First, sustainability transition and transition management are to a large extent based upon ideas drawn from a scientific trend which in a more or less justifiable way is called complexity theory or complexity science. This scientific trend is based upon a set of phenomena, processes, names and mathematical models whose proponents aim to study the complexity of natural and social phenomena with a set of simple descriptions, explanations and predictions. Since social systems are an effect of tangible and intangible components synthesized into a common meaning in intersubjective discourse, the authors of the ideas of sustainability transition and transition management are well aware of the limitations stemming from the very character of these systems. However, the ideas of complexity used in the rhetoric dealing with these two ideas is not always sufficient. Although a broad spectrum of problems are properly described and

explained using such ideas as adaptation, edge of chaos, learning, self-organization, and so forth, the main conclusion is that the sense of ideas drawn from complexity studies has not been sufficiently reflected on and scrutinized in the context of the applications. This particularly concerns the multitude of interpretations of the characteristics of complexity and the intersubjective process leading to the creation or emergence of the meaning of the term.

Second, such an approach leads to an impression of conceptual redundancy over practical needs, and also, over the sense of a theory which may not be too supportive in the development of new ideas and new methods. For example, how can one identify and then stimulate the process of self-organization among the reflexive and self-reflexive members of an autopoietic social system which is described metaphorically(?) as being at the edge of chaos? It looks as if such a rhetoric may not be too productive.

The main directions for further research are common to applications of complexity-related ideas in sustainability and sustainable development, as well as to sustainability transition and transition management.

The most important direction of research is to clarify the 'language of complexity' used in both areas. Obviously, it is neither necessary nor possible to always provide the deeper analyses of the meaning of the terms used in discussions about sustainability-related problems, but at the same time it is necessary to maintain a deeper analysis of the terms connected with complexity in the theories which are built on the concept of complexity. It is especially important when the idea has some fifty or more interpretations.

The second direction of study is to develop conceptual and methodological frameworks, skeletons of ideas and methods drawn from complexity studies, which should then be applied in the theory and practice of sustainability and sustainability development, and in sustainability transition and transition management. This set should embody advanced conceptual proposals that have been thoroughly analysed from the point of view of their relevance to complexity theory and to social reality. Both qualitative methodologies and operationalization should be included. Perhaps as a source of inspiration though not as a benchmark, the ideas of agile project management could be used, although these are relevant rather at the micro-scale. Such a methodological toolbox would not be closed, that is, it would not include only a limited number of precisely defined ideas. It should be open, but at the same time, any ideas and methods, before inclusion, should be tested for their conceptual and cognitive validity as well as for their applicability. In this way, even broad metaphors could be included, on the condition that those who would spell them out interpret them properly. The development of sets of indicators for sustainable development is the first step in this direction. In the case of transition management, where broad methodologies are already applied, it would only be necessary to raise the demands for refining the definitions.

19 Critical Approaches to Transitions Theory

Bonno Pel[1], Flor R. Avelino[2] and Shivant S. Jhagroe[3]

Abstract

Since its emergence as a theory of sustainability transformation, transitions theory has started to gain currency with both policymakers and researchers. As transitions approaches become established in research and policy, a process of institutionalization can be witnessed. Yet notwithstanding this mainstreaming, transitions theory continues to be controversial. Questions have been raised about its theorization of agency and transformation dynamics, and especially about the normative assumptions underlying its intervention strategies.
Arguably, these recurring questions call for 'critical approaches' to transitions theory. This contribution explores these, guided by a constructive attitude. The argument starts from the consideration that transitions theory harbours distinctly 'critical' elements, and that polemical juxtapositions between critical and uncritical transitions approaches are unnecessary: *What are the critical contents of transitions theory? How can the critical contents of transitions theory be retained and developed further?* These questions are answered through a historical comparison with the critical-theoretical project as initiated by Marx, Horkheimer and Adorno, amongst others. As with transitions studies, this project was meant to diagnose the social problems of its time, and to articulate corresponding remedial strategies. It ran into various internal contradictions, however, and these provide useful insights for the further development of critical transitions. The main conclusion is that transitions theory is well equipped to deal with these critical-theoretical paradoxes, but also displays tendencies towards relapsing into the pitfalls.

Keywords: Transitions, critical theory, politics, transformation paradoxes, normative foundations.

19.1 Introduction: Transitions Theory as a Critical Theory

As can be seen throughout this volume, it is probably fair to say that transitions theory is coming of age. It has started to gain currency amongst both researchers and policymakers as an integrative framework with which to grasp and manage processes of structural societal transformation towards sustainability. Recently Markard, Raven and Truffer (2012) provided an overview of transition studies in which they distinguish four main perspectives in the field: 1) the *Multilevel Perspective* (MLP; Geels 2005a, 2010); 2) *Strategic Niche Management* (SNM) (Kemp/Schot/Hoogma 1998; Schot/Geels 2008; Smith/Raven 2012); 3) *Technological Innovation Systems* (TIS; Hekkert/Suurs/Negro et al. 2007; Wieczorek/Hekkert 2012); and 4) *Transition Management* (TM; Rotmans 2006; Loorbach 2007, 2010). Alongside and in conjunction with these main strands, various other themes and approaches are developed in direct relation to sociotechnical transition studies. This is further evidence that the field is becoming more mainstream (see also chapter 4 by John Grin in this volume).

Notwithstanding this institutionalization of transitions theory, however, its maturity as a theory of soci-

otechnical systems transformation remains subject to debate. Not surprisingly, the different transition-theoretical strands and origins make for continuous debate on the dynamics and management of sustainability transitions. Yet apart from this theoretical diversity, typical of multidisciplinary fields of study more generally, there are also more specific concerns. Ever since its inception as a framework for transformations in sociotechnical systems, transitions theory has met with doubts as to whether it can live up to its particularly high ambitions. Various questions have been raised regarding its theorization of agency and transformation dynamics, for example (Berkhout/Smith/Stirling 2004; Genus/Coles 2008; Smith/Voß/Grin 2010; Jørgensen 2012): Is the niche-regime-landscape heuristic really adequate vis-à-vis the complex reality that it is supposed to describe? Moreover, the transition-theoretical repertoire of intervention and management has met with sometimes harsh reactions, especially regarding the normative assumptions underlying these—intentionally profound—interventions in society (Berkhout 2006; Smith/Stirling 2008; Hendriks 2009; Stirling 2011; Røpke 2013): What counts as sustainable development? What and whose 'systems' are in need of transformation, and in what direction? Who decides, and through which procedures and on which grounds?

Especially these interrogations of its underlying normative assumptions indicate a need for 'critical approaches' to transitions theory (and its associated practices). The above questions provide a strong reminder that the implicit choices in transitions diagnoses and remedial strategies need to be accounted for. However, this is not to side with, or argue against, earlier allusions and allegations that transitions theory amounted to a novel version of (typically uncritical) social engineering (as expressed in e.g. Shove/Walker 2007 2008; van Duineveld/Beunen/van Ark et al. 2008). This contribution seeks to avoid adversarial debates on the critical contents of transitions theory, and the attendant false dichotomies that prevent these contents from being developed further. The key consideration from which to proceed further is that transitions theory harbours distinctly 'critical' elements. In some transition-theoretical accounts these may only operate in the distant background, while being more explicit in others. Still, notwithstanding the differences in approaches that exist within this field of research, transitions theory as a whole can be considered as a 'critical' theory from the outset. Crucially, it aims to interrogate the dominant social structures of its time, a critical attitude that is captured in the cen-

tral notion of sociotechnical 'regimes'. Likewise, the different strands share a dedication to the development of alternative development paths and practical solutions, i.e. to critical remedies, where these dominant structures are held to be no longer sustainable (Geels 2005a; Grin/Rotmans/Schot 2010; Zijlstra/Avelino 2012).

To consider *transitions theory* (TT) as a *critical theory* (CT) is only one possible understanding of it, of course. As other chapters in this volume bring out, transitions theory is also in many ways a positive, solution-oriented theory, and not in the first place a line of questioning and reflection. Still, considering that the 'regime' is a key analytical concept through which current practices are relentlessly questioned for their sustainability, the proposed understanding of transitions theory as critical theory seems plausible. A consequence of this particular understanding is that this chapter tends to focus on the *multilevel perspective* (MLP) and *transition management* (TM), and pays less attention to other strands such as technological *innovation systems* (TIS) and *strategic niche management* (SNM) that are less explicitly critical in their approaches. First and foremost, this chapter is intended to provide an overview of recent developments towards more emphatically critical transitions approaches, as they are developed in different transition-theoretical strands. Closely related to this overview is the task of systematizing these somewhat dispersed advances. *What are the critical contents of transitions theory? And considering the suggestions that these have somehow become lost, how can they be retained and developed further?*

This chapter will proceed as follows. First, we explain in what sense transitions theory is considered a 'critical' theory. Its unmistakeable similarities with the critical-theoretical project, as initiated by Marx, Horkheimer, Adorno and Habermas, amongst others, allow us to answer research questions through historical comparison. As with transitions studies, this critical project was meant to diagnose the social problems of its time, and to articulate corresponding remedial strategies. Crucially, it ran into various internal contradictions, however. We shall show how these contradictions resurface in contemporary debate on transitions theory (19.2). Next, three of these paradoxes are discussed, in order to structure the debate on critical transitions theory: after discussions on normative foundations (19.3), theorization of social evolution (19.4), and agency/structure (19.5), conclusions are drawn about the critical content of transitions theory and its further development (19.6).

19.2 Critical Content of Transitions Theory: Revisiting Critical Theory and its Paradoxes

As introduced, transitions theory can be considered to harbour distinctly 'critical' elements. It should be borne in mind that the latter term is used in a specific sense. It does not imply a negative or adversarial attitude (as suggested by colloquial understandings of 'criticism' or 'being critical of'), nor should it be confused with being important or crucial (as in 'critical infrastructures' or 'critical paths'). Instead, transitions theory is considered critical in the sense that it aims to interrogate the dominant social structures of its time, and to envisage alternative development paths in cases where these dominant structures are held to be undesirable, or un*sustainable*.

This specific philosophical usage of the term originally stems from Kant, who famously argued that knowledge is necessarily mediated by subjective categories. Following this line of reasoning, Hegel and Marx argued that knowledge must therefore be inherently historical, i.e. shaped by the prevailing social conditions under which human subjects live and act. Kant's critical self-understanding allowed for all sorts of philosophical elaborations, and it was Marx who has been most influential in developing it into a basis for transformative social theory. As he witnessed how the industrial revolution created profound social changes and serious social cleavages, he considered it imperative to move beyond detached philosophizing. Instead, the critical and modern self-understanding should become relevant mainly by articulating how people's thinking and living are determined by social structures, and how these typically operate 'behind their backs'. To Marx, the key structure in need of such critical unmasking was the system of capital accumulation, with its inherent tendencies towards exploitation and alienation.

Later, Horkheimer and Adorno (1947) dissociated themselves somewhat from Marx's materialistic focus on industrial production and labour. They did seek to maintain and develop his spirit and mission, however: their Frankfurt School promoted a social theory that was likewise set to articulate the social conditions of its time, so as to unveil and counter the dominant structures impeding true self-determination. In the Germany of the 1930s, they considered, this Enlightenment promise of self-determination had become a misleading caricature of itself. Their theoretical conclusion was that the rise of Nazism signalled new structures of domination to have emerged, next to

and in conjunction with those of capitalism. In its later post-World War II stages, the critical-theoretical project continued through such debates on society's crucial structures of domination. Marxist suspicion was mobilized against 'consumerism', against the homogenizing tendencies of 'mass society' and against the 'culture industry'. The various critical accounts of society led to particularly vehement debate, often revolving around alternative interpretations of Kant, Hegel, Marx, and Horkheimer and Adorno (Honneth 1991). The most influential theoreticians in this respect have been Habermas and Foucault. Whereas the first sought to establish a normative grounding to diagnoses of domination and system pathologies (Habermas 1998), namely his ideal speech construct, the latter rather showed how any such fundament would be prone to becoming a source of domination itself (Foucault 1998). To Foucault, Kant's critical spirit could be best applied through constant questioning of thoughts and practices—and this understanding of critique emphatically included self-questioning (Kelly 1998). On the other hand, whilst agreeing with most of this critical understanding, Habermas sought to safeguard the possibility of rational critique and social diagnosis. In the process of and alongside these philosophical debates, the critical project also inspired activists, artists and political parties. And as can be witnessed from research strands such as critical sociology, critical geography, gender studies, and political economy, critical theory also had a considerable following in the social sciences (Rasmussen 1996).

As indicated earlier, transitions theory bears several fairly obvious similarities with this critical tradition, and these similarities account for its critical content. First of all, transitions theory is similar in spirit, as it is equally motivated by a sense of urgency about the social problems of its time. Even when this sense of urgency or engagement tends to be somewhat less pronounced in current transition-theoretical work, early contributions such as Elzen, Geels and Green (2004), Rotmans (2006) and Loorbach (2007) were very explicit about the authors' sustainability concerns. Second, transitions theory is premised on the assumption that these problems have structural roots: current sustainability challenges are considered to be so particularly persistent due to the societal structures that operate 'behind people's backs'. In a similar way to Marx's work on the laws of capital, transitions theory conceives of sociotechnical 'regimes' as seldom questioned rules or grammar that shape thinking, acting and producing (Kemp/Schot/Hoogma 1998; Geels 2005a). In strategic niche management, for

example (Smith/Raven 2012), the viability of an innovation is not considered to be a fixed and objective given. What is 'realistic' precisely depends on regime structures that are man-made, and—at least in principle—open to change. Third, transitions theory shares the critical-theoretical commitment to emancipation. Transitions theory refuses to limit itself to the diagnostics of system lock-in, but involves the task of devising corresponding remedies ('system lock-out', as expressed in Geels 2005a) as well. This practical orientation not only speaks from the various accounts of transition management, strategic niche management and technological innovation systems, all providing tools to empower sustainability actions, but the practical orientation also speaks from the commitments to trans-disciplinary, inclusive and socially engaged science (e.g. Grin/Rotmans/Schot 2010) and the inclusion of 'lay' expertise in experimenting and visioning processes (Loorbach 2007). Fourth and finally, both transitions theory and critical theory are historical, evolutionary theories: they co-evolve with the societal structures that they are intended to diagnose. Whilst critical theory grounded its theorization of social evolution mainly in Hegelian-Marxist dialectics, transitions theory is underpinned by a broad synthesis of social-scientific insights.

In summary, transitions theory displays strong similarities with its critical-theoretical predecessors—even when it is tapping quite different sources of knowledge. The latter fact reminds us that there are also significant differences to consider, and even suggests that transitions theory may have learned from its critical-theoretical predecessors. Indeed, detailed accounts of such lesson-drawing have been put forward, regarding both diagnostics (Geels 2005a; Geels/Schot 2007) and remedial strategies (Grin 2010; Loorbach 2007). Still, these accounts of theoretical origins mainly reveal that transitions theory is hardly directly informed by critical theory. The apparent similarities seem to stem mostly from the various 'critical' branches of social science that have developed through, and alongside, the sociological-philosophical 'critical project': one may think of science and technology studies (STS), evolutionary economics and neo-institutional theory as typically heterodox approaches that constitute essential critical ingredients of transitions theory.

So even when transitions theory can be appreciated as a contemporary form of critical theory, it cannot be considered an actual successor. The similarities between transitions theory and critical theory are quite clear, but there is only distant kinship. It is there-

fore all the more interesting to see how transitions theory and critical theory seem to coincide in the counterarguments and objections they have received. For the development of critical approaches to transitions theory, these similarities in particular merit consideration. The theoretical impasses of critical theory can be considered well rehearsed, and as such they provide ready available opportunities for learning and reflection.

Throughout its development, critical theory has met with strong criticisms, ranging from principled objections and attempts at refutation to rather adversarial and crudely formulated allegations. All in all, the critical project has lost much of its earlier appeal: to begin with, Marxism has come under a cloud not only due to the experiences with communism, but also due to a certain theoretical inertia. Class-based struggle is only one dimension of contemporary political cleavages, for example, and 'capitalism' does not capture the variety of possible political economies under that heading. These Marxist categories have become rather blunt instruments of critique. In addition, the analyses of the Frankfurt School, whose diagnoses inspired many to criticize or to fight 'the System', now appear as rather outdated and one-sided. As their cultural-critical notions of 'mass society' have been surpassed by social diversification, the associated diagnoses of systemic problems and identification of culprits have become likewise problematic. Now these assertions of outdated critique remind us that it is easy to ridicule earlier critical theory with the benefit of hindsight. Its less refined and exaggerating manifestations making for excellent 'straw man' targets, critical theory is vulnerable to easy criticisms and caricature. It is therefore important to focus on the more precise formulations amongst the many objections that have been raised. Apart from incidental misconceptions and empirical inaccuracies, internal contradictions have been identified as flaws that seem to be inherent in critical theory. These paradoxes are most relevant to this volume, as they resurface in recent transitions theory debate. In the next sections, the following paradoxes will be dealt with:

1. Normative foundations (when norms are admitted to be socially constructed).
2. Keeping up with evolution (in a theory with universal aspirations).
3. Balancing lock-in and lock-out (when sustainability challenges are considered to be both persistent and soluble).

Confronting transitions theory with these paradoxes, its critical contents can be specified, as can how these can be retained and developed further.

19.3   Critical Theoretical Paradoxes (I): Normative Foundations

The central mission of the critical-theoretical project was to interrogate and lay bare the social conditions under which the Enlightenment promise of self-determination was to be realized (McCarthy 1998). The seminal 'Dialectic of Enlightenment' by Horkheimer and Adorno (1947) was to show how this ideal was far from realized—instead, it had turned into an ideological smokescreen, serving the powers that be. Raising people's awareness about their silent subjugation was to be the critical-theoretical remedy towards achieving *true* self-determination. This line of reasoning has been most influential, and not only in the academic sense: the neo-Marxist cultural critique inspired counter-cultural movements around the world, and continues to inform new social movements. Moreover, the classical Marxist appeals to class-based struggle have even manifested themselves in many revolutions and armed struggles. Unsurprisingly, the critical-theoretical line of thinking was scrutinized ever more fiercely, the more influential it became within and outside academia. These objections often concerned the adequacy of the system diagnoses, but were particularly frequently raised against the overly confident ivory tower perspective presupposed by the objections themselves: How could the critical theorists see what the common man couldn't? How could they themselves free their diagnoses from the dominant discourses of their time? And how could the diagnoses of alienated, enslaved people hold, when the alleged patients themselves claimed to feel fine?

Through such questions, directly targeting the ways in which the critical diagnoses served as legitimizations for revolutionary action or armed resistance, the critical-theoretical project was questioned for its own implicit assumptions. Popper challenged the critical theorists to scientifically account for their historicist prophecies, for example. Other critics rather went along with the critical line of reasoning to some extent, only to turn it against the ivory tower aspirations and undemocratic tendencies that often accompanied it: especially Foucault (1998) and Luhmann (1990 2002) have relentlessly confronted the critical theorists with their lack of *self*-critique (Kelly 1998). Critically interrogating the critical accounts of system

pathologies and false beliefs themselves, the normative assumptions underlying these diagnoses often proved difficult to account for (Honneth 1996). Crucially, these investigations of normative yardsticks showed the 'ivory tower' lines of critical theory to be rather uncritical forms of critique.

Similar critiques-of-the-critical have been raised against transitions theory: especially Duineveld, Beunen and van Ark et al. (2008) and Shove and Walker (2007, 2008) echoed the Foucauldian inquiries after the distanced, 'voyeuristic' system diagnoses through the MLP, and their deployments as apparently self-evident bases for action. In particular they took issue with the notion of transition management and its suggestion of control and steering. Moreover, as transition advocates were seen to remain relatively silent on the politics and power play involved, the question was suspiciously posed as to whether there were dirty hands to hide. The issue of normative assumptions also evoked cogent inquiries by Smith and Stirling (2008, 2010) and Berkhout (2006). Following up on these critiques, Pel and Boons (2010) and Pel (2012b) addressed the practical implications of system demarcations and 'sustainability' understandings in transitions theory (see also Ulrich 2003 on this critical systems thinking). Furthermore, various authors have stressed the directionality of transitions (Stirling 2009, 2011; Cohen 2010; Røpke 2012). The key message is then that once transitions theory starts to obscure the diversity of possible transition pathways and the attendant political choices, it will lose its critical contents. These contributions usefully specify earlier inquiries after the choices and demarcations implied with transitions theory and management. The emphasis on the directionality of transition processes helps substantiate how the normative yardstick of sustainability is less than clear-cut, yet is often mistaken as 'post-political' (Kenis/Mathijs 2014). Finally, there have been critiques that focus on the politics and choices involved with transitions-based remedial strategies, i.e. with transitions practice. In a special issue on transitions-in-the-making, Voß, Grin and Smith (2009) observed the tendency of transitions approaches to be captured and co-opted by regime structures. This tragic fate of critical remedies, their proneness to reproducing the very dominant structures they were set to transform, is a classical critical-theoretical theme.

The above inquiries after its normative foundations have prompted various attempts to safeguard and bolster the critical contents of transitions theory. First of all, allegations of technocratic 'management' from the ivory tower have led to an altogether greater

awareness that the term transition *management* bears misleading connotations. This has led in turn to a stronger focus on critical contents such as negotiated visions, emphatically inclusive governance processes, and participatory future scanning. These advances help avoid critical-theoretical one-sidedness, and the associated 'totalitarian temptation' of one-sided action. Second, and related to the first issue, there are several contributions that seek to develop transitions theory more explicitly in the context of reflexive modernization (Beck/Bonns/Lau 2003; Voß/Bauknecht/Kemp 2006; Grin 2010). Avelino and Grin (2014) argue that transitions theory should embrace the tradition of critical deconstruction, while at the same time reaching for reconstruction. This work on reflexive modernization strongly reminds us of Habermas' attempts to safeguard a self-aware but constructive critical theory. Third, the attention given to the practices and politics of transitions-in-the-making has become an integral part (or branch) of transitions theory, as can be witnessed from Paredis 2008; Avelino 2009, 2011; Kern/Howlett 2009; Meadowcroft 2009; Hendriks 2009; Kemp/Rotmans 2009; Loorbach/Rotmans 2010; Smith/Voß/Grin 2010; Farla/Markard/Raven/ Coenen 2012; Geels 2014; and Jhagroe/Loorbach 2014. This reflexive attention to the diversity of interests and perspectives involved, the choices made and the uncertainties and ambiguities encountered, can be appreciated as a definitive step away from the overly self-assured, elitist critical theory of earlier days.

Finally, there is the question of whether sustainability can be maintained as a firm, foundational and unproblematic normative yardstick. Considering the pluralistic, diversity-oriented turn that can be witnessed, transitions theory is approaching the Foucauldian point at which 'sustainability' is also acknowledged to be a potentially oppressive regime-structure—an unquestioned societal 'grammar' with considerable material implications. In a way, the reification of social problems is counteracted by the analytical attention to shifting and multifaceted problems (see Penna/Geels 2012, for example). Moreover, some of the ANT-inspired work in transitions research seems to part with the 'persistent sustainability problems' (Schuitmaker 2012) as objective grounds for action. On that account, the struggle between different sustainability understandings is precisely what is at issue in transition processes. Still, such radical constructivism may be a reflexive bridge too far for most transitions theorists. The reality of a class of persistent systemic problems can be considered constitutive for transitions theory as such (Rotmans 2006), in the first place.

Moreover, one could also consider how the critical-theoretical toolbox could be perverted into interest-driven climate change scepticism (Latour 2004), i.e. into a theoretical smokescreen that undermines transitions theory. So there may be only a fine line between transitions theory and reflexive governance (Rip 2006), but it is an important line. Transitions theory is in many ways reflexive, but it is also guided by strong engagement and the desire to steer clear of relativism. Transitions theory is quite Habermasian in its normative orientation. However reflexive, it is inclined to consider relativist accounts of critique as distracting and 'quietist' (Habermas 1998; Pel 2014), i.e. as no longer critical for the normative silence on the unsustainable conditions of their time.

In other words, there are clear developments towards a transitions theory that is more critical about its normative assumptions. Still, it tends to remain somewhat less critical about the reality status of the 'persistent problems'. These operate as normative anchors for the proposed strategies for 'regime' change.

19.4 Critical Theoretical Paradoxes (II): Keeping up with Evolution

Critical theory revolves around the understanding that knowledge is shaped by social conditions, and therefore, by their evolution. Still, a recurring internal contradiction has been the very tendency to seek to escape from this predicament, and build a universally valid critical theory that somehow transcends the context in which it is formulated. One of the most well-known examples of this is Marx's universalist understanding of class struggle. In the advanced Western societies, however, the juxtaposition between the labour class and the capitalist class has to a significant extent been surpassed by the emergence of a large middle class and general increases in wealth. Moreover, the class struggle frame has not only become less adequate to the diagnosis of contemporary political economy, it can also be criticized for drawing attention away from other, newly emerging societal issues (Honneth 1991; Rosa 2012). Like 'class struggle', earlier diagnoses of 'mass society' and 'consumer society' have arguably failed to (entirely) keep up with societal evolution. The first has largely been surpassed by societal differentiation, for example, and the second can be considered negligent of global inequality: in contemporary North-South dialogues, it is increasingly acknowledged that consumer society may be some-

thing to critique and remedy in some contexts, whilst remaining a legitimate societal aspiration in others. Moreover, earlier critical theorists have been reproached for staying silent about, and therefore for sustaining, gender and ethnic inequalities (Young 1990). And finally, it is particularly relevant for transitions theory how the critical attention given to societal power relations has often overshadowed the emergence of sustainability challenges. The critical-theoretical paradox is then that the aspirations towards universality did not fortify the critique, but often even diminished the accuracy of the diagnoses. As Foucault liked to demonstrate, the foundational and presumed trans-historical critiques often turned into less than critical mental straightjackets—with oppressing tendencies themselves.

In the face of this struggle with temporality and evolution, transitions theory seems much better equipped than its predecessors (if only through the benefit of hindsight). An often-cited and telling example is the account of evolving mobility problems: the current automobility system, with its greenhouse gas emissions and other system pathologies, may be considered an unsustainable regime in need of transformation. Still, there is the transition-theoretical awareness that the era of the horse-drawn carriage wasn't ideal either. The associated pollution from horse excrement and the traffic dangers were no less persistent problems (Geels 2005b). Thanks to these technological-historical accounts, transitions theory is equipped with a strong awareness that systems, their pathologies and also the underlying ways of diagnosis evolve. Its critical contents also speak from the nuanced phrasing of regimes being *no longer* sustainable (Rotmans 2006). This avoids the pitfall of hypostasis, i.e. of maintaining critiques of systems that have transformed in the meantime. Next to the history of technology, transitions theory owes its relatively advanced understanding of system dynamics to evolutionary economics, *science and technology studies* (STS), neo-institutional theory and insights on *complex adaptive systems* (CAS). The very notion of a 'regime' implies a dynamic, evolutionary understanding of dominant systems, which crucially bypasses any reification of 'the system'. Similarly, CAS theory helps articulate how systems can be solid *and* adaptive, or 'dynamically stable' (Geels/Schot 2007; Grin/Rotmans/Schot 2010). Moreover, it offers a world view of nested and co-evolving systems, which allows for accordingly layered, differentiated and therefore *nuanced* diagnoses and remedies.

Notwithstanding these impressive theoretical resources, there is still intense debate about the transition-theoretical capacity to keep up with evolution. The debate on the different types of transition pathways (Geels/Schot 2007) is ongoing, there have been moves towards the analysis of multiple niches and regimes (Schot/Geels 2008; Raven/Verbong 2007, 2009), and there have been systematic comparisons and syntheses between the frameworks for sociotechnical and socio-ecological transitions and technological innovation systems (van der Brugge/van Raak 2007; Smith/Stirling 2010; Westley/Olssen/Folke et al. 2012). Alongside this, there are the advances in the modelling of system dynamics (e.g. Haxeltine et al. 2008; De Haan 2010). The sheer volume of work performed in that area brings out how transitions theory strongly taps into formal methods and systems science. More generally, one can consider how the combined work on the *multilevel perspective* (MLP), *strategic niche management* (SNM), *technological innovation systems* (TIS), *transition management* (TM), and *socioecological systems theory* (SES) is developing towards a transitions science, and towards a management of transitions that is thoroughly underpinned by scientific insight. Like Marx's attempts to underpin his critical theory with science-based 'laws of capital', these predominantly functionalistic approaches indicate how transitions theory is generally intended as a scientific approach to the diagnosis of systemic problems.

Arguably, the developments towards a transitions science described above do significant work in helping transitions theory to keep up with evolution. In this respect transitions theory diverges somewhat from the humanities orientation of much earlier critical theory. What is more, the very tendencies towards transitions science go against the frequent critical-theoretical charges against positivist 'scientism', which was mistrusted for its altogether system-reproducing tendencies. In that respect, it should be mentioned that there are also transition-theoretical advances that do not so much seek to solidify the accounts of system evolution, but rather take direct issue with transition-theoretical aspirations towards universality. ANT-inspired scholars continue to challenge the tendency to reify systems and the associated diagnoses of pathologies (Maassen 2012; Jørgensen 2012; Hodson/Marvin 2012; Chilvers/Longhurst 2013), stressing the dynamic and fluid character of systemic structures. Especially relevant in this regard is the trend that has recently emerged towards geographical concreteness and differentiation (Coenen/Benneworth/Truffer

2012; Raven/Schot/Berkhout 2012; Späth/Rohracher 2012; Eshuis et al. 2012). This rapidly expanding field of research takes into account that transitions theory has been very much shaped by the (North-)Western European context in which it was initially developed, and deliberately takes it to other places and spaces. This particular transition-theoretical development can be appreciated as a direct response to the above paradox: transitions theory is acknowledged to be a situated type of knowledge.

19.5   Critical Theoretical Paradoxes (III): Balancing Lock-in and Lock-out

As has become clear already, critical theory has faced many profound counter-arguments that have seriously compromised this project of research-driven emancipation. Another often-heard objection is simply that it is so depressing. The eloquent and compelling accounts of systematic oppression, inert systems and counter-productive resistance tend to dash all hopes of remedies—an issue taken up in Ernst Bloch's 'Principle of Hope', and more recently in Unger (1987). The latter especially has focused on a paradox that critical theorists have painstakingly sought to deal with: if social structures are indeed decisive for the formation of thought and action, there can be no independent position from which to articulate a critique that challenges them. Conversely, all too bright perspectives on transformation cast doubt on the underlying societal diagnoses, which apparently have underestimated conditions of system lock-in. This transformation paradox has been a recurring theme in the Habermas versus Foucault debate (Kelly 1998; Honneth 1991, 1996). More generally, the difficulty of developing a balanced perspective on both system lock-in and system lock-out continues to challenge the various practical attempts at transformation: should transformation come from a 'march through the institutions', or through revolutionary action from outsiders? Is transformation possible in the first place? Or does a proper analysis of the state of affairs rather warrant resignation, ironical distance or cautiously reflexive action?

This third paradox is of course very familiar to transitions theory. It indicates the notorious structure-agency debate, for which transitions theory has developed and assembled its own tools. Regarding the paradox, Geels (2005a) has formulated quite clearly the idea that transitions theory is set to articulate both

system lock-in and its inverse of lock-out. He acknowledges this to be a particularly challenging task, as the two tend to be split over different disciplines. Hence the elaborate theoretical construct of the Multilevel Perspective on transitions, which draws on several bodies of knowledge to achieve the desired balance. Compared with earlier critical theory, this synthesis has several features that leave transitions theory better prepared to deal with the above-stated transformation paradox: regimes are dynamically stable but not deterministic, niches are not complete outsiders in opposition to systemic structures but also co-constitutive of sociotechnical systems, and the addition of the landscape level constitutes a changing background rather than a deterministic force. Crucially, landscape factors are considered to be developments that intermittently open and close windows of opportunity. The latter alone is a significant reframing of the traditional dichotomous framing of power relations, in which revolutionaries are pitted against the 'system'. As discussed in the previous section, this dynamic, CAS-based representation of regimes beats earlier critical-theoretical accounts of monolithic and inert systems.

Not surprisingly however, the MLP synthesis has been and continues to be subject to discussion. As Geels (2010) indicated, this is a matter of maintaining the critical contents of transitions theory. The MLP cannot be a 'truth machine', he explains (see also Genus/Coles 2008; Smith/Voß/Grin 2010), as it constitutes a synthesis of different perspectives on transitions that depart from diverging, and possibly even incommensurable, paradigms. This emphatically critical contribution to transitions studies, raising attention to the diversity of its underpinning theories, clarifies much of the continuous debate on the balance between lock-in and lock-out.

First, it draws attention to the striking fact that transitions theory is a form of critical theory that goes without, and even inverts, the pessimistic, dystopian undertone that is traditional in the genre. In fact, there have been critiques of the great confidence in emerging niches as sources of transformation from the very beginning (Berkhout/Smith/Stirling 2004; Schot/Geels 2008). Second, this draws attention to the divide between 'global' and 'local' models of transitions (Geels 2010). Even when these types of transitions theory share the dynamic understanding of structure-agency relations, the first typically emphasizes structure and the second agency. This has spawned various attempts at theoretical integration and cross-fertilization, such as practice theory (Seyfang/Haxeltine 2012; Hargreaves Haxeltine/Long-

hurst 2011; see earlier Shove (2004) and ANT (Maassen 2012; Pel 2012a; Jørgensen 2012). Third, there have been various developments towards more dynamic representations of the levels distinguished: dynamic niche-regime interactions and translation processes between the two (Smith 2007; Raven/Verbong/ Schilpzand et al. 2011), alternative perspectives on the exogenous status of the societal 'landscape' (Avelino 2011; Riddell/Westley 2013), the phenomenon of active regime resistance (Geels 2014; Hess 2014); and the equally easily forgotten transformation potentials of endogenous regime renewal (Wells/Nieuwenhuis 2012).

Finally, the structure-agency debate within transitions studies has received a new impulse that relates directly to its often implicit inclination towards innovation. Indeed, this orientation may silently introduce an optimistic view on the scope for agency and change, even when the inertias of regime structures are acknowledged. Shove (2012) therefore argues that the 'shadowy side' of innovation, i.e. its relapse into earlier system states, merits more analytical attention. Similarly, Turnheim and Geels (2013) have turned transition-theoretical attention towards processes of discontinuation—the darker side of creative destruction that is easily forgotten in transitions idealism. These attempts in particular to balance innovation and decline can be appreciated as impulses towards a more emphatically critical transitions theory. After all, they question the unwarranted embraces of innovation which transitions theory may share with the societal conditions that it is set to diagnose.

19.6 Conclusion: Critical Approaches to Transitions Theory

Through these three confrontations with critical-theoretical paradoxes, the notion of 'critical approaches' to transitions theory has been clarified. In this conclusion, the two research questions can be answered: *What are the critical contents of transitions theory? And considering the suggestion that these have somehow become lost, how can they be retained and developed further?*

As regards the first question, we can conclude that transitions theory is particularly well-equipped to deal with the critical-theoretical paradoxes of 'keeping up with evolution' (19.4) and 'balancing lock-in and lock-out' (19.5). This can largely be attributed to the various dynamic, evolutionary perspectives and associated bodies of knowledge that have been assembled in the

different transition-theoretical strands. Many of these resources were not available to the earlier critical theorists, who also tended to uphold rather crude understandings of systems compared to the transition-theoretical differentiation between sociotechnical subsystems. On the other hand, transitions theory is less convincingly critical regarding the 'normative foundations' paradox (19.3). Definite advances in this respect have been made already, such as a greater attention to the politics of transitions and the methodological shift towards transitions-in-the-making. Still, much of the critical questioning remains hidden under the presumed self-evidence of persistent sustainability challenges, and the objectivity of the 'regime' structures to which these challenges are traced. This apparent relapse into objectivism and ivory tower critiques, and the more general negligence of the normative assumptions underlying transitions diagnoses and remedies, seems to be the flip side of the aspiration towards transitions science. In this process of fortification and scientization, transitions theory is somewhat uprooted from its origins in the humanities.

Regarding the second question, there are nevertheless considerable developments towards a more emphatically critical transitions theory. A great many recent advances can be witnessed that take direct issue with the paradoxes discussed: in order to keep up with evolution, not only new systemic problems but also new diagnostics are being explored. Moreover, the transition-theoretical critique is increasingly acknowledged to be situated, as the thrusts towards geographical differentiation nicely illustrate. Furthermore, the transformation paradoxes around lock-in seem to be more and more acknowledged as inevitable, and as permanent challenges to transitions theory. In this regard it is telling how the transitions research community manages to reconcile numerous disciplinary backgrounds, and how there is a general awareness of the different perspectives and theoretical assumptions at play. Finally, even when transitions theory is mainly critical in terms of 'regime' analysis, there is the self-examination that helps avoid overconfident and one-sided critique. Reflecting on ontological assumptions, and also the recent confrontations of its 'innovation-bias', can be appreciated as thrusts towards self-critical transitions theory. Interestingly, many cases of the refinements discussed can even be traced to earlier critical-theoretical discussions. We could consider, for example, how ANT scholars bring in distinctly postmodernist-Foucauldian perspectives to counter a 'transitions science' that is too confident about its systems diagnoses. Likewise, the many

efforts to provide transitions theory with a stronger scientific underpinning reflect how it is a distinctly modernist kind of critical theory—more in the spirit of Marx and Habermas than of Adorno and Foucault. Meanwhile, there is the work that develops transitions theory as a kind of reflexive modernization, which could be considered a third, intermediate position. All in all abundant advances are being made towards retaining the critical contents of transitions theory, and these can be seen to constitute different modes of critique.

Finally, we can consider whether transitions theory will develop in greater or lesser continuity with its critical predecessors. As discussed, there are clear developments towards an emphatically critical transitions theory. On the other hand, there is also the trend towards transitions science that rather drives transitions theory away from the generally more reflective, humanities-driven critical theory. In their turn, these opposite trends remind us of other differences between transitions theory and critical theory. They remind us that transitions theory is also more practical in its outlook, more future-oriented and more professionalized than most of its critical predecessors.

In these respects it goes beyond the largely deconstructive diagnostics (Avelino 2011) of its predecessors, or is at least very different from such awareness-raising activity. The existence of repertoires such as transition management, strategic niche management and the technological innovation systems framework shows how transitions theory is strongly dedicated to the development of remedies (Pel 2014). Interestingly, this very instrumental quality seems to account for at least part of its current institutionalization. Typically, such mainstreaming was treated with suspicion by most critical theorists, who had a sixth sense for the ensuing 'capture' (Voß/Smith/Grin 2009) and neutralization of critique. On the other hand, the instrumental attitude of transitions theory could also be considered very much in line with the critical theoretical project, in as far as it continues to aim for engaged research. In other words, transitions theory is likely to continue the critical-theoretical project, but only in some of its aspects. Yet however it may develop, the critical-theoretical legacy could come in useful: it reminds us that transitions theory too is shaped by the prevailing social conditions of its time.

20 Subnational, Inter-scalar Dynamics: The Differentiated Geographies of Governing Low Carbon Transitions— With Examples from the UK

Mike Hodson[1], Simon Marvin[2] and Philipp Späth[3]

Abstract

This chapter aims to improve our analytical understanding of low carbon transitions at and in between multiple geographical scales, particularly 'below' a national level. Taking the Multilevel Perspective (MLP) as our starting point we show that it offers tools for thinking through the institutional and technological conditions and rules through which regimes reproduce or change over time. But it is not very well equipped to study transitional dynamics as they unfold in space. This chapter sets out a range of levels on a spatial scale and activities that are relevant to transition activity but with which the MLP so far engages only partially. The chapter explicitly identifies very different, yet coexisting, scales of transition activity which aim at low carbon transitions in the UK. It demonstrates the possibilities of attributing particular transition activities with different spaces and levels on a geographical scale and highlights the dynamics between these scaled activities. It does this to open up debate about the 'appropriate' mechanisms for dialogue 'between' governance levels and differently scaled transition activities.

Keywords: Geography of transitions; low carbon transitions; sustainability transitions; multilevel perspective (MLP); scaling; multilevel governance; subnational climate policy; United Kingdom; urban governance.

20.1 Introduction

This chapter aims to improve our analytical understanding of low carbon transitions at and in between multiple geographical scales, particularly 'below' a national level. Activities that contribute to a transition, whether that is in electricity systems, heat and buildings, mobility systems, food systems or whatever have effects of different spatial reach, and are connected with a wide range of socially constructed spaces. From our geographical perspective, it is important to acknowledge that both spaces (e.g. cities, regions, neighbourhoods) and scales (the city scale, the regional scale) are continually being made, negotiated and remade.

One very prominent approach to understanding sustainability or low carbon transitions, and more generally to explain stability and change in sociotechnical systems like energy, mobility and so on is the so-called *multilevel perspective* (MLP). This approach provides an important heuristic by distinguishing three levels of structuration (niche, regime, landscape) and paying attention to ways in which dynamics at these distinct levels interconnect (Geels 2002; Geels/Schot 2007; Smith/Stirling/Berkhout 2005; Verbong/Geels 2010), Through the interrelated concepts of niche, regime and landscape the MLP has worked to bring together the ways in which sociotechnical systems are organized and relatively stabilized but also change gradually and more radically. Potential for agency and change is located mostly in relatively fluid 'sociotechnical niches', while the particularly long-lasting and more structural elements are attributed to the 'landscape level'. The regimes are located at an intermediary level

---

3   Dr. Philipp Späth, Assistant Professor at Freiburg University; email: <spaeth@envgov.uni-freiburg.de>.

of 'structuration'. The value of the MLP is that it offers tools for thinking through the institutional and technological conditions and rules through which regimes reproduce or change over time. It also offers insights into how regimes are reconfigured a) through internal pressures; b) as a response to broader exogenous landscape pressures; and c) through the development of sociotechnical niches of protected spaces. In doing this it allows us to assess transition dynamics and activities which aim to bring about radical or incremental systemic change. While focusing on levels of structuration and developments over time, the MLP so far has not been very well equipped to study transitional dynamics as they unfold in space, i.e. in particular places and at different levels of spatial reach (Raven/Schot/Berkhout 2012).

This chapter sets out a range of levels on a spatial scale and activities that are relevant to transition activity but with which the MLP so far engages only partially. The chapter explicitly identifies very different, yet coexisting, scales of transition activity which aim at low carbon transitions in the UK. There are two contributions in particular that the chapter makes: (1) it highlights the possibilities of attributing particular transition activities with different spaces and levels on a geographical scale, and considers the links between transition activities and spatial attributes not to be eternally fixed properties but to be constructed and contestable; and (2) it highlights the dynamics between these scaled activities and sets out the need to undertake further work to refine understanding of these dynamics, as well as the intermediary activities that operate in particular between governance levels. It does this to open up debate about the 'appropriate' mechanisms for dialogue 'between' governance levels and differently scaled transition activities.

Taking the multilevel perspective as our departure point, we engage with transition activities of different 'scaling'. We illustrate this through sections on: national political-economic configurations; urban transition; 'hyper-local' transition activity; and—as a cross-cutting issue—the role of intermediary spaces in coordinating transition activity across different scales. The chapter sets out a need for mechanisms and relationships for negotiating and coordinating activities across transition scales and governance levels. It is not intended to be totalizing in its approach but to address key issues in relation to scale. We do this because many transitions are possible. There are many ways of organizing transition activity and many scales of action—hence there is a need to understand them, their organiza-

tion, their implications and their possible points of interconnection.

The chapter is organized in six sections. In section 20.2 we review some key concepts of the MLP and the role of geography in it and how a renewed round of globalization in the last four decades has resulted in a more differentiated multilevel governance. The next three sections (20.3–20.5) identify the role of the 'national', the 'urban' and then the 'hyper-local' transition activities. Section 20.6 concludes with a synthesis of the argument and discusses the implications for future research.

20.2   The Role of Scaling in Transition Activities: Complementing the MLP

Globally the issues of climate change, resource constraints and economic crises have raised critical questions about how to respond to ecological and resource constraints. It is clear that responding to these issues requires a significant and 'systemic' transformation in energy, mobility, water, waste and other systems.

However, when it comes to specifying the extent to which systems have to be transformed, the direction of such transformations and how a transition could or should unfold, people tend to have different views. The nature of responses that are to be mobilized and in particular the scale at which responses are constructed naturally reflect different views of the nature and scaling of the problems to be addressed. There is a significant issue, therefore, that needs addressing: in system transition, how do practitioners and we as analysts understand the interplay of transition activities of different scale and in different spaces of activity? We need to ask: to what extent are the objectives, motivations and priorities of differently scaled transition activities congruent, and to what extent do they contradict each other? Are (for example) national priorities around carbon emissions reduction and the promotion of green growth compatible with local priorities of more local democracy or more localized and decentralized energy systems, and does this match well with wider public and householder views of comfort, convenience and reducing bills?

The MLP has developed three key concepts: landscape, regime and niche. These have been discussed and described in detail elsewhere (Geels 2002; Geels/ Schot 2007). Here, we note that understanding sociotechnical transitions means recognizing their non-line-

arity, the constitution of regimes, which are comprised of heterogeneous elements (contexts of rules, established practices and stability) just as niches are (sites of radical innovation), and exogenous landscape pressures and the interplay of these different levels.

Analysis of regimes requires understanding their configurations of technology, culture, science and political and institutional interests. Understanding configurations of regimes provides insight into the reproduction and possible frictions or pressures and hence points of regime transformation. The concept of landscape allows us to link exogenous political, ideological, economic and ecological pressures to regime stabilization, reconfiguration or substitutability.

Pressures can also emerge from niches that are intentionally created as 'protected spaces' in order to experiment with and grow alternative sociotechnical configurations. Such niche activities can be but not necessarily are responses to landscape pressures and may aim to put pressure on different regimes in more or less strategic ways. Processes of experimental configuration, strategy and learning are important to niche construction as is the extent to which niches generate momentum and, from this, the relationship of niches to regimes.

Most empirical analyses of transition processes, however, define the system under transformation—hence their entity of study—with reference to national boundaries (e.g. the Dutch or Danish electricity systems; see Markard/Raven/Truffer 2012). This widespread methodological nationalism has deprived Transition Studies of some of its conceptual richness.

But recently, there has been a developing body of work which addresses, for example, the urban and regional geographies of transition and questions of scale and space explicitly (Hodson/Marvin 2010; Bulkeley/Castan-Broto/Hodson/Marvin 2011; Coenen/Truffer 2012; Geel, 2010; Rohracher/Spaeth 2014, Spaeth/Rohracher 2010, 2014; Raven/Schot/Berkhout 2012).

Since around 2009, many geographers, urbanists and some scholars of Transitions and Science and Technology Studies (STS) have constructively engaged with the MLP to add some spatial sensitivity. In their work, they shed light on many scales and spaces of transitions activity that potentially contribute to processes of transition. We are convinced that the MLP provides very important inroads to understanding the stability and dynamics of sociotechnical systems and that it can be improved to also reflect the spatiality of transitions. We therefore engage with its key concepts and try to develop an understanding of how scales

interrelate and are constructed. The MLP, we conclude, would benefit particularly from a geographical and programmatic view on scale, governance and organization. In the following sections we set out different national, urban and hyper-local scales of transitions activities. We do this in terms of a selective set of issues and to highlight the critical point of this chapter which is the need to build effective mechanisms for dialogue and exchange between scales in transition activities.

20.3 The Scaling of Transition Activities in Systems of Multilevel Governance

Concurrent transition activities differ in their spatial reach and relate to very different governance levels. Despite the great importance that national territories and related legislative frameworks still have today, it is not satisfactory to focus our analysis just on nationally defined activities. There are particular reasons to relocate the 'national' in transition activity since the development of a new phase of globalization since the 1970s, when the role of the national state as a Keynesian, welfarist guarantor of mixed social democratic economies and as being necessary for redistributing and ameliorating capitalism's more inequitable impacts was challenged. The state now was seen rather as impeding the effective operation of markets.

Related to this shift, various new modes of governance emerged as national states, to varying degrees, were themselves meant to promote the benefits of privatization, liberalization, competition and markets; responsibilities were relocated 'upwards' to global and supranational bodies moved 'horizontally' to non-state organizations e.g. by contracting out, and 'downwards' through devolutions and/or decentralizations. This in fact often strengthened the authoritarian functions of the national state (Gamble, 1994). However, it also opened up the field of governing to a much wider array of actors and scales. Cultures of governing became organizationally fragmented within and across multiple scales. This also enabled the definition of an array of 'low carbon' scales and spaces and initiated a struggle over their cognitive, regulative and normative formation.

Particularly when considering the significant challenges posed by climate change, resource constraints and economic crises, many people wish there were the capacity and capability to develop effective action on transitions and in that context to coordinate

action across governance levels (Hodson/Marvin 2013). Low carbon transition will probably unfold, if at all, through mutually supportive activities at different scales and in many spatial configurations. Important scales and arenas for negotiations about decarbonization activities are not pre-given but are, as we will show, the result of very dynamic processes of scaling and contestation. There is also contestability and negotiation between differently scaled actors in the construction of low carbon spaces. For the MLP to really help us as a heuristic in understanding transitions and how they unfold, we need to think through different scales and how they relate to the basic categories of the MLP. In the following, we characterize four scalar responses in relation to low carbon transitions activity in the UK, beginning with national low carbon strategies.

20.3.1 National Low Carbon Strategy and Institutional Configurations

As briefly discussed above, the national scale has been very important in the delineation of regime contexts of most transition studies undertaken in the past. In addition, the MLP is often—but not always—applied to national systems and regimes and focuses on the nationwide creation of conditions for niches. What in fact is important here are the ways in which national institutions, particularly in the economic realm, set the parameters and priorities of what low carbon transition will entail. Institutions at a national level transform wider-landscape economic, ecological and political pressures into policies and, through their historically generated priorities, set conditions that enable, favour or disenable particular forms of low carbon activity at other levels, mostly through economic priorities, standards and regulation. This focus on economic priorities and institutions at a national level allows us to link the concept of landscape from the MLP with low carbon transition activities in the sense that it contextualizes landscape pressures in relation to national low carbon political-economic institutional frameworks. Institutional configurations, in this way, are both producers and responders at the national level. They are the historically specific institutional conditions which shape the parameters of systems' adapting.

A key issue is how national institutions condition regime and niche activities. They have significantly modified the way in which, for example, offshore wind has developed in the UK or likewise why battery vehicles, congestion charging and road pricing, domestic

retrofit, and new grid technologies are developing in the ways that they are by promoting and mobilizing particular policies, skills, finance, research, etc.

We hence need to study influential governance mechanisms with regard to (a) the coordination of national institutions with each other, (b) direct ways in which national institutions influence the reshaping of particular regimes and niches, and (c) importantly, how other scalar activities are shaped by national institutions and vice versa. This is important because it tells us something about the ways in which particular institutional configurations (coordinated in, for example, interventionist or market-oriented ways) and histories condition particular regimes and niches but also other scalar activities and the sorts of strategies that are generated through these configurations.

This poses two challenges: in order to understand institutional interrelationships and the ways in which they condition particular approaches to transition, we need to analyse their different cognitive, regulative and normative dimensions (Scott, 2008); longitudinal approaches can address the dynamics and relationships of these configurations. Institutions are often seen as being about reproduction and stability, but it is both this and their transformative potential that we are interested in for transitions and the types of institutional innovations that may be required and that actors may be experimenting with.

Such a conceptualization of institutions allows us to analyse the role of particular institutions in transitions but also the sorts of changes in institutional configurations that are necessary for effective transition activity. This means it is important to understand the mechanisms, resources and instruments through which institutional configurations are 'internally' lubricated. In terms of coordination, what is important is what type of state approach there is to low carbon (here taking the example of the UK and low carbon): a state-coordinated approach or one that promotes more market and less state

Therefore it is key to ask: how does 'the state' at the national level predominantly develop and operationalize low carbon policy/priorities? Which (legacies of) rules are involved in this and how? To what extent is this (for example) an economic agenda? What forms of organization are important in this? In terms of an analytical framework there needs to be a bringing together of three things: elements, modes and orders of governing. Loosely following Kooiman (2003), we ask:

1. *How is national low carbon governance problematized, responded to and acted upon?*—that is, the

framing of problems, strategies, visions, instruments and actions.

2. *What is the national institutional context of low carbon activities?*—that is, the governance of interactions between different national institutions of relevance to low carbon actions.

3. *What norms and principles shape ways of governing themselves?*—that is, the predominant ways of achieving political objectives, through, for example, markets and hierarchies.

20.3.2   UK Low Carbon Problem/Response

The significance of the 2008 UK Climate Change Act was in its positioning of the UK as the first country in the world to have a legally binding framework for cutting carbon emissions. The UK state is playing a central role in setting out the boundaries that will shape the parameters of low carbon futures. Key to this is the development of new forms of carbon accounting and their translation into sectoral and territorially based carbon reduction targets.

The dominant approach to implementation in many low carbon plans in the UK has been to prioritize low carbon technology-based responses (see Committee on Climate Change 2010; Skea/Ekins/Winskel 2011). This has produced a range of strategies that set out the technological options and possibilities—in the form of pathways or scenarios—to a specified time in the future, whether that is for example 2025 or 2050. In the case of national reports (Committee on Climate Change 2010), the issue that is addressed through technology pathways is how UK emissions reduction targets can be reduced and the economic costs and opportunities of different options. Often this means that technology-based responses are better understood as techno-economic responses.

These responses have produced a UK agenda which promotes a range of market-based technology-led responses including: the marketized construction of new offshore wind production systems; the promotion of low carbon vehicles and associated infrastructures; a market-based mechanism, the Green Deal, for retrofitting the UK's housing stock; and the reconfiguration of the electricity grid to facilitate and be compliant with these and other new forms of electricity generation and consumption (Hodson/Marvin 2013).

20.3.3   UK Low Carbon Institutional Configurations

Technology-focused approaches to low carbon futures have much to say about the technological possibilities and economic costs of different low carbon pathways and scenarios. This then leads to certain sectors and specialisms being promoted, for example the development of UK offshore wind capacity and capability. The UK is favourably positioned to develop offshore wind capacity and capability given the shallow water depth and consistent high wind speeds around a significant area of its coast. The Crown Estate has, in recent years, begun to shift from a relatively benign role in managing the marine estate. In doing this it has moved to playing a more active role which marries the technological possibilities afforded by the UK's position with a shifting view of its role as a sustainable manager of the marine estate that considers economic possibilities as well as environmental and social considerations. Its development planning is explicitly orientated around meeting UK targets.

In doing this the Crown Estate, working closely with UK government departments, has designated leases for offshore wind farms in three rounds from 2000. A third round of development (announced in December 2007) is estimated at between three and five times the scale of the first two rounds combined and involves the development of nine zones off the coast of the UK. This is part of a national government attempt to position the UK as a 'leader' in this field and to potentially create the world's largest offshore wind *market*. The zones are widely drawn, where the developer, chosen through competition, can develop in the parts of the zone they consider to be most fruitful. The process of development is long-term (up to four years) and requires addressing and developing an effective response to a wide range of issues. These include constructing supply chains in relation to skills, infrastructure installation, manufacturing and component supply, and so on. This has particular geographies to it related to those areas of coastline encountering beneficial wind speed and water depth, but also to the adjacent, land-based existing R&D capacity and capability.

The story here is one where there is a primacy of market-making with a secondary role for industrial interventionism. The making of offshore wind markets is based on a developing configuration of government targets and zoning, a shifting role for the Crown Estate from benign manager to active market-maker, encouraging investors and developers but on the basis

of a pre-existing culture of light touch regulation propounded through pre-existing regulatory structures. Industrial interventionism is thus largely seen as a means of creating the supply chains required in supporting the making of markets (Hodson/Marvin 2013).

The financing of low carbon futures is being constructed through experimentation that is designed to create a stable 'regime' of low carbon financing. These experiments involve attempts to develop new policy instruments, forms of financial products and innovation and new institutions, and they often and primarily involve policy and private sector interests although they do extend beyond this. The levels of investment are huge, with around £200 billion investment in the energy system alone by 2020 estimated to be required. This of course ignores investment required post-2020, investment needed in other utility networks such as water, waste and transport, and also investment in adapting to climate change through the building of defences and relocation (Vivid Economics, 2011).

20.3.4   Norms and Principles of Governing

Within this dominant market-making response the focus of discussion and action in political and policy terms concerns low carbon economies and technologies to the notable neglect of low carbon societies. The assumed techno-economic benefits of low carbon economies are laid out, celebrated and presented as the dominant 'solutions'. These solutions claim to offer not only 'new', accelerated forms of economic growth but also secure 'clean' resource flows necessary literally to power growth and—so the claim goes—to reduce human impact on global ecological change. In short, techno-economic 'low carbon market solutions' underpin and facilitate claims of widespread economic and ecological transformation to society.

This appears to add up to efforts to construct low carbon Britain as a market opportunity, where the role of the state is to govern the imposition of a low carbon transition through the preparation of subnational territories for low carbon accumulation, based on a notion of transition largely constituted by political, regulatory and business elites (Hodson and Marvin, 2013). The emerging dominant transition pathway is as an economic strategy designed to provide a context for another wave of growth-orientated development. This is a profoundly conservative and limited approach dressed within a transformational rhetoric of challenging targets, new possibilities and economic opportunity. Exclusive sets of techno-economic inter-

ests are preparing Britain for a narrowly conceived low carbon economic transition.

20.4   Urban Transition

A key issue is the extent to which these nationally defined problems, responses and institutional configurations also shape subnational transition activities. Here we examine the question: what is the role of the urban in transitions? In recent years there has been an increasing engagement with this question from the perspective of urban studies (Hodson/Marvin 2010; Bulkeley/Castan-Broto/Hodson/Marvin 2011), social studies of technology (Rohracher/Spaeth 2014), and those central to the development of the MLP (Geels 2010).

There are many ways in which transitional activities framed in national orders can interact with those framed in urban orders of governance (Späth/Rohracher 2012). Here, we are particularly interested in two typical ways in which institutional configurations at a national scale inform urban framings of problems, responses and actions. Key to understanding the role of the urban in transition is whether the urban is a site for the cascading down of national transition activity—through niche activities or efforts to reconfigure regimes—or whether urban orders of governing are mobilized to develop distinctly urban responses. In order to illustrate such dynamics between national and urban orders of governance, we now take one metropolitan area—Greater Manchester— into focus and one critical sector of transition: the energy efficiency of the built environment.

20.4.1   Retrofit as Urban Economic Competition

The dominant representation of retrofit in Greater Manchester positions the city-region externally as a low carbon first mover to attract inward investment. Underpinning this is a logic of low carbon 'entrepreneurialism' and a focus on the economic opportunities and benefits this affords. In one estimate, effectively addressing climate change in the city-region over the five-year period of Greater Manchester being a Low Carbon Economic Area could contribute to saving six million tonnes of CO_2, create or support 34,800 jobs, and be a demonstrable exemplar for the wider region and for the UK. This broad view is promoted by a number of plans and strategy documents from the Mini-Stern to the Sustainable Energy Action

Plan and the *Low Carbon Economic Area* (LCEA) for the Built Environment.

Greater Manchester plans for a retrofitting agenda are set out in the draft *Greater Manchester Low Carbon Housing Retrofit Strategy* (LCHRS) published in 2011. Retrofitting is viewed as an emissions reduction strategy in relation to Greater Manchester's carbon reduction emissions targets in a broader national context. It is also seen as a way of achieving 'first mover' economic status and positioning Greater Manchester as leader in an emerging UK retrofit market. In doing so the development of a retrofit agenda is seen as a way to attract private investment to the city-region. Retrofit is therefore being positioned as being about green growth, about job creation, skills development and product innovation. In following this narrative, Greater Manchester is positioned as a "national testbed"—a means of aligning with national retrofit programmes such as the Green Deal, implementing national programmes, and doing so to achieve national standards such as Energy Performance Certificate (EPC) ratings and to access associated national resources and subsidies such as through the *Feed-in Tariff* (FiT), *Renewable Heat Incentive* (RHI) and the *Energy Company Obligation* (ECO). With this in mind, retrofit is seen as requiring the demonstration of tangible products such as large-scale technologies, the reconfiguration of show houses and exemplar properties.

In addition to these dominant narratives of retrofit there is also a view that retrofit can address fuel poverty and improve well-being through improving existing homes, streets and neighbourhoods and the effectiveness and efficiency of the existing building stock; and that it also requires forms of behavioural change. The dominant message of retrofit in Greater Manchester is that it is about the making of new markets, that is it is about governing Greater Manchester to make it amenable to the market opportunities afforded by retrofit.

20.4.2 Urban Institutions and Governance in Making Urban Retrofit Markets

Greater Manchester's formal low carbon response has been configured through institutions that have developed a view of Greater Manchester over the last two decades as an 'entrepreneurial' metropolitan area. This seeks to position the city-region in ways that are favourable to testing the feasibility of national priorities and to attracting inward investment.

The dominant response in Greater Manchester has involved rebundling the types and sites of retrofit buildings through a threefold hierarchy of responses that involves prioritizing: (1) improving the built fabric of homes through measures such as insulation, glazing and airtightness and also of improving appliances and fittings within buildings such as lighting; (2) more 'carbon literate' home owners, involving the monitoring of energy in homes and the installation of switches; and then (3) filling any energy gap with investment in new forms of renewable energy generation. This hierarchy has been developed as a framework for addressing the application of Basic, Intermediate and Whole House bundles of retrofit measures to different 'types' of owner-occupied and privately rented households.

This packaging of retrofit measures raises the issue of where the finance for such measures will come from. The Strategy estimates that domestic retrofit in Greater Manchester over a ten-year period could require up to £27 billion of investment. Yet the broader context is one where a long period of austerity governance is likely to predominate in the UK and where public finance to underpin such developments is limited. In this context there are numerous attempts to build relationships between Greater Manchester organizations and providers of finance and investment. The Low Carbon Housing Retrofit Strategy outlines potential sources of raising finance that includes bond issue, institutional finance, government finance, bank debt, social financing and private equity. But given the limited discretion of city-regional decision-makers in framing standards and obtaining finance there are pressures to incorporate or align with the priorities of the Green Deal and other national programmes such as the *Technology Strategy Board's* (TSB) 'Retrofit for the Future' programme.

20.4.3 Shared and Implicit Understanding of the Urban Governance of Making Markets

Though there are ongoing relationships between national government departments and institutional interests in Greater Manchester it is the shared and often implicit understanding at the level of meta-governance that is important, especially in terms of the primacy of markets, the necessity for market policy instruments, and the need for economic positioning of cities in a competitive race.

This positions the city-region as a receiver of the priorities of the state in a hierarchical relationship that seeks to promote the benefits of markets for

achieving buildings retrofit. This is a way of viewing the relationship between the framing of national low carbon problems, instruments and actions as one where the transition activity is *on* the city-region. Why retrofit is an issue that has been prioritized in Greater Manchester requires an understanding of the changing governance context of Greater Manchester and its dynamics with national government, particularly since the 1970s, and the ways in which this has contributed to shaping contemporary action on retrofit.

Greater Manchester was established in 1974 and operated on the basis of two-tier governing arrangements where the strategic-level Greater Manchester County Council shared power with the ten metropolitan boroughs that constituted it. The Greater Manchester County Council was abolished in 1986 by the Thatcher government and subsequently many powers were devolved back to the ten boroughs while other powers, including transport and emergency services, operated at the metropolitan level. There was also the emergence in the post-1986 landscape of an urban growth coalition within Greater Manchester, which particularly promoted the urban core of the metropolitan area and a series of infrastructure projects and mega-events. Within the metropolitan area there has been a concentration of political and governing power in the hands of agencies and coalitions of political elites and business. This has meant a strategic tier in Greater Manchester that is opaque to the Greater Manchester public, where significant focus is on the urban core. There has been a further step-change in the second half of the 2000s with Greater Manchester being designated a Statutory City-Regional Pilot by the UK government in 2009, and subsequently with the designation and establishment of the Greater Manchester Combined Authority in 2011 constituted by ten (indirectly) elected members of the ten local authorities.

The result of this has been the emergence of a new metropolitan governance at a metropolitan scale but one where the embedded capacity to act is limited, where national priorities remain an important shaper of metropolitan priorities, and where the financial crisis post-2008 has created the conditions for an era of austerity within which efforts to constitute the capacity to shape retrofitting strategies needs to be understood.

20.5   Hyper-Local Transition Activity: Letting a Thousand Flowers Bloom?

In contrast to the dominant market making perspective there are also very many transition activities within urban areas that frame low carbon problems, instruments and actions in very different ways. These frequently mobilize framings of problems that may be about carbon emissions but also may be about a wider set of issues including local democracy, self-sufficiency, empowerment, building local economies and so on. We can characterize these as transitions in rather than on urban areas.

For example, there are many projects and schemes that emanate from neighbourhoods, community groups and settings (Hodson 2014; see also Burrai 2014; Barlow 2014). These may be community energy schemes (hydro, solar, energy efficiency), community food growing schemes, local eco-house exemplars and so on. That is not to say that there is no formal policy involvement—as there may be through, for example, national or city-regional funding schemes—but it is to say that these initiatives are largely developed by neighbourhood or place-based groups, organizations, businesses and collections of individuals to address the motivations of groups of local interests and people embedded in local contexts.

Given this, the motivations for involvement in hyper-local retrofit activities in Greater Manchester include those that seek to: promote economic development through carbon reduction; reduce the carbon footprint of a town, and promote 'sustainability'; and use the retrofit agenda as vehicle for education, outreach and building refurbishment, as part of wider processes of building community engagement.

20.5.1   Building Transitions Activity IN Places Rather Than ON Them

Motivations for local, bottom-up retrofit activity in Greater Manchester are clearly diverse and manifold. What is clear is that these cannot be understood in terms of a singularity. Local retrofit responses take place in a diversity of contexts. The different level of capacities that they can draw upon can be very wide-ranging. This means that some groups are starting out from scratch, some just have a concept, and other groups may have many years of experience. They may also have financial, planning and other forms of expertise that newcomers may not have. Some are small-scale micro-energy generation activities, other

relate to behavioural change initiatives, whilst others still work across energy, food and community resilience at a local scale.

Despite the differences across a range of projects there is often a common view in hyper-local retrofit initiatives about making communities relevant again—this is a view of trying to recover something that has been felt to be lost. In that respect this can often be seen as an antidote to the prevalence of top-down initiatives. Hyper-local retrofit has in many ways been about giving voice to community and empowering them through the development of, for example, renewable energy as a real opportunity for members to shape their own future, not only in a low carbon sense but in an economic sense as well. This means that local retrofit is often about both energy generation and conservation, and the generation of income through micro-generation projects in village halls and community buildings and income generation through larger wind or hydro turbines.

But there are frequently significant development costs with these initiatives. Constraints of capacity can mean that a challenge for local retrofit is tightly limited in resources, and this requires finding new ways of working. This highlights something of the limits to community responses with communities often actively having to cultivate networks of financial and other forms of expertise and knowledge, including national and EU funding and other forms of support including emotional support.

20.5.2 Alternatives to Top-Down Market-Making Governance: Remaking the City in Practice

The meta-governance of these hyper-local activities can be understood as an alternative to dominant, top-down approaches to the governance of urban transition activities. Specifically, drawing on thirty hyper-local retrofit projects in Greater Manchester (Hodson 2014; Hodson/Marvin/Bulkeley 2013; Burrai 2014; Barlow 2014), the following issues are important aspects in understanding the constitution of an alternative approach to governing transition activity in the city.

Rather than a singularity of vision, there are very many attempts to remake the city in practice across a range of diverse sites. To take a few examples: this has meant the transformation of a museum roof into a roof garden, an experiment in lived sustainability in a suburban house, installing a ground-source heat pump in a cathedral, and revitalizing old industrial infrastructures such as canals, reservoirs and railway lines.

This involves changing the use and value of sites from below. These initiatives aim at many different ends, whether generating local energy, growing local food, pooling collective buying power, or building local decision-making structures. These all focus on promotion of forms of localism and people taking ownership of their own energy, food and building services and infrastructures, often in ways that are not driven primarily by a profit imperative. Bottom-up and collective forms of organization are often mobilized. These are often organized in ways that bring together community energy/food generation and community ownership through forms of cooperative organization, Industrial Provident Societies, Community Interest Companies and so on.

Yet many of these organizations also connect with the city and the national levels. In many initiatives national, EU and metropolitan scales remain important. One can see this through the labyrinthine funding relationships that projects have to build. In terms of community energy in Greater Manchester this has often involved UK Department of Energy and Climate Change funding. Community renewables projects have also factored in payments from national government for generating surplus energy (through the Feed-in Tariff) in their business plans. This creates a dynamic between the priorities of community projects and the priorities of national government. There are dangers at either extreme: on the one hand community projects require funding, but on the other hand they also have their own priorities which often differ from national priorities. At one extreme this may result in an inability of community groups to act on their aims and plans while on the other they may become delivery agents for national government. This is not a fixed situation and requires those who lead initiatives to actively work to hold together and negotiate these priorities. This ongoing search for funding creates pressure but it has also resulted in new collaborations and social innovation. This raises issues about the boundedness (Vegragt/Brown 2008) or the degree of protection (Raven/ Smith 2012) of these 'niche' spaces.

20.6   Conclusion

This chapter has set out ways of thinking about different scales in relation to transition and the MLP. In doing this it also demonstrates that processes of transition are multi-scalar, with activities simultaneously occurring at multiple scales. It has done so to illus-

trate the ways in which scalar spatial configurations, and the priorities they mobilize, make contributions to processes of transition. We have shown how transition activities are defined on national, urban, hyperlocal and even smaller scales and where coalitions of interests emerge. Coalitions define spaces in particular ways. A coalition, for example, which is tightly linked to the space of the national state is promoting a view of the primacy of markets in low carbon transitions and the need for effective political coordination of institutions to shape low carbon transitions; And urban contexts are viewed and portrayed by some in a way that turns them into recipients of national transition initiatives, while others emphasize hyper-local experiments in urban contexts that contribute to a very different view of urban transitions.

With this context in mind, the diagram below shows the balance between top-down and bottom-up ways of conceiving transition activity and the degree to which transitions seek to reconfigure both systems and spaces.

There are two different axes to the diagram. The vertical axis is concerned with two conceptions of transition. Transitions 'on' conceives of the transition through more 'top-down' or 'outside-in' processes of, for example, market segmentation based on the public's propensity to engage in different forms of environmentally beneficial action. In this case activity is targeted at activating such behaviours through the transition process. Transition 'in' instead conceives of action as being embedded within particular routines, practices and cultural contexts, resulting more in a bottom-up or inside-out movement.

The horizontal axis is concerned with the role of publics in different forms of change. Spatial configuration is primarily concerned with constructing spatially or contextually embedded priorities for change. These configurations can develop contingent priorities but the responses may be consistent with the low carbon transition, or they can potentially develop competing imaginaries of transition. System configuration is primarily concerned with the purposive vision of low carbon transitions and with ensuring that the public complies in playing their role as a delivery mechanism by adopting the new roles assigned to users.

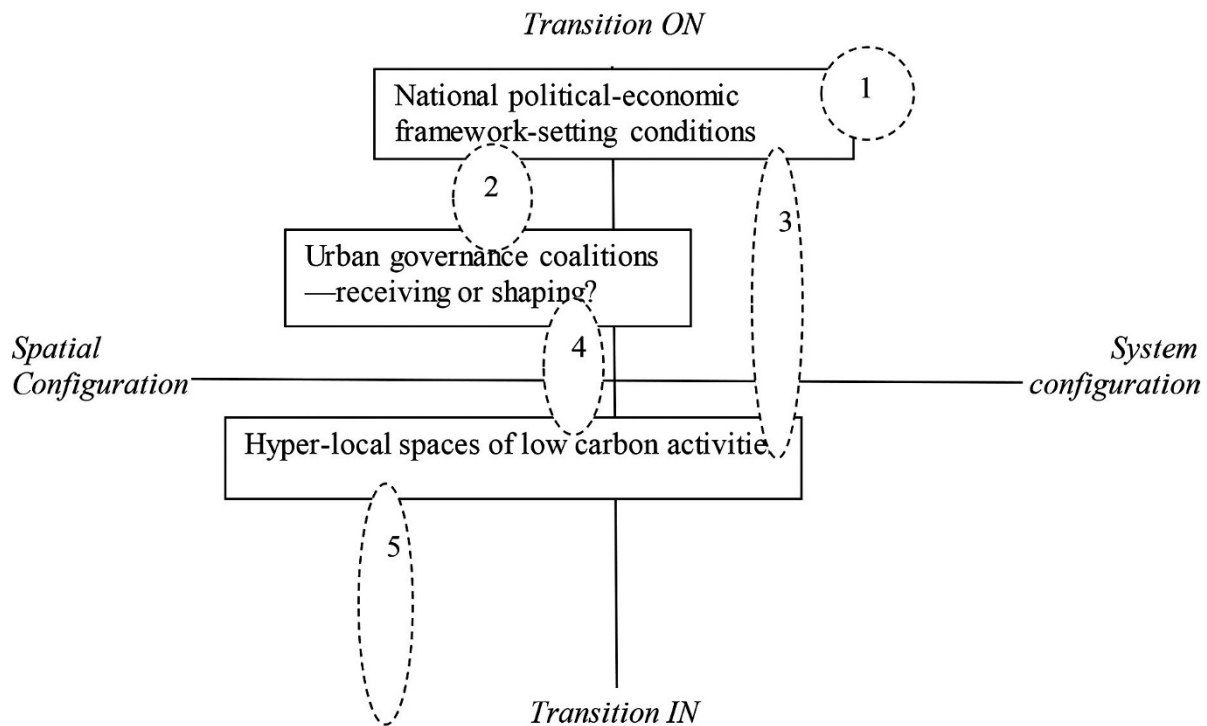
The loci that we highlight in this two-dimensional space may be seen to represent 'ideal types' of the scalar issues discussed above, but most importantly they show us that there are many different elements and aims of scalar transition activity. There are also ongoing dynamics and negotiations between different scalar interests and issues in the 'intermediary' space

between scales. This results in chains of intermediary spaces that facilitate the dynamics between scales and between different interests and priorities.

What emerges from this landscape of scalar transition activity are critical gaps between scales that require processes of intermediation between the differing conceptions of the role of publics in transition activities. We can use our understanding of the specificity of the UK transition landscape to begin to speculate about which existing instruments, activities and organizations may currently form the 'chains' linking these different conceptions of transition across scales.

Looking at these gaps—labelled 1 to 5—we can start to see how they are currently populated. In 1 the national government environment department (DEFRA) has taken a lead in working with consultancies, market research agencies and research institutions in constructing profiles of environmental behaviour through segmented demographics (DEFRA 2008). In 2 there are a series of specific instruments such as the Green Deal and Feed-in Tariffs through which the market segmentation approach to publics is passed down to urban authorities. In 3 we can see how the national energy and climate change department (DECC) has played a critical role in seedcorn funding and supporting diverse hyper-local experiment and activities that are based on particular embedded local priorities rather than demographics. Similarly urban authorities in 4 have funded community groups to work on activities in contexts when the demographic segmentation approach has failed to stimulate market activity in retrofit (Hodson/Marvin 2011). We can also see in 5 how groups developing local initiatives have attempted to upscale and aggregate activity through roadshows, working across neighbourhoods, and other attempts to embed activity in particular spatial contexts.

Our overview here shows that the chains of intermediaries are haphazard, not always well stabilized, often not interactive, and poorly coordinated. It is not clear how they work on each other or whether they can effectively produce some form of spatial reconfiguration or system change. These various scalar relationships to transition and the dynamics and intermediary spaces between them pose a question which is fundamental to transitions activities and interrelationships of scales: to what extent could they or should they be coordinated, and if so, how? This is an issue of institutional innovation and new forms of governance. The reorientation of the state and the horizontal and vertical movement of many of its functions mean that increasingly over recent decades new actors

Figure 20.1: Scalar interrelationships in transitions activities and chains of intermediary spaces. **Source:** The authors.


and institutions have become key to effectively addressing societal problems. Yet they are coordinated in various ways—in spaces of intermediation—but not in a way where this is joined up in a systemic approach.

These scalar interactions with existing systems and transition activity therefore pose significant challenges and indicate the need for further debate with the MLP. These engagements are likely to be many as issues related to scale become more commonplace in debates around transition and the MLP. There are, however, three issues that we have identified in this paper:

1. We have illustrated the ways in which political-economic institutional configurations have shaped a particular low carbon response at UK national level. It is important to comparatively understand the ways in which different national political economies mediate landscape pressures and set conditions for regime reproduction/reconfiguration and niche activities. What follows from this is the need to understand the relationship between national and urban scales. Are landscape pressures mediated through national frameworks on to urban centres? Or are landscape pressures interpreted differently through political-economic institutions

at urban scales? Following from this in terms of system transition analysis is the issue of whether system priorities can be scaled down to the urban scale from the national or (and) whether distinct systems can be constituted at an urban scale.

2. The literature on sociotechnical niches can tell us much about how, why and the extent to which hyper-local spaces are 'protected'. Hyper-local spaces can also talk back to the literature by showing the limits of geographical protection where national and local priorities may differ. Thus seeking to 'protect' a local transition space, where national and local priorities differ, may result in the local space missing out on national funding and other resources or alternatively may result in these national priorities overriding local priorities and fundamentally changing the priorities of these spaces.

3. Furthermore, there is the issue of how scalar transition activity works on one dimension to promote top-down low carbon activity or alternatively bottom-up activity; and on another dimension the ways in which scalar activity works on system (re-)configuration on the one hand or the (re-)configuration of space on the other. Of course, these are extremes and there will be scalar activity that seeks

to reconfigure both space and system although the balance may be in favour of one or the other.

Future research would benefit from addressing three issues in particular. First, further development of theoretical and conceptual contributions on scale, space and their interrelationships in processes of transition; second, work around scales of transition activity and the ways in which they can and should be organized; third, longitudinal case studies of the role of the global, international, national, urban, hyper-local and publics in transition processes. Furthermore, the analytical categories developed here may inspire and support comparative analyses of how scaled transition activities are interplaying differently in diverse polities of multilevel governance. In particular, our understanding of the important governance mechanisms that we find *in between* these scales may be improved on the basis of such comparative research.

Part VI   Analysing National Debates on Sustainability in North America

21 Policy, Politics and the Impact of Transition Studies

Twig Johnson[1]

Abstract

Transition studies are undertaken in a variety of contexts and at various levels of society. Virtually all of them entertain the hope and in some cases the expectation of being used to address challenges to the sustainability transition. The relationship between research and effective action poses a challenge that transition studies must address. As part of an effort to study the different contexts in which sustainability transition studies have developed, the author will discuss a 1999 report by the US National Research Council (NRC) entitled *Our Common Journey: A Transition Toward Sustainability* (NRC 1999). The study began in 1996 during the Clinton/Gore administration. Sustainable development and environment were high on the list of priorities again. The time seemed ripe for looking at ways in which science could better support US policy efforts to transition to sustainability. It was the best of times. Shortly after publication (December 1999) a contested election was held and the political climate changed radically. Then there were the 9/11 terrorist attacks. It was the worst of times. The author will look at this study and related efforts to address the sustainability transition challenge in the fifteen years since publication.

Keywords: Sustainability science, social science, politics (US), sustainable development, Earth Summits, Bush, Gore, Obama, sustainability transition, political gridlock and policy impact of transition studies, global climate change.

21.1 Introduction

As part of an effort to study the different contexts in which sustainability transition studies have developed, this chapter discusses a December 1999 report by the US National Research Council (NRC) entitled *Our Common Journey: A Transition Toward Sustainability* (NRC 1999). Why was such a study undertaken during the Clinton administration? What did it seek to do? What impact did it have on scientific and policy debates? Why did this discussion have so little impact during the Bush administration? Given the polarized, gridlocked and much reported paralysis in Washington, what are the prospects for the US regaining some of its lost leadership in addressing, for example, global climate change?

Addressing these questions will include observations and understandings based on decades of experience working at the interface between research and action in many of the institutions and on many of the issues central to US and global efforts to transition to equitable and sustainable development.[2] My training and fieldwork as a cultural anthropologist, while including tools from many disciplines, emphasized participant observation above all. Margaret Mead, one of my professors, in answering a question on a

2 Including my efforts to develop the Science and Technology for Sustainability programme in the Policy and Global Affairs Division of the US *National Research Council* (NRC). Though trained as a cultural anthropologist specializing in ecological and applied anthropology, most of my career and participant observations have been spent in government (Peace Corps, *US Agency for International Development* (USAID), private non-profit organizations (*World Wildlife Fund* (WWF), *International Institute for Environment and Development* (IISD)) and international organizations (United Nations Children's Fund (UNICEF), and the donor's *Forest Advisory Group* (FAG).

particular methodology, told me to "never forget that you are your most important methodology". I hope in this essay to be a useful "key informant".

21.2   Background of the Study

Well before the Clinton administration, interest in the US and global scientific community in supporting environmentally sustainable development efforts had grown. The 1980s had seen a steady growth in the number, strength, technical capacity and political sophistication of *non-governmental organizations* (NGOs) and civil society in general. Many countries had created or strengthened Ministries of the Environment in response to growing problems of transboundary air and water pollution, acid rain, drought and massive fires in remaining tropical forests and increases in cancer-causing UV radiation due to the weakening of the atmospheric ozone layer.

The 1990s in Washington DC continued to be an exciting time for those working on global issues of sustainable development.[3] Preparing for, attending and following up on the 'Earth Summit' [the 1992 United Nations Conference on Environment and Development (UNCED)] held in Rio had generated additional momentum, thanks, I observed, in large part, to non-governmental organizations, many of which had been preparing for a decade. Senator Al Gore was also on the very large US Delegation. His book *Earth in the Balance* (Gore 1992) had recently been published and he was a hero to many, especially to members of the large number of NGOs in attendance, some serving on governmental delegations, others participating in the Global NGO Forum.

Gore had long been intellectually engaged in the science and technology dimensions of global climate change and had been, along with Senators Tim Wirth of Colorado (Democrat) and John Chafee of Rhode Island (Republican), a knowledgeable and enthusiastic advocate on environmental issues. In January of 1993 he was sworn in as Vice President and wrote an introduction to the 1994 edition of Rachel Carson's *Silent Spring* (Carson 1994). There was reason to be optimistic that sustainable development would be high on the government's list of priorities. Early on, the State Department was reorganized with the crea-

tion of a Global Bureau and Tim Wirth was appointed as Under Secretary of State for Global Affairs.

In addition to the improved political climate, an activist civil society and increases in the scientific understanding of international environmental threats and opportunities, there was the upcoming end of the century, for which institutions were preparing. The *National Research Council* (NRC), the operating arm of the *National Academy of Sciences* (NAS),[4] had created a *Board on Sustainable Development* (BSD) to consider how science and engineering could best support efforts to achieve sustainable development. A consensus had formed among the leadership of the Academies that the transition to sustainability would be the defining challenge of the upcoming twenty-first century.

21.3   The Study

In this context, the Board on Sustainable Development began a study[5] aimed at strengthening and energizing the connections between science and efforts to achieve the goals of sustainable development. Unlike most NRC studies, this one was not in response to a request by government, but rather a product of the interest and support of the philanthropist George Mitchel and the NRC leadership.

The study *Our Common Journey: Toward a Transition to Sustainability* set out to "reinvigorate the essential strategic connections between scientific research, technological development, and societies' efforts to achieve environmentally sustainable improvements in human well-being" (NRC 1999: 2). Throughout the preparations for the 1992 Earth Summit, support from science had been included as important, but was treated as one of many major groups, including women, children and youth, indigenous people, non-governmental organizations, local authorities, workers and trade unions, business and industry, and

---

3   During this period I served as Director of the Office of Forestry, Environment and Natural Resources, in the Science and Technology Bureau, at *the US Agency for International Development* (USAID).

4   The National Academy of Sciences is a "private, non-profit, self-perpetuating society of distinguished scholars engaged in scientific and engineering research, dedicated to the furtherance of science and technology and to their use for the general welfare. Upon the authority of the charter granted to it by the Congress in 1863, the Academy has a mandate that requires it to advise the federal government on scientific and technical matters" (NRC 1999: iii).

5   NRC reports are produced by the unpaid efforts of scientists who volunteer significant amounts of their time over several years to participate in a study group or task force. A small staff supports their work.

farmers needing support.[6] In the enthusiastic spread of the sustainable development concept in the aftermath of the Earth Summit and many subsequent international conferences, 'science', along with other 'major groups', was marginalized. What, then, the Board asked, would a serious effort by science and technology to achieve the goals of sustainable development look like?

The study began by reviewing the internationally agreed goals, objectives and indicators for sustainable development. "To meet the needs of a much larger but stabilizing human population, to sustain the life support systems of the planet, and to substantially reduce hunger and poverty." While there had developed "a broad consensus about minimal goals and targets, … there is seldom analysis of these goals' implications, their potential interactions with one another, or their competing claims on scarce resources" (NRC 1999: 14).

Progress in achieving results had been both weak and uneven, as had many of the efforts to effectively link science and decision-making. Robust support from science would need to deal with the inevitable tensions that emerge "between broadly based and highly focused research strategies; between integrative, problem-driven research and research firmly grounded in particular disciplines; and between the quest for generalizable scientific understanding of sustainability issues and the localized knowledge of environment–society interactions that give rise to those issues and generate the options for dealing with them" (NRC 1999: 10).

Three priority actions were proposed to advance the research agenda of "what might be called sustainability science": an integrated place-based framework to understand society–environment interactions; focused research on a small set of questions needed to better understand these interactions; and better utilization of existing approaches to link knowledge and action. In addition, new ways of learning from large-scale, long-term efforts to meet major challenges were required (NRC 1999: 10-14, 279-288).

Our Common Journey was uncommon, not only in terms of its non-governmental origin, but also in the depth and breadth of its exploration of what a science in support of the sustainability transition would require. To those interested in the transition to sustainability, sustainable development,[7] and the quality

of sound, scientific information to help guide advocacy and action, the release of this study was a welcome event. Here was a serious effort to link separate academic disciplines in order to solve urgent global problems. In December of 1999 *Our Common Journey* was published.

21.4   What Was the Impact on Scientific Debates?

As *Our Common Journey* was not a typical NRC demand-driven study requested by government there was little precedent for following up. Also, as expected, not everyone agreed that a new independent "sustainability science" was necessary. Following its 1999 release, a series of seminal articles were published over the next few years.[8] These were central to the development of sustainability science and its gradual acceptance in the US and wider scientific community. In addition, the co-chairs of the Study Group, Robert Kates and William C. Clark, and many of the group members participated in the various international scientific conferences linked to preparations for the 2002 *World Conference for Sustainable Development* (WCSD).[9] The *International Conference of Scientific Unions* (ICSU), the *Third World Academy of Science* (TWAS), and the *World Federation of Engineering Organizations* played key roles in providing science and technology input into WCSD preparations leading to a parallel Side Event.

The National Research Council followed up creating a Science and Technology for Sustainability Program and using its convening power to establish a Roundtable on Science and Sustainability in order to engage leaders of government, science, business and civil society on priority topics.[10]

The most important impact of this report and the journal articles published in the next few years has

been the further development and rapid spread of a new sustainability science. Over the last fifteen years it has moved from being an interdisciplinary scientific approach to become a recognized scientific programme institutionalized in academic journals, undergraduate and graduate courses, advanced degree programmes and research centres at major universities.[11] Robert Kates (2010, 2011) has produced a freely available, carefully edited online source[12] that provides an excellent introduction to further development of sustainability science in the context of sustainable development. A recent textbook, *Sustainability Science* (Bert de Vries, 2013) builds a framework for his students at Utrecht University to use to both understand and act in relation to (un)sustainable development.[13]

21.5   Impact on Policy Debates: The Case of Climate Change

Looking at US Climate change policy is instructive. Of the sustainability challenges highlighted in *Our Common Journey*, global climate change stands out as one of the most serious for a number of reasons. It affects multiple sectors of society to move ahead toward the transition and it has cumulative or delayed consequences that are felt over a long time. In addition, its impacts are irreversible or difficult to change, and they interact with each other to damage earth's life support systems. It also provides an opportunity to learn from a uniquely large-scale, long-term effort to solve a global problem that requires new forms of linkage between the natural and social sciences. New approaches to providing policy-relevant research are

necessary, as are the means of communicating them effectively. There are also lessons to be learned from various policy and programme choices made around the world.

Some background on this issue in the United States is necessary. The year 1988 was when many woke up to the fact that the climate was changing because of our actions. Forty-five per cent of the US experienced the worst drought since the 'dust bowl years' of the 1930s. Media coverage of the 'ozone hole' caused by our use of chlorofluorocarbons (CFCs) was widespread and was now linked scientifically to cancer. Televised satellite photographs of the massive burning of tropical forests in the Amazon and South East Asia fed concerns that we were damaging the life-support systems of 'spaceship Earth'. Tropical forest burning in Central America darkened the skies of Texas if the wind was right. Dust storms following massive deforestation in China were making it impossible for Los Angeles to meet its mandated air quality targets. In Florida, insects blown in from Africa were discovered, and they had survived the trip. *Time* Magazine designated "Endangered Earth" as "Planet of the Year" (Dressler/Parson 2011: 22-30).

Global concern about what was happening to the climate led to the creation in that year of the *Intergovernmental Panel on Climate Change* (IPCC), established by the U*nited Nations Environment Programme* (UNEP) and the W*orld Meteorological Organization* (WMO) and subsequently endorsed by the UN General Assembly. It regularly produces consensus reports on the status of scientific understanding of the causes, consequences, and possible responses to global climate change caused by increasing concentrations of greenhouse gases in the atmosphere. Based on the work of thousands of volunteer scientists from around the world, it continues to be the most creditable source of information for policy-makers and policy-shapers on the current state of scientific knowledge on global climate change and its potential environmental and socio-economic impacts.[14]

National and international organizations increased their capacity to deal with environmental challenges, though often starting from a low base. Non-governmental environmental organizations sprang up alongside proliferating Ministries of the Environment (and environmental units in most other government ministries). NGOs had been negotiating among themselves and by the time diplomatic negotiations about a framework convention began they were in place and prepared.

See also <https://en.wikipedia.org/w/index.php?title=Sustainability_science&oldid=588503013> for an overview of various approaches to sustainability science (5 February 2014).

12 Available at: <http://www.hks.harvard.edu/centers/cid/publications/faculty-working-papers/cid-working-paperno.-213>.

13   Bert J. M. de Vries has taught a course on sustainability science at Utrecht University for many years, in connection with his research at the *Netherlands Environmental Assessment Agency* (PBL). This textbook is based on that course. The book provides a historical introduction into patterns of past (un-)sustainable development and into the emergence of the notion of sustainable development (de Vries 2012: 11–30).

The involvement of civil society and especially the part played by NGOs was historic. In her award-winning *Foreign Affairs* article "Power Shift", Jessica Tuchman Mathews put it this way:

> Whether from developing or developed countries, NGOs were tightly organized in a global and half a dozen regional Climate Action Networks, which were able to bridge North–South differences among governments that many had expected would prevent an agreement. United in their passionate pursuit of a treaty, NGOs would fight out contentious issues among themselves, and then take an agreed position to their respective delegations. When they could not agree, NGOs served as invaluable back channels, letting both sides know where the other's problems lay or where a compromise might be found.
>
> As a result, delegates completed the framework of a global climate accord in the blink of a diplomat's eye—16 months—over the opposition of the three energy superpowers, the United States, Russia, and Saudi Arabia. The treaty entered into force in record time just two years later. Although only a framework accord whose binding requirements are still to be negotiated, the treaty could force sweeping changes in energy use, with potentially enormous implications for every economy (Mathews 1997).

The result was the first international agreement on climate change, *the UN Framework Convention on Climate Change* (UNFCCC). Under the Framework Convention, countries agreed on a goal of stabilizing greenhouse gas concentrations in the atmosphere at a level that would prevent dangerous anthropogenic interference with the climate system. The Framework Convention was signed by US President George H. W. Bush and ratified unanimously by the US Senate. In the two decades since the signing of the Frame-

work Convention, earth scientists have confirmed the basic climate science through both modelling and observations. Warming and other changes to the earth system are under way, and the dangers look even graver than they did two decades ago.

The UNFCCC was, however, only a framework for further negotiations. By 1995, countries realized that the provisions for emission reductions in the Convention were inadequate. They launched negotiations to strengthen the global response to climate change, and, two years later, adopted the Kyoto Protocol that legally commits developed countries to emission reduction targets.

The Clinton administration had signed the treaty over the written objections of the Senate, but had not proceeded to seek the advice and consent of the Senate necessary to ratify the treaty, knowing it would be defeated. In the foreign policy arena, the Senate has the authority of "advice and consent" regarding treaty-making. Given the difficulty of winning the two-thirds vote necessary for treaty ratification in the US, the Clinton administration, as others have done in the past, was considering ways of achieving some of the goals of the treaty without formal ratification.

Yet preliminary progress had been made on this major threat to planetary sustainability and through the IPCC, scientists from around the world were playing a critically important role. *Our Common Journey* was published in October of 1999. The time seemed ripe for an important contribution from sustainability science to US policy. *Then the political climate changed radically.*

21.6   Bush: A Radical Change in Context

In 2000, shortly after publication of *Our Common Journey*, there was the disputed election of George Bush, ultimately decided by a conservative US Supreme Court. Two months after taking office in January 2001, the Bush administration announced that the US would not ratify the Kyoto Protocol for reducing greenhouse gas emissions, claiming scientific uncertainty in addition to negative effects on the US economy as two of the reasons. The "lack of scientific knowledge" argument was retracted later in the face of several NRC reports and criticisms from the larger scientific community, including many scientists working in the federal government.

Then came the September 11, 2001 attacks on the World Trade Center, the Pentagon, and the attempted

---

14 The Fifth Assessment Report (AR5) of the IPCC released in 2013 and 2014 provides a clear view of the current state of scientific knowledge relevant to climate change; see <http://www.ipcc.ch/The Fifth Assessment Report>. It comprises three *Working Group* (WG) reports and a *Synthesis Report* (SYR). The IPCC *Working Group I* (WG I) assesses the physical scientific aspects of the climate system and climate change. *Working Group II* (WG II) assesses the vulnerability of socio-economic and natural systems to climate change, negative and positive consequences of climate change, and options for adapting to it. It also takes into consideration the interrelationship between vulnerability, adaptation and sustainable development. *Working Group III* (WG III) assesses options for mitigating climate change through limiting or preventing greenhouse gas emissions and enhancing activities that remove them from the atmosphere.

attack on the White House [foiled by the heroic passengers crashing their own plane]. All was televised, recorded in heartbreaking detail, and replayed over and over. Shock, anger, and fear rocketed through modern communications media and triggered an angry patriotism not seen since the attack on Pearl Harbor that launched a previously reluctant America into World War II. When an aide whispered into the ear of President George Bush that the United States was under attack, he sat frozen in a tiny chair in a classroom where he had been reading a story to the children. He looked stunned, 'gobsmacked', momentarily paralyzed, as were millions of others around the globe, by this unexplained, horrendous event. There followed a great deal of understandable confusion. After Pearl Harbor it had been clear what America needed to do. President Roosevelt had seen the necessity for some time. In addition to his thoughts on the matter, he had a large number of ideas brilliantly and frequently articulated by the British prime minister Winston Churchill. President Bush did not know what to do. It was not clear what was happening and why. The who-what-when-where-why-and-how questions had no answers. And Bush was no Roosevelt nor was he a Churchill.

A large new bureaucracy, Homeland Security, was created and an ill-defined 'War on Terror' was launched. As the administration prepared to invade Iraq (never linked to the 9/11 attacks), the style, tone and rhetoric of US foreign policy seemed to come out of a sort of Clint Eastwood 'spaghetti western'. In the process, the G. W. Bush administration not only failed in its ill-conceived objectives, it also undermined US credibility, squandering the immense global sympathy and goodwill that followed the 9/11 attacks. The follies of the occupation of Iraq and 'nation-building' in Afghanistan followed, with an agenda dominated by claims of keeping America safe from real or suspected enemies, foreign and domestic. Having inherited a rare balanced budget from the Clinton administration, failing to pay for the immense costs of his policies G. W. Bush plunged the country into debt.

In her 10 October 2007 Congressional Testimony before the House National Security and Foreign Affairs Subcommittee, Jessica Tuchman Mathews stated that:

> The events of 9/11 have had far less of an effect on the real world than that day had on the American psyche. Iraq is a very different matter. The war's monopoly on our political energy has now stretched to 5 years—an eon in a time of fast-moving global change. One of its greatest—as yet uncounted—costs is the degree to which it has sucked the oxygen from almost every other issue. A dra-

matically changing global climate might as well not be happening. The reappearance of huge federal budget deficits is hardly noticed. The need for change in an unsustainable energy policy has barely surfaced. And, in these five years a number of international security problems have grown, from neglect, into full-blown crises (Mathews 2007: 2).

After the mess made during the first term by going to war and not paying for it, and after the failure of promised results was revealed to be based on (wilful?) ignorance, avoiding available information by knowledgeable people, and after his actions were executed with all the bravado, arrogance and sensitivity of a Hollywood gunslinger, George W. Bush was re-elected.

The electorate does not pay attention to many details. Many in the Washington foreign affairs community working on a wide range of global issues, including some colleagues working on security and terrorism issues, were shocked. Friends in the foreign press and diplomatic services expressed incredulity. I recall a social scientist talking about an analysis of voting patterns reporting that the pattern in this election was largely unchanged, with the exception of young mothers in the South, who had changed their former vote to support Bush this time. The reason most given for the switch was to "avoid changing Commanders-in-Chief in time of war". So it went.

The negative results of the Bush administration environment policies have been well documented. For example, on 16 January 2009, four days before he left office the White House released a bulletin describing Bush as a careful steward of the environment. The same day the *Natural Resources Defense Council* (NRDC), the Sierra Club and many others took vigorous exception. Suzanne Goldenberg's article "The worst of times: Bush's environmental legacy examined" in *The Guardian* of 16 January 2009 details their near universal outrage. They saw the Bush years as a concerted assault on environmental progress, from the administration's undermining of the science of climate change to its dismantling of environmental safeguards and its uncritical support for mining and oil interests. Frequently mentioned was not only his failure to act on global climate change but his administration's covert attempt to silence the science alerting us to the urgency of the problem.[15]

In terms of the very real but less immediately salient threat of global climate change and the more gen-

---

eral challenge of the transition to sustainability, the administration seemed happy to abdicate both domestic and global environmental leadership, minimize the problem, and roll back much hard-won progress (see for example Kennedy 2005).

Following the Kyoto announcement, the group responsible for coordinating and integrating US government research on climate, the *Global Change Research Program* (GCRP) was renamed with the weaker title of the *Climate Change Science Program* (CCSP). The Bush administration was to be regularly charged with suppressing scientific information and its implications for society.

21.7   Challenges of the UNFCCC Framework

Independently of the actions of the Bush administration, criticism of the UNFCCC process had been growing. In the winter of 2000, international talks on the implementation of planned emissions standards again faltered, a resolution again postponed (Victor 2011, 2011a). Outside the environmental community, and even within it, support for Kyoto weakened. Indeed Earth Summit agreements on climate, biodiversity and desertification had not produced any concrete results on climate, biodiversity or desertification.

Many reasons for the repeated failure of these attempts to forge global environmental agreements were offered (Victor 2011; Bell 2011). The most persuasive related to the architecture of negotiations under UN auspices—an inclusive process, involving 194 countries—polluters, victims and everyone in between—all of whom officially have equal weight in the proceedings and any single nation might block the will of all the others. Goals and objectives produced this way will be too broad and vague because governments in that setting are unwilling to do anything more concrete. Negotiations now include a bigger basket of issues than most multinational talks—including weaning whole economies off coal and oil, protecting disappearing forests, saving the small island states that are likely to be underwater within a few decades, and managing all the related costs.

Suggestions for improvements have included encouraging bottom-up initiatives at national, regional, and global levels and leveraging national self-interest rather than wishful thinking (Bell 2011).

> Moving to a variety of nimbler negotiating vehicles supplementing the UNFCCC is worth a try, as is disentangling goals for emissions reductions from debates about

legal structures and venues. The large docket of issues could be broken up, narrowing specific negotiations by issue or region, by greenhouse gas emissions contribution, or by tools and methods to achieve greenhouse gas reductions. Finally, climate change talks, which involve a problem with the potential to disrupt the life of every human on earth, must graduate into the elite arena. They should be directly guided by powerful ministries, which can make commitments and sell them at home in ways most environmental authorities cannot.

> Controlling greenhouse gas emissions is a messy real-world challenge that will most likely require an ... evolving progression of messy real-world solutions. But if the climate establishment can acknowledge more variation of approaches and entry points, it increases its chances of realizing its most important goals, even if it does not tie a nice, neat bow on them (Bell/Blechman/Zigler 2011: 4).

However, giving talks top-level attention, segmenting issues, and diversifying negotiating arenas all seem promising. It is precisely because climate disaster is impending that the world should get creative about addressing the problem. Within the UN negotiating framework, however, it will be hard to get them to consider approaches that might challenge the rule of consensus, which many equate with equity (Bell/Blechman/Zigler 2011: 3).

In fact, a number of countries, including the US, have been diversifying their approaches for some time. And there are some bright spots. In the absence of federal leadership, and in some cases because of it, much progressive action was led by states and cities. California, the sixteenth largest emitter of carbon dioxide worldwide, for example, is among several US states that have entered into partnerships or passed laws for controlling greenhouse gases ahead of, even in spite of, the federal government.

In August 2006, not long after the publication of the 2006 Stern report on global warming that he had requested, Prime Minister Tony Blair made history by travelling to and signing, with Republican Governor Arnold Schwarzenegger, an agreement with the state of California to cooperate on a range of global environmental issues. "California will not wait for our federal government to take strong action on global warming", said Governor Schwarzenegger, a Republican, who would also send a wake-up call to US automakers by creating emissions standards for automobiles.[16] The Bush administration attempted to halt this action, claiming federal responsibility. They were overruled by the Supreme Court on the grounds of States' Rights.

---

16   See at: <http://gov.ca.gov/news.php?id=2770>.

In August 2008, Massachusetts moved forward with a comprehensive regulatory program to address climate change. The *Global Warming Solutions Act* (GWSA) requires Massachusetts to set economy-wide *greenhouse gas* (GHG) emission reduction goals to achieve reductions of as much as twenty-five per cent below 1990 state-wide levels by 2020, and eighty per cent below those levels by 2050.[17]

A month before the 19*th Conference of Parties* (COP19) in November 2013 in Warsaw, California launched a regional pact to harmonize and intensify the efforts of California, Oregon, Washington, and British Columbia to reduce greenhouse gases. "California isn't waiting for the rest of the world before it takes action on climate change", said Governor Brown. "Today, California, Oregon, Washington and British Columbia are all joining together to reduce greenhouse gases". Recently the California Air Resources Board announced an agreement with Quebec outlining steps and procedures to fully harmonize and integrate their cap and trade programmes. In September 2013, Governor Brown joined China's top climate official, National Development and Reform Commission Vice Chairman Xie Zhenhua, to sign a first-of-its-kind agreement on climate change between the commission and a subnational entity. This followed landmark partnerships established earlier this year on the governor's Trade and Investment Mission to China, including agreements signed with China's Minister of Environmental Protection Zhou Shengxian to improve air quality and with Jiangsu province to promote renewable energy.[18]

These actions by California and New England are meant as examples of the large number of actions taken by states, municipalities, businesses, voluntary organizations, schools and churches, homeowners, and consumers of automobiles and appliances.

21.8　　Obama—Beginning the Turnaround?

On 20 January 2009, Barack Hussein Obama became the forty-fourth president of the United States. Within the week he issued two presidential memoranda on energy. One directed the Department of Transporta-

tion to increase fuel efficiency standards to 35 miles to the gallon (15 km/l) and the other directed the *Environmental Protection Agency* (EPA) to allow individual states to set stricter tailpipe emissions regulations than the federal standard. In February he provided $54 billion in funds to encourage domestic renewable energy production, make federal buildings more energy-efficient, improve the electricity grid, repair public housing, and weatherize modest-income homes.

Presidential memoranda and proclamations do not require Congressional approval. This is critically important. The US government was designed, quite deliberately, not to work very well. The design works, perhaps too well. Separations of powers, checks and balances, make it very difficult to do much in many areas. It is extremely easy to halt actions. There is a long list of actions requiring Senate confirmation, but the presidential ability to negotiate an international agreement stands out. Any agreement must receive the advice and consent of the Senate by a two-thirds majority. This is why the Clinton/Gore administration never sent the Kyoto Protocol they had signed forward to the Senate. It had no chance of passage.

In 2010 the EPA issued rules restricting greenhouse gas emissions from cars and trucks by 2012. This was based on the Agency's finding that greenhouse gasses harm human health. As in the case with CFCs, the scientific link to a threat to health created motivation and powerful justifications for action.

Obama re-engaged positively in international climate negotiations, attending the December 2009 Copenhagen COP, which left many with very reduced expectations of what was possible through the UNFCCC process.

In April of that year he launched the Major Economies Forum on Energy and Climate, to facilitate a candid dialogue among major developed and developing economies on climate change and the challenge of clean energy. The seventeen member economies are: Australia, Brazil, Canada, China, the European Union, France, Germany, India, Indonesia, Italy, Japan, Korea, Mexico, Russia, South Africa, the United Kingdom, and the United States. Their Forum on Energy and Climate works to drive transformational low-carbon technologies in the energy sector. The Climate and Clean Air Coalition to Reduce Short-Lived Climate Pollution focused on such short-lived pollutants as methane, black carbon, and *hydrofluorocarbons* (HFCs). Together these account for one-third of current global warming, and addressing them can prevent more than two million premature deaths a year, and avoid the annual loss of over thirty million tons of

crops. Partnership has expanded beyond the founding partners (Bangladesh, Canada, Ghana, Mexico, Sweden, and the UN Environment Programme) to include over thirty countries and the European Commission.

At the 2011 *Asia–Pacific Economic Cooperation* (APEC) Summit, leaders agreed to eliminate non-tariff barriers to environmental goods and services, thus lowering costs and increasing the dissemination of clean technologies. Leaders further committed to phasing out inefficient fossil fuel subsidies and aimed to reduce the energy intensity of APEC economies by forty-five per cent by 2035. In June 2013, President Obama and Chinese President Xi agreed to work together and with other countries to use the Montreal Protocol to phase down HFCs, a critical step forward towards a global agreement. In June 2013 President Obama launched a comprehensive Climate Action Plan.[19]

His Climate Action Plan, his 25 June 2013 speech on climate change[20] and his 2014 State of the Union Speech to Congress[21] leave no doubt as to the seriousness of his intentions and the effort he has made to do what he can using the powers of the Presidency. However, a polarized, gridlocked Congress dominated by right-wing extremists hampers him.

While Obama certainly represents a turnaround in the Presidency, he is in many areas limited to actions that do not require Congressional action. He must deal with a Congress that demonstrates little capacity or interest in solving problems and has dedicated much of its time to defeating anything he proposes.

21.9   Polarization, Gridlock and a Trickle of Contrarians

> The evidence from hundreds of scientific and economic studies finds serious to grave impacts on agriculture, coastlines and associated settlements, and ecosystems, as well as increasing acidification of the oceans and threats to many species around the world. Science progresses, the earth warms, glaciers melt, the oceans become increasingly acidic, but the climate contrarians change not (Nordhaus 2012: 85).

Contrarians are becoming fewer in number, less and less credible, and not nearly as well funded as in the past. People look around at storm damage, floods, and droughts and know the climate is changing. The process had been similar in the case of regulating tobacco and controlling chlorofluorocarbons.

The insurance industries in the US as in Europe were early believers in the problem of climate change as they saw the effects of the increases in the frequency and severity of storms consistently predicted by the scientists. This cost them money so they paid attention. The support funds from industries threatened by efforts to reduce greenhouse gas emissions are much reduced. Even the US Chamber of Commerce, with much of industry, has now accepted the reality of climate change caused by greenhouse gas emissions. The press has belatedly become more responsible in looking at the credibility of its sources.

The political gridlock in Washington these days is, however, different. Two of Washington's most respected and even-handed analysts[22] wrote *It's Even Worse than It Looks: How the American Constitutional System Collided with the New Politics of Extremism* which became a *New York Times* best-seller. The Republican Party today, they report, has little in common even with Ronald Reagan's GOP, or with earlier versions that believed in government. It has become "an insurgent outlier–ideologically extreme; contemptuous of the inherited social and economic policy regime; scornful of compromise; unpersuaded by conventional understanding of facts, evidence and science; and dismissive of the legitimacy of its political opposition" (Mann/Ornstein 2013: [Kindle Edition] 178).

They also charge the press with using false equivalence to explain outcomes, when Republican obstructionism and Republican rejection of science and basic facts have no Democratic equivalents. It's much easier to write stories that convey a false impression that the two sides are equally implicated.

Obama's re-election in 2012 was a setback for Republicans and a number of Republicans interested in solving problems are beginning to speak out. But too many remain worried about having to face well-funded right-wing challengers. Recent polls show a declining popularity of the Republicans, seen as too

22 Norman Ornstein of the American Enterprise Institute and Thomas Mann of the Brookings Institution are political scientists with decades of providing even-handed analysis of Washington politics, and especially of Congress. Their 2006 volume *The Broken Branch* focused on the institutional shortcomings of Congress while this volume examines the broader current political dysfunction.

extreme and out of touch. The polls also revealed new lows for the federal government but record highs for State and municipal government.[23]

21.10   Conclusions

The NRC Study *Our Common Journey: Toward The Transition to Sustainability* contributed to the process of strengthening and energizing the connections between science, technology and engineering and their efforts to support the transition to sustainability. It did this through the normal scientific channels of publishing to a largely scientific audience, and in addition through the vigorous and determined international outreach efforts of co-chairs Kates and Clark and the extraordinary scientists in the Study Group as well as Sherburne Abbott, the lead NRC staff person responsible for organizing, editing and frequently in some cases writing. They are themselves movers and shakers in influential institutions and one could track the marks they have left in intellectual contributions, institutional capacities, and undergraduate and graduate programmes. They participated in many of the preparations for the 1992 *World Conference for Sustainable Development* (UNCED) in Johannesburg, South Africa, which provided rare opportunities for strengthening international scientific cooperation in developing sustainability science. The World Conference failed to meet expectations.

Efforts aimed at global and national policy-making mostly failed not for want of trying but because of the collapse of global environmental summitry and the Bush administration's disinterest in, ignorance of, and animosity toward what many regard as the greatest strategic threat to our security we have yet faced. The high level governmental demand for support and cooperation from scientists working on sustainability issues that one could expect from the Clinton/Gore administration had been replaced with outright hostility and suppression of research results.

Fortunately, failure is mostly confined to the federal government in Washington. The front line of problem-solving has shifted to states and municipalities, to educational institutions and research centres, to the many partnerships between NGOs, scientists, engi-

neers and corporations who see a decarbonizing future as an opportunity.

The feedbacks keep on coming. Storms, wind, drought, and crazy weather are, as predicted, becoming stronger and more frequent. Dramatic and sometimes disastrous events can influence policymakers by demanding their attention. The global science assessment of the IPCC becomes ever more solid and sensitive and can now give better information on actions that work.

In an interview on 26 January 2013 during the World Economic Forum, Lord Nicholas Stern reflecting on his 2006 Stern Report said he actually underestimated the risks posed by global climate change. At the same meeting *International Monetary Fund* (IMF) Director Christine Lagarde, former Conservative Finance Minister of France, noted the "Increasing vulnerability from resource scarcity and climate change, with the potential for major social and economic disruption". She called climate change "the greatest economic challenge of the twenty-first century".[24]

Global climate change is just one of the many threats to a sustainability transition along with extreme poverty, the growing gap between rich and poor within as well as between countries, terrorism, crime, pollution, disease, weapons of mass destruction, environmental protection, non-tariff trade barriers, intellectual property, and the challenge of cooperative governance where states are challenged by an ever growing number of non-state single-interest actors. Overall there is a rapidly expanding poorly-regulated market economy that continues on a collision course with our planet. These problems are all global. They must be solved and managed globally. This will require institutional capacities and systems of governance that are currently lacking. Sustainability transition studies have begun to address this need.

22   Geopolitics, Ecology and Stephen Harper's Reinvention of Canada

Simon Dalby[1]

Abstract

The election of the Conservative Party to power in Canada in 2006 brought with it a vision of the world that was much more competitive than previous Liberal or much earlier conservative visions. Key to all this, and the focus of this chapter, is an attempt to reinvent Canada as a player in a world of competitive geopolitics rather than as a good citizen in a shared biosphere. Foreign and domestic policy have been shaped by this new view, leading to the abrogation of the Kyoto protocol and, given the identification of Canada as an energy super-power and oil exporter, substantial attacks by the government on environmental science and regulatory processes, apparently because these might obstruct resource company projects. What is being sustained in this process is a vision of Canada antithetical to what in most parts of the world would be considered sustainable. The lessons to be learnt for sustainable transitions are many, most notably the importance of thinking carefully about conventional politics and the dangers of narrowly-cast nationalist and populist attacks on environmental policies and sustainability initiatives.

Keywords: Canada, geopolitics, Harper Government, neoconservative, political strategy.

22.1   Whatever Happened to Canada?

In the 1980s Canada had a reputation as a leader in developing environmental policy. The establishment of the *International Development Research Centre* (IDRC) with its international network of activists and academics made development a key theme in policy discussions. The *Canadian International Development Authority* (CIDA) delivered aid, at least some of which was environmentally sensitive. Much of the background work on the *World Development Commission on Environment and Development* (WCED) in the 1980s was done in Ottawa. The Montreal Protocol, a key part of the international framework for controlling and subsequently stopping the production of ozone-depleting chemicals, was named after a Canadian city where some of the key negotiations were conducted. The Global Atmosphere Conference of 1988 was held in Toronto, and issued statements that explicitly linked climate change to global security in terms that are now familiar a generation later.

Focusing more explicitly on the domestic scene, environmental regulations were a fairly widespread matter for the Federal Government in the 1970s, although the division of powers in the confederation does give the ten Provinces responsibility for overseeing the exploitation of natural resources. Nonetheless given Federal responsibilities of fisheries, oceans and water issues, and the system of national parks, there was an active Federal presence on environmental matters. Major research efforts to develop plans for a "Conserver Society" were undertaken in the 1970s (Solomon 1978). By the early 1990s, coincident with the Earth Summit in Rio, 'Green Plans' were in place to deal with many matters of sustainability. Connecting the domestic and the international spheres, Canadian businessman Maurice Strong oversaw both the 1972 Conference on the Human Environment in Stockholm and the United Nations Conference on Environment and Development twenty years later in Rio de Janeiro.

Another twenty years later the Canadian situation is very different. While both the 1980s government and the Harper government in power from 2006 include the term 'conservative' in their name, they

---

1   Simon Dalby PhD is CIGI Chair in the Political Economy of Climate Change, Balsillie School of International Affairs, and Professor of Geography and Environmental Studies, Wilfrid Laurier University, Waterloo, Ontario, Canada; Email: <sdalby@gmail.com>.

were very different political entities. Canada abrogated its Kyoto protocol commitments, walking away from the agreement rather than dealing with the consequences of its failure to abide by its obligations. By 2014 CIDA effectively no longer existed. The Tar Sands in Alberta were a cause célèbre among environmentalists looking for a symbol of everything that is wrong with contemporary economic trajectories. The huge tailing ponds and massive infrastructure tearing up the boreal forest while using natural gas to power the transformation of bitumen into petroleum is the classic example of carboniferous capitalism run amok. Prime Minister Stephen Harper proudly boasted of Canada as an energy superpower while defunding environmental research and silencing scientists. Some of his ministers hinted darkly at sinister foreign interests behind environmental objections to the extraction of Canadian resources and the operation of Canada-based mining companies in many other parts of the world. Canada's environmental performance was rated with Kazakhstan and Saudi Arabia in the international environmental hall of shame! This was a very different Canada (Kaplan 2011) and one with a foreign policy that was narrowly focused and little interested in multilateral arrangements (McLeod Group 2012).

Given the ideologically driven nature of the Harper government's silencing of dissent and abandonment of much environmental science, activists and scientists ruefully joked that Canada has moved from "reality-based decision-making" to "decision-based reality-making". Watching the Federal political scene in recent years in Canada there is much truth to this assertion; the agenda for Canada's Conservative government (2006-2015) was driven by the resource sector and short-term extractive industry profitability. The mining boom stretched round the world; it wasn't just a domestic matter (Gordon 2010). The electoral support the Conservative Party drew from rural and resource extractive industries was coupled to an ideological argument that this is the route to material wealth, and hence environmentalists who would regulate the industry and examine its project proposals too closely in regulatory hearings were a danger to the prosperity and suburban lifestyle that is portrayed as the envy of much of the world. After all, immigrants supposedly come to Canada precisely to get the benefits of this mode of consumption, based on Canada's traditional economic priorities of providing resources to the North American industrial system, if not to the global economy.

While the environmentally-friendly image of Canada was never the whole story, and there are histories of industrial pollution and resource exploitation across the country that are by no stretch of the imagination 'sustainable' (Baldwin/Dalby 2010), nonetheless the abandonment of anything more than the pretence to be good environmental stewards on the part of the current Federal government is noteworthy. The rhetoric of environmental protection persists, when necessary, as in making the case that Tar Sands petroleum is extracted in a manner that is supposedly environmentally benign, but the reduction of monitoring and research and the effective muzzling of federal scientists makes it clear that this is only public relations.

There are some important lessons to be learned from the sad example of Canadian federal politics that need to be remembered in thinking about strategies for sustainable transitions in other places. The first lesson is that environmentalists forget about the finer points of politics at their and the planet's peril. As Australians with the Howard and more recently Abbott governments have also learned, the departure from power of parties sympathetic to at least some environmental causes can set sustainability back dramatically. It makes getting sustainability back on track all the more difficult by entrenching the power of certain sectors of the economy and scrapping research and monitoring that allow environmental matters to be assessed and debated in a reasonable manner. This is precisely what the Federal government in Canada set about doing in 2006 with very worrisome consequences for both Canada and the planet. All this matters because a politics very different from the policies of the Conservative Party in Canada are needed if sustainability is to be taken seriously.

22.2 Canada's Conservative Government

After a couple of minority parliaments from 2006 to early 2011, and some political manoeuvrings that raised the ire of many Canadians, the Conservative Party formed a parliamentary majority government in May 2011. Given the peculiarities of the "first past the post" Westminster-style electoral system, this was achieved with the support of only about forty per cent of those who actually voted. While the name Conservative is still there, this was a corporate agenda led government with a populist right-wing rhetoric (drawn from its 1990s predecessor "The Reform Party") determined to remake the country, and one apparently

more obsessed with partisan motivation than has usually been the case in Canadian federal politics (Nadeau 2010). The result was an ideological agenda supporting the oil industry in Alberta and Saskatchewan mainly, and defining energy security in terms of fossil fuel production. Canada is supposedly an energy superpower, and the supplier to the North American market, and possibly in the future elsewhere further afield if the Keystone pipeline to Texas or the Northern Gateway one across the north of British Columbia get built in coming years.

Stephane Dion, the former Liberal environment minister who had been a key part of the Kyoto process, was ridiculed when, as subsequently leader of the Liberal Party he introduced a set of policy suggestions for a green shift in Federal taxation to tax carbon and compensate by reducing income taxes. Populist rhetoric against taxes was used to ridicule the proposed policy and ensure that it never got reasonably discussed. Dion lost the 2008 election when he ran on a "green shift" electoral platform. This has made carbon taxes more difficult to implement in Canada, although the province of British Columbia has one that has been used to fund popular public services which might have potential for wider application should political entrepreneurs emerge willing to promote such a system elsewhere (Elgie/Mackay 2013). Michael Ignatieff who mostly ignored climate change in his subsequent unsuccessful attempt to remove Stephen Harper in the 2011 election subsequently replaced Dion as leader.

The Conservatives long made the argument that they will follow American policies when it comes to climate change so as not to impinge on Canadian business, but in the process abandoned any attempt to take the initiative and develop a comprehensive 'made in Canada' policy. Despite useful reductions in coal-burning power station emissions, mostly as a result of Provincial initiatives in Ontario in particular, it is clear that even the modest Federal promises for reductions in fossil fuel emissions are unlikely to be met. No Federal strategies on renewable energy development emerged; windmills and solar panels were left to the provinces concerned with their own energy grids and sustainability issues. While this makes sense in that these are mostly provincial responsibilities in Canada, an energy superpower means in this case one that supplies natural gas and petroleum, not one that thinks seriously about the long term and about how sustainable futures are to be powered. It was a policy that effectively locks Canadian policy into a carbon trap

dependent on markets for high-priced marginal petroleum supplies long into the future (Haley 2011).

Abandoning much of the earlier legislation and regulations that required environmental reviews of developments, the omnibus budget bill of April 2012 eviscerated Federal environmental regulations and cut government science capabilities, while censoring scientists' public statements and refusing to allow them to do media interviews without prior clearance from government political overseers (Turner 2013). This led to unprecedented protests by scientists in the summer of 2012 focused on the theme of the "death of evidence". This theme also captures other government changes such as the evisceration of census information gathering and reducing the functions of Statistics Canada as part of the overall reduction in public knowledge about Canada. Further cuts to Federal oversight of lakes and waterways followed in 2013 and the trend to abandon environmental protection continued; the mantra of business self-regulation was related to the abandonment of data collection and monitoring across the country.

Kyoto protocol abrogation fitted into this agenda too. While it was clear that Canada was never going to make cuts in energy use that would get overall emissions down to the 1990-based targets, "Canada's New Government", as the Conservative Party wished to be known in its early years in power, abandoned even the pretence that Canada would try. There was certainly no intention of spending money on offsets to pay for non-compliance. Arguing that remaining in Kyoto would unreasonably hamper Canadian oil companies and that it was obviously an ineffective agreement; the decision to abandon it was entirely in keeping with a government focused only on resource development. The lack of concern with the precedent, or the abrogation of any attempt at political leadership on a matter of global importance, was in keeping with the Conservative ideological agenda that showed scant concern for the wider world (Bosold/Hynek 2010). Unless, of course, there were domestic constituencies whose votes might count in the electoral calculus that kept the government in power by a narrow margin; foreign policy was understood here as important in so far as it generates electoral benefits.

In turn this was related to what at least initially was seen as a much more militaristic foreign policy by Harper, who was happy to lend Canadian forces to imperial actions in Afghanistan and subsequently Libya, although the total amount of resources channelled to the military was not in keeping with a major shift to a more muscular foreign policy (Lang 2012). A

persistent series of failures in the procurement process for the F-35 fighter jet programme undermined the credibility of at least some of this focus on the military (Nossal 2012/13); subsequent budget constraints in 2014 severely limited military purchases and caused outrage among veterans' groups where health benefits are limited while money is spent on commemorating past military actions. But the tone of foreign policy is clearly much more militarist than Canadian policy in previous governments; peacekeeping is a thing long abandoned by Canadian governments despite its earlier useful contributions to international affairs. NATO actions in support of American initiatives have been undertaken, including in Afghanistan and Libya; UN peacekeeping missions mostly have not (Charbonneau/Cox 2010).

The ideological orientation of the government was one where the world is understood in competitive terms, one where international action is a matter of self-interested action, a matter of "enlightened sovereignty" in foreign minister John Baird's (2011) terms where temporary coalitions of interest matter, and international institutions don't. Unless, that is, Israel was concerned, where by specifying it as a democracy surrounded by non-democracies, unabashed support for whatever it does was apparently the obviously morally correct foreign policy (Martin 2012). The abrogation of a nuanced foreign policy in favour of moralistic slogans and the periodic denunciation of Iran was quite clear. Some of this was plainly driven by domestic electoral considerations appealing to immigrant groups, but a confrontational geopolitics underlay this explicitly.

Domestically the removal of many environmental regulations and the effective carte blanche given to resource companies violated the provisions of many of the treaties signed with the indigenous groups who were conquered and dispossessed in the process of colonization by European settlers (see Grant 2014). This in turn caused protest movements and continued political opposition to the Conservative government, who disregarded their obligations to meaningfully consult with many native peoples about environmental changes and developments that take place on their territories. This may turn out to be a major source of conflict should the decision to build the Northern Gateway pipeline from Alberta to the coast of British Columbia near Kitimat be taken despite the vehement opposition of many native groups whose land would be crossed by the pipeline.

In so far as lip-service to environmental matters was served, it was entirely in environmental moderni-

zation mode; technological innovations ensure "safe" production. In the case of the Tar Sands, industry groups repeatedly invoked improved techniques in television advertising campaigns in particular, supposedly making products both more secure and environmentally benign. The argument that this is ethical oil, in contrast to petroleum imported from conflict-ridden areas or non-democracies, was simply added on to this formulation (Levant 2010). Nowhere was it countenanced that leaving the bitumen in the ground might be sound strategy and that renewable energy development would be a better priority. This was a policy devoted to resource extraction rather than building an industrial base in Canada; rent from resources rather than innovation in production reprised much of the history of Canadian development but is also a policy that, not least by inflating the Canadian dollar, undercut industrial exports too (Stanford 2008). In the Arctic where the consequences of climate change are most obvious the Harper Government's northern strategy has been to enhance resource extraction and extend property rights of corporations to facilitate their access even if this comes at the cost of indigenous inhabitants' environments and food supplies (Medalye/Foster 2012). Whatever this may be it wasn't Canadian leadership on anything that matters in terms of sustainability or responsible environmental stewardship. When the price of oil collapsed in mid 2014 the folly of an economic policy so dependent on one sector of the economy became abundantly clear.

22.3   Political Ontologies

Running through all this was a simple will to power, an agenda that saw disagreement as opposition and a view of politics that was both narrowly focused and concerned with winning rather than with the consequences that are not immediately reflected in the proverbial bottom line. The bottom lines that mattered were both the corporate balance sheets and the electoral calculus that ensured the persistence of Conservative rule. This was a view of the world that assumed competition as the given context for human activity, and one that was unconcerned about matters of environment. Indeed environmentalists were the enemy, given that they apparently obstructed corporate plans for resource extraction and hence they had to be silenced or denigrated. Therefore their expressions of alarm about climate change were to be either dismissed, or finessed with arguments that suggested

economic activity is a far more important priority in a harsh competitive world.

Such formulations relied on a worldview that discounted the consequences of Canadian actions while simultaneously boasting of being a superpower. They operated as though Canada, being a sovereign country, and an enlightened one apparently, was in some key senses simply separate from the rest of the world—foreign policy action was frequently about domestic electoral advantage, not it seemed about shaping the international order beyond pressing Canadian business advantages abroad and issuing moral condemnations of regimes outside the Western world. In such an ontological universe winning and ruling is what matters; having a sustainable biosphere isn't important given that as winners, and rulers, if environmental disruptions happen 'we' will apparently be either wealthy of powerful enough to evade the consequences. Anyway Canada is only a small player on the world scene, with half a percentage of the world's population and only a few per cent of the world's oil production so what we might do on the matter of environment is unimportant, so why pay attention if it will deprive our corporations of profits in the immediate future?

