a deal should only be considered after having a careful professional valuation analysis performed on the acquirer's stock, and any space company should consider requesting price protection for what could be a lengthy due diligence period in the event that the acquirer's stock exceeds an upper or lower bound as an insurance policy. Liquidity of the stock is also key – a publicly traded stock can be sold immediately, but sometimes the acquisition stock can take some time before it can be sold. Another element of being acquired is to look at how employee options are affected by the acquisition. Unvested options could be eliminated by the acquirer or replaced by new options and new terms or even accelerated. Typically, special equity grants are made available to retain key employees, and a closing condition may require that some percentage of key employees need to stay on. There may also be closing conditions regarding voting approvals that the seller is required to get with the threshold being set by the acquire such as requesting that at least 90% of the shareholders vote in favor of a deal to reduce the potential for some to seek legal redress. Also, usually 10–15% of the purchase price is placed in escrow to cover potential surprises over representations, litigation for actions pre-closing, and any ownership or IP claims some 12–18 months after the deal closes. Also, indemnification protects the buyer from claims that may arise post-closing. There will also likely be a request for an exclusivity period which will prevent shopping the term sheet with other investors or soliciting their interest for a period of time typically 30–60 days (determined as required by the due diligence and legal documentation period).

The second major form of exit for venture-backed space companies is the IPO which on average today has risen to take about 10 years and typically occurs for any number of reasons. The first and most obvious is to raise capital beyond what might be expected to be raised from private space investment markets, but in recent years, those markets have stepped up to larger investments in some cases. IPOs can also help a space company get recognized as having a higher profile, hopefully driving business. Such an offering also represents a liquidity event whereby employees can sell stock in the company once shares are registered. Human nature also dictates that being a public company can help customers feel more comfortable in dealing with a space company, and going public also makes it much easier to make acquisitions to keep a company's innovations stream fresh perhaps by using publicly valued and traded stock as part of the transaction.

Going public is no different for a space company than any other, and there are plenty of investment banks (underwriters) that can be considered based on several factors. First, one should choose a bank with the appropriate domain experience in the space industry considering the research analysts that will interact with and help educate institutional investors who will perform follow-up research. Another key element to look for is the strength of their ability to place the resulting founding stock with institutional investors to create the proper trading environment. The biggest effort will be to work with lead and co-underwriters to create the prospectus to provide all relevant disclosures to potential investors detailing the risk that they agree to take on by buying the stock. It is key to accurately portray the risk to avoid the potential of a class action lawsuit from investors who relied on this data when agreeing to invest.

As a new space company, revenues will be less than $1B and therefore qualify as an emerging growth company (ECG) which can help to streamline this process. In fact, ECGs offer a range of other benefits such as being able to meet with accredited investors to get feedback ahead of an IPO road show to give them more time to evaluate the opportunity to invest. The ECG allows one to file the initial prospectus confidentially and provides for lighter regulatory requirements (such as only 2 years of financial history) and disclosure requirements in the prospectus and after the IPO. The net result is that qualifying as an ECG as defined in the US Jobs Act of 2012 made it less burdensome to become a public company. In any case, once the prospectus is complete, the road show presentations will begin, and the underwriters of the offering will try to get an idea of how much demand there will be at different prices so they can determine how many shares to sell and what the initial selling price will be. Once the SEC declares the prospectus effective, the underwriter can start the public trading of the stock. Investors are generally required to execute a lockup agreement to restrict their ability to sell stock for the first 6 months post-IPO and even after that to set time intervals over which officers and directors can trade to allow for price stabilization. Two last points to consider are how one handles VCs who want to exit after the IPO and employees who may have just experienced a significant personal liquidity event. The concept of a secondary offering of shares can be an orderly and disciplined way to allow a VC to exit placing their shares in friendly institutional hands. Dealing with newly minted employees will give rise to separate questions such as the true focus of the acquired employees and their dedication to the mission of the new created entity as well as how they feel they will be are able and willing to continue to contribute. If a space startup is among the very few that successfully crosses over into a public entity, then the results will include both huge rewards and significant challenges. It is hoped that this chapter has at least begun to outline a means of navigating this opportunity.

17 Developing Patient Capital Investment for New, Longer Range, and Highly Capitalized Space Ventures

Other solutions to the patient capital or longer-term return investors must be considered as well. Many have tried to solve this problem in order to fund new space, and a possible model is publicly traded, pass-through shares (PTSs) which are used in some countries to help their mining industry. Mining horizons are similar to space in many regards in that they can take 10–12 years from exploration to mature exploitation. This structure allows all losses to be deducted from the income taxes all through the long development period. One could envision the creation of PTSs to support the development of space infrastructures where investors get trading liquidity and one could use multiple years of early loses to shield current taxable income.

Also, intergovernmental organizations (IGOs) have been used so all countries of the world could participate in building the space systems required to transmit signals across the ocean which was too big of an investment for any one country to take on. This effort resulted in the creation of Intelsat to provide communication to the ground and Inmarsat to provide communication services to ships on the ocean in a manner such that every country that wanted to join could do so by delegating a signatory to the IGO. The US created COMSAT as its signatory, while most countries used their public monopoly Telcos as theirs. Once in place, they raised billions of dollars to fund a fleet of satellites, and for many years, they were a monopoly where each country paid based on their use and most dividends were reinvested. This model worked very well to get this segment moving, and then in the 1990s, PanAmSat and SES sought to privatize the industry, and now, there are a multitude of private- as well as state-sponsored satellite communication companies in operation. This laid out a path to bridge from a worldwide intergovernmental organization (IGO) to a worldwide private industry with competitive systems that now realize hundreds of billions of dollars in revenues from providing services. One might foresee that today the same thing could be done in forming space IGOs (SIGOs) where national signatories' own shares would be commercially run but remain during this startup phase as a nonprofit entity with national investments based on historical utilization percentages or resulting services just like Intelsat and Inmarsat operated before privatization. Another model that has been proposed is the creation of a "Fannie Mae" for space which would allow long-term mortgages associated with the financing of such activities as small satellite constellations where there would be an implied government guarantee behind them. This created a vibrant mortgage market and could be applied to create an infrastructure finance market in space. Yet another approach would be to support a service fee model which could create a universal space service fee (USSF) applied to all commerce that occurs in, from, and to space to help cover the government's part of any P3 for space. Although this might in some cases burden the users, it could if properly designed create an overall benefit.

The last model might involve the creation of an Outer Space Private Investment Corp (OSPIC) like the Overseas Private Investment Corporation (OPIC) which is the US government's development finance institution mobilizing private capital to help solve critical development challenges and in doing so advancing the foreign policy of the USA and national security objectives. It would be hoped that OSPIC could find an effective way to work with US private sector to help US space businesses gain footholds in emerging markets, catalyzing revenues, jobs, and growth opportunities both at home and abroad. An OSPIC could achieve its mission by providing space investors with financing, political risk insurance, and support for private equity investment funds when commercial funding cannot be obtained elsewhere for a worthy space project. Such a fund needs to be set up so investors would be willing to wait 10–20 years for a profitable return. This model has been a huge success in over 100 countries where OPIC makes profits that go back to the treasury. As an agency of the US government established in 1971, it now operates on a self-sustaining basis at no net cost to the American taxpayer as part of the US Development Finance Corp (DFC). The discussion has been to just replace overseas with "outer space" (or space) and create a stand-alone OSPIC entity making space new "emerging market." By changing "overseas" to "space," it would be possible for new space ventures to be treated as a developing market with tremendous potential. It would also be hoped that other countries would follow suit. Thus OSPIC could be foreseen as carrying the following charter for space development for any country:

The Outer Space Private Investment Corporation (OSPIC) is a self-sustaining government agency that helps national businesses invest in emerging space markets providing businesses with the tools to manage the risks associated with space investment, fostering economic development in space markets, and advancing national foreign policy and national security priorities. OSPIC helps national businesses gain footholds in new space markets, catalyzes new revenues, and contributes to jobs and growth opportunities both at home and abroad. OSPIC fulfills its mission by providing space businesses with financing, political risk insurance, and advocacy and by partnering with private equity investment fund managers.

Another interesting example that is currently being discussed is the International Lunar Development Authority (ILDA) under design by Michael Castle Miller and the NSS Policy Committee. This model goes past the IGO model, and it would not only share the cost of developing new space systems or infrastructure but create a virtuous cycle that keeps building on the value that is developed to bring more and more capital. The key principles are that numerous countries (40 or more) and commercial companies capitalize ILDA as shareholders with the USA as lead and lunar land rental prices are set by auction, plus utilization fees operating for profit to reinvest in common cislunar infrastructure. The benefits of this approach are that this would align profit incentive with public good and allow for higher returns on investment rather than by relying upon infrastructure usage alone to allow for development financing without land ownership. This prevents the occurrence of the "tragedy of the commons" which is a situation in a shared resource system where individual users, acting independently according to their own self-interest, behave contrary to the common good of all users by depleting or spoiling the shared resource through their collective action.

The space debris problem is an example of this. The idea would be to have a commons with shared infrastructure that everyone helps to pay for and improve by having a large consortium create this authority that would be made up of nations, space agencies, corporations, and wealthy individuals. They would all be in a public benefit corporation model that would seek to run the settlement to create profits to support the common infrastructure by having auctions to lease parcels of land near the common infrastructure where the highest bidder gets to use it on a non-interference basis to do their lunar mining, establish a power plant, communications node, etc. Over time they will add value to their land, and the commons increase in value which will make the whole more valuable drawing in more investors to develop more parcels of land. Having this global consortium providing a long-term lease and giving the exclusive right to operate on this properly for a long period of time establishes that they are giving their collective approval and that they have all agreed to do this. Corporate governance of this lunar authority model structure is still in development and must still be figured out as well as the need to operate on a noninterference basis.

Lastly, one should not forget about the power of prizes and challenges. When a bold challenge like the X-prize is put out there, it excites human nature resulting in a lot of response. If this works for small prizes of $1M or less, one might envision that significant additional investment would be attracted if larger prizes like the Google Lunar X Prize or the Bigelow challenge were to be offered by governments at truly large levels, then truly exciting space initiatives might be accomplished, but clearly, it would be very hard to get this appropriated through a national legislature.

This chapter has hopefully provided the macro vision of the challenge of space finance and both the need to solve the patient equity problem to get to new space industry investment and a few concepts and new structures which could collectively be worked upon to get there. Although the ideas presented to this point are new, they are powerful and will be needed to really help take the next giant leap.

18 Conclusion

This chapter has aimed to provide some information about financing options related to new space entities in order to help promote the growth and expansion of new space industries. Choosing the right finance model and executing it with the right finance partners will be key to success. There are many approaches that might be taken for starting new space ventures starting from the most basic which can begin with angel investors, friends and family, and even crowdsourcing websites such as "Kickstarter" to capitalization through venture capital (VC) funds that lead to formation of corporations, often leading to acquisition or initial public offerings (IPOs). There are also other longer-term major new space initiatives that may be developed to enable the very large capitalizations which may be needed. These types of multibillion dollar projects may require new forms of public-private financing, and some of these longer-term and visionary approaches have also been addressed. There is no question that the future of space financing is best described by the Latin proverb "audentes Fortuna iuvat" which means "fortune favors the bold." For the future of space finance to keep up with the technical potential, bold new sources of space finance will be required. It is hoped that this chapter has provided some illumination on the road ahead while opening up thought channels for future space finance entrepreneurs to pursue and expand.

Requirements for Obtaining Spectrum and of Orbital Approvals for Small Satellite Constellations

Audrey L. Allison

Contents

Abstract

Like their larger counterparts, small satellites require assured access to radio-frequency (RF) electromagnetic spectrum from their orbital positions to support their operations and to fulfill their missions. This mission requirement applies equally to the smallest nanosatellites or picosatellites launched by academic institutions for research to the relatively small commercial satellites that are increasingly being launched into non-geostationary orbit into very large – or "mega" – constellations to provide telecommunications services. While not perhaps the first item contemplated by a designer of small satellite missions, assured access to the invisible natural resource of RF spectrum from space can prove to be a critical and long lead item, and the wise prospective operator plans accordingly. Use of RF spectrum, even from space, is a heavily regulated, highly

competitive, and increasingly congested necessary resource. Obtaining assured access to RF spectrum is often a high-risk, complex, and time-consuming task.

This chapter will briefly describe the evolving legal and regulatory regimes that face small satellite operators in terms of RF spectrum and associated orbits and will highlight recently adopted treaty provisions by the International Telecommunication Union's (ITU) 2019 World Radiocommunication Conference (WRC-19). These actions range from streamlining the regulatory requirements to facilitate entry of a broader range of operators of the smallest satellites, such as those launched by academic and other nonprofit institutions, to adding an entirely new regulatory approach for managing the small satellites that comprise emerging large constellations in non-geostationary satellite orbit to provide commercial telecommunications services.

1 Introduction

To ensure mission success, one of the many requirements of a successful satellite operation is assured access to radio-frequency (RF) spectrum from the satellite's position in space. Satellites utilize spectrum for communications with the earth (and potentially other satellites) for mission-essential purposes, such as telemetry, command and control, station keeping, payload communications, and scientific observations. Assured access means that the satellite will be able to reliably complete its radiocommunication links for the lifetime of its planned operation, free from radio interference that seriously degrades the performance of the link. While being able to confidently expect to have its operations protected from harmful interference, the satellite operator has the reciprocal obligation to ensure that its own operations do not cause such harmful interference to any other operator who possesses superior rights to use of that spectrum at that location. Obtaining rights for assured spectrum access as well as the relative responsibilities relating to spectrum use is the subject of a series of interlocking national and international regulations, as well as coordination agreements among states and operators of potentially affected systems. Knowledge of this complex web of regulations is essential for satellite system designers and operators, including operators of satellites both large and small.

This chapter briefly describes the evolving radio regulatory landscape for small satellite operators from the smallest CubeSats to those that are part of mega-LEO commercial constellations.

2 Regulation of Small Satellites: Radio-Frequency and Orbital Resources

Albeit invisible, radio-frequency spectrum is a sovereign natural resource, and its use within the territory of a nation-state is subject to regulation by that nation. A national government typically requires a license for transmission of radio waves within its territory and has laws and regulations setting technical and operational limits for such operations, such as allowable frequencies and bandwidths, power limits, antenna, and emission types, to ensure interference-free operations for other authorized operators in that territory. This requirement applies to everything from FM radio and television broadcasting stations, to mobile phone services, to fixed microwave systems, and to satellite space and earth station operators. Moreover, there are likely further regulations concerning the categories of services which may be offered using spectrum in particular frequency ranges, as well as numerous other requirements to advance national policies of a nontechnical nature.

National regulators need to be confident that the radio systems they authorize are able to operate free from harmful interference from other authorized radio operations, including the operations of other nations (a requirement of the International Telecommunication Union's Constitution and Radio Regulations). Many nations have bilateral agreements with their neighbors to this end, but that alone would not suffice to address all sources of potential radio interference. Some radio operations are inherently international, such as maritime, aviation, and space operations, and thus require a broader approach. Accordingly, multilateral mechanisms of cooperation and regulation have been developed to assure interference-free operation of radio stations within and without national territories.

The International Telecommunication Union (ITU) is an intergovernmental organization founded in 1865, originally as the International Telegraph Union, to facilitate the interconnection of telecommunications systems across national borders. Today, it performs a broad range of tasks to advance and promote the extension of all forms of telecommunications, including satellite-delivered communications, to the world's populace. As radio-based services began operating in the dawn of the twentieth century, the need swiftly arose for management of destructive radio interference to domestic services through national regulation of radio use and international cooperation. This led to the adoption of national radio regulatory regimes and ultimately to the creation of the International Radiotelegraph Union in 1906, which merged with the ITU in 1932, and became part of the United Nations (UN) system in 1947 following World War II. As space technologies developed in the 1960s, the ITU's remit expanded to address the management of radio stations in space to encourage deployment of new space-based services by managing interference to and from space-based stations (and their earth stations), to provide international recognition to space-based operations, and to ensure equitable access to spectrum and orbital resources for all countries.

As satellites operate beyond national territories in outer space, their operations are also subject to the broader outer space legal framework arising out of the 1967 Treaty on Principles Governing the Activities of Space in the Exploration and Use of Outer

Space, including the Moon and other celestial bodies (the "Outer Space Treaty") which codified the principles that outer space is the province of all mankind and that it shall be free for exploration and use by all countries on a basis of equality and in accordance with international law; and it is not subject to national appropriation by means of use or exclusive occupancy. The Outer Space Treaty, together with the other UN outer space treaties of that era, established that activities in outer space are to be carried out by state parties who bear international responsibility and liability for their actions there, including activities by the nongovernmental entities that they authorize. Activities of such nongovernment entities require continuing supervision by the authorizing state (United Nations 2002).

The ITU fulfills the international legal mandates of the outer space treaties through periodic conferences of its Member States which promulgate international law in the form of a Constitution, Convention, and Radio Regulations (RR). The ITU's Radiocommunication Bureau carries out processes for rationalizing the use of radio-frequency spectrum and orbits. These activities directly advance the non-appropriation and free exploration principles of the Outer Space Treaty.

Under the ITU's Radio Regulations, Member States are required to license the transmitting radio stations of satellite operators and represent them (including "nongovernment entities") as "notifying administrations" in the ITU's regulatory processes. The ITU's Constitution requires that "[a]ll stations, whatever their purpose, must be established and operated in such a manner as not to cause harmful interference to the radio services or communications of other Member States or of recognized operating agencies, or of other duly authorized operating agencies which carry on a radio service, and which operate in accordance with the provisions of the Radio Regulations" (ITU Basic Collection of Texts 2019a, p. 50, Art. 45). In cases of harmful interference, Member States must "exercise the utmost goodwill and mutual assistance . . . to the settlement of problems of harmful interference [and] Administrations shall cooperate in the detection and elimination of harmful interference" (ITU Radio Regulations Vol. 1 2016, p. 237, Nos. 15.22, 15.25).

The ITU's Constitution also extends "equitable access" to the electromagnetic spectrum and associated orbital resources by all countries:

> Member States shall endeavour to limit the number of frequencies and the spectrum used to the minimum essential to provide in a satisfactory manner the necessary services. To that end, they shall endeavour to apply the latest technical advances as soon as possible.
>
> In using frequency bands for radio services, Member States shall bear in mind that radio frequencies and any associated orbits, including the geostationary-satellite orbit, are limited natural resources and that they must be used rationally, efficiently and economically, in conformity with the provisions of the Radio Regulations, so that countries or groups of countries may have equitable access to those orbits and frequencies, taking into account the special needs of the developing countries and the geographical situation of particular countries. (ITU Collection of Basic Texts, p. 49 Art. 44)

The above general legal framework applies to all satellite operators, no matter whether they are tiny CubeSats or large communications satellites operating in geostationary orbit. However, as small satellites have proliferated, the applicability of some of the elements of these legal regimes and processes that were originally designed for larger geostationary satellites have become increasingly criticized as being overly burdensome and unworkable for the operators of the smallest satellites, particularly for noncommercial entities, with disproportionate impact on developing countries who may be embarking on their first space-faring activities. As a result, greater numbers of spacecraft are being launched into orbit outside of the Radio Regulations process and therefore lacking the protections afforded by regulatory status, ultimately contributing to increasing risk of unsustainability of the low Earth orbit.

3 Streamlined Procedures for Small Satellites with Short-Duration Missions

In light of the legal requirements for use of radiofrequencies in outer space, satellite operators must seek authorization, usually in the form of a space station license, from a national regulator in advance of their launch. An operator will select radiofrequencies, usually from existing satellite spectrum allocations, based on its mission requirements, the technical parameters of its spacecraft, and local regulatory requirements. Small satellites intended for commercial communications projects as part of non-geostationary satellite constellations typically have very different requirements than small satellites for research projects or scientific missions. One defining difference between the two types of missions is the length of the mission. Commercial satellite projects generally extend much longer than 3 years and have an expectation of replenishing their constellations with new satellites following their end of life. Another difference is that the commercial small satellites operate in the radio frequency allocations typically used to provide communications services – mobile-satellite service (MSS), fixed-satellite service (FSS), or broadcast-satellite service (BSS); are usually subject to coordination requirements of ITU Radio Regulations (RR) Article 9; and tend to have a greater impact on the overall spectrum environment.

For small satellite operators of short-duration missions, there are a wide range of frequency bands that are allocated, or agreed by regulators to be prioritized for satellite use, that may be used to support such operations, including the earth exploration-satellite service, meteorological-satellite service, space research satellite service, amateur-satellite service, and space operation service. Typical frequency bands downlinks and uplinks include 137–138 MHz, 144–146 MHz, 148–150.05 MHz, 399.9–400.05 MHz, 401–403 MHz, 435–438 MHz, 449.75–450.25 MHz, 460–470 MHz, 902–928 MHz, 2020–2025 MHz, 2025–2110 MHz, 2390–2400 MHz, 2400–2450 MHz, 5830–5850 MHz, 8025–8400 MHz, and 25.5–27 GHz (FCC Small Satellites Notice 2018, at p. 4161, para.18).

In the United States, for example, the Federal Communications Commission (FCC) has been authorizing small satellite operators by three methods: as commercial satellite operations under Part 25 of its regulations (with long processing times and very high filing fees); as experimental operations (limited to short-term, noncommercial operations with no regulatory status); and as amateur satellite operations (noncommercial operations for limited purposes). In 2019, in an effort to support and encourage innovation and deployment of small satellites with short-duration missions, the FCC adopted streamlined licensing procedures for qualifying small satellites featuring a simplified application form, faster processing times, and lower application fees (US $30,000). To qualify for these streamlined procedures, the proposed operation must satisfy a long list of criteria:

- Ten or fewer satellites under a single license
- Maximum in-orbit lifetime of any individual satellite is 6 years, including deorbit time
- All operations completed within 6 years.
- Maximum mass of any individual satellite will be 180 kg, including propellant.
- Deployment below 600 km altitude unless have capability to perform collision avoidance and de-orbit maneuvers using propulsion.
- Satellite(s) will release no planned debris.
- Satellite operator has assessed and limited the probability of debris being generated due to an accidental explosion resulting from the conversion of energy sources on board the satellite into energy that fragments the spacecraft.
- Probability of in-orbit collision between any satellite and large objects is 0.001 or less as calculated using current NASA software or other higher fidelity model.
- Any individual satellite is 10 cm or larger in its smallest dimension.
- Satellite(s) will have a unique telemetry marker.
- Probability of casualty resulting from uncontrolled atmospheric re-entry of any satellite is zero, as calculated using current NASA software or other higher fidelity model.
- Licensees must have the capability to eliminate harmful interference when necessary . . . [and] satellites must have the capability for immediate cessation of emissions on telecommand.
- Radiofrequency operations will be compatible with existing operations in the requested frequency bands and not materially constrain future operations of other satellites in those frequency bands. (FCC Small Satellites Order 2019, p. 8, para. 19)

In designing these streamlined national processing rules, the Commission deliberately limited the class of eligible small satellite operators to those with short-duration missions (1–3 years) and not requiring “full-time, uninterrupted availability of assigned spectrum” as compared to small satellites comprising “traditional” large commercial non-geostationary MSS constellations such as Iridium or the proposed new FSS constellations such as OneWeb and Starlink (FCC Small Satellites Notice 2018, at 4154, para. 4).

In addition to obtaining an authorization from its national regulator, small satellite operators are required to act through its administration to notify their planned use with the ITU’s Radiocommunication Bureau, a 7-year long process set forth in RR Articles 9 and 11. Application of the ITU coordination and notification procedure is required if the proposed satellite operation is capable of causing harmful interference, is planned to be used for international radiocommunication, is subject to the coordination procedure of Article 9 or if it is seeking international recognition for protection from harmful interference.

The ITU's coordination and notification procedure generally applies to all satellites, large and small, geostationary and non-geostationary, that will operate in frequency bands that are not subject to a priori plans (where spectrum/orbital resources are reserved for use by administrations to ensure equitable access). These "first come-first served" procedures for spectrum not set aside under the plans include advance publication, coordination, and notification. Acting on behalf of the satellite operators, notifying administrations electronically submit filings to the Bureau containing general and system characteristics as required by RR Appendix 4 which are then published by the Bureau for review by administrations and other operators for potential impact on planned or existing systems. Successful completion of the procedure, including coordination and payment of ITU cost recovery fees, results in international recognition of the satellite network or system via recording of the assignment in the Master International Frequency Register (Master Register). There are defined regulatory deadlines for each of these steps in the process. The ultimate deadline is that the frequency assignments must be "brought into use" by the end of the 7-year regulatory time period, which begins when the advance publication information is received by the Bureau. Failure to meet the regulatory deadline results in cancellation of the assignment and thus loss of regulatory status of the operation.

These procedures are subject to improvement and updating every 3–4 years by World Radiocommunication Conferences (WRC) convened by the ITU. WRCs may adopt or amend the Radio Regulations in response to proposals of Member States which are typically informed by the results of studies performed by the ITU Radiocommunication Study Groups, the recommendations of the ITU's Radiocommunication Bureau and Radio Regulation Board (RRB), and the input from the national regulators and satellite operators.

In 2015, a group of several countries from the Southern African region (SADC) requested the ITU to "examine the regulatory procedures for notifying space networks and consider possible modifications to enable the deployment and operation of nanosatellites and picosatellites, taking into account the short development time, short mission time and unique orbital characteristics" and that the 2019 World Radiocommunication Conference (WRC-19) consider "possible modifications to the existing regulatory procedures for notifying satellite networks to facilitate the deployment and operation of nanosatellites and picosatellites" (Angola 2015, p. 3). Although the ITU Member States were reluctant to consider creating a separate regulatory regime for small satellites, they acknowledged that the current procedures could be reviewed and possibly updated to better accommodate them. In the meantime, the ITU's 2015 Radiocommunication Assembly adopted Resolution ITU-R 68, "Improving the dissemination of knowledge concerning the applicable regulatory procedures for small satellites, including nanosatellites and picosatellites," and instructed the Radiocommunication Bureau to develop material that would help to improve knowledge of the applicable procedures for submitting filings of satellite networks to the ITU.

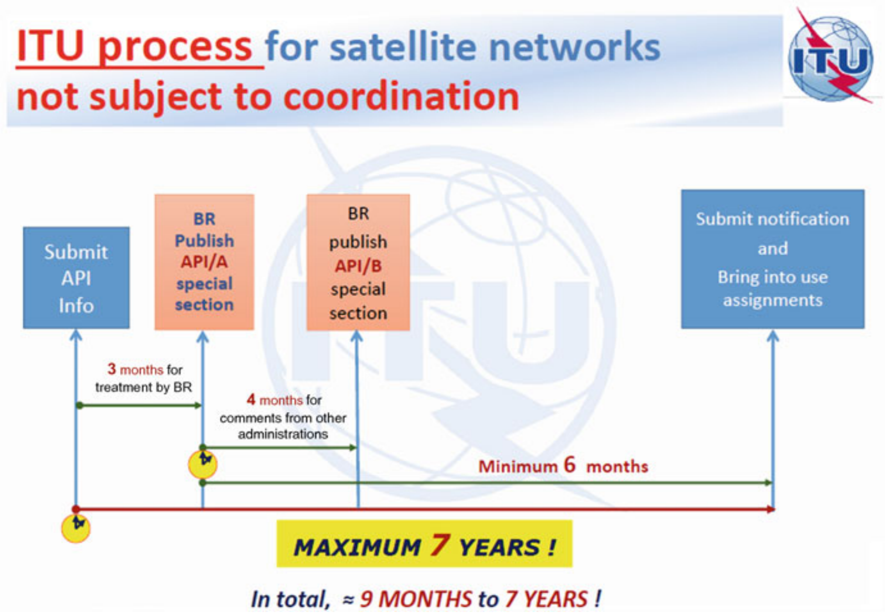

Fig. 1 Pre-WRC-19 ITU Procedure for most small satellites with short-duration missions (ITU Regulatory Procedures for Small Satellites 2018)

During the ITU-R preparatory studies for WRC-19, participants agreed that the procedures for coordination and notification, including the data elements of RR Appendix 4, are particularly difficult for small satellite operators with short-duration missions. For one thing, the overall procedure is too long relative to the length of their missions (Fig. 1). Once the notifying administration submits the Advance Publication Information (API) for the small satellite operation, the Bureau has up to 3 months to publish it. Administrations then have 4 months to review and submit comments. Then there may be additional time for administrations to reach agreement as to the acceptability of the filing. In any event, the Radio Regulations required a minimum of 6 months between publication of the API data and the submission of notification before the process can be completed – a minimum timeline of 9 months to completion. Another procedural challenge for small satellite operators is their inability to provide all the system characteristics required by RR Appendix 4 for API and notification within the required timeframes. For example, many operators do not know their orbital characteristics in advance of the actual launch of their satellite(s).

The ITU-R studies concluded that "given their short development cycle, short lifetimes, and typical missions, a modified regulatory procedure for the advance publication, notification and Master Register recording of non-GSO satellite systems with short duration missions may be beneficial for these systems . . .. [They] may require regulatory procedures that take account of the nature and timing for deployment of these systems" (ITU CPM Report 2019c, p. 595). Proposed remedies included shortening the regulatory time periods and changing the data requirements. The results of these studies formed the basis for Member States' proposals to WRC-19.

In November 2019, the 162 nations participating in the 2019 World Radiocommunication Conference, held in Sharm el-Sheikh, Egypt, agreed to provide relief to small satellite operators (and their notifying administrations) by adopting changes to the Radio Regulations to improve the regulatory situation for small satellites with short-duration missions. As recommended by the studies, WRC-19 adopted targeted amendments to the Radio Regulations and a streamlined procedure in Resolution 32, "Regulatory procedures for frequency assignments to non-geostationary-satellite networks or systems identified as short-duration mission not subject to the application of Section II of Article 9" (ITU WRC-19 Provisional Final Acts 2019e, p. 411).

The applicability of the streamlined procedure is confined to non-geostationary satellite systems or networks identified by their notifying administrations as having short-duration missions and meeting the following criteria:

1.1 The network or system shall operate under any space radiocommunication service on frequency assignments that are not subject to the application of Section II of Article 9 [subject to coordination];
1.2 The maximum period of operation and validity of frequency assignments of a non-GSO satellite network or system identified as short-duration mission shall not exceed 3 years from the date of bringing into use of the frequency assignments (see the Annex to this Resolution for the definition of date of bringing into use for such networks or systems), without any possibility of extension, after which the recorded assignments shall be cancelled;
1.3 The total number of satellites in a non-GSO satellite network or system identified as short-duration mission shall not exceed 10 satellites (with a typical mass of each not normally exceeding 100 kg). (*Id.*)

In addition, these networks or systems are required to operate within the conditions of the allocation (frequency band and service) in which they plan to operate and to have the capability to cease transmissions immediately to eliminate harmful interference to other systems.

The Annex to the Resolution provides special instructions for the application of the provisions of Articles 9 and 11 to these non-geostationary satellite networks and systems with short-duration missions. It provides alternative timing for submission of Appendix 4 information until after the launch of the satellite. In addition, the Conference amended the data elements in Appendix 4 to tailor them for these small satellites.

The Resolution also defines the date of bringing into use for these small satellites as the launch date of a satellite in a single-satellite non-geostationary satellite system or the launch date of the first satellite in a satellite system of multiple satellites. The Resolution invites administrations to avoid heavily used frequency bands when making assignments to small satellites with short-duration missions. Administrations are further encouraged to exchange information on these networks as soon as possible and to make every possible effort to resolve interference issues.

Finally, WRC-19 made changes to the provisions of Article 9 to tighten the timeframe for the processing of all satellite networks and systems under its purview, not only small satellites. In light of advancements in the electronic tools now available for filings, the Conference reduced the minimum timeframe in RR No. 9.1 for submission of notification information following publication of the API from 6 months to 4 months. Second, it reduced the time period in No. 9.2B for the Bureau to publish API information received from 3 months to 2 months. Thus, the Conference shortened this phase of the coordination and notification procedure from 9 months to 6.

Although the preparatory studies had contemplated shortening the 4-month timeframe for administrations to respond to APIs, WRC-19 refrained from doing so based on the concerns of many administrations. Instead, a footnote was added to No. 9.3 urging administrations to consider APIs for small satellites with short-duration missions "as soon as possible" within the applicable 4-month time period and for the Bureau to promptly make any comments received available on its website.

From the foregoing discussion, we can see real progress by national and international legal authorities to streamline their regulations to enable small satellites with short-duration missions to accommodate their mission requirements while preserving the stable international environment for interference management and space sustainability. Should further reforms prove necessary, the ITU's periodic process for updating its international legal instrument, the Radio Regulations, allows for continuing incremental improvements to be made to the international regime for managing satellites and their efficient use of spectrum/orbit resources.

4 New Regulations for Small Satellites in Large Non-geostationary Constellations

Another area of active regulatory development concerns small satellites of a different nature entirely – the small satellites (relative to geostationary communications satellites) that populate large non-geostationary satellite orbit constellations for provision of commercial telecommunications services (such as broadband Internet connectivity) utilizing spectrum in the MSS, FSS, or BSS allocations. Since 2014, the ITU has received a tsunami of filings for constellations of hundreds and thousands (even tens and hundreds of thousands) of satellites for these proposed systems in the Ku, Ka, and Q/V frequency bands (see Fig. 2). The ITU's historic regulatory provisions and processing procedures never contemplated filings of this magnitude.

The Radiocommunication Bureau sought guidance from WRC-15 on how to treat these mounting very large filings. The United States and United Kingdom submitted proposals to WRC-15 on the coordination of these new constellations and how to define when they are brought into use to fulfill the 7-year implementation period established in RR No. 11.44. The Conference determined that these complex issues

Fig. 2 Recommendation ITU-R V.431-8, nomenclature of the frequency and wavelength bands used in telecommunications 2015a

Letter symbols	Space radiocommunications	
	Nominal designations	Examples (GHz)
L	1.5 GHz band	1.525-1.710
S	2.5 GHz band	2.5-2.690
C	4/6 GHz band	3.4-4.2 4.5-4.8 5.85-7.075
Ku	11/14 GHz band 12/14 GHz band	10.7-13.25 14.0-14.5
Ka	20 GHz band 30 GHz band	17.7-20.2 27.5-30.0
V	40 GHz band	37.5-42.5 47.2-50.2

required study and then could be addressed by the following Conference in 2019. WRC-15 instructed that the preparatory studies should consider the definition of bringing into use for these non-geostationary satellite systems and the possible application of a milestone-based process to these systems following their being brought into use and recording in the Master Register.

In the past, when the ITU coordination and notification processes were being overwhelmed by the exuberant filing of unrealistic numbers of satellite network filings (for geostationary orbit FSS networks) – the so-called "paper satellites" era – the ITU responded with a series of regulatory changes over a number of years and the course of several meetings and Conferences from tightening the regulatory process, including reducing the regulatory period for bringing into use from 9 years to 7 (RR No. 11.44) to introducing cost recovery fees for the processing of satellite network filings (Council Decision 482 (1999)); to adding administrative due diligence measures, including a requirement to file data identifying the manufacturer and launch provider (Resolution 49 (1997)); and to supporting additional oversight by the Bureau in monitoring and determining whether satellite networks recorded in the Master Register are "real" (RR No. 13.6) (Allison 2014). Indeed, it bears noting that the ITU Council, the governing body of the ITU between Plenipotentiary Conferences, recently acted to revise its long-standing Satellite Network Cost Recovery mechanism to include a new procedure to capture the additional costs of the Bureau's processing the filings of large non-geostationary satellite systems (ITU Council, Decision 482, Doc. C/19-143, 2019).

National administrations have employed milestone requirements and other due diligence measures to ensure that their spectrum licensees build out their authorized facilities within a limited time following the grant of the license, else face regulatory consequences such as the cancellation of the license. These domestic requirements are intended to discourage licensees from warehousing spectral and orbital resources and thereby forestalling competition from others who might have provided services using those resources. The FCC requires construction build out requirements for many of its licensed systems, including milestones for its space station licensees.

In a recent update to its regulations, the FCC adjusted its milestone requirements in light of the very large systems before it which may not be able to be fully launched within the required 6-year time period normally provided following issuance of the license. The revised rules require these non-geostationary space station licensees to deploy 50% of their authorized constellations within 6 years of their authorization. Failure to meet this milestone results in a reduction of the authorized number of satellites in the constellation to those in actual use as of the first milestone date and forfeiture of a surety bond of up to US $5,000,000. Successful completion of the milestone releases the licensee from the bond obligation. The second milestone is full deployment of the remainder of the authorized constellation within the next 3 years – for a total of 9 years to full deployment. Following completion of the milestone period, licensees are required to maintain at least 50% of their authorized constellation in use at all times or the size of their authorized constellation will be decreased. In adopting this new milestone approach, the FCC stated that its goals were to discourage applicants from applying for "oversized, unrealistic constellations" noting that "unused authorizations for spectrum-orbit resources can create unnecessary coordination burdens and uncertainty for other operators" (FCC NGSO FSS Order 2017, p. 7830, para. 66).

As national administrations were processing applications for licenses for non-geostationary orbit satellite systems, the administrations and operators were also participating in ITU-R Study Group 4 studies to prepare for WRC-19. These efforts culminated in agreed general approaches for defining the date of bringing into use for non-geostationary satellite systems and a new milestone-based framework. These new approaches raised many complex regulatory questions, and there was little agreement on the details in advance of WRC-19 as the resulting regulations would have varying impacts on the relative status of the competing satellite system projects from different nations. For example, the administration of a prospective operator that was closer to the implementation of its system might support adoption of more rigorous milestone requirements that would be applied to its later-filed competitors, whereas proponents of less mature, larger, or more technologically complex systems might be better served by longer milestones with lower deployment requirements. Many administrations and satellite operators were mainly motivated by the need to preserve the stability of the management of the spectrum-orbit regime.

4.1 Bringing into Use

Bringing into use the frequency assignments of a satellite system is a prerequisite to attaining international recognition of the system and protection from harmful interference, the status achieved from recording the system's frequency assignments in the Master Register following the successful completion of the coordination and notification procedures of the Radio Regulations. Radio Regulation No. 11.44 sets the regulatory period for bringing into use a satellite frequency assignment as

7 years. The “clock” for this 7-year period starts on the date of the Radiocommunication Bureau’s receipt of the API (or other required initial filing) and stops with the “bringing into use” of that frequency assignment.

Until WRC-19, the Radio Regulations defined the bringing into use the frequency assignments of geostationary satellite networks:

> A frequency assignment to a space station in the geostationary-satellite orbit shall be considered as having been brought into use when a space station in the geostationary-satellite orbit with the capability of transmitting or receiving that frequency assignment has been deployed and maintained at the notified orbital position for a continuous period of 90 days. (ITU Radio Regulations Vol. 1 2016, p. 217)

In the absence of a regulatory definition for bringing into use the frequency assignments to non-geostationary satellite systems, the Radiocommunication Bureau applied a working definition to enable it to process such filings in its queue until such time as the Radio Regulations could be amended by a WRC. Under a Rule of Procedure approved by the ITU’s Radio Regulations Board, the frequency assignments to a non-geostationary satellite system are considered to be brought into use “when one satellite is deployed into a notified orbital plane and capable of transmitting and/or receiving those frequency assignments” (ITU Rules of Procedure 2017, Ar. 11, p. 26). For this purpose, a satellite is considered to be deployed into a notified orbital plane when its orbital characteristics match those indicated in its Appendix 4 information, including orbit altitudes and inclination. This working definition was applied for several years to MSS and FSS non-geostationary satellite filings regardless of the number of satellites notified to comprise the system.

The Director of the Radiocommunication Bureau reported to WRC-15: “[t]aking into account of the numerous non-GSO systems received so far by the Bureau, and the possible speculative nature of such submissions that could lead to spectrum warehousing and resurgence of so-called ‘paper satellite networks,’ the conference may wish to consider redefining the notion of bringing into use for non-GSO satellite networks” (ITU Director’s Report 2015b, p. 32, Section 3.2.2.4.4).

Based on the Bureau’s long-standing practice and the discussions during the 4-year preparatory cycle for WRC-19, the WRC-19 decided to add the recommended definition for the bringing into use of the frequency assignments of non-geostationary satellite systems to RR No. 11.44C:

> A frequency assignment to a space station in a non-geostationary-satellite orbit network or system in the fixed-satellite service, the mobile-satellite service or the broadcasting-satellite service shall be considered as having been brought into use when a space station with the capability of transmitting or receiving that frequency assignment has been deployed and maintained on one of the notified orbital plane(s) [footnote omitted] of the non-geostationary satellite network or system for a continuous period of 90 days, irrespective of the notified number of orbital planes and satellites per orbital plane in the network or system. The notifying administration shall so inform the Bureau within 30 days from the end of the 90-day period [footnotes omitted] On receipt of the information sent under this provision, the Bureau shall make that information available on the ITU website as soon as possible and shall publish it in the BR IFIC subsequently. (ITU WRC-19 Provisional Final Acts 2019e, p. 66)

In sum, a 1000-satellite constellation can be brought into use and meet the ITU's 7-year regulatory deadline with the launch and operation of a single satellite. Clearly, more oversight of these systems would be required beyond the 7-year bringing into use period.

4.2 Milestone-Based Approach

In taking the action to amend the Radio Regulations to adopt a new type of regulatory mechanism to facilitate the management of the spectrum-orbital regime, WRC-19 observed that:

> [I]t would be unrealistic to expect to have all the satellites of a system, in some cases consisting of hundreds or thousands of satellites, to be deployed within this seven-year regulatory period. Therefore, the BIU [bringing into use] of frequency assignments of non-GSO systems cannot always be considered as a confirmation of the full deployment of these systems, but instead may in some cases be just an indication of the commencement of deployment of satellites capable of using the frequency assignments. (ITU CPM Report 2019*,* p. 472, Section 3/7/1)

In other words, if such a constellation is brought into use (and its frequency assignments recorded in the Master Register) with the deployment of a single satellite – perhaps the first of a thousand such satellites in the constellation – a supplemental process was needed to confirm the ultimate deployment of the other 999 satellites beyond the 7-year regulatory period in order to ensure the accuracy of the Master Register. The studies recommended adoption of a series of deployment milestones that would apply during specified periods following the conclusion of the regulatory period to confirm deployment of the notified constellation. "A milestone-based approach would balance the need to prevent spectrum warehousing, especially in congested frequency bands, and the need to recognize the technical and operational challenges associated with this type of non-GSO system" (*Id.*).

The ITU-R studies recommended the following guiding principles for the Member States' consideration in developing proposals to WRC-19 on the adoption of a new of a milestone-based process:

- The bringing into use process should be separate [from the milestone-based process].
- Appropriate time should be given to allow the completion of the deployment of non-GSO systems [beyond the seven-year regulatory period].
- [T]ransitional measures should be considered to address the implications of any new milestones adopted by WRC-19.
- The milestone-based approach should be applied to all non-GSO systems in specific space services in specific frequency bands.
- The milestone-based approach should provide incentives to notifying administrations to deploy satellites in a timely manner, as a failure to meet a given milestone for a non-geostationary system will result in consequences.

- The milestone-based approach should be developed in such a way as to not constrain the development of non-GSO systems. *(Id.* at p. 473, Section 3/7/1.3)

Moreover, it concluded, acting on these principles would advance the efficient, rational, and economical use of spectrum and orbital resources and improve the transparency of the deployment of non-geostationary satellite orbit systems.

Under this recommended approach, there would be a series of milestones separated by a specific period of years following the expiry of the 7-year regulatory period. Each milestone would require a percentage of the satellites to be deployed based on the notified size of the system in one or more of the notified orbital planes with the confirmed capability of transmitting or receiving in the notified frequency. If the filer meets or exceeds the applicable milestone requirement, the characteristics of its recorded assignment in the Master Register (relating to the number of satellites comprising the system) would remain unchanged. Failure to meet the milestone would result in regulatory consequences such as a downward adjustment to the number of satellites in the system recorded in the Master Register relating to the number actually deployed (a so-called deployment factor). This milestone-based approach would be included in a new WRC resolution. In addition, transitional measures would be required for application of the procedure to systems already submitted or notified.

After the better part of 4 weeks of intensive negotiations, WRC-19 adopted Resolution 35, “A milestone-based approach for the implementation of frequency assignments to space stations in a non-geostationary orbit satellite system in specific frequency bands and services” (ITU WRC-19 Provisional Acts 2019e, p. 423). The Resolution is a mandatory treaty obligation through incorporation by reference to the Radio Regulations in new RR provision No. 11.51. The Resolution recounts that “design considerations, availability of launch vehicles to support multiple satellite launches, and other factors mean that notifying administrations may require longer than the regulatory period stipulated in No. 11.44 to complete implementation of [large] non-GSO systems” (*Id.*). Further, the preparatory studies concluded that “adoption of a milestone-based approach will provide a regulatory mechanism to help ensure that the Master Register reasonably reflects the actual deployment of such non-GSO satellite systems in certain frequency bands and services, and improve the efficient use of the orbital/spectrum resource in those frequency bands and services” (*Id.*). The Conference noted that:

> In defining the timeline and objective criteria for the milestone-based approach, there is a need to seek a balance between the prevention of spectrum warehousing, the proper functioning of the coordination mechanism, and the operational requirements related to the deployment of a non-geostationary satellite system. (*Id.*)

The Conference limited the applicability of the Resolution to non-geostationary satellite systems in specified FSS, MSS, and BSS allocations in Ku, Ka, and V-band frequencies (between 10.7 GHz and 51.4 GHz) reflecting the allocations where the ITU is receiving the highest number of filings for the largest non-geostationary satellite systems (See Fig. 3). It decided to exclude the various science services and commercial allocations in lower frequency bands (such as L- and S-bands) that had been considered for inclusion during the preparatory studies and in some of the proposals to the Conference. Because the systems filed in these services and frequency bands simply did not raise the same level of urgency and dimension of concern regarding speculative filings, misuse of resources, and potential damage to the overall satellite coordination and notification process, they were not included in the new regulatory process and were left to the consideration of a future conference.

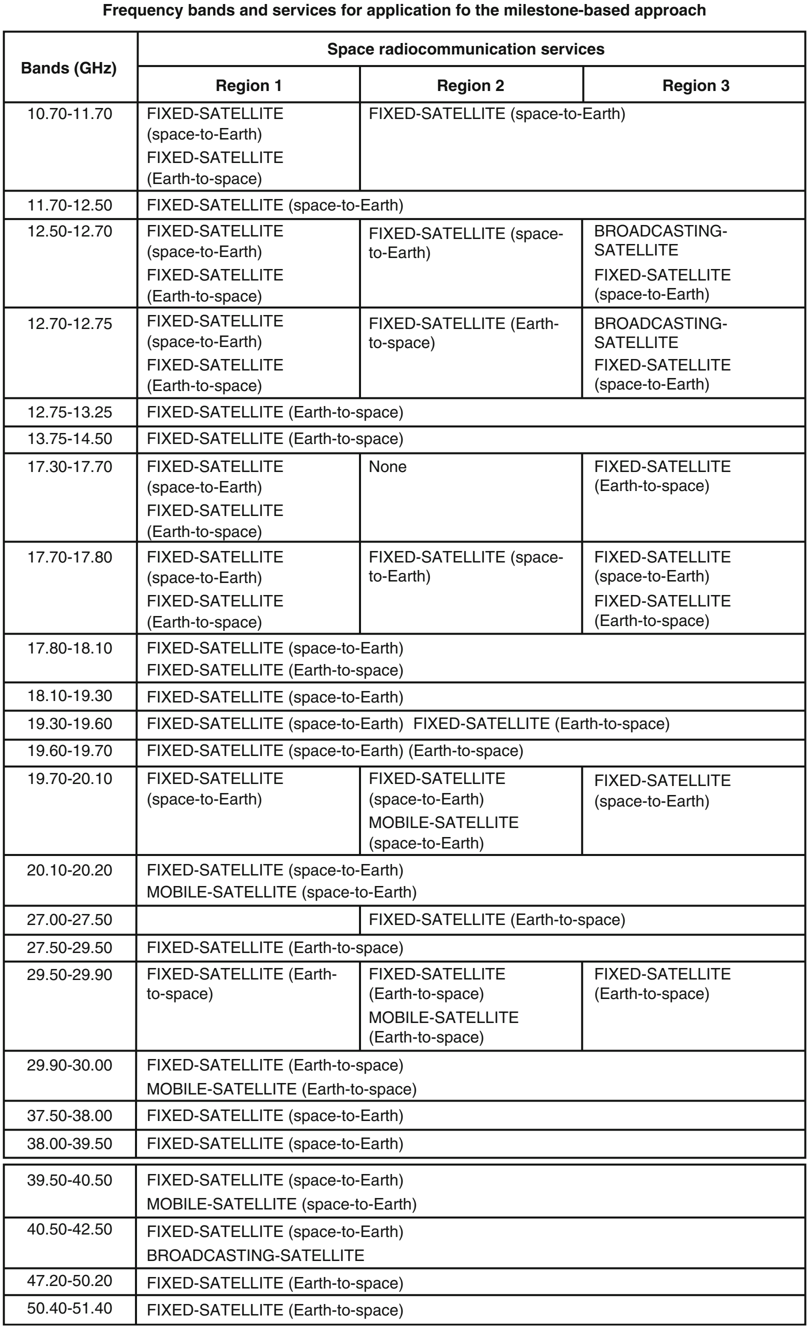
For the non-geostationary satellite systems that are subject to the Resolution having frequency assignments in the applicable allocations that will reach the end of their regulatory period on or after 1 January 2021, the first step under the new milestone-based process is that the notifying administration must submit to the Bureau deployment information no later than 30 days after the end of the regulatory period (*Id.* at 426). The deployment information required for submission is provided in Annex 1 to the Resolution:

(A) **Satellite system information**
   1. Name of the satellite system
   2. Name of the notifying administration
   3. Country symbol
   4. Reference to the advance publication information or the request for coordination, or the notification information, if available
   5. Total number of space stations deployed into each notified orbital plane of the satellite system with the capability of transmitting or receiving the frequency assignments
   6. Orbital plane number indicated in the latest notification information published in Part I-S of the BR IFIC for the frequency assignments into which each space station is deployed

(B) **Launch information to be provided for each deployed space station**
   1. Name of the launch vehicle provider
   2. Name of the launch vehicle
   3. Name and location of the launch facility
   4. Launch date

(C) **Space station characteristics for each space station deployed**
   1. Frequency bands from the notification information that the space station can transmit or receive
   2. Orbital characteristics of the space station (altitude of the apogee and perigee, inclination, and argument of the perigee
   3. Name of the space station. (*Id.* at 431–432, Annex 1)

Upon receipt of the deployment information, the Radiocommunication Bureau publishes it in the form of its receipt on its website for information. Should the deployment information indicate that the system is not yet 100% deployed, then the Bureau will add a remark to the Master Register entry (or the latest notification information) regarding the applicability of the Resolution to the frequency



Frequency bands and services for application fo the milestone-based approach

Bands (GHz)	Space radiocommunication services		
	Region 1	Region 2	Region 3

Fig. 3 Resolution 35 (Sharm el-Sheikh, 2019d) table of allocations subject to the milestone-based approach for non-geostationary satellite systems. (ITU WRC-19 Provisional Acts 2019e, pp 425–426)

assignments. The Bureau will also include this action in its regulatory publication and post it on the website (*Id.* at 426).

If the system is less than 100% deployed, then the second step of the process applies (*Id.* at 427). The notifying administration must submit updated deployment information to the Bureau no later than 30 days after the expiration of each of the following three milestone periods as they continue to apply:

M-1	2 years after end of 7-year regulatory period
M-2	5 years after end of 7-year regulatory period
M-3	7 years after end of 7-year regulatory period

Upon receipt of these updated deployment information filings, the Bureau posts them on the ITU website. Next, it conducts an examination for compliance with the applicable milestone in terms of number of satellites deployed relative to the total number of satellites in the system (as indicated in its Appendix 4 information) rounded down to the lowest integer (*Id.* at 428–429). The percentages of required satellite deployment for each milestone are:

M-1	2 years	10% of the total number of satellites
M-2	5 years	50% of the total number of satellites
M-3	7 years	100% of the total number of satellites

Based on the results of its examination, the Bureau will modify the entry in the Master Register (or latest notification information) for the frequency assignments and publish the results (*Id.* at 428).

The third step of the Resolution's milestone-based process applies only in the case the proponent fails to meet the required deployment level of that milestone. In such case, a deployment factor is applied to reduce the size of the constellation as notified or recorded in the Master Register. The notifying administration must submit to the Bureau, not later than 90 days following the expiry of the applicable milestone period, a modification to the characteristics of its recorded or notified frequency assignments as follows:

M-1	2 years	If less than 10%, then the modified total number shall not be greater than ten times the number of space stations deployed of the total number of satellites
M-2	5 years	If less than 50%, then the modified total number shall not be greater than two times the number of space stations deployed
M-3	7 years	If less than 100%, then the modified total number shall not be greater than the number of satellites already deployed (*Id.* at 428–429)

The deployment factor for each milestone is used to scale the size of a constellation based on what has been actually deployed by the operator as of the applicable milestone date. It is intended to incentivize satellite operators (and their notifying administrations) to undertake filings with realistic parameters and to maintain the accuracy of the Master Register, thus providing a clearer picture to other operators about the scale of planned operations that need to be protected.

Upon receipt of a modification request, the Radiocommunication Bureau will retain the original date of the entry in the Master Register of the reduced frequency assignments remaining for the constellation (and thus preserve their regulatory status), provided the notifying administration submits a commitment that the modified characteristics will not cause more interference or require more protection than the original ones filed (*Id.* at 429).

The Radiocommunication Bureau is charged with sending two reminders to notifying administrations at various points in the procedure regarding the deadlines for submission of information. Should the notifying administration fail to submit the initial deployment information under the first step of the process, the Bureau will maintain the entry in the Master Register and continue to take it into account until such time as the RRB takes a decision to cancel the frequency assignments. Should the notifying administration fail to submit the required information per the second or third steps of the milestone-based process, the Bureau will suppress the notified parameters of all satellites for which the required deployment information has not been received. Any satellites whose assignments have been suppressed no longer have regulatory status, and thus they may not cause harmful interference nor claim protection from other frequency assignments recorded in the Master Register (*Id.* at 429–430).

Following the completion of the milestone-based process, the subject non-geostationary satellite orbit systems are required to maintain their operations at a level of at least 95% of the satellites notified. Should the number fall below this level in any 6-month-long period, the notifying administration is required to inform the Bureau (*Id.*). Other actions are required to resume the operation and to retain the regulatory status of the system's regulatory status. The Conference indicated that this area requires further study and regulatory development (ITU Committee 5 Eleventh Report 2019).

The Conference also decided that this new milestone-based process would have some variations for different transitional cases: for earlier-filed systems whose regulatory periods will expire prior to 2021 and for systems whose regulatory period will expire before 28 November 2024. Although ITU treaty conferences are generally reluctant to make decisions with retroactive impact to the rights of Member States (or their approved private operators), the delegations to WRC-19 were in agreement that retroactive action was necessary in this case with so many large systems in the ITU-R's processing queue and their potential impact on the spectrum-orbit resource. Moreover, there was an acknowledgment that the next World Radiocommunication Conference, which is expected to be convened in the latter part of 2023, would be in a position to review (and to take any necessary action on) this new milestone-based procedure with the benefit of the experience gained over the next 4 years. Thus, the process was purposely designed to yield specific deployment information in time for consideration by WRC-23.

In the case of systems whose regulatory period ended prior to 1 January 2021, the Conference decided to apply the milestone-based procedure but with specific deadlines for submission of deployment information and the application of the milestone periods. The initial deployment information for these earlier systems must be filed by 1 February 2021 (ITU WRC-19 Provisional Final Acts 2019 at p. 426). Second, should these networks report less than 100% deployment, then their notifying administrations must file updated deployment information for the following three milestones:

M-1 No later than 1 February 2023 (corresponding to 30 days after the expiry of the two-year period after 1 January 2021);
M-2 No later than 1 February 2026 (corresponding to 30 days after the expiry of the five-year period after 1 January 2021);
M-3 No later than 1 February 2028 (corresponding to 30 days after the expiry of the seven-year period after 1 January 2021) (*Id.* at p. 427)

The second special transitional case applies to the several (approximately 20) large constellations filed during WRC-15 whose regulatory period will expire before 28 November 2022. The Resolution affords them, on an exceptional basis, the option to avoid complying with the first milestone of the regular procedure and instead submitting by 1 March 2023 special deployment information to indicate the “realness” of their systems and to confirm their progress toward meeting the second milestone (*Id.* at 429). The special deployment information to be submitted in this exceptional case is set forth in Annex 2 to the Resolution:

1. Reference to Notification Information already submitted
2. Current deployment and operational information
3. Report indicating efforts made and detailing status of coordination with systems or networks
4. Clear evidence of a binding agreement for the manufacture or procurement of a sufficient number of satellites to meet the milestone obligation in [milestone 2]
5. Clear evidence of a binding agreement to launch a sufficient number of satellites to meet the milestone obligation in [milestone 3]. (*Id.* at 432)

Annex 2 further provides that this deployment information “shall be submitted in the form of a written commitment by the responsible administration; include manufacturer or launch provider letters or declarations, and evidence of guaranteed funding arrangements for the implementation of the project, where possible. The notifying administration is responsible for authenticating the evidence of agreement” (*Id.*).

The unprecedented scope and nature of the information requested in Annex 2 arises from the fact that it is not yet clear how these pending mega-LEO constellations in overlapping frequency bands will be coordinated with one another. The Conference discussed various approaches, including the consultation procedure in Resolution 609 (Rev.WRC-07) that has been in successfully applied to coordinate systems in the radio navigation satellite and the aeronautical radio navigation services. But more time and study are needed before such an approach can be formally adopted into the Radio Regulations for these mega-LEO satellite systems.

Upon receiving this special deployment information, the Bureau is to provide it to the RRB by 1 April 2023, so that Member States may review and submit comments in time for consideration by the RRB at its second meeting in 2023. The RRB is instructed to provide a report to WRC-23 containing its conclusions and recommendations regarding the deployment efforts. This should make for an interesting discussion at WRC-23 and during the preparatory activities leading up to the Conference.

The new milestone-based procedure of Resolution 35 is a highly complex and radically different mechanism for the ITU-R's management of the spectrum-orbit regime which has been significantly challenged by the filing of so many large non-geostationary satellite orbit constellations. It is certain to be the subject of concentrated focus and studies throughout the preparatory period for WRC-23 and beyond. The Resolution includes instructions to the Radiocommunication Bureau to report any difficulties on its implementation of the procedure to WRC-23 as well as to report on other frequency bands and services that should be examined for future inclusion into this approach. Also outstanding is the further development of post-milestone procedures. Finally, the ITU-R also needs to conduct technical studies on "the tolerances for certain orbital characteristics of the [satellites covered by the milestone-based process] to account for potential differences between the notified and deployed orbital characteristics for the inclination of the orbital plane, the altitude of the apogee of the space station, the altitude of the perigee of the space station and the argument of the perigee of the orbital plane" (ITU, Minutes of Tenth Plenary Meeting 2019b). Besides informing the date of bringing into use and evaluation of milestone compliance, this information has potential implications for space safety and the sustainability of the low Earth orbit.

5 Conclusion

The advent of the small satellite era has challenged existing domestic and international regulatory constructs in two opposite ways. The needs of operators of small satellites with short-duration missions require lighter and clearer regulatory approaches to allow them to safely operate in the neighborhood of the low Earth orbit but still meeting the fundamental requirements of the international spectrum-orbit regime to protect their own and other operations. On the other hand, small commercial satellites that comprise large (and sometimes "mega") constellations require new, more rigorous national and international regulatory approaches to ensure order in low Earth orbit and to provide international protection to those systems whose frequency assignments are recorded in the Master Frequency International Register. As it has done many times in its 155-year history, the ITU has evolved its regulatory approaches as new technologies have developed and entered into service to achieve the goals of the outer space treaties and the ITU's basic instruments. But, at least for managing these emerging mega-LEO constellations, the ITU's efforts have only just begun. The 2023 World Radiocommunication Conference will be the next opportunity for the creation of new international legal measures to continue to ensure orderly, efficient, and equitable use of the spectrum-orbit resource and the provision of satellite-delivered broadband services to the world.

Obtaining Landing Licenses and Permission to Operate LEO Constellations on a Global Basis

Tony Azzarelli

Contents

Abstract

It is important to have a clear understanding of the system architecture and the business model of a satellite system before embarking on the acquisition of the requisite regulatory instruments needed for their operation (e.g., spectrum authorizations, service licenses). Getting this right may be the key to obtaining key licenses and vital authorizations and frequency allocations for a satellite network. This article provides vital information with regard to the complexity of satellite systems in general and low Earth orbit satellite constellations in

J. N. Pelton (ed.), *Handbook of Small Satellites*,
https://doi.org/10.1007/978-3-030-36308-6_72

particular. This complexity also results in a quite complicated regulatory, authorization, and standards process. Successfully winning the necessary regulatory approvals is essential to operating such satellite networks in a global environment. The article that follows provides useful details as to how these regulatory requirements, radio frequency allocation, and other types of authorizations such as "landing licenses" can be met, but this must be considered only to be a broad overview of this quite difficult, complex, and demanding field. This article addresses the regulatory processes specific to communications satellite systems. Nevertheless many of the authorization processes are similar for other satellite applications as well, and thus this article can be instructive for others seeking to deploy non-geostationary systems for other purposes.

1 Introduction

Below is a typical architecture of a satellite system. This might be a satellite system with a "bent pipe" or regenerative satellite payload. At each point in the communication chain shown in Fig. 1, there is at least one possible legal instrument required by one country or another.

From Fig. 1, it can be seen that the architecture of a satellite system is technically complex and that many interfaces exist between all the parts. Thus it becomes clear that there are many regulatory instruments required for the satellite operator to comply with before an entity can offer commercial services in a country.

The functional blocks (see Fig. 1) of a potential satellite network are:

- **Space Segment** – the physical part of the system related to all the spacecraft in outer space
- **Ground Segment** – the part related to the radio equipment and antennas that download and upload traffic to the space segment
- **Control Segment** – the part where the control function (with its space control center and radio antenna system) of the spacecraft resides

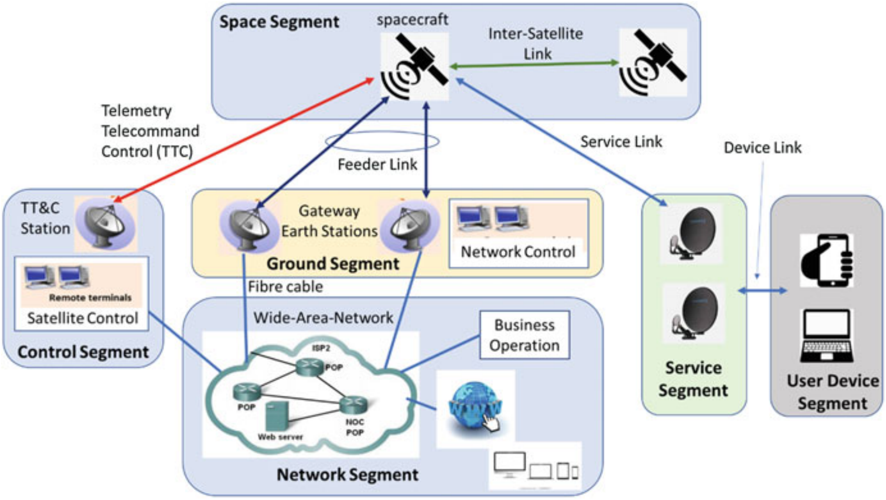

Fig. 1 Complexity of a satellite architecture. (Graphic courtesy of the author)

- **Network Segment** – the heart/core of the ground network where the global interconnections, control data functions, and people are located to run the communication network and all the data flow, including business, security, and operations functions
- **Service Segment** – the physical part of the system where the communication data flows from and to the space segment and the antenna terminals interfacing the user on Earth
- **User Device Segment** – is the physical part where the user devices such as their laptops, phones, and sensors are.

Not all satellite systems require all these functional blocks or may require additional blocks, and this depends on the business objectives/model of the system. Thus, the regulatory environment requirements may differ from system to system. What is described in this section is typical of a satellite system that provides high-speed broadband connectivity. However, some of the regulatory requirements here can extend to other types of satellite network.

1.1 The Communications Channel

Within the system architecture, Fig. 2 shows how the data flows from one end (e.g., a “web page” or a “data storage” on the Internet) to the other end (the “user”) of the system.

The data flow is transferred from one block to the other block using either cable or a radio spectrum. At each block, the data information (“1”s and “0”s) is converted

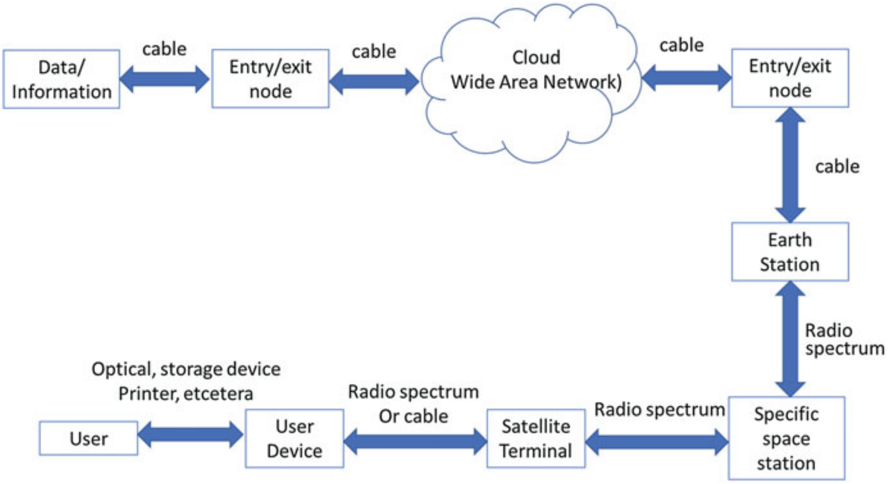

Fig. 2 The satellite broadband communication system. (Graphic courtesy of the author)

from bits of information to data or analogue signals, to be reconverted back to data information (“1”s and “0”s).

Regulatory approvals may be required as data and information transits through the communication channel. This is due to various reasons, for example:

- Crossing national borders – taxations and fees
- Control of data flow by national authorities – limited or not by law
- Using natural resources, such as spectrum – requires authorizations/license
- Control of interference when using radio frequencies
- Business transactions – taxation and authorizations to sell/buy
- Data protection and data security laws – lawful intercept

2 The Regulatory Environment for Satellite Systems

The approach taken by all countries and regulatory jurisdictions of the world are not harmonized and the regulatory requirements different from country to country or from region to region of the world.

Also, the bodies responsible for regulating the national resources related to telecommunications, radio frequencies, and space objects differ from country to country. What is the regulatory model in one country can be very different in another (see Table 1).

This makes life difficult for satellite operators that have a global reach, thus requiring large investments in resources to acquire the required approvals to access different markets around the world.

Table 1 Regulatory agencies in selected countries

	Radio frequencies	Telecommunication services	Space resources control	International representation on radio frequencies
United Kingdom	Office of Communications (Ofcom)	Department for Digital, Culture, Media and Sport (DCMS) Ofcom	UK Space Agency	Ofcom
USA	Federal Communications Commission (FCC) and NTIA	FCC	FCC Federal Aviation Administration (FAA)	FCC
Italy	Ministry of Economic Development (MISE)	MISE	Italian Space Agency (ASI)	MISE
France	Agence Nationale des Frequences (ANFR)	Ministry of Economics Agence Autorité de Régulation des Communications Électroniques et des Postes (ARCEP)	Centre National d'Etudes Spatial (CNES)	ANFR
China	Ministry of Industry, Information and Technology (MIIT)	MIIT	Chinese National Aerospace Agency (CNSA)	MIIT
India	Department of Telecommunications (DOT) Telecommunications Regulatory Authority (TRA)	Department of Telecommunications (DoT) Telecommunications Regulatory Authority (TRA)	Indian Space Research Organisation (ISRO)	DoT
UAE	Telecommunication Regulatory Authority (TRA)	TRA	National Space Agency	TRA

In addition to national regulators, satellite operators have to deal with international and regional bodies. Each of these groups have different roles and some of these are:

- **International Telecommunication Union (ITU)**: which develops international rules of engagements, through its Radio Regulations, resolutions, and recommendations. It also has the international function of registry of radio space resources (i.e., the Master International Frequency Register).
- **European Conference on Postal and Telecommunications (CEPT)**: a body representing 48 countries, under which the **European Communications Commission (ECC)** studies compatibility between systems and develops the radio decision, reports, and recommendations on how spectrum is shared and allocated, reducing or even eliminating harmful interference, and how radio equipment is regulated for circulation across European borders and licensed for the spectrum use. Thus, providing for a harmonized regional approach to licensing, whereby countries of the CEPT can adopt and ratify these decisions and recommendations into their legislations, regulations, or guidelines.
- **European Telecommunications Standards Institute (ETSI)**: which develops the radio interface standards that ensure equipment does not cause harmful interference to other radio services. Such standards can be adopted by the **European Union (EU)** as harmonized standards, which then allow free circulation and free market access for radio terminals that comply with such standards. Like the FCC mark, the EU marking (CE) is accepted by many countries around the world, as a quality assurance that such equipment does not cause harmful interference.

3 Different Satellite Links

Figure 1 shows the architecture of a typical satellite system. From this chart, it can be demonstrated that different aspects of an overall satellite communications systems can be split in functional blocks. Such blocks are interfaced or linked together using a communication link that can be either radio link, fiber, or cable transmission.

Understanding these links will help understand what kind of regulatory instruments may be required from each country or from an international institution such as the International Telecommunication Union (ITU).

The interfaces provided in Fig. 1 above are:

- **Device Link** – is the link which connects user devices to the satellite network (i.e., the satellite terminal). This can be in various forms, radio (WiFi, 3G, 4G LTE), Ethernet, or optical cable.
- **Service Link** – is the link which provides access to the space segment and where information is relayed from the satellite terminals on the ground to the satellites in outer space. This is usually a radio link, which requires to be in allocations recognized internationally by the ITU.

- **Feeder Link** – is the link that connects the space segment to the satellite ground network. This can be seen as the backhaul part of the space segment and not related to any use by the end users. Usually this is a radio link and must be recognized internationally by the ITU. Future connections could use optical/laser links.
- **Control Link (TT&C)** – this is a sensitive link which provides the control of the spacecraft through the TT&C signalling. Here TT&C means, Telemetry, Telerange and Command; i.e., through these the satellite operator will obtain the following:
  (a) **Tracking** (space-to-Earth) – for obtaining the location of the spacecraft (possibly through GPS signal received on the spacecraft)
  (b) **Telemetry** (space-to-Earth) – for obtaining the health of the subsystems of the spacecraft
  (c) **Command** (Earth-to-space) – for sending commands to the satellite to either move it in space or to command the functions of the satellite subsystems, including the payload frequencies
- **Intersatellite Link (ISL)** – it is the link between spacecrafts in outer space, and not all satellite systems use such link today. A future option is to use optical laser links. ISLs are required to transfer data from satellite to satellite before landing on the Earth, usually to avoid complex ground networks and investments on ground antennas or even avoid complex regulations. However, it provides the advantage to cut down costs and delays in delivering the date to the end user and vice versa. The radio links are also allowed under the ITU regime, but it does not require any national license to operate these.
- **Fiber/Cable Links**: these links provide connectivity to transfer data from one installation to another or even across the globe. As these are based on cable connectivity, they do not enter in the radio regulatory domain. However, other national telecoms and data security regulation may be applicable.

4 Regulatory Requirements for a Satellite System

Taking the various links and system segments described above, exploration of what might be some of the regulatory requirements for each of them is reviewed below.

4.1 Requirements for the Service Link, Service Segment, Device Link, and Device Segment

(a) The **Service Link** and **Service Segment** are the part of the system dedicated to the provision of a given telecommunication service to an end user, in a given country. As such, regulations stem from various considerations, for example:
  - Telecommunications law, which usually protects the citizens' interest
  - Radio communications regulations, which protect the sharing of spectrum and lowering of interference

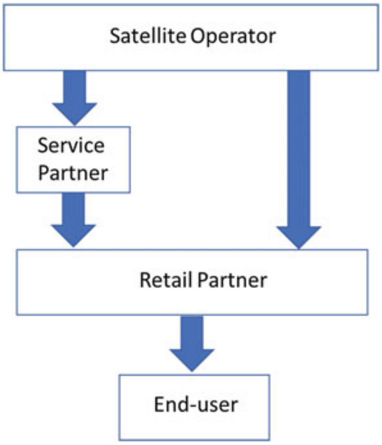

Fig. 3 Simple service provision model. (Graphic courtesy of the author)

- Taxation and duties, for services provided
- International law, for the respect of other international users

The provision of satellite services can be done in different ways, and this depends on the business model adopted by the satellite operator. A simple model is provided in Fig. 3. In this typical model, various types of requirements must be met to achieve necessary licenses and authorizations.

For example:

- Having a local company or partner
- An authorization for the sale of capacity from the satellite operators onto the service partner or the retail partner
- An authorization for the service partner or the retailer to sell the capacity it receives from the satellite operator onto the next stakeholder or the end user
- An authorization for the satellite system coverage requirement, e.g., **landing rights**, **network authorization**, or **registration of the space network**.

Under such authorization or licensing regime, there can be legal and technical conditions, such as the need for customer care services, provision of a good quality of service, lawful intercept, and more.

(b) The **Service Segment** also includes the satellite terminal provision and deployment. There are many things to consider here, but limiting this to the essential and most important things to worry about is related to ensuring that the terminals do not cause harmful interference to other services. In such case, some of the regulatory requirements are:

- **Type approval** and the related marking (e.g., CE or FCC) of the terminal are required for each terminal type and ensure that the terminal is built based on a specific standard. A qualified laboratory does the testing on a prototype and thus ensures that the terminal model does not cause harmful interference or cause harm to humans.
- **Certification** of the terminal equipment, for example, for aviation and maritime purposes. Such certification is normally related, for example, to safety

installation and aviation safety requirements. Such certification is usually obtained by the aviation or maritime authorities.

- **Authorization for satellite terminals**, which varies from country to country and regulated by the spectrum authority which ensures that the terminal equipment is operated in conformance to the laws and regulation of that country. Some countries require the licensing of individual terminals, and in others certain terminals are license exempted or are allowed to operate under a single "umbrella" license. The latter two cases are when the terminals have technical and operational characteristics which ensure that there is no harmful interference caused to other services and applications.

(c) The **Device Segment** and **Device Link** are usually outside the reach of the satellite operator, although the interface requirement between the satellite terminals and the user devices must be known and designed by the satellite operator. Typical user devices such as smartphones, tablets, and laptops can be interfaced to the satellite terminal using radio spectrum such as 3G, LTE, WiFi, or Ethernet cable. The authorization of the spectrum used and the terminal compliance to national regulations are the responsibilities of the national provider licensed or authorized for the provision of such spectrum. Hence this is outside the scope of this book.

4.2 Requirements for the Space Segment

There are several regulatory approvals that may be required at the space segment side, and these are mainly related to the spectrum used by the satellite and governed by the International Telecommunication Union (ITU) and the notifying administration of the satellite operator. Other approvals are also required and relate to the launch and space operations governed by the United Nations' Outer Space Treaty (UN OST) of 1967 and other related international law provisions.

(a) **ITU approvals**, required for satellite spectrum rights, such as:
  (i) **ITU satellite filings** are required (see Article 9 of the ITU Radio Regulations) when sending a satellite into space. Such filings describe the orbital resources required, such as the orbit type and the frequencies used by the system. Without such filings and the ITU process that goes with it, the system will not be recognized by other countries and satellite operators.
  (ii) **Frequency coordination**: after the submission of the satellite filings, the satellite operator is required to coordinate with all affected services and systems. The procedure is described in Article 9 of the ITU Radio Regulations. In particular, the date of receipt of the satellite filing by the ITU Bureau serves as a marker for the satellite operator to request coordination with all satellite systems filed before its filing. The operator has 7 years to fully coordinate the satellite filing and then to notify and bring into use the assignments of such satellite filing. Specifically to non-GSO satellite systems which operate in certain frequency bands and where

Article 22 of the ITU Radio Regulations applies, the non-GSO satellite system must comply with the equivalent power flux density limits (e.p.f.d.) which ensure that the non-GSO systems do not cause harmful interference to the GSO networks. When the non-GSO satellite system complies with such limits (the ITU Bureau has a software to check this), then the system is not required to coordinate with GSO satellite networks.

(iii) **Internationally agreed limits** are limits that apply in certain frequency bands which ensure that the emissions of a satellite system do not cause harmful interference to certain radio systems. For example, power flux density limits (see, Article 21 of the ITU RR) which protect GSO networks or terrestrial systems; off-axis antenna gain limits or e.i.r.p. density limits; interference limits; Article 22 e.p.f.d. limits. Such limits are specified in the resolutions, appendices, annexes, and the provisions of the ITU Radio Regulations. The satellite system must be designed and operated in respect of such requirements.

(iv) **Bring into use** and **notification:** before the end of the 7-year regulatory period, the assignment of the satellite filings must be notified and brought into use. This is regulated by the provisions set under Article 11 of the ITU Radio Regulations and often ITU Resolutions which regulate a particular satellite service. Once the notification has been received by the Bureau, the assignments of the satellite system or network are placed onto the Master International Frequency Register (MIFR), which is there to provide international recognition and protection from harmful interference by later filed assignments of other systems or networks.

The ITU WRC-19 has just agreed upon a milestone approach for the deployment of the satellites of a non-GSO satellite system. Such approach states that the non-GSO system must launch one satellite before the end of the 7-year regulatory period and then has to deploy the full constellation based on three milestones of length 2, 5, and 7 years from the end of the 7-year regulatory period. The percentage of the constellation that must be deployed within such milestones is 10%, 50%, and 100%, respectively. Failure to meet such milestones will have consequential penalties for the satellite constellation, such as reduction of the constellation size.

(b) **Ground coverage approvals**: As each satellite covers part of the Earth with its beams or that a full constellation may be able to cover the full globe, the landing of signals or capacity on the countries of the Earth may require a national authorization. Such authorization may take the form of a “landing right,” “spectrum authorization,” “space object registration,” or other kinds of authorization. This authorization varies from country to country. From analysis made by the authors when working with certain satellite operators, the number of jurisdictions of the world that require such authorization is limited to less than 40 countries. The author believes that such authorization is redundant because other forms of authorization are required for the operations of the satellite services on the ground, such as licensing of spectrum use and licensing of satellite equipment.

4.3 Regulatory Requirements for the Ground, Control, and Network Segments

At the ground segment side (see Fig. 1), we have large-sized antennas and electronic equipment (e.g., down-converters, filters, modems). The antenna receives signals from the satellite (and vice versa) which are then converted to data information (through the modems) that is then transmitted through fiber links to the network segment ground connections (the "ground network") to reach a particular destination. This happens through the use of a closed-circuit network, usually leased from TELCOs, by the satellite operator. At this point, certain system functions are connected to the network, such as network operations center (NOC) and billing system.

(a) For the **Ground Segment** as the corresponding Earth stations are located in certain countries, as there is use of spectrum here, and as well as there is transit of user data and information through to the core network and the World Wide Web, each national jurisdiction will require some kind of authorization. For example:
   (i) **Authorizations for the spectrum use**: by Earth stations connecting to the satellites and these will usually take the shape of a license for the use of spectrum. Such license will need to carry technical limitations which may stem from the regulations or frequency coordination which was carried out by the Earth station operator (which may be different than the satellite operator).
   (ii) **Landing rights**: required by certain countries to authorize the landing of satellite spectrum from the satellites to the Earth stations receiving/transmitting the signals. This is required by a limited number of countries, less than 40 in the world.
   (iii) **ISP license, carrier license, or equivalent**: This is a license required by a small number of jurisdictions which may want to ensure that the satellite or Earth station operators provide a service that is of good quality and that complies with certain national regulations or just for taxation purposes.
   (iv) **Lawful intercept requirements**: these stem from the national cyber security laws, which may ensure that user traffic can be monitored or filtered, for example, for policing purposes.

(b) **Control Segment**: For the purpose of regulatory approvals, authorization requirements that can be included in the above, especially (i) and (ii), also the Control Segment, which is the part of the system that sends signals (telecommand) and receives signals (Telemetry) from the satellites for the control, monitoring, and health of the spacecraft in outer space. As the **Control Link** (see Fig. 1) does not carry any user data, this part of the system is not subject to any carrier licensing or lawful intercept.

(c) The **Network Segment** (see Fig. 4) is the core of the satellite system where all the data and information flow through from users on one side of the network to users on the other side of the space segment. All telecommunication functions

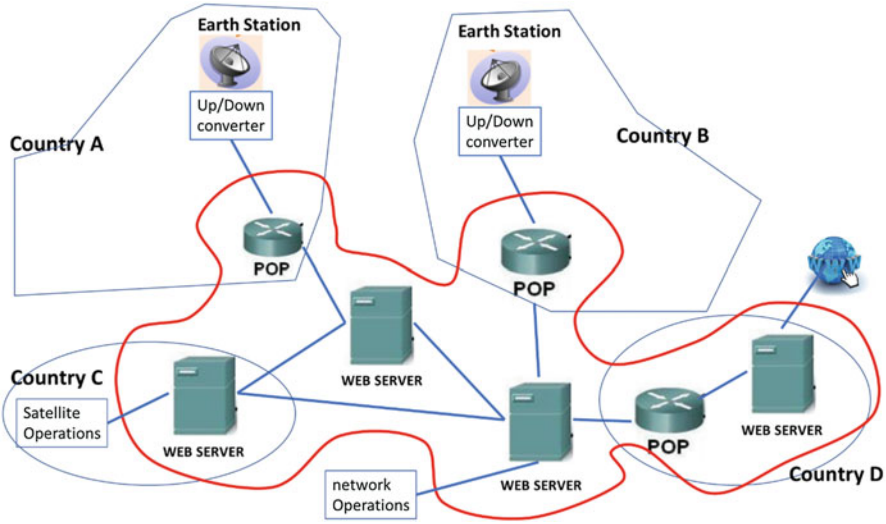

Fig. 4 Simple network model. (Graphic courtesy of the author)

of the satellite systems are practically located here, and thus it forms a very important part of the satellite system, such as:

(i) The **Point of Presence (POP)**, usually located near the Earth stations or can be isolated from these. The POP is an IP switch with related servers, where IP data flows through, controlled and monitored/filtered, and also where information of subscribers of that country or that roam in that country is also located.

(ii) The **Servers**, located within data centers scattered around the world (which are usually leased). These serve as data banks or switches, where data is processed or just switched to another server or POP.

(iii) Other functions such as switches connected to the WWW or the billing center, satellite operations, network operations, or even the server of a business client (e.g., mobile or Telco operators).

From a regulatory perspective, the pieces (e.g., POP, servers, switches) of the network segment need to be identified with the countries where these various network blocks are located. This is because the country may have special regulations and laws that apply to such functions. For example, in China the POP should be the place where data from Chinese users is processed, controlled, or filtered before it leaves or enters the country; as such the POP is captured within certain legal and technical conditions that these have to comply with. This matter will not be addressed by this section.

4.4 Other Regulatory and Legal Requirements

This section will not cover other national regulatory or legal requirements that a satellite system will need to comply with. This should not be undermined, and usually they should be discussed with a partner or a law firm of a particular country. These other requirements could be:

(a) Administrative fees such as importation duty, VAT, or taxation
(b) Universal Service Obligation tax, paid to the authorities based on revenues on that country

5 Example of Regulatory Requirements in Some Countries

It is known that regulatory requirements differ from country to country and it is no easy task to acquire authorizations and licenses for satellite services or spectrum use around the world.

It requires knowledge of the local regulations and knowledge of the satellite system and its business model. As import, the influence of geography, culture, legal system, and the country's history greatly influences the national regulations for Telecoms (Mazar 2008) and thus that for the satellite services.

Countries like France, Italy, and Spain, for example, follow formal and codified law (Napoleonic Code, or Roman Law), which sets the legal norms that authorize telecommunication services and equipment. So, any kind of telecommunication authorization for services and spectrum must be inscribed in law. In such legal environment, a ministerial department such as a ministry is required to regulate all telecommunication services, including that of satellite systems.

Other countries follow some form or another of common law (e.g., USA, UK) and thus rely on a more flexible approach to regulating telecommunication services and radio equipment.

Others still, such as those in the European Union (EU), in certain cases follow norms set by the European Parliament set to harmonize regulations for services and equipment that have a broader market access across the member states of the EU (see for example, the Authorization Directive https://eur-lex.europa.eu/legal-content/EN/TXT/?uri=LEGISSUM%3Al24164). Regulations for satellite applications and equipment may follow such approach (see for example, the Radio Equipment Directive https://ec.europa.eu/growth/sectors/electrical-engineering/red-directive_en).

It is not the scope of this section to provide details on this topic; however, information of how satellite services, and in particular non-GEO constellations, are regulated in some countries and regions of the world will be provided. Information on national requirements for non-geostationary constellations will be provided below.

In addition to the national legal environment, which sets the national regulations on allowing satellite services to be operated in the country at the international level, the International Telecommunication Union (ITU) regulates through international law access to spectrum and the management of interference that can be caused to services on a global scale. The ITU's Constitution and Convention (see, https://www.itu.int/en/history/Pages/ConstitutionAndConvention.aspx) and the other instruments of the ITU, related to the radio sector (ITU-R), telecom and standards sector (ITU-T), and development sector (ITU-D), form part of the ITU treaty laws. In particular, the Radio Regulations and its other instruments are very pertinent to the proper functions of satellite systems, including those of non-geostationary satellite constellations. Some specific information on this topic will be provided below.

What is also important in this is that certain national regulations, for example, the licensing of a hub or a gateway or the landing rights in a country, will require the existence of an ITU satellite filing, which is addressed in the following section.

International law related to the launch and operation in outer space for satellites and/or constellations of satellites will not be addressed in this section. This is a topic under the responsibility of the United Nations Office of Outer Space Activities (UN-OOSA) and the related Outer Space Treaties (see, https://www.unoosa.org/pdf/publications/STSPACE11E.pdf) which regulate through international law the peaceful operations of space objects in outer space.

5.1 Satellite Filings of the International Telecommunication Union (ITU)

5.1.1 Background

The ITU is the specialized agency of the United Nations responsible for the international development of regulations and standards governing wired and wireless information and communication technologies (ICT). Since its first Radio Conference in 1906 (Berlin; see, https://www.itu.int/en/history/Pages/RadioConferences.aspx?conf=4.36), it is responsible to regulate radio spectrum at the international level. It wasn't until the late 1950s that the ITU considered initiating international discussions on space communications and then not until the ITU's Extraordinary Administrative Conference (1963; see, https://www.itu.int/en/history/Pages/RadioConferences.aspx?conf=4.89) that radio frequencies and treaty text were adopted for the various space services. However, major modifications to the ITU-R Radio Regulations and the procedures to regulate frequency allocations of space services were introduced in subsequent radio conferences, such as that of WARC 1979 (see, https://www.itu.int/en/history/Pages/RadioConferences.aspx?conf=4.101) and WARC ORB 1988 (see, https://www.itu.int/en/history/Pages/RadioConferences.aspx?conf=4.119). The latter conference was instrumental in the structuring of regulations for the geostationary space objects.

The ITU was restructured in 1992 into the ITU, and its three sectors that are known today (i.e., Radio (ITU-R), Telecom and Standards (ITU-T), and Development (ITU-D)) and the subsequent World Radio Conference have done a great amount of work in the space communications, especially starting from WRC-1992 when the first non-geostationary constellations were studies and allocations were assigned (e.g., Motorola's Iridium, Qualcomm's Globalstar, Inmarsat's ICO-P).

5.1.2 ITU Satellite Regulations

The ITU Radio Sector, or ITU-R, has legal instruments enshrined in its Radio Regulations (https://www.itu.int/pub/R-REG-RR). The preamble of these Radio Regulations provides the principles under which these are founded, for example:

> 0.3 [...] that radio frequencies and any associated orbits, including the geostationary-satellite orbit are limited natural resources and that they must be used rationally, efficiently and economically, in conformity with the provisions of these Regulations, [...]

and

> 0.4 All stations, whatever their purpose, must be established and operated in such a manner as not to cause harmful interference to the radio services or communications of other Members [...]

Hence, space objects that use any radio spectrum in frequency allocations (from 8.3 kHz to 3000 GHz) assigned to space services must conform to these regulations for two main reasons:

- Ensure the rational, efficient, and economical use of spectrum.
- Not to cause harmful interference to other services or stations in the same service.

The first point is addressed by the Study Groups of the ITU-R, which embark in studies that ensure this principle and thus develop and adopt ITU-R Recommendations that ensure compatibility between services. And the second point, also studied by the Study Groups and the Recommendation it follows, it is ensured through the active coordination between proponents and the registration of their frequency assignments into the Master International Frequency Register (MIFR).

Hence, the objectives of a satellite company at the ITU are to (1) coordinate the assignments of its satellites with other proponents and then (2) obtain international recognition for these frequencies by recording these onto the ITU's Master International Frequency Register (MIFR) (see, https://www.itu.int/en/ITU-R/terrestrial/broadcast/Pages/MIFR.aspx).

This process is regulated by Articles 8, 9, and 11 of the ITU Radio Regulations, for example:

- Article 8 "Status of frequency assignments recorded in the Master International Frequency Register"
- Article 9 "Procedure for effecting coordination with or obtaining agreement of other administrations"
- Article 11 "Procedure for effecting coordination with or obtaining agreement of other administrations"

5.1.3 ITU Satellite Filings

General Objectives of Satellite Filings

The whole process described above starts with the satellite operator requesting to file the frequency assignments of their satellite system to a member state of the ITU, e.g., the FCC in the USA for US companies, Ofcom in the UK for British companies, or MIIT of China for Chinese companies. This is done through the ITU process whereby a satellite filing must be compiled as per the ITU-R procedures under Article 9 of the Radio Regulations. How these filings are compiled and the whole process of submissions and management will not be addressed here, but what is important for the reader here is to know that such filings are a necessary step to:

- Be recognized internationally – important for investors and financing of the satellite system.
- Start the frequency coordination process under Article 9 of the ITU Radio Regulations with other filings submitted at an earlier date – necessary for limiting the interference and thus affecting the design of the satellite system.
- And ultimately, at the launch of the physical satellite(s), the notification and bringing into use of the frequency assignments of such filings can be submitted under Article 11 of the ITU Radio Regulations and be recorded to the MIFR – necessary for the interference protection from future satellite systems.

Frequency Allocations for Non-geostationary Systems

With the advent of non-geostationary satellite constellations, WRC-1992, WRC-1995, and WRC-2000 adopted certain frequency allocations for these systems.

- **WRC-1992** adopted mobile satellite service (MSS) allocations below 3 GHz for the MEO and LEO constellations providing Global Mobile Personal Communication Systems (GMPCS) (see, https://www.itu.int/en/gmpcs/Pages/default.aspx). These systems are for the personal voice and very low-speed data communications, many of whom are used for aero and maritime safety and emergency applications. WRC-1997 adopted certain feeder link allocations (C- and Ka-band) for these systems.
- **WRC-1995** and **WRC-2000** adopted Fixed Satellite Service (FSS) allocations above 3 GHz, for the LEO and MEO constellations providing high-speed broadband connectivity globally. These allocations are now being targets by the new mega-constellations of the 2010/2020s, such as OneWeb and SpaceX.

For the latter allocations, the ITU also adopted regulatory provisions in the ITU Radio Regulations which allow the non-geostationary satellite systems the operations of their constellations within the same frequency bands as that of the geo-stationary satellite systems.

Some of these provisions are footnote No. 5.484A (similar footnote provisions also exist for other FSS bands (e.g., in C- and V-bands)), which states that (see Article 5, in Volume 1 of the ITU Radio Regulations):

> **5.484A** The use of the bands 10.95–11.2 GHz (space-to-Earth), 11.45–11.7 GHz (space-to-Earth), 11.7–12.2 GHz (space-to-Earth) in Region 2, 12.2–12.75 GHz (space-to-Earth) in Region 3, 12.5–12.75 GHz (space-to-Earth) in Region 1, 13.75–14.5 GHz (Earth-to-space), 17.8–18.6 GHz (space-to-Earth), 19.7–20.2 GHz (space-to-Earth), 27.5–28.6 GHz (Earth-to-space), 29.5–30 GHz (Earth-to-space) by a non-geostationary-satellite system in the fixed-satellite service is subject to application of the provisions of No. **9.12** for coordination with other non-geostationary-satellite systems in the fixed-satellite service. Non-geostationary-satellite systems in the fixed-satellite service shall not claim protection from geostationary-satellite networks in the fixed-satellite service operating in accordance with the Radio Regulations, irrespective of the dates of receipt by the Bureau of the complete coordination or notification information, as appropriate, for the non-geostationary-satellite systems in the fixed-satellite service and of the complete coordination or notification information, as appropriate, for the geostationary-satellite networks, and No. **5.43A** does not apply. Non-geostationary satellite systems in the fixed-satellite service in the above bands shall be operated in such a way that any unacceptable interference that may occur during their operation shall be rapidly eliminated. (WRC-2000)

Thus, this footnote states that non-geostationary satellite systems:

- Are operating under the Fixed Satellite Service (FSS), thus given the same priority rights vis-à-vis any other ITU service operating in the same frequency allocation
- Must protect and must not claim protection from geostationary satellite systems. In relation to the former, non-geostationary satellite system must comply with the equivalent power flux density limits given in Article 22 of the ITU Radio Regulations (see also Resolution 76 (WRC-15) of Volume 3 of the ITU Radio Regulations)
- Must share the allocation and coordinate on the basis of the ITU Radio Regulations

WRC2019 Milestone Rules for Non-geostationary Constellations

The World Radio Conference-2019 has developed new rules for non-geostationary, constellations under the standing agenda item 7, that come into force on 1/1/2021. These new regulations, in general, can be summarized as follows (not taking into account any transitional measures adopted for satellite filings filed and brought into use before 1/1/2021):

- A satellite filing of a non-geostationary constellation can be brought into use and notified within 7 years of being submitted to the ITU by the launch of a single satellite capable to transmit the assignments notified (A filing has an expiry date of 7 years from its submission, and a satellite must be launched and reach the intended orbit before such expiry date. If the satellite is launched and reached the intended orbit on the date before its date of expiry, the notifying administration will have another 120 days (composed of a 90 days of continuous operations at the intended orbit, plus an additional administrative period of 30 days) to notify the bringing into use of the satellite(s)). At this point, when the milestone process kicks in from the date T equal to the date when the satellite filing exprires;

- Within 2 years of the end of the regulatory period of the satellite filing (i.e., time T +2 years), 10% of the satellites of the constellation must have been launched, or failing that the difference in number between launched satellites and 10% of those filed loses priority;
- Within 3 years after that (i.e., time T+5 years), 50% of satellites of the constellation must be launched, or failing that the difference in number of satellites loses priority;
- Within 2 years after that (i.e., time T + 7 years), 100% of satellite of the constellation must be launched, or failing that the difference in number loses priority.

Fees for Satellite Filings

The ITU Council in 2019 discussed and modified Decision 482 (i.e., **Document C19/143-E**, Decision 482 "Implementation of cost recovery for satellite network filings," 20 June 2019), which provides information on the cost recovery fees by the ITU-R for all satellite filing submissions and notifications (note: The ITU Council is the interim governing body of the ITU, which meets every year and operates under delegation from the ITU Plenipotentiary Conference (see the ITU Constitution and Convention at https://www.itu.int/en/history/Pages/ConstitutionAndConvention.aspx)). For example, a typical non-geostationary filing submission may generally cost the satellite operator around 25,000 CHF and notification of around 50,000 CHF (cost varies based on the number of units and submitted forms; see the above mentioned Decision 482).

The ITU cost recovery is in addition to what the notifying administration (Term used by the ITU-R for the Member States of the ITU that submit the satellite filings) charges for the management of the satellite filings. This charge (and the management of satellite filings) is different from country to country. At the national level, fees for the management of satellite filings differ, with cost for submission of filings which could range from a total of € 20,000 in France (and no annual fees thereafter) to a much higher figure of the USA of US$471,675 (with an annual fee of US$122,775). The cost will differ also from the type of satellite mission, for example, the cost for amateur, or CubeSat-type satellites will differ than that of a constellation of larger-sized satellites.

5.2 Landing Rights

5.2.1 Definition

This term is often misused and can mean different things to different people. Also, while some countries specifically mention the word "landing rights" into their regulations, others do not, but still in practice, the practice or requirement has the same objective.

For clarity, the words "landing rights" are defined as:

> any regulatory requirement, or regulations, that allow the transmission and receptions of radio frequencies or signals of a space station to land at, or be received from, a given country.

“Landing rights” are not related to the authorizations of ground equipment transmissions or receptions, although the term landing rights can be confused with this process. Ground equipment requires additional or other regulatory approvals that are to be addressed separately below.

The term “landing rights” is used differently from country to country, and this may range from:

- Landing rights in Indonesia (We understand that the FCC has announced a major reduction in fees, at least for small companies and with an expedited processing procedure; see https://spacenews.com/op-ed-streamlined-fcc-licensing-a-big-deal-for-smallsats/)
- Satellite operating license for a foreign satellite in India (see https://www.isro.gov.in/sites/default/files/article-files/indias-space-policy-0/satcom-ngp.pdf)
- Space station frequency license in China (Article 30 of the Regulations of the People’s Republic of China on the Management of Radio Operation, first published on September 11, 1993)
- Registration of foreign space objects in Australia (see Australia’s Foreign Space Object Determination, https://www.legislation.gov.au/Details/F2018C00844)
- Market Access Grant of the FCC (see Approved Space Station List of the FCC, https://www.fcc.gov/approved-space-station-list)
- Network authorization, in some other countries

Overall the objective for a national regulatory authority is to regulate foreign satellite operators that can enter their national market. Some do this to protect the local industry (e.g., USA, India) others to know what space resources are available for their national infrastructure (e.g., Australia) while others for security purposes (e.g., China).

In general, not many countries of the world require these landing rights; from the author’s regulatory experience over the past 25 years, it is known that the number of countries requiring these landing rights is less than 40 of the 220 regulatory jurisdictions of the world.

5.2.2 Regulatory Conditions for Landing Rights

Regulatory conditions for the landing rights as discussed above, in the nearly 40 countries of the world that require these, will vary from country to country. Some examples are given in the following Table 2.

5.3 Spectrum Use and Authorizations

It has been shown above that the ITU affirms that spectrum is a natural resource and that it “*must be used rationally, efficiently, and economically.*” Hence, through the

Table 2 Some countries and examples of the regulatory conditions for satellite system operation

Country	Type	Regulatory conditions	Fees	Difficulty
Australia	Registration	None	None	None
China	Frequency license	ITU coordination with all Chinese satellite operators	None	High Requires a strong national partner
India	Operating license	Of national value or lack of Indian capacity	None	Medium-high Access granted if no other Indian system is available
Indonesia	Landing rights	Local partnership	Unknown	Medium Requires a national partner
USA	Market access	Serve the public interest Open processing round for other applicants Show sharing with others	Post a surety bond (US$ 5 million) in satisfaction of FCC Part 25 rules Paid back through milestones	Medium May restrict the use of spectrum utilized

inception of national regulations, the main aim of any national authority should be to control the assignment of spectrum to national users and operators, so that spectrum is used efficiently and does not cause harmful interference. However, such process may not ensure that spectrum is effectively utilized to its fullest, and, nowadays, regulators of many countries have adopted new principles for assigning spectrum, for example, the use of market spectrum pricing approach, or even spectrum auctions.

However, for the satellite communications, whose operational reach is beyond country's borders and whose operations of satellite platforms rely on the same conditions globally, a well-defined and easily controlled spectrum management approach is still required. This is even more the case because spectrum, between satellite operators, can be shared and a market based spectrum assignment could create unnecessary monopolies detrimental to competition.

As such, the authorization regime for satellite communications still relies on a spectrum management approach licensing and at lowest fees possible.

The type of authorizations required at the ground for a non-geostationary constellation is no different than that of a geostationary, and countries are encouraged to expand their current geostationary regulations to non-geostationary. However, such approach has several problems, such as spectrum assignment, and spectrum fees are transacted on a one-to-one basis for non-geostationary platforms. This does

Table 3 Differences in approaches used by geostationary and non-geostationary systems

	Geostationary	Non-geostationary
Equipment spectrum use	10 MHz	100 MHz
Equipment data rates	1 Mbps	50 Mbps
Emitted power levels (EIRP)	60 dBW per antenna	37 dBW per antenna
Elevation angles	20° (low)	60° (high)
Business models	Usually for use by an individual user or company	Usually for a multiuser use

not work well because non-geostationary satellite systems operate at a different business model and at different operational, technical, and business models than that of the old geostationary systems.

Some examples of technical and business parameters of equipment used by geostationary versus non-geostationary systems are provided in Table 3.

Below are some additional licensing information on satellite terminals and gateway stations/hubs.

5.3.1 Satellite Terminal Licensing and Spectrum Use

As shown in Fig. 1, at the beginning of this regulatory section, there is a service segment on the ground, which provides the connectivity to end users and businesses in a given country.

The satellite equipment of this segment is what links (through radio waves) the end user devices and the satellite system.

Because the satellite equipment, such a an antenna with its receiver/transmitter unit, is a radio station utilizing radio resources it is then captured by the national regulations (or telecom law) on electronic equipment. Such regulation will form part of a national regulatory regime which may require:

- **An authorization or license** for the **sale and installation of the satellite equipment** (e.g., in India, Indonesia), which will either be under a license exemption or an individual/blanket license (In proper English the noun is spelled as "licence," while the verb is as "license," while in the US English, it is distinguishable as "license.").
- **An authorization or license for the use of the spectrum** (e.g., in certain European countries, China, India), which will either be under a license exemption or an individual/blanket license. It is usual in some countries (e.g., in Europe) that a license exemption regime exists, whereby satellite terminals do not require a license, and as such they will not be afforded protection.
- **An equipment type approval** (in almost every country of the world) **for the distribution, circulation, and sale of the equipment to the public**. In the European Union, this is governed by the Radio Equipment Directive (see, https://ec.europa.eu/growth/sectors/electrical-engineering/red-directive_en), and the type approval of the equipment will result in a marking with a "CE" symbol. Similarly for the FCC marking. Countries around the world usually recognize

equipment markings developed by other countries. However, the equipment may still require a type approval certificate from a local laboratory (e.g., China, India, Russia).

- **An associated ITU satellite filing**, which assures the regulatory authority that the satellite system exists.
- **A landing rights license** (only for certain countries).
- And sometimes the need to **coordinate the spectrum use** with terrestrial services which may share the same band. Usually if terrestrial services exist in a particular band, these will be licensed on an individual basis and thus will be afforded protection from the satellite services.

Additionally, the service provider in the country may also require additional licensing, such as a **business license** (e.g., in China. This is pretty much a requirement in many countries) which allows him to provide services to the public and businesses.