This contradiction-ridden thinking runs directly in opposition to an ecological worldview of any sort where the interconnections between things and the common placement of all beings in one biosphere is the starting point for discussions of sustainability. It assumes a given context that simply provides the opportunity to make money, and failure to take these opportunities suggests moral and political inadequacies that should be swept aside by those who obviously know better. Ecological science simply gets in the way of what is important and so should be silenced, dismissed or ignored. This was politics in the raw, a matter of power first and foremost, as Steven Harper's political biographers make very clear (Martin 2010; Wells 2013). A strategy for a sustainable future simply has to deal with these political challenges from a corporate sector armed with both a neo-liberal ideology and a populist rhetoric if it is to be effective. This is no small challenge especially when, as is the case with the Canadian Conservative Party, it explicitly tried to use political divisions and wedge issues as a mode of political rule.

The other important point in all this is that environmental gains are not necessarily permanent. As the American environmental movement learned to its cost in the 1980s when the Reagan administration set about dismantling at least some of the legislative and administrative systems set in place in the previous decades, getting laws made is only the initial step in a sustainability agenda. Keeping the political pressure on to ensure that they are enforced and that the long-term benefits are forthcoming requires a permanent political and cultural effort. The danger of formulating matters in terms of a sustainability transition is that there is an assumption of a stable end point. Another lesson from the Canadian case in the last decade is that environmental progress can be overturned if corporate agendas driven by resource extraction priorities in particular regain the political initiative. Politics is an ongoing process, not an end point, and discussing sustainable transitions cannot afford to operate on the assumption that there is a stable end point where sustainability is ensured in perpetuity.

22.4 Neo-Conservative Rhetoric

Looking to the Canadian example it seems that at least six key sources of political thinking fed into the ideological mélange that supported the right wing coalition that constituted the Conservative party. Given the distance that they have travelled ideologically from the earlier Progressive Conservatives who were in power in the 1980s when the Montreal Protocol was negotiated, the Global Atmosphere conference was convened, and national Green plans formulated, it's perhaps appropriate to call this neo-conservatism, and not only because of its militarist inclinations. Backed by media outlets that were sympathetic to both business interests as well as populist stories of moral clarity and victimhood in the face of supposedly big government, think tanks including the Fraser Institute have shaped the predominately corporate policy agenda. The lessons of the last decade in Canada suggest clearly that policies for sustainable futures need to directly tackle all these ideological components, albeit in different combinations in particular places around the world.

The first political configuration is the larger neo-liberal logic that prioritizes the market as that which is the primary object of wealth creation, the focus for government promotional efforts and the supposed provider of welfare for the population. This notion of prosperity is the key to the good life and that agenda was key to the re-articulation of Canadian identity in terms of winners on the global stage in comparison to other states, and the provider of a commodity and real estate vision of the good life at home. Most obviously this translates into aspirations for a suburban lifestyle, one that developers are happy to provide in

the sprawling automobile suburbs that now house so many Canadians (Blais 2010). This has apparently entrenched the power of both petroleum companies and property developers in shaping the political economy of Canada. The shift of power has been both to the West, where most of the oil industry is based, with its headquarters in Calgary, and in electoral terms into the suburbs of most Canadian cities.

Second is the ambiguous impact of religion on public policy. While many of the Conservative party are what are called 'social conservatives' there are clearly networks of religious institutions especially in the Western provinces that draw on 'fundamentalist' doctrines, not least those that don't take things like climate change or evolution seriously. While it isn't clear that Prime Minister Harper's religious proclivities actually shaped his policy preferences, it is certainly a matter of discussion among those who have traced the rise of new religious organizations and their connection to the Conservative Party (Macdonald 2010). What is more important than the specifics of religious dogma is that these religious themes support the larger cultural politics of moral rectitude and the focus on personal salvation and economic success that underlies the assertion of conservative values. The alternative much 'greener' engagements between religion and environmental advocacy in North America (Wilkinson 2012), with their notions of environmental stewardship and responsibility for caretaking the earth were noticeably absent from the social conservative discourse.

Third, the rhetoric of the Conservative Party frequently used the figure of the persecuted outsider in appealing to numerous perceived grievances among Canadian voters. The regional dimensions of this were clear in the slogan used repeatedly by the Western-based Reform Party as in 'the West wants in'. Supposedly excluded from the halls of power in Ottawa, the Federal capital, and in Toronto where the financial heartland of Canada resides, the absence of parliamentary representation was a longstanding source of complaint. The social aspirations of Westerners and the much older social hierarchies in Central Canada supplied a very simple if misleading rhetoric of them and us that populist politicians used to good effect in election campaigns.

This social aspiration and sense of entitlement denied fed, fourth, into simplistic geopolitical formulations and imperial throwbacks in the formulation of Canadian foreign policy. Naïve assumptions of moral superiority were used to justify involvement in the bombing of Libya as well as the presence of Canadian

troops in Afghanistan. Language that contrasted democracies with dictators and terrorists painted the world as a dangerous place requiring moral certainties and the necessity to use force to ensure that Canada and the West is triumphant in a series of violent confrontations with evil and dangerous Others. The necessity of using virtuous violence is a given once the geopolitical formulations of distant danger and imminent threat dominate the script. It all fit with the Prime Minister Harper's proclivities for controlling things too.

Such Manichean formulations with their differential attribution of virtue and threat also spilled over into the highly charged partisan attacks on domestic political opponents. This fifth factor, the ad hominem politics, focused on the personalities and their supposed failings much more than it did on the policy prescriptions that those politicians or activists might be espousing; messengers are more important than the content of messages. While this was a widespread tactic, not least in the vitriolic campaigns against climate change activists and scientists which spilled over into the Canadian political scene, its prevalence as a way of silencing serious political discussion was especially dangerous when linked to 'gotcha' journalism and the personality politics in the talk show format of political commentary. Winning the argument was what apparently mattered. Reasoned political discussion and simple matters of factual accuracy are difficult to use effectively in such venues, a matter of considerable difficulty for sustainability advocates who unwisely assume a common acceptance of environmental values and reasoned debate as the basis for a democratic politics.

Sixth is the link between prosperity, threat and security. A key part of the Harper government's political rhetoric was the protection of Canadians from threats to their prosperity, and environmentalists who might object to pipelines and tar sands exploitation were of course linked to dangerous foreign funding arrangements. Where external threats are formulated to suburban prosperity the task for sustainable transition advocates becomes especially difficult. The insidious cultural messages celebrate conspicuous consumption as praiseworthy rather than excessive, irresponsible and eminently taxable! The inverted quarantine of suburban living where private provision of everything from security systems to bottled water is premised on a spatial division of safe internal domestic spaces from external threats, and the related cultural politics of family, masculinist safety provision and the necessity to rely on force in a dangerous

world, presents a geopolitics of division and violence that is antithetical to an ecologically sane mode of life for most of humanity (Szasz 2007).

These assumptions, powerfully reprised in conservative thinking of the Canadian variety, are now precisely the problems that need to be confronted. The claims to moral superiority, and the implicit assumptions of competition as the ontological given for humanity, likewise need once again to be confronted by a more complex geopolitical ontology that neither accepts the territorial assumptions of modern states as the final word on human organization, nor the ever-larger consumption of materials and energy as the aspirational motivation for politics. In short, the growth dynamics of capitalism and the dominance claims of extractive resource sector corporations and their political allies has to be confronted by both an alternative set of ontological premises and a political strategy that offers plausible alternative modes of governance.

22.5 Anthropocene Geopolitics?

Calls for a sustainable transition suggest the necessity of limiting consumption precisely because we live in an interconnected biosphere in which we are linked fairly directly to one another. The conservative political rhetoric and the ontological assumptions of autonomy and competition are antithetical to all this. Reinforcing assumptions of sovereignty and rivalry, of a world divided into competing states, with morality related to our success, even if that is part of a zero-sum game, the conservative invocation of the necessity of virtuous violence to ensure dominance of the current suburban mode of consumption is precisely what needs to be transcended. But that is not enough intellectually or politically now in the epoch of the Anthropocene (Brauch/Dalby/Oswald Spring 2011). Spelling out some of the implications of the Anthropocene, as the next few paragraphs do here, emphasizes how radically different a sustainable politics has to be from the kind of thinking epitomized by the Canadian Conservative Party.

The ecological premises for sustainability frequently assume a stable situation; life lived in ways that doesn't compromise the possibilities of future generations, to finesse the classic definition of sustainable development in *Our Common Future* (World Commission 1987). What the earth system analyses are making increasingly clear is that the geopolitical premises of modernity, of competing territorial states and expanding industrial power, don't work as the tools for think-

ing sustainably about the future. Neither should state boundaries be simply assumed (Fall 2010), although they are much more stable since the United Nations system has become the established institutional framework for international politics.

Ecological geopolitics has yet to come to terms with these conundrums; much hard thinking needs to be done on these matters. The irony that governance and hence political rivalry is understood through a series of categories specified in territorial terms precisely when what matters apparently crosses those boundaries is key to understanding the current dilemmas and to suggesting modes of analysis that can more effectively grapple with what is coming (Bulkeley/Andonova/Betsill et al. 2014). Shifting from a physics model of power, one of competing autonomous entities, of surveillance, territorial demarcation and military enforcement to an ecological sensibility that recognizes interconnection and change rather than permanence and fixity as key to flourishing life, is a fundamental ontological challenge to conventional understandings of politics and society. On the largest scale, that of the biosphere as a whole, this is exactly what now has to be brought into political discussion.

Many of the more thoughtful analyses of climate change have tried to tackle the matter beyond the conventional formulations that apply resource management or state administrative apparatus to the problem. The multifaceted nature of climate change, coupled with the urgency of addressing it, makes this a 'super-wicked' problem that defies a simple solution (Levin/Cashore/Bernstein et al. 2012). There are many technological innovations that are less carbon-intensive, but no technical fix that can resolve the issue in engineering terms. Climate change is part of the larger transformation of the global biosphere and as such touches on the most basic conditions of human existence. How it is tackled, or not, goes to the heart of politics, and to the big questions of world order that are the key matters of geopolitics.

Put most simply, humanity has changed the composition of the planet's atmosphere and raised the level of carbon dioxide close to 400 parts per million, well above levels that the planet has known in the last few hundred thousand years. This will inevitably set off disruptions to how weather systems function and do so in unpredictable ways. Unpredictable precisely because there is no analogous state in the recent history of the planet to which we can refer for indications as to how things might play out. Humans are part of this picture and will either suffer the consequences of disruptions or reap some benefits from

new opportunities dependent on the political and economic circumstances they find themselves in.

In so far as people avoid the worse consequences of climate disruptions, it will be because governments make reasonable preparations, but at least in terms of formal state structures so far many don't seem to be adapting quickly to the new realities of climate change. The Canadian Conservative government simply ignored climate realities in its rush to promote petroleum production and eviscerate the scientific knowledge systems that monitor changes and investigate ecological responses. Making these less susceptible to the vagaries of partisan politics is clearly something that needs further attention from all those concerned about sustainability. European states are further ahead but their record is patchy at best. Attempts to negotiating binding arrangements under the umbrella agreement of the widely adopted *UN Framework Convention on Climate Change* (UNFCC) have generated huge conferences and numerous other meetings but the carbon dioxide levels in the atmosphere continue to rise at an accelerating rate.

It is important not to focus on climate alone. The global economy has been constructed by large-scale environmental change in terms of the extension of agriculture into most of the world's ecosystems that can support crops (Ellis/Goldewijk/Siebert 2010). The loss of habitat for other species has led to the extinction of a sizeable percentage of the life forms that the planet supported until recently. Fishing combined with pollution and now increased acidification of the oceans due to rising carbon levels has transformed aquatic life systems too, with untold future consequences for many species apart from humanity. Human industrial systems 'fix' more nitrogen for fertilizers than natural processes do. Phosphorous likewise is increasingly an artificial cycle. Most large rivers have been dammed, diverted and modified, some to the extent that the waters in them don't reach their estuaries. Artificial urban habitats have been built that transform regional ecosystems as they provide the basic necessities of life for the burgeoning global population.

This is the new context for the human drama, one of our own making (UNEP 2012). It is within this new context of an increasingly artificial world that human vulnerabilities, and all sorts of insecurities, play out now. Given these new circumstances it seems fitting to many earth system scientists to designate the current period in terms of the Anthropocene, literally the age of humanity. In the Anthropocene, artificial circumstances define our existence and infrastructure,

markets and politics matter much more in terms of who lives and who dies than the immediate consequences of weather events, however severe or dramatic (see chapter 3 by Dalby in this volume). This is a global urban system that stretches beyond the actual boundaries of individual cities enmeshing people everywhere in the economic and ecological linkages that are globalization. This is a view of the world nearly entirely at odds with that of the Canadian Conservative Party.

22.6   Rethinking Politics

While the ontological premises for thinking intelligently about sustainability are easy enough to outline there remain major difficulties in challenging the dominant understandings of 'environment' that are no longer very helpful in thinking about the future. Most obviously what climate change and the discussion of the Anthropocene make clear is that what needs to be focused on much more clearly than in the past is matters of what is now being made. The point of the Anthropocene is just that; we are making the future (Brauch/Dalby/Oswald Spring 2011). The commodities, houses, roads and energy systems that power our constructions are the new ecological context, not an addition to an environment, parts of which have to be protected in the sense of preserved. Obviously crucial ecosystems need to be protected from some aspects of development, but now they need to serve also as migratory pathways for species set in motion by climate change. Stability is over and ecological responses are happening simultaneously with human changes to environments. Thinking in terms of ecological sustainability now has to work in terms of mobile ecologies.

This is antithetical to much of the territorial thinking that traditionally structured parks and preservation. Ecological planners understand this well; the questions are whether the territorial administrative tools we use to control the mobility of those considered undesirable, both human and other species, can now be adapted appropriately to facilitate migrations. A static cartographic imagination of virtuous locals facing threatening foreigners, the nationalistic impulse all too readily mobilized in the face of changes that are rendered dangerous, is precisely the wrong geographical framework for dealing with what is coming. But it is implicit in many of the formulations that contemporary 'conservative' thinking uses. If the projections of dangerous climate change that are increas-

ingly appearing in both climate science and now in the international investment analyses of future risks (PIK 2012), come to pass, rapid adjustments to changing circumstances will be needed, not militaristic attempts to prevent change by force.

In the Canadian case there has been considerable attention paid to the rapidly changing configuration of the Arctic as the ice retreats and the prospects of both new trade routes as well as oil and gas production in the newly accessible waters loom. While alarmist stories of imminent conflict there, and arguments about whose jurisdiction applies where, make good headlines, they are not what matters most (Kraska 2011). Arguing about who owns which island or what agency gets jurisdiction over sea-lanes isn't grappling with the bigger story. These are however familiar tropes that allow politicians photo opportunities and nationalist sound bites and journalists easy story lines that don't require much thinking about the causes of these changes. But this is dealing with symptoms of climate change, not dealing with the causes. It's adaptation after a fashion rather than mitigation, and while that is necessary now it's a focus that once again displaces attention from the more important issues of how to decarbonize capitalism quickly to slow the changes to many ecosystems.

Focusing only on the resource extraction sector deals with part of the problem of an unsustainable political economy, rather than the whole Canadian story. The consumption landscapes being built around the major urban centres without effective public transport, uneconomical because of the low density, and requiring extensive infrastructure construction as well as on-going energy consumption because of automobile use and the large houses that are key to the whole lifestyle, are the other side of the unsustainable ecology of this exemplary North American profligacy. The 'lock-in' of energy consumption for coming generations is part of the problem but the larger cultural politics of privatized consumption makes a politics of solidarity more difficult. Mobilizing around keeping taxes low, given the large expenditures involved in suburban houses, plays into the rhetoric of small government, not into innovative governance arrangements and the need to construct ecologically sustainable infrastructure with an eye to the long term in a changing climate.

22.7   Conclusions

At least six not particularly novel conclusions can be drawn from the Canadian federal political story of the last decade for those who wish to think seriously about sustainabilities and transitions to a post-carboniferous economy and society.

Most obviously is the simple lesson that activists concerned to make a more sustainable world ignore politics at their peril. Focusing only on narrow technical matters of environment, and assuming that legislation to protect various things will remain intact in the long run, are two dangerous tendencies that may appeal to academics in particular. The dynamics of multiple parties in the Canadian federal parliament are another factor that is less pronounced in other democratic states that have more equitable seat allocation systems than is the case in the Canadian 'first past the post' electoral arrangement. Nonetheless the rise of reactionary parties in times of crisis is a danger that sustainability campaigners need to anticipate. We do after all live in a political world, not a reasonable one. Thinking carefully how to make sustainability initiatives survive political storms is as important as building infrastructure that can survive extreme weather events.

The second lesson is that political economy matters! Confusing the rhetorics that legitimize states as the provider of services to all citizens with how power actually operates is a political trap. The rise of neo-liberal ideologies involves both numerous modes of rule that involve markets and management techniques that reassert the power of states, and does so in ways that underscore their primary function in facilitating capital accumulation. Rising inequality has been the result in most states where the business ideologies and managerial arrangements have been reasserted in the name of efficiency and prosperity. Power has also slipped away from states as they become enmeshed in complicated international trade agreements where foreign companies have the rights to sue governments trying to initiate social and environmental regulations deemed a challenge to corporate profits. In these situations states become dependent on external economic logics rather than domestic political priorities. Power doesn't reside simply with states; inter-governmental arrangements increasingly matter.

Which suggests, third, assuming that policy-making is actually coherent within states is also sometimes a mistake. Not only do different parts of state apparatuses have different priorities, forces outside the normal assumptions that modern states are coherent uni-

tary entities often drive them. This is frequently exacerbated by nationalist rhetoric and the assertion of sovereignty in perverse ways that obscures the international economic situation. In the Canadian case provincial powers are often in conflict with federal priorities and the solutions are complex political compromises, or at least they were until the Stephen Harper conservatives became the majority government and set about limiting cooperation and consultation and imposing solutions where they could.

Fourth, is a reminder that governance by market is frequently a chimera. Markets can't decide many things, not least the most important things like what the future of the biosphere should be! They may be good at some distributional issues, but the profit motive and the failure of markets to signal long-term environmental dangers have brought us to the climate crisis. In Nicholas Stern's terms (2006), in his crucial economic analysis of the issue, climate change is the biggest market failure the world has ever seen. The early 2013 crisis in European carbon markets only emphasizes the point that market mechanisms are only as good as the rules that run them and these are unavoidably political issues (Paterson 2012). Focusing on production decisions and national policies about what gets produced rather than assuming that markets will make the things we need without being constructed to do so is important. Feed-in tariffs and other financial measures have been key to getting renewable energy industries started in many places; there is a politics to this that forces innovation. But such innovations are apparently easier in states without fossil fuel producers who understand such innovations as the competition.

That said, fifth is the simple but important point that in the globalized world economy of the present authority as well as climate governance initiatives (Bulkeley/Andonova/Betsill et al. 2014) is diffusing to new sites—provinces, cities, corporations and international arrangements. Sustainability strategies need to bear in mind that cooperation in all sorts of venues is going to be needed, and in the aftermath of the global financial crisis of the last few years and the exposure of the flawed assumption that financial systems work reliably or that banks are best left to their own devices, new opportunities to use the tools that they have developed for other ends may arise. Leo Panitch and Sam Gindin (2012) close their recent overview of the rise of global capitalism by musing on the political conditions that might yet turn international financial institutions into public utilities devoted to very different priorities from profit-making through

ever more abstract derivative trading schemes. This point also needs to be remembered in coming discussions of sustainable institutions.

Finally, to return to the ontological premise point made earlier in this chapter. The assumptions that the world is an intrinsically competitive place and the only option is to play to win have to be confronted directly in any discussion of sustainable futures. The task ahead for scholars concerned about sustainable transitions is to change the assumption that politics is necessarily only about dominating a divided world. Instead we need to focus on matters of how to share a crowded one (Dalby 2014). This is going to require a much larger discussion of inter-generational and intra-generational equity and a focus on making useful things that do not foreclose future ecological flexibilities. It is going to require thinking hard about how to adapt to changing circumstances in cooperative ways, rather than trying to resist change by using old-fashioned borders and the threats of force. Such geopolitical premises have no place in a sustainable future once it is realized that we are all part of a single biosphere that we are collectively remaking at something close to breakneck geological speed. Above all it is going to require much more careful thinking about political strategy where, based on short-term economic and parochial nationalist premises, there is intense opposition to sustainability initiatives.

While the Canadian Conservative Party was defeated in a Federal Election in October 2015, their actions over a period of nine years to dramatically reduce the capacity of the Canadian state to both monitor environmental change, and facilitate policies of transition to sustainability, is a warning to transition advocates that pre-empting such political programmes has to be part of any strategy that looks to the long-term future. The Liberal Government sworn in on November 4th 2015 with Justin Trudeau as Prime Minister has much work to do to repair the damage to Canada and its international reputation. It will probably help that Stephane Dion will serve as foreign affairs minister in that new government; his record on climate will probably ensure that at least Canada will no longer be an obstacle in climate negotiations. But a possible transition to a more sustainable Canadian future has been tragically delayed by at least a decade.

23 Regime Change, Transition to Sustainability and Climate Change Law in México

Juan Antonio Le Clercq[1]

Abstract

This chapter analyses the creation of the Climate Change Law in Mexico as a governance regime where horizontal and vertical interplay became key elements. The legislative deliberations oriented towards creating the Climate Change Law, mainly between 2005 and 2012, are understood as a preliminary and as take-off phases of a pathway to a sustainable transition. The principal elements of Mexican climate policy are discussed. Three competing alternatives for climate legislation in 2012 are identified, as are the reasons for opting for a specific climate regime. The chapter argues that even though the Mexican climate regime represents a very ambitious model in its design, and although a preliminary and take-off phase can be identified, problems of fit with other policy objectives, especially the features of the energy sector, limit the possibilities for a sustainable transition in Mexico.

Keywords: Regime change, sustainable transitions, transitions phases, climate change law, institutional change, Mexico.

23.1 Introduction: Regime Change as a Pathway to Sustainable Transition

Climate change is a global collective action problem that no country can solve by itself. Its complex characteristics and differentiated impacts demand international cooperation for the distribution of rights, duties and the sharing of financial burdens (Barret 2007; Gardiner 2011). Without a more efficient and fairer global political architecture it will be extremely difficult, in fact almost impossible, for humankind to start stabilizing CO_2 emissions in the next decade in order to contain the impact of global warming around the globe (Helm/Hepburn 2009; Biermann/Pattberg 2012; Dryzek/Norgaard 2013).[2]

But it is mistaken to conceive of climate change as an exclusively international issue. Negotiations for a new global climate deal will make a difference if the deal defines more effective criteria for the parties to design their national policies from a polycentric or multilevel perspective and to develop human and organizational capabilities according to their particular needs (Paavola 2008; Ostrom 2009).

Institutional change is a prerequisite for the integration of the climate agenda into the policy framework of developing countries. It is also a priority task for the improvement of more efficient multilevel coordination mechanisms. Institutional weaknesses lead to reduced capabilities to fulfil goals and responsibilities as defined in the *United Nations Framework Convention on Climate Change* (UNFCCC), such as emissions inventories, cost-benefit analysis of available options for emissions reduction, systematic research, vulnerability assessment, and the design of adaptation strategies.

The environmental governance perspective points to a relationship between the quality of institutional design, regime interplay and effectiveness in dealing

---

with global challenges such as biodiversity loss, the degradation of ecosystem services or the impacts of climate change (Young 2002; Young/King/Schroeder 2008; Paavola 2007; Biermann/Betsill/Gupta et al. 2010; Bechtel/Scheve 2013; Van de Graaf/De Ville 2013; Young 2013). Reports from agencies such as the *Organisation for Economic Co-operation and Development* (OECD), the World Bank and the *United Nations Environment Programme* (UNEP) also tend to focus on the importance of strategies for overcoming institutional inertia and maximizing the benefits of institutional change in developing countries (WB 2010; OECD 2010).

Institutions matter in dealing with climate change. However, even when developing countries recognize the importance of institutional change, the development of new capabilities and the creation of specific regulatory frameworks for sustainable development, these are especially complex problems. Designing reportable mitigation and adaptation policies and simultaneously fostering institutional change is a difficult combination when economic growth is a top priority, there is a shortage of financial resources, and socio-economic inequalities are consequently widened.

The discussion about the importance of institutional change and its different paths in the face of global climate change is especially relevant for Mexico after its adoption of a Climate Change Law in 2012. This law, which has been internationally recognized as ambitious flagship legislation, formalizes a national climate strategy and a programme developed during the first decade of this century and establishes them in a long-term framework for coping with climate change.[3]

Between 2010 and 2012, during the legislative process that resulted in the *Climate Change Law* (CCL), it became evident that Mexico required new and different institutional mechanisms for three main reasons: 1) even as a Non-Annexe country without miti-

gation obligations according to the Kyoto Protocol, its energy matrix depends ninety per cent on fossil fuels and, as a by-product, is the major contributor to *greenhouse gas* (GHG) emissions from energy generation and consumption in Latin America;[4] 2) its territory is highly vulnerable to droughts, floods, ecosystem loss, heatwaves, changes in precipitation patterns, infrastructure destruction, damage caused by natural disasters and decline in agricultural production, with additional effects for the section of the population living in poverty;[5] 3) since the Earth summit of 1992, Mexico has played an important role in setting up the global climate architecture and has supported emission reduction goals for emerging economies.

This chapter tries to respond to three related questions: Why did legislators in Mexico opt for a climate regulation model that resembles a governance regime? Does the climate regime define a clear path to a sustainable transition? To what extent will the specific features of the *Climate Change Law* (CCL) have an effective impact on Mexico's climate policy?

The theoretical approach to answering these questions uses an environmental governance perspective that integrates the conceptual elements developed in the institutional dynamics literature (particularly the contributions of Oran R. Young, Jouni Paavola and Frank Biermann), and the theory of transition to sustainability (the works of John Grin, Frank Geels, René Kemp, Jan Rotmans and Johan Schot). In discussing the emergence of the CCL, the analysis focuses par-

---

3   The Climate Change Law (*Ley General de Cambio Climático*) was approved on 19 April 2012 after two years of legislative debate (see at: <http://www.diputados.gob.mx/LeyesBiblio/ref/lgcc/LGCC_orig_06jun12.pdf>). In 2007 the Calderon Administration defined the first National Climate Change Strategy (*Estrategia Nacional de Cambio Climático*), together with a programme with specific mitigation and adaptation goals and objectives (*Programa Especial de Cambio Climático* 2008–2012). In this chapter these documents are referred to as ENACC and PECC, and they can be consulted at: <http://cambioclimatico.inecc.gob.mx/ccygob/ccygob.html> and at: <http://dof.gob.mx/nota_detalle.php?codigo=5107403&fecha= 28/08/2009>.

4   Mexican GHG emissions grew by 33.4 per cent between 1990 (561,035.2 Gg CO_2e) and 2010 (8,748,252.2 Gg CO_2e) due to an energy balance that depends ninety per cent on fossil fuels (SEMARNAT 2012; Fifth National Communication to the UNFCCC (2012, 195-197); at: <http://www2.inecc.gob.mx/publicaciones/download/685.pdf>. According to the *International Energy Agency* (IEA) (2014: 48-57), Mexico's emissions for 2012 were 435.79 $MtCO_2$ from fuel combustion only. These figures are far lower than those of other Non-Annexe 1 Parties such as China (8,205.86 $MtCO_2$) or India (1,954.02 $MtCO_2$), but higher than any other Latin American country except Brazil (440.24 $MtCO_2$). The World Resource Institute identifies Mexico as the ninth highest global emitter, with a 1.67% contribution to global CO_2 emissions, at the same level as Indonesia, Iran, Canada, South Korea and Australia; see at: <http://www.climatecentral.org/news/greenhouse-gas-emissions-by-country-19167>.

5   The PECC (2014-2018) includes an updated diagnosis of the risks and vulnerabilities facing Mexico; at: <http://www.dof.gob.mx/nota_detalle.php?codigo=5342492&fecha=28/04/2014>.

ticularly on how a national climate regime model, a vertical and horizontal interplay design, was imposed over two less ambitious legislative alternatives, and the way this process fosters a sustainable transition to some degree.

The rest of this chapter is organized in six parts. First we discuss the relevance of some concepts central to the environmental governance perspective, such as regime and vertical and horizontal interplay, and then we distinguish the different phases of a sustainable transition. Second, the influence of international–national interplay is highlighted for the case of Mexico. Third, the main features of the Mexican climate policy implemented between 2006 and 2012 are identified. In the following two sections the analysis centres on the Mexican legislative process understood as a preliminary phase and on the approval of the CCL as a take-off moment for a sustainable transition. In the last part we conclude.

23.2   A Preliminary Phase of a Sustainable Transition

Following Paavola (2008), Ostrom (2009) and Young (2013), 'interplay' is defined as an institutional interaction with two dimensions: a) vertical or horizontal institutional levels; or b) between different arenas (environment, energy, urban planning, social or economic development, etc.). Horizontal interplay refers to an institutional or agent interaction within the same policy or organizational level (local, national, regional or international), while vertical interplay refers to multilevel or polycentric interplay. Both dimensions necessarily relate regime-building or institutional change to the problem of fit (Young/King/Schroeder 2008; Folke/Pritchard/Berkes et al. 2007; Paavola/Gouldson/Kluvánkova-Oravská 2009; Biermann/Betsill/Gupta et al. 2010; Keohane/Victor 2010).

Governance regimes are institutional compounds within the same or different levels of organization, with a non-rigid integration that produces interaction, mutual influence and feedback effects (Keohane/Víctor 2010; Oberthür/Gehring 2011; Paavola/Gouldson/Kluvánkova-Oravská 2009; Biermann/Betsill/Gupta et al. 2010; Young 2012). Interpreting the case of Mexico from the perspective of governance regimes has the analytical advantage of enabling institutional dynamics to be understood as nested interactions and overlaps instead of reducing it to the work of a single institution or a law.[6]

A first argument is that Mexican legislators involved in the creation of the CCL assumed that a central feature of the law design had necessarily to be a nested interaction or 'transversality'. They understood that dealing with the complexities of climate change required a new framework—a regime, for example, capable of solving the problem of interplay and fit. A second argument is that once they promoted a climate regime rather than alternatives oriented towards reforms of individual laws, indirectly they also linked institutional change with a transition to sustainability.

A 'transition' is a deep transformation that affects the structures, practices and value systems of a society, an open process involving multiple organizational levels and different phases. More than an instrument to operationalize governance models or a change towards sustainable development (Parris/Kates 2003; Kemp/Parto/Saed 2005; Geels 2005; Geels/Schot 2007; Grin/Rotmans/Schot 2011), this concept refers to the actors' capability to lead and determine the transformation processes in a society's sociotechnical subsystems.[7] A transition means a "radical transformation toward a sustainable society as an answer to a number of persistence problems facing modern societies" (Grin/Rotmans/Schot 2011: 11–12).

According to Kemp, Parto and Saed (2005), a transition towards sustainability requires a deliberate attempt to transform the social structure in a series of gradual stages. Geels and Schot (2007) stress the need for multilevel changes in sociotechnical regimes with the goal of establishing a new equilibrium and alignment among their constitutive elements. Grin, Rotmans and Schot (2011) differentiate the change processes involved in transitions towards sustainability using five characteristics: 1) co-evolutionary processes requiring changes or reconfigurations in the sociotechnical systems; 2) changes involving multiple actor

---

6   The idea of regime change and genesis has been central in international theory and global governance literature following the influence of Krasner 1983, Keohane 1982, Young 1986 and Haggard/Simmons 1987. Krasner (1983: 19) defines 'regime' as "implicit or explicit principles, norms, rules and decision-making procedures around which actors' expectations converge in a given area of international relations".

7   The concept 'sociotechnical system' refers to a "level of societal domains or functions such as transport, energy, housing agriculture and food, communication and healthcare". Sustainable transitions are "shifts from one socio-technical system to another" (Grin/Schot/Geels 2011: 6).

interactions; 3) radical transformations of a system or configuration towards a new one; 4) long-term gradual processes; and 5) macroscopic transformations at the organizational level.

Regardless of the approach, a transition towards sustainability involves the multilevel interaction of three core variables (Geels 2005; Geels/Schot 2011; Grin/Rotmans/Schot 2011):

1. The existence of 'niches' for innovation. This implies that a small group of innovative actors are capable of identifying and fostering changes that stem from their expectations and visions regarding a sustainable future, thus starting broader transformations in a society's sociotechnical subsystems;

2. 'Regime level' changes. In this case the impact of niche-level innovations opens windows of opportunity to change the configuration of sociotechnical regimes and guide them towards new balances that are more favourable for the development of new innovations;

3. The 'landscape change' or innovations in the regime that impact the sociotechnical picture as a whole, thus spreading the new kinds of practices and consolidating the process of transition towards sustainability.

While the degree to which political and social actors can design and control this kind of transformation is arguable, much less clear is the intention of the Mexican Congress to activate a transition; if the pre-assumptions of these approaches are correct, then by choosing a climate regime they put on the agenda the implicit need to foster some kind of transition towards sustainability. In the statement of purpose of the main initiative and the preliminary draft of the law, Congress assumed that as a consequence of the CCL a major social transformation guided by sustainability principles would be promoted. In other words, the Mexican case represents an attempt to frame a transition towards sustainability through a planned regime change.

The fact that the Mexican climate regime involves a transition towards sustainability does not necessarily imply that this objective will be achieved in the near future. On the contrary, a transition in Mexico entails conflictive and contradictory coexistence between practices oriented towards sustainable principles and the reproduction of an economic growth model based on the exploitation of hydrocarbons. Nor does the existence of a regime as a formal framework mean that an effective capability will be available to regulate individual practices or conduct. The Mexican case illustrates the problem of fit[8] between different regime types, economic development and social objectives encompassed within the general objective of transition towards sustainability.[9]

From a multiphase perspective, a transition towards sustainability can be divided into four clearly differentiated phases: 1) a pre-development phase "in which the status quo of the system changes in the background, but these changes are not visible"; 2) a take-off phase in which the "process of structural change picks up momentum"; 3) an acceleration phase when "structural changes become visible"; 4) and a stabilization phase "where a new dynamic state of equilibrium is achieved" (Grin/Rotmans/Schot 2011 2011: 4-5).

The creation of specific law for climate change in Mexico may be interpreted as the definition of a transitional agenda that encompasses two phases inherent in the transition process: first, a pre-development phase in which actors identify the problem and begin to define a public response to it; and second, a take-off phase which actually begins with the approval and publishing of the Law and with it the legislative decision on establishing a climate regime.

When we understand the creation of a climate regime as an arena for transition it is possible to identify a pre-development phase, a moment where changes in the background are still not visible as part of a sustainable transition path in which: 1) political actors and social organizations identify and diagnose the problem and its consequences for Mexico; 2) political actors acknowledge the importance of developing an agenda that involves institutional changes and the formulation of public policies; 3) the government defines national goals and adaptation and mitigation objectives and assumes international commit-

---

8 The problem of fit refers to (in)compatibility, (mis)match or contradictions between a set of social institutions or between the properties of a biophysical system and the features of an institutional framework. See Young/King/Schroeder 2008 and Folke/Pritchard/Berkes et al. 2007.

9 The particularity of climate change in Mexico is discussed in Julia Martínez and Adrián Fernández Breamauntz: *Cambio climático: una visión desde México* (Mexico, D.F.: SEMARNAT-INE, 2004); Simone Lucatello and Daniel Rodríguez Velázquez: *Las dimensiones globales del cambio climático. Un panorama desde México. ¿Cambio social o crisis ambiental?* (Mexico, D.F.: Instituto Mora-UNAM, 2011); and José Luis Calva: *Cambio Climático y políticas de desarrollo sustentable* (Mexico, D.F.: Análisis Estratégico para el Desarrollo vol. 14, Consejo Nacional de Universitarios, 2012).

ments; 4) government authorities establish programmes and specific objectives as pressure increases from *non-governmental organizations* (NGOs) for higher commitments and the private sector lobbies to avoid impacts or costs on their activities; and 5) once the agenda is defined, it is possible to evaluate and verify the level to which the programme's goals have been fulfilled.

23.3   National–International Interplay

The design of the Mexican climate legislation is framed by a context characterized by a high level of participation in international climate change negotiations. Mexico ratified the UNFCCC on 7 May 1993 and the Kyoto Protocol on 24 November 2000; promotes at international commitment level the national goals established in the *Climate Change Special Programme* (PECC) to reduce emissions of *greenhouse gases* (GHG), and became one of the first countries to define voluntary obligations in compliance with the agreements achieved in the Copenhagen Agreement.[10] Additionally, Mexico is the only country that has presented up to five national communications as a Non-Annexe Party of the Kyoto Protocol.[11]

The interplay of national politics with climate change and international negotiations was important for Ernesto Zedillo and Vicente Fox's governments, though it was Felipe Calderón who became the leading promoter of Mexican climate policy between 2006 and 2012. During this administration, international negotiation became an interplay element that influenced the definition of national policies. The

international commitments that were taken on, the activism in international negotiations, and the growing media and political impact of climate summits all played an important role in justifying the need for action in the national arena. In addition, advances in the definition of the *National Climate Change Strategy* (ENACC) and PECC, the development of methodologies to implement plans at state level, and the deliberations to create the CCL were all used at an international level as proof of Mexico's commitment to a global climate architecture.

The organization of the Sixteenth *Conference of the Parties* (COP) in Cancun in 2010, and the incorporation of a climate agenda into G20, signalled the importance of national–international interplay in this period. The organization of the COP, which involved political risks after its previous failure in Copenhagen, was translated into a success for the Calderon administration in many senses: a) it relaunched a stalled international negotiation by opening a parallel way based on a portfolio of projects and mechanisms that did not necessarily depend on a great binding agreement; 2) it integrated the proposal outlined in the PECC to create a Green Fund, oriented towards guaranteeing more resources to finance mitigation and adaptation projects in non-Annexe 1 countries; 3) it consolidated Mexican foreign policy on international negotiations and allowed Felipe Calderon's leadership to be promoted through presenting him as a central figure in global climate policy; and 4) no less importantly, it put the national climate policy, created during this government period, into the national and international spotlight (De Alba 2010; Hedegaard 2010; Le Clercq 2010).

Strengthing international cooperation and Mexico's active participation in climate negotiations were important issues during the legislative deliberations. Nevertheless, the different projects discussed do not incorporate specific mandates related to international–national interplay. Congress acknowledges the importance of defining national commitments through the law and of reinforcing the Mexican position in the negotiations, but a Non-Annexe Party condition was assumed and, therefore, the national climate policy was understood as a strictly voluntary effort.[12]

Alternatively, it would be an error to think that the climate legislation design was an inevitable conse-

---

10 The National Mitigation Actions of Mexico are included in the Copenhagen Agreement Appendix 2: "Mexico adopted its Special Climate Change Programme in 2009, including a set of nationally appropriate mitigation and adaptation actions to be undertaken in all relevant sectors. The full implementation of the Programme will achieve a reduction in total annual emissions with respect to a business-as-usual scenario of 51 million tonnes CO2e by 2012. Mexico aims at reducing its GHG emissions by up to 30 per cent with respect to the business-as-usual scenario by 2020, provided that adequate financial and technological support from developed countries is provided as part of a global agreement"; see at: <http://unfccc.int/meetings/cop_15/copenhagen_ accord/items/5265.php>.

11 The National Communications were presented in 1997, 2001, 2006, 2009 and 2012. They can be consulted at: <http://unfccc.int/national_reports/non-annex_i_natcom/submitted_natcom/items/653.php>.

12 Mexican authorities have consistently stated in their programmes and official documents that the national climate policy represents a voluntary and not an internationally binding effort.

quence of Mexican activism in international negotiations. Even if Congress identified international benefits for the Mexican position in approving the CCL, the process ran on a different track and was driven by a deliberation about the internal benefits of approving the climate legislation and providing an impulse to some form of transition towards sustainability. In other words, the approval of the CCL must be understood as a legislative outcome that responded to national objectives and as an endogenous equilibrium of the political parties' positions, the federal government's objectives, and the agendas of the social actors involved in the process.

23.4 The Definition of a National Climate Change Policy

Between 2006 and 2012 national climate programmes were designed with measurable and verifiable goals and objectives. This model of national climate policy defines a coordination scheme for the federal government agencies to fulfil mitigation and adaptation goals and objectives, and establishes a methodological definition for elaborating local climate plans that correspond to the national strategy.

The main elements of the Mexican policy (table 23.1) are linked in an extensive planning chain comprising:

1. The existence of an inter-ministerial commission (CICC) as a coordination device for the different agencies of the federal government involved.
2. Objectives defined in the *National Development Programme* (PND 2007-2012). Besides taking a Sustainable Human Development approach to the planning of public policies, this includes two objectives and eight specific strategies for mitigating GHG and the goals for adaptation to face the inevitable effects of climate change.[13]
3. Strategic guidelines defined in 2007 through the ENACC. Even though this is only binding at the federal level, it proposes a diagnosis of the national challenges, specific action lines regarding

energy generation and use, vegetation and land use, and vulnerability and adaptation, as well as Mexico's general position in international negotiations.
4. Implementation of the strategic guidelines and objectives defined in the PND 2007-2012 and the ENACC through the PECC for the period 2008-2012. This consists of 100 mitigation, adaptation and interplay objectives, translated into 294 measurable, verifiable and reportable goals.
5. Methodologies and criteria for producing state climate action plans coordinated by the *National Institute of Ecology* (INE) and the voluntary register of the private sector's emissions through the Mexican Programme on Greenhouse Gases (Programa GEI México).[14]

Regardless of its virtues and limitations, the main problem of the climate policy implemented between 2006 and 2012 was its inability to guarantee its own continuity after a change in administration. While the PECC was designed as a planning instrument that set immediate (51 million tCO2 by 2012) and long-term (indicative objective to reduce fifty per cent of total emissions by 2050) mitigation goals, and that defined an adaptation trajectory divided into stages of vulnerability assessment and evaluation of economic implications (from 2008 to 2012), capability strengthening (from 2013 to 2030) and consolidation (from 2031 to 2050), it could not legally extend its objectives beyond 2012. Even though the definitions of mitigation goals and obligations were based on a CO2 emissions trending scenario established on the Base Emissions Line, the PECC define its goals as "an indicative objective or aspirational goal", which, in addition, depended on "the industrialized countries giving the financial and technological support to complement the national efforts".[15]

From a multilevel governance perspective (Paavola 2008; Ostrom 2009; Young 2013), it became evident that this model was not capable of solving vertical national interplay or the coordination problems between government levels, and neither was it capable of establishing a fit between conflicting sectorial objectives. While it sets measurable and verifiable goals and objectives, the problems of correspondence

---

13 The *National Development Programme* (PND) is the general planning document for each government administration. It establishes national objectives, strategies and government priorities for a six-year period. The PND 2007-2012 included for the first time a sustainability axis and climate change goals. See PND (2007: 21-37, 231-265); at: <http://dof.gob.mx/nota_detalle.php?codigo=4989401&fecha=31/05/2007>.

14 The GEI Programme is a voluntary emissions registration scheme with more than 120 participating companies from different economic sectors. It is coordinated by the private sector and the environment authorities (SEMARNAT); see at: <http://www.geimexico.org/>.
15 See PECC (2009: vii, 14, 20).

Table 23.1: Climate policy instruments, objectives and goals (2006–2012). **Source:** Information from PND (2007–2012), ENACC (2007) and PECC (2009).

Instrument	Energy Mitigation	Land Change Mitigation	Adaptation	Institutional Capacity
PND 2007–2012	Four strategies: efficiency and clean technology for generation; efficient use; international standards for vehicle emissions; emission recuperation from waste	Objectives for biodiversity and forests	Four strategies: integration of adaptation and planning, climate scenarios, sector vulnerability assessment, information diffusion	PECC links its objectives with the PND 2006–2012 thematic axes
ENACC 2007	14 mitigation opportunities equivalent to +/- 106.8 MtCO2e/year 17 Guidelines	Mitigation potential: Conservation: 11,000–21,000 MtCO2 Storage: 18.08–42.16 MtCO2 Substitution 2.5 MTCO2 Mitigation agriculture and livestock: 9.7 MtCO2e 7 Guidelines	Vulnerabilities identification and capability development: risk management, water management, biodiversity and environmental services, agriculture and livestock, coastal areas, human settlements, energy generations and use 13 Guidelines	National definition for international climate negotiations

and fit with other policies also made the possibility of fostering climate policy within the broader objective of a sustainable transition difficult. Even when climate policy focused on setting the basis for encouraging the decarbonization of the economy and increasing capabilities for adaptation, the truth is that this aspiration was in conflict with an energy model based on hydrocarbon production, a tax regime with few incentives for generating renewable energy and with a high level of subsidies for fuel and electricity, and the definition

Figure 23.1: Legislative process concerning climate change in Mexico (1992–2012). **Source**: Information from the Chamber of Deputies, the Senate and the *Legislative Information System* (SIL); at: < diputados.gob.mx/>; <senado.gob.mx/>; and <sil.gobernacion.gob.mx/>.
of urban development plans that conflicted with the objectives of conservation and non-motorized mobility, to mention just a few examples.

23.5   The Mexican Legislative Process and Climate Change: the Preliminary Phase

While the process of creating the Climate Change Law began in 2010, climate change had been a relevant issue in Congress since 2000, with the inclusion of reform bills and policy calls in legislative debates.[16] Interest in climate change legislation in Mexico began early in the first decade of the twenty-first century, although it was between 2005 and 2010 when the number of amendment projects (initiatives) regarding

climate change increased. At this stage the need for an adequate legal framework was acknowledged and possible alternatives for new regulation modalities, incentives systems and policy instruments were identified. Between 1992 and 2012, 119 legislative bills and 154 policy calls were presented specifically on climate change topics in Congress by the different parties (figure 23.1).[17]

Legislative work concerned with climate change gains relevance in the Mexican Congress up to the LX and LXI legislatures (2006–2012), not to mention the nine initiatives and eighteen policy calls that were presented in the previous years. This period involved two different groups of deputies (elected in 2006 and

16 For explanatory purposes, the term 'policy calls' is used to translate the legislative mechanism "Proposición con Punto de Acuerdo", which refers to the capacity of Congress to exhort governmental authorities. Congress can ask the government to do or stop doing certain things in the policy arena but this is a non-binding power. Nevertheless these exhortations are important in deliberations concerning national policy.

17 194 bills and 244 policy calls were identified that included the word 'climate change' between 1992 and 2012. In some cases the reference was circumstantial, so in the end 119 bills and 154 policy calls were included in the sample. All the legislative information used in this article was gathered and classified by year, political party, chamber of origin and topic from the available data in *the Chamber of Deputies*, *the Senate* and the *Legislative Information System* (SIL); at: <diputados. gob.mx/>; <senado.gob.mx/>; and <sil.gobernacion. gob. mx/>.

Figure 23.2: Climate change bills by topic (2006–2012). **Source**: Information from the Chamber of Deputies, the Senate and the *Legislative Information System* (SIL); at: <diputados.gob.mx/>; <senado.gob.mx/>; and <sil. gobernacion.gob.mx/>.
2009, respectively), but the same group of senators (elected in 2006). From the perspective of the climate change debate, these administrations are characterized by encompassing the beginning and failure of international discussion on the need for a period of post-Kyoto obligations, the formulation of a national policy on climate change, and the outbreak of the greatest international economic crisis of the post-war period. This group of legislators also participated in the 2008 energy reform process, approved legislation centred on promoting renewable energies, and presented the main proposals that shaped the CCL in 2012.

The absence of projects from the Executive Power during any given period stands out, but it is especially evident during the LX and LXI legislatures, which concurred temporarily with the issuing of the ENACC, the PECC, the organization of COP 16 in Cancun and the beginning of deliberations regarding the creation of a general law to address the climate change problem. Felipe Calderon's legislative agenda focused on security and economic issues, followed at a great distance by education and energy.

If we break down the relevant law initiatives and policy calls presented by each parliamentary group since 1999 by theme, we can understand the way in which legislators and parties have tried to simplify the

complexity of climate change effects and to define criteria for an institutional response. When we analyse the content of the different legislative bills presented on climate change since 1992, it can be seen that legislators have understood that the definition of the legal basis for the mitigation of GHG derived from the generation and consumption of energy (thirty-one per cent) must be seen as a top priority, despite the fact that Mexico is a Non-Annexe 1 country and therefore not obliged to define punctual goals for emissions reduction. The second important issue is the diversity of proposals centred on problems related to adaptation (eighteen per cent). We have to add eight initiatives of a comprehensive nature that incorporate both mitigation and adaptation objectives and nine that incorporate new faculties for authorities and criteria for national strategies and programmes (figure 23.2).

It never ceases to be amazing that most initiatives centred on adaptation are only half the number of those centred on mitigation, especially if the high vulnerability that characterizes the Mexican territory and the high frequency of natural disasters and periods of drought are taken into account, as well as the fact that the legislative discourse has insisted on setting adaptation as a priority in the definition of policies and resource allocation in the face of climate change. In this case a reactive view of the inevitable conse-

Figure 23.3: Climate change legislative policy calls by topic (1992–2012). **Source**: Based on information from the Chamber of Deputies, the Senate and the *Legislative Information System* (SIL); at: <diputados.gob.mx/>; <senado.gob.mx/>; and <sil.gobernacion.gob.mx/>.
quences of climate change prevails, and this is often translated into pleas for the federal authorities to act once disasters have occurred and to allocate greater financial resources to local authorities.

Regarding the 169 policy calls that have been presented since 2001 on climate change, policies for energy mitigation and adaptation have been given high priority (16 per cent) but have come second as the main concern to the conduct of foreign policy (20 per cent). Other issues that have gained relevance are the definition of the goals and objectives of government policy (13 per cent), political discussion centred in natural disasters (12 per cent), and the demand for budgetary resources to face the effects of the rise in temperature and of natural disasters (11 per cent).

During the last decade there has been growing legislative interest in creating a new institutional framework for dealing with climate change in Mexico. Nonetheless, most bills limit their purpose to including minimal amendments and conceptual changes to current laws. It is from the legislative initiatives presented in 2010, a set of "flagship legislation" proposals or pieces oriented towards creating a new legal framework or, at least, towards modifying substantial layers of pre-existing legislation (Townsend/Fankhauser/

Matthews et al. 2011), that the idea of a climate regime took off.

23.6 The Climate Change Law as a Take-Off Phase

2010 represented a turning point in the legislative deliberation on climate change in Mexico, because a group of legislators presented a set of much more ambitious initiatives, 'flagship legislation' initiatives, that changed the terms of the debate and activated a process of deliberation involving the different parties represented in Congress, NGOs, private sector organizations, specialists and federal government authorities. From the perspective of a transition to sustainability and its division into separate phases (Grin/ Rotmans/Schot 2011), the legislative bills and policy presented between 1990 and 2010 can be understood as part of a 'preliminary' phase, but the adoption of the CCL in 2012 and the creation of a climate regime are part of a 'take-off' phase towards some modality of sustainable transition.

While legislators acknowledged the relevance of the ENACC and PECC in their proposals, and almost

all the legislative drafts took as a reference the policy instruments developed between 2006 and 2012, it was also evident that: 1) the policy did not have elements to guarantee its continuity in the long term and it was binding only at federal level, and therefore depended on the goodwill and personal commitment of future governments; 2) there were no criteria for coordination with local governments, apart from the methodologies defined by the INE; 3) it was necessary to design new institutions, planning and market instruments, and participation and information devices, to meet the mitigation objectives beyond the established 2012 goal and to advance to a second phase in the adaptation policy;[18] 4) while the PECC clearly defines mitigation goals and fosters capabilities to face adaptation problems, it does not place them in the broader context of a transition to sustainability; 5) even though the PECC established mitigation goals for 2012 and a longer mitigation path was signalled, there were no objectives or strategies to fulfil these in the long term, and it was also difficult to foster the goals without a transition towards a sustainable low carbon economy; 6) finally, the programme consisted of public mitigation efforts with no mandatory commitments on the side of the private sector following the trends indicated by the National Emissions Inventory.

The social organizations and experts involved in the legislative deliberation also questioned the sense and scope of the national policy, something that became increasingly evident in different forums and working groups that were organized between 2010 and 2012 by Congress. For the main environmental organizations, the objectives and goals set for 2012 were insufficient; they were not ambitious enough to tackle Mexican challenges and they were unrelated to a sustainability transition approach.[19]

In the case of the process of creating the Mexican climate change law, the identification of a window of opportunity (the emergence of a novel issue on the national agenda), the acknowledgement of the seriousness of the risks involved (the vulnerability of the nation in the face of the phenomenon's conse-

quences), and the recognition of institutional weakness (the non-existence of a framework legislation), all explain why between 2010 and 2011 a group of legislators presented a set of legislative bills substantively different from all those related to previous projects, and began legislative negotiations oriented towards creating a specific institutional regime for dealing with climate change.[20]

The legislative deliberation on climate change began formally with the bill presented by Senator Cardenas from the *National Action Party* (PAN), and was followed by proposals from other parties, and gradually representatives of the private sector, social organizations, experts and government authorities became involved in the process, influencing the agenda for deliberation and draft documents of the legislative commissions. It should be pointed out that, given the diversity of the actors involved, the creation of a climate regime reflected a kind of bottom-up governance deliberation, where an equilibrium was not automatically imposed.

During the legislative committees' deliberations and in the different public forums organized by Congress, five major problems were identified as key elements of the future law, issues unsolved by the national climate policy: 1) more effective coordination or horizontal interplay between federal agencies in order to fulfil strategic goals and objectives; 2) polycentric verti-

---

18 PECC defines a first phase focused on capacity-building, p 62.

19 PECC advances were evaluated both by the government—see *"Informe de Avances del Programa Especial de Cambio Climático* 2009–2012, at: <http://www.conagua.gob.mx/conagua07/contenido/documentos/pecc12.pdf>; and by social organizations and experts—see *"Evaluación del Programa Especial de Cambio Climático"*, at: <http://imco.org.mx/wp-content/uploads/2013/2/studie_2_pecc_web_ok4.pdf>.

20 The most important projects for fostering a climate regime were presented in 2010 and 2011: the proposal to create an "Instituto Nacional de Cambio Climático", from Senator Silvano Aureoles Conejo, PRD, 23 February 2010, see at: <http://www.senado.gob.mx/?ver=sp&mn=2&sm=2&id=24011>; the proposal to create the "Ley General de Cambio Climático", from Senator Alberto Cárdenas Jiménez, PAN, 25 March 2010, see at: <http://www.senado.gob.mx/index.php?ver=sp&mn=2&sm=2&id=24481>; the proposal to create the "Ley General de Adaptación y Mitigación al Cambio Climático", from Deputy Araceli Vázquez Camacho, PRD, 23 November 2010; see at: <http://sil.gobernacion.gob.mx/Busquedas/Basica/ResultadosBusquedaBasica.php?SID=74ee29a3226f14629c8ba8796e90a168&Serial=9f745acc1d1d575f4c238b92c994b3fa&Reg=44&Origen=BB&Paginas=15>; the proposal to create the "Ley General de Sustentabilidad y Cambio Climático", from Senator Ricardo Monreal Ávila of the Labour Party (PT), 8 June 2011; see at: <http://www.senado.gob. mx/index.php?ver=sp&mn=2&sm=2&id=30130>; and the proposal to créate the "Ley General de Cambio Climático y Desarrollo Sustentable", from Senator Francisco Labastida, PRI, 11 October 2011; see at: <http://www.senado.gob.mx/index.php?ver=sp&mn=2&sm=2id=32204>.

cal interplay between different government levels; 3) the problem of the fit between conflicting sectorial objectives; 4) the continuity and coherence of the climate policy in the long term; and 5) the need to define a sustainable transition agenda and the design of the proper instruments and goals to achieve it.

These deliberations were translated into an argument over three possible alternatives for a new climate-related institutional design to frame national climate policy (Keohane 2014, Aklin/Uperlainen 2013a), two of which necessarily required Congressional approval:

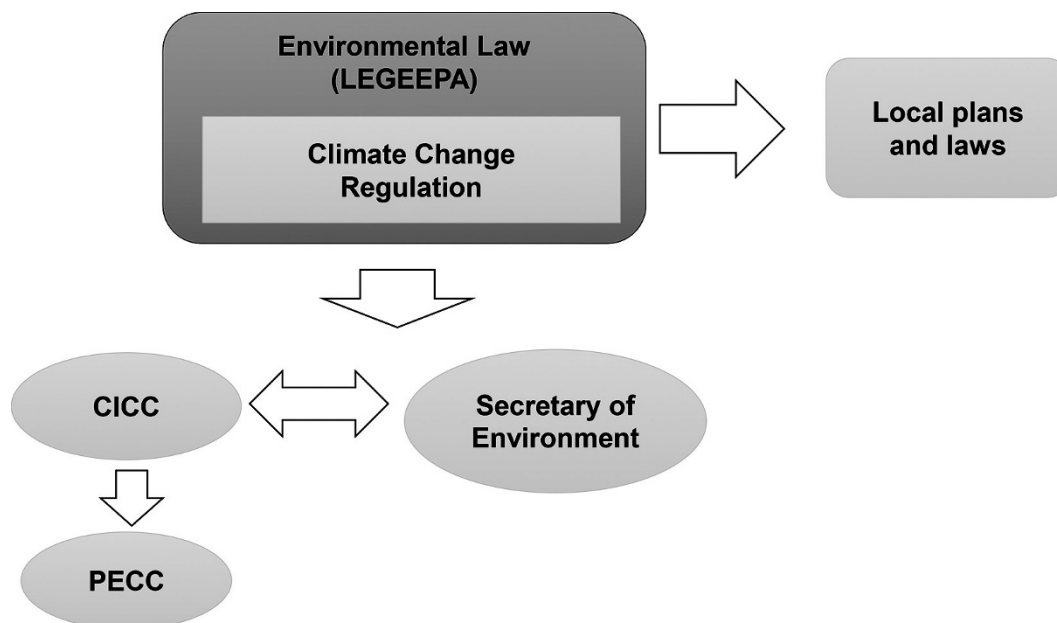
The first option for the Mexican Congress was to support the climate policy in the non-binding terms established between 2006 and 2012 (figure 23.4). The approach was made up of the climate change national policy and its instruments, and the ENACC, PECC and voluntary coordination agreements with local governments, with no changes to the law.[21] The main problem with this option was the impossibility of guaranteeing its continuity beyond Felipe Calderon's administration, because as there was no obligation in law, it depended exclusively on the priorities defined

in the PND by the next government. This perspective represented the preferred alternative for the federal government, including environmental authorities, and for the private sector. In institutional terms it consisted of an intervention in existing public programmes and policies, a "governance framework" approach (Paavola/Gouldson/Kluvánkova-Oravská 2009), or executive action within the existing legal framework, and did not legally require the design of further instruments or mechanisms to foster a transition towards sustainability.

The second alternative was to approve amendments only to the environment law (*Ley General del Equilibrio Ecológico y La Protección al Ambiente*, LEGEEPA) and include specific climate change mandates, and consequently strengthen its capability to regulate mitigation and adaptation programmes. In this case, the model sought to keep climate change definitions as an issue of a fundamentally environmental nature (figure 23.5). This perspective had also been developed in previous law project; in fact, a total of seventeen bills presented prior to 2010 had as their main proposals the modification of this particular law as the criterion for articulating public action to combat climate change. Nevertheless, during the negotiations, this variant was shaped specifically from projects presented by Green Party (*Partido Verde Ecologista de México*, PVEM) legislators and was understood as a more pragmatic approach, mainly because it took into account the resistance that the

---

21 PECC's objective 4.2.2 makes a review of the climate policy mandatory (p. 76), something that was not carried out by the government. Even though Alberto Cardenas was a member of the ruling party, his proposal must be understood as an independent legislative effort.

Figure 23.5: Proposed reform for climate regulation in environmental law. **Source:** Information from the legislative project to reform the environmental law (LEEGEPA) approved by Congress (25 April 2012); CICC: Inter-Ministerial Commission on Climate Change).


creation of a climate regime generated at different stages of the legislative process (especially from the private sector, government authorities and some legislators).

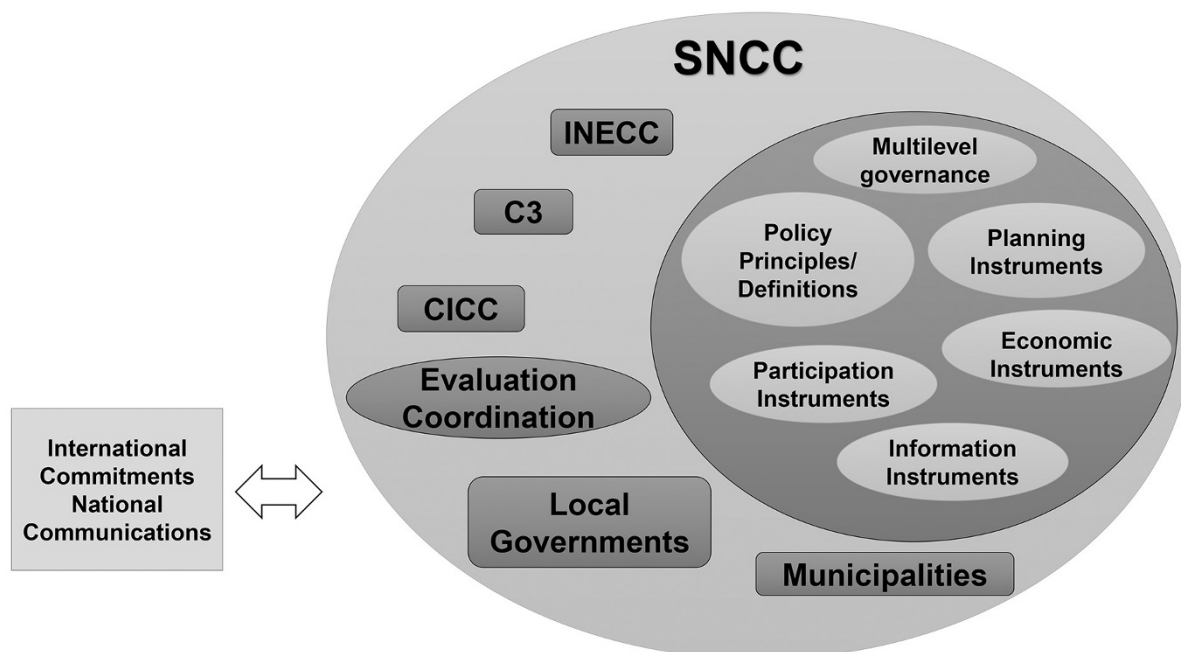
This option, which was approved in both chambers but was returned modified to Chamber of Deputies by the Senate, was dismissed only once the CCL was approved in April 2012. For some legislators, this reform was capable of balancing the agenda of the public administration, the interests of the private sector, and some of the demands of NGOs. As this reform includes minimal modifications to the environmental law, it represented a legal foundation for the climate policy implemented during the Calderon administration and a guarantee of its continuity.

Finally, Congress discussed the creation of the CCL as a more ambitious approach that included principles, institutions, coordination mechanisms between government levels and specific policy instruments, following the criteria contained in the flagship initiatives (figure 23.6). This reform involved, first, the establishment of a proper climate regime, capable of transversally integrating different realms of the policy arenas and defining criteria for horizontal and vertical interplay between the different government levels; and, second, an understanding of the legislative process as the way to foster some kind of transition towards sustainability through regime change. This model had extensive support from NGOs and experts, but faced

opposition from the private sector and some agencies of the federal government at different stages of the legislative process.

These three models coexisted as possible scenarios during the legislative process between March 2010 and April 2012. None of them imposed itself automatically nor inevitably as the best response for institutional change. The continuation of the same policy was a possibility by default in case no agreement was reached between the political forces represented in Congress, which did not necessarily have priority in legislating on climate change. The reform of the environment law stood as a viable legislative alternative until April 2012, when the climate change law gained support in the Chamber of Deputies, and the framing of the climate policy in the regime model became irreversible.

The approved CCL reflects an equilibrium derived from the negotiations between political, social and economic actors who participated in the legislative process (Greif/Kingston 2001). It did not necessarily represent the most efficient or effective response to the threat of global warming in Mexico, but as a legislative equilibrium it reflects the relative strength of the political actors in using their right of veto (Tsebelis 1992), the response of political and social actors to the unequal distributive effects of institutional change (Knight 1992), and the discourses reflecting different senses of what was understood as an appropriate kind

Figure 23.6: Climate change law structure. **Source:** Ley General de Cambio Climático (NSCC: National Strategy on Climate Change; INECC: National Ecology and Climate Change Institute; CICC. Inter-Ministerial Commission on Climate Change; C3: Advisory Council on Climate Change).


of regulation (March/Olsen 1989). In this sense, while exogenous factors account for the need for institutional change, the framing of a climate regime is explained as a process endogenous to legislative deliberation and its negotiation dynamics.

Why was the resulting equilibrium a climate regime, when the government would have preferred the minimum modifications to legislation and the private sector wanted a voluntary action model and not binding obligations supported by law? First, the core group of legislators involved in the legislative process always kept the regime option as the dominant alternative and gradually imposed this model on other legislators who were superficially involved in the discussions. Second, by presenting their own project, the legislators of the *Partido Revolucionario Institucional* (PRI, Institutional Revolutionary Party), the main veto power player, became actively involved in the process. Third, while some representative elements of the private sector, such as steel and carbon producers and manufacturing industry, tried to stop the passing of the CCL, and government authorities kept on presenting critical observations to the project even a few weeks before the final vote in 2012, in the end they were able to insert changes that contributed towards their own agenda, especially with respect to the definition of market instruments such as green taxes and the creation of a trade and cap system. Finally, the

NGOs, regardless of the particularity of their own agendas, operated as a real counterweight during legislative deliberation, and they contributed to limiting the effects of rejection by other actors. In this sense, the creation of the CCL was truly a bottom-up legislative process. The central elements and differences between the legislative models are summarized in table 23.2.

23.7 Conclusion: Implementation Challenges and the Risk of Failure of the Sustainable Transition

The concepts of climate regime, regime complex, interplay and fit, derived from an environmental governance approach, have the virtue of allowing us to understand the creation of the CCL in Mexico as a different process from the simple approval of an isolated piece of law. Environmental governance concepts are useful for structuring an analysis that integrates the deliberate design of a regime with the conflictive negotiation between actors who promote different institutional framing.

The construction of a climate regime was imposed as an equilibrium between three clearly differentiated models to regulate climate change at a national level: 1) the continuation of goals and objectives defined in

Table 23.2: Alternative models in the legislative discussion on climate change 2010–2012: **Source**: Information from the National Communications and Legislative Information System (SIL); at: <http://sil.gobernacion.gob.mx/portal>.

Elements	Climate Governance Framework based on CC Policy	Changes to the Environmental Law (LEGEEPA)	Climate Change Law as a Climate Regime
Type	Public Policy Programme	Environmental Law amendments	Creation of a specific climate regime
Legal Fundament	Constitution, Planning Law, Federal Administration Law, Environmental Law, Environmental Law regulations	Reforms articles 5, 7, 19, 23 of the Environmental Law and creates a Chapter II Bis: "On Climate Change".	New law with 116 articles. It is defined as a guarantee of the constitutional right to a healthy environment
Features	PND, ENACC, PECC, CICC, international activism	Specific mitigation and adaptation mandates in the Environmental Law	SNCC, governing principles, policy definitions, multilevel governance, planning, information, participation and economic instruments Transparency rules and sanctions
Key Feature	Special programme with objectives and goals for 2012	Specific chapter on Climate Change	National System on Climate Change
Institutions	CICC created in 2005	Formalizes CICC in the Environmental Law	SNCC, formalizes CICC, reforms INECC
Policy continuity	Non-binding at the federal level beyond 2012	Mandate to create and update the PECC	Force to create and update ENACC, PECC and local plans
Multilevel governance	CICC formally coordinates the federal government's climate actions Non-mandatory coordination with local governments for the design of local climate plans	CICC established in Environmental Law Defines federal obligations and limits local responsibilities to formulation, implementation and evaluation of local programmes	Distributes competences between the levels of government in a national system (SNCC) CICC becomes the government coordination device inside SNCC
Bottom-up Governance	ENACC and PECC subject to public consultation	None	Particular chapter and social participation and creation of advisory councils with social representation
Planning Instruments	ENACC and PECC binding at federal level Voluntary local plans and emissions registration	Mandate to create and update the PECC	ENACC, PECC, state and municipal plans, mandatory inventories, emissions registration and risk atlas; integrates information system, evaluation and transparency mechanisms and sanctions
Market instruments	PECC budget	Doesn't create new instruments besides those included in the Environmental Law	Specific chapter that includes instruments from the Environmental Law Gives authority to establish financial mechanisms and a carbon market National Climate Fund
Mitigation goals	PECC defines a short-term 50.7 MtCO2e mitigation goal by 2012; a 30% reduction by 2020 and 50% by 2050 National commitment to COP15	Mandate to fulfil PECC goals	National aspirational mitigation goals defined in 2nd temporary article; 35% renewable electricity generation in 2024

the national climate change policy without reforms to the law; 2) minimal modifications to the Environmental Law to include mitigation and adaptation objectives; and 3) the creation of a specific climate regime for solving problems of national horizontal interplay (coordination between federal departments), national vertical interplay (concurrency between government levels), fit between sectorial objectives, continuity of the climate change policy in the long term, and the impetus towards a sustainability transition.

We argued that the policy definitions, Mexico's participation in international negotiations, and the set of initiatives and policy calls presented between 1990 and 2010 can all be identified as part of the 'preliminary' phase of a sustainability transition, while the approval of the CCL in 2012 constitutes the 'take-off' phase.

Unlike the other legislative options, the creation of the CCL represented the implicit intention of promoting some kind of sustainability transition that would then enter properly into a stage characterized by the need to implement its mandates and during which the feasibility of a sustainable transition would be genuinely at stake.

Since its approval in April 2012, the mandates of the Climate Change Law have begun to be implemented by federal and local authorities. In early 2013 the federal government installed the CICC, in accordance with its new legal structure. Later, the ENACC 10-20-40 and the PECC 2014-2018 were published.[22] According to information from the *National Ecology and Climate Change Institute* (INECC), local governments are starting to develop their local climate action plans, but in most cases they are still at a very early stage of development, and overall progress is limited compared with the results reported in 2012.[23]

Even though strategy lines, mitigation and adaptation goals and objectives are defined in these new instruments, thus guaranteeing the continuity of climate change policies, those obligations that have been implemented stray from the idea of a climate regime developed by the legislators. First, the design of the ENACC and the PECC for the period 2013-2018 does not include a detailed or at least a general

evaluation of what had been achieved by 2012. In fact, there is no mention whatsoever of the previous strategy and programme. This represents an important clash with the objectives of the original legislators, who understood the continuity of environment policy as the gradual and incremental development of mitigation and adaptation objectives and goals, not as a simple six-yearly reinvention of the programmes.

Secondly, and related to the previous point, the definition of climate policy instruments in itself does not mean more effective mitigation and adaptation actions. On the contrary, the new programmes show some signs of regression. According to the PECC 2014-2018, and in spite of the mitigation goals set by 2012, "Should this trending scenario continue it is calculated that in 2020 the national GHG emissions would be a billion tons, that is to say twenty-eight per cent more than those in 2010. It is important to point out that the recent energy reform will involve an increase in the hydrocarbon production activities and it is likely that this sector's GHG emissions will increase as well".[24] In other words, the GHG reduction goals are transformed into a twenty-eight per cent increase in emissions as a consequence of the energy reforms fostered by the Peña Nieto administration, which focus on boosting hydrocarbon exploitation, especially deep-water reserves and non-conventional natural gas, as part of the government's definition of 'clean energy'.[25]

The mitigation goal is also conditional on international financing. According to the PECC 2014-2018,

> For the challenge that the mitigation of emissions of compounds and GHG poses, Mexico has made the commitment of reducing by 30 per cent in relation to the 2020 baseline as well as by 50 per cent by 2050, compared to 2000 emissions, through indicative objectives and aspirational goals as contained in the LGCC (Climate Change Law). This is why this Programme, as well as including the action lines related to the Federal Expenditure Budget, includes others, marked with an asterisk (*), that are subject to obtaining national or

25 The official definition of 'clean energy' goals in the Electric Industry Law, includes renewables sources and those defined by the authorities according to official emission norms and parameters, at: <http://www.cfe.gob.mx/ConoceCFE/1_AcercadeCFE/MarcoLegalyNormativo/Lists/Leyes1/Attachments/26/Leydelaindustriaelectrica11ago.pdf >

international financial and technological support, both private and public.[26]

On 30 March 2105, Mexico submitted to the UNFCCC its Intended National Determined Contribution with the aim of achieving an international legally binding agreement in order to keep the increase in the global average atmospheric temperature below 2 °C. Mexico assumes conditional and non-conditional reduction goals related to its emissions baseline:

Unconditional Reduction

Mexico is committed to reduce unconditionally 25 per cent of its greenhouse gases and short lived climate pollutants emissions (below BAU) for the year 2030. This commitment implies a reduction of 22 per cent of GHG and a reduction of 51 per cent of Black Carbon. This commitment implies a net emissions peak starting from 2026, decoupling GHG emissions from economic growth: emissions intensity per unit of GDP will reduce by around 40% from 2013 to 2030.

Conditional Reduction

The 25% reduction commitment expressed above could increase up to a 40% in a conditional manner, subject to a global agreement addressing important topics including international carbon price, carbon border adjustments, technical cooperation, access to low-cost financial resources and technology transfer, all at a scale commensurate to the challenge of global climate change. Within the same conditions, GHG reductions could increase up to 36%, and Black Carbon reductions to 70% in 2030.[27]

Mexico's emissions goals were well received by the international community because it was the first Non-Annexe 1 country to submit its Intended Nationally Determined Contribution. It contains an ambitious GHG emissions target even if it decreases its previous unconditional national commitments.[28] Its main problem remains the contradiction of a very ambitious formal climate agenda and a national energy matrix dependent on fossil fuels and whose emissions are expected to grow by at least twenty-eight per cent due to the energy reform.

This leads us to a central problem in the design of the Mexican climate regime: it does not matter if the modality chosen by the actors was the most complex framing possible to face climate change and foster mitigation goals or a decarbonization of the economy, if the broader objectives of energy production and consumption do not solve the problem of fit with energy policies, urban development plans, conservation objectives and fiscal priorities. The CCL represents a very ambitious design on paper, but it will become irrelevant if it is not able to transform other policy arenas as part of a transition to a sustainability agenda.

The concept of transition towards sustainability has relevance since it allows the sense of the climate regime definition to be framed before the possible alternatives are examined. However, the inconsistency between the objectives of climate policy and those of national economic development warns us that it is not enough to promote a large-scale social transformation through regime change (sustainability-oriented changes), if the contradictory practices of an economic growth model based on hydrocarbon exploitation continue. The implementation phase of a sustainability transition in developing countries means a difficult conflict between different types of regimes, policy arenas and social objectives. Even though a preliminary and a take-off stage take place as part of a transition to sustainability, solving the problem of fit is central to fostering a sustainable model through regime change. This means that sustainable transitions are not only technical problems, but politically contentious issues (Meadowcroft 2009; Akin/Urpelainen 2013b; Keohane 2014; Javeline 2014).

28 On December the 10th 2015 the Mexican Congress approved the Energy Transition Law. This law, a complement to a larger energy reform, defines new institutional basis for an energy transition and establishes obligations and goals for emissions mitigation, clean energy generation and energy efficiency. It mandates a participation of clean energy in the electric sector of at least 25% to 2018, 30% to 2021 and 35% to 2024. With its approval, the Congress finally recognizes the importance of fostering clean energy generation as a way to fulfill Intended Nationally Determined Contributions submitted to the UNFCCC and as a path to a low carbon economy. As an instrument for a transition to sustainability, the Energy Transition Law can become a game changer for the energy sector in the next years, but its success largely depends on its implementation process and the willingness of national authorities and the private sector to fulfill its mandates.

Part VII Preparing Transitions towards a Sustainable Economy and Society, Production and Consumption and Urbanization

24 Sustainability Transitions: A Discourse-institutional Perspective

Audley Genus[1]

Abstract

This chapter addresses the complex web of activities and actors necessary to achieve the much vaunted yet elusive transition to sustainability. The chapter reviews diverse contributions which have in common a concern for the role that language and institutional arrangements play in related developments. These, it is argued, have a capacity that has not been fully realized to improve our understanding of the problems involved, the issues at stake and implications for policy and practice. The chapter presents a framework which is employed to provide orientation for a discussion of these contributions which may otherwise be considered in an isolated manner or with limitations on cross-disciplinary conversation. At the heart of the discussion are sustainability transitions, neo-institutional theory, and critical discourse analysis. The chapter draws on neo-institutional theory and critical discourse analysis to highlight the role of different types of factors and actors implicated in (un)sustainable patterns of production and consumption and the (in)effective governance of environmental sustainability-related science, technology and other phenomena. It considers the potential insights to be gained from application of a discourse-institutional perspective and progress that has been made with the development of such an approach.[2]

Keywords: Neo-institutional theory; sustainable production; sustainable consumption; rules; innovation; critical discourse analysis; public engagement; legitimacy.

24.1 Introduction

There remains a great deal of consternation about the damaging effects of anthropogenic climate change, how such impacts may be mitigated and the policies and strategies that might be implemented to facilitate adaptation thereto. In the UK, to take one example, there appears to be a great deal of anxiety regarding whether and how related commitments are going to be achieved but also a lingering controversy over the 'facts' of climate change and the (over-) ambitious nature of targets set.[3] The framing of the debate tends to revolve around the discourse of competitiveness and the rhetoric of 'keeping the lights on', much to the chagrin of 'deep greens'.

Academic research has investigated some of the fundamental issues in a manner which highlights the potential contribution of a range of disciplines and sub-disciplines, sometimes in combination but often in disciplinary isolation. The chapter seeks to build on these contributions, noting that to gain a richer, more comprehensive insight into the issues at stake and implications for policy and practice it is necessary to recognize and to learn from a wide range of findings. The chapter thus reflects on research on: the processes and mechanisms which embed or reproduce pro-environmental or unsustainable values and actions; the role of language in substantiating the status quo and in 'carrying' institutional change; the role of firms, citizens/consumers and others (e.g. academic researchers) as agents of institutional change or inertia, or as catalytic intermediaries. The chapter is broad in scope, taking in where and how (un)sustainability is talked and written about or symbolized, the

creation, disappearance and re-emergence of institutions, and the role of universities and public engagement in the governance of science, innovation, technology and environmental sustainability.

At the heart of the discussion are neo-institutional theory and critical discourse analysis, focusing on attempts to develop a combined discourse-institutional approach, which might be applied to generate insights into the realization of the transition to sustainability. This is a topic of great contemporary interest, since 'discourse institutionalism' is the 'newest' of the 'new institutionalisms' (Schmidt 2010: 303). The chapter proceeds first by reviewing salient contributions from each of these areas, interweaving what may be gained conceptually from these contributions with a discussion of the difficulties experienced in relation to policy-making, technological innovation and use, and public discourse of environmental sustainability. The discussion is organized into the following sections on: (a) the nature of institutions and the relevance of institutional analysis for sustainability transitions; (b) the nature and relevance of critical discourse analysis to institutional inertia and innovation; and (c) a review of research connected with sustainability transitions which to varying degrees adopt a 'discourse-institutional' approach. Finally, the concluding section reflects on what has been gained from the work reviewed for improving our thinking and practices regarding the facilitation of a more environmentally sustainable society.

24.2   Neo-institutional Theory

This section of the chapter provides an overview of work in the broad topic area of institutional theory which bears on our understanding of the transition to sustainability, particularly that research associated with the 'new institutionalism' or neo-institutional theory. This is concerned with developments in institutional economics, institutional sociology, and institutional theory in political science, which point the way toward adopting a deeper understanding of the role of institutions—and to some extent language—in the transformations necessary to mitigate or adapt to climate change. In economics the 'new' institutionalism refers to contributions from transactions costs theory (Coase 1937; North 1990; Williamson 1985), information economics (Simon 1972), and industrial organization (Katz/Shapiro 1985), for example. An institutional economist (Ostrom/Gardner/Walker 1994), developed an IAD (institutional analysis and develop-

ment) framework, which made it clear that all (institutional) rules—defined as 'shared understandings' regarding what actions are 'desirable, prohibited or permitted'—are formulated in language. It is interesting to note that in political science March and Olsen (1984, 1989) pointed to but did not analyse the importance of language in institutions. A significant contribution has come from Rydin (1999, 2003), whose research on environmental planning has led to an 'institutional discourse' approach which builds on this earlier work. Developments connected with new institutional economics which have informed subsequent work on systems innovation and thence sustainability transition is the work of Nelson and Winter (1982) on organizational routines and technological regimes.

In organizational sociology the institutionalization of neo-institutionalist approaches was assisted by certain landmark publications. These include articles by Meyer and Rowan (1977) and Zucker (1977), the book co-edited by Powell and DiMaggio (1991), and Scott's book *Institutions and Organizations* (Scott 1995, 2008a). These drew on the earlier work of Berger and Luckmann (1967), Hughes (1936), Selznick (1957) and Parsons (1960). The foundational contributions emphasize the properties of institutions, and how institutional environments imposed 'requirements and/or constraints' on rather passive organizations, specifically in relation to the formal structure of individual organizations (Scott 2008b: 429). They observe that institutionalization is partly a matter of instilling value in an organization, which subscribes to beliefs which it considers to be legitimate. Later, researchers focused on institutional change (Dacin/Goodstein/Scott 2002) in fields of interacting organizations, in which there could be competing values, beliefs and regulative and normative rules (Scott 1987). Over time the kinds of organizations and fields studied has widened to encompass business firms in addition to the public sector or professional bodies which were the focus of much of the earlier work (such as art museums and trade unions). Delbridge and Edwards (2007) conclude that early neo-institutionalist research: (a) initially assumed the 'continuity and stability' of social systems and the conformity of organizational field-level practices, then later (b) unduly emphasized processes of institutional change, whilst failing to 'engage meaningfully' with the importance of 'action in maintaining institutional conditions'. Some researchers have sought to avoid these pitfalls by addressing the coexistence of institutionalization processes and processes of de-institutionalization, thus attending both to stability, continuity and sharing of practices within a field and to 'atrophy

or change' (Dacin/Dacin 2013; Greenwood/Suddaby/ Hinings 2002; Mohr/White 2008). There is a concern to introduce and extend a discursive approach to institutionalization (Phillips/Malhotra 2008).

A branch of institutional theory involves work on institutional entrepreneurship on the innovation of new rules and practices, and in the past emphasized "the actions of a single or small number of actors" (Lounsbury/Crumley 2007: 993). Over time the problem of realizing successful institutional entrepreneurship has turned its attention to the depth of prevailing institutional logics, the power of existing governance mechanisms to structure the behaviour of incumbents, and the prevalence of structuration processes linked to the interaction of diverse actors, which constrain non-isomorphic change (i.e. that which does not merely copy what other organizations are doing). Of relevance here are the role of transnational organizations in institution-building (e.g. supra-national treaties and legally enforceable commitments on climate change) and the empowering (not merely constraining) aspects of prevailing norms and beliefs (see Garud/ Hardy/Maguire 2007).

Scott (2008a: 48) defines 'institutions' as "comprised of regulative, normative and cultural-cognitive elements that, together with associated activities and resources, provide stability and meaning to social life". He also identifies three types of institutional rules, which guide actions in a *regularized* way within organizational 'fields'. Organizational fields are comprised of the actors which supply and consume a given set of goods and services but also those which exert influence over these, such that 'field' includes users, consumer groups, government bodies and professional associations, and others. 'Field' is thus a broader notion that 'industry' (DiMaggio/Powell 1991) and is a common object of investigation for researchers seeking to understand the nature of institutions and institutionalization.

The three types of institutional rules are briefly described as follows. First, there are *formal/regulative* rules. Typically, manifestations of these rules appear as legislation and regulations, state grants and subsidies, and technical standards. These partly structure innovative and entrepreneurial activities connected with the governance, design, production, and use of renewable energy or other sustainable technologies and the attractiveness and growth of these sectors. Their effectiveness, though, is in part due to the interpretations that actors have of the credibility and legitimacy of incentives and sanctions associated with adherence to the rules in question. Next, *normative*

rules may be identified. These relate to the norms, responsibilities and obligations, which need to be adhered to or performed. They involve norms regarding the proper role and conduct of industry, government, communities, and consumers/users, for example, in relation to prevailing ways of generating or using electricity or heat, for example, and to the promotion or inhibition of novel approaches and practices for doing so. This author argues that this should include the institutionalization of new business models and the de-institutionalization of existing ones (Genus, 2012). Lastly, *cultural-cognitive* rules are implicated in the values, beliefs and guiding assumptions, which are held regarding the effectiveness of policies for promoting sustainable technologies and practices. They also refer to beliefs about the benefits of related technology, such as those which negatively view wind turbines as dangerous to wildlife or ugly, compared with the view which sees them as a vital part of our energy future. The guiding principles may be implicated in the heuristics which routinely are employed to evaluate investments in sustainable technologies in practice.

Institutional rules are transmitted by different types of carriers. Four types of carriers have been identified (Jepperson 1991; Scott 2003, 2008a): (a) symbolic systems including rules, laws, values, expectations, categories, typifications and schema; (b) relational systems including governance systems, power systems, regimes, authority systems, structural isomorphism and identities; (c) routines including protocols, standard operating procedures, jobs, roles, obedience to duty and scripts; and (d) artefacts including objects complying with mandated specifications, objects meeting conventions, standards and objects possessing symbolic value.

One may also identify three processes of institutionalization: habitualization, objectification and sedimentation; and three mechanisms by which institutionalization occurs: coercion, normative commitment and imitation (Scott 2008a). Habitualization refers to the process, pre-institutionalization, by which new ideas and practices assume a taken-for-granted quality in the thoughts and actions of actors in a limited domain and begin to be recognized as such by others outside it. Objectification concerns the process by which the nascent institutional rules are articulated; it is the means by which institutions begin to solidify, a development which is necessary for sedimentation to occur. Sedimentation is the process through which rules seep into society, and is a matter of deep and extensive diffusion. The chapter will in section 24.4 consider the

employment of these institutional elements and processes in studies of sustainability transition which are relevant to a discourse-institutional approach. First, however, the following section provides some necessary background on discourse analysis, specifically on approaches to critical discourse analysis, to give orientation to subsequent discussions in the chapter.

24.3   Critical Discourse Analysis

Inspired by the work of Michel Foucault (1972) discourse analysis is an approach—or, rather, a collection of approaches—that emphasizes relations between language and power. *Critical discourse analysis* (CDA) is a branch of discourse analysis which provides methods—some would say a methodology—for conducting social research based on the analysis of language to expose sources of influence, persuasion and dominance in social life. The political programme of CDA brings into focus those individuals, groups or organizations excluded or marginalized from—in this case—the governance and achievement of environmental sustainability, and practices implicated in the making of or adherence to institutional rules. As a leading proponent of CDA states: "it often makes sense to use discourse analysis in conjunction with other forms of analysis, for instance ethnography or forms of institutional analysis" (Fairclough 2003: 2), to address the effects of the social construction of discourse in terms of the generation and maintenance of institutions connected with the governance of environmental sustainability.

Fairclough's version of CDA explicitly aims to expose social inequalities and to account for social change. Such a critical approach to discourse analysis, in addressing what it is about political systems (such as 'new capitalism') that constrains or facilitates our ability to develop our potential as members of society, attends to a social, rather than an individualized notion of speaking and acting. It also emphasizes the need for an honest recognition and reflection on values, including those of researchers. CDA examines connections among three levels of analysis: texts (which may be written, spoken, or symbolic), discursive practices, and social practice, the wider social 'context' that bears upon texts and discursive practices. A critical approach to discourse analysis seeks to link text with underlying power structures in society and the discursive practices upon which the text was drawn. CDA focuses on how social relations, identity, knowledge, and power are constructed through discourse. Social

structures (or 'social practice') are abstract, highly stable entities which define a set of possibilities. Social events occur within these set of possibilities. However, there is no simple causal relation between social events and structures. Their relationship is mediated by a network of discursive practices. Discursive practices are more or less durable forms of social activity, which are articulated together to constitute social fields, institutions and organizations, e.g. the field of technology assessment. Discourse analysts refer to 'fields' as networks of social practice (Chouliaraki/ Fairclough 2010; c.f. Bourdieu 1983).

Discourses 'cannot be studied directly'; one needs to scrutinize the "texts that constitute them" (Phillips/Lawrence/Hardy 2004: 636). Such analysis focuses upon the processes of text production, distribution and consumption (Fairclough 2001) and upon bodies of texts, since it is the way in which individual texts draw on other texts and discourses that creates meanings which are significant for social relations and institutionalization (Phillips/Lawrence/Hardy 2004). Further, institutionalization involves more than imitation of actions taken locally. Such actions are shared and given meaning through texts about them which diffuse through an organizational field, drawing the attention of researchers to the search for actions which generate texts and for texts which might affect action and institutionalization (Phillips/Lawrence/ Hardy 2004). Meanwhile an 'order of discourse' is a network of discursive practices in its language aspects. The elements of orders of discourse are genres, discourses and styles. A 'genre' is a way of acting in social life, examples including interviews, speeches or meetings, whereas the term 'style' refers to ways of being, which connote the identities of protagonists and those they apply to others. Both of these may be distinguished from 'representation', which refers to different perspectives applied to the comprehension of reality. Discourses do not stand alone but may be interconnected. Hence one speaks of intertextuality or interdiscursivity—which are phenomena through which one text or discourse draws upon, combines or influences others. These elements select certain possibilities within the set of possibilities provided by the language, and exclude others. Fairclough (2001) distinguishes between the discursive and the non-discursive, arguing that while all language is social, not all social activity is linguistic—he cites economic production as an example. This is at odds with more staunchly post-structuralist views of discourse, such as that advanced by Laclau and Mouffe (1985, 2001), which do not make a distinction between discursive

Table 24.1: Discursive legitimation strategies underpinning institutional pillars (rules). **Source**: The author.

Institutional pillar	Corresponding underpinning discursive legitimation strategy	Mechanism by which discursive legitimation occurs
Formal/regulative rules	Authorization	Recognition and acceptance of authority claims (e.g. of person(s), customs or laws)
Normative rules	Moral evaluation	Justification with reference to value systems
Cultural-cognitive rules	Rationalization	Justification based on beliefs about utility of action
(Institutional carrier)	Mythopoesis	Narrative (storytelling)

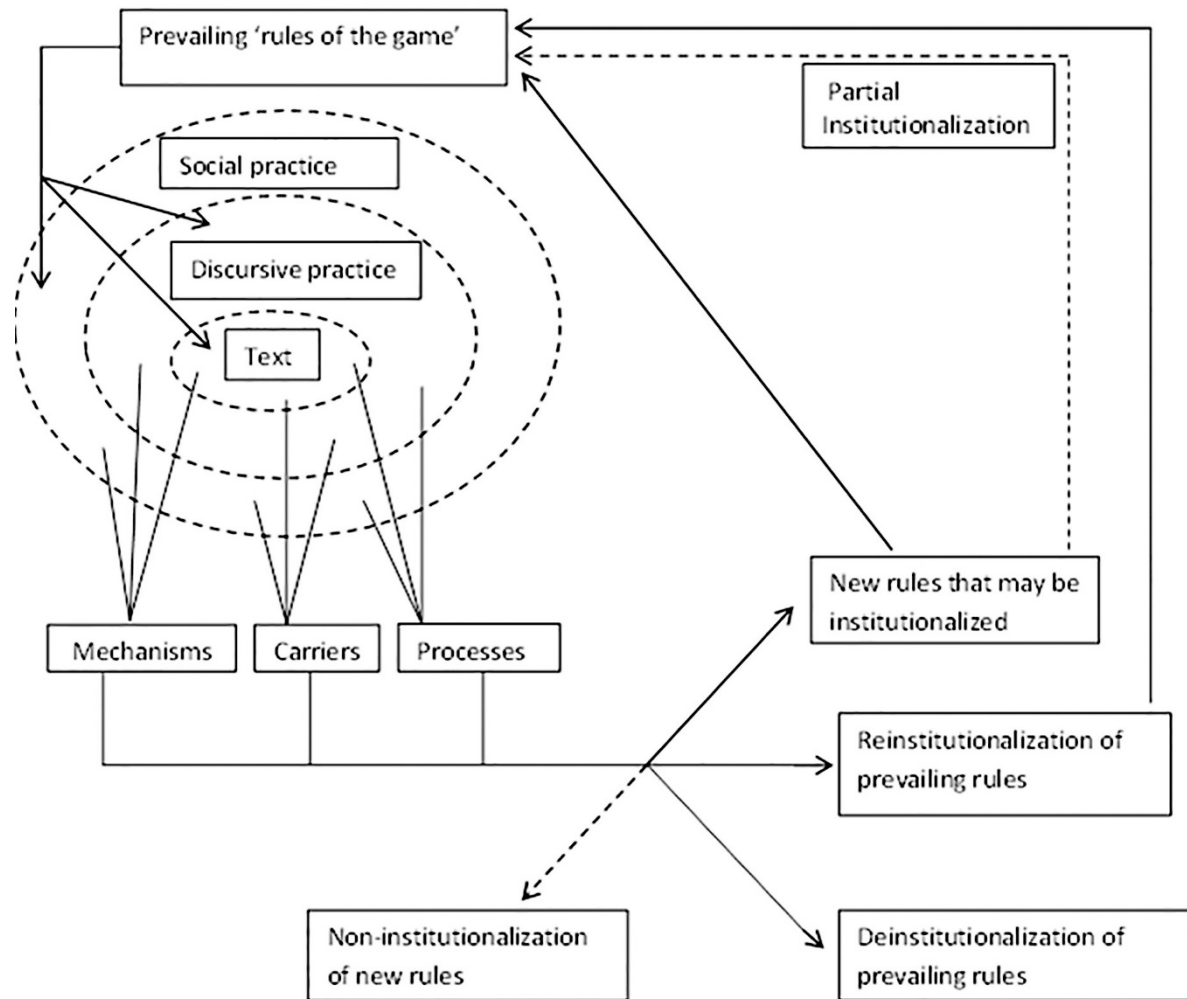
and non-discursive elements of social life such that social reality is wholly constituted in discourse. For Fairclough, discourse (in the sense of semiotics and language) is an element of the social at all the three levels of social practice, discursive practice and social events. Thus language and semiotics correspond to social practice, the orders of discourse correspond to discursive practice, and texts correspond to social events.

Ideas about legitimation provide a cross-over point for discourse analysis and neo-institutional analysis. Strategies and practices for legitimation call for institutional analysis but to elicit greater insight should be founded on an understanding of the role of discursive strategies of legitimation in giving effect to prevailing and new patterns of thinking and behaviour. At this point it is helpful to review these various strategies of legitimation, indicating their relevance to the chapter. From an institutional perspective legitimation occurs as a result of the operation of a variety of mechanisms and processes (see table 24.1). As mentioned above, the former are coercive, mimetic or normative in character and have the effect of making formal, normative and cultural-cognitive rules appear solid (Scott 2008a). Institutionalizing processes may involve the objectification and thence diffusion of novel practices across organizational fields. Zucker (1987) has identified a number of indicators of institutionalization, which include changes in language use.

Now, with the role of language in institutionalization in mind, consider a discursive standpoint on legitimation, which would involve scrutiny of a body of texts pertaining to the research questions and social context at issue. (Remember that legitimation is only one element of the analysis of text within CDA—there is also 'intertextual' analysis, which is concerned with how one text draws on other texts. Also, textual analysis is but one element of CDA—the others are the analysis of discursive practice and the analysis of broader social practice.) Discursive legitimation strat-

egies could be said broadly to underpin the aforementioned institutional pillars in the following way. Thus rather than regulative rules demanding and enforcing compliance in any straightforward direct manner, their mandating or coercive effect may rely on the discursive legitimation strategy of authorization. Here, legitimation is accorded on the basis of authority and custom, including recognition and acceptance of the authority claims of those who make or enforce laws and regulations so as to constrain the actions of those subjected thereto. Normative institutions may be said to be underpinned discursively through moral evaluation, in which legitimation is granted by reference to value systems. Cultural-cognitive institutional rules may be underpinned by the discursive strategy of rationalization, by which legitimation involves reference to beliefs about the utility of institutionalized action. This applies, for example, to beliefs about the nature and effectiveness of government policies in a particular arena (and indeed of government per se) and to heuristics and tools for analysis (e.g. cost-benefit analysis, or triple bottom-line accounting). In the discursive strategy of mythopoesis legitimation is accomplished through narrative. This storytelling is a mechanism which can carry all the types of institutional pillar referred to above. Discursive-institutional phenomena occur across somewhat conflicting discourses, which are comprised of constituent story sets characterized by certain types of discursive practices ('genres', 'styles', discourse coalitions and members/non-members), in which protagonists identify themselves or others. As mentioned above, discursive practice mediates wider social practice and specific texts in particular social events.

In addition to attending to the legitimation and carriage of existing and new institutional rules, a discourse-institutional approach may address other elements of institutionalization through language. Figure 24.1 recognizes this by suggesting that important

Figure 24.1: A discourse-institutional analytical framework. **Source:** The author.


social phenomena, in this case the institutionalization of sustainability, may be depicted as regularities in text and discursive practice; these have a dialectical relationship with social practice, the prevailing historical context and social structures (or overarching rules of the game) which shape and which are partly shaped by those discursive regularities.

New institutional rules are created in speech and writing and visual 'events' (different 'modalities' of text), and in discursive practice, as well as by non-discursive phenomena. Material conditions will be of significance, such as funding and other resource allocations and facilities. Prospective rules may (or may not) be institutionalized depending on the strength and effectiveness of the coercive, obligatory and mimetic mechanisms underpinning the three types of institutional rules in question, and the carriers via which they are transmitted. The extent to which these new

rules are pervasive is a matter of their sedimentation, connected with processes of diffusion and their legitimacy. Such diffusion may be partial and limited to 'habitualization' or 'objectification' at a level below that of the organizational field or wider society. Institutionalization may fail (non-institutionalization) and prevailing rules may be reinforced (re-institutionalization) or undone (de-institutionalization). Thus the section has presented a framework which draws on both neo-institutional and critical discourse analysis, which may be employed to inform an assessment of available discourse-institutionalist contributions to the topic of sustainability transitions. It is to this assessment that the chapter now turns.

24.4 Discourse-institutional Analysis of Sustainability Transition

This section reviews literature on discourse-institutional approaches connected with the transition to sustainability. The approach to reviewing literature taken here is now described. First, during the period from December 2013 to August 2014 the author searched for published research by entering permutations of the key words 'discourse' and 'institution', combined with 'sustainability transition', 'sustainable consumption', and 'sustainable production' into the Web of Knowledge database. Results were selected to be shown for 'all years' and with no limitation on subject area. Searches were thus conducted by topic and title. To give an indication of the extent of scholarly activity in the topic area, it may be noted that seventeen results were obtained from Web of Knowledge when searching by title words for articles on 'discourse, institution', and sustainable transition but 178 were obtained when employing the broader topic search using the key words 'discourse' and 'institution'. To capture papers published in journals not covered by Web of Knowledge and those contributions appearing in monographs or edited works searches in the SCOPUS database and Google Scholar were conducted using similar search terms and subject and date selections as above. Other relevant contributions were suggested by colleagues and contacts working in the field. The core sample of articles reviewed here was achieved after reading the abstracts of papers listed in the search results. Those which were concerned with phenomena of low relevance to the interests of chapter were eliminated from further consideration. The remaining papers were read in full and reviewed in relation to the following themes:

- disciplinary basis
- concept and analysis of institutions
- analysis of text and discursive practice
- contribution to understanding sustainable transitions.

24.4.1 Disciplinarity

There is a variety in the disciplinary basis of contributions, which affects what researchers choose to focus on and in what ways they conduct their work. With regard to institutions it is apparent that a number of projects draw inspiration from and are informed by notions of institution advanced within the field of political science or environmental sociology, as dis-tinct from treatments of institutions found in sociology or economics. Of the core outputs found in the search conducted in preparing this chapter the majority of contributions cite the work of Hajer or Schmidt, whilst few cite foundational neo-institutionalist sociologists such as Scott or Powell and DiMaggio, or institutional economists such as Ostrom. For instance, Arts and Buizer (2009) conduct a 'discursive-institutionalist' analysis of global forest governance and Palmer (2010) one of UK policy on biofuels for transport, and Den Besten, Arts and Verkoojien (2014) apply a 'discursive-institutionalist' approach to the analysis of the *Reducing Emissions from Deforestation and Forest Degradation* (REDD+) policy, based on developments that took place over the period 2004-2011. In these examples institutional analysis is informed by the work of political scientists (Marsh/ Stoker 2002; Schmidt 2008, 2010), whilst ideas regarding the combination of discourse and institutional analysis draw on Hajer (1995; Hajer/Versteeg 2005). Another example is that of Kern, whose work also draws on Hajer and Schmidt to analyse the "discursive politics of governing transitions towards sustainability" and to identify connections among ideas in conflicting discourses, interests and institutional contexts which shape policy (Kern 2011; 2012: 90). Other contributions, such as that by Young (2006), draw on neo-institutionalists such as March and Olsen (1998) and Ostrom (1990) but in general, in terms of references cited or not cited, are less clearly connected with prior work on (critical) discourse analysis. This does not mean that such work fails to provide interesting insights; indeed it sheds light on how discourse coalitions are formed and the implications of these for certain actors being able to impose their views of 'the problem' and what to do about it on others. Young's (2006) work, for example, remarks on the role of 'duelling' discourses in fragmentation of governance arrangements, dominant discourses in systems inertia, and 'blocking' coalitions in creating institutional dysfunction and uncertainty. What are called 'cognitive transitions' refers to the synthesis of previously disintegrated groups of actors, which may culminate in novel arrangements for, in this case, managing marine protection across species. It is more that this kind of research is not fully informed by an approach which systematically analyses text and discursive practices in social relations to effectively analyse particular institutional mechanisms, carriers or processes.

Readers wishing to develop an appreciation of what discursive-institutionalism can contribute to

knowledge and practice regarding sustainable transition may find that a number of publications to which they may be directed as result of searching online for relevant literature are only partially or limitedly pursuing such an approach. Either the discursive or institutional aspect may be under-developed, something which a multi- or trans-disciplinary approach could address. For example, Fairclough (2012) suggests that a 'critical discourse analyst' could work with concepts from other research disciplines, and that studies may be conducted by a project team in which the various members have expertise from a range of disciplines. However, caution is warranted. Pursuing an *inter*disciplinary approach, to build a single combined framework, may marginalize some problem definitions and interpretations of research relevance to policy (Shove 2011), or undervalue differences in approach and emphasis (Scott 2008a). Genus (2004) sees potential in *multi*disciplinary approaches which facilitate 'contact points' which enable researchers to debate and learn about diverse perspectives and methods. Such an approach will be ineffective to the extent that some researchers seek to colonize other disciplines or are insufficiently versed in the literature or methods with which they seek to engage.

24.4.2   Analysis of Institutions

In the literature on systems innovation, neo-institutional theory has been invoked by Geels (2004), for example, to analyse the 'deep structure' of sociotechnical systems. Here, there is argued to be a set of regimes which comprise sociotechnical systems; the stability of the regimes and ultimately of the focal sociotechnical system relies in part on the rules which regime members have in common and which connect regimes with each other. More specifically within studies of technological and sustainability-related transitions and transition management, neo-institutional theory has been applied to analyse the diffusion (or rather lack of diffusion) of micro-generation technologies in the UK (Genus 2012), renewable energy (e.g. Reddy/Painuly 2004; Szarka 2006), and bioenergy (e.g. Söderberg 2011) or biofuels (German/Schoneveld 2012). Wolsink (2012) has done so to examine social acceptance of smart electricity grids for distributed electricity generation. There are other streams of work which lie beyond the systems innovation/transitions domain but which share certain concerns of that literature, such as that pertaining to the democratic governance of environmental policy-making and conservation, forestry and biodiversity. Here one also finds appeals to

institutional change and neo-institutional analysis. As mentioned above in section 24.2, Rydin (2003) draws upon the work of March and Olsen (1989) and Ostrom, Gardner and Walker (1994) in attempting to fill the gap in institutional analysis of environmental planning—though not 'transition' as such—with fuller attention to "language use in communicative situations" (Rydin 2003: 49). Den Besten, Arts and Verkoojien (2014) see institutions and discourses as a 'spiral' in which embedded rules, conventions and norms are susceptible to change by ideas which are the carriers of discourses and convey interests. At the same time stabilized institutions may enable or constrain discourses. They argue that the 'spiral' helps to understand stability and change and how discourses open up or close down in relation to temporarily stable institutions.

Some general remarks may be made regarding the analysis of institutions in prior work related to the transition to sustainability. First, Coenen and Dìaz Lòpez (2010) note that the treatment of institutions in sociotechnical systems research is more coherent and consistent than that within technological innovation systems and sectoral systems of innovation branches of innovation studies, and emphasize the role of learning processes in transitions. However, a criticism of this work is that, in general, there has been insufficient or incomplete attention to ways in which these rules are created, persist or are undone. Moreover, there has not been enough explicit attention to 'carriers', mechanisms, and processes associated with institutionalization, or de- or non-institutionalization. In this and in other work, 'institution' has been used merely as a synonym for 'organization', or governmental arrangements (German/Schoneveld 2012; Reddy/Painuly 2004). Much of the research on discourses of environmental sustainability addresses institutions as organizations, particularly focusing on governmental organizations, and what contributors variously refer to as the 'institutional set-up' or 'institutional context'. Fischer (1993), for example, considers how the over-reliance on experts and a technical framing of policy issues contribute to weakening the influence of citizens over environmental politics in the US, a phenomenon which is accomplished by the growth of powerful economic and governmental institutions (which he uses to mean 'organizations'). If not employed to mean a (usually governmental) organization, 'institution' is commonly employed in a general or everyday sense without theoretical underpinning (Söderberg 2011; Szarka 2006).

Other contributions develop a line of analysis which conceives of institutions in ways which discourse analysts would term genres- and styles-related discursive practice, i.e. they draw attention to where and how sustainability is discussed, and by whom and with what effect. For example Hajer states that his focus is on analysis of institutional practices 'within which discourse is produced' and which might afford more democratic debates about environmental issues (Hajer 2003: 103–4). Rydin (1999) considers the potential of 'new' environmental policy-making institutions (or 'genres') such as citizen juries or group evaluation exercises in bringing together 'polyphonic' communities whom formal authorities must learn to trust. Smith and Kern (2009) consider the implications for more radical transition 'storylines' of the capture of environmental discourse by mainstream interests (or 'institutional priorities'). However, in addition to seeing 'institution' as ministerial priorities, Smith and Kern depict as institutional innovations the transition platforms, themes, pathways and experiments created by the Dutch economics ministry as the embodiment in practice of a new energy transition policy. In certain contributions 'discourse' is separated analytically from 'institutions'. In the work of Arts and Buizer (2009) there is on the one hand an analysis of discursive 'frames' of meaning applied by various protagonists regarding forestry biodiversity or economic management, whilst on the other the institutionalization of practices for governance are examined. Rydin considers that previous attempts to devise a synthetic approach to institutional and discourse analysis have insufficiently addressed the role of language, a shortcoming she argues may be remedied by bringing in a discursive element to the analysis. Thus she develops an institutionalist framework in which regularities in language use, actors' discursive strategies, linguistic resources and interactions in communication, analysed using a rhetorical method, take centre stage.

24.4.3 Analysis of Text and Discursive Practice

A number of contributions offer a view of discourse institutions which emphasize policy-making practices and institutional contexts, though not through textual analysis per se. Examples of this pertain to studies with disparate foci, including forestry and biodiversity (Arts/Buizer 2009; Den Besten/Arts/Verkoojien 2014; Li 2007), food (Zwartkruis/Moors/ Faria 2012), water management (Schmidt 2014), sustainable employment (Köves/Király/Pataki 2013), building policy (Melchert 2007), energy (Hisschemoller/Bode/

van de Kerkhof 2006; Jiusto and McCauley 2010; Späth 2012), urban sustainability (Mazza/Rydin 1999; Rydin 2003), national and international environmental policy-making (Young 2006; Den Besten/Arts/Verkoojien 2014; Koning/Mol 2009) and the role of universities in promoting sustainability (Dlouhá/ Huisingh/Barton 2013). Where language is central the emphasis of the work reviewed in relation to discourse is not on textual analysis, nor of the interrelation of text, discursive practice and social practice but rather the latter two elements. Hajer, for example, states that he is more concerned with these last two elements than with linguistic analysis (Hajer 2003). Indeed it has been argued that a focus on language (as text) is not as helpful to understanding institutional practices 'which are an expression of discursive power too' (Arts/Buizer 2009: 342).

Connected with the governance of sustainability transitions there have been notable contributions to our understanding of urban sustainability discourses (e.g. Mazza/Rydin 1997) and the politics of environmental discourse (e.g. Hajer 1995). Mazza and Rydin point to three constraints on the integration of environmental sustainability concerns into urban planning policy: (a) the dominant role of economic interests in shaping policy discussions; (b) the degree to which the admission of environmental issues into policy discussions relies upon the involvement of environmental groups and their representatives; and (c) the (un)availability of local tools and resources which limit discussion of sustainability themes. They base their analysis on identification of actors and their roles in urban policy-making in designated research sites, the assessment of local networks of significance to policy-making and a definition of multiple, possibly overlapping policy-making discourses. The latter they refer to as 'images' of urban sustainability. Employing rhetorical analysis, Rydin's (2003) approach to discourse and institutions makes a valuable contribution to understanding the significance of language in social organization. Yet compared with the version of critical discourse analysis discussed in this chapter, it does less to expose connections among texts, their production and consumption, and a critique of society at a general level.

Hajer (1993) combines analysis of discourse through which reality is produced with analysis of social practices from which constructs emerge and in which actors who make statements engage. At the heart of his work are discourse coalitions, which are groups of actors sharing a social construct in relation to environmental debates and policy-making. Hajer marks up the role of storylines in (more or less) syn-

thesizing different discourses into a (somewhat) coherent whole, whilst masking the complexity of discourse. For Hajer, domination and institutionalization of discursive space produce 'solidified' social practices and reasoning. In this way, practice is the medium by which certain actors impose their views of sustainability on others. Hajer (2009) develops this thinking by bringing in a dramaturgical perspective to highlight connections among the legitimacy of governance processes and the symbolism attached to the performance of certain policy-making routines. If the performance (e.g. presentation of the national budget or state-organized public debate) is not as expected or in accordance with 'the rules', the legitimacy accorded to the policy-making process and policymakers may erode. Where there is no consensus on what 'the rules' are for the process and substance of politics, this is described as an 'institutional void', in which politics carries on in multiple spaces and state policy actors need both to negotiate with plural and ad hoc networks (of NGOs, business, citizen movements) *and* conventional governmental systems and practices.

Smith and Kern (2009) analyse storylines in Dutch environmental policy-making, concerned that co-option of environmental storylines into incumbent interests and prevailing discourses impacts negatively on the subsequent institutionalization of ideas and thinking about environmental sustainability. Smith and Kern (2009) give an account of the successful diffusion of the 'flexible storyline' of Dutch environmental transition, which owes much to collaboration among researchers of sustainable transitions and policymakers in the Netherlands. The openness to reinterpretation of this storyline enabled a range of governmental actors to 'buy into' the developing environmental policy. However, this came at a price, since the coalition had to develop an approach which could 'work with the grain' of the commitments of other government ministries (other, that is, than the Ministry of Housing, Spatial Planning and Environment, which was the government department responsible for developing the new policy). Hence the transition approach in the Netherlands, fearful of remaining a 'sideshow', incorporated 'market-based instruments', the new commitment to liberalize the Dutch energy market and a concern to develop the 'knowledge economy'.

24.4.4   Contribution to Understanding Sustainable Transitions

The contributions reviewed here have added a wealth of knowledge to a wide range of sustainability-related phenomena. However, these are more or less distant from the concerns of those who wish to fully understand or intervene to realize sustainability transitions, conceived of as pervasive and environmentally sustainable transformations in the way we live. Recall that such transitions are said to occur over decades, perhaps forty to ninety years in the making, requiring innovation or revival of sustainable practices on the part of heterogeneous actors over wide geographical space and economic sectors. Reflecting on the contributions from the literature, what does one observe? First, 'discourse-institutional' sustainability research is not necessarily about 'transitions' as just outlined. There is considerable variety in the works reviewed here. Thus some albeit very interesting and thought-provoking contributions focus on relatively discrete and short-term case studies, in which the period under scrutiny is less than ten years (Den Besten/Arts/Verkoojien 2014; Genus/Theobald, in press; Palmer 2010; Zwartkruis/Moors/Faria 2012). Others consider changing phenomena focusing on a ten to twenty year period, such as Mol's (2005) study of the promotion of cleaner production in China from the early 1990s to the early 2000s. Shove and Walker (2010) refer to changes that have taken place over 'a generation' with regard to weekly baths and daily showering. Another variant is the future-orientated study, in which the researchers hypothesize (or encourage project participants to create) visions of the future. Here the researchers (and sometimes the participants) engage in 'backcasting' (Köves/Király/Pataki 2013) to understand the nature of local guiding visions and how they may link up with arguments being made more broadly in the society in question (Späth 2012), or consider the potential impact of an imagined future event on sub-sectors of a given society (such as van Koppen/Mol/van Tatenhove 2010) do in relation to the implications of a collapse in the Gulf Stream on urban infrastructure and rural planning in the Netherlands). Temporally, at least, other contributions account for deep changes taking place over thirty years or more, for example with regard to Dutch sustainable building policy (Melchert 2007) and forestry management (Li 2007).

Recent discourse-institutional contributions vary greatly in the extent to which they address core concerns of the founding literature on sustainability transitions, such as the definition and analysis of transi-

tion pathways, and systemic interactions between landscape, regimes and niches in major subsystems of society. There are those which continue the pursuit of such lines of inquiry (e.g. Hargreaves/Hielscher/Seyfang et al. 2013; Jiusto/McCauley 2010; Smith/Seyfang 2013). Others, however, fundamentally question foundational thinking about sustainable transition, as represented in the body of knowledge that has emerged over the past twenty years on systems innovation and transition management. Until relatively recently much attention was focused on technologies of energy production. An example of work with a different empirical focus is Shove's work on the conventions inherent in users' everyday unsustainable practices (such as daily resource-intensive showering) and the emergence, disappearance and reappearance of sustainable practices, such as cycling and road congestion charging in the UK (Shove 2012; Shove/Walker 2010). Other contributions focus on demodernization and ecological modernization (Koning/Mol 2009; Melchert 2007); the discursive politics and democracy of transition (Hendriks 2009; Hendriks/Grin 2007; Kern 2011; 2012; Smith/Kern 2009); and governmentality (Hajer/Versteeg 2005; Hajer 2009; Li 2007). Unsurprisingly, authors working from such standpoints do not conceive of their work in the same way as transition researchers inspired by systems innovation, nor do they draw on the same 'discursive repertoire' (Rumpala 2013). Thus, for example in the work of Mol and Spaargaren one sees the language of ecological modernization, which is advanced as a 'transhistorical' concept but not articulated in the terminology of transition, transition pathways or transition management (Mol/Spaargaren, 2000; Spaargaren/Mol, 2008; Li/Bluemling/Mol et al. 2014).

Spatially, and in terms of actor focus, the studies reviewed vary in scope. There is a distinct subtopic of research on grassroots niches and environmental activism and their relation to incumbent regimes and systems innovation (Hargreaves/Hielscher/Seyfang et al. 2013; Smith/Seyfang 2013). Other work focuses on particular regime actors or intermediaries, such as universities (e.g. Dlouhá/Huisingh/Barton 2013), national sectors such as egg production in the Netherlands (Zwartkruis/Moors/Faria 2012), Dutch sustainable building policy (Melchert 2007) and sustainable employment in Hungary (Köves/Király/Pataki 2013), international governance (Koning/Mol 2009; Arts/Buizer 2009; Den Besten/Arts/Verkoojien 2014) and disputes about scale (Lindseth 2006). In terms of methodological approach there is an interesting distinction to make between an understanding of transi-

tion as the outcome of collaborative or antagonist relations among different groups in society and as produced by discourse coalitions, domains or networks constituted by the stories and actions which become institutionalized (c.f. Knox/Savage/Harvey 2006). The former approach is apparent in contributions which emphasize the need for more inclusive engagement and communication among multiple stakeholders (Dlouhá/Huisingh/Barton 2013; van Koppen/Mol/van Tatenhove 2010). It may be characterized as being concerned with network structures, asking the question: who knows (or who talks with) whom? The latter conception draws attention to texts and practices in which certain actors are included and others excluded and which domains and story sets hold sway whether or not they enact sustainability, or particular versions of an environmental agenda. Such an approach prizes and critiques coalition-building (Hajer 1995). The building of coalitions is a potential vehicle for enabling institutional change though one in which the political role of 'boundary-crossing' scientists represents both an opportunity for science and a threat (to the autonomy and objectivity of science and scientists) (Kemp/Rotmans 2009). Such engagement may well involve actors sharing very different interpretations of what is meant by 'transition' and how it should be achieved, as well as different perspectives of what this 'sharing' should entail. The definition and making through institutionalized discursive practices of the policy context and of the boundary separating active protagonists from excluded but likely affected parties is one area that has developed and should continue to develop in improving our understanding of sustainability transitions. Another less developed area concerns explicit analysis of 're-contextualization', an aspect of discourse analysis which addresses the translation or repackaging of ideas and practices from one field or locality to others (Fairclough 2012; van Leeuwen 1993a, 1993b) where they may be legitimated, possibly at different social scales (local, subnational, national, supranational). Fairclough argues that his approach to investigating re-contextualization requires analysis of relations between existing and new discourses, including ways in which primary 'nodal' and secondary discourses are articulated together in the formulation of strategic problems, decision process, decision options and plans for their implementation (Fairclough 2012).

24.5   Conclusion

This chapter has aimed to develop our understanding of research on the transition to sustainability, based on a review of contributions which to varying degrees recognize the complementarity of neo-institutional analysis and (critical) discourse analysis. There is great diversity in this work, invoking discourse and institutions, which addresses directly and indirectly, partially and more fulsomely the core concerns of the wider body of research on sustainable transitions and transitions management. The contributions to this literature are insightful in a number of ways. Fundamentally, contributors such as Schmidt (2008; 2010), Arts and Buizer (2009), Rydin (2003) and Hajer (1995; Hajer and Versteeg 2005) have developed combined discourse-institutional frameworks which draw on both discourse analysis and institutional thinking. For example, Hajer's (2003) approach to discourse institutions has highlighted how the discourse of 'ecology' has provided a language which has 'disciplined' the debate about nature in the Netherlands, leading to new and 'enduring policy practices'. Others draw attention to the persistence of unsustainability practices and the reinstatement of once pervasive sustainable practices (Shove 2012). Further, a number of contributions highlight the potential or marginalization of certain actors, such as NGOs and citizens at large, in grassroots social movements (Hargreaves/Hielscher/Seyfang et al. 2013; Smith/Kern 2009; Smith/Seyfang 2013). Yet appreciative insights could be obtained regarding a discourse-institutional perspective if the conceptual underpinnings of such an approach were more fully articulated. This applies to the definition

of the types of institutions that may be of significance to governance and innovation linked to the transition to sustainability. It applies also to a more explicit analysis of the carriers, mechanisms and processes by which institutionalization, non-institutionalization or de-institutionalization of arrangements, norms and cultures occur. Furthermore, such neo-institutional analysis could be strengthened by addressing in a more rounded and critical way the role of discourse in substantiating the institutions and institutional processes identified. This would necessitate an approach transcending discourse as merely linguistics or purposive use of language. Previous work has addressed the nature of discourses and discursive strategies implicated in the embedding of certain perspectives relating to sustainability, and the social and political machinations connected with this and the problem of effectively challenging incumbent interests and arguments. From a critically discursive point of view, what earlier contributions have lacked is a comprehensive treatment of specific *texts*, practices and the social conditions governing these, which together (re)produce the institutional reality of governance in relation to the transition to sustainability. To do so whilst attending comprehensively to the issues of institutionalization and de-institutionalization is no small undertaking—more a research programme than a one-off project (cf. Wodak/Meyer 2008). This chapter suggests that to define and implement a research agenda informed by discourse-institutional thinking, but also mindful of the above observations regarding the opportunities and limitations of inter- and multidisciplinary research, could be beneficial to improving understanding of the transition to sustainability.

25 New Business Models: Examining the Role of Principles Relating to Transactions and Interactions

Jan Jonker and Linda O'Riordan[1]

Abstract

Different sources indicate signals that our current economic ideas no longer function. New ways of organizing are emerging in which sustainability is often central. This chapter presents the results of exploratory research initiated by Radboud University Nijmegen on new business models (NBMs). The research demonstrates that NBMs appear to be 'hot' and 'happening'. But what is a business model and in what sense is it sustainable? This study focuses on business models that create so-called 'multiple value(s)', which refers to a way of organizing that not only focuses on the task of organization itself, but also on organization between organizations—or better: organizing entities. This approach to organizing generates social and ecological value, in addition to economic value. For the purpose of this research, a series of interviews were conducted in order to gain insight into the phenomenon of NBMs. The aim was to combine this fresh empirical evidence with theoretical underpinnings from previous scholarship in order to explore the field, discover the nature of NBMs, their features, and how they function in (micro-)practice. Ultimately, this examination revealed the phenomenon of an altered balance between the simultaneous organization of different values such as nature, care, attention, and money. While many roads lead to interesting discoveries with respect to these aspects, and the research is still at an early stage, the first results from the study indicate some initial clear common denominators emerging from this journey. These preliminary findings suggest that early NBMs can be generally categorized into different streams based on the practice of sharing, trading, and creating. Most significantly, the results indicate that the ability to connect holds increasing social and economic value, and that these connections create all sorts of new consortia and constituent configurations.

Keywords: Business models, multiple value creation, new economy, sustainable development, collaborative advantage.

25.1 Introduction

This chapter presents the results of exploratory qualitative research initiated by the Radboud University Nijmegen on *new business models* (NBMs). The research study was triggered by various developments (e.g. resource depletion, environmental degradation, rise in commodity prices, grass-roots developments) which indicate that the current economic construct is under duress, suggesting that new ways of organizing are essential in which sustainability[2] might play a more

central role (Braungart/McDonough 2009). The study is based on the premise that NBMs could offer part of a potential solution to address a number of these issues. However, the extant research in this field

---

1 Prof. Dr. Jan Jonker, Radboud University Nijmegen, The Netherlands; email: <j.jonker@fm.ru.nl> and Prof. Dr. Linda O'Riordan, FOM University of Applied Sciences, Essen, Germany; email: <linda.oriordan@fom. de>.

2 We consider the 'root' definition of sustainability the one provided by the *World Commission on Environment and Development* (WCED), also known as the Brundtland Commission (1987): "a development which meets the needs of current generations without compromising the ability of future generations to meet their own needs". Core to the thinking underpinning this definition is to consider sustainability as a process, as 'work in progress' and not as a definable entity. While it can be argued that this is a rather 'old' definition, it still offers the best possible option for making sense of sustainability given a specific context, issue, and setting.

---

is still in its infancy. As a result, many analytical questions arise with respect to NBMs regarding their conceivable value as a vehicle to enhance sustainable development. Consequently, their role in fostering multiple value(s) creation as a new way of organizing[3] in order to generate social and ecological, as well as mere exclusive, economic value, requires systematic examination. Significantly, the novel approach to organizing proposed in this chapter not only focuses on the task of organization itself, but also on organization *between* organizations—or better: organizing entities.

The purpose of this research is therefore to explore this field, to discover the nature of NBMs, their features, and how they function in (micro-)practice, with the aim of understanding how they can be effectively organized. To answer these questions, the chapter commences with compact desk research to gain insight from existing literature. Following this review of the literature, a first exploratory study was carried out in the Netherlands, which resulted in the development of a research protocol, identifying a collection of thirty cases based on this protocol, and undertaking a total of twelve interviews.

In a second round of fieldwork a total of 274 cases were collected by different teams of researchers from fourteen knowledge institutes.[4] Based on the quality of the entries (assessed on the basis of the collectively-used protocol), each team selected a number of cases for interviews. These interviews were conducted in twelve countries across Europe. To ensure comparable results, the respective research teams employed the same interview protocol that was developed during the first study, which was based on seventeen 'open' questions. Part of this protocol was that each respondent was invited to draw his or her own business model. These two exploratory qualitative studies were undertaken in the spring of 2012 and of 2013. They are the main empirical sources of this chapter.

To present the results of this study, the remainder of this chapter is structured as follows. The next section sets the context in which the requirement for NBMs is established by undertaking a literature review to examine the major overall developments from which NBMs, as a form of alternative organizing construct, emerge. This includes an appraisal of the key relevant terms, their related underpinning theoretical concepts, and definition. The research design which was employed to collect the data presented in this chapter is then explained, and the preliminary fresh empirical findings which were obtained via the in-depth interviews are revealed. The chapter concludes with a summary of the phenomenon of NBMs, and an epilogue which addresses how it is envisaged that NBMs will develop in the near future.[5, 6]

25.2 Why Think Differently about Business Models?

The world as we think we know it no longer exists. Because we don't have a detailed image of the future, we stick to a world-view based on the ideas of the second Industrial Revolution, which led to enormous growth in prosperity in the years following the Second World War. There are several clues to support the prem-

---

3 Here we define the verb 'organizing' as a dynamic system (as opposed to a structural dimension) which reflects the undertakings in and between organizations. In this definition, organizations are groups of people (or systems) organized for a particular purpose (e.g. their business proposition). In this interpretation, the business undertaking is an organization [system] (as opposed to has an organization [structure]) (See Kutschker/Schmid 2008: 1084-1085 for further details).

4 The word 'knowledge institute' is used here since the fourteen participating teams were linked to 'conventional' universities, universities of applied science, and private educational institutes.

5 Conducting research is mainly a 'people' job. Valid, let alone good, research is impossible without the respondents' time, without dialogue, and without a university's entire infrastructure, consisting of libraries, search systems, employees, and students. Accordingly, we owe a great deal of thanks to everyone who has helped, either directly or indirectly, towards realizing this study. Special credit is due in particular to the interviewees. This research would never have seen the light of day without their time and willingness to share open-hearted insights into their organizational practices regarding new business models. We hope we have lived up to all their expectations, even though it is not always possible to recognize each point of view at an individual level.

6 The original working paper for this chapter was written in Dutch in collaboration with Marloes Tap and with the support of Tim van Straaten. We are indebted to them for their help and backing. The research on which the chapter is based was initiated by the *Nijmegen School of Management* (NSM) of Radboud University Nijmegen in the Netherlands in 2012, and subsequently expanded and repeated in Europe with the help of fourteen scientific partners in 2013. This expansion led to rich and valuable sources of information that is only partly incorporated here. Materials from various sources, together with a series of interviews based on a common protocol, are the basis for this chapter. The results summarized here are entirely the authors' responsibility.

ise that we are currently at such a turning point. Everywhere in the world we can see a combination of crises: a financial crisis, an energy crisis, and a climate crisis. These are global problems of size and complexity that we have never experienced before, let alone solved. There are no guidelines to follow. One thing is clear: we cannot keep heading in the direction we have chosen (Gunning 2011).

This quote from Tex Gunning (former CEO of the global paint maker Akzo Nobel) indicates that our world, our society, our way of organizing and of acting within the economy is changing. Ominously, a growing amount of research suggests that a 'linear' economic-organizational approach is no longer sustainable (see e.g. Meadows/Meadows/Randers et al. 1972; then Brundtland 1987; the UN Millennium Assessment 2001, 2005; and the many reports that followed that initiative), which means that we are, in every possible way, looking for new solutions to shape an alternative way of organizing. Ban Ki-moon, the Secretary-General of the United Nations, recently stated that our current model of economic development and growth is 'suicidal'. "Things really need to go differently, we just don't realize yet that we need to radically turn the wheel," said John Elkington (2012), the inventor of the triple bottom line concept,[7] not so long ago. Such a radically different approach to organizing is often referred to as the 'green', 'blue' or 'circular' economy.[8] The exact similarities or differences between these emerging and therefore not always

clearly demarcated concepts are not relevant here. What is however important is that these approaches strive for a different way of organizing based on the ambition of an economy that is designed in a new way. Of further significant relevance is that this different way of thinking might lead to a transition towards a circular economy, which requires a fundamental change in organizing. This development activates the need for innovative mechanisms that are gradually being termed *new business models* (NBMs).

In general, business models are structured concepts of the interlinkage between resources and competencies linked to specific needs, thus providing a logic for value creation in a specific field or sector. More specifically, they have been defined in previous research (and additionally in greater detail below) as models which illustrate both the network of parties and the different capabilities involved in creating, commercializing, and delivering value (e.g. Osterwalder/Pigneur 2010; Jonker 2012: 14). Here, we make a distinction between conventional and new business models. The logic of conventional business models leads to a purely financially-driven cost-benefit analysis. Hence, in conventional business models, only one (economic) value is central. Thus the strategic purpose of the business is ultimately focused on providing benefit based on the (narrow) interests of the organization as *the* priority, and typically, with precedence, its owners. This logic defines the exclusive economic intent, driven by a profit maximization objective, behind the creation of value in conventional business models. An enhancement to this approach is the NBM, the essence of which is to collectively create more than one value by considering a broader range of values in the cost-benefit analysis that is more broadly shared by a group of people. Significantly, the reasoning underlying this augmented approach leads to different so-called multiple value creation logic (Elkington 1997; Jonker 2012; O'Riordan 2010), one that is community-driven instead of organization-centred. Below we will present some examples of organizing multiple value creation in a collective and shared manner. To position the examples, we will examine some overall societal and organizational developments from which NBMs evolve.

Connecting these overall developments leads to a multitude of movements, pilot projects, and transitions which take the form of so-called 'organizing activities' with an eye to multiple value(s) creation based on collective organizing. Examples include initiatives in which waste becomes food; sewage water becomes a new source of income; or elderly care is

---

7   The triple bottom line concept stands for an approach to value creation where companies are supposed to simultaneously create social, ecological and financial value in a balanced way. This concept is globally used and serves for many companies as a starting point to develop a so-called sustainability strategy.

8   Reference is made to various schools of thought here, all concentrating on exploring a different economic 'design'. The 'green' economy is one that results in improved human well-being and social equity, while significantly reducing environmental risks and ecological scarcities (see <www.unep.org/greeneconomy>). The 'blue' economy was a notion launched by Gunter Pauli. Key to this approach is a circular economy based on ideas of biomimicry. This evolves from a core business based on a core competence to a portfolio of businesses that generate multiple benefits for business and society (<www.theblueeconomy.org>). A circular economy is an alternative to a traditional linear economy (make, use, dispose) in which resources are kept in use for as long as possible, the maximum value is extracted from them whilst in use, and then they are recovered and regenerated into new products and materials at the end of each life cycle (<www.wrap.org.uk>).

organized via a street-based co-operative which generates care, guidance, and education. In such co-operatives, the street residents are the shareholders and care coins serve as the currency. Further examples include a feed-in policy which enables city agriculture to flourish and perhaps in the near future, a regional 'Robin Hood' tax will emerge that offers a constant source of finance for innovative projects in which sustainability as a social and ecological task is central. All of these examples comprise illustrations of organizing between organizations and citizens, between communities and citizens, and so on, and all are based on co-creation.

Underpinning the 'fuzzy' range of activities in the examples presented above are two identifiable movements with respect to a development towards a sustainable mindset, and a transition towards organizing not only within but most significantly between organizations. To elaborate, sustainable thinking and acting is gradually beginning to find a position in business. As a result, nowadays the debate about sustainable development and about organizing in a sustainable manner has gained a solid foothold in almost every economic sector. At the same time, the position of sustainable organizing is also shifting. This means that the focus is no longer only on what happens *inside* organizations. Instead, the challenge of organizing in a sustainable manner increasingly lies in the way in which organizations develop common approaches. As a consequence, sustainability is no longer exclusively a challenge for (existing) companies or innovative entrepreneurs (Jonker 2003). Instead, it appears and has become relevant on several 'aggregation levels' in society, not only within organizations, but also within broader social settings where all kind of actors such as *non-governmental organizations* (NGOs), citizens, networks, and co-operations play a role.

This implies that sustainability must be organized not only within (existing) organizations but also and simultaneously *between* organizations, (new) parties and a whole range of stakeholders. This changing organizational approach indicates that sustainability is moving from a position as a side issue to being a central theme—at the heart of the business proposition.

Conventional business models, like all business models, provide a logic for value creation, but are not designed to create multiple value(s). This is primarily due to the fact that the value of sustainability, like so many other societal and/or environmental values, is not expressed in terms of money, and thus is not taken into account in cost-benefit analysis. The challenge of designing and implementing NBMs lies in

looking beyond financial aspects to a focus on making money *in combination* with aims, such as taking care of one another, creating safety, protecting the environment, and generating social capital. Significantly, if money is no longer the all-decisive central element, it becomes necessary to think differently about money, transactions, trade, and in particular about what exactly is of value in these. In such an approach, sustainability becomes inclusively embedded in this new way of emergent thinking. Different parties (e.g. citizens, companies, NGOs and others) in society have intuitively and deliberately 'sensed' this new development and as a result have begun to design and implement NBMs. These NBMs can be described in a variety of ways such as innovative, risky, special, or entrepreneurial, but the fact remains that a 'widening' group of people—not just entrepreneurs—are proposing these models. Sometimes this happens as a deliberate search for new business approaches, and in other cases it occurs accidentally (certainly not less valuably), simply because people wish to make changes in society. The research upon which this paper is based provides a basis for this observation.

It is therefore not surprising that NBMs appear in totally different settings and that different parties work on NBMs, sometimes purposefully and sometimes unintentionally, almost as a 'by-product'. This happens not just in the 'running of business' as a result of a transition or transformation, but also 'on the street' as a consequence of people's doing business with each other by creating co-operations within the context of a certain function (e.g. nutrition, care, or mobility). This is often also an outcome of innovative collaboration between parties, which was not previously self-evident. Gradually, whether driven by design or chance, this form of collaboration has become known as the 'sharing' or 'collaborative' economy. In this sense, NBMs can be described as the micro-translation of a value-creating logic that underpins this line of economic thinking. While multiple value creation (Elkington 1997) has marked the start of this new way of thinking about values, it also appears that the development of different ways of collaborating is crucial within this change. As a consequence, the principles of collaborative and shared value creation come into play.

Characteristic of the process of developing and experimenting with NBMs is the absence of any kind of central plan or control by a national or local government. Nobody is really steering this process, even though a lot of different initiators and 'players' can be distinguished. While it can be said to hold true for

conventional business models as well, the distinguishing feature really is the co-collective creation of a business model based on a configuration of people and companies. In general, it appears that transition movements are often decentralized, driven, and shaped by bottom-up initiatives. Altogether, a beautifully muddy yet rich 'field' of co-operative organizing comes to surface, based on the new and often unusual configurations adopted by the different parties involved, leading to multiple, shared and collective value creation. It is to this topic of new ways of organizing to create multiple value(s) that the next section now turns, and from there to the target of defining NBMs more precisely.

25.3   Confusion of Tongues and the Theoretical Essence of NBMs

Organizations were created and developed to help realize different kinds of collective value(s). To fulfil this task, organizing is not a goal in itself, but rather a means of realizing what is of value for, with, and by each other. Keeping this in mind, three common values include social, economic, and ecological components. Within this context, sustainability can be interpreted as a general (overarching) value in which these common values are embedded. Accordingly, sustainability is not in itself something that needs to be organized. Instead, in essence, sustainability is about organizing that which has value from a societal point of view (based on Jonker/Diepstraten/Kieboom 2011; Jonker 2011). In this vision of value creation, sustainability is embedded in a systematic and coherent way of thinking. Based on this new mindset, sustainability is achieved through collaboration by collectively working on that which is of value. Within this approach, multiple value creation then becomes more than a new way of working—it is a new collaborative ability or a fresh strategy, a novel philosophy which takes the form of an innovative approach for realizing value creation. Consequently it profoundly impacts companies' *raison d'être*. In return, it also impacts the meaning of sustainability which transitions from being a responsibility of governments or companies to becoming a shared endeavour. Ultimately, such a transition might even lead to a new approach to developing business models which could become the norm. In such a scenario, this concept of an NBM could comprise a construct that may itself serve to generate a more sustainable organization.

The following views support this claim. "Value co-creation is not efficient based on the traditional approach to the value creation process. Instead, it requires a complete re-consideration of how a company operates and cannot be approached within the context of a traditional value creation system" (Tanev/Knudsen/Gerstlberger 2009). Moreover, both Simanis and Hart (2009) as well as Porter and Kramer (2011) consider the idea of organizing based on the idea of multiple values to comprise a step towards a new, more inclusive form of capitalism. "Economic growth is an overly restricted concept. It's time to exchange the idea of economic welfare for the idea of total welfare, being about physical, intellectual, social, and spiritual value creation" (Gunning 2011).

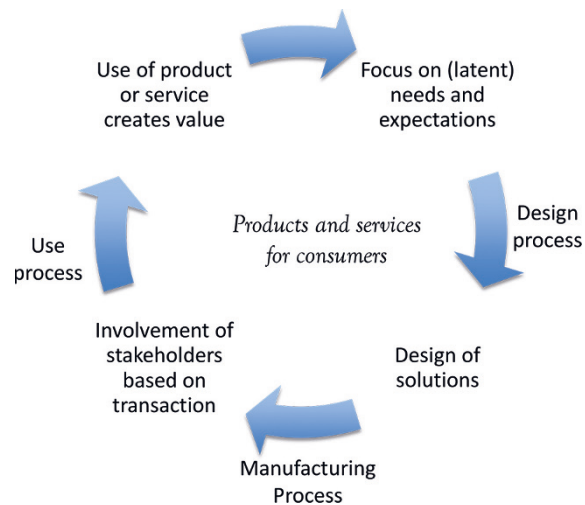
Having reviewed a selection of the major overall developments from which NBMs, as a form of alternative organizing construct, emerge, and having examined new ways of organizing to create value, we now turn to the task of attempting to define NBMs.

25.3.1   Definitions

Many definitions of business models are in circulation. While this is not the place to sum them all up and make an extensive comparison, many of the definitions share some common features. A simple standard working definition is: a business model describes the organizational logic of the process of value creation and delivery. A second definition of a business model is: the main organizational logic for creating value (Linder/Cantrell 2000). As a result, a business model provides insight into the value that an organization or co-operation can offer to different parties. In doing so, it depicts the different abilities and network partners needed for creating, marketing, and delivering that value (Osterwalder/Pigneur 2010).

What can be derived from the different definitions of business models (Bertens/Statema,2011; Houtgraaf/Bekkers 2010; Osterwalder/Pigneur 2010) is the implicit assumption of organizing *within* an organization. Organizing is something organizations 'do'. This presumes an identifiable organizational entity that intentionally translates the value proposition (the value promise) into the value that is to be delivered. The organization is then the primary subject in organizing that proposition through which stakeholders and customers, in an implicit monetary transactional relationship, express their perceived value for that proposition by buying it. It is clear that organizations are rarely capable of organizing the provision of value propositions on their own; they practically always

work within the context of a (value) chain. Many authors agree that the essence of value creation lies in what Osterwalder c.s (2010) termed "the architecture of the organization and the network of partners". Collaborating on value creation is therefore, by definition, a collective task of value chains and/or networks. Yet the consequence of this line of reasoning is that in the course of creating value, customers often do not have a choice in shaping their own logic; they are 'framed' in the value chain as predefined by the organization. This does not however mean they might not have some degree of actionable logic with which to partially create their own value. Still, if that is the case, this individually-driven part of value creation is trapped and limited within the restraints of the overall predefined logic as designed by the organization 'in charge'.

Figure 25.1: The value creation logic behind conventional business models. **Source:** The authors.


The thinking sustaining current, conventional business models is the idea of delivering products and services that are better, faster, more economical in their use, a bit 'greener', and preferably cheaper compared with their competitors; this has been the leading and often implicit thinking behind creating a 'competitive edge'. Adversely, this is the basis for a continuous improvement mindset which leads to incremental change. In this approach, the key to doing business remains in a conventional transaction model that is based on the value of money. Accordingly, sustainability is threatened within the boundaries of the organization or together with other partners in the value chain. The underpinning profit paradigm is not called into question, leading to a business case that tries to

'greenify' the actual business proposition. This, in turn, leads to strategies that opt for 'less' (less water, less oil, less energy, etc.). In such an approach, it is common to term the resulting type of strategy as eco-efficiency. All in all, it leads to tactics based on first-generation thinking about sustainability, in which the business model—let alone the nature of the transaction or the value creation—is not fundamentally questioned.

Figure 25.2: Process NBMs. **Source:** The authors, based on Shafer, Smith, and Linder (2005) and Simanis and Hart (2009).
Bertens and Statema (2011) lament the fact that they have not been able to find 'earning' models that were not based on traditional economic thinking in their explorative research on business models. That observation calls into question what needs to be 'earned' within the construct of a business model. One could propose that in the quest to qualify earnings for NBMs, values such as a sense of belonging, attention, security, enjoyment, safety, care, etc. might prove beneficial. Fundamentally, this debate critically questions the nature of the value created in the conventional model.

It is important that NBMs are not only sustainable because of the changing logic of earnings based on principles leading to a different kind of transaction, but that they additionally intrinsically possess an innovative value proposition. A good example of such a model is the Dutch construction company Dijkhuis. This company migrated from cost leader (a traditional strategy in the contractor scene) to product leader.

Sustainability, according to their idea, is about considering buildings from a fundamentally different point of view, one which involves selling a concept rather than just a building. In their approach, the value proposition is not just about the sustainable construction of the building, it is about selling and managing that building's life-cycle—as a company in co-operation with parties in and around that building.

Figure 25.3: Value creation process NBMs. **Source:** The authors, based on Simanis and Hart (2009).
Preliminary research suggests that developing an NBM is about organizing something new not just within an organization, but within the entire value network. Characteristic of a value network, compared with a classical value chain, is the high level of equality among the parties involved. In this approach, the organization(s) and the different stakeholders involved work together on an equal basis. This vision of sustainable business models further provides insight into the way in which the output of some initiatives serves as input for other parties within the value network, enabling abundant amounts of surplus value. Therefore, it is not the thinking of one party on how to organize sustainably that counts, but rather how the entire value network can collectively participate in the process of value creation.

The rationale underpinning NBMs (see figures 25.2 and 25.3) is the fact that companies *and* communities build a collaborative relationship based on recognized and enacted mutual responsibility. The following four building blocks can be distinguished:

1. a basic logic (principles and ideas which the parties share);

2. strategic choices (which the parties make);
3. ways of organizing that lead to co-operation;
4. developing and maintaining a value network.

Together, these building blocks which enable mutual value creation simultaneously serve as an entry barrier to competitors. The embedded earning model leads to collective property. Outcomes do not belong to one organization, party, or individual. Thus, a new form of advantage takes shape based on collaboration instead of competition, leading to what we term 'collaborative advantage'.

Following this review of the literature presenting the key relevant terms and their related underpinning theoretical concepts, the next section explains the research design employed to collect the fresh empirical findings presented in this chapter. The focus of that research design was to answer the research questions that arose from the gaps identified in the above review of past scholarship with respect to the nature of NBMs, their features, and how they are, or can be, organized.

25.4 Research Design: Searching for NBMs

Given the melange of debates on the theme of NBMs and organizing to achieve sustainable development identified from the literature review presented above, empirical investigation was undertaken in order to attempt to shed more light on the subject. In overview, based on the information established via the compact literature study carried out to investigate the nature of business models, two qualitative exploratory studies were conducted in the spring of 2012 and of 2013. In addition, at different stages of the research, a series of interviews were conducted with people working on NBMs. Overall, however, this study does not claim to be complete, since not all of the material collected over the years during which the research was undertaken has been used.

To elaborate, in order to carry out the empirical research to address the issues identified in the previous section, the actual search for NBMs necessitated great entrepreneurial creativity. During the summer of 2010, two databases were initially assembled which were focused on the question of *how people organize sustainability*. The research soon provided 300 Dutch examples and 400 British examples. These databases (one based on Dutch and one based on British examples) were created on the basis of (Internet) desk research guided by the characteristics of NBMs

revealed in the initial 2011 study. We hoped to find some good examples of NBMs among these, but their identification was not so obvious. More specifically, many websites provide little or no information on their business model, let alone make it possible to use this public information to make a distinction between transactions, earning money, and (multiple) value creation. Moreover, during the course of this endeavour, we found that when new entrepreneurs were asked about their business models, the answers varied according to a wide range of notions regarding the meaning of the term 'business model' itself. Following several analytical attempts, and due to the unsatisfactory results obtained, this approach was abandoned.

Subsequently, in a new approach, a search was initiated for people who claimed to work with NBMs (see below for further details). This initially led to the identification of various names, which led to the unearthing of new names at our request. Methodologically, this is a fine example of the so-called "snowball method" (e.g. Goodmann 1960; Robson 2002: 265). However, it was not clear in advance whether the potential respondents are actually working on NBMs–and if so, to what degree. As a result, the research aimed to discover what these targets were developing, while the fundamental explorative nature of the research did not prescribe in advance what the result of that research would be. Therefore, this methodology is a fine example of the classical dilemma of Baron Munchausen, who once pulled himself metaphorically out of the swamp. More specifically, resulting from this approach, a list of people who say they work on NBMs was generated in the research design, but since the notion of what an NBM denotes is only 'vaguely' known, it is not possible to identify the result *ex ante*. Consequently, it is only possible to know that we have found an NBM when this subsequently occurs (i.e. *ex post*).

Based on the literature study and several (internal) conversations, an interview protocol was constructed in an attempt to bring structure into the approach for conducting the interviews. Key questions included:

1. Can you tell us something about your business model and why it might be new?
2. What is meant by 'sustainability' within that model?
3. When and why did you start developing an NBM?
4. Which requirements should be met by an NBM which is also focused on sustainability?
5. How would you categorize the business model and what is your particular 'logic' for creating value?
6. What kinds of value does the business model create?

7. Did you start new collaborations or are previous collaborations strengthened for or by the new model? (If so, with which actors, and how?)
8. Did you encounter new products and markets by means of the NBM?
9. What results do you think have been accomplished by the NBM?

These questions were employed in the interviews, during which respondents were also asked to actually sketch a graphic illustration of their model. Although this is a relatively simple request, it is valuable to grasp on paper the internal image of the respondent's 'entrepreneurial activity' via this diagrammatic visualization. While it would have been even better to have additionally asked and identified via a process of reasoning how that 'virtual image' is consistent with the interview data, unfortunately there was not enough time to do so within the parameters of the interview setting.

The target sample included a total of a series of 274 cases from which a selection of 50 interviews[9] were conducted during 2013 by two different teams of researchers from fourteen knowledge institutes[10] spanning twelve countries. Now that the research design has been explained, the next section presents the preliminary findings from the data collected using the interview method outlined above.

---

9   Further details of the raw data are available upon request by email, should they be required.
10 The knowledge institutes involved included: Austria (University of Graz–Institut für Systemwissenschaften, Innovations- & Nachhaltigkeitsforschung), Belgium (Free University Brussels–Solvay Business School), Croatia (University College for Economics, Entrepreneurship and Management "Nikola Subic Zrinski"), France (ESC Toulouse Business School), France (Université Paris-Dauphine & Institut d'Administration des Entreprises de Paris-IAE), Germany (Universität Kassel–Wirtschaftswissenschaften–Nachhaltige Unternehmensführung), Germany (FOM University of Applied Sciences, Hochschule für Ökonomie & Management gemeinnützige GmbH, KompetenzCentrum for Corporate Social Responsibility), Ireland (University of Limerick, Kemmy Business School, Department of Accounting & Finance), Lithuania (Kaunas University of Technology, Faculty of Economics and Management, Department of Business Economics), Netherlands (Radboud University Nijmegen–Nijmegen School of Management), Poland (University of Łodz, Faculty of Management), Portugal (ISMAI–Instituto Superior da Maia), Switzerland (University of Applied Sciences and Arts Northwestern Switzerland FHNW, School of Business), and Turkey (Yaşar University, School of Economics and Administrative Sciences).

25.5 Sorting the Outcomes

During the pre-exploration and construction phase of the two databases for the study, we first attempted to discover several 'streams' or 'categories' of new sustainable business models. The purpose was not so much to categorize the models, but much more to discover where the common denominators lay, as well as to discern the value creation logic underlying NBMs. This step led to the discovery of three value-creating patterns of interaction: *sharing, trading,* and *creating*. During the interviews, most respondents appeared to place their model in one or more of these categories. The respondents also had a couple of interesting 'variations' to these streams such as mesh-working, bargaining, and collaborative use. However, the decision was made to initially focus on the following three categories.

25.5.1 Sharing

The sharing of social capital, time, and ability emerged as a recurring element in many NBMs. Sharing, in this context, means to collectively use specific assets in various degrees. The investigated models were frequently based on a variety of collaborations such as sharing people, ideas, equipment, property, data, and transport. Many of these models resemble co-operations, i.e. a form of organizing that appears to be re-emerging in popularity. This contemporary turn to the concept of 'conventional' co-operations could be interpreted as an attempt to tackle the various malfunctioning issues in the current way of organizing. Key characteristics of this approach include, for example, sharing private property, insuring differently, and collective financing or collective purchase discounts. Sharing knowledge and networks also seems to be an important basis for conducting business in many of the models that were investigated; it leads to a *raison d'être* and growth. However, as Ronald van den Hoff (Seats2Meet) put it: "How do you create a value network? How do you even create a network? It's the challenge a lot of organizations are confronted with. We believe the characteristic of a value network compared to a value chain is the high level of equality." The term 'mutuality', which was mentioned several times during the interviews, is related to this idea. Consequently, this evidence suggests that sharing of tangible and intangible assets between different parties is the essence of such NBMs.

25.5.2 Trading

Trading, meaning transactions in the form of barter based on the transfer of previously-negotiated value, emerged as a second stream of value-creating logic NBMs. Many NBMs entail transactions with alternate payment methods, such as points, credits, advertisements, tweets, time, and savings systems. Deploying these alternative means could be a way of stimulating certain demand and achieve (micro-)behavioural change. The logic of value creation in a business model is based on realizing transactions without any means of payment. The focus then shifts to trading services; for example, 'If you maintain that website for us, we'll take care of your administration' or 'If I can borrow your roof to put solar panels on it, I'll pay your rent'. The models are characterized by basing the transactions not only on money, but additionally on the social value(s) of capital, networks and attention, as well as on the sources of the capital being organized. The underlying logic is that if people deploy these in practice, they can generate value for themselves and their environment other than profits.

25.5.3 Creating

Creating multiple value(s) leading to win-win situations via a set of varying methods that are used simultaneously is a further characteristic of NBMs. As Tom Vroemen (CrowdAboutNow) put it: 'The business model generates the values of knowledge, social value (such as involvement), security, and trust.' For example, a business model can save energy and reduce CO_2 emissions while concurrently creating economic profits. The transaction model is then aligned with the mutual goals of a range of different interests. There are other ways to create a win-win situation, such as allowing the customer to determine the value, relocating funds, or shifting the concept of ownership. With respect to allowing the customer to determine the value, Google's organization of its pay-per-click[11] approach to advertising, where the final charge to the advertiser is partly determined by the client themselves or via a form of 'bidding process', is a case in point (Farris/ Bendle/Pfeifer et al. 2010). Such approaches were aptly described by Ronald van den

---

11 Also labelled cost-per-click, this is an Internet advertising model used to direct traffic to websites, in which advertisers pay the publisher (typically a website owner) when the ad is clicked. It is defined simply as "the amount spent to get an advertisement clicked".

Hoff (Seats2Meet), who stated: "We're going from value chains towards value networks. We facilitate the unexpected relevance of the meeting. Because that's apparently the surplus value we as producers have to offer." These approaches lead to the creation of economic, social, and ecological values which are often overlooked in a traditional business model. Simone Veldema (GeenbizzStartup) put it this way: "What's new about it, is many companies now looking for ways to create value. It's about sharing value. If you map it, you can look at new models more and more. It's what we know as value mapping."

These three streams share the common characteristic that connecting and reciprocity are central to the value network. This suggests that without linkages and collaborations, nothing can be traded, shared, or created. Therefore, the art and ability to connect is interpreted as an important aspect of the new way of doing business. Through those connections, all kinds of new consortia and configurations of parties come to the surface, including collaborations of different and often not-so-obvious partners or 'unlikely' or uncommon alliances. Private individuals, local governments, neighbourhood initiatives, and large commercial companies are thereby becoming connected with each other in newly-created structures.

Several values lie behind this development. The condition for the transformation is that sustainable business models need to realize, facilitate, and maintain these connections; after all, organizing sustainability emerges *between* companies, rather than just *within* them. Interviewees agreed on this point and stressed the fact that social embedding—or anchoring—is an important aspect of NBMs in society. Assuming this condition as an intrinsic premise of the new models for organizing, it then becomes difficult to think in terms of ownership—that is, who possesses the network? Such constructs can only function in terms of *access*. Ultimately, this suggests that significance appears to lie in *making connections* and *creating involvement*.

25.5.4 Other Categorizations

Besides the sharing, trading, and creating streams discussed above, the respondents were additionally asked to be creative and come up with additional categories themselves. Among the many categories which the respondents mentioned appeared so-called 'freemium' models, collective purchase models, matching models, models based on copying nature (biomimicry), circle and life cycle thinking, boosters,

thinking in shifts, and collaborators. In the words of Simone Veldema (GreenBizStartUp): "If you look at the Earth's functioning, it has been working well for so long, it's a self-providing system. Businesses or models should work the same way." A lot of these concepts and underlying ideas scratch the surface of the categorizations we have used, namely sharing, trading, and creating. All of these alternatives further demonstrate that business models generate multiple value(s) in their own way. Taking a more analytical stance, the 'building blocks' that constitute these models appear to be always the same. Apparently, a sustainable business model must meet the following four criteria: (1) sharing knowledge, (2) making connections between various constituents (more than just companies), (3) being aware of the potential for collaborating in networks, and finally (4) constituents must share the idea of multiple value(s) creation. The organizing task is then about the specific configuration of those elements in a certain context, which gives the model its unique character.

25.5.5 Aggregation Levels

Apart from a categorization based on the streams that we have chosen, NBMs can additionally be positioned at different 'aggregation' levels. This means that models can be positioned at a street, neighbourhood, or village level. To elaborate, this could be based on location, property, or function. Examples include a location level on a street (e.g. the location of the energy generation), a building (e.g. building and maintaining a school, including safety), or a function (e.g. a care co-operation). A business model could accordingly have the organizational logic of the value creation and delivery process as its target, or it could be focused on a region or even on a country level.

The research further revealed a number of business models that can be positioned at an over-arching level. These are focused on making the entire chain, market, or sector more sustainable. These models try to achieve local change by altering a sector or value network on a higher level. Lucas Simons of SCOPEinsight aims to accomplish this in the agricultural sector by focusing on the lack of access to financial backing experienced by farmers in East Africa. Simons attempts to solve this issue by increasing the transparency between farmers and the banks by means of a rating system which is designed to map the farmers' credibility. In this way, the model is focused on market transformation. Another example of a business model on this level is the *Equal Opportunity Model*

(EOM) of Diederik van Duijn. The purpose of this model is to redesign the traditional value chain model by eliminating some of its steps. This particular model tries to realize a new way of directly involving the end-users in the production chain. This way, the farmer receives a fair price, the consumer is not overcharged, and sustainable products move into the mainstream.

The various streams and tentative distinctions in the levels of NBMs that were developed in this research and presented in the findings above are anything but complete. It is therefore entirely possible that some factors may have been overlooked. Accordingly, due to the relatively short amount of time within which this research was conducted, and the large variety of NBMs existing in the field, it is likely that more categorizations will be found. In that regard, for clarification, due to the requirement to present concise results, not all of the possible categorizations and variations which emerged in the collected data are elaborated upon, and/or illustrated in detail in this chapter. Nevertheless, supplementary categorization definitely deserves added attention in further research that could well reveal organization mechanisms which do not currently receive much, or indeed any, attention.

25.5.6 Selected Inspiring Examples of NBMs

As noted previously, it is not particularly easy to find NBMs. Even when we do have a 'hit', the nature of the model's conceptualization, development, or practical experience is not immediately apparent. For instance, this may frequently arise due to a lack of background experience; websites may have been built, but may not have been maintained, and as a result detailed information is missing. This can make it difficult to understand the characteristics and mechanisms that lie behind a particular NBM, as well as creating challenges when talking about a business model in progress. Nonetheless, we did manage to find a number of good examples of NBMs, which are briefly addressed in this section.

In overview, it is evident that each model exhibits its own 'way' of sharing, creating, or trading. Many examples of the NBMs investigated in this research can be placed into the *sharing* group, a category to which almost every respondent unfailingly reacted. According to Koen Sieben, the founder of the *Centre for Young Entrepreneurship* (CvJO), sharing is in his organization's 'genes'. The business model is based on the idea of sharing knowledge and networks among affiliated entrepreneurs without presenting a bill.

Sharing knowledge also appears to be important to the consultancy organizations interviewed that were focused on sustainable entrepreneurship. Boukje Vastbinder of Enyini indicates that the innovative aspect of their concept is the focus on 'passing on' knowledge, rather than keeping it hidden internally, such as in the conventional approach adopted, for example, by McKinsey. The 'sharing' category accordingly demonstrates that organizations with sustainable business models definitely do not strive to be protective; instead, as Camille van Gestel of Off-Grid Solutions says: "They should have an open attitude". However, knowledge and networks are not the only items which can be shared. An example of collective funding is CrowdAboutNow, which transforms borrowing money into a peer-to-peer process for entrepreneurs by taking the banks out of the equation. In this initiative, entrepreneurs borrow money from a large group of people instead of one party, which spreads the risk.

There are also some interesting examples of *creating* within the stream. Boukje Vastbinder and Esther Blom of Enyini believe that their business model can lead to social and ecological, as well as economic, profits. These profits include values such as involvement, stimulation, and inspiration, but also the spread of risk, improved quality of air, and biodiversity. Nils Roemen of the Waarmakerij has identified that his customers determine the value of a service in retrospect. This is because the system of trading time for money, which stems from the industrial age, no longer applies. Apart from that, business models are based on giving new life to social surplus value, which is over-abundant, and will not be used when it is located in the wrong place. Another phenomenon within the creating stream is the movement of property. The process is less about transactions of property and more about transactions of values, as stated by Douwe Jan Joustra of TurnToo. The process involves using products rather than owning them, and this touches on the concepts denoted in the *trading* stream outlined above. For example, people do not need a lamp when they desire light; they do not want chairs, they want to sit. TurnToo is an initiative which helps to enable this process by mediating between the supplier and end-user. There is also a transition from consumer to producer and a shift of funding. Vincent Mooij has provided a good example of this with his concept of MyEnergy: the essence of the model is that there are no more fixed payments to the energy supplier; instead, you turn this payment into a bank loan and then invest in solar panels so you can generate your own energy.

25.5.7 Financial Sustainability

In addition to the three above-mentioned categories, the interview analysis revealed a further essential aspect. Almost every respondent believed financial sustainability was inseparably linked with a new sustainable business model. This highlights a focus on the requirement for a business model to generate money, and that focus emphasizes that the returns should ultimately outweigh the costs. After all, guaranteeing continuity is another form of being sustainable. This evidence suggests that NBMs do not exist just to 'contribute towards a better world'. Organizations are increasingly beginning to see NBMs as both a prerequisite for and a means of taking a stand in society, possibly because they appreciate that there is no alternative.

25.6 Key Features of NBMs

This provisional list registers seven features of organizing NBMs.

1. NBMs can be described as a form of co-operative collaboration, as a central element in which doing business is the art of the new collaboration, and where connecting increasingly drives social and economic value.
2. Deliberately creating multiple value(s) is a key attribute which aims to achieve a balance between values such as nature, care, attention, and money. Part of this involves cultivating perception or community-building regarding a product and/or service.
3. Money is no longer the only means of trade; time, energy, or care can also be earned, deployed or exchanged. This can be extended to sharing profits with participants.
4. The development of an economy based on needs and uses (now and in the future) which consequently employs credit books for energy, warmth, vegetables, or care, for example.
5. Ownership of property or the means of production is no longer central—access to these resources is perhaps more important. This could mean just paying for use, not for ownership, or 'relocating' the ownership (for example, such that the producer remains the owner).
6. Parties expressing and securing long-term commitment to each other: for example, if I am now earning 'care credits' that I will not need for another ten years, there needs to be a large amount of trust

in the relationship (i.e. governance and confidence) to ensure that these credits will be 'kept safely' and subsequently available when the need arises.
7. The use of alternative 'money' (time, care, points, etc.). Experimenting with complementary local money such as the approach taken by the *local exchange trading system* (LETS) (also known as local employment and trading system or local energy transfer system) in addition to 'care points', time dollars, and others.

Having presented the research findings which detailed the nature and features of NBMs, the next section discusses the future development of NBMS; subsequent sections then summarize and conclude the chapter.

25.7 Future Development of NBMs

How these NBMs will further develop in the near future can be perceived as an exciting journey of discovery in which conventional and new thinking will merge into innovative and not-yet-imagined forms of 'business' based on transactions with regard for a broader range of value(s). Here and there we can even see cautious attempts towards a paradigm shift (and the current system really does need to change), but it is far too early as yet to speak with any degree of confidence about such developments. However, as Tom Vroemen (CrowdAboutNow) put it: "In order to make a true leap forward with sustainable business models, there needs to be a component expressing the intrinsic motivation of the entrepreneur and the others involved to be truly sustainable." In another interview, Matthijs Sienot said: "If I wanted to make a lot of money, I would have chosen a different road. Let me put it differently: if I wanted to make a lot of money *fast*. But we chose to primarily make a difference, make a useful contribution to a transition which we believe has to take place with the talents you've got."

It is important to note that the generation of actual new 'business' models does not use the word 'business' in its classical meaning. Consequently, this new phenomenon can be viewed within the context of transaction models and of trade relations based on alternative forms of value(s). It is clear that there is a movement in society, often bottom-up, in which people try to reinvent transaction models with an altered view of value(s). While this movement is not surprising, given the social and emotional impact of the

many institutional failures of the conventional monetary systems which continue to occur without interruption, ultimately it is still early days. Many initiatives are fragile and need time to demonstrate their viability in the longer run. To become a more interesting experiment, NBMs require engagement and governance in the long run. Significantly, however, it is not yet clear how this can be secured, either socially, legally, or institutionally—to name just a few of the system requirements in which it needs to be embedded.

25.7.1   What is Standing in the Way of a Breakthrough for NBMs?

This study has shown that NBMs are emerging. They emerge in different sectors and streams and at different levels of aggregation. While they cannot yet be pronounced fully mainstream, they are becoming increasingly easy to find and to recognize. Nonetheless, there are two factors preventing a major breakthrough by NBMs.

Firstly, many respondents feel that governments have not yet joined the transition towards the so-called green or blue economy. Many financial and legal systems do not work in favour of NBMs, primarily because these systems do not recognize value other than economic profit; they thereby prevent innovation because they are still based on traditional transaction thinking, with money as the central unit of trade. The government could make things much clearer—especially in these times of crisis and uncertainty—by stimulating and facilitating a clear transition towards a green economy in every possible way. Fiscal law could play an important role here. Unblocking these barriers is crucial for the speedy creation of a new level playing field.

Another obstacle preventing the breakthrough of NBMs is that there needs to be a change of paradigm. We need to start thinking differently and to dare to do things differently, but we fail to do this, because we are waiting for the next generation of technology, the right simulating measures, the right moment, or sufficient security. Many of these factors are still missing. Waiting for that 'next-generation technology' is precisely one of the reasons for the lack of such a growth in volume so that prices can quickly decline. Another aspect here is the so-called 'rebound effect': once people adopt measures which lead to more eco-efficient behaviour, they often afterwards undertake behaviour which counteracts this activity (e.g. they tend to leave the lights on longer since it does not cost more). As a result, without the necessary awareness, such behaviour ultimately proves counterproductive to what we were actually trying to achieve in the first place.

A potential limiting factor in the enablement of NBMs is the lack of conventional data, something which might impede the development of thinking and acting based on the circles of trust noted above. The explorative research presented in this chapter does not provide data about the volume of actual returns that this new generation of business model is generating. No insights are given either by a conventional ruler (money) or an alternative ruler (value), let alone any visions into the potential they could generate. In other words: is this work on NBMs a marginal phenomenon (which will always be there), or are there new developments that, despite not yet being part of the discussion, will quickly grow in size and become an important part of the game?

It is tempting to simply give the classic academic answer 'more research is needed'. While this is true, it is worth asking whether the phenomenon of NBMs should continue to develop further. The answer to this question might be akin to when Henry Ford was asked if he had done market research before launching the successful and groundbreaking Model T Ford. His answer was: "No, because people would only have asked for a faster horse." In order to encourage progress in the right direction, it may consequently not be the best idea to 'ask the frogs about whether to drain the pool', as they say in Germany. However, an optimist would at this point note that the examples of NBMs presented in this work indicate that there is at least some light at the end of the tunnel. Or, as they say in Africa, 'not even frowning frogs can stop the cows from drinking from the pond.'

25.8   Summary

To gain greater insight into the phenomenon of NBMs, this research has explored their features, how they function in (micro-)practice, and possibly most crucially, their conceivable value as a vehicle for enhancing sustainable development and entrepreneurship via new ways of organizing in order to generate multiple value(s). Ultimately, this study has examined the phenomenon of an altered balance between the simultaneous organization of different values such as nature, care, attention, and money.

The first results from this investigation suggest that early models can be generally categorized into three different streams, based on the practices of shar-

ing, trading, and creating. Furthermore, the findings indicate that key components of almost all of the models under investigation include activities related to working to create an experience or a community or both that has to do with combining a product or products with a service or services. The actual value proposition is, as a result, and almost by definition, a product-service construct. Within this context, co-operative collaboration emerges as a central element. Organizing then becomes the art and the capability of creating and maintaining these new forms of collaboration. Most significantly, the results suggest that the ability to connect holds increasing social and economic value, and that these connections create all sorts of new consortia and configurations of parties.

25.9   Conclusion

Right at the interface of connecting, community-building, and co-operation is the location where renewal, innovation, and thus NBMs come into existence. An interesting feature of this new scenario is that money no longer predominates as the only means of trade. Economic traffic is based on 'exchanging and satisfying' needs, which among other effects, means that having 'access to' the means of production becomes more important than actually owning them. Ownership and control make way for use and employment.

However, it is only possible to organize such an economy co-operatively based on long-term commitment. This renders securing trust in relations via collaboration a necessary condition. How to actually shape this scenario raises a whole series of new questions.

Consequently, this research merely represents the beginning of a journey of discovery with respect to NBMs in which sustainability is central in several ways. Further exploration will probably reveal more streams, categories, features, and values. Accordingly, this chapter does not pretend to be complete; questions for follow-up research based on these conclusions are already waiting. Nonetheless, this work clearly demonstrates that a transition has been set in motion which is rapidly changing the conventional practice of merely economic business models.

We live in a time of great transition, in which we are searching together for new transaction models as mechanisms for achieving collaborative advantage in a new (sustainable) economy. But because everything we do and do not do is based on a financially-driven transaction model, it is difficult or sometimes even impossible to escape reality in such a way that brings new transaction models to the surface and, by using them, demonstrate their feasibility and worth. Hopefully, the insights provided in this chapter have contributed towards demonstrating the significance, viability, and value of NBMs.

26 Sustainable Consumption

Sylvia Lorek[1]

Abstract

This chapter elaborates on sustainable consumption and provides key arguments from the sustainable consumption literature. It introduces 'environmental space' as one of the early concepts which embedded sustainable consumption within natural and social boundaries. It explains why a floor as well as a ceiling for the environmental space has to be considered and reflects on the space itself, its size and how to share it. Various possible paths of transition to reach the environmental space from a position of overconsumption as well as from underconsumption are described and linked to various schools of thought in sustainability research. Specific emphasis is given to a more detailed analysis of the two concepts of 'green growth' and 'de-growth'. Relating these concepts to sustainable consumption research and politics, the chapter distinguishes between strong and weak sustainable consumption and outlines some enabling mechanisms for sustainable consumption.

Keywords: Sustainable consumption, environmental space, green growth, de-growth, enabling mechanisms, strong sustainable consumption.

26.1 Introduction

Consumption is a vital element within the economic system. The economy in turn is a social construction through which society structures the exchange of goods and services. It is embedded in the natural system of planet Earth. As the rich literature on bioeconomics or ecological economics explains (Daly 1996; Martínez-Alier/Healy/Temper et al. 2013), the way the economy is structured has led to fundamental problems because it overstretches the limits of the Earth's carrying capacity, insofar as human activities inevitably alter the face of the system Earth (Steffen/Crutzen/McNeill 2007).

There are valid reasons to make consumption sustainable. The *UN Conference on Environment and Development* (UNCED) in its 'Agenda 21' identified for the first time unsustainable consumption and production patterns, *particularly in industrialized countries*,[2] as the major cause of the continued deterioration of the global environment (United Nations 1992). The resulting call for sustainable consumption and production is based on the ideas that, firstly, planetary boundaries set the limits in the long run (Costanza 1989; Georgescu-Roegen 1966), and, secondly, that societies work better if they are based on democracy and score highly on equality (Pickett/Wilkinson 2009). It can be expected that such sustainable consumption requires more than just changing a few unsustainable habits and products here and there. It requires changes in the economy, the infrastructures serving our daily lives, and the dominant culture, as well as the institutions and power relationships which drive these (Vergragt/Akenji/Dewick 2014).

Such a broad approach was—and still is—not always reflected in the use of the term 'sustainable consumption'—neither in the academic or political literature, nor in classroom discussions on sustainability, nor in concerned statements by environmentally engaged neighbourhoods. For quite some time, mainly in the late 1990s, 'sustainable consumption' was limited to the decision-making of private consumers, following the UNCED idea that consumers are not only

---

[1] Dr. Sylvia Lorek, Sustainable Europe Research Institute; Email: <sylvia.lorek@seri.de>.

[2] At present, more than half of the 'consumer society' is based in (former) developing countries. Nevertheless, leadership towards more sustainable consumption patterns is still required from developed countries. Hence, examples in this article are taken mainly from a Northern, and especially European, context.

the victims but also the cause of environmental problems. As a result, sustainable consumption was reflected in the concepts of sustainable household consumption or sustainable consumption behaviour (Georg 1999; Haake/Jolivet 2001; Noorman/Uiterkamp 1998; Zacarias-Farah/Geyer-Allély 2003). At that time, emphasis was placed on case studies and single-product advice about what consumers could do to contribute to sustainability. The picture has developed since then, as least in scientific writing and debate. It is now increasingly recognized that such product- and/or service-oriented approaches might lead to some less unsustainable consumption here and there (Brunner/Urenje 2012), but they are hardly a contribution towards consumption pattern that can be called sustainable.

To distinguish sustainable consumption explicitly from such fragmented considerations, this chapter takes sustainable *resource* consumption as a starting point and takes the complete life cycle of products as well as lifestyles into account. In this context, sustainable consumption stands for

1. limiting the consumption of depletable resources via
   a) more efficient use,
   b) as well as their substitution by renewable resources,
   c) as well as reducing consumption levels in general, and
2. limiting the use of renewable resources to their reproduction rate.

Sustainable (resource) consumption thus involves the consumption patterns of industries, governments, households and individuals (United Nations 1992). In addition to this approach in physical terms, strong sustainable consumption also takes into account the social aspects of, for example, labour rights (ILO 2001), sustainable livelihoods (Lebel/Lorek 2008), and unequal access to and distribution of resources, as reflected in the literature on environmental rights and environmental justice (Martínez-Alier/Healy/Temper et al. 2013; Martínez Alier 1997).

To date, the physical, material flow aspects dominate research on sustainable consumption. In the late 1990s, researchers began to ask which kinds of consumption cause the most environmental impact. They found that the greatest environmental impact per capita is caused by food, housing and mobility (Gatersleben/Steg/Vlek 2002; Lorek/Spangenberg 2001; Noorman/Uiterkamp 1998; Tukker/Jansen 2006). More recent data are provided, for example, by the *Euro-*

pean Environmental Agency (EEA 2013). They point out that only a few product groups contribute significantly (between 30 and 50 per cent) to environmental pressures:

- construction works, that is, buildings and infrastructures;
- food products, beverages and alcohol;
- products of agriculture, forestry and fishing (also food products bought directly from farms rather than via food manufacturers);
- electricity, gas, steam and hot water (the majority of which is contributed by electricity).

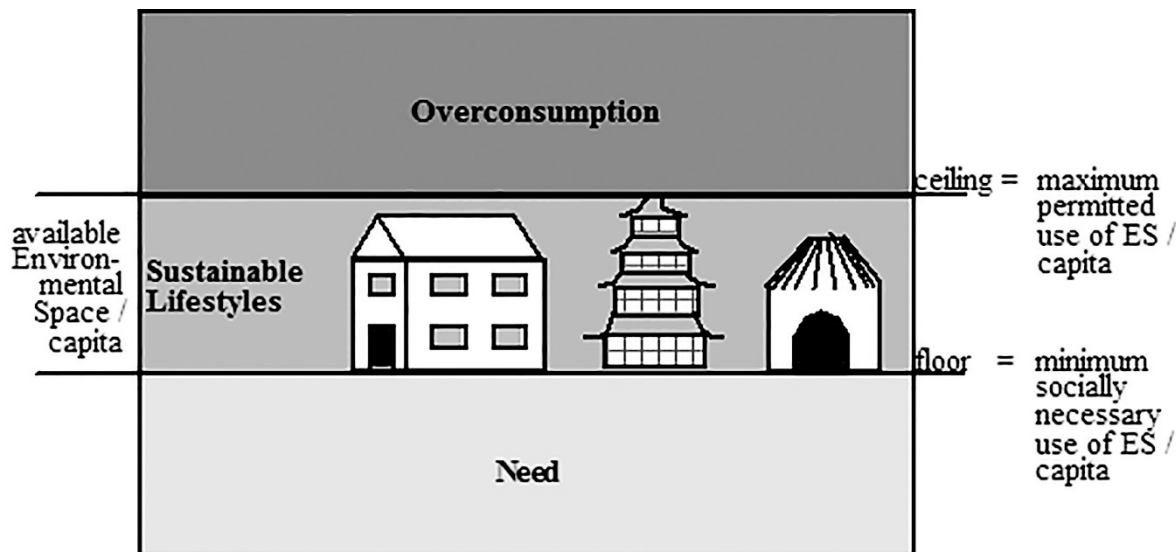
These four product groups contribute 42 per cent to greenhouse gas emissions, 52 per cent to acidifying emissions, 37 per cent to ground ozone precursors, and 55 per cent to the *Total Material Requirements* (TMR) embodied in all consumed products in 2005. Interestingly, they only represent 17 per cent of total consumption expenditure (EEA 2013).

So sustainable consumption research broadly agrees on the main sources of the environmental burdens of consumption. Now, key questions to be addressed are, 'how can the impacts be reduced?', 'who should start changing?', 'with which tools?', 'in which time frame? Still, the consideration of social or development aspects is neglected in many cases. This chapter addresses selected lines of argument from the broad literature on sustainable consumption.

Section 26.2 introduces the concept of environmental space. It explains why a floor as well as a ceiling for environmental space has to be considered and reflects on the space itself, its size and how to share it. Section 26.3 outlines some possible means of transition to reach environmental space from a position of overconsumption as well as from one of under-consumption. Section 26.4 then sharpens the focus for a more detailed analysis of two strains of concepts in sustainable consumption research and politics, distinguishing between strong and weak sustainable consumption, and section 26.5 outlines some enabling mechanisms for sustainable consumption. Section 26.6 concludes the arguments.

26.2   Consuming Within Limits

One of the early approaches towards sustainable consumption embedded it in the concept of *environmental space*. This concept was developed in the early 1990s in the Netherlands (Opschoor/Reinders 1991; Weterings/Opschoor 1994), and further elaborated in

Figure 26.1: The Environmental Space Concept. **Source:** Spangenberg (1995).


a European context (Spangenberg 1995). It distinguishes a space for free choice of consumption patterns from two zones of unsustainability: the domain of environmentally unsustainable overconsumption and one of socially unsustainable under-consumption. It is based on the insight of a limitation of various resources available for human consumption such as fossil energy, timber, and copper, as well as building and agricultural land.

The two border lines as well as the environmental space itself all deserve a closer look.

26.2.1   The Floor

The lower level, called the 'floor of the environmental space' represents the minimum requirements of material (resource) consumption necessary to live a dignified life. In Latin America this line is known as *linea de dignidad*. It necessarily applies to every citizen because no one should live below it. A dignified life should not only satisfy the physiological needs of nutrition and shelter. The level also includes the availability of the resources needed for actively participating in politics, culture, and the other processes of society (Cruz/Stahel/Max-Neef 2009; Max-Neef/Elizalde/Hopehayn 1989). The contributions of Nussbaum and Sen (1993) on the quality of life, especially their work on the capability approach (Nussbaum 2001; Sen 1999), are influential contributions to this context. Human well-being, living a good life, universal human rights (including social rights), and the extended definition of health by constituting a right

to a minimum income—see the *Preamble to the Constitution of the World Health Organization* (United Nations 1948)—are further elements that help to create the idea of a floor with concrete requirements. To operationalize the floor, the concept of a *social protection floor*, developed and promoted by the ILO in collaboration with the WHO, plays a similarly important role (ILO 2011). This suggests measures and institutional reforms to achieve both basic income security and universal access to affordable essential social services. At the UN level, the Human Development Index published annually by the *United Nations Development Programme* (UNDP 2014) since 1990 reflects such considerations.

It is important to note that such a concept is not alien to economic thinking in general. Adam Smith, as early as 1776, stressed the necessity of providing all people with the means of leading 'a life without shame'. However, its shortcoming is that it plays no role in current neoclassical economics (Lorek/Spangenberg 2014).

26.2.2   The Ceiling

The upper limit of the environmental space, called the 'ceiling', is the maximum use of resources as well as the maximal tolerable amount of environmental damage that the Earth can accept without destroying ecological systems in such a way that natural systems—and with them social and economic systems—collapse. Various studies have calculated upper thresholds on a per capita basis, including those for (auto-)mobility,

water use and meat consumption, but also, for example, for the use of mineral resources (Buitenkamp/ Venner/Wams 1992; Spangenberg 1995). The formal agreement to limit global warming to 2 °C can be seen as such a ceiling. In their article in *Nature*, Rockström and twenty-eight colleagues took a broader approach and defined a 'safe operating space for humanity' based on ten criteria (Rockström/Steffen/Noone et al. 2009). This provides an extended empirical basis, emphasizing the key dimensions to care about since a significant (biodiversity, nitrogen cycle) or slight (climate) transgression of the acceptable limits to damage has already occurred, or is soon about to happen (phosphorus cycle, ocean acidification).

Taking CO_2 emissions as an example, a global per capita level respecting global climate change reduction targets would call for a 90 per cent reduction of CO_2 emissions for overconsuming affluent consumers (Chakravarty/Chikkatur/Coninck et al. 2009). To demonstrate what this reduction target could mean in practice, Swiss researches and practitioners developed the concept of the '2000 Watt Society' (Jochem 2004). According to their concept, 2000 watts per person would be a fair share of energy consumption for the global population. Interestingly, a comparison of energy use and the Human Development Index showed that the current energy supply is sufficient for a high level of human development for everyone if it is fairly shared. The issue is not the resource availability, but its distribution (Steinberger/Roberts 2009).

26.2.3   Size of the Environmental Space

What remains between floor and ceiling are specific consumption corridor(s) (Di Giulio/Fuchs 2014). The crucial question is what size these corridors are. Let us first consider the overall environmental space. At first sight it seems to be quite fixed, as planet Earth has a relatively constant surface. Nevertheless, to some degree it can vary. Research indicates, for example, that the available productive land is shrinking—due to desertification, as a result of global warming and rising sea water levels, or simply through the overuse of renewable resources. As well as this, the amount of non-renewable resources is of course constantly depleting. On the other hand the volume could increase again—for example, if new energy sources were discovered and the energy problem were solved. This would allow land which is currently used for producing energy crops to be reallocated to food production. In addition, increasing effort is being spent to optimize technological solutions to sustain-

ing and maximizing ecosystem services and the biocapacity of the Earth—but these include some debatable attempts such as geoengineering (Anshelm/Hansson 2014) and the development of *genetically modified organisms* (GMOs).

The overall size of the environmental space is of concern because it influences what the concept calls the 'fair Earth share' of resources per person. Accepting the general idea of similar rights for every human, environmental space should be shared as fairly as possible among the global population. So, after resource availability the fair share depends on population size. In his chapter "The Rise and Fall of Consumer Cultures" for Worldwatch Institute's *State of the World 2010* (2010), Assadourian calculated different possible numbers of a global population that could live in a sustainable way from Earth's biocapacity (see table 26.1). It would allow, for example, a global population of 13.8 billion to live within its environmental space if every person lived on a biocapacity of one global hectare. At the other extreme, the calculation demonstrates that our planet only could tolerate 1.4 billion people if everyone consumed in similar way to the average US citizen.

Table 26.1: Sustainable World Population at Different Consumption Levels. **Source**: Assadourian (2010).

Consumption level	Per capita income (2005) (GNI, PPP, 2008 dollars)	Biocapacity/ person (global hectares)	Sustainable population at this level (billion)
Low-income	1,230	1.0	13.6
Middle-income	5,100	2.2	6.2
High-income	34,690	6.4	2.1
United States	45,580	9.4	1.4
Global average	9,460	2.7	5.0

This indicates that both population and affluence—taking technology into consideration—have to be targeted to limit consumption to a size that fits the available biocapacity.

26.2.4   Critical Reflections

The more detailed the calculation of environmental space appears—at a country, city or personal level—the

Figure 26.2: Possible pathways to sustainable consumption from overconsumption. **Source**: Brunner and Urenje (2012).
more difficult it is to develop precise recommendations in units of measure of specific resources. Nevertheless, the concept is relatively explicit in pointing towards both situations: where consumption is too high and where it is too low. Its main advantage, therefore, is its inherent call to increase equity of consumption opportunities (UNEP 2001). Accordingly, the concept is often used in the context of environmental justice (McLaren 2003; Rice 2007). The question of how to redistribute resources, however, is generally left open.

26.3 Structuring Transition Paths towards Sustainable Consumption

The crucial question is how to reach the environmental space from a situation of overconsumption as well as from one of under-consumption.

So far neither researchers, nor policymakers, nor members of civil society can agree on what a sustainable future might look like, despite a huge amount of modelling, visioning, and backcasting and forecasting

exercises and scenarios. To illustrate some of the main lines of argument, this section uses a simplified matrix indicating over- and under-consumption on the y axis and sustainable/unsustainable stages on the x axis. As in table 26.1, the environmental space in this illustration is represented through the *ecological footprint*, a resource accounting framework for measuring human demand on the biosphere measured in *global hectares* (gha) (Wackernagel/Rees 1996). The available environmental space for one person is assumed in this matrix to be around one gha on average. This stage of sustainability is illustrated by the dark grey field on the right-hand side of the sustainability axis. For the purpose of better visualization overconsumption is characterized by the big house in the upper left corner using 10 gha, while under-consumption is characterized by the small cottage using 0.7 gha. Figure 26.2 indicates some possible pathways through which overconsumption could shrink to a sustainable stage. Figure 26.3 outlines possible pathways by which under-consumption might be increased to a sustainable level. The arrows reflect possible pathways which can be related to typical strains of scientific and political argument.

Figure 26.3: Possible pathways to sustainable consumption from under-consumption. **Source:** Brunner and Urenje (2012).
Arrow 1 in figure 26.2 describes how proponents of green growth (OECD 2011) and of the green economy (UNEP 2011) debate the possible transition towards sustainability. They argue that resource consumption can stabilize through improvements in efficiency and investment in green technology and will then slowly reduce. Others, such as the proponents of ecological modernization (Ayres/Simonis 1993; Ayres/Ayres/Frankl 1996), promote the development represented by arrow 2, where some further growth in consumption is still accepted in the expectation that technological innovation and resource productivity will soon reduce environmental burdens quite rapidly. The development of a new source of energy often plays a crucial role in such an argument. The de-growth researchers (Demaria/Schneider/Sekulova 2013; Lorek/Fuchs 2013) argue instead that due to rebound effects economic growth always goes hand in hand with an increase in resource consumption and energy use—which is impossible in a finite world. As it is recognized that economies in developing countries need to grow to achieve equity, material throughput and energy use in developed countries need to de-grow immediately. This argument is illustrated by arrow 3.

Finally, arrow 4 indicates what will probably happen under a business-as-usual scenario: continuous growth will eventually lead to an ecological and economic collapse.

Despite being an important political challenge the question of how to raise under-consumption towards a sustainable level is rarely the focus of sustainable consumption research (Lorek/Barber/Onthank 2013). It may be roughly considered that arrows 2 and 3 in figure 26.3 characterize some kind of leapfrogging. This term describes the immediate uptake of new, less resource-intensive technologies to raise living standards (Tukker 2005). Here, arrow 1 indicates a green growth model. This promotes high growth rates for underdeveloped countries in the expectation that in line with the Environmental Kuznet Curve (see for example Stern/Common/Barbier 1996) the environmental problems related to growth will decline again as soon as a specific level of income is gained and clean technology can be afforded. Then the path turns towards more sustainability. It has to be recognized, however, that it is mainly the arrow 4 path which is promoted by current development models and is the one most likely to be preferred by many

---

Box 26.1: Green Growth and De-growth. **Source**: The author.

Green growth means fostering economic growth and development while ensuring that natural assets continue to provide the resources and environmental services on which our well-being depends. It focuses on the synergies and trade-offs between the environmental and economic aspects of sustainable development, but also considers the social aspect on the basis that without good governance, transparency, and equity, no transformative growth strategy can succeed. One important component in promoting green growth is the provision of the right economic incentives for influencing household decisions. Soft measures, however, such as labelling and public information campaigns also are recognized as having a significant complementary role. Therefore, the desired change in behaviour will require a mixture of these instruments

De-growth means a deliberate downscaling of production and consumption in order to increase human well-being and enhance ecological conditions and equity on the planet. It calls for a future where societies live within their ecological means, with open but mainly localized economies, and where resources are more equally distributed through new forms of democratic institutions. A de-growth understanding of innovation focuses on new social and technical arrangements that enable individuals and societies to live convivially and frugally. In this context, de-growth challenges the centrality of GDP as an overarching policy objective. De-growth explicitly seeks a sustainable shrinking and differentiates itself from the involuntary and painful processes of austerity or recession.

---

people in developing countries. This path therefore represents the business-as-usual scenario.

As indicated already, most academic and political debate about sustainable consumption is split between analysing and developing approaches and instruments for the pathways characterized by arrow 1 and arrow 3 in figure 26.2. The next section will therefore further elaborate on the green growth/de-growth arguments.

26.4 The Search for the Best Way: Curing Consumption Impacts or Changing Consumption Patterns?

The core of the sustainable consumption discourse revolves around the question of whether sustainable consumption needs green growth, hence a *differentiation* of the actual growth model, or a de-growth path to shrink it towards a sustainable consumption level. De-growth proponents argue using the logic of ecological economics and perceive nature (or the environment) as the framing dimension of sustainability. In their argument, human society is perceived as a subsystem of nature and economics as a constructed subsystem of societies (Schneider/Kallis/Martinez-Alier 2010). According to these scholars the ceiling is so overstretched (Rockström/Steffen/Noone et al. 2009) that it needs a substantial reduction in resource consumption first before something like a steady-state economy can be reached (Kerschner 2010; O'Neill 2012). Proponents of green growth logic appear to be more pragmatic. They see economic power as strongest in societies, and think that if it is wisely and strategically channelled it can best cure the impact of unsustainable consumption within the current economic

system (OECD 2014b, 2014a). Proponents of both lines of thought, however, argue that the path they are suggesting will lead to a higher level of well-being for a larger share of the global population (box 26.1).

Translating green growth and de-growth into the terminology of sustainable consumption, the relevant literature distinguishes in this context between strong sustainable consumption closer to the path of de-growth and weak sustainable consumption via a green growth path (Berg 2011; Fuchs/Lorek 2005; Hobson 2013; Lorek/Fuchs 2013).

Weak sustainable consumption proponents more or less take the current consumption levels as given and so encourage every effort to satisfy them with fewer resources (European Commission 2008). They see the prevailing market economy, based on free choice and consumer sovereignty, as a powerful vehicle in this context. Governments, research organizations and civil society organizations who follow this path stress their respect for individual lifestyle choices, and point out that market economy systems (as actually structured) need to constantly increase consumption in order to sustain the economy and especially to sustain full employment. Thus—in the name of sustainable consumption—interventions are carefully calibrated to address environmental problems while not slowing down the economy. They accordingly promote and foster initiatives through which sustainable consumption can be achieved via an increase in the efficiency of products, production processes, services, and the provision of these services.

Others, however, argue that this reduces sustainable consumption to sustainable consumer procurement only (Fedrigo/Hontelez 2010). In fact, in this weak form the concept of sustainable consumption is

often used to argue that it is consumers who should shift the market towards sustainability and that interventions should focus on urging consumers to improve the sustainability characteristics of their consumption choices as well as on enabling consumers to do so (Fuchs 2013). Akenji (2014) blames this attitude for making consumers the scapegoats of unsustainability.

Strong sustainable consumption researchers—and thus de-growth advocates—in their turn perceive consumers as locked in to consumption practices through their habits and routines, as well as to the structural constraints resulting from the technological, socio-economic, political and cultural environments they are living in (Cohen/Murphy 2001; Maniates 2001; Røpke 1999; Sanne 2002; Shove 2010). According to their logic, the change of structure has to be the focus. These scholars also support and appreciate the availability of environmentally or socially superior products in markets and the provision of relevant information to consumers as necessary preconditions for change. However, they claim this can only be a starting point because most decisions about sustainable or unsustainable consumption paths take place hidden from the consumers' sphere of influence. Changes in communication technologies, global finance and trade have developed a remarkable influence on the sustainability of consumption long before the consumer ever makes a choice. A similar situation is found with demographic and gender roles which, for example, induce shifts in job situations and time allocation with remarkable consequences for patterns of household consumption (Fuchs/Lorek 2002; Ropke/Godskesen 2007). What seem to be individual decisions or individual lifestyle characteristics are in fact systematic societal shifts which make individual sustainable lifestyles less and less possible.

Although this dichotomy between weak and strong sustainable consumption describes two divergent streams of thought and practice, there are conceptual and practice-based spaces where they intersect (Hobson 2013). As soon as it comes to detailed activities weak (because technology-based and/or efficiency-based) instruments might build a necessary condition into a strong sustainable consumption scenario, at least to win time. The uptake of e-mobility through e-bikes might serve as an example. As a technological innovation they can pave the way for a modal shift in mobility—as long as they indeed replace cars and not ordinary bicycles (Rose 2012). The line between weak and strong sustainable consumption is sharply drawn insofar, however, as the search for transition paths are either restricted to solutions possible within the current system or actively envision demand for and support for a change in the system(s).

A widely neglected aspect in both strains of discussion so far about why consumption habits and structures have developed and seem to be developing further in the direction of unsustainability is the question of power. Power plays a central role in creating structural barriers to sustainable consumption and in delimiting opportunities for intervention. Actors typically mentioned in regard to executing power over consumption structures are administrations from global to local level, business companies and organizations, civil society organizations, media, and last but not least individuals, whether acting as consumers in their daily household context or as engaged citizens. However, the relationship between power and sustainable consumption is only just beginning to be analysed (Fuchs/Di Giulio/Glaab et al. forthcoming). Research so far highlights the close relationship between sustainable consumption and fundamental questions of democracy: how can one assure equality in participation in today's democracies, characterized as they are by large asymmetries in resources and access to institutions and decision-makers? (Fuchs 2013).

26.5 Enabling Mechanisms for Strong (or Weak) Sustainable Consumption?

At the present time, researchers and practitioners are exploring and proposing imperatives and implementation mechanisms for fostering the sustainability of consumption. A literature review has identified eleven main ways in which sustainable production-consumption systems could be made possible (Lebel/Lorek 2010). These are presented in table 26.2, and range from initiatives which emphasize production activities to those which are more consumption-related. At first view, some of the mechanisms appear to follow a weak sustainable consumption approach, in that they try to optimize the system from within, through 'greening the supply chain' or 'certify and label'. Others indicate a rethinking of the system, through 'use less' or 'service rather than sell'. Here we can already see that strong sustainable consumption approaches are not limited to those parts of the product chain which are traditionally linked to consumer activities. In the end, however, to stay within the environmental space all the mechanisms will have to be developed further:

Table 26.2: Examples of enabling mechanisms for sustainable consumption. **Source:** Lebel and Lorek (2010).

Enabling mechanism	Short description	Concerns, constraints, or challenges
Produce with less	Innovations in production process reduce the impact per unit made.	Rebound effects occur through which gains are wiped out by increases in the number of units or how they are used.
Green supply chains	Firms with leverage in a chain impose standards on their suppliers to improve environmental performance.	There may be unfair control of small producers.
Co-design	Consumers are involved in design of products to meet functions with less environmental impact.	Incentives are not adequate to involve consumers.
Produce responsibly	Producers are made responsible for waste from the disposal of products at the end of their life.	Incentives for compliance without regulation may be too low for many types of products.
Service rather than sell	Producers provide service rather than sell products; this reduces the number of products made while still providing to consumers the functions they need.	This is a difficult transition for firms and consumers to make as it requires new behaviours and values.
Certify and label	Consumers buy labelled products. As labels are based on independent certification, producers with good practices increase their market share.	Consumers are easily confused by too much information or by a lack of transparency and credibility in competing schemes.
Trade fairly	Agreements are made with producers that may include minimum price and other investments or benefits. Consumers buy products labelled as or sold through fair trade channels while producers get a better deal.	Mainstream trade still dominates. It is hard to maintain fair trade benefits to producers when a product becomes mainstream.
Market ethically	Reducing unethical practices in marketing and advertising would reduce wasteful and overconsumption practices.	There is reluctance by policymakers to tackle very powerful private sector interests with regulation.
Buy responsibly	Campaigns that educate consumers about impacts of individual products, classes of products and consumption patterns change behaviour overall.	Converting intentions and values into actions in everyday life is often difficult for consumers. Issues of convenience, flexibility, and function still matter a lot.
Use less	Consumption may be reduced for a variety of reasons, for example, as a consequence of working less. There are many potential environmental gains from less overall consumption.	There is a dominant perception that using less means sacrifice. Less income and less consumption may not automatically translate into better consumption impacts.
Increase wisely	Increasing consumption of under-consumers can be done in ways that minimize environmental impacts as economic activity expands.	Wealthy developed countries need incentives and goodwill to assist the poor and those in developing countries, for example, by leaving adequate space and natural resources for them to develop.

26.6   Conclusion

Our consumption is embedded in the boundaries of our natural system but shaped by economic, societal and cultural structures. To direct consumption towards sustainability, the concept of *environmental space* can provide useful orientation. It helps us to visualize how consumption can be unsustainable if it exceeds an upper as well as a lower limit. What exactly these upper and lower limits are, however, has not yet been sufficiently well formulated. Even less well formulated are concrete suggestions about how to reach the safe operating space which is appropriate for the consumption of countries, regions or individuals. What is being debated is what the best pathway is that such a development should take in order to achieve sustainable consumption. This paper has developed arguments for a green growth path that relies on the trans-

formative capacity of the economic system and respects and highlights consumer sovereignty. These conditions are recognized as a necessary but probably insufficient condition for (global) consumption patterns that remain within environmental limits and so characterize a weak sustainable consumption path. The second strain of argument reflected is for a de-growth path which demands a shrinking of economic activities, investing in research and directing policies into a change of systemic structures, including the framing conditions for the economy. Such a development would require strong sustainable consumption governance. Research into this path still has to convince its opponents that the idea envisioned of a sustainable shrinking does not lead to the collapse of economic and social security systems, for example, and is completely different from austerity or recession situations. Various enabling mechanisms to foster sustainable consumption have been identified. They are ready to be used in any way.

27 Sustainable Consumption and Production in China

Hongmin Chen[1]

Abstract

The rising problem of severe resource scarcity, environmental pollution and ecological degradation has become a great constraint on economic development in China. *Sustainable consumption and production* (SCP), as a primary way to decouple economic development from environmental degradation, has been undertaken via various energy-saving and environmental protection policies in China. The main practices for SCP in China, including the adjustment of the industry structure, the promotion of a circular economy and cleaner production, the Energy Conservation and Emission Reduction Project, green procurement, and progress in waste management are discussed. Though China has made some achievements in SCP, it is still facing serious challenges. The extensive economic growth model, strengthened by local governments with the incentive of the expectation of promotion and financial reward, aggravates the problems of resources and the environment. The imbalanced development in China, including uneven development among regions, imbalanced expenditure structure between consumption and investment, and the rising inequality in income resulting in imbalanced consumption with insufficient consumption accompanied by overconsumption, is challenging the coordination of development and protection. The weak capacity for scientific and technological innovation and the underdevelopment of non-governmental organizations in China leave the government as the main player in SCP, and this is inefficient for the development of SCP. It is suggested that SCP should be put forward as a development strategy and be conducted more systematically using existing policies in China so as to promote SCP more efficiently. China's further reform is expected to lift the institutional barriers to SCP and promote economic transformation, balanced development and social equity. In addition, the long-term capacity for SCP calls for the improvement of independent technical innovation in enterprises and extensive social participation.

Keywords: Industrial restructuring, cleaner production, circular economy, energy conservation and emission reduction, green procurement, technical innovation, economic transformation.

27.1 Introduction

China has achieved great economic progress in the past three decades. Its gross domestic product (GDP) has continuously increased by an annual average growth rate of 9.83 per cent between 1978 and 2012 (NBS 2014) and it has overtaken Japan as the world's second largest economy. But the rapid economic growth has been accompanied by severe resource depletion, environmental pollution and ecological destruction (Hu/Zhang/Lin et al. 2014; Zhang 2014). The country's energy consumption has risen from

571.44 million *tonnes of coal equivalent* (tce) in 1978 to 3617.32 million tce in 2012, with an average annual growth rate of 5.58 per cent (NBS 2014). China has become the world's largest emitter of CO_2 (IEA 2014). Meanwhile, China's per capita ecological footprint rose to 2.1 global hectares, 2.5 times its ecological carrying capacity in 2008 (WWF–China 2012). Its per capita domestic material consumption as well as its per capita GHG emissions have exceeded the world average (IEA 2014; UNEP 2013). China's accumulated air pollution has led to severe haze covering almost the whole country. It is argued that the rising amount of environmental and health damage, as well as the rising costs of energy supply, waste disposal, tackling pollution and eco-remediation, offset the achievements of development (Wang/Mauzerall

---

1 Dr. Hongmin Chen, Associate Professor, Department of Environmental Science and Engineering, Fudan University, Shanghai, China; Email <swingboat77@gmail.com>.

2006; World Bank 2007; Wang 2010; Matus/Nam/Selin et al. 2012). It is widely recognized that the growing conflict between economic growth, energy and environment in China has restrained the country's further development (Hu/Zhang/Lin et al. 2014; Li/Bao/Xiu et al. 2010; Wu/Shi/Xia et al. 2014). Natural resources and ecosystems will no longer support 'business-as-usual' development while China is still in the process of industrialization and urbanization. It is estimated that by 2020, some 850 million people, about 60 per cent of the total population, will be living in China's urban areas, up from about 650 million in 2010 (Atsmon/Magni/Li et al. 2012). Thus, how to decouple economic development from resource depletion and environmental degradation (Wu 2014) and how to build a well-off society with less pressure on resources and the environment has become a crucial challenge for China.

Sustainable development, defined as development that meets the needs of the present without compromising the ability of future generations to meet their own needs (WCED 1987), has already become a global consensus since the 1992 United Nations Conference on Environment and Development. Since then unsustainable consumption and production patterns have been identified as the major cause of global environmental deterioration (United Nations 1992). *Sustainable Consumption and Production* (SCP), which aims to do "more and better with less" by minimizing the use of natural resources, toxic materials and emissions of waste and pollutants over the life cycle while increasing the quality of life for all (Oslo Symposium 1994), has been heralded as a primary way of implementing sustainable development. In order to accelerate the shift to SCP, the 2002 World Summit on Sustainable Development called on governments to promote a 10-*Year Framework of Programmes* (10YFP) in support of regional and national initiatives to boost SCP (UNEP 2011). The multi-stakeholder Marrakech Process, launched in 2003, has supported the implementation of SCP and provides inputs for the development of the 10-Year Framework. At Rio+20, a 10-Year Framework Plan on SCP was decided on, and this is now in the process of being implemented by national governments and various regional groups in cooperation with UNEP.

China was one of the first few countries to propose and implement sustainable development strategies. In March 1994, the Chinese government issued "China's Agenda 21: White Paper on China's Population, Environment and Development in the 21st Century" and then in 1996 incorporated sustainable development into national strategies. In 2003, China proposed the scientific outlook on development as the guiding principle which enriched the connotations of sustainable development in China (NDRC 2012). So far SCP, as a concept, has not yet been incorporated into China's national development plans or laws. Various policies, regulations and pilot projects promoting sustainable development have reflected the idea and practices of SCP in China. This chapter introduces and discusses the development of SCP in China. The remainder of this text is structured as follows: section 27.2 describes the main policies and practices for promoting *Sustainable Production* (SP) in China and its existing problems, followed by an introduction to China's *Sustainable Consumption* (SC) development in section 27.3, as SC has been paid less attention to than SP in China. Section 27.4 discusses the key challenges China is still facing in the promotion of SCP. Section 27.5 provides a brief summary of SCP development in China and some suggestions for its further development.

27.2   Sustainable Production in China

Unsustainable production has been recognized as the major cause of various resource and environmental problems in China. Sustainable production, which requires minimizing the impact of production on natural resources and the environment, has not yet been clearly introduced as a principle for industrial development. Many policies and practices which contribute to a shift to sustainable production have been conducted in China.

27.2.1   Adjustment of Industry Structure

China is undergoing an accelerated industrialization and urbanization process. The Chinese economy, with a high proportion of resource-intensive industries as well as severe overcapacity in a number of industrial sectors, places great pressure on resources and environment. Thus industrial restructuring, which aims at shifting from highly polluting heavy industries to a more service-oriented, high-tech economy, has become an important part of sustainable production in China.

China is the world's biggest producer of steel, aluminium and cement, producing about 48.5 per cent of the world's crude steel and 57.5 per cent of the world's cement in 2013.[2] Official statistics indicate that only 72 per cent, 73.7 per cent, 71.9 per cent, 73.1 per cent and 75 per cent of capacity was used in the

steel, cement, electrolytic aluminium, glass and ship-building sectors, respectively, in 2012, far less than that of other countries. China has issued a large number of policies to tackle excess capacity. The *State Council* (SC) issued a "Guidance on Resolving Serious Excess Capacity" in 2013 which forebade the construction of new projects in industrial sectors with excess capacity and halted new investment in iron and steel, cement and other industries with serious excess capacity (SC 2013). In the meanwhile, the elimination of outdated production capacity has also been widely carried out. Since 2011, the *Ministry of Industry and Information Technology* (MIIT) has mandated eight batches of enterprises, 7,885 enterprises in total, to eliminate outdated production capacity. The number of sectors involved has increased from thirteen in the Eleventh Five-Year Plan (FYP) period (2006–2010) to twenty-one in 2012. In addition, since 2010, the MIIT has publicized its annual progress in eliminating outdated production capacity (CDP 2014).

Besides resolving excess and outdated production capacity, efforts have also been made to promote the development of modern services and strategic emerging industries. Since the beginning of the twenty-first century, a series of policies has been issued to support and regulate the development of the service sector. The share of the service industry in the economy has increased from 34.8 per cent in 2000 to 46.8 per cent in 2013 (NBS 2014). In October 2010, China issued "the SC Decision on Speeding up the Cultivation and Development of Strategic Emerging Industries", in which seven industries such as the renewable energy industry and the energy-saving and environmental industries were identified as strategic emerging sectors (NDRC 2012).

The adjustments to the industry structure aim at broadening employment channels and reducing the pressure of economic development on resources and the environment. But existing regional protectionism in China has slowed the process. Despite the calls by the central government to curb excess capacity, local governments are reluctant to eliminate local laggard and excess capacity for the sake of GDP and employment. The achievements in eliminating laggard capacity have largely been offset by the expansion of new capacity. According to the National Bureau of Statistics, crude steel production capacity was reduced by 76 million tonnes during 2006–2012, while at the

same time the new production capacity totalled 440 million tonnes.[3] On the other hand, competition among local governments for the development of strategic emerging industries has created artificial demand for these industries, leading to another round of excess capacity. The renewable energy industry is most typical in the new round of excess capacity. Excess capacity in both traditional manufacturing and emerging sectors has made industrial restructuring more complicated and difficult to cope with. Prohibiting overlapping investment and the closure of outdated production facilities may only ease the problem, but not cure the disease.

27.2.2 Promotion of a Circular Economy and Cleaner Production

A *circular economy* (CE), proposed by two British environmental economists in 1990 as a closed loop of material flows in the economy (Pearce/Turner 1990), was first introduced into China in the late 1990s (Zhu 1998). Since China's environmental protection strategy embarked on a gradual transition from *end-of-pipe* (EOP) pollution treatment to pollution prevention in the 1990s (Shi/Zhang 2006), CE has aroused great interest and it has been regarded as a new development strategy to help China leapfrog into a more sustainable economic structure rather than being regarded as an incrementally improving environment management policy (Zhu 2008; Geng/Doberstein 2008a). Thus, a lot of policies and regulations were issued to promote a CE since 2000, including the "Circular Economy Promotion Law". It has been determined as a key strategy for China's national development plan since 2005 (Geng/Fu/Sarkis et al. 2012). The main focus of the CE has been expanded from a narrow system of waste recycling to the broad efficiency-oriented control of all stages of production, distribution and consumption (Su/Heshmati/Geng et al. 2013).

Current CE practices in China are carried out at three levels, the enterprise level, the industrial parks level, and the regional level, all of which are the basic manifestations of CE at the micro-, meso-, and macro-levels, respectively (Hong/Li 2013). CE pilot programmes have been launched in twenty-eight provinces (municipalities, autonomous regions), 133 cities (districts and counties), 256 industrial parks and 1,352 enterprises (NDRC 2012). Su, Heshmati, Geng et al.

3 See at: <http://www.chinairn.com/news/20130805/
153103234.html>.

(2013) pointed out that practices at micro- and meso-levels are more vibrant than those at the macro-level because the complexity of practices increases when the scale level increases.

A large number of studies have been conducted to evaluate the CE performance at different levels with different evaluation indicator systems (Wang/Huang/Chen 2006; Zhu/Zhu 2007; Yang/Gao/Chen 2011; Geng 2011; Zhao/Christensen/Lu et al. 2011; Li/Su 2012). However, only a few studies exist on cycle flows at the national level. Li, Zhang, and Liang (2013) used the reutilization-extended *economy-wide material flow analysis* (EW-MFA) to investigate comprehensive resource reutilization in China from 2000 to 2010, and they found that about sixty per cent of overall solid waste generation had been reutilized, and more than twenty per cent of the total resource requirement was reutilized resource by the year 2010. Official data indicated that one-fifth to one-third of raw materials for steel, non-ferrous metals and paper pulp came from the recycling of resources; twenty per cent of raw materials for cement originated from solid waste; and the overall utilization rate of industrial solid waste had reached sixty-nine per cent (NDRC 2012); while in Japan, the reutilization rate for iron and steel and aluminium in 2012 was 90.8 per cent and 99.9 per cent, respectively (Japan Business Federation 2014).

Several widely recognized and repeatedly emphasized challenges may slow down the implementation of the CE in China, including weak economic incentives, lack of reliable information, lax enforcement of regulations, shortage of advanced technology, poor leadership and management, lack of stakeholder participation, and lack of a standard system for performance assessment (Peng/Li/Shi 2005; Wen/Yuan 2005; Wang/Chen/Chen et al. 2007; Su/Heshmati/Geng et al. 2013; Liu/Bai 2014). There exists a striking gap between awareness and actual behaviour in developing a circular economy.

Cleaner production, which could be recognized as CE practice at the enterprise level, has also been widely promoted by the Chinese government. CP in China has progressed through the formation stage (1973–1992), the legislative stage (1993–2002), and the institutionalization stage (2003) (Duan/Zhou 2007). The Law of the People's Republic of China on Promotion of Cleaner Production, issued in 2002 and enacted in 2003, established the legal basis for CP in China. A number of governmental documents have been issued to guide and supervise enterprises in implementing CP (Dan/Yu/Yin et al. 2013). The

Cleaner Production Audit (CPA) has become the main measure in promoting CP for enterprises. Compared with foreign companies that conduct CPA voluntarily and actively (Howgrave-Graham/van Berkel 2007; Chavalparit/Ongawandee 2009), the promotion of CP in China has been confronted with many obstacles, such as a lack of economic incentive policies, a lack of corporate responsibility, financial obstacles, and a shortage of technology in companies (Shi/Peng/Liu et al. 2008).

In China, three categories of enterprises are required to conduct compulsory CPA regularly, covering those that exceed the national or local discharging standards or the total amount control targets for pollutants; exceed the energy consumption limits for unit product; and use toxic and harmful materials in production or discharge toxic and harmful substances. Other enterprises are encouraged to take voluntary CPA. Since 2003, many industry sectors, such as metallurgy, chemical, non-ferrous metals, and machinery have established CP centres and more than 760 CPA advisory services have been set up. Capacity-building activities, such as CPA training and relevant education programmes, are being undertaken (Geng/Haight/Zhu 2007). Over 20,000 enterprises carried out CPA, accounting for nine per cent of all industrial enterprises above a designated size in China. As a result, sulphur dioxide, ammoniacal nitrogen, chemical oxygen and energy demand were estimated to have been reduced by 939,000 tonnes, 56,000 tonnes, 2.46 million tonnes and 56.14 million tce respectively since the implementation of CP between 2003 and 2010 (MIIT 2012).

Although some progress has been made (Duan 2001), the universal adoption of CP is far from satisfactory (Mol/Liu 2005). First, there were obvious differences between regions in the promotion of compulsory CPA in key enterprises, since the provincial government plays a leading role in enforcing the related CP regulations, supervising the implementation of CP and providing technical support and capacity-building (Geng/Wang/Zhu et al. 2010). Second, *small and medium-sized enterprises* (SMEs), which account for ninety-nine per cent of all Chinese enterprises, could get little technical and economic support for their CP efforts, since governments pay more attention to big companies and provide more funds to cover their CP expenses (Wang/Shu/Wang 2014; Zhang/Zhang 2008). Thus, the application and effectiveness of CP in these SMEs is doubtful (Geng/Wang/Zhu et al. 2010). Considering the reality that most SMEs are confronted with difficulties such as

obsolete equipment and technology, untrained and inexperienced workers, and inadequate financial resources, their production has caused significant negative environmental impacts (Shi/Zhang 2006). Third, most CP in Chinese enterprises aims at savings and efficiency gains through process, technology or management improvements. It was estimated that only 44.6 per cent of the technical renovation suggestions in CPA reports were implemented (MIIT 2012). Other CP practices, such as shifting to eco-design or delivering new products and services with lower environmental impact across their life cycle, which require initiatives from enterprises, were rarely conducted in China. Though according to the "Twelfth FYP on industrial CP development", eco-design of industrial products, improvement of CP technology and substitution of toxic and harmful materials or products are taken as the main tasks of CP in the Twelfth Five-Year period (MIIT 2012), they are scarcely being conducted by enterprises under the current circumstances.

27.2.3 Comprehensively Promoting Energy Conservation and Emission Reduction

Energy Conservation (EC) strategy has always been noted as the key measure for achieving sustainable development in China, and improving energy efficiency has been on the policy agenda since the early 1980s (Hou/Zhang/Tian et al. 2011; Yuan/Kang/Yu et al. 2011). With continuous efforts, China's energy intensity, calculated as the energy consumption per unit of GDP, fell roughly fifty-five per cent between 1990 and 2010 (NBS 2014). China's CO2 intensity declined by almost 58 per cent compared with the average rate of decrease of 30 per cent for developed countries and the global average of 15 per cent during these two decades (IEA 2014).

China has set an EC target in its FYP for National Economic and Social Development for many years, but it was in the Eleventh FYP (2006–2010) that a binding target, reducing energy intensity by twenty per cent, and the main pollutant of sulphur dioxide(SO2) and chemical oxygen demand (COD) by ten per cent by 2010, was first set as of 2005 (NPC 2006; Yuan/Kang/Yu et al.2011), and this was referred to as the *Energy Conservation and Emissions Reduction* (ECER) target. In order to ensure the accomplishment of the target, all government divisions at different levels were required to make an effort. The SC approved and distributed a scheme disaggregating the national EC target to each province, and provincial governments disaggregated their targets to cities and counties (Zhou 2006). The head of the local government was responsible for the accomplishment of the targets in each administrative area. Following this requirement, a hierarchical administration system for EC ranging from the nation to the province and city level was developed during the Eleventh FYP period. Besides this, various EC policies, including legislation, government regulation, technology standards, finance and tax, as well as price policy, were released at the national level, and this laid a sound foundation for the accomplishment of the target (Yuan/Kang/Yu et al. 2011; SC 2007).

With strong determination and vast inputs, China's national energy consumption per unit of GDP was reduced by 19.1 per cent between 2005 and the end of 2010, which was 95.5 per cent of the target. Sulphur dioxide and chemical oxygen demands were reduced by 14.29 per cent and 12.45 per cent respectively, far beyond the pollution reduction targets (SC 2011). It was estimated that the amount of energy saved by the achievement of a 19.1 per cent improvement in energy intensity were about 630 million tce, taking the baseline condition as no improvement in energy intensity from 2005 levels. The carbon dioxide emissions savings were estimated at 1,550 million tonnes (Tsinghua University 2012).

The promotion of ECER during the Eleventh FYP period was conducted in a top-down manner. Command-and-control policies played the most important role. Administrative approaches, such as the Ten Key Energy Conservation Projects, the Top 1000 Enterprises Energy Conservation Programme, and the closure of small plants and outdated production capacity (Price/Levine/Zhou et al. 2011) were implemented as the main measures.

The widely adopted administrative approaches helped ensure governments at all levels implemented the ECER work. But the disadvantages of relying on administrative approaches were also apparent. Firstly, they created a great burden for the government. During the Eleventh FYP period, the government was not only the regulator, but at the same time the provider of finance and technology for EC. Secondly, administrative instruments may be effective when applied to a relatively small number of large enterprises or institutions, but they are ineffective in the case of numerous small-scale industrial plants. The success of the Top 1000 programme and the inefficiency of phasing out inefficient capacity in the steel industry is such a case (Yuan/Kang/Yu et al. 2011). Last but not least, the lack of EC initiatives by energy users made EC unsustainable. The targets were hard to meet, while the

---

Box 27.1: Top 1000 Enterprises Energy Conservation Programme. **Source**: NDRC (2006a, 2011).

China's Top 1000 Enterprises Energy Conservation Programme (Top 1000 Programme), as one of the key energy conservation promotion measures, was launched in April 2006. The programme required the largest 1,000 energy consuming industrial enterprises in nine major energy-consuming industries, each consuming a minimum of 180,000 tce in 2004, to set and implement energy-saving targets.[a]

The 1,008 enterprises on the final list of the Top 1000 Programme consumed 670 million tce in 2004, accounting for one-third of China's total energy consumption. The Top 1000 Programme aimed at reducing energy consumption by 100 million tce via energy efficiency improvement per unit product. Local energy conservation authorities were responsible for tracking, guiding and supervising the work on energy-saving in these enterprises (NDRC 2006a). The National Development and Reform Commission signed target-setting agreements with local governments, and local governments signed agreements with enterprises on their energy conservation targets (NDRC 2011). Each enterprise received an EC target which was defined by energy consumption per unit product. In order to reach

their target, the Top 1000 enterprises are expected to establish an EC working group, formulate an EC plan, establish EC incentive mechanisms, invest in energy efficiency improvement options, conduct energy audits, establish an energy utilization reporting system, enhance EC publicity and training, etc. These enterprises are required to report their quarterly energy consumption by fuel to the NBS (NDRC 2006a). It is worth noting that the Top 1000 Programme requires the integration and implementation of a series of policies and the actual boundary between different kinds of policy is not clear-cut in practice.

According to official data, the comprehensive energy intensity per unit product of aluminium, ethylene and caustic soda decreased more than thirty per cent and the comprehensive energy intensity of oil refining, electrolytic aluminium and cement more than ten per cent, while the energy intensity of coal-fired electricity generation declined by almost ten per cent. Total energy conservation through the Top 1000 Programme reached 150 million tce compared with a frozen 2005 energy intensity baseline (NDRC 2011).

---

administrative emphases changed. In fact, energy intensity increased rather than declined during the first half of 2010, since in response to the unexpected global financial crisis in 2008 the government focused on providing vast investments to stimulate the economy. Central government's rush to implement a very strict restructuring policy through strong administrative means did not change the situation (Yuan/Kang/Yu et al. 2011).

The Twelfth FYP for National Economic and Social Development (2011–2015) issued by the Chinese government continued to devote considerable attention to ECER and established new targets for the period 2011 to 2015. It called for energy intensity to decline by a further sixteen per cent and carbon dioxide emissions per unit of GDP to be reduced by seventeen per cent in 2015 compared with 2010. The carbon intensity target was first addressed in the Twelfth FYP in response to the forty to forty-five per cent reduction in carbon intensity from 2005 levels by 2020 which was first announced during the Copenhagen negotiations in 2009.

Using experience and lessons from the Eleventh FYP, the Top 10,000 Enterprises Energy Conservation Programme was created, modelled on the Top 1000 Programme. It covered industrial enterprises that consumed more than 10,000 tce per year and transport

enterprises or public buildings that consumed more than 5,000 tce per year. The Top 10,000 Programme covered sixty per cent of total energy consumption and the total number of enterprises reached about 17,000. According to data released by NDRC, the Top 10,000 Programme had achieved sixty-nine per cent of the EC targets during 2011–2012 (NDRC 2013). But as the number of enterprises grows, so do the challenges of collecting accurate data and enforcing targets. Price, Levine, Zhou et al. (2011) pointed out that both national and local government need to enhance their capacities to implement, monitor and evaluate these programmes.

During the Twelfth FYP period, market-oriented approaches are expected to take a more important role in promoting ECER. The Twelfth FYP established the goal of promoting the development of energy-saving and environmental industries and gradually establishing a carbon trading market. China is currently implementing seven regional pilot *emissions trading systems* (ETSs) which are expected to serve as a testing ground for a national ETS (Carbon Market Watch 2013).

It is recognized that the pilots have made important progress in experimenting with how to use ETS in a Chinese context. Local and national officials are already studying how to potentially go beyond pilot

---

Box 27.2: China's Carbon Emissions Trading Pilots. **Source**: Zheng (2014); Wilkening, Kachi (2014); Wu, Shi, Xia et al. (2014).

In October 2011, the NDRC designated five cities (Beijing, Shanghai, Tianjin, Shenzhen and Chongqing) and two provinces (Guangdong and Hubei) as regions for carbon emissions trading pilot projects. The seven pilot regions account for eighteen per cent of the population and thirty per cent of GDP in China.

From 2013 to 2014, the seven pilot projects have developed carbon emissions trading schemes, set out management and trading rules, and launched the carbon emission trading system. Focusing only on carbon dioxide, the seven pilot projects covered roughly forty to sixty per cent of a city or province's total emissions and the aggregate of all emissions regulated were around 0.8 billion tonnes of CO_2, which became the second largest emissions trading market in the world, after the European Union. The total number of enterprises or institutions covered reaches over 2,200, which includes heavy manufacturing sectors such as steel, cement, and petrochemicals, and non-industrial high-emitting sectors such as airports, hotels and financial service providers. Besides direct emissions generated by activities within the area/sector covered, the seven pilot projects also cover indirect emissions linked to electricity or thermal energy used in production, due to the regulated electricity prices. Most allowances in these pilot projects were allocated freely, though the Guangdong pilot project requires companies to buy a portion of their allowances through an auction (three per cent of the total in 2013 increasing to ten per cent by 2015; Zheng 2014). In July 2014, the Beijing, Shanghai, Tianjin, Guangdong and Shenzhen pilot projects completed their first compliance audit after regulated emitters surrendered their allowances. In these five pilot regions, the average compliance rate was 98.53 per cent. Though it showed a high degree of compliance, trading volumes were generally low and many pilot regions like Beijing, Tianjin and Guangdong postponed their compliance deadline due to the relatively low participation of enterprises in the carbon trading market. A tendency of allocating too many permits may have made emissions trading inefficient. But it should also be noted that the pilot schemes are not a long-term project, but rather a way to experiment with various emissions trading design elements, such as the threshold for inclusion, sector coverage, cap setting, allowance allocation and the *monitoring, reporting and verification* (MRV) system, while helping companies get used to the instrument before a national programme is rolled out (Wilkening/Kachi 2014; Wu/Shi/Xia et al. 2014).

---

programmes (Song/Lei 2014). Although the Chinese government has been ambitious to establish a national carbon market, there are still numerous challenges, including legal and regulatory barriers, lack of a mature market, interactions with existing energy and climate policies, equity concerns relating to the initial allocation where there is an uneven development background, information disclosure and the *monitoring, reporting and verification* (MRV) system, risk of carbon leakage, etc. (Han/Olsson/Hallding et al. 2012; Zhang/Karplus/Cassisa et al. 2014a; Zhang/Springmann/Karplus 2014b; Wu/Shi/Xia et al. 2014). These challenges need to be seriously considered while preparing for a national ETS in China.

27.3   Sustainable Consumption in China

Although China acknowledged the need to establish a sustainable consumption pattern in its Agenda 21 in 1994, the concept of sustainable consumption has not yet been formally defined and sustainable consumption has not received as much attention as sustainable production. But there are a few policies and practices that reflect the concept of sustainable consumption in China.

27.3.1   Eco-labelling and Green Procurement

Information provision has been regarded as an effective tool for changing consumption patterns towards sustainable consumption through a kind of "voluntary approach" (Russell/Krarup/Clark 2005). Eco-labelling, which provides environmental product information for consumers, is one of the most promising forms of environmental information policy (Loureiro/McCluskey/Mittelhammer 2002). Since the German Blue Angel was first released in 1977, a number of eco-labelling programmes have been developed all around the world (Shen/Saijo 2009).

The Chinese government issued a mandatory and comparative energy information labelling programme known as the China Energy Label in 2005, following the legal provisions of the Energy Conservation Law and supporting regulations (Zhou/Khanna/Fridley et al. 2013). So far, forty-six national energy efficiency

Box 27.3: Project "Energy-saving Products Benefiting the Public". **Source:** MFPRC (2013).

The "Energy-saving Products Benefiting the Public" project provided a promotion list of energy-efficient products which covered three major categories including household appliances, vehicles and industrial products, fifteen varieties and about 100,000 types of energy-efficient products. The central government has allocated more than 40 billion yuan and released more than twenty detailed regulations for the implementation of the project.

It was reported that since the implementation of the project, public awareness of energy-saving products had been greatly improved, and the market share of energy-efficient products rose rapidly, which promoted technological progress and industrial upgrading. Taking the air conditioner

as an example, the average price for energy-efficient air conditioners fell, while their market share rose from five per cent before the project to more than seventy per cent. New energy efficiency standards were implemented more smoothly and the production of inadequately energy-efficient air conditioners was halted. The entire energy efficiency of the air conditioner industry was increased by twenty-four per cent. Though the project "Energy-saving Products Benefiting the Public" ended in June 2013, it was concluded that the combination of subsidy policies, mandatory standards for products and the market mechanism was 'a good example of promoting the upgrading of products' (MFPRC 2013). But it should also be noted that subsidy policies may lead to excessive consumption.

---

standards, covering electronic products for home, commercial and industrial use, have been issued. The China Energy Label rates the energy efficiencies of appliances in five classes ranking from 1 to 5, where 1 is the most energy-efficient and 5 the least (Shen/Saijo 2009). It was expected to improve consumers' awareness and their preference for energy-saving products so as to ease the contradiction of boosting both domestic consumption and energy-saving targets in China. Besides providing energy information, China had also been issuing subsidies for energy-efficient lighting products

since 2007. In addition, in June 2009, the Chinese government began implementing the project 'Energy-saving Products Benefiting the Public', which aimed at promoting energy-efficient products with energy labels of rank 1 or 2 through financial subsidies.

Similarly, the China environment label, which covers products from automobiles, building materials, textiles, electronics, chemicals and furniture to packaging has formed a complete system with standards, certifications, auditing and quality assurance. More than 30,000 products within 1,500 enterprises have been

given the China environmental label. Annual output reaches 100 billion yuan (Lou 2008).

As government itself is a giant consumer, whose procurement accounts for roughly fifteen to twenty per cent of the country's GDP (European Commission 2004), by using its purchasing power to opt for energy-saving or environmentally friendly goods and services it can make a great contribution to SCP (Cao/Yan/Zhou 2009). Thus, *Green Public Procurement* (GPP) has been recognized as an effective way to develop capacity for green supplies and markets (Ho/Dickinson/Chan 2010) by encouraging manufacturers to implement energy saving and environmentally friendly design and production of products (Parikka-Alhola 2008).

Following developed countries' GPP practices, the Chinese government first adopted a policy of preferential purchasing of energy-saving products in 2004. Then in 2007 a programme of compulsory government procurement of energy-saving products began. In the meantime, government procurement began to give priority to products with environmental labels. So far, fifteen issues of government procurement lists with energy-saving products and thirteen issues of lists with environment label products have been released. Both lists are updated each year, and the past two years have seen the rapid expansion of product types and quantities in both lists.

Yet effective GPP promotion is still a major challenge for Chinese governments at different levels. Firstly, limited budgets mean that costs are still key barriers (Zhu/Geng/Sarkis 2013). Although GPP encourages government agents to purchase green products even if the cost is higher than non-green alternatives (Marron 1997), this is not true in many cases where local and government ordinances require choosing the lowest price bid (Zhu/Geng/Sarkis 2013). Secondly, the individual behaviour of procurement officials has been identified as another key factor in implementing GPP practices successfully (Meehan/Bryde 2011). The low environmental awareness of procurement personnel and long-standing relationships between local procurement officials and local suppliers have been observed to hinder the promotion of effective GPP (Geng/Doberstein 2008b). Thirdly, supplier monitoring is another important dimension for GPP practices (Wan/Lu 2009). It was revealed that the Chinese consumers are confronted by an overload of certifications and claims which they could not trust (McNeil/Hathaway 2005). Of great importance is the need to enhance the credibility and independence of China's product certification and

labelling systems. Additionally, the quality and performance standard of environmental products could be improved (Philipps/Espert/Eichhorst 2011). Last but not least, the current procurement laws and regulations do not implement a concept of sustainable procurement and a green supply chain. It is suggested that the best green procurement is no procurement and therefore it is crucially important for the government to carefully review and control government demand to avoid improper demand and procurement (Cao/Yan/Zhou 2009).

27.3.2 The Promotion of Waste Management

With the great improvement in the Chinese people's living conditions, the staggering increase in waste production throughout urban and rural China has become a critical problem. It is estimated that China annually generates 250 million tonnes of *municipal solid waste* (MSW), or a quarter of the world's total waste (Balkan 2012). The daily amount of MSW per capita in urban areas is about 1.0–1.18kg (World Bank 2005; Zhang/Tan/Gersberg 2010; Zheng/Song/Li et al. 2014), and the average annual growth rate for MSW from 1979 to 2009 was approximately seven per cent (Zou 2011). According to World Bank (2012) estimates, China will produce at least 480 million tonnes of MSW by 2030.

The increasing amount of solid waste has already overtaken the treatment capacity such as landfill and incineration, posing a great threat to the health of the people. By the year 2009, only 66.8 per cent of waste was being treated, leaving almost one-third of the total waste either not properly disposed of or untreated (Lybæk/Klemmensen/Li et al. 2010). About seventy-nine per cent of the treated waste goes to landfills. Incineration, which converts MSW to energy, is becoming an attractive option in China (Figure 27.1), while nearly two-thirds of China's cities are afflicted with chronic "waste siege" syndrome (Wang/Pei/Huang et al 2009). But increasing "*Not in My Backyard*" (NIMBY) protests (Wu/Dai 2014) have made the siting and operation of incineration plants a big challenge. The lack of reliable data and transparency on the incineration industry in China leaves a gap of trust between the citizens and the government, and public awareness of the health risks of incineration has also increased (Vanacore 2012). Thus, reducing, reusing and recycling of MSW based on waste classification has become a key solution to alleviating the city's waste disposal dilemma.

Figure 27.1: MSW treatment by type in China (2004–2010). **Source:** NBS (2014).
Therefore, in recent years, Beijing, Shanghai, Guangzhou and other big cities in China have carried out large-scale residential garbage sorting programmes. Actually, garbage sorting is not new to China's big cities. Many big cities, such as Beijing, Shanghai, Guangzhou, Shenzhen and Hangzhou, had carried out garbage sorting campaigns as trial projects in selected communities since the late 1990s. However, this has yet to be effective due to the lack of related back-end processing facilities and public participation. In the new round of garbage sorting programmes that started around 2010, these cities are aiming to gradually promote garbage sorting all around the city. More efforts have been put into the establishment of separate collecting, transport, and processing facilities and the implementation is expected to come with strict regulations and penalties. In Guangzhou, where 18,000 tonnes of waste are produced daily, city officials have implemented a fee-for-service programme to encourage residents to separate waste (Wang 2012). In Guangzhou, household garbage is required to be sorted into four categories, namely recyclable garbage, harmful garbage, wet garbage and dry garbage. Other cities have produced similar waste classification requirements. Since many Chinese families have the habit of recycling recyclable wastes such as papers and plastics which will be collected by informal waste collectors, and harmful wastes are relatively small in number, the biggest challenge for residents is separating

wet and dry waste. Wet waste covers kitchen waste and other organic waste, which accounts for between forty and seventy per cent of residential waste in different cities (Zhang/Tan/Gersberg 2010). Dry waste covers all the other waste except recyclable, harmful and wet waste. Volunteers in each community have been working to help guide and encourage the residents' garbage sorting.

Containers of different colours and instructions for different wastes showed that most people did not separate their garbage or failed to separate their garbage correctly, though most residents recognized the need for waste sorting and claimed that they knew how to sort waste. An Internet survey carried out jointly by Minyi China and Sohu.com indicated that only 18.2 per cent of the interviewees confirmed that they carried on separating the wastes as time went on, while more than 90.5 per cent support the promotion of waste separation.[4] A survey of 2,000 respondents carried out by the Shanghai Statistics Bureau revealed that 98.9 per cent of respondents were willing to sort their garbage. However, the actual sorting rate at household level in pilot regions was lower than twenty per cent.[5] Similarly, the separation ratio of MSW in

5   See at: <http://www.chinadaily.com.cn/china/2014-04/ 11/content_17425951.htm>.

Beijing was only approximately fifteen per cent (Xiao/Bai/Ouyang et al. 2007). Since so many people failed to classify wastes correctly, related regulations and punishment mechanisms[6] have not been implemented to date.

With a low rate of waste sorting at the household level, many community organizations in these big cities began to hire one or more people to do on-site garbage sorting near the litter bins (called "secondary sorting"), so as to meet the waste sorting and reduction requirement. According to a survey of 182 communities in Shanghai (Huang 2014), 74 per cent of the communities relied on secondary sorting, while 23 per cent of the communities carried out source sorting at the household level with secondary sorting as a supplementary activity (figure 27.2). Secondary sorting shows a good performance level of waste classification, but the labour cost is greatly increased and it will also destroy residents' enthusiasm for waste sorting.

Figure 27.2: Household Waste Sorting at Different Stages in Shanghai. **Source**: Huang (2014).
This phenomenon indicates the deficiency in China's government-dominated work with residents. Garbage sorting, as a project promoted by the government, may require a visible and good performance over a short time. On the other hand, garbage sorting, as a daily activity related to residents' behavioural changes, is a long-term process. The demand for the short-term effects of government projects conflicts with the need for long-term behavioural change. Cultivating the

habit of waste sorting at household level has proved to be difficult when implemented as a top-down policy. The government policy may raise people's awareness or increase their willingness to carry out waste sorting, but what matters more is how to keep them constantly practising it. As government policies do not instantly lead to behavioural changes, it calls for the transformation of the governmental function in such activity and the introduction of non-government forces to promote long-term change. Moreover, education and campaigns and clearly clarified responsibilities for different stakeholders with mandatory regulations and punishment mechanisms are needed to achieve these goals.

27.4 Challenges Facing Sustainable Consumption and Production in China

Although the Chinese government has invested great manpower and resources in promoting the transition towards a more resource-conserving and environment-friendly society, China still faces several critical challenges that hinder the transition towards SCP.

27.4.1 The Extensive Growth Model

China's economy has expanded at a staggering pace since the opening-up and the economic reforms. But China's extensive growth model, which relies on high resource inputs and results in broad resource depletion, environmental pollution and ecological degradation, is now widely agreed to be exhausted and unsustainable (Zhang 2012; Dorrucci/Pula/Santabárbara 2013).

China's extensive growth model, which successfully fires the enthusiasm of local governments at different levels to promote economic growth, is enhanced by the GDP-oriented performance evaluation and fiscal system (Oi 1992; Zhou 2004; Wang/Zhang/Zhang et al. 2007). Although central government has not formally regarded the GDP growth rate as a performance evaluation criterion, it is a prevailing phenomenon that local officials delivering punchy growth rates can get rapid promotion. This has created a political atmosphere favouring high speed (Zhou 2004). On the other hand, the existing fiscal decentralization system forces local governments at each level to gain fiscal revenue via economic growth (Wang/Zhang/Zhang et al. 2007). Although the central government provides fiscal transfers for less devel-

---

6 According to the regulation coming into force in Guangzhou from 1 April 2011, those who are caught failing to put their garbage into the right bin will be fined up to 50 yuan.

oped regions, most of the transfers require matching inputs from local governments. Thus the higher the economic growth rate, the more fiscal revenue local governments can receive, and this also covers the wages of government officials. And with more fiscal revenue, officials can achieve better performance and so find more opportunities for promotion.

Influenced by incentives regarding their political futures and financial rewards, government officials' fever for the growth rate leads to some phenomena that aggravate the problems of resources and the environment. Firstly, local governments can easily rely on investment to maintain a high rate of growth. Local government-dominated investment mania in a wide range of industries forms an investment bubble which boosts the upper reaches of industries that consume high amounts of energy, such as steel and cement. This is a major source of China's sharp increase in energy consumption and environmental pollution. Secondly, local governments compete against each other to gain investments, and this leads to a serious overlapping of investment and industries, as well as to redundant construction projects. This is an important cause of rebounding overcapacity in China. Fierce competition between local governments also leads to China's low labour costs, low land costs, and low environmental costs (Li/Gong 2013). Finally, those areas which are not suitable for industrial development and less competitive in inviting investment, including many towns and villages, also undertake responsibility for promoting GDP growth. This results in the small-scale, low-tech or highly polluting industrial enterprises spreading throughout China, and this hinders the country's economic restructuring and industrial upgrading.

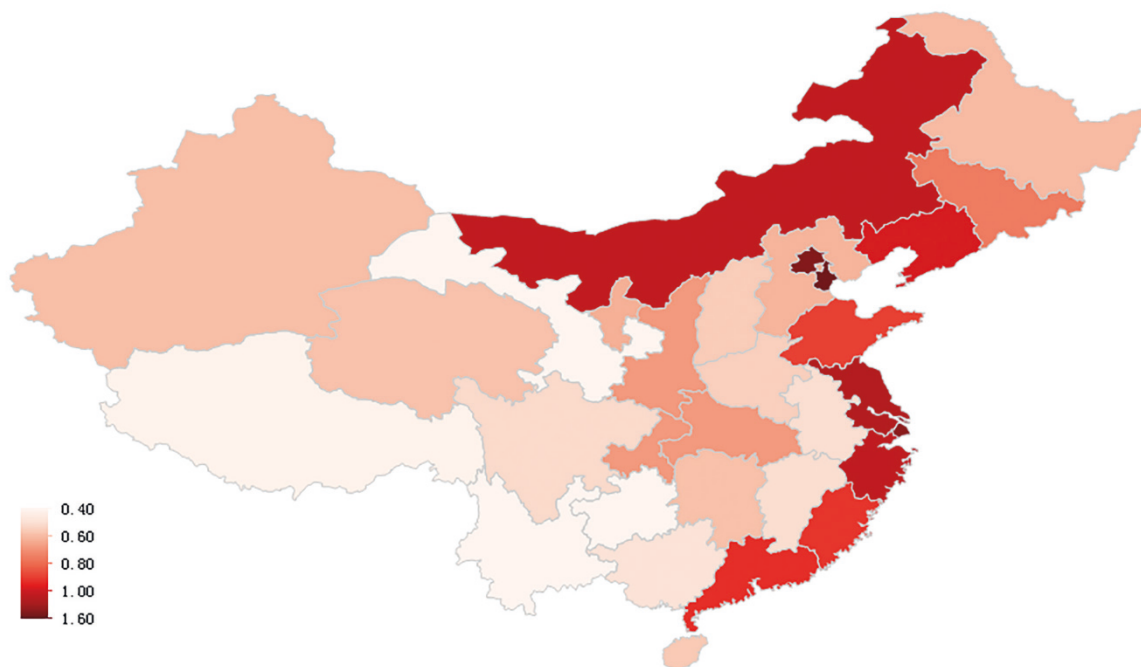
Considering the extensive growth model as unsustainable, the Chinese government has sought to shift to an intensive development model, from investment-led to consumption-driven growth. But little progress has been made until now due to little progress in shifting the incentive structure of performance evaluation and the fiscal system. Central government has stipulated a rather conservative but balanced goal of seven per cent GDP growth for the Twelfth FYP period, while only five provinces (Beijing, Shanghai, Hebei, Zhejiang and Guangdong) have formulated growth goals of less than ten per cent for the year 2011, with all the rest between twelve and thirteen per cent (Yuan/Kang/Yu et al. 2011). If unchecked, this trend would ultimately lead to over-investment and aggravate pressure on resources and the environment.

27.4.2   Imbalanced Development

The pronounced imbalanced development in various fields of China has made the integration of development and protection particularly difficult. These imbalances include pronounced differences between the developed eastern coastal provinces and the less developed central and western provinces (Keidel 2007; Feng/Siu/Guan et al. 2012), the structural imbalance in expenditure and the increasing inequality in income (Dorrucci 2013).

Apart from the eastern coastal areas, most regions of China are still in the middle or even the early stages of industrialization and urbanization (NDRC 2012). In 2013, the developed eastern coastal provinces, with forty-nine per cent of the total population, accounted for sixty-four per cent of China's GDP, and the less developed central and western provinces contributed thirty-six per cent of GDP though they held fifty-one per cent of the population. The per capita GDP in the inland regions is less than half of that in the coastal regions on aggregate (Fan/Kanbur/Zhang 2011) and the differences between individual provinces and municipalities can reach up to a factor of four (Figure 27.3). It is recognized that regional inequality has been rising since the late 1980s (Kanbur/Zhang 2005), with only modest signs of decline (Zhang/Zou 2012). In the meantime, the imbalanced development between urban and rural areas is increased by industrialization and urbanization. There are still over 642 billion people living in the rural areas (NBS 2014), where living conditions and public services have lagged far behind urban levels. This great spatial inequality in education, health care and social security is a huge threat to China's SCP. China still faces a tough task in improving people's livelihood, and so top priority has been given to economic growth in most regions.

In recent years, the eastern developed regions in China, like Beijing and Shanghai, have attempted to say "goodbye" to giving priority to GDP and pursuing a transformation in economic development. Some industries with high levels of energy consumption and pollution have begun to move out of these places. But at the same time, the less developed regions in central and western China have competed to attract these industries. It should be noted that the ecological environment of many central and western regions is more vulnerable than that of the eastern regions. This kind of inter-regional transfer of industry may increase pollution while contributing little to GDP and employment in the whole country.

Figure 27.3: Regional Distribution of Per Capita GDP in mainland China in 2013 (10^4 US dollars). **Source**: NBS (2014).


The imbalanced development also reflects on the expenditure structure, which features in high investment and low consumption (Li/Gong 2013). According to China's NBS, final consumption as a share of China's GDP fell from 62.3 per cent to 49.5 per cent between 2000 and 2012, while the investment share of GDP rose from 35.3 per cent to 47.8 per cent, and the private consumption rate declined from 46.4 per cent to 36.0 per cent (NBS 2014). However, China's private consumption has grown at more than 8 per cent per annum (Ma/McCauley/Lam 2013). Thus, the imbalance rather consists in an abnormally high contribution of resource-extensive investment to growth (Dorrucci/Pula/Santabárbara 2013), fuelled by the extensive growth model.

Rising income inequality is another reflection of uneven development. Xie and Zhou (2014) indicated that China's income inequality, measured using the Gini coefficient, has been in the range 0.53-0.55 since 2005, which was very high both from the perspective of China's past and in comparison with other countries at similar stages of economic development. These figures were also higher than has been acknowledged in government statistics, with the Gini coefficient in the range 0.47-0.49 between 2003 and 2012. Income inequality creates the problem of insufficient consumption (Li 2013) combined with overconsumption. At the end of 2012, China still had a population of over 100 million people living in poverty, according

to the new poverty line set in 2011 (rural residents' per capita annual net income being 2,300RMB, about US$350). Most of these people live in regions with harsh natural conditions and poor access to public services, making the task of poverty alleviation extremely difficult (NDRC 2012). Besides this, China's vast rural population and poor households in the urban areas face a liquidity constraint—although they have strong incentives to consume, they are unable to do so. On the other hand, overconsumption and luxury consumption is expanding rapidly. According to the World Luxury Association report, China has become the world's largest consumer of luxury goods (Li/Wang 2012). A growing middle class, affected by the global wave of consumerism, is expanding rapidly. It is projected that by 2030 China will have the largest population of consumers in the world, with an urban middle class of over half a billion people (Wetzel 2012). Consumption has become a symbol of success and social status. Overconsuming is in vogue nowadays. Traditional Chinese frugal consumption has become a byword for smallholder consciousness, belittled by the younger generation. The general public, especially the younger generation, aspire to and pursue western lifestyles, characterized by automobiles, big houses, and gated communities, and which have a deleterious effect on the environment. Therefore, China is on the way to a high-consumption society, although the current overall level of consumption is not high. Given

the large population under insufficient consumption and a rising population pursing overconsumption, the conflicts and trade-offs between building a consumption-driven economy and a resource-saving and environmentally friendly society should be explicitly addressed instead of ignored (Dai/Chen 2010). Increasing domestic consumption creates an urgent need to ensure that the emphasis is on sustainable consumption (CCICED 2013).

27.4.3   Weak Scientific and Technological Innovation Capacities

China is at a critical point for its economic transformation, in which scientific and technological innovation plays an important role. China has come a long way in encouraging domestic technological innovation. The past few years have seen a great improvement in China's innovation capacity, but there is still a big gap compared with developed countries. The independent innovation capacity of Chinese enterprises is still too weak. Though according to the "2013 world intellectual property indicator" report released by the *World Intellectual Property Organization* (WIPO), China accounted for the largest number of applications filed throughout the world for the four types of intellectual property (WIPO 2013), China has only a limited number of invention patents and few influential patents. In the 2013 Global Innovation Index list, China ranked at number 35 (Cornell University/INSEAD/WIPO 2013). It is argued that the expansion of innovation activity instead of the growth of innovation efficiency and effectiveness is the main contributor to the development of China's innovation capacity (Mu/Ren/Song et al. 2010).

The Chinese government released the "Outline of Medium and Long-term Plan for National Science and Technology Development (2006–2020)" in 2006 (SC 2006), with an ambitious goal of becoming an innovative country by 2020 (Mu/Ren/Song et al. 2010). The Twelfth FYP for National Economic and Social Development announced an "innovation target" of 3.3 patents per 10,000 people (NPC 2011). But most Chinese enterprises are not fully ready for independent innovation. Most Chinese private industrial firms are small in scale and with relatively low capital intensity and simple technology, and they also have difficulty in getting bank loans. Thus these firms' capacity for technology absorption, adaptation, and creation are often limited. Large and medium-sized *state-owned enterprises* (SOEs), who find it much easier to get bank loans, are the leading performers in

R&D activities, but the innovation efficiency of SOEs is relatively low. Meanwhile, the market ecosystem is not functioning well enough to promote innovation. Underdevelopment of market institutions, such as distortions in pricing, weak enforcement of regulations especially the weak protection of intellectual property rights, and barriers to entry, exit, and fair competition, tends to discourage firms from investing in innovation (Zhang/Zeng/Mako et al. 2009). Weak technological innovation capacities leave most Chinese enterprises in the manufacturing and assembling stage without core technologies, and their competitiveness rests more on price and quantity, thus exacerbating the pressure on resources and the environment.

27.4.4   Underdevelopment of Non-governmental Organizations

Promoting SCP continuously requires a multi-stakeholder approach which involves the government, business and civil society. In China, the government is viewed as the leader in fostering SCP. But relying on the government alone will inevitably lead to high costs and low efficiency, and with the declining public trust in government, such costs will rise rapidly. Meanwhile, an increasing number of environmental pollution events and the rising environmental awareness of residents are continuously calling for more social participation in organized activities related to environmental protection. In this way, *non-governmental organizations* (NGOs) need to and can play a vital role in many fields of SCP, such as engaging civil society, businesses, and the public sector; conducting research to facilitate policy development; building institutional capacity; taking on environmental innovation activities; carrying out environmental education; and helping people live more sustainable lifestyles (Lyuba 2000; Adeel 2003).

There are three types of NGOs operating in China: social organizations, private non-enterprise units, and foundations or branches of international NGOs (Xu/Zhao 2010). Most of the social organizations are top-down NGOs, and are usually product of government reform and in some way affiliated to the government. NGOs of this type are also referred to as government-organized NGOs (GONGOs), and are not considered non-governmental organizations in the real sense of the word (Li 2012). Private non-enterprise units are bottom-up NGOs, and do not have as close a relationship with the government, hence they are normally referred to as grass-roots NGOs (Li 2012). Statistics from the Ministry of Civil Affairs

Table 27.2: Development of three types of NGOs in China. **Source**: Website of the Ministry of Civil Affairs, <www.mca.gov.cn>.

	2006	2007	2008	2009	2010	2011	2012	2013
Social Organizations($\times 10^4$)	19.2	21.2	23	23.9	24.5	25.5	27.1	28.9
Private Non-enterprise Units ($\times 10^4$)	16.1	17.4	18.2	19	19.8	20.4	22.5	25.5
Foundations	1144	1340	1597	1843	2200	2614	3029	3549

show that officially registered NGOs including GON-GOs in China numbered 547,549 (Table 27.2), a relatively small number for China's large population.

These years saw the number of NGOs grow rapidly in China, but several key barriers, widely recognized as hampering the development of NGOs, still exist, including restricted legislative environment, shortage of human resources and funds, lack of public trust and poor management capability (Lu 2007; Ru/Ortolano 2009; Li 2012; Liu 2013; Huang 2014). Registration of NGOs in China is strictly controlled and difficult. Only when an organization finds a related government department as a sponsor and supervisor government body is it eligible to submit an application for registration to the Ministry of Civil Affairs. Many grass-roots NGOs can hardly find a government agency to act as their sponsor/supervisor, as this often means a higher workload and even political trouble for the sponsoring agency (Xu/Zhao 2010). The difficulty of registering NGOs leaves many grass-roots NGOs unregistered, which means they cannot raise funds, and they face potential legal risks. Others register as business entities or use other registration strategies (Lu 2007), which means they cannot enjoy preferential tax policies. Hence the total number of bottom-up or grass-roots NGOs is unknown (Chen 2006). Even though some grass-roots NGOs succeed in registering as social organizations or private non-enterprise units, they still suffer from insufficient and unstable funding problems, and this is a crucial problem for their operation and growth (Li 2012). In China, corporate or personal donations for public welfare must be made through a few qualified NGOs,[7] in order for these donations to receive a pre-tax deduction. This means that most NGOs including grass-roots NGOs as well as some GONGOs find it almost impossible to obtain the qualification and will have difficulty in raising funding. Due to the policy environment and low rates of pay as well as low social

status, NGOs in China, especially grass-roots NGOs, lack sufficient human resources. Few highly skilled professionals are willing to work for NGOs on a full-time basis (Li 2012). For this reason, most NGOs lack skilled workers in the legal, tax and accounting fields and in their respective working fields such as health, education, environment, etc. (Liu 2013). Insufficient funds and human resources also lead to poor management capacity in NGOs. With the majority of grass-roots NGOs unrecognized by the government, their internal governance is often problematic, characterized by irregularity and a lack of transparency (Xu/Zhao 2010). They also have difficulty in establishing and organizing medium- to large-size projects as these projects are largely dependent on government contacts and connections (Hasmath/Hsu 2008). In a social environment where government traditionally manages everything (Liu 2013), public understanding and trust in NGOs and their work is still very low. In addition, NGOs without legal recognition find it difficult to earn trust from society (Ru/Ortolano 2009), while the financial misdeeds and scandals that have been disclosed in some NGOs have left a very damaging influence on the reputation of NGOs in China. The low level of public trust in NGOs also explains why they cannot find enough funding from society.

It is quite encouraging that some restrictions on the development of NGOs are beginning to be lifted as reforms take place. Since 2011, four types of groups, namely industrial associations, science and technology organizations, charities, and organizations providing social services, have been able to register directly in a number of provinces where they do not need to find a government office to supervise their operation. The changes are expected to apply nationwide with the amendment in related laws or regulations (The Economist 2014). On the other hand, the Internet is also changing the situation of NGOs. In recent years, with the help of the Internet, Chinese NGOs have begun to earn public understanding and to rally public support for their activities. They have initiated a large number of nationwide environmentally friendly activities, such as the "clean your plate campaign", which aims at reducing food waste. The

---

7   The Ministry of Finance, the Administration of Taxation and the Ministry of Civil Affairs jointly issue the list of qualified non-government organizations (NGOs). In 2012, only 148 qualified NGOs were on the list.

campaign, initiated by NGOs, was first launched on Weibo (a Chinese version of Facebook) and was soon joined by millions of netizens across China. Based on the network, a strong NGO community is expected to play a more important role in promoting SCP in the future.

27.5   Prospect of Sustainable Production and Consumption in China

As a developing country with a large population and inadequate per capita resources, China is confronted with serious problems in dealing with development and protection. SCP, as a primary measure for implementing sustainable development and integrating development and protection, has been carried out in various areas in China. Since SCP has not been clearly put forward as a strategy in China, SCP is not conducted in a systematic pattern, but features in China's energy-saving and environmental protection-related policies and practices, such as the adjustment of industry structure, the promotion of a circular economy and cleaner production, the promotion of the Energy Conservation and Emission Reduction Project, and progress in green procurement and waste management. With great efforts and inputs, China has made some achievements in SP, especially in improvements to production efficiency. But it seems that the pace of improvements in efficiency is inadequate to offset the rapid increases in consumption (CCICED 2013), with a growing middle class affected by the global wave of consumerism. Actually, SC in China has not received as much attention as SP from the government and the public because of the relatively low proportion of consumption in the GDP expenditure structure. However, China's consumption has grown at a rapid pace, and the imbalance in the expenditure structure is

rather due to an abnormally high contribution of investment to growth. Considering China's rapidly growing middle class and its shift to a consumption-driven economy, SCP should be clearly identified in a Chinese context and put forward as a national strategy in laws and in China's medium- and long-term plans for economic and social development.

An SCP framework should be developed at the national level to provide instructions for the promotion of SCP. As mentioned above, China has already introduced many SCP-related policies and practices. The key problem lies in their effective implementation. Existing SCP-related concepts, practices and policies should be straightened out and integrated into the SCP framework, so as to reduce duplication of effort and minimize conflicts between policies. In addition, some crucial challenges, including the extensive economic growth model, imbalanced development, weak scientific and technological innovation capacities, and underdevelopment of non-government organizations, are recognized as stemming from institutional problems and hinder the effective implementation of SCP-related policies and practices. Thus, China's further reform is expected to lift institutional barriers, including the optimization of fiscal and tax systems, the adjustment of the performance evaluation system, the transition of government functions and the expansion of market and social forces spaces and the construction of the rule of law, so as to promote economic transformation, balanced development, and social equity, and to guarantee the smooth and efficient implementation of SCP policies. Though government will still play an important role in the promotion of SCP, the long-term capacity for SCP lies mainly in the improvement of independent technical innovation in enterprises and extensive social participation in SCP. As well as this, the institutional arrangements need to give full play to the role of markets and civil society.