In terms of fees for these regulatory instruments, these can vary from country to country: from a zero or small administrative fee, such as is the case in certain countries (for certain satellite services and equipment) through a proper statutory instrument which exempts these from an authorization, usually by complying to specific technical requirements (usually derived from the CEPT/ECC Decisions which establish conditions for equipment and services to be license exempted) which assures the regulator that the equipment does not cause harmful interference. This is usual in the CEPT/EU, where the regime is such that equipment which complies with certain technical requirement that assures that the equipment does not cause harmful interference to other services and/or equipment. See also the EU Authorization Directive and the “general authorization” conditions, such as “The aim is to harmonise the market for electronic communications networks and services by limiting regulation to the minimum necessary. The main innovation is the replacement of individual licences by a general authorisation for all electronic communications networks or services, alongside a special scheme for attributing frequencies and numbers. Thus the provision of electronic communications networks or services may only be subject to a general authorisation without the need to obtain an explicit decision or any other administrative act by the national regulatory authority (NRA), thus limiting the procedure to just one notification for the companies concerned.” (See https://www.ecodocdb.dk/document/category/ECC_Decisions?status=ACTIVE.)

- To a large fee, usually liked to revenues generated in a country by the satellite service provider or to the amount of spectrum occupied and/or a fee for the Universal Service Obligation Fund (usually in the range of 1–2% of national revenue). This is usual in developing countries (e.g., in Asia and Africa) where certain telecommunication services or certain geographical areas of the country may require the state to intervene and invest in the infrastructure.

5.3.2 Earth Stations' Licensing

Also, from Fig. 1, the necessity to place the gateway stations (used for feeder link or TT&C purposes; also known as "hubs" for some type of services) in certain countries of the world has been shown. Such stations serve the purpose to relay the user information back to Earth and then to the cable/fiber access points in that country that relays back the information to the service operators, which usually are different than the satellite operator of the non-geostationary constellation.

As gateway stations transmit radio signals to and from the satellite(s) from a fixed location on the ground, usually through a very large infrastructure, connected to an international fiber cable, will be captured by many licensing regulations, including those for radio spectrum and radio equipment.

Unlike the satellite terminals discussed above, these Earth stations may not require the same kind of authorizations and radio technical conditions. This is because these fixed stations are fixed to the ground and are unique.

Usually the placement of these gateways is purely decided from an engineering perspective; the best location for the satellite link is where existing telecommunication sites called Teleports exist. However, the reality is slightly different, and political and national laws intervene where such Earth stations may be placed or required for specific purposes. While in most countries of the world this selection is purely based on an engineering choice, some countries will require an Earth station gateway in their country, for example, USA, Russia, India, China, and Brazil.

Licensing of Gateway Earth Stations

Putting this aside, the regulatory requirements of gateways are usually as follows:

- Landing rights
- Spectrum authorization or license
- Spurious emission limits
- Frequency coordination with terrestrial services

All of these are the same authorizations required for the satellite terminals for the service segment. Some differences exist, and these are physical and business:

- From a physical perspective, these Earth stations can be quite large, from about 3 m in diameter (in Ka-band) to even more than 30 m (for C-band frequencies). The reason lays on the purpose of these stations, being to carry all the traffic on a satellite through the feeder link, which is generated by thousands and possibly hundreds of thousands of terminals at the service link. This also means that you may not need many of such stations around the Earth. Usually one will suffice for each geostationary satellite and thus usually one per non-geostationary satellite.
- From a business perspective, these Earth stations are part of the satellite infrastructure, very much like the cables of a mobile telecommunication service, where such cables connect the radio masts to the central operating system, in satellite jargon called the Network Control Center (see Fig. 1). Hence this private-

Table 4 Differences in license fees for fixed gateway Earth Station in some countries

Country	Fee per year
UK	Based on the Earth station parameters and the amount of spectrum occupied. For a typical Earth station with a 1 GHz occupation, the fee is around GBP 5,000 (6,500 US$) per year[a]
Italy	Spectrum fees at a maximum of € 22,200 (19,645 US$) per year per site Additional administrative fees are applicable[b]
Australia	Depends on the location of the facility, i.e., for 1000 MHz of spectrum, the spectrum fee per year is: High density: 194,200 AUS (128,609 US$) Medium density: 30,500 AUS (20,198 US$) Low density: 3,200 AUS (2,119 US$)[c]
South Africa	RAND 2344 (147 US$) per MHz RAND minimum R58 596.00 (3,662 US$) per hub station[d]
USA	$325 per license $325 for each hub[e]

[e] See https://docs.fcc.gov/public/attachments/DOC-353885A1.pdf

based infrastructure is not generating business but a pure physical part of the satellite network.

From research done by the author, license fees for gateway Earth Stations vary from country to country. A small taste of such fees is provided in Table 4.

Sharing with Terrestrial Radio Systems

From a radio perspective, these Earth stations need to be operating at certain frequency allocations, usually, in the ITU jargon, the Fixed Satellite Service. Depending on the amount of spectrum required and the design of the satellite system, Ku- and Ka-bands are quite apt to accommodate these stations, even if these bands are shared with terrestrial services.

When it comes to sharing with the terrestrial services, usually point-to-point microwave links operating under the ITU's Fixed Service, these large Earth stations will usually be able to coordinate easily with such terrestrial equipment. This is because Earth station antennas are very large, they will have extremely small beamwidth, and they are pointed to the sky toward the satellite, while microwave link antennas are also with small antenna beamwidth and will point horizontally. In such physical reality, it will be possible to operate closely without causing harmful interference to both systems.

Unlikely to the satellite terminals of the service link, gateway station license will be for an individual antenna and will be afforded protection from any radio equipment which may be deployed afterward.

Table 5 Frequency allocations for different frequency bands

Band	Receive frequency	Transmit frequency
C-band	3600–4200 MHz	5950–7075 MHz
Ku-band	10.7–12.75 GHz	12.75–13.25 GHz 13.75–14.0 GHz 14.0–14.5 GHz
Ka-band	17.7–18.6 GHz 18.8–20.2 GHz	27.5–30.0 GHz
Q/V-band (not yet commercially used but new uses are now pending)	37.5–42.5 GHz	42.5–43.5 GHz 47.2–50.2 GHz 50.5–51.4 GHz

More difficult is the sharing with terrestrial systems that are mobile, because the location of the latter is unknown a priori. However, sharing can still be possible through particular technical means.

TT&C Earth Stations' Licensing

TT&C Earth stations (see Fig. 1) are similar to the gateway Earth stations that carry feeder link data. However, as explained in the section "Different Satellite Links," their purpose is much more limited but extremely important because the control and monitoring of the satellite is done through these links.

Their licensing is similar to the gateway licensing and possibly easier because their spectral occupancy is much smaller.

Spectrum Allocations for Gateway Earth Stations for Non-geostationary Systems

The typical spectrum allocations for feeder link and TT&C Earth stations are as provided below (see ITU Article 5 of the Radio Regulations; see Table 5).

These allocations can be used for the provision of feeder link and TT&C services of non-geostationary satellite systems. Their coordination is done through the Article 9 of the ITU Radio Regulations.

6 Conclusion

This article, although it provides useful details, does not represent an exhaustive explanation of the regulatory and licensing requirements for non-geostationary satellite systems. Indeed because of the complexity of satellite networks and their regulatory frame, the rules and regulations are never static and are indeed constantly evolving. Also, it doesn't cover other complex regulations and licensing requried by outer space activities, such as the launch and the operations of satellites.

The complexity of the process to obtain frequency allocations and ensure that satellite transmissions do not interfere with other satellites, terrestrial systems, or other systems such as aeronautical-related transmissions or high-altitude platform systems is a very difficult and challenging process. And beyond the technical and operational challenges, there are regulatory requirements related to taxation and tariffs to be met. There are constantly new standards, regulations, or authorization of other types as well. These may well relate to concerns about privacy, money laundering, cyber security, policing, or national security. The basic requirements to obtain key licensing and authorizations have been covered in this brief article, but it must be noted that there are constantly emerging new regulatory requirements and the level of complexity involved only seems to increase.

1960s and 1970s. This process resulted in the negotiation and creation and implementation of the Outer Space Treaty and four additional subsidiary binding instruments. Quite understandably, these twentieth-century agreements did not anticipate many of the latest developments in space technology and systems that have arisen in the twenty-first century. One of the most significant developments in recent years is the development of small satellite technology and systems that can be designed, manufactured, and launched at much lower cost. The international space law that was agreed a half century ago is in some way not sufficient to specifically address all of the issues associated with deployment of large number of small satellites. These issues include a number of concerns related to frequency allocations and interference, removal or deorbit of small satellites at end of life, space situational awareness and space traffic control, and other concerns related to the safety of space systems in Earth orbit.

The processes of agreeing international space law are complex and are based on achieving global consensus and thus tend to be quite slow. By contrast, the current pace at which small satellites are being developed and launched is accelerating each year. This raises concerns about space safety and the avoidance of collisions in space, as well as increased levels of frequency interference. The complexities associated with achieving new levels of international agreement suggest that many of these safety, frequency interference, and improved space situational awareness and space traffic management issues will need to be addressed at the national regulatory level – especially with regard to small satellites. In this regard, issues related to the deployment of the so-called mega-constellations and removal of these satellites at the end of life are perhaps among the most urgent.

This chapter explores the background of international law and regulation with regard to the launch of satellites into Earth orbit, and especially with regard to the increasing number of small satellites that are now being launched or planned for deployment. It also suggests that national regulatory controls and safety measures to prevent the excessive buildup of space debris and increased frequency interference will be the critical near-term solution to these emerging problems. In addition, some form of "soft law" guidelines and informally agreed measures at the international level might also be helpful.

1 Introduction

On 2 September 2019, the European Space Agency (ESA) performed what it referred to as a “collision avoidance maneuver” – in layman’s terms, a change of course – of its low Earth orbit observation satellite Aeolus, (https://www.esa.int/Our_Activities/Operations/Aeolus_operations 2019) in order to avoid a potentially catastrophic collision with a SpaceX Starlink satellite. This Aeolus satellite had a mass of 1.3 tons when launched in August 2018 and thus was a substantial target. The Starlink satellite is known as Starlink 44 – represents one of some 60 satellites launched by SpaceX on 23 May 2019 as the initial phase of the constellation. This satellite with a mass of 227 kg when launched is substantially less massive than the Aeolus satellite, but a collision would have created thousands of new debris elements. While such evasive actions are not unheard of, the unique aspect of this event was that it was the first time that an operator had found it necessary to undertake such a maneuver to mitigate against the possibility of a conjunction with a small satellite that is part of a small satellite “constellation.”

Small satellite (“mega-”) constellations can be thought of as fleets of hundreds and perhaps even thousands (https://www.spacex.com/sites/spacex/files/starlink_-press_kit.pdf 2019) of spacecraft working together in orbit. Typically, they will comprise “small” or “nano-’ satellites, albeit that those terms are not strictly defined and are generally thought to include space objects ranging from tiny “femto-’ satellites weighing less than 100 gm to those “mini” satellites weighing up to 500–1000 kg, and everything in between (at this stage, most small satellites seem to be at the lower end of the scale).

For various reasons outlined below, small satellite constellations are expected to become a significant feature of space activities over the next few years and thus will give rise to a disproportionately large increase in the number of space objects that operate within the Earth’s space environment.

While such objects are much smaller than the average low Earth orbiting satellite, given the required orbital velocity necessary for them to remain in space, they are still large enough to cause serious damage to other (larger) spacecraft supplying important services such as Earth observation and meteorology. This has not escaped the attention of the national and international authorities, and there is the risk of a backlash from the established players concerned about the potential increase in collision risk from the additional number of small objects in low Earth orbit.

As the number of satellites in space dramatically increases, close approaches between two operated spacecraft will occur more frequently. In contrast to potential conjunctions with space debris – nonfunctional objects including dead satellites and fragments from past collisions – these require coordination efforts between the respective operators to avoid conflicting actions and, ultimately, collision avoidance maneuvers of the type conducted by ESA in situations of high potential disaster.

The Aeolus/Starlink 44 incident will, therefore, add further fuel to the increasingly strident debate that is emerging about the risks and opportunities that this technology gives rise to. It seems that the advent of small satellite constellations is inevitable, at least from the perspective of industry, even in the absence of clear prohibiting regulation; thus it is important to understand the major relevant legal issues related to this development. These issues are discussed in this chapter.

2 The Evolutionary Events that Have Led to Small Satellite Constellations

Since the launch of Sputnik 1, the first human-made space object to orbit the Earth, there has been a breathtaking and seemingly endless development of space-related technologies. Humankind is now engaged in a multitude of space activities far beyond the contemplation of those involved at that time. The utilization of space technology now forms a crucial part of everyday society in all parts of the globe – irrespective of the (geo)political, economic, societal, and cultural characteristics of any one country.

Simply put, our reliance on space technology is such that the world would cease to function in many respects without constant and unimpeded access to space, and this imperative is likely to become even more pronounced for future generations. This has primarily been driven by the increasing “commercialization” of outer space.

Yet, as is well known, there remains a vast gulf between the space capabilities of the relatively small number of space “powers” and the rest of the world. It has been estimated that approximately up to 60–70 States currently possess some form of direct indigenous space capability, although the extent that they are able to utilize space for their own development (and other) purposes varies quite significantly. Of course, this also means that perhaps up to 130–140 States thus far do not possess *any* independent indigenous capability to directly access space themselves, despite their reliance on the technology for many aspects of their functioning and development. These countries are instead totally dependent on others for their space access, which therefore impacts upon their space independence and national security and may well also impede opportunities for creativity, innovation, industrial development, and progress among their citizens.

The reality is that their access to satellite data and the ability to utilize vital space technology in a crisis would be largely dependent on and subject to the strength and enforceability of their existing contractual relationships and political ties. Given the changing nature of international (geo)politics, it seems that reliance upon historical and traditional strategic links, or pre-agreed international arrangements, may be more prone to uncertainty and difficulties than ever before.

This invariably operates within the space arena as well – the combination of factors arising from any State’s growing reliance on space assets and space-related data and intelligence, coupled with its increasing focus on maintaining sovereign independence and capability in areas of critical infrastructure, means that any country will seek out ways in which it can be more self-reliant in its interaction with space activities.

It is in this context that the recent development and adaptation of small satellite technology potentially represents a paradigm shift in the way humankind accesses space. These satellites are usually cheaper and less complex to develop, build, and launch than conventional (large) satellites. They therefore open up the possibilities for a significantly greater degree of space access to a much larger range of States and their space "actors." Initially, groups such as university students and nonprofit organizations in both developed and developing countries increasingly have become involved in space through these means. In many countries, the development of this technology may represent an important precursor to the establishment of indigenous and independent space programs in States that previously were not in a position to consider such activities.

In effect, by eliminating some significant barriers to entry, small satellite technology may facilitate capacity building, broader collaborative opportunities and education/training programs, as well as bridging (some) technology gaps, for hitherto "non-space-faring" States. It will also open up even more diverse commercial opportunities for a much broader range of potential service providers and, generally, "bring space to more people."

But more than that, significantly, as the technology has been developed even further, it has also opened the door also to "traditional" users of outer space – including both States and private commercial entities – to utilize it for existing as well as new purposes. This has served to broaden the scope of their capability at a significantly lower relative cost, which may present some interesting and potentially lucrative commercial opportunities. Of course, this is subject to the development of feasible and achievable business cases – although the fact that several large corporations are proceeding down this path seems to suggest that this is possible.

In addition, this has and will require a mind-shift on the part of existing space actors, as they grapple with whether and how to adapt to this relatively new technology and adjust their activities to the challenges posed by the potential for new market entrants. Yet, as is clear from the announced plans of companies such as SpaceX, One Web (2019), Planet (2019), Amazon (Sheetz 2019), and others, it is an opportunity that is being embraced in significant terms.

As a consequence, the increasing advent of this technology is already redefining the landscape of many activities in space. This new space paradigm will not see the end of more traditional satellite technology since, naturally, small satellite technology will not quench our insatiable demand for all that space can provide. However, it does open up a plethora of possibilities, many of which we are simply not in a position to comprehend or even imagine at this point. In this regard, one might liken the potential of small satellites to the way that mobile phones have revolutionized terrestrial communication activities. We simply do not know where this technology might ultimately lead and what it will allow us to do. However, we can confidently expect that it will open the door to an even more expansive array of profitable commercial opportunities.

Thus, from a technological perspective at least, small satellite technology most likely represents a "win-win" possibility that enhances the momentum for change and further promotes commercial space activities. Indeed, in many respects, this has been the primary motivation for both developers and users thus far. As with many aspects related to the exploration and use of outer space, the technology continues to move forward at a rapid pace without sufficient attention being paid to the regulatory consequences and requirements. It is therefore important not to be too caught up in this wave of optimism and innovation, without at least also considering how these developments coexist with the current international regulatory framework, which has largely been designed to govern those space activities carried on through the utilization of “big” satellite technology.

Moreover, the fact that small satellite constellations allow greater access to space for more people does not necessarily translate into an adherence to responsible space behavior. Indeed, it may have the opposite effect, particularly if the regulatory regime is not specifically relevant, appropriate, and/or respected. This, of course, gives rise to immediate questions as to what the major issues are and what the current regulatory framework has to say about these. From there one has to then consider whether a sui generis set of prescriptive rules, principles, or standards should be developed and made applicable to small satellite constellations.

The purpose of this chapter is therefore to take pause and reflect on various regulatory requirements and challenges posed by the existing international legal regime in relation to the use of small satellite technology to develop constellations. While many of the users of this technology are no doubt cognizant of these requirements, it is this author’s experience that many are not; or, put another way, they do not consider the regulatory issues with the same degree of attention as they do the technical factors.

What this discussion will highlight is the fact that the existing legal framework was not designed with small satellite technology specifically in mind. As a result, further regulation will most likely be required – particularly at the national level – and this will necessitate a “balancing” of sometimes competing interests between protecting the State from potentially very significant liability on the one hand and encouraging innovation and research and development on the other.

Coupled with these considerations, the increasingly crucial notion of responsible space behavior must also play a part in determining how to address some of these specific issues. Although the discussion below focuses on the current regulatory requirements, it leads to the conclusion that the design of future legal regimes to deal specifically with small satellite technology will necessitate some fundamental policy decisions by national lawmakers and regulatory bodies.

3 The Current International Legal Framework and Regulatory Requirements

The international regulation of the exploration and use of outer space is primarily based upon a series of five United Nations Space Treaties. These are (i) 1967 Treaty on Principles Governing the Activities of States in the Exploration and Use of Outer Space, including the Moon and Other Celestial Bodies, 610 U.N.T.S. 205 (Outer Space Treaty); (ii) 1968 Agreement on the Rescue of Astronauts, the Return of Astronauts and the Return of Objects Launched into Outer Space, 672 U.N.T.S. 119 (Rescue Agreement); (iii) 1972 Convention on International Liability for Damage Caused by Space Objects, 961 U.N.T.S. 187 (Liability Convention); (iv) 1975 Convention on Registration of Objects Launched into Outer Space, 1023 U.N.T.S.

15 (Registration Agreement); and (v) 1979 Agreement Governing the Activities of States on the Moon and Other Celestial Bodies, 1363 U.N.T.S 3 (Moon Agreement).

Also of importance are several General Assembly principles: (i) 1963 Declaration of Legal Principles Governing the Activities of States in the Exploration and Use of Outer Space, United Nations General Assembly Resolution No 1962; (ii) 1982 Principles Governing the Use by States of Artificial Earth Satellites for International Direct Television Broadcasting, United Nations General Assembly Resolution No 37/92; (iii) 1986 Principles Relating to Remote Sensing of the Earth from Outer Space, United Nations General Assembly Resolution No 41/65; (iv) 1992 Principles Relevant to the Use of Nuclear Power Sources in Outer Space, United Nations General Assembly Resolution No 47/68; and (v) 1996 Declaration on International Cooperation in the Exploration and Use of Outer Space for the Benefit and in the Interest of All States, Taking into Particular Account the Needs of Developing Countries, United Nations General Assembly Resolution No 51/122.

The treaties in particular set out a number of fundamental rules, imposing various obligations on States parties, some of which are also regarded as representing customary international law (Hobe et al. 2009).

Those States that are parties to the major United Nations Space Treaties are subject to various obligations that logically point to the need to develop national space law (Freeland 2012) to regulate those private entities within their respective jurisdiction that engage or wish to engage in "national activities in outer space."(Outer Space Treaty, Article VI) More and more States are therefore promulgating national space laws to "transform" these international obligations into their respective domestic legal spheres. The status of these various national space laws as reported here are not necessarily up-to-date for those countries, nor comprehensive in its coverage. For example, in December 2017, the New Zealand Outer Space and High-altitude Activities Act 2019 came into force in that country. Quite a number of other States have also finalized or are in the process of developing their own national space legislative framework (United Nations Office of Outer Space Affairs (UNOOSA) 2019).

Given that the advent of small satellite technology presents opportunities for hitherto non-space-faring States to engage in space activities, it may well be that the development of such technology in a particular country may "pre-date" any specific applicable national laws. Thus, the possibilities of greater access to this technology may be a driving force in the enactment of a further "wave" of national space law in various countries – for example, as was the case in Austria, which enacted its national space law in late 2011 (Freeland et al. 2018). Another example is the Austrian Outer Space Act 2011, which entered into force in December of that year and was introduced largely in response to the development of small satellite programs by a number of Austrian universities, and the impending launch of two Austrian-built small satellites, which were eventually launched from India into low Earth orbit in February 2013.

In certain respects, therefore, the development of national space law represents a major growth "industry" for space professionals and government regulators.

It should be noted that, in addition to these various instruments, and possibly also to supplement any perceived "gaps," there have recently been an increasing number of "soft-law" guidelines concluded that also relate to the conduct of particular activities in outer space. This has been for several reasons, partly related to the strategic and political nature of space, which has made the finalization of internationally binding treaties more difficult to achieve (Marboe 2012). Given the current increasingly competitive geopolitical environment between the major powers, these difficulties will, if anything, be further exacerbated.

This chapter will refer primarily to existing "hard-law" regulatory requirements that flow from the United Nations Space Treaties – although reference will be made to one important set of voluntary guidelines – from the perspective of how they may relate to the use of small satellites and seek to raise some pertinent questions that arise from their applicability. It is not intended in this chapter to be exhaustive in this regard or comprehensive as to all precise details, but rather to raise the more significant issues and the challenges they pose. This will also serve to highlight the importance of properly addressing the reality of small satellite constellations by way of specifically directed regulation, given that the use of small satellite technology, and the "management" of these constellations, will most likely continue to grow exponentially into the future.

4 International Regulatory Requirements for Deployment and Operation of Space Systems

Some of these (international) regulatory requirements are as follows.

4.1 International Responsibility: Authorization and Supervision

As noted above, the regime for space activities is structured on the basis that States bear international responsibility for "national activities in outer space," including when such activities are carried on by nongovernmental entities. While there is no precise definition in the Outer Space Treaty as to what constitutes a "national" activity, the terms of the domestic space law of a particular State will clarify the scope of activities to which it refers – in essence, representing an interpretation by the drafters of that legislation as to what they regard as constituting national activities in outer space, at least for the purposes of the specific domestic law.

A review of existing national space legislation indicates that, in most cases, States have legislated for the regulation of space activities based on the "territoriality" of the activity (i.e., where an activity, e.g., a launch, involves the territory of that State), in accordance with general international law principles of jurisdiction. In addition, many States that have national space law also regulate space activities based on the nationality of the space actor (i.e., the person/entity engaged in the space activity).

For example, one of the express objects of the Australian Space (Launches and Returns) Act 2018 is:

> to establish a system for the regulation of space activities carried on either from Australia or by Australian nationals outside Australia. . .

Thus, a launch of a small satellite in Australia by any private person or entity will in all likelihood engage the international responsibility of that State under the Outer Space Treaty, as will the involvement of that person/entity in a small satellite program – for example, the QB50 program. Under this program the satellites were launched from outside Australia. In these circumstances, therefore, (international) responsibility under the Outer Space Treaty is interpreted as extending to extraterritorial activities and is applied under the general international law concept of "nationality." (One such example is the involvement of a number of Australian universities in the QB50 mission, which involved the launching in 2017 of a network of 36 "CubeSats" built by universities all over the world, with the aim of performing various scientific experiments in the lower thermosphere at an altitude of approximately 320 kilometers. Twenty-eight of these small satellites were deployed from the International Space Station in May 2017 and eight from India in June 2017.)

Article VI of the Outer Space Treaty goes on to require that the "appropriate State" – which is thought by most commentators to refer to the State whose national activity it is – undertake the "authorization and continuing supervision" of such activities. Typically, the authorization of space activities is implemented by way of a licensing regime established under national law (at least for those States with specific domestic space legislation) (Freeland 2010). This can be through the creation of a comprehensive "one-size-fits-all" license regime or, more likely, via the establishment of different forms of license, depending upon the particular space activity for which authorization is being sought.

For example, the Australian Space (Launches and Returns) Act 2018 specifies a number of different licenses to deal with specific space activities, including an "Australian Launch Permit" for launches from Australian territory and an "Overseas Payload Permit" for launches of a space object by an Australian national from outside of Australia.

In relation to the use of small satellites, there is little conjecture that their launch/deployment and use do, indeed, constitute a space activity. Moreover, the satellite itself would in most circumstances be a space object for the purposes of international space law – including for the purposes of the Liability Convention, as well as the national law of most countries. Activities involving small satellites therefore would typically fall within the scope of Article VI of the Outer Space Treaty.

This in itself is not surprising, but must be taken into account, particularly by those wishing to engage in "experimental" and "amateur" small satellite activities. When it comes to sophisticated commercial operators, particularly those that are planning to launch/deploy small satellite constellations, one must assume that they are now familiar with this requirement. In any event, the reality is that those seeking to engage in small satellite activities, irrespective of where those satellites might be launched, should take careful note of the relevant national laws and apply for the requisite license (where applicable). As noted below, this might also have added consequences in terms of financial and liability concerns, as well as other aspects of conditionality.

Moreover, the requirement of continuing supervision on the part of the State may be quite complex. There is, for example, some conjecture as to how, in practice, the need for continuing supervision might be undertaken in circumstances where the relevant space activity is a cooperative venture between institutions in a number of States, such as the case with the QB50 project. Internal arrangements between the cooperating States should be put into place to allow for each State to, in some way, exercise a degree of supervision, at least in relation to those aspects of the activity (and over its nationals who may be involved in its ongoing operation) in which it has a specific interest.

Yet, even this presupposes that the institutions or persons engaged in the space activity have informed the relevant governmental agency of their involvement and have provided specific and comprehensive details as to the scope of the program, design, payload, issues of control, etc. The recent "tardigrades" incident on the moon illustrates precisely this point – it seems that, in this instance, one of the entities involved in the Beresheet mission allegedly failed to inform other relevant stakeholders about the fact that living organisms (tardigrades) were on board the space vehicle (Johnson et al. 2019).

Another example of the difficulties that could arise with respect to the authorization and continuing supervision obligations that arise through the Outer Space Treaty, and which involved a group of small satellites, is illustrated by the "Swarm Space Bees" incident in 2018. Four very small space objects were launched (from India) into low Earth orbit even though the relevant American regulatory authority, the Federal Communications Commission (FCC), had refused to grant authorization to the operator to proceed with the launch of those particular small satellites (Howell 2018). Although the company was ultimately fined for its actions, the case highlighted the problems that can arise when a space actor fails to comply with the relevant national regulatory requirements.

This incident also gives rise to interesting questions as to the extent of, in this case, the United States' liability under the international space regulatory framework had one of these unauthorized objects caused damage to another space object. This author has had informal discussions with officials from the United States' Administration, who confirmed that, from their perspective at least, the Liability Convention regime for fault liability (Liability Convention, Article III) would not apply, given that the Administration had exercised an authorization process (and decided *not* to authorize the launch) with respect to this group of small satellites. This is an issue that will no doubt be further debated by commentators.

Adding further to the complexity is the fact that many small satellites have, to date, not been designed with control systems, and therefore cannot be maneuvered once they are launched and operative. As a result, for these small satellites, as soon as they are placed in orbit, their position cannot be altered from Earth. This may also explain why the continuing supervision requirement may often have been disregarded, leaving the responsible State in a difficult position in terms of its obligations under the Outer Space Treaty. Of course, the features of more sophisticated satellites may change when they are a part of a commercial small satellite constellation that is required to perform more complex functions.

4.2 International Liability: National Indemnity Requirements

The general international liability provisions found in the Outer Space Treaty and the more detailed regime specified in the Liability Convention impose liability on a "launching State" for certain damage caused by a space object. There are no time limitations or caps on the amount of this liability under the Liability Convention, as long as it represents "damage" by a "space object" as those terms are defined for the purposes of that instrument.

Article VII of the Outer Space Treaty prescribes the general terms that give rise to international liability for damage caused by an object launched into outer space. The scope of international liability is then elaborated in the Liability Convention.

However, even if it is not a State Party to the Liability Convention, a State would still be subject to the liability provisions in the Outer Space Treaty, as well as any other potential claims under relevant general principles of public international law. Further, the identity of the relevant launching State(s) is determined at the time of launch, with Article I(c) of the Liability Convention defining a launching State as:

> (i) A State which launches or procures the launching of a space object;
> (ii) A State from whose territory or facility a space object is launched

Finally, Article I(a) of the Liability Convention defines "damage" as:

> . . .loss of life, personal injury or other impairment of health; or loss of or damage to property of States or of persons, natural or juridical, or property of international intergovernmental organizations.

It would be difficult, given this background to seek to argue that an operating small satellite was not a space object for the purposes of the Liability Convention, even if it is not maneuverable while in operation.

In the absence of specific indemnities in relation to claims by third parties, or where various exceptions and exonerations contained in the Liability Convention do not apply, a launching State will bear this international obligation of liability (Freeland 2001) even in circumstances where the space activity is undertaken by a nongovernmental entity and perhaps also even where the State may not be aware of the activity at all. On this point, there may be an argument that, where the only possible relevant mode by which a State could be a launching State in a specific case is by "procuring" the launch, there is a minimum "threshold" test to demonstrate whether there has in fact been a procuring, at least based on knowledge of the particular activity. However, it is unclear whether such an argument reflects the correct legal position.

This represents one compelling "incentive" for States to pass domestic space law. The enactment of national space law enables States to formalize domestic legal processes that would allow them to pass on financial responsibility to and recover from their national nongovernmental entities the full amount (or part thereof) of the damage for which the State may be liable at the international level, either under the international legal and regulatory framework for space activities or otherwise under international law.

Of course, this does not remove the international obligation of liability of a launching State under the Liability Convention – this contingent liability remains in place in relation to any space object for which a particular State is deemed to be a launching State. A well-known expression that is often used by teachers of space law is: "Once a launching State, always a launching State." However, it does enable the State to put in place a domestic mechanism by which it can transfer the financial "risk" associated with this potential international liability for third-party claims. Indeed, this is precisely the practice that a number of States have followed in their national laws in relation to "traditional" satellite technology.

As a consequence, national space legislation often attaches conditionality to the issue of a license to engage in a specific space activity, the practical effect of which is to require the applicant to provide or somehow procure an indemnity to the government for damage, although the amount may be subject to specific caps under the particular national law. Although it would be relatively straightforward to simply require the applicant in these circumstances to take out appropriate commercial insurance against third-party claims to the extent of the specified (maximum) damage, this would often be impractical (given the relative lack of depth of the international space insurance market) and, more specifically in the case of some small satellite operators, disproportionally costly. Under the Australian Space (Launches and Returns) (Insurance) Rules 2019 made under the Space (Launches and Returns) Act 2018, which also came into force on 31 August 2019, certain launch and return activities require zero insurance to be procured by an applicant, while for others, the specified minimum amount of insurance required is $100 million (Rule 6). For those activities that do require a specified amount of insurance, the Australian Space (Launches and Returns) Act 2018 envisages that, in certain circumstances, rather than satisfy those requirements, an applicant could instead show "direct financial responsibility" for the relevant launch or return as an alternative (section 47(b)).

Indeed, such a requirement might make the planned small satellite activity unaffordable, thus preventing it from going ahead at all, although this will obviously not be as much of a concern for those large corporations planning to embark on a small satellite constellation program.

For the less affluent small satellite operators, however, this could conceivably give rise to difficult considerations that would require a "balancing" between the protection of the State from potential financial liability and the desirability of encouraging expertise, research, and development, perhaps as a precursor to more profitable and commercial opportunities down the track.

Such potentially conflicting interests between a need for regulation on the one hand and the provision of incentives for new innovation on the other are not unique to the situation of small satellite operators. Indeed, similar arguments have been raised in relation to the requirement for the "equitable sharing of benefits" derived from the exploitation of natural resources under the Moon Agreement. Section 3(b)(i) of the Australian Space (Launches and Returns) Act 2018 refers to the need to consider inter alia "...the removal of barriers to participation in space activities and the encouragement of innovation and entrepreneurship in the space industry...."

However, unlike the Moon Agreement, virtually every space-faring State is a party to both the Outer Space Treaty and the Liability Convention – and, in any event, the liability regime they establish arguably is also reflective of customary international law. It is therefore incumbent on all States with an (potential) involvement in space to somehow address this issue.

The ideal scenario would be for the small satellite operator to negotiate with the relevant launch service provider for the provision of insurance cover and/or an indemnity by that provider (and perhaps also the government standing behind that provider) to the launching State and the payload owner, at least in relation to certain elements of potential third-party claims (again most likely subject to a cap). This is often the case in commercial launch service contract arrangements for large satellites. Some small satellite operators contend that the position is more complicated in the case of a collaborative small satellite program such as the QB50 project. However, the point remains that many such programs have proceeded without the issue even being raised with either the launch service provider or the intermediary arranging the launch. Potential operators of small satellite constellations should be aware of this preferable negotiating course of action when discussing their commercial contracts.

Once again, this is something that should be negotiated coincidentally with the development of the technical aspects of such a program. A failure to do so potentially not only places the launching State(s) in a difficult position but might also expose the institution or corporation supporting the small satellite operators to a real and unacceptable risk of liability. Obviously, this should be of practical concern to those involved, although one would likely assume that a large corporation planning a multimillion dollar small satellite constellation program will be sufficiently abreast of this issue to address it more comprehensively.

4.3 Registration: National and United Nations Registers

The Registration Convention provides for a two-pronged regime of registers that are relevant in respect to space objects that are launched inter alia "into earth orbit."(Registration Convention, Article II(1)) The State of Registry (as defined) is to maintain a national register in which such space objects are to be included and, in addition, shall provide certain specified information in relation to those objects to the United Nations, which itself maintains a central register (*Ibid*, Article IV(1)). In accordance with the terms of the Outer Space Treaty, the registration of a space object within a State's national register also has implications with regard to the "jurisdiction and control" of that object (Outer Space Treaty, Article VIII).

In situations where a State has not, for instance, previously been involved in launching activities, it may not have in place a national register nor a mechanism for the furnishing of the required information to the United Nations. There may be a time lag associated with the establishment of the national register, which, in most circumstances, could only be implemented and maintained on an ongoing basis under national space legislation (Australian Space 2018). Once again, this will require consultation and information flows between the small satellite operator and the relevant government agency (if indeed such an agency exists).

In addition, with widespread cooperative small satellite programs that may potentially involve institutions from many countries, there will be a need for careful coordination between the various launching States as to who should be the State of Registry – it can only be one of the launching States (Registration Convention, Article I(c)). It may not, for example, make practical sense that each launching State would seek to be the State of Registry for its specific small satellites in the context of a joint program involving a large constellation of objects launched simultaneously from the one launch vehicle.

Likewise, where a large number of (identical/similar) small satellites are launched or deployed into Earth orbit as part of a constellation program, either at the same time or over a period of time, it may not be feasible or practicable to require a separate registration filing and number for each one of them. This is a practical and policy issue for each national regulatory authority to determine and has implications also for the information that is subsequently passed on to the United Nations Office of Outer Space Affairs (on behalf of the United Nations Secretary-General) pursuant to the terms of the Registration Convention (Article IV).

5 Sustainability of the Space Environment: Space Debris Mitigation

One of the major challenges for the future exploration and use of outer space and for the long-term sustainability of space activities is the growing proliferation of space debris, which represents both a major area for environmental concern but also can and increasingly will impact upon human safety. Much has been written about the exponential growth of pollution in outer space and the hazards that it poses (Bohlmann and Freeland 2013).

There are many approaches as to how the problems should be addressed, given that the whole issue of the environment of outer space is a complex one, with many interconnecting variables at play (Bohlmann and Freeland n.d.). As noted above, these variables, and the enormous financial implications that would arise from setting in motion binding requirements, have meant that, to date, only soft law guidelines, rather than hard law treaty regulation, have been agreed to address this issue.

Nonetheless, these IADC guidelines, (2007) although voluntary and expressed in general terms, are significant in that they reflect existing practices as developed by a number of States and international organizations and set (minimum) standards toward which space-faring nations should strive. By implementing the guidelines contained in these soft law instruments via national or agency policies, policy makers might ultimately contribute to the formation of a due diligence standard, assuming that international practice is sufficiently widespread and representative.

The principles underpinning the debris mitigation guidelines are that care should be taken to minimize the risk of debris “creation” in the conduct of space activities. The UN Guidelines recognize two broad categories of space debris mitigation measures: those that curtail the generation of potentially harmful space debris in the near term, through the minimization of the production of mission-related space debris and the avoidance of break-ups, and those that limit their generation over the longer term, for example, by end-of-life procedures that remove decommissioned spacecraft and launch vehicle.

The importance of accessing and using space for all aspects of our lives necessitates a diligent adherence to these standards to the greatest extent possible. It is generally recognized that it is in the interests of all space-faring States to follow these guidelines, and this is, as noted, increasingly reflected in their practices. The long-term sustainability of outer space activities is a matter of interest and importance for the international community as a whole and has been a principal focal point for UNCOPUOS over more recent years. **During its 62nd session in June 2019, UNCOPUOS adopted the Preamble and 21 Guidelines for the Long-Term Sustainability of Outer Space Activities (Long-Term Sustainability Guidelines). These provide guidance on policy and regulatory framework for space activities; safety of space operations; international cooperation, capacity-building, and awareness; and scientific and technical research and development. The problem of space debris remains as a major element among the specific issues addressed by the Long-Term Sustainability Guidelines. UNCOPUOS is encouraging States and international intergovernmental organizations to voluntarily take measures to ensure that these guidelines are implemented to the greatest extent feasible and practicable:** (UN Doc. A/AC.105/C.1/L.366 2019)

There are some potentially significant environmental challenges that arise from the use of small satellite technology, particularly the development of plans for large constellations of small satellites as has been announced by major corporations. Growing demand, the expanding range of functions, and, ultimately, the commercial services can provide point to rapid increases in the numbers of small satellites that will be placed into Earth orbit. In order to utilize this technology to achieve “global” coverage, very large constellations of small satellites will be required, and, as noted, some are now at various stages of implementation. While, at least initially, most of these satellites will be placed into a low Earth orbit, projects such as these will “populate” important orbits with a significant number of space objects and increasingly pose a potential collision risk, as well as raising other concerns as to possible future de facto “appropriation” of particular orbits.

Even with respect to less ambitious low-cost small satellite programs, the issue may still remain. Many experimental satellite programs have been exactly that “experimental.” They have often utilized existing “off-the-shelf” components, and the expectations of mission success for any significant period of time have not necessarily been high. It is fair to say that such circumstances give rise to lower perceptions of risk and a higher tolerance toward failure. For many such programs, at least in the relatively early phases of small satellite development, the process has largely been about the journey (to space) rather than the delivery of services – though of course this is now changing.

Many of these programs have relied on “piggyback” launches, which have meant that the satellites have been placed in orbits significantly higher than the very low orbits that would allow them to decay relatively quickly. For many small satellites, therefore, there is a potentially very long period (perhaps in excess of the 25-year cap suggested by the IADC Debris Mitigation Guidelines) before orbital decay, even though the satellite itself will have been functioning for only a short timeframe.

This also highlights the seeming change in risk tolerance that is occurring due to the advent of much cheaper small satellites, as compared to large and very expensive traditional satellites. The issue of an increased “acceptable failure rate” might also apply to small satellite constellations to an even greater degree in terms of numbers of inoperable space objects. It is entirely feasible to suggest that, when a “mega-’ constellation comprising thousands of small satellites is launched/deployed, there is considerable “redundancy” built into in the system, meaning that literally hundreds of objects may fail – thus rendering them inoperable and non-maneuverable – and yet the commercial goals of the operator are still achievable.

Even though operators may claim that this is not a “problem” given that those objects will descend to and burn up in the Earth’s atmosphere in a relatively short space of time, (Henry 2019) this will certainly not always be the case. In this regard, large operators have announced plans to eventually locate small satellite constellations in orbits higher than the low Earth orbits that are currently being utilized, meaning that they will almost certainly remain in space for a long time, thus posing an increased collision risk. **It has been reported that, as part of its Starlink small satellite constellation, SpaceX hopes to launch approximately 2,800 satellites at altitudes between 1,100 and 1,325 km above the Earth** (Mosher 2019).

Moreover, as noted, there are several variants of small satellite technology. While it is too simplistic to categorize them solely on the basis of their size and weight, some satellites may be too small to be picked up by conventional tracking systems. Indeed, this was the stated reason for the FCC decision not to authorize the launch of the Swarm Space-Bees, although, that assertion has been disputed (Fernholz 2018). Yet, even such low-mass objects can cause catastrophic damage in certain circumstances. The potential consequences, and therefore the potential risks, would, of course, be greatly magnified should the development of a large-scale commercial human spaceflight industry ultimately come to fruition (Virgin Galactic website 2010).

Of course, these issues are relevant to the question of potential liability raised above. They also point to the need to carefully consider how, and to what extent, the future advent of small satellite constellations can and will be undertaken, so as to as much as possible be consistent with the overarching goal of managing the long-term sustainability of outer space activities in such a way as to maximize the (commercial) benefits that can be derived while maintaining appropriate and acceptable safety standards, particularly, but not only, for missions involving humans.

In some senses, therefore, the environmental consequences relating to small satellite constellation programs have not really been properly factored into the regulatory framework. This is also a question of education and awareness but is a highly important factor to take into account when designing the future legal regime to apply to such programs.

6 Other Regulatory Considerations: Frequency Allocation/Space Traffic Management/Impact on Science

As noted, these brief comments do not purport to be comprehensive as to the relevant regulatory factors associated with the new commercial space paradigm constituted by small satellite constellations. However, the primary regulatory issues that ultimately stem from the principal requirements under the United Nations Space Treaties have been raised.

There are, of course, other equally relevant considerations that also arise. For example, as more such programs emerge, particularly offering commercial services, the issue of radio frequency usage becomes all important. As noted, the historic use of the "amateur band" frequencies by experimental and noncommercial operators will no longer be applicable and appropriate in the case of small satellite constellations developed and operated by large commercial corporations. The regulatory framework of the International Telecommunication Union (ITU) will become even more relevant.

While the ITU operates effectively to manage the use of radio spectra, it is a large intergovernmental organization and can be highly bureaucratic. Decisions about allocations of valuable (commercial) frequencies need significant periods of time and are sometimes highly political, particularly in a context where there exist increasingly competitive pressures for spectrum. While the debate regarding the 28 gigahertz frequency may not directly impact on small satellite constellation programs, it is symptomatic of an even broader concern about the apparent "depletion" of available spectrum for space-related activities (see, e.g., Caleb Henry, "Satellite operators worried about losing Ka-band spectrum", Space News, 7 May 2019: https://spacenews.com/satellite-operators-worried-about-losing-ka-band-spectrum/ (accessed 11 September 2019).

As is well known, the coordination of frequencies so as to minimize harmful interference is complex. This lengthy process does not necessarily sit comfortably with the shorter timeframes associated with the development of small satellite constellation programs. Accordingly, procedures will need to be established to accommodate this technology without compromising the important work of the ITU. This will not be an easy task.

In addition, the introduction of small satellite constellations will highlight even more the imperatives to consider the development of international traffic management systems involving space traffic, as well as its intersection with air traffic. While this issue has been discussed already for some time, and some initial steps are being taken to consider the relevant factors, there is much work to be done by all stakeholders. For example, already in early 2015, the United Nations Office of Outer Space Affairs (UNOOSA) and the International Civil Aviation Organization (ICAO) jointly sponsored an "AeroSPACE" symposium where some of these issues were discussed.

More recently, another (nonlegal) issue has been raised – the impact that the launch/deployment of large numbers of small satellites into low Earth orbit (and beyond) will have on scientific endeavors and research such as astronomy. This objection arose (coincidentally) as a result of the launch of the first 60 Starlink small satellites (Bartels 2019) – obviously it is to be anticipated that this debate will only grow louder as more small satellite constellations come into existence.

7 Conclusion

This chapter has highlighted the fact that the current international legal framework continues to apply to new and developing space technologies and systems – such as small satellite constellations – that will contribute to the further evolution of commercial space activities. The advent of small satellite technology into the mainstream of space activities, and particularly the likely eventuality of various forms of small satellite constellations comprising large numbers of space objects, is an issue that is currently being addressed by the international community. For several years already, the Legal Subcommittee of UNCOPUOS has considered as an agenda item the issue of "General exchange of views on the application of international law to small satellite activities."

Interestingly those discussions have thus far seen a diverse range of views as to whether, and if so how, a sui generis set of rules should be established to specifically regulate small satellite constellations. The UN Committee on the Peaceful Uses of Outer Space (COPUOS) operates on the basis of decision-making by consensus. In light of the divergent opinions currently held by various UNCOPUOS Member States, this means that any such new legal or regulatory regime, if it were to be developed at all, will not be forthcoming for quite a period of time. Thus, the existing international framework continues to apply to small satellite constellations in every respect.

As it stands, however, the existing law and the technology, at least at the international level, does not represent a natural fit. The international regulatory framework was not designed specifically to deal with the advent of this technology nor for the expansive range of new space actors. Moreover, these new actors, in particular, may not be completely aware of, or understand, the relevance and implications of the existing framework.

The United Nations General Assembly and its Committee on the Peaceful Uses of Outer Space (COPUOS), as noted above, are therefore conscious of the imperative to explore the potential dynamics of the small satellite industry. There is awareness of the need to address both the challenges and to promote the opportunities posed by small satellite constellations. Yet, even putting any current initiatives aside, it is clear that such shifts in space technology and new space systems require the development of appropriate regulatory standards in a relatively short timeframe. Small satellite entrepreneurs, and large constellation operators, are anxious that any real (or perceived) barriers to entry posed by national regulatory requirements are removed.

Whether or not these fears are justified in every case, what seems increasingly likely is that, in some respects, small satellite technology and systems will become mainstream means of utilizing space for commercial purposes in the future. As part of this evolution, it seems likely that in the relatively near future that a number of small satellite constellation programs involving many thousands of space objects will be implemented. Attempting to regulate this twenty-first-century technology solely by reference to twentieth-century rules, devised for other space systems and technologies, is likely to create difficulties and uncertainties and perhaps deter some who would otherwise consider engaging in these new space industries and space-based services.

In the meantime, however, there is no doubt that small satellite technology can offer great opportunities, but it also poses some significant challenges to the broader perspective of the exploration and use of outer space. The desirability of clear regulation to specifically address this technology is clear, and it thus falls on national lawmakers to consider how to provide what is required within a more expedient timeframe (Freeland and Davis 2015).

In the end, therefore, clear national policies must be formulated. National legislatures will need to come to grips with the ever-changing range of space technology, particularly if they wish to become increasingly involved in space activities. Some governments have, through their national legislation, dealt specifically with the issues that arise through the advent of small satellite technology, (Marboe and Traunmuller 2012) but there is a long way to go, particularly as the ever-increasing plans for future programs emerge. Whatever rules are put in place must find the right balance. On the one hand, there is the need for regulation of the financial, operational, and technical elements, so as to minimize the risks to an acceptable level. On the other, there is the need to facilitate research and innovation to allow for greater and more efficient access to space and the potential for commercial returns on investment.

Complex public policy questions arise as to whether, for example, to exempt small satellite operators from several of the existing national regulatory requirements that apply to their large satellite "brethren." Yet, to do so may have the ultimate effect of minimizing the "incentives" or motivation of these operators to engage in best practice or to take simple, inexpensive steps to ensure that their local stakeholders are covered by existing protections.

Naturally, this may not necessarily be the case when it comes to those large corporations that are developing small satellite constellations; however, it is suggested that the industry as a whole would not necessarily be unduly stifled by the requirement that, in all circumstances, they take proper and appropriate risk management steps. Any relaxation of the rules for the users of this technology will bring with it added risks for the regulators and the relevant State, as well as raising some of the broader questions that have been alluded to in this chapter.

These are difficult choices, and States will take differing paths, depending upon their specific circumstances. This will, unfortunately, mean that there is unlikely to be established a uniform international set of rules to specifically address the complexities of small satellite constellations, at least in the short-medium term. One possible way forward is that we might see the emergence of a soft law code of conduct at the international level, but this may not provide a sufficiently comprehensive basis to properly regulate the conduct of those new actors in the space paradigm.

This again points to the strong role that national law and lawmakers have to play. For this to be effective, it will require close consultation between all stakeholders and emphasizes the need for regulators, the scientific community, the entrepreneurs, the large corporations, and the lawyers to all talk to each other to a far greater degree than has thus far been the case. It is clear therefore that any appropriate solution to address the many and varied issues that arise with the advent of large-scale small satellite constellations will need to be carefully thought through with responsible action taken at both the national and international levels.

The Legal Status of MegaLEO Constellations and Concerns About Appropriation of Large Swaths of Earth Orbit

Christopher D. Johnson

Contents

Abstract

The emergence and near-term bringing into use of constellations of very numerous satellite constellations raises issues of unwanted and possibly impermissible appropriation of Low Earth Orbit (LEO) or portions thereof. Currently, coordination of orbital “slots” occurs only in the Geostationary Orbit (GSO), and there

are no restrictive rules preventing individual actors, including both States and private entities, from deploying very numerous spacecraft into LEO. MegaLEO constellations may utilize LEO orbits to such an extent that other actors might be excluded from using these orbits. This chapter will explore explicit rights and obligations, principles of general nature, and economic and political aspects of addressing this emerging issue.

1 Introduction

The launching of very numerous constellations of small satellites into Low Earth Orbit (LEO) seems promising, but this activity should also give us pause. While spacecraft in LEO may only be operating in space for limited amounts of time, what does it mean to occupy LEO with such overwhelming presence – where spacecraft occupy multiple orbital planes with numerous satellites, and where other potential users of those orbits might not risk trying to share those orbits? International law currently prohibits the appropriation of outer space, whether void space itself or celestial bodies. However, this fundamental principle of space law suits uneasily with the broad freedoms to access, explore, and use outer space, along with the national interests of States to foster domestic industrial space capacity and pioneering space activities.

2 Normative Background of Space Law Applicable to Satellite Constellations

Constellations of numerous small spacecraft present challenges to the current legal and regulatory regimes governing space activities. However, their emergence will not pose fundamental threats to this regime. From the lawyer's perspective, the major difference between existing space projects and very numerous small satellites projects are the following: these missions use *smaller spacecraft* than the larger, more expensive, and often unique spacecraft of previous decades. These missions involve the use of satellites in *greater numbers* than these previous space activities. These missions are often *cheaper* and *quicker* to develop and execute. Next, these missions are often *in orbit for less time* than traditional space activities. The spacecraft used *may lack propulsion* necessary for on-orbit maneuvers, and/or they *may fail at higher rates* than traditional satellites. Additionally, the organizations and individuals developing and operating these projects are different than the traditional aerospace companies and large governmental agencies.

In summary, smaller spacecraft deployed; more numerous; cheaper and quicker to get to bring into use; shorter missions; and less capable or reliable spacecraft. Additionally, younger and more diverse teams, in smaller and more agile organizations.

These are the hallmarks of the ongoing small satellite revolution, which has been successful for precisely these attractive qualities. While these differences have interesting and attractive characteristics, such as allowing startups to get to space quicker and cheaper than in previous years, these differences also pose administrative and oversight challenges to regulators, raise difficult questions regarding the interpretation and application of space law, and raise concerns and challenges regarding the long term sustainability of outer space activities. In principle, the legal regime for outer space activities is sufficiently robust to address these innovations. However, the small satellite revolution is one where oversight, control, and space sustainability issues continue to exist.

Various specific space law topics will be discussed in more detail in other chapters, but it is worthwhile to briefly highly here some basic principles and sources of law which are applicable to large constellations in LEO. While some of these principles may be said to be vague in nature, they are nevertheless applicable and serve as “guard rails” to the use of LEO by any constellations of satellites. These norms comprise the regulatory context for any discussion on whether mega-constellations violate international law by impermissibly appropriating outer space as their own.

2.1 Freedom of Exploration and Use

According to the Outer Space Treaty of 1967, States are free to explore and use outer space. Article I of the Outer Space Treaty establishes that States which are party to the treaty are permitted to access, use, and explore outer space, including the Moon and other celestial bodies. Because this is such a fundamental principle of space law, upon which all other obligations and prohibitions are balanced, it is worth quoting in full.

> The exploration and use of outer space, including the Moon and other celestial bodies, shall be carried out for the benefit and in the interests of all countries, irrespective of their degree of economic or scientific development, and shall be the province of all mankind.
>
> Outer space, including the Moon and other celestial bodies, shall be free for exploration and use by all States without discrimination of any kind, on a basis of equality and in accordance with international law, and there shall be free access to all areas of celestial bodies.
>
> There shall be freedom of scientific investigation in outer space, including the Moon and other celestial bodies, and States shall facilitate and encourage international cooperation in such investigation.

In many respects, the language of Article I speaks for itself. The second sentence of Article I makes it clear that States are free to access and explore space without first seeking permission from any other State, or group of States, or from the United Nations Security Council, or any other authority or body. That States can freely explore space by themselves was not a foregone conclusion at the dawn of the space age, but was a right, negotiated among them, within the United Nations. First made clear by a lack of international resistance to the USSR's launch of *Sputnik-1*, this right to unilaterally access space was then enshrined in a declaration of principles at the United Nations in the early 1960s and then finally made a clear and explicit right under binding international treaty law with the Treaty on the Principles Governing States on the Exploration and Use of Outer Space, including the Moon and other Celestial Bodies (also known as the "Outer Space Treaty") This treaty was negotiated at the United Nations in 1966, opened for signature in January 1967, and came into force in October of 1967. As of 2019, the Outer Space Treaty has a total of 110 States Party to the treaty (UNOOSA 2019a), including all of the other large historical space powers, emerging space powers, and many States just entering into space activities.

It is worth noting that the subject of the first sentence is "the exploration and use of outer space," rather than merely "outer space," which is deemed to be "the province of all mankind." As we shall see in the Outer Space Treaty's Article II, outer space does in fact not belong to anyone. Conversely, nor is it the property of everyone collectively. Rather, States are free to access, explore, and use it — provided such activity conforms with any and all other applicable rights, obligations, and prohibitions in international law.

2.2 Nonappropriation

Article II of the Outer Space Treaty contains the famous, or possibly infamous, prohibition on national appropriation. Just a short 30 words long, this article has caused decades of debate regarding its interpretation and application.

> Outer space, including the Moon and other celestial bodies, is not subject to national appropriation by claim of sovereignty, by means of use or occupation, or by any other means.

This bold sentiment, that outer space is simply not a permissible subject for national appropriation, was present in even the very first discussions on outer space at the United Nations level. One of the earliest UN General Assembly resolutions on space, General Assembly Resolution 1721 A and B (XVI) of December 20, 1961, entitled 'International cooperation in the peaceful uses of outer space', first announced this principle. In 1963, the UN's Declaration of Legal Principles Governing the Activities of States in the Exploration and Use of Outer Space, which is seen as a draft precursor of the binding Outer Space Treaty negotiated just a few years later, again reiterated this principle of nonappropriation.

This prohibition, placed on States, essentially means that outer space – both void space and celestial bodies – cannot be lawfully appropriated as some sort of extraterrestrial territory ripe for annexation and possession. Drafted in an era of both Cold War tensions and rapid global decolonization, the major space powers did not want to kick off a new colonial land grab for territory outside Earth's atmosphere. Historically, unilateral sovereign claims of territory were a legitimate method for expanding a State's territory. However, such a rush to claim territory on, say, the Moon, might trigger tensions between space powers. It was better to simply say that outer space, whether it be particular celestial bodies or even particular orbits, cannot come under the direct, permanent territorial sovereign possession of any single State.

Beyond that, the nuances of this article are frankly unclear, especially in its implementation on particular activities and on how it applies to modern and emerging space missions. Some clarity is necessary regarding the structure of the phrases, however. Pared down to its subject, verb, and direct object, the sentence states that outer space (the subject) is not subject to (verb) national appropriation (direct object). From there, is lists ways that outer space is not subject to national appropriation: claims of sovereignty, by means of use, by means of occupation, or, indeed, by any other means. In other words, there is no lawful, permitted means which will legitimize the national appropriation of outer space, as space is not "subject to" or capable of "national appropriation." The list ends with the inclusive "by any other means," as a kind of a capstone to the sentence, just to make it clear that the listing of actions is not exhaustive and to prevent any loopholes. It is used out of an abundance of caution, to make it clear that outer space cannot be brought under the sovereign domain of any State, and that no State may claim exclusive rights in these areas. Consequently, there is no way for a State to appropriate space, or subsets of space, such as locations on celestial bodies or particular trajectories or orbits. Whatever they do, it does not constitute appropriation that will be recognized.

The Outer Space Treaty was negotiated on behalf of the United States of America by Ambassador Arthur Goldberg. When the treaty was finalized within the UN, and then opened for States to sign, Ambassador Goldberg returned to Washington D.C. to testify before the US Senate as to its worthiness as a treaty (US Senate 1967). In explaining Article II to the Senators before him, the following exchange occured.

> Mr. GOLDBERG: Article II is a statement that outer space is not subject to national appropriation by means of sovereignty, by means of use or occupation or by any other means, which means that outer space is the province of mankind. It is complementary to article 1.
>
> The CHAIRMAN: Any further questions?
>
> Senator CHURCH: It cannot be claimed for Ferdinand and Isabella.
>
> Mr. GOLDBERG: That is correct.

This brief exchange seems to reflect the limited extent of investigation that State legislators, in considering whether or not to ratify the treaty, investigated the limits of the prohibition on appropriation in Art. II. It seemed evident to them that the provision was meant to oppose and formally ban State appropriation of outer space.

As Article II follows directly from Article I in any direct reading of the Outer Space Treaty, the freedoms of Article I would be foremost in any readers mind when they arrived at their understanding of Article II, and logic seems to dictate that these two articles were meant to be read and applied in an internally consistent and coherent manner. This investigation as to the intent of the drafters and negotiations of Article II's prohibition on national appropriation is relevant to today's constellations of numerous satellites as it forms the normative background for these activities.

2.3 Registration

A requirement placed on States active in space is that they notify the United Nations about these activities, as well as list them on their own national registry. International registration is the expression of a desire for openness and international awareness about what objects are in outer space, where they are, where the launched from, and what they are doing. Conversely, national registries of space objects is linked to States seeking to assert their sovereign jurisdictional powers over objects (and personnel thereof) which are physically outside of their territory.

2.3.1 International Registration

The United Nations Office for Outer Space Affairs (UNOOSA) keeps two international registers for objects launched into outer space. One is older and kept pursuant to UN General Assembly Resolution 1721, from 1961. A separate one was created pursuant to the 1975 Registration Convention. The explanation for the existence of two registers is that the 1961 resolution is not mandatory; it is a recommendation from the UN General Assembly to UN Member States. Conversely, registration pursuant to the 1975 Registration Convention is mandatory for States which are party to that Treaty. In practice, however, the registers are very nearly identical. States which are not party to the Registration Convention – and are therefore not compelled to registry with the UN – still register with the UN pursuant to the Resolution 1721. UNOOSA maintains an online index of space objects listed on its register, as making information of this sort available online furthers the purpose of having an international register – namely, transparency and public awareness about what is actually in outer space (UNOOSA 2019a).

2.3.2 National Registration

Another type of registry exists, and for different purposes and maintained by different actors. States themselves keep national registries of their launched space objects. This is done as a consequence of Article VIII of the Outer Space Treaty, which grants them the right to assert legal jurisdictional authority of those space objects.

> A State Party to the Treaty on whose registry an object launched into outer space is carried shall retain jurisdiction and control over such object, and over any personnel thereof, while in outer space or on a celestial body. Ownership of objects launched into outer space, including objects landed or constructed on a celestial body, and of their component parts, is not affected by their presence in outer space or on a celestial body or by their return to the Earth.

This is more important than it may appear. Remember that Article II severely limits State sovereignty in space. How can States have any legal authority over things that they launch to space, if there is no sovereignty there? Article VIII permits this exercise of a State's jurisdictional powers in an extraterritorial manner by creating a link between a national registry and the treaty right. The article creates an internationally recognized mechanism for asserting jurisdiction (a component of sovereignty) into outer space. Consequently, States have a right to assert jurisdiction over their space object. This is important to keep in mind as this right is then balanced with the obligations of international responsibility, duty of obligation and supervision, and duty of compliance, as discussed below.

2.4 National Responsibility for National Activities, Whether Governmental or Nongovernmental (Private)

Crucially relevant to the legal status of satellites constellations and the concerns about appropriation are the unique and onerous obligations placed upon States regarding private activities and enterprises in outer space. In international law, the subject (or actors) which are bound by international law are sovereign States. States are the principal entity of the international political order. More recently, international organizations such as the United Nations, the European Union (EU), the International Committee of the Red Cross and Red Crescent (ICRC), and other organizations are also bound by the international law. In this sense, they are considered the "subjects" that international law regulates. However, the substance of international law can address many various activities. The subject matter or the "objects" of international law can be wide and diverse and include organizations of individuals and institutions, such as corporations, and even individuals. As such, international space law can impose norms for private actors such as corporations.

2.4.1 International Responsibility

Most international law does not make States responsible for the actions of private individuals. This is not the case in space law. Article VI of the Outer Space Treaty places the responsibility and even liability of private actors firmly upon the shoulders of States.

> States Parties to the Treaty shall bear international responsibility for national activities in outer space, including the Moon and other celestial bodies, whether such activities are carried on by governmental agencies or by non-governmental entities, and for assuring that national activities are carried out in conformity with the provisions set forth in the present Treaty.

2.4.2 Authorization and Continuing Supervision

The second sentence of Article VI then gives States a positive obligation to undertake authorization and continuing supervision of nongovernmental entities.

> The activities of non-governmental entities in outer space, including the Moon and other celestial bodies, shall require authorization and continuing supervision by the appropriate State Party to the Treaty.

Consequently, it is not merely sufficient that governments allow private actors to access and explore space. States have a duty to authorize and supervise them. Looking again at the first sentence of Article VI, above, gives some indication as to what standard this supervision must meet. The first sentence of Article VI ends with "... and for assuring that national activities are carried out in conformity with the provisions set forth in the present Treaty." Consequently, States must authorize and supervise private entities to make sure that these private entities conform with the Outer Space Treaty.

Additionally, Article III of the Outer Space Treaty creates a link between the treaty and the rest of international law, including the UN Charter. Therefore, and to the extent that other sources of international law create norms applicable for private entities in outer space, all national activities – including private, nongovernmental activities – must conform with said laws. Some of these other sources include the other UN treaties on outer space, such as the 1968 Astronaut Rescue and Return Agreement, the 1972 Liability Convention, and the 1975 Registration Convention. Other specialized treaties on outer space, like the international telecommunications regime of the International Telecommunications Union Convention and Constitution, international enviromental law, international humanitiarian law, and other special regimes also form the rest of the normative order for outer space.

2.5 Potential Liability

Supplemental to international responsibility for acts in space committed by private entities is the potential for liability for damage resulting from their activities. Article VIII of the Outer Space Treaty establishes a liability provision, and the 1972 Liability Convention expands the mechanisms for dealing with liability claims. Liability is a requirement to pay compensation to an injured party for the damage or suffering that has been caused to them. In space law, liability is for physical damage to a space object by another space object. These provisions on liability have not yet been enforced relating to any actual claims of damage in space. However, and just like the obligation to be internationally responsible for private actors mentioned in Article VI, the potential for liability serves as a strong motivator and incentive for States to oversee, monitor, and regulate what private actors are doing in space.

2.6 Due Regard

Article IX of the Outer Space Treaty creates some interesting and unsettled normative principles guiding space activities. And while the treaty uses the word States as the entity that it is addressing, it is important to remember Article VI. As a consequence of Article VI, the behavior of private entities is also bound by the terms of the treaty. The first sentence of Article IX creates obligations placed upon States to show due regard to the corresponding interests of others active in space, and to abide by general principles of cooperation and mutual assistance.

> In the exploration and use of outer space, including the Moon and other celestial bodies, States Parties to the Treaty shall be guided by the principle of cooperation and mutual assistance and shall conduct all their activities in outer space, including the Moon and other celestial bodies, with due regard to the corresponding interests of all other States Parties to the Treaty.

It must be admitted that these obligations are of a general nature. What the principles of cooperation and mutual assistance mean is not explicitly defined in the treaty, and no real examples are given. Similarly, the due regard obligation is not refined further.

Perhaps looking elsewhere into the Outer Space Treaty gives some examples. Elsewhere in the treaty, Article V talks about rendering assistance to astronauts. This assistance be seen as adhering to the principles of cooperation, mutual assistance, and due regard to the activities of others. The notification measures (international and national registration) also show a certain amount of regard for others.

2.6.1 Frequencies and Orbits

To also understand these obligations of cooperation, mutual assistance, and due regard, we can look to the actual history of space activities and see what States have, for themselves, determined to be its requirements. Even since before the Outer Space Treaty came into force, States were abiding by the requirements of coordinating frequencies and orbital positions – as internationally governed by the International Telecommunications Union (ITU), and administered by national frequency administers, such as the Federal Communications Commission (FCC) and the National Telecommunications and Information Administration (NTIA) in the United States of America, or by the Office of Communications (Ofcom) in the United Kingdom. The coordination of frequencies is to prevent harmful interference between users of space systems – as each and every satellite must communicate on frequencies along the electromagnetic spectrum, and these frequencies must be coordinated between users.

Additionally, Earth’s Geosynchronous orbit (GSO) is both of intrinsic value and is of a limited nature, so the coordination of orbital “slots” is necessarily required. That this coordination happens successfully across the world on an international and domestic basis is certainly a great example of cooperation, mutual assistance, and of due regard to the corresponding interests of other States.

2.6.2 Space Debris

We can also look at the growing coordination around space debris. Here, space agencies and the scientific community have pooled their expertise and reflected on the growing issue of space debris, especially in lower orbits and other useful orbits. First with the Inter-Agency Space Debris Coordination Committee (IADC) and later at the multilateral level within COPUOS, the development of space debris mitigation guidelines reflect strongly show a due regard to the interests of others, and a spirit of cooperation in their development and observance.

Much more could be written about how the principles of cooperation, mutual assistance, and due regard has developed along various fields of space activities in the previous decades. In sum, they show that States often observe these general principles, and in a manner dependent on the issue at hand (frequency and GEO orbit coordination, space debris mitigation) and in various other manners, including national implementation of previously agreed standards at the international level.

2.7 Harmful Contamination

The second sentence of Article IX prohibits the harmful contamination of outer space and celestial bodies and requires that States shall adopt appropriate measures to fulfill this requirement.

> States Parties to the Treaty shall pursue studies of outer space, including the Moon and other celestial bodies, and conduct exploration of them so as to avoid their harmful contamination and also adverse changes in the environment of the Earth resulting from the introduction of extraterrestrial matter and, where necessary, shall adopt appropriate measures for this purpose.

Again, and like previous principles, harmful contamination is not defined or made clearer with an example. However, and linked with the obligation of due regard, the mitigation of space debris is a concrete example of what contamination of space is considered to be.

3 International Governance for the Geostationary Orbit

Headquartered in Geneva, Switzerland, the International Telecommunications Union (ITU) coordinates the use of usable portions of the electromagnetic spectrum, and the use of orbital allocations (“slots”) at the Earth’s Geostationary Orbit (GEO) at 35,786 km above the Earth’s equator. ITU coordination is designed to foster the rational, equitable, efficient, and economical use of these resources. Both usable portions of the spectrum and orbital locations are regarded as limited resources, and these limited resources require coordination between actors. Consequently, there is weight given to those who first apply for rights according to a “first come, first served” basis. However, there is also respect given to potential future users. This balancing of present users with future users is difficult, but it ensures that no State or other actor can rush to seize orbital or spectrum resources.

For the purposes of ITU orbital allocations, there are only two categories of spacecraft: Geostationary (GSO) and Non-Geostationary (NGSO). Currently, the ITU only coordinates GSO. Because of the limited and unique nature of these positions in GSO, coordination there has long been regarded as a necessity. Current capabilities dictate that there are only about 1800 orbital "slots" at GSO. Consequently, GSO is relatively well ordered, especially when compared to other orbits (as shown in Fig. 1 below). It may develop that other orbits closer to Earth may one day soon require coordination, but this is currently not done.

It should also be noted that the orbital "slot" given to users at GSO is a relatively small, three-dimensional "box" in space in which to operate. These slots are therefore quite different from the multiple orbital planes of numerous satellites to be used by constellations (called orbital "shells"), which essentially envelop the entire Earth inside them. The ordered GSO region is in stark contrast to LEO and Medium Earth Orbit (MEO), where satellites owned by many users and for many different purposes are travelling in periodic transits around the Earth, where congestion and the risk of collision persist and are increasing, and where rules on the use and governance of these regions are lacking much specificity.

National administrators of frequencies, such as the Federal Communications Commission (FCC) and the National Telecommunications and Information Administration (NTIA), which administer commercial and governmental frequencies, respectively, grant licenses to operators in conformity with their interpretation of their international obligations under space law, including both the Outer Space

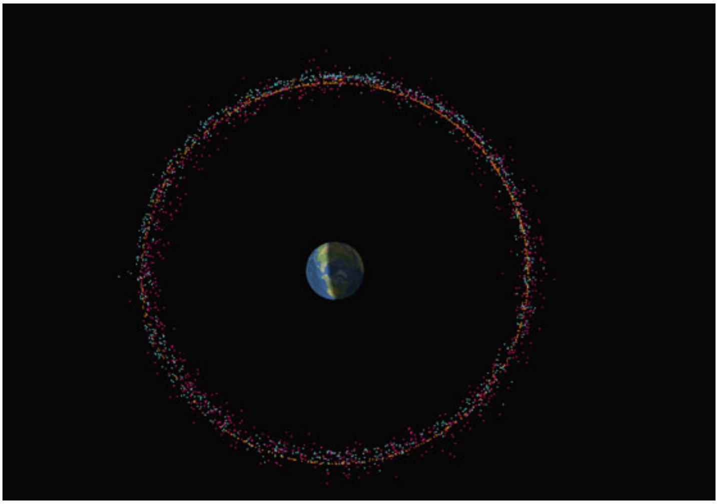

Fig. 1 The relatively well-ordered orbital regime of the Geostationary Orbit (viewed from above), as coordinated by the International Telecommunications Union (ITU). (Image with permission of Moriba Jah, University of Texas at Austin, http://astria.tacc.utexas.edu/AstriaGraph/)

Treaty and the regime of the ITU. To date, the granting of licenses for constellations has progressed without any noticeable qualms about these constellations.

4 MegaLEO Constellations

In light of the foregoing governance regimes, comprised of rights, obligations, and principles, there remains a lack of clear limits to the extent that constellations can be deployed and operated in increasingly valuable and congested orbits. Recent estimates for various commercial constellations in LEO give pause and should provoke caution. The SpaceX Starlink constellation is currently envisaged to consist of nearly 12,000 satellites in LEO by the mid-2020s, although recent filings for frequencies for an astounding potential 30,000 possible additional satellites (Henry 2019) would bring SpaceX's constellation to a truly mind-boggling 42,000 spacecraft in total. OneWeb's constellation is planned for 2000 satellites. Amazon's Kuiper system will constitute 3000 satellites. These three planned systems alone total around 17,000 new spacecraft placed into Earth orbit over the next decade. To put this in perspective, the UNOOSA online index of objects launched into outer space lists slightly less than 5300 objects currently in Earth orbit (as of the time of writing) (UNOOSA 2019a). It is true that these constellations may likely bring many benefits to society. It is also fairly certain that, in regards to outer space activities, the era of constellations will be an entirely new and unprecedented era of space activity.

4.1 SpaceX Starlink

SpaceX is one of the most visible companies with plans to create a large constellation of small satellites for commercial purposes. The SpaceX Starlink constellation is envisioned as a constellation of small satellites (227 kg/500 lbs) to provide low latency Internet services from space. The value proposition for Internet from space is twofold: faster times than terrestrial fiber optic cables is tremendously attractive to some clients, and wider access to Internet for rural and developing States is also an attractive market. Consequently, Internet from space using a constellation of small satellites is seen as a commercially attractive and achievable endeavor.

The Starlink constellation will actually be comprised of many satellites at different altitudes. According to at least one version of their constellation, based on applications to the US Government, Starlink is envisioned as 1584 satellites at 550 km altitude; 1600 satellites at 1110 km, 400 satellites at 1130 km, 375 satellites at 1275 km, and lastly, 450 satellites at 1325 km. That plan would therefore envision a total of 4409 satellites during its first phase and will grow to (as mentioned above) an envisioned 12,0000 satellites by the middle of the 2020s. In July 2019, SpaceX launched the first 60 satellites which will comprise Starlink. The effect on ground based astronomy from the Starlink satellites was almost immediate, and shocking. Within hours, the Starlink deployment was affecting ground based astronomy and the astronomical community was noticing and discussing the situation.

From the Earth and to the naked eye, viewing them in real time, the Starlink satellites appeared to be in a straight line. Figure 2 shows the satellites before they were moved up to a higher orbital altitude and thus became dimmer to the naked eye. This unprecedented sight is noteworthy and unique, like something out of a science fiction movie. Many found it a startling sight.

To ground based astronomers peering much further beyond this stream of satellites, Starlink obscures distant objects behind them. Figure 3 shows the effects of the Starlink satellites over the course of a 25 s exposure looking at the distant galaxy NGC 5353, now obscured in the background. Even nonastronomers should be able to get a feel for the impact that these constellations might have on astronomy, especially taking into account the large numbers of satellites proposed, and of the low altitude of their orbits.

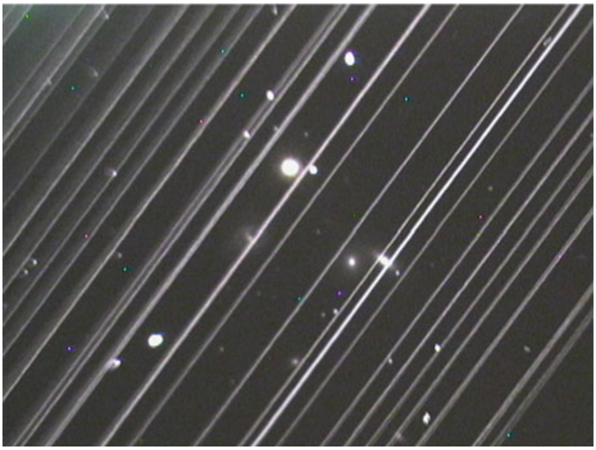

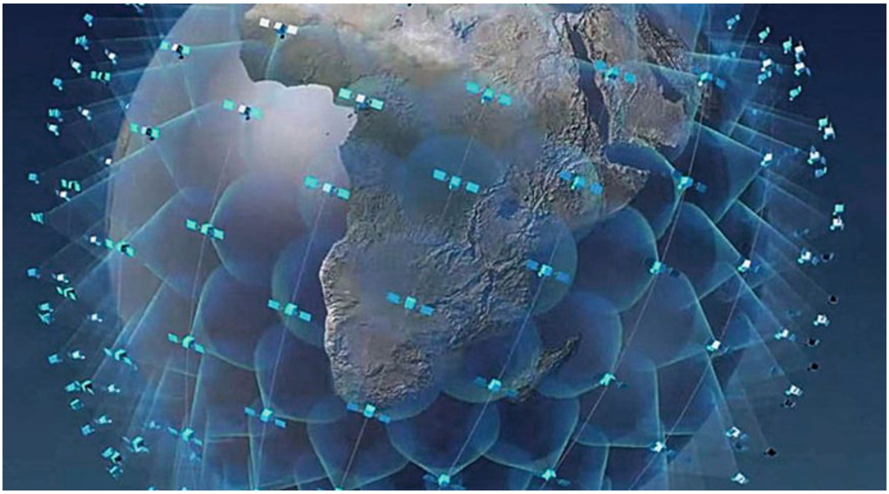

Fig. 4 OneWeb representation of its LEO constellation, upwards of 600 satellites at 1200 km in 24 individual orbital planes. One Web Small Satellite constellation (Graphic courtesy of One Web)

Of this initial deployment of 60 satellites in the Starlink formation, it was later announced that three spacecraft have ceased to operate (Foust 2019). This high failure rate should also be considered in weighing Starlink's observance and adherence of international space law.

4.2 OneWeb

OneWeb has proposed and is planning to deploy another satellite constellations, also for Internet from space, and especially aimed at delivering Internet services to people in underserved communities such as in the Arctic. The proposals for the OneWeb constellation are envisioned as 49 satellites (plus on-orbit spares) in 12 individual orbital planes at 1200 km altitude. At close to 600 satellites, this is also a serious deployment of satellites (Fig. 4).

In 2017, OneWeb announced that they were increasing this proposed 600 satellites with an additional 2000 more, which they have already secured the orbital rights for (Pultarova and Henry 2019). This plan would bring their total to 2620 potential OneWeb satellites.

4.3 Amazon, Teleset, Boeing, and Other Proposed Constellations

The particulars of the plans listed above will undoubtedly be updated and change. Additionally, other constellations are currently proposed by Amazon, LeoSat, SES, Kepler, and Telesat. Others will follow. Leosat has announced a constellation of 84 spacecraft, and Telesat plans for 300 (Pultarova and Henry 2019) (Werner 2019). Kepler Communications has plans for a constellation of up to 140 satellites between 500 and 600 km altitudes, in 7 orbital planes.

5 Are Constellations Appropriation?

The astronomy community has already voiced concerns about the impact that constellations will have on astronomy (AstronomyNow 2019). Constellations also bring potential risks from space debris and radiofrequency interference, both of which will have an effect on space sustainability. Starlink's 1584 satellites in the 550 km region would effectively triple the number of satellites in the 400–600 km region, for example.

Leaving these important concerns aside, constellations should also be considered in the context of their general legal status – and specifically whether large swaths of Low Earth Orbit are being impermissibly claimed and possessed by individual actors (whether the commercial actor itself, or by the authorizing national government).

For example, and as mentioned above, the OneWeb constellation will be in 12 orbital planes at 1200 km. Phase 1 of the SpaceX Starlink constellations will fly 66 satellites in 24 orbital planes, for a total of 1584 satellites in its initial constellation.

Do these megaconstellations constitute an impermissible appropriation (or ownership) of particular regions of outer space? Without offering a definitive conclusion, the following sections first argue why, and then why not, these large constellations in LEO constitute impermissible appropriations of sections of outer space. The reader can consider for themselves which of the following opposing arguments they find more convincing.

5.1 Yes, This Is Impermissible Appropriation

Article II of the Outer Space Treaty, discussed above, is clear on the point that the appropriation of outer space, including the appropriation of either void space or of celestial bodies, is an impermissible and prohibited action under international law. No means or methods of possession of outer space will legitimize the appropriation or ownership of outer space, or subsections thereof.

5.1.1 Excludes Others

The constellations above, because they seem to so overwhelmingly possess particular orbits through the use of multiple satellites to occupy orbital planes, and in a manner that precludes other actors from using those exact planes, constitute an appropriation of those orbits. While the access to outer space is nonrivalrous – in the sense that anyone with the technological capacity to launch space objects can therefore explore space – it is also true that orbits closer to Earth are unique, and when any actor utilizes that orbit to such an extent to these proposed constellations will, it means that other actors simply cannot go there.

To allow SpaceX, for example, to so overwhelmingly occupy a number of altitudes with so many of their spacecraft, essentially means that SpaceX will henceforth be the sole owner and user of that orbit (at least until their satellites are removed). No other actors can realistically expect to operate there until that time. No other operator would dare run the risk of possible collision with so many other spacecraft in that orbit. Consequently, the sole occupant will be SpaceX, and if "possession is 9/10th of the law," then SpaceX appears to be the owner of that orbit.

5.1.2 Done Without Coordination

Additionally, SpaceX and other operators of megaconstellations are doing so without any real international conversation or agreement, which is especially egregious and transgressive of the norms of outer space. Compared to the regime for GSO, as administered by the ITU and national frequency administrators, Low Earth Orbit is essentially ungoverned, and SpaceX and others are attempting to seize this lack of authority to claim entire portions of LEO for itself; and before any international agreement, consensus, or even discussion is had. They are operating on a purely "first come, first served" basis that smacks of unilateralism, if not colonialism.

5.1.3 Governments Are Ultimately Implicated

As we know, under international space law, what a nongovernmental entity does, a State is responsible for. Article VI of the Outer Space Treaty requires that at least one State authorize and supervise its nongovernmental entities and assure their continuing compliance with international law. As such, the prohibition on nonappropriation imposed upon States under Article II of the Outer Space Treaty applies equally to nongovernmental private entities such as SpaceX.

Nevertheless, through the launching and bringing into use of the Starlink constellation, SpaceX will be the sole occupant, and thereby, possessor, both fact and in law, of 550 km, 1100 km, 1130 km, 1275 km, and 1325 km above our planet (or whatever orbits they finally come to occupy). The same is true for the other operators of these large constellations which will be solely occupying entire orbits.

5.1.4 Long-Term Occupation Constitutes Appropriation

These altitudes are additionally significant, as nonfunctional spacecraft in orbits lower than around 500 km will re-enter the Earth's atmosphere in months or a few years, but the altitudes selected for the Starlink constellation, while technologically desirable for their purposes, also mean that any spacecraft which are not de-orbited from these regions may be there for decades, or possibly even hundreds of years. By comparison, the granting of rights for orbital slots at GSO is in 15-year increments, a length of time much less than what the altitudes of the megaconstellations threaten. Such long spans of time at these altitudes by these megaconstellations further bolster the contention that this occupation rises to the level of appropriation of these orbits.

5.1.5 Prevents Others from Using Space

Article I of the Outer Space Treaty establishes that the exploration and use of outer space is "the province of all mankind." It further requires that this exploration and use shall be by all States "without discrimination of any kind, on a basis of equality and in accordance with international law..." However, when one private corporation so overwhelmingly possesses entire portions of outer space, their use is discriminatory to other potential users and interferes with their freedom to access, explore, and use outer space. So long as these actors are so dominantly possessing and occupying those orbits, their actions exclude others from using them. What other operator would dare use orbits where there are already hundreds of satellites operating as part of a constellation? It would be an extremely unwise and risky decision to try to share these orbits with a mega constellation, so they will likely choose other altitudes and orbits. This massive occupation of particular orbits effectively defeats others from enjoying the use of outer space. While a State can issue permits for one of its corporations allowing them to launch and operate satellites to this extent, that does not automatically mean that their activities in outer space, an area beyond national sovereignty, are therefore in perfect accordance with the strictures of international law. Indeed, national permissions offer no such guarantee.

5.1.6 No Due Regard for Others

That these megaconstellations violate the prohibition on appropriation in Article II is additionally supported by Article IX of the Outer Space Treaty. Article IX requires that in the exploration and use of outer space, States "shall be guided by the principle of cooperation and mutual assistance and shall conduct all their activities in outer space... with due regard to the corresponding interests of other States..." There is hardly any way to view this deployment of megaconstellations as showing any type of due regard to the corresponding interests of others. This lack of regard further supports the notion of their unilateral transgressive violations of the purposes of space law norms.

5.1.7 Harmful Contamination

The impacts of the spacecraft on the pressing issue of space debris need not be gone into detail here. Suffice it to say, megaconstellations threaten mega-debris. The failure rate of these comparatively cheap satellites should give pause, because if 5% of a constellation of 100 satellites fails, this is 5 guaranteed new pieces of debris intentionally introduced to the fragile space domain. Article IX of the Outer Space Treaty warns of harmful contamination of the space environment and requires States to take appropriate measures to prevent this harmful contamination. A responsible government could not, in all seriousness, permit the intentional release of such amounts of space debris, especially in the already fraught orbits that many megaconstellations are headed towards.

While the threat of space debris is not directly relevant to the accusation of appropriation of outer space, it goes towards the argument that these actors are conducting activities in a manner lacking in regard to others, and in fact, amounts to excluding others from using the space domain. By excluding others, this has the effect of taking orbits for themselves, which IS occupation.

5.1.8 If This Isn't Appropriation, Then What Is?

Arguing in the alternative, if these megaconstellations — in their dominant occupation of entire orbits in orbital planes with numerous satellites — could be considered (merely for the sake of argument) to not be appropriation, we must therefore ask: what *would* be appropriation? What use of void space, including orbits of the Earth, would constitute actual appropriation? What further, additional fact of these uses of space, if added to the scenario, would cause that constellation to cross over the line into clearly prohibited appropriation? Perhaps the exact same scenario, but supplemented with an actual, formal claim of sovereignty, issued by a government, is the only element which could be added to megaconstellations which would then cross the threshold into appropriation. However, a formal claim of sovereignty would be merely an act occurring on Earth and would not change any actual facts in the space domain. Consequently, the lack of a formal claim of sovereignty should not be the deciding criteria in arriving at the conclusion that megaconstellations constitute appropriation of orbits.

5.1.9 Conclusion

In conclusion, these megaconstellations effectively occupy entire orbital regions with their vast fleet of spacecraft and in so doing effectively preclude other actors from sharing those domains. They have done so, or are attempting to do so, without any international consensus or discussion, which is most egregious for a domain outside of State sovereignty and which no State can own. Governments will ultimately be responsible for this appropriation, and both are prohibited from appropriating space. In distinction to GSO, their permission to go there means that they could occupy these regions for incredibly long periods — which again shows their appropriation. These constellations significantly prevent others from using those regions, which therefore interferes with others' right to explore and use space. And ultimately, this reckless ambition shows absolutely no due regard (as per Article IX) for the corresponding rights of others. As such, these megaconstellations constitute an impermissible appropriation of particular regions of outer space, regardless of any formal, official claim of such by a responsible, authorizing government.

5.2 No, This Is Not Impermissible Appropriation

An opposite conclusion can also be reasonably arrived at when approached along the following lines. The counter argument would assert that the deployment and operation of these global constellations, such as SpaceX's Starlink, OneWeb, Kepler, etc., are aligned with and in full conformity with the laws applicable to outer space. These constellations are merely the exercise and enjoyment of the freedom of exploration and use of outer space and do not constitute any impermissible appropriation of the orbits that they transit.

5.2.1 Freedom of Access and Use Permits Constellations

Rather than being a violation of other's rights to access and explore outer space, the deployment of these constellations is more correctly viewed as the exercise and enjoyment of the right to access and use outer space. Article I of the Outer Space Treaty establishes a right to access and use space without discrimination.

Not allowing an actor to deploy spacecraft, regardless of their number or destination, would be infringing with the exercise of their freedom. It would be discriminatory. Additionally, actors do not need permission from any other State, or group of States, to access and explore outer space.

5.2.2 Aligned with the Intentions of the Outer Space Treaty

This use of outer space by constellations in LEO, while not explicitly mentioned by the drafters of the Outer Space Treaty or other space law, actually is the fulfillment of their visions for the use of outer space. The preamble to the Outer Space Treaty (which contains the subject matter and purpose of the treaty and can be used for interpreting the operative articles of the treaty) speaks of the aspirations of humanity in exploring and using outer space. It is easy to see constellations that will provide Internet access to the world as fulfilling the visions of the drafters:

> *The States Parties to this Treaty*,
>
> *Inspired* by the great prospects opening up before mankind as a result of man's entry into outer space,
>
> *Recognizing* the common interest of all mankind in the progress of the exploration and use of outer space for peaceful purposes,
>
> *Believing* that the exploration and use of outer space should be carried on for the benefit of all peoples irrespective of the degree of their economic or scientific development,
>
> *Desiring* to contribute to broad international cooperation in the scientific as well as the legal aspects of the exploration and use of outer space for peaceful purposes,
>
> *Believing* that such cooperation will contribute to the development of mutual understanding and to the strengthening of friendly relations between States and peoples,

As such, subsequent article of the Outer Space Treaty should be read in a permissive light, as permitting constellations, rather than a restrictive light which only sees potential negative aspects of constellations.

5.2.3 Due Regard and Harmful Contamination Will be Addressed

Operators in LEO are well aware of the challenges to space sustainability that their constellations will pose and will be taking efforts to mitigate the creation of debris. OneWeb is keenly focused on space sustainability and has even argued that the current norm, whereby spacecraft are not in space for longer than 25 years and are deorbited from lower orbits at the end of their lifetime (aka post mission disposal), is not sufficient to keep outer space clean and that shorter lifespan limits should be imposed on operators, especially operators in LEO, and operators of small satellites.

Additionally, these systems will be able to cooperate with emerging space safety and space traffic management plans and can operate in ways that do not restrict or impinge on other users of the space domain. Because due regard is therefore displayed for the space domain, and to the interests of others, these constellations do not prejudice or infringe upon the freedoms of use and exploration of the space domain and are therefore not occupation, or possession, much less appropriation.

5.2.4 This Does Not Constitute Possession, or Ownership, or Occupation

The use of LEO by satellite constellations is substantially similar to the use of GSO, and therefore permissible. In each region, individual actors are given permission - either from a national administrator or from an international governing body (the ITU) via a national administer–to use precoordinated subsections of space. In a way that is overwhelmingly similar to the use of orbital slots in GSO, the placement of spacecraft into orbits in LEO or higher orbits does not constitute possession, ownership, or occupation of those orbits. This is because States (and their companies) have been occupying orbital slots in GSO for decades, and these uses of GSO have never been accused of "appropriating" GSO. The users have never claimed to be appropriating GSO, and their exercising of rights to use GSO is respected by other actors in the space domain. This is the same situation for other orbits, including LEO and other non-Geostationary orbits.

And while GSO locations are relatively stable (subject to space weather and other perturbations, and require stationkeeping), spacecraft in LEO are actually moving through space and are not stationary, so it is even more difficult to see this use by constellations as occupation, much less appropriation. Moreover, Space Situational Awareness (SSA) and Space Traffic Management (STM) will allow other uses to use these orbits, and nothing about the use of any one user necessarily precludes others. Lastly, there is no intention by operators of constellations to exclusively occupy, must less possess or appropriate, these orbits. Would not the appropriation of outer space be an intentional, volutional act? No such intention can be found in the operators of global constellations.

5.2.5 Conclusion

The development and deployment of constellations is certainly a unique and impressive technological development which will bring unprecedented advancements to both space activity and concerns here on Earth. It offers more benefits than risks. Rather than being multiple users which would threaten orbital safety, a single user at any altitude makes SSA and STM easier, and the actor merely has to govern their own spacecraft, rather than worry about others spacecraft. No such data sharing issues will exist with global constellations.

Consequently, and in conclusion, it is in the wider public interests to permit, and not prevent, actors from planning, developing, deploying, and operating constellations in LEO. This technological advancement, of plentiful, off-the-shelf spacecraft, is the wave of the future for space exploration and utilization. It should not only be permitted, it should be positively authorized, fostered, and nurtured. It is a future we want, where all can benefit from space technologies and capabilities.

6 Conclusion

This chapter has gone over some basic foundational elements in space law, as found in the Outer Space Treaty and subsequent treaties, as well as the ITU regime for frequencies and orbits. Both regimes speak of the freedom of access and use of outer space, as well as the obligations respecting the rights of others to also explore and use outer space. Various articles of the Outer Space Treaty, either creating explicit rights or obligations, or other articles iterating more general concepts (such as due regard, harmful contamination) are applicable to constellations. Some pertinent facts from proposed near-term large constellations of small satellites in LEO were mentioned, and then the legal implications of these constellations were provided.

An argument as to why these constellations constitute impermissible appropriation outer space was made. To be balanced, this argument was followed by a counter-argument as to why these constellations are not an impermissible appropriation. The reader can weigh these arguments and consider which of them, if either, is the more valid and convincing.

It is hoped that this chapter will bring greater context and clarity to those concerned with constellations in LEO and that these novel activities, while certainly attractive for various reasons, have implications under space law and should give cause for concern when considered in the context of space safety and sustainability, as well as implications for international geopolitical reasons. Constellations of small satellites in LEO are certainly the wave of the future and will continue to be developed and deployed. They should be undertaken in a way that adheres to both national and international law, and in a sustainable fashion which protects the long-term sustainability of the space domain, and takes into account not just the interests of the operators, but other users of the space domain, as well as potential future users, and of generations to come who will inherit the space domain as a place for their exploration and use. Respect for the integrity of the space environment remains a lasting value to take into account in all present activities.

Deorbit Requirements and Adoption of New End-of-Life Standards

Timothy Maclay

Contents

Abstract

Responsible end-of-life disposal measures have been recognized as a critical component of orbital debris mitigation practices from the earliest discussions on space sustainability. NASA's first orbital debris safety standard in 1995 outlined different disposal methods for missions operating in different orbital regimes, limited post-mission orbital lifetime, and called for decommissioned assets to be passivated. It also specified a reliability threshold for post-mission disposal maneuvers and capped the casualty risk resulting from an object's reentry into the atmosphere. Since then, many organizations have issued statements, policies, and standards to promote responsible disposal practices. This chapter reviews some of the more notable publications on the subject, as well as a framework in which all stakeholders can work together to encourage the international community to adopt new standards.

1 Introduction

Proper disposal of space hardware has been a central and consistent theme in debris mitigation practices from the earliest discussions on space sustainability. The orbital environment has long been recognized as a natural resource with limits in its capacity to host the hardware that spacefaring nations have been launching in pursuit of the tremendous benefits that satellite applications offer. The natural, dynamic processes that serve to cleanse the Earth's oceanic, atmospheric, and land ecosystems are virtually nonexistent in space. In fact, the only natural cleansing process for the space environment is orbital decay via atmospheric drag, a force that weakens exponentially with altitude and is only truly effective for satellites in the lowest portions of low-Earth-orbit (LEO). Without very intentional management of mission detritus, the sources of orbital debris can outpace this natural sink and threaten the sustainability of activities in this seemingly vast but fragile environment.

Donald J. Kessler and B. G. Cour-Palais forewarned of the possibility of environmental instability when they published a seminal paper in 1978 entitled, "Collision Frequency of Artificial Satellites: The Creation of a Debris Belt" (Kessler and Cour-Palais 1978). This early work postulated that an unchecked increase in the population of uncontrolled objects in LEO would eventually lead to cascading collisions and a self-perpetuating growth of orbital debris. However, well ahead of reaching such a point of instability, inadequate disposal practices can lead to increased mission cost, risk, and operational burden for those who follow.

In response, debris mitigation recommendations, standards, and even regulations have been introduced and refined over several decades. At their core, they all share a common objective to encourage space operators to design and operate their missions in ways that do not unnecessarily contribute to the orbital debris environment. Debris mitigation practices typically address four topical areas:

- Intentional debris generation
- Explosion prevention
- Collision avoidance and impact resilience
- Prompt, reliable, and safe disposal

The first of these encourages the use of bolt catchers and other devices to retain debris created by explosive actuators, discourages the release of shrouds or lens caps, and calls for a halt to on-orbit kinetic anti-satellites (ASAT) weapons testing. Explosion prevention focuses largely on preventing the energetic rupture of components (e.g., batteries and pressure vessels) through robust design of hardware, software, and operational procedures. The third category mitigates the risk of colliding with large objects or becoming disabled by a small-particle impact by recommending that satellites are designed to protect critical components and include maneuvering capabilities, and that operators monitor their surroundings for conjunctions with other known objects and take appropriate collision avoidance precautions. And while all of these contribute to an operator's ability to promptly, reliably, and safely dispose of hardware at the end of its mission, there are additional measures focused directly on this last area. This chapter looks in depth at these in particular, reviewing existing guidance and the mechanisms available to industry and policymakers to encourage the adoption of responsible disposal practices by all space operators.

2 Elements of Responsible Disposal

There are a number of elements to consider in planning for the responsible disposal of orbital hardware at the end of its useful mission life (end-of-life, or EOL). One is the method of final disposal. For objects operating in LEO, removal from orbit altogether is recommended. Lowering the orbit's perigee to facilitate atmospheric reentry is the usual means, but retrieval is an acceptable alternative and may become more practical with future developments in on-orbit servicing (OOS) and active debris removal (ADR) capabilities. For objects operating at higher altitudes (e.g., medium-Earth-orbit (MEO) and geosynchronous-Earth-orbit (GEO)), the cost of deorbiting can become unfeasible, and the use of so-called "graveyard orbits" (i.e., placing hardware in stable orbits with little chance of interfering with other operational assets) is a pragmatic and acceptable alternative.

For LEO objects that are deorbited, another consideration is the length of time the object remains in orbit after completing its operational mission. This includes the time it takes to conduct disposal maneuvers, and if the object is left in orbit to reenter the atmosphere randomly, it also includes the remaining orbit lifetime associated with natural decay. The less time decommissioned hardware spends in orbit, the less risk it poses as a collision or explosion hazard.

A third element is having the ability to "passivate" decommissioned hardware. Permanently depleting all internal energy sources after disposal maneuvers are completed diminishes the possibility of subsequent explosion. Otherwise, deterioration from extended thermal cycling, long-term exposure to radiation, and other environmental effects can create situations in which batteries overcharge, fuel tanks over-pressurize, or other explosive conditions develop. Chief among such precautions are disabling charging circuits, depleting battery charge, and venting propulsion systems.

One of the most important elements of disposal is simply to preserve the ability to execute the disposal operation at the end of an object's mission. Failing to do so, and leaving it in orbit potentially long-term, adds to the debris population and places an avoidance burden on other operators using the same altitude. In practice, this is also one of the most difficult provisions to satisfy, for several reasons. First, satellites do not always wear out gracefully; rather, they often fail unpredictably, and suddenly, leaving little or no time to perform disposal maneuvers once a mission-terminating problem is discovered. Additionally, operators naturally strive to keep their assets in service, working around anomalies as they are able, and care must be taken not to pursue mission extension at the expense of disposal reliability. Finally, maneuvering safely requires many of a satellite's subsystems to be functional, so a problem that takes a satellite out of service may very well render it unable to deorbit as well. For example, power, attitude control, communications, and propulsion are all necessary to deorbit a satellite under its own control.

Finally, if an object is to be deorbited, any hazards created as a result of reentry must also be considered. "Designing for demise," for example, assures that debris from an object reentering the Earth's atmosphere burns up completely at altitude such that no fragments reach the ground. However, launch vehicle upper stages, larger satellites, and objects with heat-resilient components often do not disintegrate entirely, and in these cases, the execution of a controlled reentry that targets an ocean or unpopulated landing zone may be warranted.

3 The Origins of Disposal Guidance

NASA first published debris mitigation guidelines in 1995, which took the form of Safety Standard NSS 1740.14 that was issued from NASA's Office of Safety and Mission Assurance (NASA Office of Safety and Mission Assurance, August 1995). With this publication, NASA laid out the following general policy objectives relating to post-mission disposal of space structures and limiting reentry risk:

> NASA programs and projects will assess and limit the probability of accidental explosion during and after completion of mission operations.
>
> NASA programs and projects will plan for the disposal of launch vehicles, upper stages, payloads, and other spacecraft at the end of mission life. Post-mission disposal will be used to remove objects from orbit in a timely manner or to maneuver to a disposal orbit where the structure will not affect future space operations.
>
> NASA programs and projects that use atmospheric reentry as a means to remove space structures from orbit at the end of mission life will limit the amount of debris that can survive uncontrolled reentry. If there is a significant amount of debris surviving uncontrolled reentry, measures will be taken to reduce the risk by establishing procedures or designs to reduce the amount of debris reaching the Earth's surface or to control the location of the ground footprint.

NSS 1740.14 goes on to articulate specific guidelines for each, the essences of which are captured in Table 1 under headings corresponding to the four responsible disposal elements identified above. The standard allowed for three disposal options for missions with perigees at LEO altitudes (<2,000 km): atmospheric reentry, a graveyard orbit between LEO and GEO, or retrieval. It called for missions in higher orbits to use graveyard orbits exclusively, either between LEO and GEO, or above GEO by at least 300 km. It also included an additional restriction for missions in

Table 1 Disposal provisions in NASA's original 1995 Safety Standard NSS 1740.14 and 2012 Technical Standard STD-8719.14A (paraphrased – see original documents for full language)

Disposal element	NSS 1740.14 (1995)	STD-8719.14A (2012)
Disposal method	Missions with perigees <2,000 km: Atmospheric reentry Storage orbit between LEO and GEO or Retrieval Missions with perigees >2,000 km: Storage orbit between LEO and GEO or Storage orbit above GEO by >300 km Additional exclusion of storage orbits that pass within 300 km of 20,200 km altitude	Missions with perigees <2,000 km: Atmospheric reentry Storage orbit between LEO and GEO or Retrieval Missions near GEO: Storage orbit above or below GEO by >200 km Missions between LEO and GEO: Storage orbit with perigee >2,000 km and apogee below GEO by >500 km Exclusion of circular storage orbits near high-value operational assets (e.g., 20,200 km)
Orbital lifetime	Limited to 25 years if disposing via atmospheric reentry Limited to 10 years if disposing via retrieval	Limited to 25 years after mission completion, but no more than 30 years after launch, if disposing via random atmospheric reentry (or as soon as practical for controlled reentry) Limited to 10 years if disposing via retrieval
Energy passivation	Depletion of all on-board sources of stored energy upon completion of mission operations and post-mission disposal maneuvers	Depletion of all on-board energy sources to level that cannot cause breakup once no longer needed for mission operations, post-mission disposal, or control
PMD reliability	Probability of successfully completing disposal of at least 0.99	Probability of successfully completing disposal of at least 0.90
Reentry risk	Controlled reentry or limitation of total debris casualty area for debris surviving an uncontrolled reentry to 8 m^2	Uncontrolled reentry: Limited to 0.0001 (1:10,000) Controlled reentry: Landing zone >350 km from non-US land masses and >50 km from continental US, US territories, or Antarctica Product of reentry burn failure and uncontrolled casualty risk limited to 0.0001 (1:10,000)

near-circular 12-h orbits to use a graveyard orbit at least 300 km above or below 20,200 km altitude to protect the semi-synchronous region.

This first standard also established 25 years as the acceptable orbital lifetime for objects being deorbited via random reentry, although it allowed only 10 years for removal if retrieval is the chosen method. It required all on-board energy sources to be depleted as soon as disposal operations are completed and stipulated a post-mission disposal (PMD) reliability of at least 0.99. Finally, it called for a controlled reentry for objects that were expected to produce a casualty area of more than 8 m^2 under random reentry conditions.

While NASA's 1995 Safety Standard clearly applied only to NASA programs, this early work served as a precedent and basis for debris mitigation policies from other organizations around the world. The National Space Development Agency of Japan (NASDA) adopted similar technical provisions when issuing their own debris mitigation standard in 1996 (National Space Development Agency of Japan, March 1996). The French space agency CNES (Centre National d'Etudes Spatiales) then published theirs in 1999 (Centre National d'Etudes Spatiales (CNES) 1999). Since then a host of additional national policies have emerged since on the subject of orbital debris mitigation practices.

In fact, NASA has even updated its own standard, the latest of which was published in 2012 as NASA Technical Standard 8719.14A, entitled, "Process for Limiting Orbital Debris" (National Aeronautics and Space Administration (NASA), May 2012).

These revised provisions are also summarized in Table 1 for comparison. The most significant changes were the relaxation of PMD reliability from 0.99 to 0.90 and an extension in the timing for passivation in order to retain control of a decommissioned asset.

National space agencies are not alone, however, in publishing guidance for the responsible disposal of space hardware. Industry associations, professional associations, international standards organizations, interagency groups, and even the United Nations have all weighed in on the topic. It is notable that across these various organizations, their treatments are similar in structure and highlight the same priorities, albeit with some variation and evolution in the specific recommendations being put forward. A more thorough historical accounting of debris mitigation publications can be found in "A Handbook for Post-Mission Disposal of Satellites Less Than 100 Kg," published by the International Academy of Astronautics (IAA) (International Academy of Astronautics, May 2019).

4 Current Guidelines and Applicability

While it is not useful to detail a comprehensive anthology of published guidance, it is perhaps worthwhile to review the current state guidance from different types of organizations and how they apply to the space industry.

4.1 UN COPUOS

The most broad, international guidance is arguably provided by the United Nations' long-standing Committee on the Peaceful Uses of Outer Space (UN COPUOS). In 2007, its member states adopted a set of space debris mitigation guidelines (UN COPUOS 2007). These guidelines were put forth by its Scientific and Technical Subcommittee and made a number of qualitative recommendations related to disposal. They called for the removal of LEO objects via controlled reentry when possible, or relocation to orbits that "avoid their long-term presence in the LEO region." GEO missions were simply requested to be left in orbits that avoid long-term interference with the GEO region. A provision was also included to seek to deplete or make safe on-board energy sources when no longer needed but makes no mention of PMD success probability. Finally, the UN guidelines noted that debris surviving reentry should not pose undue risk to people or property, including through environmental pollution. These guidelines were adopted by the full Committee on the Peaceful Uses of Outer Space and then the UN General Assembly.

In addition to these 2007 guidelines, COPUOS also adopted guidelines from the Subcommittee's Working Group on Long-Term Sustainability of Outer Space Activities on two occasions. By 2019, COPUOS membership had grown to 87 member states, and consensus was reached on 21 provisions that included two touching directly on disposal. One calls on states to encourage manufacturers and operators to limit the long-term presence of space objects in protected regions after their missions are completed, and the other calls for the application of techniques to minimize risk associated with fragments surviving reentry (United Nations General Assembly, 17 July 2018).

The COPUOS guidance is necessarily general in nature, given the large number of parties involved in creating it. However, this is also by design as these provisions are not legally binding to the member states, and it was necessary to provide fairly broad latitude for states to tailor their national implementations to suit the particular situations of their domestic programs and industry.

4.2 National Policy

Implementation of debris mitigation practices at the national level typically takes the form of national policies and commercial licensing practices, and it is at least partially motivated and informed by existing UN treaties. In particular, the United Nations adopted the so-called Outer Space Treaty in 1967. Its full name is the "Treaty on Principles Governing the Activities of States in the Exploration and Use of Outer Space, including the Moon and Other Celestial Bodies" (United Nations, "United Nations Treaties and Principles on Outer Space" 2002).

Then in 1972, the UN General Assembly adopted the Liability Convention which is formally known as the "Convention on International Liability for Damage Caused by Space Objects" ("United Nations Treaties and Principles on Outer Space" 2002). These two UN international agreements together place responsibility on the state for "national activities in outer space . . . whether carried out by governmental agencies or by non-governmental entities," require the state to authorize and supervise such activities, and assign to the state the liability for any damage caused to another state party on Earth, in air space, or in outer space (Secure World Foundation 2017 edition).

One example of how debris mitigation practices are implemented in national policy is the US Government Orbital Debris Mitigation Standard Practices (ODMSP). This document was first published in 2001, and an update was released in November 2019 (U.S. Government Orbital Debris Mitigation Standard Practices, November 2019).

The more recent edition closely follows the structure of its predecessor but revises earlier guidance and provides additional technical elaboration. With regard to disposal, the ODMSP reasserts its previous recommendations to passivate immediately upon completion of mission completion, to limit post-mission orbital lifetime for a LEO object to no more than 25 years, and to limit the casualty risk associated with an object reentering the atmosphere to 1 in 10,000. It also calls for PMD reliability to be 0.9, with a goal of 0.99, specifies a deadline of 5 years rather than 10 years if active retrieval is the means of removal, and adds a number of options and a significant amount of detail to the guidance for disposal and storage orbits.

4.3 Commercial Licensing

The authorization and oversight responsibilities a country has for commercial activities in its jurisdiction are carried out by national regulatory agencies. These agencies are often working toward competing objectives; on one hand, they are charged with assuring responsible behavior by their licensees and protecting their respective governments from any liabilities stemming from licensees' actions. On the other, regulations that are too burdensome run the risk of discouraging innovation or motivating industry to do business elsewhere. As a result, regulators often establish rules that emphasize safety while allowing some degree of flexibility in demonstrating how that safety is assured.

Specific regulatory approaches vary from one country to another, but one illustrative example can be offered by considering the approach taken by the Federal Communications Commission (FCC). The FCC licenses commercial communications satellites in the USA and requires its applicants to submit an orbital debris mitigation showing, among other information. Applicants are referred to existing standards, such as the NASA Safety Standard or the ODMSP for guidance, but they are not enforced as requirements. Rather, the FCC makes an overall judgment on the basis of the application of whether the proposed mission is in the public interest. With this approach, industry is given the flexibility to demonstrate the safety of their missions in ways that may not strictly adhere to the referenced standards.

4.4 The Inter-Agency Space Debris Coordination Committee (IADC)

The IADC is an international governmental forum in which 13 member agencies exchange information and coordinate research on space debris, review progress on cooperative activities, and identify debris mitigation options. The IADC published its first space debris mitigation guidelines in 2002 and released a revision in 2007 (Inter-Agency Space Debris Coordination Committee, September 2007). There is now a further statement on large constellations issued in 2017 (Inter-Agency Space Debris Coordination Committee, September 2017).

Some notable differences in the IADC guidance are that storage orbits are not a disposal option for LEO missions at all, and an appropriately high super-synchronous orbit is the only option for disposal of GEO missions. The IADC stresses the importance of PMD reliability but stops short of specifying a threshold either for this or for reentry casualty risk. It does reassert familiar language for a 25-year orbit lifetime limit and depletion or "safing" of on-board energy sources when no longer needed for mission operations or post-mission disposal, although on this last point, their 2017 guidance does encourage operators to shorten orbit lifetime and retain the ability to conduct collision avoidance maneuvers during the disposal phase.

The IADC has no authority to enforce its debris mitigation guidelines. However, because the organization's members are government representatives from many of the world's spacefaring nations, IADC positions are regarded as international consensus and are often cited in national policies and licensing practices, and used as a reference in discussing industry norms.

4.5 International Standards

Another source of guidance comes in the form of internationally recognized standards. The International Organization for Standardization (ISO) has weighed in on the subject of debris mitigation with ISO 24113, "Space Systems – Space Debris Mitigation Requirements." Now in its third edition, ISO's 2019 release updates previous versions published in 2010 and 2011 (International Organization for Standardization 2010, 2011, 2019). This document, as updated, transforms debris mitigation objectives laid out by the UN, the IADC, and others, into specific requirements which can then be enforced by incorporating ISO 24113 into design, manufacturing, and service contracts for satellites and launch vehicles.

ISO 24113 is accompanied by a host of lower-level requirements standards that address implementation for individual topical areas (e.g., fragmentation prevention, disposal methods, reentry safety, etc.). The high-level requirements in ISO 24113 related to disposal reflect common themes with a few minor differences. ISO specifies two protected regions for storage orbits (within 200 km of GEO altitude and LEO, with an upper limit of 2,000 km) but provides no protection of semi-synchronous orbits. It reinforces the 25-year deorbit limit but differentiates starting times for missions with different characteristics. For example, satellites with propulsion systems are given 25 years to deorbit after their operational missions are completed, but for satellites with no collision avoidance maneuvering capability, the clock starts at launch. PMD reliability is required to be at least 0.90, and energy sources capable of causing fragmentation are to be depleted prior to deactivating a spacecraft or losing control of it. Finally, with regard to reentry risk, ISO 24113 simply calls for operators to comply with the requirements imposed on them by their individual licensing conditions and by national and international authorities.

4.6 Industry Associations and Professional Organizations

One striking characteristic of the guidelines set forth by all of the organizations mentioned thus far is how little they differ or have changed over the years. Despite the recent escalation of commercial launch activity and dramatic growth of the debris population (particularly in LEO), debris mitigation standards published in 2019 look remarkably similar to those proposed by NASA in 1995.

For example, the post-mission orbital lifetime threshold of 25 years has for many years withstood the test of time (slight variations of applicability notwithstanding), even though the original architects have noted that "it was an economic compromise" between environmental protection and the cost burden on operators (Kessler 2019). Since then, with technological improvements driving down satellite manufacturing and launch costs, coupled with the proliferation of microsatellites and introduction of large constellations increasing the need for more deliberate management of the orbital environment, this foundational economic balance must assuredly be shifting.

Surprisingly, it is industry rather than governments or regulators that is putting forth today's most progressive proposals in debris mitigation. A number of industry associations and professional organizations have made statements and issued position papers on space sustainability and debris mitigation practices, and one of the most significant of these is a 2019 publication by a new group of industry stakeholders, called the Space Safety Coalition (SSC). The SSC's, "Best Practices for the Sustainability of Space Operations" (Space Safety Coalition, September 2019) puts forward 31 debris mitigation recommendations that were approved by consensus by the coalition's 37 member organizations.

The SSC's best practices call for operators to comply with guidance from the ISO, the IADC, and the UN COPUOS, but then also to adopt a number of provisions that go above and beyond these standards. Building on preexisting guidance, the SSC also makes several suggestions to increase the ability to perform disposal operations. For example, it calls for operators to consider including technologies and features that facilitate capture and deorbit in the event their spacecraft become derelict, and it suggests that passivation measures could be automated to occur if an operator loses contact or control of its asset. The SSC's best practices include a reassessment of PMD reliability prior to extending a mission beyond its design life and stress the importance of PMD by increasing the reliability threshold from 0.90 to 0.95.

With regard to orbital lifetime, the SSC raises the bar for spacecraft with propulsion systems to deorbit within 5 years of mission completion rather than allowing dead spacecraft to linger in LEO for up to 25 years. For those satellites with no active propulsion capabilities, the SSC simply urges operators to strive to deorbit as quickly as possible.

SSC guidance for passivation balances the risk of explosion that arises from retaining on-board energy sources for long durations, with the risk of collision that results from surrendering the ability to conduct collision avoidance maneuvers. The coalition's recommendation is to passivate if post-mission lifetime is expected to be longer than 5 years but to otherwise retain the capability to perform collision avoidance maneuvers during the deorbit phase.

Finally, with regard to reentry risk, the SSC restates existing guidance the reentry casualty risk should be limited to 1:10,000 per object but adds a consideration for operators of multi-satellite systems to evaluate casualty risk on a system-wide, annualized basis. This is particularly important for constellations and other systems that will be replenished on an ongoing basis.

5 Conclusion

Encouraging the widespread adoption of new end-of-life standards will require international coordination among a variety of stakeholders, including governments and regulatory agencies, commercial companies, and nongovernmental organizations. Each plays a distinct role, and the most effective means of shifting behavioral norms in a more responsible direction may be to leverage the influence each has to offer in complementary ways.

A three-tiered approach to accomplishing this was proposed by Maclay and McKnight in a paper they presented at the 2019 International Astronautical Congress (Maclay and McKnight 2019). The concept is illustrated in Table 2. At its foundational layer, a core set of minimum requirements is established within internationally coordinated licensing regimes. These requirements represent the minimum behavioral threshold an operator must meet in order to be granted authorization to launch. It is important for these to be negotiated and normalized internationally to discourage operators from "shopping" for an optimally permissive licensing regime.

A middle tier is where behavioral expectations are set. This is where standards, norms of behavior, and recommendations reside. IADC recommendations, ISO standards, industry association positions, and the like, all contribute to the establishment of what stakeholders expect of each other, which is often well above minimum licensing requirements.

Finally, there needs to be an aspirational tier. This layer articulates the spirit of a particular metric and might even be evaluated on a sliding scale with an unattainable top end. The benefit of this element is to encourage industry's best behaviors by offering some sort of incentive for going above and beyond the behavioral norms. The World Economic Forum is creating the Space Sustainability Rating to do this, with a concept that missions would be evaluated against a number of metrics and awarded an environmental rating commensurate with their achievements towards preestablished, aspirational goals. Other means of encouraging truly

Table 2 Tiered approach to encouraging the adoption of new end-of-life standards

Tier	Bar	Mechanism	Incentive
Aspirational	High	WEF SSR	Rating certification
Expected	Medium	Recommendations Norms Standards	Corporate image Peer pressure Contracts
Required	Low	Licensing	Permission to launch

best behavior include corporate peer pressure, consumer pressure, and even pressure from the investment and insurance communities.

The orbital environment is a shared natural resource and a valuable, fragile environment. Avoiding a tragedy-of-the-commons in space will ultimately require stakeholders to coordinate globally and focus on the creation and adoption of more sustainable disposal standards for space hardware.

Small Satellites and Their Challenges to Space Situational Awareness (SSA) and Space Traffic Management (STM)

Mark A. Skinner

Contents

Abstract

Small satellites have actually been flown since the beginning of the space age; Sputnik and Vanguard were only tens of centimeters in diameter. For many years however, the trend was to make larger, more powerful, and more complex satellites. Launch vehicles became more capable, able to place in orbit these larger satellites. Recently, thanks to miniaturization of electronics and standardization of sizes, there has been a resurgence in smaller, less expensive (and often less capable) satellites. Rideshare-like services coordinate among small satellites to allow many to share a launch vehicle. Rather than one rocket launching one or a few satellites, many scores are now being launched at once. Space is now more affordable and accessible than it has ever been, but how this new crowded space environment is managed has not kept up with the changes in technology and activity. Efforts to enable space traffic management (STM) are under discussion, and hopefully under way soon, but challenges remain. Such challenges include basic ones to space situational awareness (SSA), such as small satellites being hard to detect, track, identify, and characterize. Existing SSA systems have a hard time keeping up with their smaller sizes and increasing numbers. Often small

satellites are not as capable as larger, more expensive system and may lack propulsion, system redundancies, and other safety features, which can be problematic for maintaining a safe near-space environment. As the barriers to entry have lowered, new actors in the space arena have emerged, often without the hard-learned experiences of legacy space actors. Additionally, some “New Space” entrants bring with them a Silicon Valley mindset of “fail fast and break things.” This philosophy is perhaps thought incongruent to the long-term sustainability of outer space. These challenges to the status quo may be resolved through better definition of the governance regime and furtherance of regulations, guidelines, and best practices for STM, by improved technologies (including processing techniques) for SSA, and via education, outreach, and discussion with new entrants in the space regime.

Space traffic management · Space situational awareness · CubeSats · Space safety

1 Introduction

Since the start of the space age, various techniques have been devised to detect, identify, and/or obtain trajectory information for satellites. These included using optical telescopes (Institute for Astronomy (IfA) Maui History 2019) and radars (Sridharan and Pensa 1998) to detect and track these early space objects. Compared in size to a modern geosynchronous earth orbit (GEO) communications satellite, satellites from the 1950s and 1960s were quite diminutive and would be considered “SmallSats” today (as may be seen in Figs. 1 and 2).

The first man-made object to orbit the earth, Sputnik 1, was “tracked” by amateur radio operators and was essentially an RF (radio-frequency) beacon that lasted only 22 days; the USSR had no satellite surveillance capability at the time (Universe Today).

For the purposes of discussion, the term “SmallSat” is defined here to be those objects that are currently at the cusp of detection and tracking via standard

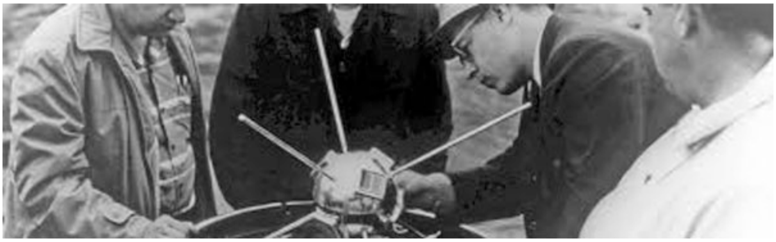

Fig. 1 NASA’s Vanguard satellite was launched on March 17, 1958. Although contact with it was lost in 1964, Vanguard 1 remains the oldest artificial satellite still in earth orbit. (Photo courtesy NASA 2019)

techniques. At present, they are roughly defined as objects ~10 cm in low earth orbit (LEO) and ~1 m at GEO (NASA).

NanoSats (generally defined as between 1 and 10 kg mass (Nano/Microsatellite Market Assessment 2014)) and CubeSats (multiples of 10 cm cubes (Mehrparvar 2014)) are in this size range and are often at the limits of detectability/trackability by space situational awareness (SSA) or space traffic management (STM) systems. Additionally, CubeSats, due to their building-block approach (***n***U form factor), are often indistinguishable from one another, and so this becomes an acute difficulty for SSA/STM systems when several are launched at once (Committee on Achieving Science 2016; Skinner in press), often in an unpowered state. The SSA/STM centers are frequently unable to associate initial orbit trajectory information with an identified CubeSat, which may delay (sometimes up to months) the CubeSat owner/operator (O/O) from making contact with their satellite.

2 Benefits Derived from Small Satellites

Small satellites offer and have realized for society many potential benefits. Their small size and lower cost have allowed for the "democratization" of space, with many states and non-state actors being afforded access to space that previously could not afford the cost of entry. This can be seen both in the number of countries that now have their own satellites for the first time and the increase in the membership of the United Nations Committee on the Peaceful Uses of Outer Space (UN COPUOS) (United Nations Office for Outer Space Affairs). Additionally, the lower cost of small satellites can allow for more proof-of-concept missions and rapid prototyping. This has been demonstrated by, among others, The Aerospace Corporation's series of AeroCube missions (The Aerospace Corporation). Another benefit can accrue to the education of space users; the rapid development cycle (a couple of years rather than ~7–10 years it would take for traditional NASA-style science missions) fits in better with the career “timelines” of undergraduate and graduate students, and the lower costs allow for meaningful participation of even high school and middle school students and hobbyists. The lower costs to acquire and launch small satellites resulted in a rapid increase in the number and variety of new satellite missions.

3 Challenges Posed by Small Satellites

In addition to the benefits afforded by small satellites, they bring with them a host of challenges to the current SSA and STM systems. One of the primary concerns with small satellites is the difficulty of detecting, tracking, and characterizing them. Their small sizes typically offer low returns of signals (radar or optical) for this task. Additionally, consolidation of launches for small satellites, offering a very low cost to orbit, means a massive proliferation of objects in LEO. As Muelhaupt et al. have pointed out (Muelhaupt et al. 2019), a large increase in the number of objects in space, especially LEO, makes the situation very difficult for the current system to react and greatly affects how existing users can conduct their space operations; “business as usual” cannot be maintained.

Small satellites can be hard to identify (due to their oftentimes similar shapes and the low signal-to-noise ratio of radar or optical signals reflected from them), especially during massive launches of CubeSats. Many objects are launched and have still not been positively identified even months after launch (Klotz; Kelso; Skinner in press). Due to their use in rapid prototyping and inexpensive pathfinder missions, and the experimental mindset for these types of missions, small satellites sometimes lack redundancy, and sometimes subsystems such as propulsion, or lack radiation-hardened parts. As one launch consolidator noted, many small satellites are just one SAA passage away from demise (Jeff Roberts, August 2019, Spaceflight Inc., 2019, private communication). This can mean that the small satellite lifetime is much lower than the orbital lifetime, and depending on the orbit of the satellite, it may not be able to be de-orbited within 25 years of the end of the mission. Lack of propulsion hinders collision avoidance with debris objects and also makes the small satellite effective “debris” during encounters with other, larger satellites that do have propulsion.

With the lower costs that small satellites can potentially afford, such as using a CubeSat kit or a shared ride to orbit, and the entrance of many new actors in the space arena (even, e.g., economic journalists (Planet Money)), it may be that the owner/operator of a small satellite is relatively inexperienced, and is perhaps not aware of rules, regulations, guidelines, and best practices, and has not experienced the “hard” lessons of space. What is also seen is the use of small satellites as a test bed for some New Space concepts that often come with an entrepreneurial “move fast and break things” mindset. As Oltrogge et al. (2019) have noted:

> From a financial perspective, this is a classic example of a “Negative Externality,” wherein a spacecraft operator may willingly lose a satellite to a collision or explosion or hardware failure, especially for large constellations with multiple redundancies and quick re-launch/refurbish capabilities. In this situation, the cost to that operator is substantially less than the

> potential cost to society for addressing the subsequent fragmentation event and the debris it generates.

A somewhat overlapping issue to the profusion of small satellites is the proliferation of large constellations of LEO satellites; while only a few of these constellations are planning to deploy small satellites as defined here, there are several constellation deployments planned of 100s and 1000s of new satellites, which may make space operations much more complex. As Muelhaupt et al. (2019) have noted:

> A key element of the problem is that an increase in the LEO population will lead to an increase in close approaches to existing satellites, and the potential for accidental collisions. Conjunction prediction, collision probability (Pc), and maneuver planning for most existing satellite operators is a time- and personnel-intensive operation. Orbit analysts, and propulsion, navigation, and communications systems personnel are involved in evaluating and planning maneuvers over several days and must do so even if the ultimate decision is to "fly through" a close approach. Since most existing systems have small numbers of vehicles and the number of conjunctions any given operator experiences is relatively small, COLA remains a manual process. For systems not designed with automated maneuver planning, a COLA assessment that progresses all the way to a maneuver plan can consume considerable effort, whether or not the maneuver is executed.... Existing operators will not necessarily have large constellations parked nearby, but they will nonetheless be affected by the new activity. The new large constellations' satellites typically will have relatively short lifetimes and will need frequent replenishment. The traffic transiting up and down will be substantial, and failures could leave stranded objects at intermediate altitudes, permanently increasing the collision risk.

Recent events that have affected the community of space users include Swarm and their Space Bees (an unsanctioned launch) (Koren 4/19), SpaceX and the European Space Agency (ESA) close approach (poor cooperation between operators) (Koren 9/19), and SpaceX and the impact of their Starlink satellites' reflections on ground-based astronomers' observations (AAS).

With the growth of commercial and other nongovernmental space missions, another challenge posed is the impact, in some jurisdictions, of the increase in launches on the national airspace. These launches have the potential to disrupt the existing air traffic regime. In the past, when there were many fewer launches, and they were mostly of national significance, the commercial airlines just put up with the disruptions. But with the current trend toward commercial space, airlines are perhaps less willing to suffer delays and loss of revenue to accommodate the new commercial space launches (CRS Reports).

4 Solutions to These Challenges

4.1 The Transition from SSA to STM to SOA

How can the challenges that the proliferation of small satellites means to safe space operations for all space actors be met? There will need to be done more than just improve the knowledge of where things are in space (SSA); better monitoring, management, and regulation of what goes into and what happens in space (STM) will be needed. If this multifaceted approach is taken, it may be possible to transition to Space Operations Assurance (SOA) (Skinner et al. 2019).

What is "space situational awareness"? What is "space traffic management" and "space operations assurance"? How do small satellites challenge them? The topic of "space traffic management" is currently being widely discussed at various international events (Global STM Workshop, STM at IAC 2017, IAASS, SWF 2017). But what is it? Various definitions abound (IAA Cosmic Study, Ailor). The International Academy of Astronautics studies on STM put forward the definition that STM is "the set of technical and regulatory provisions for promoting safe access into outer space, operations in outer space and return from outer space to Earth free from physical or radio-frequency interference (IAA STM)." STM can also be defined in relation to how it relates to space safety and what practical elements make up the activity of STM, with a comparison to the more "intent"-oriented aspects of SSA (Skinner 2018); see Fig. 3 for a graphical depiction of this. STM, unlike SSA, generally includes a "management" or "regulatory" aspect, in addition to monitoring and safety advisory elements. Recent activities within the US government have sought to hand these management aspects to the Federal Aviation Administration Office of Commercial Space Transportation (FAA AST) or the Dept. of Commerce Office of Space Commerce (DOC OSC); Space Policy Directive 3 (SPD-3) explicitly proposes to hand the bulk of the regulatory aspects to the DOC OSC. It was recognized that a regulatory agency would need to take on these responsibilities and

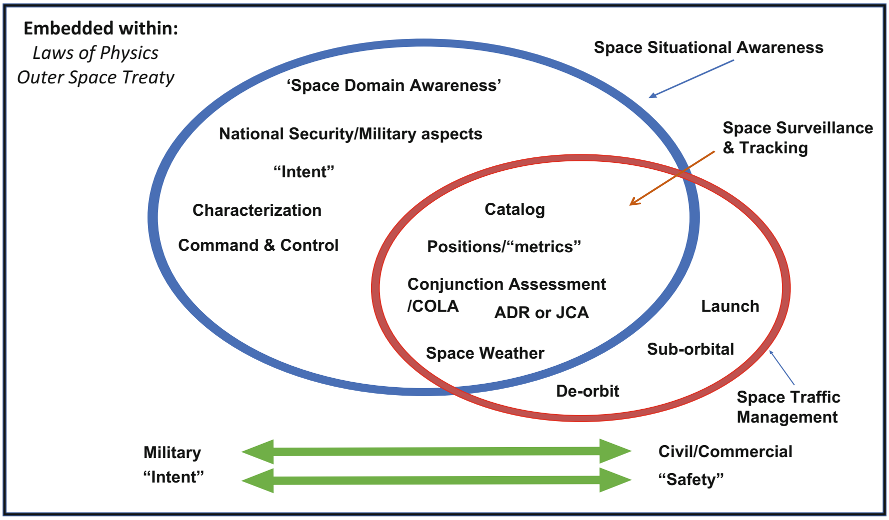

Fig. 3 Comparisons and contrasts of space situational awareness, space surveillance and tracking, and space traffic management from the point of view of a practitioner, based on constituent elements. While launch/sub-orbital/de-orbit activities are of interest to the military, they do not necessarily fall under the rubric of SSA, but the boundaries can be indistinct. ADR is defined as *active debris removal* and JCA as *just-in-time collision avoidance*

that neither of the two chief purveyors of SSA, NASA and the US Air Force, were regulatory agencies.

McKnight (Skinner et al. 2019) defines STM within the broader parameters of Space Operations Assurance (SOA), a framework that has three major categories:

> First, space environmental effects and modeling (SEM) describes why space objects behave the way that they do and informs the next major domain, space situational awareness (SSA). SSA describes what the space objects do in orbit to provide critical background context for space traffic management (STM). STM enables reliable satellite operations for all satellites but with a focus on the potentially large constellations that are slated to be deployed in the near future. Each of these three areas is normally fueled by different people with different skills, yet the final positive outcome depends on all of the players' contributions. The term Space Operations Assurance (SOA) is proposed as the overarching domain (encompassing SEM, SSA, and STM) to fulfill this need. These concepts are displayed in Fig. 4.

But what is advocated for here is that the current regime will not be able to adequately address the challenges posed by a plethora of small satellites; a new civil STM regime as per SPD-3 that can better deal with burgeoning commercial space field (Skinner 2018) will be required. As Muelhaupt et al. have noted (Muelhaupt et al. 2019):

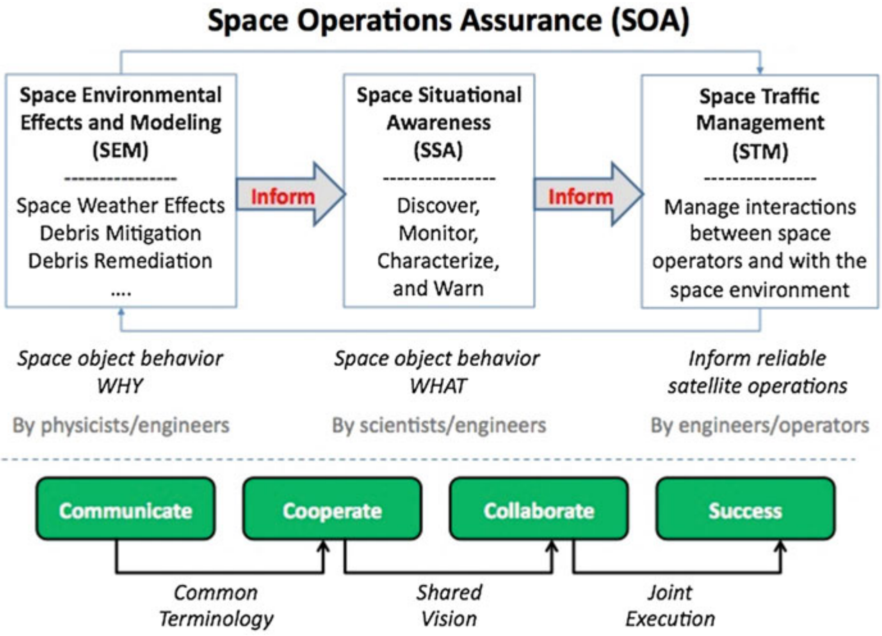

Fig. 4 Space Operations Assurance cycle and the relationship between the constituent members that include SEM, SSA, and STM

> The creation of a new civil space traffic management organization is an opportunity to change "business-as-usual" for space operations. One of the goals listed in SPD-3 is to create an open architecture for sharing SSA data, and foster innovation. A new STM agency can work to establish an effective public-private partnership with industry to address the common needs of the space community.

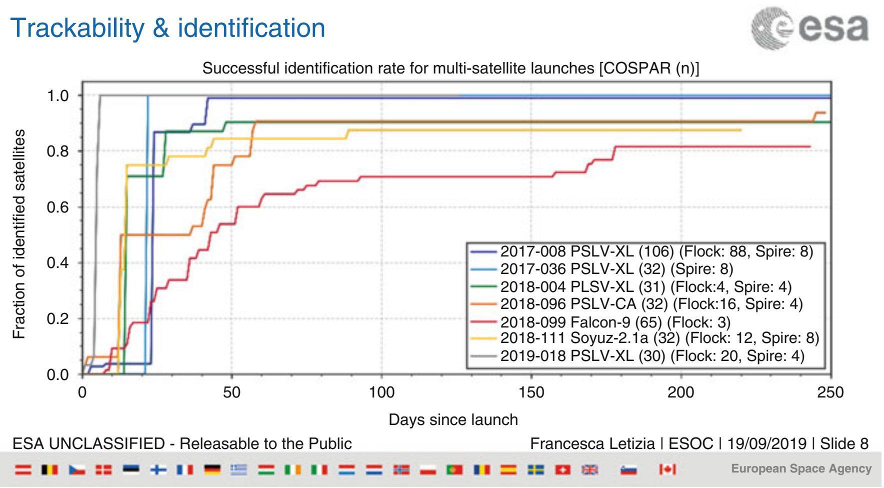
In this new space traffic management regime, how can regulators and future small satellite owner/operators work together to mitigate impacts on existing space operations? There are two key areas of possible cooperation. Primarily, given that small satellites are by definition difficult to track and identify, future STM regulations might stipulate a performance-based approach to making small satellites more visible, by identifying advanced techniques and technologies that owner/operators could choose from during mission design, which, if implemented, would make it easier to determine the location and identification of these small space objects. Such technologies could include optical corner cube reflectors, GPS signal-based positioning devices, radar reflectors, optical beacons, and the like (Skinner 10/19). The second key aspect to the partnership between STM regulators and owner/operators is to coordinate the enhanced sharing of information before, during, and after the active phases of the mission. This may include frequent updates to satellite position, status, maneuver plans, changes in orbit, information on neighboring space objects, etc. In many cases, it may be desirable for the information to be exchanged in an automatic, machine-to-machine fashion, for example, for GPS-based position updates, real-time maneuver information, etc.

As outer space lies above the national airspace (NAS), it is inherently international in nature, with potential interaction between space objects under the supervision and control of various states. Thus, the discussions in the international regime are crucial to mitigating challenges of small satellites. Important high-level multiparty discussions include the work on long-term sustainability at the United Nations Committee on the Peaceful Uses of Outer Space (UN COPOUS) (COPUOS Guidelines); the recently concluded International Telecommunication Union (ITU) World Radio Conference (WRC-19) that included treaty-level discussion on bringing into use of large constellations of satellites, shortened licensing times for short-duration satellites, and amateur frequency band allocations, among other topics (ITU WRC-19); and the Inter-Agency Space Debris Coordination Committee (IADC) technical discussions on space debris guidelines (IADC), as well as work on standards at meetings of the International Organization for Standardization (ISO) (ISO). An important addition to these high-level multilateral fora are the frequent discussions and exchanges of technical information at international conference and workshops, e.g., the International Astronautical Congress, Secure World Foundation-sponsored events, and events sponsored by Lockheed Martin and the Royal Observatory Edinburgh, as well as Embry-Riddle Aeronautical University, University of Texas at Austin, and McGill University, among others.

Technical solutions to small satellite challenges include utilizing novel techniques for tracking and identification of small space objects (Skinner et al. 2019). This can entail implementing techniques or importing information from traditional and non-traditional SSA data providers, to exploit "new" classes of information (space object phenomenologies, observables, "feature-aided tracking" (Chong), etc.) regarding space objects. Necessary standards would need to be created if not currently existing that would allow SSA/STM centers to ingest owner/operator measurements and data in an automatic machine-to-machine fashion; this is especially important for objects that are quasi-continuously thrusting (e.g., employ electric propulsion). This has the important benefit of reducing the burden on radars and optical tracking stations, with potentially improved accuracy, and by automating the process and removing the human in the loop may also improve accuracy and reduce errors.

Another especially important aspect to small satellites is reducing the time it takes to identify newly launched batches of CubeSats (Skinner 2020) (see Fig. 5), as well as development of "space safety" technologies for small satellites, such as appropriate propulsion systems, automatic id/position devices, and de-orbit solutions, including inflatable balloons and drag sails. It would be advantageous to see future small satellites that have built-in high reliability for post-mission disposal, potentially including a "dead man switch" that would allow the vehicle to automatically remove itself from orbit if it loses contact with the ground (Muelhaupt et al. 2019), as well as built-in capability for high-precision orbit knowledge from precision navigation and timing signals, and abilities to automatically share position and maneuver data.

The final aspect to dealing with the challenges to the space environment from small satellites is via education, outreach to new actors in the space arena, and the demonstration of "leadership." What should be encouraged is the development of a consensus on what constitutes "normal" or "safe" behavior in space, via a bottom-up approach, to create norms of behavior, best practices for safety in space, and guidelines to allow new entrants to know what is expected for safe space operations. Also, openness and transparency in space operations should be encouraged, while understanding that business practices and intellectual property concerns may preclude total transparency, a balance can be struck.



Trackability & identification

European Space Agency

Fig. 5 Rate at which tracked CubeSats have been successfully identified after launch; in many cases not all of the launched objects have been identified, even after months on orbit (Letizia)

Guidelines and best practices, as previously discussed, have been the subject of high-level negotiations, in such fora as the UN COPUS, IADC, etc., but much practical work has also been carried out by industry consortia, e.g., CONFERS (CONFERS), the Global VSAT Forum (GVF), the Space Safety Coalition (SSC), the Space Data Association (SDA), etc. As Muelhaupt et al. noted (Muelhaupt et al. 2019):

> Industry-driven norms and standards of behavior are among the most effective methods for preventing the new activity from contributing to space debris. Innovation by industry can create new solutions and reduce the cost of others. Government should encourage these voluntary, industry-driven approaches where possible.

Others have shown initiative to step forward and show leadership in this realm. For example, the Secure World Foundation, a nonprofit nongovernmental organization (NGO), has published a very practical how-to guide: *Handbook for New Space Actors* (SWF Handbook). Others, such as OneWeb (OneWeb), have announced that they are willing to unilaterally go beyond the current guideline, mandating disposal of LEO satellites 25 years after end of mission, to dispose their satellites promptly after the end of mission. The Space Data Association, a not-for-profit limited corporation, has demonstrated how companies and entities, perhaps in some aspects competitors, can work together to exchange potentially sensitive information to enhance on-orbit safety. It is hoped that the efforts by industry and NGOs will also goad public institutions involved in space to also "lean forward" and provide leadership in this regard.

To incorporate safety into the fabric of space operations, the space community is going to have to make space safety and the sustainable use of outer space part of the ongoing science, technology, engineering, and math (STEM) education efforts. If nontraditional entrants into space are going to be encouraged, for example, a junior high school class, as part of their project to fly a small satellite, they should also learn about responsible space behavior and their responsibilities, legal and otherwise, for being actors in the space area and not contributing to the challenges to maintaining a safe space environment. Regulators could play an important role here, in that granting a license to operate a space object could be contingent on demonstrating knowledge and set of technical proficiencies deemed necessary to safely operate in the space environment, not unlike current automobile drivers' licensing and education requirements. France, in their national space act, has codified the concept of a licensed space actor that confers concrete benefits to those who have demonstrated levels of expertise and proficiency (French Space Act).

5 Conclusion

Small satellites, given their low mass and size, can be inexpensive to acquire and launch into orbit. This has opened up access to space to many new actors in the space arena: high schools and universities, hobbyists, developing countries, research and development teams, and even artists and other nontraditional users. Given their low cost, new ideas and concepts can be investigated with much lower risk and with a much quicker development cycle. This democratization of space will stimulate new space commerce, services, and other societal benefits, as well as greater participation in space activities and knowledge of space technologies and expertise. However, this recent acceleration of small satellite-based space activities is a challenge to the existing space management institutions. Challenges are posed by dint of the satellites' small size, their large numbers, their (sometimes) lack of reliability, and the relative inexperience of some of their owner/operators in working within the existing space community. In this paper a number of potential solutions have been outlined to the challenges posed by increasing numbers of small satellites. These include regulatory changes, as the transition is made from space situational awareness to space traffic management; this transition offers an opportunity to do things in new and perhaps different ways. There are also a number of new (or not so new) technologies and techniques that can be brought to bear to mitigate some of the challenges, especially when it comes to tracking and identification, as well as automating the exchange of information between the owner/operators and the STM/SSA entities. The final approach to overcoming these challenges is via education and outreach to the new actors and getting their participation in the development of regulations, guidelines, best practices, and standards, both domestically and internationally. No one solution will alleviate all of the challenges; but it is felt that these disparate approaches, when applied in concert, stand a good chance of mitigating the various challenges and bringing space users closer to Space Operations Assurance and moving the larger space community in the direction of achieving long-term sustainable use of outer space.

Long-Term Sustainability of Space and Sustainability Requirements

Darren McKnight

Contents

Abstract

Small satellites must be designed and operated to support the long-term sustainability of safe space operations. This community responsibility is reflected in the debris mitigation guidelines that have evolved over the last 30 years. As with any space system decision, the ability to operate responsibly has many options that can be characterized by a balance of trade-offs. The cost of a system or process may be explicit by needing more power and volume or implicit by merely making the operations more complicated. This chapter provides the high-level trade-offs for means by which small satellites may meet debris mitigation guidelines. The

five major issues identified for consideration for a post-mission disposal (PMD) device are effectiveness, SWAP (i.e., size, weight, and power), reliability, orbital risk (i.e., collision risk to other objects), and risk to ground assets. While there are many new approaches to reducing the lifetime of a satellite after its mission is completed, propulsive maneuvers remain the most reliable and effective. Drag enhancement, solar sail, and electrodynamic tether systems are all also reviewed, and engineering issues for their potential use are identified.

1 Introduction

The space arena is currently experiencing a period of rapid and dramatic change. In the early decades of the space age, this domain was dominated by a few space powers, and most space actors were governmental entities that carried out national civil and military space programs. Nowadays, there is a much larger number and diversity of space actors. The global commercial space economy has grown from a fledgling enterprise to now exceeding many civil and military space investments. The number of spacefaring countries exceeds 90 depending how you define a spacefaring country: as of this writing (February 2019), over 90 countries have operated a satellite in space, 92 countries are represented in the United Nations Committee on Peaceful Uses of Outer Space (UN COPUOS), more than 50 countries can manufacture satellites, and citizens from over 40 countries have been in space. This increasing growth in the number of space actors has been facilitated by advances in space technology that have also greatly lowered the barriers to entry for new space actors, especially from the private sector. This, in turn, has accelerated the pace of technological development, further lowering entry barriers for emerging space actors.

All of these activities have produced scientific advancements, enhanced nation-state capacity building, and improved the quality of life for many global citizens. However, these positive outcomes have been at the cost of a growing threat from orbital debris in Earth orbit. More than 19,000 objects are cataloged and tracked in Earth orbit; Fig. 1 shows this accumulation by object type. Only about 8% of these are operational satellites; the remaining 92% of the trackable population is debris from over 5,000 space launches and nearly 300 satellite fragmentations over the last 60 years. Despite a concerted international effort, the growth of debris being deposited in Earth orbit has not slowed. International debris mitigation guidelines were agreed upon in the mid-1990s that have been followed to varying levels of compliance over the years; these debris mitigation guidelines will be discussed in a subsequent section.

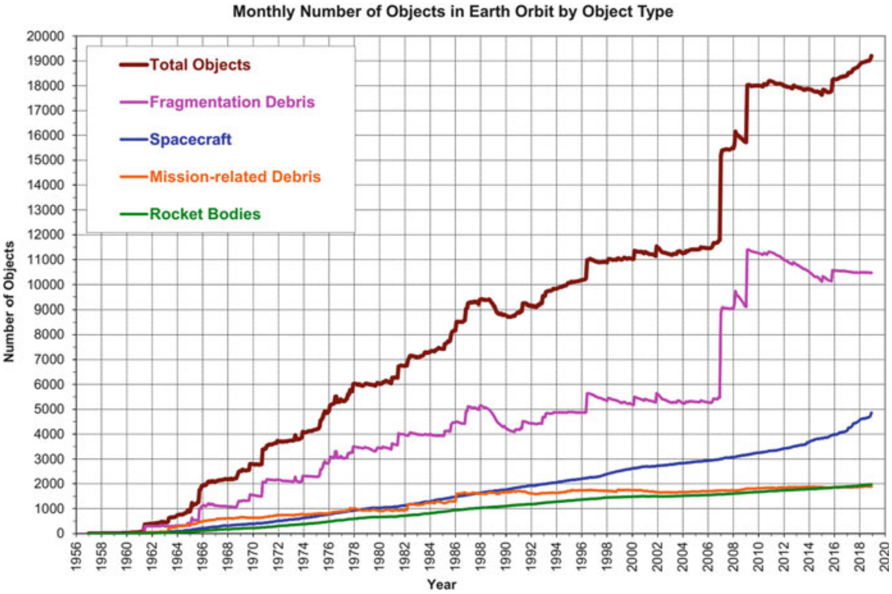

Fig. 1 The cataloged population has grown steadily over time with major fluctuations caused by fragmentation events and orbital reentries which are acccelrated by increased solar activity. (Source: NASA)

Given the risks posed by space debris to the safety and sustainability of space activities, it is the responsibility of every space operator who wants to leverage the space environment to act prudently so that generations to come have the same luxury of high reliability access to space. One way to do this is to develop and implement reliable post-mission disposal (PMD) strategies compliant with debris mitigation guidelines. In a more pragmatic construct, this encourages us all to "leave no footprints" or, possibly, leave where you visit as clean as you found it.

The designers, developers, and operators of microsatellites and smaller satellites (i.e., less than 100 kg) must be astute on ways to implement PMD approaches for these microsatellites, to be compliant with the space debris mitigation guidelines, and enhance the long-term sustainability of the near-Earth space environment. If you are developing or operating a microsatellite, you want to find the best PMD strategy for your mission.

This guidance complements other activities related to smallsats by the International Academy of Astronautics that have highlighted the emerging applications for smallsats empowered by new space technologies. Two recent publications of note are:

- The recently released (2017) International Academy of Astronautics (IAA) study titled "Definition and Requirements of Small Satellites Seeking Low-Cost and Fast-Delivery" (http://iaaweb.org/iaa/Scientific%20Activity/cost.pdf).

- The newest version of ISO/TS 20991, *Space Systems – Requirements for Small Spacecraft*, was released in 2018 (http://iaaweb.org/iaa/Scientific%20Activity/Study%20Groups/SG%20Commission%204/sg418/sg418finalreport.pdf).

It must be noted that changes to spacecraft manufacturing, debris mitigation guidelines, the debris environment, etc. may all change the landscape for debris mitigation over time. As a result, it is important to take this handbook as a snapshot in time of useful tools, insights, standards, and procedures; these may change quickly, so the reader is advised to be diligent in keeping abreast of the most up-to-date advancements in these areas.

2 Debris Mitigation Guidelines

In general, all the space debris mitigation guidelines and standards, such as the Inter-Agency Space Debris Coordination Committee (IADC) or International Organization for Standardization (ISO) Standard 24113, apply to any spacecraft, whatever its size. These various sets of guidelines have the following general four elements in common:

1. Passivate energetic sources, such as batteries, and vent excess propellant.
2. Eliminate creation of debris; this includes avoiding explosions and collisions.
3. Ensure that all objects left on-orbit are re-entered within 25 years after the end of their operational life (EOL) or moved to an acceptable graveyard orbit.
4. Suggest to limit the re-entry casualty risk to humans to less than 10^{-4} per re-entry event.

ISO 24113 (2010), first published in 2010 and a third version released in September 2019, is the highest-level standard at the international level dealing with space debris mitigation. It is complemented by second-tier standards, dealing with dedicated topics such as lifetime evaluation of an orbital object, re-entry risk management, collision avoidance, or requirements devoted more precisely to spacecraft or launchers.

These ISO standards are important as they represent requirements, which may turn out to be compulsory for designers and operators, when included in contracts. If such internationally approved requirements are indeed shared by everyone, it would guarantee that every government, academic, and industrial satellite developer or operator plays by the same rules and acts efficiently to control and reduce the threat posed by space debris.

For the common case of a microsatellite presenting no casualty risk, it should re-enter the Earth's atmosphere within 25 years starting from:

(a) The orbit injection period, if the object has no capability to perform collision avoidance maneuvers
(b) The end of operational life (EOL) epoch

This means that if a microsatellite has no propulsion onboard with a thrust level and control sufficient to perform collision avoidance maneuvers, then it should be injected into an orbit compliant with the 25-year rule. This is required even if it is equipped with a post-mission disposal device to reduce the orbital lifetime. Such an altitude, depending on the characteristics of the spacecraft, is in the 600–625 km range.

A satellite which has no onboard propulsion system should not operate in the GEO protected region as it cannot perform collision avoidance maneuvers nor post-mission disposal.

If a microsatellite is equipped with a significant propulsion capability aimed at lowering its final orbit in order to comply with the 25-year rule, then such a maneuver should have a probability of success better than 90%. Otherwise, if there is no propulsion system onboard, the initial injection orbit of the small satellite should naturally comply with the 25-year rule, i.e., be lower than 600–625 km altitude.

In general, all the space debris mitigation rules, such as ISO 24113, apply to any spacecraft, whatever its mass or size. If a microsatellite is equipped with a propulsion system with thrust and reactivity sufficient to enable collision avoidance maneuvers and end-of-life orbit altitude modification, it should (1) comply with the protected region rules in GEO and (2) comply with the 25-year rule in LEO.

The demonstrated probability of success of such end-of-life maneuvers should be higher than 90%. The satellite should also be passivated at EOL. If its structure is such that it may present a casualty risk on ground, then it should be deorbited in a controlled way to guarantee a safe disposal.

If a microsatellite has no capability to perform collision avoidance maneuvers, even if it is equipped with a PMD device, it should not be operated in GEO. In LEO, it should be injected into an orbit naturally compliant with the 25-year rule if it does not have collision avoidance capability even if it is equipped with a PMD device. The satellite should also be passivated at EOL (i.e., safe batteries, capacitors, etc.), and all efforts must be taken to eliminate creation of all debris greater than 1 mm; this includes preventing explosions and avoiding collisions.

3 Determining the Orbital Lifetime of a Microsatellite

Gravity imposes a force on a satellite that causes it to continue to orbit the Earth. If this were the only force acting on a satellite, it would stay in orbit forever. However, the interaction between Earth's atmosphere and the orbiting satellite decreases the satellite of its energy causing it to eventually reach such a low altitude that it can no longer remain in orbit. At this point, it ceases to pose a risk to other orbital assets; however, this re-entering object still has the potential for posing an impact risk to aircraft in flight (Emanuelli and Lips 2015) and to people and property on the Earth. For microsatellites, there is little chance that any material will make it to the ground unless the satellite contains some very unique materials with high melting temperatures (e.g., glass, titanium, etc.) or possibly densely packed components such as batteries and momentum wheels.

The density of the atmosphere decreases exponentially with rising altitude and increases with solar activity and (in a less predictable way) with geomagnetic activity. The solar activity parameter that correlates best with atmospheric density variations is the F10.7 cm solar flux which oscillates on roughly an 11-year cycle. As a result, the effects of drag can vary significantly over time and altitude, making determining an object's orbital lifetime nontrivial. Note: the *operational lifetime* of a satellite is how long it functions properly in space, while *orbital lifetime* is how long it physically remains in orbit.

There are analytic models that can be used to calculate the orbital lifetime from the contraction of the orbit due to atmospheric drag such as Analytical Graphics, Inc. (AGI) Systems Tool Kit (STK). There is also a semi-analytic orbital propagator called STELA (n.d.) (Semi-analytic Tool for End-of-Life Analysis) procured by CNES for lifetime computation in support of the French Space Operation Act. The OSCAR tool inside DRAMA (n.d.) also provides the capability to compute the orbital lifetime using a semi-analytic propagator, with the possibility to analyze post-mission disposal options and their effect. Any of these tools provide an accurate and responsive way to determine the orbital lifetime of a satellite in orbit. This section shows a simplified method to examine orbital lifetimes using a lookup chart taken from a classic book on determining orbital lifetimes to help illustrate the trade-offs between physical parameters relevant for determining the orbital lifetime of a satellite (King-Hele 1987). However, results from STELA are provided for quantitative comparisons, and it is suggested that some sort of high-fidelity orbital lifetime tool such as STELA be used to calculate the orbital lifetime for your respective microsatellite.

3.1 Factors in Determining Orbital Lifetime

The deceleration exerted by atmospheric drag on a satellite is given by:

$$a = \left(\frac{1}{2}\right) C_D \left(\frac{A}{M}\right) \rho\, V^2 \tag{1}$$

where

C_D = coefficient of drag, no units
A = projected satellite area (normal to velocity vector), m^2
M = mass of satellite, kg
$\frac{A}{M}$ = area-to-mass ratio, AMR, m^2/kg
ρ = atmospheric density, kg/m^3
V = velocity through the ambient atmosphere ≈ orbital velocity, m/s

Orbital velocity (approximately 7.6 km/s) varies only slightly in low-LEO, below 1,000 km, where drag affects orbital lifetimes measurably. Conversely, the coefficient of drag varies between 2 and 3 as a function of object shape and altitude (Cook 1965; Herrero 1983). As a result, the four primary variables that determine the orbital lifetime of a satellite are (1) area-to-mass ratio, (2) altitude, (3) coefficient of drag, and (4) solar activity. Each term will be characterized individually before examining how to use them for determining orbital lifetime.

Area-to-mass ratio: The area-to-mass ratio (AMR) can be calculated by dividing the area that the satellite presents in its direction of motion by the mass of the satellite. The larger the AMR, the more atmospheric drag will affect the orbit. So, simply speaking, a satellite with a larger AMR will be removed more quickly from orbit than one with a smaller AMR value at the same altitude and same time. Later in this handbook, how increasing AMR can be used to reduce orbital lifetime is examined.

Interestingly, an AMR value between 0.003 and 0.03 m^2/kg (with the typical value of approximately 0.01 m^2/kg) covers most spacecraft from small 1U cubesats to large commercial communication satellites deployed in GEO. This commonality is due to the physical limitations of how much circuitry can be packed into a payload bus. It is fairly simple to calculate the AMR of a specific satellite, but do not be surprised if it is not in this general range.

If you would like to be conservative, you can use the smallest possible cross-section as the area term. This will produce the largest possible orbital lifetime, so if you can meet the 25-year rule with that minimum value, it provides you some extra confidence that you will be compliant. However, as you will soon find out, there are other factors in the calculation of the orbital lifetime of a satellite that may have even a greater influence on the final value for orbital lifetime.

A 1U cubesat has a minimum cross-sectional area of 0.01 m^2 since one face of the bus is $10\text{ cm} \times 10\text{ cm} = 0.1\text{ m} \times 0.1\text{ m} = 0.01\text{ m}^2$. The actual average cross-sectional area for a tumbling 1U cubesat is 0.015 m^2. The mass of a typical 1U cubesat is about 1 kg so the AMR is easily determined by $0.01\text{ m}^2 \div 1\text{ kg} = 0.01\text{ m}^2/\text{kg}$ (or $0.015\text{ m}^2 \div 1\text{ kg} = 0.015\text{ m}^2/\text{kg}$ for a tumbling 1U cubesat). Some 1U cubesats can be as heavy as 1.5 kg which would produce an AMR of 0.007 m^2/kg or 0.01 m^2/kg, respectively.

A 3U cubesat has a minimum cross-sectional area of 0.01 m^2 and a mean cross-sectional area of 0.03 m^2 (without any deployable appendages). As a result, for the roughly 3–6 kg 3U spacecraft, the AMR ranges from approximately 0.002 to 0.01 m^2/kg. If the 3U cubesat has a fixed orientation so that the area exposed to the atmosphere is constantly 0.03 m^2 (i.e., travels with broadside in the direction of the satellite's motion) and it has a mass of 6 kg, then its AMR is 0.005 m^2/kg.

Altitude: Generally speaking, a satellite's orbit is elliptical – the altitude above the Earth is not constant, and the extremes in altitude of a satellite are provided by two parameters, apogee and perigee. (Alternatively, the two parameters of eccentricity and semimajor axis may be used. Eccentricity, e, is the "ellipticity" of the orbit shape. For example, $e = 0$ is a circular orbit and $0 < e < 1$ for an elliptical orbit. The semimajor axis, a, is roughly the average distance between the center of the Earth and the altitude of the orbiting object. For example, a satellite in an 800-km circular altitude has a semimajor axis of 7,178 km since the radius of the Earth is 6,378 km.) Apogee is the highest altitude that the satellite reaches above Earth's surface during an orbit, while perigee is the lowest altitude. If a satellite is in a circular orbit, apogee and perigee are identical, and the satellite remains at the same altitude throughout its orbit. It should be noted that if a satellite is in an elliptical orbit (i.e., not a circular orbit), drag will first circularize the orbit. That is to say, it will act on the satellite more at the lower altitudes of the orbit; the drag that acts primarily at and around perigee will first largely produce a lowering of the apogee, as shown in Fig. 2.

The reason that altitude is so important is that atmospheric density decreases exponentially with increasing altitude, as shown in Fig. 3.

The atmospheric density may drop by a factor of 100 as altitude increases from 200 km to 400 km. However, going from 600 km to 800 km altitude (i.e., another 200 km increase in altitude), there may only be a factor of 10 reduction in atmospheric density. Above 1,000 km, drag has almost a negligible effect except for objects with very large AMR values; if needed to consider drag at these altitudes, it is advisable to use an analytical model such as STELA.

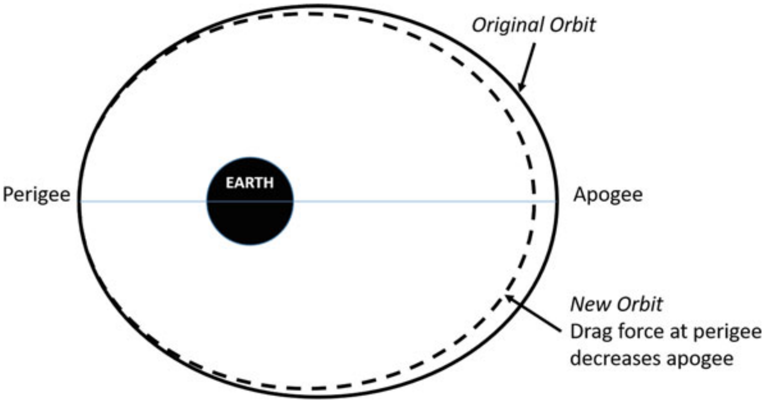

Fig. 2 Atmospheric drag acts first to reduce the apogee of an elliptical orbit

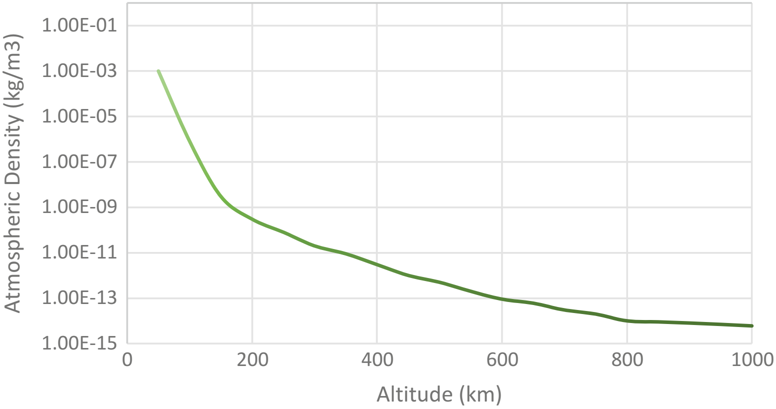

Fig. 3 Atmospheric density in LEO varies exponentially with altitude. (Space Exploration Stack Exchange for US Standard Atmosphere 1976)

Coefficient of Drag (C_D): The coefficient of drag may vary between roughly two and three in LEO depending on the altitude, solar activity, and shape of the object. For objects closer to their EOL (i.e., at 200–400 km), C_D is fairly consistent at 2.0–2.2 (i.e., average of 2.1). However, as altitude rises to near 1400 km, the C_D rises to values approaching approximately 3. Figure 4, provided as part of the STELA application, depicts the average C_D for LEO assuming a general sphere or tumbling plate (STELA Technical Note on Calculating the Coefficient of Drag 2011).

Solar activity: The calculation of a satellite's orbital lifetime is complicated by continual variations in solar activity that lead to changes in atmospheric density in LEO. Radio emissions from the Sun with wavelength of 10.7 cm have been found to correlate most closely with changes in atmospheric density; this is called the F10.7 cm solar flux.

The solar cycle is neither exactly 11 years nor does it follow exactly the same pattern of activity during each cycle. Figure 5 shows the sunspot number (which correlates directly to the F10.7 cm solar flux: F10.7 ≈ 0.9 sunspot number + 59.6) over several centuries highlighting the variability over time. Clearly, there are significant variations over time in both shape and amplitude (i.e., the maximum level and minimum level). Notice how the solar maximum in 2014/2015 (the latest solar maximum on plot) was significantly lower than the previous solar maximum in 2002/2003. Such protracted lower solar activity levels will cause orbital lifetimes to be systematically underestimated.

The uncertainty in solar activity will contribute significantly to possible mismatches between predicted and actual orbital lifetimes. Atmospheric drag effects can

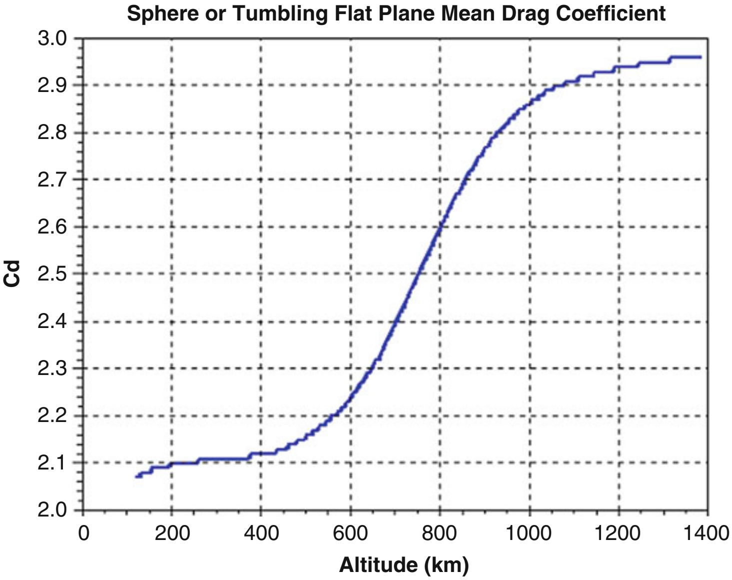

Fig. 4 Coefficient of drag, C_D, varies by altitude in LEO; curve is for a sphere or tumbling flat plate in low solar activity

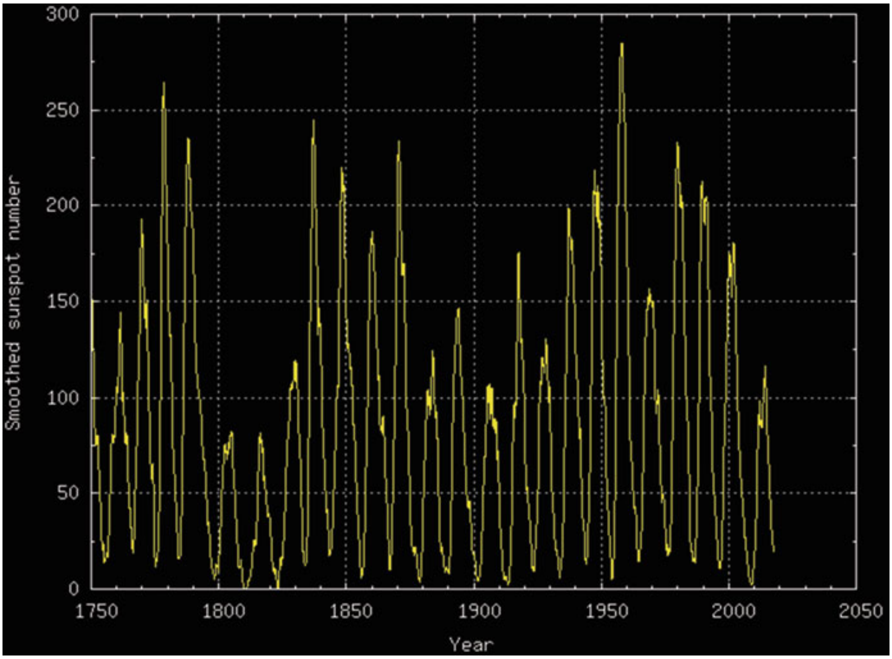

Fig. 5 The solar cycle is not as regular as the name would suggest – it varies in length, shape, and magnitude from cycle to cycle. (Source: Australian Government Space Weather Services)

easily vary by factors of 2–4 between high and low solar activity in comparison with the average values shown in Fig. 5. In other words, during periods of high solar activity, the drag effects (for the same object for same altitude) can be two to four times larger than average; the reverse is true during periods of low solar activity. The OSCAR tool implements different methods providing a forecast of solar and geomagnetic activity as recommended by recent standards. For estimation of orbital lifetime, five different methods may be used to generate future solar and geomagnetic activity data which serves as input for the orbit propagation. The methods are based on recommendations by ISO, ECSS, as well as a method which has been implemented within the French Space Operations Act.

3.2 STELA Orbital Lifetime Calculations

STELA is the Semi-analytic Tool for End-of-life Analysis that has been procured by *CNES* (The French Space Agency) to support the *French Space Operations Act*. Table 1 provides outputs for several microsatellite missions assumed to start in 2018 (for solar activity values) using STELA highlighting the importance of AMR and altitude on orbital lifetime.

The examination of the key parameters that affect orbital lifetime identifies the engineering terms available to manage orbital lifetime: altitude and cross-sectional

Table 1 Using STELA to determine orbital lifetimes for a 1U cubesat with and without a drag-augmentation device hints at the benefit of such a PMD device to limit orbital lifetime

Scenario	Parameters	STELA output
1U in 800 km circular orbit	Assume 1 kg tumbling 1U cubesat (AMR = 0.015 m^2/kg) with an inclination of 90°	92 years
1U in 600 km × 800 km orbit		24 years
1U in 400 km × 1000 km orbit		5 years
1U in 600 km circular orbit		8 years
1U in 800 km circular orbit	Assume 1 m^2 drag-augmentation device and 2 kg microsatellite (AMR = 0.5 m^2/kg) with an inclination of 90°	2 years
1U in 600 km × 800 km orbit		7 months
1U in 400 km × 1000 km orbit		50 days
1U in 600 km circular orbit		70 days

area (which may also vary over time). However, the derived term of coefficient of drag (i.e., based largely on the altitude and shape of a space object) and the dynamic solar environment contribute significantly to the final orbital lifetime and uncertainty in these calculations.

This section has identified STELA as a viable means to determine the orbital lifetime of a space system. Alternatively, ISO 27852 (Space Systems – Estimate of Orbit Lifetime) (https://www.iso.org/standard/68572.html) or other tools like OSCAR or STK can be used to calculate orbital lifetime. However, it is important to remember that the variability of actual solar activity still persists and contributes to the uncertainty in any long-term orbital lifetime calculation, no matter which tool is used. In addition, elliptical orbits with apogees above LEO will definitely require analytic means to estimate orbital lifetimes as solar-lunar perturbations become relevant and significant.

4 Re-entry and Survivability of Microsatellites

There are four primary characteristics that determine whether a given satellite will survive re-entry, as shown in Fig. 6. Microsatellites will pose little air or ground impact risks as long as they comply with the following three characteristics:

- Material: aluminum and circuit boards
- Mass: under 100 kg
- Construction: no hardened or especially densely packed components

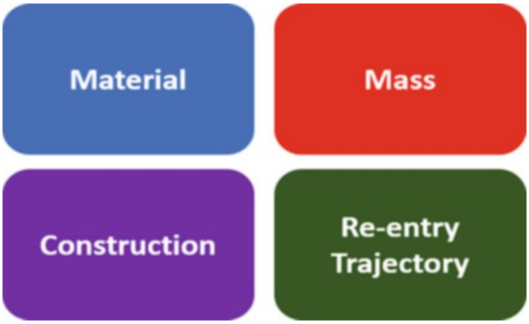

Fig. 6 A microsatellite that has typical mass, construction, and material with a natural re-entry trajectory will pose very little air or ground hazard

The probability of demise of the hardware also depends on the re-entry trajectory.

The use of materials with high melting points (e.g., steel, titanium, glass, beryllium, etc.) and very densely constructed devices should be avoided as much as possible. If the use of such materials and components cannot be avoided, an analysis tool such as ORSAT (n.d.), SCARAB (n.d.), SARA (n.d.), or DEBRISK (https://logiciels.cnes.fr/fr/content/debrisk) should be used to evaluate the probability that objects may survive re-entry to cause damage to property and/or people.

Small satellites are generally fragile objects. Yet, when their orbits decay and the satellite re-enters the atmosphere, there remains a question as to whether parts of the satellite will survive to the ground, and if so, what kind of risk might that hardware pose to population and their property.

Two types of re-entries can occur: controlled and uncontrolled. A controlled re-entry is generally a more complex process and is reserved for missions such as human spacecraft and very large spacecraft with both robust attitude control and propulsion systems. Most re-entry events are uncontrolled re-entries of spacecraft, rocket bodies, and fragmentation debris. Some of these objects can pose a risk of injury to people on the ground or aircraft in flight due to the unpredictability of their trajectories and exactly where and when they will re-enter and, should parts survive re-entry, where they will land. Since a controlled re-entry is much more difficult and expensive to execute than an uncontrolled re-entry, this section will focus on the technical issues surrounding uncontrolled re-entry.

The space object population is made up of operational payloads, defunct payloads, rocket bodies, crewed platforms, mission-related objects, and fragmentation debris. Orbiting objects below 800–1,000 km in altitude have a finite lifetime in orbit due to the interaction with Earth's atmosphere. Atmospheric drag, even with an extremely small atmospheric density, will slowly cause orbiting objects to move to lower orbits. As an object's orbit gets lower and lower, the increasing air density acts upon it until it can no longer maintain its orbit. As the object begins its final re-entry, it starts to heat up.

Fragile parts of the object (such as solar panels) break off due to heating and aerodynamic loading. As the object moves further into the atmosphere, it begins to shed more components and further breaks apart. As this process continues, each piece disintegrates (either partially or completely). Those objects that do not demise will follow their own re-entry trajectory. As the pieces that survive re-entry reach the ground, they create what is known as a footprint.

Since the majority of the Earth's surface is covered by water, a sizable percentage of objects that survive re-entry will land in the water and will consequently likely never be recovered. However, the remaining 30% will land on the ground, where they are often recovered.

4.1 Casualty Risk to the Population

While no one has yet been injured or killed from re-entries, according to the International Academy of Astronautics (IAA) Space Debris Situation Report, the cumulative expected value of the number of people on the ground to have been struck and killed by a falling piece of debris now exceeds one (IAA Space Debris Situation Report on Space Debris 2017). This is reflective of both the large number of massive objects that have re-entered and the growing global population.

Internationally, a 1 in 10,000 probability threshold for an impact casualty risk from an uncontrolled re-entry is a commonly accepted risk level by space agencies and nations around the world (Casualty Risk Tolerance for Re-entering Debris).

4.2 Recommended Design Practices for Minimizing Satellite Survivability upon Re-entry

A microsatellite that is re-entering is unlikely to pose a significant risk to a person on the ground or aircraft in flight. However, to further reduce the risk posed to someone on the ground, a satellite designer can choose materials and design features for the satellite that will increase the likelihood that the satellite and its components will melt during re-entry; this is called design for demise.

The physical characteristics of several common satellite materials are shown in Table 2. The lower the melting temperature and heats of ablation, the more likely it is that the material will burn up during re-entry. Note that the melting point

Table 2 Material properties for several common spacecraft materials shows why beryllium, glass, and titanium are more likely to survive re-entry. (Wertz et al. 2011)

Material	Melting/softening temperature (°K)	Specific heat (J/kg°C)	Heat of ablation (kJ/kg)	Heat of ablation (kJ/m^3)
Graphite/epoxy	700	720	350	550
Aluminum	850	897	900	2,400
Stainless steel	1,700	490	900	7,250
Titanium	1,940	523	1,600	7,050
Zerodur glass	2,000	800	1,400	3,550
Beryllium	1,557	1,020	4,100	7,550

(i.e., temperature at which material becomes a liquid) is related to the material's heat of ablation (i.e., measure of the effective heat capacity of an ablating material, numerically the heating rate input divided by the mass loss rate which results from ablation.). As a result, for objects to survive re-entry, they should have a high melting point, high specific heat, and a high heat of ablation. Conversely, it is best to have lower melting temperatures and lower heats of ablation to ensure disintegration during re-entry.

Materials such as aluminum and graphite/epoxy composites have very low heats of ablation and will readily demise during re-entry. Components made of materials such as titanium, glass, and beryllium have very high heats of ablation and are more likely to survive re-entry. Many variants of glass-ceramics are used in high-temperature applications, such as cooktops, stoves, and fireplaces, so it shouldn't be surprising that they are more likely to survive exposure to high temperatures.

However, there are likely applications where some of these high-temperature materials must be used. Therefore, there are some design practices that can be implemented to reduce the likelihood of them surviving re-entry or reducing the casualty risk on the ground.

First, if the designer can change the aerodynamic characteristics of the object one might encourage disintegration on re-entry. For example, decreasing the blunt edges and making the object less like a ball will decrease the probability of survival.

Second, by bundling objects that would likely survive re-entry, the number of survivable objects may be reduced. For instance, a spacecraft with several batteries that each would likely survive re-entry could be redesigned to put those batteries in a survivable box on the spacecraft. Due to a reduced casualty cross-section, the single survivable box thus poses a lower risk than multiple survivable batteries. This technique may be useful if the material is known to be re-entering over a populated area where fewer lethal pieces making it to the ground would be better. However, generally speaking, it is best to separate objects as soon in the re-entry process as possible to maximize the chances for the material to disintegrate.

Assessing the survivability of a re-entering object is a complex process, but if your spacecraft is a microsatellite or smaller and is constructed of typical spacecraft materials such as aluminum and graphite/epoxy (used for circuit boards), there is a low probability that any material will survive to the ground.

If it is deemed necessary to perform this complex demise modeling, several predictive software models are available. ORSAT (Object Re-entry Survival Analysis Tool) will be used to illustrate the utility of such analytic re-entry breakup and survivability models used in the technical community.

5 Means to Reduce Orbital Lifetime

Strategies for post-mission deorbiting rely on forces which decelerate the satellite, thereby reducing the orbital altitude and resulting in a deorbiting scenario. These strategies fall primarily into four categories:

(a) Propulsion systems
(b) Drag-augmentation devices
(c) Electrodynamic tethers
(d) Solar sails

Post-mission deorbiting of microsatellites may be accomplished either actively or passively. An active approach could be a retrograde thrust to decelerate the satellite and is typically achieved via propulsive devices. The performance of propulsive devices is typically characterized by their capability to change a satellite's velocity (i.e., its ΔV capacity) which, in turn, directly changes the satellite's orbit. Passive deorbiting utilizes the natural orbital environment to generate a retrograde "thrust." For LEO satellites at altitudes below 800–1,000 km, the Earth's atmosphere generates a retrograde force (i.e., atmospheric drag) that causes the satellite's orbit to decay along a spiral trajectory toward the Earth. The rate of the decay is dependent on the satellite's cross-sectional area in the direction of motion. Drag-augmentation devices increase cross-sectional area to passively reduce the post-mission orbital lifetime of satellites in this region. The increase in area is typically achieved by deploying either a drag sail or a gossamer structure (e.g., inflatable balloon or boom). A propulsion system could also enable collision avoidance and controlled re-entry.

Propulsive deorbiting systems rely on a retarding thrust to lower the satellite's altitude. While these systems are straightforward practical solutions, they come at a cost in terms of (i) satellite reliability (i.e., the propulsive system and the attitude determination & control system have to both be functional at the end of the mission) and (ii) require additional launch mass (e.g., a stand-alone propulsion system and/or additional propellant) that usually does not support the mission's operational objectives directly. However, these systems provide a proven way that reduces an object's orbital lifetime in an expeditious fashion and to perform collision avoidance and controlled re-entry, if needed.

5.1 Propulsive Deorbiting

Retrograde propulsive devices for deorbiting typically utilize two strategies: (i) controlled re-entry where the satellite is guided to an impact point over the ocean or an uninhabited area to reduce risk or (ii) uncontrolled re-entry, where the casualty risk to people on the ground has been met, the satellite is maneuvered to a lower perigee or lower circular orbit for an eventual uncontrolled atmospheric re-entry. Typically, high-thrust propulsive systems (e.g., chemical engines) utilize either a one- or two-impulse Hohmann-type transfer to reduce the orbital altitude. (However, the second impulse is generally unnecessary as the atmosphere completes the deorbit maneuver if the perigee is low enough.) Conversely, low-thrust propulsive systems (e.g., electric engines) typically utilize a continuous burn strategy.

The Hohmann-type maneuver uses an impulse at the higher altitude to maneuver the satellite to an elliptic trajectory toward the desired lower altitude and a second impulse to circularize to the lower orbital altitude. The continuous burn trajectories,

Table 3 The comparison of ΔV (m/s) for the two deorbiting strategies highlights the utility of dropping the perigee to 400 km for the higher-altitude LEO orbits

Initial satellite altitude (km)	ΔV (m/s)		Initial satellite altitude (km)	ΔV (m/s)	
	Circularizing strategy	Perigee drop strategy		Circularizing strategy	Perigee drop strategy
650	26.93	68.50	1350	375.86	239.15
700	53.58	81.68	1400	398.93	250.28
750	79.94	94.71	1450	421.78	261.27
800	106.03	107.57	1500	444.40	272.14
850	131.85	120.27	1550	466.80	282.89
900	157.39	132.82	1600	488.98	293.51
950	182.67	145.21	1650	510.95	304.00
1000	207.69	157.46	1700	532.70	314.38
1050	232.46	169.55	1750	554.25	324.64
1100	256.97	181.50	1800	575.59	334.79
1150	281.23	193.31	1850	596.73	344.82
1200	305.25	204.97	1900	617.66	354.73
1250	329.02	216.50	1950	638.41	364.54
1300	352.56	227.89	2000	658.95	374.24

employed by low-thrust propulsive devices, continuously remove energy and achieve lower orbital altitudes through a spiral trajectory.

For microsatellites in Earth orbit that "on paper" do not comply with the 25-year rule, active PMD methods must be considered. A direct and expedient approach is that of a propulsive maneuver to reduce the satellite's altitude such that decay can be achieved within the 25-year threshold or even sooner, if desired.

Two deorbiting strategies are considered: circularizing or perigee drop. The first one is to circularize the orbit to 600 km, and the second is to drop the perigee to 400 km. Results are presented in Table 3 and Fig. 7.

A general trend can be observed in Fig. 7. The circularizing the orbit strategy is more advantageous when the initial satellite altitude is below 800 km. However, from 800 km upward, it is better to execute the perigee drop maneuver.

5.1.1 Challenges of Propulsion System

Propulsion systems are a very well-established technology, and many devices are commercially available for small satellites, even those as small as 1U cubesats. Though there are some challenges in implementing a propulsion system that may affect satellite system design and operations, it is important to point out that a propulsion system cannot be thought of as a "stand-alone" system which will deorbit the satellite. This is because the propulsion system requires a functioning attitude determination and control capability for two reasons. First, the direction in which the thrust is to be oriented needs to be measured onboard and a pointing capability of the spacecraft is needed. Second, direction of the thrust needs to be maintained and controlled during the propulsive maneuver against the (often high) torque generated

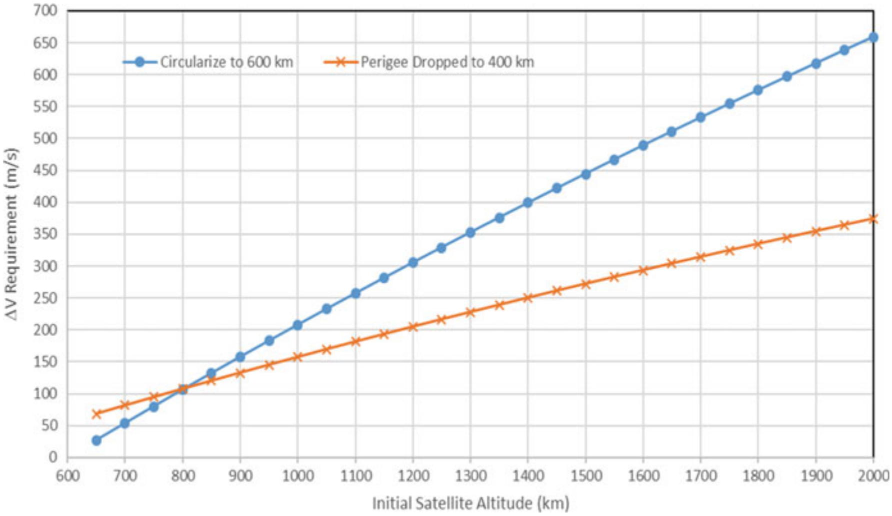

Fig. 7 The orbital altitude where a perigee drop to 400 km is superior to circularizing an orbit to 600 km is about 800 km

by the thrust itself. In addition, the propulsion system typically contributes to the overall spacecraft mass and power budgets plus adding complexity and volume depending on the propulsion system technology and required ΔV.

5.2 Drag Augmentation

Drag augmentation for post-mission disposal (PMD) of LEO satellites is nothing new – the concept has been studied since the late 1980s. An early publication by Petro (1990) discussed the use of deployable balloons as an effective mechanism for deorbiting "objects" below an altitude of 800 km. Since then, there has been a plethora of studies exploring the merits and challenges of drag-augmentation devices for PMD of LEO satellites. A paper by MacDonald provides a summary of some of these activities (Macdonald et al. 2015).

In addition to the studies, flight demonstrations of satellites equipped with devices that can be utilized for drag augmentation during PMD have been attempted. The NanoSail-D mission (ISO 24113 2010) was conceived as solar sail technology demonstrator by NASA to be flown in LEO where it would operate as a drag sail. The satellite was lost during launch in 2008, but its replacement, NanoSail-D2, was successfully flown in 2010; see Fig. 8.

Nanosail-D2 deployed a 9 m^2 sail from a 3U cubesat and managed to deorbit from an initial altitude of 650 km in only 240 days (NASA 2011). A typical cubesat with area-to-mass ratio of 0.01 m^2/kg would have taken around 25 years to deorbit unassisted from this altitude, as per section "Determining the Orbital Lifetime of a Microsatellite".

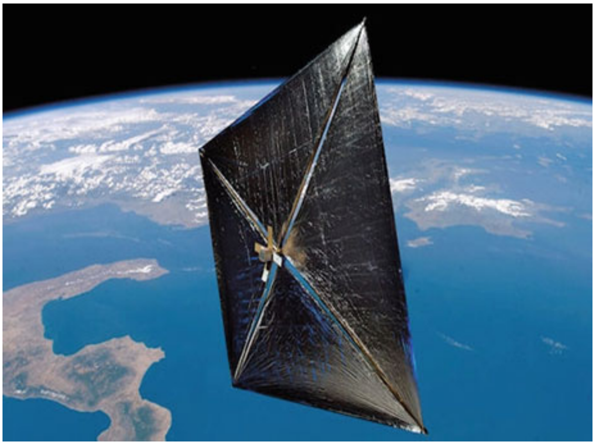

Fig. 8 The NanoSail-D2 was deployed successfully in 2011. (Source: http://www.nasa.gov/mission_pages/smallsats/11-010.html)

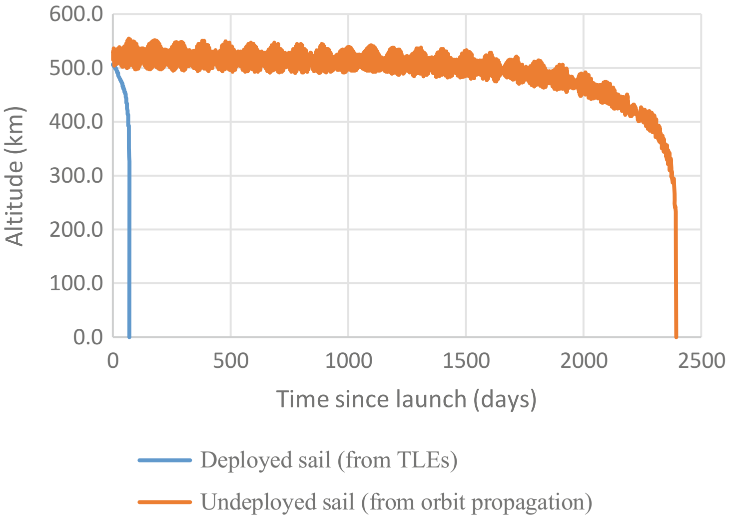

Fig. 9 The deployed sail profile for InflateSail from actual TLEs is depicted versus the simulated undeployed decay profile from orbit propagation

InflateSail was another successful demonstrator of drag-augmented deorbiting; the altitude profile with and without the sail is shown in Fig. 9. The 3U cubesat deployed a 10 m^2 sail that was extended from the cubesat bus using a 1 m inflatable mast (Viquerat et al. 2015). InflateSail was deployed from an initial 518 km × 494 km orbit and stayed in orbit for only 72 days (blue line), but it would have stayed in orbit for over 6 years without the drag sail deployment (Underwood et al. 2017). The analysis of this demonstration implies that a 100 kg spacecraft can comply with the 25-year rule from an altitude of 800 km under average solar activity and active attitude control that points the sail into the RAM direction (Taylor et al. 2018). Note

Fig. 10 Echo II undergoing stress test. (Image credit NASA)

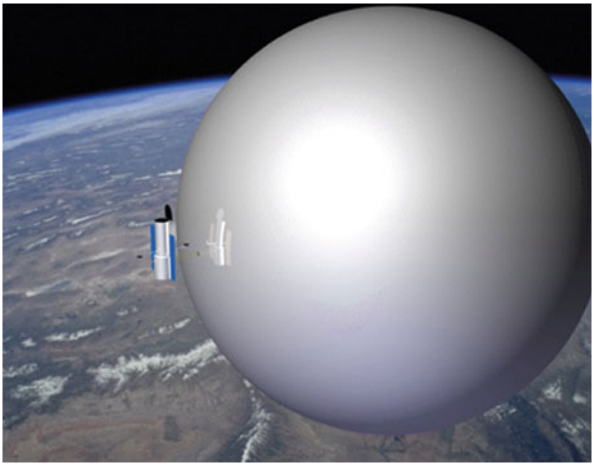

Fig. 11 Global Aerospace GOLD inflatable balloon. (Global Aerospace Corporation)

that by using active attitude control to direct the solar radiation pressure, it is possible to achieve an even shorter deorbit duration from higher initial orbits.

Drag-augmentation devices rely on the force exerted by the atmosphere on the larger exposed area to reduce the orbital lifetime of the satellite. The two most promising drag-augmentation designs are flat drag sails (as shown in Fig. 8) and inflatable gossamer devices (see Figs. 10, 11, and 12). On the one hand, a drag sail typically utilizes structural member(s) to provide support to the sail area, which is usually constructed from lightweight film material. Gossamer drag-augmentation devices are effectively large balloons either inflated or using a deployable shell to significantly increase the satellite's cross-sectional area.

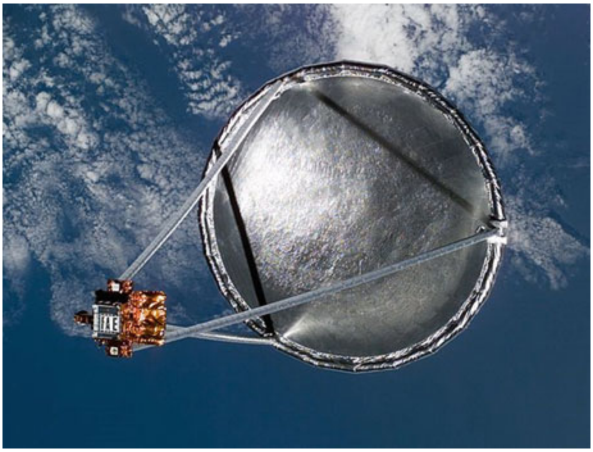

Fig. 12 Inflatable Antenna Experiment. (Image credit NASA)

Examples of successful inflatable space structure missions include the NASA Echo balloons (Fig. 10), Global Aerospace GOLD balloon (Fig. 11), and the Inflatable Antenna Experiment (Fig. 12). Although only the GOLD system was designed to demonstrate drag deorbiting, it was also the only one that did not fly in space.

One reason why an inflatable structure might be preferred is because of the three-dimensional nature of the structure – the orientation of the satellite becomes less important in ensuring a consistently maximum drag force. An inflatable sphere has the same cross-section regardless of orientation, but a flat sail has the potential to create very little drag if the orientation of the satellite is unfavorable. Concerns regarding attitude stability of a drag sail are addressed later.

Since the aerodynamic drag force is directly proportional to the cross-sectional area of the satellite, an increase in cross-sectional area is beneficial in terms of the magnitude of the generated drag force.

A larger drag surface area will lead to a shorter orbital decay duration in LEO, which is desirable from a debris mitigation point of view; however, the larger surface area will also increase the likelihood of a collision. Large structures, such as drag-augmentation devices, will be susceptible to particulate impacts from objects in LEO. While the probability of collision with a "large" object of 10 cm or more (which can lead to a catastrophic collision, catastrophic means that the satellite will be completely fragmented as a result of the encounter with typically 1–3 trackable fragments per kg of mass of the satellite) is manageable, there are many more, smaller particles which have a greater probability of impact that could still disrupt the drag augmentation significantly. The area-time-product (ATP) is often used as a relative measure of how many particulates a satellite may encounter. It is simply the collision cross-sectional area of the satellite multiplied by the time spent in orbit; however, the area to take into account is not always obvious.

Another important design aspect of a drag-augmentation device is that of materials. The intent is to use lightweight materials, otherwise the mass of the deorbiting device will negate the drag-enhancement benefit. The membrane of a drag sail usually consists of a thin polymer film substrate with coating to achieve the desired thermal and optical properties. The most common substrate materials used are Mylar, Kapton, and CP-1. Membranes as thin as 2 μm have been produced, but for such thin membranes, handling and folding become problematic. Atomic oxygen causes erosion of Kapton and aluminum-coated Kapton for exposed materials on space systems operated below 650 km altitude. If the sail has to remain intact for as long as 25 years, it is essential to apply an atomic oxygen-resistant coating.

Successful sail deployments from NanoSail-D2, LightSail-1, InflateSail, and other missions have demonstrated that drag sail deorbiting is indeed feasible for microsatellites. It is important for the technology to become more reliable so that deployment failures do not hamper the success of the deorbiting goals.

Advances in materials and the availability of ultrathin membranes enable gossamer structures that can drastically increase a satellite's AMR with minimal parasitic mass. Such a strategy can be used to comply with debris mitigation requirements. Even a slight increase in AMR will lead to a shorter deorbit duration or increase the altitude from which the satellite can start deorbiting.

Drag augmentation, however, is limited operationally to orbits below 800–1000 km. At higher altitudes the required AMR becomes problematic, such that the deployable structure will be too large and heavy for the satellite. Drag augmentation can also only be applied to situations where an uncontrolled re-entry is acceptable.

Although drag augmentation can be achieved by both deployable sails and inflatable structures, sails remain the more competitive choice for smaller satellites, due to the small mass and volume impact and undesirable complexity of an inflatable system. Drag sails still have challenges. These include guaranteeing reliable deployment, attitude stability, and integration complexity with the host satellite.

5.3 Solar Sail

J. Maxwell and P. Lebedev proved that electromagnetic radiation exerts a force upon any physical body. The value of solar radiation pressure varies with distance to the Sun according to an inverse square law and equals approximately 4.56 $\mu N/m^2$ at the distance of 1 astronomical unit (approximately 150×10^6 km) from the Sun (i.e., at the Earth).

To increase the SRP force acting upon a satellite, one can deploy a large, but lightweight, highly reflective membrane. Such a membrane, along with its mounting system, is called a solar sail. The sail membrane is typically made of some light plastic, such as Mylar or Kapton, and covered with an aluminum layer on one or both sides (McInnes 1999). Though the shape of sail-like deployable space structure is not necessarily flat, this configuration is the most common and the only one discussed.

Solar sails may also be spin-stabilized to exploit the centrifugal force during the deployment process and for keeping the membrane stable. Spin-stabilized sails are considered Class 2 sails. As a result, solar sails of the first class – mostly of square form – are used most often despite their three-axis stabilization constraint and higher operating reliability (than spin-stabilized sails). Since the SRP force is directed close to the normal of the mirrorlike solar sail, three-axis attitude control of the sailcraft is required to provide controllability of the orbital motion.

Several sailcraft have been successfully operated in space, with the first completely successful deployment being the Japanese interplanetary mission IKAROS in 2010 (Shirasawa et al. 2014). Space sailing is an emerging trend in propulsion for small spacecraft as evidenced in its wide application to ongoing missions. However, past successes of solar sails have primarily been on interplanetary missions.

Solar radiation pressure magnitude is obviously almost constant for satellites in LEO, whereas the drag force rapidly decreases with increases in altitude. However, the solar sail goes in and out of the Sun during an orbit and has to be reoriented to maintain a large area pointing toward the Sun. At altitudes above about 700–800 km, the maximum SRP force can surpass the drag force. The absolute values of these two forces for a 3U cubesat with a 5 m × 5 m square sail are shown in Fig. 13.

The behavior of the two main perturbation forces, excluding the J_2 effect (i.e., Earth not being a perfect sphere) which is irrelevant for deorbiting, allows us to come up with an idea of using a sail in the solar mode when the satellite just begins the deorbiting process from a higher LEO orbit (from 800 to 2,000 km) and

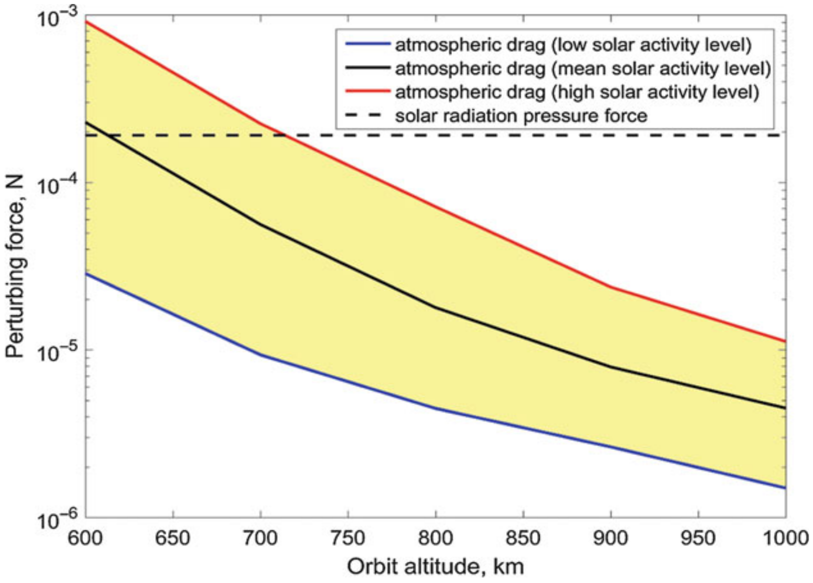

Fig. 13 Perturbing forces of atmospheric drag and solar radiation pressure acting on a 5 kg satellite with a 25 m^2 solar sail are depicted. The qualitative behavior observed is AMR-independent and would be the same for any spacecraft with any sail as long as the sail is kept ram-facing or Sun-facing

switching it to the drag mode when the satellite's orbit drops below approximately 700–800 km. The main challenge here is to properly and efficiently control the solar sail attitude to ensure an SRP-induced secular decrease in the semimajor axis.

It should be noted that there is a trade-off for a mission operator between installing a larger (and, hence, more costly and complex) solar sail and supervising the longer deorbit process: the strategy of exploiting the SRP force is not fully passive although it can be made autonomous or semi-autonomous.

The additional costs for utilizing ground stations and personnel during the deorbiting phase should be taken into account, which often makes targeting the 25-year deorbit period to be nonoptimal. Moreover, the risk of fatal membrane damage and/or failure of some control actuators rapidly rises for a mission lasting longer than 5–10 years.

As a rule of thumb, one can recommend to choose a sail providing the area-to-mass ratio of about 1 m^2/kg. For an altitude above 1,200 km, this value is advised to be upgraded to 2 m^2/kg. As modern solar sails weigh about 50 g/m^2 (including booms and the deployment mechanism), the solar sail system mass ratio can be estimated as being in the region of 5–10% of total spacecraft mass.

5.4 Electrodynamic Tether (EDT)

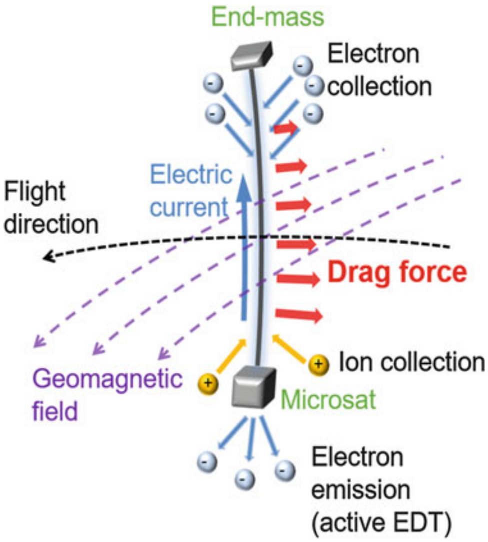
An EDT is a propulsion system which utilizes electromagnetic force as thrust (Cosmo and Lorenzini 1997). In contrast to conventional chemical and electric thrusters, the EDT does not use propellant for thrust generation but creates force by the interaction between an electric current on the spacecraft and the Earth's geomagnetic field. In this section, the principle of EDT, required components, advantages and disadvantages, and performance levels are introduced.

The principle of EDT thrust is shown in Fig. 14. When an end-mass connected with a tether is ejected from a microsatellite, the tether is stabilized in the vertical direction by a gravity-gradient force. An electromotive force is set up within a conductive tether as it moves through Earth's geomagnetic field.

If a pair of plasma contactors at either end of the tether emits and collects electrons, an electric current flows through the tether by closing the circuit via the ambient plasma. The tether then generates a Lorentz force that acts opposite to the direction of flight via interaction between the current and the geomagnetic field. Therefore, an EDT can provide deceleration without the need for propellant or high electrical power. EDT shows promise as a PMD device. An EDT stabilizes with gravity-gradient force, and so it can be installed almost any place on the spacecraft without considering the center of mass.

A bare tether (a conductive wire without insulation) can collect electrons and ions directly from the ambient plasma by the electromotive force (Sanmartin et al. 1993). Electrons are collected at a positive electrical potential part of the tether, and ions are collected at a negative electrical potential part. However, ions are hard to collect as they are heavier than electrons, and so an electron emitter can be installed on the satellite in order to get larger electric current (active EDT). A passive EDT, without

Fig. 14 The principle of operation of an electrodynamic tether (EDT) leverages Earth's magnetic field



an electron emitter, can deorbit a microsatellite as high as 800–1,000 km depending on its orbital inclination and tether configuration such as tether length and width. Alternatively, an active EDT is required for microsatellites at a higher altitude and inclination. The passive EDT is simpler and more cost-effective because no operation is required after the tether is deployed.

The performance of an EDT varies depending on solar activity, tether length, tether diameter, tether material, available electron emitter, and satellite orbit. Figure 15 shows deorbit time with EDT for various spacecraft masses and altitudes using one specific EDT solution: nanoTerminator Tape™ (Hoyt et al. 2009). It enables 3U cubesats to comply with the 25-year rule in orbits up to 1,000 km. However, it should be noted that actual orbital transfer by EDT has not been confirmed, and an on-orbit demonstration is needed.

Solar sails and EDTs have the potential for providing viable PMD options for microsatellites. They characteristically may be effective for a wide variety of relevant missions with conceptually low cost to include price, size, mass, and power required. However, these options have limited operational maturity, but several ongoing and planned on-orbit technology demonstrations may advance the viability of these options in the near future.

More specifically, a passive EDT would be sufficient for a low-inclination orbit, but a 100 kg satellite in sun-synchronous orbit would require a longer (heavier) tether for passive EDT so an active EDT with a small electron emitter may make more sense as it would impose a smaller mass penalty and provide a quicker deorbit time. However, the emitter for the active EDT requires electric power and operation; this is a classic trade-off that depends on what a microsatellite designer and operator have available for their specific mission. These are the exact issues that will be dealt in specific trade-offs for all PMD options.

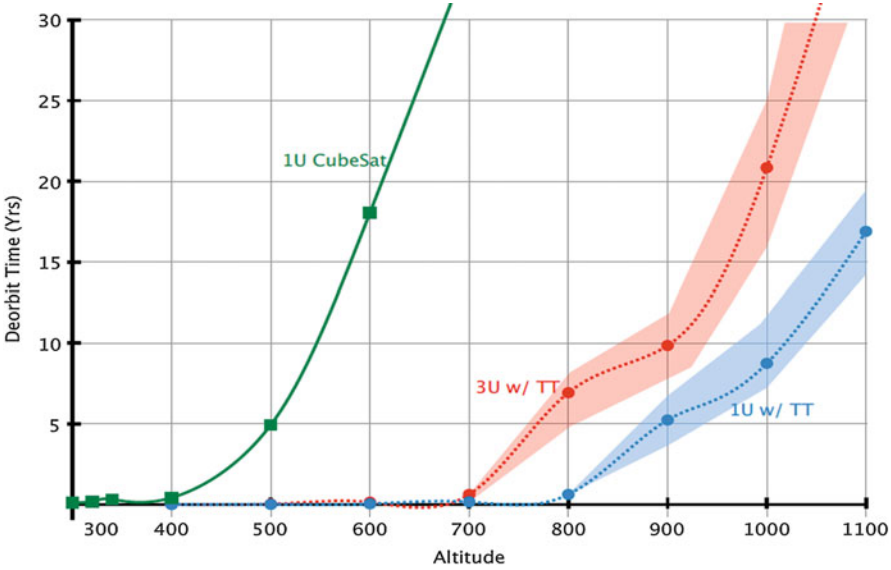


Fig. 15 The deorbit profile for 3U and 1U cubesats using nanoTerminator Tape™ (i.e., TT) follows similar general trends. (Hoyt et al. 2009)

6 Conclusion

The key issues for the selection of the best approach for a given satellite to comply with the debris mitigation guidelines are as follows:

- The potential capability of PMD options assessed have to be considered in tandem with their previous operational usage (i.e., technology readiness level) due to the 90% PMD success rate requirement.
- A propulsive maneuver strategy is the only option that works reliably for all LEO orbits, but it carries with it a large size, weight, and power (SWAP) burden.
- Satellite missions below 800 km have more available PMD options since drag can help removal and the altitude needed to move the system is less (i.e., closer to 615 km altitude).
- Drag-augmentation devices are only viable below 800–1,000 km altitude, and they impose a low to moderate SWAP penalty.
- Between 800 and 1,000 km altitudes, there are several PMD approaches that can assist in the reduction of orbital lifetime with varying SWAP and operational complexity burdens. Note how any option other than propulsion poses significant integrated collision risk when trying to deorbit from above 800 km.
  - Solar sails provide a slow deorbiting capability above 1,000 km and below 800 km behave like a drag sail. Solar sails have proven useful for interplanetary

  applications but require attitude determination and control to function optimally in low Earth orbit (LEO).
  - Electrodynamic tethers (EDTs), while having limited operational experience for deorbiting, hold promise for deorbiting effectiveness up to 1,000 km.
- If a microsatellite is deemed to require a controlled re-entry, then only a propulsion system has proven experience in this application.
- Above 1,000 km altitude, only propulsive systems and solar sails are viable.
- While there have not been any detailed reliability discussions in the trade-off analysis, it may be reasonably assessed that approaches that have been used often and reliably in the past will be more reliable. The "most used" to "least used" for orbit moving are first propulsion, then drag-augmentation, then solar sail, and lastly EDT.

Previous sections provide a clear picture of engineering and performance characteristics for four major families of PMD options for microsatellites. As can be seen from the previous sections, the determination of the best PMD strategies is affected by:

- Mission orbit and requirements
- Satellite capabilities and physical characteristics such as size, weight, and power (SWAP)
- Operational paradigms
- Cost and SWAP requirements
- Technology readiness level
- Operational complexity
- Vulnerability of the PMD options to space environmental effects, to include orbital debris

The interaction of mission parameters and PMD options will vary over time as technology and its implementation advances and regulations evolve.

The most technically developed solutions are those associated with the use of propulsion systems and provide a number of advantages if a propulsion system is already a part of the spacecraft design. Depending on the mission orbit and propulsion system technology, there may be penalties in terms of required fuel. The effectiveness of the other PMD options is more strongly dependent on mission orbits (i.e., altitude and inclination). The availability of commercially produced and space-tested hardware will affect both cost and reliability and will change over time.

A debris impact on a PMD device, however, might degrade its effectiveness or render it useless. Thus, the reliability of a PMD option should be examined carefully.