28   The Eco-restructuring of the Ruhr District as an Example of a Managed Transition

Philipp Schepelmann[1], René Kemp[2] and Uwe Schneidewind[3]

Abstract

The eco-restructuring of the Ruhr area presents a remarkable case of a managed transition, bringing out the importance of regional actors and factors, alongside external stimuli. The evidence in support of the authors' hypothesis of a managed transition in the Ruhr district is: (i) the vision of blue skies above the Ruhr, (ii) the reconstruction of the Emscher river system, (iii) the emerging energy transition. The ongoing transition of the Ruhr district requires further analysis which the authors plan to undertake. The chapter provides a first attempt at offering an evidence-based narrative of a region as a real-world laboratory for ecological modernization.

Keywords: Regional transition management, North Rhine-Westphalia, sustainability, ecological modernization, Emscher, Innovation City Bottrop, energy transition.

28.1   Introduction

This chapter offers an evidence-based narrative of the process of eco-restructuring of the Ruhr district in Germany between 1970 and 2012 in the form of the cleaning up of a polluted district, the creation of an eco-industry and a shift towards renewable energy in an economy dominated by the coal and steel industry.[4] The authors conceptualize this process of restructuring as a managed sustainability transition because of the use of various programmes and parliamentary acts to achieve an ecological modernization. It was not managed on the basis of a single master plan, but was the result of a number of plans together with sustained efforts by numerous institutional and individual actors.

The chapter documents the eco-restructuring of the Ruhr district with special attention to large projects, for which it offers some insights on the drivers behind the change, the motivating visions and the financing element.

The story of eco-restructuring in the polluted area, dominated by heavy industry, of *North Rhine-Westphalia* (NRW) contributes a case of a purposive transition to the literature of sustainability transitions. The story goes beyond an examination of green innovation in niches, and allows us to draw some conclusions about transition management.

The structure of the chapter is as follows. Section 28.2 states the research questions and explains the

Ruhr Area within the state of   Map of the Ruhr District
North Rhine Westphalia

methodological choices of the research on which the chapter is based. Section 28.3 describes the historical setting of the Ruhr district as the industrial heart of Germany and Europe. Section 28.4 discusses the vision of 'blue sky' above the Ruhr and the increase in government activity for the protection of the environment based on the idea of ecological modernization. Section 28.5 zooms in on an important project forming part of the Ruhr transition to a greener economy: the Emscher Landscape Park initiative (a €4.5 billion 'generation project' for converting the dirtiest part of the Ruhr district into a space for recreation, culture, working and living) together with the low carbon Innovation City Ruhr initiative as two high-profile initiatives based on a partnership between the North Rhine-Westphalian state government, city administrations, business and civil society. Section 6 discusses energy transition as a new political project for the Ruhr district, describing the energy transition (*Energiewende*) towards sustainable energy and the innovation city Bottrop as an important energy transition initiative in the Ruhr district. Section 7 examines the institutional element as well as the interrelationships between the three processes: the introduction of environmental laws giving rise to an eco-industry sector, the clean-up and urban revitalization of the Ruhr district and the emerging energy transition. Section 8 focuses on the local and supra-local element in considering the role of national and international policies

vis-à-vis regional policies. Section 9 draws conclusions about what the case of eco-restructuring in North Rhine-Westphalia can teach us about transition management.

28.2   Research Methodology and Analytical Framework

This chapter offers an evidence-based narrative of the ecological modernization of the Ruhr district. The authors used evidence in grey literature and internet sources as the main sources of factual information. The evidence was compiled, sorted and condensed. This process was supported using secondary sources, experts' views and our own pre-analytical views using a relational, multi-scalar perspective. The major parts of the narrative were validated by central regional stakeholders such as the *Emschergenossenschaft/Lippeverband* (EG/LV), *Regionalverband Ruhr* (RVR), *Wirtschaftsförderung Metropole Ruhr* (wmr), and the *Landesamt für Natur, Umwelt und Verbraucherschutz* (LANUV) NRW, as well as representatives of the cities of Bochum and Essen. The information was presented and discussed in a sequence of conferences and workshops with governmental and non-governmental stakeholders of the Ruhr district. Details of the stakeholder meetings (in terms of place and participants) are described in the annexe.

Figure 28.2: View of the city of Gelsenkirchen, to the right the former coal mine, today centre of the Nordstern Parks—view from a former slag heap in the city of Essen. **Source:** Hans-Jürgen Wiese—Own work. Licensed under Creative Commons Attribution-ShareAlike 3.0 via Wikimedia Commons.

The chapter is based on the proposition that the multilayered process of structural change in the Ruhrgebiet can be understood as a 'managed' process of ecological modernization. It is also based on the proposition that the 'blue sky', 'blue water' and 'green energy' projects had different drivers but also are related in ways whose details this paper seeks to uncover by presenting evidence and its framing in a consistent narrative.

Analytically, the chapter uses the concepts of ecological modernization and institutional entrepreneurs to make sense of what happened. Findings are reused to draw conclusions on transition management as an emerging field of research. To the literature on transition management, the chapter contributes a real case of a 'managed' transition. Special attention is given to the regional element but also to how the transition owed a great deal to developments outside the region, exploited by regional actors. Differently from usual, the chapter is not based on a unified analytical framework applied throughout in the study. The reason is that this chapter gives priority to *describing* the ecological modernization process and to investigating a rather diverse set of themes, namely the politics of transition (Kern/Smith 2008; Meadowcroft 2009; Voß/Smith/Grin 2009; Paredis 2013), the role of institutional entrepreneurs (Maguire/Hardy/Lawrence 2004, Coenen/Benneworth/Truffer 2012), the complex issue of heritage of old industries, and the endogenous nature of green business as additional topics. The chapter helps us to assess the prescriptive elements of transition management as formulated by

Rotmans, Loorbach and Kemp, such as the importance of vision and foresight as strategizing tools, special arenas for discussing and determining transition goals and transition initiatives that act as stepping stones for transitional change, and strategic action linking niche developments with regime and landscape developments (Loorbach 2007; Kemp/Loorbach/Rotmans 2007; Rotmans/Loorbach 2010), and also helps us to describe, for an empirical case, how processes of geographically uneven transition pathways are shaped and mediated by institutional actors and structures at different scales (Coenen/Benneworth/Truffer 2012).

28.3   The Ruhr District and its Socio-Economic Transition

The Ruhr district is Germany's largest urban conglomerate in the federal state of North Rhine-Westphalia, comprising 11 cities and 4 districts (Fig. 28.1 Germany, the state of NRW and the Ruhr area). With a population of 5.2 million (2012), a local GDP of €140 billion (2009) (LIT 2013) and a labour force of 1.7 million (2012) (BA 2012), it is one of Europe's largest industrial clusters.

The Ruhr district is named after the river Ruhr that crosses the south of the region from east to west. In Germany the name itself has become synonymous with the production of coal and steel and later with the crisis of heavy industries and structural change.

Figure 28.3: River Emscher in the Ruhr district near Herne and Herten. **Source**: Arnoldius—Own work. Licensed under Creative Commons Attribution-ShareAlike 2.5 via Wikimedia Commons.

What is now an urban agglomeration was two hundred years ago a rural area of small settlements. The development of the region towards an urbanized industrial region began with German industrialization and the rising demand for energy in the nineteenth century. The huge coal deposits of the region led to the establishment of numerous mines and steelworks along the Ruhr. During the nineteenth century the region became the backbone of Germany's coal and steel industry.

The Ruhr industry not only helped Germany to become one of the most industrialized countries but also was the armaments factory in both world wars. After World War II it was the basis for the rapid German economic recovery (*Wirtschaftswunder*). Its population of about 200,000 in the early nineteenth century rose to four million before World War I and to six million in the 1950s. The massive increase in the labour force promoted a rapid increase in the output of coal and steel. Between the 1920s and the 1940s the output of steel in the Ruhr district exceeded

the total steel production in Great Britain. In the 1930s, every sixth ton of steel consumed worldwide was produced in the Ruhr district (Schlieper/Reinecke/Westholt 1986; Kelly/Matos 2010). Production peaked in the 1950s when more than a million people were employed in the coal and steel industry, roughly seventy per cent of the whole labour force of the Ruhr district.

The economic decline of the Ruhr district began in the 1960s when world market prices for coal and steel fell below the production costs of the Ruhr industry. New mines in the US and eastern Europe supplied the markets with cheap coal mined near the surface, while the average mining depth in the Ruhr in 1960 was 650 metres. Demand also began to shift from coal to oil. The result was large-scale closures of factories and mines. Between 1960 and 1990 more than half a million jobs in the Ruhr were lost in the rapidly declining coal and steel industry. During the 1960s, the massive German economic growth compensated for the job losses. Later, the structural

change led to an unemployment rate of fifteen per cent in the region in the 1980s and the massive emigration of its inhabitants (Reicher 2011).

In order to mitigate this development, both the state government and the federal government started to support the mining industry with subsidies. The German coal industry was funded with € 295 billion (at 2008 prices) in total between 1950 and 2008 (Meyer/Eidems 2009). The largest share went to the Ruhr district. Simultaneously, the state started to invest in higher education, establishing five universities and sixteen universities of applied science. As of 2012, there were 223,000 students enrolled in these universities.

The structural change in the Ruhr district's economy coincided with the rise of environmental awareness.

28.4   Blue Sky above the Ruhr

During the federal electoral campaign of 1961, Willy Brandt, the Social Democrat candidate for Chancellor, insisted: "The sky above the Ruhr must turn blue again" (Vierhaus 1994: 86, authors' translation). This idea, which now appears a perfectly reasonable policy goal, was a radical idea at the time, because pollution was viewed as an inescapable element of industrialization. The following historical summary of the rise of environmental awareness in Germany is largely based on Brüggemeier/Scheck/Schepelmann et al. (2012).

When Brandt called for a blue sky above the Ruhr, per year 300,000 tonnes of dust particles were falling from that sky; in some quarters of the Ruhr district it was more than 5 kg per 100 square metres. In 1961 the population of the Ruhr district had to endure 1.5 million tonnes of dust, fly ash and other particles, as well as four million tonnes of sulphur dioxide, in combination with a number of other harmful substances emitted by the booming coal, steel and chemical industry.

Clinical research revealed that children who grew up in the Ruhr district were often smaller, weighed less and suffered more often from rickets than children in other regions in Germany. Their fathers, who often worked in these emitting industries, died more often from cancer. The view that the Ruhr district was a dangerous environment came out of scientific research, and Brandt made reference to it in his speech (Weichelt 1997). Alarming facts also came from the *Siedlungsverband Ruhrkohlebezirk* (SVR), an association of Ruhr municipalities, who said that

the environmental conditions constituted an assault (*Generalangriff*) against the region (Brüggemeier/Rommelspacher 1992: 63). The traditional symbol of progress was smoking chimneys, but this came more and more into question.

Voices had been raised in concern about the high levels of pollution and the health hazards. Protests began in civil society and shifted to politics, where more and more interest was shown in the issue. In December 1955, the NRW parliament held its first debate about air pollution, and in the following year it was put on the agenda of the German federal parliament, the Bundestag. National media began reporting on air pollution. The Christian Democrat state government of NRW reacted, and in 1960 Franz Meyers, the prime minister of North Rhein-Westphalen, spoke of his concerns at the federal congress of the German Christian Democratic party, but met little response (Weichelt 1993; Hünemörder 2004: 89ff.).

In contrast to Franz Meyers in 1960, the public response to Willy Brandt's speech in 1961 was overwhelming. People in the Ruhr district especially were not willing to tolerate the increasing pollution of their environment much longer and called upon regional and national politicians to take action. In 1962 the NRW parliament enacted the first regional emissions act. In 1964 this was complemented by a directive with thresholds for critical substances (Brüggemeier/Rommelspacher 1992: 62f.). The breakthrough was complete when Willy Brandt's administration took office as the German federal government in 1969. His administration initiated an immediate action programme for the protection of the environment (Sofortprogramm für den Umweltschutz) and passed a whole series of pollution control measures. The government also created a number of institutions, including an interdepartmental coordination group and a stakeholder forum, as well as the *Federal Agency for Environmental Protection* (UBA).

The 1970s witnessed a significant rise in environmental awareness among the German population. Within a few years it had moved from being a peripheral theme to the centre of political discourse. Hundreds of thousands of Germans organized themselves into environmental citizens' organizations (Wey 1982; Hünemörder 2004). Even the trade unions discovered the environment as an issue on their political agenda (IG Metall 1972).

While pollution control was the predominant mode of environmental policies during the 1970s and 1980s, attention shifted to pollution prevention through the use of cleaner production processes. In 1984, Willy

Brandt supported the position that it was not only important to react to pollution, but that precautionary approaches would be necessary, including technical innovations and production processes. He mentioned that improved energy and resource efficiency and a more careful use of air, water and soil would not only decrease environmental pressure but also save costs. Such a transition would lead to a modernization of society, improve the competitiveness of German industry, and create jobs. All of this came to be known by the name of ecological modernization, a concept first coined by Martin Jänicke and popularized by Joseph Huber (Mol/Jänicke 2009).[5]

During the late 1970s and 1980s the ecological movement in Germany gained more and more momentum. Alarming ecological trends such as the decrease in biodiversity, acidification of soils and waters, and forest die-back (*Waldsterben*), as well as a series of environmental catastrophes (e.g. Seveso, Sandoz, Chernobyl), added to the growing concern of the German population.

One result was that the dispersed anti-nuclear movement joined forces with established nature conservation organizations under the umbrella of new civil society organizations such as Friends of the Earth Germany (*Bund für Umwelt und Naturschutz Deutschland*, BUND). Environmental civil society organizations increased their membership considerably and became large and influential societal forces. Another was that the surge of the Green Party marked a greening of the German political debate, which came to dominate the general political discourse more and more. This increased the pressure on the mainstream political parties as well as federal and state governments, who reacted with an increased number of new programmes and increased legislative activity.

Under the influence of the greening of the (West) German political landscape, the prime minister of North Rhine-Westphalia, Johannes Rau, adopted the increasingly popular idea of ecological modernization. It became the conceptual background against which the Wuppertal Institute for Climate, Environment and Energy and the Energy Agency NRW were

founded in the early 1990s. After losing their absolute majority among NRW voters, the Social Democrat Johannes Rau led the first red-green coalition in 1995. With this political background, ecological modernization became more and more a part of NRWs economic development policies, yet its integration was uneven across the different economic sectors (Schepelmann 2005, 2010).

Ecological modernization as a political programme supported the transformation of "the largest contributors to problems in the Ruhr district into problem solvers" (Kilper 1996: 15, authors' translation). An important facilitating factor was that the energy, chemical, coal and steel industries had the necessary structures and knowledge to develop solutions for protecting the environment. As early as 1992, the NRW eco-industry produced goods and services with a value of about € 10 billion, about one-third of German production in the sector (Nordhause-Janz/Rehfeld 1995: 67).

According to the economic development agency of the Ruhr district (Wirtschaftsförderung Metropole Ruhr, WMR 2012), 'resource efficiency'[6] has a turnover in the Ruhr district of € 63.3 billion. About 96,000 people were employed in about 5,500 companies, representing 6.7 per cent of all jobs in the Ruhr district. Overall, every tenth German job in this leading market is based here.

At a time when production increases were driving pollution to intolerable levels, the Ruhr district became the cradle of modern environmental policy in Germany. Brandt's vision and his promise of "blue skies over the Ruhr" marked the beginning of a change of consciousness and a change of policy in Germany. Environmental end-of-pipe thinking predominated in the Ruhr district for more than thirty years. Strict environmental legislation was passed, and large investments were made in environmental clean-up technologies. Influenced by the awakening of environmental awareness at the international, national and local level, and spurred on by legislation for environmental improvement primarily at the federal level, the NRW state government invested early in the health of its population and their environment. The Ruhr district became a prime mover on the road towards an

---

5   Over time, the meaning of the term 'ecological modernization' became a topic of discussion among social theorists (Spaargaren/Mol 1992; Hajer 1995; Mol/Sonnefeld 2000), but originally "ecological modernization was essentially a political program. It was neither a theory, nor a concept which included the social dimension of this type of modernization" but simply "a practical and normative idea for pressing for far-reaching environmental reform" (Mol/Jänicke 2009).

6   WMR comprises the following economic activities under the lead market 'Resource Efficiency': energy generation and energy-related services, water and waste management, eco-industries, and raw materials extraction and processing, as well as environment-related activities such as engineering, laboratory, monitoring and consultancy services.

environmental goods and services industry.[7] Today, the economic development agency of the Ruhr district perceives eco-industries as highly dynamic and as a pillar of the regional economy (WMR 2012). This perception has been supported by a number of regional studies and assessments (Nordhause-Janz/Rehfeld 1995; Schepelmann 2005; Rehfeld/Schepelmann 2007).

28.5 Reconstruction of the Emscher Region

The ecological modernization process in the Ruhr district included greener production as well as clean-up activities pursued as part of urban revitalization. It goes beyond our ability to give a complete description of this complex multilevel transformational process. Instead of providing an overview of relevant projects, we opt to describe a high-profile project which has already achieved tangible results: the reconstruction of the Emscher region as an exemplary regional development plan and a flagship of the ecological, economic and urban revitalization of the Ruhr district.

In the 1980s the Emscher landscape had been characterized by vacant factories, closed mines and abandoned docks with mining subsidence, large spoil-heaps of mining residue and dams (Figure 28.2: View of the city of Gelsenkirchen). This devastated landscape was deliberately chosen to stimulate and symbolize change by integrating the industrial heritage in the renewal of the Ruhr district. The aim was an ecological, cultural and economic revitalization of the Ruhr district, as well as to increase the attractiveness of its cultural and recreational facilities; this culminated in the *International Building Exhibition*, IBA (1989–1999).

The structural policies symbolized by the IBA Emscher Park focused not only on economic development, but also on environmental protection, nature conservation and increased cooperation in the planning and administration of the region. There was also a desire to preserve the industrial heritage of the district by choosing to convert buildings and to develop industrial factories into tourist attractions.

The conversion of the Ruhr district was to be based on a series of projects that complemented each other. The projects were organized in seven themes (Brüggemeier/Rommelspacher 1992):

- Reconstruction of the landscape: the Emscher Landscape Park
- Ecological improvement of the Emscher river
- Reconstruction of the Rhine-Herne Canal as an experimental space
- Preservation and new use of industrial heritage
- Working in the Park
- New forms of housing and apartments
- New opportunities for social, cultural and sporting activities.

The IBA and the plans that followed it were funded by several public sources and a number of private ones. In 1988 the state of NRW created the Emscher Park Planning Company with an initial funding of € 18 million. In 1993, five years after the establishment of the IBA Park Planning Company, € 1.3 billion was spent on projects, including € 900 million from public sources—the state, the federal government and the European Union (US EPA 2006). As of 2012, private and public funds for the IBA and its successor plans have far exceeded the initial investment.

The basic idea of the Emscher Landscape Park was to convert the abandoned and industrial landscape into a new, future-oriented and clean environment with an excellent quality of life (Figure 28.3: River Emscher in the Ruhr district near Herne and Herten, Figure 28.4: Wastewater treatment plant Deusen at the river Emscher).

The backbone of the Emscher Landscape Park development consists of seven regional green corridors that cut through the Ruhr district from south to north. Originally, these green belts were defined in the 1920s by an association of Ruhr municipalities, the *Siedlungsverband Ruhrkohlenbezirk* (SVR). The green areas were supposed to limit the uncontrolled growth of the increasingly merging cities of the region in order to protect sites for recreation and leisure.

Within the Emscher Landscape Park these green corridors cover an area of 450 km² and have been used to integrate the brownfields of the coal and steel industry into a new system of parks. In 'a landscape of structural change', twenty cities and two counties have initiated 120 projects that contribute to the Emscher Landscape Park. The projects address ten guiding principles:

- Ecology
- Water and rainwater
- Living and working in the Park
- Art in the Park

---

7 It is a story of necessity as the mother of invention, or as the poet Friedrich Hölderlin wrote in his poem "Patmos", "But where danger is, deliverance also grows".

Figure 28.4: Wastewater treatment plant Deusen at the river Emscher. **Source**: Tbachner—Own work. Licensed under Creative Commons Attribution-ShareAlike 3.0 via Wikimedia Commons.

- Park infrastructure
- Leisure and tourism
- Urban development
- Agriculture and forestry
- Industrial heritage
- Landmarks.

The flagship project of the IBA Emscher Park is the revitalization of the Emscher river system, a river which had been canalized and degraded to an open sewer. Owing to ground subsidence, it was not possible to build and use underground sewage systems in the mining area. The settlements and industries of the Ruhr district discharged all wastewater directly into the river Emscher. The Emscher was considered Germany's most polluted river. The abandoning of mining in the Emscher region in the 1980s permitted all wastewater to be discharged underground and the Emscher and its tributaries to be restored. With investments of €4.5 billion over several decades, the Emscher conversion is one of the biggest infrastructure projects in Europe.[8] In the Ruhr district, the Emscher conversion encouraged several other municipalities to take similar steps in revitalizing waterways in combination with upgrading real estate along the river banks. Historical industrial monuments were given new designations, railway mineral lines were converted into bicycle routes and parks were created.

By giving a new use to abandoned buildings and the creation of parks, the area became a more attractive place to live, work and visit. Techno-cultural highlights such as the Oberhausen Gasometer, the Duisburg-Nord landscape park (Figure 28.5: Heritage of the IBA Emscher Park at night: Furnace No. 5, Figure 28.6: The river Emscher beside the Landscape Park Duisburg), the Duisburg inland port and the UNESCO world heritage site of the Zollverein Coalmine Industrial Complex (Figure 28.7: UNESCO World Heritage Site Zeche Zollverein in Essen) became tourist attractions. The recycling of abandoned land along

8   For more information visit <http://www.eglv.de/wasserportal/emscher-umbau.html>.

with the provision of reliable and sustainable infrastructure attracted enterprises and created new jobs as well as new perspectives. The ecological revitalization of a river catchment area more and more became the economic, social and cultural transformation of a region. Not only was this the express intention of the makers of the Emscher Park, who had already integrated a number of cultural initiatives into the development of the IBA, it was also accompanied by a number of successful cultural activities such as the Ruhr Triennale.

This three-yearly high-end cultural festival for performing arts started in 2002. The festival events take place in formerly industrial venues transformed by the IBA. In 2010 the Ruhr district managed to obtain the status of European Capital of Culture. The former industrial Beast was more and more turning into a formerly industrial Beauty (Schepelmann 2010). An indicator of this remarkable transformation is the number of overnight stays by foreign and domestic visitors to the Ruhr district: this nearly doubled between 1990 and 2011, rising from 3,588,394 overnight stays in 1990 to 7,026,396 in 2012, an increase of 95 per cent (RVR 2013).The Emscher Landscape Park turned out

to be the showcase of a successfully managed transition. Using the Emscher Landscape Park concept, a number of similar plans followed, such as *Konzept Ruhr* (Schwarze-Rodrian/Seltmann 2012) and the *Master Plan Emscher Landschaftspark* 2010. As of December 2012, there were 212 projects that had been realized and 240 more in development (RVR 2013).

28.6   The Emerging Energy Transition

After having discussed the Blue Skies initiative and the Emscher revitalization, we now turn to the third element of eco-restructuring in the Ruhr district: the transformation of the Ruhr district from a centre for fossil industries to a centre for sustainable energy industries. The installed power of renewable energy rose nearly exponentially from 30 MW in 2000 to 588 MW in November 2012 (Amprion 2012). This trend is continuing and is driven by public plans to invest in renewable energy.

The energy transition in the *Ruhrgebiet* (Ruhr district) and NRW is conditioned by the *Energiewende*

Figure 28.6: The river Emscher beside the Landscape Park Duisburg. **Source:** DerHexer—own work. Licensed under Creative Commons Attribution-ShareAlike 3.0 via Wikimedia Commons.

(energy transition), a national project of the German federal government with the following elements: to phase out nuclear power by 2022, to achieve a general increase in energy efficiency, and to increase the share of renewables in the energy mix (Bundesregierung 2010).

The phasing out of nuclear power necessitates extra power capacity and creates room for the use of renewables. It means nothing less than an overhaul of the existing system. During the phasing out of nuclear power plants, on the one hand the security of supply in Germany has to be guaranteed, and on the other the network of transmission lines must be adapted to the needs of decentralized sources of renewable energy. As one of the most important energy clusters in Europe, the Ruhr district is of strategic importance, and this makes it eligible for support by national resources in addition to regional policies. It also benefits from international policies, in particular from EU structural funds, which have been utilized to great effect to fund local projects.

Even when the national energy transition necessitates changes in the Ruhrgebiet and offers economic opportunities, *making* a transition to green energy in the Ruhrgebiet is a difficult issue for the regional government because of the coal industry and the resistance of power utilities, who want to make their own investment decisions. Rather than fighting the resistance, the government of NRW orients itself through its innovation and economic development policies to the opportunities that green power affords. In Germany, regions have their own innovation policies, which are oriented towards economic activities in those regions. In NRW, innovation and regional development policies are organized along the value chains of sixteen areas of competence (VDI 2009). Environmental technologies, Energy RTD and logistics are all clusters in which both business actors and knowledge actors from the Ruhr district play an important role. The fact that in the Ruhr district companies traditionally have considerable competencies in energy is beneficial for obtaining innovation support; it is why companies and research institutes have benefitted so much from regional and national innovation policies and from supporting agencies, including regional development agencies as well as thematic agencies such as the Energy Agency NRW.

Figure 28.7: UNESCO World Heritage Site Zeche Zollverein in Essen. **Source**: Thomas Wolf—own work. Licensed under Creative Commons Attribution-ShareAlike 3.0 via Wikimedia Commons**.**
Research competences in energy are mobilized through the normal science systems and through various innovation policies but especially by *Energiewende in NRW,* an ambitious programme by the NRW state government to shift to low carbon energy and reduce energy use. According to the NRW Ministry for Climate Protection, Environment, Agriculture, Nature Conservation and Consumer Protection, it consists of the following eight measures (MKULNV 2011):

1. The NRW Climate Protection Law: in 2011 the state government established Germany's first Climate Protection Law, which aims at reducing greenhouse gas emissions in NRW by at least 25 per cent by 2020 and by at least 80 per cent by 2050 compared with 1990 levels.
2. The Climate Protection Start Programme: this investment programme will allocate several hundred million euros of loans and grants to support low carbon investments in NRW industry.
3. New Wind Energy Adaption: to stimulate growth, especially in machine and plant engineering, the state government has set a goal of quadrupling the

share of wind energy in the electricity supply by 2020.
4. Cogeneration: according to studies commissioned by the NRW state government, 35 per cent of CO2 emissions and 35 per cent of raw materials can be saved in NRW's power generation through more effective use of co-generation in power plants. The state government has initiated an investment programme, 'Cogeneration', allocating € 250 million over several years.
5. Research: the state encourages research into tapping new sources and locations for renewable energy.
6. Networks and Storage: to strengthen the supply of renewable energy, the state plans to enhance the network of power transition lines by 400 km and to quadruple the capacity of pumped storage power plants.
7. Rhein-Ruhr District Heating: particularly in the densely populated Rhein-Ruhr region, heat sources in existing and planned power stations, as

well as renewable sources of heat and waste heat systems, will be promoted.

8. Resource Efficiency: with the Efficiency and Energy Agencies, the competition 'Ressource.NRW' and an efficiency loan from the public NRW Bank for businesses, the NRW state government intends to promote energy and resource efficiency.

A flagship initiative for the *Energiewende* in NRW is Innovation City Bottrop. In 2010 Bottrop won the Innovation City Ruhr competition for energy efficiency, organized by Initiativkreis Ruhr, a group of private companies. The goal of the Innovation City Ruhr project is to reshape an existing city, with all its industrial facilities, green spaces, and neighbourhoods old and new, along more sustainable lines (Reicher 2011). Sixteen cities participated in the competition which the city of Bottrop won with the blueprint for a low carbon transition process with a substantial element of participation. Interestingly, the fifteen municipalities which took part in the Innovation City competition have now created a network in order to learn from the experiments and solutions developed in Bottrop.

The stated goal of Innovation City Bottrop is to halve CO2 emissions by 2020 in an area of 25 square kilometres and 14,500 buildings (Lechtenbömer/ Fischedick 2012; Reicher 2011). The target area includes several neighbourhoods in the urban south of Bottrop and represents in many ways the rich cultural and social diversity of the Ruhr district. Housing, employment, trade and commerce are intertwined in a small area. By 2020 the city plans an exemplary application of a number of innovations in energy efficiency, decentralized power generation and electric transport.

Unlike other eco-city development schemes such as Masdar City in the United Arab Emirates or Dongtan in China, Bottrop developed its solutions in a bottom-up way, through collaboration between scientific institutions, business, politics and civil society.

The city of Bottrop plans to undertake approximately 100 projects in the following areas:

- Advice and information (e.g. preparation of energy consultancy, information, thermographic imaging of houses)
- City (e.g. greenhouses on roofs, LED street lighting, construction of photovoltaic noise barriers along an autobahn)
- Energy (e.g. a sewage treatment plant as a hybrid power plant, heat recovery from shower water, geothermal and biomass energy from mine water)

- Housing (such as energetic renovation of houses from the 1950s, 60s and 70s, construction of model houses)
- Mobility (charging infrastructure sites, car sharing of electric cars, fuel-cell powered buses)
- Industry and retail work (e.g. implementation of solar energy into production processes, carbon-neutral filling stations and climate-neutral retail).

The measures fall into two categories: measures that municipalities and big organizational actors can take (LED street lightning, hybrid power plants, energy-efficient production processes) and measures which requires different choices by consumers (energy-passive houses, car sharing of electric vehicles). The energy transition thus requires the cooperation of both consumers and business. It also involves important infrastructure issues in the domains of mobility (fast charging points for electric cars) and energy (smart grids, power storage).

28.7 Differences and Interrelationships between the Emscher and Bottrop Showcase Projects

The reconstruction and development of the Emscher river system and Innovation City Bottrop can be interpreted not only as showcase projects but also as real-world experiments ('*realexperiments*'; Groß/Hoffmann-Riem/Krohn 2005) for developing sustainable solutions for local and regional development. They are laboratories for learning about new innovations and forms of cooperation, as well as producing tangible results. For this reason they are of relevance for policy-learning not only for the Ruhr district but also for the state of NRW and for regional policy actors in general. In this section we will compare the different projects.

Both projects relied on positive visions with clearly defined outcomes. IBA Emscher Park promoted the vision of clear water flowing in a natural riverbed for one of the most polluted sewage channels in Europe. Bottrop was based on a vision of halving energy consumption and carbon emissions by increasing the quality of life. Both visions were seen as daring, standing in stark contrast to the negative reality of heavy pollution and unsustainable energy use. Bottrop is a flagship project of energy transition. It should serve as a reference point for what can be achieved through specific innovations, offering lessons about the technol-

ogy, the usefulness of support action, product imperfections and marketing and distribution (cf. Kemp/Schot/Hoogma 1998).

Both Emscher Park and Innovation City Bottrop are projects of for local ecological transformation. Large areas are being transformed (or are to be transformed) into something greener. They are real-world experiments to investigate and show what is possible. Both projects had specific goals and combined a top-down element of guidance with a bottom-up element of reaching goals, like the eco-cities Graz and Freiburg examined in Rohracher and Späth (2013). In terms of the actors as well as the type of projects there are some important differences. The Emscher project draws on an old structure of cooperation between municipalities, through the *Regionalverband Ruhr* (RVR, Ruhr Regional Association), as well as the Emscher Genossenschaft (Emscher Cooperative). The RVR is responsible for regional planning. For almost a century the RVR and its predecessors (SVR and KVR) have been a permanent platform for cooperation between the different Ruhr communities, while the Emscher Genossenschaft is a cooperative of municipalities for managing water treatment (founded in 1899).

In contrast, Innovation City Bottrop was initiated to large extent by Initiativkreis Ruhr (Ruhr Initiative Group). Initiativkreis Ruhr is an association of sixty-eight companies with a total turnover of € 630 billion and 2.25 million employees worldwide. Established in 1989, it pursues the vision of developing the Ruhr as a strong and attractive location for business. One of the initiatives of Initiativkreis Ruhr is the Zukunft Ruhr 2030 (Future Ruhr 2030) strategy. The strategy is meant to be a regional development plan with a business perspective (Osterhoff 2007).

Even though Initiativkreis Ruhrgebiet represents traditionally important actors in the Ruhr district, the institution as such is a 'new kid on the block'. Ralf Schüle, the deputy director of the Wuppertal Institute's research group for energy, transport and climate policy, observes that the cooperation model of Innovation City Ruhr represents an alternative approach to the traditional formal and informal institutions and networks. By representing primarily corporate decision-makers, it is to some extent a counter-model against established governance structures.

Transition projects must be financed, as no physical area can be converted without spending a substantial sum of money. Where did the finance come from? In the Emscher Park, financing came from various sources: the municipalities, business actors and the state of NRW. Interestingly, the most important

source of funding for the North Rhine-Westphalian structural policies are the EU structural funds. During the period from 2007 to 2013, NRW obtained € 1.3 billion for local development projects in the region. The state government and private donors provided another € 1.2 billion, making a total of € 2.5 billion that will be spent in three priority areas:

- Priority 1: strengthening the entrepreneurial base—€ 500 million
- Priority 2: innovation and the knowledge-based economy—€ 1.25 billion
- Priority 3: sustainable urban and regional development—€ 750 million.

The funding activities of the North Rhine-Westphalian energy policies are bundled in the "progress" programme. This offers a wide range of instruments to promote the efficient use of energy and the use of renewable energies in NRW, including solar heating systems, ventilation systems, district heating, combined heat and power generation, biomass facilities, and passive houses. Since 1987, the progress programme and its predecessor the REN programme have funded several thousand projects with a funding volume of more than € 500 million.

For Bottrop we do not have reliable information about money being spent. The overall costs are estimated at € 2.8 billion, of which € 2.3 billion is to come from private partners, € 454 million from the EU and the federal and state governments, and € 42 million from the city of Bottrop itself (Drescher 2012). An important difference between the Emscher and Bottrop cases is the scale of transformation. During the Emscher transformation it was possible to successfully address different levels of infrastructure transformation (Wuppertal Institut 2013):

1. Ecological revitalization
2. Creation of new spaces for broad participation
3. Improvement of the quality of life
4. Increasing the economic value of the location
5. A new image for the location.

The Emscher transformation mainly addressed the transformation of public infrastructure (the Emscher river, parks, monuments, sewage systems etc.). It was generally welcomed by the public, because it mainly affected public infrastructure. In contrast, the low carbon transformation of Bottrop will affect not only public infrastructure, but necessitates the active involvement of private actors and the spending of € 2.5 billion by those actors. Private actors are known for spending money for private matters (fitting in with

consumer needs and business profits), not for public matters. Public authorities will spend money for public matters. The dependence on private parties (consumers and companies) puts a constraint on Bottrop. Without private parties willing to spend money on energy conservation projects and low carbon energy systems, Bottrop will not succeed. We should also not expect products requiring lifestyle changes to diffuse quickly.

Energy transition also requires spending from public and private actors. According to the former president of the Wuppertal Institute, Peter Hennicke, support for the *Energiewende* from the traditional energy sector is only marginal. More than forty per cent of the money is from private consumers (civil society) who are investing in renewable energy with the help of government subsidies. Investments by the 'Fat Four' energy utilities (E-ON,[9] RWE, ENBW, Vattenfall) in green power generation amounts to just seven per cent.

In the case of energy, it has proved more difficult to enrol industry. Dieter Rehfeld, head of the research department for Innovation, Space & Culture at the Institute for Work and Technology, observes a general lack of integrated approaches in energy policy, with the explicit management of conflicting objectives in the political discourse.

28.8   Regional and Supraregional Elements

In the transition literature, spatial issues are very much neglected: "Space is only indirectly and implicitly addressed. Both socio-technical regimes and *full term* TIS [technological innovation systems] are implicitly understood as footloose cognitive and institutional structures that influence the activities of different actors largely irrespective of their geographical location" (Truffer/Coenen, 2012, p. 6). In the regional development literature, related variety, differentiated knowledge bases and policy platforms (based on relational and collective types of policy arrangements) are considered key aspects behind the creation of new clusters of innovation (Asheim/Boschma/Cooke

2012). More recently, the concept of institutional entrepreneurship has emerged as an important factor (Coenen/Benneworth/Truffer, 2012). Institutional entrepreneurship refers to 'activities of actors who have an interest in particular institutional arrangements and who leverage resources to create new institutions or to transform existing ones' (Maguire/Hardy/Lawrence 2004, cited in Coenen/Benneworth/Truffer 2012).

The Ruhr transition to a green economy is an interesting case of a managed transition in a geographical area. In this section we will examine more deeply the regional dimension as well as its interaction with national and international factors.

In our discussion of energy policies in NRW, we offered details about the innovation and development policies and specific agencies. The regional policies are important, but according to Johannes Venjacob of the Wuppertal Institute, the *Energiewende* in NRW and Ruhrgebiet is to a large extent determined by national decision-making—the phasing out of nuclear power and the shift to renewables. The national *Energiewende* is a conditioning factor in NRW, which traditionally specialized in energy generation but which is governed by a coalition of Social Democrats and Greens who pursue policy objectives highly compatible with the objectives of the national *Energiewende*.

The NRW state government had played a fruitful role in moderating and financing the activities of the many regional and municipal actors. Nevertheless, support was uneven. This was due to changing priorities, especially under Wolfgang Clement, NRW prime minister from 1998 to 2002, who later publicly turned against the central objectives of the *Energiewende* and left the Social Democratic party in 2008. Ambiguous political leadership and insufficient policy integration among the different NRW ministries got in the way but could not stop the momentum of the transition.

In NRW and particularly in the Ruhr district, regional actors have long collaborated with each other to create green business and to convert an obsolete old industrial landscape into a place for recreation, living and tourism. These changes have been largely led by regional actors who managed to get federal and EU support for their projects.

Institutional entrepreneurship in NRW appears to be a driving factor. The Siedlungsverband Ruhrkohlebezirk and its successor the *Regionalverband Ruhr* (RVR) played an important role in setting the agenda and in implementing and monitoring environmental protection. Other institutional entrepreneurs like IBA

---

9   While this article is going to press, the realities of the energy sector in NRW are in transition. As of December 2014 one of the largest German electricity providers, E-ON, will split into two companies. The larger one will be dedicated to seizing opportunities on the decentralized renewable energy path, while the other will remain on E-ON's traditional fossil and nuclear trajectory.

Emscher Park and the Emscher Genossenschaft (Emscher cooperative) seem to have given the implementation of the transformation a lasting momentum.

In the energy transition, the Ruhr Initiative Group can be viewed as an institutional entrepreneur in drawing attention to the green energy innovation, and in attempting to position the Ruhr district as a competitive centre for industry, commerce, research and services. Among the flagship initiatives of the group are Innovation City Bottrop, EffizienzCluster LogistikRuhr (cluster for regional companies in the logistic sector), the RUHR.2010 presentation of the Ruhr as a European Capital of Culture in 2010, and the Ruhr International School.

Individuals played an important role. Examples of key individuals are SVR's director Sturm Kegel and Willy Brandt, who both managed to put the issue of protecting the human environment on the agenda by highlighting the risk to public health. The seeds of the Ruhr transition were thus sown by a concerned regional decision-maker and a charismatic political leader who was able to translate this concern into a positive, concrete vision of a blue sky over the Ruhr. Another influential individual is the Director of IBA Emscher Park, Karl Ganser. He was not only able to forcefully articulate the vision of a reconstructed Emscher landscape but was also influential in coordinating the financing and implementation projects that provided integrated protection for the cultural and natural heritage of the Ruhr district along the Emscher catchment.

An interesting aspect of the Ruhr transition is that the coal regime plays a certain role as a facilitator. Some low carbon innovations in the region are based on the legacy of the coal mining industry:

- The burning of *coal mine methane* (CMM) from abandoned mines. CMM has a *global warming potential* (GWP) 23 times higher than CO_2. Burning CMM thus helps to reduce greenhouse gas emissions compared to not burning it. The burning is done in co-generation plants. In 1997 the first co-generation plant converted CMM into electricity and heat. In 2012, 148 MW of electricity were produced with CMM co-generation units (Amprion 2012).
- The use of geothermal heat of mine leachate. At many mine sites, leachate has to be pumped out regularly. In Bochum the geothermal heat of mine leachate is used to provide heat for public buildings.
- Hydroelectric storage in abandoned mines. By 2018, Prosper-Haniel in Bottrop, the Ruhr dis-

trict's last working mine, will be decommissioned. Researchers at the Universities of Duisburg-Essen and Bochum have developed plans to use abandoned mines after 2018 as pumped-storage hydroelectric power stations with underground reservoirs. These power plants will serve two purposes. On the one hand, they serve for load balancing the supply of renewable energy. On the other, the geothermal energy of the water, which is heated up to 40 degrees, will be used for district heating.

Clearly, the coal industry is *not* the driving force behind most green energy and energy-saving projects, but in some ways the mining heritage allows for the creation of green energy which is not resisted by the coal and mining actors. Two important drivers behind innovation in green energy are the strong competence in energy research, and *Energiewende* NRW. In total, more than 750 scientists in several research institutes and 250 companies in the Ruhr district work on energy supply, power control and power plant construction.[10] A prominent example of the Ruhr's energy competence is the ef.Ruhr[11] (Energieforschung Ruhr GmbH), which is Germany's largest association of research chairs in the field of energy. More than forty professors from the universities of Bochum, Dortmund and Duisburg-Essen cover the entire spectrum of energy technology. They cooperate closely with global business players of the region such as E.ON, RWE and Evonik. Focal areas of ef.Ruhr are research into reducing CO_2 emissions in power generation, CO_2 transport and storage, in particular *Carbon Capture and Storage* (CCS), and solutions for upgrading coal plants with CO_2 capture. The solutions developed include a mobile plant for CO_2 capture from flue gases, which won the "Hightech.NRW" contest in 2008.

Finally, this section turns to the interlinkages between the green business and nature conservation project, the ecological reconstruction project, and the green energy transition project in the Ruhr district and NRW. Each of the projects started at a different time and had different aims. There is no simple causality from "blue sky" to "blue water" to "green energy". They are all part of the ecological modernization process, often coupled with the belief that dealing with ecological problems creates economic opportunities.

An important background factor was that local authorities were responding to problems of pollution, depopulation and the loss of jobs in coal mining and steel. A strong environmental movement and national policies were another. Important policy decisions were taken up by parliament. Flagship projects and investments in education and research also helped to make the transition from dirty industry to a green industry in a greener landscape. The way in which the different transitions are related to or even build on each other is a topic for deeper analysis and will be discussed in further workshops with experts and stakeholders.

28.9   The Lessons for Transition Management

The Ruhr district has been in transition for four decades, ever since the decline of the coal and steel industries was associated with major job losses. The area has been revitalized thanks to investment in the clean-up and projects such as the Emscher Landscape Park. The analysis of the economic development agency for the Ruhr district WMR established that the region obtained economic strengths in resource efficiency and sustainable consumption, as lead markets.[12] In the Ruhr district, the lead market Resource Efficiency constitutes 6.2 per cent of the regional economy, which is considerably above the share for Germany (3.6 per cent) and the state of NRW (3.9 per cent) (see section 4). The strong energy sector is well placed to take advantage of the growth potential for renewable energy and energy efficiency created by the national and regional *Energiewende* goals and programmes. None of the transitions is finished: the share of coal is still higher than the share of renewable and cities are becoming depopulated. The Ruhrgebiet has 600,000 fewer inhabitants than in 1960. The city of Essen now has 140,000 fewer inhabitants (LIT NRW 2013).

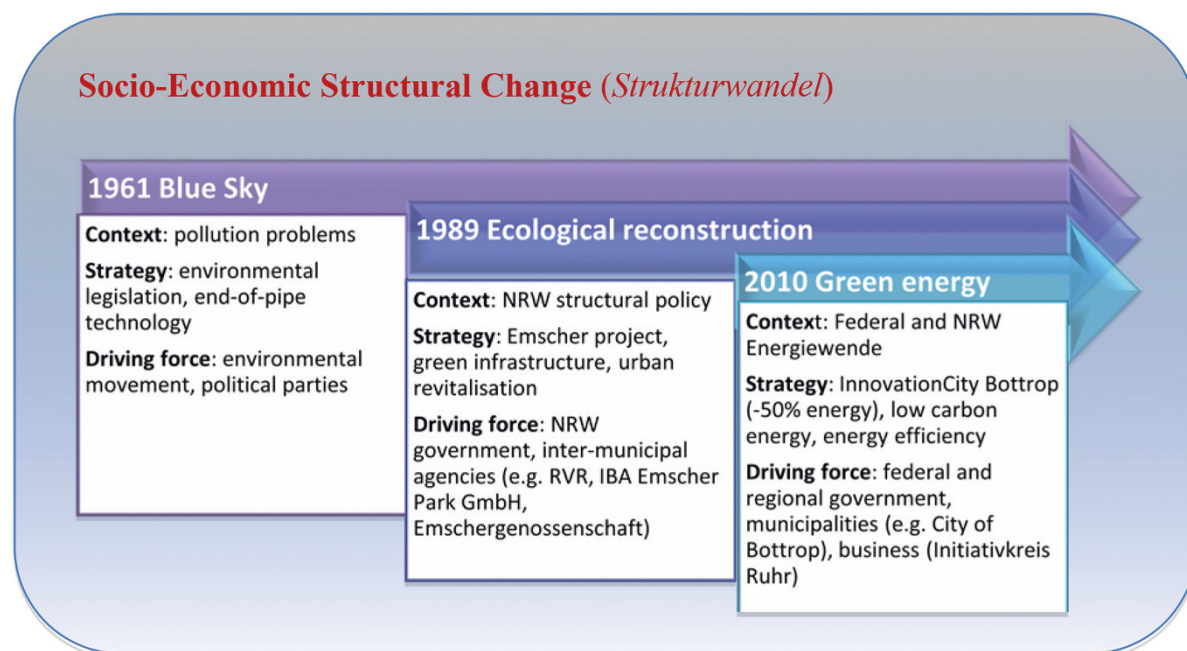
It is interesting to investigate the Ruhr transition processes from the point of view of transition man-

agement. Many of the elements of models of transition management as developed by Rotmans, Loorbach and Kemp (Rotmans/Loorback 2010; Loorbach 2007; Kemp/Loorbach/Rotmans 2007; Rotmans/Loorbach 2010), are being confirmed by the eco-restructuring of the Ruhr district: the importance of an inspiring and concrete vision shared by most actors, platforms for strategic thinking, special innovation projects acting as stepping stones for transition processes, and special transition institutions. Different agendas are being aligned by institutional entrepreneurs: improving air quality for health reasons, environmental amenities, preserving industrial heritage, improving the quality of places, keeping labour in the Ruhrgebiet and stopping depopulation. The Ruhr case also underlines the importance of transition showcases that speak to the imagination of people. It confirms what has been said about real-world experiments: that they help to "build a constituency behind a product—of firms, researchers, public authorities—whose semi-coordinated actions are necessary to bring about a substantial shift in interconnected technologies and practices" (Kemp/Schot/Hoogma 1998: 186). Methodologically, it is difficult to ascertain the precise role of specific projects in the overall transition. Flagships like IBA Emscher or Innovation City Bottrop are necessary but certainly not sufficient. Like Paredis (2013), we found that a lot of contingency is involved in individual cases and that success was not guaranteed.

We consider the proximity of cooperative actors in the state of NRW as a major reason for the success of the eco-transition. While national ministries are known to fight over competing policy choices with little regard for policy coherence, regional actors and city governments are more cooperative and more oriented towards achieving results on the ground. Despite setbacks and conflicts, there has been a long period of cooperation in the Ruhr. Unlike what is predicted by transition theory, the old regime of coal mining and heavy industry played a facilitating role: technical knowledge about pollution and waste helped to establish environmental technology businesses in the NRW area, abandoned quarries were used for storage for renewables, and more than in other states power companies in NRW can take advantage of the regional energy cluster to promote green power. A decisive factor (unique in Europe, but similar to China) is that in Germany, state authorities are responsible for innovation policy, much more than national authorities, leading to and fostering regional specialization.

---

12 A lead market is a regional market that is the first to adopt a global innovation design, thanks to a demand advantage, a price advantage, an export advantage, a transfer advantage and/or a market structure advantage (according to Beise at <http://www.rieb.kobe-u.ac.jp/academic/ra/dp/English/dp141.pdf>). In NRW and Germany, Resource Efficiency and Sustainable Consumption have obtained the official status of 'lead market'.

Figure 28.8: Main phases and elements of NRW sustainability transition. **Source**: The authors.


The ecological restructuring of the landscape in the Ruhr district and the energy transition to sustainable energy use project in NRW have top-down as well as a bottom-up elements. The top-down elements consists of a clear sense of direction and making available money for transition projects. Interestingly, the largest funder of the ecological restructuring projects is the European Commission through its structural funds.

The Ruhr transition consisted of a three waves of change, which in some ways build on each other (figure 28.8: Main phases and elements of NRW sustainability transition):

1. The greening of dirty industries through pollution control and policies for nature conservation, which helped to establish an eco-industry (1961–1990)
2. The ecological reconstruction, clean-up and urban revitalization of the Ruhr district (1989–2015)
3. The sustainable energy transition (2010 onwards).

Interestingly, the transition frame served as a frame even when the word transition was not used. The overarching transition is the socio-economic *Strukturwandel* (structural change) due to the decline of heavy industries. This coincided with growing environmental awareness by citizens and politicians, which was followed by the implementation of environmental protection. The phase of agenda-setting and the introduction of pollution control and nature conservation was marked in 1961 with Willy Brandt's promise of a blue sky above the Ruhr.

This phase was followed by a (partly overlapping) phase of ecological reconstruction, clean-up and urban revitalization of the Ruhr district, which became manifest by the start of the IBA Emscher Park in 1989.

In 2010 a third transition process began: the transition to sustainable energy. The sustainable energy transition is supported by NRW and national energy transition programmes, as well as regional innovation policies, of which the Innovation City Ruhr contest is an example.

The Ruhr district transformed against the background of wider economic and political developments. Relevant developments for the low carbon energy transition are the prices of fossil fuels, the European Emission Trading system for carbon allowances (of which prices are temporarily low), and German obligations under the UN Framework Convention on Climate Change (UNFCCC).

The eco-restructuring of the Ruhr district presents a remarkable case of a managed transition, bringing out the importance of regional actors and regional factors alongside external stimuli. The Ruhr transition was embedded in a discourse of ecological modernization, which translated into political action and matured into a societal transition. The idea of ecological modernization later became a concept in social theory. The politics of the (sociotechnical) processes and the role of institutions and actors require deeper analysis; it proved difficult to uncover these. Further

comparative analysis is needed to determine to which extent there is a unique German element in the Ruhr transition. Our chapter is simply a first attempt to tell the story of the Ruhr transition.

Annexe 28.1: Overview of Meetings with Stakeholders Involved in the Review of Information about the Ruhr Transition

This chapter is based on interaction with major stakeholders of the Ruhr district, as well as the review of various internet sources. The information was compiled in cooperation with central regional stakeholders such as the *Emschergenossenschaft/Lippeverband* (EG/LV), *Regionalverband Ruhr* (RVR), *Wirtschaftsförderung Ruhr* (wmr), and the *Landesamt für Natur, Umwelt und Verbraucherschutz* (LANUV) NRW, as well as representatives of the cities of Bochum, Dortmund and Essen. The information was presented and discussed in a sequence of conferences and workshops with governmental and non-governmental

stakeholders of the Ruhr district, involving the following individuals:

- 4.6.2012 at the Wuppertal Institute: Participants: Dr. Wolfgang Beckröge (RVR), Mrs Trenk (RVR), Mrs Herzberg (City of Bochum), Mr Mühlenkamp (City of Essen), Mrs Siepmann (City of Essen).
- 14.6.2012 at the RVR Essen: Participants: Dr. Beckröge (RVR), Mrs Trenk (RVR), Mrs Snowdon (RVR), Mr Fölster (City of Essen), Mr Hartwig (City of Bochum), Mr Herzberg (City of Bochum), Mr Hönig (City of Dortmund), Mr Mühlenkamp (City of Essen), Mrs Siepmann (City of Essen).
- 25.7.2012 at the RVR Essen: Participants: Prof. Dr. Finke, Mr Gendries (RWW), Mrs Heinemann (City of Bottrop), Mr Höing (City of Dortmund), Mr Jäger (wmr), Mrs Mann (RVR), Mr Mühlenkamp (City of Essen), Prof. Dr. Oldengott (EG/LV), Dr. Reuter (Landesarbeitsgemeinschaft Agenda 21 NRW), Mrs Semrau (EG/LV), Mrs Snowdon (RVR), Dr. Sommerhäuser (EG/LV), Mrs Raskob (Councillor City of Essen).

29 Transition towards Sustainable Urbanization in Asia and Africa

Belinda Yuen[1] and Asfaw Kumssa[2]

Abstract

Africa and Asia are two of the world's least urbanized regions. But they are fast urbanizing; eighty per cent of the world's projected urban growth to 2050 is expected to take place in Africa and Asia. Even though cities in Africa and Asia are increasingly recognized as engines of growth, they are sites of extremely high population densities, congestion, informal housing and concomitant expansion of slums and squatter settlements, infrastructure shortages and environmental degradation. As rapid urbanization continues, how Africa and Asia manage the urban transition will not just affect urban economic efficiency but will also define their greenhouse gas footprint. This chapter compares the urbanization of both regions and discusses the challenges and opportunities for transition towards sustainable urbanization.[3]

Keywords: Africa, Asia, urban transition, green growth, sustainable urbanization.

29.1   Introduction

Africa and Asia are among the world's least urbanized regions. But urbanization is occurring at an unprecedented pace; eighty per cent of the world's urban population growth to 2050 is projected to occur in Africa and Asia. The growth of their rural populations is projected to turn negative by 2018 (United Nations 2013a).

The two regions share several common trends in urbanization. The scale and rate of urbanization is unparalleled in terms of urban population size and urban extent. Cities are growing, both large and small. The key factors behind urban growth are several and include internal (rural–urban) and international migration, natural increase and reclassification of urban boundaries (from rural to urban). Even though cities are increasingly recognized as engines of growth, they are sites of extremely high population densities, congestion, informal housing and inadequate basic services such as water supply, sanitation and solid waste management. Many cities are bursting at the seams and do not have the necessary institutions, policies and investments to enable housing and infrastructure service development. Ultimately, human well-being, especially the urban poor's, will suffer.

Despite similarities, there are differences in the two regions' urbanization. The nature of urbanization seems to differ. While Asian urbanization is often associated with economic growth and has led to rising incomes and a lowering of poverty in Asian cities, Africa's urbanization has sometimes been said to occur without growth (Fay/Opal 2000; Yeung 2011). This pattern of 'urbanization without growth' is the result of inappropriate policies that could not cater for properly managed and planned urban development. In developed countries urbanization took root during the industrial revolution, at a time when there was 'redundant' labour in the rural areas and an increase in demand for labour in urban areas. The same cannot be said about the process of urbanization in Africa. This is mainly because African urban economies (weakened by institutional problems such as extreme centralization, misguided policies, rampant corruption and external factors such as unfair global trade practices) have failed to absorb the growing urban populations.

3   The views expressed herein are those of the authors and do not necessarily reflect the views of the United Nations.

This chapter will compare the two regions' urbanization and discuss the consequences and opportunities for transition towards sustainable urbanization. As rapid urbanization continues, how Africa and Asia manage the urban transition will affect not just urban economic efficiency but also their greenhouse gas footprint.

International evidence points to a strong connection between urban growth and increased energy use for a given unit of economic growth (Kamal-Chaoui/Grazi/Joo et al. 2011). Others have argued that greenhouse gas emissions and energy efficiency are directly and permanently influenced by urban form and density (The World Bank 2010; Suzuki/Cervero/Iuchi 2013). In other words, urban planning, city design and infrastructure investment choices can have a substantial impact on energy demand and emission trends. Recent evidence suggests a clear correlation between investments in energy-efficient infrastructure and economic growth (Ostojic/Bose/Krambeck et al. 2013). Against the upcoming inevitable doubling of urban population in Africa and Asia, it is imperative that cities take full advantage of the potential benefits of sustainable use of urban space. Any failure to transition to sustainable urbanization can but represent a major opportunity lost.

The remainder of this chapter is organized as follows. Section 29.2 offers a brief overview of the urbanization patterns of the two regions under discussion—Africa and Asia, focusing on distinctive characteristics and trends and comparing areas of commonalities and differences. This is followed by a rapid review of their key challenges and the implications for sustainable urbanization (section 29.3). Section 29.4 considers the opportunities for green growth, illustrated by Asian examples, and section 29.5 concludes with lessons and policy implications for sustainable urbanization.

29.2   Urbanization Patterns

Africa and Asia share many similarities. They are the world's two largest regions. Asia, covering 30 per cent of the world's land area (58 countries) and 61 per cent of its population, is the world's largest region (United Nations Economic and Social Commission for Asia and the Pacific 2013). Two countries—China and India—contribute about 60 per cent of Asia's population. Africa is the world's second largest region (55 countries), occupying 20 per cent of the world's land area and about 15 per cent of its population. Africa and Asia's populations are projected to continue to

grow. By 2100, Asia is expected to be 2.2 times as populous as Africa (United Nations 2004). Given their vast geographical expanse, Africa and Asia contain diverse cultures, economy, environment and institutions.

In terms of demography, as Zlotnik discusses elsewhere in this volume, Africa is a comparatively 'young' continent with high fertility rates. The average age of its population is 18 years; 40 per cent of Africans are aged 14 years or less and 34 per cent aged between 25 and 59 (World Review n.d.). However, by 2030, it is projected that many African countries will have a growing ageing population. The proportion of Africans who live to age 65 is anticipated to increase from 3.2 per cent in 2010 to 4.5 per cent in 2030. Several middle-income African countries such as Mauritius, Tunisia, Morocco, Algeria, Egypt and South Africa are projected to have 4.5–7.3 per cent of their population aged 65 or older (AfDB 2012a). Understanding this population structure and the changing demographic trends is crucial for urban futures.

Like Africa, Asian population is relatively young (median age in Asia is 30). But population ageing is occurring rapidly (more rapidly than it has in Western countries) and at a much earlier stage of economic development. The proportion of Asian people under age 15 is projected to decline while the number of people aged 65 and over is expected to increase by 314 per cent from 207 million in 2000 to 857 million by 2050 (United Nations 2001). Japan has the most rapidly ageing population in Asia and the world; 36 per cent of its population will be 65 or older by 2050 and median age will rise from 45 in 2010 to 53 in 2050 (United Nations 2013b). India has the youngest population in terms of size (704 million people aged below 30 with a median age of 25.4 in 2011) while Lao People's Democratic Republic is the youngest Asian country in terms of median age (median age of 20).

Africa and Asia are among the world's poorest and least urbanized regions. Asia has the largest number of the world's poor (63 per cent). Estimates indicate that some 750 million people in Asia are living on less than US$1.25 a day, 57 per cent in urban areas (Wan/Sebastian 2011). Many of the urban poor do not have proper housing and access to basic services—one-third have no access to safe water, two-thirds do not have access to adequate sanitation, more than half live in slums. In 2010, Africa was the world's least urbanized region with 40 per cent (414 million) of its population living in urban areas while 42.2 per cent (1.76 billion) of Asia's population lived in urban areas (United

Nations 2013a). However, in the coming few decades, it is anticipated that this settlement pattern will change.

29.2.1 Rapid Urbanization Anticipated

Both Africa and Asia are urbanizing rapidly. From 1990 to 2010, Asia's urban population increased from 31.5 per cent to 42.2 per cent (over 754 million people), registering the highest percentage increase among all regions in the world. No other region has experienced such an increase in absolute numbers in such a short time. Every day, an estimated 120,000 people are added to Asian cities (Roberts/Kanaley 2006). Asia's urban population is projected to increase to 63 per cent between 2010 and 2050. Many of the new urban residents are expected to be poor people.

As summarized in table 29.1, Africa and Asia will have the highest urbanization rates in the world in the coming decades. Their urban populations are projected to double between 2000 and 2030. By 2050, about 58 per cent of Africa's population will live in urban areas (United Nations 2012). Africa's urban population will increase from 414 million to over 1.2 billion by 2050 while Asia's urban population will grow from 1.8 billion to 3.3 billion. The largest increases in urban population are expected to take place in China and India in Asia, and in Nigeria in Africa. Between 2014 and 2050, China, India and Nigeria are expected to add 292 million, 404 million and 212 million urban dwellers respectively (United Nations 2014).

The urban expansion has not been uniform but varies substantially across countries and over time. There is a diversity of urbanization patterns. What this means is that there is no single urban transition.

Africa's urban populations are unevenly distributed over the continent's subregions. North Africa is the most urbanized subregion (53.5 per cent), followed by Southern Africa (47.1 per cent) and West Africa (44.1 per cent). East Africa is the least urbanized (24.6 per cent), but the most rapidly urbanizing region of Africa (UN-HABITAT 2008). The process of urbanization in Africa is usually highly influenced by the movement of people displaced by drought, famine, ethnic conflicts, civil strife and war. Acute levels of urban poverty and crime and haphazard urban settlements are common characteristics of urbanization in Africa. The poor live in poor neighbourhoods where they face dire economic and social hardships. Most are uneducated and unskilled workers who have migrated to urban areas, encouraged by the push-and-pull factors associated with rural–urban migration.

Urban centres play a pivotal role in the production of goods and services; they are centres of employment, technology and innovations. Urban areas account for about 55 per cent of Africa's GDP (UN-HABITAT 2008). The common contention is that with urban growth, there is an increase in the use of technology, especially mobile phones, flight connectivity, internet connectivity and a general improvement in information and communication technologies in Africa (Obeng-Odoom 2011). At the same time, others have argued that urbanization in Africa has deviated from an ideal development trajectory, continuing even in periods of negative growth, which the World Bank called 'urbanization without growth' (Fay/Opal 2000; Barrios/Bertinelli/Strobl 2006). Their evidence suggests that 'urbanization without growth' is caused by distorted location policies, misguided policies to stop rural–urban migration, inadequate planning, and corruption, among other factors, all of which have combined to make it difficult for African cities to properly address the ever-increasing population pressure, plan urban infrastructure and develop-

ment, and grow urban economies to become engines of growth or pivotal centres of industrialization.

Another interesting phenomenon often associated with urbanization in Africa is that a large number of the growing urban population is absorbed by the intermediate and smaller cities of 500,000 inhabitants, and not by larger cities (UN-HABITAT 2008). But smaller cities often have fewer human, financial and technical resources at their disposal to deal with urbanization (United Nations Population Fund 2007).

In Asia, the Pacific subregion, comprising Australia, New Zealand and Pacific Islands, is the most urbanized subregion (70.2 per cent) followed by North and Central Asia (63.9 per cent), East and North-east Asia (50 per cent), South-east Asia (41.8 per cent) and South and South-west Asia (33.3 per cent) (UN-HABITAT 2010a). There are variations within subregions. For instance, Singapore in South-east Asia is 100 per cent urbanized while Kyrgyzstan, Turkmenistan and Uzbekistan in North and Central Asia have less than 50 per cent of their populations living in cities and towns.

For Asia's two major countries, China's urban population has increased from 27 per cent in 1990 to 36 per cent in 2000 and 51 per cent in 2012 and is projected to reach 70 per cent (1 billion) by 2030. About 80 per cent of this increase can be traced to rural–urban migration and urban area reclassification while the remaining 20 per cent is by natural increase. This urbanization trend is reflected in India though about 60 per cent of urban growth is due to natural increase and less than 20 per cent to rural–urban migration. Even at a relatively low level of 31 per cent urbanization, India's urban population is the second largest in the world. Its urban population is projected to increase from 377 million in 2011 to 600 million (40 per cent) by 2030, an increase of over 200 million in 20 years. On current trends, by 2050, it is projected that India's urban population will constitute nearly 50 per cent of its total population.

The trend points to Asia heading towards a dispersed urbanization pattern with more pronounced expansion in small and medium-sized cities. The majority (60 per cent) of Asia's urban population lives in small (49 per cent) and medium-sized (11 per cent) towns with a population of less than 1 million (UN-HABITAT 2010a). These cities, together with metropolitan cities (with populations of 1–10 million, 29 per cent) and megacities (with over 10 million people, 11 per cent), will drive future urban growth in Asia. Asian cities are increasing in number and size, with many doubling their population every 15–20 years. Estimates

indicate that Bangkok's population has risen from 1 to 8 million within 45 years while other Asian cities increased their population by this amount in half that time—Dhaka 37 years and Seoul 25 years—as compared to 130 years in the case of London (UN-HABITAT 2004).

29.2.2   Growing Cities

The number of large cities, including megacities, with disproportionate urban primacy is growing. Currently, there are two megacities in Africa—Lagos and Cairo, with about 11 million inhabitants each—while Asia has thirteen megacities, half of the world's twenty-five megacities (United Nations 2012). The world's seven largest megacities are in Asia with Tokyo being the largest, followed by Delhi with 23 million inhabitants. The number of Chinese cities with more than 1 million people (million-plus cities) is expected to increase from about 90 to 221, including six megacities, by 2030, while the number of million-plus cities in India is projected to increase to 68 over the same period, of which six will be megacities.

Despite various efforts to restrict the growth of megacities (such as green belt and transmigration schemes), the exurban areas around megacities have continued to grow, engulfing small towns and other settlements on the urban periphery and forming sprawling mega-urban regions. Examples include the Pearl River Delta Region, China, with an estimated 150 million people, and the Jakarta-Bogor-Tangerang-Bekasi Region (Jabodetabek), Indonesia with an estimated 28 million. The planning and governance mechanisms, however, are often fragmented even though there are obvious economic interrelationships among the urban places within the mega-urban region.

That is to say, the peri-urban areas in many large cities are fast expanding, sometimes stretching to 100 kilometres from the urban core. The urban area of Shanghai, China is projected to grow from 410 square kilometres to 1,100 square kilometres (150 per cent) in less than ten years (Martin 2005). Noting the unique feature of Asian urbanization, McGee (2009) has coined the term 'desakota' (village-city) to describe Asian urban agglomerations and indicate their mixed rural–urban characteristics. Asian cities are characterized by mixed land use development and high population densities (e.g. Bangkok, Hong Kong SAR, Seoul, Singapore). Formal and informal activities often take place in the same space while residential developments are located next to commercial activities. Many Asian cities have high population densities, the high-

est in the world, ranging from 10,000 to over 20,000 people per square kilometre (e.g. Mumbai, Kolkata, Karachi, Seoul). This can be traced to several factors including market forces, planning or other government policies and transportation patterns.

Over the past two decades, many Asian countries have started to recognize cities as engines of economic growth and to reorient national policies to promote urbanization. China has championed an urbanization strategy that develops city clusters across its Central, Western and North-eastern regions into engines of growth, transitioning from a rural, agricultural society to an urban industrial economy and lifting some 660 million people out of poverty. China's Pearl River Delta Region (0.4 per cent of China's land area and 3.5 per cent of its population), for example, contributes 10 per cent of the country's GDP and 30 per cent of its exports. Chinese cities' contribution to GDP is expected to rise from 75 per cent to 95 per cent by 2025 (McKinsey Global Institute 2009).

Similarly, the urban sector in Indian cities contributes about 60 per cent of GDP (Government of India 2011). This contribution is projected to rise to 75 per cent by 2021 and over 70 per cent of new jobs are expected to be created in cities. The suggestion is that cities provide large economies of agglomeration; urbanization and economic growth are often concomitant processes in Asian cities.

29.3   Urban Challenges

While urbanization may represent economic opportunity, it also brings many and varied challenges that threaten the liveability of cities. Much has been written about the challenges and impacts of rapid urbanization (Yeung 2011; UN-HABITAT 2010a; Yuen 2009). The unprecedented scale, size and continued expansion of cities have produced enormous problems, from the decay of inner city areas to urban sprawl, uncontrolled peri-urban area development, ill-regulated land use, urban housing shortages, congestion, and environmental pollution. The demand for urban living, in terms of land, housing, transport, water and energy supplies, social services, etc., has frequently exceeded supply.

In many cities, century-old buildings are being cleared to build modern roads and high-rise buildings (Yuen 2013). Untreated domestic, municipal and industrial waste seriously pollutes rivers and local drinking water supplies and threatens coastal fisheries and livelihoods in several Asian cities (e.g. in China,

Malaysia, Vietnam). Expansion of cities and their built-up areas modifies the local and regional climate mainly by the production of pollution and the urban heat island effect with knock-on effects on agricultural land, biodiversity and ecosystem services (Crutzen 2004; UN-HABITAT 2011; Angel 2012). That is, cities are drivers of climate change.

29.3.1   The Bane of Rapid Urbanization, Africa

As cities grow in size, they become more complex and the ability to manage them becomes a daunting challenge (box 29.1). Rapid urbanization is often followed by urban poverty, with the prospects of a dignified and productive life continuing to elude the poorest among Africans and Asians. As a result, more and more urban poor are pushed into the informal sector and unplanned settlements (Figure 29.1). As many as nine out of ten urban workers in Africa are employed informally, working long hours at very low incomes. Despite African cities generating over 50 per cent of the continent's total GDP, Africa's poor, who earn less than US$2 per day, constitute about 61 per cent of the continent's population (AfDB 2012b).

The other major challenge of urbanization in Africa is related to urban crime and insecurity. The lack of employment opportunities as well as basic social services such as shelter and sanitation services have eroded the dignity of the poor, particularly youth in urban areas. As most of the youth slide into poverty, they join criminal groups and gangs in search of solidarity, identity and empowerment and hence resort to violence and crime to earn a living. In the recent past, inter-state conflict has significantly declined in Africa while urban insecurity, violence and crime have dramatically increased in African cities (UN-HABITAT 2014). Africa has the highest rate of urban crime worldwide (and Asia the lowest).

The higher incidence of Africa's crime has been traced to poverty, inequality, external economic shocks, social exclusion and weak political institutions (Fox/Hoelscher 2012). The prevalence of crime and the escalating urban crime rate can be expected to adversely affect foreign direct investment in urban Africa and reduce employment opportunities for its youth. Such reduction can potentially lead to large-scale social unrest similar to that recently experienced in Northern Africa, dubbed the 'Arab Spring'.

In Africa, inadequate and debilitated infrastructure is adversely affecting the continent's economic growth and reducing private sector productivity (UNECA 2009). Low-level energy access including an

Figure 29.1: A hotel in the slums of Nairobi, Kenya. **Source**: Authors.

Box 29.1: Cairo: Africa's Megacity. **Source**: The author.

With a population of about 11 million (2011), Cairo remains by far Africa's largest city. According to UN-HABITAT (2010b), the population of Cairo will grow by 2 per cent annually between 2010 and 2020. Cairo and Alexandria are the main economic engines of Egypt, with 57 per cent of all manufacturing activities located in the Greater Cairo area. About 67 per cent of the GDP of Egypt comes from the metropolitan area of Cairo. Industries include textiles, cotton and food processing. The service sector and tourism are the main source of revenue and employment for the workforce in Cairo. Like in any other megacity,

rapid urban growth has resulted in serious problems in most aspects of settlements and the life of its population. To address these challenges, the government has embarked on an ambitious plan to steer the urban population to new settlements or areas. In this regard, the policy is to redirect the population pressure from the Nile valley to the adjacent desert plateau. The government has also introduced policies to decentralize population and activities from Cairo to local and regional levels in order to manage its growth and address the challenges of population pressure on this megacity.

average rural electrification rate of 10 per cent and a railway network density that ranges from 30 to 50 kilometres per million people pose a major challenge to African development (AfDB 2012b). The proportion of people in Africa still without electricity is higher than in any other continent; the rate of urban electrification is lower than in any other continent. The 2010 data indicates that the urban electrification rate in Africa is 69 per cent compared to 96 per cent

for China and East Asia and 89 per cent for South Asia (International Energy Agency 2010).

Although the challenge of urban transportation in African cities is not new, the situation is getting worse daily (figure 29.2). Rising traffic and congestion levels are having far-reaching negative economic, social and environmental impacts on the cities. The increasing use of personal cars has choked roads, endangering the safety of pedestrians and the health of city residents. Pollution (including noise and automobile

Figure 29.2: Rising traffic congestion in Nairobi city, Kenya. **Source:** Authors.

emissions) has become a serious impediment to urban quality of life. This is made worse by the difficulty in enforcing regulations pertaining to vehicle inspections that address safety and emissions.

Declining urban densities associated with sprawl and combined with weak, fragmented, and underfunded authorities that are unable to maintain or expand existing urban transport services have not only increased travel distances but also pushed up the price of public transport. The poor are often the worst affected, being excluded from work and social services. Facilities for pedestrians are very poor and those for bicycles and other non-motorized transport are non-existent. Improving urban transport in African cities is an urgent priority and will depend on a strategy of coordinated measures to improve infrastructure, traffic management, service quality and network reach.

29.3.2 The Bane of Rapid Urbanization, Asia

Although Asian cities have made some progress in reducing poverty and achieving the Millennium Development Goals, basic urban infrastructure services—water supply, sewerage, solid waste management, storm water drainage, transport—still require major improvement. Over 60 per cent of the world's slum population (505 million people) continues to live in Asia. In many Asian cities, more than 50 per cent of urban residents live, often under hazardous conditions, on land where title is disputed. The living conditions of migrants are poor; they normally live in illegal, overcrowded, unhygienic squatter areas (figure 29.3).

The state of infrastructure in most Asian cities (large and small) is equally beset with problems relating to coverage, quality, operation, persistent underinvestment and poor maintenance (figure 29.4). Even though India's power sector has been expanding in recent years, it still has the problem of providing adequate power to meet the needs of its growing economy (US Energy Information Administration 2013).

Figure 29.3: Squatter settlement in Metro Manila, The Philippines. **Source:** Authors.

Estimates indicate that 25 per cent of India's population lacks basic access to electricity (6 per cent in urban areas and 40 per cent in rural areas), and electricity blackouts are common in electrified areas. In the water sector, 70 per cent of its urban population is covered by individual water connection. Duration of water supply in Indian cities is between 1 and 6 hours. Less than two-thirds of India's urban households are connected to a sewerage system and in some cities only about 20 per cent of sewage generated is treated before disposal. About 13 per cent of India's urban population defecate in the open. These problems are not unique to India. They happen to varying degrees in many other cities in the developing countries of Asia and Africa.

29.3.3   Failure to Act—the Consequences

Failure to meet infrastructure needs could stifle economic growth and, ultimately, human development. Estimates suggest that a rise of 1 per cent of GDP on infrastructure investment could generate an additional

3.4 million direct and indirect jobs in India, while the consequent deterioration in energy, housing, communications, transport and water facilities from the failure to close the infrastructure gap would restrain economic growth by 3 to 4 percentage points of GDP (Tahilyani/Tamhane/Tan 2011; McKinsey Global Institute 2013). Moving in lockstep with urbanization, US$8 trillion is estimated to be required in infrastructure investment (energy, transport, telecommunication, water and sanitation) over the next ten years to redress Asia's historical underinvestment and growing demand.

The projected increase in urban populations to Asian cities calls for unprecedented construction. Estimates suggest that Asia's daily additional 120,000 urban dwellers would require the construction of over 20,000 new houses, 250 km of new roads, and additional infrastructure to provide more than 6 megalitres of potable water (Roberts/Kanaley 2006). On an individual country level, rapidly urbanizing China could require 5 billion square metres of road, 28,000 kilometres of metro rail and 40 billion square metres

Figure 29.4: Lack of proper solid waste disposal creates an environmental problem in Jakarta, Indonesia. **Source**: Authors.

of floor space (20,000–50,000 new buildings of more than 30 floors) over the next twenty years (McKinsey Global Institute 2009). Urban China is projected to require 700–900 gigawatts of new coal-fired power between 2005 and 2025 (50 new power plants a year) to keep pace with urban and manufacturing growth. This will only further increase China's greenhouse gas emissions, strengthening its position as the world's largest emitter of greenhouse gas.

China generates 24 per cent of the world's greenhouse gas emissions (United Nations Environment Programme 2013). It urgently needs to shift towards a model of economic growth focused on low carbon emissions. More than 1 million people living in the coastal areas of China could be displaced and a land area the size of Hong Kong SAR could be submerged by 2050 if the country does not take action to prepare for rising sea levels (ADB 2013). Climate-proofing of China's infrastructure, including roads and drainage, could cost up to US$44 billion per year between 2011 and 2050.

Climate change affects the vulnerability of cities, especially those in low-elevation coastal zones. Africa and Asia (South, South-east and East Asia) are key regional hotspots of coastal vulnerability (IPCC 2014).

Several African cities such as Accra, Durban, Lagos, Luanda and Maputo are located in low-lying coastal areas that are prone to flooding. Climate change is likely to put millions of these people at risk. Changes in the frequency, intensity and duration of climate extremes (droughts, floods, heatwaves, among others) have adversely affected the livelihoods of their urban population, particularly the poor and other vulnerable communities who live in slums and marginalized settlements. Extreme changes in weather patterns have increased incidences of natural disasters and adversely affected all key sectors of the economy including the urban economy, agriculture and forestry, water resources and health.

Yet African cities' ability and readiness to predict and respond to potential complex emergencies, to mitigate natural and other disasters through disaster risk reduction, climate change adaptation planning and ecosystems management are either very weak or altogether lacking. To make matters worse, some African cities are developing new 'ecologically unfriendly' configurations (e.g. using heat-retaining building materials that raise urban temperatures) or 'urban fantasies' of modernist high-rises and highways that are disconnected from the urban core and African land-

---

Box 29.2: Africa's Path to Green Growth. **Source**: The author.

The *African Development Bank* (AfDB 2012b) has argued that green growth will have the desired impact on Africa's two major problems—poverty and climate change—if it is packaged within the following three focal areas:

1. promoting sustainable infrastructure including access to renewable/low carbon energy and energy efficiency; sustainable transport; and sustainable cities;

2. efficient/sustainable management of natural assets including land (agriculture, forests, and other land uses); water (freshwater, marine); and minerals;

3. building resilience of livelihoods including physical/climate; economic; and social.

---

scape, further compromising their resilience to climate change.

Increasingly, international organizations including UN-HABITAT (2009) have advocated proper urban planning to better respond to the growing urban population and urbanization. In the absence of appropriate and effective urban planning and implementation strategies, African and Asian countries will end up with "spiralling poverty, proliferation of slum and squatter settlements, inadequate water and power supply, and degrading environmental conditions" (UN-HABITAT 2009: 26). But with comprehensive urban planning and implementation strategies, urbanization in Africa and in Asia can transition to jump-start sustainable urbanization and promote much-needed political, social and economic development (UN-HABITAT 2010b).

29.4   Opportunities for Green Growth

In part through the effort of international organizations such as the ADB, the OECD, the World Bank and the United Nations, the notion of green growth, first introduced in Asia, has been increasingly offered as a response to cities to forge new ways of acting to reduce greenhouse gas emissions in a climate-changed world. Green growth is defined as a sustainable economic growth "that is either compatible with or driven by reduced emissions, improved efficiencies in the use of natural resources and protection of ecosystems" (AfDB 2012b: 5). As Hallegatte/Heal/Fay et al. (2011: 2) stated, green growth is "about making growth processes resource-efficient, cleaner and more resilient without necessarily slowing them."

Others have argued that haphazard and unsustainable development carries the risk of locking the city into an inferior option of development and may in the longer term result in a loss of competitiveness, retarding economic growth and generating legacy costs for decades (Anas/Timilsina 2009; Corvellec/Campos/Zapata 2013). Even so, escaping lock-ins is possible

and the case for cities to transition towards more sustainable development styles is compelling (Bulkeley/Broto/Hodson et al. 2011; Hallegatte/Heal/Fay et al. 2011; Bridge/Bouzarovski/Bradshaw et al. 2013). Moving towards such a development path would require cities to not only anticipate growth and manage its outcomes more effectively but also to fundamentally change the way they produce and consume energy and resources.

Making the transition is understandably not easy. Many questions remain, especially relating to analysing and understanding the urban complexity and the processes of transition—what are the mechanisms that can be used to effect the transition to green growth? As the effects of climate change intensify and the rising prices of energy are felt, many cities are awakening to the inevitable need to become more proactive in rethinking and repositioning to achieve greater urban sustainability. According to the United Nations Economic and Social Commission for Asia and the Pacific (2012), forty-two million Asians were pushed back into poverty in 2011 due to energy and food price increases.

In the context of Africa, the transition to green growth means "pursuing inclusive economic growth through policies, programmes and projects that invest in sustainable infrastructure, better natural resources, build resilience to natural disasters, and enhance food security" (AfDB 2012b: 5). Pursuing the path of green economy will assist Africa in overcoming the twin challenges of rampant poverty and climate change (box 29.2).

Obviously, not all green growth options are cheap. An economy that is driven by green growth cannot be created overnight. Nonetheless, some African countries have embarked on the path of green growth. Rwanda has committed itself to a long-term green growth strategy. Its *Vision* 2020, adopted in 2002, outlines a long-term national development strategy to achieve economic development and poverty alleviation by modernizing Rwanda from an agrarian economy into a regional service and knowledge-based hub

---

Box 29.3: National Strategy for Green Growth, South Korea. **Source**: The author.

Providing the national agenda and framework for government actions, green growth programmes and laws, the *National Strategy* sets out ten policy directions. These are:

1. effective mitigation of greenhouse gas emissions;
2. reduction of use of fossil fuels and enhancement of energy independence;
3. strengthening the capacity to adapt to climate change;
4. development of green technologies;
5. greening of existing industries and promotion of green industries;
6. advancement of industrial structure;
7. engineering a structural basis for green economy;
8. greening the land and water and building the green transportation infrastructure;
9. bringing the green revolution into daily lives; and
10. becoming a role model for the international community as a green growth leader.

---

with an emphasis on green economy. Similarly, Ethiopia has committed itself to an economy that is based on a green growth strategy to achieve a middle-income country by 2025. In Kenya, where only five per cent of the rural population has access to electricity, the Menengal geothermal energy project is expected to increase energy production by 26 per cent by 2018, thereby providing clean and inexpensive energy for about 500,000 households and 300,000 small businesses (AfDB 2012b).

The unprecedented increase in urban population opens new opportunities to improve urban development. As Roberts and Kanaley (2006) posited, the future prospects of Asian cities will be determined by the management of their sustainability, that is, economic, social and environmental sustainability.

29.4.1 Some Asian Examples

Green growth has been adopted as a regional sustainable development strategy in Asia since 2005 during the Fifth Ministerial Conference on Environment and Development in Asia and the Pacific. South Korea is the first Asian country to introduce a green growth strategy. Championed by its president Lee Myung-bak on the sixtieth anniversary of the founding of South Korea, green growth is put forward as the country's next growth engine with projections to generate additional economic output (206 trillion won) and new jobs (1.8 million) (Kim 2010).

Since August 2008, South Korea has adopted a new national development paradigm based on the concept of low carbon green growth. This is being pursued in a comprehensive way that includes not just strong commitment from its president, as the head of state, to climate change mitigation but also a whole-of-society concerted focus on green innovation for economic growth, green transport, green purchasing and public support for green growth and green living. The purpose is to reduce the country's greenhouse

gas emissions by thirty per cent and to position South Korea among the world's top seven leading countries in green growth by 2020. South Korea offers a case of how strong government leadership and political commitment are brought to bear to act as a catalyst for economic system change and engage businesses and the public to support the transition towards a green economy.

Under the Korean Law for Low Carbon Green Growth, which came into effect in May 2010, the state is obliged to invest at least two per cent of GDP in low carbon production and consumption. In this regard, South Korea has been implementing eco-labelling since 1992. In 2001, its Ministry of Environment implemented the *Environmental Declaration of Products*, a standardized ISO 14025/TR and life cycle assessment-based programme, and in 2005, enacted *The Promotion of Purchase of Environmentally Friendly Products Act*. The green growth effort is being implemented through the National Strategy for Green Growth (2009–2050) and five-year development plans (box 29.3).

In consequence, South Korea has increased its green overseas development assistance. It launched the *Global Green Growth Summit* at the G20 Summit in November 2009 and a *Green Technology Centre* for international green technology cooperation, including cooperating with developing countries in green growth and climate action. Even though still at the implementation stage, the number of venture start-ups in green industries has increased by more than forty per cent since 2009, and the Korean bullet train network is being expanded to connect most major cities nationwide by 2020.

More Korean citizens are becoming socially aware of green living and are participating in green lifestyle choices. The number of households who have joined the carbon point programme increased from 400,000 in 2009 to 2.9 million by July 2011 (Ministry of Environment n.d.). Under the carbon point programme,

points, i.e. incentives such as cash, metrocard, and gift coupons, are offered to consumers who save electricity, water and gas in houses and in commercial buildings. The green consumption culture is being strengthened through various efforts to promote green products and green consumption (e.g. green product information system, carbon labelling system, green consumption education). South Korea's government is developing a national carbon cap and trade system, modelled on the European Union Emissions Trading System. Set to begin on 1 January 2015, the proposed South Korean system has been described by Marcacci (2013) as the world's most ambitious cap and trade market with the highest global price on carbon.

Apart from South Korea, a growing number of countries have joined the green growth agenda. In 2010, Cambodia adopted a *National Green Growth Road Map*, while Kazakhstan presented a pioneering *Green Bridge* initiative to link Asia and the Pacific with Europe through green growth during the Sixth Ministerial Conference on Environment and Development in Asia and the Pacific. China, India, Indonesia, Japan, South Korea, Philippines, Singapore, Malaysia and Thailand have started to articulate energy-efficient policies and build energy-efficient and zero-energy buildings as well as to certify green buildings (Wen/ Chiang/ Shapiro et al. 2007). A new paradigm of mainstreaming energy efficiency seems to be emerging.

Energy consumption is a major source of greenhouse gas emissions and the building sector is a major energy consumer in Asia (about 25 per cent). Zero-energy construction has significant implications for the regional as well as the global economy and environment. More than half of the world's new building construction is taking place in China and India. Since 2005, China has introduced a number of measures for green growth including a government decree on mandatory designs to conserve energy used in cooling, heating and lighting in public buildings (United Nations Environment Programme 2013). Both the Eleventh Five-Year Plan (2006–2010) and the Twelfth Five-Year Plan (2011–2015) have emphasized energy and resource efficiency, providing a strong policy framework (energy saving, emission reduction and industrial policies) to support China's transition towards a green economy. China's 2020 emissions reduction target is to reduce its greenhouse gases by 40–50 per cent based on carbon intensity in 2005 and to produce 16 per cent of its primary energy from renewable sources by 2020.

China is actively promoting renewable energy, investing US$67.7 billion in renewable energy in 2012 (United Nations Environment Programme 2013). China is now the world's largest producer of wind power and solar energy equipment, creating millions of green jobs. The renewable (thermal, wind, solar) power generation sector is projected to create 4.4–5.05 million new green jobs between 2005 and 2020 (Wu 2012). Though early days yet, the environment industry represents over 3 per cent of China's GDP. Since 2009, several Chinese cities have started to develop various low carbon action plans (Chinese Society for Urban Studies 2011; Baeumler/Ijjasz-Vasquez/Mehndiratta 2012).

Harbin and Hangzhou, for example, have initiated energy-saving and emission-reduction programmes in communities, mobilizing families, schools, businesses and state organizations to take part in energy conservation and emission reduction. Other cities such as Shanghai and Baoding have joined the *World Wildlife Fund Low Carbon City* initiative, which seeks to find a sustainable development mode for China's urban areas through studying current energy production and utilization patterns and developing new economic approaches for cleaner growth. Other cities, for instance, Wuxi, Shenzhen, Suzhou, Yangzhou, Beijing and Shanghai, are taking action to build low carbon cities. More than eighteen provinces and 150 counties and cities are estimated to have started planning for some form of eco-development. Some of these are being developed in international partnerships, such as the *Sino-Singapore Tianjin Eco-city* (figure 29.5), the *Sino-Swedish Wuxi Low Carbon Eco-city* and the *Sino-Finland Mentougou Eco-Valley* in Beijing.

In 2010, China's National Development and Reform Commission's *National Pilot Programme on Low Carbon Provinces and Cities* was launched to encourage further local low carbon action (People's Daily 2010). Rather than just attempting to reduce carbon emissions from industry, this represents a first comprehensive regional-local government approach to low carbon performance in China, directing five provinces (Guangdong, Liaoning, Hubei, Shaanxi, Yunnan) and eight cities (Tianjin, Chongqing, Shenzhen, Xiamen, Hangzhou, Nanchang, Guiyang, Baoding) to consider the complete built environment as well as the purchasing and consumption habits of those residing, working or visiting these provinces and cities. Together, the five provinces and eight cities contribute 36 per cent of the country's national GDP, 31 per cent of its energy consumption, 27 per cent of population and 27 per cent of energy-related emissions. It

Figure 29.5: Salt pan barren land being transformed into the Sino-Singapore Tianjin eco-city. **Source:** Authors.

represents the largest low carbon city-region development in the world, a critical step in promoting the transformation of local economic development and achieving low carbon performance.

In 2008, India adopted a *National Action Plan on Climate Change* that included a range of measures for renewable energy, energy efficiency, clean technologies, public transport, resource efficiency and tax incentives. It should be noted that low carbon development is not just state action. Non-state actors have an important role. Bangalore, India, for example, has conducted various experiments in smart building technologies, renewable energy and water management. A private company, BCIL, has been developing T-ZED (*Towards Zero-Energy Development*) homes (76 apartments and 15 villas) on a five-acre site since 2004.

The award-winning project has a number of green features including energy efficiency (for example, LED and CFL lighting, renewable energy-based street lighting, solar water heating systems), no import of water (for example, rainwater harvesting, cyclical water use), no export of waste (for example, commu-nity-led waste management), no industrial floors and no toxic paints (Kikusawa 2010). The company has opted to build only 91 houses instead of the 300–400 apartments allowed by the floor space index, in order to create self-sufficiency in water.

Completed in 2009, the project yields capital savings of about 20,000 tonnes of carbon emissions and operational savings of about 1,500 tonnes of carbon emissions. Its cost and pricing, however, mean that the development is largely accessible only to the upper-middle-class income groups. Many of its residents are IT professionals, doctors, bankers, biologists and the like. In Bangalore, the upper-middle income class constitutes just five per cent of the population. As Kikusawa (2010) argued, the impact of such green building needs to be extended from the current target community of middle-upper income groups to lower-income households.

A number of other Asian cities, including small and medium-sized cities, have started to prepare and implement city development strategies to better strategize urban futures rather than develop without plan-

Figure 29.6: Turning waste to recreation land at Semakau, Singapore. **Source:** Authors.

ning (ADB 2004; Einsiedel 2004). The process would typically identify priority city development issues and formulate medium- and long-term city development strategies through a participatory process. The priority issues include livelihood (e.g. job creation and business development), environmental sustainability, energy efficiency, quality of service delivery, financial resources, governance, spatial form and infrastructure.

Designing eco-efficient cities and infrastructure will require rethinking in urban planning and design. As the United Nations Economic and Social Commission for Asia and the Pacific (2012) acknowledged, this would necessitate a shift towards eco-city development, encompassing eco-efficient transport (change the way people move, from private cars to public transport), green buildings (from energy wasting to energy saving), eco-efficient energy infrastructure (improve efficiency of the energy system and diversify to renewable energy sources), eco-efficient water infrastructure (change the way water resources are managed) and eco-efficient solid waste management (turn waste from a cost into a resource) (figure 29.6).

The 2012 United Nations Conference on Sustainable Development (Rio+20) has recognized and re-emphasized the need for a holistic approach to urban development. Its Resolution notes that, if well planned and managed, cities can promote economically, socially and environmentally sustainable societies. The need to promote an integrated approach to planning, developing and managing sustainable cities and urban settlements as well as sustainable development policies that support inclusive housing and social services and a safe and healthy living environment for all is emphasized. The rationale is simple: cities are the hubs for much of national production and consumption—economic and social progress that generates wealth and opportunities.

29.5   Conclusion

Sustainable urbanization is critical to the future of Africa and Asia. Sustainable urbanization is both more inclusive and resilient as well as more ecologically effi-

cient. The realities of climate change and resource constraints are showing that cities can no longer adopt business-as-usual practices but need to urgently improve their ecological efficiency. That is, African and Asian cities have to act urgently and immediately to close the gap between ecological, social and economic efficiencies. In particular, municipal governments and urban authorities should mainstream policies that are sensitive to energy saving, the creation of fewer sprawls and more climate-resilient infrastructure, especially with respect to drainage, flood control, housing, sanitation, transport and water distribution systems.

While rapid urbanization brings with it many issues, it provides a not-to-be-missed opportunity to pay greater attention to sustainable urbanization. Instead of the conventional 'grow first, clean later' approach to development, cities need to assiduously pursue greener growth and arrive at a green economy where economic prosperity occurs in tandem with ecological sustainability.

Various Asian and African cities have begun this system change towards greater sustainability, from China to Cambodia, Ethiopia, India, Kazakhstan, Kenya, Korea, Malaysia, Rwanda and Singapore. Numerous measures are being used to promote 'green' forms of urban development, including regulation, green building, research (for example, into renewable energy), business and community energy-saving and emission-reduction programmes. Like their counterparts elsewhere, Asian cities are redesigning and experimenting with new 'low carbon' or 'eco' cities. It is important that these be carefully considered and integrated as part of a sustainable development continuum, instead of as isolated phenomena or, worse, as 'fantasy cities' that are disconnected from the everyday needs of the majority of the urban population.

Just as there is no single urban transition, there is no single measure or pathway to sustainable futures. What is at stake is not a simple choice between different approaches to a low carbon future but rather the need to recognize that the transition is a complex and negotiated process and to accept some levels of failure and the opportunity to learn and reinvent our ways towards greater sustainability.

Obviously, Africa and Asia have different political histories and cultural differences in the manner in which both societies are organized and developed. These differences account for some of the major differences in the implementation of urban development policy and the resolution of problems. However, they also have common urban development challenges as discussed above, and this calls for common policy

points. At the economic and social levels, to effectively address these challenges, African and Asian cities need to focus on pro-poor urban growth and greener growth strategy that will reduce poverty and, at the same time, create jobs and improve living conditions for the majority of their urban dwellers.

At the physical and spatial levels, African and Asian cities need to invest in infrastructure (including green energy and green transport) that addresses the infrastructure gaps and growth needs. Given the path dependency of infrastructure and spatial locations, there are gains to be made in exploring how such investments could transition out of carbon dependence to focus more on the processes of unlocking new sustainable growth.

Needless to say, there is no 'one size fits all' prescription for implementing sustainable growth. Much depends on the institutional and policy settings and the level of development and resources as well as the specific challenges and opportunities, present and future. The absence of coherent strategies to deal with the urbanization dynamics can impede growth, or worse, exacerbate systemic economic inefficiencies and social and environmental risks.

What is needed is an actionable policy framework that is well designed to mutually reinforce economic growth and the conservation of resources as well as flexible enough to take account of changing urban circumstances and differing stages of development. It will call for policies that promote sustainable infrastructure and efficient sustainable management of natural assets and build the resilience of livelihoods.

It is increasingly apparent that such effort, to succeed, will need to build on a high degree of inter- and intra-collaboration among and between the different urban actors—the layers of government, the private sector, the non-government agencies, and the people—to identify a policy mix that is suitable to local conditions and needs. In many cases, developing appropriate institutional capacity (including vision, the capability to formulate the right agenda, work attitude improvement, coordination of functions, transparency and accountability, eradication of corruption, and improvement in skills and knowledge) will be an essential precondition. Local administrative capacity is generally weak and fragmented in many African and Asian cities.

The challenge is to build on successful experiences already developed in Africa, Asia and elsewhere. Cities would need to identify, learn from and further develop such experiences to catalyse more efficient land, infrastructure, housing and urban development.

Important to these innovation journeys is not just the practical exchange of ideas and experiences between cities but also effective local governance to develop and implement well-targeted policies and investments.

As the United Nations Economic and Social Commission for Asia and the Pacific (2012) observed, the greening of the economy will not happen automatically through the marketplace; governments must lead the systematic transition. This is not to ignore the fact that a low carbon future will not happen without the involvement of the entire society—businesses and communities. Many African and Asian countries are beginning to recognize that policies on green growth need to shift from a purely environmental concern to sustainable development, identifying the synergies with economic, environmental and social sustainability. Promoting greener growth must be an integral part of development processes at both the national and local levels.

30 The Role of University Partnerships in Urban Sustainability Experiments: Evidence from Asia

Gregory Trencher[1] and Xuemei Bai[2]

Abstract

University-driven partnerships and experiments for advancing urban sustainability are flourishing around the world. Responding to drivers such as calls for stakeholder engagement in research, tangible social and economic contributions, and government funding incentives, Asian research universities are also forming cross-sector partnerships and implementing various sociotechnical experiments. In this chapter we examine the role of university partnerships in knowledge co-production and implementation of urban sustainability experiments in industrialized Asian nations. By examining fifteen cases from Singapore, Japan, Hong Kong and Korea, we highlight common attributes (focus areas, actors, motivations and mechanisms) and then investigate the functions, motivations, barriers and significance of roles assumed by differing societal sectors. A detailed case study of an ambitious project from the University of Tokyo then follows to further illustrate these attributes in context.

Key findings are that, overall, university partnerships for urban sustainability in our Asian sample are dominated by technical approaches. Yet the most significant barriers are human aspects such as time restraints, lack of unity, and poor management and leadership, to name several. On key drivers, government funding is playing a major role in enticing partnership formation and influencing particular approaches to urban sustainability. Measures are required to encourage the participation of the social sciences and humanities, and non-technical sustainability experiments. Case study evidence suggests that the ability of partnerships to tackle complex social issues and trigger societal transitions towards sustainability is often constrained by existing research projects and the institutional capacities of universities and their partners.

Keywords: Asia, urban sustainability experiment, transition, transformation, partnership, university, co-design, co-production.

30.1 Background

Sustainability challenges facing cities in the Asian region are significant. They include rising urban populations, associated air and water pollution and other environmental degradation, social inequalities, food and energy security, a growing demand for resources and an expanding carbon footprint (Bai/Imura 2000; Bai/Shi/Liu 2014; Brown 2011). On the other hand, rapid urbanization and economic growth has enhanced the ability to address many of these sustainability problems through technological advancement and improved environmental governance. Concentration of large-scale, dense urban areas and a general cultural enthusiasm for new technologies make industrialized and rapidly industrializing Asia an ideal arena for 'sustainability experiments'.

Experimentation is considered crucial for advancing sustainability (Bai/Roberts/Chen 2010; Konig/Evans 2013). Sustainability experiments are defined as "planned initiatives that embody a highly novel sociotechnical configuration, which typically involve significant learning and are likely to lead to substantial (environmental) sustainability gains" (Berkhout/Verbong/Wieczorek et al. 2010: 262). They are typically

1 Ass. Prof. Dr. Gregory Trencher, Visiting Associate Professor, Clark University: Department of International Development, Community, and Environment; email: <gtrencher@clarku.edu>.
2 Prof. Dr. Xuemei Bai, Professor, Australian National University: Fenner School of Environment and Society; email: <xuemei.bai@anu.edu.au>.

characterized by the introduction of a new technology, policy or social arrangement on a small scale; a radical and highly exploratory nature; and involvement of various actors from industry, government, civic society and academia (Bai/Wieczore/Kaneko et al. 2009; Brown/Vergragt/Green et al. 2003). Literature from transitions theory describes the significance of such experiments as, firstly, their ability to function as 'niches' or pockets of protection for emerging forms of social or technical innovation from more established market or societal ways of doing things (i.e. the 'regime') (Geels/Schot 2010), and secondly, their value lies in the potential to trigger wider societal transitions towards sustainability when up-scaled and exported (Bai/Roberts/Chen 2010).

A second body of literature explores the idea of the urban environment functioning as a 'living laboratory', typically focusing on the role of university actors and scientific research (Evans/Karvonen 2011, 2014). However, this topic is not well explored in the sustainability experiments literature.

Cutting-edge experimentation is also prominent in the green campus movement (M'Gonigle/Stark 2009; Konig 2013). Over the past two decades, many universities have taken impressive measures in attempts to become models of urban sustainability for the broader community (ISCN 2014). Tapping into their powerful financial resources and technical expertise, universities are also functioning as test grounds for emerging technologies such as renewable energy production and *electric vehicle* (EV) transport systems, innovative energy, water and waste saving strategies, building design, and campus management. Such on-campus experimentations generate research opportunities and serve as a demonstration site that can entice broader adoption by the society.

A plethora of initiatives emerging around the globe (Trencher/Yarime/Kharazzi 2013; Trencher/Yarime/McCormick et al. 2014; Trencher/Bai/Evans et al. 2014; Zilahy/Huisingh 2009) suggests that university efforts are increasingly extending off-campus into surrounding towns, cities and regions to become key drivers of urban sustainability experiments. Collaboration and partnerships is a defining feature of this trend, which has been recently examined by a number of case studies (Evans/Karvonen 2011, 2014; Liedtke/Welfens/Rohn et al. 2012; Molnar/Ritz/Heller et al. 2011). Several factors are contributing to the rise of university initiatives to engage in research co-production and co-implementation with external stakeholders. There are growing government demands for intensified university–industry relations and outputs

with economic significance such as intellectual property, marketable inventions, spin-off firms and capacity-building for industry and government (Yusuf 2007). The governments of Singapore and Japan, for example, have created generous funding opportunities to encourage cross-sector innovation in areas such as climate change, energy and transport. City governments around the world are also showing increasing willingness to engage with other societal actors in experimental governance and policy initiatives to tackle climate change (Castan Broto/Bulkeley 2013). In addition, there is an increasing awareness within and outside the scientific community that greater innovation can result from collaboration and open networks than in traditional laboratories and closed models of R&D (Shrum/Genuth/Chompalov 2007). Further, there is a growing consensus that the scientific community should better respond to societal needs through the co-design and co-production of knowledge (Lubchenco 1998; Future Earth 2013; Mauser/Klepper/Rice et al. 2013). In the literature, this transition is often described as a shift from 'mode 1' to 'mode 2' type knowledge production, where knowledge is increasingly produced in application and in response to stakeholder needs (Nowotny/Scott/Gibbons et al. 2001).

Of note, literature examining university roles in innovation and experimentation is typically focused on North American or European cases. Very little is known on the characteristics of Asian-based experiments and to what extent cross-sector partnerships are part of such initiatives. This is despite the increasing interests and tendencies of Asian universities to engage with stakeholder networks, building cross-sector R&D platforms, and conduct various forms of technical and social experiments in urban areas.

In this chapter, we explore the role of the university in urban sustainability partnerships and experiments[3] in the context of industrialized (i.e. high-income) Asian nations. With an overall focus on environmental dimensions of urban sustainability, our study is guided by several questions:

1. What are the defining attributes (i.e. focus area, actors, motivations and mechanisms) and com-

---

3   In this study we employ the term 'partnership' to signify the broader actor network serving as an umbrella for a particular implementation project or societal intervention (i.e. the experiment). That is to say, a single partnership may consist of numerous sustainability experiments.

Box 30.1: Method. **Source**: The authors.

The fifteen partnerships and data used in section 30.2 come from a larger (n=70) global survey (Trencher/Bai/ Evans et al. 2014) that attempted to identify as many instances as possible of university-driven partnerships for urban sustainability from industrialized (high-income) nations in Europe, Asia and North America. Partnerships were located over the period June 2011 to November 2013 by a combination of i) Internet keyword searches including government funding agency databases, ii) reviews of academic literature and press articles, and iii) referrals from peers and information requests to university actors.

Data analysed in section 30.2 stem from two questionnaires. The first gathered quantitative data describing key partnership characteristics and was administered electronically to one person (in most cases the project leader) from each case. A second questionnaire was then administered to gather both qualitative and quantitative data on key barriers encountered and measures taken to overcome these. This was despatched to several actors in the various societal sectors involved (i.e. government, industry and civil so-

ciety). This led to a total of twenty-six responses from thirteen of the fifteen cases. Both questionnaires asked respondents to assign a numerical score to indicate the relevance of a particular variable (i.e. type of actor, motivation or barrier etc.) to the partnership in question. The first questionnaire on key characteristics offered the following options for each variable: 0 (not at all relevant), 1 (partly relevant), or 2 (extremely relevant). The second survey offered the following scores: 0 (not at all significant), 1 (mildly significant), 2 (very significant), and 3 (extremely significant).

In terms of data calculation, individual scores from each partnership for each variable were tallied and then divided by the total amount of scores possible (i.e. 2 x n for the first questionnaire and 3 x n for the second). This has resulted in a percentage score (observable in all figures in section 30.2) signifying the importance of a particular variable relative to others, from the overall perspective of all partnerships combined.

---

monly encountered barriers in partnership activities and experiments?

2. What are the functions, motivations, barriers and significance of roles assumed by differing societal sectors?
3. What lessons and implications for sustainability transitions research may be drawn from Asian university attempts to co-design and co-produce knowledge and solutions for urban sustainability?

Our study draws some elements (data in section 30.2) from an earlier global study (Trencher/Bai/Evans et al. 2014). Yet this previous work is furthered by focusing specifically on the region of Asia—and in particular the differing roles, motivations and barriers of various societal actors, in addition to the impacts of government policies and funding incentives. Such information is drawn from structured interviews, analysis of survey results, and university and governmental documents, as well as first-hand experience from participating in such partnerships.

The empirical backbone of this study consists of fifteen university partnerships from Singapore, Japan, Hong Kong and Korea (respondents to our survey). All of these nations and regions are characterized on the one hand by a high level of fossil energy imports, per capita *greenhouse gas* (GHG) emissions, dense and mostly urban populations, and limited natural resources such as land, and on the other hand, advanced innovation bases, highly developed university sectors and knowledge-driven economies. Japan is

also facing the dual and interrelated concerns of rapid population ageing and potential socio-economic decline as a result.

Our chapter is structured as follows. Firstly we analyse survey results from the fifteen partnerships to define key trends and barriers in the Asian sample. In the next section we then examine the core roles, motivations and challenges of each societal sector engaging with university attempts to advance urban sustainability. Thirdly, in a detailed case study we examine an attempt by the University of Tokyo to address emerging challenges of climate change and population ageing through research and societal experiments. This project aims to lay a blueprint for a low carbon and elderly-friendly reform of the neighbouring City of Kashiwa. Finally, we reflect on previous sections and conclude with challenges, lessons and implications for sustainability transitions scholarship on Asia.

30.2 Characterizing University Partnerships for Urban Sustainability in Asia

In this section we offer a brief macro-analysis of fifteen university-driven partnerships for advancing urban sustainability in industrialized Asia (listed in table 30.1). Partnerships are scrutinized firstly in terms of urban systems targeted, external and internal actors, and motivational factors and mechanisms, and secondly, of commonly encountered barriers. The

sample consists of eight cases from Singapore, three from Japan, three from Hong Kong and one from Korea. Samples are a subset of a global study (see box 30.1). While this is not sufficient to fully represent university initiatives in industrialized Asia, it can nonetheless highlight some key trends and characteristics. It may also inform attempts from other scholars to more exhaustively survey the region.

30.2.1   Sectors Targeted

Results in figure 30.1 demonstrate that *energy and heating/cooling*, *built environment* and *economy,*

employment and industrial production are the most commonly targeted urban systems in the fifteen cases. The preoccupation with the built environment and energy and heating/cooling appears to be driven by awareness that these areas represent key opportunities to mitigate climate change through reduced GHG emissions and higher energy efficiency. The overall focus on *economy, employment and industrial production* is indicative of strong collaborations with industry. Overall, a moderately strong resolve to influence government planning and policy can be observed from *governance and planning*. As an overall trend it can be seen that partnerships tend to be

Figure 30.1: Urban systems targeted (n=15 cases). **Source:** The authors.
Figure 30.2: Types of internal actors (n=15 cases). **Source:** The authors.
less focused on transforming systems such as *transportation*, *solid waste* and *food, agriculture and forestry*.

Of note, the bulk of partnerships are simultaneously targeting several of the ten urban systems listed in figure 30.1. The choice and quantity of systems targeted appears to be determined by a combination of factors such as the expertise of actors involved, the needs and challenges of the target area, and government funding priorities.

30.2.2 Internal Actors

Figure 30.2 reveals that the main university actors forming, coordinating and implementing urban sustainability partnerships are predominantly *faculty and researchers*. This is followed by postgraduate *students,* usually playing a supporting and secondary role. This demonstrates that sustainability partnerships can generate important educational opportunities. Non-academic actors such as bridging organizations (such as technology transfer offices and community outreach platforms) are also present in several partnerships. This reflects several important supporting roles they

can play in project coordination, establishing external contacts and leveraging university resources. Most partnerships involve more than one of these internal actors.

30.2.3 External Actors

Figure 30.3 below demonstrates that *local or regional government/public services, large or multinational corporations* and *state or national government* constitute the most common external partner. The strong links with local or regional government actors may be reflecting the focus on the local or city scale, while the strong overall linkages with corporations appears to reflect the tendency noted above to target the *economy, employment and industrial production* sector. Only about half of the cases involve collaboration between academic institutions (i.e. other universities or research institutes) or the civic sector. This contrasts with findings from North America where civic society actors such as *non-governmental organizations* (NGOs), grassroots organizations and local residents tend to constitute a more frequent external part-

Figure 30.3: Types of external actors (n=15 cases). **Source:** The authors.
Figure 30.4: Number of external actor types involved (n=15 cases). **Source:** The authors.
ner for university sustainability initiatives (Trencher/ Bai/Evans et al. 2014).

The potential of university partnerships in Asia to integrate multiple societal sectors into the co-design and co-production of urban sustainability is evident in figure 30.4, which shows the number of external actor types from figure 30.3 actively participating in each partnership. It can be seen that the bulk of cases involve two, three, four or even five categories of external actors (specific roles of societal actors are discussed in section 30.3). This structural view suggests that the simplistic analytical lens of 'triple-helix' relations (Etzkowitz/Leydesdorff 2000) between academia, industry and government does not accurately capture the societal inclusiveness of many partnerships.

30.2.4   Motivations and Triggers

Figure 30.5 presents various motivations and triggers behind the university partnership initiatives. Again, for most cases several variables apply simultaneously. Overall, the three most significant motivating factors are *developmental/strategic*, *scientific/scholarly* and *funding*. The developmental/strategic motivation refers to desires to influence development trajectories and transform societal systems in response to external

environmental or socio-economic conditions. With universities described as 'anchor institutions' not having the luxury of being able to relocate (Birch/David/ Louis 2013), many university actors are aware that the long-term well-being of their institution is highly dependent on surrounding environmental and socio-economic conditions. The prevalence of the scientific/scholarly motivation shows that virtually all cases were strongly driven by the desire to enhance academic knowledge production by engaging with real-world situations and translating scientific knowledge into tangible and useful outcomes. Lastly, the finding that *funding* also constitutes a crucial motivating factor supports arguments that targeted funding schemes can play a major role in fostering university collaborations for sustainability with external stakeholders (Dedeurwaerdere 2013; Whitmer/Ogden/Lawton et al. 2010).

Interestingly, *entrepreneurial* motivations (i.e. the prospect of generating income for any of the partners involved) least explain the emergence of partnerships for urban sustainability. This is despite earlier noted strong relations with *large or multinational corporations*, and a common focus on *economic, employment and industrial production*. This evidence suggests firstly that the widely documented and

Figure 30.5: Factors motivating partnership formation (n=15 cases). **Source:** The authors.
Figure 30.6: Mechanisms (n=15 cases). **Source:** The authors.
promoted entrepreneurial paradigm driving conventional technology transfer practices (Etzkowitz/Webster/Gebhart et al. 2000; Mowery 2007) in other fields such as IT and the life sciences has little relevance for sustainability partnerships in the region. Results from Asia, and other regions around the world (Trencher/Bai/Evans et al. 2014), suggest that other motivational factors (e.g. the desire to influence surrounding development trajectories towards greater sustainability; to enhance research with external knowledge, situations and 'urban laboratories'; and to secure funding as either a means or an end) are pushing university actors to initiate or engage in urban sustainability research and experiments with societal stakeholders.

30.2.5   Mechanisms

Figure 30.6 shows that activities corresponding with *knowledge management* (for example, stakeholder consultations, data production and analysis, publication and communication of results) are the most commonplace mechanism by which university sustainability partnerships seek to co-design and co-produce urban sustainability. This is in agreement with wider trends in Europe and North America (Trencher/Bai/

Evans et al. 2014). Results suggest a prevalence of technical approaches (i.e. *technical demonstrations and experiments*) and relative under exploitation of softer approaches involving social innovation (i.e. *sociotechnical experiments*). This is another defining characteristic that can be retained from our Asian sample.

The overall bias towards technocentric approaches reflects on the one hand a preponderance of R&D-based platforms from faculty and researchers in the fields of engineering and the natural sciences, and on the other government research and funding priorities. In countries such as Singapore, for example, National Science Foundation and government funding programmes have explicitly linked the collaborative pursuit of urban sustainability with areas such as energy- and space-efficient urban development, and disciplines such as the physical sciences and engineering.[4] With technocentric avenues to pursuing urban sustainability shown to be highly limited (Notter/Meyer/Althaus 2013), the integration of social aspects and approaches (i.e. *sociotechnical experiments* and social

4   See URL: <http://www.nrf.gov.sg/research/r-d-ecosystem/research-priorities/physical-sciences-engineering>.

Figure 30.7: Barriers and negative factors (n=13 cases). **Source:** The authors.
sciences) merits attention in future university efforts in Asia to advance urban sustainability.

Technology transfer and economic development has also emerged as a common means by which partnerships seek to advance urban sustainability. Firstly, this should be seen as a natural consequence of the strong linkages with industry noted earlier. Secondly, this reflects several R&D and demonstration platforms in Singapore fostered through programmes such as the *Campus for Research Excellence and Technological Enterprise* (CREATE) from the National Research Foundation. In such government strategies to enhance national innovation and economic competitiveness, there are explicit expectations for the generation of commercializable intellectual property and economic outcomes such as ventures, employment and technology transfer to industry.[5]

Although not the most significant, mechanisms such as *reform of built or natural environment* and *governance and collaborative planning* are also present. In several cases, interventions on the physical environment (e.g. *Underwater Infrastructure and Underwater City of the Future* and *Low Voltage Direct Current Grid Network*) and activities such as collaborative planning and policy making with government decision-makers, political lobbying and advocacy (e.g. *Urban Design Centre Kashiwanoha* by the University of Tokyo) also represent important avenues by which academic actors seek to translate knowledge into concrete contributions to the advancement of urban sustainability.

30.2.6   Barriers

Figure 30.7 demonstrates that with the exception of *funding*, it is predominantly internal dynamics and project management-related factors such as *time restraints*, *lack of unity/harmony* and *poor management and leadership* that most commonly hamper partnerships. In connection with the *time restraints* issue, university and societal actors typically engage in cross-sector sustainability initiatives in addition to existing job commitments (Hoover/Harder 2014). The creation of supporting staff and infrastructure such as project offices is vital for addressing these project management-related issues (Hanleybrown/Kania/Kramer et al. 2012). With regard to funding, qualitative responses indicated that the societal impact of university partnerships can be reduced for two reasons. Firstly, funding shortages force actors to divert valuable time from core partnership activities to pursuing funds from other sources, and secondly, decrease the capacity to recruit other necessary partners.

The lack of unity/harmony and poor management and leadership typically impede partnerships when differing values, approaches, goals and expectations can dilute the synergistic effect of cross-sector collaboration. For example, some partnerships cited differing interpretations of timelines and project outcomes between industry and academia as a major challenge, with others suggesting that the cohesiveness and synergy of large-scale sustainability partnerships can deteriorate not only across societal sectors, but also across academic departments and disciplines. With university sustainability partnerships mobilizing numerous partners from differing academic fields and societal sectors, the fostering and maintaining of partnership unity,

harmony and a common vision and set of expectations is therefore crucial.

Interestingly, despite a preponderance of R&D platforms centred on developing and trialling new and emerging technologies, *technical barriers* have emerged as the least significant, in alignment with other studies examining urban sustainability experiments in Asia (Bai/Roberts/Chen et al. 2010). Evidence from Asia therefore suggests that when collaboratively pursuing urban sustainability, political and human rather than technical barriers are most critical.

30.3 Roles, Motivations and Potential Barriers in Societal Sectors

The following sections summarize potential roles and motivations for each societal sector participating in university partnerships for co-designing and co-producing sustainability knowledge and societal transformations. A summary of this discussion appears in table 30.2.

30.3.1 University

Partnerships examined in this study are mainly from large research-intense universities from various Asian metropolises. The majority originate from engineering and natural sciences, and often from interdisciplinary research institutes with dynamic industry and government linkages, with few including social scientists and other non-engineering disciplines. In all cases, it is university actors who are responsible for the conception, formation and overall direction of each partnership. During formation stages, it is typically senior faculty who apply for research funds, design the overall structure and objectives, and recruit external partners. Coordination and project management roles are typically handled by junior faculty and researchers. Only one project (*CUHK Jockey Club Initiative Gaia*) was formed and coordinated by administration.

Not surprisingly, the chief role for faculty and researchers concerns scientific research. For many partnerships involving R&D in fields such as energy, EVs and *information and communications technology* (ICT) (e.g. *TUM-Create* and *Green Society ICT Life Infrastructure*), such research can be highly fundamental and initially far from the stage of demonstration or application. Nevertheless, such basic and frontier research is vital for innovation. Intense relations with industry and expectations for utility and

concrete outputs to national innovation systems (e.g. technology transfer to industry and venture creation) in several partnerships, especially in Singapore, pose an interesting challenge for the distinct and traditional culture of academic research.

For other partnerships such as *NUS-JTC Industrial Infrastructure Innovation Centre, Sustainable Supply Chain Centre–Asia Pacific* and *Triple Water Supply System*, scientific research can be more mature, applied and driven by ambitions of implementation and diffusion to industry. In such cases, conventional technology transfer channels of patenting, licensing, consulting and personnel transfer to industry (Mowery/Nelson/Sampat et al. 2004) play an important role.

At one point or another, many partnerships serve as testing platforms for unproven technologies or sociotechnical innovation. For example, *Urban Reformation Programme for Realization of Bright Low Carbon Society* involves technical demonstrations of electric mobility solutions for elderly citizens, trials of biofuel production, and attempts to integrate vacant land into citizen-led urban agriculture networks. *Low Voltage Direct Current Grid Network* utilizes the technology park (CleanTech One) at Jalan Bahar Singapore as a test bed for emerging low voltage direct current lighting and solar technology. Such demonstrations and pilot projects typically aim to monitor performance and interactions between human and technical systems and assess suitability for, or encourage, wider diffusion. The value of using urban spaces as 'living laboratories' is that such experiments allow a live preview of potential sociotechnical systems for tomorrow and the type of policies and other preconditions required to support, up-scale and export them.

Earlier cited evidence (section 30.2, 'Mechanisms') shows that other common university roles include sharing and communicating research results with societal actors. This can occur through various channels such as publications in academic journals, conference presentations, consulting to industry and government (e.g. *Infrastructure Supporting Project for Wind Power Generation Business in Jeju Region* and *Hong Kong SME Business Sustainability*), and the provision of specialist training to industry and government (e.g. *DHI-NTU Research Centre)* or citizen education and public sector capacity-building efforts (e.g. *CUHK Jockey Club Initiative Gaia*). Evidence from Mowery/Nelson/Sampat et al. (2004) and Philpott/Dooley/O'Reilly et al. (2011) suggests that important transfers of knowledge will also occur through informal meetings and interactions with government and

industry partners or stakeholders Other channels for the transferring of research results related to urban sustainability include inputs into government policy and long-term planning. This can also involve the creation and transfer of modelling or visualization tools for aiding government (e.g. *Energy and Environmental Sustainability Solutions for Megacities*) and industry decision-making (e.g. *Sustainable Supply Chain Centre–Asia Pacific*).

30.3.2   Government

Survey results suggest both local or regional government/public services (the most common) and national government participate and play an important role in university partnerships.

Actors from local or regional government are diverse. In Japanese and Korean partnerships, these typically consist of senior members of city planning teams and departments related to transport, industrial development and energy. Short-term roles include the provision of data and urban planning expertise, the provision of land, buildings and test sites for experiments, introduction to other societal stakeholders, public endorsement or promotion of partnership activities, and participation in partnership steering and decision-making.

Participation in cross-sector partnerships for urban sustainability promises much reward for local government. As in Western nations, municipal actors in industrialized Asian countries are faced with various and converging challenges such as pursuing economic development and societal well-being whilst coping with threats such as climate change, ageing and declining populations, energy security, and deterioration of the natural or built environment. With government functions broken up across departments and limitations imposed by existing policies and financial, time and manpower resources, the capacity to single-handedly generate innovative and comprehensive solutions to complex and long-term societal challenges is limited (Hanleybrown/Kania/Kramer et al. 2012; Orr 2013). The opportunity to collaboratively address such problems with universities and other societal experts offers municipalities the precious opportunity to tackle many of these problems simultaneously, and usually with minimal financial contributions. Other ensuing benefits include access to new knowledge and outside best practice, and valuable insights into the type of government policy and planning required to support the collaboratively generated solutions.

Despite potential benefits, several barriers should be expected. These may include tensions between the typically short- to mid-term and implementation-focused priorities of city planners and the long-term and research focus of academics. They may also stem from the radically different cultures of academia and local government where, on one hand, academics are rewarded for risk-taking and innovation, and on the other, government officials are typically encouraged to avoid risks and duplicate established patterns and procedures (Vigoda-Gadot/Shoham/Schwabsky et al. 2005). These differing 'world views' (Trencher 2014: 196) may deter some municipalities from taking a high level of interest in university-driven partnerships and will also influence the ability to assimilate and implement new knowledge and innovation in future policy and planning.

In several cases in Singapore and Hong Kong, participating government actors tend to correspond more with a national level. These include, for instance, officials from national agencies dealing with water supply and drainage, economic and industrial development, and environmental protection. In partnerships such as *Triple Water Supply System* and *DHI-NTU Research Centre,* officials from water-related bodies are assisting with the establishment of pilot plants and testing of emerging technologies (i.e. energy recovery from waste water, energy efficient treatment and recycling, and seawater flushing) in existing government water treatment infrastructures. In partnerships such as *NUS-JTC Industrial Infrastructure Innovation Centre,* actors from national urban planning and engineering divisions play a key role in the design of research agendas, steering and project management. This is in addition to research, marketing and integration of new knowledge into government policy, legislation and construction projects. The value of such contributions is the ability to absorb new knowledge and technologies and contribute to large-scale, rapid societal transformations and 'regime shifts' (Berkhout/Verbong/Wieczorek et al. 2010) through national level policy and legislation.

Motivations for national government actors working in the above contexts appear to be the desire to remain at the forefront of knowledge and innovation, to enhance effectiveness and environmental sustainability of core functions (for example, land planning and water treatment), to accelerate progress towards objectives such as reducing GHG emissions, and to boost national or international competiveness. Barriers to be expected from national level actors concern budgets, political agendas and priorities. Swayed by

national political cycles and voters, these largely determine the ability to take up particular technologies and tackle certain societal challenges.

Another important set of government actors operating behind the scenes as 'enablers' in many cross-sector partnerships are national funding agencies. As also described in the triple-helix literature (Etzkowitz/ Leydesdorff 2000), such actors play a crucial role in fostering the formation of cross-sector collaborations by creating institutional conditions and incentives through shaping national research priorities and targeted funding programmes. Singapore is a striking example. One recent measure involved the preparation of a physical infrastructure for university–industry collaboration and sustainability innovation. The National University of Singapore was chosen for construction of the *Campus for Research Excellence and Technological Enterprise* (CREATE)–itself a feat of green building innovation. This *National Research Foundation* (NRF) initiated and financed green technology park is enticing and housing collaborations between prestigious international research universities (e.g. MIT, ETH-Zurich and Munich Technical University), local universities and industry around four themes of human, energy, environmental and urban systems. Fostered in this way are several partnerships such as *TUM-Create* and *Energy and Environmental Sustainability Solutions for Megacities*. Utilitarian motivations behind such generous support are explicit. It is expected that these collaborations generate "positive social and economic outcomes" and lay the knowledge and workforce foundations for a transition to a low carbon, innovation-driven economy in Singapore.[6] Another example is the 'Sustainable Urban Systems' competitive research programme initiated by NRF. This has brought into formation partnerships such as *Sustainable Urban Waste Management for* 2020 and *Underwater Infrastructure and Underwater City of the Future*, each allocated SD\$ 10 million over five years.

30.3.3   Industry

As noted earlier, large and multinational corporations, rather than *small and medium-sized enterprises* (SMEs) tend to engage with university initiatives for urban sustainability–a trend corresponding with conventional university–industry collaborations in fields

such as life sciences and software engineering. As observed by Laursen and Salter (2004), larger firms with existing capabilities in R&D and open approaches to innovation are most likely to engage in partnerships with universities. Key roles for corporate researchers include participation in research and provision of resources such as company data, expertise and funding. Some cases such as *Sustainable Supply Chain Centre–Asia Pacific* and *Low Voltage Direct Current Grid Network* demonstrate that non-scientific actors from high-level corporate management can also become involved, and in the former case, even assume a partnership direction role. As in conventional technology transfer patterns, a chief long-term role for industry in Asian sustainability partnerships is the assimilation of new technologies and knowledge and introduction to the market.

An important motivational factor for firms investing in R&D and commercialization efforts with universities is the prospect of procuring *intellectual property rights* (IPRs) for new inventions and eventually generating income. This entrepreneurial motivation is detectable in several partnerships in Asia, particularly those involving intense R&D collaborations. Another motivation on the industrial side appears to be the prospect of gaining university-won funds from national research bodies. This explains why a plenitude of research funds is so critical in engaging stakeholder support, as reported earlier.

Several factors could potentially impede industry participation in university partnerships for urban sustainability. One would be a limited appreciation of academic topics of enquiry and demands for scientific value and robustness when co-designing projects. Contrary to general belief, industry does not generally place great importance on university research as a source of innovation (Laursen/Salter 2004; Mowery/ Nelson/Sampat et al. 2004). This would particularly be the case for research activities not necessarily connected to near-term income generation. Other potential tensions could arise from differences between academic and industrial decision-making protocols. Industry has a capacity to make rapid and fundamental decisions, with scientific research communities typically driven instead by consensus and slower, deliberative decision-making. Nevertheless, the engagement of large industry is crucial for university attempts to advance urban sustainability through academic research. This is due to expertise in manufacturing, commercializing and marketing, and a unique ability to manifest sustainability impacts on national or inter-

---

national markets though the introduction of new technologies, knowledge or services.

30.3.4   Civic Society

Involvement of civic society in our sample includes NPOs, think tanks, civic associations and individual citizens. Civic society does not feature as prominently in Asian partnerships as in North America (Trencher/Bai/Evans et al. 2014), a core reason being the dominance of R&D platforms. Nonetheless, civil society is playing a key role in several partnerships, both inside and outside Singapore.