The pros/cons of PMD options highlight five major issues that must be addressed by any PMD option:

- **EFFECTIVE**: Is it effective? Can the change in altitude be made by the approach selected? The higher the altitude, the more change is needed.
- **SWAP**: What size, weight, and power (SWAP) is required to implement a given PMD approach? Certain approaches have greater engineering requirements that require additional hardware, software, and controls to be deployed. Clearly, the smaller your satellite, the more likely that these requirements will be demanding.
- **RELIABILITY**: How reliable is the PMD option? The reliability required for PMD execution is at least 90%, but evolving discussions are pushing likely reliability levels to 95% and even to 99%. This may limit PMD options for your use even further. This metric is even more challenging when it is likely that many of these PMD devices will be activated after having been on-orbit for many years.
- **ORBITAL RISK**: Does executing a given PMD strategy actually create more risk? This is examined as the area-time-product for collision risk but also includes issues of potential debris generation during a PMD device deployment (e.g., tether release or deployment of a drag-augmentation device).
- **GROUND RISK**: Does the given satellite pose a hazard above the accepted 10^{-4} probability of casualty on the ground? If you have to execute a controlled re-entry due to the potential of some of your hardware posing an impact risk to people on the ground, this will likely limit your PMD option to a propulsive system with assured attitude control until re-entry.

Abstract

This Chapter endeavors to identify the current international and national regulatory and legal framework as well as the guidelines and recommended practices which provide guidance to those space actors that are planning to launch and operate satellites into Earth orbit(s) – especially those anticipating and planning launch of small satellites. Thus, the specific topics addressed in this Chapter include, inter alia, requirements for various types of national licenses, the registration with the United Nation as well as International Telecommunication Union procedures with regard to the use of radio frequencies and intersystem coordination. It also addresses other aspects such as due diligence prior to launch, launch operations and range safety concerns, safety certification of launch facilities, safe operation of small satellites in orbit, orbital debris mitigation efforts to achieve long-term sustainability of such outer space activities, liability for damage caused by space objects, the space situational awareness and space traffic management and space militarization concerns, etc.

1 Introduction

The world of spacecraft (satellites or space objects) operations and their regulation is not simple (Jakhu and Pelton 2013). Any person or enterprise which is considering designing, manufacturing, launching a satellite into Earth orbits and operating such space object for specific uses/applications with the use of radio frequency spectrum (predetermined or allocated to the specific nature of services which such person or enterprise seeks to offer) have to be consistent with international treaties, guidelines, and procedures, intersystem frequency coordination, technical standards, and regulatory procedures as well as due diligence procedures and mechanisms established by national governments respectively and in accordance with national laws and regulations. Space operations are, and are becoming more of, a heavily regulated arena, both at international and national levels, primarily because of the increase in number of space actors and activities as well as new problems, such as space debris, radio frequency spectrum, space traffic management, space militarization, etc.

The international space governance efforts in the early days of the space age resulted in negotiation for and adoption of five international conventions related to exploration and use of outer space. These include, inter alia, the Outer Space Treaty (1967), the Liability Convention (1972) (Convention on International Liability for Damage Caused by Space Objects 1972), and the Registration Convention (1974) (Convention on Registration of Objects Launched into Outer Space 1974). These three international conventions, negotiated within the United Nations (UN) Committee on the Peaceful Uses of Outer Space (COPUOS) and subsequently adopted by the UN General Assembly, are most pertinent in the context of this Chapter regarding launch(es) of spacecraft(s) into Earth orbit(s) or beyond. They deal with regulation and conduct of space activities. During the time these conventions were negotiated and adopted, the United States (USA) and the then Union of Soviet Socialist Republics (USSR) were the only two States that possessed launch capability in the world, and the membership of COPUOS was also limited; and thus, it was easier to reach agreement on key issues related to legal rights and obligations pertaining to the conduct of all space activities, including small satellites.

In over five decades since the conclusion of the Outer Space Treaty in 1967, and four decades since the adoption of the last of the five international conventions (the Moon Agreement that was adopted on 5 December 1979) (Agreement governing the Activities of States on the Moon and Other Celestial Bodies 1979), there has been no adoption of a new significant international convention regulating the conduct of space activities, including launching and operation of small satellites. While there are recommended guidelines, safety standards, and procedures in place which are required to be observed with regard to, for example, mitigation of space debris; none of these guidelines and recommended practices have the status of a binding international treaty, and thus, have no specific sanction(s) to support their enforcement.

Unfortunately, the early international agreements could not anticipate how significantly the world of space would change in the half century that would follow. In this time, conduct and operation of space activities have shifted from being in the exclusive domain of States to a time where these activities are largely being carried out by private companies and enterprises. Moreover, back in the 1960s and 1970s when these early international agreements were negotiated and adopted, there was also no anticipation of the vast number of satellites that are currently being launched into Earth orbits, individually as well as in very large constellations, with some of these constellations now envisioning numbers of small satellites numbering in the thousands. This leads to serious concerns and complexities with regard to orbital space debris, frequency interference, difficulties of orbital and radio frequency management, space situational awareness, on-orbit services, space traffic management, and related liability issues. The addition of high altitude platforms (HAPs) and space plane flights has also raised the issue of where space traffic management processes begin and end as more activities in so-called 'Proto-space' become of regulatory concern.

Primarily due to the lack of progress in the adoption of appropriate international regulations, various governments of space faring nations have started enacting their respective national laws, regulations, and procedures. Thus, they are required to be followed prior to launch, at launch, as well as during a particular satellite/satellite networks' operation. Similarly, there are recommended processes and procedures in place to be followed after the satellite's end of life and other regulatory concerns regarding de-orbiting a launcher's different stages after it has performed its functions of releasing its payload to the stipulated Earth orbit(s). Moreover, with the increasing accumulation of space debris (junk) in Earth orbits, there are emerging concerns about the risks posed by orbital debris. These concerns have only increased in intensity and with time due to deployment of large-scale constellations, bringing to the front, issues regarding space situational awareness and space traffic management. These are often characterized as issues related to the long-term sustainability of outer space activities. Some countries (States) are enacting space-related national legislations which create incentives, as well as penalties, as means to aid in the solution of these emerging problems, and correspondingly, increase safety at all levels for people on the ground, people in aircraft, and people that may travel on new emerging space vehicles and objects. Accordingly, a vast array of international and national legal and regulatory procedures which may be looked into and may be required to be adhered to by space object manufacturers and operators, launch vehicle service providers and operators, etc. are detailed below.

2 National Launch Licensing, Launch Safety, and Due Diligence

States Parties to the Outer Space Treaty are internationally responsible for all their national space activities (Outer Space Treaty, Article VI.). Consequently, the States are obliged to (a) assure that these activities are carried out in conformity with the Outer Space Treaty and (b) to impose the requirement of authorization and continuing supervision on their nongovernmental entities (private companies), if they undertake space activities. In order to fulfill these obligations, space faring nations have adopted their respective national laws and regulations thereby imposing licensing requirements on their private companies and applying technical safety standards.

In all space-faring countries that possess launch capabilities, mainly nongovernmental space launches, launch sites, and facilities are required to be licensed by designated governmental authorities. This launch licensing procedure is separate and distinct from, and in addition to, the national licensing procedure of space objects (as detailed in section "National Payload Licensing"). A part of this process are the preparation of an environmental impact assessment, the possible creation of orbital space debris and fragmentation processes of launcher stages that return to Earth. Finally, there is also a licensing process for launch sites.

The first priority in launch licensing process are safety inspections and safety certifications in order to insure the safety of the people on the ground or in aircraft in flight, who may potentially be injured, or possibly killed, by a launch operation.

A 2-year study conducted by the George Washington University in 2005 highlighted that more number of people have been killed or injured from accidents on the ground by rocket motor explosions or by rockets/spacecraft that have gone off course and crashed into bystanders as compared to the number of astronauts who have been killed while involved in space activities (Pelton et al. 2005: Space Safety Report).

In the United States, NASA and the Air Force certify the launch sites for governmental and military launches respectively (See National Aeronautics and Space Administration 2019). In the case of commercial launch sites, including spaceports used for launch of spaceplanes for space tourism-related launches, it is the US Federal Aviation Administration Office of Commercial Space Transportation (FAA-AST) that, on a 5 year inspection cycle, certifies the safety of these sites (US Department of Transportation 2019). Space launch facilities and sites are certified in accordance with detailed lists of safety standards, criteria, and procedures. Some of the key elements of this inspection process are: (i) the safe storage of combustible fuels and noxious or poisonous materials; (ii) test stands for engine firings; (iii) control facilities that are well removed from launch gantries; (iv) a large well-controlled perimeter that separates the launch facilities from other inhabited areas and preferably has frontage with an ocean area; and (v) a number of other more specific requirements.

The other key element of launch safety is certification of launch operations through issuance of a launch license. This process varies from country to country and has different requirements for systems that intend to launch crew and passengers. In the United States, all commercial launches that involve space planes with crew onboard are being issued experimental licenses only at this time (Coleman et al. 2018). The legislative mandate in terms of responsibilities and organizational arrangements are spelled out in the US Commercial Space Launch Competitiveness Act of 2015 (US Commercial Space Launch Competitiveness Act 2015). Subsequently, the so-called Space Policy Directive 3 issued by the White House on 18 June 2018 has revised some of the responsibilities with regard to commercial space situational awareness and space traffic management from the US FAA-AST to the Office of Space Commerce in the Department of Commerce (United States 2018).

In many other States, there are several common aspects of safety and liability concerns that are now a part of every launch operation review in many countries. The primary concerns are that a launch should not produce any additional orbital debris, that all safety-related matters have been addressed, and that a proper environmental impact review has been carried out. These safety-related requirements prior to a space launch essentially caution States to consider the consequences of their space activities before undertaking them and abstain from them if it is foreseen that they will cause harm or hinder the activities of other States; or alternatively, they should take all necessary steps to avoid such consequences (Madry et al. 2018). Thus, for example, there is a requirement for an environmental impact review to be completed and statement to that effect furnished prior to all launches conducted in the United States (See US Department of Transportation 2015), even for governmental and military launches (National Aeronautics and

Space Administration 2019). An environmental impact assessment (EIA) and review covers a number of different areas. A complete environmental impact assessment in the USA covers such aspects as: (i) negative visual effects; (ii) impact on farms and coastal resources; (iii) air quality (largely in terms of green-house gases); (iv) climate conditions; (v) noise and noise-compatible land use; (vi) biological resources affected; (vii) water resources; and (viii) hazardous materials, solid waste, and pollution prevention (See United States Federal Aviation Administration 2018).

Due to proliferation and rapid increase in numbers of space launches, there are increasing concerns that the environmental impacts associated with rocket (space vehicle) launches have been underestimated in the past. There have been studies conducted of launch vehicle launches which highlight that several relevant factors have not been considered in the environmental impact statements, which statements have now rather become routine and proforma in nature (Grush 2018). These reports, for instance, highlight that routine EIA statements should not only take into account the quantity of green-house gas emissions of a launch but also should consider the key factor of the altitude at which these pollutants are released into Earth's atmosphere; that is, the effect of carbon gases being released at an altitude where the atmosphere is perhaps a hundred times thinner is a key factor to be considered. A report by the Aerospace Corporation suggests that although emissions from liquid fuel burns of kerosene generating black carbon or soot are typically considered in EIA statements, heavier and harmful particulate releases such as chlorine and alumina from solid rocket motors can create particularly negative polluting effects to the Earth's atmosphere and negatively impact Earth's protective ozone layer. The harmful effects of these emissions are not currently being directly addressed although such heavier and larger alumina particles (from solid rocket motors) tend to remain in the northern hemisphere, where most launch sites are located, and in the lower stratosphere (20–30 km above sea level). This study by Aerospace scientists Ross and Vedda recommends that environmental impact studies should consider these factors and address their effects with greater depth; and that more research is required to be carried out in areas of environmental concerns (Ross and Vedda 2018).

3 National Payload Licensing

In addition to the requirement of licenses for launch of vehicles/rockets (addressed above) and for the use of radio frequencies (addressed below), there are several other national legal, regulatory, and procedural requirements that are to be complied with as regards the "payload" of a launch (i.e., satellites or satellite networks or constellations) as well as to its de-orbiting processes. Almost all countries have some form of national laws and regulations pursuant to which they use services provided by satellites. While some countries have made minor amendments to their existing laws to extend their scope to cover space services, others have adopted new and detailed legislations and regulations to regulate the use of satellite(s) for specific applications. For example, in the United States, the operators of satellites (including small satellites) for telecommunications and broadcasting are required to obtain payload licenses from the Federal Communications Commission (FCC) under several very complex laws and regulations (United States, Communications Act 1934). Similarly, Canada regulates small satellites for telecommunications and broadcasting under a group of national laws and regulations (Canada, Telecommunications Act, S.C 1993). In case one wishes to operate a satellite (including a small satellite) for remote sensing (earth observations), there is a need for procuring a specific license for this purpose. Licensing of remote sensing satellites is regulated in the United States under Title 51 of the US Code (United States, U.S.C 2010) and in Canada under the 2005 *Remote Sensing Space Systems Act* (S.C. 2005). It should be noted that payload licenses are generally issued subject to various terms and conditions, some of which often include that the licensee avoids any breach of the State's international obligations, preserves the national security of the State, insures himself against possible liability incurred in respect of damage suffered by a third party, disposes the payload, at the end of its life, according to established policies and procedures, etc.

4 National Radio Frequency Licensing and Support

Once a small satellite project is conceived and designed, at least in a conceptual sense, it is a good idea to give some serious thought to the regulatory matters related to assessment of what spectrum (or radio frequencies) may be required for its operation, including for operational activities of such small satellite(s) such as remote sensing, telecommunications, relay of scientific observation data to ground systems, planned orbital characteristics, and so on.

All satellite operators in all countries are required to get license approvals from their national administrations (relevant governmental agencies) to use spectrum frequency under their respective nationally-sanctioned licensing systems, where specific frequencies are approved for the use of satellites during their lifetimes. Such a national radio frequency licensing requirement is in addition to other licenses (as discussed above) related to launching of payload and launch services as well launch sites and facilities.

The State Parties to the International Telecommunication Union (ITU) Constitution (Article 45(1), ITU Constitution 1992) and Radio Regulations (Article 4(4), ITU Radio Regulations 2016) are under obligation to allow the use of radio frequencies by their operating agencies and entities only in accordance with the Table of Frequency Allocations and other provisions of the Radio Regulations. States are also obliged not to permit the establishment or operation of a radio station by a private person or by any enterprise without a license issued in an appropriate form and in conformity with the provisions of the ITU Radio Regulations (Radio Regulations, Article 18 (1)). Thus States require their private enterprises or entities to seek radio frequency licenses from the designated national governmental bodies and to report their proposed space activities and to make their filings to such national bodies. Thus, in most cases, through national legislations and licensing processes, national administrations have their own internal procedures to consider the merits of filings by a private person or enterprise and the national licensing of the satellite(s) and its launch, before it sends the filings onwards to the ITU in accordance with their international law obligations (discussed below). In the United States, for instance, the Federal Communications Commission (FCC) has been given the role and responsibility for grant of radio frequency (spectrum) licenses for operation of all satellites, including small satellites (Title 47 – Telecommunications 2010). Moreover, it has separate procedures and requirements, for issuance, of licenses satellites in geostationary orbits (U.S. 47 C.F.R § 25.158 2019) and for satellites in other orbits (U.S. 47 C.F.R § 25.157 2019). There are limited requirements in the case of individual CubeSat type launches, but more exacting requirements in the case of commercial filings to deploy new satellite networks (FCC, Guidance on Obtaining Licenses for Small Satellites 15 March 2013). The FCC, since the issuance of the public notice of 15 March 2013, has also provided simplified guidelines for licensing of small satellites which are to be issued under Parts 5 (Experimental Radio Service) or 97 (Amateur Radio Service) of the FCC Rules (FCC Rules and Regulations for Title 47 CFR 2019b).

There are specific and more detailed requirements in the case of filings to deploy satellite-constellations to undertake commercial services (FCC Satellite Licensing Procedures May 2009). In such instances, there is a requirement to define the technical aspects of the proposed system in terms of spectrum usage, mass, power emission levels, orbits, and ground segment specification. In addition, there is a requirement to supply information as to the cost of the spacecraft, the manufacturer of the satellites, the launch services contract, etc. In order to provide the information for the ultimate filing with the ITU that will be made on behalf of the US, there is also the need to spell out all frequencies which are to be used for tracking, telemetry, and command (TT&C) as well as all frequencies assigned to specific services and such aspects as spot beam configurations. This information is needed by other satellite operators around the world to assess whether the proposed new satellite system would result in harmful interference with their own satellites. Thus, an FCC assessment in such cases would consider the technical, operational, financial, and legal viability of the commercial, academic, or scientific activities of the proposed new satellite-constellations or networks.

The US National Telecommunications and Information Administration (NTIA) and Department of Defense (DoD) oversee governmental and military space activities (See NTIA - Driving Space Commerce through Effective Spectrum Policy 2019). The US State Department, as the designated Administration, officially communicates information to the ITU after national licensing processes are completed (US Department of State - International Telecommunication Union 2019). Thus, it becomes important to allow sufficient time prior to the planned launching of satellites for processing of the national license under existing laws and regulations as well as for subsequent filing of required and relevant information with the ITU, which often takes time ranging from months to years.

The US National Aeronautics and Space Administration (NASA) began its CubeSat program in collaboration with colleges and universities some three decades ago and is also another resource that could be consulted with regards to small satellite initiatives. In 2016, NASA created at its NASA Ames Research Center, its Small Spacecraft Systems Virtual Institute (S3VI) (NASA S3VI 2016). Some initiatives of S3VI include the Cube Quest Challenge and the CubeSat Launch Initiative (CLSI). These programs provide opportunities for small satellite payloads built by university students and nonprofit organizations to be launched as auxiliary payloads on upcoming NASA launches. When the program was established, Steve Jurczyk, the then associate administrator for NASA’s Space Technology Mission Directorate (STMD), had said: “NASA sees enormous benefits from investing in research and technology development in small spacecraft systems, such as propulsion, that will be essential in advancing the commercial space sector” (NASA 2016). Thus, in addition to the general objective of providing assistance to small satellite initiatives, NASA also has several programs to assess and test CubeSat designs for safety and reliability of operation. These programs, rather than playing a specific governmental regulatory role, provide useful advice to support many small satellite projects and initiatives. Their objectives and functions include assisting with launch arrangements and a technical review of small-sat/CubeSat missions to make sure that its design is safe. This is particularly important if a CubeSat is intended to be launched via the International Space Station (ISS) through its NanoRacks CubeSat Deplorer or other ISS launch options.

Other countries have their own national regulatory licensing requirements, processes, and mechanisms. Similarly, space agencies of many other States provide useful advice and support to small satellite initiatives. To find out more about such support offerings, it would be useful to refer the websites of the Canadian Space Agency (CSA), the European Space Agency (ESA), the German Space Agency (DLR), the United Kingdom Space Agency, the French Space Agency (Centre national d’études spatiales or CNES), the Italian Space Agency (ASI), the Japanese Space Agency (JAXA), the Russian Space Agency (RosCosmos), the China National Space Administration (CNSA), the Indian Space Research Organization (ISRO), etc.

Further, the various designers and manufacturers of small satellites or companies that provide small satellite launch operations are often well equipped to provide assistance. Many of these companies can provide useful advice and guidance with respect to the necessary filings to be made and detailed information which is required to be prepared for the purpose of obtaining a national license as well as on such information which is required to be furnished to the national administrations for the purpose of subsequent filings by such administrations with the ITU and UN Office of Outer Space Affairs (OOSA).

5 International Radio Frequency Allocation Procedure, Coordination, and Challenges

Once the national radio frequency licensing process is successfully completed, there is an international process of intersystem coordination which is carried out by the ITU in order to coordinate the use of a particular frequency so as to avoid or minimize frequency interference with other existing and planned users and operators that have registered their satellite systems with the ITU.

The ITU’s intersystem radio frequency coordination procedures are required to be complied with if the operator wishes to have international protection against harmful interference, satellite will be operated for international service or if its operation is likely to cause interference with other existing satellite systems or with ground systems, including radio telescopes that are usually sensitive to radio frequency interferences.

National administrations (of countries or States), which are parties to the ITU have certain responsibilities to provide detailed information with regard to frequency usage and orbital characteristics that is required to be filed with the ITU (ITU Regulatory Procedures for Small Satellites 2019a). After such information is formally shared with the members States of the ITU, there may be a possibility that other entities or administrations of other States could indicate that a new satellite or satellite constellation might cause harmful interference and request for ITU’s intersystem coordination processes, mainly bilaterally, to take place in order to avoid or significantly minimize the possible harmful interference (ITU Radio Regulations 2016).

All uses of radio frequencies for satellites need to conform to the requirements of the ITU Radio Regulations. These Radio Regulations are complementary to the ITU Convention and the Constitution (Constitution and Convention of the International Telecommunication Union 1992). Deriving from the principle enshrined in Article 44 of the ITU Constitution of efficient use and equitable access to spectrum/orbit resources, these documents prescribe conditions for use of radio frequencies that are based on the principle that the right to use orbital and spectrum resources for a satellite network or system is acquired through negotiations with the administrations concerned by actual usage of the same portion of the spectrum and orbital resource (ITU Radio Regulatory Framework for Space Services 2019b).

Based on this principle, the ITU spectrum Table of Radio Frequencies included Article 5 of the Radio Regulations is a quite complicated specification and allocation of which radio frequencies are allocated for particular uses. It notes, in some cases, allocations based on a primary, secondary, and even a tertiary basis. There are some uses that can be conducted on a non-inteference basis, and some usage, that operate in a very localized and low power level, can only be used in such a manner. Moreover, this ITU spectrum table of radio frequencies is divided into three zones around the world geographically, where Zone 1 is for Europe, Africa, and the Middle East; Zone 2 covers the Americas and the Caribbean countries; and Zone 3 is for Asia and Australasia.

States/National Administrations agree and adopt this global spectrum allocation table at Plenary Sessions of the World Radiocommunication Conferences of the ITU that meet periodically. Countries, can by adding footnoted exceptions, impose some other restrictions on, or indicate prohibition of, use of a particular frequency allocation within their respective territories. As satellites by their nature are global in their coverage, except for geosynchronous satellites that cover a more limited and specific area, allotment of frequencies and specific assignment of spectrum to global satellite networks is a difficult and very important process to avoid interference with radio frequencies being used by terrestrial systems, aeronautical and high altitude platforms, as well as other satellite systems or their ground stations. Although there are some allocation of spectrum usage in the VHF and UHF bands for academic, scientific, amateur radio, and military usage, the main commercial bands are in the L-band (1–2 GHz; used for mobile communications satellite services), C-band (4–8 GHz), Ku-band (12–18 GHz), Ka-band (26–40) GHz, and most recently, V-band (40–75 GHz) services (ESA 2019).

The procedure of intersystem coordination within the framework of ITU is essentially detailed in Articles 9 and Article 11 of the ITU Radio Regulations. The crux of this procedure is comprised of: (a) Coordination; (b) Notification; and (c) Registration (ITU Radio Regulatory Framework for Space Services 2019). This process is heavily dependent on global cooperation and mutual respect for proper use of spectrum according to coordinated plans. However, as the ITU does not have enforcement measures, policing capability or even the power to impose fines, this is not always completely successful. If the coordinated agreements are not followed, or if jamming occurs, either on an intentional or unintentional basis, this can jeopardize satellite communications or relay of information from remote sensing or other satellite application services.

In the event, there is a reported instance of interference or jamming, the procedure which the ITU officials follow is to bring the issue to the attention of the national administration (State), which is a party to the ITU Convention and from whose territory the interference or jamming occurs or whose national entity or person is determined to be responsible for such activity. The issue of interference is essentially resolved between the allegedly interfering State and the interfered State, with the support of the ITU (Radio Regulations, Article 15, Section VI – Procedure in a case of harmful interference). However, if in such a case, the source of the interference or jamming is the national administration (government) of the allegedly interfering State itself or if such interference or jamming is sanctioned by its national government, there is no obvious further recourse under the current international regime. Moreover, if a State or its national government in question engages in jamming radio or television transmissions in order to protect itself or its sovereignty against acts which it considers as hostile attacks, it can also claim that it is acting in national defense. Fortunately though, most States and commercial entities and organizations typically act in a highly responsible manner, and efforts made worldwide to act in accordance with the ITU spectrum use regulations as well as its own national spectrum controlled by a designated governmental entity which provides oversight of radio frequency and spectrum use within its borders. On a national level, these national administrations or designated governmental entities operate within the purview of applicable national laws and regulations and as such have the power to pursue enforcement measures through fines, or in appropriate circumstances, even criminal prosecution (For United States, see FCC Technical Rule Violation 2019). Similarly, operators of commercial satellite or space systems also have the right to engage in or initiate civil suits and claim compensation for damage.

There is another area of concern with regard to filing of frequency and orbital usage with the ITU; i.e., the problem of "paper satellites", although this has now been largely resolved. This problem arose due to the fact that commercial satellite companies have to first publicly file for national licenses of their new satellite system(s) with the appropriate regulatory body of the concerned State, such as the FCC in the United States. This process can take many months, if not years to complete. This national regulatory review and licensing process precedes the subsequent official filing with the ITU. In addition, due to the ITU's own "first-come, first served" procedure of filing for frequency allocation as well as its international coordination procedures (Radio Regulations, Article 9.), this entire process may sometimes take years to complete for a complex satellite network system. This led to some States' national administrations to file in advance with the ITU for orbital slots and radio frequencies, in order to preserve those slots for its own possible future use or in order to lease or sell them to other users for economic benefits, even without any real intention of using these slots and radio frequencies in the near future (Galeriu 2018). Thus, in order to skirt and exploit the long period of review in the USA, Europe, Japan, or elsewhere, overseas entities operating out of the jurisdiction of such States or national administrations which allowed an immediate filing with the ITU simultaneously with a filing under their national laws to obtain the benefit of the ITU's "first filed, first served" priority (i.e., obtain a priority filing status), indulged in reserving frequencies and spectrum without any intention of actually using it. These artificial filings thus came to be known as "paper satellites." The first of these initiatives was called the "Friendly Skies Company" which was set up in the Kingdom of Tonga, and it filed a series of satellite systems for registration with the ITU, with the hope of "leasing" their early filing precedence status, and thus obtain legal priority over the actual system.

In response to complaints about this practice, the ITU has implemented a series of changes to its rules and procedures. At its World Radiocommunication Conference, 2015, the ITU introduced revised Resolution 49 pertaining to administrative due diligence applicable to some radiocommunication services (ITU Administrative Due Diligence 2015). It now requires verified data and contracts regarding the manufacturer of satellites, information about the entity which is to launch the satellites, etc. Through its Council Decision 482, which has periodically been modified (ITU Cost Recovery for Satellite Network Filings 2019d), it also increased the cost of submitting filings and for its intersystem coordination processes. These steps have largely served to significantly minimize the practice of filing for "paper satellite" systems that were never intended to be built, but rather were simply a ploy to obtain priority filing status, which could then be economically exploited at the expense of those actually seeking to launch a new satellite system (Galeriu 2018).

Additionally, and with specific regard to operation and launch of small satellites, it is also worthwhile to note some important developments and resolutions adopted by the ITU. In recent years, small satellite operators have been using amateur radio frequencies for their noncommercial operations. This has the distinct advantages of lower costs, easier process of coordination, as well as significantly less time period as compared to the full ITU intersystem coordination procedures. However, for commercial uses of small satellites, satellite manufacturers and operators have to still adhere to the intersystem coordination procedures. Recognizing the proliferation of nanosatellites and picosatellites, the ITU had adopted Resolution 757 at its World Radiocommunications Conference in 2012 to "examine the procedures for notifying space networks and consider possible modifications to enable the deployment and operation of nanosatellites and picosatellites, taking into account the short development time, short mission time and unique orbital characteristics" (ITU Resolution 757 2012). Noting that no special coordination procedures are required for small satellites, the ITU, at the 2015 World Radiocommunications Conference adopted another Resolution 659 to "assess the suitability of using existing allocations for the space operations service below 1 GHz to accommodate the telemetry, tracking and command (TT&C) requirements for non-geostationary satellites with short duration missions" (ITU Resolution 659 2015). A short duration mission is stated as any satellite mission with its operating period less than three years. In this regard, studies are ongoing (See International Telecommunication Union 2019), and a decision is to be made at the impending World Radiocommunications Conference 2019 (Oct-Nov 2019). The important take-away of these developments is that a lot of initiatives are being taken by the ITU and its member States to facilitate and simplify procedures relating to small satellites, and specifically with regards to satellites with short duration missions, and it would be worthwhile to keep a track of and stay abreast developments in this field.

6 International Registration with the United Nations

In addition to aforestated filing requirement with the ITU regarding radio spectrum usage and orbital position(s) as well as network coordination, there is also a requirement for a Launching State (i.e., that launched a satellite), to register this space object pursuant to the Registration Convention by providing relevant and applicable information to the UN through the Secretary General (Registration Convention, Article IV 1974). States that are not Parties to the Registration Convention are expected to provide such information in terms of UN General Assembly Resolution 1721 B (XVI) (UNGA Resolution 1721 B (XVI) 1961). Information for the purposes of registration under these instruments are to be provided by a State (its national administration or a designated authority) and not by the commercial entity that has launched a satellite or the launch services contractor/provider. This information is crucial in order to establish which State is the "Launching State" for the launch of such satellite. In turn, obligations are placed upon the State. This registration procedure thus becomes crucial and necessary for several reasons, including to determine which State may be responsible under the Outer Space Treaty and liable for damages under the Liability Convention (Liability Convention, Articles II – V.). Thus, in order to assist States and International Organizations in registering space objects and pursuant to UN General Assembly Resolution 62/101 of 2007, the UN Office for Outer Space Affairs has developed a Model Registration Form (See United Nations Office for Outer Space Affairs 2019).

7 Space Situational Awareness (SSA) and Space Traffic Management (STM)

The issue of space situational awareness and space traffic management has become increasingly important in both a technical competence sense as well as a regulatory sense for several reasons. Prime among these reasons is the rather massive number of new small satellite constellations proposed to be launched at a record rate in the next 5 years. Over 20,000 new satellites are proposed for launch (Madry et al. 2018), which is a number that far exceeds the 2062 operational satellites now in GEO, MEO, and LEO orbits (data by the Union of Concerned Scientists as of 31 March 2019) (Union of Concerned Scientists 2019). On 24 May 2019, a Falcon nine rocket/spacecraft placed 60 small satellites into LEO orbit with a single launch (New York Times 2019). This was only the first step by SpaceX to launch some 4409 Ku-band Starlink satellites into LEO orbit that would be followed by another 7518 satellites operating in the V-Band (Grush 2019b). If these two Starlink networks are fully deployed, it would far exceed all of the satellite launches into Earth orbit prior to 2019. (See Fig. 1).

The increase in space debris the size of a baseball or larger to nearly 18,000 is a clear concern to everyone involved in active space operations. The shooting down of the Chinese weather satellite, Fengyun-1C, created over 2000 major trackable debris elements in 2007 followed by the Russian Cosmos 2251 Satellite and Iridium 33 Satellite collision in 2009 that also created over 2000 more debris present serious

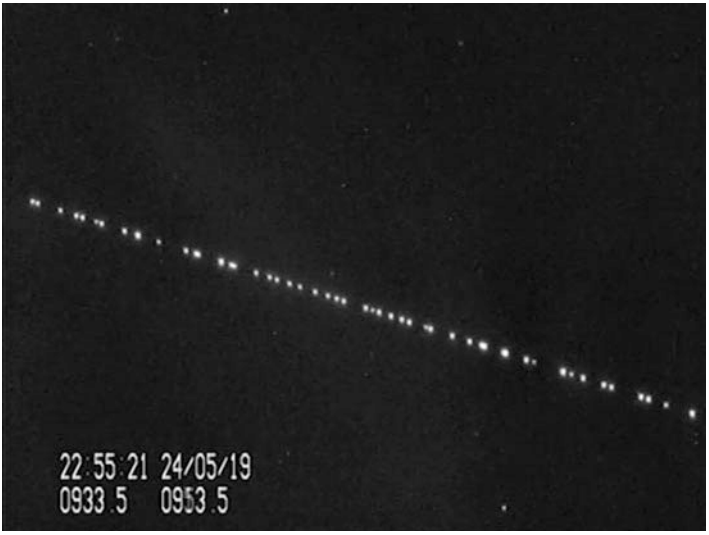

Fig. 1 Night time photo of 60 satellites in the SpaceX Starlink Constellation. (Graphic courtesy of Marco Langbroek)

concerns. Debris created by India's conduct of anti-satellite test on 27 March 2019 is expected to remain in orbit for years and will keep posing threat to active satellites (Henry 2019). The new S-band radar system that will be able to track LEO debris elements down to the size of a ping-pong ball represents an important new capability to improve space situational awareness, but exactly how space awareness will be carried out in the future and what methods will be employed to pursue space traffic management are far from clear. Further, the manner in which these activities will be conducted in terms of separate commercial satellite operations as opposed to military tracking and control has not been clearly established as well. Increasingly, there are a number of commercial companies that have precise space tracking capabilities; and under the US Space Policy Directive 3 issued by the White House on 18 June 2018, it appears that Military SSA capabilities will be separated from the commercial operations (US Space Policy Directive - 3 2018). Commercial companies which provide tracking services to support SSA now include Analytic Graphics Inc. (AGI), EtaMax, Exoanalytics, Globvision, Lockheed Martin, Norstar Space, Polaris Alpha, Schafer, and Spacenav. But it is not clear yet as to how the US Office of Space Commerce, which under US Space Policy Directive 3, has been assigned responsibility for commercial SSA for the USA, will move forward so that this task can best be completed. It is also yet to be determined if this will be carried out by a competitively selected group of commercial operators, and if so, how will this activity be discharged in notifying satellite operators of possible conjunctions that could occur. Till date, there has been a significant problem in this regard. If operators are notified virtually constantly of a possible collision, this overwhelming amount of data or notifications could lead to inaction or indecision by such operators. On the other hand, if there are only very few notifications with a very narrow window set for very close collision possibilities, this could result in too little opportunity for evasive action (Market Watch 2019).

There are several new satellite constellations that are being deployed whose capital valuation might be as high as over $10 billion dollars, and thus these assets are becoming enormously valuable. Further, if an actual collision should occur, the potential of a true run-away avalanche of space debris is extremely high (Pelton 2018) that could have a devastating impact on the global economy. There are now various videos online with titles such as "If there were a day without satellites" (Benedict 2019). These tutorial messages outline and highlight how a loss of satellite networks globally could have an enormous impact on the Internet, global broadcasting, fishing, farming, banking, airline travel, and even global retailing, rescue, and emergency operations as well as national defense and military systems.

It is truly vital that military and commercial systems cope with the increase in space traffic and satellite deployments to make sure that they are safe, and collisions are avoided. The consequences of a major mistake, and a resultant series of major collisions, could have a dramatic impact on the global economy, on human life, and worldwide supply chains of food, water and vital supplies, and national defense systems.

8 International Liability for Damage

As stated above, determination of a “Launching State” status is important for establishing international liability in case of damage caused by a space object, including small satellite. Under the Liability Convention, there is “absolute liability” in case of a space object causing damage on the surface of the Earth or to aircraft in flight (Liability Convention, Article II.). This could, for instance, be due to a launch failure as the Liability Convention specifies that this liability includes liability arising out of attempted launches (Liability Convention, Article I (b).). Thus, this is the reason as to why there is a space range officer in the case of most launches, who can fire a self-destruct button in case an errant rocket is headed for populated areas.

Moreover, damage could also be due to a deorbiting space object that might hit a house, an office building, or an aircraft with passengers. The most prominent example to date is of a spacecraft that crashed in a fairly isolated area in Canada but unfortunately released radiation from its radioactive power source of about 50 kilograms of Uranium-235. The reference here is to the Soviet satellite (COSMOS 954) with a nuclear power source that crashed in northern Canada near the Great Slave Lake on 24 January 1978. The government of the then USSR negotiated a settlement with the Canadian government under the provisions of the Liability Convention as well as general international law. The nuclear power source leaked radiation across a substantial area and the settlement included negotiated compensation for Canada’s clean-up operation (Protocol in respect of the claim for damages caused by the satellite ‘Cosmos 954’ April 1981). (See Fig. 2).

Some countries, that are or become the “Launching States” for small academic or commercial satellites, may not have fully considered the liability implications that they are assuming or have assumed as a small satellite may be seen quite harmless. Some of the “small satellites” now being launched are in the range of 150–500 kg,

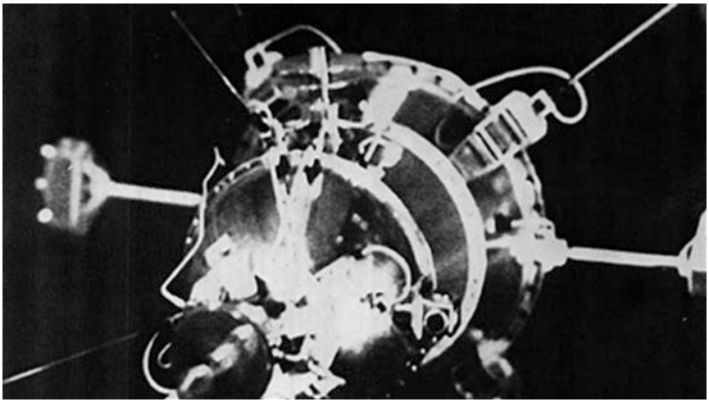

Fig. 2 The Rorsat-Type “Spy” Satellite that Crashed in Canada in 1978. (Graphic courtesy of Canadian Government archives)

and thus sufficiently large to represent a fairly large cross section to become a target for impact by smaller debris elements – especially if hundreds and thousands of them are deployed.

The biggest concern that involves "absolute liability" remains the case of a launch failure where a rocket (space vehicle) and spacecraft might somehow hit an aircraft or a ship with passengers onboard. In this case the liability claim might potentially be quite substantial. It is for this reason that all air flights are currently diverted during a launch from the vicinity of the area from which launches are conducted. Certainly, liability claims are a major concern. Legislation has been passed in many space-faring countries such as the United States, France, Japan, etc. In each instance, there is explicit language in such legislation that spells out the liability that the government is assuming in the case of launches, and in most cases, also places responsibility on a commercial entity or organization to acquire liability insurance for claims that exceed the specified levels; and thus governments provide a level of liability claim protection (51 USC § 50914, 51 USC § 50915; French Space Operation Act 2008, Articles 14 and 15.).

Each country's legislation tends to be different and thus it is important to consult with the relevant governmental officials that provide licensing for commercial launches in order to better understand the level of liability assumed, and the type and levels of liability insurance required. This is, of course, in addition to conventional launch insurance which might be required. The following passage taken from an overview analysis of this subject aptly summarizes the situation as follows:

> The new Japanese law [of November 2016] also provides government support in the provision of financial guarantees required by commercial space launch operators, such as by arranging third-party liability insurance coverage. The required coverage is calculated on the basis of the maximum probable loss estimated in line with the rocket type and the payload content; in the case of damages in excess of this coverage, the law provides that the government is to pay for the residual damages up to a certain limit. This is similar to arrangements that have been adopted in the United States and France, although the French government sets no limit on payments. (Aoki 2017)

To a certain extent, the Government of France has assumed the highest level of liability coverage for Arianespace launches under the French Space Operations Act, 2008, (France, French Space Operation Act 2008) rather than a tiered coverage used by other countries. This does provide an advantage to its launch services provider.

The UN Liability Convention was negotiated and adopted in 1972. As there were only two suppliers of launch services in the world at the time, it was not anticipated then that there could be many scores of suppliers of launch services, and that most of them would be commercial companies. Further, no one anticipated that there could be GNSS systems that provided guidance for aircraft, synchronize the Internet, or that there could possibly be problems such as orbital space debris, or that satellite with a nuclear power supply or noxious gases will be able to bring down destructive spacecraft from the skies. Moreover, the concept of small satellites, such as CubeSats, Nano, and Pico satellites, were also entirely unknown and their proliferation unseen.

Many space lawyers are of the view that the current UN international agreements such as the Outer Space Treaty or the Liability Convention are not adequate to deal with the complexities and challenges of the new space age that we now live in. These instruments that were negotiated 40 to 50 years ago appear to be inadequate to the realities of today's world of space and the many innovations that "NewSpace" industries have brought to the modern world. The provision that creates "absolute liability" under the Liability Convention leaves ambiguous the dangers of damages that might occur in outer space, where liability for damages is only based on fault of an entity (Liability Convention, Article III.); and thus, does not create incentives for active debris removal, or even for its mitigation. It also does not create the appropriate incentives for responsible space activities as regards rendezvous and proximity operations (RPO). It is clearly time to recognize that the long-term sustainability of outer space activities is now closely linked to the modern global economy and extremely vital to human activities on Earth.

Until a new international agreement on liability for damages can be negotiated and adopted, however, there must be ways to incentivize responsible actions to remove space debris from outer space, avoid accidents and collisions in outer space, and create better systems for SSA. One step forward would be to authoritatively define "space objects" in a better and more appropriate manner so as to at least include active spacecraft with human crew and passengers, working and maneuverable spacecraft, partially functional and maneuverable spacecraft. Space debris, on the other hand, should be those space objects that are not functional and not maneuverable.

9 Space Debris: Mitigation and IADC and UN COPUOS Guidelines

It seems unlikely that means will be found in the near future to renegotiate or amend the Outer Space Treaty, or its four supplementary international agreements related to outer space. Thus, in the meantime, the best hope for addressing the issue of space debris problem and to achieve safer means of removing space debris from orbit or to control its deorbiting process in a way so that it constitutes the least risk, lies with two entities. These entities are the UN COPUOS and the Inter-Agency Space Debris Coordination Committee (IADC). The UN COPUOS did finally agree on voluntary guidelines for space debris mitigation in 2007 (United Nations 2007). These voluntary guidelines were, however, essentially based on the work of the IADC that were agreed amongst the participating space agencies, and then with some modifications, were agreed by UN COPUOS and ultimately adopted by the UN General Assembly (UN General Assembly Resolution 62/217 2007).

The UN COPUOS guidelines as adopted are just seven in number and their basic elements are provided in Table 1 below:

The full guidelines can be found in the website of the UN Office of Outer Space Affairs that also maintains the official UN register of launched space objects. One of

Table 1 The basic descriptors of the seven UN COPUOS voluntary guidelines on orbital debris mitigation adopted by the general assembly in December 2007

U.N. COPUOS voluntary guidelines for orbital debris mitigation	
Guideline number	Basic description of guideline
1	Limit debris released during normal operations
2	Minimize the potential for break-ups during operational phases
3	Limit the probability of accidental collisions in orbit
4	Avoid intentional destruction and other harmful activities
5	Minimize potential for post-mission break-ups resulting from stored energy
6	Limit the long-term presence of spacecraft and launch vehicle orbital stages in the low-earth orbit (LEO) region after the end of their mission
7	Limit the long-term interference of spacecraft and launch vehicle orbital stages with the geosynchronous earth orbit (GEO) region after the end of their mission

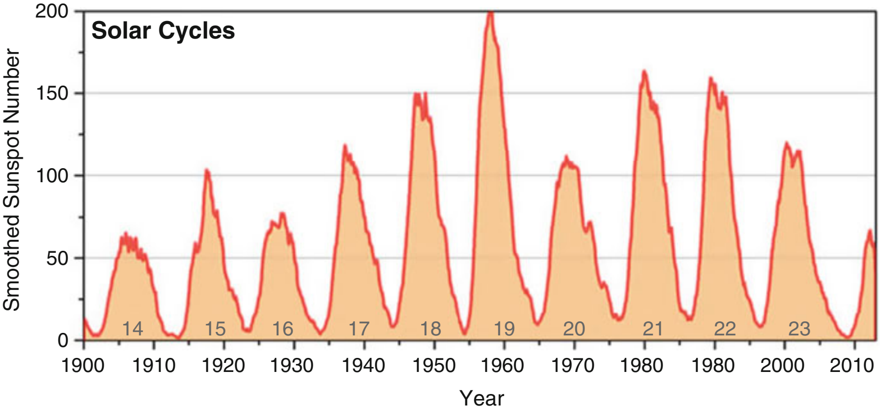

Fig. 3 A depiction of the 11-year Solar Max to Solar Minimum Cycle from 1900. (Graph of solar max cycle by US geospatial services)

the key differences between the COPUOS voluntary guidelines and the IADC developed guidelines is that the COPUOS' recommended practices did not include the concept that space objects should be removed within 25 years of the end of mission. This concept that is present in the IADC guidelines was apparently based on the idea that this would allow the space object to be subject to at least two solar max environments. During solar max conditions which occur in 11-year cycles, there is the maximum atmospheric drag on the spacecraft, thus facilitating satellites or spent rocket stages to naturally deorbit. (See Fig. 3).

Today many large-scale small satellite networks, with lifetimes in the typical range of 6–8 years, might need a resupply of small satellites to their orbits around three times within the above stipulated period of 25 years. Clearly in such an environment, a redeployment schedule for removal of defunct satellites every

25 years would no longer make sense and serve its purpose. If new satellites were deployed say every 8 years, while defunct satellites were removed every 25 years, the buildup over a period of time would be unacceptable. Even the operators of the new large constellations have seen that this guideline would no longer serve their needs as well of those concerned about space debris. It is hoped that the IADC and UN COPUOS will recognize the extent of this problem and develop new guidelines recommending much more rapid removal of spacecraft at end of life or mission. Some analysts have suggested that national regulators should have control of the removal cycle but so far any specific or particular progress on this point of view has not been achieved.

10 Space Safety and Debris Removal or Mitigation

Some have observed that since international progress has been difficult and slow on the topic of space debris mitigation and removal, the key to this problem is action at the national legislative level. Additionally, the UN COPUOS Guidelines on Long-Term Sustainability of Outer Space Activities also stipulate that States should consider a number of elements when developing, revising, or amending, as necessary, national regulatory frameworks for outer space activities including implementing the UN COPUOS Space Debris Mitigation Guidelines through applicable mechanisms (United Nations Guidelines for Long-term Sustainability of Outer Space Activities 2018) as well as States should consider the utilization of recommended practices and voluntary guidelines proposed by the Inter-Agency Space Debris Coordination Committee Guideline A.2 (2) (f)). In addition, it encourages States to develop and use relevant technologies for the measurement, monitoring, and characterization of the orbital and physical properties of space debris (Guideline B.3). It also provides that States should encourage manufacturers and operators of space objects, regardless of their physical and operational characteristics, to design such objects to implement applicable international and national space debris mitigation standards and/or guidelines in order to limit the long-term presence of space objects in protected regions of outer space after the end of their mission (Guideline B.8 (2).) and to investigate and consider new measures to manage the space debris population in the long term (Guideline D.2). Although these guidelines are nonbinding, they represent the common consensus of all States, and thus assume an important role in building and developing national legislation.

In this regard, the Technical Regulations of the French Space Operations Act, 2008, which were adopted in November 2013, have been seen as model legislation from several perspectives. These technical regulations have sought to address a number of space safety and space orbital debris-related issues and created specific guidelines, standards, and have even created a process where penalties could be imposed for noncompliance. This Act, along with the Technical Regulations, specifies a process to make sure that launchers and spacecraft are designed for a safe deorbit process and that the breakup of deorbiting fragments are designed in a manner so as to create the least amount of safety threats and avoid the intentional release of space debris into Earth orbit during normal operations. It also provides for liability coverage of launches and specifies that space objects or orbital stages of a launch vehicle that are not made to deorbit within a 25-year period from end of mission life and are left in LEO orbit would be subject to administrative fines (Lazare 2013). Unfortunately, for reasons set forth above, the 25-year period for deorbiting process is no longer seen as the best or functionally appropriate standard to use.

The United Sates has a number of regulations created by NASA, the FAA-AST, the US Air Force, the National Environmental Protection Agency (NEPA), as well as several laws enacted by the US Congress coupled with the four US Space Policy Directives which seek to define US space practices and standards. However, certain actions and stipulations contained in such legislation and space directives are considered controversial at the international level and are not necessarily appropriate guideline(s) on safety standard for the international community to endorse and follow.

The idea of using national law and regulations for setting standards of safety, de-orbiting guidelines, liability coverage, and perhaps, creating incentives or fines/penalties for not meeting such standards may be a key way forward for sustainable development of space activities in the long term. In light of the fact that international space treaties are quite difficult to negotiate and adopt, national standards and laws are emerging as a way to achieve best practices and perhaps act as a method for space-faring nations to agree on what reasonable practices should be followed.

11 Proto-Space or Proto-Zone

One of the new concerns in terms of space safety and regulatory oversight that has emerged in recent years is with regard to the areas sometimes called subspace, near-space, proto-space, or proto-zone. This is the area above commercial air space (i.e., above 20 km), and below the area where a satellite can orbit on a sustainable basis for the longer term (i.e., 160 km). For many years, this zone was of little practical use, except perhaps the flight of very high-altitude surveillance or spy planes. Increasingly, there has been proposal for stratospheric platforms like high-altitude platform systems (HAPS), hypersonic space planes for space tourism or ultimately point to point transportation, robotic freighters, dark-sky stations, or other applications.

Elsewhere in this Handbook, there is discussion on how an alternative to small satellite systems could be HAPS for some States so as to provide communications, broadcasting, or remote sensing services using such platforms that could, for instance, provide complete coverage for an island State. Such systems could be deployed at lower cost for special applications. Systems such as the Stratobus by Thales Alenia are being offered to provide services that range from detection of forest fires and diseases, rural and remote telecommunications, emergency medical services, as well as many other services (Pelton 2019a).

The problem is that today's radar or software for Global Navigation Satellite Systems (GNSS) services are not optimized to provide services in the 20–160 km range. Further, there are no fixed responsibility for safety and traffic control that have been defined for these areas, especially over international waters and the Polar Regions. Even for proto-space situated above national territories, there are currently no fixed regulatory authorities that relate to and regulate activities such as licensing of HAPS to provide commercial services. Clarification of the regulatory control of the proto-zone and improvement of relevant technical systems for safety and control will become increasingly important in the next decade or so. This will be particularly the case if, in time, there are conflicting uses of the proto-zone for purposes such as hypersonic transport, robotic freighter service, dark sky research facilities, HAPS operation as well as potential activities conducted by military agencies or defense ministries (Pelton 2019b).

There is a fascinating book written by David Loth titled "*How High Is Up*" that considers the legal and military implications of national airspace. This book considers how national airspace of States has ascended upward over time as States were increasingly able to defend and exercise sovereignty over higher and higher altitudes (Loth and Ernst 1964). It has also been suggested earlier that the international law of the seas, with its various protective zones with its littoral area, might serve as a useful model for developing governance for policing and perhaps licensing activities at high altitude or even the stratospheric regions (Pelton 2014). As efforts are being made by States to improve both national military and commercial space situational awareness and space traffic management, it is important that those discussions and agreements cover not only Earth orbit but also the proto-zone region as well.

12 Small Military Satellites, Space Systems, and MILAMOS

There are now a number of small satellite experimental projects for verification of new space technology and systems for military applications. In the last few years, there has also been an attempt to define standards of behavior and military codification of accepted space-related practices. The increased discussion of possible military actions and weapons systems in outer space and the creation of "space forces" have tended to make these attempts at standardization of practices and communications more important and urgent.

The number of dedicated military and dual use satellites being used and operated by armed forces, especially by the armed forces of major space powers, is increasing as they provide inexpensive and efficient services, particularly during geopolitically tense times. Any threat or perceived threat to these satellites could create serious security situations. Even their accidental destruction could be perceived as armed attack, thus creating a possible war situation. International rules are currently not clear on the use of outer space for military purposes. Thus, the Institute of Air and Space Law, McGill University, in collaboration with an international team of legal and technical experts from academic institutions, the industry, armed forces, and government ministries, has undertaken the drafting of the McGill Manual on International Law Applicable to Military Uses of Outer Space (MILAMOS) (More details of MILAMOS 2019). The Manual is intended to objectively articulate and clarify existing international law applicable to military uses of outer space in times of peace, including challenges to peace. The vision of this international effort is to contribute to a future where all space activities are conducted in accordance with the international rules-based global order, without disrupting, and preferably contributing to, the sustainable use of outer space for the benefit of present and future generations of all humanity.

While several aspects of space activities and their legal and regulatory procedures remain the same for civilian as well as military activities, there are also many aspects in which there are significant differences or where special rules and regulations apply to military activities in outer space; and thus, the MILAMOS Project's objective of capturing and clarifying such aspects of law as are specifically applicable to military activities will be beneficial for the international community. To further elaborate a few aspects, for instance, while all telecommunication aspects of civilian satellites are covered under ITU's intersystem coordination mechanism and procedures, however, all Member States of ITU retain their entire freedom with regard to military radio installations and are obligated to observe the ITU regulations only so far as possible (ITU Constitution, Article 48.). Similarly, under national legislation and regulations, in most cases, different and separate regulatory bodies or governmental entities regulate military activities of satellites. Accordingly, in the USA, it is the US Air Force which is responsible for most of military activities in outer space, including those that involve satellites or satellite networks and constellations. It is the US Air Force that certifies launch sites for military launch activities and promulgates regulations and oversees launch activities, as compared to the US Federal Aviation Administration Office of Commercial Space Transportation which provides for certification of launch sites to be used for commercial purposes. Similarly, as noted above in this Chapter, there are distinct and separate standards for Range Safety for military launches in the USA. Moreover, operating a satellite for monitoring or surveillance of military targets has been fully recognized as a legitimate activity. As also discussed, while commercial use of airspace extends to about 10 km, military activities occur up to a much higher altitude; and thus, would have a significantly different effect on legal and regulatory implications for the protozone.

Thus, for satellite (including small satellite) manufacturers and operators, it becomes crucial to refer to national legislation as well as applicable rules of international law if their satellites are intended to be used for military activities or is being manufactured and/or operated at the behest of national administrations solely for military activities.

13 Conclusion

Appropriate laws, regulations, technical standards, and procedures are imperative for smooth and safe operation of small satellites. Since the number of such satellites, the applications they provide, and their operators is rapidly increasing, the necessity for compliance with the existing laws as well as formulation of new "rules of the road" is becoming urgent, not only for the satellite operators but all the concerned governmental authorities, which are internationally responsible for, and could be held liable for damage caused by, small satellites. It is advisable for manufacturers and operators of small satellites to be proactive in supporting their respective governments in the drafting and adoption of new treaties, national laws, regulations, technical standards, and procedures so that such new "rules of the road" are appropriate and effective for the safe design, operation and disposal of small satellites.

Part XIII

Small Satellites: Essential Technical, Regulatory, and Management Information

Partial Listing of Small Satellite Constellations and Related System Infrastructure

Joseph N. Pelton and Vatsala Khetewat

Contents

Abstract

This chapter provides a listing of many of small satellite constellations that are being deployed or have been announced for launch by many commercial and governmental entities around the world. There are now so many of these governmental units, organizations, and companies deploying small satellite networks it is quite difficult to monitor the rapid rate of change in the filing of new networks. Further, the network configurations for these constellations are also often in a state of flux. Thus, one might go to the web sites for specific constellations to seek the latest information about these systems. Further, there are various organizations that provide reports on small satellite constellations. Northern Sky Research, Bryce, and Euroconsult are just some of such sources.

This chapter is a technical document with key information regarding the Handbook of Small Satellites.

Keywords

Launcher organizations · Small satellite constellations · Sources of further organization

In the early days of space era, there were only sporadic launches of satellites one at a time. Each launch was a widely reported global news event. Today, over a half century later, the world of "NewSpace" that has revolutionized launch vehicle technology and created the smallsat phenomenon, the space industry, has radically changed. Today SpaceX has managed to directly deploy into low Earth orbit, on a single one of its Falcon rockets, 60 satellites for its Starlink constellation in a single launch. And Space X intends to repeat this process until many thousands of its small satellites are deployed to complete its mega-constellation. The Indian Polar Satellite Launch Vehicle launched 104 CubeSat-sized satellites in a single launch with 88 of these satellites being for the Planet's remote sensing constellation. Clearly the world of space has changed.

Small satellites and large-scale constellations numbering in hundreds or even thousands of satellites complicate such issues as space situational awareness, space traffic management, orbit satellite debris, and debris removal. Another thing that it complicates is a clear accounting of what satellites are now up and operational, which satellites are planned for launched, and even keeping track of which spacecraft have deorbited or now represent space debris. This presentation seeks to provide a reasonable accounting of small satellite constellations currently operating in space, hosted payloads that are flying on currently deployed constellations and a reasonable representation of small satellite systems that are planned or have been proposed for deployment in coming months or years.

The preparation of this "accounting" of small satellite constellations has been restricted to civil projects and does not include military- or defense-related projects since information concerning such activities are generally classified. It is hoped that this listing of constellations is reasonably complete and up-to-date even though some projects may have transitioned from planned to operational. Some proposed projects may have been cancelled due to technical, operational, or financial reason. One of the interesting trends is that more and more operators of GEO satellite systems have explored entering the small satellite market through direct investment or in partnerships. To date SES, Intelsat, Sky Perfect, Inmarsat, Iridium, Eutelsat, Telesat, and Yahsat among others have sought partnerships or direct investments in LEO constellations. Also new entrants from the world of cyberspace such as Google, Facebook, and Amazon have invested or are investing into small satellite constellations. Launch vehicle developer SpaceX has made the largest commitment of all with plans to launch a composite total of over 12,500 small satellites with the Skylink and V-band network.

To assist researchers URLs have been provided where possible in order to assist in finding out the latest information concerning particular constellations of interest. It is urged that those seeking the latest status on various constellations go to current websites to learn about the latest updates. It is worth noting that simply because a small satellite constellation is proposed it may not actually be deployed. It must undergo a frequency coordination process under procedures indicated by the International Telecommunication Union (ITU). It must be authorized to operate in particular countries via a landing license in the case of provision of telecommunications services, and it must be licensed by a launching nation that must file the appropriate launch registration with the United Nations consistent with the Registration Convention. Thus many technical, operational, and regulatory actions must be completed before a system is actually launched and deployed in orbit. Every effort has been made to provide the latest and most accurate information, but some data may be incomplete, missing, or misstated. Any errors or omissions are unintentional.

Part 1: Operational Systems (Table 1)

Part 2: Hosted Payload Small Satellite Systems (Table 2)

Part 3: Planned or Proposed Small Satellite Systems (Note all will actually be deployed. Please excuse any omissions that were unintentional not included) (Table 3)

Table 1 World's operational small satellite constellations

Satellite image	Country of origin and type of service	Number of satellites in constellation	Owner and operators website URL
https://spacenews.com/viasat-shrinks-meo-constellation-plans/ **Globalstar 2nd Generation (graphic courtesy of Globalstar)**	**United States** Mobile Communications to handheld transceivers and antennas on the move	24 Satellites in 2nd generation with mass of 700 kg deployed at 1414 km (876 mile) orbital altitude with 55 degree inclination. 80% coverage of the world. 24 ground stations for global interconnection	**Globalstar Inc.** https://www.globalstar.com/en-us/ https://www.orbcomm.com/en/networks/satellite https://www.orbcomm.com/en/networks/satellite
 **Iridium next sat w/ Aerion and exactEarth hosted payloads (graphic courtesy of Iridium)**	**United States** Mobile communications to handheld transceivers. Also provides Aerion aircraft tracking via hosted payload units and exactEarth hosted payloads for automatic identification service (S-AIS)	75 satellites in 2nd generation (66 operational and 9 spares) L-band spectrum in LEO orbit of 781 km with an inclination of 86.4° inclination	**Iridium** https://www.iridium.com https://en.wikipedia.org/wiki/Iridium_satellite_constellation#Second_generation
 **OneWeb satellite manufactured by Airbus (graphic courtesy of OneWeb)**	**European (Britain, Channel Islands)** LEO constellation to provide global networking services. Initial 600 satellites are currently being deployed by Soyuz launch vehicles. Plans seeks to ultimately deploy up to 4000 sats. System operates under the name of WorldVu satellite Ltd. and OneWeb and in filings is also known as L5	Initial operational service now beginning as the first of the large-scale LEO constellations. Investors include Intelsat, Airbus, Arianespace, Virgin Orbit, SoftBank, Qualcomm, Coca Cola, and others. First 600 now being deployed	**WorldVu/OneWeb URLs** https://www.oneweb.world/ https://en.wikipedia.org/wiki/OneWeb_satellite_constellation

 **Second generation of Orbcomm sat (0G2) (graphic courtesy of Orbcomm)**	**United States** Store and data relay to small receivers to provide M2M, AIS, and IoT services globally	Many first generation smallsats plus 12 OG2 satellites operational and others on order for planned launch. 720 km LEO orbits	**Orbcomm** **URL** https://www.orbcomm.com/en/networks/satellite
 Planet's "Dove" 3U CubeSat (graphic courtesy of Planet)	**United States** Medium and high resolution with daily updated global information	Nearly 300 active smallsats of 3 types 1. Skybox's sats 80 cm^3 (high res) (30) 2. Flocks 3 U "Dove" CubeSats (well over 200) (med res) 3. Planet Swift (6) RapidEye sats (medium res) by Surrey Space Tech LLC	**Planet** **URL** https://www.planet.com/
 Spire's Lemur 3U CubeSat (graphic courtesy of Spire)	**United States in cooperation with Europe's Galileo system**	Spire's constellation This is currently a LEO constellation of 80 satellites that are being expanded to collect AIS, meteorological data, and locational data in cooperation with the European Galileo system	**Spire Global's** **URLs** https://www.spire.com https://en.wikipedia.org/wiki/Spire_Global

 21 AT Three Satellite constellation (graphic courtesy of SSTL)	**China** **Private company known as 21 AT in cooperation with Surrey Space Technology LLC and Urthecast**	3 satellite remote sensing systems in Sun-synchronous polar orbit of 651 km. TIFF format. Provides 1 m and 4 m resolution imaging	Twenty-First Century Aerospace Technology (21 AT) using DHC-3 constellation manufactured by SSTL URL: https://www.prnewswire.com/news-releases/urthecast-and-twenty-first-aerospace-technology-sign-a-strategic-partnership-for-urthedaily-constellation-in-china-662013063.html
 Jilin-1 commercial imaging satellite (image from the Jilin-1 satellite). Image courtesy of NASA spaceflight)	**China** **Jilin's commercial satellite imaging Operated by change Guang Satellite Technology Co. of China established in 2014**	New commercial Chinese commercial imaging company with 1 m resolution imaging (planned to be 60+ satellite constellation)	4 satellite constellations www.charmingglobe.com/EWeb/index.asp
Argos constellation of 7 satellites. This system was first created in 1978. This is a LEO constellation for data relay. It is to be augmented and then replaced by 25 Kineis satellites in 2022. This is an international project led by CLS of France on behalf of NOAA, CNES, EUMETSAT, and ISRO of India. See Kineis in the planned systems below	**CLS of France on behalf of NOAA, CNES, EUMETSAT, and ISRO of India. Founded in 1978**	International data relay system	7 satellite constellation to be replaced by 25 satellite Kineis constellation in 2022 http://www.argos-system.org/great-news-for-argos-users/

O3b constellation in medium Earth orbit (MEO) is not included in this listing because its 24 satellites are considered too large to be considered small satellites

Table 2 Hosted payload small package constellations

Satellite image	Country of origin and type of service	Number of satellites in constellation	Owner and operators website URL
 **Aireon payload on Iridium Next (image courtesy of Iridium)**	Canada (aircraft aviation precision navigation)	66 sats (hosted payloads on Iridium Next)	Aerion hosted payload in partnership with Iridium to provide ADS-B services. **URL** https://www.aireon.com
 **ExactEarth hosted Payload on Paz Radar Sat (image courtesy of Hisdesat) and on Iridium Next**	Canada (automatic identification service)	In flux	Hosted payload on board the Spanish radar satellite PAX owned and operated by Hisdesat S. A. to provide maritime satellite-AIS services. And 58 operating units plus 7 spares on Iridium Next constellation **URL** https://www.exactearth.com/technology/exactview-rt-powered-by-harris

Table 3 Planned and proposed smallsat constellations (This listing represents an effort to list as many of the proposed and planned smallsat constellations as possible. It may not include the latest filings or provide the latest information. See websites for later information. MEO constellation satellites such as now envisioned by SES and VIASAT are too big to be considered small satellites although the VIASAT system MEO sats were included since their size and characteristics may ultimately be such that they might be considered "small satellites" as definitions change.)

Country of origin and constellation name	Type of service provided	Number of satellites	Orbit, network description, and website URL
Argentina **Satellogic's NuSat Aleph-1 constellation**	U/V sensing to 1 m resolution. Remote sensing services commercially offered	300 sats	500 km orbit. Operates in the U-/V-band for global remote sensing. (8 satellites launched prior to 2019, 13 launched in 2019) first phase of 77 sats to be launched in 2020) mass: 37 kg. Chinese launchers **URLs** https://en.wikipedia.org/wiki/%C3%91uSat http://space.skyrocket.de/doc_sdat/nusat-1.htm
Australia **Fleet**	Satellite-based Internet global networking constellation	100 sats Only a few launched by rocket labs	580 km orbit **URL** https://www/fleet.space/about
Australia **Sky and Space Global**	Global IoT connectivity	200 nanosats being built by GOMSpace	To be deployed in 2020–2021 **URL** https://spacenews.com/sky-and-space-global-low-on-cash-seeks-new-investors-for-iot-constellation/
Canada **Canpol 1**	Networking services to support military/defense-related services of Canada	72 sats	LEO constellation plus a number of highly elliptical orbit satellites. LEO 9 sats each in 8 planes. LEO Orbit in VHF-, UHF-, X-, and Ka-bands
Canada **GHGSat's Claire**	Emissions monitoring – measure CO_2 and methane	1 demonstration satellite has been launched and another 19 are planned	Sensors include 2D wide-angle Fabry-Perot imaging spectrometer with 15 kg satellite **URL** https://www.ghgsat.com

Canada Helios Wire Helios constellation	IoT/M2M – uses 30 MHz of S-band spectrum to receive tiny data packages from remote sensors	2 launched and 28 more to come	First payloads hosted on Astro Digital Corvus/Landmapper CubeSats https://helioswire.com
Canada **Kepler**	To provide Internet of Things (IoT) and data services. LEO constellation of 6U CubeSats. Manufactured by ÅACAAC Clyde with TARS platform. 140 6U CubeSats to provide Internet of Things	140 6U cube sats	Service provided in 575 km orbits. **Frequencies:** Ku band (10.7–12.7 GHz transmit 14.0–14.5 GHz **URLs** https://www.keplercommunications.com/ https://spacenews.com/kepler-communications-raises-16-million-for-telecom-constellation/ https://en.wikipedia.org/wiki/Kepler_Communications
Canada **Optistar by Urthecast**	Constellation of 16 satellites. Launch date not known	16 sats	16 satellites in polar orbit, 8 tandem pairs in 2 orbital planes. 1 m resolution in X-band and 5 m resolution in L-band. Provide nearly simultaneous imaging from the paired systems in optical bands and synthetic aperture radar imaging. Also provides geospatial analytics. Satellites to be built by Surrey Space Technology Ltd. **URL** https://www.urthecast.com/optisar/ https://blog.urthecast.com/updates/urthecast-announces-worlds-first-commercial-sar-and-optical-1
Canada **Telesat**	LEO constellation for networking. Proposed to operate at two different orbital altitudes	117 to begin and ultimately 794	72 sats at 1000 km 45 sats at 1248 km To expand to 794 satellites 27.5–30 GHz (uplink) and 17.8–20.2 GHz (downlink) (Ka-band) **URL** https://www.telesat.com/services/leo/why-leo

(continued)

Table 3 (continued)

Country of origin and constellation name	Type of service provided	Number of satellites	Orbit, network description, and website URL
China **Commsat**	LEO constellation for internetworking	800 sats	600 km LEO orbit. This new constellation is intended to provide Internet of Things and data communications services **URL** https://spacewatch.global/2018/12/chinas-new-space-race-iot-startup-commsat-launches-seven-cubesats/
China **Head –“Skywalker” constellation**	LEO constellation for EO and AIS services and data fusion	Head-1 launched and others to follow	AIS/IoT satellite constellation “Skywalker” for Earth observation and automatic identification services. Data fusion of AIS and remote sensing data **URL** http://www.iafastro.org/societes/china-head-aerospace-technology-co/
China **Hongyan**	LEO constellation for internetworking	300 sats	1100 km LEO orbit **URL** https://gbtimes.com/china-to-launch-first-hongyan-leo-communications-constellation-satellite-soon https://gbtimes.com/china-to-build-300-satellite-hongyan-communications-constellation-in-low-earth-orbit/
China **Lucky Stars**	LEO constellation for internetworking	156 sats	1000 km LEO orbit
China **Xiaoxiang-1-02**	Test satellite for a laser communications network	When implemented it would involve 100s of sat	Joint project of Spacety and Laser Fleet. This would be a constellation to provide laser communications-based high-speed Internet access for civil aircraft **URL** https://spacenews.com/more-satellites-in-orbit-following-second-mission-of-2018/
China **Xinghe**	Earth imaging data network	192 sats LEO orbit. Partnership between Spacety and AdaSpaceYalin	**URL** https://spacenews.com/more-satellites-in-orbit-following-second-mission-of-2018/
China **Xinwei**	LEO constellation for internetworking	32 sats 1100 km LEO orbit	**URL** http://www.xinwei.com.ua/en http://en.people.cn/n3/2018/0305/c90000-9433041.html

China **Zhuhai Orbita**	500 km constellation for video and hyperspectral remote sensing	4 OHS hyperspectral and 1 OVS video. Part of larger constellation	**URL** https://spacenews.com/china-launches-five-commercial-remote-sensing-satellites-via-long-march-11/
France **Eutelsat for LEO objects (ELO)**	500–600 km	Network still being defined	**URL** https://news.eutelsat.com/pressreleases/eutelsat-commissions-elo-its-first-low-earth-orbit-satellite-designed-for-the-internet-of-things-2440770 https://spacenews.com/eutelsat-planning-small-leo-internet-of-things-constellation/
France **Kineis (to replace Argos satellite system)**	LEO constellation for IoT and data Internet relay	25 sats 600 km LEO orbit	**URL** https://www.kineis.com/en/
France **MC-Sat constellation by the Thales Group**	LEO constellation for data relay, 5G, and internetworking	800 sats that would potentially grow to 4000	Combination of LEO, MEO, and highly elliptical. Intended to operate in Ku- and Ka-bands
Germany **80 LEO**	LEO constellation for IoT services	80 nano satellites?	**URL** www.80LEO.com/
Germany **SAT4M2M**	Combination of terrestrial and space-based IoT sensor connection network	Design of ground WAN network and satellite still in development	**URL** www.sat4m2m.com/ https://www.newspacepeople.com/company/sat4m2m https://www.microwavejournal.com/articles/29976-sat4m2m-and-fujitsu-to-develop-iot-communications-via-satellites
India **Astrome Tech**	Internet-working	600 sats	1400 km orbit
Korea **Samsung constellation**	Internetworking and support to broadband 5G mobile services	4500 sats	1500 km orbit
Liechtenstein **3Ecom**	Communications and inter-networking	288 sats	24 sats in 12 planes) **URL**

Russia **Yaliny**	Internet connectivity and international telephone calls via Internet	135 sats	600 km LEO orbit which is seeking to offer consumers global access to the Internet and international calls via Internet for $10 a month **URL** https://the-dialogue.com/en/en39-pioneers-of-private-astronautics-in-russia-yaliny/
Swiss (Astrocast-Else)/Emirates (Yahsat/Thuraya)	LEO orbit constellation for IoT services	500–600 km 64 satellite constellation	**URL** https://spacenews.com/meet-else-the-thuraya-backed-smallsat-startup-that-wants-to-connect-things-with-cubesats/
Spain **AISTech's Danu and Hydra**	2-way comms, thermal imaging to detect forest fires, aviation tracking (ADS-B)	2 CubeSats launched and 148 are planned	Satellites will be built by GomSpace **URL** https://www.aistechspace.com
United States **Analytical Space**	Experimental CubeSat deployed as precursor to constellation	CubeSat released from iSS as precursor to operational constellation	Data relay constellation intended to use laser communications to support ultimate deployment of high data rate download or remote sensing data www.engine.xyz/founders/analytical-space-inc
United States **Astro Digital Landmapper**	Earth observation	10 satellites have been launched (5 are currently operational) and another 15 to follow	6U CubeSat has 22 m resolution. 16U CubeSat has 2.5 m resolution in RGB, red edge, and NIR using one 70 MP sensor **URL** https://astrodigital.com
United States **Athena**	Networking and broadband services on a global basis	Only one experimental sat as prelude to constellation	LEO constellation filed by PointView technology a subsidiary of Facebook. Frequencies not yet confirmed. Experimental authorization to launch and operate a single low Earth orbit satellite in 2019. The satellite would be in a sun-synchronous orbit between 500 and 550 km. This would presumably be a prelude to a large-scale constellation in Sun-synchronous orbit **URL** https://arstechnica.com/information-technology/2018/07/facebook-follows-spacex-and-oneweb-into-high-speed-satellite-broadband/

(continued)

Table 3 (continued)

Country of origin and constellation name	Type of service provided	Number of satellites	Orbit, network description, and website URL
United States **Audacy**	Data relay network	3 satellite constellation in MEO orbit of 14,000 km	Financing for this system is currently unclear This data relay network of 3 satellites, each orbit Earth every 8 h is designed to provide continuous download capability to a ground-based data relay antenna system. https://audacy.space/constellation
United States **Black Sky**	Remote sensing system and data analytics	60 sats	450 km orbit. This system plans to deploy 21 high-resolution SkySats, 2 medium resolution, 3 low resolution, and one SAR radar satellite (TerraSAR-X) as it initial global system. In late 2018 it launched in global 1 and 2 small satellites to begin its system deployment. It is working in cooperation with AWS **URL** https:www.blacksky.com
United States **Boeing constellation**	Two large-scale LEO constellation to provide global networking services	1396 to 1396–2996 sats	1396 satellites 1025 km orbit 2996 satellites in 1275 km orbit **URL** Currently Boeing has delayed plans for deployment https://spacenews.com/boeing-constellation-stalled-spacex-constellation-progressing/
United States **Capella**	Constellation of X-SAR satellites for radar imaging	36 sats that might expand to 48 sats	500 km orbit. This is a synthetic aperture radar system deploying sub-50 kg microsatellites. This system that will provide radar imaging for the X-band (9.4–9.9 GHz). The satellites will have only a 3-year life time, so it will require frequent replenishment. Full deployment of 36 sat network planned to be achieved around the end of 2021 or early 2022 **URL** https://www.capellaspace.com/ https://directory.eoportal.org/web/eoportal/satellite-missions/content/-/article/capella-x-sar

United States GeoOptics' CICERO	Weather forecast – using GPS radio occultation for weather data	First operational satellite has been launched in 2017, and there are more planned	LEO constellation; Satellites procured from Tyvak **URL** http://www.geooptics.com
United States HawkEye 360	RF geolocation Radio frequency (RF) mapping with 15 kg nanosats to help monitor transportation across air, land, and sea and assist in emergencies	3 microsatellites launched and another 27 planned. Ultimately a 54 satellite constellation consisting of 18 "trios" of nanosats for triangulation of RF usage to provide global service	LE constellation Built by GomSpace **URL** https://www.he360.com
United States Iceye	Radar-based remote sensing network	18 small satellites of about 100 kg by 2021 or so	Synthetic aperture radar imaging. Seeking to provide coverage several times a day. Negotiating with Audacy to use the MEO data relay satellites for rapid instantaneous download capability. See Audacy **URL** https://www.iceye.com/resources/satellite-missions
United States Iridium/Magnitude Space	Joint Intelsat/ Magnitude Space constellation IoT services	18–24 nanosat constellation	This is to be an L-band system for Internet of Things data relay **URL** https://spacenews.com/iridium-teams-up-with-internet-of-things-startup-magnitude-space/
United States Karousel LLC (backed by Columbia Capital and Telecom Ventures	MEO system for high-throughput satellite service	12 to 24 sats	MEO Orbit 8200 km system that would deploy 5 satellites each in 4 different planes. This is a high-throughput communications and networking system **URL** https://www.defensedaily.com/wp-content/uploads/post_attachment/149310.pdf

(continued)

Table 3 (continued)

Country of origin and constellation name	Type of service provided	Number of satellites	Orbit, network description, and website URL
United States KLEO startup	LEO polar orbiting constellation for IoT-enabled devices	300 sats planned	24 satellites plus spares in 12 polar orbits. Aimed at target market of 80 billion IoT-enabled devices worldwide. To operate in Ka-band. Financing unclear **URL** https://kleo-connect.com/constellation
United Staes Kuiper constellation by Amazon.com	Large-scale LEO constellation	3200 satellites	Details are still pending clarification **URL** https://www.cnbc.com/2019/04/04/amazon-project-kuiper-broadband-internet-small-satellite-network.html
United States LeoSat	Broadband services for corporate enterprise networks	108 sats	1400 km orbit. This is intended to be a highly secured, meshed network of satellite to support business enterprise communications and networking with low latency service. Claims to have signed $2 billion in contracts for service **URL** http://leosat.com
United States O3b mPower satellites	Broadband services	20 satellites to be expanded	Next generation mPower network These satellites at 700 kg each are technically not smallsats, but are still smaller than most commercial GEO satellites **URL** https://03b.com/
United States Orbital Micro Systems	Weather constellation utilizes microwave technology to capture temperature and moisture measurements, refreshed and delivered every 15 min	They plan to have a constellation of 40	LEO; 3U/6U, nanosatellites up to 20 kg in mass, About 24 months lifetime **URL** https://www.orbitalmicro.com

United States Orbital Sidekick (OSK)	A space-based infrastructure of hyperspectral sensors to provide monitoring services and solutions to the energy sector and others	First sensor on ISS. constellation planned for 2020–2021	**URL** https://orbitalsidekick.com
United States PlanetiQ	Weather monitoring using radio occultation measurements	20 satellites microsats	The initial constellation is expected to be 20 satellites. This system will monitor both space weather and atmospheric data using radio occultation data using measures from the GPS, BeiDou, Galileo, and Glonass GNSS systems. It is planning 3 min updates through the use of data relay satellites in GEO orbit **URL** http://planetiq.com/about/aboutplanetiq/
United States SpaceX Starlink	Very large-scale LEO constellation to provide global networking services	4425 sats	Large-scale constellation that is designed to be deployed in mid 2020s at 1150 km altitude **URL** https://en.wikipedia.org/wiki/Starlink_(satellite_constellation)
United States SpaceX V-band constellation	Very large-scale LEO constellation to provide global networking services	7518	335–345 km orbit. This would operate in V-band super high frequencies (SHF) **URL** https://www.theverge.com/2018/11/15/18096943/spacex-fcc-starlink-satellites-approval-constellation-internet-from-space
United States Swarm Technologies	Constellation of CubeSats to provide low-cost texting messages	36	CubeSat constellation with satellite known as “Space Bees” to provide low-cost global texting service. Experimental initial satellites were illegally launched without an FCC license http://fortune.com/2018/12/21/swarm-technologies-fcc-satellite/ **URL** http://fortune.com/2018/12/21/swarm-technologies-fcc-satellite/

(continued)

Table 3 (continued)

Country of origin and constellation name	Type of service provided	Number of satellites	Orbit, network description, and website URL
United States **Theia**	LEO constellation to provide a combination of remote sensing, communication, and networking services as well as data analytics	112 larger satellites and smaller satellites for data relay	800 km LEO orbit. This constellation with radar and infrared optics will also provide networking and data analytic services. Note: this project is not to be confused with the All-Star/Theia project sponsored by Lockheed Martin and Colorado Space Grant Consortium **URL** www.theia.com http://www.khaosodenglish.com/politics/2018/06/05/thailand-to-spend-billions-on-satellites-from-unknown-company
United States **Viasat**	Global MEO system that would compete with SES's 03b MEO constellation	20 satellite MEO constellation to link with Viasat 1 and 2 GEO satellites	This is now a 20 satellite MEO constellation planned for a 8200 km orbit to complement the VIASAT 1 and VIASAT 2 GEO satellite. In some ways it is similar to the SES system of GEO satellites what work in tandem with its MEO network of 03b satellites https://spacenews.com/viasat-shrinks-meo-constellation-plans/. (It is not clear as to the size of these spacecraft and whether they will be considered to be small satellites) **URL** https://viasat.com/
United Kingdom Sky and Space Global's Red Diamond, Green Diamond and Blue Diamond	IoT/communication service (voice, data, and M2M)	3 nanosatellites have been launched, and another 197 are to follow	LEO; Plans to use inter-satellite links. Satellites outsourced from GomSpace; **URL** https://www.skyandspace.global

This chart is copyrighted by Joseph N. Pelton and is licensed to Springer Press for this publication. All rights reserved. Also note that the status of various smallsat constellations can rapidly change and that it is useful to consult relevant websites to seek the latest information on these networks

Companies Involved in Design, Manufacture, and Testing of Small Satellites

Joseph N. Pelton

Contents

Keywords
Smallsats · Small satellite components · Small satellite integration · Small satellite testing · Smallsat manufacturing

1 Introduction

The small satellite industry has grown at a significant rate over the past decade as it has spread across the world. The most dynamic part of this international growth has been those who design and build cube sat and even smaller-sized satellites. The creation of PocketQube and other new satellite standard for spacecraft even smaller than cube satellites has contributed to this rapid global expansion. The following listing of a number of small satellite companies seeks to provide a representative listing of the companies around the world that have sought a place in the small satellite industry. Inclusion of particular companies in this listing should not be considered an endorsement of individual companies or their particular products or services.

An sincere effort has been undertaken to include as many small satellite companies and component suppliers as possible, but because of the large number

Table 1 A Representative Listing of Small Satellite Companies Around the World

A global guide to many of the firms involved in designing, manufacturing, operating CubeSat systems, or supplying key components (This list is representative of the global market but should not be considered complete. Sources such as the NANOSAT database should be consulted at https://www.nanosats.eu/#page-top to monitor new suppliers.)

Firms	Location/HQ	Year founded	Main product	Main application	Web site
AAC Microtec	Scotland	Acquired ClydeSpace Ltd in late Dec. 2017	Turnkey production of nanosats	All types of applications for nanosats	http://aacmicrotec.com/
Accion Systems	USA	2014	Thrusters and propulsion for nanosats	Component production for nanosats	https://www.nanosats.eu/org/accion-systems
Adcole Maryland Aerospace	Crofton, Maryland, and Marlborough, Mass, USA	2002 and changed its name in 2017 when Adcole Aerospace merged with Maryland Aerospace	Sun sensors and attitude controls and nanosat components	Component production for nanosats	www.adcole.com/2017/05/adcole-aerospace-division
Aeolus Aero Tech PVt Ltd	Bangalore, India	2010	Smallsat components	Scientific missions	http://www.Aeolusaerotech.com
AIS Tech	Spain	2008	Constellation for remote sensing and remote asset tracking	Earth observation, aviation tracking, and surveillance	http://www.aistechspace.com/
Akash Systems	San Francisco, CA, USA	2016	Nanosats	Nanosat RF transmitters	http://www.akashsystems.com
Alba Orbital	Glasgow, Scotland	2014	Unicorn 1 and 2 nanosats	Pocket nanosats	https://www.albaorbital.com/
Aniara Communications	India	2001	Nexstar 1 & 2	Telecommunications via Nexstar 1 & 2 smallsats	https://www.aniara.co.in/
Avellan Space Technology & Science (AST&Science)	California (USA)	2011	Hyper-integrated satellite	Space exploration	https://www.ast-science.com/

Clyde Space	Scotland	2008	Nano and cube satellite	Research satellites	www.clyde.space/about-us
CubeSatShop	US based	Unknown	Service to connect smallsat designers and builders with suppliers from around the world	Provides connection to 25 nanosat component suppliers with those seeking to build CubeSats/nanosats	https://www.cubesatshop.com/vendor-information/
CubeSpace	Stellenbosch,South Africa	Spin-off of Stellenbosch Univ.	Computer sensors and actuators and attitude determination and control systems for CubeSats	All types of application and research smallsats	https://cubespace.co.za
Dauria Aerospace	Germany, Russia	2011	Small satellite design and manufacture	Earth observation, communications, and navigation satellites	http://eng.dauria.ru/
Deimos Space, SLU, wholly owned subsidiary of Elecnor Deimos	Spain	2001	Small satellites	Earth observation	www.deimos-space.com
Deimos Space, UK, wholly owned subsidiary of Elecnor Deimos	Harwell, Oxford, Didcot, Oxfordshire (UK)	2013	Small satellites and ground segment systems	Earth observation	www.ukspace.org/member/deimos-space-uk-ltd
DHV Technology	Malaga, Spain	2010	Solar panel systems for CubeSats	All types of CubeSat systems	dhvtechnology.com
Enpulsion	Austria and San Jose, California (USA)	Unknown	Nano and micro thruster ion thruster propulsion	All types of small satellites	https://www.enpulsion.com/

(continued)

Table 1 (continued)

A global guide to many of the firms involved in designing, manufacturing, operating CubeSat systems, or supplying key components (This list is representative of the global market but should not be considered complete. Sources such as the NANOSAT database should be consulted at https://www.nanosats.eu/#page-top to monitor new suppliers.)

Firms	Location/HQ	Year founded	Main product	Main application	Web site
			for small satellites and for de-orbiting		
EyasSat	Denver, Colorado, USA	2010	Functionalteaching CubeSat system for engineering in the classroom and laboratory	Training materials for CubeSat design and operation	eyassat.com/products
EagleView	Bellevue, Washington and Rochester, New York (USA)	2013 (in current form since merger with Pictometry International	Data analysis through use of smallsat remote sensing	Geomatics analysis to support geo-intelligence needs of various companies	www.eagleview.com
HCT – Helical Communication Technologies	Rockledge Florida (USA)	2014	Specialized antennas for space and ground systems supporting smallsat projects	Quadrifilar helical antennas supporting all types of smallsat programs	www.helicomtech.com
GeoOptics	Pasadena, California (USA)	2006	24 small satellite constellations	Environmental, weather monitoring	https://www.corporationwiki.com/California/Pasadena/geooptics-inc/67116978.aspx
GomSpace	Denmark	2007	Nano and cube satellite	Research, low-cost science	https:///www.comspace

HEAD Aerospace Group	Beijing, China with offices in Hong Kong, Shanghai, the Netherlands, and France	2007	Attitude and orbit control systems, calibration, electronic components, on-ground testing, technical consulting, market analysis	Components and services for all types of nanosats	https://www.spacebizguide.com/4198-head-aerospace
ISIS – Innovative Solutions In Space	Netherlands	2010	CubeSat bus/platform, deployer and dispensers, launch services	All types of CubeSats	https://www.nanosats.eu/org/isis-innovative-solutions-in-space
Karten Space	Spain	2015	6U CubeSat constellation for remote sensing	Earth observation smallsats (known as KEOSats). Geo-intelligence for business	https://www.nanosats.eu/org/karten-space
Kineis (CLS)	France	2018	Intend to deploy 20 smallsats for remote system by 2021	Earth observation constellation	https://www.nanosats.eu/org/kineis
Kleos Space	Luxembourg	2017	Plans to acquire CubeSats from GomSpace	Geolocation and automatic identification services (AIS) and spectrum monitoring	https://www.nanosats.eu/org/kleos-space
Kubos	Denton, Texas (USA)	2017	Mission design and onboard software	An operating system that can be used on many CubeSat and nanosat missions	https://www.tmro.tv/2017/06/25/kubos-operating-system-cubesats-orbit-10-23/
KU Leuven	Belgium	2010	Attitude control systems, etc.	ADCS for all types of microsats and nanosats	https://www.cubesatshop.com/vendor-information/ku-leuven/

(continued)

Table 1 (continued)

A global guide to many of the firms involved in designing, manufacturing, operating CubeSat systems, or supplying key components (This list is representative of the global market but should not be considered complete. Sources such as the NANOSAT database should be consulted at https://www.nanosats.eu/#page-top to monitor new suppliers.)

Firms	Location/HQ	Year founded	Main product	Main application	Web site
Lens R & D	Noordwijk, Netherlands	2016 (first flight qualified 2018)	Sun sensors	Sun sensors for all types of nanosats	https://lens-rnd.com/
Maryland Aerospace, Inc. (see Adcole Maryland Aerospace)	Crofton, Maryland (USA)	2017	Guidance, navigation, and control systems	All types of smallsats, attitude control systems, KEDS simulation software	https://www.cubesatshop.com/vendor-information/maryland-aerospace-inc/
Microspace	Singapore	2000	Electronics, prototyping, software, etc.	Many components for nanosatellites designed and fabricated	http://www.micro-space.org/engineering.html
Microspace	Italy	This is a part of same company in Singapore	MEMS-based micro-propulsion systems	Microelectromechanical systems	http://www.micro-space.org/engineering.html
NewSpace Systems	Somerset West, South Africa	2012	Components for CubeSats, especially attitude control systems	Key components for all types of CubeSats	https://www.cubesatshop.com/vendor-information/new-space-systems/
Novananoalso provides “nanosat” bus	Lyon, France	2009	Nano satellite	Earth observation	www.novanano.com
NovaWurks	Los Alamitos, California (USA)	2011	Hyper-integrated satellite (HISats), CubeSat platforms	Space exploration, hosted payloads, and small satellite missions	www.novawurks.com

OmniEarth (see EagleView)	Virginia (USA)	2013	18 small satellites (but project now discontinued after acquisition by EagleView	Earth observation analysis	spacenews.com/omniearth-acquired-by-eagleview
Planet Labs (now part of Planet)	Mountain View, California (USA)	2010	Large-scale 3U CubeSat constellation	Earth observation	www.planet.com
PlanetiQ	Maryland (USA)	2012	12–24 small satellite constellation growing to a 300 satellite network	Weather monitoring and weather sensors	planetiq.com
Pumpkin	(USA)	2010	CubeSat kits, components, and software	All types of 1U CubeSat kits	www.cubesatshop.com/product/pumpkin-cubesat-kits
RUAG Aerospace	Switzerland, Austria, Finland, Sweden, USA		Integration, testing, dispensers, etc.		https://www.cubesatshop.com/vendor-information/ruag/
Satrec Initiative	Republic of Korea, Daejeon	1999	Small satellites	Earth observation	www.iafastro.org/societes/satrec-initiative
SCS Space	South Africa		Spacecraft subsystems and ground systems	Imagers for remote sensing	https://www.cubesatshop.com/vendor-information/scs-space/
Skybox Imaging (now part of Planet)	Mountain View, California (USA)	2009	24 satellite constellation	Earth observation	www.planet.com
Solar Mems Technologies SL	Seville, Spain	2009	Microelectromechanical system technology uses in nanosats	Sun sensors for research and solar power satellites	https://www.cubesatshop.com/

(continued)

Table 1 (continued)

A global guide to many of the firms involved in designing, manufacturing, operating CubeSat systems, or supplying key components (This list is representative of the global market but should not be considered complete. Sources such as the NANOSAT database should be consulted at https://www.nanosats.eu/#page-top to monitor new suppliers.)

Firms	Location/HQ	Year founded	Main product	Main application	Web site
					vendor-information/solarmems/
Space Advisory Group	Somerset West, South Africa	2010	Subsidiary of SCS Space	Engineering support, design, and testing for CubeSat projects	https://www.cubesatshop.com/vendor-information/space-advisory-company/
Surrey Space Technology LLC (SSTL) (This is a wholly-owned subsidiary of Space Bus)	University of Surrey (UK)	1985 (perhaps oldest of the small satellite companies and now owned by Airbus	Small satellites of all types	Earth observation, navigation, telecommunications, research, and experimental	www.surrey.ac.uk/surrey-space-centre
Swarm Technologies	California(USA)	2016	4 quarter of a full CubeSats launched without license from FCC. Now have plans for a global constellation	Global low-cost communications	https://www.swarm.space/
Teledyne Paradise Datacom			Supplier of satellite modems, solid-state power amplifiers (SSPA), low-noise amplifiers (LNA), block up converters (BUC), and associated redundancy subsystems	CubeSat and small satellite component suppliers especially for communications and IT systems	https://www.cubesatshop.com/vendor-information/teledyne-paradise-datacom/

Theia Space. This should not be confused with the Theia Constellation (USA)	Spain		ESAT platform for educational purposes	Systems engineering, communications, mission analysis, onboard software, guidance, navigation and control, testactivities, thermal design	https://www.cubesatshop.com/vendor-information/theia-space/
Thoth Technology, Inc.	Based in Africa	Unknown	Environmental payloads, Argus spectrometer, and infrared imagers	Remote sensing by nanosat and high-altitude platforms	https://www.cubesatshop.com/wp-content/uploads/2016/06/thoth.png
TY-Space	China (located at Tsinghua University)	2014 (spin-off of Tsinghua University	Optical sensors, precision star trackers. Used on Vilin-1CubeSats	Scientific and applications nanosats	http://www.ty-space.com/en/
TyvakNano-Satellite System	Irvine, California (USA)	2011	Nano and cube satellites	Scientific missions	www.tyvak.com
VACCO Industries	El Monte, California (USA)		Nano and cube satellites	Micro-propulsion systems for CubeSats	https://www.cubesat-propulsion.com/

of new companies in this field this has proven quite difficult. Any omissions are unintentional. An effort has been made to be as comprehensive as possible, but the large number of companies involved in building small satellites or satellite components is very large and growing daily. Any omission is unintentional.

Global Launch Vehicle Systems for Potential Small Satellite Deployment

Joseph N. Pelton and Scott Madry

Contents

This chapter key technical and other practical information of launch arrangement and performance for the Handbook of Small Satellites.

J. N. Pelton (✉)

J. N. Pelton (ed.), *Handbook of Small Satellites*,
https://doi.org/10.1007/978-3-030-36308-6_82

Abstract

This chapter provides a useful guide to a global listing of various launcher vehicles that have been recently used in small satellite launches, are active in the global launch services market, or are now under immanent development for launch to support commercial space business internationally. Most of these launch vehicles have multiple launch configurations that include strap-on boosters. Further the designs of many launch vehicles have evolved in time and become more capable and with greater lift capability. Thus one must focus on not only the name of a launch system but its actual detailed name and complete model number. In short, the capabilities of launch vehicles change over time. It is best to consult with the latest web site information to obtain the latest information.

Keywords

Angara · Antares · Ariane · Atlas · Blue Origin · Delta · Dream Chaser · Electron · Falcon 9 and other Falcon vehicles · H1 and H2 launch vehicle · International Space Station small satellite dispenser · Launcher One · Launch vehicles · Long March · Minotaur · Nanoracks · New Glenn · Pegasus · Polar Satellite Launch Vehicle · Proton · Rockot · Soyuz · SpaceX · US Launch Alliance · Vega · Vulcan · Zenet

1 Introduction

This chapter provides a useful guide to a global listing of various launcher vehicles that have been recently used in small satellite launches, are active in the global launch services market, or are now under immanent development for launch to support commercial space business internationally. Most of these launch vehicles have multiple launch configurations that include strap-on boosters. Further the designs of many launch vehicles have evolved in time and become more capable and with greater lift capability. The first version of an Atlas, Ariane, Delta, Long March, Soyuz, PSLV, and Minotaur, for instance, and their latest version can be huge – perhaps like the difference between a canary and large-scale Pelican. Thus one must focus on not only the name of a launch system but its actual detailed name and complete model number.

Virtually all of the listed launch vehicles or launch system arrangements (such as an arranged launch through NanoRacks via the International Space Station) can provide a suitable launch configuration or launch dispenser appropriate to be used to support small satellite launches. This listing of launch options thus includes launch from the International Space Station via the Japanese Experiment Module, Reusable Microsat Deployment System, and NanoRacks Kaber system as one of the available launch options for small satellites that are under 82 kg and 1 m^3.

Accordingly, launchers that have not been used for commercial mission and which are not on current offer such as those developed by North and South Korea, Israel, or Iran are not included in the more detailed listing of mature vehicles with a track record of a number of successful launches. Thus the first part of this Appendix does not provide detailed listing for new launch systems such as the Naro-1, Shavit, Kaituozhe-1, Unha, Prime, and Miura 5 or the now bankrupt Firefly. These and other new launch vehicles now under development are, however, included in the second part of this chapter, along with the many new launch vehicle development efforts. These are in some cases also discussed in earlier articles in the Handbook that discuss launcher options for small satellites.

To the extent new launcher systems are developed and are ultimately provided on the global service market, they will be included in future editions of this Handbook.

The costs to launch rocket systems that are cited in this Appendix typically represent figures for 2018 or 2019. Those seeking actual launch arrangements for small satellites should go to the web site URL sources cited in this appendix to seek updated information. It is important to find online the current user's handbook for various launch vehicles that are frequently available online for many launchers and launch service provider and then contact a service representative.

Also those contemplating a launch of a small satellite must also be aware of the need to not only make suitable launch arrangements but arrange for a registration with the United Nations of the all spacecraft that is launched in accord with the provisions of the Registration Convention. These requirements for the launching nation to register all spacecraft launches, including small satellites, are spelled out in Appendix E. Also provided for information purposes are the UN registration forms. Finally it should be noted that satellites that use radio frequencies for command and control of spacecraft and for transmitting telemetry information back to ground receivers or otherwise involve the use of radio frequencies must be licensed by national authorities and the satellites frequencies coordinated by the national relevant administration with the International Telecommunication Union (ITU).

Below is a guide to the launch vehicles and launch opportunities listed in the following Appendix. It provides a listing of the various launch systems, the manufacturer, and country of origin in the order that they appear in this book. Background notes seek to provide the latest status of development and updates on new launchers under development.

Index to Global Launcher Systems Included in This Appendix

Name of launch system	Manufacturer	Country of origin
Angara 1,2, and 5	Khrunichev, KBKhA	Russia
Antares	Northrop Grumman	USA
Antares with Cygnus Capsule	Northrop Grumman	USA
Ariane 5	Arianespace	France-European nations
Ariane with Automated Transfer Vehicle (ATV)	European Space Agency	ESA members
Atlas up to Atlas 5	Lockheed Martin/ULA	USA
Delta up to Delta 4 Heavy	Boeing/ULA	USA
Delta (or Atlas/Falcon/Vulcan) with CST-100 Starliner Capsule	Boeing	USA
Delta-Atlas-Vulcan options	ULA	USA
Dnepr	Yuzhmash et al.	Ukraine/Russia
Dream Chaser	Sierra Nevada	USA
Electron	Rocket Lab	NZ/USA
Falcon 9, Falcon 9 Full Thrust, Falcon Big Rocket	SpaceX	USA
Falcon with Dragon capsule	SpaceX	USA
HII/HIIA	JAXA, Mitsubishi, NG Innovation Systems (subcontractor)	Japan
HIIA (H2 Transfer Vehicle)	JAXA	Japan
ISRO Polar Satellite Launch Vehicle (PSLV)	Indian Space Research Organization (ISRO)	India
ISS Deployment options	NASA	USA
LauncherOne	Virgin Orbit	UK-USA
Long March Series 2ACDEF, 3ABC, 4ABC, 5	Long March	China
Minotaur C, II, XLS (formerly known as Taurus)	Northrop Grumman	USA
New Glenn	Blue Origin	USA
Pegasus	Northrop Grumman Innovation Systems	USA
Proton	Khrunichev	Russia
Rockot	Eurockot	Russia/France
Soyuz	Arianespace	Russia
Vector	Vector Space Systems	USA
VEGA	European Launcher Development (ELD)-Fiat-Veio	Europe
Vulcan	United Launch Alliance (ULA)	USA
Zenit	Being phased out of production	Ukraine

2 Angara 1, 2, and 5 Launch Systems

Angara 5 on launch Pad (Graphic Courtesy of Roscosmos)

Background notes: The Angara rocket family is designed to replace the Proton family. There are several versions currently active that include:
Angara 1, 2 and 5A. Also now proposed are: Angara A3, Angara A5P, Angara A5V Angara A7, Angara A7.2B. The 5A is able to lift able to lift 24.5 tons to LEO (200km). The Angara 7.2 if built would double this payload to 50 tons.

Angara 1, 2 and 5 Launch Vehicle
Manufacturer: Khrunichev, KBKhA
Country of origin: Russia
Height: 42.7 m (140 ft)-64 m (210 ft)
Width: Angara 1.2 2.9 m (9 ft 6 in) Angara A5: 8.86 m (29.1 ft)
Mass: 171,500 kg (378,100 lb)-790,000 kg (1,740,000 lb)
Stages 2 or 3
Capacity
Payload to LEO (Plesetsk) 3,800 kg (8,400 lb)-24,500 kg (54,000 lb)
Payload to GTO (Plesetsk) 5,400 kg (11,900 lb)-7,500 kg (16,500 lb)
Associated rockets
Comparable Naro-1 used a modified URM-1 first stage
Launch history
Status Active
Launch sites Plesetsk Site 35 Vostochny
Total launches 2 (A1.2PP: 1, A5: 1)
Successes 2 (A1.2PP: 1, A5: 1)
First flight A1.2PP: July 9, 2014 A5: Deb 23, 2014
No. boosters 4 Boosters (A5) – URM-1
Engines 1 RD-191
Thrust 1,920 kN (430,000 lbf) (Sea level)
Total thrust 7,680 kN (1,730,000 lbf) (Sea level)
Burn time 214 seconds
Fuel RP-1/LOX
First stage – URM-1 Engines: 1 RD-191 Thrust 1,920 kN
Burn time: Angara 1.2: 214 seconds Angara 5: 325 seconds
Fuel RP-1/LOX
Second stage – URM-2 Engine: 1 RD-0124A Thrust: 294.3 kN
Burn time Angara A5: 424 seconds
Fuel RP-1/LOX
Third stage (A5) – Briz-M (optional)
Engines: 1 S5.98M Thrust: 19.6 kN Burn time: 3,000 sec
Fuel N2O4/UDMH
Third stage (A5) – KVTK (optional, under development)
Engines 1 RD-0146D Thrust 68.6 kN Burn time: 1,350 sec
Fuel LH2/LOX

3 Antares 230 Launcher

Antares 230 Launcher at Pad (Graphic courtesy of NASA)

The Antares was developed by Northrop Grumman/Orbital ATK based on the Taurus Rocket. Antares is sometimes referred to as Taurus II. The Ukrainian company Yuzhnoe which designed the Zenit rocket adapted this design for the first stage of the Antares rocket. Thus the first stage is a liquid fueled rocket while the second stage is a solid fuel rocket based on shortened version of the Castor 30 rocket.

The Antares was developed to lift The Cygnus Transfer Vehicle to bring cargo or other materials to the ISS and then become expendable as it re-enters the atmosphere. The Cygnus can bring cubesats or microsats to the ISS for launch. (See next page)

Antares Launch Vehicle by Northrop Grumman

Function: Medium Expendable Launcher
Manufacturer: Northrop Grumman Innovation Systems
Country United States
Launch cost: US$80-85 million

Height 230 series: 42.5 m (139 ft)
Diameter 3.9 m (13 ft)
Status: 100 series cancelled. 230 series active. 300 series in development
Mass 230: 298,000 kg (657,000 lb)
Stages 2 to 3
Capacity
LEO Payload 8,000 kg (18,000 lb[
Associated rockets
Comparable: Delta II and Atlas III
Expendable TV Cygnus (See Next Page)
Status • 200-series: operational
• 230 series: operational
Launch sites Mid Atlantic Rocket Site
Total launches 9 (110: 2, 120: 2, 130: 1 (Failed), 230: 4)
First stage (Antares 200-series)
Empty mass 20,600 kg (45,400 lb)
Gross mass 262,600 kg (578,900 lb
Engines 2 ×RD-181
Thrust 3,844 kN (864,000 lbf)
Burn time 215 seconds
Fuel RP-1/LOX
Second stage CASTOR A/B/XL
Gross mass 30A: 14,035 kg (30,942 lb)
30B: 13,970 kg (30,800 lb)
30XL: 26,300 kg (58,000 lb)
Propellant mass: 30A: 12,815 kg (28,252 lb)
30B: 12,887 kg (28,411 lb)
30XL: 24,200 kg (53,400 lb)
Thrust for 30XL: 474 kN (107,000 lbf)
Fuel: HTPB

4 Antares with Cygnus Capsule

**The Upgraded Cygnus with Increased Cargo Capacity
(Graphic Courtesy of NASA)**

Background Notes: Cygnus has been upgraded to increase the cargo carrying capability on the Antares 230. This improved design increases the payload from 2000 kg to 3200 kg. The Cygnus and Cygnus 230 are also compatible with a launch on an Atlas V 401. This can allow up to 1500 kg more cargo on this launcher vis a vis the original Cygnus.

Cygnus Capsule for Re-Supply of the ISS

Manufacturer	**Northrop Grumman Innovation Systems (formerly Orbital ATK)**
Country of origin:	**United States**
Operator:	**NASA**
Applications:	**ISS resupply**
Specifications	
Spacecraft type :	**Unmanned cargo vehicle**
Design life	**1 week to 2 years**
Dry mass	**3,400 kg (7,500 lb) (Standard)** **3,750 kg (8,270 lb) (Enhanced)**
Payload capacity:	**2,000 kg (4,400 lb) (Standard)** **3,200 kg (7,100 lb) (Enhanced 230)** **3,500 kg (7,700 lb) (Enhanced -Atlas V 401)**
Dimensions	**5.1 m × 3.07 m (16.7 ft × 10.1 ft) (Std)** **6.3 m × 3.07 m (20.7 ft × 10.1 ft) (Enhanced)**
Volume:	**18.9 m^3 (670 cu ft) (Standard)** **27.0 m^3 (950 cu ft) (Enhanced)**
Power	**3.5 kW**
Production	
Status	**In service**
Built	**10**
On order	**11**
Launched	**10**
Operational	**1**
Retired	**8**
Lost	**1**
First launch:	**18 September 2013**

5 Ariane 5 Launch Vehicle

Ariane 5 on Launch Pad
Guiana Space Centre ELA-3
(Graphic courtesy of Arianespace)

Website URL for Updates
http://www.arianespace.com/

Ariane 6 is under development as a comparable sized vehicle but much more cost effectivie. It will use Vulcan engines or possibly the reusable Prometheus engines are are being designed for much more cost-effective manufacture and might be 10 times less costly. CNES, Airbus-Safran and ESA are developers.

Background Notes:
Ariane 4 (no longer active),
Ariane 6 under development,
Ariane 5 ME no longer under development. Also see Vega.

Ariane 5 Heavy Launch Vehicle

Manufacturer Airbus Defence and Space for ESA
Country of origin: France, ESA member states
Cost per launch: $165–220M
Size
Height 46–52 m (151–171 ft)
Diameter 5.4 m (18 ft)
Mass 777,000 kg (1,713,000 lb)
Stages 2
Capacity Payload to LEO
(260 km (162 mi)
circular, 51.6°) G: 16,000 kg (35,000 lb)
ES: over 20,000 kg (44,000 lb)
Capacity Payload to GTO
G: 6,950 kg (15,320 lb) (Now Canceled)
G+: 6,950 kg (15,320 lb) (Now Canceled)
GS: 6,100 kg (13,400 lb) (Now Canceled)
ECA: 11,115 kg (24,504 lb) (Active)
Small Satellite Launch Capability:
SPELDA Adaptor for Smallsat 'Piggy Back' Launches

Associated Rocket Family: Ariane ECA now active. Development of Ariane ME halted. Ariane 6 to replace Ariance ECA in 2020s and operate at half the cost.

Comparable Launchers
Atlas V 551, Delta IV Heavy, Falcon 9 Full Thrust
JAXA H-IIB, Chinese Long March 5, Proton-M
Launch site: Guiana Space Centre ELA-3
Total launches 103
Successes 98

Fuel AP, Al, HTPB and LH2 / LOX in stage 2

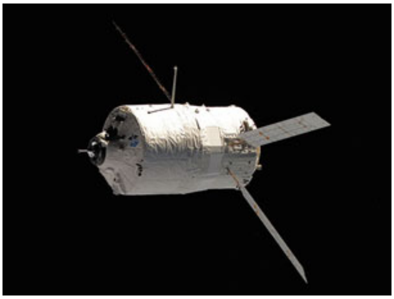
http://www.spacelaunchreport.com/ariane5.html

6 Ariane with Automated Transfer Vehicle



(Graphic courtesy of Arianespace)

Background Notes

The Automated Transfer Vehicle(ATV) is just one of the re-supply options providing key cargo to the ISS. The Cygnus and ATV are now expendable vehicles that on the return burn up in the atmosphere. The SpaceX Dragon capsule and the Boeing CST 100 Starliner are being qualified to carry and return crew from the ISS.

Automated Transfer Vehicle

Role: Supply the International Space Station with propellant, water, air, payload, experiments, and smallsats for deployment.

Crew: None, but human-rated.[1]

Dimensions

Height: 10.3 m (34 ft)

Diameter: 4.5 m (15 ft)[2]

Launch Payload: 7,667 kg (16,903 lb)[3]

Return Payload: None. Disposable.

Mass at launch: 20,750 kg[2]

Pressurized Volume: 48 m3[4]

Electrical Energy Source: 4 solar panel wings of 4 panels each and 40Ah rechargeable batteries

Size: total span 22.3 m

Generated Power: 3,800 W

On-board engines

Main engine: 4 × 490N, Aerojet (GenCorp) Model R-4D-11

Thrusters : 28 × 220N for attitude control & braking, ArianeGroup Lampoldshausen

Performance Endurance: Docked with the ISS **for up to six months**

Apogee: 400 km

Perigee: 300 km

Inclination: 51.6 degrees

Launch Location: CNES's Guiana Space Centre, Kourou in French Guiana

Site: ELA-3

Booster: Ariane 5 ES

7 Atlas V Launch Series

Atlas V 401 Launch Vehicle

(Gaphic Courtesy of Lockheed Martin)

Background Notes

The Atlas V 400 and 500 series and Atlas Heavy is marketed by the United Launch Alliance. They also market the Delta 4 launchers. The 2 pages below show pertinent information on the size and characteristics of Atlas and Delta Vehicles. The direct marketing of these services by ULA is anticipated to reduce costs. When the Vulcan vehicle is certified, the Delta vehicle is expected to be phased out of service. All of these vehicles can be configured for the launch of cubesats, microsats, and minisats.Although Lockheed Martin is the main contractor for ULA on the Atlas V. There are Russian engines and other sub-contractors that Include Aerojet General, and Northrop Grumman Innovation Systems. SpaceX, in contrast, has moved to vertically integrate the production of its Falcon vehicles and produced a much lower cost launch vehicle. Note: ULA may be sold to Aerojet General.

Atlas V Launch Series of Expendable Rockets

Function: EELV/medium-heavy launch vehicle
Manufacturer: United Launch Alliance-Lockheed Martin et al
Country of origin: United States
Cost per launch: US$110 million in 2016
Height 58.3 m (191 ft)
Diameter: 3.81 m (12.5 ft)
Mass: 334,500 kg (737,400 lb)
Stages: 2
Payload to LEO 8,250–20,520 kg (18,190–45,240 lb)
Payload to GTO4,750–8,900 kg (10,470–19,620 lb)
Comparable: Delta IV Falcon 9 H-IIB Long March 3B Proton-M
Status Active
Launch sites: Cape Canaveral SLC-41 & Vandenberg SLC-3E
Total launches 79
(401: 38, 411: 5, 421: 7, 431: 3)
(501: 6, 521: 2, 531: 3, 541: 6, 551: 9)
Successes 78
(401: 37, 411: 5, 421: 7, 431: 3)
(501: 6, 521: 2, 531: 3, 541: 6, 551: 9)
Partial failures 1 (401 – low orbit, customer declared success)
First flight 21 August 2002
<u>0 to 5 Boosters</u> – AJ-60A engine
Length 17.0 m (669 in)
Diameter 1.6 m (62 in)
Gross mass/Propellant: 46,697kg (102,949lb) 42,630 kg (93,980lb)
Thrust 1,688.4 kN (379,600 lbf)
Burn time 94 seconds
Fuel HTPB

First Stage Length 32.46 m(106.5ft) Diameter 3.81m(12.5ft)
Empty mass 21,054 kg (46,416 lb)
Propellant mass 284,089 kg (626,309 lb)
Engines 1 RD-180 **Fuel**: RP-1/LOX

Second stage – Centaur
Length 12.68 m (41.6 ft) Diameter: 3.05 m (10.0 ft)
Empty mass 2,316 kg (5,106 lb)
Propellant mass: 20,830 kg (45,920 lb)
Engines 1 RL10A or 1 RL10C Fuel: LH2 / LOX

8 Boeing: Delta IV Heavy Launch Vehicle

By NASA/Kim Shiflett - http://mediaarchive.ksc.nasa.gov/detail.cfm?mediaid=71145 (image link), Public Domain, https://commons.wikimedia.org/w/index.php?curid=37939869

Delta IV Heavy Launch Vehicle

Function: Orbital heavy-lift launch vehicle

Manufacturer: United Launch Alliance/Boeing

Country of origin: United States

Cost per launch $350 million (2018)

Height 72 m (236 ft)

Diameter 5 m (16 ft)

Width 15 m (49 ft)

Mass 733,000 kg (1,616,000 lb)

Payload to LEO 28,790 kg (63,470 lb)

Payload to GTO 14,220 kg (31,350 lb)

Associated rockets

Family Delta I, II, III and IV now discontinued and Delta IV Heavy to be replaced by the Vulcan.

Comparable Vehicles:

Ariane 5 Falcon Heavy Long March 5 New Glenn Proton-M Vulcan

Status Active but slated to be replaced

Launch sites: SLC-37B, Cape Canaveral
SLC-6, Vandenberg AFB

Total launches 10

Successes 9

Partial failures 1

First flight: 21 December 2004 (USA-181)

Last flight: to be replaced in 2021

https://en.wikipedia.org/wiki/Delta_IV_Heavy

9 Atlas V, Atlas-Centaur, Atlas Vulcan, and Delta IV Heavy Launch Vehicles Marketed by United Launch Services

These launchers are marketed by United Launch Services. Lockheed Martin is the manufacturer of the Atlas V and Atlas-Centaur vehicles, and Boeing is responsible for the Delta 4 and Delta 4 Heavy vehicles. The Delta IV and Delta IV Heavy, because of their high cost, are being phased out of service. The replacement vehicle will be the Vulcan. The Boeing CST Starliner Crew Transfer Vehicle is being designed to be compatible with the Atlas V, the Delta IV, the Vulcan, and the Falcon High Thrust vehicles.

There are multiple ways that these vehicles can be configured to launch small satellites (Fig. 1).

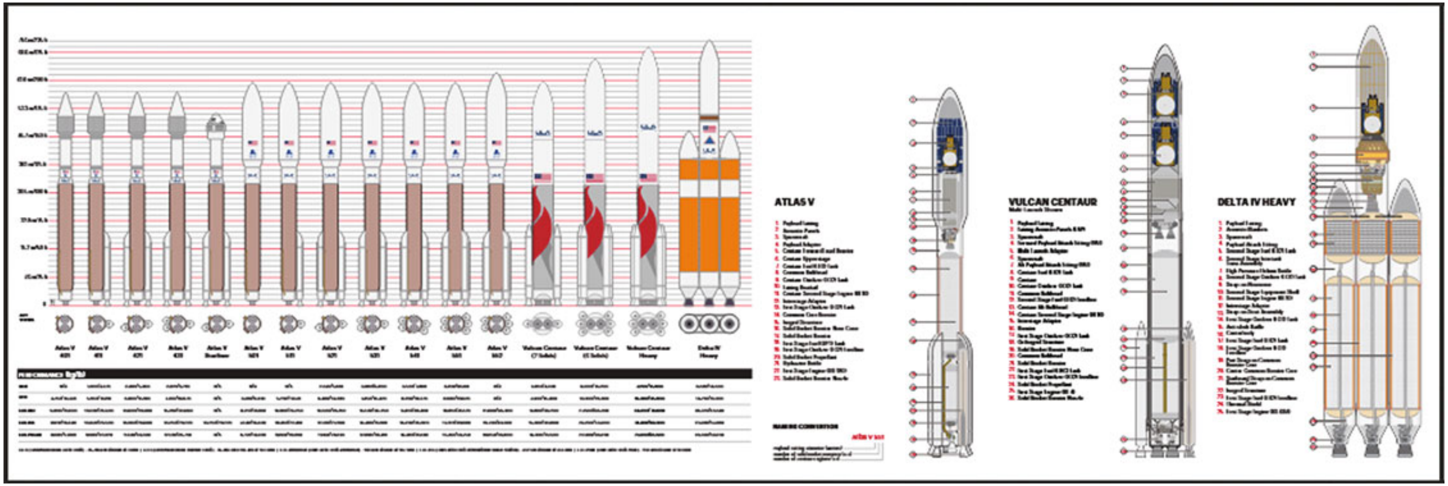

Fig. 1 Graphic showing the range of Atlas V, Atlas Centaur, Atlas Heavy, and Delta launchers in various configurations currently available. (Graphic Provided by United Launch Alliance). (Source: https://www.ulalaunch.com/docs/default-source/rockets/atlas-v-and-delta-iv-technical-summary.pdf)

10 Boeing CST 100 Starliner with Delta 4, Atlas V, Falcon High Thrust, and Vulcan Launchers

(Graphic courtesy of NASA)

This capsule with is a modified version of the Orion capsule that is somewhat smaller in size is also designed to be compatible with Delta 4 (scheduled to be phased out due to high cost), Atlas V, Falcon High Thrust, and new Vulcan Launcher.

Boeing CST 100 Starliner

Manufacturer: Boeing
Country of origin: United States
Operator: Boeing
Applications: Crew Transfer Vehicle
Specifications
Spacecraft type : Crewed Capsule
Design life: 60 hours (free flight)
210 days (docked)
Launch mass 13,000 kg (29,000 lb)
Crew capacity 7
Dimensions
Diameter (CM): 4.56 m (15.0 ft
Length (CM+SM): 5.03 m (16.5 ft)
Volume: 11 m^3 (390 cu ft)
Operational: 2019

Capable of carrying small sats to the ISS for Deployment in Orbit. The Boeing CST-100 Starliner (Crew Space Transportation) crew capsule was developed under NASA's Commercial Crew Development (CCDev) program. Its primary purpose is to transport crew to the International Space Station (ISSand to private space stations such as the proposed Bigelow Aerospace Commercial Space Station. **ompatible with four launch vehicles: Atlas V, Delta IV, Falcon 9, and Vulcan. It can carry supplies to the ISS and small satellites to the ISS for launch.**

11 Dnepr Launch Vehicle

Dnepr Vehicle Launch

(Graphic Courtesy of Global Commons)

Background Notes: This vehicle is now Retired from service.

Dnepr Orbital Carrier Rocket

Manufacturer: Yuzhnoye (design), Yuzhmash (manufacturing), Khartron (control system)

Country of Origin: Soviet Union (original build), **Ukraine (commercial launches after 1999)**

Cost per launch: US$29 million

Height 34.3 meters (113 ft)

Diameter 3 meters (9.8 ft)

Mass 211,000 kilograms (465,000 lb)

Stages 3

Capacity

Payload to LEO:4,500 kilograms (9,900 lb)

Payload to the ISS: 3,200 kilograms (7,100 lb)

Payload to SSO 2,300 kilograms (5,100 lb)

Status Retired

Launch sites: Baikonur, LC-13, Yasny

This launch vehicle was reconfigured from an earlier missile system used for military purposes.

12 Dream Chaser Space Plane

Artist Image of what the Sierra Nevada Corp Dream Chaser would look like mated to the ISS (Graphic Courtesy of Sierra Nevada Corp.)

Background notes: In January 2016, NASA announced that SN's Dream Chaser had been awarded one of the contracts under the Cargo ReSupply 2 program and committed to six Dream Chasers for this purpose. This is called the Dream Chaser Cargo System.
This latest version of the Dream Chaser Cargo features an expendable cargo portion and also has solar array panels to supply power. It is also capable of returning 1,750 kg (3,860 lb) of cargo to Earth. It could be uprated to return crew from the ISS. The Dreamer Chaser lost out to SpaceX and Boeing for the crewed version

Dreamchaser Space Plane and Cargo Resupply to ISS

Manufacturer Sierra Nevada Corporation

Related spacecraft: Derived from NASA developed HL-20 Personnel Launch System

Hybrid Fueling System: Original version developed using a polymide fuel with nitrous oxide oxidizer as developed by Pioneering space developer Benson of Orbitec . Sierra Nevada Corporation developed its own new polymide fuel after acquiring Orbitec, but has kept nitrous oxide as system oxidizer.

Other Missions:

1. Mission for U.N. Office of Outer Space Affairs for orbital experiments in conjunction with non-space-faring nations.

2. The DC4EU (Dream Chaser for European Utilization), this project is studying using it for sending crews and cargo to the ISS and on missions not involving the ISS, particularly in orbits of substantially greater altitude than the ISS can reach.

3. Stratolaunch and Dream Chaser: This would be a 75% scaled version of the Dream Chaser for commercial missions.

4. Hubble Telescope Service Mission. This is a project under study by NASA but not funded.

13 Electron Launch Vehicle

Electron Launcher at N.Z. Launch Site (Graphic courtesy of Rocket Labs)

Mahia Launch Center New Zealand (Graphic Courtesy of Rocket Labs)

Background Notes: This is one of the most trend setting of the new small launcher ventures. Its many innovations include: the 3D printing of the Rutherford launch engines, it has an unique electric-pump-fed engine (a first), the rockets are fabricated from a light-weight carbon-composite materials. The 3-D printing of the engines saves both time and money. The new plant that Rocket Labs has now opened is producing rocket engines with high efficiency that could support a large number of launches a year if there is sufficient market demand.

Electron Small Launch Vehicle	
Function	Orbital launch vehicle
Manufacturer	Rocket Lab
Country of origin	United States and New Zealand
Cost per launch	About US $6 million
Height	17 m (56 ft)
Diameter	1.2 m (3 ft 11 in)
Mass	12,500 kg (27,600 lb)
Stages	2–3
Capacity	
Payload: 500km Sun-Synchronous orbit: 150–225 kg (330–495 lb)	
Associated rockets	
Comparable: Vector and Launcher One.	
Status	Active
Launch sites: Mahia LC-1 N.N.(active) Mid Atlantic (MARS) planned	
Total launches	4 Successes: 3 Failures : 1 on 1st Test
First flight	25 May 2017
Last flight	16 December 2018
<u>First stage</u>	
Diameter	1.2 m (3 ft 11 in)
Engines	9 × Rutherford
Thrust	Sea level: 162 kN (36,000 lbf)[6]
	Vacuum: 192 kN (43,000 lbf)
Specific impulse	303 seconds (2.97 km/s)
Fuel	RP-1/LOX
<u>Second stage</u>	
Diameter	1.2 m (3 ft 11 in)
Engines	1 × Rutherford
Thrust	Vacuum: 22 kN (4,900 lbf)
Specific impulse	333 seconds (3.27 km/s)
Fuel	RP-1/LOX
<u>Third stage (optional)</u>	
Engines	1 × Curie[8]
Thrust	Vacuum: 0.12 kN (27 lbf)[8]
Fuel	unspecified "green" monopropellant

14 Falcon 9 Lifts Off from Kennedy Space Center

Falcon 9 Launch May 2018, Kennedy Space Center-LC-39A with the Bangabandhu-1 satellite (graphic courtesy of SpaceX)

Falcon Rocket Family

From left to right:

Falcon 9 v1.0, v1.1, Full Thrust, Block 5, and Falcon Heavy. The Falcon Heavy is similar to the Atlas V Heavy and Delta 4 Heavy in lift capability. The Falcon family of rockets are all priced significantly below other launchers of similar lift capacity. The ability to recover and reuse the first stage of the Falcon rockets is expected to cost further.

SpaceX's Falcon 9 Block 5 Rocket

Function Orbital launch vehicle

Manufacturer SpaceX

Country of origin United States

Approx. Cost per launch: $50M to $65M (2018)

Height: Full Thrust: 70 m (230 ft)
v1.1: 68.4 m (224 ft)
v1.0: 54.9 m (180 ft)

Diameter: 3.7 m (12 ft)

Mass
Full Thrust FT: 549,054 kg (1,210,457 lb)
v1.1: 505,846 kg (1,115,200 lb)
v1.0: 333,400 kg (735,000 lb)

Stages: 2

Capacity

Payload to LEO (28.5°)
Full Thrust (FT): 22,800 kg (50,300 lb)
v1.1: 13,150 kg (28,990 lb)
v1.0: 10,450 kg (23,040 lb)

Payload to GTO (27°)
Full Thrust (FT): 8,300 kg (18,300 lb)
v1.1: 4,850 kg (10,690 lb)
v1.0: 4,540 kg (10,010 lb)

Launch Sites:
Cape Canaveral SLC-40
Kennedy Space Center LC-39A
Vandenberg SLC-4E
Boca Chica

First Stage Engines
FT: 9 Merlin 1D+
v1.1: 9 Merlin 1D
v1.0: 9 Merlin 1C

Second Stage Engines
FT: 1 Merlin 1D Vacuum+
v1.1: 1 Merlin 1D Vacuum
v1.0: 1 Merlin 1C Vacuum

15 HIIA Japanese Launch Vehicle

HIIA Launcher at Tanegashima (Graphic courtesy of JAXA)

Background Notes

Mitsubishi who handles the commercial launch of the Japanese HII, HIIA, HIIB Launch Vehicles has a launch alliance agreement with Arianespace and Boeing to provide backup arrangements In the event of a need for an earlier launch.

HII , HIIA, HIIB Japanese Medium-lift launch vehicles

Manufacturer: Mitsubishi Heavy Industries (prime)
Northrop Grumman-Orbital ATK (sub)
Country of origin: Japan
Cost per launch: US$90 million
Height 53 m (174 ft)
Diameter: 4 m (13 ft)
Mass 285,000–445,000 kg (628,000–981,000 lb)
Stages: 2 plus 2 to 4 solid rocketer boosters
Payload to LEO 10,000–15,000 kg (22,000–33,000 lb)
Payload to GTO 4,100–6,000 kg (9,000–13,200 lb)
Status Active
Launch sites Tanegashima LA-Y
Success by version: 202 version: 26; **204 version**: 4; **2022 version:** 3
2024 version: 6
Recent Failures of 2024 version: 1
First flight by version: 202: 29 Aug. 2001; **204**: 18 Dec. 2006
2022: 26 Feb. 2005; **2024**: 4 Feb. 2002
Boosters (All variants) – SRB-A
No. boosters 2–4
Thrust of booster: 2,260 kN (510,000 lbf)
Total thrust 4,520–9,040 kN (1,020,000–2,030,000 lbf)
Specific impulse: 280 seconds (2.7 km/s)
Burn time 120 seconds
Fuel: HTPB
Boosters (2022 / 2024) – Castor 4A-XL
No. Solid Boosters 2–4
Thrust 745 kN (167,000 lbf)
Total thrust 1,490–2,980 kN (330,000–670,000 lbf)
Specific impulse: 280 seconds (2.7 km/s)
Burn time: 60 seconds
First stage: Engines : 1 LE-7A **Fuel** LOX / LH2
Thrust 1,098 kN (247,000 lbf)
Burn time: 390 seconds
Second stage: Engines: 1 LE-5B **Fuel** LOX / LH2

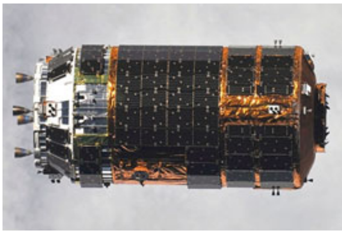
16 HII Transfer Vehicle



(Graphics Courtesy of JAXA)

The Japanese Name for the HTV is Kounotori which means White Stork. It is approximately the size of a sight-seeing bus. It has made only minimal trips to the ISS since its development by JAXA.
As of 2015 Japan began a process to Replace the HTV with the HTV-X transfer vehicle. It was designed to carry 6 tons of supplies to the ISS. It is incinerated in the Earth's atmosphere after it leaves the space station.

As part of the agreement to extend the lifetime of the ISS to 2024 there is an agreement to develop the HTV-X as well as a possible return capsule as well.

HII Transfer Vehicle of Japan

Role: Automated cargo spacecraft to resupply the International Space Station. Provides supplies but does not support crew or human passengers.
Crew: None
Dimensions
Height: ~9.8 m (including thrusters)[1]
Diameter: 4.4 m[1]
Spacecraft Mass: 10,500 kg
Total Launch Payload: 6,000 kg/ 6,200 kg
Pressurized Payload: 5,200 kg
Unpressurized Payload: 1,500 kg / 1,900 kg (HTV-6 -
Return Payload: None
Mass at launch: 16.5 ton
Pressurized Volume: 14 m^3

Comparable Transfer Vehicles: European Automated Transfer Vehicle (ATV), Soyuz, Cygnus Capsule**. The Dragon Capsule by Space X and the CST-100 Starliner by Boeing can perform similar functions but these later two capsules/transfer vehicles are designed to support crew as well.**

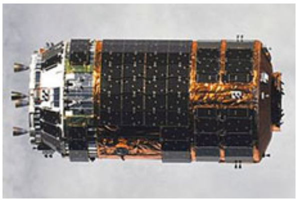
Performance and Endurance: Solo flight about 100 hours, stand-by more than a week, docked with the ISS about 30 days.

Apogee: 460 km
Perigee: 350 km
Inclination: **5**1.6 degrees

Sources:
https://web.archive.org/web/20101116044853/http://www.jaxa.jp/projects/rockets/htv/design_e.html

https://en.wikipedia.org/wiki/H-II_Transfer_Vehicle

17 H2 Transfer Vehicle of Japan



H2 Transfer Vehicle (Graphic Courtesy of NASA)

Background Notes: This H2 transfer Vehicle is being upgraded with HTV-6 To carry an additional 400 kg of unpressurized payload . This like the European ATV does not carry crew. This vehicle can carry microsats and cubesats to the ISS for redeployment via various systems such as Nanoracks and JEM (Kibo) deployment systems. The Japanese name for the H2 Transfer Vehicle is "Kounotori" which means White Crane a name picked by the citizenry of Japan.

H2 Transfer Vehicle of JAXA of Japan

Role: Automated cargo spacecraft to resupply the International Space Station

Crew: None. Expendable vehicle **on return flight from ISS**

Dimensions

Height:	9.8 m (including thrusters)
Diameter:	4.4 m
Spacecraft Mass:	10,500 kg
Total Launch Payload:	6,000 kg / 6,200 kg
Pressurized Payload:	5,200 kg
Unpressurized Payload:	1,500 kg / 1,900 kg (HTV-6)
Return Payload:	None, but can be used to cispose of trash.
Mass at launch:	16.5 ton
Pressurized Volume:	14 m3[

Performance

Endurance: Solo flight about 100 hours, stand-by more than a week, typically docked with the ISS about 30 days

Apogee:	460 km
Perigee:	350 km
Inclination:	51.6 degrees

Sources: https://web.archive.org/web/20101116044853/http://www.jaxa.jp/projects/rockets/htv/design_e.html

18 Indian Space Research Organization. Polar Satellite Launch Vehicle ISRO/PSLV

The PSLV CA Launcher on Pad (Graphic courtesy of ISRO)

PSLV Medium Lift launch system

Manufacturer: ISRO

Country of origin: India

Cost per launch: $21-31 million

Height 44 m (144 ft)

Diameter 2.8 m (9 ft 2 in)

Mass **PSLV-G**: 295,000 kg (650,000 lb)

PSLV-CA: 230,000 kg (510,000 lb)

PSLV-XL: 320,000 kg (710,000 lb)[2]

Stages 4

Payload to LEO:3,800 kg (8,400 lb)[3]

Payload to SSO: (620 km)1,750 kg (3,860 lb)

Payload to Sub-GTO: 1,425 kg (3,142 lb)

Payload to GTO: 1,200 kg (2,600 lb)[4]

Status: PSLV G, PSLV-C A , PSLV-XL & PSLV-DL all active

Launch sites Sriharikota

Total launches 46

Successes 43

Failures: 2 **Partial failures**: 1

First flight: PSLV-G: 20 Sept. 1993; PSLV-CA: 23 April 2007; PSLV-XL: 22 October 2008; PSLV-DL: 24 January 2019

PSLV-G Key Characteristics: 6 boosters of S9 type

Thrust 510 kN (110,000 lbf)

Burn time 44 seconds

Fuel HTPB

Thrust 703.5 kN (158,200 lbf)

PSLV-XL Key Characteristics: 6 boosters of S12 type

Thrust 703.5 kN (158,200 lbf)

Burn time 70 seconds

Fuel HTPB

PSLV-DL) Key Characteristics: This is a 4 stage rocket with fuels for the 4 stages as follows:

Stage 1] Solid S139 Rocket Engine: **Fuel**: HTPB

Stage 2: Vikas Liquid Engine **Fuel:** N2O4/UDMH

Stage 3: HTPB Solid Rocket engine

Stage 4: 2-PS-4 liquid Engines **Fuel :** MMH/MON

19 International Space Station-Japanese Experiment Module SmallSat Deployment and NanoRacks

ISS/JEM Cubesat/Microsat Deployment Systems (Graphic courtesy of JAXA)

Background Notes: There are three ways that space experiments or small satellite deployments can be accom-plished via the International Space Station (ISS) that have be designed and implemented by Nanoracks of Houston, Texas. 1. One system is for on-board experiments that are flown up to the ISS on resupply transport vehicles. These are installed on the Nanoracks experimental system that can be attended to by Astronauts. There are many programs to support student participation in such space experiments such as National Center for Earth and Space Science Education (NCESSE) and the Arthur C. Clarke Institute for Space Education. 2. The second method is to qualify cubesats (up to 6 U cubesats) that are deployed via the Nanoracks External Platform for cubesat release. 3. The third way is the Kaber Reusable Microsat Deployment system developed by Nanoracks that can deploy up to 1 meter micro-sats up 82 Kg in size like "Remove DEBRIS" that was developed the Surrey Space Centre.

JEM (Kibo) Small Sat Deployment Systems
This is the largest module on the International Space Station. Kibo in Japanese means hope.
Pressurized module
Length: 11.19 m (36.7 ft)
Diameter: 4.39 m (14.4 ft)
Mass: 15,900 kg (35,100 lb)

Experiment logistics module
Length: 4.21 m (13.8 ft)
Diameter: 4.39 m (14.4 ft)
Mass: 8,386 kg (18,488 lb)

Exposed Facility: This is also known as "The Terrace" It is equipped with an airlock and 12 experimental stations, 8 of which are replaceable.

Current Experiments in progress:
NREP: Nanoracks External Platform (for Cubesat Deployment)
MAXI: X-ray Astronomy
ICS-EF: Inter-orbital Communications System
CALET: Electron Telescope
CREAM: Cosmic Ray Energetics
ECOSTRESS: Ecosystem Radiometer
GEDI: Global Ecosystem Dynamics

JEM Remote Manipulator System (JEMRMS)
This is robot system intended for operation in space. It is attached to the Pressurized Module (PM). JEMRMS is utilized for experiments being conducted on JEM and to launch microsats (up to 1 meters In size from the Nanoracks Kaber system.

20 Launcher One

'Cosmic Girl' Carrier Vehicle on Test Run

(Graphic courtesy of Virgin Orbit)

Background Notes: The Launcher One and Virgin Orbit enterprise by Sir Richard Branson has evolved over time. The start of this project began with the SpaceShipOne Xprize contest with Burt Rutan, Paul Allen and Richard Branson were involved and the effort to create SpaceShipTwo to fly 'space tourists' or more correctly 'spaceadventurers' on sub-orbital flights. The development's cost and business plan has suggested that additional business was needed to sustain a longer term profitability. The result was to create a "Launcher One" vehicle to lift small satellites to orbit. Originally the. White Knight carrier vehicle was to be used for its air launch, but the larger carrier is now to be used to increase Launcher One's payload. Launcher One has been booked for OneWeb launches and NASA has also contracted for launches.

Launcher One-Air Launched Orbital Rocket

Manufacturer	**Virgin Orbit**
Country of origin:	**United States/ United Kingdom**
Cost per launch	**$10 million - $12 million**
Height	**16 m (52 ft)**
Stages	**2 with optional 3**
Payload to 500 km SSO:	**300 kg (660 lb)**
Payload to 230 km SSO	**500 kg (1,100 lb)**
Associated rockets	
Comparable	**Electron, Vector-H**
Launch history	
Status	**In development**
Launch sites	
	Mojave Air & Space Port, California
	Kennedy Space Center, Florida
	Cornwall Airport Newquay, England
	Ellison Onizuka Kona, Hawaii
First stage	
Diameter	**1.6 m (5 ft 3 in)**
Engines:	**NewtonThree (N3)**
Thrust in Vacuum:	**327 kN (74,000 lbf)**
Burn time:	**180 sec**
Fuel	**Kerosene/LOX**
Second stage:	
Diameter:	**1.3 m (4 ft 3 in)**
Engines	**NewtonFour (N4)**
Thrust	**Vacuum: 22 kN (4,900 lbf)**
Burn time:	**360 sec**
Fuel:	**Kerosene/LOX**

21 Long March 5 Launch Vehicle

A Long March 5 Launch Vehicle in Transit to Pad (Graphic Courtesy of CNSA)

A discussion of the Long March launch vehicle family is presented in the following two pages including information on Long March 6,7, 8 and 9.

Long March 5 Heavy orbital launch vehicle

Manufacturer: CALT (Chinese Academy of Launch Technology
Country of origin: China
Height 57 m (187 ft)
Diameter 5 m (16 ft)
Mass 867,000 kg (1,911,000 lb)
Stages 2 plus 4 boosters
Payload to LEO: (200 km × 400 km × 42°) 25,000 kg (55,000 lb)
Payload to GTO: 14,000 kg (31,000 lb)
Payload to TLI 8,200 kg (18,100 lb)
Associated comparable rockets: Ariane 5 Delta IV Heavy, Falcon Heavy New Glenn, Proton-M, Vulcan
Launch Status : Active: 5 launches through 2019 with 1 failure
Launch sites Wenchang LC-1
First flight 3 November 2016
Boosters : 4 of CZ-5-300 type
Length 27.6 m (91 ft)
Diameter 3.35 m (11.0 ft)
Gross mass/Propellant: 155,700kg (343,300 lb) 144,000kg (317,000 lb)
Total thrust **9,600 kN (2,200,000 lbf)**
Burn time 180 seconds **Fuel:** RP-1/LOX
First stage – CZ-5-500
Length 31.7 m (104 ft)
Diameter 5 m (16 ft)
Gross mass/Propellant: 175,600kg (387,100lb) / 158,300 kg (349,000lb)
Engines: 2 × YF-77
Burn time: 480 seconds **Fuel** LH2/LOX
Second stage – CZ-5-HO
Length 10.6 m (35 ft)
Diameter 5 m (16 ft)
Gross mass/Propellant: 22,200kg (48,900lb) /17,100 kg (37,700l
Engines: 2 × YF-75D
Thrust: 176.52 kN (39,680 lbf)88.26
Burn time: 700 seconds **Fuel** LH2/LOX
Third stage – YZ-2(Optional)
Diameter 3.8 m (12 ft)
Engines: 2 x YF-50D
Thrust 6.5 kN (1,500 lbf)
Burn time 1105 seconds **Fuel** N2O4/UDMH

https://en.wikipedia.org/wiki/Long_March_5

22 Long March Family for the Long March 2, Long March 3, and Long March 4

The Chinese space program has discontinued its Long March 1, but it now has a full range of launch options that are pictured or described below. The chart immediately shows the Long March 2A, 2C, 2D, 2E, and 2F; Long March 3, 3A, 3B, and 3C; and Long March 4A, 4B, and 4C. The Long March 5, 6, and 7 are the newest Chinese launch vehicles developed since 2015, and the Long March 8 and Long March 9 are currently only in the planning stages.

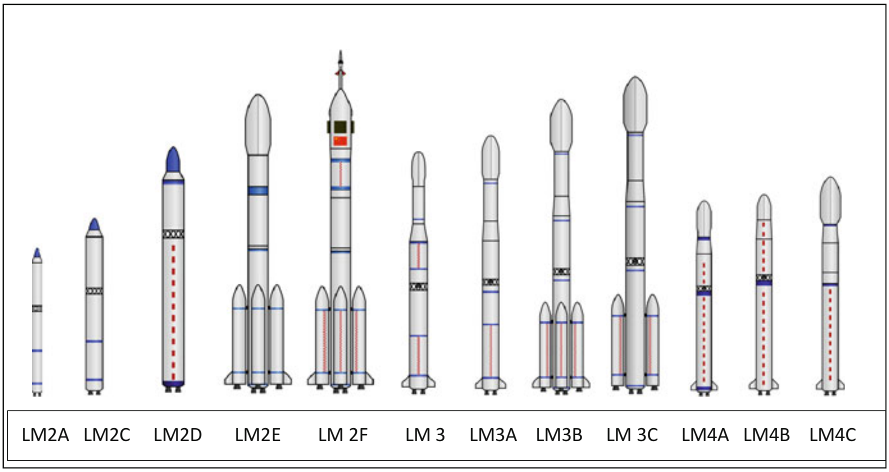

Chart below shows the relative size of various Long March vehicles in series 2, 3, and 4. (Graphic courtesy of the Wikipedia Commons)

23 Long March 6, 7, 8, and 9

There is currently also just a single version of the Long March 5 which is China's heavy-lift vehicle, as described in the page above. In addition there are also the **Long March 6** and *Long March 7*. These are smaller vehicles than the Long March 5 heavy lift.

A detailed description of the characteristics of the Long March 6 which can lift a payload of 1080 kgs to 700 KM sun-synchronous orbit can be found at https://archive.is/20150918112832/http://www.spaceflight101.com/long-march-6.html and at: https://en.wikipedia.org/wiki/Long_March_6.

The details of the characteristics of the Long March 7 launch vehicle which can lift a payload or 13,5000 kg to low Earth orbit (LEO) can be found at http://sinodefence.com/cz-7/ and at https://en.wikipedia.org/wiki/Long_March_7.

Future plans call for a Long March 8 that will be medium-lift vehicle to launch spacecraft to sun-synchronous orbit (SSO) but which will be partially reusable by reclaiming the first stage. The Long March 9 is for launch at the super heavy-lift stage and is comparable to the US Space Launch System (SLS). The comparison of super heavy-lift launch vehicles in the Figure below allows a comparison of the Long March 9 and the Space Launch System rocket.

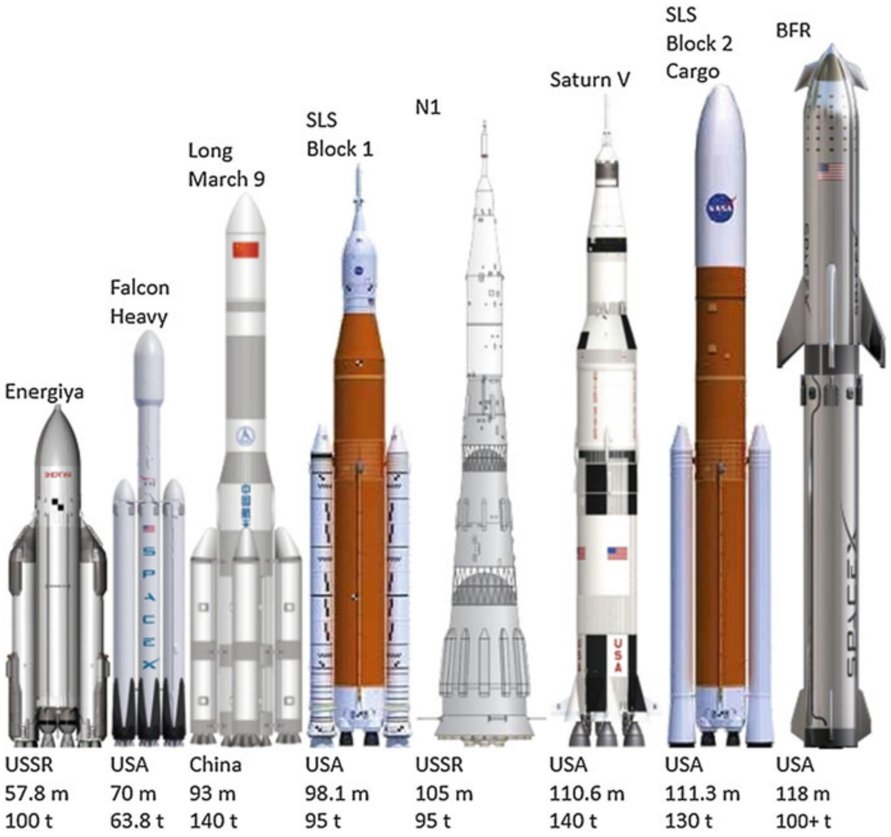

Figure showing the comparative sizes of super heavy-lift rockets from around the world. (Graphic courtesy of the Wikipedia Commons)

24 Minotaur II

MinotaurII Launcher in Flight

(Graphic courtesy global commons)

Background Notes*:* This vehicle is Based on a converted solid fueled And decommissioned Minuteman Missile. This was originally developed by Orbital Science-ATK which is now know as Northrop Grumman Innovation Systems. This system has also become the basis for the Antares launcher. This family of launchers ranges from the Minotaur I to V. The Minotaur II And III are suborbital. The Minotaur IV and V, with an Orion, 3rd stage can launch to LEO orbit.

Minotaur I, II, III, IV, and V Launch Systems

Function Suborbital and LEO launch systems
Manufacturer Northrop Grumman Innovation Systems
Country of origin: United States
Height: 19.21 metres (63.0 ft)
Diameter: 1.67 metres (5 ft 6 in)
Mass: 36,200 kilograms (79,800 lb)
Stages: 2 or 3
Capacity
Payload to 8000km S/O400 kilograms (880 lb)
Launch history
Status: Active
Launch sites: Vandenberg LF-06
Total launches: 8
Successes 8
First flight 28 May 2000
First stage : M55E1
Engines: 1 Solid
Thrust: 935 kilonewtons (210,000 lbf)
Fuel: Solid
Second stage – SR19AJ1
Engines: 1 Solid
Thrust: 268 kilo-newtons (60,000 lbf)
Fuel Solid
Third stage (Baseline) – M57A1
Engines 1 Solid
Fuel Solid
Third stage (Minotaur II+) – SR-73-AJ
Engines: 1 Solid
Fuel: Solid
Third stage (Heavy): – Orion 50XL
Engines: 1 Solid
Thrust: 118.2 kilonewtons (26,600 lbf)
Burn time: 74 seconds
Fuel Solid for Minotaur 1 and II Launch Vehicle

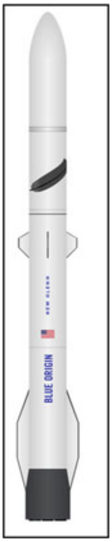
25 New Glenn Launcher



(Graphic courtesy of Blue Origin)

Background Notes: The Jeff Bezos owned Blue Origin company is developing the New Glenn heavy lift launcher, new liquid oxygen fueled Be-4 engines for the new Vulcan rocket to be marketed by ULA. It has its own spaceport in West Texas. The first stage of the New Glenn launcher is being designed for the potential of 100 reuses. Blue Origin is developing a smaller launch for sub-orbital flights.

New Glenn Launch Vehicle

Function: Partially reusable heavy orbital launcher
Manufacturer: Blue Origin
Country of origin: United States
Height 2-stage: 95 m (313 ft)
Diameter: 7 m (23 ft)
Capacity
Payload to LEO 45,000 kg (99,000 lb)
Payload to GTO 13,000 kg (29,000 lb)
Comparable associated rockets: Delta IV Heavy ,Falcon Heavy, Long March 5, Saturn C-3 Vulcan
Launch: Status In development
Launch sites: Cape Canaveral LC-36, Vandenberg Air Force Base
First stage
Diameter: 7 m (23 ft)
Engines: 7 × BE-4
Thrust 17.1 MN (3,850,000 lbf)
Fuel Methane / LOX
Second stage
Diameter: 7 m (23 ft)
Engines: 2 × BE-3U
Thrust: 980 kN (220,000 lbf)
Fuel: H2 / LOX

Note: Blue Origin is also developing new rocket engines to be used with the new Vulcan launcher. The first stage engines are reportedly being designed for re-use on up to 100 different launches.

https://en.wikipedia.org/wiki/New_Glenn

26 Pegasus

Pegasus in flight after release from Lockheed 1011 Carrier Aircraft (Graphic courtesy NG Innovation)

Background Notes: This is a fairly expensive launch cost for a small payload capacity. This will have to compete with the offerings of Vector, Launcher One by Virgin Orbit, and Rocket Labs. The Pegasus XL played key role in the launch and deployment of the first generation of the Orbcom store-and-forward small satellite constellation.

Pegasus Launch Vehicle

Manufacturer: Northrop Grumman
Function: Launch vehicle
Country of origin: United States
Cost per launch: US$40 million
Height 16.9 meters (55 ft) (Pegasus)
17.6 meters (58 ft) (Pegasus XL)
Diameter: 1.27 meters (4.2 ft)
Mass: 18,500 kilograms (40,800 lb) (Pegasus)
23,130 kilograms (50,990 lb) (Pegasus XL)
Stages: 3. Solid rocket engines developed by Alliant.
Payload to LEO 443 kilograms (977 lb)
Payload dimensions: 1.18 by 2.13 meters (3.9 ft × 7.0 ft)
Derivatives: Taurus and Minotaur-C
Comparable launchers: Launcher One and Vector
Launch history: Early launch failures but after early 40% failures there has been high reliability.
Status: Pegaus XL Still Active
Launch sites: Air launch to orbit via Lockheed 1011 aircraft
Total launches: 43 Successes: 38 Failures: 3 Partial failures: 2
First flight: 5 April 1990 (Pegsat / NavySat)

Note on Pegasus Special Advantage: For many small satellite launchesit is desirable to be the primary payload and thus be placed directly into the desired orbit. This is not possible when launched as a secondary payload and thus being placed in a compromise orbit. The ability to launch from the equator region can avoid the high radiation levels of the South Atlantic Anomaly and place small satellites into equatorial LEO orbits more efficiently.

27 Proton

Proton Launch Vehicle in Flight (Courtesy of Roscosmos)

Background Notes: The Proton is a well proven vehicles with 91 successful flights. Its heavy lift capability and low relative cost makes it competitive. It has been primarily to launch communication satelites to Geosynchronous orbit. The latest version of the Proton M is the Phase IV Proton Briz-M has allowed a payload increase to 6320 kg to a reference GTO orbit with 1500 m/s of residual boost to achieve GSO. This rocket is considered comparable to Atlas 5 Heavy, Delta 4 Heavy, Ariane 5, HIIB, and the Falcon 9 Full Thrust. As of June, 2018 this family of rockets is being discontinued and is to be replaced with the Angara 5.

Proton Heavy-lift launch vehicle

Manufacturer Khrunichev
Country of origin: Russia
Cost per launch: US$65 million
Height 58.2 m (191 ft)[2]
Diameter 7.4 m (24 ft)
Mass 705,000 kg (1,554,000 lb)[2]
Stages 3 or 4
Capacity
Payload to LEO[a] 23,000 kg (51,000 lb)[3]
Payload to GTO 1800 m/s[b] 6,920 kg (15,260 lb)[3]
Payload to GTO 1500 m/s[c] 6,300 kg (13,900 lb)[4]
Payload to GSO[d] 3,250 kg (7,170 lb)[3]
Associated rockets
Family Universal Rocket
Comparable: Ariane , Atlas V 551, Delta IV Heavy, Falcon Full Thrust, H-IIB, Long March 5
Status Active
Launch Sites: Baikonur Site 81/24 & 200/39
Total launches: 102 Successes: 91 Failures: 9 Partials: 2
First flight: 7 April 2001
1st Stage: Length: 21.18 m (69.5 ft) Diameter: 7.4 m (24 ft)
Empty mass: 30,600 kg (67,500 lb)
Propellant mass: 428,300 kg (944,200 lb)
Engines: 6 RD-275M Burn time: 108 sec
Fuel N2O4 / UDMH
Second stage: Length: 17.05 m (55.9 ft)
Diameter: 4.1 m (13 ft)
Empty mass: 11,000 kg (24,000 lb)
Propellant mass: 157,300 kg (346,800 lb)
Engines: 3 RD-0210 1 RD-0211 Burn time: 206 sec
Fuel N2O4 / UDMH
Third stage: Length 4.11 m (13.5 ft)[7]
Diameter 4.1 m (13 ft)[7]
Empty mass: 3,500 kg (7,700 lb)[7]
Propellant mass 46,562 kg (102,652 lb)[7]
Engines 1 RD-0212 Burn time 238 sec
Fuel N2O4 / UDMH
Fourth stage (optional) – Briz-M or Blok DM-2 or Blok DM-03

28 Rokot or Rockot Launch Vehicle

Rockot in Launch Flight
(Graphic courtesy of Eurockot)

Backgroun Notes: ROCKOT (meaning 'boom' in Russia) is a three stage liquid propellant launcher largely based on the Russian SS-19 Intercontinental Ballistic Missile which provides Rockot with its first and second stages. The SS-19 has flown over 150 times with only 3 failures. The Breeze-M third stage allows a 2140 kg payload to be launched to LEO orbit. Arianespace is the partner in the Eurockot partnership with the Russian company Khrunichev. The Rockot version with a Ukrainian control system is to stop flying after 2019, due to the Ukrainian ban on technology exports to Russia. A full Russian-made Rockot-2 light carrier rocket may begin flying again in 2021

Rokot Orbital Carrier Rocket
Manufacturer: Eurockot Launch Services,
Country of origin Soviet Union
Cost per launch US$41.8 million[1]
Size
Height 29 metres (95 ft)
Diameter 2.5 metres (8 ft 2 in)
Mass 107,000 kilograms (236,000 lb)
Stages: 3
Payload to LEO 1,950 kilograms (4,300 lb)
Payload to SSO 1,200 kilograms (2,600 lb)
Status Active
Launch sites Baikonur 175/1 & Plesetsk 133/3
Total launches 32
Successes 29
Failures : 2 Partial failures: 1
First flight: 20 Nov. 1990 26 Dec1994 (orbital)
First stage
Diameter: 2.5 m (8.2 ft)
Engines: 3-RD-0233 (15D95)
1 RD-0234(15D96)
Thrust 2,080 kN (470,000 lbf)
Burn time 120 seconds
Fuel N2O4 / UDMH
Second stage
Diameter: 2.5 m (8.2 ft)
Engines 1 RD-0235 (15D113)
1 RD-0236 (15D114)[2][3]
Thrust 255.76 kN (57,500 lbf)
Burn time: 180 seconds
Fuel N2O4 / UDMH
Third stage – Briz-KM
Engines: 1-S5.98M
Thrust: 19.6 kilonewtons (4,400 lbf)
Burn time: 3,000 seconds
Fuel: N2O4 / UDMH

29 Soyuz

(Grpahic from Global Commons)

Soyuz 2 is used for commercial launches and is marketed by Arianespace and is launched from the Kourou launch site in Guiana as well as the Angara. See illustration above under Angara to see possible configurations for minisatellites launces on both the Soyuz and Angara. The Soyuz 2 can be booked with the ST fairing and Starsem configuration for $80 milliion per launch.

Soyuz Launchers

Soyuz: A Russian family of expendable launch systems developed by OKB-1 and manufactured by TsSKProgress Rocket Space Centre in Samara, Russia. There have been over 1700 flights of this launcher since its debut in 1966. It has been redesigned and upgraded many times since the 1960s. The Soyuz is the most frequently used launch vehicle in the world. It has an outstanding reliability record, with over 98% reliability in its launches. This exceeds that of the Space Transportation System of the U.S. It is used to launch astronauts to the International Space Station until the U.S. Commercial Crew program is fully qualified as is expected soon.

Country of Origin: Russia/USSR
First flight: November 28, 1966
Stages: 3
Key Vehicles: Soyuz U (retired in 2017), Soyuz FG. Soyuz 2
Type of Fairings for Commercial Flights: A-type or S Type
Type S dimensions: 3.7 m x 7.7m
Type ST with Starsem and Soyuz 2: 4.1 m x 11.7m
Rocket it was Derived from: Vostok
Function: Launch vehicle
Manufacturers: Energia, Progress Rocket Space Centre
Launch sites: Kourou (for Soyuz 2) , Ensemble de Lancement Soyouz, Vostochny Cosmodrome Site 1S
Launcher Stages with dimensions, thrust and specific impulse are provided a sources below:

Sources:
https://en.wikipedia.org/wiki/Soyuz_(rocket_family)

30 Vector Launch Vehicle (due to bankruptcy is not available)

Vector Launch on Pad

(Graphic Courtesy of Vector Space Systems)

https://vector-launch.com/vector-r/

Background Notes:

The Vector-R provides a 60kg payload capability that can be configured for a wide range of CubeSat and Small Satellite mission profiles. The Vector-R fairing is a traditional two-piece design that is of sufficient size to accommodate a wide range of deployment options for multiple smallsats. The R in Vector-R stands for rapid deployment.

Vector Family of Small Launchers

Cost of Launch : **2-3 Million USD**

Height 12 m

Diameter 1.2 m

Mass 5,000 kg

Stages 2/3

Capacity

Payload to LEO: 60 kg

Payload to SSO: 26 kg

Associated rockets

Family: Vector (rocket family)

Derivatives: Vector-H

Comparable: Electron, Falcon 1

<u>Launch history</u>

Status: 2 prototype launches

Launch sites: Pacific Spaceport Complex – Alaska

MARS Pad OB, Spaceport Florida Launch Complex 46

<u>First stage</u>

Diameter: 1.2 m (3 ft 11 in)

Engines: 3 X LP-1

Thrust 18,300 lbf (81,000 N)

Burn time: 143 seconds

Fuel Propylene / LOX

<u>Second stage</u>

Diameter .635 m (2 ft 1.0 in)

Engines 1 X LP-2

Thrust 1,000 lbf (4,400 N)

Burn time 433 seconds

Fuel Propylene / LOX

31 Vega and Vega C Small Launch Vehicle

(Graphic courtesy of ESA)

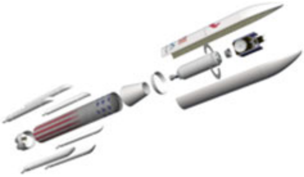
Vega can be configured to launch five 200 Kg minisats to Low Earth Orbit (LEO) and its HEXA 1 &2 adapter can accommodate many 'piggyback' options for nanosat/ picosat launches. Vega C is an upgraded version of Vega with 60% greater payload capability. A Vega Lite launcher is under active study that would be designed to compete with Rocket Labs and Virgin Orbit launchers.

Vega Small Lift Launch Vehicle

Manufacturer: European Launcher Development (ELD)/ Avio
Country of origin: Italy, European Space Agency/ELD
Cost per launch: US$37 million
Height 30 m (98 ft) **Diameter** 3 m (9.8 ft)
Mass 137,000 kg (302,000 lb)
Stages 4
Payload Polar Orbit(700km / inclination 90°) 1,430 kg (3,150 lb)
Payload SSO (400km) 1,450 kg (3,200 lb)
Associated rockets
Delta II 7420, Minotaur IV, Minotaur-C PSLV, Rokot Soyuz-2-1v
Status Active
Launch sites Guiana Space Centre ELV
Total launches 13 **Successes** 13
First flight: 13 Feb. 2012
First stage – P80
Length 11.7 m (38 ft) **Diameter** 3 m (9.8 ft)
Thrust 2,261 kN (508,300 lbf)
Specific impulse 280 s (2.7 km/s)
Burn time 110 s
Fuel HTPB (Solid)
Second stage – Zefiro 23
Length 8.39 m (27.5 ft) **Diameter** 1.9 m (6.2 ft)
Thrust: 871 kN (195,800 lbf)
Specific impulse: 287.5 s (2.819 km/s)
Burn time: 77 s
Fuel HTPB (Solid)
Third stage – Zefiro 9
Length 4.12 m (13.5 ft) **Diameter:** 1.9 m (6.2 ft)
Thrust 260 kN (58,450 lbf)
Specific impulse 296 s (2.90 km/s)
Burn time 120 s
Fuel: HTPB (Solid)
Upper stage – AVUM
Length 1.7 m (5.6 ft) **Diameter**: 1.9 m (6.2 ft)
Engines: 1 RD-843
Thrust 2.42 kN (544.0 lbf)
Specific impulse 315.5 s (3.094 km/s)
Burn time 667 s
Fuel UDMH / N2O4
Sources: https://en.wikipedia.org/wiki/Vega_(rocket) https://web.archive.org/web/20150923180829/http://www.avio.com/files/catalog/pdf/motore_p80_75.pdf

32 The Vulcan Centaur Rocket

By the United Launch Alliance



(graphic courtesy of United Launch Alliance)

Backgroud Notes: The Vulcan is under final development . The ACES is in design development and contains the concept of reusability of the first stage. The Vulcan-ACES Rocket is proposed for the 2020s

A simulated expanded view of the 562-configuration Vulcan Centaur rocket.

Function Partly-reusable launch vehicle
Manufacturer United Launch Alliance
Country of origin United States
Height 58.3 m (191 ft)
Diameter 5.4 m (18 ft)[1]
Mass 546,700 kg (1,205,300 lb)
Stages 2 stages plus 0 to 6 boosters
Capacity
Payload to LEO 34,900 kg (76,900 lb)[2] (Vulcan Heavy Centaur)
Payload to GTO 16,300 kg (35,900 lb)[2](Vulcan Heavy Centaur)
Payload to GEO 7,200 kg (15,900 lb)[2](Vulcan Heavy Centaur)
Launch sites: Cape Canaveral SLC-41
Vandenberg SLC-3E[3]
Projected First flight 2021 (planned)[4]
No. boosters 0–6
Motor GEM 63XL[5]
Thrust 2,201.7 kN (495,000 lbf)
Fuel for Boosters: HTPB 1st Stage: CH4 / LOX
2nd stage: LH2 / LOX (ACES proposed for Mid 2020s
First stage
Diameter
Engines: Two BE-4
Thrust 4,900 kN (1,100,000 lbf)
Fuel CH4 / LOX
Second stage – Centaur (initial flights, late-2010s)
Engines: Two RL10-C
Thrust: 207.6 kN (46,700 lbf)[citation needed]
Specific impulse: 448.5 seconds (4.398 km/s)
Fuel LH2 / LOX
Future Second Stage – ACES (proposed, mid-2020s)
Engine: BE-3 engine
Fuel LH2 / LOX
Source: (Accessed March 2019)

33 Zenit Launch Vehicle

Zenit Launcher on Pad
(Graphic courtesy of Sea Launch)

Background Notes: The Zenit 3F was Launched by Sea Launch until it ended Service. The Zenit 2 is launched from The Baikonur launch site. The failure **of a Zenit in the launch of an Intelsat** satellite in 2013, and the earlier failure of a Zenit in a launch of multiple Globalstar small satellites and the Closure of the Sea Launch operation that was based in San Diego in the U.S. have a major negative impact on the commercial use of this launcher.

Zenit Launch Vehicle

Function Medium-lift expendable carrier rocket
Manufacturer Yuzhnoye & Yuzhmash
Country of origin: Zenit-2: USSR Zenit-3SL: Ukraine, Russia
Height 57–59.6 m (187–196 ft)
Diameter 3.9 m (13 ft)
Mass 444,900–462,200 kg (980,800–1,019,000 lb)
Stages 2 or 3
Capacity
Payload to LEO Zenit-2: 13,740 kg (30,290 lb)
Payload to SSO Zenit-2: 11,380 kg (25,090 lb)
Payload to GTO Zenit-3SL: 6,000 kg (13,000 lb)
Status Active
Launch sites: Baikonur LC-45 Odyssey (ocean platform)
Total launches: 84
Zenit 2: 36 **Zenit 3SL:** 36 **Zenit 2M:** 2 3SLB: 6 **Zenit 3F:** 4
Successes: 71 **Failures:** 10 **Partial Failures:** 3
First flights: 1985 for Zenit 2 thru 2011 for Zenit 35F.

First stage
Engines: 1 RD-171 Thrusy: 8,180 kilonewtons (1,840,000 lbf)
Burn time 150 seconds **Fuel** RP-1 / LOX

Second stage
Engines 1 RD-120 &1 RD-8
Thrust 912 kilonewtons (205,000 lbf)
Burn time: 315 seconds **Fuel**: RP-1/LOX

Third stage (Zenit-3SL/3SLB) – Block DM-SL
Engines 1 RD-58M
Thrust 84,900 newtons (19,100 lbf) **Burn time** 650 seconds
Fuel RP-1 / LOX

Third stage (Zenit-3F) – Fregat-SB
Engines 1 - S5.92
Thrust 19,600 newtons (4,400 lbf)
Specific impulse : 327 seconds (3.21 km/s)
Burn time: 877 seconds
Fuel: N2O4 / UDMH

New launch systems from around the world seeking to develop new launch vehicle capabilities. (Courtesy of Paper by Carlos Niederstrasser, Northrop Grumman, 32nd Annual AIAA/Utah State University (AIAA/USU Conference on Small Satellites, 2018))

Launch vehicle development company or organization	Name of launch vehicle	Country of origin	Date seeking to offer services	URL for launch vehicle organization
ABL Space Systems	RS1 which is launched from truck-mounted launch systems from an FAA-licensed launch site	USA	Late 2020 or 2021. To launch up to 1200 kg to LEO. Batch and multi-manifest missions	https://www.ablspacesystems.com/
Aphelion Orbitals	Helios and Feynman Launch System. System to place 6 U cubesats in LEO at low cost	USA	2021	https://www.satellitetoday.com/innovation/2017/07/31/startup-aphelion-orbitals-secures-500000-seed-funding/
Bagaveev Corporation	Bagaveev. This is a 3D printed rocket motor. It is designed to place a 12 kg payload into LEO orbit. Pricing of $100 K per kg	USA	2019	https://mach5lowdown.com/2017/03/14/bagaveev-corp/
bspace	Volant: Hosted payloads launched on ARQ system to be launched to the International Space Station in 2020. $80 K for 1 U cubesat	USA	2020	http://www.bspacelaunch.com
Celestia Aerospace	Sagittarius Missile launched from a MiG 29 jet (known as Archer 1) to put 1 U nanosats into orbit at a cost of 200 k euros	Spain	2020–2021	https://medium.com/spacer/celestia-aerospace-a-company-that-is-planning-to-use-a-fighter-plane-
Chinese Aerospace Science and Technology Corporation (CASC)	Kaituozhe-1. No longer active	China	2002 to 2010 developed key concepts for other Chinese launchers	https://en.wikipedia.org/wiki/Kaituozhe_(rocket_family)

(continued)

Cloud IX	Cloud IX vehicle that is balloon launched that is seeking to develop a 22 kg to LEO orbit system at low cost	USA	Not currently known	http://www.cloudix.space/ https://spacenews.com/cloudix-joins-race-to-develop-small-rocket/
CONAE Comisión Nacional de Actividades Espaciales (National Space Agency of Argentina)	Tronador II. Liquid-fueled rocket to lift 250 kg payload to polar orbit. Launches from Puerto Belgrano Naval Base in Argentina	Argentina	2020 or 2021	https://en.wikipedia.org/wiki/Tronador_(rocket)
CubeCab	Cab-3A. Launch vehicle for just one 3 U cubesat. $250 K per launch. Bitcoin Latina has indicated it will launch 300 3 U sats for a LEO network to provide service to Latin America	USA	2020–2022	http://www.cubecab.com http://www.parabolicarc.com/2018/02/11/bitcoinlatina-foundation-cubecab-launch-300-satellite-network-support-bcl-blockchain/
Brazilian Departamento de Ciencia e Tecnologia Aeroespacial	VLM-1 (Microsatellite Launch Vehicle). Planned capability of 150 kg to LEO. CTA is the manufacturer	Brazil in cooperation with Germany (DLR)	2019	https://en.wikipedia.org/wiki/VLM_(rocket)
ESA	Space RIDER (Space Reusable Integrated Demonstrator for Europe Return). Space lifting body (reusable) and compatible with Vega C launcher	Europe Italian Aerospace Research Center (CIRA) and Thales Alenia Space	2022	https://www.esa.int/Our_Activities/Space_Transportation/Space_Rider
Firefly Aerospace	Firefly Alpha	USA	Not active	Now bankrupt and ceased operations
Gilmour Space Technologies	One Vision launcher (tests in 2019). Hybrid rocket engine. Scaled version of Ariel sounding rocket	Australia/ Singapore	Q4 2020	https://www.gspacetech.com/ https://www.gspacetech.com/single-post/2019/02/01/Gilmour-Space-unveils-One-Vision-rocket-ahead-of-suborbital-test-launch

ispace	Hyperbola 1S (SQX-1Z) (active) Hyperbola 1 and 3 (under development)	China	H-1S active and H-1 and H-3 under development 2021	https://en.wikipedia.org/wiki/I-Space_(Chinese_company)
Israel Aerospace Industries	Shavit (meaning "comet" in Israeli)	Israel	Currently (only used for Israeli launches and launched to the west rather than to the east)	https://en.wikipedia.org/wiki/Israel_Aerospace_Industries
ISRO	PSLV Light (launch of LEO satellites of up to 500Kg and can be assembled in 3 days)	India	2020	https://www.spaceflightinsider.com/organizations/isro/isro-plans-develop-light-lift-rocket-launch-small-satellites-orbit/
LandSpace	Zhuque-1 launcher by private LandSpace company. Capable of 300 kg to LEO orbit or 200 kg to SSO orbit Launch in early 2019 failed to achieve orbit	China	2019	https://en.wikipedia.org/wiki/LandSpace https://spacenews.com/landspace-ready-for-first-chinese-private-orbital-launch-but-looks-to-grander-plans
Launcher, Inc.	Rocket-1. They are currently developing 3D printed rocket engines on a 10-year schedule to have a small satellite launcher by 2025	USA	2025	https://3dprint.com/220518/launcher-a-space-start-up-making-3d-printed-rocket-engines/

(continued)

LEO Aerospace LLC (associated with Purdue University)	Rockoons. High-altitude balloons ascend to 18 km and then sent to orbit by a rocket release. Projected cost of $60,000 per kg	USA	Q4 2018	https://www.purdue.edu/newsroom/releases/2018/Q2/rockoons-may-soon-make-launching-satellites-into-space-more-accessible.html
Link Space Aerospace Technology Group (private Chinese company)	New Line 1 Xin Gan Xian 1. Capable of 200 kg payload to sun-synchronous orbit. Objective is $2.5 million launch cost with reusable first stage	China	2020–2021 (eventually to support point-to-point rocket launches)	https://en.wikipedia.org/wiki/LinkSpace
Naro Space Center in cooperation with GKNPTs Khrunichev	Naro-1 (retired as of 2013)	South Korea in cooperation with Russia	Retired as of 2013	https://en.wikipedia.org/w/index.php?search=&title=Special%3ASearch&fulltext=Search
North Korea National Aerospace Development Administration (NADA)	Kwangmyongsong' and Unha-3 Missile Systems	North Korea	Active systems since 2012	http://www.astronautix.com/u/unha.html
One Space Technology Group (also known as Zero One Space) (private Chinese launch company)	OS-M1 to OS-M4, OS-M4 is capable of lifting 552 kg to LEO and 307 kg to sun-synchronous orbit of up to 800 km. Will seek to develop reusable rockets and even crewed vehicle to LEO orbit	China	2018	https://en.wikipedia.org/wiki/OneSpace On April 3, 2019 the launch of this solid fuel OS-M1 rocket failed to achieve orbit.
Orbex	Prime launch vehicle. Seeks to launch 150 kg to sun-synchronous orbit of 500 km. Seeking to develop a reusable 1st stage rocket. Shares launch site with Rocket Lab's Electron vehicles	UK	2020–2021	https://orbex.space/ https://en.wikipedia.org/wiki/Orbex

(continued)

Orbital Access	Orbital 500R is an air-launched, two-stage to orbit system, designed to deliver payloads of 500kgs to a 600 km sun-synchronous orbit, aircraft deployed with space plane delivery system	UK	2020	https://www.orbital-access.com/
PLD Space	Miura 5 (previously Arion 2). This is a Spanish-developed rocket engine. This is a 3-stage liquid-propelled launch vehicle capable of inserting with a kick state a 300 kg payload into a 400 km LEO orbit	Spain	3Q 2021 (this expected date for Miura 5 with doubled payload up to 300 kg)	https://spacenews.com/pld-space-after-esa-input-doubles-lift-capacity-of-smallsat-launcher/ https://en.wikipedia.org/wiki/PLD_Space
Reaction Engines, Ltd.	Sabre Engine for Skylon single-stage-to-orbit vehicle. This company founded by Alan Bond is the leading developer of SCRAM jet engines	UK	2021	https://www.reactionengines.co.uk/
Relativity	Terran 1 launch vehicle with 3D printed rocket motor. Relativity has partnered with mu space. Terran 1 can be configured to launch 185–1250 kg to LEO. Nominal payload is 700–1200 kg to sun-synchronous orbit. Design reduces launcher to 1000 parts	USA	2022	www.relativity.com
Rocket Crafters Inc. (RCI)	Intrepid-1 RCI is developing hybrid rocket engines (HREs) with an oxidizer and sold fuel for integration with Intrepid-1's 1st and 2nd stages	USA	2019 or 2020	http://rocketcrafters.space/

(continued)

RocketStar	The StarLord is being designed to carry 300 kilograms to LEO and up to 150 kilograms to GEO	USA	2019	http://rocketstar.nyc/satellite-launch-platform.html
Skyrora Space Technologies	Skyrora XL. This is a 3-stage launch vehicle powered by hydrogen peroxide and kerosene. This rocket system is derivative of the Black Arrow and Skylark rockets that preceded Skyrora I and Skyrora XL that is launched from Scotland	UK/Ukraine	2019–2020	https://www.skyrora.com/ https://spacenews.com/uk-ukrainian-launch-vehicle-developer-skyrora-to-establish-smallsat-launch-site/
SpaceOps	RTS-1 Rocky 1. This project is seeking to develop (return to sender) reusable rocket systems	Australia	2019	http://spaceops.com.au/
Spaceflight Industries	This is a service company that locates the best launch services at low cost. They also provide transportation to launch site, integration, and ongoing communications after launch. On Dec. 3, 2018, a Falcon 9 launched 64 small satellites as brokered by Spaceflight	USA	Active	https://www.spaceflightindustries.com https://www.cnbc.com/2019/02/01/morgan-stanley-spaceflight-industries-disrupting-rocket-launch-market.html

Forms for Registration of Small Satellites Consistent with the Registration Conventions

Joseph N. Pelton

Contents

Abstract

There is a requirement for all space objects launched into orbit or beyond to be formally registered with the Secretary General of the United Nations by nation states responsible for these launches. This is a requirement of the so-called Registration Convention as well as the subsequent UN General Assembly Resolution 62/101.

This part of the Handbook on small satellites is designed to provide key documentation and forms associated with outer space activities. Thus, the registration form required to be provided to the United Nations is provided below.

Keywords

General assembly · Launching State · Nanosat · Office of outer space affairs · Registration convention · Secretary general · Space object · Small satellite · United Nations

1 Introduction

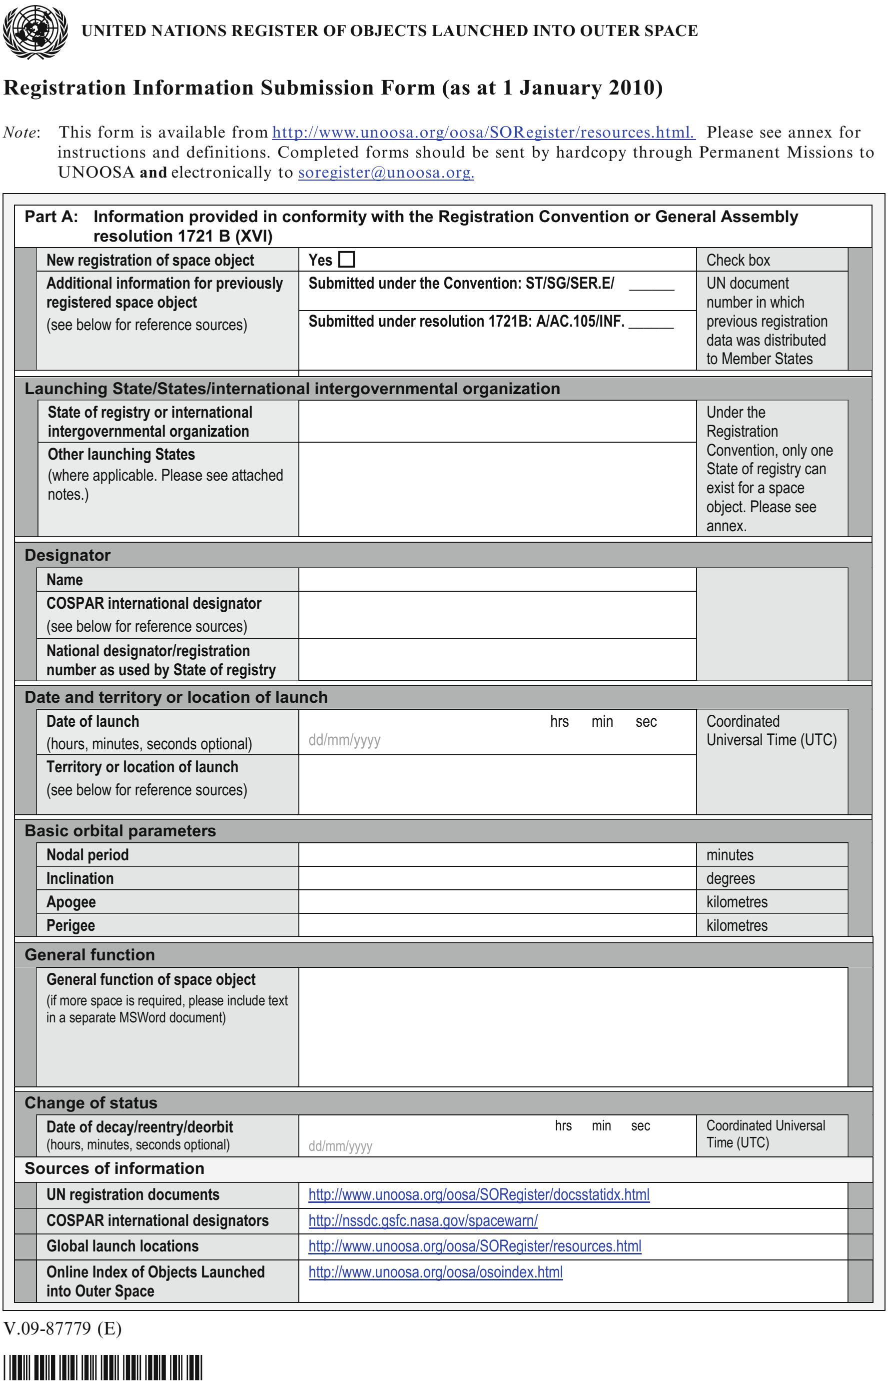
The Registration Convention or General Assembly Resolution 1721 8 (XVI) requires all launching states to register this information with Secretary General who has designated the UN Office of Outer Space Affairs to discharge this duty. The Registry Form that is provided in the next four pages that follow also makes reference to the UN General Assembly Resolution 62/101 that has been added to allow the registration to become more flexible and informative as conditions change over time.

Thus this form, consistent with the changes provided by UNGA Resolution 62/101, allows states to offer updates with regard to a change of function, a transition to a nonfunctional state, a change of orbital parameters or removal from orbit, the intent to engage in activities such as on-orbit servicing or rendezvous and proximity operations, a modification in ownership, the designation of a new spacecraft operator, or other changes to the spacecraft or space object itself. This type of registration currently applies to all space objects launched even for the smallest spacecraft such as femtosats, picosats, or nanosats.

The United Nations Registration form that Launching States are to file with the UN Office of Outer Space Affairs for all objects launched into outer space as provided in this Appendix below can be accessed at the following web site. In the Adobe format, this form can also be filled out online, but this form must be submitted by the launching state. See http://www.unoosa.org/res/oosadoc/data/documents/2008/unoosaregfrm/unoosaregfrm1_0_html/UNOOSA-REG-FRM-01E.pdf.

Important note: Registration of space objects with the Secretary General can only be performed by the government of a state of registry through accredited Permanent Missions to the United Nations or by the headquarters of an international intergovernmental organization that has declared acceptance of rights and obligations under the Registration Convention. Direct submissions by national space agencies, academic institutions, and private entities are not considered to be valid registration submissions.

Editor's note: The information provided here is simply to provide entities seeking to launch small satellites of any type into orbit useful background as to the type of information the official national or international intergovernmental organization would be required to file with the United Nations. Thus the information indicated in the form below is indicative of the information that will be needed to be supplied but that direct filing of this information is not permitted by private organizations for the reasons indicated above. In short this information is simply provided as background. Official filings must come from authorized agencies recognized by the United Nations.



UNITED NATIONS REGISTER OF OBJECTS LAUNCHED INTO OUTER SPACE

Registration Information Submission Form (as at 1 January 2010)

Note: This form is available from http://www.unoosa.org/oosa/SORegister/resources.html. Please see annex for instructions and definitions. Completed forms should be sent by hardcopy through Permanent Missions to UNOOSA **and** electronically to soregister@unoosa.org.

Part A: Information provided in conformity with the Registration Convention or General Assembly resolution 1721 B (XVI)

New registration of space object	**Yes** ☐	Check box
Additional information for previously registered space object (see below for reference sources)	**Submitted under the Convention: ST/SG/SER.E/** ______ **Submitted under resolution 1721B: A/AC.105/INF.** ______	UN document number in which previous registration data was distributed to Member States

Launching State/States/international intergovernmental organization

State of registry or international intergovernmental organization		Under the Registration Convention, only one State of registry can exist for a space object. Please see annex.
Other launching States (where applicable. Please see attached notes.)		

Designator

Name		
COSPAR international designator (see below for reference sources)		
National designator/registration number as used by State of registry		

Date and territory or location of launch

Date of launch (hours, minutes, seconds optional)	dd/mm/yyyy hrs min sec	Coordinated Universal Time (UTC)
Territory or location of launch (see below for reference sources)

UNITED NATIONS REGISTER OF OBJECTS LAUNCHED INTO OUTER SPACE

Annex

Section A. Instructions for completing the form

1. Download the electronic version of the form from http://www.unoosa.org/oosa/SORegister/resources.html.
2. Reference sources and other resources for completion of the form are available from the above web-link.
3. Review definitions in Section B below and complete the form. If there are any queries, please e-mail soregister@unoosa.org.
4. The **completed hardcopy form** should be sent through official government channels to the relevant Permanent Mission to the United Nations (Vienna) to be formally transmitted to the United Nations.
5. The **completed electronic form** should be sent by the appropriate government entity to the United Nations Office for Outer Space Affairs using e-mail soregister@unoosa.org.

Section B. Definition of terms

Part A: Information provided in conformity with the Registration Convention or General Assembly resolution 1721B (XVI)

Launching State/States/international intergovernmental organization

State of registry/international intergovernmental organization:	The State of registry is the launching State which carries the space object on its national registry of objects launched into outer space. The international intergovernmental organization is an organization which has declared its acceptance of the rights and obligations provided for in accordance with Article VII of the Registration Convention. *Note*: In accordance with Article II of the Registration Convention, **only one State of registry can exist for a space object**. When more than one launching State exists, they should jointly determine which State should register the space object.
Other Launching States:	As defined in the Registration Convention, "launching State" means: (i) A State which launches or procures the launching of a space object; (ii) A State from whose territory or facility a space object is launched.

Designator

Name:	The common name/names used to identify the space object.
COSPAR international designator:	Alphanumeric designator established by the Committee on Space Research (COSPAR) for space objects that successfully reach Earth orbit or beyond. The SPACEWARN Bulletin (available at http://nssdc.gsfc.nasa.gov/spacewarn) confirms the designators assigned by the World Warning Agency for Satellites on behalf of COSPAR. The designator can also be obtained from the Online Index of Objects Launched into Outer Space at http://www.unoosa.org/oosa/osoindex.html.
National designator/ registration number:	Designator or registration number assigned to a space object by the State of registry.

Date and territory or location of launch

Date of launch:	The date of launch of the space object using Coordinated Universal Time (UTC) (also referred to as Greenwich Mean Time (GMT)).
Territory or location of launch:	The territory or location of the launch of the space object. For a table of global launch locations, see http://www.unoosa.org/oosa/SORegister/resources.html.

Basic orbital parameters: Basic data on the space object's orbit around the Earth or a celestial body such as the Sun, Moon, etc. If object is orbiting a body other than Earth, please specify. The parameters are:

Nodal period:	Time taken by the space object to complete one revolution around the body it is orbiting.
Inclination:	The angle relative to the equator of the Earth or celestial body the space object is orbiting. Measured counter-clockwise from the equator.
Apogee:	The furthest distance in the space object's orbit from the surface of the body it is orbiting.
Perigee:	The closest distance in the space object's orbit from the surface of the body it is orbiting.

UNITED NATIONS REGISTER OF OBJECTS LAUNCHED INTO OUTER SPACE

General function:	General information on the space object. Can include mission objectives, frequency plans, etc. If required, please attach text in a separate page.
Change of Status:	The date of the space object's decay, reentry, recovery, deorbit or landing.

Part B: Additional information for use in the United Nations Register of Objects Launched into Outer Space, as recommended in General Assembly resolution 62/101

Change of status in operations

Date when space object is no longer functional:	The date using Coordinated Universal Time (UTC) (also referred to as Greenwich Mean Time (GMT)) when the space object ceases to perform operational functions for the State of registry.
Date when space object is moved to a disposal orbit:	The date using Coordinated Universal Time (UTC) when the space object is moved into a disposal orbit. See COPUOS Space Debris Mitigation Guidelines for recommendations on disposal orbits, http://www.unoosa.org/oosa/SORegister/resources.html.
Physical conditions when space object is moved to a disposal orbit:	The physical conditions when the space object is moved into a disposal orbit. Conditions can include the change in orbit (e.g. +300 km above GSO), passivation of the space object and other measures as recommended in the COPUOS Space Debris Mitigation Guidelines.

Basic orbital parameters

Geostationary position:	Applicable only to space objects in the geostationary orbit. Planned and/or actual location of space object in ± degrees East along the equator from the Greenwich meridian (e.g. for 10.5 degrees West, use -10.5 degrees East).

Additional Information

Website:	Address on the World Wide Web for information on the space object/mission/operator.

Part C: Information relating to the change of supervision of a space object, as recommended in General Assembly resolution 62/101

Change of supervision of the space object

Date of change in supervision:	The date using Coordinated Universal Time (UTC) (also referred to as Greenwich Mean Time (GMT)) when the new owner or operator takes supervision of the space object.
Identity of the new owner or operator:	The identity of the new owner or operator of the space object.
Change of orbital position in the geostationary orbit	
Previous orbital position:	The previous operational location of the space object in ± degrees East along the equator from the Greenwich meridian.
New orbital position:	The new operational location of the space object in ± degrees East along the equator from the Greenwich meridian.
Change of function of the space object:	The function of the space object following change in supervision.

Part D: Additional voluntary information for use in the United Nations Register of Objects Launched into Outer Space

Basic information

Space object owner or operator:	The entity that owns or operates the space object.
Launch vehicle:	The launch vehicle used to launch the space object into Earth orbit or beyond.
Celestial body space object is orbiting:	The body that the space object is in orbit around, if not Earth (i.e. the Moon, the Sun, Mars, Jupiter, etc.).
Other information:	Information relating to the space object that the State of registry may wish to furnish to the United Nations.

Abstract

On January 2, 2016, the United Nations General Assembly adopted 17 Millennium Development Goals. A short summary of these goals as well as explicit targets to be achieved by 2030 is provided below as provided in United Nations documentation. This document, in addition to providing the official brief explanation of the 17 Goals, also provides the UN-approved specific targets for each goal. Also provided is the United Nation's characterization of the issues to be addressed in terms of related facts and figures associated with each objective as well as supporting rationale for their adoption. For the complete UN text on the 17 SDGs, please go to https://www.un.org/sustainabledevelopment/sustainable-developmentgoals/.

1 Introduction

On January 2, 2016, the United Nations General Assembly adopted 17 Millennium Development Goals. A short summary of these goals as well as explicit targets to be achieved by 2030 is provided below as provided in United Nations documentation. This document, in addition to providing the official brief explanation of the 17 Goals, also provides the UN-approved specific targets for each goal. Also provided is the United Nation's characterization of the issues to be addressed in terms of related facts and figures associated with each objective as well as supporting rationale for their adoption. For the complete UN text on the 17 SDGs, please go to https://www.un.org/sustainabledevelopment/sustainable-development-goals/.

2 Goal 1: End Poverty

Eradicating poverty in all its forms remains one of the greatest challenges facing humanity. While the number of people living in extreme poverty dropped by more than half between 1990 and 2015 – from 1.9 billion to 836 million – too many are still struggling for the most basic human needs.

Globally, more than 800 million people are still living on less than US $1.25 a day, many lacking access to adequate food, clean drinking water, and sanitation. Rapid economic growth in countries like China and India has lifted millions out of poverty, but progress has been uneven. Women are more likely to live in poverty than men due to unequal access to paid work, education, and property.

Progress has also been limited in other regions, such as South Asia and sub-Saharan Africa, which account for 80% of those living in extreme poverty. New threats brought in by climate change, conflict, and food insecurity mean even more work is needed to bring people out of poverty.

The SDGs are a bold commitment to finish what we started and end poverty in all forms and dimensions by 2030. This involves targeting the most vulnerable, increasing access to basic resources and services, and supporting communities affected by conflict and climate-related disasters.

Goal 1 Targets

- By 2030, reduce at least by half the proportion of men, women, and children of all ages living in poverty in all its dimensions according to national definitions.
- Implement nationally appropriate social protection systems and measures for all, including floors, and by 2030 achieve substantial coverage of the poor and the vulnerable.
- By 2030, ensure that all men and women, in particular the poor and the vulnerable, have equal rights to economic resources, as well as access to basic services, ownership, and control over land and other forms of property, inheritance, natural resources, appropriate new technology, and financial services, including microfinance.
- By 2030, build the resilience of the poor and those in vulnerable situations, and reduce their exposure and vulnerability to climate-related extreme events and other economic, social, and environmental shocks and disasters.
- Ensure significant mobilization of resources from a variety of sources, including through enhanced development cooperation, in order to provide adequate and predictable means for developing countries, in particular least developed countries, to implement. Programs and policies to end poverty in all its dimensions.
- Create sound policy frameworks at the national, regional, and international levels, based on pro-poor and gender-sensitive development strategies, to support accelerated investment in poverty eradication actions.

Facts and Figures

- Eight hundred thirty-six million people still live in extreme poverty.
- About one in five persons in developing regions lives on less than US $1.25 per day.
- The overwhelming majority of people living on less than $1.25 a day belong to two regions: Southern Asia and sub-Saharan Africa.
- High poverty rates are often found in small, fragile, and conflict-affected countries.
- One in four children under age 5 in the world has inadequate height for his or her age.
- Every day in 2014, 42,000 people had to abandon their homes to seek protection due to conflict.

3 Goal 2: Zero Hunger

Rapid economic growth and increased agricultural productivity over the past two decades have seen the number of undernourished people drop by almost half. Many developing countries that used to suffer from famine and hunger can now meet the nutritional needs of the most vulnerable. Central and East Asia, Latin America, and the Caribbean have all made huge progress in eradicating extreme hunger.

These are all huge achievements in line with the targets set out by the first Millennium Development Goals. Unfortunately, extreme hunger and malnutrition remain a huge barrier to development in many countries. Seven hundred ninety-five million people are estimated to be chronically undernourished as of 2014, often as a direct consequence of environmental degradation, drought, and loss of biodiversity. Over 90 million children under the age of 5 are dangerously underweight. And one person in every four still goes hungry in Africa.

The SDGs aim to end all forms of hunger and malnutrition by 2030, making sure all people – especially children – have access to sufficient and nutritious food all year round. This involves promoting sustainable agricultural practices: supporting small-scale farmers and allowing equal access to land, technology, and markets. It also requires international cooperation to ensure investment in infrastructure and technology to improve agricultural productivity. Together with the other goals set out here, we can end hunger by 2030.

There is an imperative today to foster sustainable development. A vision for what this encapsulates is laid out in the new sustainable development agenda that aims to end poverty and promote prosperity and people's well-being while protecting the environment by 2030. As the UN's Development arm, UNDP has a key role to play in supporting countries to make this vision a reality – putting societies on a sustainable development pathway, managing risk and enhancing resilience, and advancing prosperity and well-being.

Goal 2 Targets

- By 2030, end hunger and ensure access by all people, in particular the poor and people in vulnerable situations, including infants, to safe, nutritious, and sufficient food all year round.
- By 2030, end all forms of malnutrition, including achieving, by 2025, the internationally agreed targets on stunting and wasting in children under 5 years of age, and address the nutritional needs of adolescent girls, pregnant and lactating women, and older persons.
- By 2030, double the agricultural productivity and incomes of small-scale food producers, in particular women, indigenous peoples, family farmers, pastoralists, and fishers, including through secure and equal access to land, other productive resources and inputs, knowledge, financial services, markets, and opportunities for value addition and non-farm employment.
- By 2030, ensure sustainable food production systems and implement resilient agricultural practices that increase productivity and production; that help maintain ecosystems; that strengthen capacity for adaptation to climate change, extreme weather, drought, flooding and other disasters; and that progressively improve land and soil quality.
- By 2020, maintain the genetic diversity of seeds, cultivated plants, and farmed and domesticated animals and their related wild species, including through soundly managed and diversified seed and plant banks at the national, regional, and international levels, and promote access to and fair and equitable sharing of benefits arising from the utilization of genetic resources and associated traditional knowledge, as internationally agreed.
- Increase investment, including through enhanced international cooperation, in rural infrastructure, agricultural research and extension services, technology development, and plant and livestock gene banks in order to enhance agricultural productive capacity in developing countries, in particular least developed countries.
- Correct and prevent trade restrictions and distortions in world agricultural markets, including through the parallel elimination of all forms of agricultural export subsidies and all export measures with equivalent effect, in accordance with the mandate of the Doha Development Round.
- Adopt measures to ensure the proper functioning of food commodity markets and their derivatives and facilitate timely access to market information, including on food reserves, in order to help limit extreme food price volatility.

Facts and Figures

- Globally, one in nine people in the world today (795 million) is undernourished.
- The vast majority of the world's hungry people live in developing countries, where 12.9% of the population is undernourished.
- Asia is the continent with the most hungry people – two thirds of the total. The percentage in Southern Asia has fallen in recent years, but in Western Asia it has increased slightly.

- Southern Asia faces the greatest hunger burden, with about 281 million undernourished people. In sub-Saharan Africa, projections for the 2014–2016 period indicate a rate of undernourishment of almost 23%.
- Poor nutrition causes nearly half (45%) of deaths in children under age 5 – 3.1 million children each year.
- One in four of the world's children suffers stunted growth. In developing countries, the proportion can rise to one in three.
- Sixty-six million primary school-age children attend classes hungry across the developing world, with 23 million in Africa alone.
- Agriculture is the single largest employer in the world, providing livelihoods for 40% of today's global population. It is the largest source of income and jobs for poor rural households.

4 Goal 3: Good Health and Well-Being

4.1 Ensure Healthy Lives and Promote Well-Being

Ensuring healthy lives and promoting the well-being for all at all ages are essential to sustainable development. Significant strides have been made in increasing life expectancy and reducing some of the common killers associated with child and maternal mortality. Major progress has been made on increasing access to clean water and sanitation and reducing malaria, tuberculosis, polio, and the spread of HIV/AIDS. However, many more efforts are needed to fully eradicate a wide range of diseases and address many different persistent and emerging health issues.

Goal 3 Targets

- By 2030, reduce the global maternal mortality ratio to less than 70 per 100,000 live births.
- By 2030, end preventable deaths of newborns and children under 5 years of age, with all countries aiming to reduce neonatal mortality to at least as low as 12 per 1000 live births and under age 5 mortality to at least as low as 25 per 1000 live births.
- By 2030, end the epidemics of AIDS, tuberculosis, malaria, and neglected tropical diseases, and combat hepatitis, water-borne diseases, and other communicable diseases.
- By 2030, reduce by one third of premature mortality from noncommunicable diseases through prevention and treatment, and promote mental health and well-being.
- Strengthen the prevention and treatment of substance abuse, including narcotic drug abuse and harmful use of alcohol.
- By 2020, halve the number of global deaths and injuries from road traffic accidents.
- By 2030, ensure universal access to sexual and reproductive health-care services, including for family planning, information and education, and the integration of reproductive health into national strategies and programs.

- Achieve universal health coverage, including financial risk protection, access to quality essential health-care services, and access to safe, effective, quality, and affordable essential medicines and vaccines for all.
- By 2030, substantially reduce the number of deaths and illnesses from hazardous chemicals and air, water, and soil pollution and contamination.
- Strengthen the implementation of the World Health Organization Framework Convention on Tobacco Control in all countries, as appropriate.
- Support the research and development of vaccines and medicines for the communicable and noncommunicable diseases that primarily affect developing countries; provide access to affordable essential medicines and vaccines, in accordance with the Doha Declaration on the TRIPS Agreement and Public Health, which affirms the right of developing countries to use to the full the provisions in the Agreement on Trade-Related Aspects of Intellectual Property Rights regarding flexibilities to protect public health; and, in particular, provide access to medicines for all.
- Substantially increase health financing and the recruitment, development, training, and retention of the health workforce in developing countries, especially in least developed countries and small island developing states.
- Strengthen the capacity of all countries, in particular developing countries, for early warning, risk reduction, and management of national and global health risks.

Facts and Figures

- Seventeen thousand fewer children die each day than in 1990, but more than six million children still die before their fifth birthday each year.
- Since 2000, measles vaccines have averted nearly 15.6 million deaths.
- Despite determined global progress, an increasing proportion of child deaths are in sub-Saharan Africa and Southern Asia. Four out of every five deaths of children under age 5 occur in these regions.
- Children born into poverty are almost twice as likely to die before the age of 5 as those from wealthier families.
- Children of educated mothers – even mothers with only primary schooling – are more likely to survive than children of mothers with no education.
- Maternal mortality has fallen by almost 50% since 1990.
- In Eastern Asia, Northern Africa, and Southern Asia, maternal mortality has declined by around two thirds.
- But maternal mortality ratio – the proportion of mothers that do not survive childbirth compared to those who do – in developing regions is still 14 times higher than in the developed region.
- More women are receiving antenatal care. In developing regions, antenatal care increased from 65% in 1990 to 83% in 2012.
- Only half of women in developing regions receive the recommended amount of health care they need.
- Fewer teens are having children in most developing regions, but progress has slowed. The large increase in contraceptive use in the 1990s was not matched in the 2000s.

- The need for family planning is slowly being met for more women, but demand is increasing at a rapid pace.
- At the end of 2014, there were 13.6 million people accessing antiretroviral therapy.
- New HIV infections in 2013 were estimated at 2.1 million, which was 38% lower than in 2001.
- At the end of 2013, there were an estimated 35 million people living with HIV.
- At the end of 2013, 240,000 children were newly infected with HIV.
- New HIV infections among children have declined by 58% since 2001.
- Globally, adolescent girls and young women face gender-based inequalities, exclusion, discrimination, and violence, which put them at increased risk of acquiring HIV.
- HIV is the leading cause of death for women of reproductive age worldwide.
- Tuberculosis deaths in people living with HIV have fallen by 36% since 2004.
- There were 250,000 new HIV infections among adolescents in 2013, two thirds of which were among adolescent girls.
- AIDS is now the leading cause of death among adolescents (aged 10–19) in Africa and the second most common cause of death among adolescents globally.
- In many settings, adolescent girls' right to privacy and bodily autonomy is not respected, as many report that their first sexual experience was forced.
- As of 2013, 2.1 million adolescents were living with HIV.
- Over 6.2 million malaria deaths have been averted between 2000 and 2015, primarily of children under 5 years of age in sub-Saharan Africa. The global malaria incidence rate has fallen by an estimated 37% and the mortality rates by 58%.
- Between 2000 and 2013, tuberculosis prevention, diagnosis, and treatment interventions saved an estimated 37 million lives. The tuberculosis mortality rate fell by 45% and the prevalence rate by 41% between 1990 and 2013.

5 Goal 4: Quality Education

5.1 Ensure Inclusive and Quality Education for All and Promote Lifelong Learning

Obtaining a quality education is the foundation to improving people's lives and sustainable development. Major progress has been made toward increasing access to education at all levels and increasing enrollment rates in schools particularly for women and girls. Basic literacy skills have improved tremendously, yet bolder efforts are needed to make even greater strides for achieving universal education goals. For example, the world has achieved equality in primary education between girls and boys, but few countries have achieved that target at all levels of education.

Goal 4 Targets

- By 2030, ensure that all girls and boys complete free, equitable, and quality primary and secondary education leading to relevant and Goal 4 effective learning outcomes.
- By 2030, ensure that all girls and boys have access to quality early childhood development, care, and preprimary education so that they are ready for primary education.
- By 2030, ensure equal access for all women and men to affordable and quality technical, vocational, and tertiary education, including university.
- By 2030, substantially increase the number of youth and adults who have relevant skills, including technical and vocational skills, for employment, decent jobs, and entrepreneurship.
- By 2030, eliminate gender disparities in education, and ensure equal access to all levels of education and vocational training for the vulnerable, including persons with disabilities, indigenous peoples, and children in vulnerable situations.
- By 2030, ensure that all youth and a substantial proportion of adults, both men and women, achieve literacy and numeracy.
- By 2030, ensure that all learners acquire the knowledge and skills needed to promote sustainable development, including, among others, through education for sustainable development and sustainable lifestyles, human rights, gender equality, promotion of a culture of peace and non-violence, global citizenship, and appreciation of cultural diversity and of culture's contribution to sustainable development.
- Build and upgrade education facilities that are child, disability, and gender sensitive, and provide safe, nonviolent, inclusive, and effective learning environments for all.
- By 2020, substantially expand globally the number of scholarships available to developing countries, in particular least developed countries, small island developing states, and African countries, for enrollment in higher education, including vocational training and information and communications technology, technical, engineering, and scientific programs, in developed countries and other developing countries.
- By 2030, substantially increase the supply of qualified teachers, including through international cooperation for teacher training in developing countries, especially least developed countries and small island developing states.

Facts and Figures

- Enrollment in primary education in developing countries has reached 91%, but 57 million children remain out of school.
- More than half of children that have not enrolled in school live in sub-Saharan Africa.
- An estimated 50% of out-of-school children of primary school age live in conflict-affected areas.
- One hundred three million youth worldwide lack basic literacy skills, and more than 60% of them are women.

6 Goal 5: Gender Equality

6.1 Achieve Gender Equality and Empower All Women and Girls

While the world has achieved progress toward gender equality and women's empowerment under the Millennium Development Goals (including equal access to primary education between girls and boys), women and girls continue to suffer discrimination and violence in every part of the world.

Gender equality is not only a fundamental human right, but a necessary foundation for a peaceful, prosperous, and sustainable world.

Providing women and girls with equal access to education, health care, decent work, and representation in political and economic decision-making processes will fuel sustainable economies and benefit societies and humanity at large.

Goal 5 Targets

- End all forms of discrimination against all women and girls everywhere.
- Eliminate all forms of violence against all women and girls in the public and private spheres, including trafficking and sexual and other types of exploitation.
- Eliminate all harmful practices, such as child, early, and forced marriage and female genital mutilation.
- Recognize and value unpaid care and domestic work through the provision of public services, infrastructure, and social protection policies and the promotion of shared responsibility within the household and the family as nationally appropriate.
- Ensure women's full and effective participation and equal opportunities for leadership at all levels of decision-making in political, economic, and public life.
- Ensure universal access to sexual and reproductive health and reproductive rights as agreed in accordance with the Programme of Action of the International Conference on Population and Development and the Beijing Platform for Action and the outcome documents of their review conferences.
- Undertake reforms to give women equal rights to economic resources, as well as access to ownership and control over land and other forms of property, financial services, inheritance, and natural resources, in accordance with national laws.
- Enhance the use of enabling technology, in particular information and communications technology, to promote the empowerment of women.
- Adopt and strengthen sound policies and enforceable legislation for the promotion of gender equality and the empowerment of all women and girls at all levels.

Facts and Figures

- About two thirds of countries in the developing regions have achieved gender parity in primary education.
- In Southern Asia, only 74 girls were enrolled in primary school for every 100 boys in 1990. By 2012, the enrollment ratios were the same for girls as for boys.
- In sub-Saharan Africa, Oceania, and Western Asia, girls still face barriers to entering both primary and secondary schools.

- Women in Northern Africa hold less than one in five paid jobs in the non-agricultural sector. The proportion of women in paid employment outside the agriculture sector has increased from 35% in 1990 to 41% in 2015.
- In 46 countries, women now hold more than 30% of seats in national parliament in at least 1 chamber.

7 Goal 6: Clean Water and Sanitation

7.1 Ensure Access to Water and Sanitation for All

Clean, accessible water for all is an essential part of the world we want to live in. There is sufficient fresh water on the planet to achieve this. But due to bad economics or poor infrastructure, every year millions of people, most of them children, die from diseases associated with inadequate water supply, sanitation, and hygiene.

Water scarcity, poor water quality, and inadequate sanitation negatively impact food security, livelihood choices, and educational opportunities for poor families across the world. Drought afflicts some of the world's poorest countries, worsening hunger and malnutrition.

By 2050, at least one in four people is likely to live in a country affected by chronic or recurring shortages of fresh water.

Goal 6 Targets

- By 2030, achieve universal and equitable access to safe and affordable drinking water for all.
- By 2030, achieve access to adequate and equitable sanitation and hygiene for all, and end open defecation, paying special attention to the needs of women and girls and those in vulnerable situations.
- By 2030, improve water quality by reducing pollution, eliminating dumping and minimizing release of hazardous chemicals and materials, halving the proportion of untreated wastewater, and substantially increasing recycling and safe reuse globally.
- By 2030, substantially increase water use efficiency across all sectors, and ensure sustainable withdrawals and supply of fresh water to address water scarcity and substantially reduce the number of people suffering from water scarcity.
- By 2030, implement integrated water resources management at all levels, including through trans-boundary cooperation as appropriate.
- By 2020, protect and restore water-related ecosystems, including mountains, forests, wetlands, rivers, aquifers, and lakes.
- By 2030, expand international cooperation and capacity-building support to developing countries in water- and sanitation-related activities and programs, including water harvesting, desalination, water efficiency, wastewater treatment, recycling, and reuse technologies.
- Support and strengthen the participation of local communities in improving water and sanitation management.