As advocated by the Future Earth framework (Mauser/Klepper/Rice et al. 2013), civic society can assume a core role in the co-design of academic research agendas for sustainability by interrogating scientific research questions and activities from the perspective of societal needs and conditions. With less evidence of this occurring in Asia, key roles appear to be more related to implementation and knowledge production activities. Especially for those partnerships targeted at specific locations and sets of community stakeholders, civic society performs functions such as provision of local knowledge (particularly in the three Japanese cases) and co-implementation of various sociotechnical demonstrations and experiments (particularly those requiring human engagement such as *Sustainable Urban Waste Management for* 2020, *Green Society ICT Life Infrastructure* and *CUHK Jockey Club Initiative Gaia*). The value of citizen participation in scientific demonstrations is that it allows the verification of sociotechnical innovation on living human systems—not only for technical performance, but also for social demand and acceptance. Civic actors can also contribute by mobilizing political and wider community support to either integrate new technologies or social configurations or tackle specific sustainability issues in general. Further, they can also provide academics with valuable connections to other community or political resources and networks.

An important factor motivating civil sector participation in university sustainability partnerships is the prospect of securing capacity-building support for pre-existing commitments and activities. This can entail allocations of university-won funding and enhanced knowledge and learning by engaging with other experts. Other important motivations can include the opportunity to interact with government officials and influence public policy, which might not be possible otherwise.

Barriers that can potentially impede civil society participation include a preponderance of technocentric approaches to urban sustainability, currently dominated by fields of engineering and natural sciences. Without a focus on place-specific human systems and lifestyles, civil society does not form a necessary component for many R&D-based platforms. Other barriers could stem from the undervaluing of time-consuming and uncertain interactions with 'non-experts' from civil society in academic incentive systems (Crow 2011; Yarime/Trencher/Mino et al. 2012). This is particularly relative to exchanges with industry, which can potentially bring economic benefits.

30.4   Case Study: Urban Reformation Programme for the Realization of a Bright Low Carbon Society (University of Tokyo)

To provide a more detailed picture on the particular functions, activities and potential impacts of university-driven sustainability experiments in Asia, this section focuses on a front-runner case from Japan. Data for this case come predominantly from a series of interviews with a total of eight faculty and researchers over the period April 2011 to February 2014, in addition to participation in workshops, steering meetings, conferences and field experiments over the same period .

The *Urban Reformation Programme for the Realization of a Bright Low Carbon Society* (henceforth 'the programme') from the University of Tokyo aims to design the blueprint for a low carbon and elderly-friendly urban transformation of the local City of Kashiwa (30 km from Tokyo) by creating and demonstrating the necessary technologies, and reforming various social systems. The programme is a large-scale sustainability experimentation characterized by a high level of ambition and numerous societal interventions. It brings together various disciplines from the two campuses of Hongo and Kashiwa. The programme has emerged as a dual response to converging challenges of climate change and an ageing society. External partners and stakeholders include local government officials, residents, NPOs, private firms and a corporate think tank. Implementation extends from April 2010 to April 2015, with a total research budget of approximately JP¥ 550 million. This initiative emerged in response to a competitive funding call from the Japan Science and Technology Agency 'Social System Reformation Programme for Adaptation to Climate Change' in 2010.

Table 30.2: Summary of key roles, motivations and potential barriers.

Societal Sector	Common roles	Common motivations	Potential barriers
University	• Conception, design and formation of partnership • Procurement and allocation of funding • Overall direction and project management • Scientific research and implementation of experiments • Technology transfer to industry and government via patenting, licensing, consulting or personnel transfer • Sharing and communication of research results with other actors via publications and conferences • Input to government policy	• Learn from real-world settings, external actors • Increase visibility and impact of research • Influence societal development trajectories • Procure funding (See section 30.2 *Motivations*)	• Academic incentive systems undervaluing time-consuming and uncertain collaborations with societal stakeholders • Poor project management and leadership skills • Funding shortages (See section 30.2 *Barriers*)
Government (National/ state)	• Creation of funding and institutional incentives • Assistance with establishment of test beds in government infrastructure • Steering and project management • Co-design of research agendas • Co-production of knowledge • Integration of new knowledge into government policy, legislation and construction projects	• Enhance effectiveness and environmental sustainability of core functions and infrastructure • Boost national or international competiveness through acquisition of new knowledge and innovation • Accelerate progress towards objectives such as reducing GHG emissions etc.	• Budgets, political agendas and priorities (swayed by political cycles and voters)
Government (Local/ regional)	• Provision of data, urban planning expertise and resources for experiments such as land, buildings and test sites • Introduction to other societal stakeholders • Public endorsement or promotion of partnership • Partnership steering and decision-making • Integration of results into policy, planning and projects	• Opportunity to tackle multiple societal problems simultaneously with minimal financial contributions (often not possibly with departmentalization) • Access to new knowledge and outside best practices • Insights into type of policies and planning required to support emerging sociotechnical solutions	• Tensions between short to mid-term/implementation-focused priorities of city planners and long-term/research focus of academics • Different cultures in academia and local government (academics rewarded for risk-taking and innovation, government officials often encouraged to avoid risks and duplicate established patterns and procedures)
Industry	• R&D and knowledge co-production • Provision of resources such as data, expertise and funding • Steering and project management • Assimilation of new technologies and knowledge, then introduction to market	• Prospect of acquiring new knowledge via innovation networks • Prospect of procuring intellectual property rights (IPRs) and generating income. • Prospect of gaining university-won funds	• Limited appreciation of academic enquiry and demands for scientific value and robustness in projects • Differences between academic and industrial decision-making protocols.

Table 30.2: Summary of key roles, motivations and potential barriers.

Societal Sector	Common roles	Common motivations	Potential barriers
Civic society	• Co-design of research agendas • Provision of local knowledge • Co-production of knowledge • Co-implementation of demonstrations and experiments • Mobilization of political and wider community support • Provision of connections to other community or political resources and networks	• Prospect of securing capacity-building support (university-won funding and knowledge from other experts) • Opportunity to interact with government officials and influence public policy	• Preponderance of technocentric approaches to urban sustainability (not requiring civil society participation) • Undervaluing of interactions with 'non-experts' from civil society in academic incentive systems (in relation to industry)

Activities are organized into six research groups: *energy* (development and testing of solar-heat-driven heating and cooling systems), *mobility* (development and trials of super-compact electric vehicles and sharing infrastructure), *clinical plant science* (citizen training and capacity-building for diagnosing and alleviating plant diseases), *agriculture and landscape planning* (exploitation of local land and forestry resources for agriculture, greening and biomass production), *urban planning* (creation of mixed-use urban land policies and social networks to prevent urban decay), and lastly, *information systems* (creation and demonstration of supporting ICT infrastructure). As a whole, these groups encompass various disciplines such as engineering, urban design, plant science, environmental design and environmental sciences and involve over forty faculty and researchers. Designed overall to be a catalytic action plan for low carbon urban reform and societal transformation, the bulk of programme activities concern scientific research, both basic and applied. A large proportion of these research projects existed prior to the programme. As such, faculty and researchers engaging in the project are keenly motivated by the desire to advance and increase the visibility of research activities. With procured funding also serving to increase the scale of existing research projects, scientific learning is enhanced by collaborating with other disciplines and external stakeholders, and utilizing the local city as a test bed for emerging technologies and newly conceived 'social experiments' (Yarime/Trencher/Mino et al. 2012). Clearly such motivations correspond with earlier observed factors from section 30.2. A steering committee oversees all activities. Members include the overall project leader, leaders from each research group and external advisors such as senior members of a private sector think tank, the ex-president of the University of Tokyo, the deputy mayor of Kashiwa and senior city planners.

The key challenge addressed by the programme is how to achieve decarbonization in the context of a rapidly aging population. With 23 per cent of the citizens over sixty-five (Statistics Bureau),[7] Japan is a 'hyper-ageing society'—by far exceeding greying trends in any other nation. It is predicted that economic contraction following a shrinking working population could significantly hamper Japan's ability to mitigate and adapt to climate change (University of Tokyo 2014). Although Kashiwa's proportion of elderly sits just below the national average at 19.8 per cent, the working population has already peaked, and resident numbers are forecast to decline as of 2020. With this greying population facing concerns such as access to health care, services and recreation, a patchwork of some 1,000 vacant lots has emerged across the city (University of Tokyo 2014). Any effort to reduce future carbon emissions must therefore contend with this destabilizing decline of urban vitality and socio-environmental conditions.

Regarding external stakeholders, two levels of government are involved: the City of Kashiwa and the surrounding Chiba prefecture. Officials are predominantly senior members from various departments such as city planning, transport, parks and greenery, and agriculture. Immediate roles include official endorsement and decision-making; co-design and implementation of demonstration projects; provision of data, knowledge and test sites; and assistance with legal and political matters. Long-term roles include the integration of research results and the ensuing model for low carbon urban reform into city planning, policy and projects. The civic sector plays a core role. Individual residents and groups provide local

---

7   See URL: <http://www.stat.go.jp/english/data/nenkan/ 1431-02. htm>.

knowledge and participate in consultations and demonstrations, with a local NPO undertaking commissioned research and assisting in project demonstrations and implementation. Although present, industry plays somewhat a lesser role overall. The think tank Mitsubishi Research Institute provides project management and strategic decision-making support, also mediating stakeholder consultations. Private firms supply technical assistance, data and facilities. Active participation of the civic sector—more so at the level of knowledge production and project implementation—is a defining characteristic of this partnership. It is also a notable deviation from the overall tendency in Asia to collaborate with actors from industry more than civil society (reported earlier in section 30.2).

Table 30.3 offers an overview of the objectives, activities and expected impacts of the six research groups. A defining characteristic of the programme is the prevalence of scientific demonstrations, societal interventions and implementation projects. Being highly experimental in nature, these are often referred to as 'social experiments' (Yarime/Trencher/Mino et al. 2012) and complement traditional scientific activities such as basic research and formal knowledge production. Two factors appear to have contributed to the large quantity of social experiments. Firstly, for several years preceding the programme, the nearby station-front development of Kashiwanoha has sparked a culture of cross-sector innovation between industry, the university and the city and experimental pilot projects such as a rental cycle and EV vehicle network. Secondly, funding requirements from the Japan Science and Technology Agency have explicitly stipulated that qualifying projects involve demonstrations and initiatives to reform urban systems, in addition to basic research and development of new technologies.

Social experiments and implementation projects in the programme are marked by the intimate and ongoing involvement of the civic sector and an array of non-technical approaches and efforts to create new social configurations. For example, trials of *Micro-Electric Vehicles* (MEVs) from the mobility group have heavily involved local residents and NPOs, who are also core actors in field test activities for other groups such as biomass production and forest management experiments of the agriculture and landscape planning group. With activities of the energy and mobility group mostly centred on the creation and trialling of emerging technologies, the social innovation-driven approach of the clinical plant science group is noteworthy. This may be said when recalling from section 30.2 that there appears to be an overall tendency in

Asia to pursue urban sustainability through predominantly technical approaches. Activities in the *clinical plant science* group are focused on capacity-building and the transfer of plant science knowledge to local citizens. The idea is that this knowledge can be used to treat common diseases troubling local farmers and gardeners, thereby reducing wastage and, consequently, GHG emissions (from saved fertilizer and so on). Co-benefits of this approach entail the creation of social insertion opportunities for elderly residents, who through university-led training become certified and functioning 'plant doctors'. A core outcome of this group is the creation of a large-scale and fully functioning 'plant doctor' training and deployment network, which to date has trained approximately 700 local residents (mostly seniors). Experiments are currently under way to establish an on-demand despatch and transport system for trained plant doctors, who would subsequently conduct 'house visits' to farms and gardens in response to Internet reservations. At present, plant science initiatives are heavily planned and directed by university faculty. Yet efforts are being made to make the volunteer plant doctor system an entirely citizen-run and self-sustaining platform, supplemented by revenue from workshops and training courses. Citizen engagement and social innovation-driven approaches are also defining attributes of various initiatives in the urban planning group. At present, one area of activity includes experiments to foster mixed land use and utilize vacant lots for urban agriculture and 'rental gardens'.

From this perspective, outputs from the *Urban Reformation Programme for the Realization of a Bright Low Carbon Society* move far beyond traditional scientific activities such as basic research, publications and conference presentations. Experimental interactions with local government and the civic sector are leading to the co-design and co-production of prototypes of new social systems, which importantly, will continue functioning after the withdrawal of scientific enquiry and completion of the programme. Other outcomes include trials of new technologies and improved scientific learning gained from their insertion into living human systems in the 'urban laboratory'. This is in addition to an enhancement of social capital and provision of valuable policy recommendations for local government concerning, for example, land use and transport. In terms of overall impacts, the various outputs of each group contribute to a wider knowledge base, toolkit and blueprint for urban and social reformation, to counter the dual chal-

Table 30.3: Overview of Urban Reformation Programme for the Realization of a Bright Low Carbon Society. **Source**: The authors.

Focus area	Aim	Core activities	Expected outputs and impacts
Energy	Develop and test solar heat pump driven, super-efficient heating and cooling systems.	• Technological development • Laboratory experiments on CO_2 and energy consumption reduction potential, also using industry on-site data • Field testing	• Prototype creation and testing • Decarbonization and optimization of residential and commercial building heating and cooling systems (potential energy savings of 20 per cent relative to conventional technology)
Mobility	Develop and trial various Micro-Electric Vehicles (MEVs) and sharing network to decarbonize and optimize transport system for elderly citizens.	• Technological development of various models of wireless charging and capacitor-storage MEVs • Field demonstrations, testing with citizens and acceptance studies • Creation of smartphone-enabled sharing network	• Prototype creation and testing of MEVs and supporting infrastructure (charging and sharing network) • Decarbonization and optimization of individual transport system • Social insertion of elderly and activation of lifestyles • Knowledge about public acceptance and demand for MEVs
Clinical plant science	Contribute to decarbonization of agriculture through recruitment and training of elderly plant doctors for diagnosing and alleviating crop diseases	• Creation and implementation of plant science certification and training programme for senior citizens • Deployment of plant doctors throughout gardens and farms in Kashiwa City • Investigation of CO_2 reductions	• Contribution to decarbonization of agriculture by reducing crop loss from disease • Social insertion of elderly and activation of lifestyles • Fully functioning diagnosis and treatment service for plant disease and improved maintenance of parks and gardens • Knowledge base including textbooks, website and plant hospital
Agriculture and landscape planning	Develop citizen-based system for maximizing effective use of urban land and forestry resources for agriculture, greening and biomass production	• Field experiments and investigation of biomass fuel production potential • Study of GHG emissions from rice paddies and agriculture • Design of citizen-run management system for local land resources	• Opportunities for elderly citizens to engage in management of local land resources • Improvement of conservation and resilience of local land and forestry resources against declining population and agricultural activity • Stimulation of urban agriculture and contribution to GHG emissions reduction
Urban planning	Create mixed-use urban land policies and social networks to prevent urban decay and cater to needs of elderly population	• Survey investigation of elderly citizen living conditions, needs and geographical distribution of services • Creation and testing of land rotation system for integrating vacant lots into urban agriculture system	• Policy recommendations and social network prototypes for governance, maximizing effective land use and countering decomposition of city • Quantitative and qualitative understanding on citizen needs, living environment and future changes to urban fabric
Information systems	Study and create various ICT systems for enhancing the integration and decarbonization of various urban elements and functions	• Creation and trials of dynamic sensing and visual feedback technologies for electricity consumption • Creation of storage archive for quantitative and qualitative data from various demonstrations in other groups	• ICT system prototypes for enhancing connectivity and efficiency of various urban elements and functions

lenges of climate change mitigation and an ageing society.

However, an unprecedented and highly experimental nature also means that programme members are confronted by various challenges and uncertainties. Many stem from the large-scale and interdisciplinary structure of the programme. Key issues at stake appear related to communication difficulties. Also a commonly reported barrier for other partnerships (see section 30.2), this is contributing to a loss of unity, harmony and synergy. With the programme uniting over forty faculty and researchers from various disciplines, in addition to countless government and civil society stakeholders, several rifts have occurred between research groups. These appear to be exasperated by differences in activities, approaches and understanding of project goals and expected results. Overall synergy is further hampered by conflicting motivations between groups and individual researchers. Some are seemingly focused on advancing pre-existing research agendas whilst others are more committed to pursuing the goals of the programme. Consequently, at times research groups have functioned as independent research communities, with little cooperation and exchange with others. Although some groups have found areas for collaboration and functioned well together, the overall coordination and integration of the programme has been a key challenge. A recent measure taken to address this is the establishment of an additional project management group and recruitment of a dedicated project coordinator. Other challenges relate to the complexity and locked-in nature of the problems the programme seeks to address, uncertainty regarding results and the lack of an overarching vision for social reform in the community.

Also deserving critical examination is the programme's glowing promise of creating the blueprint for a realizable and exportable model of a 'bright', low carbon and elderly citizen-friendly society in the space of five years. Rapidly approaching the final year of implementation, the mechanisms by which this blueprint will be translated into reality remain unclear, just as the ability to achieve meaningful reduction of GHG emissions with tools such as electric vehicles and improvements in air-conditioning efficiency, plant health and land use. As observed by Bulkeley and Castan Broto (2012: 361), many urban sustainability experiments "promise more on paper" than they actually deliver. The capacity of this programme to achieve its objectives is largely restrained by the scope of existing university research agendas and strengths

(i.e., energy, MEVs, plant science and urban planning). It appears that the relevancy of these fields and research activities to the overarching objective was taken for granted in the design of the programme.

Yet the value of this initiative is nevertheless significant. It lies more so in the new model of knowledge production with stakeholders than in knowledge outcomes *per se*. This case provides an insightful preview into how the modern research university can apply its resources to the co-design and co-production of knowledge, solutions and societal transformations to address complex and place-based societal challenges.

30.5   Concluding Remarks

Several observations can be made about university partnerships attempting to advance urban sustainability through collaborative research and sociotechnical experiments in Asia.

Firstly, the power of government funding programmes to entice the formation of partnerships is evident at various points. Survey results demonstrated that the presence of suitable external funding programmes was a significant motivating factor for many cases. On the other hand, when financial resources were inadequate, funding also constitutes a common barrier. The effectiveness of government funding programmes in spurring cross-sector sustainability innovation was also demonstrated by Singapore and Japan. It was observed that national competitive grant schemes, and the preparation of physical infrastructure in Singapore (CREATE), had successfully brought into fruition several cases. These results suggest that an expansion of such government funding opportunities would have a driving effect on the formation of other partnerships. Such findings give weight to calls from other scholars that government funding programmes can serve as powerful incentives and shapers of university initiatives to initiate or engage in collaborative networks and experiments to advance sustainability (Dedeurwaerdere 2013; Whitmer/Ogden/Lawton et al. 2010).

Secondly, our study has revealed an overall preponderance of technical approaches to urban sustainability in Asia. With numerous R&D platforms and partnerships headed by engineering and physical sciences, it seems that the more human dimensions of urban sustainability and the involvement of the social sciences, the humanities and civil society, which are crucial for the co-design and co-production of knowledge for sustainability transitions, are largely underde-

veloped. One influencing factor behind the plenitude of technology-driven platforms in tandem with industry appears to be government funding programmes. In nations such as Singapore and Japan, competitive funding schemes are distinctly privileging fields such as engineering and the physical sciences by explicitly associating urban sustainability with the creation and testing of new technologies. Yet the capacity of predominantly technocentric approaches to reform lifestyles and trigger societal transformations to sustainability has been shown to be limited (Notter/Meyer/Althaus 2013). Measures are therefore required to create more favourable funding opportunities for the social sciences and humanities, and to encourage university actors to engage in social innovation-orientated sustainability experiments in tandem with civil actors.

As argued by Dedeurwaerdere (2013), one pragmatic strategy could involve the 'fine-tuning' of selection criteria and focus areas in existing funding programmes to demand greater collaboration across academic disciplines and engagement with civil actors. Such measures could entice partnerships to move beyond the development and trialling of new technologies to the co-production of new sociotechnical systems (also inclusive of technical elements), social arrangements and services. The case study from the University of Tokyo illustrated to some extent the possibility of such an approach. On the other hand, however, this programme also demonstrated that when large numbers of faculty and researchers from different fields come together, problems of project unity, communication and differences in approach can reduce partnership synergy and alienate certain research groups. Clearly, calls for interdisciplinarity in sustainability partnerships need to take into account these potential tensions and obstacles.

A third point of reflection concerns rising demands from both governments and academic research communities for utility, relevance to stakeholder needs, solutions for societal challenges and economic contributions. How much should be expected from university partnerships for urban sustainability? Can they really prove a 'miracle fix' for converging needs such as achieving innovation-driven growth and responding to complex social and environmental challenges? The case from Japan suggests that progress can be slow, complex and uncertain. Furthermore, the ability of the university to demonstrate relevance or tailor activities to the demands of external stakeholders is also restricted by existing strengths and research projects, and the effective balancing of these with new approaches, activities and stakeholder participation.

These were major factors affecting the ability of the Japanese case (a new programme incorporating many 'old' strengths and research projects) to generate solutions for addressing the designated challenge. Calls for universities to engage in cross-sector sustainability partnerships and experiments should take into account evidence that they can frequently fall short of expectations (Fadeeva 2004; Trencher/Bai/Evans et al. 2014).

In spite of such uncertainty, university partnerships in Asia and the rest of the world are demonstrating a promising capacity to generate important knowledge, technologies, tools and societal transformations for advancing urban sustainability. Also, cases including that from the University of Tokyo suggest that university partnerships are ideal mechanisms for linking broad areas of society and implementing multiple sociotechnical experiments designed to respond to diverse place-specific challenges. That is, they can potentially serve as 'umbrellas' or 'portfolios' for various societal experiments and interventions (i.e. protected spaces or 'niches' of innovation) that can be implemented alongside conventional knowledge production. A wealth of mechanisms highlighted in this study (i.e. knowledge management, governance and planning, technology transfer or economic development, technical demonstrations and experiments, reform of the built and natural environment, and sociotechnical experiments) suggest that university actors in Asia are experimenting with a myriad of ways to co-produce knowledge, co-implement such experiments and magnify societal impacts by facilitating the transfer of lessons elsewhere. Further, there is also evidence to suggest that such activities are increasingly likely to constitute a 'mission' for the university and complement existing, more established functions such as education, basic research and technology transfer or entrepreneurialism (Trencher/Yarime/McCormick et al. 2014).

In closing, in this chapter we have scratched the surface of a potential wealth of university initiatives in Asia to advance the sustainability of particular urban systems or communities, cities and nations. Our contribution to the literature has been our focus on several highly innovative partnerships in Asia that do not typically feature in discussions on sustainability transitions in English-speaking or European settings. Further, our study of fifteen cases (admittedly a modest sample size) has allowed us to extract lessons and common trends. This could not have been possible by a study of one or two cases alone—an approach tending to dominate the existing scholarship. Although

our study has shed some light on potential trends of university sustainability partnerships and experiments in industrialized Asia regarding key characteristics, roles, motivations and barriers of each societal sector, further research is required at both a micro- and macro-level. Clearly, a larger survey is needed to better assess the characteristics, roles and impacts of different university partnerships across Asia. As well as encompassing nations such as Korea and Taiwan, it could cover emerging economies such as China and India, which are increasingly significant players in research and innovation in the region. Further understanding is also required at the micro-level. Future studies are required, to examine the potential long-term impacts of different models of partnerships and the processes by which co-designed and co-produced knowledge, technologies, and sociotechnical experiments can be up-scaled to effect wider societal change.

Part VIII Examining Sustainability Transitions in the Water, Food and Health Sectors from Latin American and European Perspectives

31   Future Global Water, Food and Energy Needs

Cecilia Tortajada[1] and Martin Keulertz[2]

Abstract

If present trends continue, it is unlikely that increasingly overused ecosystems subject to deterioration and depletion will be able to meet global water, food and energy needs. Current academic thinking is that scarcity, pollution, mismanagement and misallocation of natural resources will impact every sector on which humankind depends for survival. In a globalized economy with increasingly free movement of commodities and financial and human capital, a poor understanding of the most pressing issues and their interconnectedness and interdependences will cause irreparable damage to the Earth and its billions of people: a clear case of *fait accompli.* This is a challenging context for global development, and to understand and manage the interdependencies between the various sectors and their global impact will require comprehensive planning and policy implementation, institutional resilience, partnerships across economic sectors, and innovation in development in order to sustainably manage resources in the wake of population growth and climate change.

Keywords: Water, food, energy, interconnectedness, globalization.

31.1   Introduction

In an increasingly globalized and interconnected world, societies have become less resilient with respect to water, food and energy resources. Long-term developments such as population growth, urbanization and industrialization in emerging markets, as well as the impending threat of climate change, have increasingly resulted in global impacts on natural resources; consumption of water, energy and food is at risk of becoming unsustainable. At the same time, institutions have not been able to respond to the enormous challenge of implementing policies that address the requirements of the various sectors in an interrelated manner.

Humankind's influence on the global environment and its exploitation of Earth's resources have both escalated to such an extent that Earth is said to have entered a new era, the Anthropocene. This is a human-dominated, geological epoch that has supplemented the Holocene, the warm period of the past ten to twelve millennia (Crutzen 2002). There are clear signs that these changes will affect water resources (Biswas/Tortajada 2009; Rockstrom/ Falkenmark/Allan et al. 2014), food resources (FAO 2011) and energy resources (IEA 2013, 2014) so dramatically that humankind will have to be content with adapting to the new conditions. Consequently, it has become necessary to focus on establishing resilience to an increasing number of stresses, as well as on understanding their impact on the stability of natural, social and economic systems (Rockstrom/Falkenmark/Allan et al. 2014).

In the past, Europe, North America and Oceania were able to meet their water, food and energy security needs in terms of availability and accessibility (affordability and acceptability depend on a number of external factors) through either surplus production or strategic imports. Nonetheless, global economic change is inevitably shifting economic centres from the West to the East. With this economic change have come new demands for food, water, timber, fibre and fuel from populations growing on a scale never before witnessed. For example, a report by McKinsey in 2009 foresaw a forty per cent gap between the demand for

1   Dr. Cecilia Tortajada, Senior Research Fellow, Institute of Water Policy, Lee Kuan Yew School of Public Policy, Singapore; Email: <Cecilia.tortajada@gmail.com>.
2   Dr. Martin Keulertz, Post-Doctoral Research Associate, Department for Agricultural and Biological Engineering, Purdue University, West Lafayette, IN, USA; Email: <mkeulert@purdue.edu>.

and the supply of water by the year 2030, if practices do not change (Boccaletti 2009). Similarly, the United Nations *Food and Agriculture Organisation* (FAO) concluded that the world will have to grow sixty to seventy per cent more food by 2050 in order to feed nine billion people (FAO 2011). The future of the availability of natural resources to meet the needs of increasingly demanding populations is thus surrounded by complexity and uncertainty, since it depends on global forces that are constantly changing (Hajkowicz/Cook/Littleboy 2012; Ringler/Biswas/Cline 2010).

The consequences of environmental degradation and change are increasingly associated with non-traditional notions of environmental security. While environmental change and degradation, as well as resource scarcity, increase instability and poverty and hold back social development, a discussion of their contribution to insecurity and vulnerability per se is outside the scope of this study. It is important, however, to acknowledge how the intrinsic relationships between societies and their political, human and natural environments are understood (Andrews-Speed 2013; Brauch/Oswald Spring/Grin et al. 2009), as well as the role the environment plays in promoting peace, stability and human security and the potential conflicts and vulnerabilities caused by environmental degradation (Biswas 2011).

In order to understand the complexity surrounding future water, food and energy needs, this chapter will aim to locate the management of these resources in a wider context of development. Most studies either provide a local or regional analysis or emphasize one issue individually, but do not address the three of them in an interrelated manner. Such analyses cannot lead to full comprehension of the crucial role of these resources in twenty-first century development, since they are embedded in complex interdependencies such that attempts to solve problems in one sector may create new problems or exacerbate existing ones.

The rationale for our analysis is that, in the present changing global environment, policy-making and the management, development and governance of natural resources are more and more influenced by numerous social and economic forces and scientific and technological developments; and that these are based on the policies, politics and economic priorities of various actors and sectors who do not take each other into consideration, and who operate concurrently in different geographies. A key concern is that their interconnections, interdependences and feedback loops, as well as their global impacts, are still not fully understood. As a consequence, planning and implementation at national levels are still based on individual sectors without considering their economic, social, physical and political environments, and this frequently makes decisions impracticable.

There is no doubt that things are further complicated by the diversity of views on what should be developed, what sustained, and over what period, particularly when such challenges as the above are involved. Moreover, if current trends in environment and development continue, it is unlikely that the desired state of sustainable development will be achieved (Kates 2001). Although change is inherent in humans, countries have not created systems to cope sustainably with transitions. At a time when our global context is being profoundly transformed, political, economic, social, environmental and technological advances are challenging prevailing assumptions about what was assumed to be a stable state of affairs in the age of the Holocene.

According to the *Millennium Ecosystem Assessment* (MA 2005), there is established but incomplete evidence that changes in ecosystems are increasing the likelihood of non-linear and sometimes irreversible events in the natural environment. As already mentioned, a major aspect of this problem is that the institutional arrangements, policy, legal and regulatory frameworks and management and governance practices necessary to reverse this situation are not currently in hand, and often not even on the drawing boards of decision-makers. This is likely to severely limit the alternative ways in which humankind can provide for global water, food and energy needs, both at present and in the future.

Finally, "needs" is a subjective term. Usually it refers to specific requirements that are essential or very important rather than just desirable. In this chapter, we will discuss both needs and demands, as in many cases this may be a more appropriate phrase given that it refers to "the desire of consumers, clients, employers, etc., for a particular commodity, service or other item".[3] By outlining present and future challenges for the future needs and demands for global water, food and energy, and placing them in a wider framework of development, we aim to broaden the approach from mere resource use to the interconnections and interdependences among a whole series of complex issues, such as population growth, urbaniza-

---

tion, resource scarcity, infrastructure development, agricultural trade, and energy generation, all of which in many cases are driven by geopolitical interests.

31.2 Water, Energy and Food Resource Management

The complexities of water, food and energy sectors need to be analysed in relation to each other as well as within their social, economic, natural, political and cultural environments, and not simply in isolation from each other. Water is a prerequisite resource for global sustainability, with a fundamental role in every other sector, and it has the distinct potential to sustain political, economic, social and environmental systems. Its proper management has an enormous value as it provides an entry point to address broader development objectives that are usually closely linked. On the other hand, its management all over the world does not reflect this value.

Water is also essential for crop production, be this for food, feed, fibre or fuels. Food sustainability, as discussed by Willaarts, Garrido and Llamas (2014), depends on the resilience of related agro-ecosystems, of which water is a fundamental component.

Water, and its proper management, are also indispensable for energy production and power generation. Water is used extensively in energy extraction, refining, processing and transportation; and energy is essential for transporting water over long distances and raising it, treating it and distributing it to end users, as well as for collecting and treating wastewater.

Policies that take into account trade-offs between water, food and energy are not being developed systematically, and much less in a coordinated manner, in spite of the urgent need for them.

As demands for water, food and energy continue to increase, competition for water between the domestic, energy, agriculture, environment and industrial sectors has the potential to have a negative impact on the reliability and security of all of these sectors (Pate/ Hightower/Cameron et al. 2007). If a sustainable future is to be achieved, the management of water resources requires balancing the competing needs for the increasing type and number of uses and users while taking into account the availability of water supplies and storage capacity. Such considerations should include the numerous impacts water policies and regulations have on food and energy supplies and demands and vice versa. This is, however,

still far from being implemented anywhere in the developed or developing worlds.

Terms of engagement are also affecting resource utilization policies and practices, contributing to more intense competition and also reshaping how emerging economies and global players are interacting in terms of trade and aid, with commercial and development-oriented policies becoming ever more closely dependent on one another (Lum/Fischer/Gomez-Granger et al. 2009; Tortajada 2014). An example of this is China and India, where competition for natural resources is global in reach, putting pressure on the global environment, and all this within specific political dynamics. The water, energy and food resource needs of both countries are likely to affect the availability of resources for numerous uses and users beyond their borders. In turn, the interlinkages and interdependences of the above sectors are likely to impact on the socio-economic development of different countries (Goldman Sachs 2010).

Within this context, the formulation of policy alternatives able to respond to related changes and challenges and how they could be implemented in a timely, socially and environmentally acceptable and cost-effective manner is becoming a security issue. The unprecedented and accelerating developments at national, regional and global scales and their implications in the individual sectors require in-depth, multidisciplinary and multisectoral policy debates from the strategic viewpoint about how they impact on peace, stability and human security. The resulting analyses will help realistic yet flexible resource-use policy alternatives for the common good to be devised. National, regional and global scenarios need to be formulated, including future-oriented frameworks that are able to respond to upcoming challenges and to further national and international interests.

With regard to water resources, their perceived global scarcity reflects not necessarily their physical availability but rather poor planning, management and governance, and this has resulted in overexploitation and deterioration of both surface and groundwater all over the world, which has had an impact on the food and energy sectors, among others. This sad state of affairs, where the management of water resources has responded to specific agendas rather than contributed to the goal of efficiency, has proved detrimental. In some cases, it has undermined functioning management systems, set back needed agendas for reform, or even become a tool to mask other agendas (see Biswas 2008; Giordano/Shah 2014; Molden/Lautze/Shah et al. 2010).

Global forecasts predict a bleak future where water stress forces river basins and their millions of inhabitants into a transition from a state of water abundance to one of water scarcity. While changes in the urban, energy and environment sectors continue to drive competition between sectors, it is the agricultural sector (already the largest consumer of water globally, with an estimated seventy per cent of total freshwater withdrawals) that will result in further inequities and environmental degradation (Molden/Lautze/Shah et al. 2010). Global water demand (measured as withdrawals) is likely to increase by approximately fifty-five per cent by 2050 because of growing demands from manufacturing (400 per cent), generation of thermal electricity (140 per cent), and domestic use (130 per cent) (UNESCO 2014), not to mention irrigation.

It would be useful to remember at this point that, even though forecasts may give an indication of the global situation, they can be misleading as data can be inaccurate, incomplete or outdated. Previous estimates have been wrong as they have depended on statistics from countries where the systematic collection of water use data has been rare, and where some water uses or needs have been unquantified or unquantifiable. It has been proved that improved management and conservation measures are able to offset population and economic growth (Gleick 2003).

Population growth, rising meat and dairy consumption and expanding biofuel production, among other factors, will continue to put pressure on the agricultural sector. Observations of the yields of major cereal crops have raised the concern that agricultural productivity may not be able to meet demand without major new investments in underperforming regions and without strategies to continue increasing yields in high-performing areas. The focus will be mostly on irrigated agriculture, taking into account the potential impacts of climate change (Scheierling/Treguer/Brooker, et al. 2014). For food and agriculture production and water used for irrigation, the FAO estimates for the 2005/2007–2050 period a growth rate in world consumption of agricultural products of 1.1 per cent per year, and an estimated increase in agricultural production of sixty per cent by 2050. Using optimistic assumptions, water withdrawals for irrigation are projected to increase by six per cent, from 2,761 km3 to 2,926 km3 (Alexandratos/Bruinsma 2012), adding to the already severe competition between uses and users of water.

There is a fragile balance not only between the water, agriculture and energy sectors, but between the users of each of these sectors. With regard to water for human use, in much of the developing world water supply and sanitation facilities are still not adequate or sufficient and untreated solid and liquid wastes are discharged and affect surface and groundwater bodies. In the case of the developed countries, most systems need to be improved as effectively as they were developed in the early twentieth century. According to the European Union, twenty per cent of all surface water in Western Europe is severely polluted; sixty per cent of all cities overexploit their groundwater resources; and fifty per cent of wetlands have "endangered status" because of groundwater overexploitation. Even where wastewater treatment has improved significantly since 1980, the percentage of the population connected to wastewater treatment is still relatively low in Belgium, Ireland, southern Europe and the accession countries. Overall, the wastewater infrastructure needs are so large that wastewater treatment is the largest category of the water industry, with thirty-five per cent of a water market currently worth US$500 billion annually (Stiehler/Vogel 2014).

Depletion of groundwater has lowered water tables in urban and rural areas in developing countries in the semi-arid and arid tropics, as well as in developed countries, causing subsidence in major cities, increasing salinity, and forcing numerous lakes and wetlands to run dry. Groundwater mining for potable use and mostly for irrigation has been documented mostly in arid and semi-arid regions of the world, including China, India, Pakistan, Mexico and Iran (Kumar/Scott/Singh 2013), where very large amounts of energy are required for surface as well as groundwater pumping.

This is the case in India, the largest user of groundwater and the fourth largest energy consumer globally. During the 2003–2004 period alone, around 12.8 million electric pumps with a total of 51.84 gigawatts (GW) of connected load consumed 87.09 billion kilowatt-hours (kWh) of electricity (Kumar/Scott/Singh 2013). Satellite-based estimates of groundwater depletion confirm unsustainable withdrawals in the north-west states of Rajasthan, Punjab and Haryana. Should this situation remain unchanged, some 114 million people in these states may be affected by potable water shortages and a reduction in agricultural outputs, leading, in turn, to extensive socio-economic stress (Rodell/Velicogna/Famiglietti 2010). Figure 31.1 shows groundwater changes during 2002–2008, with losses shown in red and gains in blue, based on GRACE satellite observations. According to the

Figure 31.1: Satellite-based estimates of groundwater depletion in India. **Source**: I. Velicogna, University of California, Irvine; at: <http://www.nasa.gov/topics/earth/features/india_water.html>.
National Aeronautics and Space Administration (NASA),

the estimated rate of depletion of groundwater in north-western India is 4.0 centimeters of water per year, equivalent to a water table decline of 33 centimeters per year. Increases in groundwater in southern India are due to recent above-average rainfall, whereas rain in northwestern India was close to normal during the study period.[4]

The findings of this study can be contested, however, as they indicate positive groundwater balance in north Gujarat and parts of peninsular India where problems of overexploitation of groundwater and aquifer mining have been studied and documented extensively. These studies are based on monitoring of water level fluctuations pre- and post-monsoon over a

4 See <http://www.nasa.gov/topics/earth/features/india _water.html>.

five-year time period (Central Ground Water Board 2005, 2012), which make them more accurate.

In the case of the United States, studies by NASA and the University of California (Castle/Thomas/ Reager et al. 2014) show that the water of the Colorado River Basin was over-allocated by at least thirty per cent in the 2004–2013 period. More than seventy-five per cent of the water loss calculated at 64.8 km3 since late 2004 was groundwater, used to fill the gap between the demands for all uses and users in the basin and the annual renewable surface water supply. The study showed that future water management scenarios that take into account population growth and climate change point to the inability of reservoir storage alone to meet the allocations in the basin. Groundwater depletion poses a significant threat to the long-term development of the region since as groundwater supplies reach their limits, the ability to supply fresh water during drought conditions or increase the gap between supply and demand will be severely constrained, posing "a greater threat to the water supply of the western United States than previously thought." (Castle/Thomas/Reager et al. 2014: 5910).

Ignored for decades, deterioration in water quality has become one of the most pressing problems facing the world, as it further accentuates problems of water scarcity. It has increasingly undermined global economic growth and worsened the physical and environmental health and the quality of life of billions of people because of point and non-point sources of pollution. Concerns about water contaminants that affect human health through drinking water include the presence of arsenic and fluoride that in some places occur naturally in groundwater. The main problem, however, is the billions of litres of untreated discharges that flow into water bodies every year all over the developed and developing world.

One example is China, where the economic, social and environmental costs of water pollution have been estimated at one per cent of *gross domestic product* (GDP) or approximately 150 billion yuan (World Bank 2007). Additionally, subsidence to a depth of several metres has been reported in cities such as Beijing, Tianjin, Shanghai, Taiyuan and Shijiazhuang, and in Shanxi and Hebei provinces. The damage to infrastructure in general caused by subsidence has been estimated to be 1.4 billion yuan. The extent of the potential negative impact of the overexploitation of water and the deterioration in the different sectors in general is so extensive that it threatens to undermine the economic growth of the country as well as the health and quality of life of billions of people.

As analytical procedures have improved, it has been possible to detect an increasing number of so-called emerging contaminants that are the result of human intervention. A range of human and synthetic hormones as well as pharmaceuticals and their metabolites are found in treated sewage effluents and this can have serious implications for drinking water. Countries with poor regulatory control of pharmaceutical manufacturing facilities may face serious problems in the future (Fawell/Ong 2012).

In sum, the current perceived water crisis all over the world is one of mismanagement with strong features concerning public governance. The global landscape of energy and food needs will continue to be strongly influenced by this mismanagement, where decisions are taken in isolation from requirements and from the influencing forces of other sectors. The obstacles to improving water management, which may impact negatively on the food and energy sectors in the future due to their interdependences and interconnectedness, are the same ones that have been identified for several decades: institutional fragmentation, weak legal and regulatory frameworks, poor multi-level governance, limited capacity at local level, weak allocation of roles and responsibilities among sectors and institutions, lack of cooperation between government institutions with common interests, funding gaps and questionable allocation of financial resources. Good and implementable policies and management practices are still needed, not only for the water sector but also for sectors such as energy, agriculture and environment, so that economic, social, and equitable development can be achieved in the long term (OECD 2011).

31.3   Energy Sources in a Changing World

Energy services are provided by converting primary forms of energy (e.g. coal, oil, gas, wood, wind, sunlight, uranium) to intermediate forms (e.g. electricity, liquid fuels) and these to a multitude of services (Wilkinson 2011). As global energy consumption continues to increase, by as much as fifty per cent by 2030, the demand for water supplies and resources will also grow concurrently. This will place the energy sector in greater competition with other water users for already limited resources in many regions of the world. The competition for water resources will impact on future energy development and could have significant impacts on energy reliability and energy

security in regions around the globe. The current trends in energy development could significantly increase the water footprint, rather than decrease it (Hightower 2012).

At present, electric power generation is one of the largest water withdrawal and use sectors in countries such as the United States and France, with the energy sector requiring levels beyond forty-five per cent of water withdrawn nationally (NETL 2011). Future energy developments such as biofuels, hydrogen, oil shale development, carbon sequestration and nuclear power could significantly increase water use and consumption and energize economic development. A major concern of gas shale development is the limitation imposed by access to reliable water supplies, as anywhere from eight to twenty-four million litres of water are required for hydraulic fracturing in each well (Mantell 2009). In the United States, the Bureau of Land Management (BLM 2008; Miller 2011) estimates that one to three barrels of water would be needed for each barrel of oil produced by in-situ extraction. Also, the water recovered after fracturing can be extremely high in salinity, presenting concerns not only about water quantity but also about the quality of wastewater (Hightower 2012).

Water availability has also proved to be a limiting resource for thermoelectric generation (NETL 2011; Hightower 2012), and permits to construct thermoelectric stations have been denied because of water-related considerations. Metals and mining, utilities production and supply and manufacturing segments are especially vulnerable to water scarcity as this would mean no electricity and no raw materials. Mining activities have been affected mostly in South America and African countries, where companies have opted to pull out due to high energy costs and competing water demands (Ernest/Young 2014).

Overall, the global landscape of energy consumption indicates nothing but an acceleration in growth. Global energy demand is expected to continue growing by more than one-third over the period to 2035, with China, India and the Middle East accounting for about sixty per cent of the increase and South East Asia emerging as an expanding demand centre. In 2013, energy consumption and production increased for every fuel type except nuclear power, at a rate below the ten-year average of 2.5 per cent, but still resulting in a growth in global CO2 emissions, though this also was below average (BP 2014). Emerging economies dominated global growth with eighty per cent of the global increase in energy consumption.

China once again had the largest growth increment followed by the United States (BP 2014).

Because of economic growth, China and India, together with the ASEAN countries,[5] have transferred the so-called global 'Centre of gravity' from the West to Asia (IEA 2013b: 15). The ten ASEAN member countries, whose combined GDP has increased by around three-quarters since 2000, resulting in increasing energy and water use, have very different patterns of resources use. Their individual policies on energy and water security, affordability and efficiency result from country-specific economic development and endowment with natural resources, as well as from political considerations. In all cases, energy security is driven by increasing reliance on imported energy; reduction of economic costs is linked to rising imports; and sustainability aspects of energy use are driven by concerns about local pollution. The ASEAN Power Grid and Trans-ASEAN Gas Pipeline are examples of collaboration but they are still a long way of implementation due to (for example) a lack of harmonization of technical and regulatory standards, the phasing out of end-user price subsidies, the guarantee of a third-party grid and pipeline access, and the establishment of a regional regulator (IEA 2013b).

The dynamic growth of the Chinese economy and energy demand is reshaping global energy markets with implications of global reach which are not totally understood at present. Together with India, China drives the growing dominance of Asia in global energy demand and trade, and, together, they are building approximately forty per cent of new generation capacity (IEA 2013a). China, the second largest economy in the world, is planning to add 1.2 terawatts (TW) of water-resilient power capacity by 2030, equivalent to 5.9 times India's current installed generation capacity. China is also planning to add 453 GW of coal-fired power capacity by 2020, in many cases in water-stressed areas, further increasing competition for water. By 2030, some eighty-seven per cent of power capacity will still require water for cooling and generation, down from ninety-seven per cent in 2012 (Chan/Robins/Knight 2012). This expansion will place further stress on water resources unless efficiency is greatly improved. Hydropower is also at risk from changing water availability brought about, for

---

5   The International Energy Agency uses the terms *ASEAN* and *South East Asian countries* interchangeably. These include Brunei Darussalam, Cambodia, Indonesia, Lao PDR, Malaysia, Myanmar, Philippines, Singapore, Thailand and Vietnam.

example, by more frequent and more extreme droughts and floods. Energy efficiency is as important as water efficiency because using less energy would reduce demand for power and alleviate some of the water stress. The question remains as to whether there is enough water to fuel China's power expansion.

The rise of unconventional oil and gas and of renewables, both important components of national energy programmes, is transforming our present understanding of the distribution of the world's energy resources. Unconventional oil and gas, or resources with atypical geological locations and that require a specific set or production techniques, include, among others, shale gas. Shale gas has the potential to displace fossil fuels and potentially slow the development of renewable sources. It also has the potential to turn countries that traditionally import natural gas into producers, making them more self-sufficient in domestic supplies. A clear example is the United States, with vast reserves of natural gas commercially available. Shale gas represents at present forty per cent of total natural gas production, a fact reflected in a lower market price for natural gas and that has changed the geopolitics of oil globally. Together with China, the US is expected to join the top tier of producers, allowing both of these major energy consumers to reduce their demand for coal and ultimately for oil (Shell International BV 2013).

Unconventional natural gas and oil resources are not free of criticisms. These relate to the challenges associated with the availability and use of surface water and groundwater for hydraulic fracturing; migration of stray gas and potential effects on overlying aquifers; and contamination of surface and groundwater. Science, technology and policies still have to develop these resources in a manner that is environmentally safe.

There is the question of when or whether the world will achieve an energy system based on one hundred per cent renewable resources. This may be feasible in theory but there are too many societal, political, technological, geographical and market-related concerns that make it improbable and perhaps not even desirable. The first challenge is the geographical location of the renewables resource base, which is frequently a long way from the centres of energy demand, often in different countries or continents. Furthermore, the absence of substantive investment for research and development compared with conventional generation and the fact that such resources still depend on subsidies have significantly reduced their impact (Shell International BV 2013).

Biofuels are not a new concept but the scale of production that is currently proposed is unprecedented. This is expected to more than triple by 2040, representing eight per cent of global demand for road transport fuel, if it is not affected by the cheaper availability of natural gas. Biofuel policies have created and supported a new demand for traditional food crops and this has triggered a cascade of impacts on food, agriculture and energy systems as well as land and water resources, not all of them sustainable. One example is the European Union, whose targets cannot be fully met using only EU domestic biomass. EU biofuel policy has thus triggered the creation of an increasingly globalized market for biofuels and biofuels feedstock, relying on agriculture in developing countries, mostly in Latin America and Asia. At the same time, such production must conform to 'sustainability' criteria (e.g. the Fuel Quality Directive and the *Round Table on Sustainable Biofuels* (RTSB). This is not always the case as it has the potential to influence food prices, further degrade land and water resources and limit access to natural resources for small landholders (HLPE 2013).

Table 31.1 shows the regional production and consumption of total biofuels in 2011. It indicates that the largest consumer and producer of biofuels (including biodiesel and ethanol) is North America (mostly the United States), followed by Central and South America.

Table 31.1: Regional production and consumption of biofuels, 2011. **Source:** Adapted from HLPE (2013). This information is originally from the US Energy Information Administration/ International Energy Statistics, available at: <http://www.eia.gov/>.

Oceania	6	6
Eurasia[a)], Middle East and Africa	0.2	0.2

a) The U.S. Energy Information Administration defines Eurasia as follows, see http://www.eia.gov/tools/glossary/index.cfm?id=E.

A main question is whether biofuels are a possible solution to the challenges posed by demand for fuel.

This is not a simple question and it is unclear what the impacts will be when biofuels become a significant part of agricultural production in any country, as the demand for certain crops will increase whether they are used for food, feed or fuel. This will have consequences for the production of other crops and for the use and distribution of scarce resources all along a diversity of supply chains. Policy and market decisions to stimulate such a large conversion towards biofuels are risky since understanding of the direct and indirect consequences is still uncertain. The interconnectedness of the world markets has shown that decisions taken with regard to agricultural production and use in one area might have enormous impacts on others as they can affect both supply and price (Stattman/Bindraban/Hospes 2008).

Global investment to supply populations with energy is of the order of US$1,600 billion annually. It has more than doubled in real terms since 2000 (IEA 2014). Some additional US$53 billion of investment is required in energy supply and efficiency to move the world on to a 2°C path away from fossil fuels and towards renewables, *carbon, capture and storage* (CCS) and nuclear power. The caveat is that fossil fuels will continue supplying much of the energy used worldwide and will still do so in 2035. This has enormous implications in terms of climate change as electricity demand is expected to increase by 4.2 per cent per year on average until 2035 (Stattman/Bindraban/Hospes 2008).

For energy production, water withdrawals in 2010 were of the order of 580 *billion cubic meters* (bcm), of which 70 bcm were consumed, with the power sector accounting for over ninety per cent of the total amount (IEA 2012). This indicates the strong dependence between water and energy. In the New Policies Scenario of the Organisation of Economic Cooperation and Development (OECD) and of the International Energy Agency (IEA), withdrawals will increase by about twenty per cent between 2010 and 2035 and consumption will rise even more, by eighty-five per cent. These trends will be driven by a shift towards power plants that are more efficient and have more advanced cooling systems where withdrawals will be reduced but consumption per unit of electricity produced will increase, and by expanding production of biofuels (table 31.2).

Given the projected rise in energy demand and the growing burden on natural resources, energy savings can be a very important and cost-effective source of additional energy supply, as well as having a beneficial effect on water resources (Wilkinson 2011). The so-called *Energy Efficiency* (EE) market is expected to deliver substantial economic gains. For example, investment in EE technology by 2020 could reduce energy consumption in the EU by 250 megatonnes and in the US by 200 megatonnes (Burchardt/Hering/Klose et al. 2014). Challenges that need to be addressed include enhancing national policy coordination and regulatory frameworks, eliminating market distortions, encouraging the financing of energy efficiency projects, improving capacity building and data collection and monitoring, and evaluating the effectiveness of energy efficiency policies (IEA 2013).

The future of energy and thus of water in the world depends on the interplay of economics, social issues, pricing, technology and policies, as well as on political considerations. Demands in Asia, for example, are expected to grow at more than twice the global average, because of strong economic growth and rapid urbanization. Sustained and sustainable growth will require strong policies that are implementable and that encourage the adoption of the best management practices and available technologies to improve energy efficiency and thus improve effective water use (IEA 2013a).

There is a changing energy landscape as the energy future for which we need to plan will happen in an exceptionally different political landscape in the twenty-first century. Trying to think through energy futures while dealing with the pressing problems of energy resources and prices as well as food security and climate change is particularly difficult. To this complexity is added the fact that both developed and developing countries lack energy policy frameworks. Instead, there are energy policy conclusions that are drawn from environmental policies, such as the focus on renewables, and which are not based on environmental considerations but often depend on the requirements of market competition policy (Stattman/Bindraban/Hospes 2008).

Developing an energy system that meets climate targets, sustainable development objectives, and energy, food and water security concerns is a massive challenge. We still have to learn from the individual through to the institutional level that decisions about the ways we produce and use energy cannot be made without regard to wider concerns. Energy system development must be an integral part of sustainable development (Stattman/Bindraban/Hospes 2008).

31.4   The Next Phase of Globalization— The Role of Food

Food security will be one of the most important political topics of the twenty-first century. The FAO has said that food production must increase by seventy per cent in order to feed 9 billion people globally by 2050 (FAO 2011). This increase is needed because of the rising incomes and living standards of the largely urbanized middle classes in Asia. Food security has been a crucial topic throughout the history of humankind. As 'the father of the green revolution', Norman Borlaug, stressed in his Nobel Prize acceptance speech in 1970, "civilization as it is known today could not have evolved, nor can it survive, without an adequate food supply". Yet the development of food security affirms that it encompassed a wider notion of development. While agricultural development was important, food security addressed far wider social, political and economic developments. Since Europe was central to the global economy in the past centuries, the development of food security in Europe will be analysed first.

The pessimist Thomas Malthus predicted as early as 1798 that population growth would outstrip available food supplies, leaving (European) countries with nothing but starvation. Influenced by the dark experiences of the sixteenth and seventeenth centuries when farmers were unable to supply growing urban populations, Malthus foresaw deeper structural problems. However, although Malthus has been repeatedly quoted in history (e.g. by the Club of Rome in the 1970s), his sombre predictions were always nullified by the ability of farmers to produce more for growing populations. This was due to wider economic, political and social developments. European farmers increased their food output by up to 1000 per cent in the past 200 years due to reflexive governance by governments and societies in Europe. Mercantilism and agricultural markets that forced landowners to rethink their strategies replaced the old feudal systems. As a result, newly imported staple food crops such as potatoes from North America were introduced in the seventeenth and eighteenth centuries and allowed farmers to supply growing urban populations with much-needed additional staple foods (Kiple 2000). Another major shift in food security policy occurred in the

nineteenth century. At first, agricultural imports from colonies in Asia and Africa permitted the European upper and later middle classes to consume more diversified and affluent diets. The end of colonialism in the twentieth century marked another evolution in food security policy. Agricultural trade increasingly contributed to domestic food security in Europe (Allan 2011). Food security was thus by no means limited to agricultural development but involved wider socio-economic shifts.

However, the most important gains were achieved during the twentieth century. Technological improvements brought about by research and development in Europe and North America increased agricultural outputs. The introduction of fertilizers, improved seeds and irrigation enabled farmers in the rich, Western part of the world to produce more food. In particular, the period after the Second World War saw a period of unprecedented agricultural growth. Governance complemented technological improvements. While America introduced the Farm Bill, and with it agricultural subsidies, during the Great Depression of the 1930s, Europe followed by pooling the agricultural policy of western European states in the 1950s. Europe's cooperation echoed the advent of a liberal functionalist paradigm of food security. This governance shift resulted in an over-supply of crops culminating in the butter mountains and milk lakes of the 1980s and 1990s. North American farmers further expanded their production capacities from the 1940s onwards to supply the world with US staple crops (McMichael 2009).

The successful shift in governance to producing more food also affected wider policy areas. The United States used this outcome of over-supply as part of their bargaining power in foreign policy in the 1970s to contain import-dependent regions such as the Middle East and countries in the former Eastern bloc around the Soviet Union (Woertz 2013). The Carter administration even issued a food export ban on the Soviet Union after the invasion of Afghanistan by the Soviet army in 1980. This had a decisive impact on the US farm sector. American small farms went bankrupt and this led to larger farms operated by fewer farmers (Paarlberg 1980). This laid the foundations for another shift in agricultural governance in the United States. As farm sizes grew, enabling economies of scale, food became increasingly commercialized. As a result of a power shift from small farmers to agribusiness, supermarkets took over increasing parts of the food supply chain. As food supply chains became longer and more sophisticated, supermarket

chains such as WalMart or Carrefour took over from small retailers in providing consumers with fresh food. The enormous outputs of farmers and a strategic subsidization of fodder crops such as wheat and soy in both North America and Latin America allowed the meat and dairy industry to supply more meat and dairy products to consumers (Keulertz 2013). At the same time, eating out in food outlets has increasingly become the norm in most Western countries since the 1980s. In sum, the commercialization of food provided a bullish market for the unprecedented growth of the food sector (McMichael 2009).

The food sector responded to wider shifts in development in the Western world. Farmers increasingly produced cheap food for more diversified economies. Technology played one part, consumer demand and governance of the food system another. Despite stagnating middle-class incomes since the 1970s, economies of scale derived from better technology and improved on-farm and off-farm supply chain management kept food prices low and thus demand growing (Keulertz 2013).

Farmers and agribusiness responded to increasing demand through ever-increasing yields that were quickly absorbed by the market. The size of the global food market was estimated at US$4.21 trillion in 2009 compared to US$3.7 trillion in 20005 (and it is estimated to have grown to US$5 to 7 trillion by 2014). Fresh food accounted for 52.6 per cent of the total value. Packaged foods contributed the rest. The reasons for the rapid expansion of the food market are seen in the economic growth of the first decade of the century alongside population increases that boosted global food consumption. A large part of this growth was driven by increasing prosperity in emerging markets, which have expanded faster than their counterparts in the developed world (Alpen Capital, 2011). However, climate change will severely test the resilience of the food system. As land endowed with water resources is already a very valuable resource, the food system may have to be prepared for systemic shocks that may have a number of effects. Although the role of North America, Australia and Europe remains strong, global economic change in favour of Asia has triggered a new round of food politics specifically related to food trading houses. Traders are of particular importance as they directly liaise with farmers to purchase, store and ship their produce. In 2003, seventy-three per cent of traded agricultural commodities were handled by only four multinational companies: Archers Daniels Midlands, Bunge, Cargill (all from the United States) and Louis Dreyfus (France)

(Keulertz 2013; Murphy 2012). All four companies not only trade the majority of bulk commodities in their home markets but have also acquired market leadership in Latin America and Australia.

31.5   You Can't Build Peace on Empty Stomachs

A pivotal moment for the future reliability of the global food system was the price shock that cast a shadow over the global food system at the end of the first decade of the new millennium. The food price spikes of 2007/08 and 2010/11 reminded decision-makers around the world of the centrality of food in state security. Highly volatile global commodity markets signalled to decision-makers that the food question embedded highly systemic risks for future development (Woertz 2013). Without adequate and reliable access to food, emerging economies could be trapped. As the first general director of FAO, Lord John Boyd Orr, stated, "You can't build peace on empty stomachs" (Borlaug 1970).

It is therefore clear that in a world that will hold 9 billion human beings by 2050, there are significant risks to future food supply and possibly peace *across the globe*. The current and future net exporters are located in water- and land-endowed regions such as Brazil, eastern Europe, Australia and Central Asia. These countries and regions could be pivotal for future peace. The risk areas are those regions affected by high population growth and/or natural resources constraints, such as the Middle East and North Africa, and South and East Asia. The only region that is notably different is sub-Saharan Africa, where food security is uncertain despite the ample availability of land and water resources.

31.6   Countries and Regions with a Positive Outlook

Russia, for example, seeks to utilize its opportunities in this next phase of globalized food. Russia seeks to become the leading wheat producer by 2019 using state capital by fostering the *United Grain Company* (UGC) that invests in farmland along the 'Chernozem belt' (the belt of highly fertile Black Earth soils that stretches from the Ukraine to Siberia). The ambitious goal of this venture is to export 200m tonnes of wheat by 2019. This has enabled Russia to curry favour with import-dependent countries such as Egypt

to which it supplies approximately forty per cent of wheat imports (Woertz/Keulertz forthcoming). Russia also plays a central role in another grain hot spot of the world, the Black Sea region. This region has been a target for investors since the mid-1990s, primarily by Western agribusiness, because it is one of the major agricultural growth zones of the world. With output increases of approximately four per cent per annum, the Black Sea region is expected to export 80m tonnes of grains by 2019 (Marshall 2014). It is expected that the *Middle East and North Africa* (MENA) region will absorb most of these production gains, providing investors with unique market opportunities if both regions achieve political stability.

In Latin America, on the other hand, the agricultural transformation process started during the 1960s and 1970s. Initially largely supported by Western capital (note, for example, that Cargill is the biggest agribusiness company in Argentina because its company policy is to re-invest the profits of its national branches in the market of origin), Latin America is today the biggest soy producer in the world (WWF 2014). Soy is especially important as it is used as animal feed across the world to keep the *proteinization* of diets in place. Europe and Asia are seen as the main destinations of Latin American soy (WWF 2014).

The final continent that has been able to grow and market its food in the global political economy is Australia. China has become one of the key markets for agricultural exports from Australia during the past fifteen years. In addition, Australia enjoys trade opportunities through the *Asia–Pacific Economic Cooperation* (APEC) trade agreement with the United States and the European Union, which has enabled the Australian agricultural sector to utilize opportunities for trade with a region associated with high population and economic growth. As a result, Australia's total agricultural goods and service provisions grew from AUS$3.5 in 1967 to AUS$301.5 billion in 2013 (DAFF 2013). The main commodities that have underpinned growth are wine, fisheries, meat and dairy, staple commodities, fruits and vegetables. At the same time, Australia has become a sought-after target country for agricultural investment from regions faced with water and/or land shortages. The situation of countries that seek farmland in countries like Australia is markedly different. These are seen as the losers in the new round of food globalization.

31.7 Risk regions and countries

The *Middle East and North Africa* (MENA) is a region that since the 1970s has effectively run out of the water needed to achieve self-sufficiency in food (Allan 2003). The tragic political developments in the MENA region in the past decades have also taken their toll with respect to agricultural production. Only 3.9 per cent of MENA arable land is under cultivation, in part due to conflict, in part due to water scarcity (Al Masah Capital 2012). The MENA region imports approximately half of its required food from other world regions (World Bank, 2008). In terms of US dollars, the bill for food imports is projected to reach US$92.4 billion by 2020 (Al Masah Capital, 2012). Rising food prices and poor public budgets have already contributed to social unrest, as seen during the Arab Spring in 2011. Thus, the MENA region will be hit hardest of all the regions in the world when trying to meet future food security goals.

India and sub-Saharan Africa face similar food security concerns. However, India's cultural preference for 'green proteins' has allowed the country to take a less aggressive stance in the global market. Sub-Saharan Africa has shared a similar fate to the MENA region. High population growth and persistent severe poverty will translate into severe food security concerns in the coming decades. However, in theory, sub-Saharan Africa enjoys readily available water and land resources that could be made more productive to feed the continent (Binswanger 2009).

The other major food importer is China. At the advent of the 'Asian century', it is clear that food controlled by Western agribusiness has the potential to limit Asia's future growth. In an attempt to decouple itself from the Western world, the population giant of the world, China, has traditionally pursued a strategy of food self-sufficiency (Brautigam 2013). However, China's food security strategy has markedly changed during the past ten years. China can no longer feed its population through domestic food production. In particular, industrialization has taken its toll on food production. The Chinese have not only become more affluent, but the natural resources of the country have been decisively directed towards energy. For example, China's focus on coal has led to significant pollution of groundwater resources. It is estimated by the Beijing government that sixty per cent of China's groundwater is polluted. Fifteen per cent of the groundwater cannot be used as potable water (World Bank 2007).

The response by China has been a largely unnoticed paradigm shift. Through the Chinese state food company CofCo, the Republic of China has become increasingly active around the world. For example, China purchased the largest US pork producer, Smithfield, in 2013 (Koons/Venkat 2014). In addition, CofCo has launched a joint venture with agricultural traders in Asia such as the Noble Group, in order to increase its global food footprint (Koons/Venkat 2014). In terms of sales, the Noble Group is already larger than the US trader ADM. Yet Noble still mainly acts as a buyer on the global market. In contrast to Western traders, Noble still needs to establish relationships with farmers across the world. Thus, China's food security will depend on the development of cooperation with farmers around the world.

31.8 The Next Phase of Development in Practice: The Pivotal Role of Africa

Sub-Saharan Africa is the only region in the world where food supply can be significantly increased for both domestic and international consumers. By expanding the area under cultivation, which is currently less than half of its arable land, sub-Saharan Africa could become a crucial region for global peace. For this reason, sub-Saharan Africa is a major region of concern for domestic and international investors as well as for Western and Eastern development agencies seeking to increase food production. However, sub-Saharan Africa's farming sector faces wider development challenges. In particular, social, political, economic and cultural factors make food production in sub-Saharan Africa challenging. With a strong feature of smallholder agriculture dominated largely by female subsistence farmers or pastoralist family farmers, food output has lagged significantly behind other world regions (Keulertz 2013).

In addition, sub-Saharan Africa's infrastructure is in need of multi-billion dollar investments, including both on- and off-farm investments. Potential 'food bowls' such as Nigeria, Ethiopia, the Democratic Republic of Congo, Tanzania, South Sudan and Mali have either experienced long and devastating internal or external wars and conflict or have poor governance systems in place. Nevertheless, sub-Saharan African countries have seen global interest in their farmland resources since the mid-2000s (Deininger/Byerlee/ Lindsay et al. 2011; McMichael 2011). Estimates of farmland acquired range from thirty to sixty-two million, but only a tiny proportion of this assumed investment has been made operational. For a while, China

was regarded as the major investor in African agriculture. What was by some labelled as 'land grabbing' was deconstructed by analysts with field experience (Brautigam 2013; Woertz 2013). Instead of investing in land and water resources, China has pursued a different, broader development approach.

Although the data is highly opaque, researchers have analysed media reports about China's aid to sub-Saharan African countries. They analysed 1,673 projects that appeared in Chinese, African and international media. In contrast to previous widely-held assumptions, only eighty-three projects were associated with the energy sector, and forty-four were in mining. Instead, the largest Chinese investments were made in the health/government/society sectors and in transport (Strange/Parks/Tierney et al. 2013). This underlines China's wider engagement with Africa, which reflects the fact that Africa is not merely a source of natural resources for China, but also a market for finance, manufacturing, and construction. It is further assumed that thirty per cent of transport projects in Africa are financed by Chinese public and private sector companies (Lancaster 2014). Transportation infrastructure is especially important for the agricultural sector, as it allows farmers to access markets such that their produce remains fresh and edible. Whether or not China will attempt to transform Africa's agricultural sector through direct investment in agriculture remains an open question, but China seems to have learned a lesson from its Western counterparts by understanding how the development of infrastructure is vital to achieving sustainable development on all sides.

A recent initiative by China and its economic allies has signalled a further shift in the global political economy of development. On 15 July 2014, representatives from Brazil, Russia, India, China and South Africa signed an agreement to establish the New Development Bank, seen as a direct countermeasure to the Western-led World Bank. The goal of the new bank is to raise US$100 billion over time to directly fund infrastructure projects in developing countries (Bax 2014). Such a move could tip the global balance of power towards the newly emerging economies in Asia, Africa and Latin America. The lessons of this initiative are directly drawn from the Western model that emerged in the days when the primary sector of the economy was predominantly in the hands of the nobility. It took Europe and America several centuries to produce the immense amounts of food used in foreign political and economic relations. The new Asian century may see a similar model emerging within a

few decades, in which a wider model of development to achieve food security will be pivotal. It could be nothing less than the next phase of globalization, yet this time created by Asian economies instead of by Europe and North America.

31.9   Innovation and Partnerships as the Way Forward

Concerns about the impact that the deterioration of the environment and resource scarcity can have on the livelihoods of billions of people and on all productive sectors have prompted a series of partnerships and innovation initiatives. An increasing number of private sector groups, UN and international organizations, *non-governmental organizations* (NGOs), universities and environmentalists are working towards the common goal of sustainable development and the promotion of peace, stability and human security. Innovative ideas, processes and products focused on conservation and efficiency are being promoted all over the world, reliable data is being collected and cutting-edge technology is being developed, although the necessary policies for their implementation in the longer term are still lagging behind.

Traditional partnerships as well as previously unthinkable ones between the private sector and international organizations and NGOs are being developed by different actors at different scales for the common good. And they are delivering higher outputs than expected. A change of mindset on the part of all actors that encourages them to work together has proved beneficial on the road towards sustainable development (SustainAbility 2014).

A growing number of mostly multinational companies are embracing sustainability policies and practices as integral components of their business models. Water and energy risks are being considered by financiers, investors and companies as a core feature of capital expenditure plans. They are also much more aware of water quotas and pollution targets as their aim is to make operations more efficient, and they are examining the effects of potential water shortages on facilities located in water-scarce provinces.

Companies still aim to achieve the normal goals of continuous profitability and growth but many are also looking to concurrently create social and environmental benefits in the communities within which they operate. Development led by the private sector has been essential in creating numerous communities of interest between producers, factory workers, consum-

ers and stakeholders, with the objective of bringing about sustainable rural development in the developing world. Evidence-based research shows that the private sector can make a major impact in improving the human environment, contributing to social progress through the alleviation of poverty, and increasing the standards of living of millions of people, as well as making a profit (Biswas/Tortajada/Biswas-Tortajada et al. 2014; Biswas-Tortajada/Biswas 2015). As for resource use, many companies are increasingly managing their own water needs and looking for trade-offs along their entire production chain, as well as taking responsibility for the protection and conservation of ecosystems that supply fresh water (see, for example, ILSI 2013).

Decisions taken have the potential to scale across supply chains all over the world multiplying sustainability gains and benefitting large populations. These initiatives are essential for the future water, food and energy needs of the world. Examples include agricultural water management; watershed restoration, protection and payments programmes; eco-compensation models; water funds; green infrastructure investments; alternative management choices for terrestrial, freshwater and marine ecosystems; the Water Risk Atlas (analysis of water risks in terms of quantity, quality, regulatory and reputational risks); development of water markets; water quality trading; and environmental impact bonds (SustainAbility 2014).

In the past decades the water and energy sectors have seen several major technological breakthroughs. Membrane technology has developed to the point where desalination is commercially viable and where wastewater can be treated to convert it to drinking water quality. Anaerobic and biological technologies have greatly improved the sustainability and cost-effectiveness of wastewater treatment. Network monitoring and modelling technologies have reduced water losses in piped water supply systems and allowed the optimization of water resource systems. Drip and micro-irrigation solutions have reduced agricultural water consumption.

The strength of new forms of energy and especially water will be the direct result of strong policies but also of social acceptability. For Singapore, within very strong policy and monitoring frameworks, in addition to communication strategies that have resulted in social acceptability, desalinated water and highly-treated reused wastewater (NEWater) are able to supply up to twenty-five percent and thirty percent of total demand for the city-state respectively for non-direct potable, commercial and industrial uses. There

are plans to augment the capacities of both sources of water to supply up to eighty per cent of Singapore's total water demand by 2060 (Tortajada/Joshi/Biswas 2013). Australia is another country that has planned for the use of desalinated water and recycled wastewater for human consumption, but has not achieved social acceptability for this last one. In the case of desalinated water, one of the largest schemes, the 232,000m3/day Western Corridor Recycled Water Project in Queensland constructed during the Millennium Drought, has now become non-operational because it is no longer necessary following the end of the drought. Several cities in the United States as well as Windhoek in Namibia have developed schemes for direct and non-direct potable use of reused water, all with immense energy implications (Lahnsteiner/Lempert 2007; EPA, at: <http://www. twdb.texas.gov/publications/shells/WaterReuse.pdf>). One way or another, cities and countries are looking for additional resources for their continued development.

The rise of unconventional water, oil and gas and of renewables will continue transforming our present understanding of the distribution of the world's energy resources and, most importantly, has the potential to make countries more resilient to the changing environment if policy mixes are developed that take into account the interconnectedness of related sectors. Administrators would do well to consider the water, food and energy sectors among their policy priorities.

31.10   Conclusions

This chapter has framed water, energy and food security in a wider developmental context. It has shown that all three types of security cannot be understood without placing them in a wider conceptual and historical framework of past and future developments. Water, energy and food security will be unquestionably at the heart of the development challenges of the twenty-first century. However, given the interlinkages between the three sectors, only integrated approaches will yield successful management outcomes. Within this challenge of integrated decision-making lies the need for policy-making. All three sectors are decisively characterized by the paramount role of public policy. People in charge of 'statecraft' had for long not worried about natural resources management and in particular water was seen as a 'free' and abundantly available resource. Yet 'business-as-usual' approaches will no longer suffice in the decades ahead. On the contrary, new policy frameworks that promote policy-

making outside policy silos will be required to achieve security in all three sectors. The profound environmental and economic changes the world is facing will no longer allow one-dimensional approaches. It will be up to decision-makers to understand that change is inevitable but that it also holds tremendous opportunities. If rightly addressed, those opportunities will yield economic development and prosperity for an unparalleled number of human beings.

The notion of water, energy and food needs, demands and securities within a framework of sustainable development is not new, but it is being recon-sidered in the current challenging environment, and invites closer scrutiny. A shared understanding of the challenges is needed as a basis for multi-stakeholder collaboration. This has increasingly been recognized as the most effective way to address global risks and to build resilience against them. However, bringing a very diverse group of stakeholders to the table is not an easy task, as the ill-fated meetings of the Conference of Parties (COP) demonstrate annually. Getting decision-makers to overcome silo thinking is key to achieving new policy outcomes. It is indeed the mega-challenge of our time.

32 Sustainability Transition in a Vulnerable River Basin in Mexico

Úrsula Oswald Spring[1]

Abstract

This chapter examines a transition process in a river basin in the central part of Mexico that is highly affected by climate change, social deterioration and the drugs war. The *Yautepec River Basin* is particularly prone to climate impacts because of its abrupt slopes, numerous affluents, and high population density in its floodplain, which is frequently exposed to hurricane impacts. Taking into account laissez-faire policies, illegality, government corruption, and public insecurity in a region with high levels of dual vulnerability (environmental and social), as well as subject to hazard impacts, the chapter reviews the constraints of the process of transition towards sustainability, especially when the goals of the people and of the government are not identical. People organized themselves regionally in order to simultaneously increase public security and freedom from hazard impacts, which both directly affect life and livelihood. Using original survey data, the study examines the risks perceived by the people and the ways in which they reduce these risks of extreme events, as well as how they cooperate with the authorities to improve environmental conditions, to enhance disaster risk reduction activities and to reduce the impact of criminal acts. The transition process requires the integration of numerous social, economic, political, environmental, judicial, cultural and mental factors in order to develop processes and resilience from the bottom up to deal with this complex emergency, as well as to force the different levels of government to enhance all four aspects of the human security of the people: 'freedom from fear', 'freedom from want' 'freedom from hazard impacts', and 'freedom to live in dignity'.

Keywords: Sustainable development, engendered and sustainable peace, Anthropocene, peace concept, patriarchy, civilization, empowerment, equity, values, cultural identity.

32.1 Introduction, Objectives, Research Question, the Scientific Approach and Methods

This chapter examines a transition process in a river basin in the central part of Mexico that is highly affected by climate change, social deterioration and the drugs war.[2] Mexico as a country and the *Yautepec River Basin* (YRB) in particular are particularly prone to climate impacts. They Yautepec River emerges from the glacier of the volcano Popocatepetl at an altitude of 5,450 metres and its basin extends outwards as far as the Federal District of Mexico and the states of Morelos and Mexico (figure 32.1).

The study region depends for its agriculture on a supply of water from the monsoon and from irrigation. The topography consists of high mountains and a wide floodplain, with two dominant ecosystems: pine-oak and low-lying dry deciduous forest, whose trees lose their leaves during the dry season. The climate is influenced by both oceans, and because of the steep mountains the region is extremely vulnerable to flash floods, soil erosion and periodic droughts. People also suffer periodic eruptions of the volcano Popocatepetl and other geophysical hazards such as earthquakes, which are frequent in the region. As well as erosion caused by logging, which is in the hands of organized crime, the mountain part of the basin (Los Altos) is also losing topsoil, and all the affluents are being eroded. Together, these natural and illegal phenomena have caused environmental vulnerability aggravated by poverty, socio-economic stagnation and poor public services (education, health, water, poverty

1 Prof. Dr. Ursula Oswald Spring, full time Professor/Researcher at the National University of Mexico (UNAM) in the Regional Multidisciplinary Research Center (CRIM); Email: <uoswald@gmail.com>.

alleviation, etc.), together with a high degree of government corruption (Oswald Spring 2014a: 151 ff; Bogardi, Oswald Spring, Brauch 2016).

Organized crime has taken further advantage of this situation and involved underemployed and unemployed young people in illegal activities. Drugs are produced and to some extent also consumed in the region, which is also affected by other illegal activities such as drug production, trafficking, kidnapping, extortion and also logging in the national parks. The result is an increasing dual environmental and social vulnerability in a region where law is almost non-existent (98.5 per cent of crimes are not punished, Acosta 2011: 79) because of inadequate investigations and corrupt judges. This has resulted in the loss of the legal right to defence, public insecurity, high homicide rates and a deterioration in environmental and social conditions.[3]

32.1.1   Objective of the Study

The chapter studies possible alternative pathways for a process of transition to sustainability in the face of laissez-faire policies, illegality, government corruption, and public insecurity in a region with a high level of dual vulnerability (environmental and social) and which is subject to extreme events. The social and environmental vulnerability of the people means there is a dual constraint on the process of transition towards sustainability. The goals of the people and of the government in this process are not identical. Government activities are uncoordinated, and this offers opportunities for corruption, where some government depart-

ments protect organized crime. The people want both public security and freedom from hazard impacts, both of which directly affect life and livelihood. Thus a transition process would require major changes to the numerous existing social, economic, political, environmental, cultural and mental constraints imposed by federal government on the people exposed to the problems. Confronted by the lack of action from the top down, and the absence of the rule of law, people are developing processes of resilience from the bottom up to deal with the complex emergency[4] and to force the different levels of government to enhance their human security (Adger, Pulhin, Barnett et al. 2014) as exemplified by 'freedom from fear' and 'freedom from hazard impacts' (Brauch 2005a).

32.1.2   Research Questions

How have the federal, state and municipal governments responded (top-down) to this dual vulnerability in the YRB? How can a bottom-up social organization in cooperation with the three levels of government reduce the hazard impacts of flash floods and droughts, in order to make safe life and livelihood and at the same time find a way to reduce corruption, reduce organized crime and create sustainable jobs? What worries people most? What have been the obstacles and constraints that have prevented and slowed down the implementation process and how could they be overcome? How can an integrated basin management reduce government corruption and organized crime and take advantage of the opportunities offered by the business community to improve the living conditions of the people of the YRB?

32.1.3   Structure of the Chapter

The chapter is divided into seven parts. After this introduction, part 32.1 explains the quantitative and qualitative methodology. Part 32.2 describes the study

3   Transparencia International (2014); at: <http://www.transparencia.org/>; Human Rights Watch (2014).

4   Unicef (1997) defined complex emergency as as "any situation in which the lives and well-being of children are at such risk that extraordinary action, i.e. urgently required action beyond that routinely provided, must be mobilized to ensure their survival, protection and well-being." (See E/ICEF/1997/7 and 15.) IASC (1994) defined it as "a humanitarian crisis in a country, region or society where there is total or considerable breakdown of authority resulting from internal or external conflict and which requires an international response that goes beyond the mandate or capacity of any single agency and/or the ongoing United Nations country program."

area and defines the key scientific concepts of transition goals, dual vulnerability, disaster risk reduction and management, complex emergencies, and resilience. The third part examines the complexity of the river basin and its environmental, social, and political constraints within a contradictory social arena[5] in the region. Part four discusses how social actors cope with these multiple threats, the socio-environmental activities developed by the authorities and the people, the struggle against organized crime, and the resultant agenda for a sustainable transition. Using original survey data, part 32.5 analyses the risks perceived by the people and the way they reduce these risks of extreme events, and how the authorities cooperate with them to improve environmental conditions and to enhance *disaster risk reduction* (DRR) activities. In part 32.6, data on public insecurity in Mexico, the state of Morelos and the river basin are analysed, together with proposals for resilience-building against flood and drought within a context of organized crime and public insecurity. The concluding part (32.7) suggests as a possible outcome an integrated river basin management scheme (IWRM; GWP 2009), together with a reconstruction of the social tissue[6] and the development of policies and practices geared towards a process of sustainable transition.

32.1.4 Scientific Approach and Methods

This chapter is based on original empirical data that were collected and analysed by a multidisciplinary research group at the *National Autonomous University of Mexico* (CRIM/UNAM). This research group compared the activities of different actors; it reviewed the arena of environmental and social threats, assessed the policy agenda in response to dual vulnerability (environmental and social) and the complex emergency in the river basin, and it put together activities carried out by the people to deal with both environmental and social problems.

The scientific background of the research project was multidisciplinary: ecology, anthropology, psychology, geography, demography, and development studies (Adger, Pulhin, Barnett et al. 2014). The research group compiled quantitative and qualitative data using participative observation, semi-structured interviews, focus group discussions, in-depth interviews, and examination of official databases. The survey was conducted in three phases between 2010 and 2013, guided by the research questions.

The full research included three random surveys of 3,955 persons: after the great flood in 2010, later in 2012, and finally in 2013 to assess the impact of the floods in the YRB (table 32.1). In-depth interviews were conducted with local leaders, politicians and key people in the communities and in the state of Morelos. The results from both quantitative and qualitative data together with partial analysis were discussed with the affected communities and authorities. During the fieldwork, participant observation was used, five focus group discussions were conducted, and several participatory rural studies were carried out on water security (Oswald/Brauch 2015), desertification, garbage management, migration, and government support. The research group also explored local social movements and developed comparative regional studies of the processes of adaptation and resilience that women heads of household had developed when, in the absence of their partners, they were confronted with floods, droughts and soil degradation and desertification. During four years of fieldwork, the research

---

5 The term social arena was developed by Pierre Bourdieu (1993) and refers to a field in which agents and their social positions are located. Each particular agent develops activities in the field, which is a result of interactions between existing and created rules of the field, the habitus of the agent and their social, economic, political and cultural capital. In this social arena people manoeuvre to get the necessary resources to achieve their interests. The arena works like a market in which actors compete for resources and benefits. Education and culture together with existing resources, social representations, social classes and economic position play a crucial role in the activities that each agent may develop. Competition and alliances depend on the available types of capital, how they contribute, their history within the arena and their ability to adjust to the rules of this field. Bourdieu (1988) introduced the term habitus, which is to be understood as the subjective system of predispositions and expectations acquired by past experiences which facilitate manoeuvring in the arena and define the activities that strengthen the interests of the actors.

6 Social tissue refers to a set of social relations that increase the cohesion of individuals, consolidate social groups and support social rights. Neo-liberalism has created important contradictions (unemployment among youth, elimination of older workers, increasing poverty, informal economy, etc.), but economic factors do not account entirely for the satisfaction of societies. Improving social relations among individuals may mitigate some of the problems created by dominant and exclusive globalization. Social relations based on confidence and mutual support may improve the ability to live together among social groups with similar interests and create social tissue.

team obtained sensitive information using both quantitative and qualitative methods. After the 2010 floods, corrupt disaster management by the three levels of government obliged the authorities to form the Citizen Council of the Yautepec River Basin, in which several researchers became actively involved. This meant that the research group was not only able to understand adaption and resilience processes but also the sociopolitical limits existing in the whole river basin, as well as the context of organized crime.

Table 32.1: Representative survey in the Yautepec River Basin (YRB). **Source:** Field research (CRIM/UNAM 2010–2013).

Phases of survey	Persons	Families	Percentage of women
First phase	1,440	385	49%
Second phase	2,515	634	51%
Third phase	415	100	57%
Total	4,370	1,119	51%

The communities developed different strategies to deal with the increasing threat of floods and droughts, as well as with deteriorating public security. As a citizen member of the Yautepec River Basin Council, the author had direct access to the representatives of the three levels of government, their reactive and preventive behaviour, and to the data concerning investments from the *National Disaster Fund* (Fonden) as well as government investment in the prevention and mitigation of natural hazards and societal disasters.

32.2 Location and Conceptual Considerations: Dual Vulnerability, Disaster Risk Reduction, Disaster Risk Management, Complex Emergencies and Sustainability Transition

What is the goal of sustainability transition not just in a single community, but also within the whole study region, where institutional, environmental, political and security constraints first of all limit the survival of the people and then limit their attempts to improve their livelihood and to build resilience in order to reduce their dual vulnerability? In this chapter transi-

tion towards the goal of sustainable development is understood as a systemic process with positive and negative feedback, where various actors intervene at different levels. All these actors claim to promote sustainability, but cooperation among the three levels of government and with the people affected is inefficient because of the lack of agreed agendas based on the needs of the people affected and because of government corruption. It is also very hierarchical since most of the investment comes from the federal level in the pursuit of national interests and is not adapted to specific regional conditions. Instead of being used to alleviate the high levels of poverty, the budget is primarily used to maintain an extensive and expensive government bureaucracy in a country where functions are often duplicated at state and local level. The bureaucracy is mainly interested in keeping its jobs, power, and incomes after each election, and so the problems of the people have to wait until the next electoral period. Meanwhile the social, political, and environmental conditions become worse and the interaction between the natural and sociopolitical conditions becomes more and more complex and contradictory. Thus, the transition process is blocked in most sectors and during a disaster its progress is erratic. Public infrastructure is rebuilt with money from the Mexican Disaster Fund (Fonden), and people's livelihoods recover slowly thanks to public and private support and at a rate depending on the severity of the impact. Public security fares worst because of the presence of organized crime and local delinquency. For this reason it is impossible to speak of a change in the landscape (Grin/Rotmans/Schot 2010), but various developments indicate a gradual movement towards change and towards an increase in the social tissue in this contradictory political arena.

The study area of the *Yautepec River Basin* (YRB) is located in central Mexico and represents a bridge between the Atlantic and the Pacific, between the towns of Oaxaca and Toluca, and between Acapulco and Mexico City. This central location has meant an increase in the pressure from organized crime, with different criminal cartels competing with each other following the assassination of the kingpin leader Arturo Beltrán Leyva.

32.2.1 The Study Area

The research area of the YRB is in the centre of Mexico (figure 32.1). It covers the complete areas of fourteen municipalities and parts of five more, giving a total of nineteen municipalities, four in the state of Mexico

Figure 32.1: Location of the study area in the central part of Mexico. **Source:** The author.

(Juchitepec, Atlautla, Ozumba, Tepetixtla, Amecameca), thirteen in Morelos (Totolapan, Tlalnepantla, Tepoztlán, Tlayacapan, Juitepec, Atlatlahucan, Yautepec, Tlatizapan, Tlaquiltenango, Jojutla, Zacatepec, Cuautla, Huitzilac), and a small part of the mountain area of Milpa Alta in Mexico City (figure 32.2). In hydrological terms, the YRB rises from the glacier of the volcano Popocatépetl (5,452 m) and receives hundreds of tributaries and springs from the neovolcanic axis (Chichinautzin 3,476 m; Tepozteco, Ajusco, Sierra de Juchitepec, etc.). Most of the northern part of the basin is located in national parks (Popo-Ixta; Corredor Biológico Chichinautzin, Tepozteco) and the centre and south lies in the Biosphere Sierra de Huautla, El Texcal, Sierra Montenegro, and Las Estacas. Along with dozens of small intermittent tributaries, six sub-basins (Nexpayosutla, Gorge Totolapan, Atongo-Apanquetzalco, Dulce, Tepexi, Apatlaco) converge in the Yautepec floodplain. These rivers recharge the aquifer of Yautepec-Cuautla and supply water to the metropolitan region of Cuautla, the second largest economic region in the state of Morelos (figure 32.3).

32.2.2 Goals of the Transition Process

The governmental goals of the transition process are to get rid of the environmental threats, to overcome the existing poverty, and to reduce the floods in the densely populated floodplain, where the most important agricultural, industrial and service activities are located. During the monsoon the threats to the people are linked to periodic flash floods, and during the

dry season in the agricultural sector they mean lack of water for agricultural and domestic activities.

The people complain about the lack of jobs in the industrial and service sectors, the high cost of living, and especially about threats related to organized crime, where homicides, kidnapping, extortion, prostitution, rape, trafficking of women[7] and drug trafficking are leading to loss of life and livelihoods. This means that the transition process is starting simultaneously on different tracks, since temporary emergencies trigger government actions that limit the implementation of a more stable medium-term strategy. For the people, public insecurity, extreme events, and poverty place limits on a systemic process of development and a transition to sustainability from the bottom up. In this precarious situation, periodic disaster impacts not only constrain a rapid recovery, but also constrain investment for the future and resilience-building. On the other hand, kidnapping and extortion may consume all assets accumulated over a lifetime (savings, homes and means of transport). Frequently kidnapped people are found dead despite having paid the ransom, and so social rage is increasing and people have started to take justice into their own hands.[8] Environmental and social vulnerability are interlinked with public insecurity and threats to life and livelihood. The four pillars of human security (freedom from fear, from want, from hazard impacts and the free-

dom to live in dignity; Brauch 2005a, 2005b) are frequently threatened.

---

8 In Atlautla, basically a peasant community with an incipient urban development, three policemen were lynched, after months of extortion, when they arrested two elderly peasants who were collecting dead wood for cooking. In the mountain area of Guerrero, 132 indigenous communities organized their security through a communitarian police force and built the organization CRAC-PC (Coordinadora Regional de Autoridades Comunitarias-Policías Comunitarias) to protect themselves against organized crime and corrupt police.

32.2.3   Dual Environmental and Social Vulnerability

The dual vulnerability concept (Bohle 2001, 2002) combines environmental and social factors in a scenario of *Global Environmental Change* (GEC) and destructive globalization (Held/McGrew 2007; Calva 2012a; figure 32.4). Environmental vulnerability influences both climate variability and climate change, resulting in floods and drought and the loss of soil fertility by erosion and desertification. Further, the scarcity and pollution of water and the loss of ecosystem services (MA 2005) and biodiversity may trigger disasters, environmentally-induced migration (Oswald Spring 2013; Oswald Spring/Serrano/Flores et al.

Figure 32.3: Complexity of the river basin. **Source:** The author.

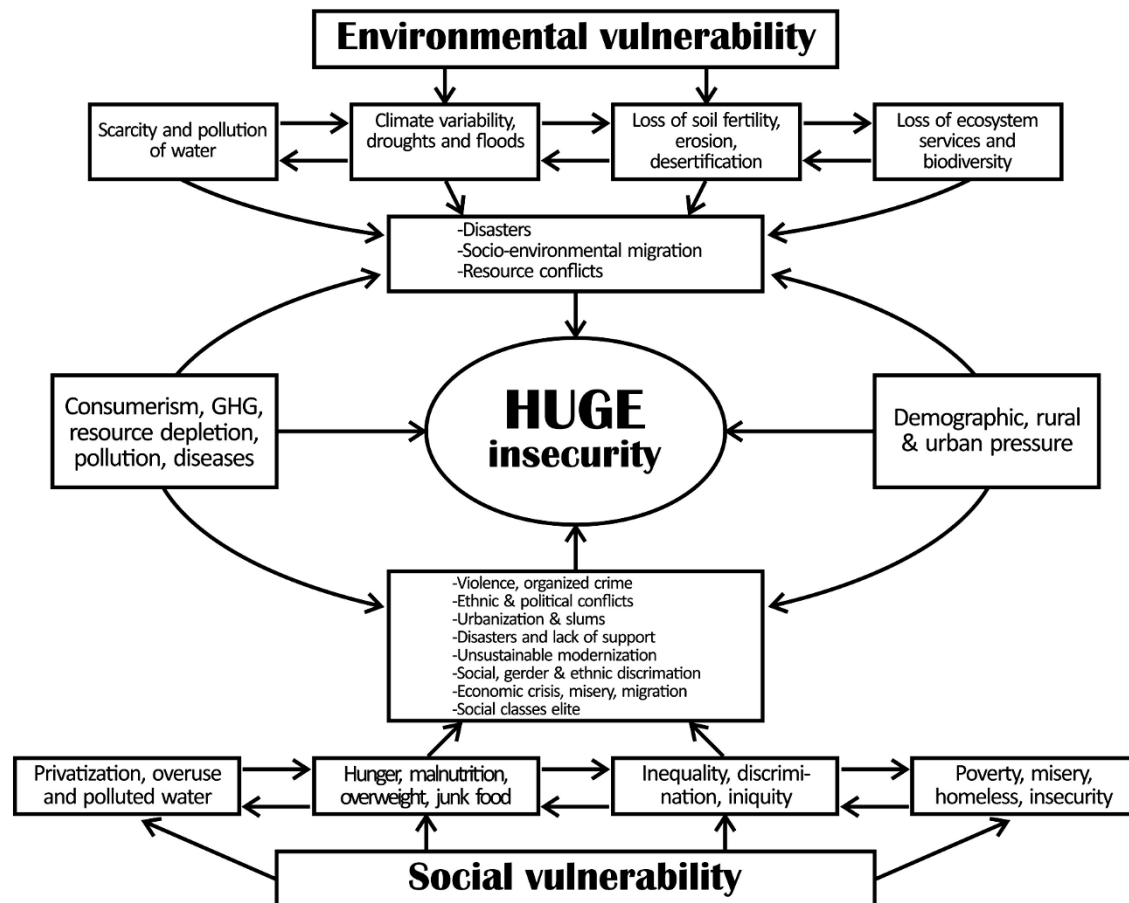
2014), and resource conflicts (Homer-Dixon 1999; Bächler 1998).

Local and regional disasters aggravate the loss of fertile soil, trees and clean water and have increased conflicts over access to natural resources (UNISDR 2013). In the YRB the Spaniards transformed the irrigated floodplain into sugar cane fields, and land grabbing forced peasants to fight, first with Morelos in 1810 against the colonial power, and then in 1910 with the Southern army and Emiliano Zapata against private landlords and sugar mills. During the last two decades, urban landlords have also been converting natural and agricultural land into urban estates in the mountain areas, where the difficult natural conditions caused by the steep-sided volcanoes have caused the fragile soil to further deteriorate and have increased water scarcity during the drought season.

A number of economic crises (1976, 1982, 1988, 1994, 2007–2014; Solis 1973; Sunkel/Paz 1993) and the lack of local jobs and income have confronted an increasing number of families with a survival dilemma

(Brauch 2008; Oswald/Serrano/Flores et al. 2014). In the whole region, the precarious living conditions have forced most families to send one or more members to work in the cities or to migrate to the US. Their remittances have alleviated poverty, and in many cases women who were left behind have become heads of households (Oswald 2013). They have thus become responsible for economic and educational activities and often also for agricultural production, besides taking care of their extended family. This excessive workload has often increased their social vulnerability. In the YRB, twenty-seven per cent of households have a woman as head of household, and these generally experience high levels of poverty because of lack of education and work opportunities.

According the concept of dual vulnerability, environmental vulnerability is the result of physico-chemical changes in the atmosphere produced by intensive use of fossil fuels, which have increased the threat of climate change. Rivers, lakes, seas, groundwater and wetlands become polluted and water from the aqui-

Figure 32.4: Dual vulnerability. **Source:** Adapted by the author from Bohle (2002).


fers and the surface is overexploited. In the lithosphere, shallow soils on steep slopes are easy prey for wind and water erosion and thus lose their potential to sustain the natural vegetation, wildlife and ecosystems, as well as agricultural activities in the highlands, while riverbeds and urban areas have been flooded with mud and sludge. Most of these negative environmental processes affect crop and livestock yields.

These environmental changes have been primarily caused by human intervention into the earth system since the industrial revolution, but especially since the 1950s, through the intensive use of fossil energy, the rapid increase in greenhouse gas emissions into the atmosphere, changes in land use, deforestation, and the pollution and warming of the seas and the diversion of rivers. Taking into account all these anthropogenic interventions into the earth system, Paul Crutzen (2002, 2011) observed a transition in earth history from the Holocene to what he has called the Anthropocene, as a result of anthropogenic *climate change* (CC). According to the Intergovernmental Panel on Climate Change (IPCC 2007, 2012, 2013, 2014), the

direct physical effects of CC include a rise and greater variability in temperature (extreme heat and cold), changes in precipitation, a rise in sea level and an increase in extreme weather events. Higher variability in the monsoon and the interaestival drought in August, together with less rain and more heat, accelerate the process of desertification, resulting in the loss of natural soil fertility and biota. Most ecosystems cannot cope with these fast-changing natural conditions, and once the food chain is affected, wildlife is drastically reduced. The loss of ice in the polar regions and glaciers produces a rise in sea level, which exacerbates coastal erosion and causes seawater intrusion into the coastal aquifers. Warmer seas and sea level rise increase the amount of moisture in the atmosphere and generate more and stronger cyclones and droughts. Both phenomena are becoming more extreme (IPCC 2012, 2014), and in Mexico and Central America extreme weather events have also occurred more frequently (INECC 2012). In the YRB, extreme temperatures, hurricanes, flash floods, drought and hail are the changes related to climate

variability, particularly affecting the peasants with rain-fed agriculture, but also traders and people living near the river.

In Mexico and in the YRB, the deterioration and pollution of natural resources has reduced the income and well-being of the people affected. Social vulnerability has increased, due to neo-liberal processes of privatization (Calva 2012a; Stiglitz 2010; Rosas 1996) of water and public services, and the Washington Consensus (Held 2004). The service has rarely improved, but prices have increased. As jobs are rare and often badly paid, people change their diet from nutritious to junk food, often containing sugar, fat, and other carbohydrates (ENSANUT 2013). Health conditions have worsened due to obesity, and Mexico has the second highest incidence of diabetes and the highest incidence of child diabetes mellitus (SS–DGE 2013). Changing environmental conditions are increasing water-borne diseases, especially dengue fever and more recently chikungunya, as well as gastro-intestinal illnesses following floods (WHO 2013).

In Latin America, Mexico and Honduras were the sole two countries where poverty was not reduced between 2008 and 2013 (CEPAL 2013) The lack of job opportunities, especially for young people, with eight million young people known as 'ninis', that is, lacking education or jobs, is exploited by organized crime which seeks to involve these unemployed people in criminal activities (Human Rights Watch 2014; Serrano/Oswald Spring/ de la Rúa 2015). In the YRB the situation is worse. Almost thirty per cent of households are headed by women, with high levels of poverty. In 2014, the municipality of Yautepec had the highest rates of rape and women trafficking, the second-highest rate of extortion, and the fourth-highest of kidnapping, and is among the ten municipalities in Mexico with the highest rates of armed robbery (SNSP 2014). These economic, social and security reasons, together with gender inequity, racism and ethnic discrimination, aggravate the difficult socio-economic conditions (Oswald Spring/Moreno/Tena 2014). They have forced people to migrate (Oswald/Serrano/Flores et al. 2014) or to escape poverty through illegal activities (Jaime/Tapia/Goode et al. 2010). Thus social vulnerability is reinforcing environmental destruction, but also social *anomie* (Durkheim 1999), often triggered by disasters.

There is no doubt that environmental and social vulnerability has increased, especially among social groups that depend on natural resources for their survival (in the study area, peasantry with rain-fed land affected by climate change in the mountain regions).

They lack social capital, understood by Bourdieu (1983: 21) as

> the aggregate of the actual or potential resources which are linked to the possession of a durable network of more or less institutionalized relationships of mutual acquaintance and recognition—or in other words, to membership of a group which provides each of its members with the support of collectively-owned capital, a 'credential' which entitles them to credit, in the various senses of the word.

The lack of institutional support and also, because of migration, family support, reduces people's capacity to overcome obstacles (Land/Hannafin 1996), limits the use of other types of capital (Sen 1995), and limits mechanisms for the resolution of conflict (Reychler/Paffenholz 2001; Lederach 1983). Thus, Perona and Rocchi (2008: 1) define social vulnerability as a "status of risk, of difficulty, which disables and overrides, now or in the future, the capacity of affected groups to meet their welfare requirements—subsistence and quality of life—in specific socio-historical and cultural contexts".

Villagrán (2006: 12) analysed dual vulnerability and distinguished between *socio-environmental perspectives* (lack of or inadequate management of the natural environment); *theories of empowerment* (social vulnerability prevents people with little or no education from optimizing existing resources, demanding their rights or improving their living conditions); and *political-economic phenomena* (where inequality, class structure, mechanisms of exploitation, discrimination, and violence rooted in the patriarchal system produce exclusion, exploitation, and conflicts between social groups and the government).

32.2.4 Disaster Risk Reduction and Disaster Risk Management

Disaster risk reduction (DRR) is defined by UNISDR (2009: 10–11) as the "concept and practice of reducing disaster risks through systematic efforts to analyse and manage the causal factors of disasters, including through reduced exposure to hazards, lessened vulnerability of people and property, wise management of land and the environment, and improved preparedness for adverse events". In response to intensive extreme geophysical and climate events, an *international strategy for disaster reduction* (ISDR) has been developed, based on the *Hyogo Framework on Action* (UNISDR 2007), to assist and promote cooperation among governments, civil organizations and private actors in order to better understand extreme events and to stop these natural conditions resulting

in disasters through lack of knowledge or the absence of systems for early warning, and through preventive evacuation and mitigation and adaptation to the different natural conditions of the environment. All these processes require knowledge of the risks, systematic monitoring, analysis and forecasting of hazards, and dissemination and mass communication of warnings in order to alert all potentially affected people and to create local capacity to respond effectively to the warnings.

Disaster risk management (DRM) is defined as "the systematic process of using administrative directives, organizations, and operational skills and capacities to implement strategies, policies and improved coping capacities in order to lessen the adverse impacts of hazards and the possibility of disaster" (UNISDR 2009: 10). DRM is oriented towards avoiding, reducing or transferring through insurance the adverse effects of hazards.

The IPCC (2014) has said that besides mitigation, adaptation is crucial in preparing people to proactively adopt measures and actions for the prevention of disasters. Extreme events cannot be avoided, but negative outcomes in terms of loss of life and livelihoods can be reduced through preparedness and early warnings (Villagrán/Pruessner/Breedlove 2013). Often disasters without an early warning can seriously affect people's survival and trigger political responses (Basher 2005). The price hike of basic food in 2007–2008 was instrumental in causing worldwide hunger riots. Physical violence may act as a trigger in existing conflict situations (Schneider 2008), e.g. those existing in the Middle East, or due to the drug war in Mexico (Human Rights Watch 2014). The disappearance of forty-three student teachers in September 2014 led Mexicans to protest in the streets and demand a prompt judicial enquiry by the authorities.

32.2.5   Complex Emergencies

Complex emergencies refer to "a humanitarian crisis in a country, region or society where there is total or considerable breakdown of authority resulting from internal or external conflict and which requires an international response that goes beyond the mandate or capacity of any single agency and/or the on-going United Nations country program" (Oxford Pocket Dictionary 1992).[9] Complex emergencies create massive impacts on human security, increase difficulties for reconstruction and produce extensive violence and loss of life and livelihoods (see earthquake in Haiti; González 2011). As a result, groups of refugees

try to escape the violence, and this means that within the country or in the neighbouring countries large-scale and multifaceted humanitarian assistance is required (Sudan; USAID 2013). The financial, military and political constraints often limit this humanitarian assistance, especially when there are security risks for humanitarian relief workers (e.g. in Syria; IFRC 2013). Emergencies may be created by natural, epidemiological or technological disasters aggravated by conflict, and they disrupt family life and community services and overwhelm the coping capacities of the governments, societies and people affected (Brauch/Oswald Spring/Mesjasz et al. 2015). A complex emergency may initially result from natural or human-made causes, but is outcomes may be magnified by political or military crises.[10]

---

9 The International Federation of Red Cross and Red Crescent Societies (IFRC) [at: <https://www.ifrc.org/en/what-we-do/disaster-management/about-disasters/definition-of-hazard/complex-emergencies/>] states that "some disasters can result from several different hazards or, more often, [from] a complex combination of both natural and man-made causes and different causes of vulnerability. Food insecurity, epidemics, conflicts and displaced populations are examples. A humanitarian crisis in a country, region or society where there is total or considerable breakdown of authority resulting from internal or external conflict and which requires an international response that goes beyond the mandate or capacity of any single agency and/or the on-going UN country program (IASC). Such 'complex emergencies' are typically characterized by:
   - extensive violence and loss of life;
   - displacements of populations;
   - widespread damage to societies and economies;
   - the need for large-scale, multi-faceted humanitarian assistance ;
   - the hindrance or prevention of humanitarian assistance by political and military constraints;
   - significant security risks for humanitarian relief workers in some areas.

   The World Health Organization (WHO) defines complex emergencies as "situations of disrupted livelihoods and threats to life produced by warfare, civil disturbance and large-scale movements of people, in which any emergency response has to be conducted in a difficult political and security environment." See: WHO 2002: *Environmental health in emergencies and disasters: a practical guide.* According to WHO: "Complex emergencies combine internal conflict with large-scale displacements of people, mass famine or food shortage, and fragile or failing economic, political, and social institutions. Often, complex emergencies are also exacerbated by natural disasters"; at: <www.who.int/environmental_health_emergencies/complex_emergencies/en>.

32.2.6 Resilience

The concept 'resilience' was initially used in physics and was later adapted by psychologists. The IPCC (2014) uses the definition of the Arctic Council (2013), namely "[t]he capacity of a social-ecological system to cope with a hazardous event or disturbance, responding or reorganizing in ways that maintain its essential function, identity, and structure, while also maintaining the capacity for adaptation, learning, and transformation" (Arctic Council 2013). UNISDR (2009: 24) refers to "[t]he ability of a system, community or society exposed to hazards to resist, absorb, accommodate to and recover from the effects of a hazard in a timely and efficient manner, including through the preservation and restoration of its essential basic structures and functions". In this sense resilience refers to the ability to recover from a shock, whenever the impact of the hazard, and the capacity of the community, internal and external help and the economic situation of the people affected play a crucial role.

32.3 Structural Data on Vulnerable River Basin in Mexico

The state of Morelos has a historically high population density of 364 persons/km² (INEGI 2011), second only to Mexico City and the state of Mexico, the *Metropolitan Valley of Mexico City* (MVMC). This is the result of a favourable climate and favourable environmental conditions that allowed indigenous people to develop irrigated agriculture in the floodplain of the Yautepec as early as three thousand years ago. They produced corn, cotton, chillies, beans, tomatoes and other fruits and vegetables (Maldonado 1984; Mentz 2008), and Cortés introduced sugar cane. This long-standing human impact on the fragile environmental conditions of the mountains, an area of steep slopes, a long dry season, a monsoon from June to October which supplies rain-fed agriculture with water and recharges the aquifers, meltwater from the high volcanoes, and more recently climate variability and climate change, has resulted in a severe deterioration of environmental conditions (Cruz/Delgado/Oswald Spring 2015).

But the floodplain with its deep soils did not experience a loss of soil fertility, and after more than five hundred years of intensive exploitation for sugar cane,

soil fertility is still high, although an increasing area has suffered from land use changes. In 2015, half of the territory of the YRB was used for agriculture, livestock and urban development.

32.3.1 Complexity of River Management Facing Multiple Disasters

Flash floods have increased in the YRB as a result of changes in land use from forest to agriculture and then to urban settlements. Both problems have been further aggravated by logging in the highlands which has had a major impact in the form of the erosion of tributaries and its effect on sedimentation in the valley. Deforestation and change in land use have also reduced the infiltration of rainfall, and with stronger tropical depressions and hurricanes flash floods have increased because of the lack of infiltration of water in the highlands. In 1985, a severe flood caused several deaths and was considered by the authorities and also by older people to be a once-in-a-hundred-years disaster. But in 1998 (a severe Niño year), the YRB and the municipality of Yautepec were flooded once more, and again in 2003. Since 2010, the plain has been flooded every year, and twice in 2010, when at the entrance of the town the river rose twenty-one metres in less than half an hour and flooded the town and the communities downstream (Oswald Spring 2012). During 2013, there was no flood because the river was dredged and some river banks reinforced, despite the double cyclone Ingrid-Manuel, which left 2.5 metres of sediment in the Nexapa derivation dam. But in 2014, due to a lack of preventive behaviour by the three levels of government, five flash floods occurred. All tributaries and the main river together with the four diversion dams were filled with sediment, making them unable to absorb the excessive water from several hurricanes in the Pacific. The YRB faces serious environmental (32.3.1), social (32.3.2) and political (32.3.3) challenges.

32.3.2 Environmental Challenges

In the study region, during the summer the volume of water in the YRB rises due to the melting of the glacier of Popocatepetl and due to tropical depressions and hurricanes. As a consequence, flash floods increasingly threaten life, livelihoods and productive activities, but in addition the natural conditions have worsened, since flash floods tear up trees, rocks and sediment. About 89 per cent of the natural forests has

---

10 Master 2 Action Humanitaire Internationale, accessed 07/12/2014 at: <ahio6.files.wordpress.com/>.

disappeared, and only 11 per cent of the original forest survives (table 32.2).

Table 32.2: Land use changes in the YRB. **Source:** Field research (CRIM/UNAM 2010–2013).

Land use	Area (km²)	Percentage
Agriculture	634.6	50.7
Grassland/livestock	68.3	5.5
Secondary vegetation	372.2	29.7
Forest	112.1	9.0
Dry tropical forest	24.6	2.0
Urban	22.7	1.8
Without vegetation	9.1	0.7
Bodies of water	4.4	0.4
Desert scrub	1.5	0.1

Land use change, deforestation, erosion, extraction of timber and soil, land and water pollution by agrochemicals and human and animal waste have caused the beautiful landscape to deteriorate and have increased environmental vulnerability in the basin (Oswald/Jaramillo 2012). Rain-fed agriculture in the mountains of the north and south of the YRB is highly affected by the variability in rainfall. Agriculture that depends on the monsoon has declined from 10,000 ha in 2009 to less than 9,000 ha in 2012. The pressures caused by flash floods, droughts and more irregular midsummer (interaestival) drought have negatively affected crop yields. Lack of water and irregular rains have also forced subsistence farmers to leave their land, both in the highlands and in the Sierra Madre del Sur. After several years of bad harvests and due to a lack of seeds for the next harvest cycle, whole families have left, in order to escape extreme poverty (Oswald/Serrano/Flores et al. 2014). In the irrigated areas in the central valley, these climatic variations have not affected agriculture, and during the past decade 43,000 ha have been regularly planted each year. Irrigation therefore has become an effective adaptation strategy in a region with high rainfall variability.

What are the concerns of the people who suddenly face changing environmental conditions and how are they responding? According to the survey by Oswald, Serrano, Flores et al., thirteen per cent of the people complained about an excess of water (mostly urban dwellers), while fifteen per cent complained about a shortage of water (basically peasants). The farmers also mentioned longer periods of drought (30 per cent) and irregular rains (42 per cent), in a region where warm temperatures and extreme cold in the

Altos document the impacts of climate change (INECC 2012).

With regard to risk perception, the survey indicated that 62 per cent of the inhabitants feared a lack of water, 26 per cent were afraid of floods and 12 per cent of crop losses. In the mountains, all inhabitants were afraid of a lack of water, while in the river plain over half feared flash floods. In the whole basin 12 per cent mentioned the loss of crops. Thus regional differences and perceptions related to agricultural or service activities influenced their perceptions of risk. When asked about ecological conservation, 45 per cent answered that no natural resources were conserved, 22 per cent mentioned the good quality of air, 20 per cent water and 13 per cent forests and rivers.

In the valley, perceptions differed because the natural ecosystems were different. In the Altos environmental conservation is better, though organized crime is now logging in the protected national parks, where there is limited government control. Thirty-three per cent of the inhabitants also mentioned problems with waste management, 28 per cent the lack of water (Altos), 15 per cent air pollution (around the sugar cane factory in Zacatepec), and 20 per cent other environmental problems, such as the invasion of natural areas, changes in land use, hunting, and clandestine logging; all of them have resulted in a degradation of ecosystem services. This important environmental vulnerability triggers social problems. Lacking clean water and suffering crop failures, families lose their income and food. The absence of income from agriculture increases poverty and social vulnerability.

Environmental and social vulnerability affects the YRB through the loss of biodiversity, which is related to the deforestation of pine-oak forests and especially of the deciduous forest (Maldonado/Ortiz/Dorado 2004; Arias/Dorado/Malddonado et al. 2002; Rzedowski 1973). This environmental deterioration creates additional pressures on social aspects of life, especially with the decline in hunting and gathering of plants, fruits and roots. The loss of corn crops and pasture for livestock in the eroded southern Sierra Madre, together with extreme hydro-meteorological hazards, has forced the people to migrate (Oswald/Serrano/Flores et al. 2014) and in Lorenzo Vázquez, a village in the southern Sierra Madre, two-thirds of the families have at least one emigrant member in the US.

32.3.3   Social Challenges

In terms of social vulnerability, Coneval (2013), the national Mexican institution for poverty evaluation,

has stated that nationwide 53.4 million (45.5 per cent) members of the population are living in poverty, and 11.7 million in extreme poverty. ENSANUT (2013) indicates that 53.8 per cent of children and young people between 0 and 17 years do not have enough food. Babies under one year suffered higher levels of deprivation: 27.5 per cent lacked access to health services and 28.2 per cent faced moderate to severe food insecurity. In addition, 54.6 per cent were in poverty, compared with 50.1 per cent of children aged between 12 and 17 (UNICEF 2014). In 2013, of 20.2 million young people, 7.34 million (OECD 2012) were also considered 'ninis' (neither in education nor work). Youth unemployment accounts for 44.7 per cent (ILO 2013). In December 2012, among young people between 20 and 24 years of age, about 1.31 million were without jobs (INEGI-ENOE 2013). The situation among college graduates is particularly difficult: only 70 per cent have found jobs, and of these only four out of ten have a job related to their studies.

The indigenous population in Mexico has the highest poverty rate with 72.3 per cent, compared to the national average (45.5), and rural (61.6) and urban (40.6) populations. They suffer from low income, shortfalls in education, health, social security, housing, food and utilities. Half of the population lacks access to health services, 28 million are hungry, 23.2 million are educationally backward, and 17.1 million lack a home of decent quality. Hence only 23.2 million people (19.8 per cent) suffer no disadvantages (Coneval 2013). In the YRB more than eighty per cent of the rural indigenous population lives in poverty, and in El Pañuelo, a migrant indigenous community from the Mountain of Guerrero, 84 per cent of the women cannot read or write. They are generally 'sold' for marriage at twelve years of age and their life is the most precarious in Mexico, because they live in the poorest municipalities of Mexico.

32.3.4 Political Challenges and a Complex Social Arena

The sugar cane region was historically an active participant in the economic and political struggles of the country. In the state of Morelos, the sugar cane workers were actively involved during the Independence of 1810 and during the revolution of 1910. Social nonconformity is common in the region of the YRB. Environmental vulnerability has also exacerbated local conflicts, especially in the valley, where the control of water and access to irrigated land and wells is crucial

for income and for the export of downstream (Oswald Spring 2012).

Traditional relationships have facilitated corruption and allowed local oligarchies to grab these resources. Nowadays, export agribusiness needs water, while sugar cane still uses water highly inefficiently. Conflicts also exist in the rural villages with limited water services. In several communities empowered women have struggled to control the water service and succeeded in allocating more water to poor people (Oswald 2013). Existing conflicts have increased the uncertainty of access to water and increased the social vulnerability of the disadvantaged, whose lack of income is exacerbated by the country's global socioeconomic situation (Calva 2012b) and the lack of public support.

However, the main political conflict today is related to government agricultural policy, where rural subsidies have been dramatically reduced and basic food prices adjusted to international market prices through NAFTA (the *North American Free Trade Agreement*), and imports of subsidized basic food crops from the US (2013: 16 million tonnes) have increased with no compensatory mechanisms for poor peasants.

Poverty, migration and the absence of conditions for survival have increased among the half of the population with the lowest income, while at the same time the wealth controlled by the top fourteen per cent has increased. The Mexican Study on Household Income and Expenditure (INEGI–ENOE 2008, 2010, 2012) noted important changes in the Gini coefficient in the state of Morelos, which first increased to 0.467 in 2008 (before the effects of the crisis were felt at household level) but then declined to 0.408 in 2010 because of the crisis and because of organized crime, then increased again to 0.425 in 2012. In terms of income, in 2008 the lowest ten per cent of the population earned about 7,950 real pesos (M$), in 2010 M$ 5,272 and in 2012 M$5,562, while the highest strata (ten per cent) spent M$ 222,047 (2008); M$ 117, 980 (2010); and M$ 141,680 (2012) real pesos.[11] The average values of M$ 53,702 (2008); M$ 34,426 (2010); and M$ 38, 666 (2012) therefore do not reflect the living conditions of the people but rather an enormous difference.

In our research area, 44.7 per cent of people live in communities with very high and high levels of mar-

---

11 Real or deflated pesos eliminate the impact of inflation and permit a stable basis of comparison. In 2014 one dollar was equivalent to an average of 12.8 Mexican pesos.

Figure 32.5: Flood over bridge in the centre of Yautepec. **Source:** Photograph taken by Civil Protection, Yautepec, during the 2010 flood.

ginalization, 19.3 per cent with regular levels, and only 13.6 per cent in communites with low standards of poverty. This social inequality has created social resentment, and when the minimum income is not adequate for survival, families explore additional sources of revenue, often in the illegal sector. Therefore, in the YRB the crime rate, especially for kidnapping and extortion, has increased. People no longer trust their neighbours, and they trust the local authorities even less. Crimes are not reported in case local politicians might be involved. Out of every ten kidnappings, a police officer is involved in eight (Segob 2014; INEGI 2014).

32.4   Sustainability Transition from the Top Down and from the Bottom Up

The flood of 2010 in particular affected economic activity in the central market of the municipal capital of Yautepec. River defences, bridges, drinking water pipes, the sewage system and the wall of the market were destroyed by the flood, together with many

houses (figure 32.5), and other municipalities were also flooded. Many people lost their income, furniture, domestic animals, water supply and drainage facilities. The authorities managed the emergency situation with a lack of transparency and people lost trust in the authorities. This resulted in bottom-up initiatives to prevent future corruption in the rebuilding process.

32.4.1   Social Actors in the River Basin

After the disaster of 23 August 2010, the victims of the flood in Yautepec city who were protesting against the limited compensation from the official disaster fund (Fonden), peasants organized in the *ejido*[12] of Yaute-

---

12 Ejido is land given collectively and after intensive struggles by agricultural workers after the Mexican Revolution in 1910. Today, ejido land is normally managed individually, wherever in the region the allocation of water and credits "oblige" peasants to produce sugar cane for the sugar mill. With the constitutional reforms of 1992, ejido land is a private good that can be sold or rented, and peasants can form an association with agribusiness.

pec, market women, small entrepreneurs, NGOs and academics from different institutions joined together in a first analysis of the damage and the short-term needs in the YRB.

Representatives from the local authorities of the municipalities affected, and later from the state and federal governments, joined to avoid greater unconformity, and based on an informal collective leadership an emergency plan was developed. Specific groups monitored the reconstruction work, budgets were compared and engineers from the informal disaster community organization checked the quality and the prices of the public work. Due to the public unrest the authorities had to accept this citizen control. Public services were re-established very soon and at a lower cost than originally estimated. The key questions raised were how the remaining money could be used in a more sustainable way to avoid new floods, and how this collective work should be organized.

32.4.2 Socio-environmental Activities by Authorities and People

After the informal network of peasant leaders, market representatives, NGOs, municipal authorities, private constructors and academics was created, it held weekly meetings and carried out collective field trips. Conagua, the federal commission in charge of water management, joined the political arena and the system of organization and in November 2010 they organized the first meeting of the Council of the Yautepec River Basin. Federal departments of the environment, water, forestry and agriculture, the ministries of the state of Morelos and the thirteen municipalities of Morelos, together with the water users of the YRB (peasants, enterprises, private users) and academics formed the electoral assembly. The Council elected about fifty-two members, but the large number of people involved meant it was not functional. Therefore an executive group was elected to represent the different interests of stakeholders and to work out a master plan. Conagua and the state water agency (CEA) sent technicians with a appropriate capabilities and an interest in the work. Peasant leaders with local knowledge, engineers and private enterprises were involved, along with academics from the *National Autonomous University of Mexico* (UNAM) and the *Mexican Institute of Water Technology* (IMTA). This constellation offered an effective division of labour and an interdisciplinary working group.

After several months key ideas about sustainable water management were developed, but the group lacked concrete data about the people threatened, their socio-economic conditions, their risk perception, the views of the population of the YRB on waste management, health and education, and detailed knowledge of water management in the river. UNAM supported a multidisciplinary research group that conducted quantitative and qualitative research aiming at short-, middle- and long-term YRB management plans. Demographic, health, socio-economic and educational data were systematized, the investments needed for the restoration of treatment plants, collectors and drinking water facilities were analysed, measures for waste management were proposed, and schools and teachers became involved in the project.

Different sustainable innovation journeys were organized together with universities and technological centres. A photographic exhibition about environmental diversity and the threats to the river basin opened to all citizens. Schoolteachers joined the project and an integrated management was proposed, involving all stakeholders. The narrative explanations with an integrated vision were synthesized in a didactic map (figure 32.6). The short-term activity plan includes: the recovery of the three diversion dams, the reconstruction of drinking and sewage facilities, an association for a collective river management by all ejidos in the basin, the municipal management of solid waste and composting of organic waste, a mathematical model of risk management at municipal level, local reforestation especially in the highlands, and conflict resolution of the Michiate spring. A first proposal for a middle-term management plan was developed collectively, including the restoration of a pre-Hispanic diversion of the river Yautepec, an executive project for the construction of a dam able to retain water for irrigation, municipal urban and territorial planning, and the environmental restoration of the YRB. Some initial proposals for a long-term management plan comprised integrated social, economic, environmental, political and legal actions, together with a socio-environmental museum, that should consolidate the sustainable transition in the river basin (Oswald Spring 2014d, 2015a).

This broad vision clashed with the different interests of governmental officials, mining business and farmers. Conagua favoured the construction of several diversion dams, the municipalities opposed this due to the annual costs of dredging, and the authorities of the *ejidos* wanted to reopen the former diversion to better regulate the amount of water in the

Figure 32.6: Part of the Didactic Map of the Yautepec River Basin. **Source:** The author.

basin, to reduce the risks of flood, and to recover three existing *jagüeyes* (natural water pools) for irrigation in an area with serious problems of desertification. Both proposals were integrated into the didactic map and the map was very widely distributed among different actors, shops, markets and schools.

32.4.3 Agenda for a Sustainability Transition

After the 2012 elections, in December the federal, state and local governments changed and the new officials began to try and understand the tasks facing them. When hurricanes Ingrid (from the Atlantic) and Manuel (from the Pacific) simultaneously merged over Morelos and Guerrero, the YRB was not seriously affected because the sediments from the river and the diversion dams had been dredged, but dams and tributaries were filled with sediment after the extreme event. During the dry season of 2013-2014, the new authorities failed to act on the YRB plan and no meetings of the YRB Council were held.

In 2014, when a new Niño year gradually began to emerge and many floods started to occur, both the authorities and the public were taken by surprise. The change of governments—at the federal level from PAN to PRI and at the state level from PAN to PRD—interrupted the preparation of a broader vision with multi-

ple pathways for short- and middle-term actions, and no budget was available for concrete action during 2013-2014. None of the actions that had previously been agreed between all stakeholders were carried out and from June 2014 five floods demonstrated the lack of prevention measures by federal, state and municipal governments.

The officials reacted to these extreme events too late. The federal government forgot to give permission for the river to be dredged, the state officials did not send the machinery, and the mayor of Yautepec had financial problems in paying for the operators and the gasoline. When the first hurricanes arrived it was too late to dredge the dams and the river.

Subsequent strong flash floods produced several disasters, a consequence of combined factors: the sediments accumulated during the rainy season in 2013 together with waste, rocks and vegetation within the river and its tributaries produced barriers which limited its flow. In the diversion dams, sediments of 2.5 metres in depth had accumulated from previously and the dams could not mitigate the flood; municipal waste was badly managed because the people threw their garbage into the river; and the monsoon began much earlier in summer 2014 with five tropical storms within the first month and twenty-three tropical depressions and hurricanes on the Pacific side during the 2014 monsoon.

All this damage could have been avoided if the actions agreed by all stakeholders had been implemented. These were similar to the first ten steps on the sustainability transition pathway proposed by Dirven, Rotmans and Verkaik (2002). The route towards transition collectively developed before the change of government received organizational and innovative support from different stakeholders. In the YRB, the organization of multi-actor processes had created room for innovation and governance. The processes leading to fewer environmental threats brought about by flash floods and drought, mentioned as transition problems by Dirven, Rotmans and Verkaik (2002), were delineated within a multi-domain, multilevel and multi-actor system (Hillebrand/Hetsen/Souwer 2003). Short-, middle- and long-term action plans existed with clearly defined goals. In the transition paths different options (dams vs. diversion of the river) were left open and intermediate goals were adopted related to the regular policy and budget allocations. Instruments and the division of responsibilities were defined, but no intermediate evaluation occurred within a process of learning-by-doing and doing-by-learning. This lack of an intermediate assess-

ment also limited the next transition round and meant restarting the development of new transition arenas, especially after the change of government. Facing these limits and confronted with new disasters, additional inputs into the transition arena were necessary, and the Executive Committee decided to undertake an additional representative survey about the preferred DRR and DRM plans and implementation activities among 415 affected people from 100 families.

32.5 Disaster Risk Reduction and Management from Below

From the analysis of their answers to the questions about DRR and DRM in the YRB, different perceptions of risk emerged. In the highlands (Los Altos) all municipalities mentioned volcanic eruptions as their key threat (between 25.4 to 91.4 per cent), because these communities are permanently exposed to ash and forest fires from the active volcano Popocatepetl, and they have been evacuated several times. Frequent and relatively strong earthquakes (between 6 and 7 on the Richter scale) also explain why six of the fourteen municipalities prioritized this risk, with values between 34 and 51 per cent. Forest fires were mentioned by between 11 and 52 per cent, and landslides were referred to in five municipalities with values between 13 and 18 per cent, distributed across the whole basin. Flash floods were mentioned in four municipalities (Taltizapan, Yautepec, Tlaquiltenango and Zacatepec) which are part of the floodplain, with values between 23 to 37 per cent. Putting together all existing risks in the YRB, only 23.4 per cent of people think that they are not at risk, while the key threats are earthquakes, volcanic eruptions and flash floods (figure 32.7).

- no risk

Figure 32.8: Main disasters occurring in the YRB. **Source:** Survey (CRIM/UNAM 2011–2013).

Geophysical events (earthquakes, tsunami, volcanic eruption)

Meteorological events (cyclone, windstorm, thunderstorm)

Hydrological events (flood, landslide)

Climate events (extreme temperature, drought, wildfire)
32.5.1   Risk Perception by the People

Frequent exposure has created risk perception and consciousness among the people about the threats posed by extreme events. When asked directly which disaster had affected them most, 85.9 per cent mentioned flash floods, followed by drought, earthquake and forest fires (figure 32.8). Houses and furniture were affected according to the answers of 69.3 per cent of the respondents, followed by destruction of infrastructure and services, to which 18.6 per cent of the respondents referred, while 12.1 per cent pointed to the impact on trade and economic activities.

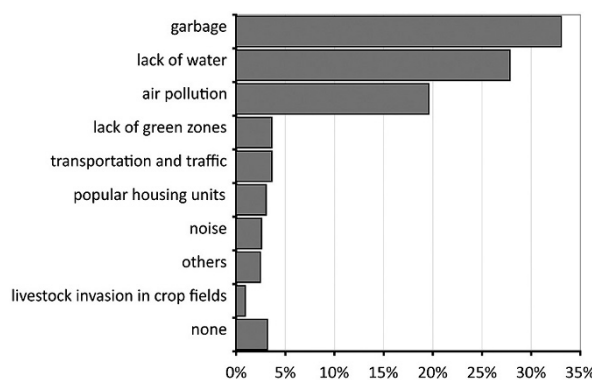
The difference between perception and reality could be related to mass media, films, news, etc., but also to the fact that the people know how to deal with flash floods, after several floods almost every year. During the monsoon season they move their belongings to the upper floor, and when the siren sounds they rush to the nearest refuge. This behaviour also explains why almost nobody has died due to flash floods in the last few years. Another explanation is psychological and linked to the fact that earthquakes and volcanic eruption cannot be prevented. In both cases early warning, building codes, evacuation and training are the ways to reduce negative impacts. In flash floods the lack of dredging, insufficient waste

management, deforestation and invasion in the river by blockages are problems for the authorities, so people focus on protecting their own life and furniture. Field research even showed that some disaster victims have learnt how to take advantage of their situation: they put old furniture in the flooded part, cash in the money and buy new furniture which is later sold, and in this way improve their lifestyle. For this reason they do not want to move to a safer place.

Most people relate extreme events to the deterioration of natural resources (with the exception of volcanic eruptions and earthquakes). During the survey, 51 per cent stated that important natural resources were destroyed and 28 per cent claimed that they were somewhat affected, while 17 per cent saw little impact and 4 per cent noted no natural devastation. Figure 32.9 indicates that most of the people interviewed mentioned solid waste, lack of water, and air pollution as the key environmental problems. When asked about other environmental problems, 37.50 per cent mentioned sewage and water pollution.

32.5.2   Reducing the Risks of Extreme Events

When people were asked how to prevent risks increasing, 82 per cent said that human activities were damaging the environment and 80 per cent were con-

Figure 32.9: Environmental destruction in the YRB. **Source:** Survey (CRIM/UNAM 2011–2013).


scious that this destruction could be stopped through changes in their lifestyle. About 62 per cent were aware that they had to collaborate with the authorities to recover the affected environment and only 16 per cent believed that it was the exclusive responsibility of the authorities (figure 32.10).

When asked directly what they did after the disaster: 22.2 per cent stated that they went to meetings; 5.4 per cent demanded compensation; 11.9 per cent participated in cleaning up the river and forest; 10.6 per cent reforested, and 49.9 per cent did nothing. This passivity is the result of years of populist policies, where people relied completely on the government. When asked what they had learned from the disaster: 59.9 per cent of those affected mentioned prevention; 29.3 caring for the environment; 10.3 per cent participated in DRM; and only 9.6 per cent did not learn anything. This behaviour indicates that disasters occur at multiple levels and in multi-actor systems, often with contradictory responses.

Figure 32.10: Dealing with increasing risks in the YRB. **Source:** Survey (CRIM/UNAM 2011–2013).
With regard to actions undertaken by all persons interviewed, in first place they mentioned reducing water use and recycling grey water, actions directly related to water scarcity. Then they mentioned recycling organic waste and finally reforesting. This indicates some social learning, bridging individual and collective knowledge, crucial for transition actions capable of dealing with complexity and uncertainty (Wittmayer/Neuteboom 2011), such as the multiple risks existing in the YRB. It has also been called "double loop learning" (Grin/Rotmans/Schot 2010) and demonstrates existing values and conflicting situations, where changes must be carried out through negotiations within the family and community. Grin and Van de Graaf (1996) and Grin and Loeber (2007) insist that surprise, outside views and safe spaces facilitate this second-order learning where the affected are able to go beyond their existing convictions and change their behaviour.

32.5.3 Role of the Authorities in Reducing Disaster Risks

With regard to the role of the authorities in DRR, people noted a lack of preventive actions, a low level of efficiency and a lack of leadership (Villagrán/Pruessner/Breedlove 2013). People claimed that reforestation is a key activity,[13] but the government did their job inadequately. They used seeds from other regions and often from different ecosystems that did not survive in the harsh local environmental conditions, such cold spells and heatwaves. They did not involve the people in the reforestation process and often cows, sheep and goats ate the newly planted trees because the authorities had reforested land belonging to peasants without their permission. The second problem is related to waste management, where municipal authorities do not collect garbage, or only collect it after a long time. So people burn it or throw it into the river. The municipality also destroys the efforts of people who separate their solid waste by mixing it all together, and it does not promote the composting of organic waste, which makes up at least half of all the garbage. A third problem is the lack of communica-

---

13 Additional studies of infiltration of rain and retention of sediments carried out in Los Altos indicated that 72 per cent of water is retained in the upper basin when steep slopes are covered by dense forest, able to produce a healthy soil. This water is slowly infiltrated into the soil and later into the aquifer, thus substantially reducing the threat of flash floods.

tion, training and workshops where the authorities could promote DRR and DRM, improve environmental practices and reduce the risks of extreme events.

Confronted with this lack of government interest, those interviewed proposed campaigns such as the cleaning up and dredging of the YRB and the deviation dams, using the dredge for organic agriculture, fumigating against dengue mosquitos and fruit flies, improving the quality of water, rebuilding drainage and treatment plants, opening up gaps against bush fires, and improving the activities of civil protection. The short period of incumbency of local authorities means that those responsible at the local level can gain no advantage from these proposals, and so they generally ignore them. The people claimed that the authorities were not carrying out the tasks for which they were elected and now they face greater risks from extreme events and feel abandoned. But not all threats in the YRB are related to extreme natural events, and another key concern of those interviewed is public insecurity.

32.6 Complex Emergencies Due to the Drug War and Hydrometeorological Extreme Events

Disasters and organized crime in Mexico and especially in the YRB have created complex emergency scenarios where people with low income and no social security try to create resilience in order to survive under highly precarious conditions.

32.6.1 Public Insecurity in Morelos and the River Basin

With regard to public security, Morelos experiences high crime rates in comparison with the rest of the country and with most parts of the world. The state, one of the smallest in Mexico, has the highest incidence of extortion. In most cases this crime is not reported because political and judicial or municipal authorities are often involved. Morelos has the second highest incidence of kidnapping, which is often not reported because the victim can be killed if the abductors discover the involvement of the police. There are also doubts about which authorities may be involved in this crime. Morelos has also the fourth highest level of homicides (80.01 in 2012; 66.28 in 2013/100,000 inhabitants) and high levels of violent robbery of houses and persons (SNSP 2014).

The violence has increased during the last five years, especially after the drug boss Marcos Arturo Beltrán Leyva was killed in December 2009. Police are frequently involved in crime and the most brutal drug cartel, the Zetas, is composed of highly trained former military and special police forces. The Zetas have widened their illegal activities from drug trafficking to trafficking with humans, arms, women, children, human organs, timber, species threatened with extinction, art and archaeological artefacts, as well as kidnapping and extortion, where migrants to the US are vulnerable victims, including those from Central America. Finally the judicial system is so corrupt that only two per cent of all crimes committed are investigated and only one per cent of the criminals are jailed; often those jailed are innocent victims with no money to pay for a lawyer. This has resulted in a lack of confidence in public authorities.

The precarious socio-economic situation, along with extreme events, public insecurity and the absence of the rule of law, have triggered a situation of *social anomie* (Durkheim 1991, 1999), where each household tries to survive individually. Private security companies seek to supply the public deficiency and in several parts of the YRB the government has lost control of the territory to organized crime. It is the municipality of Yautepec that has the highest figures nationally for rape, directly related to trafficking of girls and prostitution, but the rate of pregnancy among adolescent girls is also very high.

By analysing this public insecurity and linking it to an arena of transition, the first question must be who benefits from these illegal activities. Without doubt most criminals are linked to networks at different levels, but illegal money has to be laundered. According to estimates by the US Department of Homeland Security in 2013, about US$ 400 billion were transferred to the US based on illegal activities in the Americas (INCSR 2014). In Mexico about US$ 30 billion were laundered, permitting a precarious balance between poverty and illegality to be maintained.

Thus a sustainable transition also requires changes at the global level, where Wall Street, financial havens, transnational banks, enterprises and other economic actors are involved, and where only the legalization of drugs could reduce this illegal financial flow and thus the crime rate. As problems at this level can be resolved neither by the Mexican government nor by the authorities of Morelos, the question arises as to what could be done at the local and state level to transform this complex emergency.

At local level, there is a crucial factor related to the theory of social representation and family organization. When we asked all the interviewees about the conditions of their life in the community or colony 66 per cent were highly satisfied or satisfied and 54 per cent were also satisfied with the existing health services. But 35 per cent were highly unsatisfied or unsatisfied with their conditions of life and 46 per cent with the health services. This indicates an important polarization. When the people were interviewed about their emotional links to the colony or village (figure 32.11), almost half of them said that they identified with traditions and nature, while public services and economic facilities were less important. These data indicate a strong identity with traditional values that are deeply anchored in the community and also in urban colonies. Integration into a smaller community is more important than economic facilities or public services. As Moscovici (1984) indicates, the key representation they identify with is significant for its members when they accept norms and values and evaluate their abilities objectivized through cultural processes where identities are permanently being readjusted, and the basic identity of belonging to this social group is anchored (Serrano 2010). A social group, activities and opinions in relation to group expectations, and this permits the group to influence their attitudes and behaviours (Turner 1987: 1). Their identities develop within their primary groups; later they are confronted with different values and they first resist change, but later adapt together with the group to the changing external conditions or reject the new ones. This behaviour is typical for the existing representation of the social group (Duveen 1997, 2001), whether in daily life they adapt collectively or individually to the new necessities.

Figure 32.11: Identity in the YRB (two posible answers). **Source:** Survey (CRIM/UNAM 2011–2013).
Social representations are crucial to understanding the risks and threats posed by extreme events. But the theory also helps us to understand the links between legality and illegality in the YRB. Three decades of neo-liberal policy with drastic reductions in livelihood, an increase in social inequality, governments becoming more and more corrupt, police involved at local and federal level in illegal activities, and judges letting murders, kidnappers, drug dealers and members of organized crime go free have changed the perception of legality and illegality. The rule of law is permanently broken and the changing reality affects the identity processes. Greed, economic ambitions and social prestige have further increased illegal activities, and the borders between legality and criminality are diluted.

Family units are based on their identity; this identity reinforces the social tissue; organized crime is based on family ties (Segob 2014). The present situation of insecurity creates among members of some groups the necessity of sometimes justifying actions which are considered illegal, such as lynching and producing or selling drugs, and most organized crime is based on extended family structures,[14] called by Garzón (2003) (amoral) *familism*. The term "refers to a model of social organization, based on the prevalence of the family group and its well-being placed against the interests and necessities of each of its members" (Garzón, 2003: 546). To maintain the social tissue within a family, criminal acts are sometimes justified; in other cases part of the family influences another part of the same family without participating in the criminal activities. This complex social process explains why the level of criminality in the region has increased so fast, how existing social tissue has been destroyed and how other social tissues were produced when gangs offered newcomers a social framework, income and social acceptance. Nevertheless, in the longer term these criminal acts create social instability and public insecurity, where the absence of the rule of law leaves people highly exposed. The municipality of Yautepec featured in the international news when in March 2014 forty-four people, including students, were kidnapped and eighteen were killed, even though their families had paid the ransom. Military and state police with a new security scheme called 'mando único' (one sole police controlled by the state authorities), a trained police for all the municipalities

---

14 The cosa nostra in Mexico is basically related to seven families: Arellano Félix, Osiel Cárdenas Guillén, Joaquín Guzmán Loera, Carrillo Fuentes, Armando Valencia, Pedro Díaz Parada and Amezcua Contreras.

(2014: 343), based on data from SIAP [Statistics from the Ministry of Agriculture].
in Morelos, manage to control part of the illegality, but existing family structures and smaller criminal gangs threaten the security of all citizens. The priority given to combatting this high level of crime was also a reason for forgetting preventive behaviour in the YRB, and the start of the Niño year increased the threats of flash floods.

With these multilevel socio-political, security and environmental conditions, how can local people reinforce their resilience and deal with the growing threats of global environmental and climate change (Oswald Spring 2015b) triggered by organized and petty crime? How can especially individual women as heads of household in highly marginal conditions in the YRB increase their resilience?

32.6.2   Resilience Against Floods, Droughts and Crime

All the above three threats were addressed from a bottom-up perspective in cooperation with the three levels of government. People observed that they were unable to deal with the growing threats at family level, which is why they organized themselves in their neighbourhoods. Red buttons in the streets facilitate early alerts against kidnapping, robbery and rape. People generally do not go out after sunset, and festivities take place at home, where those invited normally stay overnight to avoid risks. This type of self-imposed curfew is a rational answer to new threats of crime. As for flash floods the early warning system is working

and people know where their nearest refuge is. As the flash flood comes in very fast, due to the great difference in altitude, the water in the flooded area also disappears very fast, leaving sludge, destruction and diseases behind. Solidarity among the local population helps them to survive the first few days after a flood; later family members and some government support helps them to regain normality. Bigger floods which destroy merchandise and machines sometimes mean it is three years until the small businesspeople regain their former level of income and they are often affected again in the meantime.

With regard to drought the situation is more complicated, because it affects not only the productive cycle but also the livelihood of the people. Drought is especially difficult to manage where it affects rain-fed agriculture in Los Altos, and most families have decided to diversify their economy. At the national level, and with similar conditions to the YRB (figure 32.12), peasant income is complex and only covers ninety per cent of necessities. Only seventeen per cent of this inadequate income comes from agricultural activities (production and agricultural wages), fifty-five per cent comes from off-farm activities, mostly paid labour, nine per cent from national and international remittances, four per cent from government subsidies and another four per cent from pensions. The reduction in income provided by agricultural production from twenty to nine per cent demonstrates the crisis among the peasantry and the absence of a policy of food security of Mexico (Oswald Spring

2009), especially when one takes into account that in 2013 Mexico imported more than sixteen million tonnes of basic grain. Therefore, peasants in regions of rain-fed agriculture have often opted for one of the family members to migrate, and sometimes the whole family has left the region, especially when organized crime wants to make them grow drugs, or the young people are abducted and have to work for the criminal gangs (Oswald Spring/Serrano/Flores et al. 2014).

32.7 Conclusions: Sustainability Transition in a Region Highly Affected by Climate Change and Public Insecurity

The analysis of the complex emergency in the YRB indicates that decentralized governance and citizen participation was possible when the authorities at all three levels were unable to manage the crisis produced by the flash floods. Traditional knowledge held by women and peasants and grass-roots movements against desertification and floods helped the people to deal with these emergencies and to construct step by step a mode of resilience able to deal not only with disasters but also with organized crime and public insecurity; that is, able to deal with complex emergencies.

32.7.1 Integrated River Management

The participative Council of the YRB was able to develop a didactic map (figure 32.6) that let children and adults understand the threats related to global environmental and climate change, and how to manage these threats. The didactic map presented a global understanding of the river basin and its threats from hazards. Later on it was used to illustrate a synthesis of crucial actions where all stakeholders needed to get involved. The most recent survey, in 2013, indicated that people have understood that waste in the river is a threat for everybody not only because of the increase in dengue fever but also because of the waste barriers that increase dangerously when water breaks though, ripping out trees, vegetation, land and sometimes houses. The map also suggests several productive activities, such as composting organic waste and producing safe food for the family in orchards. Conagua proposed a union with the *ejido* that would be able to manage the river water and avoid hydro-conflicts. Today 95 per cent of the surface water and 23 per cent of the groundwater is used in agricultural

activities, in which 16 per cent of the people are employed in generating four per cent of the gross domestic product of the region. This overuse of water is producing conflicts with other productive and service uses, but also removes water needed for ecosystem services.

At the societal level, the collection of seeds from the ecosystem and the reproduction of plants and reforestation is crucial, since 72 per cent of the rain could be retained upstream and infiltrated into the aquifer. This would substantially reduce the number of flash floods, but it will take at least fifteen years before the new trees and the associated recovery of the soil produces this ecosystem service. Additional activities with a more immediate impact must be developed. A waste separation and recycling centre is planned as a combined activity between private enterprise and the municipality, where the regional markets can get involved in separating out the organic waste. Municipal authorities, peasants and NGOs can transform this waste into compost and sell it for organic agriculture. The conflict around the spring of Michiate requires a negotiation process between peasants and local, state and federal authorities. Conagua is responsible for controlling holiday resort companies, who have built infrastructure in the YRB within the protected federal area. It is their responsibility to dismantle these constructions and prevent any new invasion of the YRB.

In the middle term (five to ten years) ecotourism, composting and nurseries using local seeds is society's responsibility. Peasants are committed to transforming 5,000 ha into organic production. Together with the state and federal government, sixty million trees should be planted, especially upstream, and the area should be reforested in order to improve the infiltration of water and reduce flash floods. It is responsibility of the federal and state governments to control the loggers (often linked to organized crime), especially in the national parks in Los Altos. The three levels of government will be involved in the construction of the dam Morelos 1 which will retain water during the monsoon. The diversion canal, with its archaeological ruins, will restore the traditional river flow and recover four *jagüeyes* and six springs for irrigation in areas of rain-fed agriculture. The building and repair of collectors for sewage water and treatment plants will allow the water quality of the river to be recovered. A regionally established landfill programme and improvement in waste recollection will reduce the amount of garbage in the river. Environmental education in schools, clubs and *ejidos* and the eco-manage-

ment of the natural flora and fauna of the region will protect endemic plants and animals. The municipalities are committed to thirteen plans for urban and environmental management, centres of waste separation and local recycling, and the rehabilitation of the existing treatment plant. Reforestation activities and ecotourism in the two 'magic cities' (Tepoztlán and Tlayacapan) will help to recover the cultural identity and history of the region, attract tourism, and facilitate the establishment of 2,000 micro-businesses in the areas of handicrafts, souvenirs and food facilities, thus consolidating tourism, income and employment.

In the long term (fifteen to thirty years), education and social activities for youth should reduce adolescent pregnancies, diabetes mellitus, obesity, trafficking of girls, and insecurity. Business communities and society will promote healthy communities and cities, where traditional medicine and indigenous cures can support ecotourism. In economic terms, all these activities will allow small businesses to be consolidated and integrated into chains of support (administration, taxes, legal, labour, market studies, export, etc.) by young professionals who are today unemployed (Cadena 2009). The rational management of the existing natural and social resources in the region can produce 10,000 formal jobs. The restoration of national parks and ecotourism is an additional source of income for poor peasants, together with payment for ecosystem services. An improved socio-economic stability will reduce illegal activities and a better-controlled public administration will offer fewer opportunities for corruption. In environmental terms, seven diversion dams, Morelos 1 and the deviation may protect the region against flash floods and store water for irrigation. In this last phase, about 150 million trees would restore the destroyed ecosystems. Additionally, 20,000 ha of recovered soil thanks to compost, three regional landfills and 5,000 ha of agriculture with efficient irrigation will offer the potential to improve regional food security. Five hundred hectares of fruit trees and 10,000 ha of organic plantations might transform the region into a centre of attraction for tourism, education, archaeology, health and sustainable culture. This model also opens up the potential for international fair-trade markets, where fruit, vegetables and medicinal plants can be exported. At the local level, the recovery of orchards irrigated with recycled grey water and composted waste will improve the availability of healthy food. In the northern area, payments for ecosystem services, the recovery of the national parks and sport and outdoor pursuits in the highlands will offer a variety of ecotourist activities and in the surrounding regions forestry will offer additional jobs and income.

32.7.2 Reconstruction of the Social Tissue

Ecological education and cleaning up the YRB are two activities where schools and citizens can get involved. The government scholarship-salary for high school students programme opens the door to the active participation of students in communities. Social tissue can only be reconstructed through healthy daily living together where people lose their fears and reclaim public places for social coexistence (Moreno/ Mojica 2013). The reconstruction of social tissue also includes greater transparency in government, the judicial system and the police. The government of Morelos has developed a police force under a single command, and more than 200 corrupt police officers have been dismissed and replaced by professional officers. But it is at the societal level where corruption needs to be stopped, and new roles for the law can be achieved through social pressure.

The consolidation of leadership at the local level is crucial, and teachers, doctors, priests and academics can play a role in reconstructing the social tissue. Unemployment creates not only poverty and a lack of social esteem, but also provides the temptation to become involved in organized crime or to migrate. Migration in adverse condition can be a coping strategy, but may also increase vulnerability at home, especially for women heads of household when the remittances are missing. Integrated labour activities based on concrete action programmes with government support may reduce migration, crises, criminality and conflicts. The concatenation and integration of productive activities at the local level offers jobs for young unemployed high school graduates, reduces the failure of micro-businesses, decreases the cost of professional support in production, marketing and administration, and increases the potential for solid regional development. The consolidation of agricultural, livestock, forestry and off-farm jobs may open up new productive processes, increase financial resources and with local savings can open new development processes. Combined with composting, the recovery of eroded land, integrated water management and a diversity of small local activities, it may create a stable regional economy, able to feed the ple (Oswald Spring 2014c). This may be a way to reconstitute the social tissue and to reduce criminality in the region, especially when unemployed young people have the opportunity to study and find paid jobs.

32.7.3 Sustainability Transition: A Long Path Towards a Desirable Future

A sustainable transition explicitly promotes participatory activities, where top-down investment and support from the government and private sectors should consolidate the bottom-up efforts. The development plan for the YRB was jointly developed and is an initial attempt by different stakeholders to understand the present situation of environmental, political and socio-economic deterioration. It also represents the first steps towards designing a framework leading towards a sustainable transition. The integration of a Committee representing different stakeholders and

local and regional interests increases the capacity for strategic thinking and innovative experimentation.

Figure 32.13 synthetizes the interaction among arenas, agendas, actors and activities of dual vulnerability and proposes a transition to an agenda of a sustainable socio-economic, political and cultural change towards an integrated HUGE (human, gender and environmental) security and peace (Oswald 2015).

The rapidly deteriorating environmental and socio-political conditions have forced people to establish a diagnosis and later a framework for resilience-building to deal with the complex emergency in the YRB. The social mobilization and inconformity has also forced the government to intervene, to collaborate and to

recover part of the lost governance. Under the leadership and with the involvement of different stakeholders within the Executive Committee of the YRB, the authorities together with the citizens have focused on increasing freedom from fear and from hazard impacts (Brauch 2005a). It was basically through the activities from the bottom up that a social consensus was established and that initial policies for a sustainability transition were established in a consensual way. The regular meetings and the evaluation of some of the goals established on the didactic map reduced the disaster impacts from flash floods and drought in 2013. Nevertheless, the change of government in December 2012 and the increase in public insecurity in 2014 created new vulnerabilities, triggered by a severe Niño year with twenty-three hurricanes and tropical depressions in the Pacific.

The representatives of the three levels of government are aware that the complex emergency in the YRB can only be managed with the collaboration of organized society. Complex emergencies have a massive impact on various levels of human security, and make the reconstruction or prevention of climate threats difficult. The initial natural and human-made disasters were magnified by the loss of public security and the politicization of the crisis. Cooperation among the three key actor groups (organized people, business, and government; Weber 1987) was able to reduce the disaster impacts in 2013. Without improving environmental and social conditions and creating new jobs, especially among young people, the crime rate cannot be reduced. Only when these young peo-

ple have the opportunity to study (e.g. at the state university UAEM, which recently opened a branch in Yautepec) and acquire stable jobs, when criminal activities are prosecuted and severely punished and their economic advantages are prevented, is a transition to a safe life and livelihood feasible.

The transition to sustainability in the YRB began with a common problem analysis, made urgent because of the existing complex emergency. By involving crucial stakeholders, a future desirable vision was developed, where people proposed items for short-, middle- and long-term agendas taking into account social (equality), economic (development), gender (equity), environmental (sustainability), political (participation), and cultural (diversity) development (Oswald Spring 2015c). Opportunities came from the appropriate stakeholders and from the three levels of government and merged into a common vision, where collective effort and negotiation allowed a shared agenda to be developed. Activities were planned, but during the change of government several crucial actors disappeared, while the representation of civil society was stable. New threats related to an increase in public insecurity, climate variability, a Niño year and new flash floods forced the authorities to address the integrated agenda again in 2014, when it was possible to reconstruct the social tissue and to support resilience-building by those affected. The lessons learnt include regional consolidation of the agenda (Oswald Spring 2014b), the assigning of a budget for the next five years, the step-by-step evaluation of each activity, and the orientation of activities towards an integrated sustainable transformation.

33   Sustainability Transition in the Health Sector in Brazil

Monica de Andrade[1]

Abstract

Identifying sustainability transition in the health sector involves analysis of the dynamic and the forces influencing political, sociotechnical and cultural features. The aim of this study is to identify transition in health in a Brazil facing globalization, demographic, migration, environmental and climate change effects and inequities. Brazil has improved its capacity to formulate, implement, monitor and evaluate multi-sectoral and universal public policies in the last twenty years, with the implementation of universal health care and conditional cash transfers. These policies have resulted in the improvement of the health indicators of extreme poverty and hunger, under-five mortality, maternal health, infectious diseases, and primary education coverage. Since the frequency of extreme weather events has been increasing globally and in Brazil, and cardiovascular diseases are a leading cause of death, the consequences for health systems must be considered. Mortality due to traffic accidents has also increased, despite policy efforts and restrictive laws, overwhelming health services and public financial resources.

Keywords: Sustainable transitions, health, environmental health, health policies.

33.1   Introduction

The world population reached 7.2 billion in 2014 and is expected to increase by more than two billion by 2050.[2] Most of the future population growth will occur in the less developed regions. There is considerable diversity in the expected future trajectory of population change across major areas and various countries. More than half of the world's population now lives in urban areas. While the number of large urban agglomerations is increasing, approximately half of all urban dwellers reside in smaller cities and towns. The number of young people has grown rapidly in recent decades and is expected to remain relatively stable over the next thirty-five years. In contrast, both the number and proportion of older persons are expected to continue rising well into the foreseeable future (United Nations 2014).

Good health for all populations has become an accepted international goal and there have been broad gains in life expectancy over the past century. But health inequalities between rich and poor persist, while the prospects for future health depend increasingly on the relative new processes of globalization.

Globalization is causing profound and complex changes in the very nature of society, bringing new opportunities as well as risks. In addition, the effects of globalization are causing a growing concern for human health, and the intergenerational equity implied by sustainable development forces us to think about the right of future generations to a healthy environment and a healthy life (Huynen/Martens/Henk 2005).

Health and development are intimately interconnected. Insufficient development leading to poverty, or inappropriate development resulting in overconsumption, coupled with an expanding world population, can result in severe environmental health problems in both developing and developed nations.

Health security is defined in different ways. In order to distinguish between traditional and socially committed health transition, we use a wider concept of health security,[3] proposed by Leaning (2009). This is a people-centered understanding of health security that integrates underlying aspects such as globaliza-

tion, demographic effects, the effects of environmental and climate change, the growing disparity between rich and poor nations and between rich and poor people, and migration. Health security is therefore related to the sustainable management of the environment and to the changing conditions posed by climate change, population growth, urbanization and environmental deterioration (Brauch/Oswald Spring/Mesjasz et al. 2008, 2011; Brauch/Oswald Spring/Grin et al. 2009, Oswald Spring 2011).

Sustainable development (SD) as a goal was placed on the policy and scientific agenda by the Brundtland Commission in 1987. This challenge addresses the need for long-term structural changes or transitions in sectors such as energy supply, mobility, agriculture and healthcare. It is increasingly becoming a core focus of many disciplines that link subfields such as urban studies, economics, political studies, ecology and health.

The negotiations at the *World Summit on Sustainable Development* (WSSD 2002) demonstrated a major shift in the perception of sustainable development, away from environmental issues and towards social and economic development. This shift was driven by the needs of the developing countries and strongly influenced by the Millennium Development Goals.[4]

In 2012, the United Nations Conference on Sustainable Development took place in Rio de Janeiro. Its aim was to shape policies to reduce poverty, advance social equity and ensure environmental protection on an ever more crowded planet. One of the

main outcomes of the Rio+20 Conference was the agreement by member states to launch a process to develop a set of *Sustainable Development Goals*[5] (SDGs), which will build on the Millennium Development Goals and converge with the post-2015 development agenda. It was decided establish an "inclusive and transparent intergovernmental process open to all stakeholders, with a view to developing global sustainable development goals to be agreed by the General Assembly".

Over the last few years, a large number of scenario-based assessments of global environmental problems and human development have been published. These have used an explorative approach with widely diverging scenarios to assess what might happen in the future. They include the *Intergovernmental Panel on Climate Change* (IPCC) climate assessment, the Global Environment Outlook reports (UNEP 2007, 2002), the *Millennium Ecosystem Assessment* (MA 2005a), the *International Assessment of Agricultural Science and Technology Development* (IAASTD 2009b) and the *World Water Development Reports* (UNESCO 2006, 2009).

In a recent study, a combination of policy options—including the expansion of protected areas into a well-chosen network covering twenty-nine per cent of the world's surface, an increase in agricultural productivity and reduced post-harvest losses, dietary change, improved forest management, and climate mitigation—was put forward, with the aim of achieving a significant restoration of natural areas and reduced biodiversity loss (Ten Brink/van der Esch/Kram et al. 2010).

In order to understand the dramatic changes and transitions in the world's health, it is necessary to access the scenarios using theories that can help to explain the process involved in sustainability transition.

Sustainability transition (ST) is a socio-economic, political and technological process that aims to achieve the goals of sustainable development. Sustainability is an essential part of health during transition and beyond and aligns itself with the sustainability goals agenda.

---

3   Health security is a concept that refers to strategies, policies and measures of sustainable development and preventive behaviour that may contribute to a healthy, participative society and a sufficiency of environmental services.

4   The UN Millennium Declaration (2000) adopted and committed countries to reach eight Millennium Development Goals by 2015. The eight goals included: halving extreme poverty, halting the spread of HIV/AIDS, providing universal primary education, eliminating gender disparity in education, reducing the under-five mortality rate, reducing the maternal mortality rate and achieving universal access to reproductive health, developing a global partnership (to address the needs of the poorest countries, furthering an open non-discriminatory trade system, and dealing with developing country debt); and ensuring environmental sustainability (by integrating sustainable development into national policies and programmes, reducing biodiversity loss, improving access to safe drinking water and sanitation, and improving the lives of slum dwellers) (UN 2010).

5   *Sustainable Development Goals* (SDGs) are under discussion and the proposed SDGs consist of four modules measured through a range of proxy indicators: (i) health (life expectancy; maternal mortality; infant mortality; child mortality); (ii) education (gender ratio in secondary education; years in education); (iii) income (per capita income); (iv) environment (per capita annual carbon emissions).

In order to understand the sustainability transition process, transitions theories[6] have been used as frameworks that allow us to understand the dynamics of ST. The core problem regarding sustainability transitions is how green innovations and sustainable practices (in behaviour and policy) 'struggle' against existing systems or regimes. Incumbent systems in the domains of transport, energy, and agri-food are difficult to dislodge because they are stabilized by various lock-in mechanisms (related to vested interests, low costs, established beliefs, sunk investments, and favourable institutions) that lead to path dependence and entrapment. Green innovations and new practices therefore tend to face an uphill battle, played out in economic, technical, political, scientific, and cultural dimensions (STRN 2010).

Science and technology studies (STS) and innovation studies have developed a 'quasi-evolutionary' approach to studying technological change (van den Bergh/Truffer/Kallis 2011). This innovation process model is characterized as a coupled dynamic of selective pressures and adaptive capacity in the dominant system ('regime'), in which a technology is embedded (Smith/ Stirling/Berkhout 2005).

One approach that has been used to analyse sustainability transition is the *multilevel perspective* (MLP) method, which analyses sociotechnical systems seen as consisting of niches, regimes and landscapes, a nested hierarchy of structuring processes. The multilevel perspective on sociotechnical transitions provides a framework in terms of both organizing analysis and of ordering policy interventions. It identifies three levels within societal systems (such as the health system): *niches*, in which radical innovation emerges; the *regime*, which comprises dominant institutions and technologies; and the *landscape*, which represents macro-level trends and contextual drivers and barriers to change. The main dynamics of change occur within and between the regime and niche levels, which may interact synergistically or antagonistically (Geels/Schot 2007).

Sustainability indicators and the composite index are additional tools that are gaining in importance and increasingly recognized as powerful mechanisms for policy-making and for public communication to provide information on countries and corporate performance in fields such as environmental, economic, social and technological improvement (Singh/Murty/ Gupta et al. 2012).

The main contribution of this chapter is to provide an interaction between anthropogenic drivers, their impacts on and the policy responses to climate change, their interrelationship with the dominant productive systems of globalization, and their effects on human health. It will attempt to contribute to the understanding the consequences of policies that target the reduction of poverty and hunger, sustainable development, environmental protection, and the reduction of social inequities in Brazil.

The chapter is structured as follows. Section 33.2 addresses the national scale, very important in the delineation of regime contexts of transition studies, as a description of socio-economic, political, and technological scenarios in Brazil. Section 33.3 presents an overview of indicators of improvements in health in the context of sustainability transitions.

33.2 Socio-economic, political, and technological transition scenarios in Brazil

Brazil has the fifth largest population in the world, 197 million people (World Bank 2012), thirty per cent of whom are under the age of 18 (Unicef 2012). Demographic transitions present a major challenge because the population of Brazil increased from 72,775,000 in 1960 to about 202,768,562 in 2014, with 2,938,214 births, corresponding to a crude birth rate of 15.20 per 1,000 inhabitants.

In 2011, Brazil's gross national income was US$11,500 per capita (World Bank 2012). However, it has one of the highest rates of inequality in the world: its 2012 Gini index (51.9) was the sixteenth highest out of 136 countries worldwide (Central Intelligence Agency 2013). Ranking eighty-fifth out of 187 countries on the Human Development Index in 2011, Brazil still faces considerable challenges in meeting the whole population's needs for education, health care, and income.

Brazil is internationally recognized as one of the countries with the widest range of social inequalities. However, in recent years there has been an extraordinary liveliness in social innovation. Declining rates of income inequality have been reported since democratization at the end of the 1980s.

---

6 Transitions theories are theoretical approaches that analyse the development of 'sociotechnical transitions'. 'Sociotechnical' refers to the co-evolution of social and technological relationships, while 'transitions' refer to the dynamics by which fundamental change in these relationships occur (hence the relevance to sustainable consumption).

There have been three main periods of political regimes in Brazil, from military dictatorship (1964–1974) through a transition mix of military dictatorship and political transition called the 'Nova República' (1985–1990) to political (1974–1989) and democratic (1989–2002) consolidation (see table 33.1).

Various social movements emerged during this period, where the union movement in the metropolitan area of São Paulo was of particular importance. In addition, the *Association of Independent Unions* (CUT) was founded (in 1983) as well as the *Labour Party* (PT, in 1980), and these demanded fair wages and working conditions as well as comprehensive social reforms (Lindelow/Araujo 2014).

Urbanization has increased from fifty-four per cent in 1960 to eighty percent in 2010. Improved access to water and sanitation achieved solid economic growth and reduced income inequality.

The Brazilian health situation is going through a process of epidemiological transition in which non-communicable diseases and diseases resulting from external causes (especially violence) are increasing in place of infectious and parasitic diseases.

33.2.1   Social Policy

In Brazil, social policy was seen as a counter-concept to the Bismarckian 'social insurance' model, enabling the creation of a universal welfare regime: education, pensions and healthcare benefits as well as social transfers were universally available to all citizens in urban and rural areas. For the first time, the rural population was included in the welfare system, which has mainly been set up using cash transfers (Leubolt 2014).

The social security system for private workers (general system) is an unfunded defined benefit programme. There is still debate regarding when it began. In 1888 some measures were taken to provide pension benefits for postal workers and employees of the national press. In the following years, retirement benefits were extended to railroad workers, employees of the Ministry of Finance, the Mint and the armed forces. In 1923, the *Lei Eloi Chaves* legislation was approved to regulate social security for both civil servants and private sector workers. This law decentralized the pension system, as each company became responsible for its own employees. The first reform took place in 1933, when the pension funds were structured by professional category. The general pension system was centralized only in 1966, when the House of Representatives approved the Social Security Ordinary Law. The *National Social Security*

Administration (INPS) incorporated all the revenues and expenditures from sector-specific programmes as well as its own assets and liabilities. Another major change during this time was that the scheme changed from a capitalization system to PAYGO (Turra/Queiroz 2005).

The last major reform occurred with the 1988 Constitution, which extended mandatory social security coverage to most of the previously excluded groups, including rural workers, without requiring equivalent increases in revenues from contributions.

The main social policy achievements was the establishment of minimum standards of "social security" which can be viewed as an expression of a political equilibrium (or stalemate) between progressive and conservative forces.

The presence of social issues in the 1988 Constitution can be interpreted as a consequence of the 'cultural hegemony' that the left obtained and fortified during the military dictatorship. After that, the group known as *Movimento pela Ética na Política* (Movement for Ethics in Politics) formed an important national social movement against hunger and misery, *Ação da Cidadania contra a Fome, a Miséria e pela Vida* (Citizens' Action against Hunger and Poverty and for Life) in 1993. This further strengthened the national anti-poverty consensus (Leubolt 2014).

The strategies adopted in 2003, such as *conditional cash transfers* (CCTs), can be seen as an instrument of social policy reflecting the widespread belief in Brazil that people are poor through the "fault of an unjust society".

Zero Hunger, Brazil's national strategy for food and nutritional security, consists of more than twenty initiatives on four axes of intervention. Its creation in 2003 was a milestone in the recognition of food and nutritional security as a leading and cross-cutting priority on the political agenda. *Zero Hunger* is a combination of continuity and innovation. It introduced major programmes such as Bolsa Família (Chmielewska/Souza 2011).

Another policy example comes from programmes that link horticultural producers directly to markets. One example is the Family Farming Food Acquisition Programme, part of the Zero Hunger Programme in Brazil. In this programme, the government purchases food produced by family farms. The programme ensures food supplies for poor families, as well as school meals and public hospitals, while creating a market for the small farming sector. There is some evidence that the programme has had a positive nutritional impact in north-eastern Brazil.

Table 33.1: Characterization of sustainability transitions in Brazil: structural changes at local level (landscape level).HD = Hydroelectricity. **Source**: The author.

Structural changes (landscape level)									
Timeline	Political Regime	Pop. (million)	Energy	Transport	Social security	Health	Food & Nutrition	Economy	Environment
Technological innovation (regime)									
1946–1964	Populist Democratic	72.775(1960) 66% rural 44% urban	HD	Fossil fuels	1923 Social security for workers			Agriculture Mineral exportation Industrialization	High deforestation rates
1964–1974	Military dictatorship		HD	Fossil fuels			Subsistence agriculture Cattle ranching	'Economic miracle' Automobile industry	High deforestation rates
1974–1990 "Nova República" (1985–1990)	Mix of military dictatorship and political transition		HD +World-renowned technology for exploring deep off-shore oil reserves	Fossil fuels +biofuels (ethanol)		Health system exclusively for workers		High inflation (1980) Growth of agribusiness	High deforestation rates
1988 Constitution		80% urban 20% rural			Extended mandatory social security coverage	Universal publicly-funded, rights-based health system (SUS)		Growth of agribusiness	High deforestation rates
1990–2000	1994's Plano Real (Real Plan) Inclusive liberalism	170	HD +World-renowned technology for exploring deep off-shore oil reserves				Growth of agribusiness Agriculture Expansion and modernization of traditional cattle ranching		1997 law limiting deforestation to 20% of the private property in the Amazonian region
2001–2010	Developmental welfare		HD Oil + Thermoelectricity + Sugarcane burning	Increased expansion of private transport	Conditional Cash Transfers	Family Health Programme Smiling Brazil Mobile Emergency Services, Popular Pharmacy Programme Health Promotion Policy	(2003) Zero Hunger Programme Bolsa Família (2004) Food and Nutrition Policy (2010)	Automobile industry Growth of agribusiness Mechanization Slow growth of small-scale agriculture	(2006) Decreasing deforestation rates Implementation of Climate Change Policy
2013–2014		202,768,562 86% urban 14% rural	HD Oil + Thermoelectricity + Sugarcane burning Wind power electricity		Unemployment, social exclusion				

33.2.2   The Health System

Brazil was one of the first Latin American countries to establish *universal health care* (UHC) as a fundamental right, based on the principles that health care is a duty of the state and should be free at the point of use. There form in the late 1980s created the *Unified Health System* (*Sistema Único de Saúde*, or SUS) and was based on the principle that health care should be free at the point of use to all Brazilian citizens (Lindelow/Araujo 2014).The goals of universal health coverage are to ensure that all people can access quality health services, to safeguard all people from public health risks, and to protect all people from impoverishment due to illness, whether from out-of-pocket payments for health care or loss of income when a household member falls sick. Brazil's *Unified Health System* (SUS), a universal health care system, was established by the Constitution of 1988, after more than two decades of military dictatorship. It increased access to healthcare for a substantial proportion of the Brazilian population, at a time when the system was becoming increasingly privatized.

The previous system INAMPS (*Instituto Nacional de Assistência Médica da Previdência Social*) had several vertical, independent, and uncoordinated systems, each with its own source of funding, network of facilities, and beneficiary population.

The Brazilian health system is formed by a complex network of public and private institutions devoted to providing, financing and managing health services; surveying, producing, and distributing resources; human resources training; and regulation, legislation and jurisdiction of the system. The *Unified Health System* (SUS) is responsible for exclusive coverage of 78.8 per cent of the Brazilian population, being the main network of public institutions devoted to the provision, financing, and management of health services. The remaining 21.2 per cent of the population, covered by the Supplementary System, also have the right to access the services provided by SUS. SUS is also responsible for the provision of the collective services of health surveillance, disease control and sectorial regulation (WHO 2013a). It has been designed and put in place in an era where neo-liberal reforms elsewhere in the world have driven the marketization of health services, and offers important lessons for future health systems.

The *technological innovation* of the SUS is that institutional mechanisms for popular involvement and accountability are part of the architecture of the governance of the system.

Public involvement has the potential to sustain a compact between state and citizens and to ensure the political momentum required to broaden access to basic health services, while at the same time providing a framework for the emergence of "regulatory partnerships" capable of managing the complex reality of pluralistic provision and multiplying sources of health expertise in a way which ensures that the needs and rights of poor and marginalized citizens are not relegated to the periphery of a segmented health system (Cornwall/Shankland 2008).

The Brazilian health agenda from 2003 to 2008 had as its priorities the Family Health Programme, Smiling Brazil, Mobile Emergency Services, and the Popular Pharmacy Programme (table 33.1). The first is a policy with high institutional density launched by the previous administration, and constitutes an example of path dependence. The other three are innovations in areas where there had been weaknesses in federal government action. The four policy priorities are strategies focused on solving key problems in the Brazilian health system. However, they display important differences in their historical development, political and institutional base, inclusion on the federal agenda, and implications for the principles of the Unified National Health System. Although incremental changes have been introduced, national health policy has been characterized predominantly by continuity (Machado/Baptista/Nogueira 2011).

The main primary health care programme in Brazil, the *Programa Saúde da Família* (Family Health Programme, FHP), is a large-scale national programme, implemented over the past several years. By 2011, it had reached 94 per cent of municipalities, covering 53 per cent of the Brazilian population. FHP aims to broaden access to public health services, especially in deprived areas, by offering free, community-based health care (Programa Saúde da Família 2000).

The National Policy on *Science, Technology and Innovation* (STI) in Health Policy, established in 2004, resulted from a democratic process with inputs from investigators, stakeholders and the public in general. Itis guided by six principles: (a) improving the Brazilian population's health conditions in the short, medium and long term; (b) overcoming all forms of inequity and discrimination (regional, social, ethnic, gender-based and others); (c) respecting people's lives and dignity; (d) ensuring the implementation of high ethical standards in health research; (e) respecting methodological and philosophical plurality; and (f) social inclusion, citizen control and respect for the environment and sustainability (Brasil 2008).

The National Agenda of Priorities in Health Research was created at that time to reduce the gap between scientific knowledge and health practice and activities, and aims to contribute to improving Brazilian quality of life. These efforts in guiding health research policy have achieved and legitimated an unprecedented developmental spurt in strategic health research (Pacheco Santos/Moura/BarradasBarata et al. 2011).

33.2.3 Brazilian Environment Policy

Brazil has traditionally been playing an active role in the international climate change arena. It was the first country to sign the United Nations Framework Convention on Climate Change (UNFCCC), in 1992. And during Copenhagen's COP15 run-up, it announced its voluntary pledge of a -36 to -39% reduction in GHG emissions by 2020 compared to a business as usual scenario. In 1997, by signing the Kyoto Protocol, Brazil agreed on limited compulsory greenhouse gas (GHG) reduction emission targets, and in the same year, the country passed law strictly limiting deforestation to twenty per cent of private property in the Amazonian region. However, resistance to the law was very strong until 2005, with the federal government unwilling to enforce the law and strong opposition from most state governments. From 2005 until 2009, the reduction of deforestation in the Amazon was at the core of the federal government's programme.

In 2003, the federal government approved the creation of the Permanent Group for Interministerial Work (*Grupo Permanente de Trabalho Interministerial*, GPTI), which was made up of the heads of thirteen key ministries and led by the Chief of Staff. The group's goal was to propose and coordinate actions aimed at reducing deforestation in the area known as *Amazônia Legal*[7] or Legal Amazon (Casa Civil 2013).

In 2004, the GPTI presented the operational project "Action Plan for the Prevention and Control of Deforestation in the Legal Amazon" (Plano de Ação para a Prevenção e o Controle do Desmatamento na Amazônia Legal, PPCDAm). This action plan is a large set of strategic conservation measures to be implemented and executed as part of a collaborative

---

7 The Legal Amazon of Brazil is defined by law to include the states of Acre, Amapa, Amazonas, Para, Rondonia, Roraima, Mato Grosso, Maranhao, and Tocantins in order to facilitate the economic development planning and integration to other Brazilian regions. Its are represents 61% of Brazilian territory and 13% of population (IBGE 2010).

effort between federal, state, and municipal governments, alongside specialized organizations and civil society. The launch of the plan in 2004 integrated actions across different government institutions and introduced innovative procedures for monitoring, environmental control, and territorial management (IPEA 2012).

The National Plan on Climate Change (NPCC) was lauched in 2007, which aims to promote actions on both mitigation and adaptation measures to face climate change, involving federal, regional and local governments, and all segments of the national society (Brasil, 2008).

Since 2007, the capacity of the state to control illegal deforestation in large areas has increased so dramatically that a significant part of the remaining deforestation has been reduced to small areas that are more difficult to detect by satellite. It is important to stress that this process was carried out without any negative impact on economic growth (Moutinho 2009).

After 2010, the federal government no longer aims to reduce deforestation, but rather to avoid any new increase. Between 1970 and 2010, approximately eighteen per cent of the Brazilian Amazon was deforested (Baccini/Goetz/Walker al. 2012), with the primary cause being demand for new land for the cultivation of soybeans and expansion of pasture.

With a view to creating a scenario for Brazil, and taking into account MLP as it is applied to particular national systems, to regimes, and to the nationwide creation of conditions for niches, some impacts of policy intervention are presented in table 33.2.

Brazil is a global leader in renewable energy sources, hydropower (designing reservoirs) and ethanol (fuel from sugar cane).The relevant technological innovations are interoperable and interdependent between the agricultural and transport sectors. In 2002, the government announced the *Incentive Programme for Renewable and Alternative Energy* (PROINFA), which supported renewable energy sources, including wind (Dutra/Szklo 2008).

33.3 Impacts of Anthropogenic Drivers on Health Security in Brazil

This section describes the consequences of policies targeting poverty reduction, hunger, sustainable development, environmental protection and the reduction of social inequities in Brazil. By means of universal

Table 33.2: Timeline of main policy interventions in Brazil and their impacts on health andthe ecosystem, together with their social and economic aspects. **Source**: The author.

Driver	Policy interventions (landscape)	Time	Technological Innovation		Impacts	
			green innovations (niches)	non- environmental	Negative	Positive
Energy supply	Building of hydroelectric power plants	1960 2014	Hydropower		Changes in ecosystem, loss of biodiversity	Increased access to energy
	Incentive Programme for Renewable and Alternative Energy	2002 2014	Solar power			Decreased demand for other energy sources
	Incentive for exploring deep offshore oil reserves	2000 2014		Oil	Increased GHG emissions, environmental pollution	Increased commodities
	Incentive to create thermos-electric power plants	2000 2014		Oil + Thermo-electricity	Increased GHG emissions environmental pollution	
	Building of wind power plant	2010	+Wind power electricity			Decreased demand for energy
	Incentive for bioelectricity	2000	Sugarcane bagasse burning			Decreased demand for other energy sources
Mobility	Incentive for sugarcane mills	1970 2014	Use of ethanol for transport (fuel from sugar cane)		Changes in land use Ecological disequilibria	Decreased GHG emissions
	Public transport	1980 2014		Poor public transport	Increased GHG emissions	Increased job opportunities in industry
	Incentive for acquisition of self-transportation vehicles	2000 2014		Increase expansion of private transport	Increased individual energy expenditure Increased number of deaths from motorcycle accidents (67%)	Increased job opportunities in industry
Industry	Incentives for automobile industry	1970 2014	Cars running on biofuel		Increased GHG emissions	Increased job opportunities in industry
Agriculture	Growth of agribusiness Mechanization	2000 2014		Expansion of culture, habitat fragmentation	Changes in land use Increased unemployment, social exclusion, violence	Improvement of economy
	Expansion of agriculture Modernization of traditional cattle ranching	2000 2014		Intensive use of agro-toxic substances	Deforestation Increased GHG emissions, health issues, use of agro-toxic substances in food production Migration	Food availability
	Food Acquisition Programme(PAA)	2003	Incentive for organic agriculture			Improvement in family agriculture
Healthcare	Unified Health System (SUS)	1988	Popular involvement and accountability		See table 33.3	See table 33.3.3
Poverty Hunger Social inequities	Zero Hunger Strategy	2003	Improvement nutritional status			Reduction in 1. under-5 mortality 2. malnutrition 3. diarrhoea
	Brazil without Extreme Misery	2011				
	Establishment of Bolsa Família	2004	Improvement of income Improvement of education			
Environmental protection	Law limiting deforestation to 20% of private property in the Amazonian region. Policy for solid waste	1997 2006	Decrease in rate of deforestation			Decreased infectious disease transmission related to deforestation Decreased GHG emissions
Sustainable development	National Plan on Climate Change	2008	Stop burning and smoke emissions			Improvement in hospital admissions

Table 33.3: Transition of heath indicators in Brazil. **Source:** The author.

	Indicator	Time	Source
Life expectancy	Life expectancy at birth (years)	67 (1990) 73 (2009) 73.9 (2013)	PNUD 2014
Infant mortality	Infant mortality rate (probability of dying by age 1 per 1000 live births)	50 (1990) 31 (2000) 17 (2010)	
Infant mortality	Under-5 mortality rate	59 (1990) 36 (2000) 19 (2010)	
Adult mortality	Probability of dying between 15 and 60 years old per 1000 population	275 (2000) 219.67 (2011)	World Bank 2014
Extreme poverty eradication	Extreme poverty	15 million (2015)	PNAD, IBGE 2013
External causes	Deaths per 100,000 population	68.7 (2006) 78.4 (2012)	DATASUS 2014
Education	Proportion of people with seven or more years of formal education	19% (1976) 47% (2008)	Paim/Travassos/Almeida et al. 2011
Income inequality	Gini coefficient	0.530 (1960) 0.636 (1989) 0.594 (1999) 0.530 (2012)	IPEA 2012

health coverage, conditional cash transfers and environmental policies, the process of sociotechnical transition has had an impact on quantitative indicators (health indicators), such as life expectancy and mortality among infants and adults (table 33.3).

In Brazil, life expectancy has improved from 67 years in 1990 to 73 years in 2009 and to 73.9 in 2014, according to PNUD or UNDP (2014). The infant mortality rate (the probability of dying by age 1 per 1000 live births) has decreased from 50 in 1990 to 31 in 2000 and 17 in 2010; and the under-5 mortality rate has also decreased from 59 in 1990, to 36 in 2000 and 19 in 2010, according to WHO (2013b). The adult mortality rate (the probability of dying between 15 and 60 years old per 1000 population) has decreased from 275 (2000) to 219.67 (2011) (World Bank 2014).

The leading global risks for mortality in the world are high blood pressure (responsible for 13% of deaths globally), tobacco use (9%), high blood glucose (6%), physical inactivity (6%), and overweight status and obesity (5%).The leading cause of death in Brazil is cardiovascular disease, second is cancer, and external causes are third (Brasil 2014).

The *World Health Organization* (WHO) estimates that the warming and precipitation trends caused by anthropogenic climate change over the past thirtyyears have already claimed over 150,000 lives annually. Many of the prevailing human diseases are linked to climate fluctuations, from cardiovascular mortality and respiratory illnesses caused by heat-waves, to the altered transmission of infectious diseases and malnutrition from crop failures.

Researchers report (Li/Cheng/Cui et al. 2014, Wang/Lin 2014) that an increase of 1°C in the daily maximum temperature increases mortality and the number of urgent and emergency room visits due to cardiovascular diseases. Considering that extreme weather events have been increasing not only in Brazil but globally, and that cardiovascular disease is the leading cause of death, the consequences for the health systems must be considered.

Another worrying indicator is external causes, the third most common cause of death in Brazil. There was an increase of 14.1 per cent in deaths from external causes, up from 68.7 deaths per 100,000 population in 2006 to 78.4 deaths per 100,000 in 2012.

Among the specific causes of death, homicides increased by 10.5 per cent, from 26.6 deaths per 100,000 population in 2006 to 29.4 deaths per 100,000 in 2012.

Traffic accidents increased by 19 per cent, from 19.9 deaths per 100,000population in 2006 to 23.7 deaths per 100,000 in 2012. The vehicles most frequently involved in traffic accidents were motorcycles, with an increase of 67.8 per cent in the mortality rate (Ortiz 2014).

The implications of these data for understanding the dynamics of sustainability transition are crucial. Policy issues that need to be addressed are the creation of incentives for economic bases such as the automobile industry and sugar cane agribusiness, policies for improved mobility, such as public transport and policies that take into account the forces influencing political, sociotechnical and cultural features.

Deforestation is part of the increasing threat of new illnesses and loss of public health.Measurements carried out in southern Amazonia have demonstrated that exposure to PM2.5 particulates has a positive association with children's respiratory health (Ignotti 2010).

Another study (Smith/Aragão/Sabel et al. 2014) showed a significant increase (from 1.2% to 267%) in hospitalizations forrespiratory diseases in children aged under five in municipalities highly exposed to drought. Aerosols were the primary driver of hospitalizations in drought-affected municipalities during 2005.

The transition to sustainability in Brazil during the last decades has been driven by political regimes and socio-economic and technological processes, and may be summarized as follows. The 2000s were marked by diminishing inequalities. The main impact factors were better employment conditions for the poorer segments of the population and a remarkable expansion in cash transfers. This expansion was accompanied by a slight diminishment in social services and infrastructure until 2005, which corresponded with neo-liberal concepts of social policies. From 2006 onwards, the trend towards 'monetarization' has been reversed, as investments in social services and infrastructure have been raised considerably. The overall strategy has shifted from 'inclusive liberalism' to 'developmental welfare', where the reduction of inequalities through state-induced measures is viewed as an important factor in raising the level of consumption and thereby boosting economic growth (Leubolt 2013).

In a study of the effect of a conditional cash transfer programme on childhood mortality, Rasella, Aquino, Santos et al (2013) show that *Bolsa Familia* had a significant role in reducing under-5 mortality, both overall and from poverty-related causes such as malnutrition and diarrhoea, in Brazilian municipalities between2004 and 2009. The effect was maintained even after adjusting for socio-economic covariates and the FHP. The increase in the duration of *Bolsa Familia* and in the coverage of both the total and target populations strengthened the effect of the programme. The authors concluded that a large-scale programme such as *Bolsa Familia*, combined with an effective primary healthcare system, can strongly

reduce childhood mortality, both from poverty-related causes and overall. Mechanisms included the effects on social determinants of health services and the increased use of preventive services for children and pregnant women through programme conditions.

Brazil has not yet embarked on a low carbon green economy paradigm, and lacks serious planning and long-term goals. What is important is the way in which Brazil, particularly in the economic realm, will set the parameters and priorities for alow carbon transition.

The globalization of markets (landscape pressures) is related to international factors of development, and in the case of Brazil it puts pressure on deforestation: Brazil's primary issue being the demand for new land for the cultivation of soybeans and the expansion of pasture.

The growth of agribusiness, together with agricultural expansion and the modernization of traditional cattle ranching, have brought about enormous changes inland use. Land use change and forestry have traditionally been the major drivers of Brazilian greenhouse gas (GHG) emissions.

This has been exerting pressure through demographic trends, with an increase of the population in urban areas from 44 per cent urban to 86 per cent urban in about seven decades.

Agricultural expansion and the modernization and mechanization of large agricultural holdings has resulted in the loss of jobs for rural workers, who then migrate to urban areas.

This migration from rural to urban areas puts pressure on the urban sector and increases the demand for health, education, food and nutrition, social security, energy, and transport, among other things. When there is no planning or policies to meet the demand, there is expansion of human settlement in areas of environmental risk, together with social exclusion and an increase in violence and homicides.

33.4   Conclusions

Transitions are about radical change in systems that are there to meet the needs of societal systems—in this case, healthcare systems.

Brazil has shown how *universal health care* (UHC) can serve as a vital mechanism for improving the health and welfare of its citizens, and can lay the foundations for economic growth and competitiveness grounded on the principles of equity and sustainability. These findings are intended to provide lessons

that can be used by countries aspiring to adopt, achieve, and sustain UHC.

The lack of urban planning, the lack of public policies for public transport and to provide the incentive for the acquisition of self-transportation vehicles has increased the number of deaths from traffic accidents by 19.0 per cent. Transport systems in Brazil must be decarbonized, but this depends on increasing energy efficiency and disseminating low carbon energy sources.

The mortality statistics demonstrate how the health infrastructure is under pressure, health services overwhelmed and public financial resources put in danger. The health services need urgently to fit themselves for the future, creating an environment of efficiency, quality and the wise use of resources, and incorporating

actions that reduce inequities in the health budgets of municipal, state and federal governments.

The implementation of effective social policies has enabled Brazil to partially reduce absolute poverty and income inequality, thus contributing to decreasing death rates in the population and to the improvement of the health indicators of extreme poverty and hunger, under-5 mortality, maternal health, infectious diseases, and primary education coverage. Reducing income inequality may represent an important step towards improving health and increasing life expectancy.

Despite inter-sectoral collaboration between health, education and social governmental sectors, strong efforts have to be made in the economic area in order to achieve sustainability transition.

Part IX   Preparing Sustainability Transitions in the Energy Sector

34   Enabling Environments for Sustainable Energy Transitions: The Diffusion of Technology, Innovation and Investment in Low-Carbon Societies

Jürgen Scheffran[1] and Rebecca Froese[2]

Abstract

A sustainability transition requires innovations, investment and learning to support transformation processes in different fields, including new technologies, products and infrastructures, as well as new social rules, norms and interactions. Greening the economy rests on the rapid and effective dissemination of climate-friendly technologies, and in particular of renewable and efficient energy systems. Substantial financial support and smart governance are required in this process in order to develop the economic, sociopolitical and technological capacities of all countries. Within this progression, the international diffusion of know-how, technologies and investments requires enabling environments to build up local production capacities and demand for low-carbon goods. Further, business, governmental and non-governmental actors rely on social learning to establish cooperation at multiple levels in order to adapt technologies to local contexts within national and global frameworks and to support the transformation towards low-carbon societies. Various mechanisms are analysed and discussed.

Keywords: Diffusion, enabling environments, technology transfer, innovation, knowledge, learning, private investments, low-carbon societies, sustainable energy transition.

34.1   Introduction: The Innovation Challenges for Environment and Development

The world is facing two major challenges which are closely related. On the one hand, atmospheric CO_2 concentration needs to be stabilized at a level that avoids catastrophic climate change. On the other, access to affordable, reliable, and clean energy is required to alleviate poverty and to drive economic development for a growing world population, especially in rural areas of the developing world, where approximately 1.5 billion people are still not connected to the power grid. Within this nexus of environment and development, major innovations in the technical, sociopolitical and financial sectors are required. The main problem is to understand the conditions and linkages of the technical, sociopolitical, economic and financial challenges facing the sustainable energy transition.

34.1.1   The Challenge of Technical Innovation

Replacing fossil-based energy systems with renewable energy sources and the complementary improvement of energy efficiency and other low-carbon energy options can play a key role in simultaneously addressing global warming and access to energy (Santarius/Scheffran/Tricarico 2012).[3] Fast-developing technical innovations and a radical change towards environmentally sound technologies will be essential to solve this

---

double challenge, especially if global climate disasters are to be prevented. The urgent need for action means that even technology that is not completely 'clean', 'green' or 'climate-friendly' may be acceptable, provided that it is practically available and adequately meets the sustainability criteria.

34.1.2   The Challenges of Sociopolitical Innovation

Innovation is also on the agenda in the social and political realm. The global climate policy debate is no longer about whether to take action but about how, when and where to act, which actions need to be taken and by whom. While the struggle against global climate change ranks high on global political agendas, policymakers are striving to find and agree upon the best policy frameworks. Various conflicting issues need to be mediated, bridged and peacefully integrated in the future: economics and the environment, science and society, international and domestic policies, global and local governance, public and private spheres, governments and civil society, developed and developing countries.[4] Overcoming these differences requires a level of coordination and cooperation across multiple levels and unprecedented in history. The problems can best be solved by collaboration.

34.1.3   The Challenges of Economic and Financial Innovation

Managing the energy revolution requires massive technological and financial resources. Countries worldwide, from China and India to Germany and the United States, have recognized this need and they have already achieved considerable changes through substantial investment in the transformation of their economies' energy base. However, a large gap still remains between current investment levels and the amount of climate investment needed (see table 34.1). Actual climate finance levels in 2011/12 were estimated at €200 billion at global level and €120 billion at EU level. Future investment needs for 2020 are suggested to be €780 billion globally and €280 billion for the EU (EC 2015: 111).

The EU Commission's Impact Assessment of the 2030 Climate and Energy Framework forecasts that €193 billion needs to be invested per year between 2011 and 2030 in order to modernize ageing infra-

---

4   In parts of the literature "North" and "South" are used for developed and developing countries respectively.

Table 34.1: The gap between actual and required climate financing. **Source**: Own representation, data from EC (2015).

	EU	Globally
Actual climate finance levels 2011/12	€120 billion	€200 billion
Future investment needed by 2020	€280 billion	€780 billion
Remaining investment gap	€160 billion	€580 billion

structure and to avoid lock-in of inefficient technologies, so that the 2030 climate and energy targets of a forty per cent reduction in emissions can be achieved (EC 2014). A European scenario dealing with the financing of technologies in power production, road transport, and buildings between now and 2020 identified accumulated investment requirements of €350 billion in technology development and €1.65 trillion in technology procurement (Accenture/Barclays 2011).

These figures mean that the accountability of the private sector has to be increased, since public finance is not sufficient to address this global problem. However, public initiatives are essential to leverage private capital and to catalyse it in the most climate-friendly direction (Santarius/Scheffran/Tricarico 2012). Since businesses can be seen as both part of the problem and part of the solution, climate change policies need to encourage business to contribute more constructively to the transformation process. This means that international investment policies are to be incorporated into the climate change framework, with guiding principles for *transnational corporations* (TNCs) and foreign investment. Public and private sectors have to be synergized to galvanize low-carbon investment aimed at climate change mitigation. This process needs time to make an impact and gain a certain visibility. However, an increasing number of TNCs have attempted to integrate sustainable development issues into their strategies, under pressure from consumers and advocacy groups (World Investment Report 2010). At the end of 2014, more than 8,000 corporations had signed up to the United Nations Global Compact, including more than 250 of the world's largest companies (Moon 2014).

Even though some countries are already notable producers and exporters of climate-friendly technologies, a worldwide energy revolution and sustainable economic transformation will only succeed if the economic and technological capacities of all countries are involved. The main task governing the transformation

is to significantly scale up production capacities for clean and energy-efficient technologies all over the world, and in developing countries in particular.

34.2 Context and Framework of Technology Transfer

34.2.1 Shifting Historical Contexts

Technology transfer and related finance mechanisms are key instruments in bridging technology gaps, in particular between developed and developing countries. Technology transfer is widely seen as an important element of development and cooperation, but it can also raise concerns where there is a competitive and conflicting environment that technology may become the object of economic and political power games, because of its role in efficiency increase, path creation and force multiplication. This was a dominant feature of the East–West conflict: *research and development* (R&D) was heavily involved in the arms race, with exploitation of the links between civilian and military science and technology (Altmann/Scheffran 1983; Scheffran 1986). At the same time, comprehensive restraints on technology development were established between the NATO and Warsaw Pact alliances as part of arms control and export control regimes; notable examples were the *Coordinating Committee on Multilateral Export Controls* (COCOM), the Nuclear Suppliers Group, and the *Missile Technology Control Regime* (MTCR). Some of these activities were carried forward into the post-Cold-War era to create instruments of the non-proliferation of weapons of mass destruction in the nuclear, chemical and biological fields of technology, as well as in other hi-tech domains such as missiles, space, and information and communication technologies, with the aim of restricting the transfer of technology to developing countries, notwithstanding the dual-use potential of modern technology (Brauch/Graaf/Grin et al. 1992; Scheffran/Karp 1992; Scheffran/Liebert 1994; Liebert/Rilling/Scheffran 1994).

The focus shifted as part of the push towards conversion of the huge military complexes of the superpowers and their allies, and the growing relevance of addressing environmental problems. Both together led to the idea of transforming the enormous resources in science and technology that existed in the military complex towards environmental purposes. These resources included information and communication technologies, which appeared as particularly promising because

of their dual-use potential and ambivalent role (Scheffran/Vydra 1991, UN 1991; Scheffran 1992a, 1992b). When subsequent attempts to include peace-related issues in the 1992 Earth Summit in Rio de Janeiro failed, the processes and discourses on security/peace and environment/development fell apart, and the opportunity for a peace dividend was missed. This process can be traced through a series of conferences on conversion in Dortmund, Moscow and Hong Kong that led to the foundation of the *Bonn International Center for Conversion* (BICC), and the series of *Conferences of the Parties* (COP) of the *UN Framework Convention on Climate Change* (UNFCCC), whose secretariat is also located in Bonn (for a ten-year review, see Scheffran 2002). While in the first process the dual use of technology became a key dimension of high-tech warfare and its control (most notably in the wars in Iraq and the Balkans, as well as in space and cyber warfare), the second process highlighted technology transfer as an important element in avoiding dangerous climate change and environmental degradation (IPCC 2000). Occasionally the dual role of technology in environment and security was made apparent, e.g. in the use of satellites for Earth observation and reconnaissance (Scheffran 2001).

Following the 1992 Earth Summit and the UNFCCC–COP process, the discourse on technology transfer has been shaped considerably by the merging of calls for sustainable development, for energy transition and for a low-carbon society. R&D is essential for energy supply and distribution as well as for the reduction of greenhouse gas emissions from fossil energy sources that drive climate change, and so science and technology infrastructures are key components of an enabling environment for sustainable energy transitions. In this context, there are three main areas in which the thinking on climate change mitigation has been transformed (see box 34.1 and Lema/Iizuka/Walz 2015, summarizing a special issue of *Innovation and Development*):

- from 'technology' to learning and innovation;
- from international 'transfer' to interactive collaboration;
- from 'diffusion' to systems building.

Cutting across these areas, a comparative assessment of different studies discerns the need for more context-specific and interactive approaches towards the transition to *low-carbon development* (LCD). This includes the idea that the "learning, innovation, and competence-building system lens can help to understand the diverse settings in which 'developing coun-

Box 34.1: Aspects of technology transfer and learning in low-carbon development. **Source**: Adapted and condensed from Lema/Iizuka/Walz (2015).

From 'technology' to learning and innovation:
- Going beyond the narrow concept of technology development, distinguish between designs, complete equipment, and installation services (hardware) and skills, knowledge, and expertise for short-term operation and maintenance and long-term change (software).
- Attainment of capabilities (learning) may enable local low-carbon innovation effectively.
- Innovation is a comprehensive and interactive process, which is about breakthrough hi-tech equipment emerging from R&D labs.

From international 'transfer' to interactive collaboration:
- Compared to providing access to hardware technologies, little regard was paid to the facilitation of knowledge exchange and development of local technological capabilities and system building.
- Discussion on trade and intellectual property rights focuses on technology transfer rather than on fitting local circumstances to ensure the absorption, contextualization, and deployment of technology.
- Discussions in UNFCCC took the traditional view, where stimulation of climate-friendly technology transfer was limited to hardware and financing assistance, a strategy widely deemed unsuccessful.

- There is a growing consensus that international action for climate change mitigation and development in the global South must focus on innovation cooperation, i.e. joint action to accelerate the development, adaptation, and deployment of suitable technologies.
- Innovation-cum-cooperation needs to support the deployment of technology, and to identify collaborative patterns for better knowledge creation and diffusion for LCD.

From 'diffusion' to systems building:
- Technology diffusion has been seen as the deployment of low-carbon technologies, e.g. renewable energy technologies or energy efficiency measures.
- Increasing attention is paid to the complexity of the underlying process, which is not simply about rolling out technologies, but also about transforming the relevant sociotechnical setting.
- Effective LCD needs to include organizational and institutional change as well as changes in the realms, instruments, and techniques of policy-making.
- Calling for a systems approach in analysing LCD, we include learning, innovation, and competence-building systems rather than focusing on innovation systems, which is an approach arising from studies in developed countries.

tries' are situated and ultimately help to enhance synergies between climate change mitigation and socio-economic development" (Lema/Iizuka/Walz 2015: 183). Finally, the assessment shows that what is required is a more integrated view of trajectories of innovation towards low-carbon societies, including the *water–energy nexus*; it also raises questions about the *political economy* of low-carbon innovation and development; and it identifies new, diverse and changing innovation *pathways* and conditions for low-carbon transformation that are on the horizon in developing countries (Lema/Izuka/Walz 2015). These are "likely to differ markedly among countries because of the diversity in policies, endowments, and technological capabilities" (Lema/Izuka/Walz 2015: 177), and this has implications for "the effectiveness of mitigating climate change and tackling related domestic energy challenges as well as [for] the degree to which low carbon technologies and solutions can become a source of national competitiveness" (Lema/Iizuka/Walz 2015: 177). There is a need for new frameworks to enable LCD to be understood in developing countries.

There is a range of literature on the process of technology transfer that covers the various issues of innovation, development, behavioural change and socio-economic development (see the overviews in

IPCC 2000; Karakosta/Doukas/Psarras 2010). Empirical evidence, theoretical advancements and policy recommendations on low-carbon technology transfer are provided in Ockwell and Mallett (2012), who draw on the literature on adaptive and incremental innovation and sociotechnical transitions to highlight various critical issues: co-evolution of technologies and society; insights from innovation studies and sociotechnical transitions; the context-specific, spatially situated technology needs of different people in different spaces; the way in which innovation capacities are developed via the development of 'innovation capacities' in order to adopt, adapt, develop, deploy and operate technologies effectively within specific contexts (Bell 2009). While there are no overarching theories, in the following sections a conceptual framework of analysis will be considered, applied to the analyses of technology transfer, the role of technology transfer in innovation, and the diffusion of low-carbon energy technologies.

34.2.2 Conceptual Frameworks

34.2.2.1 Adaptive Technology Life Cycle

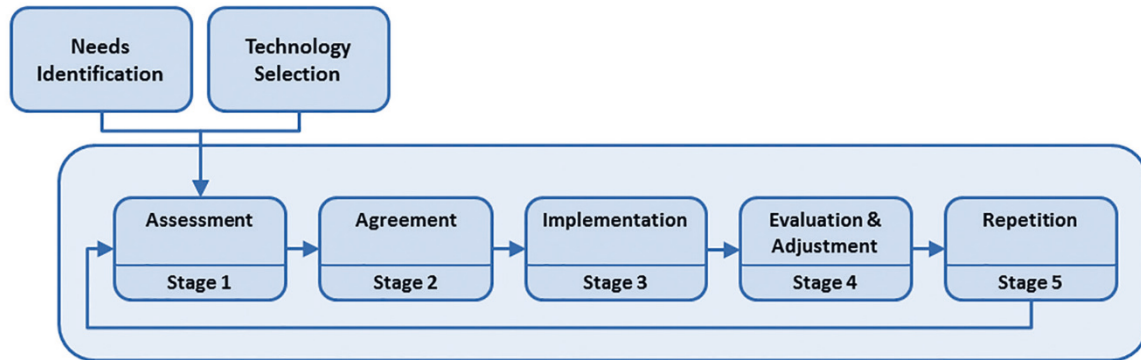
Technology is made up of processes that create new pathways for action or allow the realization of actions more effectively according to given criteria, such as cost or resource efficiency, the gaining of benefits or the reduction of risk. From a narrow economic viewpoint, technologies are treated as 'objects' or 'hardware' that can be moved around from one location and context to another and sold on markets like goods. In the context of sustainable development, the life cycle approach is more appropriate. In production processes, technology uses input factors (such as material, energy, land, labour or investment) to realize intended output actions. The quality of a technical system is determined by how many input factors are needed to realize a certain action. For instance, a wind turbine converts wind into electricity, and a biorefinery converts biomass into various bioproducts, including bioenergy. Here the quality of a technology is measured by the energy balance and the carbon emissions per energy unit. If investment is the input variable, the quality indicator then is the net financial return throughout the stages of the life cycle (R&D, design, testing, assembling, building, production, maintenances, transportation, utilization, dismantling and waste management). To support the different stages in this life cycle requires an enabling environment and infrastructure that provide the necessary linkages and networks to absorb the input needed to produce the required output, while minimizing side effects and risks. To be effective, the technical system and its natural and social environment must fit to each other, and technology should adapt to local needs and conditions. In particular, an enabling environment and infrastructure are important to facilitate the development of technology in other parts of the world. Without an adequate interface of connections, a technical metabolism and life cycle cannot operate and survive in a new environment. An example is a power plant transferred to a remote area in a developing country without transportation, power lines, water resources, trained employees or the capacity to maintain it under adverse climatic conditions.

34.2.2.2 Enabling Environment and Knowledge

The concept of an 'enabling environment' is not clearly defined and has many different interpretations. According to UNFCCC (2001), an enabling environment "focuses on government actions such as fair trade policies, removal of technical, legal and administrative barriers to technical transfer, sound economic policy, regulatory frameworks and transparency, all of which create an environment conducive to private and public sector technology transfer" (cited in IPCC 2014: 1178). One definition emphasizes government policies for "creating and maintaining an overall macroeconomic environment" (UNCTAD 1998: 24). Another definition interprets an 'enabling environment' as the wider context within which development processes take place, i.e. the role of societal norms, rules, regulations, and systems (Bolger 2000). This environment may either be supportive (enabling) or constraining (IPCC 2014: 1222).

To facilitate technology development, the necessary enabling environment and infrastructure need to be created in the recipient country, following three separate technology flows: a) capital goods and equipment; b) skills and know-how for operating and maintaining equipment, and c) knowledge and expertise for generating and managing technological change in order to adapt technologies to the local context. It is not sufficient to transfer technology without knowledge of how to (re-)produce it and the skills in using it. The knowledge component of technology includes "both codified knowledge (e.g. engineering and manufacturing processes) and tacit knowledge (human-embodied knowledge acquired by doing, e.g. applied engineering and systems integration skills)" (Ockwell/Mallett 2012: 8). This dynamic differentiates between know-how skills (e.g. ability to operate and maintain 'hardware') and know-why skills (ability to understand the principles behind how such 'hardware' works).

For the creation of an enabling environment, particular attention needs to be paid to building the soft elements, such as intellectual property, organizational knowledge and managerial skills, as well as corporate culture, values, norms and standards (Ockwell/Haum/Mallett et al. 2010). Accordingly, Schnepp, von Glinow, Bhambri et al. (1990) define technology transfer as "...a process by which expertise or knowledge related to some aspect of technology is passed from one user to another for the purpose of economic gain". This implies that an infrastructure for establishing these soft skills is required, including education and research facilities for transferring the scientific-technical knowledge about the principles and practical use of technology. When technology is being transferred through an organization such as a manufacturer, there is tacit knowledge associated with the procedures of the organization. For the host developing country, there are knowledge requirements for the

Figure 34.1: The process of technology transfer. **Source**: Adapted from Karakosta/Doukas/Psarras (2010).


people and institutions who want to interface with the technical systems, including their supply and support chains (Karakosta/Doukas/Psarras 2010).

34.2.2.3 Stages of Technology Transfer

Within the technology transfer process five basic stages can be identified (IPCC 2000; Karakosta/ Doukas/Psarras 2010): 1) Assessment; 2) Agreement; 3) Implementation; 4) Evaluation and Adjustment; 5) Repetition and Replication (see figure 34.1). The processes are not necessarily sequential and can occur in parallel, adding to the complexity of technology transfer. The last two stages, for instance, involve the transfer to and adoption in the local energy user market. The Assessment stage is preceded by the identification of needs and the selection of the technology to be assessed. A hierarchical description distinguishes between *vertical transfer* from the laboratory or test bed into commercial use, and *horizontal transfer* from one geographical location to another. The transfer of low-carbon technology between developed and developing countries can also vary depending on industrial sectors, national circumstances and the type of technology. Technology flows can be assisted and supported along various pathways, such as through direct purchases and trade; foreign direct investment; licensing, subcontracting and franchizing. Cooperative activities include joint ventures; cooperative research and co-production (IPCC 2000).

34.2.2.4 Resources and Infrastructures

To be produced, used and maintained, a technical system needs resources and infrastructures for its operation as well as human and social capital that rests on the working capacity and skills of the people who maintain, operate and use it. A viable technology infrastructure requires a "manufacturing capacity, supply chain capacity, end-of-life/waste disposal, institutional capacity and sustainability of the whole process and the social networks between them" (Karakosta/Doukas/ Psarras 2010). Some elements of the infrastructure may exist in a country, others not. Some gaps can be closed domestically by building the capacity needed, other gaps have to be acquired internationally—this may be more feasible for individual components (such as mechanical tools or vehicles) but is more difficult for whole networks and systems (such as power grids or transportation systems). Knowledge is a resource central to successful capacity building in recipient countries, and is potentially transferrable as human beings may relocate in limited numbers. Unlike traditional accumulation theories that see knowledge as a transferable entity following investment flows, assimilation theories of technology transfer consider the impact of the knowledge and the characteristics of suppliers and recipients who assimilate that knowledge (Ockwell/Haum/Mallett et al. 2010). The mutual dependency between consumer behaviour, markets created by new technologies and associated social structures need to be considered in planning for the transfer of the technology and is one of the reasons why technology transfer has to be treated as a complex process in which local organizations and communities take the lead.

34.2.2.5 Technology Development as a Learning Process

Technology development and transfer is a continuous process of learning and decision-making between competing alternative technology pathways which are selected within societal and organizational structures that enable informed choices. To a large extent, the state of the world today is the result of the technological choices of the past. Similarly, the future state of the world will be determined largely by the technologies we choose today (Trindade 1991). The role of

learning has been already raised in the definition used by IPCC (2000), where technology transfer involves the process of "learning to understand, utilise and replicate the technology including the ability to decide which technology to transfer and adapt it to local conditions and integrate it with indigenous technologies". According to Archibugi and Michie (1997): "policy to support technology should address the diversity of learning mechanisms and the conditions which enhance the learning capabilities of firms". Schnepp's definition above also emphasizes the economic benefits, which for the transfer of low-carbon technology includes the mitigation of the future costs associated with climate change as well as any financial benefits to the companies involved in the transfer process (Karakosta/Doukas/Psarras 2010). Newer and broader conceptions of technology transfer see it as a process of incremental and cumulative learning by which the results of the initial choice are internalized. Like R&D, it is an essential component of what is described as social learning (Brooks 1995).

34.2.2.6 Technology Transfer in the Context of Climate Change

Preventing dangerous climate change, sustainable development and decarbonization will require radical technological, economic and societal changes in both developed and developing countries, favouring technologies that support adaptation and mitigation strategies. Although most new carbon abatement technologies are being developed in industrialized countries, much of the potential for low-carbon energy production and emission reductions is located in developing countries where fossil fuel consumption is still increasing rapidly. Low-carbon sustainable technologies need to be adopted by both developed and developing countries, and this requires that developing countries avoid being locked into unsustainable practices and technologies and move quickly to environmentally sound and sustainable practices, institutions and technologies. The basic technologies for renewable energy and energy efficiency already exist and promise to address the problem of climate change. The transfer or innovation processes must be rapid enough to prevent dangerous climate change and to make themselves readily available where they are needed most. Economic development is most rapid in developing countries, but it will not be sustainable if these countries follow the historic emission trends of developed countries. Renewable energy investments in the developing world deliver lower carbon abatement costs than in the developed world, while also achieving a broad range of additional social, economic, and environmental benefits. For these reasons, the transition of global energy systems to lower-carbon pathways depends upon "creating an institutional capacity for a national environmental policy" as an important precondition for North–South collaboration (Ipsen/Rösch/Scheffran 2001: 323), and the successful transfer to and absorption of low-carbon technologies within developing country economies (Mallett/Ockwell/Pal et al. 2009). In the absence of strong policy support mechanisms and incentives, as well as for cheap and readily available fossil fuels, public and private funds are unlikely to deliver the necessary technologies at the cost and scale necessary to address climate change. These goals can only be achieved through major changes in the investment framework (WBCSD 2010).

34.3 Implementing the Technology Transfer Framework

34.3.1 Science and Technology Infrastructure

The basis of technology development and transfer depends upon its technology infrastructure, made up of a set of specific, industry-relevant capabilities such as technology centres, research facilities and educational institutions that support the development of technical skills. Establishing a technology infrastructure requires considerable efforts and long lead times; on the other hand it depreciates slowly. Aspects include information relevant for strategic planning and market development and forums for joint industry–government planning and collaboration, as well as the assignment of intellectual property rights.

34.3.1.1 Technology Infrastructure

Technology infrastructure may not be of direct economic value to firms, and this reduces the incentive to build technology infrastructure on their own. To develop a public technology infrastructure, governments can invest public money, stimulate demand and attract technological capabilities that may exist elsewhere but will need to be imported, adapted, and absorbed in the local economy. In addition, it is important to induce institutional change and organizational development in order to adapt the technology infrastructure to various supportive measures. Finally, governments can increase public awareness and spread capability through public networks (Justman/Teubal 1995). National policies and regulations are essential

---

Box 34.2: Public–Private Partnership for Electricity from Peanut Shells in Senegal. **Source**: Assembled by the authors.

Many villages in remote rural areas of the Senegal lack access to the national power grid. Particularly in the energy development sector, public–private partnerships play an important role in enabling technology transfer and adaptation to the local context. In 2010, Stadtwerke Mainz, a local energy provider for the city of Mainz in Germany, launched a project for rural electrification in collaboration with the German Investment and Development Society (*Deutsche Investitions- und Entwicklungsgesellschaft*, DEG).

The project was implemented in Kalom, a village with 1,200 inhabitants who have no access to the national power grid. Within the framework of the project, a biomass power plant fuelled by peanut shells and millet stalks has been built. Most of the fuel required is purchased from local farmers, providing a secure income for the farmers. The rest is bought from a bigger producer of peanut oil. A foreign private stakeholder has provided the technology for the biomass power plant and supported the project with on-site training for the villagers.

Within the centre of the village, the electricity produced is distributed via underground cables. Households that are not connected to the local grid get electricity access though rechargeable mini solar modules or rental batteries. Some electricity distribution businesses have already been set up in outer parts of the village. Besides the socio-economic and environmental benefits, these renewable energy sources are steadier and more reliable than the previously used diesel generators or car batteries.

In 2012 the power plant was handed over to a local operating company with the Energy for Africa Foundation and about a dozen villagers as shareholders. The local villagers have been provided with on-site technical and business know-how by the technology provider in order to run and maintain the power plant independently. Since then, seven local employees have been hired by "Kalom Mainz Industries" and run the power plant.

---

for building on the technological capabilities developed by domestic companies and for inducing foreign investment. Domestic progress in low-carbon processes can then be distributed throughout the international network of operations of TNCs, and consequently attract further foreign investment (WIR 2010).

34.3.1.2 Energy Infrastructure

A vital resource within the technical infrastructure is energy which should be integrated into national development strategies. Energy is necessary for preparing food, heating and lighting homes, maintaining schools and hospitals, and driving industry, as well as for connecting people and goods to markets. Public policies and public–private partnerships could focus on improving grid transmission, local electricity generation and energy storage systems, where renewable energy is essential (boxes 34.2 and 34.3). The IEA estimates that about US$5.2 trillion is required in generation investments, and an additional US$6.1 trillion for transmission and distribution networks from now until 2030 (WBCSD 2007).

34.3.1.3 Research and Development Infrastructure

Investing in R&D is an essential precondition for building the technology infrastructure of a country. Historically, governments have played a key role in supporting research and development through national laboratories, universities, and international collabora-

tive ventures. Public funding remains a major source for R&D activities in both industrialized and developing countries, involving either general support for national R&D institutions and laboratories, or direct funding of specific projects according to set government priorities. Effective R&D policies alleviate technical barriers and reduce costs by improving materials, components, system design and tools for installers and users.

34.3.2 Framing Conditions for Innovation

34.3.2.1 Leapfrogging and Diffusion

In addition to the transfer of knowledge and technology, which is in itself not sufficient for effective implementation, a country would be "equipped with a complementary system to enable such acquired knowledge to be diffused and adapted locally. International collaboration should go beyond the technology focus to a capability and system-building focus" (Lema/Iizuka/Walz 2015: 176). If the "political economy is favourable and new actors are allowed to create spaces for innovation", this can be a 'window of opportunity' to leapfrog towards carbon-efficient systems, following multiple and diverse trajectories (Lema/Iizuka/Walz 2015: 185). According to IPCC (2014: p.258), "leapfrogging", or the "skipping of some generations of technology or stages of development, is a useful concept in the climate change mitigation literature for enabling developing countries to avoid the more emissions-intensive

stages of development" (Watson/Sauter 2011). The same source notes that "innovation in and diffusion of new technologies also require skills and knowledge from both developers and users, as well as different combinations of enabling policies, institutions, markets, social capital, and financial means depending on the type of technology and the application being considered" (IPCC 2014: 301). Harnessing these kinds of capabilities and processes may require novel mechanisms and institutional forms.

One of the critical phenomena is rapid urbanization in developing countries, associated with radical changes in the provision of large physical infrastructures. At the city scale, a high degree of land use mix can result in significant reductions in vehicle kilometres travelled by increasing the proximity of housing to office developments, business districts, shops, and malls. In service-economy cities with effective air pollution controls, mixed land use can also have a beneficial impact on citizen health and well-being by enabling walking and cycling (IPCC 2014: 955).

34.3.2.2 Societal Structures and Networks in Technology Transfers

Technology development and transfer are embedded in societal structures and at the same time transform them. Technology is interwoven with the social networks of producers and users who depend on the technology. Throughout the process of technology development and transfer, various stakeholders are involved. Their decisions and actions differ depending upon the stages and pathways of technology development, and on the type of technology, especially whether it is bioenergy, wind or solar power. To overcome the various barriers to technology transfer, the interests and influences of stakeholders at each stage need to be considered and incorporated through stakeholder dialogues. In the context of climate change, technology transfer has been defined as a set of processes "covering the flows of know-how, experience and equipment, for mitigating and adapting to climate change amongst different stakeholders such as governments, private-sector entities, financial institutions, non-governmental organizations (NGOs) and research/education institutions" (IPCC 2000). Among the diverse stakeholders in North-South transfers are "project developers, technology owners, technology suppliers, product buyers, recipients, users of the technology, financiers and donors, governments, international organizations, NGOs, and community groups" (IPCC 2000). Not mentioned are institutions for research, trade and education. Technology transfer can take

place between government agencies, within vertically integrated firms, and within partnerships across a network of diverse entities (e.g. information service providers, business consultants, financial firms) (Karakosta/Doukas/Psarras 2010). Networks in technology transfer are critical for market creation and the generation of a social pool of knowledge (Teubal/Yinnon/Zuscovitch 1991). The relevance of the information is different for different stakeholders: governments and end-users need to understand the costs and benefits of a technology; innovators need to understand how to adapt it; firms how to market it; and consumers how to use it.

34.3.2.3 Pathways of Technology Transfer

Different 'pathways' can be distinguished in the actual transfer of technologies, depending on the stakeholder and country context, as well as on technology scale and type (IPCC 2000; Karakosta/Doukas/Psarras 2010). Regarding the type of actors, we differentiate between (1) government-driven pathways of technology transfer to fulfil specific policy objectives, (2) private sector-driven pathways involving commercially oriented entities, and (3) community-driven pathways with a high degree of collective decision-making (see table 34.2). While private-sector driven pathways are still the dominant mode of technology transfer (e.g. *transnational corporations* (TNCs)), multilateral organizations and NGOs are playing an increasing role in promoting technology transfer to support development in a more sustainable and equitable manner (Santarius/Scheffran/Tricarico 2012).

34.3.2.4 Innovative Capacity, Push and Pull Factors

Investments are essential to foster technical innovation and its diffusion. Adequate investment strategies could play a key role in increasing a country's ability to absorb new technologies and improve its innovative capacity. An enabling environment may complement a set of technology-push and demand-pull policies. Technology transfer is part of the innovation chain that ranges from research and development to the commercialization and diffusion of technology. Developing countries may consider three areas of innovative capacity (Tomlinson/Zorlu/Langsley 2008): *disruptive innovation* (radically different from current technologies, e.g. small-scale power generation with thin film solar cells); *orphan areas of research* (neglected by the industrialized world, e.g. small-scale desalination); *adaptive innovation* (e.g. adapting tech-

nology to local renewable resources). There is also a need for *incremental innovation*, where user and producer interfaces are important. Innovation incorporates 'push' and 'pull' factors along the innovation chain, with varying levels of public–private finance and policy interventions at different stages (figure 34.2). Push factors drive investors to invest abroad, and include government policies, market conditions, production costs and business conditions, all of which influence investment decisions. Some factors are climate-specific, such as green branding strategies, regulations and pressure from consumers and investors to avoid climate risks or pursue green energy technologies. Pull factors are locational host-country-specific determinants that influence where investors choose to invest, such as policy frameworks, economic conditions, resource endowment and access to skilled labour.

34.3.2.5 Absorption and Capacity Building

Going beyond a narrow focus on technology transfer that predominantly seeks to support access to specific technologies, diffusion of new innovations will require a broad approach for capacity building to enable developing countries to generate their own innovation system. Increases in low-carbon diffusion rates across countries can be achieved at differing development stages through system-wide capacity building to improve internal innovation and absorption. International collaboration will be vital if low-carbon innovations are to be introduced on a commercial scale (Tom-

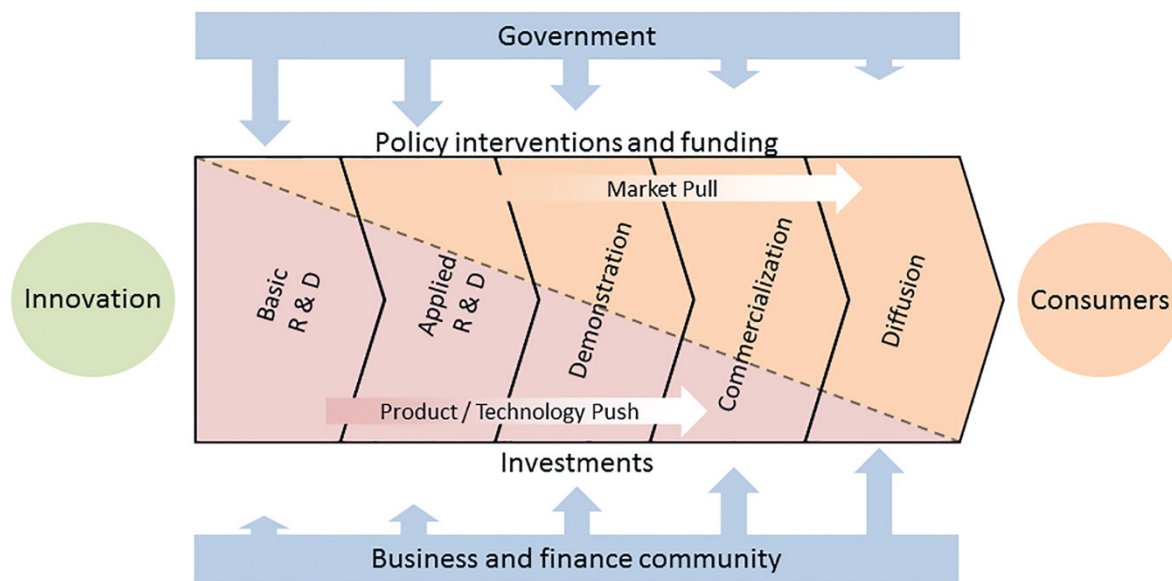
linson/Zorlu/Langsley 2008). Furthermore, international technology dissemination requires the acquisition, mastery, diffusion and indigenization of knowledge, technology and skills in the host country, and these must be not only transferred across borders but also absorbed by local actors (WIR 2010).[5] This approach is vital for the adaptation of technology to the local context and the fostering of the development of endemic technologies.

34.3.2.6 International Collaboration

In responding to climate change and moving towards a low-carbon economy, developing countries face two major challenges: (1) the mobilization of the requisite finance and investment, and (2) the acquisition, generation and dissemination of the relevant technologies and knowledge. In both areas, foreign investment can make a valuable contribution (WIR 2010). While the future international climate change regime—including specific carbon reduction commitments as well as financial and technological support for developing countries—is still to be agreed upon, countries need to

---

5 In this context, 'acquisition' means movement of the technology to local players; and 'mastery' requires that local actors are fully capable of using the knowledge and building on it (i.e. they have the 'absorptive capacity' to do this). 'Indigenization' of technology is a long-term concept, implying that the technology has become part of the national knowledge and innovation system, including diffusion to other enterprises and further research, development and innovation in the host country.

Figure 34.2: Innovation Chain. **Source:** Adapted from Grubb (2004) and Tomlinson, Zorlu, Langsley (2008).


examine how to facilitate low-carbon domestic and foreign investment, including technology transfer from developed to developing countries. Nevertheless, transfers from and within developing countries and especially *triangular cooperation* (TC) should also be considered. The innovation of integrating developed countries into South–South cooperation programmes in order to support these collaborations appears to be a promisingly sustainable approach (UNCTAD 2012). The *United Nations Environment Programme* (UNEP) has described the weaving together of the complementary challenges of investment support in developed countries and investment governance in developing countries as a "Green New Deal" in global climate policy (UNEP 2009). This approach aims at "reviving the global economy and boosting employment, while simultaneously accelerating the fight against climate change, environmental degradation and poverty".[6] Before one can elaborate on and discuss the concept of the "Green New Deal", it is important to analyse the conditions and environments that are needed in developing countries to enable a transfer of low-carbon technologies, and to discuss key areas for future action (see Santarius/Scheffran/Tricarico 2012). In particular, it is recommended that a significant portion of the estimated US$3 trillion that has already been pledged in economic stimulus packages be

invested in five critical areas (Santarius/Scheffran/Tricarico 2012):

1. raising the energy efficiency of old and new buildings;
2. transitioning to renewable energies including wind, solar, geothermal and biomass;
3. increasing reliance on sustainable transport, including hybrid vehicles and high-speed rail and bus rapid transit systems;
4. bolstering the planet's ecological infrastructure, including fresh water, forests, soils and coral reefs;
5. supporting sustainable agriculture, including organic production.

34.3.2.7 Mobilizing Virtuous Cycles through Local Public Policy and Private Investment

While the UN approach suggests that a globally coordinated effort is needed to address the above-mentioned challenges of developing countries, measures at a national or business level could well support technology transfer before global agreements or activities have been achieved. The core idea is to build up public support and unleash private capital for foreign investments while establishing sustainable framework conditions to maximize the mitigation and development potential of these investments on the ground, especially in the energy sector. After establishing such an enabling environment, foreign investments can be a valuable tool to support the transfer of technology as well as related know-how and capacities. Further-

Box 34.3: China–Zambia South–South Cooperation on Renewable Energy Technology Transfer. **Source**: Assembled by the authors.

Worldwide, more than one billion people have no access to modern electricity services, in particular households at the bottom of the income pyramid. Like many other developing countries, Zambia is facing the challenge of the absence of grid coverage in remote rural areas, where only three per cent of the population have access to the national power grid. In these areas, most of the power is provided by diesel generators, resulting in high fuel import costs and inherent environmental impact.

The Government of Zambia has launched a project in collaboration with the Ministry of Science and Technology in China and related UNDP offices in both countries to foster technology transfer for promoting rural electrification. The project is supported and funded by several national and international public and private stakeholders, including the *International Centre on Small Hydro Power* (ICSHP) in China, the *Global Environmental Facility* (GEF), the *United Nations Industrial Development Organization* (UNIDO), UNEP, the *Zambia Electricity Supply Corporation Limited* (ZESCO), the *Development Bank of Zambia* (DBZ) and the *Rural Electrification Authority* (REA). The partnership promotes not only the transfer of renewable energy technology but also its adaptation to the local Zambian context, ensuring that the technology meets the needs of the local population in the optimum way.

The partnership is creating enabling environments for the implementation of isolated mini-grids through the inclusion of national and international know-how. Additionally, the efforts are increasing the share of renewable energy

and consequently supporting the country's socio-economic and environmental objectives in a sustainable way. The provision of clean and sustainably-produced electricity will enhance the livelihood and quality of life of the rural population. Within the framework of the project, the following energy facilities will be installed:

- a biomass gasifier-based power plant (1 MW capacity) for electricity generation;
- a small hydropower station (1 MW capacity);
- a solar energy mini-grid to introduce solar lanterns for fishing activities at night.

Further, the project aims to provide an enabling environment for the commercial deployment of mini-grids based on renewable energy, by contributing to the development of a legal, institutional and policy framework. Such measures facilitate public and private partnership and foster the implementation and expansion of renewable technologies on the market. In contexts like this, South–South cooperation can play a central role in the provision of technology and know-how for the adoption and adaptation of technologies to the local context.

Resources: <http://www.unido.org/where-we-work/africa/selected-projects/zambia-mini-grids.html>; <http://www.unido.org/fileadmin/media/documents/pdf/Energy_Environment/rre_Zambia_factsheet.pdf>; <http://ssc.undp.org/content/dam/ssc/documents/Expo/solutions/2008_to_2012/20132221636470.UNDP-GSSD 2012 -UNIDO-Zambia-v2.pdf>.

more, private investments are attracted into such an environment by new opportunities for overcoming limited demand and market size, while the companies' financial risks are reduced by public money, adequate regulation and standards, in order to make foreign investments work for climate protection. To bring such a 'virtuous cycle' into being, complementary steps are required by developed and developing countries, affecting the public and the private sector. A 'virtuous cycle' combines learning in research and development from technology push and market pull, leading to improved products, more market demand and reduced costs, as well as a cycle of policy learning (Jänicke 2012; IPCC 2012; IPCC 2014: WG3).

In this cycle, private investments can be stimulated by five steps: 1) strategic goal-setting and policy alignment; 2) an enabling process and incentives for *low-carbon and climate-resilient* (LCR) investment; 3) financial policies and instruments, 4) harnessing resources and building capacity for an LCR economy, and 5) promoting green business and consumer behaviour (see IPCC 2014: 1041, based on Corfee-Morlot/

Marchal/Kauffmann et al. 2012). Such an approach needs to be broadened to include the demand-side aspects of innovation systems, including their political and institutional contexts, and to ensure that technology development proceeds on a self-determined and needs-based basis (Ockwell/Mallett 2012). While the merits of an integrated approach can best be realized if ambitious mandatory emission reduction targets are set and implemented, this concept is not dependent on global agreement. It is not necessary that national investment support or bilateral investment governance are managed by a global fund. As many decisions as possible can be left to each country's national policies, and these policies will create the framework conditions for technology transfer in a market environment. Global top-down decisions and one-size-fits-all prescriptions can be avoided.

Figure 34.3: Global New Investment in Renewable Power and Fuels, Developed and Developing Countries, 2004–2013. **Source**: Adapted from REN 21 (2014).
34.4 Global Trends in Sustainable Energy Investment

34.4.1 Trends in Renewable Energies

By the end of 2012, the twenty largest emitting countries were producing seventy per cent of global energy-related CO_2 emissions. This makes them attractive for international private sector investment in low-carbon technologies. Since 2000, significant growth in new investment in sustainable energy has been seen globally, with annual growth rates exceeding fifty per cent. Between 2005 and 2009, the developed countries provided US$2.5 billion of official development assistance to support enabling environments in developing countries (Stadelmann/Michaelowa 2011). With appropriate enabling environments, along with the public sector, the private sector can play an important role in financing mitigation; it represented around 74 per cent and 62 per cent of overall climate finance in 2010 and 2011 on average (IPCC 2014: 1211). In 2011, a record amount of US$279 billion was reached (excluding large hydroelectric projects), followed by a 23 per cent reduction to US$214 billion in 2013, largely in response to a sharp fall in solar system prices and the effect of pol-

icy uncertainty in many countries (Bloomberg 2014). As in previous years, public and private investments in new renewable capacity (including large hydroelectric projects) in 2013 were larger than investment in new fossil fuel capacity.

A decrease of about 14 per cent in 2013 (to US$122 billion) with respect to 2012 was seen not only in developed countries (to US$93 billion) but also in developing economies, interrupting an eight-year trend of increasing investments (figure 34.3). According to the Renewables 2014 Global Status Report, 144 countries had renewable energy targets and 138 countries had renewable energy support policies by early 2014. Although investments weakened in most renewable energy sectors by between 16 and 28 per cent (solar 20 per cent, biofuels 26 per cent, waste-to-energy 28 per cent, small-hydro 16 per cent), investments in the wind sector were quite resilient, falling by only 1 per cent (Bloomberg 2014). However, in 2013 the implementation of onshore wind and solar projects without subsidy support in a growing number of locations around the world was driven by efficiency improvement and cost reductions (Bloomberg 2014).

The most remarkable trend of recent years was the decisive shift towards investments by developing and emerging countries, in particular by China and other Asian countries. In 2013, China invested more in

Figure 34.4: Global New Investment in Renewable Energy by Technology, Developed and Developing Countries, 2013. **Source:** Adapted from REN 21 (2014).
renewable energy than Europe for the first time. While Chinese investment also declined by 6 per cent in 2013 to US$56 billion, European investments shrank by 44 per cent, to US$48 billion. Investments also declined by 10 per cent to US$36 billion in the US, while Indian investments fell by 15 per cent to US$6 billion and in 2013 Brazil reached its lowest investment level since 2005, with a drop of 54 per cent to US$3 billion (Bloomberg 2014). The only regions where investment increased were the Americas (excluding the US and Brazil), with a rise of 26 per cent to US$12 billion in 2013, and Asia and Oceania (excluding India and China), with an increase of 47 per cent to US$43 billion. The largest rise, an 80 per cent increase in renewable energy investments to US$29 billion, was due to the solar boom in Japan after the nuclear catastrophe in Fukushima (Bloomberg 2014).

34.4.2   Foreign Direct Investment

Global *foreign direct investment* (FDI) inflows experienced an 18 per cent drop in 2012; such investment was recovering only slowly due to economic fragility and risks following policy uncertainties and regional instabilities. Inflows increased by only 9 per cent in 2013, to US$1.45 trillion, and are projected to further increase to US$1.6 trillion in 2014, US$1.7 trillion in 2015 and US$1.8 trillion in 2016 (WIR 2014). These projections lie far below the expectations of the *World Investment Report* 2010, where investment was expected to reach between US$1.6 trillion and US$2 trillion in 2012 (WIR 2010).

The nature and role of FDI varies between regions. Developing and transition economies attracted 54 per cent of global FDI inflows, and reached a record level of 39 per cent of global FDI outflows in 2013, due to increasing action by *transnational corporations* (TNCs). Global FDI is mainly shaped by three mega-regional groupings (TPP, TTIP and RCEP),[7] which are currently in negotiation, each accounting for a quarter or more of global FDI flows. The largest regional economic cooperation grouping remains *Asia–Pacific Economic Cooperation* (APEC), with 54 per cent of global inflows (WIR 2014). Africa is seeing the rise of new sources of FDI. Overcoming barriers for attracting FDI remains a key challenge for small, vulnerable and weak economies. *Overseas development assistance* (ODA) can act as a catalyst for boosting the role of FDI in *least developed countries* (LDCs). Focusing on key niche sectors is crucial if *Small Island Developing States* (SIDS) are to succeed in attracting FDI.

Low-carbon FDI reached roughly US$90 billion in 2009 in three key industries: (a) alternative/renewable electricity generation; (b) recycling; and (c) manufacturing of environmental technology products (such as wind turbines, solar panels and biofuels). These industries form the core of new low-carbon business opportunities. The following developments could be seen in these industries (WIR 2010):

---

7   Trans-Pacific Partnership (TPP), Transatlantic Trade and Investment Partnership (TTIP), Regional Comprehensive Economic Partnership (RCEP).

Figure 34.5: FDI inflows, global and by group of economies, 1995–2013 and projections, 2014–2016 in billions of US dollars. **Source**: Adapted from UNCTAD FDI-TNC-GVC Information System, FDI/TNC database; at: <www.unctad.org/fdistatistics> (WIR 2014).
- A rapid increase in low-carbon FDI in recent years, though it declined in 2009 as a result of the financial crisis.
- Around forty per cent of identifiable low-carbon FDI projects by value during the period 2003–2009 were in developing countries.
- Established TNCs are major investors, but new players are emerging, including those from the South. TNCs from other industries are also expanding into the field.
- About ten per cent of identifiable low-carbon FDI projects in 2003–2009 were generated by TNCs from developing and transition economies. The majority of these investments were in other developing countries.

Over time, low-carbon investment is expected to permeate all industries. While foreign investments have recovered and started growing again in recent years, significantly more is required for the level of sustainability transformation envisaged. The global scale of the challenge in reducing *greenhouse gas* (GHG) emissions requires an enormous financial and technological response. Estimates for the period 2015–2030 are that US$550 billion to US$850 billion of recurrent additional global investment per year is required to limit GHG emissions to the level needed for a 2°C target to be met, as specified in the Copenhagen Accord (WIR 2010). Current investment in 2014 amounts to US$170 billion (WIR 2014).

Various studies stress that the financial contribution of the private sector is essential for achieving progress in making economies more climate-friendly, particularly in view of the huge public fiscal deficits worldwide. The average level of the private sector in current mitigation investment is in the area of US$40 billion in developing countries and US$90 billion in developed countries (WIR 2014).

TNCs can make significant contributions in the transition towards a low-carbon economy, because they are significant emitters across their vast international operations, but also because they are in a special position to generate and disseminate technology and to finance investments to mitigate GHG emissions (WIR 2010). TNCs are thus not only part of the problem but can also be part of the solution.

34.5   The Context of International Climate Negotiations

34.5.1   UN Conference on Environment and Development (UNCED) 1992

The importance of technology transfer has been realized in the agreements achieved at the 1992 *UN Conference on Environment and Development* (UNCED). In Chapter 34 on the "Transfer of environmentally sound technology, cooperation, and capacity building", Agenda 21 calls for access to scientific and technical information, promotion of technology transfer pro-

Table 34.3: Current investments, investment needs and gaps, and private sector participation in key sustainable development goals (SDG) sectors in developing countries. **Source:** Adapted from WIR 2014; at. <www.unctad.org/fdistatistics>.

Sector	Description	Estimated current investment (latest available year) $ billion	2015 – 2013 Total investment required	2015 – 2013 Investment Gap	Average private sector participation in current investment Developing countries	Average private sector participation in current investment Developed countries
		Annualized $ billion (constant price)	Annualized $ billion (constant price)	Annualized $ billion (constant price)	Per cent	Per cent
		A	B	C = B - A		
Power	Investment in generation, transmission and distribution of electricity	~260	630 - 950	370 – 690	40 - 50	80 – 100
Transport	Investment in roads, airports, ports and rail	~300	350 - 770	50 – 470	30 - 40	60 – 80
Telecommunications	Investment in infrastructure (fixed lines, mobile and internet)	~160	230 – 400	70 – 240	40 – 80	60 – 100
Water and sanitation	Provision of water and sanitation to industry and households	~150	~410	~260	0 – 20	20 – 80
Food security and agriculture	Investment in agriculture, research, rural development, safety nets, etc.	~220	~480	~260	~75	~90
Climate Change mitigation	Investment in relevant infrastructure, renewable energy generation, research and deployment of climate-friendly technologies, etc.	170	550 – 850	380 – 680	~40	~90
Climate Change adaptation	Investment to cope with impact of climate change in agriculture, infrastructure, water management, coastal zones, etc.	~20	80 – 120	60 – 100	0 – 20	0 – 20
Eco-systems/ biodiversity	Investment in conservation and safeguarding ecosystems, marine resource management, sustainable forestry, etc.		70 – 210			
Health	Infrastructural investment, e.g. new hospitals	~70	~210	~140	~20	~40
Education	Infrastructural investment, e.g. new schools	~80	~330	~250	~15	0 - 20

jects, promotion of indigenous and public domain technologies, capacity building, intellectual property rights, and long-term technological partnerships between suppliers and recipients of technology (UN 1993). It points out: "Technology cooperation involves joint efforts by enterprises and governments, both suppliers of technology and its recipients. Therefore, such cooperation entails an interactive process involving government, the private sector, and research and development facilities to ensure the best possible results from transfer of technology" (UN 1993: 305). The document also recommends the utilization of existing technological information, and the promotion and development of research partnerships and assessment networks.

34.5.2 UN Framework Convention on Climate Change (1992)

Technology transfer from the countries and companies that have developed them to other countries in order to reduce GHGs has been a main plank of the UNFCCC. Article 2 of the UNFCCC aims at "preventing dangerous anthropogenic interference with the climate system" by stabilizing greenhouse gas concentrations as an ultimate objective of the Convention. Article 4.1.c requires that the Parties "promote and cooperate in the development, application, diffusion, including transfer, of technologies, practices, and processes that control, reduce, or prevent anthropogenic emissions of greenhouse gases". The promise of access to new technologies was a central incentive for developing nations to support the UNFCCC in 1992 but success has been widely questioned and many developing nations feel frustrated at the lack of technology transfer in practice (Feldmann 1994).

34.5.3 Kyoto Protocol (1997)

The importance of technology transfer was also recognized in the Kyoto Protocol, which in its Article 10c asks all Parties to:

> Cooperate in the promotion of effective modalities for the development, application and diffusion of, and take all possible steps to promote, facilitate and finance, as appropriate, the transfer of, or access to, environmentally sound technologies, know-how, practices and processes pertinent to climate change, in particular to developing countries, including the formulation of policies and programmes for ... the creation of an enabling environment for the private sector.

The Kyoto Protocol has created mechanisms to reduce emissions, including the *Clean Development Mechanism* (CDM), which is focused on low-carbon technology transfer to developing countries. While developing countries are not bound to climate change policies, they are free to choose whether they want to move towards a low-carbon economy, and to what extent. For this purpose, a continuum of options with varying implications, development benefits and costs is available. Although the CDM and its *Certified Emissions Reductions* (CERs) as well as *Joint Implementation* and the *Emissions Reductions Units* (ERUs) were expected to generate foreign investment and technology flows, this expectation has largely not been met. Problems have occurred in the issuing of carbon credits, the determination of emissions baselines, the setting of allowance/credit values or carbon prices, the levying of carbon taxes, and the imposition of rules and procedures for carbon trading.

Because the Protocol's mechanisms were designed for compliance with emission reduction targets at the national level, individual governments were left to decide how best to involve the private sector in the process. Uncertainties about the post-Kyoto framework weakened the private sector's ability and willingness to make decisions in the area of climate change. Strong international and national commitments by governments are nowadays the key conditions to enable and persuade the private sector to take part in the transformation process. In recent years this commitment has been missing and negotiations on these issues have been controversial, with clean technology nearly ignored at the Conference of the Parties (COP) 13 in Bali 2007, because of disagreements between the United States and G77/China.

34.5.4 Green Climate Fund (2009)

New regulations and reformed legislation are needed to enable an environment where climate-friendly innovations can occur and to achieve a breakthrough in this area. This includes innovation in climate finance alongside disagreements on clean technology. One of the critical questions for the nations will be how the necessary financial obligations can be met without taking an excessive amount of money from taxpayers. A possible approach to raising US$100 billion was discussed in the 2010 report by the UN's *Advisory Group on Climate Change Financing* (AGF 2010: 12). It calls this amount "challenging, but feasible", provided that policy would "lay out a clear road-map for making this funding a reality." During the 2009 COP in Copenhagen, Denmark, the *Green Climate Fund* (GCF) was proposed. The aim was to assist developing countries in their efforts to combat climate change through provision of grants and other financing for mitigation and adaptation projects, programmes, policies, and activities. The design of this financial institution, which is linked to the UNFCCC, was agreed on during the 2011 COP in Durban, South Africa, and it came into operation in summer 2014. Contributions from donor countries and other sources, potentially including innovative mechanisms and finance from the private sector, are required to activate the GCF. Over the course of the first year, an immediate activation of US$10 to US$15 billion was requested by the Parties. By December 2014, the GCF had already activated US$10.2 billion and thus fulfilled the call of the Parties (UNFCCC 2015). The GCF contributes to the

future targets of financial transfers from the developed to the developing countries; the UNFCCC aims to jointly mobilize US$100 billion per year (UNFCCC 2015). Besides US$100 billion from the public sector, the report suggests that the private sector could mobilize up to US$500 billion a year. With such large amounts of climate finance, an unprecedented scale of investment in energy efficiency, renewable energy and low-carbon technologies can be expected.

34.5.5 Poznan Strategic Programme on Technology Transfer (2010)

The 2010 COP 16 in Cancun approved the *Poznan Strategic Programme on Technology Transfer* (PSP) to support developing countries in moving towards a low-carbon development path through the adoption of environmentally sound technologies. The concept was first presented to COP 14 in Poznan and later developed into a final version. The process of implementing the PSP is structured as four milestones: (1) a *Technology Needs Assessment* (TNA) for the necessary technologies for adaptation to and mitigation of climate change, (2) pilot projects to realize and evaluate the diffusion and transfer of technologies, (3) the dissemination of experiences and (4) long-term implementation (GEF 2012). Here, private investments come into play, especially for reaching the last milestone 'long-term implementation' which seeks to support:

- climate technology centres and climate technology networks;
- pilot priority technology projects to foster innovation and investments;
- public–private partnership for technology transfer;
- technology needs assessments;
- the GEF as a catalyst for technology transfer.

34.5.6 Ad Hoc Working Group on Long-Term Cooperative Action under the Convention (2010)

Building on the PSP, a new chapter was opened at the 2010 COP 16 in Cancun where an agreement adopting a very concrete and practical approach for technology transfer and investment was achieved. The decision made by the "Ad Hoc Working Group on Long-Term Cooperative Action under the Convention" introduced several new elements, including a large section on Finance, Technology and Capacity Building (section 34.4). In this chapter, the working group decided to establish a Technology Executive Committee and a

Climate Technology Centre and Network to guide and facilitate the implementation of a Technology Mechanism. The working group also identified various opportunities for collaboration between governments and private sectors, non-profit organizations and academic and research communities, including the priority areas:[8]

a.) Development and enhancement of endogenous capacities and technologies of developing country Parties, including cooperative research, development and demonstration programmes.
b.) Deployment and diffusion of environmentally sound technologies and know-how in developing country Parties.
c.) Increased public and private investment in technology development, deployment, diffusion and transfer.
d.) Deployment of soft and hard technologies for the implementation of adaptation and mitigation actions.
e.) Improved climate change observation systems and related information management.
f.) Strengthening of national systems of innovation and technology innovation centres.
g.) Development and implementation of national technology plans for mitigation and adaptation.

A conceptual framework was implemented into the more precise and practical Technology Transfer Framework (box 34.4) by the UN Technology Executive Committee, which was initiated in 2010 by the "Ad Hoc Working Group on Long-Term Cooperative Action under the Convention". This Committee has oversight over this framework so that the transfer of environmentally sound technologies and know-how can be increased and improved. The approach describes the relevant conceptual and analytical frameworks comprising the five key themes.

34.5.7 Paris Agreement at COP21 (2015)

In December 2015, the *21st session of the Conference of the Parties in Paris* (COP21) agreed to hold "the increase in the global average temperature to well below 2°C above pre-industrial levels and to pursue efforts to limit the temperature increase to 1.5°C above pre-industrial levels, recognizing that this would significantly weather events and slow onset events, and reduce the risks and impacts of climate change" (Paris

Box 34.4: Mechanisms for Technology Transfer. **Source**: Assembled from UNFCCC <http://unfccc.int/ttclear/templates/ render_cms_page?TTF_home>.

1. *Technology Needs Assessments:* country-driven activities that identify and determine the mitigation and adaptation technology priorities.
2. *Technology Information:* defines the means to facilitate the flow of information between the different stakeholders to enhance the development and transfer of environmentally sound technologies (including hardware, software and networking).
3. *Enabling Environments:* foster private and public sector technology transfer through focusing on government actions, such as fair trade policies, removal of technical, legal and administrative barriers to technology transfer, sound economic policy or regulatory frameworks and transparency.
4. *Capacity Building:* seeks to build, develop, strengthen, enhance and improve existing scientific and technical skills, capabilities and institutions in developing countries to enable them to assess, adapt, manage and develop environmentally sound technologies.
5. *Mechanisms for Technology Transfer:* facilitates the support of financial, institutional and methodological activities to (a) enhance the coordination of stakeholders in different countries and regions, (b) engage them

in cooperative efforts to accelerate development and diffusion, through technology cooperation and partnerships (public/public, private/public and private/ private), (c) to facilitate the development of projects and programmes to support such engagement. The mechanism comprises four sub-themes:

5.1 *Innovative Financing*: aims at improving access to financing for the development and transfer of technology from a wide variety of available public and private sources.
5.2 *International Cooperation*: aims at identifying ways and means to enhance cooperation with relevant conventions and intergovernmental processes involved in the development and transfer of technology.
5.3 *Endogenous Development of Technologies*: aims at identifying actions to promote endogenous development of technology through the provision of financial resources and joint research and development.
5.4 *Collaborative Research and Development:* aims at promoting collaborative research into and development of technologies.

Agreement 2015, Article 2a). The agreement also recognizes "the importance of averting, minimizing and addressing loss and damage associated with the adverse effects of climate change, including extreme the role of sustainable development in reducing the risk of loss and damage" (Article 8). To this end, the Parties address the "urgent need to enhance the provision of finance, technology and capacity-building support by developed country Parties" and formulate the objective of considering "how to enhance linkages and create synergy between, inter alia, mitigation, adaptation, finance, technology transfer and capacity-building, and how to facilitate the implementation of coordination of non-market approaches". Further the Parties recognized the need to incorporate climate-proofing and climate resilience measures into their development assistance and climate finance programmes. To reach these goals they committed themselves to accelerating, encouraging and enabling innovation to reach a long-term global response to climate change, and they called on the established technology framework to

a.) undertake and update *technology needs assessments* (TNA) and technology action plans;
b.) enhance financial and technical support for the implementation of the TNAs;

c.) assess technologies that are ready for transfer; and
d.) enhance enabling environments for and address barriers to the development and transfer of socially and environmentally sound technologies.

These commitments further strengthen the Parties' commitments to sustainable development and create opportunities across institutions and the private sector for participation in the implementation of environmentally sound development.

34.5.8 Other Non-UN Frameworks for Climate Finance and Technology Transfer

Besides the level of the United Nations, various other frameworks have been developed to foster technology cooperation on energy and climate change. For instance, at the Gleneagles summit in July 2005, the G8 highlighted the importance of strengthening technology cooperation in order to develop low-carbon energy options. Many developing countries pressed for a new approach to international cooperation in the area of clean energy technologies. As a follow-up, the UK government and the government of India decided to collaborate on a study to assess the barriers to the transfer of low-carbon energy technology between developed and developing countries (Mallett/Ockwell/Pal et al. 2009). In May 2015 the G7 launched

the Hamburg Initiative for Sustainable Energy Security, which supports "the further improvement of the performance and reduction of the cost of technologies such as smart grids, systems optimization, energy storage, electric vehicles, offshore wind energy, and other flexibility options" (G7 2015a: 3). The G7 Declaration at the Summit in Germany on 8 June 2015 took the decision to "foster growth by promoting education and innovation, protecting intellectual property rights, supporting private investment with a business friendly climate especially for small and medium-sized enterprises, ensuring an appropriate level of public investment, promoting quality infrastructure investment to address shortfalls through effective resource mobilization in partnership with the private sector and increasing productivity by further implementing ambitious structural reforms" (G7 2015b: 2). However, the private sector needs a clear, stable and predictable policy framework to reorient its business strategies. Regardless of progress on a global regime, it is left to national governments and private investors to contribute to such a policy framework. It has become clear that creative mechanisms are in demand both at national and international levels to effectively mobilize the private sector's contributions to cross-border capital flows and technology diffusion, especially to developing countries.

34.5.9   Financing Needs for Climate Policies

A challenge in this area is the uncertainty over the financial resources currently available, partly due to the lack of an agreed list of these technologies; there are also no agreed definitions of the costs of technology research, development, deployment, diffusion and transfer. At the time of the 2009 Copenhagen climate summit (COP 15), estimates of the financial resources currently available were classified by UNFCCC (2009) by stage of maturity of the technology they are intended for, whether the resources are from the public or private sector, and whether they are covered by or outside the Convention. The estimates for mitigation technologies, shown in figure 34.5, lie between US$70 billion and US$165 billion per year. As far as adaptation is concerned, R&D is focused on tailoring the technology to the specific site and application. Spending on adaptation projects in developing countries was estimated at about US$1 billion per year, while future spending needs are estimated to be between tens and hundreds of billions of US dollars per year. Financial support for technology

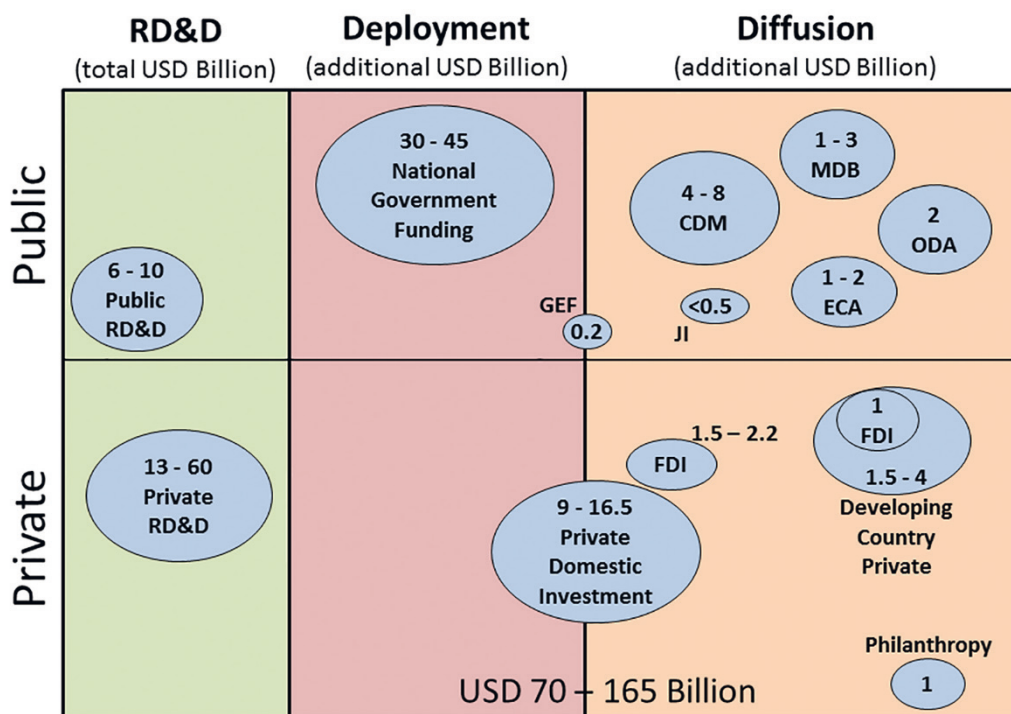
transfer was likely to amount to less than US$2 billion per year (UNFCCC 2009).

Several estimates are available for the additional financing that will be needed for RD&D of mitigation technologies in order to stabilize the levels of GHGs in the atmosphere. The estimates are sensitive to the baseline and to the mitigation scenarios used. As shown in figure 35.6, they indicate that current financing for mitigation technologies needs to increase three- to fourfold. Such increases are consistent with current R&D targets and priorities for developed countries as well as for regions with large R&D budgets. The economic and social benefits of investing in climate change technologies are likely to be greater than the cost of making the investments (UNFCCC 2009). In addition to changing investment in energy-generation sectors, scenarios compatible with the 2°C goal show a rise in annual investments in energy efficiency in the fields of transport, buildings and industry, amounting to US$336 billion (WBGU 2014; IPCC 2014).

34.6   Benefits and Incentives of the Sustainable Energy Transition

To achieve success in the new 'industrial revolution' that has been envisaged and that is required for a climate-smart sustainability transition, as well as for a low-carbon society, it is essential to understand the significance of the task. Energy systems, as key drivers of economic growth and social progress, are the core of the transformation process. They are considered "essential to fuelling industry, powering infrastructure, connecting goods, people and services to markets, and delivering basic services such as heating, lighting and cooking" (WBCSD 2007: 3).

If concerns about climate injustice are to be addressed, countries and communities around the world need to receive their fair share of the fruits and benefits of the technological transformation. Therefore, it is essential to clarify the opportunities, benefits and incentives to encourage support from governments, private sectors and the public in recipient countries. Questions of justice will concern the sharing of benefits from new climate-related investments and financial transfers and the distribution of benefits, costs and risks among the different regions, as well as in the public and private sectors. If these questions are taken seriously, then the groundwork can be laid for a lasting, sustainable and, especially, peaceful energy transition, with concurrent benefits.

Figure 34.6: Estimates of financing for mitigation technologies. **Source**: Adapted from UNFCCC (2009).