Facts and Figures

- 2.6 billion people have gained access to improved drinking water sources since 1990, but 663 million people are still without.
- At least 1.8 billion people globally use a source of drinking water that is fecally contaminated.
- Between 1990 and 2015, the proportion of the global population using an improved drinking water source has increased from 76% to 91%.
- But water scarcity affects more than 40% of the global population and is projected to rise. Over 1.7 billion people are currently living in river basins where water use exceeds recharge.
- 2.4 billion people lack access to basic sanitation services, such as toilets or latrines.
- More than 80% of wastewater resulting from human activities is discharged into rivers or sea without any pollution removal.
- Each day, nearly 1000 children die due to preventable water- and sanitation-related diarrheal diseases.
- Hydropower is the most important and widely used renewable source of energy and, as of 2011, represented 16% of total electricity production worldwide.
- Approximately 70% of all water abstracted from rivers, lakes, and aquifers is used for irrigation.
- Floods and other water-related disasters account for 70% of all deaths related to natural disaster.

8 Goal 7: Affordable and Clean Energy

8.1 Ensure Access to Affordable, Reliable, Sustainable, and Modern Energy for All

Energy is central to nearly every major challenge and opportunity the world faces today. Be it for jobs, security, climate change, food production or increasing incomes, access to energy for all is essential.

Sustainable energy is opportunity – it transforms lives, economies, and the planet.

UN Secretary-General Ban Ki-moon is leading a Sustainable Energy for All initiative to ensure universal access to modern energy services, improve efficiency, and increase use of renewable sources.

Goal 7 Targets

- By 2030, ensure universal access to affordable, reliable, and modern energy services.
- By 2030, increase substantially the share of renewable energy in the global energy mix.
- By 2030, double the global rate of improvement in energy efficiency.
- By 2030, enhance international cooperation to facilitate access to clean energy research and technology, including renewable energy, energy efficiency, and

advanced and cleaner fossil fuel technology, and promote investment in energy infrastructure and clean energy technology.

- By 2030, expand infrastructure and upgrade technology for supplying modern and sustainable energy services for all in developing countries, in particular least developed countries, small island developing states, and landlocked developing countries, in accordance with their respective programs of support.

Facts and Figures

- One in five people still lacks access to modern electricity.
- Three billion people rely on wood, coal, charcoal, or animal waste for cooking and heating.
- Energy is the dominant contributor to climate change, accounting for around 60% of total global greenhouse gas emissions.
- Reducing the carbon intensity of energy is a key objective in long-term climate goals.

9 Goal 8: Decent Work and Economic Growth

9.1 Promote Inclusive and Sustainable Economic Growth, Employment, and Decent Work for All

Roughly half the world's population still lives on the equivalent of about US $2 a day. And in too many places, having a job doesn't guarantee the ability to escape from poverty. This slow and uneven progress requires us to rethink and retool our economic and social policies aimed at eradicating poverty.

A continued lack of decent work opportunities, insufficient investments, and underconsumption lead to an erosion of the basic social contract underlying democratic societies: that all must share in progress. The creation of quality jobs will remain a major challenge for almost all economies well beyond 2015.

Sustainable economic growth will require societies to create the conditions that allow people to have quality jobs that stimulate the economy while not harming the environment. Job opportunities and decent working conditions are also required for the whole working age population.

Goal 8 Targets

- Sustain per capita economic growth in accordance with national circumstances and, in particular, at least 7% gross domestic product growth per annum in the least developed countries.
- Achieve higher levels of economic productivity through diversification, technological upgrading, and innovation, including through a focus on high value-added and labor-intensive sectors.
- Promote development-oriented policies that support productive activities, decent job creation, entrepreneurship, creativity, and innovation, and encourage the formalization and growth of micro-, small-, and medium-sized enterprises, including through access to financial services.

- Improve progressively, through 2030, global resource efficiency in consumption and production and endeavor to decouple economic growth from environmental degradation, in accordance with the 10-year framework of programs on sustainable consumption and production, with developed countries taking the lead.
- By 2030, achieve full and productive employment and decent work for all women and men, including for young people and persons with disabilities, and equal pay for work of equal value.
- By 2020, substantially reduce the proportion of youth not in employment, education, or training.
- Take immediate and effective measures to eradicate forced labor, end modern slavery and human trafficking, and secure the prohibition and elimination of the worst forms of child labor, including recruitment and use of child soldiers, and by 2025 end child labor in all its forms.
- Protect labor rights and promote safe and secure working environments for all workers, including migrant workers, in particular women migrants, and those in precarious employment.
- By 2030, devise and implement policies to promote sustainable tourism that creates jobs and promotes local culture and products.
- Strengthen the capacity of domestic financial institutions to encourage and expand access to banking, insurance, and financial services for all.
- Increase Aid for Trade support for developing countries, in particular least developed countries, including through the Enhanced Integrated Framework for Trade-Related Technical Assistance to Least Developed Countries.
- By 2020, develop and operationalize a global strategy for youth employment and implement the Global Jobs Pact of the International Labour Organization.

Facts and Figures

- Global unemployment increased from 170 million in 2007 to nearly 202 million in 2012, of which about 75 million are young women and men.
- Nearly 2.2 billion people live below the US $2 poverty line, and poverty eradication is only possible through stable and well-paid jobs.
- Four hundred seventy million jobs are needed globally for new entrants to the labor market between 2016 and 2030.

10 Goal 9: Industry, Innovation, and Infrastructure

10.1 Build Resilient Infrastructure, Promote Sustainable Industrialization, and Foster Innovation

Investments in infrastructure – transport, irrigation, energy, and information and communication technology – are crucial to achieving sustainable development and empowering communities in many countries. It has long been recognized that growth in productivity and incomes and improvements in health and education outcomes require investment in infrastructure.

Inclusive and sustainable industrial development is the primary source of income generation, allows for rapid and sustained increases in living standards for all people, and provides the technological solutions to environmentally sound industrialization.

Technological progress is the foundation of efforts to achieve environmental objectives, such as increased resource and energy efficiency. Without technology and innovation, industrialization will not happen, and without industrialization, development will not happen.

Goal 9 Targets

- Develop quality, reliable, sustainable, and resilient infrastructure, including regional and transborder infrastructure, to support economic development and human well-being, with a focus on affordable and equitable access for all.
- Promote inclusive and sustainable industrialization, and, by 2030, significantly raise industry's share of employment and gross domestic product, in line with national circumstances, and double its share in least developed countries.
- Increase the access of small-scale industrial and other enterprises, in particular in developing countries, to financial services, including affordable credit, and their integration into value chains and markets.
- By 2030, upgrade infrastructure and retrofit industries to make them sustainable, with increased resource use efficiency and greater adoption of clean and environmentally sound technologies and industrial processes, with all countries taking action in accordance with their respective capabilities.
- Enhance scientific research; upgrade the technological capabilities of industrial sectors in all countries, in particular developing countries, including, by 2030, encouraging innovation and substantially increasing the number of research and development workers per one million people and public and private research and development spending.
- Facilitate sustainable and resilient infrastructure development in developing countries through enhanced financial, technological, and technical support to African countries, least developed countries, landlocked developing countries, and small island developing states.
- Support domestic technology development, research, and innovation in developing countries, including by ensuring a conducive policy environment for, inter alia, industrial diversification and value addition to commodities.
- Significantly increase access to information and communications technology, and strive to provide universal and affordable access to the Internet in least developed countries by 2020.

Facts and Figures

- Basic infrastructure like roads, information and communication technologies, sanitation, electrical power, and water remains scarce in many developing countries.
- About 2.6 billion people in the developing world are facing difficulties in accessing electricity full time.

- 2.5 billion people worldwide lack access to basic sanitation, and almost 800 million people lack access to water, many hundreds of millions of them in sub-Saharan Africa and South Asia.
- 1–1.5 billion people do not have access to reliable phone services.
- Quality infrastructure is positively related to the achievement of social, economic, and political goals.
- Inadequate infrastructure leads to a lack of access to markets, jobs, information, and training, creating a major barrier to doing business.
- Undeveloped infrastructures limit access to health care and education.
- For many African countries, particularly the lower-income countries, the existent constraints regarding infrastructure affect firm productivity by around 40%.
- Manufacturing is an important employer, accounting for around 470 million jobs worldwide in 2009 – or around 16% of the world's workforce of 2.9 billion. In 2013, it is estimated that there were more than half a billion jobs in manufacturing.
- Industrialization's job multiplication effect has a positive impact on society. Every 1 job in manufacturing creates 2.2 jobs in other sectors.
- Small- and medium-sized enterprises that engage in industrial processing and manufacturing are the most critical for the early stages of industrialization and are typically the largest job creators. They make up over 90% of business worldwide and account for between 50% and 60% of employment.
- In countries where data are available, the number of people employed in renewable energy sectors is presently around 2.3 million. Given the present gaps in information, this is no doubt a very conservative figure. Because of strong rising interest in energy alternatives, the possible total employment for renewables by 2030 is 20 million jobs.
- Least developed countries have immense potential for industrialization in food and beverages (agro-industry), and textiles and garments, with good prospects for sustained employment generation and higher productivity.
- Middle-income countries can benefit from entering the basic and fabricated metal industries, which offer a range of products facing rapidly growing international demand.
- In developing countries, barely 30% of agricultural production undergoes industrial processing. In high-income countries, 98% is processed. This suggests that there are great opportunities for developing countries in agribusiness.

11 Goal 10: Reduced Inequalities

11.1 Reduce Inequality Within and Among Countries

The international community has made significant strides toward lifting people out of poverty. The most vulnerable nations – the least developed countries, the landlocked developing countries, and the small island developing states – continue to make inroads into poverty reduction. However, inequality still persists and large disparities remain in access to health and education services and other assets.

Additionally, while income inequality between countries may have been reduced, inequality within countries has risen. There is growing consensus that economic growth is not sufficient to reduce poverty if it is not inclusive and if it does not involve the three dimensions of sustainable development – economic, social, and environmental.

To reduce inequality, policies should be universal in principle paying attention to the needs of disadvantaged and marginalized populations.

Goal 10 Targets

- By 2030, progressively achieve and sustain income growth of the bottom 40% of the population at a rate higher than the national average.
- By 2030, empower and promote the social, economic, and political inclusion of all, irrespective of age, sex, disability, race, ethnicity, origin, religion, or economic or other status.
- Ensure equal opportunity and reduce inequalities of outcome, including by eliminating discriminatory laws, policies, and practices and promoting appropriate legislation, policies, and action in this regard.
- Adopt policies, especially fiscal, wage, and social protection policies, and progressively achieve greater equality.
- Improve the regulation and monitoring of global financial markets and institutions and strengthen the implementation of such regulations.
- Ensure enhanced representation and voice for developing countries in decision-making in global international economic and financial institutions in order to deliver more effective, credible, accountable, and legitimate institutions.
- Facilitate orderly, safe, regular, and responsible migration and mobility of people, including through the implementation of planned and well-managed migration policies.
- Implement the principle of special and differential treatment for developing countries, in particular least developed countries, in accordance with the World Trade Organization agreements.
- Encourage official development assistance and financial flows, including foreign direct investment, to states where the need is greatest, in particular least developed countries, African countries, small island developing states, and landlocked developing countries, in accordance with their national plans and programs.
- By 2030, reduce to less than 3% the transaction costs of migrant remittances, and eliminate remittance corridors with costs higher than 5%.
- More must be done to stop babies from dying the day they are born, United Nations agencies said in a new report issued Thursday, which argued that life-saving know-how and technologies must be made readily available – particularly in Southern Asia and sub-Saharan Africa – where they are most needed.

Facts and Figures

- On average – and taking into account population size – income inequality increased by 11% in developing countries between 1990 and 2010.
- A significant majority of households in developing countries – more than 75% of the population – are living today in societies where income is more unequally distributed than it was in the 1990s.

- Evidence shows that, beyond a certain threshold, inequality harms growth and poverty reduction, the quality of relations in the public and political spheres, and individuals' sense of fulfillment and self-worth.
- There is nothing inevitable about growing income inequality; several countries have managed to contain or reduce income inequality while achieving strong growth performance.
- Income inequality cannot be effectively tackled unless the underlying inequality of opportunities is addressed.
- In a global survey conducted by UN Development Programme, policymakers from around the world acknowledged that inequality in their countries is generally high and potentially a threat to long-term social and economic development.
- Evidence from developing countries shows that children in the poorest 20% of the populations are still up to three times more likely to die before their fifth birthday than children in the richest quintiles.
- Social protection has been significantly extended globally, yet persons with disabilities are up to five times more likely than average to incur catastrophic health expenditures.
- Despite overall declines in maternal mortality in the majority of developing countries, women in rural areas are still up to three times more likely to die while giving birth than women living in urban centers.

12 Goal 11: Sustainable Cities and Communities

12.1 Make Cities Inclusive, Safe, Resilient, and Sustainable

Cities are hubs for ideas, commerce, culture, science, productivity, social development, and much more. At their best, cities have enabled people to advance socially and economically.

However, many challenges exist to maintaining cities in a way that continues to create jobs and prosperity while not straining land and resources. Common urban challenges include congestion, lack of funds to provide basic services, a shortage of adequate housing, and declining infrastructure.

The challenges cities face can be overcome in ways that allow them to continue to thrive and grow while improving resource use and reducing pollution and poverty. The future we want includes cities of opportunities for all, with access to basic services, energy, housing, transportation, and more.

Goal 11 Targets

- By 2030, ensure access for all to adequate, safe, and affordable housing and basic services and upgrade slums.

- By 2030, provide access to safe, affordable, accessible, and sustainable transport systems for all, improving road safety, notably by expanding public transport, with special attention to the needs of those in vulnerable situations, women, children, persons with disabilities, and older persons.
- By 2030, enhance inclusive and sustainable urbanization and capacity for participatory, integrated, and sustainable human settlement planning and management in all countries.
- Strengthen efforts to protect and safeguard the world's cultural and natural heritage.
- By 2030, significantly reduce the number of deaths and the number of people affected, and substantially decrease the direct economic losses relative to global gross domestic product caused by disasters, including water-related disasters, with a focus on protecting the poor and people in vulnerable situations.
- By 2030, reduce the adverse per capita environmental impact of cities, including by paying special attention to air quality and municipal and other waste management.
- By 2030, provide universal access to safe, inclusive and accessible, and green and public spaces, in particular for women and children, older persons, and persons with disabilities.
- Support positive economic, social, and environmental links between urban, peri-urban, and rural areas by strengthening national and regional development planning.
- By 2020, substantially increase the number of cities and human settlements adopting and implementing integrated policies and plans toward inclusion, resource efficiency, mitigation and adaptation to climate change, and resilience to disasters, and develop and implement, in line with the Sendai Framework for Disaster Risk Reduction 2015–2030, holistic disaster risk management at all levels.
- Support least developed countries, including through financial and technical assistance, in building sustainable and resilient buildings utilizing local materials.

Facts and Figures

- Half of humanity – 3.5 billion people – lives in cities today.
- By 2030, almost 60% of the world's population will live in urban areas.
- Ninety-five percent of urban expansion in the next decades will take place in developing world.
- Eight hundred twenty-eight million people live in slums today, and the number keeps rising.
- The world's cities occupy just 3% of the Earth's land but account for 60–80% of energy consumption and 75% of carbon emissions.
- Rapid urbanization is exerting pressure on freshwater supplies, sewage, the living environment, and public health.
- But the high density of cities can bring efficiency gains and technological innovation while reducing resource and energy consumption.

13 Goal 12: Responsible Consumption and Production

13.1 Ensure Sustainable Consumption and Production Patterns

Sustainable consumption and production is about promoting resource and energy efficiency and sustainable infrastructure and providing access to basic services, green and decent jobs, and a better quality of life for all. Its implementation helps to achieve overall development plans; reduce future economic, environmental, and social costs; strengthen economic competitiveness; and reduce poverty.

Sustainable consumption and production aims at "doing more and better with less," increasing net welfare gains from economic activities by reducing resource use, degradation, and pollution along the whole life cycle while increasing quality of life. It involves different stakeholders, including business, consumers, policymakers, researchers, scientists, retailers, media, and development cooperation agencies, among others.

It also requires a systemic approach and cooperation among actors operating in the supply chain, from producer to final consumer. It involves engaging consumers through awareness-raising and education on sustainable consumption and lifestyles, providing consumers with adequate information through standards and labels, and engaging in sustainable public procurement, among others.

Goal 12 Targets

- Implement the 10-year framework of programs on sustainable consumption and production, all countries taking action, with developed countries taking the lead, taking into account the development and capabilities of developing countries.
- By 2030, achieve the sustainable management and efficient use of natural resources.
- By 2030, halve per capita global food waste at the retail and consumer levels, and reduce food losses along production and supply chains, including postharvest losses.
- By 2020, achieve the environmentally sound management of chemicals and all wastes throughout their life cycle, in accordance with agreed international frameworks, and significantly reduce their release to air, water, and soil in order to minimize their adverse impacts on human health and the environment.
- By 2030, substantially reduce waste generation through prevention, reduction, recycling, and reuse.
- Encourage companies, especially large and transnational companies, to adopt sustainable practices and to integrate sustainability information into their reporting cycle.
- Promote public procurement practices that are sustainable, in accordance with national policies and priorities.
- By 2030, ensure that people everywhere have the relevant information and awareness for sustainable development and lifestyles in harmony with nature.

- Support developing countries to strengthen their scientific and technological capacity to move toward more sustainable patterns of consumption and production.
- Develop and implement tools to monitor sustainable development impacts for sustainable tourism that creates jobs and promotes local culture and products.
- Rationalize inefficient fossil fuel subsidies that encourage wasteful consumption by removing market distortions, in accordance with national circumstances, including by restructuring taxation and phasing out those harmful subsidies, where they exist, to reflect their environmental impacts, taking fully into account the specific needs and conditions of developing countries and minimizing the possible adverse impacts on their development in a manner that protects the poor and the affected communities.

Facts and Figures

- Each year, an estimated one third of all food produced – equivalent to 1.3 billion tonnes worth around $1 trillion – ends up rotting in the bins of consumers and retailers or spoiling due to poor transportation and harvesting practices.
- If people worldwide switched to energy-efficient lightbulbs, the world would save US $120 billion annually.
- Should the global population reach 9.6 billion by 2050, the equivalent of almost three planets could be required to provide the natural resources needed to sustain current lifestyles.
- Less than 3% of the world's water is fresh (drinkable), of which 2.5% is frozen in the Antarctica, Arctic, and glaciers. Humanity must therefore rely on 0.5% for all of man's ecosystem's and freshwater needs.
- Man is polluting water faster than nature can recycle and purify water in rivers and lakes.
- More than 1 billion people still do not have access to fresh water.
- Excessive use of water contributes to the global water stress.
- Water is free from nature, but the infrastructure needed to deliver it is expensive.
- Despite technological advances that have promoted energy efficiency gains, energy use in OECD countries will continue to grow another 35% by 2020. Commercial and residential energy use is the second most rapidly growing area of global energy use after transport.
- In 2002 the motor vehicle stock in OECD countries was 550 million vehicles (75% of which were personal cars). A 32% increase in vehicle ownership is expected by 2020. At the same time, motor vehicle kilometers are projected to increase by 40%, and global air travel is projected to triple in the same period.
- Households consume 29% of global energy and consequently contribute to 21% of resultant CO2 emissions.
- One fifth of the world's final energy consumption in 2013 was from renewables.

- While substantial environmental impacts from food occur in the production phase (agriculture, food processing), households influence these impacts through their dietary choices and habits. This consequently affects the environment through food-related energy consumption and waste generation.
- 1.3 billion tonnes of food is wasted every year, while almost 1 billion people go undernourished and another 1 billion hungry.
- Overconsumption of food is detrimental to our health and the environment.
- Two billion people globally are overweight or obese.
- Land degradation, declining soil fertility, unsustainable water use, overfishing, and marine environment degradation are all lessening the ability of the natural resource base to supply food.
- The food sector accounts for around 30% of the world's total energy consumption and accounts for around 22% of total greenhouse gas emissions.

14 Goal 13: Climate Action

14.1 Take Urgent Action to Combat Climate Change and Its Impacts

Climate change is now affecting every country on every continent. It is disrupting national economies and affecting lives, costing people, communities, and countries dearly today and even more tomorrow.

People are experiencing the significant impacts of climate change, which include changing weather patterns, rising sea level, and more extreme weather events. The greenhouse gas emissions from human activities are driving climate change and continue to rise. They are now at their highest levels in history. Without action, the world's average surface temperature is projected to rise over the twenty-first century and is likely to surpass 3 °C this century – with some areas of the world expected to warm even more. The poorest and most vulnerable people are being affected the most.

Affordable, scalable solutions are now available to enable countries to leapfrog to cleaner, more resilient economies. The pace of change is quickening as more people are turning to renewable energy and a range of other measures that will reduce emissions and increase adaptation efforts.

But climate change is a global challenge that does not respect national borders. Emissions anywhere affect people every.

Goal 13 Targets

- Strengthen resilience and adaptive capacity to climate-related hazards and natural disasters in all countries.
- Integrate climate change measures into national policies, strategies, and planning.

- Improve education, awareness-raising, and human and institutional capacity on climate change mitigation, adaptation, impact reduction, and early warning.
- Implement the commitment undertaken by developed country parties to the United Nations Framework Convention on Climate Change to a goal of mobilizing jointly $100 billion annually by 2020 from all sources to address the needs of developing countries in the context of meaningful mitigation actions and transparency on implementation and fully operationalize the Green Climate Fund through its capitalization as soon as possible.
- Promote mechanisms for raising capacity for effective climate change-related planning and management in least developed countries and small island developing states, including focusing on women, youth, and local and marginalized communities.
- Acknowledge that the United Nations Framework Convention on Climate Change is the primary international, intergovernmental forum for negotiating the global response to climate change.

Facts and Figures

- From 1880 to 2012, average global temperature increased by 0.85 °C. To put this into perspective, for each 1° of temperature increase, grain yields decline by about 5%. Maize, wheat, and other major crops have experienced significant yield reductions at the global level of 40 Mg per year between 1981 and 2002 due to a warmer climate.
- Oceans have warmed, the amounts of snow and ice have diminished, and sea level has risen. From 1901 to 2010, the global average sea level rose by 19 cm as oceans expanded due to warming and ice melted. The Arctic's sea ice extent has shrunk in every successive decade since 1979, with 1.07 million km^2 of ice loss every decade.
- Given current concentrations and ongoing emissions of greenhouse gases, it is likely that by the end of this century, the increase in global temperature will exceed 1.5 °C compared to 1850–1900 for all but one scenario. The world's oceans will warm and ice melt will continue. Average sea level rise is predicted as 24–30 cm by 2065 and 40–63 cm by 2100. Most aspects of climate change will persist for many centuries even if emissions are stopped.
- Global emissions of carbon dioxide (CO2) have increased by almost 50% since 1990.
- Emissions grew more quickly between 2000 and 2010 than in each of the three previous decades.
- It is still possible, using a wide array of technological measures and changes in behavior, to limit the increase in global mean temperature to 2 °C above pre-industrial levels.
- Major institutional and technological change will give a better than even chance that global warming will not exceed this threshold.

15 Goal 14: Life Below Water

15.1 Conserve and Sustainably Use the Oceans, Seas, and Marine Resources

The world's oceans – their temperature, chemistry, currents, and life – drive global systems that make the Earth habitable for humankind.

Our rainwater, drinking water, weather, climate, coastlines, much of our food, and even the oxygen in the air we breathe are all ultimately provided and regulated by the sea. Throughout history, oceans and seas have been vital conduits for trade and transportation.

Careful management of this essential global resource is a key feature of a sustainable future.

Goal 14 Targets

- By 2025, prevent and significantly reduce marine pollution of all kinds, in particular from land-based activities, including marine debris and nutrient pollution.
- By 2020, sustainably manage and protect marine and coastal ecosystems to avoid significant adverse impacts, including by strengthening their resilience, and take action for their restoration in order to achieve healthy and productive oceans.
- Minimize and address the impacts of ocean acidification, including through enhanced scientific cooperation at all levels. By 2020, effectively regulate harvesting and end overfishing, illegal, unreported, and unregulated fishing and destructive fishing practices, and implement science-based management plans, in order to restore fish stocks in the shortest time feasible, at least to levels that can produce maximum sustainable yield as determined by their biological characteristics.
- By 2020, conserve at least 10% of coastal and marine areas, consistent with national and international law and based on the best available scientific information.
- By 2020, prohibit certain forms of fisheries subsidies which contribute to overcapacity and overfishing; eliminate subsidies that contribute to illegal, unreported, and unregulated fishing; and refrain from introducing new such subsidies, recognizing that appropriate and effective special and differential treatment for developing and least developed countries should be an integral part of the World Trade Organization fisheries subsidies negotiation.
- By 2030, increase the economic benefits to small island developing states and least developed countries from the sustainable use of marine resources, including through sustainable management of fisheries, aquaculture, and tourism.
- Increase scientific knowledge, develop research capacity, and transfer marine technology, taking into account the Intergovernmental Oceanographic Commission Criteria and Guidelines on the Transfer of Marine Technology, in order to improve ocean health and to enhance the contribution of marine biodiversity to

the development of developing countries, in particular small island developing states and least developed countries.
- Provide access for small-scale artisanal fisheries to marine resources and markets.
- Enhance the conservation and sustainable use of oceans and their resources by implementing international law as reflected in UNCLOS, which provides the legal framework for the conservation and sustainable use of oceans and their resources, as recalled in paragraph 158 of The Future We Want.

Facts and Figures
- Oceans cover three quarters of the Earth's surface, contain 97% of the Earth's water, and represent 99% of the living space on the planet by volume.
- Over three billion people depend on marine and coastal biodiversity for their livelihoods.
- Globally, the market value of marine and coastal resources and industries is estimated at $3 trillion per year or about 5% of global GDP.
- Oceans contain nearly 200,000 identified species, but actual numbers may lie in the millions.
- Oceans absorb about 30% of carbon dioxide produced by humans, buffering the impacts of global warming.
- Oceans serve as the world's largest source of protein, with more than three billion people depending on the oceans as their primary source of protein.
- Marine fisheries directly or indirectly employ over 200 million people.
- Subsidies for fishing are contributing to the rapid depletion of many fish species and are preventing efforts to save and restore global fisheries and related jobs, causing ocean fisheries to generate US$ 50 billion less per year than they could.
- As much as 40% of the world oceans are heavily affected by human activities, including pollution, depleted fisheries, and loss of coastal habitats.

16 Goal 15: Life on Land

16.1 Sustainably Manage Forests, Combat Desertification, Halt and Reverse Land Degradation, and Halt Biodiversity Loss

Forests cover 30% of the Earth's surface, and in addition to providing food security and shelter, forests are key to combating climate change and protecting biodiversity and the homes of the indigenous population. Thirteen million hectares of forests are being lost every year, while the persistent degradation of drylands has led to the desertification of 3.6 billion hectares.

Deforestation and desertification – caused by human activities and climate change – pose major challenges to sustainable development and have affected the lives and livelihoods of millions of people in the fight against poverty. Efforts are being made to manage forests and combat desertification.

Goal 15 Targets

- By 2020, ensure the conservation, restoration, and sustainable use of terrestrial and inland freshwater ecosystems and their services, in particular forests, wetlands, mountains, and drylands, in line with obligations under international agreements.
- By 2020, promote the implementation of sustainable management of all types of forests, halt deforestation, restore degraded forests, and substantially increase afforestation and reforestation globally.
- By 2030, combat desertification; restore degraded land and soil, including land affected by desertification, drought, and floods; and strive to achieve a land degradation-neutral world.
- By 2030, ensure the conservation of mountain ecosystems, including their biodiversity, in order to enhance their capacity to provide benefits that are essential for sustainable development.
- Take urgent and significant action to reduce the degradation of natural habitats, halt the loss of biodiversity, and, by 2020, protect and prevent the extinction of threatened species.
- Promote fair and equitable sharing of the benefits arising from the utilization of genetic resources, and promote appropriate access to such resources, as internationally agreed.
- Take urgent action to end poaching and trafficking of protected species of flora and fauna, and address both demand and supply of illegal wildlife products.
- By 2020, introduce measures to prevent the introduction and significantly reduce the impact of invasive alien species on land and water ecosystems and control or eradicate the priority species.
- By 2020, integrate ecosystem and biodiversity values into national and local planning, development processes, and poverty reduction strategies and accounts.
- Mobilize and significantly increase financial resources from all sources to conserve and sustainably use biodiversity and ecosystems.
- Mobilize significant resources from all sources and at all levels to finance sustainable forest management, and provide adequate incentives to developing countries to advance such management, including for conservation and reforestation.
- Enhance global support for efforts to combat poaching and trafficking of protected species, including by increasing the capacity of local communities to pursue sustainable livelihood opportunities.

Facts and Figures

- Around 1.6 billion people depend on forests for their livelihood. This includes some 70 million indigenous people.
- Forests are home to more than 80% of all terrestrial species of animals, plants, and insects.
- 2.6 billion people depend directly on agriculture, but 52% of the land used for agriculture is moderately or severely affected by soil degradation.
- As of 2008, land degradation affected 1.5 billion people globally.
- Arable land loss is estimated at 30–35 times the historical rate.

- Due to drought and desertification, each year 12 million hectares are lost (23 ha per minute), where 20 million tons of grain could have been grown.
- Seventy-four percent of the poor are directly affected by land degradation globally.
- Of the 8300 animal breeds known, 8% are extinct and 22% are at risk of extinction.
- Of the over 80,000 tree species, less than 1% have been studied for potential use.
- Fish provide 20% of animal protein to about 3 billion people. Only ten species provide about 30% of marine capture fisheries, and ten species provide about 50% of aquaculture production.
- Over 80% of the human diet is provided by plants. Only three cereal crops – rice, maize, and wheat – provide 60% of energy intake.
- As many as 80% of people living in rural areas in developing countries rely on traditional plant-based medicines for basic health care.
- Microorganisms and invertebrates are key to ecosystem services, but their contributions are still poorly known and rarely acknowledged.

17 Goal 16: Peace, Justice, and Strong Institutions

17.1 Promote Just, Peaceful, and Inclusive Societies

Goal 16 of the Sustainable Development Goals is dedicated to the promotion of peaceful and inclusive societies for sustainable development, the provision of access to justice for all, and building effective, accountable institutions at all levels.

Goal 16 Targets

- Significantly reduce all forms of violence and related death rates everywhere.
- End abuse, exploitation, trafficking, and all forms of violence against and torture of children.
- Promote the rule of law at the national and international levels and ensure equal access to justice for all.
- By 2030, significantly reduce illicit financial and arms flows, strengthen the recovery and return of stolen assets, and combat all forms of organized crime.
- Substantially reduce corruption and bribery in all their forms.
- Develop effective, accountable, and transparent institutions at all levels.
- Ensure responsive, inclusive, participatory, and representative decision-making at all levels.
- Broaden and strengthen the participation of developing countries in the institutions of global governance.
- By 2030, provide legal identity for all, including birth registration.
- Ensure public access to information and protect fundamental freedoms, in accordance with national legislation and international agreements.
- Strengthen relevant national institutions, including through international cooperation, for building capacity at all levels, in particular in developing countries, to prevent violence and combat terrorism and crime.

- Promote and enforce nondiscriminatory laws and policies for sustainable development.

Facts and Figures

- Among the institutions most affected by corruption are the judiciary and police.
- Corruption, bribery, theft, and tax evasion cost some US $1.26 trillion for developing countries per year; this amount of money could be used to lift those who are living on less than $1.25 a day and above $1.25 for at least 6 years.
- The rate of children leaving primary school in conflict-affected countries reached 50% in 2011, which accounts to 28.5 million children, showing the impact of unstable societies on one of the major goals of the post 2015 agenda: education.
- The rule of law and development has a significant interrelation and is mutually reinforcing, making it essential for sustainable development at the national and international level.

18 Goal 17: Partnerships for the Goals

18.1 Revitalize the Global Partnership for Sustainable Development

A successful sustainable development agenda requires partnerships between governments, the private sector, and civil society. These inclusive partnerships built upon principles and values, a shared vision, and shared goals that place people and the planet at the center are needed at the global, regional, national, and local level.

Urgent action is needed to mobilize, redirect, and unlock the transformative power of trillions of dollars of private resources to deliver on sustainable development objectives. Long-term investments, including foreign direct investment, are needed in critical sectors, especially in developing countries. These include sustainable energy, infrastructure, and transport, as well as information and communications technologies. The public sector will need to set a clear direction. Review and monitoring frameworks, regulations, and incentive structures that enable such investments must be retooled to attract investments and reinforce sustainable development. National oversight mechanisms such as supreme audit institutions and oversight functions by legislatures should be strengthened.

Goals 17 Targets

- Strengthen domestic resource mobilization, including through international support to developing countries, to improve domestic capacity for tax and other revenue collections.
- Developed countries implement fully their official development assistance commitments, including the commitment by many developed countries to achieve the target of 0.7% of ODA/GNI to developing countries and 0.15–0.20% of ODA/GNI to least developed countries. ODA providers are encouraged to consider setting a target to provide at least 0.20% of ODA/GNI to least developed

countries. Mobilize additional financial resources for developing countries from multiple sources.

- Assist developing countries in attaining long-term debt sustainability through coordinated policies aimed at fostering debt financing, debt relief, and debt restructuring, as appropriate, and address the external debt of highly indebted poor countries to reduce debt distress.
- Adopt and implement investment promotion regimes for least developed countries.
- Enhance North-South, South-South, and triangular regional and international cooperation on and access to science, technology, and innovation, and enhance knowledge sharing on mutually agreed terms, including through improved coordination among existing mechanisms, in particular at the United Nations level, and through a global technology facilitation mechanism.
- Promote the development, transfer, dissemination, and diffusion of environmentally sound technologies to developing countries on favorable terms, including on concessional and preferential terms, as mutually agreed.
- Fully operationalize the technology bank and science, technology, and innovation capacity-building mechanism for least developed countries by 2017, and enhance the use of enabling technology, in particular information and communications technology.
- Enhance international support for implementing effective and targeted capacity-building in developing countries to support national plans to implement all the sustainable development goals, including through North-South, South-South, and triangular cooperation.
- Promote a universal, rule-based, open, nondiscriminatory, and equitable multilateral trading system under the World Trade Organization, including through the conclusion of negotiations under its Doha Development Agenda.
- Significantly increase the exports of developing countries, in particular with a view to doubling the least developed countries' share of global exports by 2020.
- Realize timely implementation of duty-free and quota-free market access on a lasting basis for all least developed countries, consistent with the World Trade Organization decisions, including by ensuring that preferential rules of origin applicable to imports from least developed countries are transparent and simple and contribute to facilitating market access.
- Enhance global macroeconomic stability, including through policy coordination and policy coherence.
- Enhance policy coherence for sustainable development.
- Respect each country's policy space and leadership to establish and implement policies for poverty eradication and sustainable development.
- Enhance the global partnership for sustainable development, complemented by multi-stakeholder partnerships that mobilize and share knowledge, expertise, technology, and financial resources, to support the achievement of the sustainable development goals in all countries, in particular developing countries.
- Encourage and promote effective public, public-private, and civil society partnerships, building on the experience and resourcing strategies of partnerships.

- By 2020, enhance capacity-building support to developing countries, including for least developed countries and small island developing states, to increase significantly the availability of high-quality, timely, and reliable data disaggregated by income, gender, age, race, ethnicity, migratory status, disability, geographic location, and other characteristics relevant in national contexts.
- By 2030, build on existing initiatives to develop measurements of progress on sustainable development that complement gross domestic product, and support statistical capacity-building in developing countries.

Facts and Figures

- Official development assistance stood at $135.2 billion in 2014, the highest level ever recorded.
- Seventy-nine percent of imports from developing countries enter developed countries duty-free.
- The debt burden on developing countries remains stable at about 3% of export revenue.
- The number of Internet users in Africa almost doubled in the past 4 years.
- Thirty percent of the world's youth are digital natives, active online for at least 5 years.
- But more four billion people do not use the Internet, and 90% of them are from the developing world.

Abstract

There is increasing concern about the proposed deployment of tens of thousands of small satellites in constellations deployed in low-Earth orbit (LEO) without new more strict procedures being agreed for removal of satellites at end of life under more stringent and mandatory processes. This chapter provides the full text of the U.S. Federal Communications Commission's analysis of the proliferation of satellite being deployed in LEO. Recent filings to deploy even larger small satellite constellations and increased congestion in the orbital altitudes between 700 and 1000 km have only served to increase concerns since this FCC analysis was published.

Keywords

Active Debris Removal · Causality Risk Assessment · European Space Agency · Federal Communications Commission (FCC) of the US · Kessler Syndrome · Long term sustainability of access to outer space · Low Earth Orbit (LEO) · Medium Earth Orbit (MEO) · MegaLEO Constellations · NASA · Orbital Debris Removal Techniques · UN Committee on the Peaceful Uses of Outer Space (COPUOS) · UN Guidelines on Orbital Debris Removal · Working Group on the Long Term Sustainability of Outer Space Activities (LTSOSA)

Part 13.6

US Regulatory Approach to Space Debris Mitigation by the Federal Communications Commission

The entire future of small satellite enterprises and projects of all types may very well hinge on the ability to find a systematic solution to orbital debris mitigation and thus avoid possible onset of the Kessler syndrome. This is an ever-increasing concern in that there are currently projections by the European Space Agency and by NASA that there will be a major collision generating a significant degree of new debris elements in the range of every 5 years (ESA) to perhaps every 10 years (NASA). The concern is that despite no new launches, orbital debris will mount over time.

The current situation is that as many as 20,000 new small satellites could be deployed, largely in LEO orbit, by 2025. Unless there is a new program for consistently removing satellites in the crowded region of the LEO orbit, where over 40% of the debris now resides, the situation could spiral out of control.

Thus there is concern that with the relatively immediate future of the next decade or so, there could be the start of a runway avalanche of debris. Such a condition would not only make the deployment and operation of small satellite constellations quite impossible for the future but actually create dire consequences for all types of future satellite launches and operations.

Some countries such as France have enacted the French Space Operations Act (FSOA) that has specified the requirements by French commercial and governmental aerospace operators to follow United Nations recommended guidelines for orbital debris removal and also set standards for maximizing the safety of deorbiting debris from orbit. In the United States, such safety measures have not been enacted into law. Also there are many entities and governmental agencies and departments that are considered with space safety such as the Department of Space, NASA, the US State Department, the Environmental Protection Agency, the Federal Aviation Agency's Office of Commercial Space Transportation, and the Occupational Safety and Health Administration. The US Federal Communications Commission, an independent agency, has developed the most systematic assessment of orbital debris concerns and possible mitigation procedures that might be implemented.

The following FCC paper on migration techniques and processes is a valuable review of the concerns and possible processes that might be implemented to help alleviate this problem. This FCC Fact Sheet is provided as one of the most useful official assessments of this problem and further actions that might be taken. Other countries are developing their own analysis, guidelines, and procedures for those deploying small satellites and due diligence procedures to limit orbital space debris.

It is anticipated that the Inter-Agency Space Debris Coordination Committee (IADC) and the UN COPUOS may seek to address the subject of additional guidelines or actions that might be undertaken to mitigate the creation of additional space debris in the future. Currently the US FCC document "Mitigation of Orbital Debris in the New Space Age" is among the most detailed and comprehensive analysis of this subject. It sets forth the relevant concerns and possible actions that might be undertaken to limit orbital space debris. It is a useful document that is provided for all that are concerned with this important area of concern.

FCC FACT SHEET∗

Mitigation of Orbital Debris in the New Space Age

Notice of Proposed Rulemaking and Order on Reconsideration, IB Docket No. 18-313

Background: Since 2004, when the Commission first adopted rules regarding orbital debris mitigation for Commission-authorized satellites, there have been numerous developments in technologies and business models that could pose new or additional orbital debris risks. These developments include the proliferation of lower-cost small satellites and proposals to deploy large constellations of nongeostationary satellite orbit (NGSO) systems, some involving thousands of satellites. Prompted by our experience and these developments, we now undertake a comprehensive update of our orbital debris mitigation rules for all Commission-authorized satellites, including experimental and amateur satellites.

What the Notice Would Do:

- Propose new and revised application disclosures regarding:
- deployment and use of deployment devices
- risk of collision with large objects
- choice of operational orbital altitude

- potential impact to operations of manned spacecraft
- trackability and maneuvering capabilities of NGSO satellites
- probability of human casualty resulting from uncontrolled atmospheric re-entry of a satellite
- Seek comment on a design reliability standard for large NGSO satellite constellations.
- Make proposals and seek comment related to satellite disposal reliability and methodology, appropriate deployment altitudes in LEO, and on-orbit lifetime.
- Propose new rules for geostationary orbit satellite (GSO) license term extension requests.
- Propose that NGSO satellite operators maintain ephemeris data for each satellite they operate and share that data with the operators of other systems operating in the same region of space.
- Propose new rules and rule updates on additional topics, such as release of persistent liquids, proximity operations, coordination of communications for NGSO orbit-raising maneuvers, and encryption of telemetry, tracking, and command links.
- Propose that Commission satellite licensees indemnify the United States against any costs associated with a claim brought against the United States related to the authorized facilities and seek comment on whether to require that licensees have insurance coverage to provide for payment for any costs associated with such a claim.

What the Order on Reconsideration Would Do:

- Deny a petition for reconsideration of the Commission's 2004 orbital debris mitigation rules filed by the Radio Amateur Satellite Corporation (AMSAT).

1 I. INTRODUCTION

1. In many respects, we are at a turning point in the history of space development. Driven by innovation from both established commercial enterprises and new entrepreneurial endeavors, a new landscape for the private space industry is emerging, sometimes referred to as "New Space." Companies have proposed new satellite constellations, some with satellites numbering in the thousands and would provide broadband and other services worldwide. Relatively inexpensive small satellites, many based on what is known as a "CubeSat" form factor,[1] have demonstrated their utility and capabilities across a wide range of satellite services. The launch industry is more dynamic than ever, with new entrants into the launch vehicle market bringing new capabilities and lowering launch costs. There are risks inherent in any operations in space, however, and while we seek to facilitate the development of this new landscape through our role in satellite authorization, the Commission also has a responsibility to ensure that the operations it authorizes are conducted safely and consistent with the public interest.[2] The current period of innovation in the space industry has resulted and will likely continue to result in a significant increase in the number of satellites and types of operations in orbit, both of which have the potential to increase the amount of orbital debris. Thus, mitigating the growth of orbital debris is more critical than ever to ensure continued, safe operations in space. Orbital debris, also known as "space debris", consists of artificial objects orbiting the Earth that are not functional spacecraft, and can be created under a variety of scenarios involving satellite systems. Orbital debris can affect the cost, reliability, integrity, and capability of new satellite systems and valuable services to the public, and it has the potential to cause physical harm to both people and property.[3] As the Commission has previously found, consideration of orbital debris issues can thus play an important role in preserving access to space for the long term and in ensuring the safety of persons and property in space and on the surface of the Earth.[4]

2. This Notice of Proposed Rulemaking (NPRM or Notice) represents the first comprehensive look at the Commission's orbital debris rules since their adoption in 2004. The proposed changes are designed to improve and clarify these rules based on experience gained in the satellite licensing process and on improvements in mitigation guidelines and practices, and to address the various market developments

---

[1] A "CubeSat" is a standardized small satellite interface consisting of one or more "units." As originally conceived, a CubeSat unit is approximately 10 cm x 10 cm x 10 cm in size. See Streamlining Licensing Procedures for Small Satellites, Notice of Proposed Rulemaking, IB Docket No. 18-86, FCC 18-44 at 4, para. 5 (April 17, 2018) (Small Satellite NPRM).

[2] Mitigation of Orbital Debris, Second Report and Order, 19 FCC Rcd 11567, 11575, para. 14 (2004) (Orbital Debris Order). The Commission has observed that robotic spacecraft are typically controlled through radiocommunications links, and thus there is a direct connection between the satellite's radiocommunications functions and the physical operations of spacecraft. Id.

[4] Id.

described above. In addition, we deny a petition[5] seeking reconsideration of the Commission's decision in 2004 to apply orbital debris mitigation requirements to amateur service satellites.[6]

2 II. BACKGROUND

3. Pursuant to its authority to determine whether the public interest would be served by the authorization of satellite communications systems, the Commission adopted comprehensive rules on orbital debris in 2004.[7] The core of these rules consists of disclosure requirements that yield information critical to the Commission's overall determination of whether the public interest will be served by approving the proposed operations. Under the Commission's satellite application rules, applicants must include a statement that they have assessed and limited the amount of debris released in a planned manner during normal operations, and have assessed and limited the probability of the satellite becoming a source of debris by collisions with small debris.[8] Applicants must also state that they have assessed and limited the probability of accidental explosions during and after completion of mission operations.[9] The rules also require a statement that the satellite applicant has assessed and limited the probability of the satellite becoming a source of debris by collisions with large debris or other operational satellites.[10] Finally, applicants must include a statement detailing the post-mission disposal plans for the satellite as it enters its end-of-life stage, including the quantity of fuel—if any—that will be reserved for post-mission disposal maneuvers.[11]

4. In addition to general disclosure obligations, the Commission has adopted other rules related to physical spacecraft operations, such as requirements for the maintenance of orbital locations in the geostationary-satellite orbit (GSO),[12] and for GSO inclined-orbit operations.[13] In addition, the Commission has specific post-mission disposal requirements for both GSO and non-geostationary (NGSO) satellites.[14]

[13] 47 CFR § 25.280.

[14] 47 CFR § 25.283.

5. The Commission reviews these disclosures and determines, on a case-by-case basis, whether the public interest will be served by approval of the proposed operations.[15] The rules adopted in 2004 provided some general guidance on the content of disclosures, but the Commission generally declined to adopt a particular methodology for the preparation and evaluation of an applicant's orbital debris mitigation plans.[16] Both applicants and the Commission, however, have relied in a number of cases on standards and related assessment tools, such as the technical standards and related software tools developed by NASA for its space activities,[17] to, respectively, prepare such orbital debris plans and assess their adequacy.[18]

6. Since the Commission's orbital debris rules were adopted in 2004, there have been a number of significant developments with respect to this topic. Internationally, within the United Nations Committee on the Peaceful Uses of Outer Space (UN COPUOS), the Working Group on the Long-term Sustainability of Outer Space Activities of the Scientific and Technical Subcommittee has developed a set of voluntary guidelines to assist States and international intergovernmental organizations, recognizing that "[t]he proliferation of space debris, the increasing complexity of space operations, the emergence of large constellations, and the increased risks of collision and interference with the operation of space objects may affect the long-term sustainability of space activities."[19] The Inter-Agency Space

---

[15] Orbital Debris Order, 19 FCC Rcd at 11577, para. 19; 47 U.S.C. § 309(a). The Commission's public interest determination regarding an applicant's request for authorization of a satellite communications system is not, of course, based solely on the sufficiency of an applicant's plans for managing orbital debris. It also requires a number of other findings (e.g., that the applicant possesses the basic qualifications to hold the authorization and that the proposed system will conform to the FCC's technical operational rules).

[16] Orbital Debris Order, 19 FCC Rcd at 11577, para. 21

[17] In the Orbital Debris Order, the Commission observed that NASA had adopted publicly-available safety standards that provided a handbook for debris mitigation analysis and activities. Orbital Debris Order, 19 FCC Rcd at 11577, para. 21. See NASA Technical Standard, Process for Limiting Orbital Debris, NASA-STD-8719.14A (with Change 1) (May 25, 2012), http://www.hq.nasa.gov/office/codeq/doctree/871914.pdf (NASA Standard). The NASA Standard is "consistent with the objectives of the U.S. National Space Policy of the United States of America (June 2010), the U.S. Government Orbital Debris Mitigation Standard Practices (February 2001), the Inter-Agency Space Debris Coordination Committee (IADC) Space Debris Mitigation Guidelines (October 2002), the Space and Missile Center Orbital Debris Handbook, Technical Report on Space Debris (July 2002), the space debris mitigation guidelines of the Scientific and Technical Subcommittee of the United Nations Committee on the Peaceful Use of Outer Space, (A/AC.105/720, 1999 and A/AC.105/890, Feb 2007)." Id. at 5.

[18] See, e.g., Part 25 Second Report and Order, 30 FCC Rcd at 14824-25, para. 361 (stating the Commission will rely on the NASA Standard, among other guidance, when assessing satellite end-of-life passivation plans); Orbital Debris Order, 19 FCC Rcd at 11603-04, para. 88 (providing that entities may wish to look at NASA standards as a guide when preparing their human casualty risk assessments); Guidance on Obtaining Licenses for Small Satellites, Public Notice, 28 FCC Rcd 2555, 2558 (IB/OET 2013) ("An orbital debris assessment report prepared consistent with NASA standards is generally sufficient to meet FCC requirements.").

[19] Guidelines for the long-term sustainability of outer space activities, UN Document A/AC.105/L.315 (2018) at 1-2, para. 1.

Debris Coordination Committee (IADC), an inter-governmental committee, updated its Space Debris Mitigation Guidelines in 2007,[20] and more recently, has studied the orbital debris population in the LEO region[21] and has issued a preliminary statement on large constellations of satellites in that region.[22] Domestically, NASA has issued revised versions of its "Procedural Requirements for Limiting Orbital Debris"[23] and its "Technical Standard on the Process for Limiting Orbital Debris",[24] and has updated software available to assess compliance with its guidelines.[25]

7. In addition, the number of debris objects capable of producing catastrophic damage to functional spacecraft has increased. Orbital debris objects greater than one centimeter in diameter can cause catastrophic damage to functional spacecraft.[26] Over 100,000 objects between 1 and 10 cm were estimated to be in orbit in 2004.[27] Approximately 500,000 such objects were estimated to be in orbit as of 2012.[28] Of these, the U.S. Joint Space Operations Center (JSpOC) tracks approximately 23,000 man-made objects achieving orbit.[29] Satellite breakups have been a significant contributor to the increase in the orbital debris population. For example, fragments associated with the intentional fragmentation of the Fengyun 1C spacecraft in 2007 and the accidental collision of the Cosmos 2251 spacecraft with the commercial Iridium 33 spacecraft in 2009 account for over 25% of cataloged on-orbit space objects.[30] The orbital altitudes where these fragments are located is an area of significant density of space objects.[31]

8. Proposed deployments of large satellite constellations[32] in the intensely used LEO region, along with other satellites deployed in the LEO region, will have the potential to increase the risk of debris-generating events. Work continues in international forums, such as in the IADC, on improved debris limitation practices, including with respect to these "mega constellations."[33] New satellite and deployment technologies currently in use and under development also may increase the number of potential debris-generating events, in the absence of improved debris mitigation practices.

3 III. DISCUSSION

9. We propose a number of changes to our existing disclosure and operational requirements and seek comment on additional potential revisions. In addressing orbital debris mitigation, the Commission has drawn from the technical guidance and assessment tools developed by NASA and the modifications to our rules proposed in this NPRM reflect this approach. In some areas where we have proposed general disclosures in lieu of specific design or operational requirements, we believe such disclosures will provide flexibility for us to address ongoing developments in space station design and other technologies. As a general matter, however, if there are well-defined metrics in any of those areas that could provide a basis for a more specific requirement, we ask that those be identified by commenters.

10. We also note that on June 18, 2018, the President issued Space Policy Directive-3, relating to National Space Traffic Management Policy.[34] Recognizing, among other things, that the volume and location of orbital debris are growing threats to space activities and that it is in the interest of all to minimize new debris and mitigate effects of existing debris,[35] the memorandum directs the Administrator of NASA, in coordination with the Secretaries of State, Defense, Commerce, and Transportation, and the Director of National Intelligence, and in consultation with the Chairman of the Commission, to lead efforts to update the U.S. Orbital Debris Mitigation Standard Practices and establish new guidelines for satellite design and

operation, as appropriate and consistent with applicable law.[36] It states that the United States should eventually incorporate appropriate standards and best practices into Federal law and regulation through appropriate rulemaking or licensing actions, and that such guidelines should encompass protocols for all stages of satellite operation from design through end-of-life.[37] These efforts are at an early stage and do not provide a basis for specific proposals in this proceeding. However, the Commission's efforts to formulate this NPRM on orbital debris mitigation have been underway for some time, and we believe delaying notice and public comment on proposed improvements to FCC rules would be counterproductive. To the extent that there are updates to the U.S. Orbital Debris Mitigation Standard Practices or other domestic orbital debris guidance documents while this proceeding is open,[38] those developments could be considered in this proceeding.

3.1 A. Control of Debris Released During Normal Operations

11. We start by proposing additional disclosure requirements designed to keep pace with how satellite deployments have evolved over the past decade.

12. In 2004, the Commission observed that satellites used primarily for telecommunications applications do not typically involve the planned release of orbital debris.[39] As part of the orbital debris mitigation disclosure, the Commission nevertheless adopted a requirement that satellite operators represent that they have assessed and limited the amount of debris released in a planned manner during normal operations.[40] It concluded that a statement confirming that no debris would be released by a satellite during normal operations would be sufficient to meet disclosure obligations, and that in any instances where release of operational debris was planned, the Commission would examine such plans on a case-by-case basis and retain the discretion to seek additional information or take action to condition or deny approval, in the event that such a release was found not to serve the public interest.[41] Under this rule, applicants must address any potential operational debris associated with spacecraft operations, except for those directly under the control of the launch vehicle provider.

13. In several recent instances, applicants have sought to deploy satellites using deployment mechanisms that detach from or are ejected from a launch vehicle

---

[37] Id. at Sec. 5(b)(1).

[38] See, e.g., Space Policy Directive-3 at Sec. 6(b). The existing U.S. Orbital Debris Mitigation Standard Practices were issued in 2001 and were considered as part of the development of the Commission's orbital debris mitigation rules in the 2000s. See Mitigation of Orbital Debris, Notice of Proposed Rule Making, 17 FCC Rcd 5586, 5590, at para. 10 (2002).

[39] Orbital Debris Order, 19 FCC Rcd at 11578, para. 24.

[40] 47 CFR § 25.114(d)(14)(i).

[41] Orbital Debris Order, 19 FCC Rcd at 11579, para. 24.

upper stage and are designed solely as means of deploying a satellite or satellites, and not intended for other operations. Once these mechanisms have deployed the onboard satellite(s), they become orbital debris. For example, special temporary authority was granted for a spacecraft known as SHERPA, designed to deploy smaller spacecraft from five ports.[42] An experimental authorization was also sought for a satellite that would be one of two satellites deployed from a tubular cylinder deployer, using a spring mechanism.[43] Thus, the deployment of two satellites resulted in three objects, one of which became a debris object very shortly following the beginning of its time in orbit. In other cases, the use of deployment devices, such as separation rings used to facilitate the launch of two geostationary satellites on a single launch vehicle, is an established practice and, while involving the release of operational debris, may in some instances reduce overall debris risk, for example by reducing the number of launches from two to one. As with other manmade objects in space, however, such deployment devices have the potential to collide with other objects and thereby create additional orbital debris. In some instances, the deployment device itself may not require an application for a license from the Commission for radio communications, if it does not have any radio frequency (RF) facilities.

14. In general, generation of operational debris, including from deployment devices, should be minimized. We propose to require disclosure by applicants if such devices are used to deploy their spacecraft, as well as a specific justification for their use. In addition, we propose that the disclosure include information regarding the planned orbital debris mitigation measures specific to the deployment device. Where appropriate, this description of orbital debris mitigation measures may be obtained from the operator of the deployment device.[44] If the deployment device is itself the subject of a separate application for authorization by the Commission (e.g., SHERPA), then the entity seeking a license or a grant of U.S. market access for a satellite may satisfy this disclosure requirement by referencing the deployment device's FCC application or grant. We seek comment on this proposed informational requirement.

3.2 B. Minimizing Debris Generated by Release of Persistent Liquids

15. Most conventional propellant and coolant chemicals evaporate or dissipate if released from a spacecraft. However, certain types of liquids, such as low vapor pressure ionic liquids, will, if released from a satellite, persist in the form of droplets.

---

[42] Spaceflight Inc., IBFS File No. SAT-STA-20150821-00060 (the mission was ultimately cancelled).

[43] See Open Space Networks, ELS File No. 0957-EX-ST-2016, Exh. ODAR at 1-2.

[44] See Appendix A, Proposed Rule Changes, Section 25.114(d)(14)(i).

At orbital velocities, such droplets can cause substantial or catastrophic damage if they collide with other objects.[45] In the last several years, there has been increasing interest in the use by satellites (including small satellites) of alternative propellants and coolants, some of which would become persistent liquids when released by a deployed satellite.

16. Our current rules include a disclosure requirement that satellite operators have assessed and limited the probability of accidental explosions during and after completion of mission operations.[46] This includes a demonstration that debris generation will not result from conversion of energy sources on board into energy that fragments the satellite.[47] But our rules do not require disclosure of liquids that, while not presenting an explosion risk, could nonetheless, if released into space, cause damage to other satellites due to collisions. Accordingly, we propose to include within the rules a requirement to identify any liquids that if released, either intentionally or unintentionally, will persist in a droplet form. We seek comment on this proposal.

3.3 C. Safe Flight Profiles

17. In 2004, the Commission concluded that while the choice of orbit regime (e.g., LEO or GSO) and specific orbital parameters (altitude, inclination, etc.) was generally best left to the operator, in some instances the public interest would be served by a more detailed discussion of how an operator would avoid potential collisions.[48] Our current rules require that an applicant provide a statement regarding the probability of the satellite becoming a source of debris by collisions with large debris or other operational satellites.[49] The existing rule identifies a number of specific disclosures that must be made by applicants in certain circumstances.[50]

18. In an effort to ensure that the physical operations of both existing and planned systems do not contribute to the orbital debris environment, particularly in the heavily-used LEO region, we propose to update our rules. We note that the Commission has fielded an increasing number of applications for NGSO systems for large constellations, as well as for individual small satellites.[51] In an effort to update our rules, as well as implement emerging best practices in an increasingly-crowded

---

[45] A notable example of this type of debris source involves sodium potassium reactor coolant released from Sovietera satellites. "New Debris Seen from Decommissioned Satellite with Nuclear Power Source," NASA Orbital Debris Quarterly News, Volume 13, Issue 1 at 1-2 (January 2009), https://orbitaldebris.jsc.nasa.gov/quarterlynews/pdfs/odqnv13i1.pdf.

space environment, we propose modifications to the current rule, and additional specific disclosures regarding selection of orbit and deployment, trackability, maneuverability, and other related matters.

3.3.1 1. Quantifying Collision Risk

19. Our rules provide for an assessment of the probability of a satellite becoming a source of debris as a result of large object collision, but do not require that the operator quantify this probability.[52] We propose to incorporate into our rules a metric based on the current NASA Standard. Specifically, we propose that applicants for NGSO satellites must demonstrate that the probability that their spacecraft will collide with a large object during the orbital lifetime[53] of the spacecraft will be no greater than 0.001.[54]

We seek comment on whether, if a spacecraft's orbital debris mitigation plan includes maneuvering to avoid collisions, we should, consistent with current licensing practice, consider this risk to be zero or near zero during the period of time in which the spacecraft is maneuverable, absent contrary information. The NASA Standard applies the 0.001 metric on a per-spacecraft basis.[55] We invite comment on whether this metric should also be applied on an aggregate, system-wide basis, i.e., 0.001 for an entire constellation. If such a requirement is adopted on an aggregate basis, would it provide an incentive for evasion of the aggregate limit, for example, through a single controlling party applying for multiple satellite constellations, each of which meets the limit, but which collectively would not? Are existing procedures adequate to identify any such instances of evasion? We also seek comment on whether we should specify a size for what is considered a large object, or whether we should continue our current case-by-case approach, which in practice typically results in consideration of catalogued objects.[56] We note that advancements in capabilities and practices suggest that smaller objects may be catalogued and perhaps routinely tracked in the coming years. The Space Fence ground-based radar, scheduled to begin regular operations in 2019, is designed to

---

[52] 47 CFR § 25.114(d)(14)(iii).

[53] For purposes of this NPRM and our proposed rules, "orbital lifetime" is defined as the length of time an object remains in orbit. Objects in LEO or passing through LEO lose energy as they pass through the Earth's upper atmosphere, eventually getting low enough in altitude that the atmosphere removes them from orbit. NASA Technical Standard, Safety and Mission Assurance Acronyms, Abbreviations, and Definitions, NASA-STD 8709.22 at 94 (with Change 2) (October 31, 2012), http://www.hq.nasa.gov/office/codeq/doctree/NS870922.pdf.

[54] NASA Standard at 32, Requirement 4.5.2. This is consistent with the Commission's recent proposal for satellites licensed pursuant to the proposed streamlined satellite process. Small Satellite NPRM, FCC 18-44 at 18, para. 37. NASA applies this metric to programs and projects involving spacecraft "in or passing through LEO." Id. We propose to apply this to all NGSO satellites.

[55] Id.

[56] Space-Track.org, FAQ, https://www.space-track.org/documentation#/faq (stating 10 cm diameter or "softball size" is the typical minimum size object that current sensors can track and that is maintained by the JSpOC in its catalog).

provide the U.S. Air Force with the ability to detect objects smaller than what can be detected by current systems.[57] Nonetheless, the specific ways in which this new data will be incorporated into the space object catalog, and the extent to which the addition of one sensor can support routine tracking, including tracking sufficient for collision avoidance activities, have not yet been specified.

20. We also propose other revisions to the NGSO-related provisions of the existing rule regarding collision risk.[58] The existing rule states that where a satellite will be launched into a LEO region orbit that is identical, or very similar, to an orbit used by other satellites, the orbital debris mitigation statement must include analysis of potential risk of collision, disclosures regarding whether a satellite operator is relying on coordination with the other system for collision avoidance, and what coordination measures have been or will be taken.[59] First, we propose to revise the wording of the rule to require that, instead of identifying satellites with similar orbits, the orbital debris mitigation statement must identify the planned and/or operational satellites to which the applicant's satellite poses a collision risk, and indicate what steps have been taken or will be taken to coordinate with the other spacecraft or system and facilitate future coordination, or what other measures the operator may use to avoid collision.[60] This revision may provide applicants with more certainty about what must be included in the disclosure and help to identify additional collision risks. We believe that concerns about the risk of collisions involving active spacecraft may be best addressed in the first instance through inter-operator coordination.[61] Second, we propose to extend this rule to all NGSO satellites, rather than only those that will be launched into the LEO region, since overlap in orbits among NGSO spacecraft in other regions could equally result in collision creating orbital debris.[62] We anticipate that in lightly-used orbits, the statement can simply indicate that there are no other planned or operational spacecraft posing a collision risk.

---

Oct. 8, 2015).

[58] See 47 CFR § 25.114(d)(14)(iii).

[59] Id.

[60] See Appendix A, Proposed Rule Changes, §25.114(d)(14)(iv).

[61] See, e.g., Telesat Canada, Petition for Declaratory Ruling to Grant Access to the U.S. Market for Telesat's NGSO Constellation, Order and Declaratory Ruling, FCC 17-147, 32 FCC Rcd 9663, 9668, para. 12 (2017). The Commission conditioned grant of market access to Telesat Canada on the provision of additional information about its orbital debris mitigation plan, including: a discussion of any steps that Telesat has taken to coordinate physical operations with authorized and proposed NGSO systems at similar orbital altitudes (both for the main mission and disposal phases); a discussion of the level of data-sharing that would be required with other operators, including analysis of likely requirements for ephemeris refresh rates and time frames for coordination of planned maneuvers (both for the main mission and disposal phases); and whether Telesat has considered alternative orbital altitudes for its operations and whether those altitudes would materially affect Telesat's ability to provide service. Id. at 9669, para. 14.

[62] See Appendix A, Proposed Rule Changes, §25.114(d)(14)(iv).

3.3.2 2. Orbit Selection

21. In addition to quantification of collision risk described above and identification of other relevant planned or operational NGSO satellites, we propose two additional informational requirements with the goals of preventing collisions in crowded orbits, particularly those in the LEO region, and protecting important assets in space.

22. First, for any NGSO satellites planned for deployment above the International Space Station (ISS)[63] and that will transit through the ISS orbit either during or following the satellite operations, we propose that the applicant provide information about any operational constraints caused to the ISS or other inhabitable spacecraft and strategies used to avoid collision with manned spacecraft.[64] For example, will the normal operations of the ISS be significantly disrupted or otherwise constrained by the number of collision avoidance maneuvers that may be necessary as satellites in the constellation transit through the ISS orbit, such as during an uncontrolled de-orbit phase?[65] As noted in the Small Satellite NPRM, deployment of satellites lacking maneuvering capabilities above the ISS, to orbits from which they will eventually transit through the ISS altitude band, increases the likelihood that the ISS will need to conduct avoidance maneuvers, potentially disrupting ISS operations.[66] In that proceeding, the Commission proposed that satellites without propulsion seeking to be processed on a streamlined basis be deployed either from or at altitudes below the ISS.[67] We do not propose similar criteria for satellites authorized outside the streamlined process, but we believe information regarding operational constraints caused to inhabitable spacecraft could help us and any other interested parties to assess the public interest in authorizing any particular satellite or constellation.

---

[63] The ISS operates at an altitude of approximately 400 km.

[64] Between 1999 and July 2015, the International Space Station (ISS) conducted 23 total collision avoidance maneuvers. National Aeronautics and Space Administration, Orbital Debris: Quarterly News, "International Space Station Performs Two Debris Avoidance Maneuvers and a Shelter-in-Place," Vol. 19, Issue 3 at 1 (July 2015), https://orbitaldebris.jsc.nasa.gov/quarterly-news/pdfs/odqnv19i3.pdf; see also J.-C. Liou, National Aeronautics and Space Administration, "Orbital Debris Mitigation Policy and Unique Challenges for Cubesats," presentation to the 52nd Session of the Scientific and Technical Subcommittee, Committee on Peaceful Uses of Outer Space, United Nations, February 2015, at 9, available at https://ntrs.nasa.gov/archive/nasa/casi.ntrs.nasa.gov/20150020943.pdf.

[65] See NASA NGSO Constellation Comments at 2 (expressing concern about aspect of disposal plan for SpaceX LEO constellation and recommending that SpaceX "seek out creative ways to guarantee they can avoid the ISS and other high value assets" for the entire deorbit phase of their planned spacecraft); Science Applications International Corporation, Orbital Traffic Management Study Final Report, Prepared for NASA Headquarters, at E-1-E-2 (Nov. 21, 2016) (SAIC Orbital Traffic Management Study) ("As debris populations grow in LEO, the odds of [micro-meteoroid or orbital debris] root cause events on ISS will become higher (i.e. worsen)[.]" "Recent analysis by the Aerospace Corporation suggests that the current large planned constellations could increase collision warnings with ISS six-fold, as the decommissioned spacecraft in those constellations decay through the ISS orbit.").

[66] Small Satellite NPRM, FCC 18-44 at 17, para. 34.

[67] Id. at 17, paras. 33-34.

23. Second, we propose that an applicant planning an NGSO constellation that will be deployed in the LEO region above 650 km altitude specify why it has chosen that particular orbit given the number of satellites planned, and describe any other relevant characteristics of the orbit such as the presence of existing debris. Satellites deployed below 650 km will typically re-enter Earth's atmosphere within 25 years,[68] even absent any propulsive or other special de-orbit capabilities. Thus, the collision risks presented by such satellites are generally lower, even if the satellites fail on-orbit and are unable to perform any affirmative de-orbiting maneuvers.[69] Above this approximately 650 km threshold, a satellite that is not affirmatively de-orbited will remain in orbit for significantly longer periods of time. Accordingly, for NGSO deployments above the 650 km altitude, we propose that applicants provide a rationale for choosing a higher orbit, even if the satellites will have propulsive de-orbit capabilities.[70] While we recognize that satellites may be designed to de-orbit within 25 years from altitudes above 650 km, those missions may involve greater risk from an orbital debris perspective due to the possibility of a satellite failure resulting in the satellite remaining in orbit for periods of time in as much as the hundreds or thousands of years.

24. Third, we seek comment on whether we should also require a statement concerning the rationale for selecting an orbit from operators of satellites that will remain in orbit for a long period of time relative to the time needed to perform their mission. For example, a technology demonstration mission in LEO that lasts only a few weeks could result in up to 25 years of collision risk to other operators. One example of an alternative guideline is that operators select orbits such that orbital lifetime exceed mission lifetime by no more than a factor of two. We seek comment on this metric, or alternative metrics that could be incorporated into our rules.

25. Fourth, we note that certain areas of space are more populated with debris, such as that from the Cosmos 2251/Iridium 33 collision. It may be in the public

---

[68] This is consistent with the benchmark contained in the current NASA Standard. NASA Standard at 37, Requirement 4.6.2.

[69] This altitude may vary depending upon the characteristics of the spacecraft and solar activity, but 650 km represents an average approximation. See Inter-Agency Space Debris Coordination Committee, Support to the IADC Space Debris Mitigation Guidelines, IADC-04-06, Rev. 5.5 at 32 (May 2014) ("It is recommended that orbital lifetime be reduced to less than 25 years at the end of mission (approximately 750 km circular orbit for $A/m = 0.05$ m^2/kg, and approximately 600 km circular orbit for A/m=0.005 m2/kg, depending on solar activity to be more exact."); ESA NGSO FSS Comments at 2 (recommending that for large constellations low operational orbits should be considered, noting that average orbital altitudes of less than 650 km for average satellites (< 1 ton) are normally still compatible with a natural decay within 25 years).

[70] As explained in the Orbital Debris Order, the U.S. Government Orbital Debris Standard Practices call for the selection of an orbit from which the spacecraft will remain in orbit no longer than 25 years after mission completion, if the planned disposal method is re-entry into Earth's atmosphere through means of natural atmospheric drag, without the use of propulsion systems. Orbital Debris Order, 19 FCC Rcd at 11592, para. 61; U.S. Government Orbital Debris Standard Practices 4-1, available at https://www.orbitaldebris.jsc.nasa.gov/library/usg_od_standard_practices.pdf (U.S. Government Standard Practices).

interest for new constellations to avoid deployment in such areas to minimize risk, or, stated differently, to design constellations to operate in regions of space where the density of objects is lower, and consequently where the risk of collision with debris objects is lower.[71] We ask whether to require applicants to include an additional disclosure regarding orbit selection based on such risks, or to provide assurances on how the applicant plans to reduce these risks. We also ask whether we should seek additional information or assurances from applicants in more narrow circumstances, for example, where they seek to deploy a large constellation in certain sun-synchronous orbits that have an increased likelihood of congestion.

26. Fifth, in lieu of an informational requirement, should we require all NGSO satellites planning to operate above a particular altitude to include propulsion capabilities reserved for station-keeping and to enable collision avoidance maneuvers, regardless of whether propulsion is necessary to de-orbit within 25 years? If so, above what altitude?

27. Finally, we ask whether we should adopt a maximum limit for variances in orbit for NGSO systems. That is, should we limit the variance in altitude above or below the operational orbit specified in an application for an NGSO system,[72] in order to enable more systems to co-exist in LEO without overlap in orbital altitude, and if so, how should an appropriate limit be set? If such a limit is adopted, should it apply only to near-circular obits, or also to elliptical orbits? We seek comment on these questions, as well as on any additional changes to our rules and policies that may help operators avoid collisions and ultimately reduce the risk of debris generation in heavily-used or otherwise critical orbits.

3.3.3 3. Tracking and Data Sharing

28. The identification of satellites and sharing of tracking data are important to provide timely and accurate assessments of conjunction with other spacecraft.[73] The increase in the number of small satellites, for example, has begun to pose some unique tracking and identification challenges.[74] We believe that improvements in the

---

[71] NASA NGSO Constellation Comments at 2-3 (NASA expressed some concerns regarding proposed orbit of Theia Holdings A, Inc., NGSO satellite constellation, because of the location of other government satellites nearby and the high percentage of Iridium-33/Cosmos-2251 and Fengyun-1C debris in that region).

[72] As an example of the discussion of issues related to variances in orbital altitude for a particular system, SpaceX expressed concern regarding the proposed operational range for OneWeb's planned NGSO system. See Letter from William M. Wiltshire, Counsel to SpaceX, to Marlene H. Dortch, Secretary, FCC, at 2-4, IBFS File Nos. SAT-LOA-20161115-00118 and SAT-LOA-20170301-00027 (filed Dec. 12, 2017).

[73] A conjunction event is one in which space objects, such as an two operational spacecraft or an operational spacecraft and a debris object, are predicted to come within close proximity to each other. A conjunction event may or may not result in a collision.

[74] JSpOC CubeSat Recommendations for Optimal CubeSat Operations, Joint Space Operations Center at 1 (2015), https://file.space-track.org/documents/Recommendations_Optimal_Cubesat_Operations_V2.pdf (JSpOC CubeSat Recommendations); Small Satellite NRPM, FCC 18-44 at 18-19, para. 38.

ability to track and identify satellites in NGSO may help to reduce the risk of collisions. As an initial matter, we propose to require a statement from the applicant regarding the ability to track the proposed satellites using space situational awareness facilities, such as the U.S. Space Surveillance Network.[75] We propose that objects greater than 10 cm by 10 cm by 10 cm be presumed trackable for any altitude up to the geostationary region.[76] For objects with any dimension less than 10 cm, we propose that the applicant provide additional information concerning trackability, which will be reviewed on a case-by-case basis. We also propose that applicants for NGSO systems disclose, as part of their orbital debris mitigation plans, whether satellite tracking will be active and cooperative (that is, with participation of the operator by emitting signals via transponder or sharing data with other operators) or passive (that is, solely by ground based radar or optical tracking of the object).[77] We also ask whether applications should certify that the satellite will include a unique telemetry marker allowing it to be readily distinguished from other satellites or space objects.[78] We further seek comment on whether there are hardware or information sharing requirements that might improve tracking capabilities, and whether such technologies are sufficiently developed that a requirement for their use would be efficient and effective.

29. In addition, we note that the Air Force's 18th Space Control Squadron is currently responsible for maintaining the space catalog and managing United States Strategic Command's space situational awareness sharing program to United States, foreign government, and commercial entities.[79] Among other things, the Air Force's 18th Space Control Squadron currently provides satellite owner/operators with on-orbit conjunction assessments.[80] We seek comment on whether we should adopt an

---

[75] Space situational awareness facilities track satellites and other space objects using radar and other means.

[76] In the Small Satellite NPRM, the Commission proposed that small satellites using the streamlined review process be no smaller than 10 cm x 10 cm x 10 cm, which would help the Commission to process those systems in a streamlined fashion. Small Satellite NPRM, FCC 18-44 at 18-19, para. 38.

[77] See Committee on Achieving Science Goals with CubeSats – Thinking Inside the Box, Space Studies Board, Division on Engineering and Physical Sciences, National Academies of Sciences, Engineering, and Medicine, Achieving Science Goals with CubeSats: Thinking Inside the Box at C-7 (2016), http://www.nap.edu/catalog/23503/achieving-science-with-cubesats-thinking-inside-the-box (discussing tracking technologies).

[78] See Small Satellite NPRM, FCC 18-44, at 19, para. 38. The Commission proposed that small satellites applying under the proposed streamlined process make this certification.

[79] See Peterson Air Force Base, Fact Sheets, 18th Space Control Squadron, https://www.peterson.af.mil/About/Fact-Sheets/Display/Article/1060346/18th-space-control-squadron/.

[80] See SSA Sharing & Orbital Data Requests, Space-Track.org, https://www.space-track.org/documentation#/odr (last visited Oct. 22, 2018) (Space-Track SSA Services Website); See JSpOC CubeSat Recommendations for Optimal CubeSat Operations, Joint Space Operations Center at 2, 3-4.1 (2015), https://file.space-track.org/documents/Recommendations_Optimal_Cubesat_Operations_V2.pdf.

operational rule requiring NGSO satellite operators to provide certain information to the 18th Space Control Squadron or any successor civilian entity, including, for example information regarding initial deployment, ephemeris, and any planned maneuvers. As an example, communication with the Air Force's 18th Space Control Squadron may be particularly important in the case of a multi-satellite deployment, to assist in the identification of the satellite.[81]

30. We also propose that applicants for NGSO systems certify that, upon receipt of a conjunction warning, the operator of the satellite will take all possible steps to assess and, if necessary, to mitigate collision risk, including, but not limited to: contacting the operator of any active spacecraft involved in such warning; sharing ephemeris data and other appropriate operational information directly with any such operator; and modifying spacecraft attitude and/or operations.[82] We seek comment on this approach as one designed to reduce collision risks and enhance certainty among operators, and ask whether any different or additional requirements should be considered regarding the ability to track and identify satellites in NGSO or respond to conjunction warnings.

3.3.4 4. Maneuverability

31. We also propose that applicants for NGSO satellite authorizations demonstrate the extent of any maneuverability. For example, the demonstration could include a description of the number of collision avoidance maneuvers the satellite could be expected to make, and/or any other means the satellite may have to avoid conjunction events. We propose that the description include a discussion of maneuverability both during satellite's operational lifetime and during the remainder of its time in space prior to disposal. We tentatively conclude that such information can assist us in our public interest determination, in particular regarding any burden that other operators would have to bear in order to avoid collisions and false conjunction warnings. We seek comment on this conclusion and note that, as proposed, this is an informational requirement, and would not require that all satellites have propulsion or maneuverability. In addition, we observe that some applications have been granted based on an assessment of information regarding differential drag maneuvers. Recognizing that this is an emerging area from the perspective of collision avoidance, we seek comment concerning effectiveness and suitability of this or other particular maneuvering technologies under real world conditions, and on whether we should implement any specific disclosure requirements with respect to this or other types of emerging maneuvering technology.

---

[81] See JSpOC CubeSat Recommendations at 1 (noting that there were challenges associated with the ORS-3 mission, launching 37 CubeSats, and the DNEPR rocket, launching 31 CubeSats, both in late 2013).

[82] See Appendix A, Proposed Rule Changes, Section 25.114(d)(14)(iv)(A).

3.3.5 5. Multi-Satellite Deployments

32. In recent years, we have observed an increasing number of cases where a single launch vehicle will deploy large numbers of NGSO satellites,[83] often involving some groups of satellites having homogenous designs and others of varying design. A single deployment of a number of satellites from a launch vehicle or free-flying deployment device could result in some heightened risk of collision between objects, or on a longer-term basis due to the similarity of orbits for the released objects. We seek comment on whether we should include in our rules any additional informational requirements regarding such launches.[84] Are there mitigation measures that are commonly employed that mitigate such risks, for example through use of powered flight during the deployment phase and/or through phasing of deployment, that we should consider adopting as requirements under some circumstances?

33. In seeking comment, we recognize that an applicant for a Commission license or authorization may not have access to information regarding other satellites that will be deployed, and ask whether an applicant could obtain general information from the launch provider or aggregator that would assist the Commission in evaluating the risk of collision presented by the deployment itself, even if the launch manifest has not been finalized.

3.3.6 6. Design Reliability

34. In comments filed regarding proposed large constellations of NGSO satellites, NASA suggested that for such constellations, a design and fabrication reliability standard may be appropriate.[85] A design or reliability flaw resulting in malfunction of spacecraft during deployment or mission operations could result in a significant number of non-functional spacecraft in an operational orbit, contributing to the orbital debris population.[86]

35. We seek comment on whether it would be appropriate to impose a design and fabrication reliability requirement, for example, 0.999 per spacecraft, if a NGSO

---

[83] In 2017, for example, a record 104 satellites were launched on a single rocket, the Indian Space Research Organisation's Polar Satellite Launch Vehicle (PSLV). See Department of Space Indian Space Research Organisation, "PSLV-C37 Successfully Launches 104 Satellites in a Single Flight," https://www.isro.gov.in/pslv-c37-successfully-launches-104-satellites-single-flight (last visited Oct. 22, 2018); Santanu Choudhury, "India Breaks Record for Launching Most Satellites from a Single Rocket," Wall Street Journal (Feb. 15, 2017), https://blogs.wsj.com/indiarealtime/2017/02/15/india-breaks-record-for-launching-most-satellites-from-single-rocket/.

[84] See Spaceflight, Inc., IBFS File No. SAT-STA-20150821-0006 (analysis of "within-plane" collision risk for 91 objects planned for deployment in a single launch).

[85] Letter from Anne E. Sweet, NASA Representative on the Commercial Space Transportation Interagency Group, Program Executive, Launch Services Office, Human Exploration and Operations Mission Directorate, NASA to Marlene Dortch, Secretary, FCC, IBFS File Nos. SAT-LOA-20161115-00118, SAT-LOA-20161115-00121 at 1-2 (filed June 26, 2017) (NASA NGSO Constellation Comments).

[86] Id.

satellite constellation involves a large number of satellites or will be initially deployed at higher altitudes in LEO.[87] Deployment of large numbers of satellites increases the spatial density of objects in the region of space where the satellites are deployed, and provides an indicator of potential collision risk. We consider a deployment of 100 satellites over a typical 15-year license term to be a deployment of a large number of satellites, but seek comment on whether a different number may be appropriate. We consider higher altitudes to be those with a perigee above 600-650 km.[88] From these orbits, spacecraft will typically remain in orbit for several decades to centuries, and present a long-term collision risk, unless active measures are taken to shorten orbital lifetimes. We also seek comment and suggestions on other possible metrics, and methods for verifying and assessing compliance with any such metric.

3.4 D. Post-Mission Disposal

36. Post-mission disposal consists of measures taken, often at the end of a spacecraft's useful life, that result in removal of the spacecraft from Earth's orbit, or relocation of the spacecraft to a long term orbit that reduces the risk of collision with operational spacecraft. In 2004, the Commission observed that effective disposal of non-functional spacecraft can both protect operational spacecraft from accidental collisions with orbital debris and reduce the probability of non-functioning objects colliding with one another and creating additional debris.[89] The concerns associated with non-functioning spacecraft are magnified as more satellites are launched, particularly to altitudes where a failed spacecraft may remain in orbit more than 25 years.[90] Under our rules, an applicant's orbital debris mitigation statement must include several elements regarding post-mission disposal, including a description of the planned disposal orbit, for GSO satellites, and a casualty risk assessment for NGSO satellites where planned post-mission disposal involves atmospheric re-entry of the satellite.[91]

---

[87] See id. (suggesting for discussion purposes a design and fabrication reliability on the order of 0.999 or better per spacecraft in a 4,000+ spacecraft constellation); see also Letter from Johann-Dietrich Wörner, Director General, European Space Agency, to Marlene H. Dortch, Secretary, FCC, IB Docket No. 16-408 at 3 (filed Sept. 15, 2017) (ESA NGSO FSS Comments) (noting the exponential relationship between environmental effect and the number of failed spacecraft).

[88] For objects orbiting the Earth, the point in orbit that the object is closest to the Earth is known as the object's "perigee."

[89] Orbital Debris Order, 19 FCC Rcd at 11591, para. 58.

[90] See, e.g., IADC Statement on Large Constellations at 6 (noting that most proposed concepts for large constellations in LEO target at operational altitudes above 1000 km, where the average natural atmospheric drag-induced orbital lifetimes are "quasi eternal"); ESA NGSO FSS Comments at 2 (making the same observation).

[91] 47 CFR § 25.114(d)(14)(iv).

37. Based on our experience since 2004 in evaluating post-mission disposal plans, as well as concerns regarding satellite reliability and large constellations,[92] we propose below specific revisions to our existing disclosure requirements regarding post-mission disposal of NGSO satellites.

3.4.1 1. Probability of Success of Disposal Method

38. Incorporation of Disposal Reliability Metrics. We propose to require that applicants provide information concerning the expected reliability of disposal measures involving atmospheric reentry, and the method by which that expected reliability was derived. We also seek comment on the metric by which such information should be evaluated; for example, should we specify a probability of success of no less than a set figure, such as 0.90?[93] The NASA Standard notes that failure of spacecraft to execute a planned disposal maneuver or operation on a routine basis will result in a more rapid increase in the orbital debris population.[94] Moreover, in the 2004 Orbital Debris Order, the Commission noted that "[r]eliability may be relevant to both the assessment of whether the satellite will meet end-of-life goals, and to the assessment of whether the public interest benefits arising from the satellite's activities will, in fact, be provided."[95] Adding a specific metric for reliability of disposal may help us to better evaluate the applicant's end-of-life disposal plan. We also invite comment as to whether, when assessing the reliability of disposal, we should do so on an aggregate, system-wide basis as well as on a per-satellite basis, and on whether, for large constellation deployments, where due to large numbers of spacecraft aggregate effects could be more damaging to the space environment, a more stringent metric should apply. A recent NASA study of large constellations concluded, for example, that a 0.99 spacecraft post-mission disposal reliability is needed to mitigate the serious long-term debris generation potential from large constellations.[96]

39. Other Requirements for Satellites with Planned Operations in LEO. We propose two additional disclosure requirements related to reliability and seek comment on other possible requirements as well.

---

[92] See, e.g., IADC Statement on Large Constellations at 6 ("It is clear that significant improvements in the reliability of the disposal function at end of life will be needed for the new [large LEO] constellations compared with that currently demonstrated by space systems on orbit.").

[93] See NASA Standard at 41, Requirement 4.6.3.n (specifying that for NASA missions, the probability of success of post-mission disposal operations should be no less than 0.90). This probability metric would apply where post-mission disposal operations will lead to atmospheric reentry or maneuvering the spacecraft into a storage orbit. See id. Consistent with the Commission's discussion in the 2004 Orbital Debris Order, we do not propose to foreclose direct retrieval of the spacecraft from orbit as a means of post-mission disposal. Orbital Debris Order, 19 FCC Rcd at 11591, para. 60.

[94] NASA Standard at 41, Requirement 4.6.3.n.

[95] Orbital Debris Order, 19 FCC Rcd at 11602-03, para. 86.

[96] See J.-C. Liou, et. al., "NASA ODPO's Large Constellation Study" NASA Orbital Debris Quarterly News, Volume 22, Issue 3 at 4-7 (Sept. 2018), https://www.orbitaldebris.jsc.nasa.gov/quarterly-news/pdfs/odqnv22i3.pdf. The study analyzed three hypothetical constellations operating at 1000 to 1325 km altitudes. Id.

40. First, we propose that the applicant certify that all satellites that will operate at an altitude of 650 km or above will be initially deployed into orbit at an altitude below 650 km and then, once it is determined that the satellite has full functionality, be maneuvered up to their planned operational altitude.[97] This would help to ensure that if satellites are found to be non-functional immediately following deployment, such that they will be unable to perform any maneuvers, they will re-enter the atmosphere within 25 years and not persist in LEO for longer periods of time. As briefly discussed above, [98] ensuring functionality of spacecraft in a large constellation may be particularly important, since an unforeseen flaw could result in the failure of hundreds of satellites of a planned constellation immediately following deployment. We recognize that this requirement may involve additional reserves of fuel, for example, for orbit-raising. In some respects, this is similar to the analysis undertaken in the Commission's 2004 Orbital Debris Order, which resulted in the adoption of a requirement to maneuver GSO spacecraft at end-of-life to a particularly calculated disposal orbit, even though this maneuver required additional fuel.[99] There, the Commission concluded that the additional costs were warranted in order to achieve the public interest in minimizing the hazard posed by orbital debris to the continued safe and reliable use of the GSO region.[100] Similarly, we posit here that the benefits of the continued viability of the LEO region may outweigh the costs of orbit-raising, and seek comment on the costs and benefits associated with this proposal. Relatedly, we seek comment on whether we should require that applicants for large constellations test a certain number of satellites in a lower orbit for a certain number of years before deploying larger numbers, in order to resolve any unforeseen flaws in the design that could result in generation of debris.[101]

41. Second, we propose that applicants seeking to operate NGSO satellite systems provide a statement that spacecraft disposal will be automatically initiated in the event of loss of power or contact with the spacecraft,[102] or describe other means to ensure

---

[97] Appendix A, Proposed Rules. See ESA NGSO FSS Comments at 2 (suggesting that spacecraft be injected into orbits 650 km or lower, and then only move to operational altitude after a successful functional check-out).

[98] See supra Part III.C.6.

[99] See Orbital Debris Order, 19 FCC Rcd at 11593, para. 75.

[100] Id. The GSO region is the region surrounding a circular orbit along the plane of the Earth's equator at an altitude of approximately 35,786 kilometers. Id. at 11568, n. 4. A spacecraft in this orbit can be maintained at a constant longitudinal position relative to the Earth, thus allowing the satellite to be "seen" continuously from, and at a fixed orientation to, any given point on the Earth's surface. Id.

[101] As an example, Telesat Canada, the recipient of a grant of access to the U.S. market for a planned NGSO constellation of 117 satellites, is using prototype satellite(s) for testing and design verification purposes. Telesat Canada, Petition for Declaratory Ruling, IBFS File No. SAT-PDR-20161115-00108, Telesat LOI, Exh. 3 at 5 (granted Nov. 2, 2017). The ESA NGSO FSS comments noted that critical components inducing break-ups are sometimes identified only years after the satellite has been operational, which could result in a large problem with large numbers of satellites, particularly with short production times involved. ESA NGSO FSS Comments at 3.

[102] This type of proposal was suggested by ESA in its comments to the NGSO FSS proceeding, with respect to large constellations. See ESA NGSO FSS comments at 3.

that reliability of disposal will be achieved, such as internal redundancies, ongoing monitoring of the disposal function, or automatic initiation of disposal if communications with the spacecraft become limited.[103] These means would be designed to limit the situations in which the satellite remains on-orbit after a spacecraft failure, or otherwise presents an enhanced hazard for explosions, collisions, or other debris-causing events. Consistent with this rationale, this requirement would help ensure that spacecraft failures do not result in concentration of debris in the LEO region.

42. We recognize that these design features have some associated costs. We seek comment on the costs and benefits associated with this proposed requirement. We also ask whether we should simply require the design to include automatic disposal by a de-orbiting device in the event of loss of power, and on whether any such requirement would provide adequate flexibility for operators to react, for example, if the particular failure mode results in further propulsive maneuvers running a high risk of explosive fragmentation. Are there other technologies that can be used to ensure that satellite disposal is completed, even in the event of a major anomaly, and should we require use of those technologies for satellites that will operate in particular regions?

43. We propose that these two requirements would apply to satellites that will operate above 650 km and below 2,000 km, in other words, in the higher portion of LEO.[104] We also seek comment on whether any requirements should only apply to LEO satellite constellations of a certain size or greater or whether they should apply to all LEO satellites that will operate in the area described.

44. Means of LEO Spacecraft Disposal. Additionally, we seek comment on whether there are other rule changes we should consider related to the disposal of spacecraft from the LEO region. Should we adopt a rule that disposal of spacecraft in the LEO region must be by either atmospheric re-entry or direct retrieval? The U.S. Government Standard Practices, originally developed in the 1990s, recognize disposal to a region above LEO as an option for non-geostationary satellites,[105] but the IADC Guidelines do not recognize this option. The IADC Guidelines instead list the following options for disposal for spacecraft terminating their operational phase in the LEO region: de-orbit, maneuver to an orbit with a reduced lifetime (where the spacecraft will naturally re-enter the atmosphere), or retrieval.[106]

45. We observe that satellites left at higher altitudes will remain in orbit indefinitely, and removal from orbit is generally preferable.[107] With respect to direct retrieval, the Commission concluded in 2004 that direct retrieval was not feasible at that time, but did not preclude direct retrieval as a possible method of post-mission disposal.[108] In assessing whether a post-mission disposal plan is sufficiently reliable, what weight, if

---

[103] Appendix A, Proposed Rules.

[104] Appendix A, Proposed Rules.

[105] U.S. Government Standard Practices at 4-1.

[106] IADC Guidelines at § 5.3.2.

[107] See ESA NGSO FSS Comments at 3 (noting that disposal of satellites in large LEO constellations by orbit raising should be avoided).

[108] Orbital Debris Order, 19 FCC Rcd at 11591, para. 60.

any, and under what circumstances, should we give to proposals to directly retrieve the spacecraft from orbit at its end of life?[109] Should direct retrieval be considered as a valid debris mitigation strategy, for example, only if the retrieval spacecraft are presented for licensing as part of or contemporaneously with the constellation license?

46. Disposal of NGSO Satellites In Orbits Above LEO. We also seek comment on whether to modify the Commission's existing rules regarding end-of-life disposal for satellites to include additional provisions concerning disposal of certain NGSO satellites operating in orbits above LEO. The current rules require disclosure of such plans, and in 2004 we concluded that we would assess disposal plans for satellites that do not pass through the LEO or GEO regions, such as those in highly elliptical orbits or medium Earth orbits, on a case-by-case basis.[110]

47. As a general matter, there appear to be two types of approaches to post-mission disposal above LEO. One approach is to remove a satellite from its operational orbit to another, relatively stable orbit that is sufficiently distinct from those orbits that are currently used or expected to be used for regular operations, so as to eliminate the risk of collisions with such operating satellites.[111] Another approach is to place a satellite into an unstable orbit, i.e., one in which gravitational forces and solar radiation pressure force a growth in the eccentricity of the orbit, ultimately resulting in lowering of the satellite's perigee and re-entry into the atmosphere.[112] While this latter approach may result in disposed satellites traversing other operational orbits and passing through the LEO region, they can ultimately result in removal of the satellite from orbit. Thus, this latter approach may result in less long-term collision risk, although perhaps at the cost of increased short-term risk.

48. We seek comment on whether these practices are sufficiently developed to formalize in our rules. We also seek comment on whether there are any specific guidelines we should include in our rules with respect to these approaches, or with respect to any particular type of orbit.[113]

---

[109] Direct retrieval of satellites implicates the need to assess rendezvous and proximity operations, and any risk of debris generation from those operations.

[110] Orbital Debris Order, 19 FCC Rcd at 11603-04, para 87.

[111] See Satellite CD Radio Inc., IBFS File No. SAT-MOD-20091119-00123, Attachment A at 3-7; O3b Limited, IBFS File No. SES-LIC-20100723-00952, Technical Information to Supplement Schedule S at 37-40; Karousel, LLC, IBFS File No. SAT-LOA-20161115-00113, Letter from Monish Kundra, Karousel LLC, to Jose P. Albuquerque, Chief, Satellite Division, International Bureau, FCC (April 11, 2017) at 7-8. The geostationary disposal requirement in our rules, intended for satellites orbiting at inclinations of approximately 15 degrees or less, can be viewed as an example of this type of disposal.

[112] Space Norway AS, IBFS File No. SAT-PDR-20161115-00111, Technical Information to Supplement Schedule S at 15-18. This approach appears to be more readily available for satellites operating at higher inclinations.

[113] End-of-life Disposal in Inclined Geosynchronous Orbits, Luciano Anselmo & Carmen Pardini, Proceedings of the 9th IAASS Conference, International Association for the Advancement of Space Safety, 2017, pp. 87-94 (outlining modified version of the IADC formula for geostationary satellite disposal, to address satellites in highly-inclined geosynchronous orbits and resulting orbital perturbations).

3.4.2 2. Post-Mission Lifetime

49. As some types of designs lead to satellites that are smaller and less expensive to construct and launch, there has been a corresponding trend toward shorter mission lifetimes for NGSO satellites deployed into the LEO region. For example, the anticipated lifetime of a typical "CubeSat" operating in the Earth exploration-satellite service is only one or two years.[114]

50. Consistent with these shorter mission lifetimes, as well as the number of satellites planned for deployment, we ask whether the 25-year disposal guideline contained in the NASA Standard remains a relevant benchmark.[115] That is, does the guideline that a spacecraft reenter the atmosphere no more than 25 years after the completion of the spacecraft's mission permit spacecraft designs that result in a longer disposal period than may be in the public interest for a particular satellite mission? Should the disposal guideline instead be proportional to mission lifetime, or specific to the orbital altitude where the spacecraft will be deployed?[116] We also note that solar activity can influence the re-entry periods of satellites in LEO,[117] and that future solar activity may vary from predictions[118] In what manner, if any, should we account for variations in solar activity in our rules and in crafting conditions on the grant of specific licenses? Should satellite operators planning disposal through atmospheric re-entry be required to continue obtaining spacecraft tracking information, for example by using radio facilities on the spacecraft, to the greatest extent

---

[114] See, e.g., Planet Labs Inc., Application for Launch and Operating Authority, IBFS File No. SAT-LOA-20130626-00087, Exh. 43 at 2 (describing the nominal lifetime of its Flock 1 satellites as 11 months, with maximum lifetime of 18 months); Planet Labs Inc., Modification Application, IBFS File No. SAT-MOD-20150802-00053, Exh. 43 at 1 (describing expected operational lifetime of a series of additional satellites as approximately two years); Spire Global, Inc., Application for Launch and Operating Authority, IBFS File No. SAT-LOA-20151123-00078, Exh. A at 23 n.73 (describing the operational lifetime of a typical Spire satellite as approximately two years). In the Small Satellite NPRM, the Commission proposed that the total on-orbit lifetime, including both mission and time to de-orbit, be five years or less for small satellites licensed under the proposed streamlined process. Small Satellite NPRM, FCC 18-44 at 15, para. 28. This proposed five-year on-orbit lifetime would apply only to satellites licensed under the streamlined process, see id., and we anticipate that the streamlined process would be used by some, but not all, CubeSats.

[115] NASA Standard at 37, Requirement 4.6.2. The NASA Standard provides the option that, for a spacecraft with a perigee altitude below 2,000 km that will be disposed of through atmospheric re-entry, the operator shall leave the space structure in an orbit in which natural forces will lead to atmospheric reentry within 25 years after the completion of mission but no more than 30 years after launch. Id.

[116] See IADC Statement on Large Constellations at 6 (noting that, in reference to the proposed large NGSO constellations, the 25-year lifetime may need to be reduced to limit residence times in orbit).

[117] Relatively weak solar activity can result in a decrease of the atmospheric drag on satellites in LEO, causing longer re-entry periods for retired spacecraft, including beyond a 25-year predicted re-entry period. For a brief summary of satellite drag and its causes, see National Oceanic and Atmospheric Administration, Space Weather Prediction Center, Satellite Drag, http://www.swpc.noaa.gov/impacts/satellite-drag.

[118] See, e.g., Robert Lee Hotz, Strange Doings on the Sun, Wall Street Journal (Nov. 10, 2013), http://www.wsj.com/articles/SB10001424052702304672404579183940409194498.

possible following the conclusion of the primary mission? In addition to these questions, we seek comment generally on how to prevent satellites from becoming sources of orbital debris during the period following their mission lifetime and before disposal through atmospheric re-entry.

3.4.3 3. Casualty Risk Assessment

51. The U.S. Government Orbital Debris Mitigation Standard Practices and the NASA Standard include a policy of limiting to 1 in 10,000 the risk of at least one human casualty, anywhere in the world, from a single, uncontrolled reentering space structure.[119] In order to assist the Commission in evaluating the spacecraft design with respect to human casualty risk, we propose two specific informational requirements for satellites with a planned post-mission disposal of uncontrolled atmospheric re-entry.[120]

52. First, we propose that the human casualty risk assessment include all objects that would have an impacting kinetic energy in excess of 15 joules. This is consistent with the NASA Standard, wherein the potential for human casualty is assumed for any object with an impacting kinetic energy in excess of 15 joules.[121]

53. Second, we propose that where the calculated risk of human casualty from surviving debris is determined to be greater than zero, as calculated using either the NASA Debris Assessment Software or a higher fidelity model,[122] the applicant must provide a statement indicating the actual calculated human casualty risk, as well as the input assumptions used in modelling re-entry. We tentatively conclude that these additional specifications will enable the Commission to better evaluate whether the post-mission disposal plan is in the public interest and seek comment on this approach. We further invite comment on whether, when assessing human casualty

---

[119] See Orbital Debris Order, 19 FCC Rcd at 11603, para. 88; NASA Standard at 44, Requirement 4.7.3.

[120] For missions planning controlled reentry, we anticipate evaluating such plans on a case-by-case basis, consistent with the NASA Standard. See NASA Standard at 44, Requirement 4.7.2.

[121] Id. The 15 joule limit has been determined to be the limit above which any strike on a person will require prompt medical attention. NASA Standard, at 45, Requirement 4.7.3.c. The 1:10,000 standard does not account for sheltering, as it is estimated that as much as 80% of the world's population is either unprotected or in lightly-sheltered structures for purposes of protection from a falling object with a kilojoule-level kinetic energy. NASA Standard, at 45, Requirement 4.7.3.d.

[122] The Debris Assessment modeling software is available for use without charge from the NASA Orbital Debris Program office at https://www.orbitaldebris.jsc.nasa.gov/mitigation/das.html. The NASA Standard notes that the re-entry risk assessment portion of Debris Assessment Software contains a simplified model which does not require expert knowledge in satellite reentry analyses and is designed to be somewhat conservative. NASA Standard at 46, Requirement 4.7.4.d. The use of a simplified model may result in a higher calculated casualty risk than models employing higher fidelity calculations and inputs. See, e.g., NASA Orbital Debris Program Office, Orbital Debris Object Reentry Survival Analysis Tool, https://orbitaldebris.jsc.nasa.gov/reentry/orsat.html (last visited Oct. 22, 2018) (explaining that the Object Reentry Survival Analysis Tool (ORSAT) is frequently used for a higher-fidelity survivability analysis after the Debris Assessment Software has determined that a spacecraft is possibly non-compliant with the NASA Safety Standard).

risk, we should do so on an aggregate, system-wide basis as well as on a per-satellite basis, and, if so, what metric should be used to evaluate aggregate risk.

3.4.4 4. Part 25 GSO Satellite License Term Extensions

54. Operators of GSO satellites routinely request that the Commission grant license modifications to extend their authorized satellite operations beyond the initial license terms.[123] When requesting such modifications, licensees typically provide information to the Commission that includes the requested duration of license extension, an estimate of the total remaining satellite lifetime, a statement that the satellite has no single point of failure that would affect its ability to complete end-of- life procedures as planned, a statement concerning the adequacy of remaining fuel reserves to complete deorbit as planned, and a statement on the status of tracking, telemetry, and command links.[124] The Commission reviews these statements and requests additional details when warranted, such as when a satellite has a record of malfunctions, known defects, or experienced other anomalies in its operational history. If satisfied with an applicant's showing, the Commission will grant a modification extending the license term, with the duration of the extension established through a case-by-case analysis.[125]

55. Although there is some evidence that GSO satellites can operate beyond their initial license terms without any significant decrease in their operational capabilities or increase in their risk of on-orbit failure,[126] we are aware of instances in which GSO satellites have experienced sudden failures.[127] Although these cases are exceptional (operators have been able to satisfy their obligation to perform end of-life procedures in almost all cases), the potential consequences of introducing additional debris to the geostationary arc are significant—debris from a collision in

---

[123] The license terms for grants under Part 25 are specified in Section 25.121 of the Commission's rules. 47 CFR § 25.121. With some exceptions, licenses are typically issued for a period of 15 years. See id. We will continue to assess requests for license term extensions for NGSO satellite systems on a case-by-case basis.

[124] See, e.g., Intelsat License LLC, Modification Application, IBFS File No. SAT-MOD-20161004-00097 (granted Dec. 8, 2016) (requesting an extension of the license term of the Galaxy 25 satellite).

[125] See 47 CFR § 25.121(b).

[126] One study on satellite on-orbit mortality provides evidence that satellites that survive their first years of operation tend to exceed their expected design life. Cf. Gregory F. Dubos et al., A Satellite Mortality Study to Support Space Systems Lifetime Prediction, IEEE Aerospace Conference Proceedings (Mar. 2013).