Abbreviations: CDM = clean development mechanism, ECA = export credit agency, FDI = foreign direct investment, GEF = Global Environment Facility, JI = joint implementation, MDB = multilateral development bank, ODA = official development assistance, RD&D = research, development and deployment.

34.6.1 Electrification of Remote Areas in Developing Countries

Investment in energy infrastructures (on- and off-grid) is essential if the billions of people without access to modern energy services are to escape poverty and enter into productive economic activities. One example of successful investment is the combination of small-scale renewable energy systems combined with micro-finance that offers opportunities for less developed countries, as in Bangladesh (see box 34.5). Despite government efforts to promote rural electrification, many remote rural areas in least-developed countries experience shortfalls in energy capacity. Increasing access to electricity by installing off-grid energy generation, such as solar home systems supported by micro-finance institutions, enables low-income communities to enhance their living standards and improve their livelihoods.

34.6.2 Reduction of Future GHG Emissions

With the growing energy demand from developing countries, their share of GHG emissions is also expected to rise, from 39 per cent in the middle of the last decade to 52 per cent by 2030, with China responsible for 29 per cent of the predicted rise (UNDP 2006). India is already the third biggest emitter of CO_2 emissions, yet approximately 25 per cent of its population does not have access to electricity and approximately 68.8 per cent of the population lives on less than US$2 per day (World Bank 2010). Clean energy could possibly help satisfy the growing energy demands of developing countries and at the same time cut their carbon emissions.

34.6.3 Independence from Fluctuating Fossil Fuel Prices

Rising oil prices and dependence on energy imports from the Middle East have increased the demand for alternative energy paths. In response to the OPEC oil embargos and the subsequent price shocks of the 1970s, incentive programmes were implemented to encourage the development of renewable energy. Despite these programmes, and despite increased research efforts, renewable energy production grew only slowly through the 1980s and stagnated during

---

Box 34.5: Solar Home Systems for Bangladesh. **Source**: Assembled by the authors.

A lack of energy generation, distribution and storage facilities, high upfront costs and insufficient funding sources, coupled with inefficient management, knowledge, manpower, operations and maintenance, has kept economic development potential low in Bangladesh. Especially in remote rural areas, shortfalls in energy capacity are very common, although the Government of Bangladesh has put considerable effort into increasing the generating capacity and promoting rural electrification.

In contrast to government agencies, decentralized private actors and non-profit enterprises can contribute significantly to providing energy infrastructure that are adapted to local needs and that meet the high level of demand for electricity in rural areas. A prominent case is Grameen Shakti (GS), a subsidiary of the Grameen Bank in Bangladesh, which since its foundation in 1996 has provided rural electrification through renewable energy, combined with small-scale loans and micro-credits to the poor. GS is one of the largest and fastest-growing rural-based renewable energy companies in the world, with almost 25,000 solar home systems sold by June 2004 and more than 1 million *solar home system* (SHS) installations in rural areas by end of 2012 with more than 22,250 SHSs installed per month. Part of the success is the combination of the technical system, micro-financing, on-the-spot installation, customer training, and a three-year maintenance warranty. A complete range of services provided, enabling its customers to become independent of central, state-controlled sources of power (Kebir/Philipp/Scheffran et al. 2005).

A complementary approach is the *Infrastructure Development Company Limited* (IDCOL) which was established in 1997 by the Government of Bangladesh and licensed by the Bangladesh Bank as a *non-bank financial institution* (NBFI) in 1998. IDCOL is playing a major role in bridging the financing gap for developing medium to large-scale infrastructure and renewable energy projects in Bangladesh. In 2003, IDCOL began the installation of SHSs in Bangladesh to support the country`s vision of ensuring "Access to electricity for all by 2021". Ten years later, 2.5 million SHSs had already been installed in a growing market where the demand was for over 75,000 systems per month.

Standard financing is based on micro-finance institutions, enabling people with very low incomes to afford an SHS. The monthly instalments are in the range of the average monthly expenses of conventional electricity, as for example kerosene or recharging and carrying batteries. Furthermore, after paying the last instalment the owner saves money, achieving a long-term effect. By selling excess energy to their communities, the owners could further create a small income and thus enhance their standard of living. A development of this system is the establishment of a payment system via mobile phones. This technology does not require a bank account and enables end-users in remote and isolated regions to pay their instalment plan from almost everywhere. In Bangladesh, this system has not been implanted yet. However, examples from other countries, for instance Tanzania, indicate a high success rate in capacity building and decreasing energy poverty.

A German-based company is MicroEnergy International, which develops access to renewable energy technologies and energy efficiency through micro-finance and supporting financial, technical and scientific actors to provide households and micro-entrepreneurs with reliable, affordable and sustainable energy solutions. MicroEnergy International works with micro-finance institutions, energy product and service providers, international development actors and research institutions in order to set up clean energy micro-finance schemes.

Resources: <http://www.gshakti.org>; <http://www.idcol.org/>; and <http://microenergy-project.de>.

---

the 1990s, but the rate of growth considerably increased in the first decade of this millennium. With increasing oil prices, the competitiveness of renewables will further improve, but it can be slowed down by the current lock-in of high-carbon fossil energy pathways in most sectors. The transportation sector is almost completely dependent on energy from fossil fuels such as gasoline, diesel and kerosene. Developing countries whose oil supply largely relies on imports are particularly dependent, and thus vulnerable.

34.6.4   Reduction of Vulnerability, Long-Term Costs and Risks of Climate Change

Climate change is expected to have many negative impacts in vulnerable developing countries, and these negative impacts could also affect commercial inter-ests. Reducing carbon emissions contributes to alleviating the long-term economic, social and environmental costs and the risks of climate change, and helps to accomplish the targets for GHG emission reduction as set out in the UNFCCC and the Kyoto Protocol.

Protecting the environment and preserving natural resources can provide additional economic benefits, in particular a reduction in vulnerability to climate change. Although many developing countries are not major GHG emitters, new technology and investment would help them enter low-emission pathways, avoiding the polluting development paths that industrialized countries have pursued in the past. (For a review of pathways of technology cooperation for sustainable energy, see Mallett 2013).

34.6.5   Structural Changes and Employment

The quest for energy security and concerns about global warming is encouraging the search for low-carbon energy alternatives to fossil fuels. Large-scale production of renewables would significantly reduce oil imports and diversify energy sources. Home-grown domestic energy sources offer important development opportunities to structurally weak rural areas and can lead to beneficial structural changes in land use and agricultural practices. Benefits are particularly relevant for the agricultural community, which is expecting fast-expanding future markets for energy and land resources. These will create new sources of income and job opportunities in the agricultural sector, leading to an increase in farmers' income. An example is the production of biofuel resources. According to the UNEP (2009: 20), renewable energy generates more jobs than employment in fossil fuels. Projected investments of US\$630 billion by 2030 could translate into at least twenty million additional jobs in the renewable energy sector.

34.6.6   Future Projections

Stabilizing the atmospheric CO_2 concentrations at non-dangerous levels will require a rapid increase in the scale and speed of introduction of low-carbon innovation and technology. To achieve the 2°C guard rail with a probability of 67 per cent, by the middle of the twenty-first century no more than a maximum of approximately 750 gigatonnes (Gt; billion tonnes) of CO_2 would have to be released into the atmosphere; for a probability of 75 per cent, the CO_2 budget would have to decline to 600 Gt CO_2 (WBGU 2009: 2). To achieve a 450 ppm (*parts per million*) scenario by 2050, global emissions would need to be reduced by 50 per cent compared with 2005 levels (IEA 2008). The same source also estimates that an additional US\$45 trillion in total investment will be required by 2050 for a 450 ppm scenario. With an increase in energy demand in non-OECD countries expected to account for 85 per cent of the increase in world energy demand, a major challenge will be to accelerate the diffusion of low-carbon technologies to developing countries.

34.6.7   Political Incentives Broadening the Economic Basis of Renewables

In both developing and developed countries, there is a significant growth potential for innovative technolo-gies for heating, electricity generation and transportation fuels. Recent years have shown a dramatic shift in policy in many parts of the world; the growing demands and subsidies for renewables have broadened their economic basis (WBCSD 2010). This is expected to lead to a large expansion of sustainable energy and energy efficiency technologies in developing countries over the next decade and beyond. To succeed, renewable energy systems will have to become fully competitive with fossil energy and to avoid some of the current market distortions such as domestic subsidies and import barriers.

34.6.8   Mutual Benefits of Developed and Developing Countries

Although developed and developing countries have different responsibilities and capacities, a smartly designed transformation of the global economy can bring benefits to both. While developed countries are expected to be the main source of the finance needed for the transition, this may become an opportunity rather than a burden for them. Increased foreign investments in environmentally sound technologies will diversify the portfolio of companies, link them to international markets, create new jobs and generate a return on investments. Financial transfers can create social and economic benefits for rural and urban communities in developing countries, including employment opportunities, reduction of poverty, and access to advanced technology. Investments can further strengthen domestic markets and develop future export markets, leading to economic diversification, accelerated commercialization and competitive advantages in developing countries. Successful investment translates into new jobs and infrastructure development and leads to an increase in *gross domestic product* (GDP) and a reduced share of GDP spent on energy imports, either through energy efficiency or through the use of local renewable sources (WBCSD 2010).

34.6.9   Advantages for the Public Sector

The green transformation is significant for the public sector, which in the past has been a main source of political and societal interventions (OECD 2015). Direct governmental expenditure, as well as public choices, regulations and policies, can be drivers of technology development and transfer. Renewable energy systems receive a high level of public support justified by the expected energy, economic and environmental benefits of renewables. Further, a number

of co-benefits are included, such as the sectoral effects of rural electrification, energy security through energy diversification and improved efficiency, local environmental benefits, and international funding opportunities.

34.6.10 Advantages for the Private Sector

Major advantages for the private sector to pursue climate change mitigation and the transfer of low-carbon technologies may yield financial benefits for the companies involved in the transfer process. These advantages are likely to improve production processes, including the enhancement of energy efficiency, material efficiency and resource efficiency. Early adopters profit from strengthened productive capacities and enhanced export competitiveness, giving them an edge over competitors. Driving this process would accelerate a developing country's transition and facilitate leapfrogging into a green economy. This is obviously in the best long-term interest of the business sector, assuming that there will be an increasing market and new export opportunities for low-carbon products and services. On the demand side, a growing pool of responsible consumers and the rise of a sustainability-oriented civil society shaping consumer preferences will help to establish such a market (UNCTAD 2010).

34.7 Barriers and Risks to Technology Transfer and Investment

Developing and utilizing the huge potential for low-carbon technology in the developing world means overcoming a number of barriers, obstacles and risks that limit their availability and efficiency. Barriers arise at each stage of the technology transfer and investment process, including infrastructure and ownership, cost and finance, as well as regulation and policy. These factors may vary across developing countries, depending on national context and economic sector, project, pathway and technology, application area, region and geography, as well as the local security situation. Here we can only highlight some of the obstacles and barriers without covering the extensive discussion in the literature (for a list, see box 34.6). Not addressing these issues can undermine the efficiency of technology transfer and investment policies. They can result in social costs, ranging from job losses to the reduced affordability of essential services, and/or reduced taxes. The consequences are likely to hit low-developed and other vulnerable countries the hardest. When promoting low-carbon foreign investment, policymakers have to weigh the advantages and disadvantages, both in terms of economic growth on the one hand, and environment, human health and sustainable development on the other.

Box 34.6: Barriers to technology transfer and investment. **Source**: Based on Santarius, Scheffran and Tricarico (2012).

1. Lack of capacity building and domestic infrastructure.
2. Macro-economic conditions and market failure.
3. Lack of access to and sharing of data, information and knowledge.
4. Lock-in due to lack of innovation and diffusion.
5. Failure of R&D spending policy for low-carbon innovation.
6. Tensions and competition undermining the potential for international collaboration.
7. *Intellectual property rights* (IPR).
8. Financial, social and political obstacles for foreign investment.
9. Resource scarcity and environmental impact.

34.7.1 Power Structures and Technology Imperialism

Many of these barriers are subject to vested interests and power games which have not disappeared with the East–West conflict but have re-emerged in the North–South context. The globalized world is driven by an enormous accumulation of capital and concentration of power which shapes technology transfer and financial flows. The large-scale investments necessary for the transitions mentioned above are an expression of the world's power structures and at the same time are transforming them. In the process of technology transfer, the developed countries should act with caution, and take care that they do not establish a 'technology imperialism' by overwhelming their partners and suppressing local companies and economies. The invasion of large companies into local markets is to be avoided. Instead local partnerships, where all stakeholders are at the same level and interdependent, should be established in order to work towards the benefits mentioned above.

34.7.2   Conflict Potential and Ambivalence of Renewable Energy Sources

In a highly competitive environment, the struggle for access to and control of technology can not only strengthen cooperation but also contribute to conflict among the major players, nations as well as corporations. Conflicts may also emerge at a local level, when citizens and non-governmental organizations resist the introduction of mitigation and adaptation measures such as biomass, wind and hydropower (Scheffran/Cannaday 2013). While renewables are highlighted as being largely carbon neutral, GHG savings can vary significantly for specific production and conversion paths and their fossil fuel inputs. There is an ongoing debate about the carbon balance of biofuels and their impact on land use and food security in developing countries (Scheffran/Summerfield 2009; Hamelinck 2013). If not addressed properly, concerns about the possible adverse implications of renewables may undercut their support. This means that renewable energy production and consumption needs to be established in a sustainable and conflict-sensitive manner in both developed and developing countries.

34.7.3   Policy Frameworks to Address Barriers

To address the barriers and overcome the obstacles it is important to develop a practical framework for policymakers, facilitating technology transfer and foreign investment through public money, regulation and standards, and international cooperation. In each stage of the technological process—R&D, demonstration, deployment, diffusion and commercial maturity—existing barriers need to be overcome in order to develop a commercially mature technology. Adjusting the response to a particular barrier helps to identify the financing vehicles appropriate to it. However, the limiting factors and barriers to technological transformation are not primarily of a technological nature but are rather part of the social, economic, political, and cultural milieux in which technologies are developed, diffused, and used. Market incentives, the structure of regulations, the content and quality of research and education, and social values and preferences all determine technological pathways (Heaton/Repetto/Sobin 1991). To develop effective policy tools, it is important to tailor action to the specific barriers, interests and influences of different stakeholders. Further, requirements such as stable political conditions and an educational system to train and qualify local workers have to be established.

34.8   Policies for Technology Transfer and an Enabling Infrastructure for Innovation

34.8.1   Assessment of Innovation, Investment and Technology Needs

To address the challenges and overcome the barriers described above, it is essential to create the adequate framework conditions with incentives that will cause a large-scale technological shift toward a lower-carbon and more energy efficient economy that can also deliver affordable energy solutions (ICSTD 2012). This shift relies on directing investment flows into the development and deployment of lower-carbon technologies, as well as adapting behaviours and lifestyles to favour these technologies. Deploying low-carbon technologies to developing countries requires innovative mechanisms and a joint effort by the private sectors of developed and developing countries (Byrne/Zhou/Shen et al. 2007; Watson/Byrne/Ockwell et al. 2014). Previous efforts to support developing countries in creating enabling environments for low-carbon growth have been insufficient, and more efforts need to be made.

34.8.2   National Systems of Innovation

For the transformation of the energy system and a consequent implementation of an enabling environment three steps have to be fulfilled: (1) the true costs of the current emission-intensive energy system have to be determined; (2) targeted support for new technologies has to be provided; and (3) opportunities for refinancing the high investment cost of renewable energy have to be identified (WGBU 2011). However, the transformation process is knowledge-based, involving all social actors and thus attributing a high degree of social responsibility (WGBU 2014). *National Systems of Innovation* (NSI) "integrate the elements of capacity building, access to information and an enabling environment" for investment and technology transfer (IPCC 2000: 6). NSI concepts rest on a complex mixture of institutions, public policies, and business and social relationships, including networks and partnerships with public and private stakeholders in the business, legal, financial and service domains. NSIs can be enhanced by investment and low-carbon technology diffusion through international partnerships.

34.8.3   The Nexus of Public and Private Investments

In this context, the private sector may serve as a major source of innovation, capital and capacity that can potentially make major contributions to a low-carbon global economy. Most low-emission energy technologies will however not be cost-competitive at scale without some combination of investment support mechanisms, technological advances or regulatory regime improvements. A lesson from CDM proposals is that an abundance of potential projects, technologies or investment opportunities will not necessarily mobilize capital flows for implementation and optimization (an analysis of technology transfer in CDM projects can be found in Seres/Haites 2008). Thus, governments can accelerate or guide the process although the private sector could offer innovative market-based solutions without government intervention. However, government involvement can be supportive in some cases, by creating adequate frameworks for investment, including specific regulations tailored to particular technologies and their stage of maturity (for trends in investment and innovation systems in global energy research, development, and demonstration, see Gallagher/Anadon/Kempener et al. 2011).

To facilitate the release of private sector resources, governments need to understand how capital markets work. As a consequence, corporate investment strategies can be incentivized to deliver results consistent with energy and climate policy goals. It should be kept in mind though that quite different mental models and perceptions among policymakers exist, and this could result in inefficient policies, hindering rather than supporting the involvement of the private sector (WBCSD 2007).

34.8.4   Technology Needs Assessments

Many projects in developing countries fail because of inappropriate technology use which is due to lack of capacity building, ill-defined ownership, or a lack of infrastructure. A new technology framework should minimize this risk and ensure efficient diffusion of the appropriate technologies (see section 34.3). Another reason for failing projects is also the lack of reliable statistical data on issues such as energy use, infrastructure, or demand. Solid data will "help policymakers design the most cost-effective policy options and impact assessments, while business can reduce uncertainty and thus risk premiums" (WBCSB 2010).

To overcome information barriers, governments have a key role in creating the necessary information assessment and monitoring capacity. A comprehensive *technology needs assessment* (TNA), by government agencies, think tanks, research institutions, and international and non-governmental organizations, will provide the understanding required for informed decision-making about future technology options and to select the strategies most appropriate to the country, and its capability and technology options. This implies the identification and assessment of specific needs for a technology and how it fits into the domestic environment. To fully undertake TNAs, developing countries might need administrative and technical support by international organizations (UNDP 2010).[9]

Technology roadmaps help to draw future pathways in terms of capabilities, locations and timelines. They prepare the ground for the promotion of technology prototypes, demonstration projects and extension services through linkages between manufacturers, producers and end users. They also facilitate planning for the identification and development of solutions to technical, financial, legal, policy and other barriers. A number of factors might affect host governments' prioritization and targeting of foreign investment to boost prospects for technology dissemination. A government might identify targets by comparing potential growth sectors and assessing the country's natural resources and assets that have been created. For example, Morocco has chosen to enter into renewable power generation and the manufacturing of environmental technologies for a number of reasons (reducing dependence on foreign fossil fuels, supplying and exporting power, encouraging rural electrification), including an assessment of where the technology can best be secured, as well as an analysis of patterns of low-carbon foreign investment in the sector (WIR 2010). Similar approaches are relevant in concentrated solar power projects in North Africa and the Middle East (see box 34.7).

Technology assessment allows synergies to be created from the careful matching, harmonization and utilization of all technological resources and of the relevant actors from private and public sectors. Mechanisms can be put in place to adapt technologies to local needs, or to generate new ones if necessary.

---

9   For TNA guidebooks, see at: <http://www.tech-action. org/Publications/TNA-Guidebooks> and at: <http:// www.unep.org/roap/Activities/ClimateChange/TechnologyNeedsAssessmentandTechnologyAction/tabid/ 6847/Default.aspx>.

Attracting low-carbon foreign investment is not only about new and emerging business opportunities, but also about encouraging foreign investments in traditional sectors, with a view to improving their energy, material or resource efficiency.

34.8.5   Building Human, Social and Institutional Capacities

Developing countries not only require finance for energy projects but also capacity building and related funding from public and private sector investors. Capacity building programmes and enabling environments that reduce the risks and restrictions associated with low-carbon technology transfer will increase the flow of technologies close to the commercial margin. Capacity building targets technology acquisition, development of skills, local policies and institutions in order to support the technology transfer process. It focuses on enhancing scientific and technical skills, capabilities, and institutions in developing countries, as a precondition for assessing, adapting, managing, and developing technologies (UNCTAD 1998). But the need for enhanced skills and capabilities can also occur throughout all stages of the technology life cycle. Several studies acknowledge that the needs of capacity building vary greatly from country to country (see Mugabe 1996).

34.8.6   Requirements for Capacity Building

The transfer of green technologies demands a wide range of technical, business and regulatory skills. Human and institutional capacity is needed to assess, select, import, develop and adapt appropriate technologies, including the capacity to optimize and innovate. Not only specific know-how should be transferred, but also related systemic knowledge of the relevant technologies that will enable recipients to add value. Lack of human capital is one of the barriers to the development, acquisition, deployment, and diffusion of technologies required for meeting energy-related CO_2 emissions reduction targets (IRENA 2012). Human capacity is critical in providing a sustainable enabling environment for technology transfer in both the host and recipient countries (IPCC 2014). Previous experiences have demonstrated that the absence of human capacity was a major cause of the many failures of technology transfer. This makes adequate human capacity essential at every stage of the transfer process.

Education and training is important in developing human capital for business, municipalities and governments. The training of employees, engineers as well as operators and users, builds local competency in the use of the technology. Training helps to overcome the lack of knowledge, which is an important barrier to technology diffusion (e.g. for advanced solar technologies). Training should not only focus on the technical aspects but also involve the sales and marketing aspects. Training and support services could be largely public but may involve multinationals and consultancy firms that have extensive training and technical capacity but rarely divert those resources from commercial activities.

Capacity building targets knowledge and gaps in skills, and aims to improve enabling environments by overcoming market, human, and institutional capacity barriers. While frequent and unpredictable policy changes can undermine capability and efficiency, stable, reliable and predictable government policies need well-established legal institutions and the rule of law to reduce uncertainty about the expected return on investment (IPCC 2014).

34.8.7   Outlook for an Improved Integrated Concept of Capacity Building

Future approaches will be more effective if they lay stress on the integration of technology transfer and human resource development, and focus less exclusively on developing technical skills and more on creating improved and accessible competence in associated services, organizational know-how and regulatory management. High-quality training is needed to give the personnel of the receiving firm the skills, knowledge and expertise applicable to particular products and processes. This is an important consideration for developing countries, because the workforce requires continual and cumulative learning. Human capacity building needs to be tackled for large-scale infrastructure projects as well as for small-scale solutions, driven and implemented by local entrepreneurs. For large-scale projects, it is crucial to strengthen the strategic planning capabilities and project management skills of both regulatory authorities and project developers. For small-scale solutions, knowledge of the local market is crucial and needs to be complemented with the strengthening of business skills and the adaptation of technologies to local needs (WBCSD 2007). i

Training skills and learning are an important part of any technology transfer package and can serve as a learning vehicle for the workforce of the recipient

---

Box 34.7: Clean Power from the Desert—Concentrated Solar Power. **Source**: Assembled by the authors.

The highest solar irradiance can be measured around the equator, roughly between 40°N and 40°S. Therefore, this 'Sun Belt Region' is especially interesting for a new emerging renewable energy technology–*Concentrated Solar Power* (CSP). The idea is simple: incoming sunlight is concentrated through mirrors onto a receiver. The receiver transfers the energy to a heat transfer fluid which can supply the heat when needed–either as end-use heat supply or for electricity generation through steam turbines. The heat can even be stored, to produce energy when sunlight is not available or only to a limited degree, e.g. at nights or on cloudy days. This decoupling can improve the grid integration of CSP-generated electricity and consequently increase economic competitiveness.

The Sun Belt Region bears high potential for the implementation of these technologies, not only, because most of the irradiance can be received here but also because of available space. Many of the world's deserts and less populated areas lie within the subequatorial regions, providing good opportunities to install large-scale CSP. Further, the region's local development can be fostered through the implementation of CSP technology with the jobs that are created for local production of components, operation and maintenance of the power plant.

Due to the low population density and the sparseness of industrial activities, electricity generation from such power plants will exceed the electricity demand in these regions many times over, and this bears high potential for the export of electricity. The idea of large-scale energy export from these regions is also part of the aims of the DESERTEC Foundation. Their project aims to combine and integrate the most efficient and abundant renewable energies in a transnational grid to provide clean energy

from the deserts for ninety per cent of the world's population:

- *Concentrated Solar-Thermal Power* (CSP) in desert regions;
- wind power in coastal areas;
- hydropower in mountain regions with high precipitation;
- photovoltaics in sunny areas;
- biomass and geothermal power where geographic conditions are favourable.

All these technologies already exist and are in use in different parts of the world (IEA 2014). However, a global supergrid as proposed by DESERTEC has so far failed due to the political and socio-economic situation of many of the core countries of the project. CSP plays an integral part in this concept since it has the potential to balance fluctuations emerging from wind or photovoltaic power plants. The power can be transmitted over up to 3,000 kilometres using *High Voltage Direct Current* (HVDC) lines. Since ninety per cent of the world's population lives less than 3,000 km from a desert, DESERTEC aims to expand the idea of clean power from the desert to a global network. To harvest solar power for climate, human and energy security on a larger scale, the future of the concept depends on financial support and favourable political conditions, to be embedded into an integrated framework of environmental, economic and social sustainability (Schinke/ Klawitter 2011; Klawitter/Schilling/Scheffran 2010).

---

firm (Brooks 1995). In those regions of the developing world where existing capabilities are weak in specific technology areas, a basic level of technological capability could be built via the establishment of regional institutes that provide training in technology assessment and management. Experience with implementing the Montreal Protocol provides a useful example for capacity building within enterprises where a multilateral fund, established by the treaty, supports training, research and network building.

34.8.8   Strengthening of Absorptive Capacities

While rural electrification and poverty alleviation is still an issue for emerging economies and small developing countries, a distinct need exists to understand and chart the distribution of capacities for absorbing and working with different low-carbon technologies (Ockwell/Mallett 2012). The absorptive capacities of local firms determine whether they can acquire and

master technologies which depend on technical competencies and commercialization skills. Host developing countries can put in place policies to develop domestic capacities to absorb technology and know-how. To strengthen absorptive capacities, policy seeks to enhance the innovative and competitive performance of firms. Here, innovation and diffusion are two facets of the same process. To reap the benefits of incremental innovations in developing countries, technology transfer should foster technological innovation in recipient firms. This will provide them with the technical capability to generate improved processes and products. In this context, government-driven R&D in green technologies can play an important role, since private investors tend to underinvest in public goods, such as the environment.

The ability to absorb new technology depends on the stages of technology development and transfer, and can be acquired through collaborative initiatives in research, development, demonstration and the

deployment of low-carbon technologies. It is important to take into account the potential for regional partnerships to absorb and disseminate information to local business on the best available technologies that suit the local circumstances. To enhance absorptive capacity and build trust between technology developers and users, governments and the private sector could develop local management capabilities and go into partnership with business to find solutions. They could address installation and maintenance as a key element of technology deployment (WBCSD 2010).

34.8.9   Inter-Firm Linkages

Generation of inter-firm linkages through regular local production by foreign operators is also seen as integral to generating knowledge that will result in new technological capacity in recipient countries. Saad and Zawdi (2005) point out how the transfer of plants and equipment to developing countries has often been based on 'turnkey' and 'product-in-hand' contracts that focus on boosting industrial growth rather than fostering innovation. They also highlight the fact that restrictive terms of contracts between TNCs and firms based in developing countries have limited the scope for fostering innovation through 'reverse engineering'.

34.8.10   Creating a Legal and Regulatory Framework

To attract investment in low-carbon infrastructure projects and create new markets for low-carbon products, credible, consistent and non-conflicting regulatory obligations are needed that address the long-term nature and high capital cost of energy infrastructure projects (WBCSD 2007). To operate under the rule of law, business requires stable political and legal systems that will ensure a sound investment environment. Harmonizing regulations and standards are important, especially in sectors that are subject to strong international trade. Open markets, fair trade and rules of competition are essential for enhancing technology diffusion to developing countries.

34.8.11   Institutional Framework Conditions

The quality of a country's enabling environment has a substantial impact on whether private firms invest in new technologies and infrastructures. An effective technology policy will address the framework conditions, including the effectiveness of institutions, regu-

lations and guidelines regarding the private sector, the security of property rights and the credibility of policies, political models, laws, social norms and preferences, individual behaviours, skills, and other characteristics (IPCC 2014: 1178). The enabling environment for low-carbon business activities is "the overall environment including policies, regulations and institutions that drive the business sector to invest in and apply low-carbon technologies and services" (Stadelmann/Michaelowa 2011; Stadelmann 2013). Accordingly, the enabling environment "has three main components: (1) the core business environment, which is relevant for all types of businesses, e.g., tax regime, labour market, and ease of starting and operating a business; (2) the broader investment climate, including education, financial markets, and infrastructure, which is partially low-carbon related, e.g., via climate change education or investments in electricity grids; and (3) targeted policies that encourage the business sector to invest in low-carbon technologies" (IPCC 2014: 1223).

34.8.12   Government Contributions

Governments in developing countries can make significant contributions to build or strengthen regulatory frameworks and institutions to stimulate technology transfer and investments. On the one hand, legal barriers that slow or diminish access to low-carbon technology by local business need to be removed. On the other hand, developing new international standards and regulations is particularly relevant for energy efficiency and could create demand to support the innovation and diffusion of more efficient end-user products. If designed properly, markets will respond to regulatory policies to promote the reduction of GHG emissions.

A number of strategies can create a political and regulatory framework to facilitate the implementation of emission reduction options in the energy sector. These strategies could include but are not limited to:

- Allowing full cost pricing that includes the external costs of fossil energy and recognizes the indirect benefits of renewables such as improvement of the environment, creation of more local jobs, balance of trade, etc.
- Encouraging the implementation and enforcement of energy and environmental standards, including recruitment and training of enforcement personnel together with the necessary tools and administrative support for credible implementation of sanctions. Developing countries can learn from existing environmental standards, e.g. the CAFE

standards for vehicles in the US, the Top Runner Programme of Japan or the EU Eco-Design Directive. *World Trade Organization* (WTO) standards can be influenced to facilitate the trade of products and goods produced from the use of low-carbon technologies.

- Promotion of so-called 'green-labelling' programmes and certification systems for sustainable energy technology to employ trademark or related principles, such as an environmental seal to satisfy and approve certain requirements to products and vendors.
- Establishment of requirements for environmental impact assessment and environmental reporting.

34.8.13   UNFCCC Contributions

Establishing criteria for *measurable, reportable, verifiable* (MRV) action would set out the conditions under which national R&D and development spending would qualify as a contribution to UNFCCC commitments on technology, financing and capacity building support. These conditions would be additional to existing development assistance as well as R&D spending and have a demonstrable link to a developing country's low-carbon development plan. They should meet criteria for enhanced developing country access to new technology and increase the capacity to innovate and adapt.

34.8.14   Protection of Intellectual Property Rights

A major focal point is to regulate the protection of *intellectual property rights* (IPR) in a way that strengthens technology development and transfer in any country (WBCSD 2010). Issues of transferring or purchasing IPR polarize the interests of Parties and prevent progress in global climate negotiations. In some cases companies seem to have strategically withheld or delayed technology from certain markets in order to maximize profits. This contradicts the need to spread technologies into developing countries and is not a sustainable strategy for addressing climate change (Tomlinson/Zorlu/Langley 2008). There is no firm evidence from previous case studies of how IPR affect the diffusion of climate-friendly technologies, and there is no absolute system of IPR protection in any country.

To develop appropriate and effective mechanisms for low-carbon and climate-resilient innovation, the incentives for private innovation and for maximizing public benefit need to be balanced. To break the deadlock between developed and developing countries over intellectual property, a new agreement for IPR and licensing would provide government-to-government commitments to protect and share low-carbon technologies and encourage joint ventures and public–private partnerships. Access to international R&D funding and credit for national R&D programmes could be made conditional on implementation of agreed protect-and-share principles for IPR. Possible options are improved licensing and parallel markets, as well as 'pay to play' agreements (in exchange for services to engage in certain activities) to meet the climate challenge (Tomlinson/Zorlu/Langley 2008). Support would be made available under a fund to strengthen IPR protection measures in developing countries, consistent with their existing international commitments under the *World Intellectual Property Organization* (WIPO) and World Trade Organization (WTO). Since renewable energy technologies still require some form of government support in many markets, these developments have led to trade-related disputes, via the WTO and domestic trade channels (Lewis 2015). An ambitious example of managing IPR in cross-border clean energy collaboration has been the US–China *Clean Energy Research Center* (CERC) (Lewis 2014a; Lewis 2014b; Watson et al. 2011).

34.8.15   Strengthening Economic Conditions and Incentives

The efficiency of policies for strengthening national systems of innovation depends to a considerable degree on the state of the economy in developing countries. Improving economic conditions is a key factor in creating a long-term viable infrastructure that will absorb low-carbon technology and accelerate development in order to facilitate leapfrogging into a low-carbon future. A diversified economy is also required to handle shocks from climate change and other destabilizing events, and recombine resources in new ways to adjust to a continuous process of change. In the mid- to long term, new fields of economic growth need to be opened, often requiring a different and more skilled workforce; this has implications for education systems and related policies. Already, significant public and private investment in low-carbon innovation in high-income countries is being developed. However, this is often done with a view to creating a national competitive advantage. Competition is a crucial factor in driving innovation but it does not fully capture all

Table 34.4: Summary of actions and incentives for the public and private sectors in the developed and developing countries. **Source**: Adapted from Santarius, Scheffran, Tricarico (2012: 50).

	Public sector	Private sector
Developed country (Investing)	• Reduce the role of current export credit agencies • Build new institutional mechanisms that promote foreign investments to make them work for climate protection and sustainable development • Raise public money to support and leverage climate-friendly foreign investments so as to insure investments against financial and market instabilities, incentivize investments into markets with limited demand, and thus make investments attractive, even where returns on investments are expected to be low	• Support should be offered to companies, e.g. renewable energy companies that aim to invest in countries with low production capacities • The level of support should significantly raise companies' interest in going abroad • Only those investments should be supported that conform to the highest standards at home • Both public and private money raised may be used by countries to fulfil their international climate finance obligations
Developing Country (Recipient)	• Implement strong, stable, transparent, coherent, credible, and ambitious long-term enabling environments • Develop domestic technology roadmaps that identify countries' nationally appropriate mitigation actions • Establish investment policies to effectively govern foreign investment inflows • Design these policies in a way that maximizes the mitigation potentials of foreign investment as well as economic diversification and sustainable development	• Setting the stage for sustained economic growth as 'green growth' and 'energy autonomy' through domestic renewable energies which have more long-term prospects than 'fossil growth' • Provide opportunities for economic diversification by catalysing foreign capital to climate-friendly sectors • Foster ownership and competitive strength of domestic/local companies in the global market by demanding that foreign investors engage in joint ventures and purchase local goods

the global public beneficial aspects of low-carbon technologies (Tomlinson/Zorlu/Langley 2008).

34.9   Conclusions and Outlook

Developing North–South Transitions into Green Economies (Santarius/Scheffran/Tricarico 2012) requires the rapid and effective dissemination of climate-friendly technologies, and in particular of renewable and efficient energy systems. A sustainability transition needs an effective combination of financial mechanisms and smart governance strategies in order to develop the economic and technological capacities of all countries, including products and infrastructures as well as new social rules and norms. Key elements in this process are the international diffusion of know-how, investments and technologies to build up production capacities and the demand for low-carbon goods, and to establish international cooperation between business and government actors to adapt technologies to the local context in a low-carbon society. The different actions and incentives for the public and private sectors in developed and developing countries are summarized in table 34.4.

34.9.1   Innovative Business Concepts Required

New business opportunities will be created for moving to low-carbon economies in developing countries and for establishing new technologies and production modes based on energy efficiency, renewable power generation and low-carbon production pathways. Due to high unit costs, difficult management, lack of markets and infrastructure, new low-carbon products and services can only develop and emerge on a sustainable basis if they are supported by market-creation mechanisms, even if only on a temporary basis (WIR 2010). To overcome initial hurdles, economic incentives are required to compete with existing technologies that are more advanced in their life cycle. As the production costs of new pathways decrease over time and new products become attractive to more people, the need to support emerging markets declines and should eventually be abandoned to avoid market distortions.

34.9.2   Innovative Policy Portfolio Required

To realize the social and environmental benefits of technologies that will not yet diffuse commercially, developing countries can implement policies that combine fiscal and regulatory measures by lowering

costs and stimulating demand, thus steering investments into a more desirable direction. Governments can take various measures and tools that will provide incentives for investment in sustainable energy technologies and become a catalyst for establishing new markets. There is a wide range of policies in place that support renewable energy around the world, including mandates and standards, innovation policies, carbon pricing, and others. These include encouraging investment in low-carbon and energy efficient production and transportation systems or accelerated depreciation of existing assets; public procurement of low-carbon products and technologies; energy performance standards or mandatory energy labelling schemes; renewable portfolio standards; blending mandates for alternative fuels; taxes for high-emission technology or tax incentives for green electricity; tendering procedures for green electricity or green certificate systems; and feed-in tariffs to guarantee a preferential price.

34.9.3   Incentive structures and market opportunities

Most of these measures have already been developed and applied in developed countries, in particular in the EU, which has considerable experience with various approaches and mixes (Karakosta/Doukas/Psarras 2010). While developed countries will continue to take the lead in market-creation mechanisms, their experience could be fed into technology support programmes in developing countries, who may wish to adopt market-creation policies in order to build local markets for certain low-carbon products and services. This could support their own export capacity and facilitate the introduction of technologies adapted to their development needs, such as rural electrification using renewable energy sources. Preferences for the various incentive policies vary by country, sector and technology.

While governments have a special role in creating incentive structures, the specific situation of developing countries has to be taken into consideration. Instruments such as 'Feed-in Tariffs' have been established in developed countries where governments have the financial resources to pay for the special treatment required by low-carbon technologies. Most developing countries, however, have limited financial means for setting up market creation programmes to match those of developed economies. This puts them at a disadvantage concerning the attraction of low-carbon foreign investment; it is therefore imperative for more advanced countries to take care not to undermine

efforts being made by poorer countries towards a transition to a low-carbon economy. Furthermore, home countries can help by actively promoting outward low-carbon foreign investment and by avoiding distortions in market mechanisms.

New market opportunities arising from changes in consumer behaviour in the main developed country markets should also be tapped, including markets for organic food, goods produced under responsible practices (fair trade, no child labour, fair treatment of workers), and low-carbon products. Appropriate policies can help protect and promote a host country's economic, social and other interests.

34.9.4   Community Involvement and Micro–Macro Transformations

Due to the failure of top-down and technology-centred approaches, it is now widely recognized that the involvement of community institutions is an essential contribution to environmental projects and is therefore an important factor in successful technology transfer. The involvement of local government agencies, consumer groups, industry associations and NGOs can help to ensure that the technologies being adopted within their particular country/region are consistent with their sustainable development goals. Besides the involvement of such community institutions, lessons from technology-intensive economies teach us that technology increasingly flows through private networks of information and assessment services, management consultants, financial firms, lawyers and accountants as well as through technical specialist groups. Governments can strengthen the growth of such networks for technology transfer (IPCC 2000). This includes a national dialogue of different stakeholders representing various private as well as public interests. Participatory approaches can engage private actors, public agencies, NGOs and grassroots organizations at all levels of environmental policy-making (Brinkerhoff 2004).

The moves towards decentralized and self-organized electricity generation and smart grids may challenge the power structures of large-scale energy producers, e.g. when residents install solar systems in their homes or citizen-driven cooperatives install their own wind power stations. When big utility companies are seeing their value drop substantially, this has been termed the "utility death spiral".[10] Three social chal-

---

10 See at: <http://www.whebgroup.com/the-utility-death-spiral>.

lenges are especially salient as far as the social management of technological systems is concerned: "(1) the size and visibility of transfers and assets created; (2) the predictability of pressure to expand the focus of the policies to broaden the social benefits; and (3) the potential for market incentives and framings of environmental issues to undermine normative motivational systems" (IPCC 2014).

If the micro–macro linkages between mutually impacting action levels are to be bridged, the multi-level interactions across social and technological elements (megatrends, sociotechnical regimes, niche level) need to be involved (Grin/Rotmans/Schot 2010; Geels 2011; Meadowcroft 2011; Foxon 2011; WBGU 2011). Know-how from forerunner actors needs to be tapped and made available at all levels from local to global (Hasselmann/Cremades/Filatova et al 2015). In this context there is a need for understanding policy–business relationships (Scheffran/Leimbach 2006) and organizational learning in technology–society interactions (Engels/Knoll/Huth 2008; Vieira 2015), in order to explain mechanisms such as emissions trading or the substitution of established technologies by new ones, which is at the core of sustainability transition towards the decarbonization of energy systems and society.

35 Considering a Structural Adjustment Approach to the Low Carbon Transition

Karlson 'Charlie' Hargroves[1]

Abstract

As the world comes to grips with the need to significantly reduce greenhouse gas emissions, a range of questions are being asked about how to effectively transition economies to low carbon operation over the coming decades. A growing number of pressures are now being felt across a range of sectors to reduce emissions, in particular carbon-related fuel consumption, which is leading to autonomous emissions reduction efforts—typically ad hoc and business-led. However, in order to meet ambitious targets for the reduction of greenhouse gas emissions now set by the world's largest economies a structural adjustment approach may be needed that is effectively underpinned and appropriately expedited at an economy-wide level. This chapter presents an introduction to key lessons from structural adjustment programmes to inform the low carbon transition, and in the absence of conditional lending requirements that have driven structural adjustment programmes the chapter considers how the willingness to adjust structures of the economy to deliver low carbon outcomes can be increased.

Keywords: Structural adjustment, low carbon transition, greenhouse gas emissions, low carbon, carbon structural adjustment.

35.1 Introduction[2]

In the twenty-first century much of the world will experience untold wealth and prosperity that could not be conceived of just a hundred years ago. Much of this prosperity has been based on rapid industrialization, mechanization, electrification, and digitization, beginning in the mid-1700s with the Industrial Revolution, as shown in figure 35.1. However as with many of the human civilizations over the last 5,000 years the rapid growth in prosperity has accumulated significant environmental damage that now threatens to result in what esteemed sustainable development expert Lester Brown refers to as '*environmentally induced economic decline*' (Brown 2008).

Governments around the world will face a range of serious global environmental challenges in the twenty-first century, with one of the most pressing due to the fact that the fuel source that has underpinned the industrial revolution and allowed the staggering amounts of development to be undertaken in much of the world, namely fossil fuels, is now widely recognized to have a sinister legacy (Hargroves/Smith 2005; Brown 2008; Stern 2005; OECD 2008). The combustion of fossil fuels such as oil and coal has resulted in the generation of vast quantities of air pollution, a proportion of which that when combined with specific agricultural and industrial emissions are

---

Figure 35.1: Waves of Innovation. **Source**: Hargroves/Smith (2005).

referred to as '*greenhouse gases*' as they increase the atmosphere's capacity to store and release heat. Such emissions are in quantities that now threaten to impact the global heat transfer processes and leading to increases in the average global temperature that can have devastating effects on the planet's biosphere and in turn on our vast developments and settlements. In his 2006 book, *Heat,* George Monbiot laments that "Ours are the most fortunate generations that have ever lived. Ours might also be the most fortunate that ever will" (Monbiot 2006).

Governments around the world are now understanding the threat posed by human-induced climate change and the associated imperative to respond with the world's largest economies setting ambitious greenhouse gas emissions targets. By the end of 2014 the European Union had committed itself to reducing emissions by at least 40 per cent by 2030 (compared to 1990 levels), China committed to 40–45 per cent by 2020 (compared to 2005 levels), India committed to 20–25 per cent by 2020 (compared to 2005 levels), and the United States committed to 26–28 per cent by 2025 (compared to 2005 levels). These ambitious targets will create significant pressure to reduce emis-

sions in the coming decades in a manner that delivers ongoing prosperity, jobs, and profits. The challenge for nations to achieve such targets will be to tackle the temporal issue with the economic impacts of climate change standing to hit hardest in the future (Stern 2008), while political attention and business strategy is firmly focused on performance in the very short-term (Hargroves/Smith 2005). Balancing this mismatch between short- and long-term imperatives will be a crucial aspect of the low carbon transition, one that if not appropriately considered may well lead to significant impacts on economies.

This chapter considers the notion that the scale and pace of economy-wide changes required to significantly reduce greenhouse gas emissions are akin to the results of the application of *structural adjustment programmes* (SAPs) in developing countries in order to improve economic performance as part of conditional lending requirements by financial institutions such as the *International Monetary Fund* (IMF) and the World Bank. According to the IMF, structural adjustment is focused on "changing the way in which an economy is organized in order to raise productive capacity".[3] It may in fact be the case that in the same

way that fiscal structural adjustment was implemented largely as a solution to underdevelopment in third world economies in the twentieth century, a new form of structural adjustment, that of *Carbon Structural Adjustment* (CSA), may be needed as a solution to unsustainable development around the world in the twenty-first century. Carbon Structural Adjustment is defined here as "an agenda of swift adjustments to structures across economies to transition to low carbon operation".

A key point of difference however is that unlike SAPs that were enforced as part of the conditions of development loans, Carbon Structural Adjustment programmes will need to be driven by national governments as an economic development strategy. Hence the question considered in this chapter will be, "How can lessons from structural adjustment programmes inform the low carbon transition, and how can a strategic approach be developed to deliver carbon structural adjustment?"

In response to these questions the theoretical approach used in the chapter is based on both 'quantitative' and 'qualitative' approaches; however, the chapter assumes that the most appropriate ontological approach to the questions above is to consider them as largely 'subjective', meaning that it tends to be more qualitative, informed by quantitative aspects including survey and focus group data. Considering the potential for axiological assumptions, although the author has personal values that align to achieving significant reductions in greenhouse gas emissions globally, this bias was separated from the analysis of the literature, surveys and focus groups, and discussions with experts, to allow an 'unbiased and value-free' approach. The chapter takes the methodological approach to the research questions of considering them to be mostly 'deductive' with an 'inductive' component. This means that when considering the various literature and findings the main focus was on a deductive process to consider the 'cause and effect' of various actions and interventions to inform the development of generalizations of the overlying context. Given the growing international interest in achieving a low carbon transition there has been an increasing level of materials released by industry groups, companies, NGOs and other sources that have been used to inform the chapter rather than a purely academic literature approach.

35.2   Considering the Economics of the Low Carbon Transition

In the 1700s if it were possible to comprehend the future impacts of a fossil-fuel-based system it may have been feasible to take swift action to reduce such pollution with a global population of less than one billion people. However, today in a world with some seven billion people the potential for large-scale change in the basis of the energy system is a seemingly overwhelming task, especially considering that the tools and strategies that have led to the highly successful fossil-fuel-based economy may not be as useful to transition to low carbon operation, and new tools and strategies may be needed. Ironically it may also prove to be the case that without having first harnessed fossil energy to develop industries it would not have been possible to develop the technology required for a transition to large-scale non-fossil-based energy production (such as through solar photovoltaic panels, solar thermal, wind turbines, ocean turbines, fuel cells, geothermal, co-generation equipment, etc.).

Economists have pondered for many years the thought that perhaps if the world stopped focusing on continually increasing economic growth then the unsustainable growth in demands on the environment would slow to a point where it would be sustainable without changing much about the way the economies operate. The challenge is that most of the national economies of the world are built on the prediction that there will be strong economic growth, and further that in its absence the economy will be bailed out by government, as in the 2008 global financial crisis. This assumption underpins many economies, which in reality are an incredibly complex system that for various conditions in various countries leads to a balancing point that allows the economy to run. This fragile balance sets the level of taxation, the price of commodities and products and the spending and saving habits of citizens, and affects levels of investment, insurance, interest rates, public spending, private development, education, research, etc. *The reality is that on any given day the complexity of the average economy is in itself overwhelming, and trying to incorporate future impacts from environmental pressures is an even higher order level of complexity—one that will not be achieved by reducing the level of economic growth alone, or by taking isolated actions in parts of the economy.*

We are now at a point in the development of humankind that offers the most sophisticated and technologically advanced platform upon which to

Figure 35.2: Gross Domestic Product vs. Estimated Environmental Costs (billions) for the United States of America from 1950 to 2004. **Sources**: Smith, Hargroves and Desha (2010), with data reinterpreted by K. Hargroves from Talberth, Cobb and Slattery (2006).
tackle large-scale problems, one that has the potential to underpin a transition in the coming decades to a global society that is able to sustain its preferred living conditions (von Weizsaecker/Hargroves/Smith et al. 2009). However, to achieve such a future this platform needs to be harnessed to address the significant complexities involved in reducing greenhouse gas emissions across economies. Further, the literature shows that it is crucial to understand that even if the impacts of global warming alone may be significantly mitigated or adapted to, when combined with deforestation, the expansion of freshwater intensive modern agriculture and ocean fisheries, and increasing urban waste streams, the overall environmental pressures may still be too much for ecosystems to handle (Brown 2008; OECD 2008).

The longer action is delayed on a meaningful scale the higher the resulting costs from the environmental damage will be to current and future generations, adding to the already high cost of environment-related impacts to the economy. For instance figure 35.2 shows that while US GDP has risen steadily since 1950, the costs related to environmental pressures have also risen, effectively offsetting a growing proportion of GDP rising from 22 per cent in 1950 to 37 per cent in 2004. These costs included household pollution abatement, water pollution, air pollution, loss of wetlands, loss of farmland, loss of primary forests, resource depletion, carbon dioxide emissions damage, and ozone depletion (Talberth/Cobb/Slattery 2006). This simplified example is complicated by a number of factors related to measurement and assumptions

regarding the distribution of costs; however, it provides a clear picture of the trends associated with economic growth and costs related to environmental pressures (Smith/Hargroves/Desha 2010).

Considering the costs from climate change in particular, the *Stern Review* estimated that "the total cost of business-as-usual climate change to equate to an average reduction in global per capita consumption of 5 per cent at a minimum now and forever" (Stern 2006). The *Stern Review* also describes that this cost would increase to as much as twenty per cent per year if the modelling was to take into account the impacts related to human health, various amplifying effects, and the disproportionate burden of climate change on the poor and vulnerable globally. Thus to pay for such costs governments in the future will need to raise taxes, privatize public assets, borrow money, or pass it on to the market. Some argue that future generations will be wealthier and more able to pay, but this assumes that the costs of inaction will not rise, and further that if these costs rise it will be a predictable and manageable increase (Smith/Hargroves/Desha 2010). However, the *Stern Review* is clear that due to the complexity of natural systems and the potential for feedbacks and amplification effects the costs on inaction will continue to rise unless action is taken (Stern 2006).

Those moving early to respond to this challenge are learning that there are in fact a number of ways that reducing pressure on natural systems can underpin continued economic growth—which is possibly the most important finding, or 'convenient truth', of

the twenty-first century (von Weizsäcker/A/B et al. 2010). However, the time frame for action is short and the consequences for inaction will be long-lasting (Stern 2006). In order to ensure that the most cost-effective, efficient, and successful transition to low carbon operation is achieved it is crucial that a range of adjustments are made to the various structures of the world's economies—and further that efforts from societies around the world are monitored and quickly learned from to inform further efforts. A number of countries have developed 'National Strategies for Sustainable Development', and although they are largely symbolic this is an encouraging sign of a focus on national-level strategies and frameworks, specifically Cameroon, Canada, Denmark, Finland, France, Germany, Greece, Ireland, Latvia, Mauritius, Mexico, Moldova, Netherlands, Norway, Philippines, South Korea, Sweden, Switzerland, the Czech Republic, the United Kingdom, and the European Union.

Changing an industrial economy to run on non-fossil energy will require significant investments in new energy technology for generation and distribution—such as building vast solar panel arrays, wind farms and ocean turbines, while upgrading electricity distribution systems to be able to manage a network of small-scale energy generation—together with reducing the energy intensity of a range of operations to both reduce overall demand for energy and allow greater levels of economic growth, particularly in developing countries. According to the Pathways to Deep Decarbonization Project, "Directed technological change should not be conceived as picking winners, but as making sure the market has enough winners to pick from to achieve cost-effective low-carbon outcomes" (SDSN/IDDRI 2014).

35.3   Achieving Low Carbon Economic Multipliers

The key to achieving carbon structural adjustment will be the effective implementation of strategies that reduce greenhouse gas emissions in ways that deliver economic multipliers and support economic growth. For instance, investing in improvements to the efficiency and/or productivity of energy, water and other resources can deliver flow on benefits such as reduced input costs, reduced running and maintenance costs, and reduced waste-related costs, and hence can be recovered over a reasonable time frame to then deliver ongoing cost savings that can then be invested to achieve even greater resource productivity improve-

ments. Furthermore, as such investments can lead to reduced levels of consumption of resources, such as water and electricity, this can lead to delays in, or even the avoidance of, costly investments in increasing the capacity of energy and water supply infrastructure, as well as plant and infrastructure in extractive industries (Smith/Hargroves/Desha 2010). Typically such investments are at a local level and can spur jobs growth and economic development, attracting companies and operations keen to be part of such initiatives.

There is strong evidence to show that significant reductions in the energy consumption of our economies can not only be achieved, but can be achieved cost-effectively and in a timely manner. Fortunately unlike some thirty years ago when many of the campaigners for responding to climate change began their important work, such as Amory Lovins (Hawken/Lovins/Lovins 2009), Ernst von Weizsäcker (von Weizsäcker/Lovins/Lovins 1997), Hunter Lovins (Lovins/Cohen 2012), Jim McNeill (World Commission on Environment and Development 1987), Bill McDonough (McDonough/Braungart 2002), Lester Brown (Brown 2008), and others, there are now a vast number of examples of leading practice showing that significant reductions in greenhouse gas emissions can be achieved profitably, such as shown in table 1.1 (von Weizsäcker/Hargroves/Smith et al. 2009). As the *International Energy Agency* (IEA) reported in 2006, "Many processes have very low energy-efficiency and average energy use is much higher than the best available technology would permit" (IEA 2006).

A critical barrier to the achievement of improvements in energy productivity is that the designers, engineers, architects and technicians of today are not versed in a systems-based approach to design (Stasinopoulos/Smith/Hargroves/Desha 2009). The reality that the engineering and design professions now face is that even with significant advances being made by designers across the world, the shift from an incremental approach to a systems approach is in its early stages. This is a problem as our amazing Earth cannot wait for many years of trial and error, research and debate, publications and textbooks, before steps are taken to significantly reduce greenhouse gas emissions. Hence we need to learn from what is being done around the world and rapidly bring this knowledge together. In researching evidence to support the feasibility of carbon structural adjustment it has become clear that in each of the successful examples of such improvements a common set of questions has

been considered, namely (von Weizsäcker/Hargroves/Smith et al. 2009):

- Is the current method of delivering the product or service the only way to do so? (Often the first thought when answering this question is 'yes'; however, further investigation often leads to a range of alternatives—from system upgrades, such as energy-efficient motors in an industrial application, to completely new processes, such as shifting to a process to predominantly use scrap metal rather than processing primary resources to make steel.)
- If it is the only way, what are the major areas of energy, water and materials usage, and a) what options are available to reduce the need for such inputs, and b) what alternatives are available to provide these inputs? (The search for such alternative options and inputs can be driven by a requirement to reduce environmental impacts, but also be part of a strategy to improve competitive advantage by reducing input costs, which are inevitably set to increase in the future as availability and impact are factored in.)
- If it is not the only way, what alternatives are there to the system that can be used to profitably deliver the product or service with less resource intensity and environmental pressure? (For instance, geopolymers can be used to create cement with as much as eighty per cent less energy intensity, partly by eliminating the process emissions of greenhouse gases associated with Portland cement production.)

When considering strategies to support such a pragmatic enquiry it is important to understand that once the initial questions as to the best way to meet the design requirement have been answered the conceived system needs to be benchmarked against best practice in order to understand the potential for performance. However, in many cases the new design concept will be part of an emerging wave of innovation and hence there may be little precedent to provide a benchmark. Further, even if there are established examples of the new design, such processes and methodologies are unlikely to have had time to be incorporated into higher education or professional development courses. It is of crucial importance that the feasibility of widespread implementation of low-carbon technologies and processes is established across all sectors of the economy.

It is not possible to consider strategies to reduce greenhouse gas emissions without considering the potential for such achievements to be overwhelmed by growth, referred to as the 'Rebound Effect'. This area of consideration is largely inspired by the 1865 book *The Coal Question* that found that the result of improving the efficiency of coal engines did not lead to an overall reduction in coal consumption, as many assumed it would, but rather a vast increase (Jevons 1865). The book pointed out that those who anticipated that a reduction in the amount of coal needed to produce a ton of iron by over two-thirds in Scotland would lead to a significant reduction in coal demand were mistaken. In reality the lower coal requirement to make iron meant that iron could be made more cheaply, and in a rapidly growing economy that could always use more iron, the overall consumption of coal grew tenfold between the years 1830 and 1863. Applying this logic to modern energy demand reduction programmes and initiatives, many consider these rebound effects to be significant, but they need not be.

Counteracting the rebound effect is based on the observation that, when a more efficient technology, process, or product is introduced into the market, it does not automatically imply that due to the lower consumption of the particular product there will be a reduction in resource consumption overall. This is due to the fact that as the product is more efficient it may be cheaper to purchase and to run, leading to the potential for more people being able to afford to use the product, or to use it more often. In short, as one would expect, a single intervention into a complex system will not necessarily lead to a preferred change in that system. This is why significant economy-wide reductions in greenhouse gas emissions cannot be achieved by a focus on the market-driven uptake of low carbon technologies and process alone, but must be part of an agenda to adjust structures across entire economies.

35.4 Key Aspects and Impacts of Structural Adjustment Programmes

Fundamentally the term 'Structural Adjustment' can be interpreted as the process of making system-wide changes to the very structure of an economy, typically through government policy, to improve its performance. According to the OECD Glossary of Statistical Terms, structural adjustment is a "process of market-oriented economic reform aimed at restoring a sustainable balance of payments, reducing inflation,

Table 35.1: Examples of cost-effective reductions in carbon intensity in various sectors that deliver strong economic multipliers. **Source:** von Weizsäcker, Hargroves, Smith, Desha and Stasinopoulos (2009).

Sector	Best Practice Case Studies
Residential Buildings	Passive house designs have achieved significant reductions in heating requirements in Germany with an eighty per cent improvement over contemporary German standards, and a ninety per cent improvement over the average German building stock (Clinton Climate Initiative 2008). There are now examples of *Passivhaus* design in many OECD countries.
Steel Industry	Leading US steel company, Nucor Steel, is around seventy per cent more energy-efficient than many steel companies around the world (Boyd/Gove 2000), using state-of-the-art electric arc furnace systems, adopting leading practices such as net shape casting, and implementing options such as energy monitoring and systems for energy recovery and distribution between processes (Worrel/Price/Galitsky 2004).
Cement Industry	Ordinary Portland cement manufacture is responsible for between six and eight per cent of global greenhouse emissions and this is rising with demand. The good news is that an Australian company, Zeobond Pty Ltd, based in Melbourne, is now making geo-polymer cement which reduces energy usage and greenhouse gas emissions by over eighty per cent (TNEP 2009). Geo-polymers can be used for most major purposes for which Portland cement is currently used.
Supermarkets	Supermarket chains Tesco (UK) and Whole Foods (USA) are showing that there are numerous ways to significantly reduce electricity usage through, for instance, reducing cooling and heating loads and utilizing more efficient lighting (Faramarzi/Coburn/Sarhadian 2002). They are also experimenting with solar energy and wind micro-turbines (Tesco 2008). Whole Foods Market are set to power an entire store using solar panels and a combined cycle co-generation using fuel cells and heat recovery (Whole Foods Market 2008).
Restaurants	Four profitable restaurants—*Bordeaux Quay*, Bristol UK (The Independent 2006), *Foodorama*, Berlin Germany (Sonnenberg 2009), *The Acorn House*, London UK (Carvalho 2007) and *The Water House* (UK)—demonstrate that restaurants can significantly reduce their energy consumption through building design, energy-efficient lighting and cooking equipment, purchasing their electricity from accredited renewable sources, buying organic fresh local food in season, composting and recycling all waste, and investing in carbon offsets.
Transport—Vehicle Efficiency	Integrating technical advances in light-weighting, hybrid electric engines, batteries, regenerative breaking and aerodynamics is enabling numerous automotive and transport vehicle companies to redesign cars, motorbikes, trucks, trains, ships and aeroplanes to be significantly (fifty to eighty per cent) more fuel-efficient than standard internal combustion vehicles. Plug-in vehicle technologies are opening up the potential for all transportation vehicles to be run on batteries charged by renewable energy (Light Rail Now 2008).
Transport—Efficiency from Modal Shifts. (Passenger)	Shifting transport modes can also lead to significant energy-efficiency gains. One bus with twenty-five passengers can reduce energy and greenhouse gas emissions per capita by over eighty per cent per kilometre compared to twenty-five single-occupant vehicles. Trains are even more efficient. Typically, rail systems in European cities are seven times more energy-efficient than car travel in US cities (Newman/Kenworthy 2007).
Transport Efficiency from Modal Shifts (Freight)	Shifting freight transport from trucks to rail can also lead to large efficiency gains of between seventy-five and eighty-five per cent (Freight on Rai, 2009; Frey/Kuo 2007). Several countries are moving to improve the efficiency of their transport sectors by making large investments in rail freight infrastructure, including improving the modal interfaces. For instance, China has invested US$292 billion to improve and extend its rail network from 78,000 km in 2007, to over 120,000 km by 2020, much of which will be dedicated to freight.

and creating the conditions for sustainable growth in per capita income" (Alexander/Baden 2000). In practice such 'market-oriented economic reform' is typically driven by an intention to improve the economic performance of the economy in a response to a need to reduce debt or position itself to replay development loans. For instance, structural adjustment mechanisms are typically required by financial institutions, such as the IMF or the World Bank, when offering development loans, typically to clear existing debt, or in order to secure lower interest rates on such loans.

In such cases the intention is to enforce structural changes to reduce the risk of the loan by requiring restructuring of economic policy, typically around:

- the level of taxation,
- controls on inflation,
- the provision of subsidies to support selected industries,
- the privatization of government assets and industries,
- levels of government expenditure,
- trade barriers, and
- the de-regulation of markets to encourage greater competition.

The implementation of such adjustments has been heavily criticized for its impact on social and environmental outcomes in the country due to the main focus being on economic performance. Social impacts from this form of restructuring include an increase in the cost of living from a focus on wealth generation, an increase in unemployment from a focus on short-term cost reduction by industry, and a decrease in social welfare expenditure by government (including health care and education). Environmental impacts include increased pressure to rapidly liquidate natural resources for profit (leading to significant environmental degradation) rather than diversification through the development of secondary and tertiary industries. According to Friends of the Earth,

> Exports of natural resources have increased at astonishing rates in many countries under IMF adjustment programs, with no consideration of the environmental sustainability of this approach. Furthermore, the IMF's policies often promote price-sensitive raw resource exports, rather than finished products. Finished products would capture more added value, employ more people in different enterprises, help diversify the economy and disseminate more know-how (Montanye/Welch 1999).

In order to make certain industries more viable, governments often provide subsidies, particularly to the agricultural sector in response to international competition, and to fossil-fuel-based industries in response to high costs for infrastructure development and maintenance. The intended result is that the product or service is made more affordable to the consumer and economic development is accelerated; however, the unintended result is that the product or service is able to be sold with little consideration of the environmental pressure it may create, and the associated real costs to the economy in the short and long terms. Furthermore, a lower cost not only increases the uptake of the product or service (which is after all the point of a subsidy), it may also lead to its inefficient or wasteful use, further compounding the environmental pressure, and the resulting associated costs.

For example, despite the fact that subsidizing chemical companies to produce fertiliser has led to improved agricultural yields, the low cost has often led to excessive and poorly controlled use, which in turn can lead to contaminated groundwater and waterways. Further examples include the overuse and wastage of water, because of the subsidies for the use of water; wastage of electricity, with appliances, equipment and lights being left on when not needed because of the subsidies for electricity and the absence of a 'carbon price' making it so cheap to households and industry. Further, by making fossil-based energy cheaper, subsidies distort the market and make it harder for renewable and low carbon options to compete. The literature shows that a proportion of the costs that result from the increased environmental pressures from subsidized activities, with such subsidies estimated to be as much as US$650 billion per annum globally, are mostly borne directly by governments—and therefore citizens—through health care costs and public taxes (Roodman 1999). The remaining burden is borne by individuals through health-related impacts, and by the environment itself as the increased levels of toxins and pollution lead to the degradation of ecosystems.

When considering interventions into the market by providing subsidies, governments need to understand the broader implications in the short and long term, and where possible assign a price to these implications. Many experts have campaigned for higher prices for electricity, and/or reductions in government subsidies for the industry, as the increased price would encourage efficiency and reduced consumption, and promote exploration for alternatives to fossil-fuel-based electricity, leading to reduced negative impacts. The challenge here is that any economy exists as part of a complex balance, and increasing the cost of electricity without reducing costs elsewhere may result in an undue burden for citizens—which may then affect voter preferences. As Ernst von Weizsäcker points out in *Factor Five*, "Ultimately, resource consumption should be so expensive that total resource consumption rests in a perfect balance with sustainable supplies of renewable (or recycled) resources, and the resulting ability of the biosphere to assimilate the associated pollution and by-products" (von Weizsäcker/A/B et al. 2010). However, this is not yet the case in our current society, where the major reason environmental degradation occurs is because the current balance reached in many economies around the world makes it cheaper to degrade nature than to appropriately manage its use (Daily/Ellison 2002).

35.5 Harnessing Structural Adjustment Mechanisms for Carbon Management

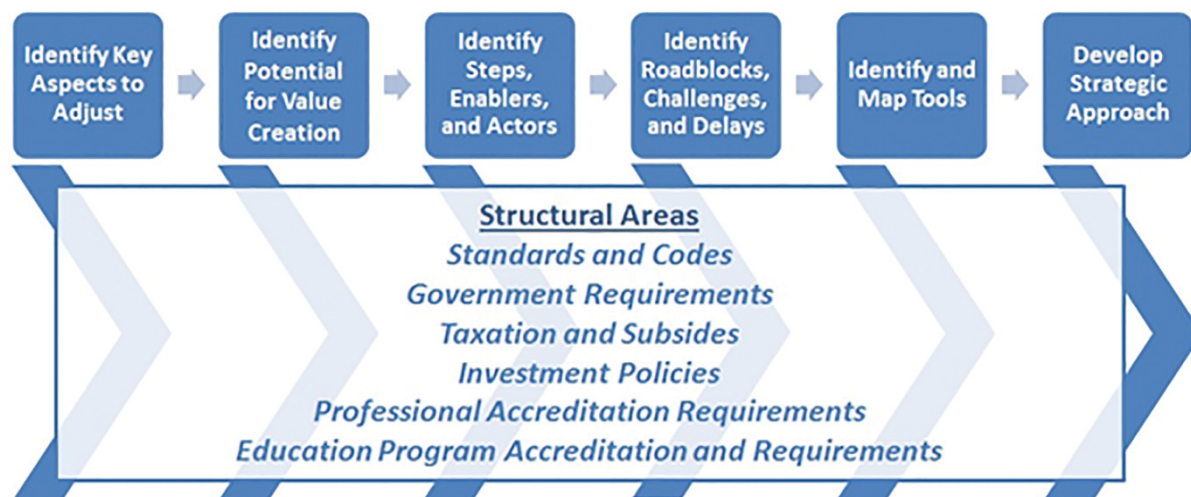
In order for economies to achieve the 'conditions for sustainable growth in per capita income', advocated by the OECD, the scope of structural adjustment needs to be expanded to include mechanisms that lead to a significant reduction in environmental pressures, and in particular the reduction of greenhouse gas emissions (Smith/Hargroves/Desha 2010). As mentioned above, however, unlike SAPs that are enforced as part of the conditions of large national financial loans, structural adjustments to reduce greenhouse gas emissions will need to be enforced by national governments as part of an agenda of economic development. Such a process would need to be underpinned by effective policies and strategies which address a range of market, institutional, and information failures.

Considering the key mechanisms used in structural adjustment programmes—namely a focus on taxation, inflation, subsidies, government assets, government expenditure, trade, and the regulation of markets—a number of such mechanisms along with a range of others can be used to underpin significant greenhouse gas emissions reductions across economies to achieve *Carbon Structural Adjustment*. As part of a CSA agenda typical structural adjustment mechanisms can be used in a number of ways, including:

- *Taxation*: Pollution taxation is now used by many countries to discourage the generation of greenhouse gas emissions by placing a price on their generation. Revenue from such taxation can be used to provide tax cuts to low carbon-intensive operations and products.
- *Inflation*: Encouraging a transition to low carbon intensive operations can reduce the demand for non-renewable raw materials and avoid future stagflation. For instance a focus on reducing the carbon intensity of the steel industry will see a shift to greater recycled steel affecting the price of iron ore.
- *Subsidies*: Shifting subsidies from fossil-fuel-based energy to renewable and low carbon alternatives will encourage innovation and industry development in low/no carbon alternatives to energy generation.
- *Government Expenditure:* A range of government expenditures can be aligned to support options with lower carbon intensity, such as procurement policies, transport infrastructure spending, and upgrading publically owned built environment infrastructure.
- *Trade*: Encouraging the export of low carbon technologies and expertise will encourage manufacturing and production of products that require less carbon-intensive energy to create and operate in the country to which the trade is destined.
- *Regulation*: Following a focus on pollution regulation many countries are now focused on regulations related to the energy consumption requirements of residential homes (UK Code for Sustainable Homes), banning energy-intensive light bulbs (Cuba and Australia) and requiring levels of renewable energy generation (China's Renewable Energy Laws).

Fundamentally, structural adjustment is about avoiding future negative impacts on the economy by taking steps to achieve system-level change focused on reducing inefficiency and improving performance and stability—while making profits for international moneylenders. Hence, given the imperative to reduce greenhouse gas emissions, it is clear that efforts need to be focused at aligning the structure of economies to significantly reduce carbon intensity over the coming decades, with many options being tested and proven in numerous countries. Such a shift in focus would result in a significant recasting of the various structural adjustment mechanisms, this may include and not be limited to:

- Rather than promoting a reduction in government programmes and spending, *carbon structural adjustment* would include governments investing in research and development of low carbon technologies and processes, along with a strong focus on renewing education and professional development programmes.
- Rather than the deregulation of industry sectors to allow greater wealth generation through reduced environmental charges and requirements, CSA would include regulation and policy designed to drive industry to take innovative approaches to reducing greenhouse gas emissions.
- Rather than focus taxation on employees and businesses, CSA would include a focus on resource taxation to price externalities related to environmental damage that will have future direct impact on economic growth. According to Hawken, Lovins and Lovins. (2009), "Shifting taxes towards

Figure 35.3: Schematic of Key Elements of Carbon Structural Adjustment. **Source**: Hargroves (2014).


resources creates powerful incentives to use fewer of them".

- Rather than focusing on exporting raw commodities, CSA would focus on creating opportunities to enhance secondary and tertiary industries with such commodities to allow greater value-adding and increased wealth generation through increased exports of low carbon technologies and expertise.

In order to significantly reduce greenhouse gas emissions a focus on reducing the need for energy will need to be complemented by a rapid transition to non-fossil energy. Fortunately our world has an abundance of non-fossil energy due to our sun creating geological energy in the form of underground heat stores, creating kinetic energy in the form of wind that can be harnessed, and providing direct energy through sunlight that we can now transfer into electricity with as much as twenty per cent conversion efficiency.

35.6   A Proposed Carbon Structural Adjustment Road Map[4]

Considering the potential to re-orient structural adjustment programme-type interventions to achieve significant reductions in greenhouse gas emissions as outlined above, the Sustainable Built Environment National Research Centre based at Curtin University in Australia has created a project to propose a carbon structural adjustment road map led by the author and supervised by Professor Peter Newman.[5] The project focuses on six key structural areas that each have a direct impact on the greenhouse gas emissions of

economies. Changes to these structural areas stand to deliver significant reductions in emissions, while building understanding and institution learning outcomes (Hargroves 2014):

1. Standards and codes
2. Government requirements (local, state, federal, and statutory agencies)
3. Taxation and subsides
4. Investment and procurement policies (government and private)
5. Professional accreditation requirements, and
6. Education programme accreditation requirements (higher and vocational).

Building on the growing level of work being done to encourage a transition to sustainable development this project seeks to contribute to nations around the world when responding to inevitable calls in the coming decade(s) for economy-wide structural approaches.

---

4   The following is an edited extract from Hargroves (2014), developed as part of the Sustainable Built Environment National Research Centre (SBEnrc) 'Greening the Built Environment' Programme, led by Professor Peter Newman. The project is supported by the Western Australia Government Department of Treasury, Queensland Government Department of Transport and Main Roads, Main Roads Western Australia, John Holland Group, and the New South Wales Roads and Maritime Services. The research is advised by ClimateWorks Australia and the Clean Energy Finance Commission. The research team is based at the Curtin University Sustainability Policy Institute (CUSP).

5   SBEnrc, at: <http://www.sbenrc.com.au/research-programs/1-24-a-roadmap-for-carbon-structural-adjustment-in-the-built-environment-sector/>.

Figure 35.4: Whole of Society Approach to Sustainable Development. **Source**: Hargroves and Smith (2005).

According to the findings of the project, 'When such a call is made it will be important to undertake a strategic process to identify specific areas of the economy to adjust, establish the value in doing so, identify barriers and enablers, select tools and interventions, and develop a strategy specific for each economy and its sectors' (Hargroves 2014), as shown in figure 35.3.

According to the report it is important to understand that each stop will involve a range of actors from across society and that in order to maximize the potential for carbon structural adjustment to be successful a 'whole of society' approach is recommended, as presented in figure 35.4. This is particularly important as unlike SAPs, where there is a strong and enforceable imperative to implement the adjustment measures, a carbon structural adjustment agenda will need to be led by government with organizations, businesses, institutions, and various groups across society actively involved and empowered to contribute to the overall process (Hargroves 2014).

The following provides an overview of each of the steps of the proposed 'Carbon Structural Adjustment Road Map' along with anticipated deliverables (Hargroves 2014).

35.6.1 Identify Key Aspects of Structural Areas to Adjust

The first stop on the road map to achieve carbon structural adjustment is to identify specific aspects of

the structural area being considered, such as 'Standards and Codes' that are deemed to 'need' adjustment in order to ensure greenhouse gas emissions reductions across the sector.

This stop would deliver the following outcomes:

1. The identification of specific aspects of the structural area being considered that contribute to increasing the greenhouse gas emissions of the built environment sector.
2. The provision of a clear and concise summary of the aspects, demonstrating the direct link to greenhouse gas emissions in the sector, and highlighting precedent and evidence for cost-effective emissions reductions.
3. The identification of any current or previous efforts to bring about change in this aspect of the structural area, both those that have gained traction and those that have not. This may include the identification of existing recommendations related to the adjustment of the areas or similar areas internationally.

35.6.2 Identify Potential for Value Creation

Once the specific aspects of the structural areas that require adjustment have been identified, the next stop on the road map involves identifying the potential value that can be created by the adjustment of these aspects. This is important as it identifies potential supporters for the adjustment and demonstrates the value

to the economy, sector, and community for taking action to adjust the structural areas to reduce greenhouse gas emissions. Value can be created in a number of direct and indirect areas with the initial focus on both the economic value and the reductions in greenhouse gas emissions. Other areas of value may include job creation, increased trade in services and high value manufactured goods, generation of voter goodwill, along with direct savings to business through reduced energy use.

This stop would deliver the following outcomes:

1. The identification and quantification, where appropriate, of the potential value that would be created through the adjustment of the aspects of the structural area being considered, both direct and indirect.
2. The identification of evidence to support this value creation and precedent of such value being captured. This would include identification of value created for particular parties and stakeholders.

35.6.3   Identify Steps, Enablers, and Actors

Once the specific aspects of the structural areas that require adjustment have been identified, and the value of such adjustments demonstrated, the next stop on the road map involves identifying the main steps required to adjust the aspects. Consideration of the steps includes an investigation into the existence of current enablers to such adjustment that will support the process. Further, as mentioned above it is important to take a whole-of-society approach to the process and at this stage the various actors that should be involved in each step are identified. It may be the case that investigations have been undertaken to identify steps to adjust the selected aspects either in Australia or internationally that can inform the identification of specific steps.

This stop would deliver the following outcomes:

1. The identification of specific steps to be undertaken to achieve the adjustment of the particular aspect of the structural area being considered. (Note: at this stage the steps are identified rather than the actions needed to achieve the steps, which is the focus of stop 5.)
2. The identification of existing enablers to support the adjustment of this aspect of the structural area.
3. The nomination of actors and parties that should be involved in each step, such as business, industry groups, economic think tanks, university research-

ers, government agencies etc. This may involve the consideration of methods to engage and mobilize particular actors that may not be already engaged in the low carbon agenda.

35.6.4   Identify Roadblocks, Challenges, and Delays

Once the steps required to adjust the aspects of the structural area being considered have been identified, the next step in the road map involves the identification of major roadblocks, challenges and areas of potential delay that will be faced should the steps be implemented. Once identified, investigation can be carried out on how to avoid, amend, or remove such barriers.

This stop would deliver the following outcomes:

1. The identification of potential roadblocks, challenges and/or delays to the specific steps to adjust the structural area under consideration, which may include technological, institutional, or market barriers.
2. The identification of possible ways to avoid, amend, or remove the potential roadblocks, challenges or delays, with specific mention of the parties involved.
3. The consideration of the strength of such barriers to carbon structural adjustment and the identification of leverage points to focus tools to reduce such barriers.

35.6.5   Identify and Map Tools

Once the potential for value creation has been established, and the existence of major roadblocks, challenges, and/or delays identified, the next stop in the road map involves identifying and mapping tools that can either manage roadblocks, challenges, and delays, or enhance the value created by the adjustment.

This stop would deliver the following outcomes:

1. The identification of potential tools that may be used to implement the steps. It is anticipated that these tools will be suitable for implementation with involvement across the various actors involved in the process.
2. The mapping of such tools to specific roadblocks, challenges, and/or delays, as well as specific opportunities to enhance value creation.
3. The investigation of perceptions related to the identified tools held by stakeholders in the pro-

Figure 35.5: A method for the prioritization of efforts based on the likely impact on greenhouse gas emissions and the likely willingness to adjust in the area of focus. **Source:** Adapted by K. Hargroves from an adaptation by K. Hargroves and C. Desha of the CBSM Methodology (McKenzie-Mohr/Smith 1999).
cess as to their suitability and requirements for implementation.

35.6.6   Develop Strategic Approaches

Now that the process of following the road map has created a list of specific aspects of the structural area being considered that are recommended for investigation, an estimate of the potential value that can be created, identification of steps involved and the associated barriers, and a list of possible tools to both reduce the barriers and increase the value creation, the final stop in the road map is to develop strategic approaches. Such approaches will draw on enablers and engage with key actors to create work plans to undertake each step and implement the associated tools. This may include consideration of options for cross-sectorial collaborations. Understanding that it is not feasible for all aspects of each structural area to be adjusted at the start of the carbon structural adjust-

ment process, there needs to be a prioritization process.

In order to identify the priority of aspects to focus on it is important to consider two factors,

a.) the likely 'Carbon Impact Factor', and
b.) the likely *'Willingness to Adjust'*.

The carbon impact factor would take into account the impact on the greenhouse gas emissions in the built environment sector should the aspect identified at stop 1 be adjusted as per the steps at stop 3. The willingness to adjust would take into account the roadblocks, challenges, and delays identified at stop 4, along with a range of other considerations including gauging political will, potential business and industry support, and community views.

Based on figure 35.5, the following three routes can be undertaken:

- *Route A:* A focus on progressing actions with high 'Carbon Impact Factor' and high 'Willingness to Adjust'.
- *Route B:* A focus on progressing parts with high 'Willingness to Adjust' and low 'Carbon Impact Factor' by either:

    B1.) 'Leapfrogging', by starting with an aspect with a high 'Willingness to Adjust' and low 'Carbon Impact Factor' to build momentum to then move on to aspects with slightly less willingness and slightly higher carbon impact, and so on..., and/or

    B2.) 'Aggregating', by grouping aspects high willingness to adjust and lower carbon impact factor into a single multi-pronged programme that delivers a combined high carbon impact factor.

- *Route C:* A focus on increasing the low 'Willingness to Adjust' of aspects, including targeting specific barriers, starting with those with high 'Carbon Impact Factor'.

The willingness to adjust of each of the structural areas along Route C can be influenced by various activities, namely:

- *Standards and Codes:* The willingness to adjust standards and codes can be influenced by the development of voluntary programmes that build industry support and create experience to road-test potential changes. This may be influenced by demonstration projects for new technologies or practices.
- *Government Requirements:* The willingness to adjust government regulations can be influenced by community behaviour change programmes that can build voter support for action towards reducing greenhouse gas emissions.
- *Taxation and Subsides:* The willingness to adjust taxation and subsides can be influenced by providing transparency on the payment of subsides and the impacts on the economy. Furthermore, understanding of the various options for adjusting such structures can provide clarity on the feasibility of using them to encouraging activities that reduce greenhouse gas emissions.
- *Investment and Procurement Policies:* The willingness to adjust investment and procurement policies can be influenced by industry associations through the development of voluntary industry-led sustainability rating tools for infrastructure sustainability that can lead to the inclusion in request for tenders of the nomination of a minimum rating to be achieved by the project.

- *Professional Accreditation Requirements:* The willingness to adjust professional accreditation requirements can be influenced by providing the industry or sector with evidence of the value of ratcheting requirements in line with advances in technology or processes. Furthermore, an indication of the interest in such professional attributes by major employers in the sector can influence the emphasis placed on particular areas.
- *Education Programme Accreditation and Requirements:* The willingness to adjust education programmes can be influenced by programmes to recognize and reward leadership in the coverage of low carbon-related topics in programmes, such as the Australian Campuses Towards Sustainability Green Gown Awards.[6]

35.7   Concluding Remarks

Given the wealth of evidence regarding the economic, social, and environmental impacts of not responding swiftly to climate change, it is clear that a holistic and strategic response is called for that will involve economy-wide adjustments to key structures in a manner that involves multiple actors across society. It is also clear that if undertaken in a robust fashion such a focus could not only alleviate pressures on the environment that stand to impact on economies, but also contribute to delivering sustained economic growth, job creation, and poverty eradication. The costs associated with the environmental pressure created by activities that contribute to GDP are rising and forming a greater proportion of GDP. Further, such costs are set to rise with the impacts of climate change affecting all parts of the world's economies in some way. Hence the twenty-first century is looking to be an era of major transition, one that requires a long-term strategic approach.

Given that the world's economies have experienced many decades of growth based on unbridled fossil fuel consumption, there has been little impetus to act to reduce greenhouse gas. This means that much of the policy and industrial strategy used to achieve development in the past will need to be critically reassessed if it is to continue to deliver progress into the future. Efforts to achieve a low carbon transition will need to be balanced with the level of embedded infrastructure in each economy, as it does not make financial sense to prematurely discard large

---

6   ACTS at: <http://www.acts.asn.au/initiatives/ggaa/>.

amounts of existing fossil-fuel-intensive industries and replace them overnight. Nor does it make sense to do nothing until such infrastructure reaches natural recommissioning or replacement time frames. As has been common in each of the previous waves of innovation, all sectors of the economy will be affected to differing degrees by the imperative to reduce greenhouse gas emissions, some requiring minor changes and others requiring significant overhauls, and even closure.

This presents a significant challenge as if the process takes too long we may fail the ecological imperative, and if it is forced too soon we may fail the economic and social imperatives. The challenge to transition the economy to a low greenhouse gas emissions future will need to be met with sophisticated strategies that build on easily expanded emissions reduction opportunities in the short term to provide a platform for advances in the future. The risk of continued complacency and delayed action is that if greenhouse gas emissions are not significantly reduced it is very likely that the complexity of the impacts on our planet's biosphere may well overwhelm society's ability to find solutions.

There is now a greater level of clarity around actions that can be taken to significantly reduce greenhouse gas emissions across the world's economies. What is missing is a serious agenda to accelerate progress in this area that involves actors from across society dedicated to working in a manner that delivers economic growth and social well-being while achieving preferred greenhouse gas stabilization levels. Such economy-wide changes are akin to the *structural adjustment* of developing countries to improve short-term economic performance. As mentioned in this chapter, it may be the case that in the same way that fiscal structural adjustment was formulated as a solution to underdevelopment in third world economies in the twentieth century, a new form of structural adjustment, such as '*carbon structural adjustment*', may need to be formulated as a solution to unsustain-

able development around the world in the twenty-first century. Hence the scope of traditional structural adjustment needs to be expanded to include mechanisms that lead to a significant reduction in environmental pressures, especially the reduction of greenhouse gas emissions.

In order for such an approach to be successful it will need to draw on lessons learned over the last two decades from efforts to progress the sustainable development and climate change response agendas, and merge this knowledge into an economy-wide structural change agenda. This chapter recommends a focus on six key areas for carbon structural adjustment, namely standards and codes, government requirements, taxation and subsides, investment and procurement policies, professional accreditation requirements, and education programme accreditation and requirements. An important consideration in the undertaking of structural adjustment in these areas is the understanding that they involve a range of actors from across society and that in order to maximize the potential for carbon structural adjustment to be successful a 'whole of society' approach is recommended.

Given that as part of a comprehensive carbon structural adjustment agenda each of the structural areas above would be investigated through the six stops above, and that this would create a comprehensive set of possible actions, this calls for a prioritization process. It is recommended that each possible action generated by the process be considered for its likely 'Carbon Impact Factor', and the likely 'Willingness to Adjust'. Although the Carbon Structural Adjustment Road Map process stands to identify a range of direct interventions for each structural area, the leadership and commitment from government for such an approach has yet to be demonstrated. Hence it is of vital importance that efforts are made to develop complementary activities that increase the willingness to adjust across the economy.

36   Drivers and Barriers to Wind Energy Technology Transitions in India, Brazil and South Africa

Britta Rennkamp[1] and Radhika Perrot[2]

Abstract

This chapter examines the drivers and barriers to innovation in the wind energy sectors in Brazil, India and South Africa. We analyse actors and institutions that have played a role in the development and diffusion of wind energy technologies in these countries from a technological innovation systems (TIS) perspective. We introduce innovation capabilities, the enabling environment and policy-independent strategies as the main drivers for the development of the TIS. This analysis will contribute to improving our understanding of drivers of and barriers to innovation relevant to successful transitions towards cleaner technologies and less carbon-intensive economies. We found that some countries are more successful in developing wind energy technologies because of three factors: stronger technological capability, prime movers, and big market size, and this relates to the enabling environment and policy incentives. We found that in India and Brazil, entrepreneurial activities independent of public policy were critical for the development of the local wind energy industry. In South Africa, policy-independent entrepreneurial activity was scarce and operated in an unfavourable environment which hampered the development of a local wind energy industry.

Keywords: Renewable energy, wind energy, technological innovation systems, innovation, enabling environment, India, South Africa, Brazil.

36.1   Introduction

Why are some countries more successful than others in catching up with creating local renewable energy industries? What drives and hinders innovation in and transitions towards clean technologies? These questions have only partially been answered in the research literature. This chapter examines the drivers and barriers to innovation in and development of local wind energy industries in three developing countries: Brazil, India and South Africa. All three countries are latecomers in developing renewable energy industries, with the intention of catching up in the competition for mature technologies.

The research literature on industrial development provides some explanations for the process of catching up, which is never unique. Success and failure depend on global competition and on the economic, political and cultural circumstances as well as the available skills. The literature often attempts to explain the process of catching up in industrial development as a whole. In this chapter, we will focus on one technology. We propose a framework for the analysis of drivers and barriers in wind energy technology development, based on the concept of *technology innovation systems* (TIS) and the main drivers and barriers identified in the research literature. The technology innovation system approach is a well-established framework, which is useful for explaining technological transitions through seven functions. We apply this framework to new evidence in the wind energy sectors in Brazil, South Africa and India.

Wind energy technologies were first developed in Denmark and Germany in the 1970s. The leading companies[3] in both nations enjoyed the benefits of the first movers in this innovation and continue to lead

the global markets. In the early 2000s, the governments of Spain and China helped the industry to catch up through imposing local content requirements, and this supported the creation of now globally operating companies.[4] India and Brazil were the next in line, and attempted to attract global investment to grow local industries. Although these countries had the advantage of a large market, many of the countries' institutional and carbon lock-ins features either prevented or slowed down the diffusion of wind energy technologies. South Africa only started a structured renewable energy programme in 2011, and this did not include the limited manufacturing capability in the country. The programme aimed to attract investment from the struggling industry through local content requirements, which fall short as a stand-alone industrial policy instrument. An analysis of drivers and barriers in all three countries contributes to a better understanding of different approaches to technological catch-up strategies and factors for success and failure.

The main contributions of this chapter are i) the allocation of the technology innovation system (TIS) to new empirical evidence from the wind energy industries in Brazil, India and South Africa and ii) the refining of the technology innovation system framework towards identifying drivers and barriers from the evidence and from additional research literature.

This chapter is structured as follows. In section 36.2 we present the current research literature on drivers and barriers to technological catching up and present the technology innovation system framework based on Bergek, Jacobson and Carlsson (2008) and Perrot (2012). Section 36.3 presents an analysis of technological transition in the wind energy sectors in Brazil, India and South Africa, building on a dataset of 54 interviews, most of which were conducted for a research project on low carbon development in 2012 and 2013.[5] Section 36.4 presents the findings and conclusions.

36.2 Towards a Framework of Analysis of Drivers and Barriers to Successful Technological Development

Success factors for the technological and innovative capability of a country depend on its enabling environment or innovation infrastructure, the business environment for innovation in the industrial clusters, and the strength of the linkages between those two (Furman/Porter/Stern 2002), as well as economic policy and taxes, access to resources, foreign technology, and comparative advantages to competitors (Fu/Pietrobelli/Soete 2011; Lundvall/Borrás 2005; Peteraf 1993). The research literature identified these factors quite clearly. It is less clear on successful strategies for technological catching up.

Technological catching up is a difficult and competitive endeavour, which is even more competitive in at-the-frontier technologies (Cimoli/Dosi/Stiglitz 2009). The race for new technologies reflects the inequalities and income gaps between the industrialized and developing worlds (Amsden 2003). A decision-maker needs to be well informed on the prospects of funding a technology before allocating scarce public funds. Choosing strategic sectors at earlier stages will be more successful if decisions are well informed through consultations with local innovators (Lundvall/Borrás 2005). Catching up in a technology race requires strategic policy intervention. These interventions are ideally grounded on a careful evaluation of the factors that drive innovative capability. The history of industrial development shows that most countries have used localization and trade barriers at some point to protect their industries from international competitors (Cimoli/Dosi/Stiglitz 2009). Successful strategies for catching up vary. There is no unique way to pursue it (Fagerberg/Godinho 2005). The timing, the number and quality of global competitors, other countries trying to catch up in the same technology, the interest and demand from local firms and the public, the local skills base and the stage of technology maturity are important to the success and likelihood of catching up in an existing technology. A government needs to assess carefully if it is worth trying if numerous other countries have already tried to attract investment from a global industry.

Studies on innovation have produced the idea that innovation is systemic, and best supported through measures that understand innovation policy as a wider economic policy which focuses on transforming the institutional and organizational settings in which inno-

vation occurs. As opposed to just 'picking winners' and supporting individual firms, innovation policy creates incentives, platforms and network opportunities for businesses to interact with academic research and society to maximize innovative output (Lundvall/Borrás 2005). This understanding goes beyond the neoclassical idea of policy intervention in the case of market failure. The innovation systems approach has been recognized as a useful tool for the analysis of technological transitions. In particular, the technology systems approach has managed to specify concrete functions which help to capture the structural characteristics, performance and dynamics that lead to technological change (Bergek/Jacobsson/Carlsson et al. 2008).

A technology innovation system is a network of agents who interact within a particular institutional infrastructure with the purpose of generating, diffusing, and utilizing technology, according to the definition by Carlsson and Stankiewicz (1991). The unit of analysis is the technology, as opposed to a nation, region or sector. The technology innovation system emphasizes institutions (government, universities, research institutes and firms) that both drive and constrain the performance of a *national innovation system* (NIS) (Winter 1993). The approach has successfully compared the development and diffusion of wind turbine industries in Germany, the Netherlands and Sweden (Bergek/Jacobsson 2003); analysed renewable energy cases in Sweden and discussed the two key processes that formed the TIS–legitimation and the development of positive externalities (Johnson/Jacobson 2001); and analysed the development of biopower in Sweden (Jacobsson 2008). There is a need for further empirical analysis in developing countries that are in the process of catching up with renewable energies.

36.2.1   Functions as Main Components of a Technology System

Bergek, Jacobsson, Carlsson et al. (2008) suggest seven functions in the technology innovation system that influence the development, diffusion and use of new technology or a transition to a low carbon technology:

1. Legitimation refers to creating social acceptance of a technology and compliance with existing institutions. Legitimacy is a crucial consensus of the beliefs and interests of actors in society, political decision-making, research, and private business, which allows for supportive regulation and resource allocation.

2. Entrepreneurial experimentation refers to activities by firms in experimenting, probing and testing technologies under conditions of high uncertainty regarding the outcomes. Experimentation determines the success or failure of a TIS, which otherwise will stagnate and fail to create innovation, business opportunities and wealth.

3. Resource mobilization refers to the allocation of financial, material or human capital.

4. Influence in the direction of search refers to the evolution of the TIS, which suggests a direction which other firms and organizations follow. Sufficient business opportunities or public regulations are necessary to incentivize firms to do so.

5. Knowledge development and diffusion refers to the actions that lead to the exchange of information and learning between actors or networks of actors.

6. Development of positive externalities results from investments or from favourable economic activities beyond the TIS.

7. Market formation refers to activities that lead to the creation of a demand or the provision of protected space for the new technology.

The research literature has acknowledged the seven functions as a useful measure for the development and diffusion of new technologies (e.g. Musiolik/Markard 2011; Suurs/Hekkert/Kieboom et al. 2010). These functions help to identify drivers and barriers to innovation and technological development (Negro/Alkemade/Hekkert 2012). Most papers use the framework to analyse innovation dynamics in industrialized countries and mature markets. The literature on innovation processes in developing countries identifies innovation capabilities and the enabling environment as key determinants for the innovative performance of a developing nation (Musiolik/Markard 2011). We combine the seven functions from the TIS with the concepts of innovation capability, enabling environment and policy-independent firms' strategies. These three concepts determine the success or failure of innovation in developing countries, as we will see in the literature and the analysis in the following sections. We summarize the framework in table 36.1 and group the functions as drivers and barriers in a framework for the analysis of the evolution of the TIS in wind energy in three developing countries.

36.2.2   Innovation Capabilities

Five factors often hinder the diffusion of technologies in developing countries: i) capability failures; ii) short-

Table 36.1: Overview of the framework for analysis of Wind Energy Technology Drivers and Barriers. **Source**: The authors based on Bergek, Jacobsson, Carlsson et al. (2008).

Drivers	TIS Functions	Barriers	Description
Innovation Capability	• Knowledge • Development and Diffusion • Entrepreneurial Activities • Resource mobilization • Influence in the direction of search	• Weak or fragmented innovation capability • Local search processes	Capabilities are weakened or fragmented when there are weak local linkages between institutions and industry. Capabilities drive these four functions of the TIS. Capability depends on pre-existing manufacturing and industrial capacity with skills, design and innovation proximity to the technology and industry under consideration
Enabling Environment	• Market Formation • Influence in the direction of search • Knowledge Development and Diffusion • Resource mobilization • Legitimation	• Unclear, conflicting policies • Poorly articulated demand • Market control by incumbents creating institutional and technological lock-ins • Technology characterized by increasing returns	An enabling environment unlocks institutional lock-ins and drives the five functions of the TIS.
Policy-independent Prime Mover Strategies	• Legitimation • Positive • Externalities • Entrepreneurial Experimentation	• Strategies of firms are stymied due to a non-conducive policy environment • Market control by incumbents creating institutional lock-ins	Policy-independent Prime Mover Strategies are those strategies or initial activities of a firm or firms that prompt entrepreneurial activities and spur the development of an industry. Such strategies induces these three functions of a TIS

falls in the technical skills needed to adopt a new technique; iii) organizational inadequacies which prevent the exploitation of a new technique; iv) deficiencies in business skills; and v) information asymmetry which prevents firms from taking rational decisions (Arnold/Guy 1991). Innovation capability[6] distinguishes between the capability i) to create new configurations of product and process technology, and ii) to absorb and implement changes and improvements to technologies, which are already in use. In the case of low carbon innovation in developing countries, the absorptive capability matters most. Absorbing solar and wind energy technology imports into the national energy mix, requires a strong base of local innovation capability.

Absorptive innovation capabilities emerge from existing industrial structures and the knowledge base generated in a country. These capabilities are often deeply entrenched in old industry and knowledge structures, behaviours and institutions. For example, finance and banking, and skills and human capital development, all critical for knowledge diffusion, entrepreneurial experimentation and resource mobilization, are centred on old processes and technologies and often in large state owned companies. Market control by large companies and monopoly constellations impede a 'free' choice for customers and bring the search processes of firms to a halt (Johnson/Jacobsson 2001). Power shortages, which cause strong regulatory changes, are often the only way to diversify from the existing energy mix and institutional bases towards innovative energy technologies such as wind.[7]

---

6   Bell and Pavitt (1995) distinguish between production-based and innovation capabilities under technological capability as the capability to carry on producing goods and services with given product technology, and to use and operate given forms of process technology in existing organizational configurations.

36.2.3   Policy-independent Firms Strategies

The literature shows several examples of successful innovation in wind energy technologies through firms that have acted independently of public policy incentives. Early grass-roots innovators of wind turbines and solar collectors in Denmark and Austria evidence entrepreneurial activities that started independently of public policies. Although subsidies for renewable energy from the Danish government created a large home market later on, an important condition for a successful industry was its early environment of learning-by-doing and technological development among the innovators and network of actors within the industry (Brandt/Svendsen 2004).

Such firms and organizations influence the direction of search substantially, because they identify new opportunities. So-called 'infrastructural' organizations have often played an important role in shaping major new technologies and in identifying new opportunities (Bergek/Jacobsson/Carlsson et al. 2008).

In other non-renewable energy cases, firms independently initiated the development of an entire industry (Carlsson 2007):[8] examples are the US-based Texas Instruments' move to Bangalore, India; Olds Motor Works in Detroit, US; and Shockley Semiconductor's move to Silicon Valley from Bell Labs, New Jersey, US. The environment that existed in these cities or regions at that time was not unique, for similar conditions existed elsewhere in the respective countries. Success or failure also depended on the creativity and persistence of the entrepreneur—with a good element of luck (Carlsson 2007).

Public policy can support and sometimes even initiate the development of an industry in its early phase—although spontaneous development and serendipity seem to be more prevalent mechanisms (Carlsson 2007). Carlsson (2007) shows that the frequent role of public policy was to provide support and reinforcement at the late phases of industry formation—once the technology and/or product has been legitimized and positive externalities have been created. The initial activities of one firm or a few firms might prompt entrepreneurial activities among other firms within the same location that share the same advantages and policy environment, which leads us to the next point.

36.2.4   The Enabling Environment

When a technological trajectory is very 'powerful', it will be difficult to switch from one trajectory to an alternative one (Dosi 1982). We find these so-called path dependencies created through specific technological trajectories, especially in energy systems based on fossil fuels, but they also emerge around other technologies, such as hydropower in Brazil. The beneficiaries of the established energy system in developing countries follow their interests in maintaining the status quo and slow the diffusion of renewable energy technologies through their influence on institutions and policies.

Energy based on fossil fuels still forms a techno-institutional complex which is locked-in by mutually reinforcing technological and institutional factors. The techno-institutional complexes evolved historically into 'systems of accumulation', which benefit the incumbent holding most of the capital and for whom it is not in their vested interest to change existing structures. Lagging efforts to transition to renewable energy systems is partly attributed to the path-dependent nature of these countries' institutions, industry, and organizational incumbents. Structural barriers to alternative energy development are the close ties between fossil fuel industries and state-owned or private utilities, which monopolize national energy generation and distribution, as Fine and Rustomjee (1996) explain in the case of South Africa. Energy production and distribution structures are based on fossil fuels that are deeply entrenched and locked-in within fossil-fuels-based technological and industrial paradigms. Moreover, fossil fuels are heavily subsided and this makes them very competitive in comparison to fledgling and unsubsidized renewable energy technologies.

For this reason, a so-called enabling environment matters for renewable energy to take off in energy systems which are locked in to large fossil fuel or hydro powered energy systems. Often energy security and power outages, rather than environmental concerns, are the motivation for support programmes for alternative and renewable energy sources.

The role of public policy in creating an enabling environment has been widely acknowledged in the research literature. The innovation systems literature emphasizes the role of agencies and public support institutions in the interplay with researchers and engineers based in innovating firms and universities (Lun-

---

7   The cases of Brazil and South Africa show that regulatory changes were only applied after severe power shortages in 2001 and 2007 (Rennkamp/Fortes Westin 2013).

8   See Carlsson (2007), which examines the role of individual actors as well as public policy in ten industry clusters around the world.

dvall 1992; Lundvall/Borrás 2005; Nelson 1993). The technology innovation systems (TIS) approach also recognizes the importance of actors, institutions and key policy issues in their influential roles within the seven functions. The role of public policy is especially relevant for the five functions of legitimation, knowledge creation, resource mobilization, market formation, and influencing the direction of search.

The first TIS function, legitimation, refers to the legitimacy of policy processes and determines political outcomes. Legitimacy is a social construct of shared beliefs, logic and interests, which establishes success and failure in policy-making (Wallner 2008). Beliefs in a political order sustain legitimacy and make policy more likely to succeed. Legitimation refers to the process of legitimizing the institutional order (Luckmann/Berger 1991). In unequal developing countries, it is more difficult for policymakers to achieve legitimacy, because beliefs and interests diverge more widely among social groups. These difficulties unfold especially in the field of science, technology and innovation policy, because the interventions are mostly designed on the basis of industrialized countries' experiences and benefit the privileged rather than the poor (Rennkamp, 2011).

This problem translates into the second and third functions of knowledge creation and resource mobilization, because ministries of science and technology battle with small budgets and low R&D expenditure rates of less than one per cent of GDP. In unequal societies where poverty prevails, priorities focus on policy measures with more immediate and visible results that matter to low-income voters. It becomes more difficult to make the case for longer-term investment in industrial development and innovation that provides support to established companies and research institutions where the outcome is uncertain, because other social grants payments, investments in general infrastructure and safety seem more urgent.

The limited resources allocated for innovation often benefit companies in the established technological trajectories rather than benefitting new markets. This problem relates to the fourth function, market creation, which is directly related to the enabling environment. In many developing countries in Asia, Africa and Latin America, governments strictly control their energy markets. Historically, energy and electricity generation counted as a state function with parastatal electricity companies at its core. These governance structures favour the use of the historically predominant large-scale energy technologies, such as coal, nuclear and large hydro. These technologies demand central-

ized energy systems which involve firm governmental regulation. The interplay between actors in the government and the electricity and mining sectors can lead to fixed political economic structures that exclude any alternative trajectory. Once governments decide to promote alternative and renewable energies, there are several choices. Feed-in tariffs fix the price and vary in quantity, whereas quotas and auction systems fix the quantity allocated in the market and allow the price to vary. Both approaches have advantages and disadvantages. International experience has shown that feed-in tariffs can be beneficial in creating a demand that leads to industrial development in first-mover countries such as Germany. Auction and quota systems, in turn, bring market prices down significantly below the levels of the feed-in tariffs. The size of the allocated market then determines whether local content requirements added into the programmes can have positive impacts on industrial development (Lewis/Wiser 2007).

The choice of the incentive system has an immediate impact on the fifth function, the direction of search. The incentive system determines the behaviour of firms and other organizations in developing and diffusing new technologies. The market size and local content levels, for example, shape the competition, visions and expectations in the sector.

36.3   Analysis: Wind Energy Technology Innovation in South Africa, Brazil and India

India, Brazil and South Africa count as emerging markets in the wind energy sector. These markets differ in maturity and size. This comparative analysis of the wind energy sectors reveals similarities and differences in the transitions towards cleaner energy technologies. We apply the technology systems framework introduced in the previous section. We structure the analysis according to the three main factors that influence the ability to catch up: innovation capability, policy-independent firm strategies, and the enabling environment. We find that in all three countries innovation capability was built up over time through a combination of individual firm strategies and government incentives.

36.3.1   Policy-Independent Prime Mover Strategies

In all three countries, we find prime mover companies who have sought to deploy wind energy technologies independently of any public policy incentive. These three strategies differ from each other and have led to very different outcomes.

36.3.1.1   India

Suzlon Energy Limited is an Indian wind power company and the fifth largest wind turbine manufacturer by cumulative installed capacity, with 22,000 megawatts of installations globally. Suzlon was founded by Tulsi Tanti in a move to secure his textile company's energy needs. India's erratic grid power supply and the rising cost of electricity were offsetting any profits the textile company was making. The company was situated in the coastal region of Gujarat and the energy generated using the wind turbines technology made economic sense. It was a few years earlier that the *Danish International Development Agency* (DANIDA), at the request of the *Ministry of New and Renewable Energy* (MNRE), had begun two demonstration projects in the state of Gujarat and was creating interest among the private sector.

Tanti realized that other companies such as his could benefit similarly and so started advising on the use of the technology and introduced a business model that helped its diffusion. Suzlon sought complete ownership of the design and technology of wind turbines while its clients were responsible for twenty-five per cent of the upfront capital investment. Suzlon arranged the remaining seventy-five per cent on loan, which banks were initially very reluctant to fund.[9] In Jolly and Raven (2013), this is an example of "the activities of actors who have interest in particular institutional arrangements and who leverage resources to create new institutions or to transform existing ones" (Maquire/Hardy/Lawrence 2004: 657).

DANIDA was the first foreign development agency to show interest in the potential Indian wind power market back in 1986. DANIDA helped two state agencies[10]—*Tamil Nadu Electricity Board* (TNEB) and the *Gujarat Energy Development Agency* (GEDA)—to

develop demonstration wind farms, and experience was gained in wind farm planning, implementation and management. Three Danish firms worked closely with local partners to develop indigenous technical capacity and skills while Danish contractors manufactured and delivered the turbines and most of the towers (Jolly/Raven 2013).

These demonstration projects in India were very successful, for they legitimized the technology by widening participation and creating interest among the private sector regarding the potential of wind energy. They also influenced the direction of search by establishing technical and economic viability. The programme also instigated new entrepreneurial and industrial activities, including cooperation between Indian and foreign firms (Jolly/Raven 2013). Because of these programmes, Danish–Indian joint ventures between NEPC India Ltd. and Micon and between Vestas and RRB Energy Ltd. were established in 1987.

36.3.1.2   Brazil

As in the cases of Indian and South Africa, there was no direct innovation capability in the Brazilian wind energy sector until the early 1990s. The first wind turbine in Brazil started to rotate its blades in 1992, as test equipment on Fernando de Noronha, a small island 500 km off the shores of Pernambuco in northeastern Brazil. The islands' energy supply depends on shipped petrol. Wind was supposed to diversify this dependence, but visual concerns about polluting the island's landscape made a larger use of wind energy unfeasible.

Two companies entered the wind energy sector in Brazil in the mid-1990s independently of any government programme.

The *original equipment manufacturer* (OEM) Wobben, a subsidiary of the German company Enercon, was the first company to build turbine factories in Brazil. Wobben was founded in 1996. Eighteen years later, the company has three factories in the country, with the main production site in São Paulo and two smaller sites in the north-east.

Enercon's CEO recognized Brazil's market potential for wind energy early and founded the Brazilian subsidiary six years prior to any renewable energy incentives programmes.[11] The rationale for Enercon to invest in local production rather than choosing an import strategy was to build up local capability for the Latin American market and use the advantages of the

---

9   By 2008, about forty to fifty Indian banks were financing wind power projects for Suzlon clients (Nirmalya 2009).

10 The states of Tamil Nadu and Gujarat have long costal shores along the Arabian Sea and the Indian Ocean respectively.

11 Interview CEO Wobben Brasil.

prime mover. In the 1990s, investing in Brazil seemed safer than investing in the Asian markets, where cases of industrial spying and reverse engineering were more frequently reported.[12] Registered as a Brazilian company, Wobben can set up its contracts and project finance in local currency and reduce the exchange risk. The company employs exclusively local staff totalling 1,200 employees. German staff is usually only present temporarily for specific training purposes.[13]

The Brazilian wind blade manufacturer Tecsis was founded in 1995 as a spin-off from the aviation industry. The company received its first contract from Wobben/Enercon for blade manufacturing. Wobben was manufacturing blades in-house at the time and wanted to outsource this production line. Tecsis had the necessary know-how from the aviation industry and started to produce 19 m blades. Tecsis managed to establish itself slowly in the market through this opportunity.[14] Today, the company is the leading blade manufacturer in Latin America and continues to supply Wobben for its export market.

Wobben and Tecsis' entrepreneurial experimentation activities contributed significantly to at least three other functions in establishing the wind technology innovation system. Firstly, the investment increased legitimation of wind energy technologies in the countries. The company managed to set up a number of parks before the government's support programme for renewable energies started. This helped to show that wind energy is a functional alternative technology, although the prices at the time were still comparatively high because of the lack of scale. Secondly, resource mobilization into local production and staff helped build innovation capabilities in the firm and in the country. Thirdly, knowledge diffused through subcontracting and the drawing of innovation capabilities from third-tier sectors, such as the aviation sector.

36.3.1.3   South Africa

South Africa is a latecomer to wind energy compared to Brazil and India. Like the other two countries, it took a long time to decide on an incentive programme. In the meantime, some companies developed independent demonstration projects. The Klipheuwel wind farm came on grid in 2003 with 3.2 MW and the Darling wind farm in 2008 with 5.2 MW. The equipment

for these parks was mostly imported, apart from a few towers which were built on site.

One company, IWEC, tried to manufacture wind turbines locally in anticipation of a larger wind energy market from 2006. IWEC entered into a licence agreement for technology and knowledge transfer with the German manufacturer Aerodyn. In 2012, IWEC produced its first full turbines with sixty per cent locally manufactured components. The main challenges for reaching scale in production were restricted finance opportunities for locally manufactured technologies, and restrictive regulation which made it difficult to acquire power purchase agreements. After the main investor pulled out of the business, the market closed up for IWEC and the company went into liquidation in 2013. The *Renewable Energy Independent Power Producer Procurement* (REIPPP) Programme, which opened the market to independent power producers for the first time, initially targeted renewable energy plants that produce more than 5 MW. It also required at least two years of experience and proof of successfully established plants, a condition which was difficult for local newcomers to meet and which advantaged foreign multinational companies.

36.3.1.4   Summary

The Indian joint venture strategy combined a local firm strategy through joint ventures with more mature wind energy companies. This strategy combined existing innovation capability with technology transfer from the more mature companies. The South African case showed a similar case of a South African company, although run by foreigners, partnering with a German company, but only through a licence agreement. The absence of incentives for new independent producers at the time disadvantaged local prime movers in entering the local market. The Brazilian case demonstrated that capability emerged mostly from the strategy of one multinational company which sought to strategically build up domestic capability to position itself for a future market. All three countries demonstrated entrepreneurial experimentation. The success and failure of these efforts depended to some extent on the enabling environment, and this will be explained in more detail in the following section.

36.3.2   Enabling Environment

The regulatory frameworks for renewable energy differ significantly between India on the one hand and Brazil and South Africa on the other. The Indian government engaged in a wider industrial policy reform

---

13 Interview Enercon representative.

14 Interview CEO Tecsis Brasil, see at: <https://www.youtube.com/watch?v=_1s07ELbJgk>.

whereas the Brazilian and South African administrations only applied local content requirements as their main industrial policy instruments.

36.3.2.1 India

Foreign companies could legally increase their equity shares to above forty per cent after the industrial policy reforms of the early 1990s. Equity rose to forty-nine per cent in most sectors and a hundred per cent in some. This move encouraged private sector participation in many sectors and several Indian companies faced increasing technological and competitive pressures. As a counter-reaction, Indian companies began importing more efficient technologies and increased in-house R&D expenditure (Lall 1987). At the same time, the government of India started to focus its wind energy policy on stronger private sector involvement. This involved extending public finance to private sector wind power projects and providing fiscal and financial incentives to encourage private investment.

The industrial reforms of the 1990s removed many of the restrictions. At the time of the emergence of a wind energy industry in the 1970s, Indian companies lagged behind the technological frontier and innovation capabilities of its international counterparts. Importing older technologies was common practice at the time. Little effort was made in adapting and improving these technologies for domestic use (Kristinsson/Rao 2008). Most Indian firms were observed to make minimal R&D investment in technologies as they already had access to a highly protected and uncontested home market (Lall 1987).

Actual development and growth of the wind energy sector in India began in the 1990s under the Ministry of New and Renewable Energy (MNRE), and by the late 2000s wind power had significantly increased, making India the country with the fifth largest installed wind power capacity in the world. The development and implementation of wind energy technology in India co-evolved with major institutional interventions such as financial support schemes, technology policies, technical standards, grid connection rules, industry organizations and international collaborations (Jolly/Raven 2010). Each state has its own power regulatory, transmission and generation authority, and a range of state-level wind energy programmes and economic incentives associated with the state's renewable energy resource.

Entrepreneurial activities with the Danes further spurred on domestic manufacturing through a series of licensing agreements with other foreign companies such as the German Enercon, Nordex and DeWind.

Many Indian companies diversified to reap the benefits of the economic and technological opportunities which the reforms presented. For example, Shriram had diversified from the financial sector into an energy engineering company by 2001. The company entered into a technological joint venture with an Italian company in 2007 to jointly manufacture and install large-scale wind energy generators. This process of licensing the production of foreign-developed wind turbines resulted in the introduction of somewhat old and small models but it nonetheless allowed for the use of local labour assets and the local production of wind turbines at a lower cost (Neij/Dannemand Anderson 2012).

Suzlon bought two European companies that helped expand its technological capability in gearbox manufacturing. Knowledge development and diffusion processes in India are being enhanced and supported through the development of such international knowledge links and networks. The innovation path in India is characterized by massive support for domestic market formation and an enhanced knowledge development and diffusion process made possible through knowledge spillover from foreign manufacturers (Neij/Dannemand Anderson 2012).

A series of incentives and policies formulated in India influenced the direction of search and market formation. These policy and fiscal incentives successfully assisted the development of the wind energy industry in India (Kristinsson/Rao 2007). Tax exemptions of 100 per cent for some wind turbine components, and an accelerated tax depreciation of 80 per cent, along with feed-in tariff rates for large scale wind technologies, were implemented (GWEC 2011). Since 2011, the Indian government has allowed 100 per cent *foreign direct investment* (FDI) in renewable energy generation projects.

A notable barrier to wind energy in India is the presence of a single utility that monopolizes the entire energy market, including national electricity transmission. This structure hinders the diffusion of renewable energy in many developing countries. The utilities often pursue their interest in fossil fuel technologies, and hinder the development of a successful wind energy industry (Kristinsson/Rao 2008). In India, there is resistance among the state-run utilities[15] to granting 'third party sale'[16] facility to wind power producers (Kristinsson/Rao 2008). Further, there is lack of an appropriate regulatory framework to facilitate

---

15 Each state in India has its own independent power generation and distribution facilities owned and managed by state-run utilities.

the purchase of renewable energy from outside the host states; inadequate grid connectivity; high wheeling costs[17]; and bureaucratic delays in acquiring land and obtaining statutory clearances (GWEC 2011).

36.3.2.2 Brazil

Both in Brazil and South Africa, incentives for renewable energies were direct consequences of shortages in the electric power supply. In Brazil, the shortages resulted from the lack of rain for the hydropower plants, but the blackouts also demonstrated the lack of planning and lack of investment in the electricity supply sector. Hydropower is the main source of electricity production in Brazil.

In 2002, the government announced the *Incentive Programme for Renewable and Alternative Energy* (PROINFA), which supported other renewable energy sources, including wind, in form of a feed-in programme. The programme offered a price of R$ 300 (US$ 128) per MWh of wind energy to power producers under a power purchase agreement for twenty years through the utility Eletrobrás. The aim was to add 3,300 MW generation capacity, of which forty-three per cent was supposed to come from wind. The national development bank (BNDES) offered inexpensive loans for financing up to eighty per cent of the project value. Despite these high-level incentives, the implementation of the programme progressed very slowly.

By 2006, only six of the seventy-five planned parks had been built. The reasons for the delay were the sluggish bureaucracy, which issued environmental permits very slowly, and the local content requirements of sixty per cent. PROINFA intended to attract foreign OEMs to produce in Brazil, but it was difficult for new companies to fulfil these requirements from scratch.[18] Wobben and Tecsis benefitted from the local content requirements and supplied most of the technology to the developers. In 2012, Wobben provided 1 GW of the 2 GW installed wind capacity, most of which still came from contracts under PROINFA. However, the capacity to produce locally was mostly limited to these two companies. The slow implemen-

tation of PROINFA eventually led to a change in the incentive system.

In 2009, the Brazilian government decided to procure additional wind energy capacity through a competitive auction system implemented through the regulator ANEEL, the *Energy Research Enterprise* (EPE), and BNDES. Local content requirements of sixty per cent remained the main industrial policy component, but now these requirements were optional for those companies who wanted to take advantage of the loans of 0.9 per cent from BNDES. Companies with their own financial schemes were free to import, but only a Chinese manufacturer tried this in Aracajú, and failed.

The auction system produced wind energy capacity at a very quick pace. The competitive bidding process brought prices down to a third of the original feed-in tariff under PROINFA. The auction system worked on the opposite principle from the feed-in tariff. It did not set a fixed price but a fixed quantity, which bidders competed for at a flexible price. In 2014, the incentive system produced 3.6 GW installed capacity in 148 wind parks.[19]

The incentive systems both under PROINFA and the auctions increased legitimation for wind technologies and the development of the sector in the country. The auction system attracted twelve international OEMs to do business in the country. After three years, five OEMs managed to set up local manufacturing facilities to fulfil the local content requirements, while others left the market.

Significant resources to support wind energy sector development within the incentive programme came through the loans at 0.9 per cent from BNDES. These resources were compensated to some extent through determining the market size rather than guaranteeing a fixed price, because the costs came down. Market size matters for the successful implementation of local content requirements, because markets that are too small deter investors. The Brazilian government solved this problem by announcing 11 GW of total capacity by 2020 according to the EPE.

36.3.2.3 South Africa

The South African electricity supply system is locked in to coal just as the Brazilian system is locked in to hydropower as the main source. In 2008, the country experienced major blackouts, which raised serious questions about planning and investment in future

---

16 Third-party sale amounts to allowing wind power producers to use the grid infrastructure to sell power to any industrial client at any mutually agreed rate.

17 Wheeling refers to the transfer of electrical power through transmission and distribution lines from one utility's service area to another's.

19 Brazilian Wind Energy Association Abeeólica; see at: < http://www.portalabeeolica.org.br>.

capacity. The *National Energy Regulator* (NERSA) started a process for a feed-in tariff for renewable energies in 2009. Eventually, the Department of Energy and the National Treasury decided in favour of a competitive bidding programme for a determined market size, rather than paying out feed-in tariffs. The reasoning for this decision was that a feed-in did not comply with the country's procurement rules.

In 2011, the REIPPP Programme started to procure 3.7 GW of renewable energy including wind through three bidding rounds, which concluded in November 2013. In these three rounds, 562 MW, 634 MW and 787 MW respectively were allocated to wind power, which leaves almost 2 GW to be built by 2016. The prices dropped by twenty-two per cent from the first bidding round to the second—from R1140 (US\$ 114.27) to R890 (US\$ 89) per MWh—and again in the third round to R310 per MWh (US\$ 31), which is lower than current new-build coal prices.[20]

As with the Brazilian programme, the REIPPP Programme requires the bidders to fulfil socio-economic development criteria, including local content. The bidding criteria are composed of seventy per cent price determination and thirty per cent local content and social development criteria. The local content requirements are slightly different from the Brazilian ones in that the bidders can provide a range and not a fixed percentage. The targets increased in each bidding round from twenty-five per cent to forty-five per cent and then to sixty-five per cent. Translated into actual technologies, this means that the local content in the first round can be covered through the balance of plant, that is, the infrastructural components. The second round requires locally made towers. In the third round, nacelle boxes and blades would have to be made locally, and this requires a local manufacturer (Rennkamp/Fortes Westin 2013). The local content requirements were met to averages of twenty-one per cent and thirty-nine per cent in the first two rounds. Meeting the local content requirements for the third round will require blade manufacturing. Two local companies and the Danish LM blade manufacturer are currently assessing the possibilities of local manufacturing in South Africa.

Like the Brazilian programme, the South African REIPPP Programme targets knowledge transfer and diffusion through investment from international OEMs in the local market. Both countries have highly regulated electricity markets in which the government can determine the market space for each technology. The allocated market size for wind, however, is much smaller than in Brazil and does not necessarily translate into profitable investment opportunities.[21] In terms of resource allocation, the South African programme offers just the market opportunity and the power purchase agreement. The programme does not provide for any loans or tax reductions. The developers need to acquire finance from the commercial banks, or the development bank IDC whose rates are similar to the offers of the commercial bank. The National Treasury claims one per cent of the investment to cover the administration costs. These have now become a surplus and the Treasury is looking into ways of spending these resources. The programme does not rely on support from tax revenue and is currently producing additional revenue. The impact on legitimation of renewable energy was very high, as the market could not take off for a long time without changes in the regulatory framework.

36.3.2.4 Summary

The successful industrial policy reform in India spilled over into the wind energy sector and allowed Indian companies to enter joint ventures and acquire foreign firms, and this increased the R&D activities. State utilities remain obstacles to the market size by objecting to power purchase agreements. In Brazil and South Africa, in turn, industrial policy was rather designed as trade policy, through the narrow local content requirements. In Brazil, these requirements were more fruitfully implemented, because the allocated market size was more significant, and the foreign OEMs could enjoy the incentive of inexpensive loans and existing innovation capability in Wobben and Tecsis. In South Africa, however, local content requirements were not connected to any fiscal incentive or loan scheme. Local firms especially struggled to enter the market because the incentive system narrowed down access and the relatively small market size made the bidding process highly favourable to experienced international OEMs.

36.3.3 Innovation Capabilities

This section analyses the innovation capabilities touched on in the previous sections from a historical perspective. Innovation capabilities were built through

21 Interview LM representative.

the sum of independent prime mover strategies and the effects of the enabling environment.

36.3.3.1 India

It was in the early 1900s that Poul Le Cour of Denmark started experimenting with wind turbines and blade designs. At that time, knowledge about aerodynamic flows around blades was underdeveloped and a new aerodynamical theory emerged, largely due to the efforts of three Danish scientists (Kristinsson/Rao 2007). Developing and exchanging the theoretical and applied knowledge of aerodynamic flows became critical to the success of the Danish wind energy industry.

The *Council of Scientific and Industrial Research* (CSIR) established the *National Aerospace Laboratories* (NAL) of India in 1959. Its mandate is to develop civilian aerospace technologies with strong science and design capabilities while its multidisciplinary focus allowed it to initiate one of the first projects on wind energy in India back in the 1960s, when NAL developed the first models of wind turbines for rural applications, used for water pumping and battery charging.

In 1983, India decided to develop a *Light Combat Aircraft* (LCA) for which NAL began to work closely with two other institutions, the *Indian Space Research Organisation* (ISRO)[22] and the *Defence Research and Development Organisation* (DRDO).[23] Collaborations with and research projects with these institutions quickly pushed up NAL's capabilities several notches and by 1990, NAL had become a world-class aerospace laboratory. Its technological capabilities covered advanced computational and experimental fluid dynamics, including the use of smart materials, all capabilities required in the development of wind energy technologies. Around 2006, NAL became involved in the development of a 500 kW low-cost, indigenous, horizontal axis *Wind Energy Generator* (WEG) that claimed to be cheaper and better suited to Indian conditions than the European ones being sold in India at that time. This was a joint venture between the *Structural Engineering Research Centre* (SERC), Sangeet Group of Companies and the *Centre for Wind Energy Technology* (C-WET).

Research and knowledge linkages between the industry and NAL were weak. Public resources for technological development were mobilized in a frag-

mented and silo-like manner. Although innovation capabilities and skills in aero- and fluid dynamics existed in organizations such as NAL, there is no evidence of these capabilities directly spilling over into entrepreneurial activities within the industry.

This fragmentation in resource mobilization and the fracture in knowledge links between the industry and public research organizations came about as a result of the restrictive nature of import-led substitution industrial development policies and the Licence Raj system[24] that was in place for four decades from the 1950s. Though this encouraged industrial and innovation development capabilities in large-scale industries such as petrochemicals, steel and automobile manufacturing, the licence system significantly restricted the wider participation of entrepreneurial firms and activities in high-level and medium-level technology-based areas. It is also for this reason that many of the innovative capabilities built within *public research organizations* (PROs) were unable to translate into applications for the industry. The importance of the criticality of the link between PROs and the industry went under the radar for a long time in India.

One of the essential components of the successful development of the Danish wind energy industry since the 1970s has been the testing and certification[25] of its turbine and blade technologies (Douthwaite 2002). Testing and quality certification programmes and initiatives influence the direction of search by affecting the perceptibility of the requirements of actors and may influence further investments in the technology by improving the reliability of the technology in the market.

From quite early on, there were strong influences on the direction of search in India, and this helped build a wind energy industry through new investments and entrepreneurial activities that improved the perception and reliability of the technology. In 1994, two training institutions were established under a Danish cooperation programme to train regulatory authorities, municipalities and companies about the importance of and need for quality assessment and certification of wind turbines (Kristinsson/Rao 2008). In 1998, the Indian Ministry of New and Renewable Energy

---

22 By then India had launched its first successful space vehicle and its space programme had begun to mature.

23 Soon afterwards, DRDO started its own missile development programme.

24 Licences were given to a select few and up to eighty government agencies had to be satisfied before private companies could produce something and, if granted, the government would regulate production.

25 In Denmark, this process was led and institutionalized by Risø Laboratories.

(MNRE)[26] set up the Centre for Wind Energy Technology (C-WET), an R&D institution with similar testing and certification facilities to Risø. Both India and China have developed technology certification programmes to ensure high-quality domestic wind turbines (Kristinsson/Rao 2008; Neij/Dannemand Anderson 2012). Countries such as the US that did not have testing and certification processes for emerging wind turbine models experienced severe market trust problems (Neij/Dannemand Anderson 2012).

In 1995, MNRE (previously MNES) issued guidelines that obliged private wind farm developers to produce *Detailed Project Reports* (DPRs) that contained detailed information on micro-siting,[27] the selection of wind turbine equipment, operation and maintenance data and performance evaluation (Jolly/ Raven 2010). Although this was to ensure that incentives provided by the central and state governments were not misused, it contributed to influencing the direction of search and strengthening knowledge links between various actors. State electricity boards, state nodal agencies, manufacturers, developers, and investors became aware of the need for joint and planned development and implementation of wind power projects (Jolly/Raven 2010).