[127] See EchoStar Satellite Operating Corporation, IBFS File No. SAT-STA-20170728-00112 (granted July 27, 2017) (grant of special temporary authority associated with an anomaly that caused EchoStar to temporarily lose control of the EchoStar III satellite); see also SES Americom, Inc., IBFS File No. SAT-STA-20170619-00091 (granted June 19, 2017) (grant of special temporary authority associated with an anomaly that caused SES to temporarily lose control of the AMC-9 satellite). We note that in both instances the operators were ultimately able to regain control of the satellites and deorbit them as planned.

geostationary Earth orbit (GEO) will remain on orbit virtually forever and "[t]he wide-spread distribution of debris across GEO could result in the degradation of the reliability of GEO satellite communications for the foreseeable future."[128]

56. We propose to codify our current practice of requesting certain types of information from GSO licensees requesting license term extensions. The rule would specify that applicants should state the duration of the requested license extension and the estimated total remaining satellite lifetime, certify that the satellite has no single point of failure or other malfunctions, defects, or anomalies during its operations that could affect its ability to conduct end-of life procedures as planned, that remaining fuel reserves are adequate to complete deorbit as planned, and that telemetry, tracking, and command links are fully functional.[129] In the event that the applicant is unable to make any of the certifications, we propose that the applicant provide a narrative description justifying the extension. We seek comment on this approach.

57. We propose to continue to assess the duration of the license term extension on a case-bycase basis, but propose to limit extensions to no more than five years in a single modification application. We tentatively conclude that five years may be an appropriate upper limit for a single modification to help ensure reasonable predictions regarding satellite health while affording operators some flexibility. Additionally, if subsequent extensions are sought, we would have the opportunity to review those extension requests in intervals of five years or less. We seek comment on this tentative conclusion. We also seek comment on whether we should further limit license term extensions or place a cap on the number of times which a GSO satellite license can be extended.

58. We further seek comment on whether there are certain types of satellite buses[130] that may warrant heightened scrutiny for purposes of license extensions. In addition, we seek comment on whether, apart from the review undertaken when a license is extended, there are types or categories of anomalies that should trigger immediate reporting, in order to assess whether reliability of post-mission disposal has been compromised to the point that immediate actions may be required.

3.5 E. Proximity Operations

59. With increasing interest in satellite servicing and other non-traditional missions, there have been an increasing number of commercial missions proposed that involve

---

[128] See, e.g., Orbital Debris Order, 19 FCC Rcd at 11595, para. 66.

[129] Appendix A, Proposed Rules, Section 25.121.

[130] A satellite "bus" is the colloquial term sometimes used to describe a satellite design (structure, power and propulsion systems, etc.) developed by a manufacturer and adapted for specific missions in response to individual customer requirements.

proximity operations and rendezvous of spacecraft.[131] We propose that applicants be required to disclose whether the spacecraft will be performing any space rendezvous or proximity operations. The statement would indicate whether the satellite will be intentionally located or maneuvering near another spacecraft or other large object in space. Such operations present a potential collision risk, and operators will need to address that risk, as well as any risk of explosions or generation of operational debris that might occur through contact between spacecraft, as part of debris mitigation plans. Accordingly, we propose a disclosure requirement regarding these types of operations.

3.6 F. Operational Rules

60. We also propose several updates to satellite operational rules relevant to physical operations.

3.6.1 1. Orbit Raising

61. The Commission's rules provide that, for satellites authorized for normal operations in the geostationary orbit, the Commission authorization also includes authority for telemetry, tracking, and command functions to raise the satellite to its normal orbit following launch.[132] This rule was adopted to make it clear that orbit-raising types of maneuvers in the pre-operational phrase are authorized operations, even though they may vary from the orbital parameters specified in the license.[133] Such authority is currently limited to operations on a non-harmful-interference, unprotected basis.[134] Because orbit-raising maneuvers are performed by satellites intended for non-geostationary orbits as well as for the geostationary orbit, and the number of satellites engaging in orbit-raising maneuvers may increase if other proposals in this Notice are adopted,[135] we take this opportunity to propose and seek comment on expanding the provision to include NGSO system operations.

---

[131] See, e.g., Space Logistics, LLC, Application for Launch and Operating Authority, IBFS File No. SAT-LOA-20170224-00021, Narrative at 1, 6-7 (filed Feb. 24, 2017, granted December 5, 2017).

The Defense Advanced Research Projects Agency (DARPA) has initiated a Consortium for Execution of Rendezvous and Servicing Operations to help develop technical and safety standards for performance of on-orbit activities involving commercial satellites. "CONFERS to establish 'Rules of the Road' for On-Orbit Servicing of Satellites," DARPA, News and Events (Oct. 4, 2017), https://www.darpa.mil/news-events/2017-10-04.

[132] 47 CFR § 25.282; see also Orbital Debris Order, 19 FCC Rcd at 11585, para. 40.

[133] Orbital Debris Order, 19 FCC Rcd at 11585, para. 40.

[134] See 47 CFR § 25.282(b) and (c).

[135] See supra Part III.D.1 (proposing that NGSO space stations planned for operation at certain altitudes be initially deployed in a lower orbit, then subsequently moved to the planned operational altitude).

62. In addition, in a manner similar to the provisions for maneuvering at the end-of-life for a GSO satellite,[136] we propose to require such telemetry, tracking, and command operations to be coordinated between satellite operators as necessary to avoid interference events, rather than require the operations to be performed on a non-interference basis. We tentatively conclude that it is in the public interest that these types of telemetry, tracking and command communications, critical to effective spacecraft maneuvering, be coordinated as necessary to avoid interference, rather than being authorized only on an a non-harmful-interference, unprotected basis. We seek comment on revising our existing rule regarding orbit raising maneuvers to require coordination of such operations to avoid interference events and to extend the application of the rule to NGSO satellites as well as GSO satellites.[137]

3.6.2 2. Maintaining Ephemeris Data

63. The Commission recently adopted a rule requiring that all NGSO FSS licensees or market access recipients ensure that ephemeris data[138] for their constellations are available to all operators of authorized, in-orbit, co-frequency satellite systems.[139] The purpose of the current rule is to ensure compatible operations of NGSO FSS constellations, because knowledge of the physical locations of NGSO FSS satellites is an essential element of spectrum sharing under the Commission's rules.[140] It also may be in the public interest for the physical locations of NGSO satellites to be known for purposes of collision avoidance, regardless of whether that information is necessary for spectrum sharing among systems.

64. We propose that NGSO operators be required to maintain ephemeris data for each satellite they operate and share that data with operators of other systems operating in the same region of space.[141] Specifically, we propose to require that operators share ephemeris data with any other operator identified in its disclosure described above of any operational space stations that may pose a collision risk. We believe this requirement will help to facilitate communications between operators, even before a potential conjunction warning is given. We also propose that the information be shared by means mutually acceptable to the parties involved, to allow for flexibility and efficiency in sharing of information.[142] We seek comment on

---

[136] 47 CFR § 25.283(b) (providing for a space station to operate using its authorized tracking, telemetry, and control frequencies for the purpose of removing the satellite from the geostationary orbit at the end of its useful life, "on the condition that the space station's tracking, telemetry, and control transmissions are planned so as to avoid electrical interference to other space stations, and coordinated with any potentially affected satellite networks.").

[137] See Appendix A, Proposed Rule Changes.

[138] Ephemeris data give the orbital positions of satellites at a given time or times.

[139] 47 CFR § 25.146(e); Update to Parts 2 and 25 Concerning Non-Geostationary, Fixed-Satellite Service Systems and Related Matters, Report and Order and Further Notice of Proposed Rulemaking, 32 FCC Rcd 7809, 7827-28, paras. 56-58 (2017) (NGSO FSS R&O).

[140] NGSO FSS R&O, 32 FCC Rcd at 7827-28, paras. 56-57.

[141] Appendix A, Proposed Rules.

[142] See NGSO FSS R&O, 32 FCC Rcd at 7828, para. 58.

this proposed revision to include these proposed requirements regarding availability of NGSO satellite ephemeris data.[143]

3.6.3 3. Telemetry, Tracking, and Command Encryption

65. There is currently no requirement in the Commission's rules that space station licensees encrypt telemetry, tracking, and command communications.[144] As a practical matter, most satellites do operate with secure encrypted communications links, and all operators have an interest in securing against unauthorized actors interfering with their mission. Certain low-cost satellite missions—some CubeSats or other small satellites, particularly those operated for academic purposes—may not use encryption for telemetry, tracking, and command communication links.[145] The developers in these cases may have concluded that the costs or time associated with implementing encryption of telemetry, tracking, and command communications outweigh the potential risks.[146] Some have observed that a satellite outfitted with onboard propulsion capabilities could pose some risk to the operations of other spacecraft if a malevolent actor were able to take control of and command the satellite and that encryption should therefore be required.[147]

66. We seek comment on whether to include any provisions in our rules concerning encryption for telemetry, tracking, and command communications for satellites with propulsion capabilities, and propose to add a requirement to our operational rules.[148] Should this rule be applicable only to satellites having propulsion systems with certain capabilities, for example, certain ΔV capability? More generally, should we consider such a requirement, regardless of propulsion capabilities, recognizing that other possible harms, such as radio-frequency interference, could result from such scenarios? We anticipate that this rule will have no practical impact for most satellites and systems, which already encrypt communications, and seek comment on whether any burden that would result from adoption of such a rule is justified by the resulting improvements to the security of satellite control operations. Additionally, we seek comment on whether, if such a rule is adopted, there are any criteria that should be identified with respect to the sufficiency of encryption methods.

---

[143] See Appendix A, Proposed Rules. Although not currently included in the Proposed Rule Changes, we also propose to adopt this requirement for satellite operations under Parts 5 and 97.

[144] Section 25.271 of the Commission's rules, relating to control of transmitting stations, for example, specifies some measures for security of earth stations authorized under Part 25, but does not include any provisions regarding

[145] A. Kurzrok, M. Diaz Ramos, and F.S. Mechentel, "Evaluating the Risk Posed by Propulsive Small-satellites with Unencrypted Communications Channels to High-Value Orbital Regimes," 32nd Annual AIAA/USU Conference on Small Satellites, at 1 (2018).

[146] See id. at 4.

[147] See id. at 8; Eleni M. Sims and Barbara M. Braun, "Navigating the Policy Compliance Roadmap for Small Satellites," The Aerospace Corporation, at 9 (2017).

[148] See Appendix A, Proposed Rules. Transmissions by amateur stations can include encrypted telecommand (See 47 CFR § 97.211(b)), and space telemetry transmissions (47 CFR § 97.207(f)).

3.7 G. Liability Issues, Insurance, and Economic Incentives

67. In 2004, the Commission noted that, under international law, the United States government could potentially be presented with a claim for damage resulting from private satellite operations such as disposal or generation of orbital debris.[149] At that time, the Commission considered what role liability and insurance considerations should play in licensing.[150] While the Commission declined to adopt a general insurance requirement, it anticipated that insurance and liability relating to the post-launch period could play a role in determining whether approval of a particular debris mitigation plan serves the public interest.[151]

68. As part of this general update of our rules related to orbital debris mitigation, we now revisit these topics. In so doing, we note that the Commission is a regulatory agency, and unlike agencies with statutory authority to conduct space operations, cannot accept risk on behalf of the United States by encryption of communications. See 47 CFR § 25.271(c) (securing transmitting stations operating by remote control), 25.271(d) (securing transmitting earth station facilities against unauthorized access or use whenever an operator is not present at the transmitter). Our review of an applicant's debris mitigation plan, or grant of a license, does not alter any liability of the applicant or licensee.[152]

69. First, we propose to require Commission space station licensees to, at a minimum, indemnify the United States against any costs associated with a claim brought against the United States related to the authorized facilities. Given the potential risk of a claim being presented to the United States under international law, we tentatively conclude that an indemnification by these U.S.-licensed private operators is appropriate. We propose that the indemnification would take the form of an indemnity agreement, and that we will consult with interagency partners, including the U.S. Department of State, to establish the parameters of such an agreement, including the scope of the indemnification and the means to execute the agreement, including by the appropriate U.S. government official or officials. We seek comment on this proposal, including on the form and content of such an agreement.

70. We further propose that the indemnification agreement would in most cases be completed following grant of a space station license, within thirty days. If no indemnification agreement has been approved within thirty days following grant, the space station license would be terminated. In order to ensure that the agreement is approved well in advance of launch of the space station, we also propose that in no case would the agreement be completed fewer than 90 days prior to the planned date of launch. In rare instances, this may require applicants to begin the agreement process prior to grant. We seek comment on these timing matters, including on whether the timeline should be based on the date on which the satellite is integrated

---

[149] Orbital Debris Order, 19 FCC Rcd at 11612-13, paras. 109-10.

[150] Id.

[151] Id.

[152] Orbital Debris Order, 19 FCC Rcd at 11614, para. 113.

into the launch vehicle in preparation for launch rather than launch date. Finally, we propose to limit the requirement of an executed indemnification agreement to U.S.-licensees only at this time, as U.S. licensees generally have a manifest connection to the United States.[153]

71. We also seek comment on whether we should follow the example of other spacefaring nations and require an insurance policy to be obtained by our licensees to provide for payment for any costs associated with a claim brought against the United States related to the authorized facilities, which may be particularly important in the event of bankruptcy of the licensee. Similar to how the Commission's existing bond requirement ensures that the licensee demonstrate to a surety company that it is willing and able to proceed with the construction of the satellite the licensee has requested authority to construct,[154] this insurance requirement would be a demonstration that the potential risks associated with the satellite activities have been considered. As the Commission noted in the 2004 Orbital Debris Order, insurance can, in some instances, provide an economic incentive for operators to undertake debris mitigation measures.[155] We revisit the Commission's 2004 discussion and conclusions and seek comment on what amount and type of insurance may be appropriate.

72. We also seek comment on whether we should separate this requirement where applicable as between on-orbit liability and spacecraft re-entry liability since on-orbit liability is addressed through a fault regime and re-entry liability is addressed through strict liability regime under the Convention on International Liability for Damage Caused by Space Objects (Liability Convention),[156] and if there are particular indicators that would make insurance necessary in particular cases, or, on the other hand, suggest that categories of operators should be exempt from the requirement to obtain insurance. For example, should small satellites applying under the new streamlined process proposed in the Small Satellite NPRM be exempt from an insurance requirement, since space stations in that category would be relatively

---

[153] See Appendix A, Proposed Rule Changes (proposed Section 25.166). In the United Kingdom, for example, the U.K. Outer Space Act of 1986 requires that a party carrying out certain space activity indemnify the government against claims arising out of that activity. Licensees typically must obtain third-party liability insurance in the amount of 60 million euros. See UK Space Agency, Guidance; License to operate a space object: how to apply; Obligations of licensees, https://www.gov.uk/guidance/apply-for-a-license-under-the-outer-space-act-1986; Outer Space Act, 1986, c. 38, § 5(2)(f) (U.K.), http://www.legislation.gov.uk/ukpga/1986/38. Other nations similarly have requirements with respect to indemnification and insurance. See, e.g., United Nations Office for Outer Space Affairs, Selected Examples of National Laws Governing Space Activities: Sweden, Act on Space Activities (Unofficial Translation) at Section 4, available at http://www.unoosa.org/oosa/en/ourwork/spacelaw/nationalspacelaw/sweden/act_on_space_activities_1982E.html (Sweden's Act on Space Activities indemnification provision).

[154] See, e.g., Amendment of the Commission's Space Station Licensing Rules and Policies, First Order on Reconsideration and Fifth Report and Order, FCC 04-147, at para. 17.

[155] Orbital Debris Order, 19 FCC Rcd at 11614, para. 111.

[156] See Convention on International Liability for Damage Caused by Space Objects of 1972, Articles I and II.

lower risk from an orbital debris perspective? As another example, we ask whether GSO space station licensees should be exempt from an insurance requirement since they may present less risk in the post-mission disposal process since they do not typically re-enter Earth's atmosphere. Relatedly, and/or alternatively, we ask if it would be appropriate to consider differential amounts of insurance that would be required for different types of operations.[157]

73. We further invite comment generally on what economic approaches might be feasible and effective in creating incentives such that appropriate launch vehicle and satellite design choices are made, and appropriate decisions regarding the number of satellites launched are made as well. That is, recognizing debris creation as a negative externality, what approaches might induce private decisions on these design and launch choices to be consistent with the public interest in limiting the growth of orbital debris?

3.8 H. Scope of Rules

3.8.1 1. Amateur and Experimental Operations

74. We are also proposing to amend our rules governing experimental satellite and amateur satellite authorizations to maintain consistency with the proposed revisions to the orbital debris mitigation plan application requirements in our commercial rules.[158] In 2002, the Commission observed that amateur and experimental spacecraft can present the same public interest concerns regarding orbital debris as operations under other rule parts.[159] In the 2004 Orbital Debris Order, the Commission adopted rules requiring that a description of the design and operational strategies used to mitigate orbital debris be provided by an applicant seeking to conduct experimental or amateur satellite operations.[160] These disclosure requirements were consistent with the disclosure requirements adopted for commercial satellite applicants.[161] We

---

[157] We are not considering a limit on the proposed indemnification requirement.

[158] See 47 CFR Part 5, Experimental Radio Service; 47 CFR Part 97, Amateur Radio Service. In this document we use the term "commercial" when referring to operations under Part 25 of the Commission's rules, but we note that there is no requirement in Part 25 that operations authorized under that Part must be for an inherently commercial purpose. 47 CFR Part 25.

[159] Mitigation of Orbital Debris, Notice of Proposed Rulemaking, 17 FCC Rcd 5586, 5612, para. 63 (2002).

[160] Orbital Debris Order, 19 FCC Rcd at 11607-09, paras. 98-101, Appendix B. Specifically, the Commission adopted revisions to Sections 5.63 and 97.207 of the Commission's rules. Id. at Appendix B; 47 CFR § 97.207. The relevant disclosure requirements in Section 5.63 for experimental licensing were subsequently moved to Section 5.64 of the Commission's rules. 47 CFR § 5.64(b); Promoting Expanded Opportunities for Radio Experimentation and Market Trials Under Part 5 of the Commission's Rules and Streamlining Other Related Rules, 2006 Biennial Review of Telecommunications Regulations – Part 2 Administered by the Office of Engineering and Technology (OET), Report and Order, 28 FCC Rcd 758, 823, Appendix B (2013).

[161] Compare 47 CFR §§ 5.63, 97.207 with 47 CFR § 25.114(d)(14).

continue to believe that it is appropriate for amateur licensees[162] and experimental applicants to provide a similar amount of disclosure regarding debris mitigation plans as will be required of commercial satellites under any of the changes to Part 25 discussed above that are adopted by the Commission.[163] We seek comment on this proposal.[164]

75. Since most satellites authorized as amateur operations or licensed as experimental satellites operate at low altitudes, the new proposed informational requirements related to collision avoidance and post-mission disposal for higher LEO altitudes would not apply as a practical matter to amateur or experimental systems, and therefore the burden on applicants for compliance with these new proposed rules would in most instances be non-existent. We tentatively conclude that the proposed requirements that would typically apply, such as quantification of collision risk, would not be unduly burdensome, since these applicants and licensees are already providing orbital debris mitigation information to the Commission, and depending on the types of operations, may currently be asked to provide additional details in order for the Commission to determine that grant of the application or authorization is in the public interest. Including the proposed additional disclosure requirements in the rules applicable to experimental space station applicants and amateur space station licensees would help provide concrete requirements with respect to operations in space. We recognize that there may be differences in the scale and longevity of experimental and amateur satellites versus commercial satellite deployments. In general, however, amateur and experimental operations present the same public interest concerns as operations by commercial operators. For example, some individual amateur or experimental satellites may present the same risks with respect to creation of orbital debris as some individual commercial satellites licensed under Part 25. Thus, we believe that the benefits of the new requirements, such as the disclosure rule relating to the protection of manned spacecraft, in ensuring the continued safe use of the space environment, may outweigh the potential costs to amateur operators or experimental licensees.

76. The proposed rule revisions related to GSO satellite license term extensions[165] and orbit-raising[166] would not, if adopted, apply to amateur or experimental satellites, since those rules are not currently applicable to amateur or experimental services. We also propose to exempt amateur and experimental satellites from the ephemeris data requirement, since authorizations and licenses in those services do

---

[162] In seeking Commission approval of amateur satellite operations, the license grantee of the amateur satellite must submit a pre-launch notification to the Commission, as specified in Section 97.207(g) of our rules. 47 CFR § 97.207(g)(1). This notification must include, among other things, information regarding design and operational strategies for mitigation of orbital debris. Id.

[163] See Guidance on Obtaining Licenses for Small Satellites, Public Notice, 28 FCC Rcd 2555, 2558 (IB/OET 2013) (“An orbital debris assessment report prepared consistent with the NASA standards is generally sufficient to meet FCC requirements.”).

[164] See Appendix A, Proposed Rule Changes, Sections 5.64 and 97.207.

[165] See supra Part III.D.4; Appendix A, Proposed Rule Changes, Section 25.121.

[166] See supra Part III.F.1; Appendix A, Proposed Rule Changes, Section 25.282.

not typically involve many satellites.[167] We seek comment on these proposals. Consistent with the above discussion, and bearing in mind that U.S. treaty obligations do not vary based on the Commission's regulatory classification, we also inquire whether we should require indemnification and/or an insurance policy to be obtained by experimental licensees and authorized amateur operators.

3.8.2 2. Non-U.S.-Licensed Satellites

77. We generally propose that the new and amended rules discussed in this NPRM should be applicable to non-U.S.-licensed satellites seeking access to the U.S. market. In other words, an entity seeking access to the U.S. market must continue to submit the same technical information concerning the satellite involved as is required to be submitted by U.S. satellite license applicants.[168] We seek comment on this proposal. With respect to the proposals regarding indemnification and insurance, we ask whether there are any circumstances where it would be appropriate to apply these potential requirements to applicants requesting operations with non-U.S.-licensed satellites, for example, where the applicant is substantially U.S.-based and the foreign licensing administration has not committed to registering the satellite with the United Nations as that administration's space object.

78. In the Orbital Debris Order, the Commission observed that a categorical exemption for any class of satellites serving the United States would undermine the legitimate public policy objective of mitigating orbital debris.[169] The Commission explained that by requiring technical information concerning orbital debris mitigation from these non-U.S.-licensed space stations, the Commission is ensuring that foreign operators that "seek access to the U.S. market for commercial reasons meet the same public interest requirements as U.S.-licensed operators."[170] In some instances, we note that applicants have sought approval to engage in very limited transmission and reception activities between non-U.S.-licensed space stations and earth stations in the United States, such as communications exclusively for telemetry, tracking, and command. Although applicants seeking approval for communications such as telemetry, tracking, and command only may have a limited commercial connection to the United States, there is nonetheless a commercial reason those applicants are seeking to transmit and/or receive from a U.S. earth station. Therefore, we seek comment on whether these applicants should be subject to the same public interest requirements as a U.S.-licensed satellite operating with a U.S. earth station.

79. We further propose that non-U.S.-licensed satellites may continue to satisfy the disclosure requirement by showing that the satellite system's debris mitigation

---

[167] Therefore, no rule related to ephemeris data is proposed for either part 5 or part 97 of the Commission's rules. See Appendix A, Proposed Rule Changes.

[168] Orbital Debris Order, 19 FCC Rcd at 11605, para. 92; see 47 CFR § 25.137(b) (requiring legal and technical information for the non-U.S.-licensed space station of the kind that § 25.114 would require in a license application for a space station).

[169] Orbital Debris Order, 19 FCC Rcd at 11606, para. 93.

[170] Id.

plans are subject to direct and effective regulatory oversight by the satellite system's national licensing authority.[171] Recognizing that in other countries authority over radiofrequency communications and authority over space operations are often addressed by different entities, in order to satisfy our orbital debris mitigation disclosure requirements, we would expect information showing that the operator has received a license from the entity overseeing space operations, or has initiated that process. This would include information about whether or not that administration is expected to register the space object with the United Nations Register of Objects Launched into Outer Space.[172] We seek comment on whether it is appropriate to continue assessing the direct and effective oversight of a foreign licensing authority on a case-by-case basis. Under this approach, approval of foreign oversight for a system design in one case will not necessarily imply similar approval for a different system design.

I. Regulatory Impact Analysis

80. In this section, we seek comment on whether regulation of U.S. Commission-licensed space stations will help to limit such debris and result in a net benefit, even if it may give rise to some regulatory costs. From an economic perspective, the earth orbital region of space can be viewed as essentially a "commons"— that is, a resource that is "non-excludable" in consumption (use of space is available to all countries), but "rivalrous" (each country's use of space reduces the amount available to others). A significant and fundamental problem with economic commons is the tendency of individuals to exploit the commons in a manner that is unsustainable long term and diminishing the usefulness for others. In the context of the earth orbital environment, operators have an incentive to maximize the use of orbital resources for their own gain, which may result in an unsustainable level of activity for long term use of the same orbits. Space is vast and the distances between objects are generally quite large, and it is generally the case that a large number of operational satellites can share the same or similar orbits with relatively low risk of collision, particularly when they have the ability to maneuver to avoid collisions. However, once a satellite reaches its end-of-life or otherwise ceases to operate, for example, it will become a piece of debris, posing a risk to the safe operations of other existing and future satellites.

81. Debris generation by on-orbit activities is a negative externality, and is one which could lead to the degradation of the commons of the Earth orbital environment. Some unique, relevant aspects of debris include the fact that, particularly at higher orbits, the debris population will not naturally decrease with time even if no additional objects are launched into orbit, and that over time existing pieces of debris

---

[171] 47 CFR § 25.114(d)(14)(v); Orbital Debris Order, 19 FCC Rcd at 11606, para. 95.

[172] The United Nations Register of Objects Launched into Outer Space is maintained by the United Nations Office for Outer Space Affairs. The United Nations Office for Outer Space Affairs reports that 92% of all satellites and other spacecraft launched into Earth's orbit and beyond have been registered. United Nations Office for Outer Space Affairs, Space Object Register, http://www.unoosa.org/oosa/en/spaceobjectregister/index.html.

will tend to collide with other existing pieces of debris producing a "cloud" of debris which increases the likelihood of future collisions. While the debris problem is a significant consideration for the long-term use of orbital resources, such considerations may not play a significant role in economic decision making in the short-term. Individual satellite operators may have an interest in preserving the earth orbital environment for their continued operations, but a desire to avoid the short-term costs associated with deorbiting satellites to mitigate debris risk could override those long-term interests. Given these incentives, in the long term, the debris population is likely to continue to grow and could result in an exponential increase in the debris population such that use of certain valuable orbital configurations may no longer be economically feasible. This tendency of debris to generate yet more debris has come to be known as the "Kessler syndrome," a cascade in which so much debris is created that certain orbits can become unusable for decades or centuries.

82. Private sector revenues from space-based businesses are in the hundreds of billions of dollars per year, and there are hugely important scientific and national defense uses of certain orbits as well. A Kessler syndrome type of scenario could render the use of certain orbits economically infeasible and could have significant and far reaching impacts on the global economy for years to come.[173] Although orbital debris is a global problem, our focus in this proceeding is limited to reassessing the Commission's rules concerning orbital debris that are in place today, which we propose to strengthen in certain respects. The Commission's efforts in this area are only one component in addressing an issue of global concern, but as noted, such efforts are undertaken alongside other domestic and international efforts related to mitigation of orbital debris.[174] We further reiterate the Commission's statement from the 2004 Orbital Debris Order that, "we do not believe that the theoretical possibility that other countries could take ill-considered actions, at variance with international norms, in any way should prevent the Commission from adopting objective and transparent measures concerning orbital debris mitigation that serve the public interest."[175] Moreover, while reduced production of debris by operators with U.S. licenses or market access grants will necessarily benefit the space activities of all nations, we focus here only on benefits to citizens and residents of the U.S.[176]

83. We seek comment on six approaches to reducing debris in orbit, which include the proposals discussed in the individual rule sections above:

84. Fewer Launches. One method of reducing orbital debris would be for the Commission to adopt rules that would have the effect of reducing the overall number of satellites launched. This approach is not proposed above, but would involve, as an example, a limit on the number of individual NGSO satellites that could be

---

[173] See, e.g., Adilov, N., Alexander, P.J., Cunningham, B.M, "An economic analysis of earth orbit pollution," Envr. Resour. Econ. 60, 81-98 (2014).

[174] See supra Section II.

[175] 19 FCC Rcd at 11607, para. 97.

[176] This is in accord with established guidance regarding RIAs. See Circular A-4 (2003), page 15.

authorized in a particular time period, which could have the overall effect of limiting the number of satellites launched. It is not clear, however, that such an action by the Commission would in fact reduce the number of satellites launched, since applicants that would normally be licensed by the Commission could potentially seek authorization from a non-U.S. administration. Moreover, the approach could also limit system capabilities and burden new entrants to the satellite industry, even though prior entrants were not subject to a limit. This approach could also prevent the improvement of services and the introduction of new services, and could, perversely, slow technology development that enables improved debris mitigation. Regulations targeted to address particular activities that create risk from an orbital debris perspective may be more effective than a blanket limitation on U.S. commercial activities in space.

85. Changes in Satellite Design. Another method of reducing orbital debris would be for the Commission to regulate how satellites or satellite system are designed. These regulations would limit the types of design features that increase the orbital debris population or increase the risk that such debris will be created. Some of the proposals above would potentially have the effect of changes in satellite design, for example, if more fuel was necessary onboard to perform orbit raising for satellites being deployed in an NGSO constellation.[177] We recognize that there may be some costs associated with these types of proposals and seek comment on those potential cost in the discussion above. We do not propose to mandate particular designs for satellites and systems, however, such as use of a particular satellite bus design. While costs related to satellite design may be necessary to help achieve the goal of limiting creation of orbital debris, we believe such detailed mandates as specific satellite bus design would be too restrictive to cover the wide range of satellite systems and operations, would be difficult to develop and maintain, and could impose hardware and design costs on Commission-authorized satellites as well as costs related to limitations on innovation, that may be beyond what is necessary to achieve the desired ends.

86. Changes in operations and disposal procedures. This is the approach we propose in the individual rule sections above. We believe this approach gives operators sufficient flexibility in implementing their systems, while achieving results consistent with the public interest in preserving access to space for the long term, as well as the safety of persons and property in space and on the surface of the Earth. There are some costs associated with this approach in preparation of information for Commission review, and in potential modifications related to satellite design, operations, or choice of launch opportunities, in order to comply with the Commission's proposed rules. For example, there may be satellites which, because of planned design, may have structures which survive atmospheric re-entry resulting in certain risks to persons on Earth.[178] An applicant under the Commission's rules, as proposed, would need to assess its satellite plans and make changes as necessary to comply with the rule. As

---

[177] See supra Section III.D.1.

[178] See supra Section III.D.3.

another example, an operator may need to deploy its satellites to a different orbit than originally planned in order to comply with the Commission's rules, as proposed, which could impact its system operations or require choosing a different launch opportunity. In some instances, additional fuel may be necessary to perform maneuvers in order to achieve compliance with the Commission's proposed rules. We consider these costs, of course, in view of the benefits from mitigation of the orbital debris population, as discussed, including the safety and reliability of long-term operations in space, as well as the benefits of safety of manned spaceflight as well as believe that regulation of the operational and disposal procedures, as discussed in this NPRM, will allow satellite operators flexibility in achieving business goals as compared to the other discussed alternatives well as safety of persons and property on the surface of the Earth. We such as limiting numbers of satellites launched, while helping to limit the creation of orbital debris in ways that are more effective than use of economic incentives alone, or active debris cleanup, for example.

87. Use of Economic Incentives. In this NRPM, we ask whether there are other economic incentives available that the Commission could offer that would help achieve the public interest in this area.[179] We seek comment on, for example, the possibility of requiring insurance for on-orbit and re-entry liability.[180] This could encourage satellite applicants to design system operations in ways that would enable them to obtain lower cost insurance products. Economic incentives could serve as a supplement—or an alternative—to adopting the changes in operations and disposal procedures contemplated in this NPRM. Given that debris creation is a negative externality, however, we believe that economic incentives alone may not be sufficient.

88. Active Collision Avoidance. The Commission could also potentially reduce orbital debris by requiring all operators to engage in active collision avoidance, which would involve coordination and maneuvering of spacecraft by operators to limit collisions with other objects in space. The proposals set forth in this NPRM include a certification that the space station operator will take appropriate action(s) following receipt of a space situational awareness conjunction warnings in order to help mitigate risk of collision.[181] We observe that in some instances this may include modifying the spacecraft attitude and/or operations, where possible.[182] Thus, we have proposed a rule that would require an operator to review a conjunction warning and take steps to mitigate collision risk if necessary. This proposed rule would not, however, require execution of collision avoidance maneuvers in response to each and every conjunction warning, since many warnings, upon further review by the operator, are found to not require action. In general, we note that operators with maneuvering capabilities already have an economic incentive to determine whether collision avoidance maneuvers are necessary in response to warnings of potential "conjunctions" from organizations that collect and disseminate such data, and to

---

[179] See supra Section III.G.

[180] Id.

[181] See supra Section III.C.3.

[182] Id.

execute any necessary maneuvers.[183] The Commission's proposal does not require all operators to take actions to avoid collisions, and some satellites may not be equipped to make maneuvers. Moreover, if the Commission were to require an operator to take avoidance action based on each conjunction warning it receives, such action would typically require an expenditure of fuel or other changes to the satellite's operational configuration, which can reduce the expected life of the spacecraft or interrupt the satellite's primary mission. Other satellites would have to add maneuvering capabilities to their designs, even where the risk of the satellite being involved in a collision was relatively low, for example because of deployment to a very low altitude and a resulting short orbital lifetime. As such, there would be an economic burden imposed by a requirement that satellites take active collision avoidance maneuvers in all instances. Spacecraft location data is not so precise that it is easy to make decisions about avoiding collisions, and a collision avoidance maneuver could result in a collision with different objects. Thus, there are costs associated with the planning and execution of maneuvers.

89. Active Debris Cleanup. Another alternative to the rules proposed in this NPRM is for the Commission to consider requiring operators to engage in active debris removal. We ask questions about this disposal method in this NPRM.[184] While the technologies needed to conduct these retrieval operations are continuing to be developed and the cost of launching satellites has fallen significantly, these sorts of operations remain at the more experimental side of satellite operations and still have significant costs. Furthermore, direct retrieval is not without its own risks, and attempts to recover satellites directly may result in the production of more debris than the satellite that was to be retrieved. Even when effective, direct retrieval may make sense only for the largest pieces of debris.

90. We seek comment on this proposed regulatory impact analysis. In connection with this analysis, we also seek comment on the relative costs and benefits of performance-based regulation versus prescriptive regulation in the context of orbital debris mitigation. Although the costs of our proposed approach may in some instances be borne by proponents of amateur satellites as well as experimental licensees, who in some instances may be small businesses, amateur and experimental satellite operations present the same public interest concerns as commercial satellite systems, as discussed above. A Kessler syndrome scenario rendering certain orbits or areas effectively unusable would also impact these types of operations. We believe that from a practical perspective, the additional costs of compliance for amateur and experimental satellites will be limited, and to the extent that there are additional costs, such costs may be reasonable given the potentially significant benefits.

91. In connection with this Notice, we seek comment on the benefits and costs of various combinations of these approaches. In addition, to the extent feasible, we identify alternative options, as described in this Notice.

---

[183] See Id.

[184] See supra Section III.D.1.

4 IV. ORDER ON RECONSIDERATION

92. In this Order on Reconsideration, we reject AMSAT's petition for reconsideration of the Commission's decision to apply orbital debris mitigation requirements to amateur service satellites.[185] AMSAT's Petition relies primarily on arguments that were fully considered in adopting those rules. In addition, to the extent that the Petition advances new arguments that could have been raised earlier in the proceeding, there is no basis to consider such arguments favorably.[186] The reconsideration process is not intended to allow petitioners to alter their position or advance new arguments after the rules are adopted, absent new factual developments.[187] In any event, for the reasons stated below, these arguments lack merit. Accordingly, we dismiss or alternatively deny the Petition pursuant to Section 1.429 of the Commission's rules.[188]

93. Background.—On July 17, 2002, AMSAT filed comments in IB Docket No. 02-54, supporting the Commission's establishment of policies to regulate orbital debris and commenting on the ability of amateur satellites to comply with the proposed orbital debris mitigation requirements.[189] AMSAT also filed a comment regarding the Initial Regulatory Flexibility Analysis in the NPRM.[190] On August 15, 2002, AMSAT filed Reply Comments in that proceeding.[191]

94. In the Orbital Debris Order, the Commission applied debris mitigation rules to amateur satellite licensees, noting that no comments had opposed requiring amateur

---

[185] AMSAT Petition at 1. In the Orbital Debris Order, the Commission amended Section 97.207 of the rules to include debris mitigation requirements for amateur satellite operations. Orbital Debris Order, Appendix B – Rule Revisions, § 97.207.

[186] See 47 CFR § 1.429(b).

[187] See id. Because we are simultaneously initiating a new proceeding concerning these rules, AMSAT may address in that context any factual developments it considers relevant that have occurred since the Orbital Debris Order.

[188] Id.

[189] See Comments of the Radio Amateur Satellite Corporation, IB Docket No. 02-54 (filed July 17, 2002) (AMSAT Comments). In addition, AMSAT filed comments addressing orbital debris mitigation plans in Amendment of Part 97 of the Commission's Rules Governing the Amateur Radio Services et al., Notice of Proposed Rulemaking and Order, 19 FCC Rcd 7293 (2004). See Comments of Radio Amateur Satellite Corporation, WT Docket No. 04-140 (filed June 15, 2004). It also made a further filing in that proceeding, citing to the Orbital Debris Order and noting its intent to file a petition for reconsideration of the Orbital Debris Order. Letter from Perry I. Klein, Vice President, Government Liaison, Radio Amateur Satellite Corporation, to the Commission, WT Docket No. 04-140, at 2 (filed Sept. 16, 2004). In the Commission's Report and Order in the Amendment of Part 97 of the Commission's Rules Governing the Amateur Radio Services et al., it noted that the issue of orbital debris mitigation

[190] Comments of the Radio Amateur Satellite Corporation Regarding Initial Regulatory Flexibility Analysis, IB Docket No. 02-54 (filed July 17, 2002) (AMSAT IRFA Comments). The AMSAT IRFA Comments stated that AMSAT, some universities and colleges building and launching amateur satellites, and individual licensed amateurs should be classified as "small entities" for consideration in the Commission's formulation of new rules. Id. at 1.

[191] Reply Comments of the Radio Amateur Satellite Corporation, IB Docket No. 02-54 (filed Aug. 15, 2002).

service and experimental radio service licensees to disclose their orbital debris mitigation plans.[192] It concluded that the costs involved with modifying amateur service spacecraft to satisfy the orbital debris mitigation requirements were "justified when balanced against the public interest in mitigating orbital debris."[193]

95. In its Petition, filed on October 12, 2004, AMSAT argued that the requirement to provide an orbital debris mitigation plan should not apply to individual amateur satellite operators because that individual may be different than the satellite owner or builder, and the owner or builder should be responsible for matters pertaining to the space vehicle, such as orbital debris mitigation.[194] AMSAT further argued that, to the extent the Commission declines to submit otherwise required filings to the International Telecommunication Union (ITU) due to concerns with debris mitigation plans, such Commission action would be contrary to U.S. obligations under the ITU Radio Regulations.[195] AMSAT also contended that the Commission did not provide any cost-benefit analysis supporting its decision to extend the requirements to amateur satellites, and that the necessary adjustments for amateur satellites to satisfy the rules are cost prohibitive.[196] Finally, it stated that the Commission has not indicated what constitutes an acceptable orbital debris mitigation plan or what action it will take if it finds that a plan is unacceptable, which has resulted in regulatory uncertainty.[197]

96. On November 19, 2004, the Commission issued a Public Notice announcing the filing of AMSAT's Petition.[198] A number of parties filed comments on AMSAT's Petition.[199]

In the Commission's Report and Order in the Amendment of Part 97 of the Commission's Rules Governing the Amateur Radio Services et al., it noted the issue of orbital debris mitigation (Dec. 28, 2004, AMSAT filed a Reply to Oppositions.[200]

97. Discussion. Pursuant to Section 1.429 of the Commission's rules, parties may petition for reconsideration of final orders in a rulemaking proceeding.[201]

[198] Petitions for Reconsideration and Clarification of Action in Rulemaking Proceeding, Public Notice, Report No. 2682 Correction (rel. Nov. 19, 2004).

[199] See Comments of Clifford Buttschardt, IB Docket No. 02-54 (filed Dec. 16, 2004); Comments of California Polytechnic State University faculty Jordi Puig-Suari, Clifford Buttschardt, and Edward English, IB Docket No. 02-54 (filed Dec. 20, 2004); Comments of Ed Larsen, IB Docket No. 02-54 (filed Dec. 20, 2004), Comments of Emily E. Clarke, Project OSCAR Board Member and Vice President, IB Docket No. 02-54 (filed Dec. 20, 2004).

[200] AMSAT Reply to Oppositions.

[201] 47 CFR § 1.429.

Reconsideration is generally appropriate only where the petitioner shows either a material error or omission in the original order or raises additional facts not known or not existing until after the petitioner's last opportunity to respond. Under Section 1.429(b) of the Commission's rules, petitions for reconsideration that rely on facts or arguments that have not been previously presented to the Commission will be considered only under certain limited circumstances. AMSAT's Petition does not meet the requirements of Section 1.429(b). The Petition relies on facts and arguments that either could have been presented earlier in the proceeding, or were fully considered and rejected.[202]

98. In its Comments in IB Docket No. 02-54, AMSAT agreed with the approach the Commission proposed, stating that the "FCC licensed amateur . . . would become responsible for meeting whatever orbital debris requirements the Commission might decide to include in Part 97 of the Rules."[203] In its Petition, AMSAT provided no explanation for its adoption of the directly contrary position, that an amateur station license grantee under Part 97 of the Commission's rules is not the appropriate party to hold responsible for reporting orbital debris mitigation plans.[204] Section 1.429(b) of the Commission's rules provides for three specific circumstances in which the Commission may, in response to a petition for reconsideration, consider arguments not previously presented. A party's unexplained reversal of a prior position is not one of the permitted circumstances.[205] Nor is there any basis here under Section 1.429 for advancing new arguments with respect to the application of the Commission's rules to amateur station facilities. Accordingly, we dismiss AMSAT's petition.

99. As an alternative and independent ground for rejecting AMSAT's petition, we conclude that AMSAT's arguments are also unconvincing on the merits. As discussed in the Orbital Debris Order,[206] the Communications Act of 1934, as amended (the Act) provides the Commission with broad authority to license radio communications, and encourages "the larger and more effective use of radio in the public interest."[207] In the Orbital Debris Order, the Commission stated that "orbital debris and related mitigation issues are relevant in determining whether the public interest would be served by authorization of any particular satellite system, or by any particular practice or operating procedure of satellite systems."[208]

The Commission's rules[209] pertain only to the apparatus necessary for carrying on radio-communications from space, and not to the vehicle on which the amateur

---

[202] See 47 CFR §§ 1.429(l)(2)-(3).

[203] AMSAT Comments at 4.

[204] AMSAT Petition at 1-5.

[205] See 47 CFR § 1.429(b).

[206] Orbital Debris Order, 19 FCC Rcd at 11575, para. 14.

[207] 47 U.S.C. §§ 301, 307(a).

[208] Orbital Debris Order, 19 FCC Rcd 11575, para. 14.

[209] 47 CFR § 97.3(a)(5), (41); see also ITU Radio Regulations No. 1.61 (2012) (defining "station" as "[o]ne or more transmitters or receivers or a combination of transmitters and receivers, including the accessory equipment, necessary at one location for carrying on a radiocommunication service[.]" (emphasis in original)).

station is carried.[210] However, as established in the Orbital Debris Order, the Commission's public interest considerations in licensing radiocommunications in the amateur-satellite service extend to the physical operations of the satellites and satellite hardware.[211] Indeed, the Act defines "radio communication" as "the transmission by radio of writing, signs, signals, pictures, and sounds of all kinds, including all instrumentalities, facilities, apparatus, and services … incidental to such transmission."[212] The satellite hardware is an integral part of conducting radiocommunications from space. As the Commission explained in the Orbital Debris Order, "[b]ecause robotic spacecraft are typically controlled through radio-communications links, there is a direct connection between the radio-communications functions we are charged with licensing under the Communications Act and the physical operations of spacecraft."[213]

100. AMSAT contends that the individual amateur licensee should not be required to submit information pertaining to what it describes as a space vehicle because, in most circumstances, the amateur will not be responsible for the space vehicle construction, design, or ownership. AMSAT, however, does not explain why the licensee could not obtain this information from the builder or owner.[214] AMSAT claims that amateur licensees are inherently different from commercial operators, and yet, we observe that commercial licensees also do not typically build or design satellites.[215] Nevertheless, commercial licensees have obtained orbital debris mitigation information related to their proposed operations and have supplied such information to the Commission.[216] Neither amateur nor commercial licensees are

[211] Orbital Debris Order, 19 FCC Rcd at 11575, para. 14.

[212] 47 U.S.C. § 153(33). As a general matter, those "instrumentalities, facilities, apparatus, and services…incidental to such transmission" could include the physical facilities of a robotic spacecraft, and thus the Commission would have authority to review those physical facilities in connection with authorization of amateur satellite operations. Specific factual scenarios may need to be analyzed in order to determine what is "incidental" to transmissions. In the most common factual scenario, in which the radio transmitter is installed on a robotic spacecraft, and relies on spacecraft power generation facilities, attitude control, or similar equipment needed for successful transmission, the entirety of a satellite on which the transmitting facilities are located can, as a practical matter, be considered a station. Other cases, such as those involving human spaceflight and cargo delivery spacecraft, present a more complex factual scenario, in that a particular transmitting station may be distinct from, but located at least temporarily on another satellite. For example, in recent years numerous small satellites have been deployed from the International Space Station, and many of these have been FCC-licensed. In such cases, Bureau analysis of debris mitigation plans for the small satellite has been limited to the physical apparatus of the deployed satellite, and its operations.

[213] Orbital Debris Order, 19 FCC Rcd at 11575, para. 14.

[214] To the extent AMSAT argues that a grantee of an amateur club station license should not be responsible for orbital debris mitigation information, this rationale also applies. See AMSAT Petition at 2-3.

[215] See, e.g., the Commission's previous Part 25 milestone requirements, which contemplated that a licensee would contract with another party for construction of a satellite system. 47 CFR § 25.164 (2015).

[216] Licensees have often submitted documentation provided by the satellite manufacturer.

required to have the technical competence to single-handedly design an orbital debris mitigation plan. Instead, they must provide information about the plan to the Commission, so the Commission can evaluate whether the proposed operations are in the public interest.[217]

101. AMSAT's newly raised argument that there is an inherent conflict between debris mitigation regulations and coordination and notification procedures in the ITU Radio Regulations is also without merit.[218] Specifically, AMSAT argues that the ITU Radio Regulations themselves may not permit the Commission to delay submitting a notification to the ITU Radiocommunication Bureau because of concerns about orbital debris.[219] We note, however, that there is no duty imposed by the ITU Radio Regulations on any Administration to submit a filing if that Administration is unwilling to authorize such operations. In fact, the ITU Radio Regulations recognize that operations of stations by private persons, such as amateur station operators, are subject to national regulation.[220] Moreover, the Commission's regulations require that, while Commission-licensed amateur operators may operate satellites, the satellite must be on a craft that is "documented or registered" in the United States.[221] We do not consider a craft to be "documented" in the United States if a satisfactory debris mitigation plan has not been prepared, submitted, and favorably reviewed.[222] Further, because Commission authorization is in many instances the sole mechanism by which U.S. amateur satellite operations are authorized and supervised, a contrary interpretation could raise a significant question as to consistency of such operations with U.S. treaty obligations under the Outer Space Treaty.[223]

---

[217] See 47 CFR §§ 97.207(g)(1), 25.114(c)(14), 25.283.

[218] AMSAT Petition at 5.

[219] Id.

[220] See ITU Radio Regulations Article 18.1. ("No transmitting station may be established or operated by a private person or by any enterprise without a license issued in an appropriate form and in conformity with the provisions of these Regulations by or on behalf of the government of the country to which the station in question is subject.").

[221] 47 CFR § 97.5(a)(3).

[222] In an effort to improve the transparency of FCC records in this regard, the Wireless Telecommunication Bureau has begun including approved debris mitigation plans in the ULS file associated with the satellite. In the amateur service, this is the file for the satellite amateur station licensee grantee.

[223] Treaty on Principles Governing the Activities of States in the Exploration and Use of Outer Space, including the Moon and Other Celestial Bodies, Art. 6 ("States Parties to the Treaty shall bear international responsibility for national activities in outer space, including the Moon and other celestial bodies, whether such activities are carried on by governmental agencies or by non-governmental entities, and for assuring that national activities are carried out in conformity with the provisions set forth in the present Treaty. The activities of non-governmental entities in outer space, including the Moon and other celestial bodies, shall require authorization and continuing supervision by the appropriate State Party to the Treaty."). The U.S. State Department generally considers FCC authorization prior to launch to provide a basis for registering a spacecraft under the U.N. Convention on Registration of Objects Launched into Outer Space. U.S. practice is to register such objects following launch, typically some months following launch. Thus, a U.S. amateur satellite must typically be considered "documented" in order for transmissions to be considered authorized in the period before registration is completed.

102. AMSAT's remaining arguments are also without merit. AMSAT argues that the Commission failed to consider the costs of modifying spacecraft to meet the orbital debris mitigation requirements, and therefore has not presented a cost-benefit analysis to support applying those requirements to amateur radio operators.[224] Specifically, AMSAT argues that it is impracticable to add a propulsion system for small LEO spacecraft and that the atmospheric re-entry of these spacecraft within 25 years is not feasible.[225] AMSAT also notes that amateur satellites are typically a secondary payload, and as a result, cannot certify delivery to a particular orbit to ensure proper end-of-life disposal.[226] The Commission has previously addressed the concerns from amateur operators that AMSAT now raises.[227]

In response to comments from AMSAT and others to the NPRM, the Commission declined to exempt amateur service satellites from the rules, on the basis that "amateur satellites pose the same public interest concerns with regard to orbital debris."[228] While recognizing that "post-mission disposal requirements may necessitate modifications in the current design and operation," including the addition of propulsion and or other strategies to cause atmospheric reentry within 25 years, the Commission concluded that "the costs involved with these modifications are justified when balanced against the public interest in mitigating orbital debris."[229] The Commission determined that closer adherence to the disposal methods described in the rules was "warranted in order to limit the growth of orbital debris in LEO[,]"[230] despite the fact that "changes in the design and operation of certain types of LEO spacecraft may be necessary in order to follow these practices and may limit an operator's ability to deploy spacecraft in certain orbital regimes or use certain spacecraft designs."[231] In any event, in the years since the debris mitigation rules were adopted, and notwithstanding any costs imposed by FCC regulations, well over 150 small satellites have been authorized, with at least 20 of those considered amateur satellites. It appears that, to the extent that any costs have been incurred, the main contributor to costs for amateur and similar LEO missions has to do with the availability of launches to appropriate orbits.[232]

103. Finally, we address AMSAT's argument that the Orbital Debris Order does not outline what would constitute an acceptable orbital debris mitigation plan, which according to AMSAT, makes it difficult for the satellite owner/builder to estimate,

[225] Id. at 6.

[226] Id. at 7.

[227] Orbital Debris Order, 19 FCC Rcd at 11608, para. 100.

[228] Id.

[229] Id. (emphasis added).

[230] Id. at 11602, para. 85.

[231] Id.

[232] Since most amateur satellites have not been equipped with propulsion or other means of actively de-orbiting, such amateur satellites would need to be launched into appropriate orbits, i.e. those orbits from which the satellites will naturally deorbit within a reasonable period of time.

budget for, and fund the cost of compliance.[233] The various components of an acceptable orbital debris mitigation plan, including post-mission disposal, were addressed extensively in the Orbital Debris Order.[234] We observe that in the years since the Commission issued the Orbital Debris Order, numerous licensees, including amateur satellites operating in LEO, have successfully satisfied our orbital debris mitigation requirements.[235] In addition, the Commission has issued a Public Notice titled Guidance on Obtaining Licenses for Small Satellites, which includes guidance for amateur radio service satellite operators.[236]

104. In summary, the Commission provided ample opportunity for comment on its proposals and then fully considered the public record developed in response to the proposals. The arguments presented by AMSAT should have been presented in AMSAT's Comments to the NPRM, or were already fully considered. In addition, its arguments fail on the merits. Therefore, AMSAT's Petition does not warrant further consideration.

5 V. PROCEDURAL MATTERS

105. Ex Parte Presentations. The proceeding this NPRM initiates shall be treated as a "permit-but-disclose" proceeding in accordance with the Commission's ex parte rules.[237] Persons making ex parte presentations must file a copy of any written presentation or a memorandum summarizing any oral presentation within two business days after the presentation (unless a different deadline applicable to the Sunshine period applies). Persons making oral ex parte presentations are reminded that memoranda summarizing the presentation must (1) list all persons attending or otherwise participating in the meeting at which the ex parte presentation was made, and (2) summarize all data presented and arguments made during the presentation. If the presentation consisted in whole or in part of the presentation of data or arguments already reflected in the presenter's written comments, memoranda or other filings in the proceeding, the presenter may provide citations to such data or arguments in his or her prior comments, memoranda, or other filings (specifying the relevant page and/or paragraph numbers where such data or arguments can be found) in lieu of summarizing them in the memorandum. Documents shown or given to Commission

[236] Guidance on Obtaining Licenses for Small Satellites, Public Notice, 28 FCC Rcd 2555 (rel. Mar. 15, 2013).

[237] 47 CFR §§ 1.1200 et seq.

staff during ex parte meetings are deemed to be written ex parte presentations and must be filed consistent with rule 1.1206(b). In proceedings governed by rule 1.49(f) or for which the Commission has made available a method of electronic filing, written ex parte presentations and memoranda summarizing oral ex parte presentations, and all attachments thereto, must be filed through the electronic comment filing system available for that proceeding, and must be filed in their native format (e.g., .doc, .xml, .ppt, searchable .pdf). Participants in this proceeding should familiarize themselves with the Commission's ex parte rules.

106. Comment Filing Requirements. Pursuant to Sections 1.415 and 1.419 of the Commission's rules, 47 CFR §§ 1.415, 1.419, interested parties may file comments and reply comments on or before the dates indicated on the first page of this document. Comments may be filed using the Commission's Electronic Comment Filing System (ECFS). See Electronic Filing of Documents in Rulemaking Proceedings, 63 FR 24121 (1998).

- Electronic Filers. Comments may be filed electronically using the Internet by accessing the ECFS: http://apps.fcc.gov/ecfs.
- Paper Filers. Parties who choose to file by paper must file an original and one copy of each filing. If more than one docket or rulemaking number appears in the caption of this proceeding, filers must submit two additional copies for each additional docket or rulemaking number.

  Filings can be sent by hand or messenger delivery, by commercial overnight courier, or by first-class or overnight U.S. Postal Service mail. All filings must be addressed to the Commission's Secretary, Office of the Secretary, Federal Communications Commission.
  - All hand-delivered or messenger-delivered paper filings for the Commission's Secretary must be delivered to FCC Headquarters at 445 12th Street, SW., Room TWA325, Washington, DC 20554. The filing hours are 8:00 a.m. to 7:00 p.m. All hand deliveries must be held together with rubber bands or fasteners. Any envelopes and boxes must be disposed of before entering the building.
  - Commercial overnight mail (other than U.S. Postal Service Express Mail and Priority Mail) must be sent to 9050 Junction Drive, Annapolis Junction, MD 20701.
  - U.S. Postal Service first-class, Express, and Priority mail must be addressed to 445 12th Street, SW, Washington DC 20554.
- People with Disabilities: To request materials in accessible formats for people with disabilities (braille, large print, electronic files, audio format), send an email to fcc504@fcc.gov or call the Consumer & Governmental Affairs Bureau at 202-418-0530 (voice) or 202-418-0432 (TTY).

107. Initial Regulatory Flexibility Analysis. As required by the Regulatory Flexibility Act of 1980, as amended,[238] the Commission has prepared an Initial

---

[238] 5 U.S.C. § 603.

Regulatory Flexibility Analysis (IRFA) for this Notice, of the possible significant economic impact on small entities of the policies and rules addressed in this document. The IRFA is set forth as Appendix B. Written public comments are requested on this IRFA. Comments must be identified as responses to the IRFA and must be filed by the deadlines for comments on the Notice provided on or before the dates indicated on the first page of this Notice. The Commission's Consumer and Governmental Affairs Bureau, Reference Information Center, will send a copy of the NPRM, including this IRFA, to the Chief Counsel for Advocacy of the Small Business Administration.

108. Paperwork Reduction Act. This document contains proposed new and modified information collection requirements. The Commission, as part of its continuing effort to reduce paperwork burdens, invites the general public and the Office of Management and Budget to comment on the information collection requirements contained in this document, as required by the Paperwork Reduction Act of 1995.[239] In addition, pursuant to the Small Business Paperwork Relief Act of 2002,[240] we seek specifically seek comment on how we might further reduce the information collection burden for small business concerns with fewer than 25 employees.[241]

6 VI. ORDERING CLAUSES

109. Accordingly, IT IS ORDERED, pursuant to Sections 1, 4(i), 301, 303, 307, 308, 309, and 310 of the Communications Act of 1934, as amended, 47 U.S.C. §§ 151, 154(i), 301, 303, 307, 308, 309, 310, that this Notice of Proposed Rulemaking IS ADOPTED.

110. IT IS FURTHER ORDERED that the Commission's Consumer and Governmental Affairs Bureau, Reference Information Center SHALL SEND a copy of this Notice of Proposed Rulemaking, including the initial regulatory flexibility act analysis, to the Chief Counsel for Advocacy of the Small Business Administration, in accordance with Section 603(a) of the Regulatory Flexibility Act, 5 U.S.C. § 601, et seq. (1981).

111. IT IS FURTHER ORDERED that, effective upon release of this Order, the Petition for Reconsideration filed by the Radio Amateur Satellite Corporation on October 12, 2004, IS DISMISSED and, on alternative and independent grounds, DENIED, and IB Docket No. 02-54 IS TERMINATED.

FEDERAL COMMUNICATIONS COMMISSION
Marlene H. Dortch
Secretary

[239] Pub. L. 104-13.

[240] Pub. L. 107-198.

[241] 44 U.S.C. § 3506(c)(4).

APPENDIX A

Proposed Rules

The Federal Communications Commission proposes to amend title 47 of the Code of Federal Regulations, parts 5, 25, and 97, as follows:

PART 5 – EXPERIMENTAL RADIO SERVICE

1. The authority citation for Part 5 continues to read as follows:

Authority: Secs. 4, 302, 303, 307, 336 48 Stat. 1066, 1082, as amended; 47 U.S.C. 154, 302, 303, 307, 336. Interpret or apply sec. 301, 48 Stat. 1081, as amended; 47 U.S.C. 301.

2. Amend Section 5.64 by revising paragraph (b)(1), revising and re-designating paragraphs (b)(2), (b)(3) and (b)(4) as (b)(3), (b)(4) and (b)(5), respectively, and adding paragraphs (b)(2), (c), and (d), to read as follows:

§ 5.64 Special provisions for satellite systems.

* * * * *

(b) * * *

(1) A statement that the space station operator has assessed and limited the amount of debris released in a planned manner during normal operations. Where applicable, this statement must include an orbital debris mitigation disclosure for any separate deployment devices not part of the space station launch that may become a source of orbital debris;

(2) A statement that the space station operator has assessed and limited the probability of the space station(s) becoming a source of debris by collisions with small debris or meteoroids that would cause loss of control and prevent post-mission disposal;

(3) A statement that the space station operator has assessed and limited the probability of accidental explosions or release of liquids that could become debris during and after completion of mission operations. This statement must include a demonstration that debris generation will not result from the conversion of energy sources on board the spacecraft into energy that fragments the spacecraft. Energy sources include chemical, pressure, and kinetic energy and debris includes liquids that persist in droplet form. This demonstration should address whether stored energy will be removed at the spacecraft's end of life, by depleting residual fuel and leaving all fuel line valves open, venting any pressurized system, leaving all batteries in a permanent discharge state, and removing any remaining source of stored energy, or through other equivalent procedures specifically disclosed in the application;

(4) A statement that the space station operator has assessed in the aggregate and limited the probability of the space station(s) becoming a source of debris by collisions with large debris or other operational space stations, including the following information:

(i) Where the application is for an NGSO space station or constellation:

(A) The statement must indicate whether the probability in the aggregate of a collision between the space stations(s) and another large object during the total orbital lifetime of the constellation, including any de-orbit phase, is less than 0.001.

(B) The statement must identify any planned and/or operational space stations that may raise a collision risk, and indicate what steps, if any, have been taken to coordinate with the other spacecraft or system, or what other measures the operator plans to use to avoid collision. This includes disclosure of any planned proximity operations. If the planned space station operational orbit is above 650 kilometers, the statement must specify why the planned orbit was chosen, and if the space station will transit through the orbit of the International Space Station (ISS) or orbit of any other manned spacecraft, at any time during the space station's mission or de-orbit phase, and the statement must describe the potential impact to the ISS or other manned spacecraft, if any, including design and operational strategies that will be used to avoid collision with manned spacecraft.

(C) The statement must disclose the accuracy – if any – with which orbital parameters will be maintained, including apogee, perigee, inclination, and the right ascension of the ascending node(s). In the event that a system is not able to maintain orbital tolerances, i.e., it lacks a propulsion system for orbital maintenance, that fact should be included in the debris mitigation disclosure. Such systems must also indicate the anticipated evolution over time of the orbit of the proposed satellite or satellites. All systems should describe the extent of satellite maneuverability, whether or not the space station(s) design includes a propulsion system; and

(D) In addition, the statement must include a description of the means for tracking the spacecraft, including whether tracking will be active or passive. The space station operator must certify that upon receipt of a space situational awareness conjunction warning, the operator will review the warning and take all possible steps to assess and, if necessary, to mitigate collision risk, including, but not limited to: contacting the operator of any active spacecraft involved in such warning; sharing ephemeris data and other appropriate operational information with any such operator; modifying spacecraft attitude and/or operations.

(ii) Where a space station requests the assignment of a geostationary-Earth orbit location, it must assess whether there are any known satellites located at, or reasonably expected to be located at, the requested orbital location, or assigned in the vicinity of that location, such that the station keeping volumes of the respective satellites might overlap or touch. If so, the statement must include a statement as to the identities of those parties and the measures that will be taken to prevent collisions; and

(5) A statement detailing the post-mission disposal plans for the space station at end of life, including the quantity of fuel—if any—that will be reserved for post-mission disposal maneuvers. In addition, the following specific provisions apply:

(i) For geostationary-Earth orbit space stations, the statement must disclose the altitude selected for a post-mission disposal orbit and the calculations that are used in deriving the disposal altitude.

(ii) For spacecraft terminating operations in an orbit in or passing through the low-Earth orbit region below 2,000 km altitude, the statement must indicate whether the spacecraft will be disposed of either through atmospheric re-entry within 25 years following the completion of the spacecraft's mission, or by direct retrieval of the spacecraft.

(iii) Where planned post-mission disposal involves atmospheric re-entry of the space station(s):

(A) The statement must include a demonstration that the probability of success for the disposal method will be no less than 0.90, calculated on an aggregate basis.

(B) For space stations with a planned operational altitude between 650 km and 2,000 km, the statement should include a certification that the satellites will be deployed at an altitude below 650 km, and describe the means that will be used to ensure reliability of disposal, such as through automatic initiation of disposal in the event of loss of power or contact with the space station.

(C) The statement must also include a casualty risk assessment. In general, an assessment should include an estimate as to whether portions of the spacecraft will survive re-entry, including all objects that would impact the surface of the Earth with a kinetic energy in excess of 15 joules, as well as an estimate of the resulting probability of human casualty. Where the risk of human casualty from surviving debris is greater than zero, as calculated using either the NASA Debris Assessment Software or a higher fidelity model, a statement must be provided indicating the actual calculated human casualty risk as well as the input assumptions used in the model.

(c) As a condition of their licenses for experimental satellite facilities, licensees must submit an executed agreement indemnifying the United States against any costs associated with a claim brought against the United States related to the authorized facilities. The agreement, or an updated version thereof, must be submitted no later than 30 days after the grant of the license, an assignment of the license, or a transfer of control of the licensee, or at least 90 days prior to planned launch of the space station, whichever is sooner.

(d) For space stations that include onboard propulsion systems, operators must encrypt telemetry, tracking, and command communications with the space station.

PART 25 – SATELLITE COMMUNICATIONS

3. The authority citation for part 25 continues to read as follows:

Authority: 47 U.S.C. 154, 301, 302, 303, 307, 309, 310, 319, 332, 605, and 721, unless otherwise noted.

4. Amend Section 25.114(d)(14) by revising paragraph (i), revising and redesignating paragraphs (ii), (iii) and (iv) as (iii), (iv) and (v), respectively, redesignating paragraph (v) as (vi), and adding paragraph (ii), to read as follows:

§ 25.114 Applications for space station authorizations.

* * * * *

(d) * * *

(14) * * *

(i) A statement that the space station operator has assessed and limited the amount of debris released in a planned manner during normal operations. Where applicable, this statement must include an orbital debris mitigation disclosure for any separate deployment devices not part of the space station launch that may become a source of orbital debris;

(ii) A statement that the space station operator has assessed in the aggregate and limited the probability of the space station(s) becoming a source of debris by collisions with small debris or meteoroids that would cause loss of control and prevent post-mission disposal;

(iii) A statement that the space station operator has assessed and limited the probability of accidental explosions or release of liquids that could become debris during and after completion of mission operations. This statement must include a demonstration that debris generation will not result from the conversion of energy sources on board the spacecraft into energy that fragments the spacecraft. Energy sources include chemical, pressure, and kinetic energy and debris includes liquids that persist in droplet form. This demonstration should address whether stored energy will be removed at the spacecraft's end of life, by depleting residual fuel and leaving all fuel line valves open, venting any pressurized system, leaving all batteries in a permanent discharge state, and removing any remaining source of stored energy, or through other equivalent procedures specifically disclosed in the application;

(iv) A statement that the space station operator has assessed in the aggregate and limited the probability of the space station(s) becoming a source of debris by collisions with large debris or other operational space stations, including the following information:

(A) Where the application is for an NGSO space station or constellation:

1. The statement must indicate whether the probability in the aggregate of a collision between the space station(s) and another large object during the total orbital lifetime of the constellation, including any de-orbit phases, is less than 0.001;

2. The statement must identify any planned and/or operational space stations that may raise a collision risk, and indicate what steps, if any, have been taken to coordinate with the other spacecraft or system, or what other measures the operator plans to use to avoid collision. This includes disclosure of any planned proximity operations. If the planned space station operational orbit is above 650 kilometers, the statement must specify why the planned orbit was chosen, and if the space station will transit through the orbit of the International Space Station (ISS) or orbit of any other manned spacecraft, at any time during the space station's mission or de-orbit phase, and the statement must describe the potential impact to the ISS or other manned spacecraft, if any, including design and operational strategies that will be used to avoid collision with manned spacecraft;

3. The statement must disclose the accuracy – if any – with which orbital parameters will be maintained, including apogee, perigee, inclination, and the right ascension of the ascending node(s). In the event that a system is not able to maintain orbital tolerances, i.e., it lacks a propulsion system for orbital maintenance, that fact must be included in the debris mitigation disclosure. Such systems must also indicate the anticipated evolution over time of the orbit of the proposed satellite or satellites. All systems must describe the extent of satellite maneuverability, whether or not the space station(s) design includes a propulsion system; and

4. In addition, the statement must include a description of the means for tracking the spacecraft, including whether tracking will be active or passive. The space station operator must certify that upon receipt of a space situational awareness conjunction warning, the operator will review the warning and take all possible steps to assess

and, if necessary, to mitigate collision risk, including, but not limited to: contacting the operator of any active spacecraft involved in such warning; sharing ephemeris data and other appropriate operational information with any such operator; modifying space station attitude and/or operations.

(B) Where a space station requests the assignment of a geostationary-Earth orbit location, it must assess whether there are any known satellites located at, or reasonably expected to be located at, the requested orbital location, or assigned in the vicinity of that location, such that the station keeping volumes of the respective satellites might overlap or touch. If so, the statement must include a statement as to the identities of those parties and the measures that will be taken to prevent collisions; and

(v) A statement detailing the post-mission disposal plans for the space station at end of life, including the quantity of fuel—if any—that will be reserved for post-mission disposal maneuvers. In addition, the following specific provisions apply:

(A) For geostationary-Earth orbit space stations, the statement must disclose the altitude selected for a post-mission disposal orbit and the calculations that are used in deriving the disposal altitude.

(B) For spacecraft terminating operations in an orbit in or passing through the low-Earth orbit region below 2,000 km altitude, the statement must indicate whether the spacecraft will be disposed of either through atmospheric re-entry within 25 years following the completion of the spacecraft's mission, or by direct retrieval of the spacecraft.

(C) Where planned post-mission disposal involves atmospheric re-entry of the space station(s):

1. The statement must include a demonstration that the probability of success for the disposal method will be no less than 0.90, calculated on an aggregate basis.

2. For space stations with a planned operational altitude between 650 km and 2,000 km, the statement should include a certification that the satellites will be deployed at an altitude below 650 km, and describe the means that will be used to ensure reliability of disposal, such as through automatic initiation of disposal in the event of loss of power or contact with the space station.

3. The statement must also include a casualty risk assessment. In general, an assessment should include an estimate as to whether portions of the spacecraft will survive re-entry, including all objects that would impact the surface of the Earth with a kinetic energy in excess of 15 joules, as well as an estimate of the resulting probability of human casualty. Where the risk of human casualty from surviving debris is greater than zero, as calculated using either the NASA Debris Assessment Software or a higher fidelity model, a statement must be provided indicating the actual calculated human casualty risk as well as the input assumptions used in the model.

(D) Applicants for space stations to be used only for commercial remote sensing may, in lieu of submitting detailed post-mission disposal plans to the Commission, certify that they have submitted such plans to the National Oceanic and Atmospheric Administration for review.

(vi) For non-U.S.-licensed space stations, the requirement to describe the design and operational strategies to minimize orbital debris risk can be satisfied by demonstrating that debris mitigation plans for the space station(s) for which U.S. market access is requested are subject to direct and effective regulatory oversight by the national licensing authority.

* * * * *

4. Amend Section 25.121 to add paragraph (f) as follows:

§25.121 License term and renewals.

(f) Geostationary Satellite License Term Extensions. License term extensions for geostationary space stations may be authorized by grant of a modification application in increments of five years or less.

5. Amend Section 25.161 to add paragraph (e) as follows:

§25.161 Automatic termination of station authorization.

(e) The failure to file an executed indemnification agreement in accordance with § 25.166.

6. Add Section 25.166 to read as follows:

§25.166 Indemnification.

As a condition of their licenses, space station licensees must submit an executed agreement indemnifying the United States against any costs associated with a claim brought against the United States related to the authorized facilities. The agreement, or an updated version thereof, must be submitted no later than 30 days after the grant of the license, an assignment of the license, or a transfer of control of the licensee, or at least 90 days prior to planned launch of the space station, whichever is sooner.

7. Revise paragraph (e) to Section 25.271 to read as follows:

§25.271 Control of Transmitting Stations.

* * * * *

(e) An NGSO licensee or market access recipient must ensure that ephemeris data for its space station or constellation is available to all operators of operational satellite systems identified pursuant to § 25.114(d)(14)(iv)(A)(2) that may raise a collision risk.

8. Revise Section 25.282 to read as follows:

§ 25.282 Orbit raising.

A space station may operate in connection with short-term, transitory maneuvers directly related to post-launch, orbit-raising maneuvers, in the telemetry, tracking, and command frequencies authorized for operation at the assigned orbital position. Such orbit-raising operations must be coordinated on an operator-to-operator basis with any potentially affected satellite networks.

9. Add Section 25.290 to read as follows:

§ 25.290 Telemetry, tracking, and command encryption.

For space stations that include onboard propulsion systems, operators must encrypt telemetry, tracking, and command communications with the space station.

PART 97 – AMATEUR RADIO SERVICE

5. The authority citation for part 97 continues to read as follows:

Authority: 48 Stat. 1066, 1082, as amended; 47 U.S.C. 154, 303. Interpret or apply 48 Stat. 1064-1068, 1081-1105, as amended; 47 U.S.C. 151-155, 301-609, unless otherwise noted.

6. Amend Section 97.207 by revising paragraph (g)(1)(i), revising and redesignating paragraphs (g)(1)(ii), (g)(1)(iii), and (g)(1)(iv) as (g)(1)(ii), (g)(1)(iv), and (g)(1)(v), respectively, redesignating paragraph (g)(1)(v) as (g)(1)(vi), adding paragraph (g)(1)(ii), and adding paragraphs (h) and (i), to read as follows:

§ 97.207 Space station. * * * * *

(g) * * *

(1) * * *

(i) A statement that the space station licensee has assessed and limited the amount of debris released in a planned manner during normal operations. Where applicable, this statement must include an orbital debris mitigation disclosure for any separate deployment devices not part of the space station launch that may become a source of orbital debris;

(ii) A statement that the space station licensee has assessed in the aggregate and limited the probability of the space station(s) becoming a source of debris by collisions with small debris or meteoroids that would cause loss of control and prevent post-mission disposal;

(iii) A statement that the space station licensee has assessed and limited the probability of accidental explosions or release of liquids that could become debris during and after completion of mission operations. This statement must include a demonstration that debris generation will not result from the conversion of energy sources on board the spacecraft into energy that fragments the spacecraft. Energy sources include chemical, pressure, and kinetic energy and debris includes liquids that persist in droplet form. This demonstration should address whether stored energy will be removed at the spacecraft's end of life, by depleting residual fuel and leaving all fuel line valves open, venting any pressurized system, leaving all batteries in a permanent discharge state, and removing any remaining source of stored energy, or through other equivalent procedures specifically disclosed in the notification;

(iv) A statement that the space station licensee has assessed in the aggregate and limited the probability of the space station(s) becoming a source of debris by collisions with large debris or other operational space stations, including the following information:

(A) Where the space station is a NGSO space station or constellation:

(1) The statement must indicate whether the probability in the aggregate of a collision between the space station(s) and another large object during the total orbital lifetime of the constellation, including any de-orbit phases, is less than 0.00;1

(2) The statement must identify any planned and/or operational space stations that may raise a collision risk, and indicate what steps, if any, have been taken to coordinate with the other spacecraft or system, or what other measures the operator plans to use to avoid collision. This includes disclosure of any planned proximity operations. If the planned space station operational orbit is above 650 kilometers, the statement must specify why the planned orbit was chosen, and if the space station

will transit through the orbit of the International Space Station (ISS) or orbit of any other manned spacecraft, at any time during the space station's mission or de-orbit phase, and the statement must describe the potential impact to the ISS or other manned spacecraft, if any, including design and operational strategies that will be used to avoid collision with manned spacecraft;

(3) The statement must disclose the accuracy – if any – with which orbital parameters will be maintained, including apogee, perigee, inclination, and the right ascension of the ascending node(s). In the event that a system is not able to maintain orbital tolerances, i.e., it lacks a propulsion system for orbital maintenance, that fact must be included in the debris mitigation disclosure. Such systems must also indicate the anticipated evolution over time of the orbit of the proposed satellite or satellites. All systems must describe the extent of satellite maneuverability, whether or not the space station(s) design includes a propulsion system; and

(4) In addition, the statement must include a description of the means for tracking the spacecraft, including whether tracking will be active or passive. The space station licensee must certify that upon receipt of a space situational awareness conjunction warning, the licensee or operator will review the warning and take all possible steps to assess and, if necessary, to mitigate collision risk, including, but not limited to: contacting the operator of any active spacecraft involved in such warning; sharing ephemeris data and other appropriate operational information with any such operator; modifying space station attitude and/or operations.

(B) Where a space station requests the assignment of a geostationary-Earth orbit location, it must assess whether there are any known satellites located at, or reasonably expected to be located at, the requested orbital location, or assigned in the vicinity of that location, such that the station keeping volumes of the respective satellites might overlap or touch. If so, the statement must include a statement as to the identities of those parties and the measures that will be taken to prevent collisions; and

(v) A statement detailing the post-mission disposal plans for the space station at end of life, including the quantity of fuel—if any—that will be reserved for post-mission disposal maneuvers. In addition, the following specific provisions apply:

(A) For geostationary-Earth orbit space stations, the statement must disclose the altitude selected for a post-mission disposal orbit and the calculations that are used in deriving the disposal altitude.

(B) For spacecraft terminating operations in an orbit in or passing through the low-Earth orbit region below 2,000 km altitude, the statement must indicate whether the spacecraft will be disposed of either through atmospheric re-entry within 25 years following the completion of the spacecraft's mission, or by direct retrieval of the spacecraft.

(C) Where planned post-mission disposal involves atmospheric re-entry of the space station:

(1) The statement must include a demonstration that the probability of success for the disposal method will be no less than 0.90, calculated on an aggregate basis.

(2) For space stations with a planned operational altitude between 650 km and 2,000 km, the statement should include a certification that the satellites will be

deployed at an altitude below 650 km, and describe the means that will be used to ensure reliability of disposal, such as through automatic initiation of disposal in the event of loss of power or contact with the space station.

(3) The statement must also include a casualty risk assessment. In general, an assessment should include an estimate as to whether portions of the spacecraft will survive re-entry, including all objects that would impact the surface of the Earth with a kinetic energy in excess of 15 joules, as well as an estimate of the resulting probability of human casualty. Where the risk of human casualty from surviving debris is greater than zero, as calculated using either the NASA Debris Assessment Software or a higher fidelity model, a statement must be provided indicating the actual calculated human casualty risk as well as the input assumptions used in the model.

(vi) If any material item described in this notification changes before launch, a replacement pre-space notification shall be filed with the International Bureau no later than 90 days before integration of the space station into the launch vehicle.

* * * * *

(h) At least 90 days prior to planned launch of the space station, the license grantee of each space station must submit an executed agreement indemnifying the United States against any costs associated with a claim brought against the United States related to the authorized facilities.

(i) For space stations that include onboard propulsion systems, operators must encrypt telemetry, tracking, and command communications with the space station.

APPENDIX B

Initial Regulatory Flexibility Analysis

As required by the Regulatory Flexibility Act of 1980, as amended (RFA),[242] the Commission has prepared this present Initial Regulatory Flexibility Analysis (IRFA) of the possible significant economic impact on a substantial number of small entities by the policies and rules proposed in this Notice of Proposed Rulemaking (NPRM). Written public comments are requested on this IRFA. Comments must be identified as responses to the IRFA and must be filed by the deadlines specified in the NPRM for comments. The Commission will send a copy of this NPRM, including this IRFA, to the Chief Counsel for Advocacy of the Small Business Administration (SBA).[243] In addition, the NPRM and IRFA (or summaries thereof) will be published in the Federal Register.[244]

---

[242] See 5 U.S.C. § 603. The RFA, see 5 U.S.C. § 601 et seq., has been amended by the Small Business Regulatory Enforcement Fairness Act of 1996, (SBREFA) Pub. L. No. 104-121, Title II, 110 Stat. 847 (1996).

[243] See 5 U.S.C. § 603(a).

[244] Id.

A. Need for, and Objectives of, the Proposed Rules

The Commission originally adopted comprehensive rules relating to the mitigation of orbital debris in 2004. Consideration of orbital debris issues remains an important part of preserving access to space for the long term, as well as the safety of persons and property in space on the surface of the Earth. This NPRM represents the first comprehensive update to our rules on orbital debris mitigation since their adoption. The basis for these revisions and additions to those rules includes the Commission's experience gained in the licensing process, updates in mitigation guidelines and practices, and market developments. Our objective is to ensure that space stations applying for a license or grant of market access, or otherwise authorized by the Commission, including experimental and amateur satellite systems, provide a statement concerning plans for orbital debris mitigation that enables the Commission to fully evaluate whether the proposed operations are in the public interest.

With this in mind, this NPRM seeks comment on a number of proposals revising the Commission's rules and policies for limiting orbital debris. Adoption of the proposed changes would modify 47 CFR parts 5, 25, and 97 to, among other things:

1) Require satellite applicants to demonstrate compliance with certain metrics developed for assessing orbital debris mitigation plans by the National Aeronautics and Space Administration (NASA).

2) Require additional disclosures to the Commission regarding risk of collision, trackability, maneuverability, proximity operations, if any, choice of orbit, and impact on manned spacecraft, if any.

3) Require information regarding the probability of success for the chosen disposal method, where disposal is planned by atmospheric re-entry.

4) Require satellite applicants with planned operations in certain orbits to make certifications related deploying at a lower orbit and then raising the satellite(s) for operations.

5) Require satellite licensees to indemnify the United States government against any costs associated with a claim brought against the United States related to the authorized facilities.

B. Legal Basis

The proposed action is authorized under Sections 1, 4(i), 301, 303, 307, 308, 309, and 310 of the Communications Act of 1934, as amended, 47 U.S.C. §§ 151, 154(i), 301, 303, 307, 308, 309, and 310.

C. Description and Estimate of the Number of Small Entities to Which the Proposed Rules May Apply

The RFA directs agencies to provide a description of, and, where feasible, an estimate of, the number of small entities that may be affected by adoption of proposed rules.[245] The RFA generally defines the term "small entity" as having the same meaning as the terms "small business," "small organization," and "small governmental jurisdiction."[246] In addition, the term "small business" has the same

---

[245] 5 U.S.C. § 604(a)(3).

[246] 5 U.S.C. § 601(6).

meaning as the term “small business concern” under the Small Business Act.[247] A small business concern is one which: (1) is independently owned and operated; (2) is not dominant in its field of operation; and (3) satisfies any additional criteria established by the Small Business Administration (SBA).[248] Below, we describe and estimate the number of small entity licensees that may be affected by adoption of the proposed rules.

Satellite Telecommunications and All Other Telecommunications

The rules proposed in this NPRM would affect some providers of satellite telecommunications services, if adopted. Satellite telecommunications service providers include satellite and earth station operators. Since 2007, the SBA has recognized two census categories for satellite telecommunications firms: “Satellite Telecommunications” and “Other Telecommunications.” Under both categories, a business is considered small if it had $32.5 million or less in annual receipts.[249]

The first category of Satellite Telecommunications “comprises establishments primarily engaged in providing point-to-point telecommunications services to other establishments in the telecommunications and broadcasting industries by forwarding and receiving communications signals via a system of satellites or reselling satellite telecommunications.”[250] For this category, Census Bureau data for 2007 show that there were a total of 512 satellite communications firms that operated for the entire year. Of this total, 482 firms had annual receipts of under $25 million.

The second category of Other Telecommunications is comprised of entities “primarily engaged in providing specialized telecommunications services, such as satellite tracking, communications telemetry, and radar station operation. This industry also includes establishments primarily engaged in providing satellite terminal stations and associated facilities connected with one or more terrestrial systems and capable of transmitting telecommunications to, and receiving telecommunications from, satellite systems. Establishments providing Internet services or voice over Internet protocol (VoIP) services via client-supplied telecommunications connections are also included in this industry.”[251]

The NPRM proposes and seeks comment on a number of rule changes that would affect reporting, recordkeeping, and other compliance requirements for space station operators. Each of these changes is described below.

The NPRM proposes to require several disclosures specifying compliance with several metrics established by NASA, such as probability of collision between the

---

[247] 5 U.S.C. § 601(3) (incorporating by reference the definition of “small business concern” in 15 U. S.C. § 632). Pursuant to the RFA, the statutory definition of a small business applies “unless an agency, after consultation with the Office of Advocacy of the Small Business Administration and after opportunity for public comment, establishes one or more definitions of such term which are appropriate to the activities of the agency and publishes such definition(s) in the Federal Register.” 5 U.S.C. § 601(3).

[248] Small Business Act, 15 U.S.C. § 632 (1996).

[249] See 13 CFR § 121.201, NAICS codes 517410, 517919.

[250] U.S. Census Bureau, 2007 NAICS Definitions, “517410 Satellite Telecommunications.”

[251] U.S. Census Bureau, 2007 NAICS Definitions, “517919 Other Telecommunications.”

spacecraft and large objects. Many of the entities, for example, experimental licensees, that would be affected by these proposed rules already use a format for their orbital debris mitigation plans that is consistent with the NASA Orbital Debris Assessment Report (ODAR). The ODAR format includes several of the proposed NASA metrics that are incorporated into the proposed rules such as calculations related to re-entry casualty risk. Thus, to the extent that these entities already use the ODAR format, there would be no change to their existing recordkeeping and compliance requirements as a result of these proposed changes. For other entities that have not or would not use the ODAR format to report their orbital debris mitigation plans, some of these changes will involve some additional proposed calculations to provide the appropriate certifications, such as certifying that the probability of collision between a space station and another large object is less than 0.001. Given the engineering associated with development of a spacecraft, we expect that these calculations will be a natural outgrowth of work already being performed in designing and planning space station(s) operations. The NPRM also proposes to require that collision risk information be provided in the aggregate, that is, for the space station constellation as a whole. Since most small entities do not launch and operate large satellite constellations, we do not anticipate that this requirement to provide a collision risk assessment in the aggregate will be burdensome. In addition, we note the new requirement for demonstration that the probability of reliability for a particular disposal method is no less than 0.90, calculated on an aggregate basis. We anticipate that most small entities will be planning disposal of their spacecraft by atmospheric re-entry. So long as the spacecraft is deployed into a low altitude orbit, which most small entities' spacecraft are, atmospheric re-entry will be virtually guaranteed within a certain amount of time.

The NPRM also proposes to require that applicants for a space station license or authorization provide disclosures regarding methodologies used for tracking and certifications related to space situational awareness, as well as disclosures regarding choice of orbit and potential impact to manned spacecraft. Information regarding tracking and sharing of data for purposes of space situational awareness should be readily available to applicants and operators. We anticipate that disclosures relating to choice of orbit and potential impacts to manned spacecraft should be an extension of analysis undertaken by a space station operator as part of selection of a launch vehicle and operational orbit.

In addition, the NPRM proposes that operators of spacecraft make ephemeris data available to all operators of operational satellite systems identified as potentially raising a collision risk with its system. We anticipate that small entities will generally be operating only a few spacecraft, and so will only need to address this ephemeris data requirement for a limited number of space stations.

11 See 13 CFR § 121.201, NAICS code 517919.

12 U.S. Census Bureau, 2007 Economic Census, Subject Series: Information, Table 5, "Establishment and Firm Size: Employment Size of Firms for the United States: 2007 NAICS Code 517919" (issued Nov. 2010).

We do not expect that the any of the proposed changes relating to the operation of geostationary-orbit (GSO) space stations would affect small entities, since GSO space stations generally cost hundreds of millions of dollars to construct, launch, and operate. Similarly, we do not expect that the proposed requirements applicable to NGSO space stations operating between 650 km and 2,000 km will apply to small entities, since we expect that most lower-cost space systems are deployed at lower altitudes.

The NPRM also proposes that U.S. space station licensees or grantees submit an executed agreement indemnifying the United States against any costs associated with a clam brought against the United States related to the authorized facilities. This proposal would apply to experimental licensees and authorized amateur space station license grantees, and would likely increase the compliance requirements for some entities. The NPRM also seeks comment on possible insurance requirements for space station licensees/grantees.

Steps Taken to Minimize Significant Economic Impact on Small Entities, and Significant Alternatives Considered

The RFA requires an agency to describe any significant, specifically small business, alternatives that it has considered in reaching its proposed approach, which may include the following four alternatives (among others): "(1) the establishment of differing compliance or reporting requirements or timetables that take into account the resources available to small entities; (2) the clarification, consolidation, or simplification of compliance and reporting requirements under the rules for such small entities; (3) the use of performance rather than design standards; and (4) an exemption from coverage of the rule, or any part thereof, for such small entities."[252]

With respect to the additional orbital debris mitigation plan disclosure requirements described above, we believe that the disclosures will in most instances be consistent with, or a natural outgrowth of, analysis that is already being conducted by space station applicants and/or operators. These additional disclosures should be consistent with the types of operations that are in the space station operator's best interest, such as avoiding collision with other spacecraft. In several instances, certifications are proposed, but in other instances, we believe that a descriptive disclosure is superior to a certification alternative, to provide the applicant with an opportunity to fully explain its plans for Commission evaluation. As an alternative to the disclosures, we could propose not to require any additional information, but as described in the NPRM, the public interest in mitigating orbital debris and ensuring the long-term viability of the space environment may weigh in favor of the additional disclosures. Several of the proposals apply only to space stations with planned deployment altitudes between above 650 km. This 650 km altitude is based upon anticipated on-orbit lifetimes, as described in the NPRM, and we anticipate will not be applicable to most small entities' space stations. That specific altitude was proposed to address orbits where deployments may be of particular concern, without burdening operators planning to deploy in lower orbits. We seek comment in the

---

[252] 13 5 U.S.C. § 603(c)(1)-(4).

NPRM on the costs and benefits of the proposed requirements applying to space stations deployed above 650 km.

The Commission seeks comment on the proposed indemnification requirements related to space station authorization. Given the basis for proposing such a requirement in the NPRM, which relates to the role of the Commission generally, we do not consider categorical exemptions relevant to small entities. As to the insurance proposals, the NPRM asks whether certain entities should be exempted, including entities such as relatively low risk systems, which could ease the potential compliance burden for small entities.

The NPRM seeks comment from all interested parties. Small entities are encouraged to bring to the Commission's attention any specific concerns they may have with the proposals outlined in the NPRM. The Commission expects to consider any economic impact on small entities.

US Space Policy Directive-3: National Space Traffic Management Policy

Joseph N. Pelton

Contents

Abstract

The issues of space situational awareness (SSA) and space traffic management (STM) have come increasingly to the fore as a result of a growing number of proposals to deploy an ever increasing number of satellite constellations that are populated by a huge number of small satellites. There have been new efforts to provide much-improved tracking of these satellites through the deployment of the new S-band radar system by the United States on the Marshall Islands that will be able to track orbital debris and satellites of a size of marble and as many as 400,000 to 500,000 space objects. There are also many new initiatives to provide private tracking capability of space debris through the use of optical telescopes as well as radar systems.

There are also a number of new ideas as to how national regulatory systems might provide expanded space traffic management and space traffic control capabilities. The US Space Policy Directive-3 issued on June 18, 2018, set forth in some detail how the United States might approach both the issues of improved space situational awareness, especially in low Earth orbit (LEO), and

improved approaches to space traffic control. This US Space Policy Directive-3 is perhaps most significant in that it sets for the idea that there should be separate approaches with regard to commercial satellite tracking and traffic control and such activities with regard to national defense activities. The main purpose of this chapter is to provide the full text of US Space Policy Directive-3.

Keywords

Civil space activities · Commercial space activities · Long-term sustainability of space · Mitigation of space debris · National defense · Optical tracking of satellites · Orbital debris · S-band radar · Space data · Space debris · Space object registry · Space situational awareness (SSA) · Space traffic management (STM) · US Department of Commerce (DOC) · US Department of Defense (DOD)

1 Introduction

This technical and regulatory document issued by the US White House on June 18, 2018, is provided as a key resource and useful background information to the discussion of the consideration of the need to improve space situational awareness (SSA) and efforts to increase national systems to undertake enhanced space traffic management (STM) to avoid the increased buildup of orbital space debris and to avoid new collisions of space objects, particularly in low Earth orbit (LEO).

The document provided below which is an official space policy statement issued from the US White House is important in terms of defining a new approach that divides the efforts related to SSA and STM between those activities related to commercial space systems and activities related to national defense. It is also key in that it calls from the development of new science and technology in this field to improve national systems for both SSA and STM capabilities. The full text of the US Space Policy Directive-3 is provided below.

2 US Presidential Memorandum: Space Policy Directive-3, National Space Traffic Management Policy

Issued on: June 18, 2018

MEMORANDUM FOR THE VICE PRESIDENT
THE SECRETARY OF STATE
THE SECRETARY OF DEFENSE
THE SECRETARY OF COMMERCE
THE SECRETARY OF TRANSPORTATION
THE SECRETARY OF HOMELAND SECURITY
THE DIRECTOR OF NATIONAL INTELLIGENCE
THE DIRECTOR OF THE OFFICE OF MANAGEMENT AND BUDGET

THE ASSISTANT TO THE PRESIDENT FOR NATIONAL SECURITY AFFAIRS

THE ADMINISTRATOR OF THE NATIONAL AERONAUTICS AND SPACE ADMINISTRATION

THE DIRECTOR OF THE OFFICE OF SCIENCE AND TECHNOLOGY POLICY

THE DEPUTY ASSISTANT TO THE PRESIDENT FOR HOMELAND SECURITY AND COUNTERTERRORISM

THE CHAIRMAN OF THE JOINT CHIEFS OF STAFF

SUBJECT: National Space Traffic Management Policy

Section 1. Policy. For decades, the United States has effectively reaped the benefits of operating in space to enhance our national security, civil, and commercial sectors. Our society now depends on space technologies and space-based capabilities for communications, navigation, weather forecasting, and much more. Given the significance of space activities, the United States considers the continued unfettered access to and freedom to operate in space of vital interest to advance the security, economic prosperity, and scientific knowledge of the Nation.

Today, space is becoming increasingly congested and contested, and that trend presents challenges for the safety, stability, and sustainability of U.S. space operations. Already, the Department of Defense (DoD) tracks over 20,000 objects in space, and that number will increase dramatically as new, more capable sensors come online and are able to detect smaller objects. DoD publishes a catalog of space objects and makes notifications of potential conjunctions (that is, two or more objects coming together at the same or nearly the same point in time and space). As the number of space objects increases, however, this limited traffic management activity and architecture will become inadequate. At the same time, the contested nature of space is increasing the demand for DoD focus on protecting and defending U.S. space assets and interests.

The future space operating environment will also be shaped by a significant increase in the volume and diversity of commercial activity in space. Emerging commercial ventures such as satellite servicing, debris removal, in-space manufacturing, and tourism, as well as new technologies enabling small satellites and very large constellations of satellites, are increasingly outpacing efforts to develop and implement government policies and processes to address these new activities.

To maintain U.S. leadership in space, we must develop a new approach to space traffic management (STM) that addresses current and future operational risks. This new approach must set priorities for space situational awareness (SSA) and STM innovation in science and technology (S&T), incorporate national security considerations, encourage growth of the U.S. commercial space sector, establish an updated STM architecture, and promote space safety standards and best practices across the international community.

The United States recognizes that spaceflight safety is a global challenge and will continue to encourage safe and responsible behavior in space while emphasizing the need for international transparency and STM data sharing. Through this national policy for STM and other national space strategies and policies, the United States will enhance safety and ensure continued leadership, preeminence, and freedom of action in space.

Sec. 2. Definitions. For the purposes of this memorandum, the following definitions shall apply:

(a) Space Situational Awareness shall mean the knowledge and characterization of space objects and their operational environment to support safe, stable, and sustainable space activities.
(b) Space Traffic Management shall mean the planning, coordination, and on-orbit synchronization of activities to enhance the safety, stability, and sustainability of operations in the space environment.
(c) Orbital debris, or space debris, shall mean any human-made space object orbiting Earth that no longer serves any useful purpose.

Sec. 3. Principles. The United States recognizes, and encourages other nations to recognize, the following principles:

(a) Safety, stability, and operational sustainability are foundational to space activities, including commercial, civil, and national security activities. It is a shared interest and responsibility of all spacefaring nations to create the conditions for a safe, stable, and operationally sustainable space environment.
(b) Timely and actionable SSA data and STM services are essential to space activities. Consistent with national security constraints, basic U.S. Government-derived SSA data and basic STM services should be available free of direct user fees.
(c) Orbital debris presents a growing threat to space operations. Debris mitigation guidelines, standards, and policies should be revised periodically, enforced domestically, and adopted internationally to mitigate the operational effects of orbital debris.
(d) A STM framework consisting of best practices, technical guidelines, safety standards, behavioral norms, pre-launch risk assessments, and on-orbit collision avoidance services is essential to preserve the space operational environment.

Sec. 4. Goals. Consistent with the principles listed in section 3 of this memorandum, the United States should continue to lead the world in creating the conditions for a safe, stable, and operationally sustainable space environment. Toward this end, executive departments and agencies (agencies) shall pursue the following goals as required in section 6 of this memorandum:

(a) Advance SSA and STM Science and Technology. The United States should continue to engage in and enable S&T research and development to support the practical applications of SSA and STM. These activities include improving fundamental knowledge of the space environment, such as the characterization of small debris, advancing the S&T of critical SSA inputs such as observational data, algorithms, and models necessary to improve SSA capabilities, and developing new hardware and software to support data processing and observations.

(b) Mitigate the effect of orbital debris on space activities. The volume and location of orbital debris are growing threats to space activities. It is in the interest of all to minimize new debris and mitigate effects of existing debris. This fact, along with increasing numbers of active satellites, highlights the need to update existing orbital debris mitigation guidelines and practices to enable more efficient and effective compliance, and establish standards that can be adopted internationally. These trends also highlight the need to establish satellite safety design guidelines and best practices.

(c) Encourage and facilitate U.S. commercial leadership in S&T, SSA, and STM. Fostering continued growth and innovation in the U.S. commercial space sector, which includes S&T, SSA, and STM activities, is in the national interest of the United States. To achieve this goal, the U.S. Government should streamline processes and reduce regulatory burdens that could inhibit commercial sector growth and innovation, enabling the U.S. commercial sector to continue to lead the world in STM-related technologies, goods, data, and services on the international market.

(d) Provide U.S. Government-supported basic SSA data and basic STM services to the public. The United States should continue to make available basic SSA data and basic STM services (including conjunction and reentry notifications) free of direct user fees while supporting new opportunities for U.S. commercial and non-profit SSA data and STM services.

(e) Improve SSA data interoperability and enable greater SSA data sharing. SSA data must be timely and accurate. It is in the national interest of the United States to improve SSA data interoperability and enable greater SSA data sharing among all space operators, consistent with national security constraints. The United States should seek to lead the world in the development of improved SSA data standards and information sharing.

(f) Develop STM standards and best practices. As the leader in space, the United States supports the development of operational standards and best practices to promote safe and responsible behavior in space. A critical first step in carrying out that goal is to develop U.S.-led minimum safety standards and best practices to coordinate space traffic. U.S. regulatory agencies should, as appropriate, adopt these standards and best practices in domestic regulatory frameworks and use them to inform and help shape international consensus practices and standards.

(g) Prevent unintentional radio frequency (RF) interference. Growing orbital congestion is increasing the risk to U.S. space assets from unintentional RF interference. The United States should continue to improve policies, processes, and technologies for spectrum use (including allocations and licensing) to address these challenges and ensure appropriate spectrum use for current and future operations.

(h) Improve the U.S. domestic space object registry. Transparency and data sharing are essential to safe, stable, and sustainable space operations. Consistent with national security constraints, the United States should streamline the interagency process to ensure accurate and timely registration submissions to the United Nations (UN), in accordance with our international obligations under the Convention on Registration of Objects Launched into Outer Space.

(i) Develop policies and regulations for future U.S. orbital operations. Increasing congestion in key orbits and maneuver-based missions such as servicing, survey, and assembly will drive the need for policy development for national security, civil, and commercial sector space activities. Consistent with U.S. law and international obligations, the United States should regularly assess existing guidelines for non-government orbital activities, and maintain a timely and responsive regulatory environment for licensing these activities.

Sec. 5. Guidelines. In pursuit of the principles and goals of this policy, agencies should observe the following guidelines:

(a) Managing the Integrity of the Space Operating Environment.

  (i) Improving SSA coverage and accuracy. Timely, accurate, and actionable data are essential for effective SSA and STM. The United States should seek to minimize deficiencies in SSA capability, particularly coverage in regions with limited sensor availability and sensitivity in detection of small debris, through SSA data sharing, the purchase of SSA data, or the provision of new sensors.

  New U.S. sensors are expected to reveal a substantially greater volume of debris and improve our understanding of space object size distributions in various regions of space. However, very small debris may not be sufficiently tracked to enable or justify actionable collision avoidance decisions. As a result, close conjunctions and even collisions with unknown objects are possible, and satellite operators often lack sufficient insight to assess their level of risk when making maneuvering decisions. The United States should develop better tracking capabilities, and new means to catalog such debris, and establish a quality threshold for actionable collision avoidance warning to minimize false alarms.

  Through both Government and commercial sector S&T investment, the United States should advance concepts and capabilities to improve SSA in support of debris mitigation and collision avoidance decisions.

  (ii) Establishing an Open Architecture SSA Data Repository. Accurate and timely tracking of objects orbiting Earth is essential to preserving the safety of space activities for all. Consistent with section 2274 of title 10, United States Code, a basic level of SSA data in the form of the publicly releasable portion of the DoD catalog is and should continue to be provided free of direct user fees. As additional sources of space tracking data become available, the United States has the opportunity to incorporate civil, commercial, international, and other available data to allow users to enhance and refine this service. To facilitate greater data sharing with satellite operators and enable the commercial development of enhanced space safety services, the United States must develop the standards and protocols for creation of an open architecture data repository. The essential features of this repository would include:

- Data integrity measures to ensure data accuracy and availability;
- Data standards to ensure sufficient quality from diverse sources;
- Measures to safeguard proprietary or sensitive data, including national security information;
- The inclusion of satellite owner-operator ephemerides to inform orbital location and planned maneuvers; and
- Standardized formats to enable development of applications to leverage the data.

To facilitate this enhanced data sharing, and in recognition of the need for DoD to focus on maintaining access to and freedom of action in space, a civil agency should, consistent with applicable law, be responsible for the publicly releasable portion of the DoD catalog and for administering an open architecture data repository. The Department of Commerce should be that civil agency.

(iii) Mitigating Orbital Debris. It is in the interest of all space operators to minimize the creation of new orbital debris. Rapid international expansion of space operations and greater diversity of missions have rendered the current U.S. Government Orbital Debris Mitigation Standard Practices (ODMSP) inadequate to control the growth of orbital debris. These standard practices should be updated to address current and future space operating environments.

The United States should develop a new protocol of standard practices to set broader expectations of safe space operations in the twenty-first century. This protocol should begin with updated ODMSP, but also incorporate sections to address operating practices for large constellations, rendezvous and proximity operations, small satellites, and other classes of space operations. These overarching practices will provide an avenue to promote efficient and effective space safety practices with U.S. industry and internationally.

The United States should pursue active debris removal as a necessary long-term approach to ensure the safety of flight operations in key orbital regimes. This effort should not detract from continuing to advance international protocols for debris mitigation associated with current programs.

(b) Operating in a Congested Space Environment.

(i) Minimum Safety Standards and Best Practices. The creation of minimum standards for safe operation and debris mitigation derived in part from the U.S. Government ODMSP, but incorporating other standards and best practices, will best ensure the safe operation of U.S. space activities. These safety guidelines should consider maneuverability, tracking, reliability, and disposal.

The United States should eventually incorporate appropriate standards and best practices into Federal law and regulation through appropriate rulemaking or licensing actions. These guidelines should encompass protocols for all stages of satellite operation from design through end-of-life.

Satellite and constellation owners should participate in a pre-launch certification process that should, at a minimum, consider the following factors:

- Coordination of orbit utilization to prevent conjunctions;
- Constellation owner-operators' management of self-conjunctions;
- Owner-operator notification of planned maneuvers and sharing of satellite orbital location data;
- On-orbit tracking aids, including beacons or sensing enhancements, if such systems are needed;
- Encryption of satellite command and control links and data protection measures for ground site operations;
- Appropriate minimum reliability based on type of mission and phase of operations;
- Effect on the national security or foreign policy interests of the United States, or international obligations; and
- Self-disposal upon the conclusion of operational lifetime, or owner-operator provision for disposal using active debris removal methods.

(ii) On-Orbit Collision Avoidance Support Service. Timely warning of potential collisions is essential to preserving the safety of space activities for all. Basic collision avoidance information services are and should continue to be provided free of direct user fees. The imminent activation of more sensitive tracking sensors is expected to reveal a significantly greater population of the existing orbital debris background as well as provide an improved ability to track currently catalogued objects. Current and future satellites, including large constellations of satellites, will operate in a debris environment much denser than presently tracked. Preventing on-orbit collisions in this environment requires an information service that shares catalog data, predicts close approaches, and provides actionable warnings to satellite operators. The service should provide data to allow operators to assess proposed maneuvers to reduce risk. To provide on-orbit collision avoidance, the United States should:

- Provide services based on a continuously updated catalog of satellite tracking data;
- Utilize automated processes for collision avoidance;
- Provide actionable and timely conjunction assessments; and
- Provide data to operators to enable assessment of maneuver plans.

To ensure safe coordination of space traffic in this future operating environment, and in recognition of the need for DoD to focus on maintaining access to and freedom of action in space, a civil agency should be the focal point for this collision avoidance support service. The Department of Commerce should be that civil agency.

(c) Strategies for Space Traffic Management in a Global Context.

(i) Protocols to Prevent Orbital Conjunctions. As increased satellite operations make lower Earth orbits more congested, the United States should develop a set of standard techniques for mitigating the collision risk of increasingly congested orbits, particularly for large constellations. Appropriate methods, which may include licensing assigned volumes for constellation operation and establishing processes for satellites passing through the volumes, are needed. The United States should explore strategies that will lead to the establishment of common global best practices, including:

- A common process addressing the volume of space used by a large constellation, particularly in close proximity to an existing constellation;
- A common process by which individual spacecraft may transit volumes used by existing satellites or constellations; and
- A set of best practices for the owner-operators of utilized volumes to minimize the long-term effects of constellation operations on the space environment (including the proper disposal of satellites, reliability standards, and effective collision avoidance).

(ii) Radio Frequency Spectrum and Interference Protection. Space traffic and RF spectrum use have traditionally been independently managed processes. Increased congestion in key orbital regimes creates a need for improved and increasingly dynamic methods to coordinate activities in both the physical and spectral domains, and may introduce new interdependencies. U.S. Government efforts in STM should address the following spectrum management considerations:

- Where appropriate, verify consistency between policy and existing national and international regulations and goals regarding global access to, and operation in, the RF spectrum for space services;
- Investigate the advantages of addressing spectrum in conjunction with the development of STM systems, standards, and best practices;
- Promote flexible spectrum use and investigate emerging technologies for potential use by space systems; and
- Ensure spectrum-dependent STM components, such as inter-satellite safety communications and active debris removal systems, can successfully access the required spectrum necessary to their missions.

(iii) Global Engagement. In its role as a major spacefaring nation, the United States should continue to develop and promote a range of norms of behavior, best practices, and standards for safe operations in space to minimize the space debris environment and promote data sharing and coordination of space activities. It is essential that other spacefaring nations also adopt best practices for the common good of all spacefaring states. The United States should encourage the adoption of new norms of behavior and best practices for space operations by the international community through bilateral and multilateral discussions with other spacefaring nations, and through U.S. participation in various organizations such as the Inter-Agency Space Debris Coordination Committee, International Standards Organization, Consultative Committee for Space Data Systems, and UN Committee on the Peaceful Uses of Outer Space.

Sec. 6. Roles and Responsibilities. In furtherance of the goals described in section 4 and the guidelines described in section 5 of this memorandum, agencies shall carry out the following roles and responsibilities:

(a) Advance SSA and STM S&T. Members of the National Space Council, or their delegees, shall coordinate, prioritize, and advocate for S&T, SSA, and STM, as appropriate, as it relates to their respective missions. They should seek opportunities to engage with the commercial sector and academia in pursuit of this goal.
(b) Mitigate the Effect of Orbital Debris on Space Activities.
    (i) The Administrator of the National Aeronautics and Space Administration (NASA Administrator), in coordination with the Secretaries of State, Defense, Commerce, and Transportation, and the Director of National Intelligence, and in consultation with the Chairman of the Federal Communications Commission (FCC), shall lead efforts to update the U.S. Orbital Debris Mitigation Standard Practices and establish new guidelines for satellite design and operation, as appropriate and consistent with applicable law.
    (ii) The Secretaries of Commerce and Transportation, in consultation with the Chairman of the FCC, will assess the suitability of incorporating these updated standards and best practices into their respective licensing processes, as appropriate and consistent with applicable law.
(c) Encourage and Facilitate U.S. Commercial Leadership in S&T, SSA, and STM. The Secretary of Commerce, in coordination with the Secretaries of Defense and Transportation, and the NASA Administrator, shall lead efforts to encourage and facilitate continued U.S. commercial leadership in SSA, STM, and related S&T.
(d) Provide U.S. Government-Derived Basic SSA Data and Basic STM Services to the Public.
    (i) The Secretaries of Defense and Commerce, in coordination with the Secretaries of State and Transportation, the NASA Administrator, and the Director of National Intelligence, should cooperatively develop a plan for providing basic SSA data and basic STM services either directly or through a partnership with industry or academia, consistent with the guidelines of sections 5(a)(ii) and 5(b)(ii) of this memorandum.
    (ii) The Secretary of Defense shall maintain the authoritative catalog of space objects.
    (iii) The Secretaries of Defense and Commerce shall assess whether statutory and regulatory changes are necessary to effect the plan developed under subsection (d)(i) of this section, and shall pursue such changes, along with any other needed changes, as appropriate.
(e) Improve SSA Data Interoperability and Enable Greater SSA Data Sharing.
    (i) The Secretary of Commerce, in coordination with the Secretaries of State, Defense, and Transportation, the NASA Administrator, and the Director of National Intelligence, shall develop standards and protocols for creation of an open architecture data repository to improve SSA data interoperability and enable greater SSA data sharing.

   (ii) The Secretary of Commerce shall develop options, either in-house or through partnerships with industry or academia, assessing both the technical and economic feasibility of establishing such a repository.
   (iii) The Secretary of Defense shall ensure that release of data regarding national security activities to any person or entity with access to the repository is consistent with national security interests.

(f) Develop Space Traffic Standards and Best Practices. The Secretaries of Defense, Commerce, and Transportation, in coordination with the Secretary of State, the NASA Administrator, and the Director of National Intelligence, and in consultation with the Chairman of the FCC, shall develop space traffic standards and best practices, including technical guidelines, minimum safety standards, behavioral norms, and orbital conjunction prevention protocols related to pre-launch risk assessment and on-orbit collision avoidance support services.

(g) Prevent Unintentional Radio Frequency Interference. The Secretaries of Commerce and Transportation, in coordination with the Secretaries of State and Defense, the NASA Administrator, and the Director of National Intelligence, and in consultation with the Chairman of the FCC, shall coordinate to mitigate the risk of harmful interference and promptly address any harmful interference that may occur.

(h) Improve the U.S. Domestic Space Object Registry. The Secretary of State, in coordination with the Secretaries of Defense, Commerce, and Transportation, the NASA Administrator, and the Director of National Intelligence, and in consultation with the Chairman of the FCC, shall lead U.S. Government efforts on international engagement related to international transparency and space object registry on SSA and STM issues.

(i) Develop Policies and Regulations for Future U.S. Orbital Operations. The Secretaries of Defense, Commerce, and Transportation, in coordination with the Secretary of State, the NASA Administrator, and the Director of National Intelligence, shall regularly evaluate emerging trends in space missions to recommend revisions, as appropriate and necessary, to existing SSA and STM policies and regulations.

Sec. 7. General Provisions.

(a) Nothing in this memorandum shall be construed to impair or otherwise affect:
   (i) the authority granted by law to an executive department or agency, or the head thereof; or
   (ii) the functions of the Director of the Office of Management and Budget relating to budgetary, administrative, or legislative proposals.

(b) This memorandum shall be implemented consistent with applicable law and subject to the availability of appropriations.

(c) This memorandum is not intended to, and does not, create any right or benefit, substantive or procedural, enforceable at law or in equity by any party against the United States, its departments, agencies, or entities, its officers, employees, or agents, or any other person.

(d) The Secretary of Commerce is authorized and directed to publish this memorandum in the Federal Register.

3 Conclusion

Pursuant to this policy directive, efforts have now been undertaken within the US government to respond to the directives provided in the above document. The Office of Space Commerce in the US Department of Commerce has been creating staff competency to address the requirements established in Space Policy Directive-3. These activities have been particularly focused on US commercial space activities and sought to create new SSA and STM capabilities consistent with that directive. The US Department of Defense continues their efforts to be able to track space objects in a comprehensive way to provide for the national defense of the United States.

US Government and NASA Documents Related to Orbital Space Debris Mitigation

Joseph N. Pelton

Contents

Abstract

The US Governmental Agencies most concerned with orbital space debris and its mitigation are NASA, the Federal Communications Agency, the Department of Defense, the Department of Commerce and its Office of Commercial Space, the Department of Transportation and its Office of Commercial Space Transportation in the Federal Aviation Agency (FAA-AST), and the National Space Council. The National Space Council has just approved for distribution in November 2019 the latest version of the US Government Orbital Debris Mitigation Standard Practices (ODMSP). This is provided below and also can be found on line (NASA, Orbital debris mitigation standard practices. https://orbitaldebris.jsc.nasa.gov/library/usg_orbital_debris_mitigation_standard_practices_november_2019.pdf. November 2019).

J. N. Pelton (ed.), *Handbook of Small Satellites*,
https://doi.org/10.1007/978-3-030-36308-6_108

The summary of this report from Space News highlighted its five key elements as follows: “The new document retains four objectives from the original version regarding control of debris in normal operations, minimizing debris from accidental explosions, use of safe flight profiles and operational configurations, and post-mission disposal of space structures. The new version adds a fifth objective to cover additional issues, such as operation of cubesats and large constellations as well as satellite servicing.” (Jeff Frost, U.S. government updates orbital debris mitigation guidelines. Space News, Dec 9, 2019. https://spacenews.com/u-s-government-updates-orbital-debris-mitigation-guidelines/)

Also provided is the reference documents compiled the NASA that prepared the ODMSP update in coordination with all relevant agencies concerned with orbital space debris issues. It is hoped that these procedures will be considered the U.N. Committee on the Peaceful Uses of Outer Space and the UN Office of Outer Space Affairs updates to the U.N. COPUOS prepared guidelines as official agreed in 2007 and ratified by the U.N. General Assembly.

1 US Government Orbital Debris Mitigation Standard Practices (ODMSP), November 2019 Update

1.1 Preamble

The United States Government (USG) Orbital Debris Mitigation Standard Practices (ODMSP) were established in 2001 to address the increase in orbital debris in the near-Earth space environment. The goal of the ODMSP was to limit the generation of new, long-lived debris by the control of debris released during normal operations, minimizing debris generated by accidental explosions, the selection of safe flight profile and operational configuration to minimize accidental collisions, and post-mission disposal of space structures. While the original ODMSP adequately protected the space environment at the time, the USG recognizes that it is in the interest of all nations to minimize new debris and mitigate effects of existing debris. This fact, along with increasing numbers of space missions, highlights the need to update the ODMSP and to establish standards that can inform development of international practices.

This 2019 update includes improvements to the original objectives as well as clarification and additional standard practices for certain classes of space operations. The improvements consist of a quantitative limit on debris released during normal operations, a probability limit on accidental explosions, probability limits on accidental collisions with large and small debris, and a reliability threshold for successful postmission disposal. The new standard practices established in the update include the preferred disposal options for immediate removal of structures from the near-Earth space environment, a low-risk geosynchronous Earth orbit (GEO) transfer disposal option, a long-term reentry option, and improved move-away-and-stay-away storage options in medium Earth orbit (MEO) and above GEO. The update also incorporates new sections to clarify and address operating practices for large constellations, rendezvous and proximity operations, small satellites, satellite servicing, and other classes of space operations.

The updated standard practices are significant, meaningful, and achievable. The 2019 ODMSP, by establishing guidelines for USG activities, provides a reference to promote efficient and effective space safety practices for other domestic and international operators. The USG intends to update and refine the ODMSP as necessary in the future to address advances in both technology and policy. The USG will follow the ODMSP, consistent with mission requirements and cost effectiveness, in the procurement and operation of spacecraft, launch services, and the conduct of tests and experiments in space. When practical, operators should consider the benefits of going beyond the standard practices and take additional steps to limit the generation of orbital debris. Together with continued development of standards and best practices for space traffic management, the updated ODMSP will contribute to safe space operations and the long-term sustainability of space activities.

2 Objective 1. Control of Debris Released During Normal Operations

Programs and projects will assess and limit the amount of debris released in a planned manner during normal operations. Objects with planned functions after release should follow standard practices set forth in Objectives 2 through 5.

1-1. In all operational orbit regimes: Spacecraft and upper stages should be designed to eliminate or minimize debris released during normal operations. Each instance of planned release of debris larger than 5 mm in any dimension that remains on orbit for more than 25 years should be evaluated and justified. For all planned released debris larger than 5 mm in any dimension, the total debris object-time product in low Earth orbit (LEO) should be less than 100 object-years per upper stage or per spacecraft. The total object-time product in LEO is the sum, over all planned released objects, of the orbit dwell time in LEO.

3 Objective 2. Minimizing Debris Generated by Accidental Explosions

Programs and projects will assess and limit the probability of accidental explosion during and after completion of mission operations.

2-1. Limiting the risk to other space systems from accidental explosions and associated orbital debris during mission operations: In developing the design of a spacecraft or upper stage, each program should demonstrate, via commonly accepted engineering and probability assessment methods, that the integrated probability of debris-generating explosions for all credible failure modes of each spacecraft and upper stage (excluding small particle impacts) is less than 0.001 (1 in 1000) during deployment and mission operations.

2-2. Limiting the risk to other space systems from accidental explosions and associated orbital debris after completion of mission operations: All on-board sources of stored energy of a spacecraft or upper stage should be depleted or safed when they are no longer required for mission operations or postmission disposal. Depletion should occur as soon as such an operation does not pose an unacceptable risk to the payload. Propellant depletion burns and compressed gas releases should be designed to minimize the probability of subsequent accidental collision and to minimize the impact of a subsequent accidental explosion.

4 Objective 3. Selection of Safe Flight Profile and Operational Configuration

Programs and projects will assess and limit the probability of operating space systems becoming a source of debris by collisions with human-made objects or meteoroids.

3-1. Collision with large objects during orbital lifetime: In developing the design and mission profile for a spacecraft or upper stage, a program will estimate and limit the probability of collision with objects 10 cm and larger during orbital lifetime to less than 0.001 (1 in 1000). For the purpose of this assessment, 100 years is used as the maximum orbital lifetime. 3-2. Collision with small debris during mission operations: Spacecraft design will consider and limit the probability to less than 0.01 (1 in 100) that collisions with micrometeoroids and orbital debris smaller than 1 cm will cause damage that prevents planned postmission disposal.

5 Objective 4. Postmission Disposal of Space Structures

Programs and projects will plan for disposal procedures for a structure (i.e., launch vehicle components, upper stages, spacecraft, and other payloads) at the end of mission life to minimize impact on future space operations.

4-1. Disposal for final mission orbits: A spacecraft or upper stage may be disposed of by one of the following methods:

(a) Direct reentry or heliocentric, Earth-escape: Maneuver to remove the structure from Earth orbit at the end of mission into (1) a reentry trajectory or (2) a heliocentric, Earth-escape orbit. These are the preferred disposal options. For direct reentry, the risk of human casualty from surviving components with impact kinetic energies greater than 15 joules should be less than 0.0001(1 in 10,000). Design-for-demise and other measures, including reusability and targeted reentry away from landmasses, to further reduce reentry human casualty risk should be considered.

(b) Atmospheric reentry: Leave the structure in an orbit in which, using conservative projections for solar activity, atmospheric drag will limit the lifetime to as short as practicable but no more than 25 years after completion of mission. If drag enhancement devices are to be used to reduce the orbit lifetime, it should be demonstrated that such devices will significantly reduce the area-time product of the system or will not cause spacecraft or large debris to fragment if a collision occurs while the system is decaying from orbit. The risk of human casualty from surviving components with impact kinetic energies greater than 15 joules should be less than 0.0001(1 in 10,000).

(c) Storage between LEO and GEO: I. Maneuver to an eccentric disposal orbit (e.g., GEO transfer) where (1) perigee altitude remains above the LEO zone for at least 100 years, (2) apogee altitude remains below the GEO zone for at least 100 years, and (3) the time spent by the structure between 20,182 +/− 300 km is limited to 25 years or less over 200 years; or, II. Maneuver to a near-circular disposal orbit to (1) avoid crossing 20,182 +/− 300 km, the GEO zone, and the LEO zone for at least 100 years, and (2) limit the risk to other

US Government Orbital Debris Mitigation Standard Practices, November 2019 Update 6operational constellations, for example, by avoiding crossing the altitudes occupied by known missions of 10 or more spacecraft using near-circular orbits, for 100 years. d. Storage above GEO: Maneuver to an orbit with perigee altitude sufficiently above 35,986 km (upper boundary of the GEO zone) to ensure the structure remains outside the GEO zone for at least 100 years. e. Long-term reentry for structures in MEO, Tundra orbits, highly inclined GEO, and other orbits: Maneuver to a disposal orbit where orbital resonances will increase the eccentricity for long-term reentry of the structure. In developing this disposal plan, the program should (1) limit the postmission orbital lifetime to as short as practicable but no more than 200 years, (2) limit the time spent by the structure in the LEO zone, the GEO zone, and between 20,182 +/− 300 km to 25 years or less per zone; and (3) limit the probability of collisions with debris 10 cm and larger to less than 0.001 (1 in 1,000) during orbital lifetime. To limit human casualty risk from the reentry of the structure, surviving components with impact kinetic energies greater than 15 joules should have less than 7 m^2 total debris casualty area or less than 0.0001 (1 in 10,000) human casualty risk. f. Direct retrieval: Retrieve the structure and remove it from orbit preferably at completion of mission, but no more than 5 years after completion of mission. 4-2. Reliability of disposal: The probability of successful postmission disposal should be no less than 0.9 with a goal of 0.99 or better. The geosynchronous Earth orbit (GEO) zone is defined as the region between the altitudes of 35,586 and 35,986 km. The low Earth orbit (LEO) zone is defined as the region below 2000 km altitude. The medium Earth orbit (MEO) is the region between LEO and GEO. Because of fuel gauging uncertainties near the end of mission, a program should use a maneuver strategy that reduces the risk of leaving the structure near an operational orbit regime.

6 Objective 5. Clarification and Additional Standard Practices for Certain Classes of Space Operations

These classes of space operations and structures should follow Objectives 1 through 4 plus additional standard practices for orbital debris mitigation set forth in this section.

5-1. Large Constellations: A constellation consisting of 100 or more operational spacecraft cumulative is considered a large constellation. a. Each spacecraft in a large constellation should have a probability of successful postmission disposal at a level greater than 0.9 with a goal of 0.99 or better. In determining the successful postmission disposal threshold, factors such as mass, collision probability, orbital location, and other relevant parameters should be considered. b. For large constellations, Objective 4-1.a. is the preferred post-mission disposal option for the spacecraft. In developing the mission profile, the program should limit the cumulative reentry human casualty risk from the constellation. 5-2. Small satellites, including CubeSats, should follow the standard practices set forth in Objectives 1 through 4. For spacecraft smaller than 10 cm × 10 cm × 10 cm when fully deployed: a. Any spacecraft in LEO should be limited to an orbital lifetime as short as practicable but no more than 25 years after completion of mission. b. The total spacecraft object-time product in LEO should be less than 100 object-years per mission. 5-3. Rendezvous, proximity operations, and satellite servicing: In developing the mission profile for a structure, the program should limit the risk of debris generation as an outcome of the operations. The program should (1) limit the probability of accidental collision and (2) limit the probability of accidental explosion resulting from the operations. Any planned debris generated as a result of the operations should follow the standard practices for mission-related debris set forth in Objective 1.

US Government Orbital Debris Mitigation Standard Practices, November 2019 Update 85-4. Safety of Active debris removal operations: In developing the mission profile for an active debris removal operation on a debris structure, the program should limit the risk of debris generation as an outcome of the operation. The program should (1) avoid fragmentation of the debris structure, (2) limit the probability of accidental collision, and (3) limit the probability of accidental explosion resulting from the operations. Any planned debris generated as a result of the operations should follow the standard practices for mission-related debris set forth in Objective 1. The operations should be designed for the debris structure to follow applicable postmission disposal practices set forth in Objective 4. 5-5. Tether systems will be uniquely analyzed for both intact and severed conditions (a) for collision risk with large objects during orbital lifetime and collision risk with small debris during mission operations and (b) when performing trade-offs between alternative disposal strategies.

6.1 Orbital Debris Program Office Reference Documents – NASA

orbitaldebris.jsc.nasa.gov/reference-documents.htm

1. **Technical Report on Space Debris (Adobe PDF 579 kb)**
   This is a report published by the Scientific and Technical Subcommittee (STSC) of the United Nations on space debris in 1999. This report summarizes the reviews within the STSC between 1996 and 1998 on orbital debris measurements, modeling, risk assessments, and mitigation measures.
2. **US Government Orbital Debris Mitigation Standard Practices (Adobe PDF 117 kb)**
   The United States Government has formally stated in this document its objectives and practices of limiting the amount of space debris. The four objectives are (1) control of debris released during normal operations, (2) minimizing debris generated by accidental explosions, (3) selection of safe flight profile and operational configuration, and (4) postmission disposal of space structures.
3. **History of On-Orbit Satellite Fragmentations (Adobe PDF 2,251 kb)**
   The 14th edition of this document was published in 2008. This document summarizes all known satellite and upper stage fragmentations prior to 1 August 2007. Available information includes breakup date, breakup altitude, number of debris generated, and references to each event. Gabbard diagrams for many breakup clouds are also included in the document.
4. **Orbital Debris: A Technical Assessment (Adobe PDF 9,371 kb))**
   This is a document published by US National Research Council in 1995. It examines the methods used to characterize the orbital debris environment and assesses the hazards a debris population poses to spacecraft. Recommendations to improve debris research and the protection of spacecraft and specific recommendations on methods to reduce future debris creation are also included in the document.
5. **Interagency Report on Orbital Debris (Adobe PDF 7,456 kb)**
   This document was published by the National Science and Technology Council Committee on Transportation Research and Development in 1995. It contains an up-to-date portrait of the orbital debris measurement, modeling, and mitigation efforts and a set of recommendations outlining specific steps necessary to minimize the potential hazards posed by orbital debris.
6. **IADC Space Debris Mitigation Guidelines (Adobe PDF 99 kb)**
   This document describes the guidelines adopted by the 11 members of the Inter-Agency Space Debris Coordination Committee (IADC) in 2002 and slightly revised in 2007. The guidelines were developed via consensus within the IADC, with an emphasis on cost effectiveness that can be considered during planning

and design of spacecraft and launch vehicles in order to minimize or eliminate generation of debris during operations.

7. **UN Space Debris Mitigation Guidelines (Adobe PDF 1,382.4 kb)**
   This document describes the guidelines adopted by the Scientific and Technical Subcommittee (STSC) of the United Nations (UN) Committee on the Peaceful Uses of Outer Space (COPUOS) in February 2007. The guidelines were developed via consensus within the STSC, and the full COPUOS endorsed the guidelines in June 2007, followed by General Assembly endorsement later in 2007. These guidelines are consistent with the US Government Orbital Debris Mitigation Standard Practices and the IADC Space Debris Mitigation Guidelines.
8. **NASA Procedural Requirements for Limiting Orbital Debris – NPR 8715_006B (Adobe PDF 102 kb)**
   NPR8715.6B became effective on 16 Feb 2017. It reflects NASA's policy to limit future orbital debris generation. The applicability, authority, and references of the requirements and the responsibility within NASA organizations are all clearly stated in the document.
9. **NASA Standard 8719.14 (Adobe PDF 445 kb)**
   NASA has adopted a policy to control the generation of orbital debris in NASA Procedural Requirements 8715.6A and has implemented this policy in NASA Standard 8719.14. All NASA flight projects are now required to provide debris assessments and end-of-mission planning as a normal part of the project development.
10. **Handbook for Limiting Orbital Debris – NASA-HDBK 8719.14**
    This NASA-HDBK serves as a companion to NASA Procedural Requirements (NPR) 8715.6A, NASA Procedural Requirements for Limiting Orbital Debris and NASA-STD 8719.14, Process for Limiting Orbital Debris and contains the background and reference materials to aid in understanding the foundation and science for predicting and limiting orbital debris.

7 Conclusion

The current plans for deployment of a significant number of small satellite constellations populated by a large number of satellites numbering in the thousands have greatly raised concerns about orbital space debris and the need for new procedures to be adopted that require more stringent guidelines for the mitigation of the formation of new space debris. The analysis that has been undertaken by the Aerospace Corporation has suggested that all of the large constellations that are being deployed or that have been proposed could result in unintended collisions both during deployment and during removal at end of life (Muelhaupt et al. 2019).

The USA has undertaken several efforts to devise stricter controls to monitor all launches so as to prevent the formation of new debris and ensure safe removal of space structures at end of life. It has sought to share this information with the international community to seek tighter procedures that are enforced around the world.

Part XIV

Conclusions

Conclusion: The Many Technical, Market, Economic, and Practical Aspects of the World of Small Satellites

Joseph N. Pelton

Contents

Abstract

The most significant change in the world of space applications in the past decade is what might be called the small satellite revolution. This small satellite revolution is closely aligned with what is also now known as "Space 2.0" or "NewSpace." Probing discussions of this small satellite revolution and efforts to identify the prime factors that gave rise to this profound change in the space industry produce a number of diverse but convincing answers to what has produced this small satellite revolution. The drivers of this change, largely within the past decade, include (i) new types of flat panel user antennas that can

electronically track low Earth orbit satellites in mega-constellations; (ii) new more efficient ways to design and manufacture small satellites at much lower cost and sometimes with the use of off-the-shelf technology; (iii) new lower-cost launchers that can deploy small satellites at much lower cost; (iv) advances in microelectronics, smaller but higher performance sensors, improved component design and manufacture, etc.; (v) a rapid evolution of space services markets through the creation of new types of commercial satellite applications as well as expanded attempts to provide expanded space services to unserved markets in developing economies – especially in the case of broadband Internet streaming and remote sensing; (vi) entrepreneurial business innovation in the space field, often driven by out-of-the-box thinking from the world of computer services and social media; and (vii) new ways of financing small satellite startup ventures based on mechanism such as "Kickstarter," crowdsourcing, rounds of venture capital funding, and crossover investment in satellite applications from new industries such as from the world of computer and information services, investment banking, and other revenue sources.

This *Handbook of Small Satellite* has sought to examine in some depth all of the sources of change that has produced the small satellite revolution. It has examined the technical, operational, financial, business, economic, regulatory, launcher, and institutional aspects of this important new world of space applications. Innovation is everywhere. There are actually contributions not only on the technical and operational side but from every other side of the business as well. Thus change has come from the small satellite business (i.e., new entries and startups that operate on completely different business models and timetables). There are key changes, from the world of manufacturing and design (i.e., additive manufacturing and use of off-the-shelf components). The small satellite business models have helped reinvent the world of space business and finance that is quite different from the approach taken by giant aerospace companies born of the so-called world of the military-industrial complex. Thus new business practices from the world of small satellites reflect many new patterns of thinking (i.e., new sources of financing and "clean enough rooms"). This new type of entrepreneurial thinking has led to many new ideas such as about sparing philosophies and rapid prototyping and new generations of satellite design in months rather than years. Small satellites have, in short, shaken up thinking throughout the space industry, and change has percolated almost everywhere one might imagine – and then some.

This final chapter seeks to sum up the many areas of change and innovation that have been born of the new world of small satellites. Thus this concluding chapter is divided into discussing important new aspects of the world of small satellites that have permeated the entire space industry. These various sections that are drawn from the component parts of the book include defining the various types of small satellites; satellite technology; design and manufacturing; launch and deployment; operations and sparing philosophy; ground systems technology; business, financing, risk-minimization, and insurance; and regulatory, safety, and institutional issues.

This chapter concludes with some notes about the practical aspect that are available to readers of the handbook. This includes some guidance with regard to what detailed information is available concerning actual small satellite systems

that have been deployed and projects to test new technology or to address space debris concerns. This includes some background with regard to information provided in Section 13 related to small satellite businesses, launch vehicle providers, small satellite networks deployed or planned to be deployed, registration processes related to small satellite systems, the UN sustainability guidelines, and how small satellite systems might relate to the meeting of these goals.

Finally, this conclusion underscores how dynamic both the small satellite market and the launch vehicle systems newly designed to support the launch of small satellites is at this early stage of development. Bankruptcies, mergers, and other realignments are already happening. The COVID-19 will serve to accelerate downturns for small satellite ventures and new launch vehicle developments alike. OneWeb declared bankruptcy as of May2020, but bailout financing from the UK Government and financing from Indian mobile communications carrier Bharti Global has managed to rescue this system. ‘New Space’ ventures Speedcast Ltd. and Leosat plus launcher companies Vector and Firefly have all now gone bankrupt, and many other companies have indicated a pause or withdrawal from possible small satellite enterprises. And most of these negative impacts preceded the economic downturns that will be a consequence of the Covid-19 virus that most economists foresee as likely to generate a global economic recession. Some economists forecast that the downturn on space-related ventures might be as much as a 30% reduction in new investment. Not until 2022 will the impact be clearly quantifiable.

1 Introduction

The very first satellites that were launched into orbit such as Sputnik 1, Explorer 1, Score, etc. were, in fact, small satellites. The rapid growth of demand for expanded satellite services for telecommunications, remote sensing, meteorology, and especially the concept of human space travel and the development of larger launch vehicles quickly led to more and more massive satellites to be launched. The pattern of larger and more capable satellites launched by larger and more powerful satellites continued for at least four decades. The advantages of communications satellites operating from Clarke orbit so that ground stations did not have to track the geostationary spacecraft that seemed to hover overhead tended to sustain that pattern of more powerful satellites with larger, high gain antennas for many years.

A combination of factors that evolved in recent years has tended to favor a new focus on smaller satellites for testing new technologies and for experimentation (by students and scientists). There has now been a rapid growth in small satellites for many different reasons. This has led in particular to the building of lower-cost small satellites to be deployed low Earth orbit for a variety of new commercial applications. Microelectronics, smaller but higher quality sensors, lower-cost components, new manufacturing techniques and processes, lower-cost launch vehicles, and new phased array, and flat panel antennas that can be used for satellites and also for ground user systems, all support the feasibility of small satellites for commercial networks such as broadband networking via so-called mega-constellations. Now many thousands of small satellites are proposed for launch in these small satellite constellations for broadband networking, remote sensing, and other entirely new services such as RF geolocation, data relay, automatic identification systems, and more.

Currently, there are less than 2000 operational satellites in Earth orbit. If all of the proposed networks of small satellites were to be launched in coming years, the number of operational satellites would increase by a factor of over ten times. On the one hand, these seem to offer new opportunity for a variety of new lower-cost satellite services to be offered on a global basis and reduce the cost of services for communications, networking, remote sensing, and more. On the other hand, there are serious concerns about the rapid expansion of small satellite constellations in Earth orbit of potential space debris and an increased rate of orbital collisions that could greatly accelerate the creation of new debris and threaten the opportunity of access to space in future years.

The prospect of new lower-cost space services, on the one hand, that is offset by serious concerns that large-scale mega-constellations leading to additional space collisions and rapid debris buildup is creating concern about what these new deployment of small satellites portend for the future.

This *Handbook of Small Satellites* has sought to provide a comprehensive set of information about all aspects of these new small satellite systems and their threats and opportunities to future space services. It also notes that volatility in the markets will continue for the decade ahead. Technological, market, and regulatory changes plus competitive suits will create churn, consolidation, and bankruptcy.

The COVID-19 pandemic that occurred in 2020 has caused health and economic consequences of staggering worldwide consequences that will accelerate the instability in the small satellite markets. This horrific pandemic will impact the small satellite and launch industry in the months ahead. Despite these economic failures, the innovative new small satellite technologies, the new more efficient launch systems, the new ground systems, and the many other innovations discussed in this handbook remain valid and very useful sources of new enterprise in this field. In the late 1990s, the original small satellite constellations saw major economic collapses. The economic failures constituted by Iridium, Globalstar, ICO, and Orbcomm made a huge impact on satellite development and the ready access to capital financing for some time. Yet recovery was achieved in the years that followed. The same seems likely to occur in this instance as well. Despite these setbacks, the information in this handbook remains useful and quite relevant.

It is, nevertheless, best to consult current websites to chart the latest status of the companies seeking to compete in these markets.

2 Defining the Various Types of Small Satellites

One of the least clear terms in the field of space systems is that of a small satellite. There are truly small satellites in range of nanosats and below. These diminutive satellites are often used for the proof of concept or testing of new satellite technologies and systems or student or scientific experimentation. These quite small satellites include femtosats in the range of 10–100 g, picosatellites from 100 g to 1 kg, and nanosat that range in mass from 1 to 10 kg. Nanosats more or less include 1–6 unit cubesats. Other terms that are in common use are "chipsats" that are usually femtosats and "pocket satellites" that are one-eighth the size of a cubesat and are typically picosats. Increasingly, we are also seeing the deployment of commercial constellations that operate with satellites that are often 3 unit cubesatellites such as those deployed by Planet or Spire. In this handbook, there have been a number of articles that address the design, operation, and usages related to cubesats/nanosats and below and many other articles that address the larger microsats (10–100 kg) and minisats. Minisats are sometimes referred to as 100–500 kg and sometimes referred to as 100–1000 kg. Most of the large-scale or mega-constellations for broadband networking, mobile communications, or radar sensing are in these larger classes of "smallsats." The satellites for optical remote sensing, data relay, machine-to-machine (M2M), Internet of Things (IoT), or automatic identification systems (AIS) can range from cubesats/nanosats to microsats. These are, however, only general approximations.

The point is that "smallsat" is truly a very broad term of art. One must know a number of details before one can understand what is actually being referred to as a "smallsat." Key characteristics include such aspects as mass, physical dimensions in stowed and deployed conditions, power, operational radio frequency spectrum utilized, function or service provided, orbital characteristics, and stabilization, orientation, and thruster capabilities. In the increasingly complicated world of small satellites, there are other aspects to consider.

Some "smallsats" are not free flyers. They can actually be "hosted payloads" that can be launched on board a larger to medium-sized satellite. Alternatively, a very small payload such as the Aireon constellation, for ASD-B aviation navigation services, can be deployed on board another small satellite constellation. In this

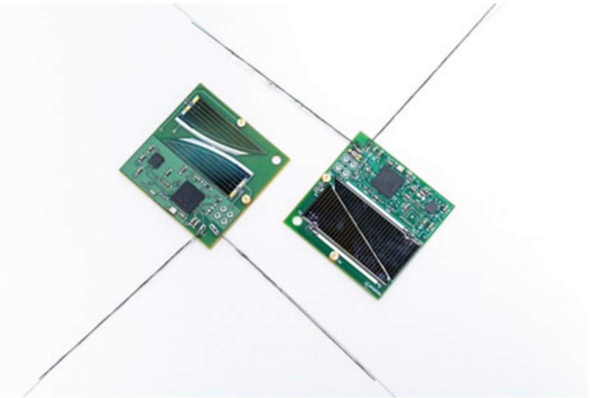

Fig. 1 Both sides of chipsat or femtosat that range in size of 10–100 g. (Graphic courtesy of the global Internet commons)

particular case, this small payload was hosted on the 66 satellites of the Iridium NEXT mobile satellite network.

Yet another alternative in terms of small satellite-type capability is not launching of a small satellite at all. Thus, one might deploy high-altitude platforms (HAPS) or stratospheric systems that operate in proto-space or subspace. Such platforms can provide telecommunications, remote sensing, or other services from high-altitude location in order to provide services that are quite similar in concept to a satellite operating at low altitudes. Thus relevant information and some analysis have also been presented in this handbook on both hosted payload systems and high-altitude platforms.

The first chapters in this handbook have sought to provide useful definitions and typical types of functions for various kinds of small satellites that range from femtosats to minisats. This is a gigantic range to contemplate. Femtosats, as represented by a chipsat, begin on the lowest mass of 10 g (Fig. 1). The highest end of the "smallsat" range is the minisat. These satellites can be as massive as 500 kg to even 1000 kg (Fig. 2).

This great dynamic range in size represents five orders of magnitude of scale. This is a differential divide represented by the relationship between 1 and 100,000. This is more or less equivalent to the size difference between a mouse and a hippopotamus.

3 Small Satellite Technology and Systems

The amazing development of small satellite technology and systems has enabled smaller and smaller satellites to be developed to carry out an ever-expanding range of services in the fields of telecommunications, networking, remote sensing, data relay and machine-to-machine (M2M) communications, RF geolocation, and scientific experimentation. Some of the innovations are a direct application of new commercial devices and components developed in microelectronics; phased array antenna design; optical processors; new types of optical, near infrared, and infrared sensors; and other new

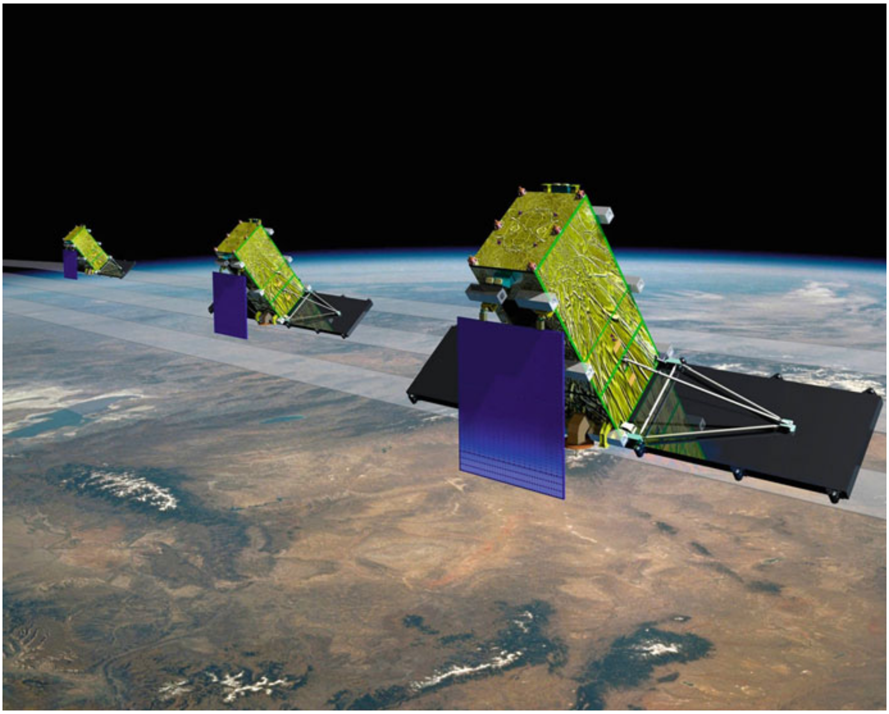

Fig. 2 New Trio of Canadian Radarsats – each minisat with a mass of about 550 kg. (Graphic courtesy of the Canadian Space Agency)

electronic and optoelectronic inventions. Other systems and subsystems are specifically developed by small satellite designers, integrators, and manufacturers seeking to provide more cost-efficient and compact components for small satellite systems. Advances have come from every possible angle and perspective.

There are improvements everywhere. There are enhanced miniaturization and lower-cost components and sensors. Devices with higher spatial, temporal, or radiometric resolution enhanced digital processing or encoding techniques or simply better or higher throughput production systems for these devices. There are improved miniaturized radio devices and sensors; improved navigation, stabilization, orientation, and pointing systems; better digital communications processing and encoding units; shrunk application-specific integrated circuits; better stabilization systems and torque rods; and improved and lower-cost batteries, social cells, and, coming soon, quantum dot solar power systems.

Part 3 of this handbook details the many technical innovations that are being developed in every aspect and subsystem associated with small satellites. These many innovations are linked to the development of smaller, more efficient, higher throughput, higher resolution, and in some cases lower-cost smallsat components. Innovations at every level of design and subsystem technical improvement are needed to create lower-cost and higher performance small satellite units.

Application-specific integrated circuits (ASICs), digital processors (electronic and optical), advanced encoding systems and software (e.g., turbo coding), advanced sensor design, improved smallsat components of all types, and small satellite kits have facilitated the ability of more and more students, experimenters, and even small satellite operators to build small satellite systems more quickly, at lower cost, with greater reliability and with fewer delays. In order to explore specific technical innovations related to the various subsystems involved with the engineering and optimization of small satellites, refer to the chapters in Part 3 of this handbook.

Although improvements in the technical design of many components included in small satellites has led to significant advances, it should also be remembered that satellites, both big and small, are essentially software-defined digital processors in the sky. This means that many of the advances in performance, cost-efficiency, and capability derive from improved software and processing and coding efficiencies. In short, advances are combination of both better hardware and software upgrades as well.

4 Design, Manufacturing, Testing, and Resiliency of Small Satellites

A great deal of the progress that has been made in developing higher performance, higher efficiency, and more cost-effective small satellites has been due to technical improvement of the components involved in small satellites, or enhanced software that allows these satellites to achieve faster throughput, spectrum efficiency, or improved preprocessing of remote sensing data. There are other types of improvements related to manufacturing, testing, design processes, and approaches to resiliency that are also key to improvements in small satellite systems. These innovations are more closely related to process and management concepts that technology per se.

Companies such as Planet, Spire, and other constellations that are deploying three-unit cubesat-type satellites employing a different type of approach to manufacturing and testing that employed by commercial operators who typically order a limited number of large GEO type satellites costing many millions of dollars and which take a number of years to design, manufacture, test, and arrange for launch. These small satellite companies take more of an incremental approach.

It is based on constant improvement in the design and manufacturing of its satellites. There is greater reliance on in-orbit testing of a design that is improved almost satellite to satellite and reliability and performance enhanced based on orbital experience. A network that is based on hundreds of satellites with a mean time to failure of perhaps 3–4 years involves a much different approach to design, manufacturing, reliability, and quality testing and resiliency of a so-called mega-constellation. This type of approach allows the possibility to additive manufacture of component parts that can be enhanced with each production run of small satellites.

Particularly in the area of remote sensing, one batch of small satellites might have a slightly better optical sensor, and another might have an improved battery or better efficiency type of solar cell. With a large number of small satellites constantly in

Fig. 3 The Planet LLC Dove 3 U Cube Satellite has now had 18 generations of design innovation and in-orbit testing. (Graphic courtesy of Planet LLC)

production, efforts can be made to improve the reliability of a satellite design based on monitoring the cause of any in-orbit failures. If each small satellite launched into orbit has a net cost of $100,000 rather than $250,000,000, then the approach to quality testing, design innovation, manufacturing, sparing philosophy, and resiliency changes dramatically.

Those commercial systems that are deploying hundreds if not thousands of telecommunications or networking minisats for large-scale constellations (i.e., smallsats in the 100–500 kg class) might require more homogenous designs and more quality testing in their approach to satellite production than that used by Planet or Spire. Nevertheless, their design, manufacture, and testing operations will tend to be more like the production of a television set or aircraft, than a handcrafted electronic product that goes through years of quality testing as was the case with large GEO satellites. In essence, part of the small satellite revolution has come from entrepreneurial insight and even rebelliousness that has concluded the ways of the past are no longer the best way forward. Small satellites such as the Planet Dove, produced in large numbers for LEO constellations, can lead to faster rates of innovation, more in-orbit testing, new modes of production, and even competitive designs (Fig. 3).

5 Launch and Deployment

Another part of the “Space 2.0” or the “NewSpace” revolution is not only small satellites but new low-cost commercial launch systems. There are scores of new launch service companies that are offering new types of launchers designed to offer launch services geared to accommodate small satellite missions. Rocket Labs, Vector, and Virgin Orbit’s LauncherOne are some of these new rocket systems.

As Virgin Orbit has noted in its promotional materials: “Small satellites are ushering in a new era of space capabilities – connecting us across vast distances, stimulating the global economy, and expanding the limits of human knowledge. This rapidly growing industry requires a launch service that is as agile and affordable as the satellites themselves. But until now, there hasn't been one." The implication is that the LauncherOne rocket system is the solution (Virgin Orbit 2019). The issue of launch arrangements for small satellites is not only that of the convenient availability of launch dates, but it is also cost-effectiveness and reliability of the launcher services. There are indications that larger launch systems might be able to respond effectively to all three aspects of convenience of scheduling, cost competitiveness, and reliability of service.

Conventional launch service providers as characterized by Soyuz/Progress, Ariane, United Launch Services, etc. are seeking to upgrade the launch operations to make them more cost-effective and flexible as to schedule, but the advent of new commercial launch services that employ reusable rockets seems to be particularly well positioned to cater to small satellite launch requirements.

Some analysts have suggested that the biggest innovation in terms of new cost-effective launch arrangements is, in fact, coming from reusable launcher systems that are being developed by SpaceX (i.e., Falcon 9R) and Blue Origin (i.e., New Glenn). These launch systems that are designed to recover launcher stages and then reuse perhaps 25 times or more offer the promise of major cost economies for a wide range of launcher missions. Not only are they offering what seem to be very reliable and cost-effective services, but there are new launch schedules now being offered that will launch once a month and reserve a portion of the launch to accommodate small satellite requirements (see F9R launch vehicle in test flight).

And there are now competitive responses from Ariane with its proposed Themis launcher that is now planned to be available by 2023 which is 2 years earlier than the original planned date of 2025 (ArianeGroup 2019). Further Airbus has announced plans for its new Adeline winged booster stage which is under design development (Airbus Enters 2019) (Fig. 4).

What is clear is the cost to launch a cubesat into orbit will continue to come down and that the flexibility to launch based on the schedule of the smallsat clients will also likely continue to improve. What is unclear is what will be the ability of reusable vehicles to truly achieve 25 reflights with the same launcher stages and the reliability of these reusable systems. Also unclear is whether the truly small launcher systems such as Vector, LauncherOne, and Rocket Labs will be able to remain competitive against the larger reusable systems now active or planned by SpaceX, Blue Origin, Ariane, Airbus, and perhaps others.

6 Operations and Sparing Philosophy and Space Safety Consideration

There are now many student and scientific experiments, test flights of new technology and systems, and one off small satellite missions that will continue to fly into space that are one of a kind missions. If there is a launch failure or the smallsat for some reason does not perform, then the experiment or test flight will simply be tried again. These small satellites typically have no redundancy or backup capability.

Fig. 4 Test flight of the Falcon 9 Reusable (F9R) launcher that promises new economies for smallsat launches. (Graphic courtesy of SpaceX)

They often use off-the-shelf components, and there are no planned backup capabilities to keep costs to the minimum. A majority of these systems have an in-orbit lifetime of less than 3 months, and they are often deployed at a low altitude so that they naturally degrade from their orbit and burn up on reentry. The technical and reliability model for these types of experiments and test flight is clear. No sophisticated sparing, operational resilience plan, or active deorbit process is needed. It is possible that there might be some sort of passive device to create atmospheric drag that might be deployed at end of life to facilitate early deorbit.

The small satellites that are deployed as operational constellations, whether commercial, governmental, or defense related, are a different matter. The planning for network reliability, safe deployment, and safe removal from a constellation is a matter of some importance. Indeed since some of these large networks involve capital investments that will exceed in excess of an estimated ten billion dollars (e.g., the SpaceX Starlink and V-band networks) and also involve significant safety risks to long-term sustainability of space, the risk elements are enormous.

There have been new ways to look at the reliability and resilience of satellite constellations. The design and introduction of the mobile satellite networks as represented by the Iridium and Globalstar constellations involved system planning that relied to some extent on deploying orbital spares. These networks had sufficient satellites in orbit that there was thought that holes in the network could be worked around until replacements deployed. This was particularly the case for the Iridium satellite network that had the additional feature of intersatellite links. The use of intersatellite links to work around failed satellites was also envisioned in the case of the proposed MegaLEO constellation known as Teledesic. Furthermore, the second generation of mobile voice communications systems, i.e., Iridium NEXT and Globalstar (OG2), has intersatellite links to minimize ground system investment and the ability to work around in-orbit satellite failure.

The latest planning for operational system reliability for large mega-constellations has focused on using the entire deployed system as the sparing concept as the size of these networks has increased to hundreds or even thousands of satellites. The sparing philosophy for large small satellite constellations seems adequate to provide for reliability of service for these systems.

The problem of safety and avoidance of potential satellite collisions in the case of very large constellations remains. Studies carried out by the Aerospace Corporation for five of the largest low Earth orbit constellations found that there were significant risks of orbital collisions associated with the initial deployment of these systems as well as significant risk of collision as satellites are removed from service at end of life and deorbited.

This statistical analysis considered the potential risk of a collision occurring over a 10-year period first in terms of the deployment and operational period and second during the removal and deorbit phase for constellations where detailed filing information as to number of satellites, orbital configuration, and density of satellites per orbital configuration. The results of those calculations are shown in Table 1.

This analysis, of course, had to make a number of assumptions in this modeling process, and there is no indication of the level of accuracy that is attributed to the calculations. Nevertheless, even if one assumes that the risks of potential collision have been overestimated by a factor of 2, there is substantial reason for concern that during operations and disposal operations, the risks of collisions seem to be substantial. This analysis also shows that there is an overconcentration in the current filings of LEO satellite constellations that are to be deployed between 850 and 1000 km altitudes (Muelhaupt et al. 2019). The above and other assessments of the ever-growing number of large-scale constellations planned for launch in the next decade have given rise to concerns about space debris removal and efforts to minimize orbital collisions.

There have been calls to revise the UN voluntary guidelines for space debris removal. Many of the operators of mega-constellations have voluntarily committed to rapid removal of satellites at the end of life. The problem with rising concerns about the large number of small satellites now planned to be deployed in large constellations is the lack of system limitations. As the threat of possible orbital collisions rises – both during smallsat constellation systems operation and removal – lack of regulatory control comes into clear focus. Currently, there are no effective

Table 1 Possible collision assessment from mega-constellation as conducted by the Aerospace Corporation (Aerospace Corporation)

Future constellation model	Probability of a collision over 10-year period during operations	Probability of a collision over 10-year period during disposal
FCM 1	8	15
FCM 2	0.5	1.25
FCM 3	1.1	0.6
FCM 4	0.33	0.55
FCM 5	1.25	0.80

controls that limit the number of systems proposed or approved at the national licensing procedures or ITU system coordination processes that now limit the number of satellites or constellations. Table 2 provides a tally of satellite constellations that are just related to proposed broadband telecommunications and networking services. If one totals the maximum number of satellites that could eventually be deployed according to potential full deployment, the number of smallsats as listed in Table 2 could conceivably tally over 27,000 satellites (Pelton 2019a).

This lengthy table just provides proposed smallsats for broadband communications and networking services. It thus does not include, for instance, many more satellites that are now already deployed or proposed for remote sensing, for narrow band data relay, for RF geolocation, or for mobile communications satellite services. What makes the numbers of proposed satellites listed in Table 2 seem so totally remarkable is that the total number of operational satellites now in service as of the start of 2020 is less than 2000. The launch and deployment of so many satellites, followed by the successful operation and maintenance of such massively sized constellations, and then clean disposal of so many satellites are perhaps the greatest challenge of the decade for the space applications industry. This operational challenge might be matched by the growing regulatory challenge. This would be to find

Table 2 The growing number of smallsat constellations for broadband telecommunications. (A compilation of the author)

Proposed small satellite constellations for broadband telecommunications			
Country	System name	Number of sats	Radio frequency bands
Canada	CANPOL-2	72	LEO and highly elliptical Earth orbit in VHF-, UHF-, X-, and Ka-bands
Canada	Telesat constellation	117 satellites plus spares	LEO in Ka-band
Canada	COMSTELLATION	Nearly 800 sats	LEO in Ka-band
France	Thales Group's MCSat	Between 800 and 4000	LEO, MEO, and highly elliptical Earth orbit in Ku- and Ka-bands
Liechtenstein	3ECOM-1	264	Ku- and Ka-bands
Norway	ASK-1	10	Highly elliptical Earth orbit in X-, Ku-, and Ka-bands
UK	L5 (OneWeb)	650–750 initially but in time 1200–4000	Ku- and Ka-bands
USA	Boeing	1396–2956	V-band in 1200 km orbit
USA	SpaceX	4500+	Ku-Ka band
USA	SpaceX	7500 plus	V-band
USA	LeoSat	Initially about 80	Ka-band
USA	Athena-Facebook		Ka-band
USA	Karousel MEO	20 MEO satellites	Ka-band
USA	Kuiper-Amazon	3236	Ka-band in three orbital tiers
USA	O3b mPower MEO	24	Ka-band

means to control and limit the proliferation of smallsat constellations and to facilitate active disposal of satellites at the end of life to cope with related liability issues.

7 Ground Systems Technology

One of the great miscalculations of those that do not know the space applications industry well is to overemphasize the importance of satellites and launchers and underrate the importance of the ground segment. The ground segment associated with space applications as an industry is three to four times the size of the launch services industry. The key to the future of small satellite industry, particularly in the context of constellations, is much more crucially tied to break through in ground system design and performance than perhaps any other factor.

The first step toward new user antenna systems and technology came with the small satellite constellations in low Earth orbit (LEO) that required user transceivers that could receive signals from horizon to horizon as the Iridium and Globalstar satellite crossed over the sky in about 7 min or so. These new type satellite receivers were designed to capture signals coming from the sky and relied on the signal processing power and digitally encoded transmission that were provided by means of application-specific integrated circuits (ASICs). These digital transceiver units could not electronically track the satellites, but they still demonstrated that small compact handheld units could nevertheless receive satellite signal for voice communications from LEO orbit.

The next step forward was to develop ground systems that can provide electronic tracking of LEO satellites in a global constellation without the need for active mechanical tracking. This required computer-generated electronic beams that could be generated by new flat panel antenna systems. The trick is to develop this type of electronic tracking transceivers that would be reliable enough to switch from beam to beam at the rate of about once a minute and from satellite to satellite about every 7 min and also be produced at low cost. Today, there are over 20 companies developing flat panel antennas for users for not only mobile satellite communications but now to support even broadband digital networking services.

As identified in the Northern Sky Research report on Flat Panel Antennas, these companies include ALCAN Systems, Anoki Systems, Ball Aerospace, Boeing, C-Com, GetSat, Gilat Satellite Networks, Kymeta, HiSky, Honeywell, Hughes Network Systems, Isotropic Systems, Omni Wave, Phasor Systems, SatixFy, StarWin, ThinKom, Tianyi Satcom Company, Toshiba, and Viasat. Several other companies deploying large-scale constellations such as SpaceX might become self-producers. In addition, there are other companies that may serve as integrators for military communications satellite companies (Northern Sky Research 2019).

This is an area that is rapidly developing in terms of technology and in achievable cost reductions. One of the many innovators in this area is Isotropic Systems that claim that their optical processing technology will allow one of the most cost-effective designs for low-cost user flat panel satellite antennas (Fig. 5).

Fig. 5 Isotropic Systems flat panel satellite antenna. (Graphics courtesy of Isotropic Systems)

8 Business, Markets, Financing, Risk Minimization, and Legal Challenges

Few industries around the world have shown more dramatic changes than that of the small satellite industry. This is not only change in their technologies but also in terms of new business innovation, new business industries, financial change in terms of capital investment, market focus, and even new approaches to risk management and institutional arrangements. Almost anywhere one looks in the small satellite industry, change is afoot.

8.1 Business and Market Shifts

At the level of business innovation, there are scores of new entities identified in Part 13 of this handbook involved in some aspect of the small satellite industry. There are a large number of companies who are involved in designing and building small satellites, in deploying and operating small satellite constellations, in providing launch services for small satellites of all types and sizes, and in manufacturing ground antennas for users and network connectivity. This has created a somewhat chaotic market, and result may see mergers, acquisitions, spinoffs, and even bankruptcies. Companies that were predominant in some space services for remote sensing, telecommunications, broadcast satellite services, or construction of satellites or Earth stations for some decades may see their roles shift, and new innovators take commanding new market leads. The rate of change and the market shifts are still in a state of flux, and predictions of winners and losers are still unclear in this era of rapid market trajectories – some upward and others down.

While this handbook has been in production, the Vector small satellite launcher company, that offered flexible and quick launching opportunities for small satellites, has been forced to declare bankruptcy. LeoSat that was seeking to deploy a high-performance, corporate-based broadband service using a small satellite constellation has also declared bankruptcy. Intelsat and OneWeb were planning to merge under a financing plan offered via the Japanese banking giant SoftBank, and now Intelsat has filed a very substantial suit against both OneWeb and SoftBank. Audacy that is seeking to provide data relay services via a new constellation has recently pursued talks with Iceye about possible strategic partnerships to achieve support for its high capital costs to complete its network.

Companies that are pursuing total new markets and services have a great challenge of deploying new products or services and establishing a successful business and market as essentially totally new startups. Thus totally new offerings such as the HAPS Stratobus by Thales Alenia and the RF Geolocation offerings by Hawkeye360 have to balance startup costs versus establishing totally new streams. The bottom line is that many of these small satellite ventures and new launch vehicle ventures could fail. On top of this, the most profitable revenue stream for satellites historically has been broadband broadcast of video services that are now being challenged by over-the-top Internet streaming. One of the large market questions is whether LEO small satellite constellations can find a successful way to offer both 5G broadband and video streaming services which are the largest potential markets. These are questions that are still unanswered. The bottom line is that small satellite markets are still quite unsettled and market volatility is a part of the small satellite domain. The fact that Silicon Valley giants such as Google, Facebook, and other Internet backers are a part of the story leads to confidence that many of these ventures can succeed, although some may fail.

8.1.1 Finance and Capitalization

One of the most significant changes is that there are new sources of business innovation and new types of businesses providing innovative sources of capital financing that range from crowdsourcing, Kickstarter, and a number of industrial heavyweights. These include the computer services and networking industries, largely coming from Silicon Valley such as Google, Facebook, Amazon, etc. There are yet others that are heavily involved such as SpaceX and new launch services companies, as well as international banks such as SoftBank of Japan, and others such as Liberty Media, venture capital firms, and others from the Space 2.0 or “NewSpace” industries (Pelton 2019b).

8.2 Risk Management and Insurance

The whole new set of economics associated with the design, manufacture, and operation of small satellites coupled with reduced launch costs and entrepreneurial talent and sense of reinvention has not only reduced the barriers to market entry, but it has created a whole new concept about approaches to sparing philosophy, approach to manufacture and deployment, and strategy related to insurance coverage. The traditional approach associated with high-throughput GEO satellites with very strong cost-effective performance has challenged conventional GEO satellite design from one perspective and has moved toward economies of scale achieved with only a few very high-cost satellites. On the other hand, the new small satellite constellations have initiated a new form of economy of scale by the launch of hundreds if not thousands of small satellites. This approach creates a whole different business model. The business concepts can all be different: (i) system design; (ii) the approach to design and procurement of satellites and launch services; (iii) the sparing, the insurance, and risk minimization philosophy; and (iv) design and implementation of the ground system architecture. These issues and more are now all potentially different. New models are being created and new approaches embraced.

8.3 Legal and Regulatory Concerns

The enormous change created by small satellite technology, constellation design, new ground systems, new businesses, and entrepreneurial innovation has created new businesses and new approaches to space application services and innovative new markets. But there are also new and major concerns about the national and international space regulatory environment. There are key concerns about liabilities, space debris, and sustainable space operations within this new environment. The issues and regulatory concerns cut in different directions. On the one hand, there are concerns that the advantages that small satellites can offer to student experimentation, space programs for developing countries, and use of space technology to meet the sustainable development goals of the UN all argue for limits on overregulation of small satellites. On the other hand, the prospect of the number of operational satellites increases by an order of magnitude in the next decade, and the amount of orbital debris in orbit swelling out of control and making the so-called Kessler syndrome a reality could have catastrophic impact.

There is today a lack of new international regulatory authority to cope with the many changes that have occurred since the five international agreements negotiated and agreed within the United Nations Committee on the Peaceful Uses of Outer Space and the General Assembly in the late 1960s and 1970s. The proliferation of small satellites, LEO and MEO constellations, and space debris poses regulatory challenges. The analysis in this handbook suggests that new international agreements to cope with these problems will not likely be achieved in the near term. Thus national procedures to address orbital debris, space debris removal, space situational awareness, and space traffic management will likely need to lead the way forward in the nearer term. These legal and regulatory concerns will play a key role in how the new space industries and the small satellite industries evolve in the coming decade and perhaps the decade to follow.

9 Practical Reference Information

The field of small satellites is evolving rapidly, the dimensions of the smallsat world seem to be expanding every day, and the complexity will only continue to grow. This handbook has sought to cover every aspect of the small satellite revolution in terms of the satellite and ground system technology, the regulatory, business and financial issues, and the practical aspects of various small satellite projects with useful case studies. Part 13 of this handbook provides useful information on small satellite companies, satellite constellations, launch vehicle companies, processes for registration of satellite launches, the UN Sustainable Development Goals, and more.

10 Conclusion

The *Handbook of Small Satellites* is an interdisciplinary, comprehensive, and hopefully useful guide to every aspect of the world of small satellites. If covers the true small satellites used for experimentation and technology demonstration that range from femtosats, picosats, and nanosats on one hand to the other larger and business-oriented systems on the other hand.

It thus covers commercial small satellite constellations that typically range from three-unit cubesatellites up to microsats and minisats. It has sought expertise from around the world from Africa, Asia, Australia, Europe, North America, and South America and scores of space, satellite, and launch vehicle companies around the world. It seeks to cover the technology; the operational, market, and financial challenges; the regulatory shifts; and the fact that the world of small satellites is still volatile and sometimes uncertain. This is always the case with new technology, new markets, and totally new ways of providing services to a global environment that is rapidly shifting. The unusual market dynamics plus the further complication of the Covid-19 Corona virus makes it difficult to forecast how the world of small satellites will evolve in the next few years.

It has been a collaborative process with careful thought given to every aspect of this complicated new world of small satellites. It is hoped that this reference work proves to be of value to those that consult it as a reference source.

Small Satellites: Glossary of Terms and Listing of Acronyms

Joseph N. Pelton

Keywords

Definitions · Miniaturization · Small satellites · Space 2.0 · Space systems innovations · Small satellite applications · New launch systems for small satellites · Standards

The following text provides a listing of many of the acronyms found in the *Handbook of Small Satellites* as well as a brief definition of the many specialized terms found in this reference book. There are also a listing of many of the proper names of constellations, launch services organizations, and small satellite companies discussed in the text. If they are not found below, they can also likely be located in Part 13 of this handbook that provides essential technical, regulatory, and management information relevant to the field of small satellites.

ACM	Attitude Control Module
Active Debris Removal (ADR)	This refers to a space-based activity designed to accomplish the active removal of debris. This could involve using various techniques to deorbit them from Earth orbit. This is in contrast to passive systems that lead to the ultimate uncontrolled deorbit of a space object due to gravitational effects, atmospheric drag, or other natural effects such as space weather

https://doi.org/10.1007/978-3-030-36308-6_86

ADCS Module	Attitude Determination and Control System Module
ADS-B	Automatic Dependent Surveillance-Broadcast (ADS-B) is a new GNSS-based technology that enables aircraft broadcast signals to be broadcast via satellite while in the air. This information can include flight-related information, i.e., identification, position, altitude, velocity, and other relevant information. This can include surveillance information that is provided on a regular basis to air traffic controllers (ATCs) as well as to other aircrafts (see Aireon).
Aerial	An aerial and an antenna can be used interchangeably. However, an aerial usually implies a very simple type antenna such as dipole or Yagi-type antenna.
Aerobraking	Aerobraking in a maneuver carried out in space to change the speed and direction of a spacecraft by utilizing the atmosphere of a planetary body as a slowing force. This is one of the most common techniques for reducing the speed of a spacecraft in the case of reentry for the purpose of re-landing on Earth or to cause a defunct satellite or space debris object to descend to Earth and in most instances eventually to burn up in the Earth's atmosphere.
Aerodynamics	Aerodynamics is the study of atmospheric effects on various bodies do as to make, in the case of aircraft, spacecraft, or launch vehicles, their flight more efficient and lift or descent achieved in a more controlled and effective manner. One of the key concerns in the space field is aerodynamic heating and thermal protection against aerodynamic heating. When a spacecraft or rocket moves through the atmosphere at hypersonic speeds, temperatures in well above 1000 °C can occur.
AGI	Analytic Graphic Inc. This company is one of the leading companies involved in orbital debris tracking and is the leading contractor for the Space Data Association.
A-GPS	This acronym refers to Augmented Global Positioning Satellite (GPS) System Agreement Governing the Activities of States on the Moon

	and Other Celestial Bodies (also known more simply as “The Moon Agreement”): This international agreement was signed on 5 December 1979 and was the fifth and last of the major space agreements adopted by the General Assembly. The Moon Agreement was adopted via resolution 34/68, and this document reiterates many of the provisions of the Outer Space Treaty but is notable in adding the concept of “the common heritage of mankind” with regard to celestial objects including special emphasis of the Moon.
AIAA	The American Institute of Aeronautics and Astronautics, headquartered in Reston, Virginia
Aireon	This is a hosted payload system that is deployed on the Iridium Next satellites that is designed to provide precise location of aircraft in the new precise navigation system that is being increasingly used on a global basis. These packages are on all 66 operational Iridium satellites plus the 9 spares. These platforms provide Automatic Dependent Surveillance Broadcast (ADS-B) services to aircraft and aircraft controllers. This is a new GNSS-based technology that enables aircraft to engage in precision navigation and assist air traffic controllers to prevent accidents.
Airspace	The definitions of airspace and outer space, as well as the demarcation between the two, have never been clearly decided in terms of international space law. Commercial airspace is that which is regulated for aircraft safety, and this extends from the ground up to 20 km. Military airspace extends beyond these altitudes. Some define airspace as extending up to the von Karman line which is the point where it is physically not possible for aircraft to fly. The von Karman lines are generally thought to be 100 km from the surface of the Earth. States have “complete and exclusive sovereignty over the airspace above [their] territory” as per Art. 1 of the Chicago Convention.
AIS and S-AIS: Automatic Identification System and Satellite-Automatic Identification System	AIS is a global standard for ship-to-ship, ship-to-shore, and shore-to-ship communications, while S-AIS is satellite-automatic identification system. This AIS service has been mandated for all

	shipping since the International Maritime Organization's (IMO) adopted in 1974 the International Convention for the Safety of Life at Sea (SOLAS). This service is designed to provide for maritime collision avoidance, search and rescue (SAR) operations. It creates a system for identifying maritime vessels and allows vessel tracking. Satellite AIS (S-AIS) allows for enhanced coverage in remote areas, such as oceanic and Arctic regions, and complements terrestrial AIS coverage. There are now several constellation of nanosatellites capable of picking up S-AIS signals to increase visibility of vessels in remote areas of the world.
Aleph-1 Constellation	This is an Argentina-based system owned by Satellogic NuSat. Eventually the objective is to launch 300 satellites in this constellation. Nearly 30 of these 37 km satellites have been launched by Chinese launchers to date. The objective for this remote sensing network is to provide 1 m resolution.
Antares	This is a launch vehicle developed by Northrop Grumman Innovation (originally Orbital Sciences Corporation) to provide resupply missions to the Space Shuttle.
Angara	This is the new launcher that is being developed by Khrunichev, KBKhA that is to replace the Proton launcher. It is to be offered with a range of launch capabilities that range from the Angara 1 to the Angara 2 and the largest Angara 5 with the heaviest lift capability.
Antares	This is the launcher developed by Northrop Grumman Innovation (Orbital ATK) that is derived from the Taurus launcher and was selected for the NASA commercial resupply of the International Space Station (ISS). The Antares 230 is the vehicle currently operational, and the Antares 300 is currently in development.
Antenna Gain	The shaping of a parabolic dish in a satellite communication to focus a beam more tightly in comparison to an omni-beam or isotropic beam that has transmit equally in all directions is known as gain. This means, in effect, gain in effective power concentration from 'one' as

	represented by a omni-directional antenna. The shaping of an electronic beam is also a function of the transmission frequency and thus the wavelength. The formula for an electronic antenna's gain is given as: $\text{Gain}\,(dB) = 10 \times \log_{10} k\left(\frac{\pi D}{\lambda}\right)^2$ In this formula D = diameter of the antenna, λ= the wavelength, and k = the efficiency of the antenna. The resulting gain in power is expressed in logarithmic decibels based on a log 10 scale. Thus a gain of 3 dB is an increase of two, a 10 dB gain is a 10-fold increase, a 20 dB increase is a 100-fold increase, and a 30 dB increase represents a 1000-fold increase.
Aperture	This is the size of a satellite transmitting or receiving antenna. The larger the antenna aperture size, the greater the gain and thus the effective performance of a radio antenna.
Aphelion Orbitals	Aphelion Orbitals, a US company offers the Helios and Feynman Launch System for small satellite launches. This launch system is able to place 6U CubeSats into LEO at low cost.
Apogee	The highest point or apex in an elliptical orbit. In Earth orbit, for instance, this would be when a satellite is farthest away from the Earth's surface but travelling at the slowest speed. Also see perigee which represents the reverse condition.
Argos	This is a constellation of seven satellites. This international system was first created in 1978. This is a LEO constellation for data relay. It is to be augmented and then replaced by 25 Kineis Satellite in 2022.
Ariane 5 and Ariane 6	The Ariane 5 is currently the largest launcher operated by Arianespace from its French Guiana launch site. The Ariane 6 is currently underdevelopment and is designed to provide more cost-effective launch capabilities when it is tested and operational.
Arianespace	Is the French aerospace company that is responsible for the development, manufacture, and launch of the Ariane 5 and in the future the Ariane 6 launch vehicle. Arianespace also operates the launch site in French Guiana which

	currently supports launches by not only the Ariane 5 but also the Soyuz and Vega launchers that can both be configured for multiple small satellite launches.
ATC	Air traffic control. This is the responsibility of ICAO at the international level and national or regional air traffic regulatory entities such as the FAA in the United States and EASA in Europe. With the advent of space planes and other near Earth activity involving high-altitude platform systems and robotically controlled vehicles at high altitude, there has been increasing concern, interest, and consideration of the issue of space traffic management, and the interface between missions involve air traffic, robotic aircraft operations, near Earth orbit space activities, and space planes and other vehicles that may travel in both air and outer space. Also see ATM.
ATM	Air traffic management. This is the responsibility of ICAO at the international level and national or regional air traffic regulatory entities such as the FAA in the United States and EASA in Europe.
ATO	This is a term developed by NASA in a case where the launcher has enough velocity to achieve orbit but without achieving the desired orbit required for a particular mission. In many cases there would need to be a decision as to whether to abort the mission and to deorbit from this irregular orbit.
Atlas	This is one of long-term use launch vehicles developed in the United States. It can be used for launch of small satellites, using residual or so-called “piggy-back” launch capacity or for launch of many small satellites at one time.
Bagaveev launcher	The Bagaveev Corporation has developed a 3D-printed rocket motor for its launcher. It is designed to place a 12 kg payload into LEO orbit. Its initial pricing is to launch small satellites at a cost of $100K per kg.
BeiDou	One of two Chinese precision navigation and timing satellite systems. This is the first-generation system, and its translation from Chinese is the “Big Dipper.” Compass is the second-

	generation Chinese system, and it will eventually replace the BeiDou system.
Black Arrow 2	This is a project of the Horizon Space Technologies, Ltd. in the United Kingdom to develop a low-cost launcher based on the original efforts to develop the Black Arrow 1 launcher. Current status unknown.
Blue Origin	This is the commercial launch company founded by Jeff Bezos that is developing the New Shepard and New Glenn launcher. Blue Origin is also developing new launch motors for the United Launch Alliance.
Boeing	Boeing is one of several companies that have filed to launch a large-scale constellation to provide global networking services. It is not clear as to how soon Boeing intends to move forward with this project. Boeing also has a part of its company that provides tracking of orbital debris under contract.
bSpace	This is a new enterprise that is developing the Volant launch system that would similarly to NanoRacks offer launch services via release from the International Space Station using an ARQ. The estimated cost is $80K per kg.
Canpol-1	This constellation of 72 satellites is to be deployed to provide networking services to support military-/defense-related services of Canada. This 72 sats LEO Constellation will be augmented by a number of highly elliptical orbit satellites. This constellation will be deployed with LEO nine sats each in eight planes. The satellites will be equipped to operate in the VHF-, UHF-, X-, and Ka-bands.
Capella	US constellation of 36 satellites that might expand to 48 satellites in a 500 km orbit. This is a Synthetic Aperture Radar System deploying sub-50 kg microsatellites. This system will provide radar imaging for the X band (9.4–9.9 GHz). The satellites will have only a 3-year lifetime, so it will require frequent replenishment. Full deployment of 36 sat network planned to be achieved around the end of 2021 or early 2022.

CDMA	Code-Division Multiple Access. This is a digital multiple access system that is commonly used in digital satellite communications. This is also sometimes called spread spectrum. Also see TDMA.
Celestia Aerospace	This small satellite launcher is accomplished via a Sagittarius Missile launched from a MiG 29 jet (known as Archer 1). This launching arrangement is able to put 1U nanosats into orbit at an estimated cost of 200k euros.
ChipSat	A ChipSat is a type of extremely miniaturized small satellite – often a femto satellite of less than 100 g mass based on system-on-a-chip or embedded systems type of architectures and hardware. With the advantage of easily building and deploying, very large numbers of such ChipSats at very low-cost concepts like fractionated spacecraft or massive distributed missions become feasible – with the negative side effect of possible creation of large number of very small space debris.
Comm Module	Communications Module that provides the particular telecommunications services needed to support a small satellite mission's needs.
Commsat	This is a private Chinese LEO constellation for designed to provide global Internetworking services via a network of 800 sats deployed in a 600 km LEO orbit. This new constellation is intended to provide Internet of Things and data communications services. The launch and full deployment dates are not now known.
Constellation	This is a term widely used to describe a network of satellites that is deployed in a particular way that is most typically designed to provide a global coverage of Earth. The number of satellites that are deployed in a constellation to provide worldwide coverage increases at lower altitudes since the viewing coverage of a satellite decreases as it orbits at lower heights. A three satellite constellation in GEO orbit can provide nearly complete coverage except for the polar region. A MEO constellation can provide worldwide coverage with about 12 to 18 satellites. A

	LEO orbital system will typically require about 50 satellites to provide worldwide coverage.
COPUOS	Committee on the Peaceful Uses of Outer Space. This United Nations committee meets in Vienna and has standing Technical and Legal Committees. It now has over 80 member counties. It was this committee that was responsible for the drafting and agreement of the text for the Outer Space Treaty of 1967 and to follow on subsidiary international agreements related to registration of space objects, astronaut safety, liability, and the so-called Moon Agreement. The UN Office of Outer Space Affairs serves as the secretariat for the COPUOS and also carries out other functions related to outer space activities.
CubeCab	The Cab-3A launch vehicle is being designed to place just one 3U CubeSat into LEO orbit and do so at a cost of $250K per launch. Bitcoin Latina has indicated it will launch 300 3U sats for a LEO network to provide service to Latin America.
CubeSat	A standardized type of small satellite that is 10 cm × 10 cm × 10 cm in size and up to 1.33 kg (often just 1 kg) in mass per one unit (or 1U) according to the CubeSat Design Specifications. The concept of a CubeSat was first introduced in 1999 by professors J. Puig-suari and B. Twiggs. This was also accompanied with the concept known as a CubeSat deployer mechanism (P-POD). Common sizes are 1U, 2U (2 units), 3U (3 units), or 6U (6 units) CubeSats. There are today even with larger sizes like 12U or 24U small satellites for various applications. CubeSats are usually compactly stowed in deployers such as a P-POD system. The advantage of CubeSats is standardized dimensions and mechanisms that allow them to be efficiently launched from launch vehicles or via airlock from the International Space Station or even from other small satellites (like microsatellites) as part of distributed missions.
Delta launch vehicle	This is one of the US developed launch vehicles. The largest of these vehicles is the Delta 4. This

	vehicle that is arranged for launch by the United Launch Alliance is being phased out in favor of the new and more cost-efficient Vulcan launch vehicle.
Dream Chaser	This is a reusable launch system developed by Sierra Nevada. One of the future capabilities under study is the Stratolaunch and Dream Chaser: this would be a 75% scaled version of the Dream Chaser for commercial missions.
DSS	Dark Sky Stations. These are high-altitude platforms that can be used for sustained stratospheric research and might also be used as staging platform to fly small satellites into Earth orbit using electronic propulsion engines.
DHM	Data Handling Module
EPS	Electrical Power Supply
exactEarth	This is a Canadian-based company's hosted payload on board the Spanish Radar Satellite PAX. This satellite is owned and operated by Hisdesat S.A. The mission of exactEarth is to provide maritime satellite-automatic identification services (AIS).
ExoAnalytic	This is one of several private start-up companies that is involved in the tracking of orbital debris and provides data to defense agencies under contract.
EyasSAT	A special small satellite teaching system to aid in the identification of components included in the design of a CubeSat.
FAA-AST	This acronym stands for the US Federal Aviation Administration-Assistant Administrator for Commercial Space Transportation. This is the US Agency that provides the licensing for commercial space launches and has developed safety standards for commercial suborbital flights for so-called space tourism. If the ICAO assumes responsibility for so-called space traffic management (STM), then the FAA-AST will likely be involved in some role in this activity as well.
Falcon family of launch vehicles	These are the rocket systems developed by SpaceX. These have included the Falcon 1, Falcon 9 Full Thrust, Falcon Heavy, and the largest of which is to be the Falcon Big Rocket.

Femto satellite (or Femtosat)	A femto satellite is a highly miniaturized small satellite that is up to 100 g (about 3.5 ounces) in mass according to the most common definition. It is often a CHIPSat or similar stand-alone spacecraft. It can also be a part of a distributed mission concept like a fractionated spacecraft.
Firefly Aerospace	This was a start-up to develop a low-cost launch vehicle for small satellites, but it is now bankrupt and no longer active.
5G	This is the fifth generation of cellular service that enables fast broadband applications for Internet-related and data streaming services. These include over-the-top data streaming video to cell phones and laptops, Internet of Things, and interactive data networking associated with driverless vehicles and their sensors. This will over time replace 4G long-term evolution cellular services.
Flat Panel Antenna	This is an antenna that uses electronic beamforming technologies to track satellites or to send signals from satellites down to Earth. These types of antennas thus do not have to physically track by movement of an antenna reflector. These electronic beamforming antennas can be of any shape and can, for instance, conform to the shape of a roof, a car, or aircraft.
Fleet	This is an Australian constellation that eventually intends to deploy up to 100 satellites to carry out global Internet-based networking services. Initial launches have been provided by Rocket Labs. The network is being deployed in LEO at 580 km altitude.
FOSA	French Operations Space Act
GEO	This is a special orbit, whereby a satellite deployed some 35,870 km above Earth appears to rotate exactly with the Earth's daily rotation. In this orbit ground, antennas do not have to track the satellites since GEO satellites seem to hang about the globe at a constant location.
Globalstar	This LEO constellation has 24 small satellites in its second-generation constellation with each satellite having a mass of 700 kg. These satellites are deployed at 1414 km (876 mile) orbital

	altitude with 55° inclination to provide 80% coverage of the world. There are also 24 ground stations that create the latest infrastructure for global interconnection.
GLONASS	This is the Russian global navigational satellite system.
GNSS	This acronym stands for global navigational satellite system. This type of service is also known as precise navigation and timing (PNT).
GPS	Global Positioning Satellite System of the United States. This system is also known as NAVSTAR. This system is useful to Space Situational Awareness and Space Traffic Management.
GSO	Geostationary Orbit. This is the precise orbit that would stay constantly in the Earth's equatorial belt and also travel around the Earth once every day. This is a theoretical orbit in that there is some excursions by GEO satellites North and South of the equatorial belt as they orbit the Earth. A GEO satellite that moves more than 7° above or below the equatorial location (i.e., North or South of the belt) is no longer considered to be in GSO and not protected with its special status with regard to frequency interference from non-geostationary satellites.
GUI	Graphical User Interface
HII and HIIA Launch Vehicle	This is the launch vehicle developed by JAXA in Japan and represents one option for future small satellite launches.
HAPS	High-Altitude Platform Systems (HAPS)
Hosted Payload	This is a package that flies on another satellite. This is often a smaller payload that flies on a global constellation. One example is the Aireon hosted payload that is flying on the Iridium Next **constellation**.
Hyper-Spectral Sensing	This refers to the latest technology that is used to sense across the spectral band and does so by dividing the optical band into smaller and smaller segments. Obtaining the data broken down into narrow frequency bands can allow much more sophisticated analysis of the data. Increasingly sensing is carried out in 20 to even a 100 or more segmented bands. This can thus now be accomplished even on small remote sensing

	satellites due to the miniaturization of optical sensors.
ICAO	International Civil Aviation Organization, the UN Specialized Agency that is responsible for international coordination of aviation safety standards, known as SARPs, and auditing the safety practices and standards of air carriers. It has been discussed as a possible agency to coordinate international practices and processes related to space traffic management, particularly with regard to the operation of low Earth orbit (LEO) of satellites and perhaps space debris removal.
International Telecommunication Union (ITU)	The specialized agency of the United Nations that is responsible for the international setting of standards for telecommunications, broadcasting, and networking services. This includes standards related to satellite and space services and the allotment of spectrum for space services and coordination of the frequencies and orbits of various satellite systems that are planned by various system operators.
Iridium Satellite Constellation	The second generation of the LEO constellation for mobile satellite communications has been deployed. This network with a total of 75 satellites (i.e., 66 satellites plus 9 spares) is now fully deployed at 781 km altitude with an inclination of 86.4°. All these satellites have a hosted payload called Aireon to provide navigation and tracking information for aircraft on a global basis.
iSpace	iSpace is a Chinese launcher company that has developed the Hyperbola 1S (SQX-1Z) launcher which is under test and also developing in the 2021 time frame the H-1 and H-3 launch systems as follow on programs.
Jilin Commercial Satellite Imaging	This is a Chinese private company's four satellite constellations for remote sensing and provides 1 m resolution imaging. It is operated by Chang Guang Satellite Technology Co. of China that was established in 2014.
Kepler	This is a Canadian-based constellation that has been licensed by the FCC and coordinated with the ITU processes to operate a LEO system

	operating in the Ku-band. This 140 satellite system that will deploy 6U CubeSats to complete this constellation intends to provide Internet of Things (IoT) and data services. These 6U CubeSats are being manufactured by ÅAC Clyde with a TARS platform and when fully deployed this constellation will include 140 small satellites.
Kineis Constellation	This is a new constellation for data relay and other services of 25 satellites to be deployed in 2022. It is to replace the Argo constellation of seven satellites.
LauncherOne	This is the Virgin Galactic launcher that is designed for small satellite launches and will be used as one of the vehicles to deploy satellites in the OneWeb constellation.
LED	Light-Emitting Diode
LEO	This acronym stands for low Earth orbit.
Liability Convention	This is formally called the Convention on International Liability for Damage Caused by Space Objects. This convention formally entered into force in September 1972. See http://www.unoosa.org/oosa/en/ourwork/spacelaw/treaties/introliability-convention.html
Lockheed Martin	This company designs and builds launchers that include the Atlas series of rockets. Lockheed has another part of its company that provides commercial tracking services for orbital space debris.
Long March Launch Vehicle	This name relates to the family of Chinese launch vehicles that are used by the Chinese government, Chinese space companies, and international aerospace business. These currently include Long March Series 2ACDEF, 3ABC, 4ABC, and 5.
Magnetorquer	A magnetorquer or magnetic torquer (also known as torque rod) is a key component of a small satellite design. This device is used in a satellite system for attitude control, detumbling, and stabilization. It is designed by putting together a series of electromagnetic coils. The magnetorquer thus built creates a magnetic dipole that interfaces with the Earth's magnetic field so that the counter-force helps to maintain

	attitude control and stabilization (see Torque Rod).
MEO	This acronym stands for Medium Earth Orbit. This is typically considered to in the range of about 8000 km to 12000 km altitude and represents a location that is above the Van Allen lower belt and more or less lower that the outer Van Allen belt that carries a relatively high level of radiation.
Microsatellite (or Microsat)	A microsatellite is a small satellite with a mass between 10 kg and 100 kg according to common definition. The first artificial satellite, Sputnik 1 with 84 kg mass, was a microsatellite, and many milestones in spaceflight or first satellites of countries were achieved with microsatellites. Today the 100 kg limit is more and more raised toward 120–150 kg (into the minisatellite range) due to available payload capacities and mounting adapters but still within common microsatellite envelopes of about ¼ m^3. Sometimes a microsat is defined as only being in the 10 kg to 50 kg ranges.
Minisatellite (or Minisat)	A minisat is a small satellite of more than 100 kg mass and up to 1000 kg according to the most common definition. There is usage that defines the mass range of a minisat to be between 50 kg and 500 kg again depending on the source. Most satellites that are to be deployed within large constellations or other distributed missions for satellite telecommunications and networking, but also small- and medium-size science mission satellites and probes are in the minisat range.
Minotaur 1 and II	This is a launcher developed by Orbital ATK (now Northrop Grumman Innovation) that is being phased out of production and replaced by the Antares launcher.
Multispectral Remote Sensing	This was the type of sensing done by remote sensing satellites that took images of the Earth divided into a few spectral ranges but splitting the entire visible spectrum into perhaps five to eight spectral ranges. Today the latest technology slices the spectrum into much narrower spectral images with what is called hyper-spectral imaging. (Also see Hyper-Spectral Sensing).

Nanosatellite (or Nanosat)	A nanosatellite has a mass of between 1 kg and 10 kg according to common definition. With many nanosatellites being built according to the CubeSats specifications, this term is often (but incorrectly) used interchangeably with a multiunit CubeSat. Nevertheless there are also several other non-CubeSat type of standardized platforms for nanosatellite available on the commercial market – many ranging from less than 10 kg to often up to 25 kg or more and therefore entering the range of small micro-satellites. CubeSat-based designs are commonly launched using a deployer mechanism, but a range of new options are now becoming available.
Navstar	This is the actual name of the satellites in the GPS System. NAVSTAR stands for NAVigation Satellite Timing and Ranging satellites.
NDGPS	The Nationwide Differential GPS System.
New Line-1	LinkSpace Aerospace Technology Group which is a private Chinese company (which is Xin Gan Xian-1 in Chinese) is seeking to develop a launcher named New Line-1 that is capable of launching a 200 kg payload to Sun-synchronous orbit. The ambitious target is to make the New Line-1 launch available for a $2.5 million launch cost and also to achieve a reusable first stage.
New Shepard and New Glenn Launch Vehicles	These are new launch systems being developed by Blue Origin. These systems are developing reusable launch systems.
Northrop Grumman	This is a large aerospace company that has acquired the Orbital Science and ATK that is now known as Northrop Grumman Innovation. Thus Northrop is now the supplier of all the Pegasus, Taurus, and Antares.
Office of Outer Space Affairs (OOSA)	This is the Office of the United Nations that has its offices in Vienna, Austria, and carries out a number of functions to support the functions of COPUOS and its subcommittees and working groups but also additional functions such as maintaining the registry of all satellites and missions launched into space on behalf of the UN Secretary General, the SPIDER emergency

	communications relief program, and various workshops, meetings, and centers around the world.
One Vision launcher	This is a project of the Gilmour Space Technologies Company and is based on a scaled-up version of the Ariel sounding rocket and will use a hybrid rocket engine. Tests are planned for a prototype in 2020.
OneWeb	This is a proposed “swarm constellation” or mega LEO network that would provide global Internet access using initially about 600 small satellites (150 kg class) in low Earth orbit including spares. This will be expanded further in time. These satellites turn to the side on their axis as they approach the equatorial orbital arc to avoid interference with satellites in GEO orbit and then return to pointing to Earth as they pass the equatorial zone.
OOSA	Office of Outer Space Affairs of the United Nations that is headquartered in Vienna, Austria
Optistar	Optistar is a constellation of 16 satellites. This Canadian-owned network is being developed by Urthecast, and the launch date has not been firmly established. The constellation design is for 16 satellites in polar orbit, with 8 tandem pairs in 2 orbital planes, and with 1 m resolution in X-band and 5 meter resolution in L-band. The objective is to provide nearly simultaneous imaging from the paired systems in optical bands as well as synthetic aperture radar imaging. Optistar has indicated that it will also provide geospatial analytics. Satellite manufacturing contracts have been announced, and they are to be built by Surrey Space Technology Ltd.
Orbcomm	This is a small sat store and data relay constellation that connects to small receivers to provide machine to machine (M2M), Automatic Identification Services (AIS), as well as Internet of Things (IoT) services globally. The constellation, in its second generation, when full, will consist of 46 satellites in 720 km altitude LEO orbits.
OS-1 to OS-4	These are rocket systems developed by One Space Technology (it is also known as Zero

	One Space). This is a private Chinese commercial company that has developed the OS-M1 to OS-M4 launcher family. The most capable of these launchers is the OS-M4. It is designed to be capable of lifting 552 kg to LEO and 307 kg to Sun-synchronous orbit and at an altitude of up to 800 km. This company is seeking to develop reusable rockets.
OTT	This stands for over-the-top. This relates to data streaming of video services that are provided via broadband Internet services to set top boxes. This is competitive with satellite subscription television and paid cable television subscription services. This type of service will have a major impact on direct broadcast satellite paid subscription services and the type of traffic LEO satellite constellations carry versus traffic carried on GEO high-throughput satellites.
Outer Space Treaty	This is the Treaty on Principles Governing the Activities of States in the Exploration and Use of Outer Space, including the Moon and Other Celestial Bodies that entered into force in October 1967. There are four subsidiary international agreements that followed on to this cornerstone treaty governing the use of outer space. See: http://www.unoosa.org/oosa/en/ourwork/spacelaw/treaties/introouterspacetreaty.html
PANS	Procedures for Air Navigation Services (PANS). This is a term of art used by the International Civil Aviation Organization (ICAO).
Pegasus Launch Vehicle	This is a smaller launch vehicle originally developed by Orbital Sciences (now Northrop Grumman Innovation). This small rocket was flown to a high altitude and then launched from an especially equipped carrier aircraft. This launcher was used for the launch of the first of the Orbcomm constellation satellites. It is being phased out of production because of its relative high cost for small satellite launches.
Pico Satellite (or Picosat)	A very miniaturized small satellite with a mass between 0.1 and 1 kg according to the most common definition. It can often be a 1U CubeSat when applying the CubeSat Design

	Specifications as a standard. This quite small satellite is most typically used for simple experimentation or component testing and verification in the space environment.
Piggyback	This is a term where a smaller payload is included as a supplementary mission on a launcher where additional mass is available for launch.
Planet LLC	This is a start-up company that combines into a constellation of remote sensing satellites, small 3-Unit CubeSats known as Doves, the higher resolution satellites once known as Skybox and Terra Bella, plus other satellites. It has revolutionized the economics of remote sensing operations and created a new business model in terms of what types of information that it sells to a global network of users. Planet LLC, which acquired Terra Bella from Google, has an ongoing relationship with Google to whom it provides information for Google Maps.
PNT	This acronym stands for precise navigation and timing satellite services.
PocketQube Satellite	A PocketQube is a relatively new type of a very miniaturized small satellite – based on a standard proposed by B. Twiggs in 2009. It represents a follow-up concept to the CubeSat standard. It’s size is 5 cm × 5 cm × 5 cm. (Thus is exactly one-eighth the size of a CubeSat) and also represents a mass of up to 250 g. Due to its very small size, it is typically used for space research or commercial-off-the-shelf component validation and verification in the space environment – especially in the area of electronics or software testing.
Proton	This is the Russian launcher that is manufactured by Khrunichev Manufacturing and represents one of the most utilized launchers of the space age. This is being phased out of production and is to be replaced by the new Angara launcher system that is currently underdevelopment.
Protozone/Protospace	This is the area below sustained orbital space and above commercial air space. This is an altitude below 160 km and above 20 km. Activities that might be carried out in this region might include

	high-altitude platform systems (HAPS), Dark Sky Stations, robotic aircraft, the stratosphere arc of a hypersonic transport vehicle, stratospheric ascent dirigibles or balloons, or military craft for surveillance or other missions.
PSLV	Polar Satellite Launch Vehicle is a launcher developed by the Indian Space Research Organization which has an excellent launch record. Currently it has the record for the most CubeSat launches by launching 104 CubeSats in a single launch in December 2017.
Reaction Wheel Module	This is also known as inertial wheel or momentum wheel, and it is used to maintain a satellite in a three-axis stabilized orientation.
Rocket Labs	This is a start-up launcher company designed to launch small satellites. It is a joint New Zealand and US venture with its launch site in New Zealand. Its electron rockets use unique new materials to reduce the mass of its launch vehicles and additive manufacturing to increase the reliability of its rockets and to reduce manufacturing costs.
Rocket-1	This new small satellite launcher known as Rocket-1 is currently underdevelopment by Launcher, Inc. Unlike most start-ups, this US-based company has a decade-long development schedule. The first step, currently in development, is to have a reliable 3D printed rocket engine. This will be followed by additional development steps that are intended to result in a very low cost and reliable smallsat launcher by 2025.
Rockoons	LEO Aerospace LLC which is associated with Purdue University is seeking to develop what they call Rockoons. The first step in their launch system will be a high-altitude balloons that are designed to ascend to 18 km. Then a rocket will be release to launch small payloads into LEO orbit. There pro then sent to orbit by a rocket. There currently estimate cost would $60,000 per kg or the equivalent of one CubeSat unit.
Rockot	This is the rocket launcher that is marketed by Eurockot which is a joint French-Russian company.

RS-1 launcher	The RS-1 launcher is being developed by ABL Space Systems, a US-based company. It is designed to be a low cost and easily mobile system for the launch of small satellites. The RS-1 could be launched from any approved and licensed location, which is designed to be launched from a truck-mounted launch system or essentially from any FAA licensed launch site.
SARPS	Standards and Recommended Practices (SARPS). This is the mechanism used by the International Civil Aviation Organization (ICAO) to coordinate international safety standards for airlines and aircraft flying in international airspace.
Shavit	This is an Israeli launcher that has been developed by the Israel Aerospace Industries. Shavit means Comet in Israeli. This rocket is launched to the east rather than to the west because of strategic constraints local to the Middle East geopolitical environments.
Sierra Nevada	This is an aerospace company that has among other projects developed the Dream Chaser space plane system. It also can design and fabricate small satellites.
Small Satellite (or Smallsat)	A miniature satellite of less than 500–1000 kg mass (depending on the definition used). This term is actually quite broad in its meaning and application. Thus the term smallsat is now divided into several subcategories. Thus, in descending order, there minisats, microsats, nanosats, picosats, and femto satellite. (See above descriptions.) Small satellites are often launched as secondary or piggyback payloads taking advantage of remaining available payload mass of the launch vehicle. Common goals of small satellite missions are reduction of spacecraft cost, project schedule, or enabling distributed mission concepts such as to deploy satellites in a constellation. Other phrasings that represent much less common terms are “compact satellites,” “light satellites,” or “lean satellites.”
SOLAS	International Convention for the Safety of Life at Sea (SOLAS).

Soyuz	This is a Russian launcher that is currently internationally marketed by Arianespace and is launched from the Ariane launch site in French Guyana.
Space Data Association	This is an organization founded by Intelsat, Inmarsat, and SES to share information about possible conjunction of satellites in orbit or other threats of orbital collisions. It has grown to now include many dozens of space system operators who actively share information to avoid collisions. Also arrangements have been made to obtain critical information from defense agencies who are carrying out defense monitoring and space object tracking. There have been new space policies directed by the US government to seek to develop separate but parallel tracking capabilities for defense space situational awareness and commercial space situational awareness capabilities as set forth in the US Space Directive 3.
Space Rider	The European Space Agency (ESA) (Space Rider project stands for Space Reusable Integrated Demonstrator for Europe Return). It is a joint project of the Italian Aerospace Research Center (CIRA) and Thales Alenia. This is a small reusable space lifting body that is compatible with Vega C launcher.
SpaceX	This company is primarily owned by Elon Musk. It has developed the Falcon series of satellites from the Falcon 1 to the Falcon 9, to the Falcon 9 Heavy and the Big Falcon Rocket. These series of rockets, including the latest capabilities to now reuse the early stages of the rockets, have been instrumental in lowering the cost of launches and have contributed to new economics for small satellite launches. It is intended by SpaceX to launch two very large small satellite constellations known as Starlink. One constellation with over 4500 smallsats and another with over 7500 satellites or a total of over 12,000 satellites.
Spectrum	This is the measure of bandwidth that is used for various satellite applications. The radio-wave spectrum allocated for commercial satellite communications, for instance, is typically either

	500 MHz or 1000 MHz across. One practical problem is that the ITU that is responsible for allocation of radio spectrum for practical or scientific use has divided the world into three regions and the allocations can be and indeed are different for different regions of the world.
Spire	The Spire's constellation is currently a LEO constellation of 80 satellites that is being expanded in its service offering so as to collect AIS, meteorological data, and locational data in cooperation with the European Galileo System.
SSA	Space Situational Awareness. This is a term of art that relates to the tracking of all objects in Earth orbit or a suborbital flight. These activities are carried out in order to track operational satellites and all space objects such as space debris and defunct satellites. Also for security and strategic reasons, space situational awareness is performed to detect possible missile launches that could represent an attack by an armed rocket. Initially these operations were carried out by defense agencies, but more recently there have been a number of private companies and agencies that have developed the capability to monitor and track objects in Earth orbit. An organization known as the Space Data Association (SDA) has been formed to share data on space objects in Earth orbit with a view to avoid collisions of satellites or satellites with space objects that could disable or destroy operational satellites.
SSTL	Surrey Space Technology Limited. This is one of the leading leaders in the design, development, and fabrication of small satellites. This entity which spun off from the University of Surrey is now wholly owned by Airbus.
Starlink	This is the name that Elon Musk has given to his two constellations of small satellites operating in the Ku, Ka, and V band that are planned for launch in the next few years. See SpaceX.
STC	Space Traffic Control. (See Space Traffic Management.)
STM	Space Traffic Management. This concept has many different definitions and possible

	interpretations since it is concept about creating a system for implementing space safety and a future means to avoid collisions of space objects. The International Academy of Astronautics in its study of this subject has posed the following possible definition. “Space Traffic Management is a set of technical and regulatory provisions for promoting safe access into outer space, operations in outer space, and return from outer space to Earth free from physical or radio-frequency interference.”
Satellogic NuSat Aleph-1 Constellation	This is an Argentine constellation for remote sensing. It is ultimately planned to have 300 small satellites in this constellation.
TDMA	Time-Division Multiple Access. This multiplexing system along with CDMA is the most common method of digital communications used on modern telecommunications satellite systems as well as ground-based cellular communications systems. CMDA is used on the Globalstar Mobile Satellite System, and TDMA is used on the Iridium Mobile Satellite System. These types of digitally based multiplexing systems are key to use when satellites are creating a large number of spot beams that involve geographic isolation of frequencies so that spectrum can be reused multiple times.
Telesat Constellation	This is a Canadian network of 117 satellites that will eventually seek to deploy 794 small satellites at a variety of altitudes ranging from 1000 to 1248 km that will operate in the Ka-band and provide networking services on a global basis. This is one of several systems where a satellite operator intends to operate both LEO and GEO satellite networks to service a range of telecommunications and networking markets.
Theia	This is a newly organized company that was organized in 2016. It is planning the deployment of satellites in LEO orbit that will work in tandem with a MEO constellation to distribute remote sensing and strategic business information on a global basis.
Torque Rod	A torque rod, also known as a magnetorquer, consists of a series of electromagnetic coils.

	This thus is able to create a magnetic dipole that interfaces with the Earth's magnetic field. This allows a counter-force to be created to help to maintain attitude control and stabilization. It thus allows a small satellite to avoid tumbling.
21 AT	A Chinese private remote sensing company that currently operates a three satellite constellations. System was designed and manufactured by SSTL and Urthecast.
Unha-3 Launcher	This is under development by the North Korean National Aerospace Development Administration (NADA) (Kwangmyongsong). There launcher is known as the Unha-3 Missile Systems. There is limited knowledge of the launcher system.
Urthecast	This is a Vancouver, Canada-based Earth observation and data analytics company.
VLM-1 Launch Vehicle	Brazilian Departamento de Ciencia e Tecnologia Aeroespacial (CTA) is developing the VLM-1 (Vehicle for the Launch of Microsats). The VLM-1 is planned to have the capability to lift a 150 kg small satellite to LEO. CTA is also the manufacturer
Tronador II	Liquid-fueled rocket that is being designed to lift 250 kg payload to polar orbit. It will launch from Puerto Belgrano Naval Base in Argentina.
United Nations and UN Space-Related Specialized Agencies	This is the public international organization formed to address all matters related to international cooperation and peacekeeping. All so-called specialized international organizations related to various functions come under the UN structure. Entities in the UN structure that have a particular relationship to space include the International Telecommunication Organization (ITU), the International Civil Aviation Organization (ICAO), the United Nations Office on Disarmament Affairs (UNODA), and the United Nations Committee on the Peaceful Uses of Outer Space (COPUOS).
United Nations Sustainable Development Goals	These are the 17 Sustainable Development Goals set by the UN General Assembly with quantitative objectives set for 2030. These replaced the Millennium Development Goals set for 2015.

Vector	A US-based low-cost launcher developed to launch small satellites. It currently offers a Vector A and Vector B launcher option.
Vector launcher	The Vector-R provides a 60 kg payload capability that can be configured for a wide range of CubeSat and small satellite mission profiles. The US developed Vector-R fairing is a traditional two-piece design that is of sufficient size to accommodate a wide range of deployment options for multiple smallsats.
VEGA and VEGA C	These are new and more cost-efficient launchers that have been developed by European Launcher Development (ELD)-Fiat-Veio to respond to the need to launch smaller satellites for large-scale constellations. The Vega and Vega C will be launched from the Arianespace launch facility in French Guiana. It can be configured to launch five 200 kg small satellites into orbit.
Venture Class Contract	This is a low level of easy to execute contract that can be used by NASA to encourage new start-up ventures that are seeking to create new launch capabilities or to build low-cost new small satellites.
Vulcan-Centaur Launcher	This is a new launcher system that is being developed and will be marketed by the United Launch Alliance. This will replace the Delta 4 launcher which has become expensive relative to other launchers that have achieved significant new economies in the past decade.
Zenit	This is a Ukrainian/Russian launcher that is being phased out of production.
Zhuque-1	This small satellite launcher is being developed by the Chinese private aerospace company known as Landspace. The Zhuque-1 is being designed to be capable of lifting 300 kg to LEO orbit or 200 kg to Sun-synchronous orbit (SSO). The initial test launch in 2019 failed to achieve orbit.