36.3.3.2 Brazil

In Brazil, innovation capabilities in the wind energy sector emerged through a combination of the resource mobilization, entrepreneurial experimentation and knowledge diffusion of Enercon and the spin-off firm Tecsis from the aviation sector. Local capabilities from a related sector matched with the opportunities created through the foreign OEM. Capability at a larger scale only really took off once the auction programme opened the market to the international industry. The content requirements, however, only incentivized the local manufacturing of low to medium technological content, namely the infrastructural components of the balance of plant, the tower, blades, nacelle box and the hub. The gearbox and other micro-electrical components continue to be imported (Rennkamp/Fortes Westin 2013).

Local content requirements were the only instrument to stimulate 'knowledge creation' through foreign direct investment-driven technology transfer in the auction programme. There were no explicit support mechanisms for innovation beyond the technology transfer through the OEM. When 2 GW were installed in 2012, the Wind Energy Association initiated a network to seek public policy support for innovation through a network of business, university researchers and government to fill the gap.[28]

36.3.3.3 South Africa

In the South African situation, the wind energy sector started building innovation capabilities mostly from scratch. The innovation capabilities before the procurement programme were built up tediously through partnerships with international companies. IWEC tried through licensing, the Darling wind farm through imports. Finally, the procurement programme limited market access to only mature OEMs that can present evidence of at least two years of experience, which inadvertently excluded start-up firms. Nationally, innovation capability increased through the REIPPP incentive programme, but it channelled these capabilities through the foreign OEM (Rennkamp/Fortes Westin 2013). As a result, the focus on local content requirements nurtured low technological content and benefited civil construction firms more than wind energy technology companies in the first and second bidding rounds. With growing content, the industry accounts for producing medium technological content including blades in order to fulfil the content requirements.

As in the Brazilian case, the incentive programme influenced the direction of search and entrepreneurial experimentation significantly. The programme attracted significant international investment into the country. So far, there has not been significant resource mobilization through the REIPPP programme to support R&D. Several initiatives fill part of the gap. Research at the Universities of Cape Town and Stellenbosch focuses on smaller scale wind turbines. The Cape Peninsula University of Technology and the Nelson Mandela Metropolitan University host a joint training centre for wind energy engineers with support of the German development cooperation agency. By 2014, the Local content requirements produced two tower factories who manufacture about 140 towers per year. The first manufacturer in Port Elizabeth

received most of the contracts from the OEMs for towers in rounds 2 and 3. The second manufacturer in Cape Town opened its gates only towards the end of 2014. Some local companies struggle to meet the current demand on time. The debates on sense and nonsense of local content requirements under the current market size continue between the OEMs and the Department of Trade and Industry. While the DTI aspires to increase the local content requirements to 60–75 per cent and to move to the next step of localizing blade manufacturing, the OEMs worry about the quality, timely delivery and cost of local production.[29]

36.3.3.4 Summary

The three drivers and barriers to successful technological catch-up have had significant impacts on the evolution of wind technology systems in all three countries. Existing innovation capability in India and Brazil facilitated the evolution of the wind sector. Once the incentive systems were put in place, companies could draw on this comparative advantage. In the Indian case, significant innovation capability entered through Suzlon's acquisition of Danish companies. In the Brazilian case, the policy-independent firm strategies of Enercon and later Tecsis built a significant base of innovation capability, which advantaged the companies in complying with local content rules. Their capability also allowed others to be supplied with the necessary local content. The main influence on the direction of search, which sped up the wind energy technology system, was the auction system. The auctions created a significant market size of 11 GW, which attracted the interest and investment of the global wind energy industry. Five international original equipment manufacturers have established themselves in the market over the last five years.

The South African case showed that a lack of an enabling environment can become a barrier to innovative capability built through policy-independent strategies. Once these rules were changed, the technology system could evolve. As in the Brazilian case, the competitive bidding programme attracted the global industry's interest and investment. The market size is not as significant as in Brazil.

All three cases show that innovation capability only builds up over time and requires long-term commitment over time from companies and public support programmes. Capabilities and the knowledge

base lie at the core of the technology system. The Indian case showed that historically-grown capability in the NAL flourished once the enabling environment supported it. In the Brazilian case, the international equipment manufacturer built capability with a long-term vision, which paid off once the market was established. In the South African case, early capabilities and knowledge bases could not unfold in an unfavourable environment. Subsequent initiatives by universities are attempting to establish a knowledge base, and this will build capability in the longer term. Longer-term private sector commitment will be necessary to turn this knowledge into the market, which again will depend on a significant market size. Local content requirements function effectively as a trade barrier, but will have to be complemented through further support in order to establish a knowledge base to support the technology system.

36.4 Conclusion

The three cases above show that different combinations of the seven TIS functions are prevalent in the different countries. Each of these functions can contribute to the success or failure of a wind energy innovation system. In all these countries, knowledge diffusion, entrepreneurial activities, experimentation, and resource mobilization were found to be locked in to each country's existing knowledge, industrial structures and institutions. However, they do in fact induce positive externalities and initiate a process of legitimation within the TIS of each country.

A common feature of these countries is a 'powerful' technological trajectory based on fossil fuels, or large hydropower in the case of Brazil. When trajectories are powerful it is difficult to switch from one trajectory to an alternative one, and elements of path dependencies and institutional lock-ins become commonplace.

We found that Brazil and India have been more successful in catching up so far because of two factors: firstly, in both countries prime moving companies accumulated innovation capabilities independently from public policy incentives. This absorptive capability sped up the development of the wind technology system in both India and Brazil, whereas the South African market needed to build capability almost from scratch.

There is no guarantee that independent firm strategies will succeed or fail. In all three cases, a partnership with a company from a mature wind energy market was necessary to trigger knowledge and technology

---

29 Interviews with OEMs at Windaba 2014; Discussion Panel of OEMs and DTI at Windaba 2014.

Table 36.2: Synthesis of the results. **Source:** The authors.

	Innovation capability	**Policy-independent firm strategies**	**Enabling environment**
India	Historical capability in the NAL, built through joint ventures.	Joint ventures and successful technology transfer through firm acquisition.	Tax incentives, renewable energy certificates and feed-in tariffs in various provinces.
Brazil	Significant capability built through multinational and aviation sector.	Technology transfer through multinationals and local spin-offs.	Significant market size nationally allocated in an auction system. High influence on the direction of search, evolution of TIS.
South Africa	Limited capability in local companies and demonstration projects.	Individual efforts which did not succeed because of a lack of an enabling environment.	REIPPP Programme in support of large plants, adjusted later for smaller plants, which targets mature companies and FDI rather than boosting local firms.

transfer. In the Indian case, the Danish cooperation agency supported the joint venture between Danish and Indian firms, which eventually led to the successful transfer of technologies to Indian companies. In Brazil, the well-established OEM operated under a Brazilian name and invested significant resources. The South African case, in turn, was smaller in scale, with fewer resources and support from an overseas company or donor. Another important factor for the failure of IWEC's strategy was the difficult and unsupportive policy environment for smaller-scale, local innovators.

Innovation capabilities emerged through a combination of resource mobilization, entrepreneurial experimentation and knowledge diffusion in Brazil, so the local capabilities from a related sector, the aviation sector, matched the opportunities created through the foreign OEM in the wind energy sector; while in India, although innovation capabilities and skills in aero- and fluid dynamics existed within public research organizations (PROs), there is no evidence of these capabilities spilling over to the industry. So innovation capabilities in India emerged through a combination of entrepreneurial experimentation, influence in the direction of search (testing and certification programmes), and knowledge diffusion (and technology transfer) from foreign joint ventures.

The second critical factor for innovation in the wind energy sector is the enabling environment. The market size and trade barriers influenced the decisions of investors on whether to enter an emerging market or not. In Brazil and South Africa, local content requirements (LCR) are used as an instrument to stimulate knowledge creation and create legitimation of the technology. In India, there are no explicit local content requirements in the wind energy sector, but its restrictions on foreign direct investment, which

require foreign firms to engage in 49:51 joint ventures with local firms, is a similar rule that benefits the local industry. These joint ventures stimulate knowledge creation and entrepreneurial experimentation and influence the direction of search and eventually legitimation. Positive externalities were created as a result because these functions were enabled. In the case of India, an enabling environment was created after the industrial policy reforms of the early 1990s. Foreign companies were allowed to increase their equity shares in the form of joint ventures with local Indian companies. This move encouraged private sector participation in the wind energy sector, thus greatly influencing entrepreneurial activities. A series of incentives and policies were formulated in India and Brazil, which legitimized and influenced the direction of search and formed markets. Market size was found to be critical for the successful implementation of wind energy policies. For example, the Brazilian and South African governments solved the problem of market constraints by announcing wind energy targets. Such a move legitimates the technology in the market place, encouraging further investment. In Brazil, the auctioning process increased legitimation for wind technologies and the development of the sector, and stimulated the expansion of wind energy capacity in the country.

However, in the case of South Africa, the allocated market size for wind is much smaller than in Brazil, and this has translated into fewer profitable investment opportunities and slower and smaller-scale wind technology development.

37 Sustainability Transitions and the Politics of Electricity Planning in South Africa

Lucy Baker[1]

Abstract

After decades of cheap, abundant coal-fired electricity, from which large international mining and energy conglomerates and wealthy households have benefitted disproportionately, South Africa is experiencing a supply-side crisis. In 2011, the country's first integrated resource plan for electricity (IRP) was promulgated following a prolonged and contested consultation process throughout 2010. This plan anticipates that renewable energy will constitute twenty per cent of installed generation capacity by 2030, which will deliver approximately nine per cent of supply. Coal will retain the greatest share alongside a potential yet currently uncertain nuclear fleet. The objectives of this chapter are twofold: to examine electricity governance in South Africa and the highly politicized policy-making process in relation to IRP in which vested interests have played a major role; and to consider the extent to which the IRP has facilitated a low carbon transition. The chapter finds that despite the creation of a successful renewable energy 'niche', the coal-fired 'regime' is also being reinforced and the electricity mix under analysis is fuelling an unsustainable trajectory of production and consumption. The chapter also considers definitions of sustainability and concepts of a 'just' transition.

Keywords: South Africa, sociotechnical transitions, electricity, integrated resource plan, renewable energy, coal.

37.1 Introduction

South Africa is experiencing a long-term electricity supply-side crisis.[2] One of the cheapest electricity providers in the world until 2010 (Edkins/Marquard/Winkler (2010: 14), following a series of tariff increases, by July 2011 Canada surpassed South Africa as the cheapest provider of electricity.[3] It has had further yearly increases of eight per cent approved between 2013 and 2018.[4] The country's historical dependence on cheap coal and cheap labour for the production of cheap electricity, from which the mining and minerals beneficiation industry and wealthy households have benefitted disproportionately, is subject to change. The supply-side crisis has been exacerbated by, amongst other factors, rising coal costs, climate change mitigation requirements and a failure to build any new generation capacity since the 1980s. The approval of the *Integrated Resource Plan* for electricity (IRP) in 2011 allows for the construction of 23,500 MW of renewable energy generation capacity by private suppliers by 2030 for a coal-fired electricity sector which until now has been controlled by the monopoly utility Eskom. Electricity is South Africa's largest energy subsector and supplies 29 per cent of its energy demand. About a quarter of the population, 12.3 million people, lack access to electricity (IEA 2011).

This chapter has two objectives. Firstly, to examine electricity governance in South Africa and the policy-making process in relation to the integrated resource plan (IRP) for electricity as a key regulatory instrument. This objective is guided by the research question: *What is the nature of policy-making in South Africa's electricity sector?* This question is informed by Keeley and Scoones's (2003: 2) explorations of how science and different forms of expertise engage in the policy-making process, the institutional location of the experts in question, "the political context in which decisions are being made", and "the politics of policy-making" (Keeley/Scoones 2003: 17). By demonstrating how any transition to sustainability must involve wider political, economic, social and technological shifts and realignments (Grin/Rotmans/Schot 2010), the chapter seeks to be of value to those trying to understand transitions and/or seeking to influence them in the direction of sustainable development.

In tandem with the Renewable Energy Independent Power Producer Procurement Programme, which has been studied in depth elsewhere (Baker/Newell/Phillips 2014, Eberhard/Kolker/Leigland 2014), the IRP has facilitated significant changes in the country's electricity mix, in particular the rapid introduction of a new renewable energy sector which will constitute over twenty per cent of generation capacity and deliver approximately nine per cent of supply. Exploring the negotiation of the IRP demonstrates how electricity planning, and by implication the governance of sustainability transitions, is an inherently political process and takes place within competing and conflicting economic, political, industrial, environmental and social priorities.

The chapter's second objective is guided by the research question: *To what extent has the Integrated Resource Plan for electricity facilitated a transition to sustainability?* In evaluating the negotiation and implementation of the IRP it can be argued that despite considerable delays in its introduction and criticisms of the negotiation process, on some levels the plan has successfully enabled the emergence of a low carbon niche in South Africa. However, a broader analysis reveals that the gains made by a new renewable energy sector are embedded within a broader and much less sustainable trajectory of demand and supply. Using the multilevel perspective on sociotechnical transitions, I evaluate how low carbon 'niches' are taking place in parallel to the country's continued high carbon 'regime'. This echoes previous findings that low carbon initiatives in South Africa's electricity sector are being integrated into a high carbon industrial

infrastructure, which has limited benefits for the energy-poor and high inequality of access (Baker 2014, Hallowes/Munnik 2007)

In order to obtain rich insights into how national electricity planning is negotiated, this chapter is based on a deep and critical enquiry into the complexity of competing interests and priorities in South Africa. I illustrate the non-linear nature of policy-making following Wildavsky's (1979: 410) argument that policy analysis is concerned with both planning and politics, and that due to the difficulty in defining policy analysis it "should be shown not just defined". The case study of South Africa's IRP shows how the contested and complex nature of policy-making generally constitutes a series or web of decisions that take place over a long period of time and is often carried out by a complex network of actors. It further demonstrates how the policy process is embedded in socio-economic power structures (Dahl 1956, in Grin 2010: 223). Drawing on extensive field research carried out in 2010 and 2013, including approximately sixty qualitative interviews, I evaluate the role of national and international stakeholders and beneficiaries from the public and private spheres including government departments; industrial conglomerates; renewable energy companies; national banks and international investors; bilateral and multi-lateral donors; civil society and grassroots organizations; unions; and academics. Interviews cited in the text have been heavily anonymized in the interests of confidentiality.

In this chapter I firstly consider understandings of 'sustainable' and 'sustainability', particularly in relation to energy and the concept of a 'just transition'. Secondly I put forward the multilevel perspective on sociotechnical transitions as an analytical framework. Thirdly I explore the nature and overarching challenges of electricity governance which I then apply to South Africa by situating the country's electricity sector in a broader political, economic, social and technical context. This sets the context for the case study—that of the negotiation of the country's integrated resource plan for electricity.

37.2   Defining a 'Just' Transition to Sustainability

Motivated by a concern for poverty reduction and social, economic and environmental justice, this chapter should be read in the context of other studies which assert that a fundamental transformation to a low carbon future and industrial structure is needed

(Weischer/Wood/Ballesteros et al. 2011). The starting point is that the world's natural resources are limited (Meadows/Meadows/Randers et al. 1972; Rockström/Steffen/Noone et al. 2009) despite the innovative role that can be played by technological developments. Secondly, global economic dependence on fossil fuels is one of the fundamental obstacles to global environmental change (Adger/Brown/Conway 2010). In this light, the biggest governance challenge is how to manage an equitable low carbon transition that drastically reduces global consumption levels. This challenge includes cross-border dynamics, including the role that national and global institutions have played in driving and perpetuating the high carbon export-based growth of South Africa and other countries. I therefore acknowledge the very complex nature of system innovations and transitions to sustainability (Grin/Rotmans/Schot 2010) and how they may apply to questions of energy.

This study does not assume that all of South Africa's energy needs, however defined, can currently be met with renewable energy and acknowledges the significant technological uncertainties that exist on this point. I also recognize the immense challenges of the entrenched and highly inequitable legacy in the energy sector inherited by the post-apartheid government in 1994 and pay all due respect to the struggle and dedication of the numerous individuals and institutions that have fought to overcome this.

In these times of climate consciousness, 'sustainability' is an oft-used platitude. Despite the origins of the term 'sustainable development' as "development which meets the needs of the present without compromising the ability of future generations to meet their own needs" (WCED 1987), there is no internationally agreed standard or accepted definition of what it should mean. It is a highly contested concept that is a matter of subjective political judgement (Grin 2010: 235). Perhaps for this reason the term has now been co-opted by corporate and financial interests whose core activities may be some distance away from the intentions of its originators (Banerjee 2008). Ambiguities also exist over the term 'low carbon', which is simultaneously applied to various coal technologies, large hydroelectricity and nuclear power.

If the concept of sustainability, in reference to energy at least, is to include a social as well as an environmental dimension it must incorporate the issues of energy poverty, access to energy for the poor, the social consequences of energy exploitation, and the role of labour. This is particularly relevant in light of the failure of grid expansion plans and large infra-

structure projects that meet the needs of economic and industrial centres but often neglect the needs of the rural and urban poor (Prasad 2008). Any sustainable energy transition must also consider ethical debates over how the pressure to decarbonize should be balanced against the need to provide pro-poor energy and/or economic growth on equity and justice principles (Roberts/Parks 2007), possible conflicts that may exist between these two objectives, and potential accusations of being 'anti-development' or 'anti-technology'. A key debate is to what requirements low-income countries should be subjected, in light of their minimal historical carbon emissions and the lack of access of the majority of their populations when compared to developed countries. And what in turn should be the obligations of high-income countries in providing financial and technological assistance: how much, via which channels and to whom (Ockwell/Ely/Mallett et al. 2009: 12)?

With this in mind, the emerging literature on 'just transitions' (Swilling/Annecke 2012; COSATU 2012; Newell/Mulvaney 2013) plays a poignant role in marrying concepts of social justice with the need for a global low carbon shift. In essence, any low carbon energy transition must be based on modes of production and consumption that do not depend on resource depletion, environmental degradation or the exploitation of socio-economic inequalities. Such an argument addresses the tendency of the sociotechnical transitions literature to overemphasize environmental and 'green' concerns in defining sustainability (Geels 2011) with its implicit assumptions that 'radical green niches' will automatically result in concomitant human co-benefits and the realization of social equity. Or in other words, that a 'low carbon' transition will automatically result in a 'just' transition.

We now turn to the literature on sociotechnical transitions and in particular the use of the *multilevel perspective* (MLP) as a framework of analysis with which to explore developments within South Africa's electricity sector.

37.3 Analytical Framework: Sociotechnical Transitions

The MLP analyses sociotechnical systems change from the level of 'landscapes' (macro), 'regimes' (meso), and 'niche-innovations' (micro) (Geels/Schot 2007). It is concerned with the way in which incumbent regimes lose stability and experience low carbon, sociotechnical transitions as a result of coordinated

selection pressures from the niche and landscape levels (Byrne/Smith/Watson et al. 2011: 57). As this chapter illustrates, defining the empirical and geographical parameters of the different levels is obviously an incomplete, subjective and temporary exercise. As Smith, Stirling and Berkhout (2005: 1504) explain, "regime membership is neither homogeneous nor clearly bounded" and does not neatly align to the boundaries of the nation state. This lack of conceptual clarity also raises the question as to whether an electricity regime refers only the level of primary fuel such as coal, or encompasses the entire system of generation, transmission and distribution (Berkhout/Smith/Stirling 2004).

With this in mind, I have interpreted the regime concept in this case to refer to South Africa's coal-generated, state-owned, electricity sector under Eskom's monopoly control, supplied by powerful privately-owned coal mining companies and of particular benefit to energy-intensive users. I have interpreted the niche to refer to the renewable energy independent power producers who are supported by national banks and various sources of national and international finance and investment (Baker 2012). The niche and the landscape, so-defined, interact with and are influenced by actors and events at the 'landscape' level, which in this case can include: international trends in renewable energy investment; increasing national and international demands for South Africa's coal resources; and the role of international resource conglomerates. Though not without its own conflicts and tensions, the relative 'stability' of South Africa's coal-fired electricity regime has been characterized by the political, institutional and market dominance of entrenched beneficiaries and stakeholders. This has been supported at the level of national policy and in terms of implicit and explicit subsidies such as cheap coal supply and preferential electricity tariff deals.

In this chapter the MLP framework is employed flexibly rather than rigidly. This is appropriate for a creative interpretation and empirical analysis of the study of complex, interlinked, multidimensional and co-evolving dynamics (Geels 2011: 34; Foxon 2010). I do not test the viability of this model in predicting or determining systems change or measuring the relationship between different variables in a positivist sense, but rather use it as a framework to analyse different stakeholders, institutions and technologies involved in the governance of South Africa's electricity sector. This facilitates "narrative explanations" (Geels/Schot 2007: 414) of the case study in question and allows for an examination of interactions between "technol-

ogy, policy/power/politics, economics/business/markets and culture/discourse/public opinion" (Geels 2011: 25).

Another strand of the sociotechnical transitions literature, Transitions Management, takes a more prescriptive approach and aims to generate low carbon transitions in unsustainable regimes by "steering evolutionary dynamics towards specific visions" using consensus-based decision making (Scrase/Smith 2009: 708). The difference between the MLP and the Transitions Management approach can be related to the difference identified by Ham and Hill (1993: 4) between analysis *of* policy and analysis *for* policy. While the former, which I apply here, is concerned primarily with advanced understanding, the latter refers to applied activity "concerned mainly with contributing to the solution of social problems".

This chapter goes some way towards responding to criticisms of the sociotechnical transitions literature for its inadequate analysis of politics and power relations (Lawhon/Murphy 2012; Smith/Stirling/Berkhout 2005; Meadowcroft 2011). Specifically, I integrate a political economy approach which is crucial for the analysis of relationships between political and economic power, structural change, and the underlying interests of dominant actors and beneficiaries of governance mechanisms (Moe 2007; Büscher 2009; Baker/Newell/Phillips 2014). Such a perspective allows us to examine the interaction between state institutions and private capital in the policy process and the dynamics of global economic expansion. In such a way we avoid reducing a complex debate to a largely technocratic perspective on policy and governance (Torgerson 2003) which is mostly politics-free, ignores the influence of human agency and fails to address "pressing issues of social justice on two fronts: both *within* industrialized nations and *between* highly industrialized and third world nations" (Hajer 1995: 32). As Moe (2009: 1731) explains, technology and economics are insufficient for an analysis of structural change and long-term growth and development. Instead, "*politics*—or the political economy, with its focus on actors and decision-makers, on institutions and regulations, and on past and present interactions—must be included". Following Grin (2010), who places politics and power as an essential aspect of governance in the case of sustainability transitions, decision-making in South Africa's electricity sector cannot be understood without situating it within the complexity in which it is embedded. This complexity refers to a political economy and historical path dependency characterized by

the country's minerals-energy complex (Fine/Rustomjee 1996), explored below.

Finally, by applying sociotechnical transitions to South Africa, the chapter adds to limited studies of this literature in relation to a *low- and middle-income countries* (LMICs) context, whose economic growth is based on natural resource extraction and polluting industries within the context of a globalized and financially interdependent world (Lawhon/Murphy 2012: 10).

37.4 The Challenges of Electricity Governance

> Electric power systems demanded of their designers, operators, and managers a feel for the purposeful manipulation of things, intellect for the rational analysis of their nature and dynamics, and an ability to deal with the messy economic, political, and social vitality of the production systems that embody the complex objectives of modern men and women (Hughes 1983: 1).

A determining factor in the realization or impediment of sustainable development and climate change mitigation, energy, like water, is a global good but has billions of people without access to it or with access only to poor quality; it is in rapidly growing global demand; it is constrained by natural resources; it varies in regional availability; and it operates in heavily regulated markets (Bazilian/Rogner/Howell et al. 2011: 7897). It is as much a part of a country's development policy (Ljung 2007: 37) as policy on industry, infrastructure development, the environment, foreign relations, trade, climate change and social development. The conflict for policy-making that results from such a complexity of competing and fragmented interests is central to this investigation.

Electricity, defined here as a subset of energy, is a large technological system embedded in broader political, economic and social forces (Hughes 1983; Rip/Kemp 1998). Goldthau and Sovacool (2012: 233) describe electricity as "perhaps one of the most obvious large-scale socio-technical systems involved in converting energy fuels into services", which goes far wider than the arenas of science and engineering. As a technology, electricity is "site-specific" (Hughes 1983: 47), determined by natural and human geography. For all these reasons, electricity is not easily governed or manipulated and is compounded by path-dependency, the role of vested interests and uncertainty in the adoption of new technologies and their integration into the grid.

Electricity as an infrastructural and network technology (Rip/Kemp 1998) and natural monopoly is difficult to separate from the concept of its governance in that it lends itself towards economies of scale. According to Victor and Heller (2007: 1), the treatment of electricity as a commodity like any other, and its separation into generation, transmission, distribution and supply for sale along market principles, is highly flawed. It has proved one of the hardest network industries to reform and it has been difficult to "replace the state with private enterprise because infrastructures usually display strong economies of scale, which arise through network interactions that are prone to natural monopoly".

Yi-chong (2006: 803) classifies electricity as a process rather than a commodity, formed from the conversion of different forms of energy which are then consumed shortly after production. The simultaneous production and consumption process is achieved through "a complex 'coordination' system that integrates a large number of generating facilities dispersed over wide geographic areas to provide a reliable flow of electricity to dispersed demand nodes while adhering to tight physical requirements to maintain network frequency, voltage and stability" (Yi-chong 2006: 804). Smith, Sterling and Berkhout (2005:1493) describe how the electricity-generating regime "is dominated by rules and practices relating to centralized, large-scale (usually thermal) power technology and high voltage alternating current grid infrastructures", which at the national level is "nested within a global energy regime organized primarily around the extraction, trade and combustion of fossil fuels". The national level in turn oversees subordinate regimes, such as "the coal-fired steam turbine, the nuclear fuel cycle... or gas-fired combined cycle turbine systems" (Yi-chong 2006: 1493).

In South Africa there are two different framings of the electrification problem competing for institutional and policy dominance (Bekker/Eberhard/Gaunt et al. 2008). The first one, pioneered by the socially-oriented policy analysts such as the University of Cape Town's Energy and Development Research Centre in the late 1980s and 1990s, was based on an analysis of low-income household energy use which saw electrification as a key intervention in addressing energy poverty. The second framing, inherent in the approach of the national utility Eskom, perceives electrification as a development to be integrated with other service-oriented infrastructure development processes. The first framing aligns with the energy commons approach (cf. Wamukonya 2003: 1284) which perceives energy

as a public good rather than as the commodity it is often treated as. Such an approach asserts that concerns of equity and efficiency should be included in energy policy-making and that the natural availability of renewable energy resources "make them potential energy commons". Meanwhile the treatment of energy as a commodity underpins a profit-oriented urban bias in national electrification policy which results in the marginalization of rural communities, overlooks goals of universal access and leans towards technologies based on fossil fuels, in disregard of environmental concerns (Wamukonya 2003: 1284). This brings us back to the concept of 'just transitions' discussed above and debates over how sustainability should be defined.

37.5   South Africa's electricity sector in context

> The energy sector is governed by a monopoly. Huge profits are made by lucky winners. People are trying to put this into the renewable market such as wind. The creation of monopolies is a key theme in energy governance in South Africa. Every player in the market is trying to create their own monopoly. Lack of knowledge and lack of transparency allow this to happen (Energy Specialist, in interview, December 2010).

The structure of South Africa's electricity sector and its coal-dominated sociotechnical 'regime' is characterized by its minerals-energy complex (Fine/Rustomjee 1996). This incorporates national activities organized in and around energy, mining and associated subsectors, and includes the evolving relationship between the state and corporate capital. The minerals-energy complex is central to the country's historical dependence on cheap coal and cheap labour for electricity which in turn serves the interests of export-oriented industry. Central to this is the country's social, political and economic legacy of apartheid, which created an infrastructure to meet the needs of industry and the white minority (Ziramba 2009). According to the IEA, in 2012, 59 per cent of the country's electricity was consumed by industry and 20 per cent by residential consumers.[5]

South Africa has historically been dependent on abundant sources of low-cost coal for ninety per cent of its electricity and this has resulted in an incredibly energy-intensive economy. The country's emissions

are higher than the UK's per capita, while its GDP per capita is only a sixth as much. Electricity is South Africa's largest energy subsector, supplying 29 per cent of its energy demand and generating approximately 50 per cent of its carbon emissions compared to 26 per cent globally (CDP 2011). In financial year 2012/2013, the utility Eskom burned 123 million tonnes of coal (Eskom 2013: 85) and emitted 227.9 tonnes of carbon dioxide (Eskom 2013: 34). The country's remaining emissions come from synthetic fuel production, energy-intensive industries (mining, iron and steel, cement), and the transport sector.

South Africa's electricity sector has been characterized by its monopoly parastatal Eskom. The country defied the "standard model" of power sector reform which became universally accepted during 1980s and 1990s (Gratwick/Eberhard 2008). This model, which involves the unbundling of the electricity sector into separate transmission, distribution and generation companies and the introduction of private competition, was unsuccessfully imposed upon other countries in sub-Saharan Africa as part of World Bank-led structural adjustment programmes. Eskom is the sole transmitter of electricity via the country's high-voltage transmission grid, generates 96 per cent of national electricity and is responsible for 60 per cent of distribution, which is consumed by a third of South Africa's customers. Municipal distributors purchase their energy and services from Eskom Distribution and supply about two-thirds of the country's customers, who account for 40 per cent of total sales. This has resulted in a highly fragmented local governance system with poorly performing service delivery departments and the existence of separate local black municipalities (Eberhard 2007: 231).

The historical influence of a small number of large resource-based conglomerates over South Africa's energy policy and economy more generally is a central feature of South Africa's minerals-energy complex. These conglomerates, now internationalized with privileged access to cheap energy, tax breaks and infrastructure, have acute levels of control and concentrated ownership over the country's mining and minerals beneficiation sectors (Fine/Rustomjee 1996) and maintain "enormous collective bargaining power" (Nakhooda 2011: 21). These conglomerates include the country's five largest coal mining companies: BHP Billiton, Glencore-Xstrata, Anglo-American, Sasol and Exxaro. They are in turn members of the country's *Energy Intensive User Group* (EIUG)[6] which has

---

5   See at: <http://www.iea.org/statistics/statisticssearch/report/?year=2012&country=SOUTHAFRIC&product=ElectricityandHeat>.

6   See at: <http://www.eiug.org.za/about/membership/>.

thirty-six members and consumes around 44 per cent of the electricity sold in South Africa.

South Africa is one of the most socially unequal countries in the world with 70 per cent of its income going to approximately 20 per cent of its population, 1.6 per cent of its income going to the poorest 20 per cent (The Presidency 2009:23), and an unemployment rate of 31 per cent including 'discouraged work seekers' (Statistics South Africa 2012). Reflecting the country's history of racially determined differentiation (Bekker/Eberhard/Gaunt et al. 2008), one-third of households lack access to electricity. Before the end of apartheid in 1993, only 36 per cent of the population was connected to the electric grid (CURES 2009). While Eskom's unprecedented expansion programme between 1994 and 2000 saw 2.4 million houses connected to the grid and many more connected by local government municipal utilities (McDonald 2009: 15), one-third of the country's population is still without access, particularly in rural areas. Millions of low-income households, who account for no more than five per cent of national electricity consumption, cannot afford to buy electricity even if they are connected to the grid (McDonald 2009: 16), and prioritize paraffin, coal, wood fuel and other sources. Middle- to high-income urban households consume an average of 96,000 kilowatt-hours per annum (McDonald 2009: 15), just below that of the US at 112,000 kWh.

In the course of just two decades South Africa has gone from a period of electricity surplus in the mid-1980s, with some of the lowest electricity prices in the world as a result of the construction of excess generation capacity, to capacity restraints and a severely constrained reserve margin and imminent deficit, resulting in load-shedding in 2008 (Eberhard 2011). The complex reasons for this crisis go beyond the scope of this paper and are the culmination of events over many years (Baker 2012). In policy terms, this crisis can be referred to as a "trigger event" (Keeley/Scoones 2003) in that it has been used simultaneously as a legitimizing discourse for the construction of further coal-fired power stations, the integration of new renewable energy and a potential nuclear fleet. This is now explored in the following section in relation to the Integrated Resource Plan for electricity.

37.6 The Politics of Electricity Planning

South Africa's second *Integrated Resource Plan* (IRP) approved in May 2011 is an electricity master plan cov-

ering total generation requirements from 2010 to 2030. It was initially based on a doubling of national generation capacity from current levels of approximately 41,000 MW to 90,000 MW by 2030. However this project has been under revision since late 2013. The IRP was celebrated in some arenas for diversifying the country's electricity generation mix away from coal by allowing for approximately 23,000 MW of grid-connected renewable energy (of which 9,200 MW wind, 8,400 MW PV [photovoltaics] and 1,200 MW CSP [concentrated solar power]) (DoE 2011a: 14) until 2030, the majority of which will come from independent power producers. However, figure 37.1 reveals that in addition to the construction of new renewable energy, 6,250 MW of new coal will also be introduced. This is in addition to the Medupi and Kusile coal-fired power plants that were approved prior to the IRP and are currently under construction, constituting a combined generating capacity of approximately 9,600 MW. Hence while the proportion of coal in the overall electricity mix decreases from 85 to 46 per cent, in absolute terms it will increase to 41,071 MW. The final plan claimed to be consistent with an emission constraint of 275 million tonnes of carbon dioxide annually after 2024 (DoE 2011a: 6) though the actual emissions associated with it have not been specified.[7] An ambitious nuclear fleet is also planned whose undetermined cost has since been the subject of significant national controversy. A project must be in the IRP in order for the national energy regulator to be able to grant it a licence (Pienaar/Nakhooda 2010), though according to the new generation regulations for electricity the minister holds the right to license generation capacity if s/he deems fit.

This plan has been under revision since late 2013 in keeping with the requirement that it be updated every two years. The revised draft proposes a downward adjustment in the demand forecast which would result in an overall decrease in generation capacity of 6,600 MW. The proposed revisions include a reduced contribution from coal (from 6,250 MW to 2,450 MW) and wind (from 9,200 MW to 4,360 MW), and increased contributions from Solar PV (from 8,400 MW to 9,770 MW) and CSP (from 1,200 to 3,000 MW). There is also a lack of clarity in the draft over the proposed nuclear fleet and a potential increased role for gas, including shale gas. The implications of these revisions, which are some months from being

finalized, will be uncertain for some time. In brief therefore, despite a decrease in the demand forecast, coal is still set to remain the dominant energy source for the foreseeable future, with minerals extraction and related manufacturing still constituting the bulk of demand.

This section examines the way in which the IRP as a crucial national planning instrument for electricity was negotiated, focusing on participation and transparency; parliamentary oversight; assumptions of demand; the political nature of technical advice; and modelling. In doing so it illustrates how in South Africa the governance of electricity and the nature of sustainability transitions is a highly contested and political process. The IRP claims to "indicate a balance between different government objectives, specifically economic growth, job creation, security of supply and sustainable development" (DoE 2011a: 13). Such a statement encapsulates the nature of conflicting objectives that must be tackled in order for any meaningful transition to take place.

Following various delays, the stakeholder engagement process for IRP took place throughout 2010 and early 2011. The process included representatives of the coal, renewable, and nuclear industries; the country's energy-intensive users; financial stakeholders; and civil society and academics. Government was heavily criticized from all sides for the rushed nature of the plan's

negotiation process; the lack of transparency of critical assumptions; problems with its methodology and input parameters; costs; the overall energy mix; the feasibility of the plan; and its potential impacts on the poor. Despite this, it was considered by some stakeholders as a significant advance on previous electricity planning processes (Hughes 2010, Mainstream Renewable Power 2010b). Nakhooda (2011) argued that while the process was dominated by relatively specialized stakeholders able to engage with the inevitable technical complexity of electricity planning, opening it up to public participation still set an important international precedent.

37.6.1   The Process: Participation and Transparency

Following strong public pressure from civil society, business and the media (Nakhooda 2011: 11), in February 2010 the *Department of Energy* (DoE) announced that a public consultation process would be initiated, with the aim of completing the IRP by June 2010. In the event the final plan, referred to as the 'Policy-Adjusted' IRP (DoE 2011a) was promulgated almost a year later in May 2011. Throughout the consultation civil society groups and academics pushed for an extension to the timeline to ensure sufficient time for public comment (Earthlife Africa 2010). Meanwhile,

according to one energy-intensive user, government was keen for the plan to be approved as quickly as possible in the "rush to create more generation capacity" and in the interests of finalizing agreements with international suppliers and contractors for new coal and nuclear build.

Transparency and participation was one of the key concerns cited throughout the process, in particular over a lack of clarity in the IRP's critical assumptions (Hughes 2010). In June, WWF (2010) said that it was "disappointed that the documentation provided to date, as well as the way in which documents have been released, does more to obfuscate the process and issues, than to enable informed engagement in transparent and accountable integrated resource planning". The first 'stakeholder plenary sessions' were held in June 2010 in Pretoria and extended from one to two days at the last minute to accommodate the volume of interest. These heard a total of thirty-two presentations (DoE 2010a) and focused on the input parameters for the IRP modelling (DoE 2011a: 7). According to the DoE (2011b) in its briefing to the parliamentary portfolio committee on energy in January 2011, at the first round of consultations eighty-one submissions were received and "831 specific inputs based on the parameter sheets were captured and analysed", with the major contributors being 67 NGOs and civil society organizations, 63 academics and consultants and 70 organizations.

However, these submissions were not made publicly available and how they contributed to the IRP 2010 was not clarified by the DoE. In October 2010 an NGO report stated that the DoE failed to respond to many of the comments made in relation to its input parameter documents and that there was no recognition as to whether the technical inputs had been included in the modelling or even meaningfully considered (McDaid/Austin/Bragg 2010). On a similar note, in its June 2010 presentation the EIUG (2010) commended the government on its transparency but stated that it should publish a summary of submissions from the first round of consultations and be transparent about the criteria it had used to evaluate scenarios. Sappi, the global pulp and paper giant and EIUG member, also called for greater clarity over the twenty-nine parameters issued and for better structure in the way in which they were presented and the ability of people to comment (Sappi 2010). In the event there was no response to such calls.

On 8 October the DoE put forward a second draft of the plan (DoE 2010b) with a thirty-day comment period to run until 10 November 2010, subsequently extended to 10 December 2010. Four days of public hearings in Cape Town, Durban and Johannesburg were held at the end of November and in early December 2010.

In the midst of the second comment period, twenty-eight South African faith-based, environmental and social organizations issued a report calling for national electricity planning to be developed within the context of "broader sustainable development goals" and to be connected to "various other processes aimed at addressing these issues arising from our historical legacy" (McDaid/Austin/Bragg 2010: 4). The report, *Power to the People: raising the voice of civil society in electricity planning—IRP 2010 inputs and departmental responses*, outlined key concerns over the nature of the IRP participation process, including its failure to uphold national laws on public participation which are central to the post-apartheid regime's principles of empowerment and democratization, such as the *Protection of Administrative Justice Act* (PAJA) (Nakhooda 2011: 8). The report also pointed to the inability of the general public to be able to participate, firstly given that the main opportunity to do so was via the Internet, which would thereby exclude the majority of South Africans, and secondly in light of the complexity of the process, which would restrict the ability of those with limited education to engage with it. Lastly the report argued that the process had failed to adequately account for rural communities who suffer from poor electricity connections and would be the most affected by rising electricity prices.

Despite the above criticisms from civil society, others welcomed what they saw as the DoE's commitment to participation and transparency. For instance, in November 2010 an energy-intensive user referred to it as "the first consultative electricity plan that South Africa has ever had". In August 2011, Standard Bank's head of energy, utilities & infrastructure, Paul Eardley-Taylor, said that "the IRP is an impressive document, both the speed of the document's promulgation and the transparency of the process".[8] In November 2010 the DoE (2010c) stated "It is clear that the public relished the participation process and its continued use in long-term planning must be ensured".

37.6.2 Parliamentary Oversight

The Parliamentary Portfolio committee on energy has a formal oversight role over the Department of

---

8 L. Pretorius, "Renewable Energy—Moving forward a cause for concern", in: *Financial Mail*, 24 August 2011.

Energy. However the IRP 2010 negotiation process raised doubts over the extent to which the committee complies with this role. For instance, the first parliamentary briefing on IRP 2010 was not held until 3 August 2010 and was criticized for coming too late, after the first hearing and the critical modelling exercises had taken place. Lance Greyling, MP for the Independent Democrats and member of the committee, said "I would go so far as to say that Parliament—and, particularly, the energy committee—has been negligent in its duties at providing proper oversight over the energy sector; and in particular, energy planning" (Greyling 2010). The technical expertise of some of the members of the committee may also be inadequate. For instance at one meeting in June 2010 one member requested clarification over the difference between a wind turbine and a hydroelectric turbine (PC Energy 2010). At the same meeting, a discussion took place about PetroSA's offer to provide committee members with tickets to the World Cup, suggesting that hydrocarbon companies may hold an influence over the committee.

The committee's timing was better in the second round, however, with a second parliamentary hearing on 26 January 2011 (DoE 2011b) which gave a summary of inputs and key debates throughout the consultation process.

37.6.3   Supply and Demand: 'Business as Usual on Steroids'

Despite significant changes that the plan proposes to the generation mix, the IRP was based on assumptions that electricity demand would almost double by 2030, from 260 TWh in 2010 to 454 TWh in 2030. Winkler explained that "the growth in electricity demand outweighs the reduction in the CO_2 intensity of electricity" [9] and would result in "GHG emissions from electricity generation increasing from 237 million tons of CO_2 in 2010 to 272 million tons in 2030". It will also increase electricity prices "by at least 250 per cent in real terms from their current level by 2020 and by a much higher rate with inflation factored in" (Winkler 2011). This doubling in electricity capacity is based on the moderate energy forecast in the IRP 2010's Revised Balanced Scenario (DoE 2011a: 36) and a projected GDP growth rate of 4.51 per cent (Eskom Systems Operation and Planning 2010: 2). This anticipates a doubling in mining and minerals

beneficiation, something which prompted a representative of the City of Cape Town's climate and energy branch to refer to the plan as "business as usual on steroids".[10]

Energy-intensive users were strong proponents of the doubling of the demand forecast. In June 2010 the EIUG (2010) asserted that it is "essential that we all understand and accept the growth assumptions" of the IRP, which are its "key parameter". This was bolstered by statements in September 2010 by then executive director of Xstrata Alloys, Mike Roussow, who asserted that mining and minerals beneficiation has a major role to play in the economy and nation-building, for which energy is essential.[11] However, despite the EIUG's demands being met in the subsequent demand forecast, their quest to achieve national consensus over such high growth assumptions was challenged in a number of submissions (in DoE 2011a: 10). The Cape Town Chamber of Commerce (2010), for example, stated that the "energy plan may provide for more power than we actually need". Details about how the demand forecast was calculated were not made public, which, Nakhooda (2011: 15) argued, "raises further questions about its reliability, and made it all the more difficult to propose enhancements to the same". Energy analyst (2) stated that the demand forecast was based on a rate of GDP growth which was "politically, not analytically derived".

37.6.4   The Political Nature of Technical Advice

> Essentially then, the department has succeeded in locking all vested-interest groups into the Technical Advisory Panel and even though they claim that it is just about technical expertise, we are not allowed to see the minutes of these meetings; nor are we allowed to see the thinking behind the different energy assumptions that they come up with (Greyling 2010).

The strong influencing role of vested interests in this case reveals how an assumed technical exercise of electricity planning can be inherently political. A technical advisory group set up to provide inputs into the modelling of the plan's input parameters was criticized in the media[12], by civil society (McDaid/Austin/

Bragg 2010), and by the renewable energy industry (Mainstream Renewable Power, *in interview*), for consisting largely of representatives from government, Eskom, coal miners and the EIUG. Notably, representatives from the renewable energy industry, civil society and experts from the field of social and environmental impact assessment were not included in the advisory group (see table 37.1). For this reason, concern was expressed that the modelling process on which the committee was advising was likely to reflect the industrial bias of the interests of its members (McDaid/Austin/Bragg 2010: 6). Confirmation of the committee's existence and the names and affiliation of its members was made public in June 2010 in a letter from the Minister of Energy to a request for information from civil society (see Peters 2010).

All committee members signed confidentiality agreements with the DoE and its meetings and minutes were not made publicly available (Peters 2010). Despite this the Minister took "exception to the classification of [its] Technical Task Team as secretive", stating that its members were selected for their technical expertise alone, and that they "are not meant to represent the interests of their constituencies/ employer organizations" (Peters 2010). The company Mainstream Renewable Power (2010a) countered that the "inaccuracies and assumptions in the modelling could be better addressed if the renewable energy industry were able to participate as part of the technical task team".

The constitution of this team illustrates the privileged access that energy-intensive stakeholders had to decision-makers, and the influential role that regime incumbents continue to play in electricity policy-making in South Africa, despite the incremental steps made by the emerging renewable energy industry. However, a mining industry expert has suggested that, rather than a deliberate conspiracy, the influence of this team was due to the lack of expertise of Eskom's Systems Operator who carried out the IRP on behalf of the DoE: "the chairman of the technical task team of IRP has never built a power station, the Systems Operator has never built a power station either. They are all demand-side specialists and have based their assumptions on EPRI reports. The Systems Operator is a black box. It doesn't distinguish between the needs of different types of plant and it doesn't understand local risks either". This was corroborated by energy analyst (3) who stated, "Eskom writes the IRP, it goes to the DoE who checks it with its little 'in-group', largely coal miners, and then carries out consultation with identified stakeholders. These are people with whom the DoE has a relationship. It is not necessarily a big conspiracy, but there is a serious lack of capacity in the DoE."

37.6.5   Modelling

There were twenty-nine parameters drawn up with inputs from the technical advisory group and made available by the DoE in May 2010. These were divided into matters of: i) demand, such as price elasticity of demand and energy efficiency; ii) supply, such as: reserve margin, discount rate and exchange rate; iii) externalities, such as climate change and carbon tax; and iv) key outputs, such as base scenarios and rate of inflation. As I now discuss, while a number of participants at the hearings felt that publication of the IRP's parameters was a breakthrough in terms of transparency, others found the modelling to be inaccessible and highly specialized and in some cases based on inaccurate assumptions.

For example, the University of Cape Town's Energy Research Centre found that while the report by US-based *Electric Power Research Institute* (EPRI) was a good basis for assessing technology costs, it was difficult to comment at the time of the public hearing in June 2010 in light of its complexity and because the full report had been made available only one day before (Hughes 2010). Hughes (2010) also pointed to major inconsistencies between the previously-released executive summary and the full report. For instance the latter included a tripling of coal costs. Furthermore the modelling process had failed to include technology learning rates, which would make wind competitive with nuclear by 2014. It was also unclear if price elasticity would be incorporated into the modelling. In December 2010, Pienaar and Nakhooda (2010:6) asserted that "the comparative life cycle costs of conventional and renewable energy technologies are arguably the most important input into the IRP 2 modelling process as the emergent scenarios are largely being assessed on the basis of expected costs".

Other examples that contested the accuracy of the model's assumptions include EarthLife Africa (2010), who stated that the modelling had failed to include externalities in the cost of coal, including mono-nitrogen oxides (NOx) and sulphur oxides (SOx). In June 2010 Mainstream Renewable Power (2010a) stated that the key parameters were "informed by myths around RE technologies and their benefits" and that fossil fuel externalities such as price volatility and carbon taxes had not been included. In sum it found that the modelling relies on an "outdated least cost/levelized cost approach" and would not be able "to accurately model the proper value of a fully diversified supply-side mix".

In an interview, energy analyst (2) described how the IRP's "base plan and selected scenarios" was modelled on an expansion planning software tool named PLEXOS@R (DoE 2010c: 3), which is "very expensive and proprietary" when compared for instance to the IEA's Markal model. S/he added that the Markal model is used extensively internationally, is the official model used in the UK, and is low cost and easy to buy, install and run. Moreover, "Eskom have hardly begun to use PLEXOS@R capabilities" and had not made the model available. In response, WWF–SA commissioned a counter-model called the Sustainable National Accessible Power Planning (SNAPP) tool, developed by the University of Cape Town. Freely available online,[13] this tool allows users to "interrogate proposals for South Africa's new build plan using objective cost analysis, environmental impacts and the reliability of the system" (WWF 2010:22). It allows members of the public to examine the "assumptions and input data and resulting technology choices" of the IRP "without undertaking the complex modelling on which the plan is based". A subsequent report by WWF–SA demonstrated that investing in renewable energy (wind and solar), along with energy efficiency in industry, would provide cheaper electricity for South Africa by 2020 than investing in coal or nuclear power (WWF 2010).

37.7   Conclusion

The case of the IRP's negotiation process illustrates Keeley and Scoones's (2003: 3) claim that policy "is co-constructed across space, through particular networks and connections linking global and local sites", particularly in cases where "national science capacity is weak and under-confident". As we have witnessed, "a lack of interrogation of the nature of expertise in the policy-making process conceals important power dynamics" (Keeley/Scoones 2003: 5). The nature of the plan's negotiation process further illustrates how vested interests are embedded in the technical expertise employed and/or created by government, with the technical task team as the most obvious example. This links to Jasanoff's (2003: 160) claim that "far from being neutral and apolitical, scientific research follows the preferences of those with the power to set research agendas". For this reason, she continues, "expertise has legitimacy only when it is exercised in

---

13 Available at: <http://www.erc.uct.ac.za/Research/Snapp/snapp.htm>.

ways that make clear its contingent, negotiated character and leave the door open to critical discussion" (Jasanoff 2003: 160).

The IRP process further demonstrates that an assumed technical exercise, such as electricity modelling, can be deeply political, and that technical and political processes are "deeply intertwined" (Keeley/ Scoones 2003: 5). While the public consultation process claimed a relatively high level of participation, the 'technical task team' in which coal miners and energy-intensive users were dominant had the greatest influence over the modelling process, which was itself opaque and subject to contradictory assumptions. This illustrates the privileged access that stakeholders of the country's minerals-energy complex still retain over decision-making processes in electricity policy, as compared to interests in the emerging renewable energy niche, or organizations concerned with social and environmental justice. This relates to Smith, Stirling and Berkhout's (2005: 1505) assertions, who find, in writing about the sociotechnical transition, that "actors more intensively involved than others in system reproduction enjoy quite powerful positions, benefit strongly from the *status quo*, and occupy important gate-keeping positions".

The role of politics in the relationship between energy and industry is central to this case study given that South Africa's energy-intensive users are also the country's major coal miners. They therefore have vested interests in both supply and demand. As Moe (2010: 1733) states, "vested interests tied in with the existing industrial and energy regime is the main factor standing in the way of structural change ... and the state the main actor capable (or incapable) of dealing with these vested interests". However, where the state lacks capacity, vested interests have a wide scope to intervene in policy-making (Hajer 2002). Consequently, powerful actors are likely to undermine the implementation of the 'right' policies (Scrase/Smith 2009:710). As Fine (2009: 38) asserts, "even if the conglomerates know best and have the best capacity, they do not necessarily do best ... those with superior resources may have unacceptable motives and pursue them dysfunctionally for the rest of the population and even for themselves".

Returning to the MLP as a framework for the analysis of sociotechnical change, it can be argued that in order to meet the needs of the country's energy-intensive export-oriented growth trajectory, South Africa's IRP has simultaneously allowed for the entry of a low carbon niche at the same time as supporting the expansion of the incumbent coal-based regime, whilst facilitating the potential introduction of nuclear energy. Clearly the MLP operates within a much messier, less linear, less predictable and more ambiguous reality than is often implied, and this is often ignored in policy interventions. Leach, Scoones and Stirling (2010) refer to such a reality as "dynamic complexities".

In analytical terms this poses a challenge to the way in which the conceptual and geographical boundaries of a sociotechnical transition within the MLP should be defined, given that what can be considered a sustainability transition at one level may be contributing to a much less sustainable trajectory of supply and demand at another. What is also significant is that this demand has international linkages far beyond the national boundaries of South Africa, which reiterates Smith, Stirling and Berkhout's (2005: 1504) assertion that the regime does not align neatly within the confines of the nation state.

To a certain extent, groups involved in the IRP consultation process succeeded in getting their preferences adopted. Hence, rather than a definitive move away from one technology to another, it leaves the door open for various different technological configurations in which, for time being at least, coal is still set to dominate. At the same time, it can be argued that coal stakeholders have had to compromise a certain level of access, aligning with Meadowcroft's (2011: 72) assertion that political action on sustainability is hampered by uncertainties and that "intervention disrupts established entitlements". As we have witnessed in the case of the IRP, the real politics of sustainability is a "site of conflict" and involves making hard choices and picking winners and losers, particularly among competing technologies and the capital that backs them, as money invested in one particular technological pathway cannot be invested in others (Meadowcroft 2011: 72). For this reason, changes to "the regulatory frameworks within which economic actors conduct their affairs ... are essential to encourage sustainability transitions. And that such changes can only be engineered through political processes, and legitimized and enforced through the institutions of the state. So whatever else they may be, sustainability transitions are inherently political" (Meadowcroft 2011: 71).

Despite plans for significant diversification in the electricity mix, demand is still projected to increase significantly, albeit at a lesser scale than originally planned. As previously discussed, this demand is led by the country's mining and related manufacturing sector which consumes over half the country's elec-

tricity supply. Such a trajectory, it can be argued, undermines claims of a transition to sustainability and reveals the fundamental disconnect between the creation of a lower carbon electricity mix and industrial demand. This can be related to Geels, Elzen and Green's (2004: 6) assertion that in order for transitions to take place, they must do so in a co-evolutionary way, involving both supply and demand. On a similar note, Marquard (2010) argues that, "viewing demand as God-given leads to an obsession with low prices resulting in overinvestment, surplus capacity, very low prices, and even faster demand growth, and then incentivization of energy-intensive industries".

Returning now to discussions of a 'just transition' as discussed in 37.2, it is important to note that while the IRP will facilitate a renewable energy niche, its ability to address issues of energy poverty and access to energy for the poor appears to be limited. The plan will contribute to the ongoing increase in electricity prices and fail to reach the thirty per cent of the population who are not connected to the grid. More broadly, it will not tackle the consumption-led model of economic growth or the high levels of national socio-economic inequality in terms of consumption and access to power (Swilling and Annecke 2012). In conclusion, then, any claims of a transition to sustainability and its governance and policy must be evaluated in the most holistic sense, including social, economic, environmental, financial and technological factors.

38 Low Carbon Green Economy: Brazilian Policies and Politics of Energy, 2003–2014

Eduardo Viola[1] and Larissa Basso[2]

Abstract

Achieving sustainability is a complex issue because of the lack of a precise definition of the term. Very recently, science has acknowledged that the human species has become the main driver of transformations in bio-geo-physical systems, and has identified boundaries to be respected if a systemic planetary disruption is to be avoided. A low carbon green economy—a development model in which environmental concerns are at the same level as economic and social concerns—is a good paradigm for guiding policy-making that aims at respecting these boundaries; and it includes the objective of the decarbonization of energy systems in order to mitigate climate change, the most studied and best understood of the boundaries. Having these parameters in mind, this chapter shows how Brazilian policies and politics of energy evolved in the period between 2003 and 2014. It identifies an upward and later downward trend in the production of energy from low carbon sources, and a stable trend in energy efficiency. It concludes that, despite the higher proportion of low carbon energy sources in the Brazilian energy matrix compared with other countries, Brazil has not yet embraced the low carbon green economy or the decarbonization paradigms: in spite of significant forces promoting both these, important political and cultural features are preventing them from being adopted.

Keywords: Energy governance, low carbon green economy, decarbonization, policy and politics, Brazil.

38.1 Introduction

The transition to sustainability has been on the international agenda since the 1970s and it still generates more heat than light. Complexity and the lack of a precise definition of sustainable development has led to the use of new terms for guiding domestic and international policy-making, including 'low carbon development'—a pattern that sets global climate stability as a condition for national and global economic growth—and 'green economy'—an economy that results in improved human well-being and social equity, while significantly reducing environmental risks and ecological scarcities. However, science has proved that the world has entered a new geological epoch, the Anthropocene, in which human beings are the key drivers of Earth's system transformations; therefore, a low carbon green economy—one that respects the nine planetary boundaries that need to be monitored to prevent a systemic disruption of Earth's systems (see chapter 3 above by Dalby)—is a better guideline for policies that face up to current sustainability challenges.

Applying the 'low carbon green economy' paradigm means changing the way in which policy-making is thought about and enforced. Environmental concerns must be at the same level as economic and social ones. As far as energy is concerned, for instance, reliable energy sources and access to energy for all are not enough: energy production and consumption need to decrease their impact on the environment; in order to respect climate stability, the most studied and best

E-mail: <larissabasso@gmail.com>

understood of the planetary boundaries, energy must be decarbonized. Investing in energy efficiency and employing low carbon sources–especially renewable sources–to produce energy is a must.

Brazil has a relatively low carbon energy matrix, compared to other countries: 46 per cent of its total primary energy production and 42.4 per cent of its total primary energy supply[3] come from low carbon sources (EPE 2013: 21–22). In fact, *land use, land use change and forestry* (LULUCF) have traditionally been the major drivers of Brazilian greenhouse gas (GHG) emissions. Deforestation has been successfully tackled in recent decades: by about 2008, LULUCF was no longer the main source of Brazil's emissions. The year marked a new upward trend in emissions induced by the effects of enhanced economic development:[4] emissions from energy, agribusiness, industry, transportation and waste treatment had increased (Brasil 2010; Brasil 2013; Lapola/Martinelli/Peres et al. 2014).

When it comes to the challenge of embracing the 'low carbon green economy' paradigm and the central role of energy in achieving an embedded challenge, that of decarbonization, given that energy accounts for more than 60 per cent of global GHG emissions[5] it is very relevant to understand how energy policy and politics evolve. There are hardly any academic papers about energy in the transition to a low carbon green economy, and only a few analyse the evolution of low carbon energy sources and energy efficiency in Brazil. This chapter aims to address this topic. Further reflections on how energy policy-making should be designed to respect the other eight planetary boundaries are needed.

The chapter focuses on how Brazilian energy policy and politics evolved between 2003 and 2014. The topic will be explored in sections. First, a reflection on the definition of low carbon green economy, and how decarbonization is embedded in it. Next, an analysis of the Brazilian energy matrix transformations and energy policy and politics between 2003 and 2014. This analysis will show (i) two trends in the production of energy by low carbon sources: first an upward trend, where these sources in the energy matrix increased, and then a downward trend, due to the discovery of deep offshore oil reserves and the use of oil prices as a heterodox policy tool to artificially maintain greater economic growth rates; and (ii) a stable trend in energy efficiency: no consistent development of policy and politics during the decade. Finally, some traits of Brazilian culture that hinder the implementation of a low carbon green economy in general, and of decarbonization in particular, will be described, focusing on 'crony capitalism' and short-term thinking. The conclusion argues that Brazil has not yet embarked on a low carbon green economy paradigm, and serious planning and long-term goals, including tackling deep-rooted cultural traits, are needed.

38.2   Low Carbon Green Economy

Sustainability has been on the international agenda since the *United Nations Conference on the Human Environment* (1972), when it was stated that development should consider its impact on the environment. In 1987, the *Brundtland Report* was released; it defined sustainable development as "development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (WCED 1987). This concept was adopted by the *United Nations Conference on Environment and Development* (UNCED 1992), and has become the leading guideline for international and national policies directed towards sustainability. However, the term is very loose. It does not translate the impact of human development patterns in the environment, nor the action necessary to mitigate them. For this reason, other definitions have been developed, among which are 'low carbon development' and 'green economy'.

Low carbon development aims at a consistent reduction of GHG emissions per GDP unit (beyond the 'normal' reduction derived from business-as-usual economic development). By reducing carbon emissions, economic growth and climate stability become structurally compatible (UNDESA 2012: 51). The concept was developed within the scope of the *United Nations Framework Convention on Climate Change* (UNFCCC) and gives, in fact, a clear direction to policy-making.

Still, it is not enough, because the world has entered a new geological epoch. Humanity has developed during the Holocene, the era that started approximately 11,000 years ago, when the last glaciation ended and the climate became warmer and more stable. During this period, human beings changed

---

3   Excluding and including energy imports, respectively; 2012 data.
4   While LULUCF accounted for approximately 57 per cent of total emissions in 2005, its share was approximately 23 per cent in 2010.
5   Data are available at <http://www.grida.no/graphicslib/detail/world-greenhouse-gas-emissions-by-sector_6658>, (15 Dec 2013).

from a few groups of hunter-gatherers to a complex population of seven billion people, most of whom require an unprecedented amount of Earth's resources to live. The expansion of human population—both in numbers and in per capita exploitation of the Earth's resources (Crutzen/Stoermer 2000)—was such that it became the driver of the transition to a new geological epoch, the Anthropocene. This is unprecedented: from the evidence currently available, all previous changes in Earth systems were caused either by Earth's natural dynamics or the dynamics of the cosmos; instead, in the Anthropocene, human beings are the main drivers of transformations in Earth systems (Crutzen/Stoermer 2000; Viola/Franchini/Ribeiro 2013; see chapter 3 by Dalby in this volume).

The concept of a 'green economy' was developed in order to deal with this new reality. There is no official definition of a green economy, but the one most frequently used refers to an "economy that results in improved human well-being and social equity, while significantly reducing environmental risks and ecological scarcities" (UNEP 2011). The concept was discussed during the *United Nations Conference on Sustainable Development* (UNCSD 2012), but there was no agreement to make it more prescriptive—the final report of Rio+20 states that a 'green economy' is "one of the important tools available for achieving sustainable development and that it could provide options for policy-making but should not be a rigid set of rules" (UNCSD 2012). Even if it represents an evolution from the loose concept of sustainable development, this more recent definition of a green economy[6] remains almost as elusive as the former definition, unable to guide effective policy-making.

A more precise concept should acknowledge the nine biophysical planetary boundaries science has identified whose transgression would lead to a planetary disruption of Earth systems, a disruption which would threaten life on Earth, especially human life: (i) climate change, (ii) biodiversity loss, (iii) the nitrogen cycle and the phosphorus cycles, (iv) stratospheric ozone depletion, (v) ocean acidification, (vi) global freshwater use, (vii) change in land use, (viii) aerosol pollution, and (ix) chemical contamination (Rockström/Steffen/Noone et al. 2009). Three of the boundaries have already been already trespassed on. First, the nitrogen cycle, due to the massive use of

nitrogenized fertilizers since the 1950s. Second, biodiversity loss, especially since the 1970s, when an expanded human population started impacting natural ecosystems and other species to the point of exhausting them. Third, climate stability, due to the accumulation of GHG in the atmosphere—currently, 400 part per million (ppm),[7] when the safe boundary is 350 ppm. Trespassing on the boundaries indicates that change is needed, and urgently: development must take into account its effects on Earth's equilibrium and on human survival in the long term; yet policy-making is stuck in an outdated framework, incapable of establishing a new development pattern.

Take, for instance, climate change. Of the nine planetary boundaries, climate change is the most studied and best understood by science; yet tackling it is still a great challenge, because of the discrepancy between the nature of the issue and the characteristics of current political models. Climate change has been defined as a truly wicked or diabolical problem because its complexity defies standard problem-solving (Prins/Galiana/Green et al. 2010; Steffen 2011). First, it is intrinsically global: it is led by changes in the concentration of GHG in the atmosphere, a global common good. However, there are no institutions for direct global policy-making: policy-making is still mostly carried out by nation states that only occasionally cede small shares of their sovereignty to international institutions. Second, climate change is not linear (see chapter 11 by Schellnhuber et al. in this volume): vulnerabilities to and responsibilities for the problem are skewed—the poorest in every society usually contribute the least to the problem, but suffer its effects the most. Third, climate change operates on a timescale beyond human daily experience, so the appeal of passing the burden to future generations is always present. Climate is a key civilizational driver, together with the expansion and deepening of globalization and the diffusion of democracy (Viola/Franchini/Ribeiro 2013). Yet policy-making has only marginally faced up to the challenge of its stabilization, especially in the international arena.

After signing the UNFCCC, in 1992, countries have tried to build a multilateral framework to tackle climate change. In 1997, by signing the Kyoto Protocol, countries agreed on limited compulsory GHG reduction emission targets (seven per cent reduction

---

6   The European Union proposed a more scientifically based concept of green economy, which was vetoed by the BRICS countries, the United States and most developing countries.

7   The concentration of GHG in the atmosphere was 401.85 ppm on 12 June 2014, according to the Carbon Dioxide Information Analysis Center. Data are available at <http://cdiac.ornl.gov>, accessed 19 June 2014.

in twenty years) for developed countries (Annex I countries) and on mechanisms for their implementation; emerging economies rejected any commitment to reduce the curve of emissions growth (moving out from business-as-usual scenarios). For this reason, and fearing what it considered unfair competition in global markets, the United States withdrew from the protocol in 2001 (Viola 2002). This was the first setback for the protocol: in 1997, mandatory commitments covered countries responsible for 65 per cent of global GHG emissions, but the amount was reduced to around 45 per cent when the United States left. The second setback occurred in 2012, when the period in which the protocol was to be in force expired. At that moment, Japan, Canada and Russia decided not to sign the extension of the protocol,[8] so countries currently obliged to reduce GHG emissions—the European Union, Switzerland, Norway and New Zealand—account for only 13 per cent of the global amount.[9]

Discussions to establish a new legally binding agreement have advanced by the presentation of *Intended National Determined Contributions* (INDCs) by the members of UNFCCC prior to the Paris Conference, in December 2015. There has been some advance toward an agreement, even if it will be short of what science identifies as needed to guarantee climate stability. Only European Union's pledge to reduce emissions is in tandem with what science defines as needed to avoid serious climate change. The United States, Canada and Japan pledges have 2005 as baseline, and none means substantial reduction of GHG emissions when translated into 1990 baseline. China committed to peak its emissions by 2030, but Chinese emissions are expected to reach 35% to 40% of total global emissions by then. India did not commit to peak emissions. Mexico promises reductions regarding a business as usual scenario. Russian commitments are poor considering that the baseline is 1990 and after that Russian emissions were reduced in more than 50% due to economic collapse. Brazil pledged to cut 37% of its GHG emissions until 2025, compared to 2005 levels, and 43% until 2030, an important advance compared to previous pledges.

Yet, commitments for specific sectors are either not ambitious (energy, easily met before 2025, raising concerns over the increase of fossil fuels in the energy matrix), or too broad (agriculture, transport and industry), or shameful (LULUCF, as Brazil pledges to zero illegal deforestation only by 2030).

It is clear that current policy-making patterns are not going to achieve the results that are needed to mitigate climate change. This is so because mitigation requires the implementation of measures that interfere with core issues of the contemporary lifestyle, such as energy sources and use, institutions, governance, economic organization and values (Steffen 2011: 21; Jamieson 2011: 38–42). It has been said that it "will only be successfully achieved as a benefit contingent upon other goals which are politically attractive and relentlessly pragmatic" (Prins/Galiana/Green et al. 2010). However, a clearer paradigm guiding national and international policy-making may be helpful.

The concept of low carbon green economy aims at doing this.[10] It has three main assumptions: (i) the nine planetary boundaries identified by science should be respected to prevent a systemic disruption of Earth systems—starting with climate change, since science has already produced clear indicators on how to achieve climate stability; (ii) economic growth should be guided by equity; (iii) population dynamics should be considered a central issue (Viola/Franchini 2012b). If this concept is applied, development will involve a balance of economic, social and environmental aspects (Viola/Franchini 2012b). Environmental concerns become embedded: they should be incorporated in any policy-making as one of its pillars.

Under the low carbon green economy paradigm, energy policies must take into account the environmental impacts of producing and using energy. It is not enough to guarantee energy security and energy access; the processes by which energy is produced and distributed are relevant. For example, if climate change is to be mitigated, stabilizing the concentration of GHG in the atmosphere is necessary. This can

---

8 In 2012, countries agreed on an extension of the Kyoto Protocol from 2013 to 2019. In 2015, it is expected that they will have agreed on the terms for a legally binding agreement to replace the Kyoto Protocol from 2020 onwards.

9 2013 figure, data from the US Environmental Protection Agency, available at <http://www.epa.gov/climatechange/ghgemissions/global.html>, accessed 9 July 2014.

10 The paradigm was inspired by the European Commission communication "Rio+20: towards the green economy and better governance", released ahead of the UNCSD 2012 Conference, and the UNDP Report "Green Economy in action: articles and excerpts that illustrate green economy and sustainable development efforts"; but by acknowledging the need to respect the nine planetary boundaries before a systemic planetary disruption, as well as equity in economic growth and population dynamics, it goes further as a concrete policy guideline.

be done either by reducing emissions or capturing and storing carbon (CCS) (UNFCCC 1992); but since CCS is still a limited option (IEA 2013a), it is imperative to reduce emissions. Energy supply and use accounts for more than sixty per cent of the world's GHG emissions, and it is likely that this share will increase even more once emerging economies achieve higher levels of development. Energy systems must be decarbonized, and decarbonization depends to a large degree on increasing energy efficiency and disseminating low carbon energy sources (Viola/Franchini/Ribeiro 2013), especially among the biggest energy producers and consumers. Brazil is one of these.

38.3   The Brazilian Energy Matrix and its Transformations (2003–2014)

Brazil is a big country, in all aspects: it has a territory of 8,514,215 km2, the fifth largest in the world; as one of the emerging countries, Brazil is boosting its international power assets: it is among the ten biggest economies—economic growth averaged 3.6 per cent a year between 2003 and 2012, compared with 2.8 per cent during the previous decade,[11] and it has considerably reduced inequality–from a Gini score of 57.78 (2003) to 54.70 (2009).[12] It has limited military power, despite its increased role in peacekeeping and human rights missions, but has important soft power assets (Nye 2011): it is a pacific, multi-ethnic, multicultural and multi-religious country, with magnificent nature and extraordinary tourism potential. Between 2003 and 2014, Brazil's enhanced international role could be seen in several different arenas, including energy governance in the transition to a low carbon green economy: it is among the eight largest GHG emitters; with 190,732,694 inhabitants (IBGE 2010), it is the eleventh largest energy producer and seventh largest energy consumer;[13] and it already occupies the fifth place among producers of low carbon technology[14] (WWF/Roland Berger 2012; The Pew Charitable Trusts 2012).

Brazil is generally self-sufficient in energy: it imports natural gas from Bolivia, and oil and coal from several countries, but in amounts that are small compared with its domestic production. The same is true of hydroelectricity, where a small amount is imported from Paraguay. It has developed world-renowned technology for exploring deep offshore oil reserves, and it is a world leader in hydropower technology (especially in designing reservoirs) and in producing electricity and fuel from sugar cane.

With its large territory located in a warm climate, its relief system of plains and plateaux, and its extensive drainage basins, Brazil has enormous potential for developing renewable energy. In fact, it is safe to say that, given the currently available technology, Brazil has one of the world's biggest potentials for renewable energy resources. The reality, however, does not match the potential. From 2003 to 2012, both Brazilian energy production and domestic supply increased by approximately 40 per cent; however, during the same period, energy production and energy supply from non-renewable sources increased by 42.5 per cent and 45 per cent respectively, and from renewable sources by only 37 per cent and 36 per cent respectively. The data show that non-renewable energy sources answered for a greater share of energy production and supply in Brazil during the decade from 2003 to 2012.

When it comes to energy efficiency, the picture is even gloomier. Energy efficiency is crucial for a low carbon green economy. In fact, due to (i) the time span required for research and development into low carbon energy sources, and (ii) the intrinsic need to reduce energy consumption so as to assimilate a low carbon way of living, and given that saving energy reduces costs and enables resources to be used for something else, investing in energy efficiency is the most rational choice for achieving low carbon development. Yet in Brazil, energy efficiency plays second fiddle to the expansion of energy supply: from 1984 to 2004,[15] the amount of energy effectively employed in final use (in relation to total energy input) increased from 46.9 per cent to merely 57.8 per cent (EPE 2013, 193); performances in many sectors were even poorer, for example, from 31.4 per cent to 37.5 per cent in transport (EPE 2013, 193) ; compared with the US,

(*) Includes wind and solar.

Brazilian truck freight consumes 85 per cent more fuel (MME 2011).

Why has energy production from non-renewable sources surpassed renewable sources between 2003 and 2014, in a context of increasing national and international debates about the importance of a low carbon green economy and the need to commit to it? And why is energy efficiency such a marginal topic in Brazil? In order to answer these questions, it is necessary to analyse how energy policy and politics evolved in Brazil over the decade.

38.4   Brazilian Energy Policy and Politics (2003–2014)

Energy policy and politics of the last decade are part of the big picture of Brazilian recent economic and political developments and their consequences for domestic politics and international affairs. From 2003 to 2010, Brazil's economy grew faster than the average world economy, due to three factors: (i) a big change in the relative prices of industrial products and primary commodities, favouring the latter—and Brazil is a big exporter of primary commodities—; (ii) the effects of the pro-market macroeconomic reforms carried out during the second half of the 1990s; and (iii)

high rates of *foreign direct investment* (FDI). The redistribution of income was initiated during the Cardoso administration (1995-2002) and deepened in Lula da Silva's administration (2003-2010). This virtuous cycle of economic growth ended around 2010. The consequences of the lack of pension, labour, fiscal, tax and political system reforms—reforms that should have been undertaken in order to finish the process initiated in the 1990s—began to be felt during the Rousseff administration (2011-present): economic growth declined to less than 2 per cent a year; inflation was always significantly above the target defined by the Central Bank (target 4.5 per cent, real inflation around 6 per cent); FDI, compared with the period to 2010, stagnated—although it remains among the highest in the world—as a result of uncertainty generated by federal government interventionism into the economy. Tackling inequality became more difficult with lower growth rates and higher inflation.

Nevertheless, the effects of a stronger economy were felt politically. Very powerful and competitive media and a more attentive society were more perceptive of corruption—corruption was actually lower during this decade compared with previous ones, but there was much more information about it. Brazilian courts demonstrated a level of independence rare in non-OECD countries: core members of the first Lula

administration (except the former president himself) were convicted of corruption offences in 2012. In June 2013, massive demonstrations against corruption and the state of public transport, education and health care surprised political actors and analysts.

Brazil has not yet incorporated the low carbon green economy paradigm; not even a clear decarbonization outcome was envisaged. During the last decade, two trends in low carbon energy sources can be observed: from 2003 to 2007, an upward trend in which progressive forces—committed to low carbon development—were stronger, and the proportion of renewable sources in the energy matrix increased; from 2007 to 2014, a downward trend in which regressive forces—which favour fossil energy sources—were empowered due to the discovery of deep offshore oil reserves and the use of oil prices as a heterodox policy tool to artificially maintain greater economic growth rates and fight inflation. As for energy efficiency, however, the trend was stable: there was no consistent development of policy and politics during the decade.

38.4.1 Energy Sources

38.4.1.1 Fossil Fuels: Oil, Gas and Coal

Oil remains the main source of fuel employed in transportation in Brazil. The Brazilian transport system is not adequate for the country's characteristics and needs: a large country with mostly plain relief, important river basins and an extensive coastline could make a better use of those assets in transportation. Instead, its transport system is highly dependent on roads—terribly built and poorly maintained—, and its cargo fleet employs diesel as fuel.

Brazilian diesel had traditionally been of low quality because of the high level of sulphur in its mix, but recent regulation has attempted to improve it (though very slowly).[16] Despite some delays and implementa-

tion problems,[17] the new regulation contributes to the provision of cleaner air. It has minimal impact on reducing carbon emissions, though: other measures—such as increasing the use of biodiesel or other biofuels in transportation and adopting railways and coastal and inland navigation systems—would bring greater benefits in this area.

The competition between oil/derivatives and renewable fuel prices is not a fair one. Until 2006, the domestic prices of oil/derivatives followed international prices; after that, however, due to the discovery of the deep offshore reserves—and the illusion that Brazil would rapidly become a big producer and exporter of oil—the federal government was misled into using domestic prices as a heterodox economic tool. In 2007, the Brazilian government subsidized oil prices to maintain economic growth rates at a high level, changing the relative prices of gasoline and ethanol and undermining the competiveness of the latter. After the economic crisis that followed the collapse of Lehman Brothers, some contracyclical measures were adopted, including tax exemptions for the automobile industry. The exemptions led to an increase in car ownership and a dramatic increase in fuel demand, while ethanol prices were still not competitive. These heterodox policies enhanced short-term economic growth but increased long-term macroeconomic imbalance and penalized both Petrobras[18]—who faced several important losses—and the ethanol production chain.

General expectations of economic gains from the deep offshore reserves were high between 2008 and 2010. Action by environmentalists was of a very low profile: there was no significant environmental movement to defend exploring low carbon energy sources rather than the new oil reserves. Nevertheless, it was a victory without a battle: while it was expected that exploitation would start soon after the discovery, disputes between state governments over the distribution of revenues from the reserves postponed the auctions (of the reserves) for a couple of years; in this period, economic production of the technology to exploit shale gas was achieved in the US—supposedly the big-

---

16 There are two types of diesel: metropolitan diesel (used in larger cities with poor air quality) and interior diesel (used in smaller cities, roads and other parts of the country). From 2001 onwards, sulphur concentration in the mix began to be limited: 2000 mg/kg for metropolitan diesel and 3500 mg/kg for interior diesel (2001); 500 mg/kg for metropolitan and 1800 mg/kg for interior diesel (2005–2006); 50 mg/kg for metropolitan and 500 mg/kg for interior diesel (2009, coming into force in 2013); finally, 10 mg/kg for metropolitan (2013). See National Oil Agency (in Portuguese, ANP) Resolutions nr. 310/2001, 12/2005, 15/2006, 31/2009, 42/2009, 65/2011 and 50/2013.

17 E.g. the 500 mg/kg sulphur concentration goal in metropolitan diesel, determined in 2006, was not achieved until 2012, due to technical problems at refineries and in the automotive industry; the switch to S500, determined in 2009, was delayed in some cities by up to fifteen months.

18 Petrobras is the most famous Brazilian energy corporation. It is worldly known for its vanguard technology to explore oil in offshore platforms.

gest market for the Brazilian deep offshore oil—and Mexico passed a bill that would end PEMEX monopoly over oil, facts that appealed to American companies such as Chevron and Exxon Mobile; Petrobras, whose participation in the auction was obligatory due to the requirement to include national companies in the exploitation, had lost the financial capacity to act due to the continued losses it faced through subsidizing oil derivatives. In 2013, when only one consortium presented itself at the auction for the exploitation of the Libra field, enthusiasm for deep offshore oil reached its lowest point. Subsidies for gasoline peaked in 2014—in fact, estimates indicate that gasoline would cost on average thirty per cent more without the subsidies.

The use of natural gas in Brazil more than doubled during the decade. This is a progressive trend, especially when natural gas is employed in place of gasoline or diesel (in part of the metropolitan transport system and taxis) and coal (in industries, especially in Sao Paulo state after the building of the gas pipe from Bolivia). Nevertheless, the share of gas in the Brazilian energy matrix is still very small; it could be bigger if there were incentives to employ natural gas in the thermal power plants that currently rely on oil or coal. Nowadays, some old practices, such as gas flaring on offshore oil platforms, are beginning to be condemned by (a minority in) Brazilian society; it is expected that this trend will increase and a more environmentally-friendly use of this gas will become mandatory in Brazil. The rational use of the flared gas is also an argument against the exploitation of shale gas: Brazil has important reserves, but it lacks the technology, infrastructure (pipes and transport) and policies (incentives for its production and the creation of a market) that are vital for its exploitation.

Coal has never been a relevant energy source in Brazil. The quality of Brazilian coal is low; it is employed mostly in producer regions, such as the south of the country. Brazilian society is against the use of coal, and groups in favour of it have very limited appeal. Recently, the steel industry, the largest consumer of coal in Brazil, has started to employ vegetable charcoal from planted forests to replace the charcoal from native forests that was used previously,[19] an important advance towards sustainability and a low carbon green economy. The greatest backwards step involving coal is its inclusion among the accepted

sources for electricity generation in Brazil: in August 2013, the federal government authorized coal's participation in future auctions for electricity, along with hydropower, natural gas and biomass.

38.4.1.2 Hydropower

Hydropower is the main source of Brazilian electricity. In 2012, 70.1 per cent of Brazilian electricity production and 76.9 per cent of the Brazilian electricity supply[20] came from hydro (EPE 2013: 16). From 1920 to the 1970s, relying on hydropower for electricity generation was a 'natural' process in a country with little coal and oil; after 1973, the process gained strategic importance due to concerns about energy security in the context of world oil crises. Brazil has one of the world's greatest hydropower potentials, but most of its southern river basins are already largely exploited; 70 per cent of the remaining potential is located in Amazonian basins (Eletrobras 2012),[21] a region with complex ecosystems and where it is of great importance to maintain the local and regional climate and biodiversity.

Most of Brazilian hydroelectricity comes from hydropower plants that have an installed capacity of at least 30MW and a reservoir larger than 3 km2, called by the Brazilian government and in this article *Usinas Hidrelétricas* (UHEs). Most UHEs were built between 1968 and 1984, when lower environmental standards were in force and financial resources, both national and foreign, were available. Since 1985, it has become much more difficult to license a new UHE; many of those projected had their construction postponed or disrupted due to further environmental demands and the fiscal crisis of the Brazilian state. It was mainly after the 2001 crisis in the electricity supply[22] that the federal government resumed efforts to build new hydropower plants, including several in the Amazon region—not without controversy (table 38.2). Two of the biggest sources of controversy are run-of-the-river technology and the impact of UHEs on the indigenous populations of the Amazon forest.

---

19 The Climate Change law prescribes the substitution of mineral coal with charcoal from planted forests, but this prescription has not been implemented yet.

---

20 Excluding and including electricity imports, respectively.
21 According to official data, the rivers of the Amazon basin have 34,000 MW of hydropower potential not yet explored.
22 In 2001, the Brazilian electricity supply was disrupted after an abnormal dry summer reduced water levels at key dams; the government rationed electricity, and fossil-fuel thermal power plants were put into operation as a backup system.

Table 38.2: UHEs in the Amazon region (Amazon basin and Tocantins-Araguaia basin). **Source**: Author's elaboration, based on data from Agência Nacional de Energia Elétrica—Banco de Informações sobre Geração; at: <http://www.aneel.gov.br/aplicacoes/capacidadebrasil/GeracaoTipoFase.asp?tipo=1&fase=3>, and Programa de Aceleração do Crescimento—PAC; at: <http://www.pac.gov.br/infraestrutura-energetica/geracao-de-energia-eletrica> (26 July 2014). PCHs and UHEs under study or not found on any of the government websites above are excluded from the table.

Tucuruí I and II	Tocantins	8,535.00	8,535.00	In operation since 1984

Run-of-the-river technology was developed to accommodate demands from both environmentalists and defenders of development at all costs. This technology allows for smaller reservoirs to be created, so, in theory, it diminishes the impact of hydropower on the environment—especially on biodiversity. Nevertheless,

the results obtained from the Amazon UHEs are, to date, ambiguous.[23] For hydropower to be efficient, the amount of water that goes into the turbines must remain constant over time. River flows change over the course of the year, so either dams or backup systems must be built to maintain electricity production at a stable rate. Amazonian rivers present great hydrological variation over the seasons; by applying run-of-the-river technology to the basin, the choice of backup system becomes ever more relevant—and, sadly, in recent years, this role has been played by fossil-fuel thermal power plants. Therefore, when the aggregate impacts—impacts from the plant plus impacts from the backup system—are taken into account, it is not a straightforward conclusion that a run-of-the-river UHE in the Amazon region would cause less environmental impact than a UHE with a large reservoir built in the same or another region of the country.

The impact of UHEs on indigenous populations is a great source of conflict in Brazil. Take, for instance, the UHE Belo Monte. It is a controversial project. First attempts at implementation—including the building of a large dam—date from the second half of the 1980s, but these failed in the face of strong opposition from both environmentalists and indigenous people, as well as the fiscal collapse of the Brazilian state. In the second half of the 2000s, the project was redesigned to apply run-of-the-river technology. In 2010, the construction contract was signed, and in 2011 the environmental licence was issued. The construction is advancing; it has, however, faced several legal battles, including disputes between the Brazilian federal state and the Inter-American Court of Human Rights.[24] Public opinion is mostly against the project, because of both the environmental impact and the impact on

indigenous populations. UHE projects in the Tapajos River face the same controversy.

Adding to the controversy, the federal government has changed some environmental laws to speed up the construction of new UHEs in the Amazon region. In 2011, the boundaries of several national parks and national forests were modified, and areas judged to be flooded were excluded from the obligation to be preserved.[25] The government is also postponing the demarcation of indigenous lands—a potential retaliation to demands from indigenous populations to be consulted about the projects, since they will be built on land that the indigenous populations have historically occupied. On several occasions in 2013, the indigenous population of the Tapajos River area demanded prompt and diligent action regarding this matter from government officials.

Plans to construct hydropower plants in Peru in order to export electricity to Brazil were also developed. In 2010, Brazil and Peru signed an Energy Agreement[26] specifying the construction of six hydropower plants in the Peruvian Amazon: the plants would be built with Brazilian money (both private and public); the electricity produced would be directed to the Peruvian market, but the surplus would be exported to Brazil; and, after thirty years, the ownership of the plants would be Peruvian. This measure is also highly controversial: part of the Peruvian population, in the manner of a traditional South American ideological dispute, argue that the country has

23 Of many works on the environmental impacts of dams, three sets of international guidelines are especially recommended: World Commission on Dams: *Dams and Development: A New Framework for Decision-Making* (2000); at: <http://www.internationalrivers.org/files/attached-files/world_commission_on_dams_final_report.df>; International Hydropower Association: *IHA Sustainability Guidelines* (2004): at: <http://www.ydropower.org/downloads/IHA%20Sustainability%20Guidelines Feb04.pdf> (7 November 2013); IEA Hydropower Agreement, *Annex III—Hydropower and the environment: present context and guidelines for future action*; at: <http://www.ieahydro.org/reports/HyA3S5V2. pdf>, revised in 2010: *Update of Recommendations for Hydro-power and the Environment*; at: <http://www.ieahydro.org/uploads/files/finalannexxii_task2_briefingdocument_ oct2010.pdf> (7 November 2013).

24 In 2011, the Inter-American Court of Human Rights, following a claim presented by NGOs that the UHE Belo Monte would create social and environmental impacts not covered by the environmental licensing in process, asked Brazil to suspend the licensing. The request came after the Brazilian government had answered several demands from the Court on the same issue, and was not welcomed. The relationships between the country and the Court reached its lowest ebb; Brazil has occasionally supported the pledge by Venezuela, Ecuador and Bolivia to diminish the Court's powers concerning interventions on matters of human rights.

25 Law 12.678/2012, available at <http://www.planalto.gov.br/ccivil_03/_Ato2011-2014/2012/Lei/L12678.htm> (13 January 2014).

26 Agreement between the government of the Federal Republic of Brazil and the government of the Republic of Peru for the supply of electricity to Peru and exports of surplus to Brazil, available in Portuguese at <http://dai-mre.serpro.gov.br/atos-internacionais/bilaterais/2010/acordo-entre-o-governo-da-republica-federativa-do-brasil-e-o-governo-da-republica-do-peru-para-fornecimentos-de-energia-eletrica-ao-peru-e-exportacao-de-excedentes-ao-brasil> (12 January 2014).

become the subject of Brazilian imperialism, since there is an imbalance between the large social and environmental impacts of the hydropower plants on local communities and the small benefits for the Peruvian population (whose energy demand is low and could be met without the new projects). Peruvian indigenous populations are challenging the Agreement by arguing that they should have been consulted before the government signed it, since their interests are at stake. The treaty is not yet in force and its ratification was delayed, although some of the projects are at an advanced stage of planning.

An alternative is building hydropower plants with an installed capacity between 1 and 30 MW and reservoirs smaller than 3 km², referred to as *Pequenas Centrais Hidrelétricas* (PCHs).[27] PCHs are an important alternative source of hydroelectricity: they can be located near consumer regions, reducing transmission costs; their smaller dams also reduce the environmental impact; their employment on a large scale increases the redundancy of electric systems, reducing the risks of blackouts during peak demand hours. They were included among the renewable energy options in the *Alternative Energy Sources Incentive Programme* (in Portuguese, PROINFA).[28] Between 2004 and 2011, PCHs sold around 1,800 MW in electricity auctions (Nogueira/Costa 2012); nevertheless, they produce only 3.63 per cent[29] of Brazilian electricity. Unlike other renewable sources, PCHs are not acknowledged by public opinion; the political strength of groups related to UHEs prevents the development of policies that would benefit this energy source.

Another alternative would be to diversify Brazil's renewable electricity sources, by making serious investments in wind and solar power and using hydropower as a reserve source. The complementarity between wind and hydroelectric power, for example, is scientifically proven (Amarante/Schultz/Bittencourt et al.

2001; Jaramillo/Borja/Huacuz 2004; Dutra/Szklo 2008; Ricosti/Sauer 2013). Brazil has great wind and solar power potential, and their intermittency can be compensated for by hydropower, saving the environmental and economic costs of accumulators. The world already has cases of successful joint exploration of the sources.[30] Joint exploitation in Brazil is not wishful thinking: the country already has the *National Interconnected System* (in Portuguese, SIN), an extensive electricity grid that connects the whole country;[31] however, massive investment would be needed in order to make the grid a smart one.

38.4.1.3 Ethanol

Brazil is the leading producer of ethanol from sugar cane. The high price of oil during the crises of the 1970s and reasons of energy security played important roles in encouraging its use as fuel—back then, reasons of sustainability were absent. With Brazilian government incentives and subsidies, large sugar cane plantations were established, mainly at São Paulo and in the north-eastern states of Pernambuco and Alagoas. In the 1990s, due to a severe crisis in supply, ethanol's role as a biofuel faded; it came back into the spotlight in 2003, after the development of flexible fuel technology.

Brazilian ethanol does not compete with food production. Brazil has more than 200 million hectares of land occupied by cattle grazing, almost half of which is degraded land no longer in use or used but with very low productivity; sugar cane plantations occupy around six million hectares. It is also important to note that Brazilian sugar cane production is currently concentrated in São Paulo state and the surrounding areas, and there is no prospect of expanding it into the Amazon region (Goldemberg 2008), so ethanol cannot be blamed for Amazonian deforestation, though it could be for the conversion of the Cerrado savannah.[32]

Ethanol has faced unfair competition with gasoline since 2007, when the federal government began

---

27 ANEEL Resolution 304/98.
28 The policy was enacted by the federal government in 2002 and was regulated in 2004. It specifies that ten per cent of Brazil's energy supply in the 2020s should to be produced by alternative renewable sources, and lists small hydropower plants, wind and biomass among them. After 2004, these sources took part in the federal government's auctions for electricity, sometimes selling important amounts, but still facing difficulties in competing with traditional sources due to the minimum cost criteria employed in the auctions.
29 Data from <http://www.aneel.gov.br/aplicacoes/capacidadebrasil/capacidadebrasil.cfm>, accessed 12 February 2014.

---

30 For example, the partnership between Denmark, a big producer of wind energy, and Norway, a big producer of hydroelectric power.
31 There are some isolated systems in the north of the country.
32 Until 2007, the expansion of the ethanol industry was an indirect driver of deforestation in the Amazon, because some areas in which there was substitution of cattle raising and soybeans were pushed in the Amazon by ethanol. Since 2008, it has not happened any more.

to subsidize oil prices, reducing the competitiveness of ethanol. Its competitiveness is also affected by the transportation system: since Brazil has not developed a piped distribution system and other transport options are underdeveloped, ethanol travels around Brazil on trucks fuelled with diesel. It is a true paradox: oil prices affect ethanol prices even when there is no direct manipulation by the federal government, just by adding the freight costs to the price of the biofuel.

From 2005 to 2007, ethanol played an important role in Brazilian diplomacy. Brazil supported the creation of a global market for ethanol, and tried to make it an international commodity. It has exported technology and established partnerships in order to develop ethanol markets in various countries such as Colombia, El Salvador, Honduras, Argentina and some African countries; multinational companies (Shell, Petrobras and Chevron) bought assets from ethanol companies during this period. This situation suited the Brazilian national interest but not the positions of China, India and Indonesia, who were Brazil's allies in climate negotiations, and it did not last. By the time the deep offshore oil was discovered, ethanol vanished from Brazilian official speeches, as did investment in ethanol companies.

It is uncertain how ethanol will develop over the next few years. Brazilian public opinion favours the biofuel, but few groups are mobilized or understand the big picture. A clear example is the positive connotation the federal government subsidies for gasoline had for the average Brazilian. If there is no revolutionary change in the next few years (creating strategic reserves to avoid price volatility and maintain reliability of supply; investing in the production of pure ethanol vehicles), it is likely that ethanol will remain a fuel of secondary importance in Brazil. Other important obstacles to greater ethanol production are the influence of oil and gas groups in the government and the misconception that investing in ethanol implies a further commoditization of the Brazilian economy and another step towards the Dutch disease.[33] In the international market, competition with ethanol from corn produced by the US, and a possible ethanol from cellulose produced in the US and Europe, undermines the possibility of the export of significant quantities of Brazilian ethanol.

38.4.1.4 Biodiesel

Biodiesel production is still in its infancy in Brazil. Created in 2005, the National Biodiesel Programme aims at increasing the uptake of biodiesel nationally. Following its creation, several regulatory developments[34] established a minimum percentage of biodiesel in the diesel mix; there is no pure biodiesel in Brazil.[35] Biodiesel currently being produced is mixed with the diesel used by the freight sector: type B diesel has eight to ten per cent biodiesel in its mix.[36]

Soybeans are the main source of Brazilian biodiesel; despite the proven possibilities of making biodiesel out of other vegetable species,[37] these crops are mostly produced on small family farms, making it difficult for the crops to be commoditized and sold on a large scale. Just like ethanol, biodiesel production cannot be blamed for deforestation: the share of soybeans employed in biodiesel production is almost insignificant when compared with the share exported for human and animal consumption. The situation could change if the federal government's predicted incentives and subsidies for biodiesel production should materialize in the next few years.

In order to become a competitive biofuel in Brazil, biodiesel needs to go through a technological and economic transformation revolution, and this is unlikely to happen in the near future.[38]

---

33 Dutch disease refers to the relative deindustrialization of the Brazilian economy due to expanded agriculture production and exports and energy commodities (deep offshore oil reserves).

34 Law 11.097/2005 and ANP Resolution 15/2006 and 14/2012.

35 The current restrictions that prevent engines from being fuelled by biodiesel could be overcome with technology innovation, and an official programme in support of it would be highly beneficial (Dias, 2007).

36 Besides the different sulphur concentrations, Brazilian diesel is classified according to the absence (type A) or presence (type B) of biodiesel in the mix. Therefore, following ANP Resolution 50/2013, there are four types of diesel in Brazil: S10A, S10B, S50A and S50B.

37 Studies were mandated by ANP Resolution 14/2012 and were carried out.

38 Soybean producers are currently more interested in exporting their crops for human and animal food production; other crops must be produced intensively in order to support biofuel production, and no relevant movements towards this can be seen in Brazil; in addition, there are significant vested interests in exploiting deep offshore oil reserves instead of investing in biofuel production.

38.4.1.5 Nuclear

Despite being non-renewable,[39] nuclear power is a low carbon energy source. Nuclear power was developed in Brazil by the military regime (1964–1985). It was seen as both an alternative source of energy and a strategic technology to be dominated by Brazilian scientists. Brazil has two nuclear power plants: Angra 1, built between 1972 and 1984, in operation since January 1985, and Angra 2, whose construction started in 1976, was paralyzed between 1983 and 1995 due to lack of financial resources, and was resumed in 1996; the power plant began operation in 2001. A third nuclear power plant, Angra 3, had its foundation laid at the beginning of the 1980s, but construction never got off the ground due to a lack of finance. Building began in earnest in 2010, and it is predicted that the plant will become active in 2018. Plans for developing four new nuclear power plants in Brazil were postponed after the Fukushima accident.

Nuclear power is an important low carbon energy source for a great part of the world, and could be most successfully applied as a transitional source; since it is highly effective in generating electricity, it can replace fossil fuels until technology for renewable sources is developed (Carvalho 2012). Nevertheless, it is important to bear in mind that nuclear energy involves risks that are more obvious than those of other energy sources, since the consequences of nuclear accidents spread out in space and time; so its externalities and requirements for safe operation have to be fully understood before it is employed on a large scale.

Brazilian public opinion does not favour nuclear energy. Interestingly, it is one of the energy sources with the strongest opposition in the country—even most of the academic community is against it. The lobby in favour of nuclear power (nuclear engineers, the military, some diplomats) is losing ground, especially since nuclear engineers, its fiercest defenders and the most politically engaged group, are starting to retire. Nuclear power will never be an important source of energy in Brazil, although it will remain among the sources linked with technological know-how (Brazil is one of the few countries in the world able to enrich uranium) and with the fact that the country has huge uranium reserves. And maybe this is for the best, since Brazil has other options for low carbon energy sources and nuclear power involves important considerations about dealing with nuclear waste and managing evacuation exercises.

38.4.1.6 Wind and Solar Power

Wind and solar power, together with small hydro-power plants, are classified as alternative renewable energy sources in Brazil. Brazil has enormous potential for wind and solar power, and a very small amount is currently employed in energy generation. Besides low carbon reasons, wind and solar energy development would (i) enable the decentralization of energy production in Brazil, once places with high potential for both are located in areas at the borders of the grid (wind) or with a precarious connection to the grid (solar); (ii) result in technological gains, since Brazil still imports most of the components for both types of energy system (though it exports wind blades) and could develop the national industry; and (iii) increase employment opportunities in both sectors. Wind power, in particular, has even more in its favour: the Brazilian wind regime is complementary to important Brazilian river basin regimes (highs/lows), and the connection of both energy systems to the same grid would guarantee renewable electricity throughout the year.

Wind power has expanded greatly in the last decade, due to PROINFA. In the first auction for electricity from alternative sources (2004), wind sold 1,422.9 MW; between 2005 and 2008, however, there were eight auctions in which alternative renewable energy sources competed with other sources, such as the UHEs of Jirau, Santo Antonio and Belo Monte and several fossil-fuel thermal power plants—which, in the end, sold 73 per cent of the total auctioned (Nogueira/Costa 2012). At the beginning of 2007, the federal government established specific auctions for each alternative source, and there were impressive results for wind power in 2009. In 2010 and 2011, wind sold 2,047.8 MW and 1,928.8 MW respectively (Nogueira/Costa 2012).

Despite the great expansion in Brazilian wind power, beyond earliest expectations, there is neither an official policy to establish long-term incentives, quotas and minimum prices for alternative energy sources, nor is there a legal obligation to auction alternative energy production periodically. The fact that there are no regional auctions for electricity (all auctions are national, and controlled by the federal government) is an important obstacle to the best use of different regional renewable electricity potential. Wind power is gaining momentum in Brazil, but a large part of the Brazilian electricity bureaucracy does

---

39　Nuclear energy production is limited by the availability of uranium ore, or similar elements.

not seriously consider it an alternative to other energy developments.

Solar power faces even more challenges. It was not included in PROINFA, because the federal government argued that the costs of production were too high. In fact, lack of competitiveness when compared to other energy sources is still the argument of most of those who dismiss solar energy. Besides, top technical decision-makers in the Brazilian energy matrix make some valid arguments against the development of solar power in the present decade: they consider that technological innovation in solar power is advancing very fast and a choice of technology at this point could be a trap. On top of that, the taxation system does not favour solar energy. Since 2013, solar energy has been included as a possible energy source in the electricity auctions, but it has still not sold anything.

38.4.1.7 Biomass for Electricity Generation

In addition to producing fuel, biomass is a source of Brazilian electricity. Production started in ethanol plants, where sugar cane pomace is used for electricity generation—the co-generation process. It has helped ethanol plants to become self-sufficient in electricity: co-generation is employed at all stages of the ethanol production chain, especially in the state of São Paulo, and has increased the efficiency of the sector in energy conversion, carbon intensiveness and economic productivity. Besides this, PROINFA authorized biomass to take part in the electricity auctions, and the results were significant: from 2004 to 2011, it sold around 2,500 MW (Nogueira/Costa 2012).

Currently, electricity from biomass comes mostly from sugar cane. Several other raw materials are being tested, as well as waste—a useful destination for one of the biggest outputs of the modern lifestyle. Initial projects using waste received certified carbon credits through the *Clean Development Mechanism* (CDM) of the Kyoto Protocol, but its use on a large scale requires further research. Public opinion favours this energy source, but it is unlikely that it will be extensively developed in the next few years.

38.4.2 Energy Efficiency, the Ignored Issue

The topic of energy efficiency has been on the agenda since the 1980s. Brazil has developed a regulatory framework and mandatory programmes of energy efficiency: the *National Electrical Energy Conservation Programme* (in Portuguese, PROCEL) aims at reducing the consumption of electricity; the *National*

Programme of Rational Use of Oil and Natural Gas By-products (in Portuguese, CONPET) targets the use of oil and derivatives; the *Brazilian Labelling Programme* (in Portuguese, PBE) classifies domestic appliances, devices and light utility vehicles according to their energy use. Law no. 9991/2000 requires electricity companies to invest a specified minimum amount in energy efficiency research and development. However, public debate about energy efficiency and public response to the initiatives were minimal.

The picture changed during the 2001 electricity supply crisis. Electricity was rationed, and surprisingly, Brazilian society was capable of a rapid and efficient response to electricity scarcity. Following this, the National Policy for Conservation and Rational Use of Energy (Law no. 10295/2001) was enacted, and an inter-ministerial committee was set up to manage and enhance initiatives related to energy efficiency; labelling became much more stringent; industries were obliged to increase energy efficiency so as not to face economic losses. After the crisis, though, energy waste resumed its high levels.

Electricity transmission also performs very poorly. Brazilian electricity is mostly transmitted through the SIN. An integrated transmission system has supply security advantages, as long as the transmission lines are quality-built and well maintained; unfortunately, the criterion in Brazil is short-term cost, not reliability and efficiency: lines are of inferior quality and undergo little maintenance—even cheap electronic leak detectors are not yet in place in the country. In addition, the expansion of the electricity supply and grid improvements are not coupled together: for instance, UHE Belo Monte's connection to the SIN will be concluded two years after it starts producing electricity; several wind farms are disconnected as well. The lack of a smart grid prevents consumers from becoming energy 'prosumers' by injecting electricity produced by solar panels and wind farms into the grid, and prevents the intelligent use of renewable energy potential utilizing the characteristics of the Brazilian regions, as well as hindering the joint exploitation of complementary renewable energy sources (solar and wind with hydropower).

Energy inefficiency is also a concern in the automotive industry. Since the 1950s, this has been one of the main sectors of the Brazilian economy; the federal government has always encouraged car production, for domestic consumption or to be exported to markets that are undemanding in terms of carbon emissions. The automotive industry accepts only vague energy efficiency labelling: Brazilian branches of Euro-

pean and US companies lobby against strict energy efficiency labelling and sell in Brazil outdated and inefficient models that are no longer commercially viable in their home countries.[40] Most consumers do not understand the concept of energy efficiency, and still buy cars according to short-term costs only. Even flex-fuel technology was not developed though purely environmental concerns, but as a means of employing a boosted ethanol production.

The *Brazilian Association for Energy Efficiency* (in Portuguese, ABEE) and other NGOs are in favour of energy efficiency and a smart grid in Brazil, but they are not strong enough to change the picture. Given that energy access is no longer a major issue in the country—electricity is available to 99 per cent of the Brazilian population; LPG for cooking, to 94 per cent (IEA 2013b)—and the recent supply crises,[41] quality in production and transmission of energy should be a priority. However, government propaganda is always based on quantity only; recent policies—reducing prices for electricity, based on a distorted calculation that benefited inefficient companies who do not invest in productivity and efficiency—were clearly energy populist measures targeting the 2014 elections. If Brazil is to become an energy efficient country, quality, defined in economic, social and environmental terms, needs to become the criterion for energy production and consumption. This is a major transformation, and will not be achieved through increasing economic interventionism and the reduction of macroeconomic predictability.

38.5 Crony Capitalism and Short-term Thinking: a Major Stumbling Block to a Low Carbon Green Economy

Every society has deeply-rooted cultural traits that shape social relations at every level. Some of the traits are positive, others negative. Understanding policy and politics without keeping in mind these traits and their

impact on social relations is counterproductive and will lead to superficial analysis (Hochstetler/Viola 2012).

When countries face the challenge of becoming low carbon green economies, it is necessary to check which cultural traits might be behind the difficulties of putting environmental concerns on the same level as economic and social concerns. In Brazil, this is a double challenge, since the struggle between economic and social concerns is still far from being resolved. Big inequalities in income translated into a high Gini index, a low level of education, inequality of opportunities and a bureaucratic culture are big stumbling blocks to setting up a low carbon green economy, but two cultural features play a pivotal role: crony capitalism and short-term thinking.

Crony capitalism has existed in Brazil from the time it was a Portuguese colony: personal relationships call the tune of almost every venture that takes place in the country. Following the democratization of the 1980s and the macroeconomic reforms of the 1990s, crony capitalism had been on a downward trend; unfortunately, the trend was reversed in the late 2000s. Unlike mostly social democratic Europe, Brazil is a plutocratic democracy, even more so than the US: big money and in particular vested interests have a major influence on government decision-making and the political system. When hardship hits, instead of investing in productivity and efficiency, big companies look for more concessions from the federal government to solve their problems; in exchange, they fund election campaigns. In absolute terms Brazilian electoral campaigns are the second most expensive in the world (after the US); by per capita comparison, they are the most expensive. Around seventy per cent of the spending in electoral campaigns comes from companies and very rich individuals—with big providers of government services at the top—; thirty per cent comes from large trade unions and public funding. There is almost no tradition of small individual contributions.

Crony capitalism is spread all over the Brazilian economy, but its effects are stronger in sectors whose activities require large initial capital and substantial investment. This is the case with energy production and distribution. Long-established energy groups are powerful in Brazil, and they exert great pressure on federal government decisions concerning both energy sources and energy efficiency. The developers of UHEs, for instance, have special access to decision-making and public financial resources. This has an impact on electricity policies: because they defend the expansion of investment in UHEs over investment in PCHs, wind and solar (insisting on Brazil's UHE

---

40 Japanese and Korean companies are exceptions to this rule.

41 In February 2014, due to an unusually hot summer and the increased use of cooling devices, there were several cuts in the electricity supply due to the incapacity of the system to answer the demand; given that the summer was also unusually dry and Brazil relies on summer rains to refill the reservoirs of UHEs, either electricity will be rationed or fossil-fuel thermal power plants will be further employed over the winter.

potential and technological know-how and dismissing the social and environmental impacts of UHEs— Basso/Viola, forthcoming), diversification of the renewable matrix, investment in a smart grid and the decentralization of electricity production are endlessly postponed. It is true that Brazil will not be able to maintain its low carbon electricity profile for the next ten years without UHEs, and it should not abandon them; still, current UHE projects have problems and should be examined.

The oil sector is also very powerful. The federal government is the major shareholder in Petrobras, so company interests and state interests become entangled; the use of subsidized oil as a heterodox economic measure to increase consumption and maintain an artificial economic growth, imposing sequenced financial losses on the company, is an example of this. Vested interests in oil block bigger investment in natural gas and renewable fuels.

Crony capitalism in the energy sector is best understood through examining the general business culture of the country. In Brazil, in general (there are exceptions, of course, but they are still a minority, especially among the big companies), the business sector lacks an entrepreneurial culture: companies are mostly focused on rent-seeking. The manoeuvres of business, supported by governmental measures,[42] distort the market and create uncertainty for foreign investors. This is not inevitable, and the picture is different in the energy sectors of other countries: in Scandinavia and Germany, markets work well and the state interferes to accelerate investment in renewable energy and energy efficiency; in the US, markets work quite well, and the state interferes, in a limited way and directly, to fix market failures; in Brazil, however, not only are energy markets distorted, but the state interferes to solve the short-term problems of specific companies or to enhance its electoral prospects, creating a self-perpetuating vicious circle that deepens the problem and takes Brazil further away from low carbon green development.

Short-term thinking does not bring any relief. Brazil has more organized forces that oppose traditional energy sources (fossil fuels, UHEs) than it has forces that are in favour of new renewable sources or energy efficiency. This is due to the reactive nature of civil society movements: civil society reacts to government action concerning a specific venture or energy source, for instance, the movement of people affected by dams associated with UHEs or the movement in favour of indigenous peoples' rights over forests that would be affected by UHEs, and these lobbies later attract NGOs and academia and form opposition to the venture or energy source. But there are no consistent proactive movements directed towards promoting an energy source or encouraging strategic energy assessment in Brazil. In order to change this state of affairs, think tanks are needed and research must be conducted to understand the big picture concerning energy production and consumption. The large number of published papers on strategic environmental and energy assessment in China and the negligible number in Brazil is evidence of the different situation in the two countries.

Furthermore, energy efficiency is hardly part of the Brazilian mindset. Brazilian culture favours short-term benefits over long-term gains, and most consumer decisions only consider the immediate costs; concerns about maintenance, the cost of electricity or fuel consumption, waste generated, damage to public health or harm caused to the environment are not taken into account by the majority of the population, rich or poor. In fact, once they are given the opportunity,[43] the actions of the poorer population mirror the irresponsible consumerism of the richer population. This is not to say that the poor should not be given the opportunity to consume or that socio-economic policies are wrong: they have been very effective and have helped reduce the abnormal inequality of the country. But it is important to note that the environment, renewable energy, energy efficiency or any other improvement that would mean that the links between economic, social and environmental issues are understood are not present in social claims—an example is provided by the demands made during the demonstrations of June 2013. The absence of long-term thinking will only be lessened through education, through transparent rules that tackle privileges and dissolve crony capitalism, and through accountability, creating a sense of community and belonging that is still lacking in Brazil.

And even if crony capitalism and short-term thinking have started to be tackled by some groups in Brazilian society, this approach will never spread and become the national rationale if the Brazilian political system is not reformed. In Brazil, politics is not the

---

42 E.g. the large subsidies received from BNDES by Eike Batista for risky projects that lacked consistency without guarantees being requested from him; the Bank incurred great losses that are unlikely to be recovered.

43 Due to the socio-economic policies of the last decade, for example.

game of achieving national consensus about what is needed in order to further the development of its population; it is the game in which parties fight each other to have their particular interests met, whatever the consequences for the country. Patronage practices are the main strategy for gaining votes; states fight each other for resources and investments in a predatory fashion; the federal government has a large, compartmentalized and, in general, inefficient bureaucracy, privileged with job stability and the right to receive a full-salary pension, unlike private workers. The system must be reformed so that fragmentation is decreased and meritocracy and universal policies are promoted.

38.6   Conclusions and Perspectives

Brazil has so far not adopted the low carbon green economy paradigm. This type of transformation cannot be achieved without planning, without long-, medium- and short-term goals, and without consistent implementation policies. Even the attempt at the goal of decarbonization, a smaller share of the paradigm, lacks consistency in Brazil.

It is true that low carbon energy sources form a higher proportion of the Brazilian energy matrix than the world average. Nevertheless, the share of nonrenewable energy sources increased during the last decade, due to both heterodox economic measures that distorted the relative prices of oil/derivatives, and the lack of long-term policies to promote renewables. Two trends can be seen in the energy policy and politics of the last decade for low carbon energy sources. From 2003 to 2007, there was an upward trend in which progressive forces, committed to low carbon development, were stronger, and the participation of renewable sources in the energy matrix increased. From 2007 to 2014, there was a downward trend in which regressive forces, which favour nonrenewables, especially fossil energy sources, were empowered, due to the discovery of deep offshore oil reserves and the use of oil prices as a heterodox policy tool to artificially maintain greater economic growth rates. As for energy efficiency, however, practices are underdeveloped and the trend during the last decade was stable: there was no consistent development of energy efficiency policy and politics.

There is no clear direction towards decarbonization in Brazil. A clear sign would be sent if the federal government opted for: (i) an intelligent use of the Brazilian potential for renewable energy, by offering incentives for exploiting solar and wind energy and making the SIN a smart grid—actions that would allow consumers to become 'prosumers' and fewer hydropower plants to be built, reducing their impact on the environment and the local population—; (ii) serious policies leading towards systemic energy efficiency in the Brazilian economy, not just by labelling domestic appliances but also by promoting better efficiency targets for vehicles, by supporting green building and by investing heavily in collective transport; (iii) a change in the criteria for electricity auctions, from the lowest price possible to the greenest and least carbon-intensive energy; (iv) the removal of all subsidies for oil and derivatives, and the enforcement of only limited exploitation of the deep offshore oil reserves, prioritizing that exploitation where it can be proved that natural gas is also present; (v) the use of natural gas, and not oil or coal, in thermal power plants, and the phasing out of oil and coal over the next decades; (vi) changing the incentives for the use of fuel by taxing fuel by its carbon emission and other impacts of the cycle of production and use on the planetary boundaries; (vii) supporting public transport and limiting the promotion of the automobile industry; and (viii) intermodal transportation, through a combination of railroads and river navigation.

It is difficult to predict how energy policy and politics will develop from 2014 onwards. It is clear that without undertaking consistent tax, pension, labour, fiscal, political system and energy policy reforms, Brazilian reality will not match up to its low carbon potential. National and foreign economic agents are almost as concerned about Brazil's economic prospects as they were before the 2002 elections, when the expected victory of a party that supported increased economic interventionism by the state shook economic expectations.

The public demonstrations of June 2013 did not have enough impetus to being about significant change in the general election of 2014. Marina Silva, the candidate of the Socialist Party/Sustainability Network alliance, whose manifesto laid emphasis on the transition to a low carbon economy, gained 22 per cent of the vote in the first round. This was a small increase on 2010, when she received 19 per cent of the vote, but still not enough for her to make the second round. In the second round, Ms Silva supported the Social Democratic Party's candidate Aécio Neves, on the condition that he laid more stress on sustainability; her support was contested by a significant part of Ms Silva's Sustainability Network, however—they decided to cast a "white" vote (an unmarked ballot paper; voting is

compulsory in Brazil). President Dilma Rousseff was re-elected by the lowest margin in Brazilian history in the second round (51.6 per cent of the valid votes, with abstentions, white and null votes totalling more than 30 per cent, meaning that more than 60 per cent of the electorate did not support her re-election). In an extremely fragmented multiparty system (twenty-eight parties are represented in the new Congress), the parliamentary election was overwhelmingly won by traditional parties. In this beginning of second mandate of President Rousseff, the status quo of an underdeveloped low carbon economy is being maintained. The federal government is trying to implement partial economic reforms but the disagreements between the Presidency and the Parliament have slowed the process. The emergence of serious corruption scandals, linking high officers of state, politicians and large Brazilian corporations to the contracts and operations of Petrobras and other major companies of the energy area has put the country in the middle of the major crisis it has faced after the redemocratization. In this scenario, in which the government is focused in surviving, low carbon energy situation is becoming even worse.

Above all, it is vital to acknowledge that Brazil has not embraced decarbonization, let alone become a low carbon green economy, and that deep-rooted features of Brazilian culture, especially crony capitalism and short-term thinking, are great barriers to the implementation of these goals. Crony capitalism has been on an upward trend during the last few years and this has undermined investment in energy efficiency and new renewable energy sources. Federal government manoeuvres to reduce electricity prices at the expense of quality and reliability led to more inefficiency in the electricity system and to crises of supply in February 2014, and this led to the operation of more fossil-fuel thermal power plants in order to prevent the situation recurring during the winter of 2014. The lack of incentives for producing energy from renewable sources, such as higher prices in electricity auctions, undermines the possibility of their being employed on a large scale. In a country in which energy access is almost universal, energy security depends less on the expansion of energy production at distorted prices and more on cost-effective long-term quality and reliability of the supply and the transmission systems.

As well as tackling crony capitalism, minimizing short-term thinking should be taken very seriously. Brazil lacks strategic planning at all levels, from government policies to household budgets; measures take into account specific situations, usually urgent ones, and often create contradictory situations when seen in succession. Recent socio-economic policies that have been successful in reducing economic inequality spread irresponsible consumerism—encouraged by the government—throughout social groups, revealing that the pattern lies much deeper in Brazilian culture. There is no easy or quick fix: only with quality education, transparency, accountability and rules that tackle privileges in Brazilian society will there develop the sense of community and belonging—a sense that lies at the basis of a low carbon green economy—that it still lacks.

39 Sustainable Electricity Transition in Thailand and the Role of Civil Society

Carl Middleton[1,2]

Abstract

The chapter explains the creation and resistance to change of Thailand's centralized and fossil-fuel intensive electricity regime through a Sustainability Transition and Multilevel Perspective lens, with an emphasis on the sector's political economy. The incumbent electricity industry has evolved from a state-owned monopoly to a partially-privatized industry structure dominated by the state utility and several large independent power producers. The analysis demonstrates how important global landscape shifts articulate with the sector's domestic political economy, including a shifting global development paradigm from developmentalist state to liberal market principles, as well as the impact of waves of global economic crisis. The chapter highlights the role played by civil society coalitions in unsettling the incumbent electricity regime since the late 1970s, despite significant power asymmetries, through opposing problematic projects, advocating for progressive policy, and proposing alternative plans, values and visions for Thailand's electricity sector. Important but small steps towards sustainability transition are identified, including greater energy conservation and distributed renewable energy generation, the creation of an independent regulator, and a small increase in public participation and accountability in the power planning process. The chapter argues that civil society has been—and will continue to be—important in shaping the incumbent electricity regime and often acts as a catalyst for transition towards sustainability.

Keywords: Thailand, electricity, civil society, sustainability transition, multilevel perspective.

39.1   Introduction

Since the 1960s and more rapidly since the 1980s, Thailand's economy, society and environment have witnessed a major transformation. Throughout this period of high economic growth, as the country rapidly industrialized and urbanized, a centralized electricity system was established led by the state's utility, the *Electricity Generating Authority of Thailand* (EGAT). At first a monopoly, several waves of privatization since the 1980s have created a partially-privatized electricity regime that remains dominated by fossil fuels and centralized generation owned by EGAT and a small number of *independent power producers* (IPPs).

Whilst largely meeting the rapid growth in demand for electricity, the environmental and social costs have been high. Since the 1970s, an increasingly established civil society has emerged within Thailand's often precarious democracy (Phongpaichit/ Baker 2002), which has included project-affected communities, their wider social movements, and various *non-governmental organizations* (NGOs) (Foran 2006). Nowadays, Thailand's electricity policy is an active arena of policy deliberation, including on the impacts of domestic projects and power-import projects from neighbouring countries, as well as on the transparency and accountability of the electricity plan-

ning process as a whole. There are wide power asymmetries between actors in decision-making, however, and this remains largely one-sided and favours the established electricity industry. Despite these power asymmetries, there have been several important reforms, including some towards energy conservation, and the introduction of small-power producer and very-small-power producer legislation that has allowed a growing proportion of renewable energy generation within Thailand's electricity system.

Thailand's electricity system faces a number of contemporary challenges. Whilst on paper there may be a commitment to low-carbon economic growth (EPPO 2012), in practice higher on the policy agenda is ensuring energy security for Thailand's sustained economic growth. Meanwhile, policies on electricity production are fragmented and often contradictory in relation to other policy issues such as water resource management and food production (Middleton/Dore 2015). Finally, Thailand's electricity generation is also heavily dependent on natural gas, yet domestic reserves are rapidly depleting and growing dependence on imports (together with hydroelectricity) has raised concerns about national energy security.

Drawing upon the concepts of *sustainability transition* (ST) and the *multilevel perspective* (MLP) and adopting a political economy approach (actors, interests, power), the purpose of this chapter is to analyse the emergence and embedding of Thailand's incumbent electricity regime and the role played by civil society within it (Verbong/Loorback 2012). Synthesizing diverse literature on Thailand's power sector through an ST and MLP lens, the chapter addresses a general gap in ST literature on *newly industrialized countries* (NICs) in South East Asia, and on strategies taken by actors in incumbent electricity regimes to resist change, together with the role played by civil society in catalysing alternative pathways. The next section outlines the conceptual framework of ST and the MLP as relevant to electricity system transitions in NICs. Section 39.3 maps out the emergence and embedding of Thailand's electricity regime, differentiated into two phases: the construction of a centralized national power system (1950–1980); and the partial privatization of this system (1980–present). The section shows how globalization landscape pressures reformulated the regime over the two periods, and how the partially-privatized regime has emerged as a stable industry formation. Section 39.4 demonstrates how civil society has challenged and shaped the incumbent regime, including through transforming the landscape in which the regime exists, unsettling

the regime directly through resistance and cooperation, imagining a new regime, and catalysing new innovative niches. Section 39.5 draws conclusions and suggests strategic directions for transitions towards sustainability in Thailand's electricity sector.

39.2 Sustainable Electricity Transition and the Role of Civil Society

39.2.1 Transitions Studies and the Multilevel Perspective

Sustainability Transition (ST) explores how sociotechnical systems change over time. It is a mid-range theory that sees technology and innovation as emerging from, embedded within, and shaping society. The scope of ST aims to incorporate "multi-level dynamics, multi-actor networks, radical innovation and uncertainty, and the impossibility of full control" (Verborg/Loorback 2012: 7). ST adopts a multi-disciplinary perspective, drawing on evolutionary economics, science and technology studies, structuration theory and neo-institutional theory (Geels 2011).

The *Multilevel Perspective* (MLP) conceptualizes processes of sociotechnological change as occurring at and between three levels: niche, regime and landscape (Geels 2002). 'Regime' refers to the existing dominant and dynamically stable sociotechnical system with its associated scientific knowledge, policy, industrial networks, markets and user practices, technology, infrastructure, and cultural meaning (Geels 2002: 1263). Markard/Raven/Truffer (2012: 956) note that a regime:

> consists of (networks of) actors (individuals, firms, and other organizations, collective actors) and institutions (societal and technical norms, regulations, standards of good practice), as well as material artefacts and knowledge.

Geels (2011) warns against reifying the regime, emphasizing that it is the actors within the regime who hold agency, intentionality and strategy.

'Niches', meanwhile, are spaces where radical sociotechnical innovation can occur and that are protected from regime selection criteria, for example by subsidized research and pilot projects, or by culturally-held values. Finally, 'landscape' refers to the exogenous environment in which regimes evolve and niches also exist; it includes broad geographical factors, and political, economic and societal trends. In response to recent critiques of MLP's conceptualization of scale, which implies that micro-meso-macro levels are

nested and hierarchical (e.g. Shove/Walker 2010), Geels (2011: 37) has proposed that levels may refer to "different degrees of stability, which are not necessarily hierarchical".

The transition from one sociotechnical regime to another is a set of non-linear process entailing a radical change in configuration of technologies, infrastructures, institutions, governance and actors. Existing sociotechnical regimes may become unsettled when: broad landscape-level changes create pressure (macro-economic environment, society values, and so on); there are growing processes towards and within the regime itself that destabilizes it; and niche-level experiments offer alternatives (Geels 2002; Grin/Rotmans/Schot 2010) and gain momentum, for example through learning processes, price/performance improvements, and support from powerful groups (Geels 2014: 23). Other have noted that over long periods, incremental changes in regime can amount to significant transformation; As Smith/Voß/Grin (2010: 440) put it: "In a Kuhnian vein, regimes tend to produce 'normal' innovation patterns, whilst 'revolutionary' change originates in 'niches'" (see also Pavitt, 1984).

The incumbent regime may be resistant to significant rapid change for a range of economic, institutional, cultural, and technical reasons, including the resistance of existing actors that benefit from it. The regime can be analysed in terms of its lock-in, path dependence, and inertia; Geels (2014: 35) emphasizes, however, that an incumbent regime is not monolithic, and its stability is not guaranteed. Smith/Voß/Grin (2010:433) observe that "radical niche practice can be co-opted by a regime without unduly unsettling and transforming it" (Smith/Voß/Grin 2010: 443). Recent literature has considered in more detail how existing regimes exhibit resistance to change, and thus how sustainability transitions are inherently a political process (Smith/Stirling/Berkhout 2005; Meadowcroft 2011). One approach has been to adopt a political economy perspective, giving explicit consideration to various forms of power, agency and resistance (Geels, 2014; see also Schreuer/Rohracher/Späth 2010). This perspective rebalances previous literature that placed too greater emphasis on green niche innovation leading to ST, without also considering how the incumbent regime might also be resistant to being destabilized; as Geels (2014: 25) puts it, "we should better understand the 'destruction' part of Schumpeter's 'creative destruction' concept".

Studies of ST, by explaining how sociotechnical transitions occur, ask how they can be steered (or 'managed' or 'governed') towards sustainability, and ideally how transition can be accelerated given the urgency of the sustainability challenge faced (Smith/Voß/Grin 2010). This approach is normative in that it recognizes that social and environmental values, alongside economic efficiency, are—and must be—accounted for in policy and practice. Thus the focus is not only upon the technical regime and its associated innovation, but also its relationship with broader social arrangements (Smith/Stirling/Berkhout 2005).

39.2.2 Sustainability Transition in South East Asia

ST as a concept has been developed and applied predominantly in *Organisation for Economic Co-operation and Development* (OECD) country contexts, with a particular focus on Europe (Markard/Raven/Truffer 2012). The concerns of geography matter to ST, however, ranging from the role of place and associated spatial relationships, to the transnational flows of capital, actors and ideas, to the availability of domestic resources and the implications of sovereignty (Smith/ Voß/Grin 2010). Despite this, a literature on ST in developing Asia is only now beginning to emerge (Berkhout/Angel/Wieczorek 2009; Smits 2012; Sawdon 2014).

For Asia's NICs, the spatial dynamics and flows of knowledge, technology and investment as well as export-market driven growth have held significant implications for economy, society and politics (Nevins/Peluso 2008). To understand the sociotechnical regimes of NICs in Asia, therefore, it is important to account for the international context (Berkhout/Angel/Wieczorek 2009: 225). At the same time, global diffusion of technology, knowledge and policies are not transplanted off-the-shelf, but articulate with local context (Dobbins/Simmons/Garrett 2007). Regarding sustainability transformations in Asia's NICs, Angel/Rock (2009) propose that whilst initial development was at the sacrifice of environment quality, there has been a second wave of environmental governance reform building on pragmatic policy innovation, institutional strengths of the development state, and the changing norms of globalization, although impacts on sustainability have actualized unevenly.

39.2.3 Electricity System Transition

Geert/Loorbach (2012: 5) emphasize that "current energy systems are deeply entrenched in our economy, consumption patterns, regulations and infrastructure". In most cases around the world, electricity provision

was initially provided by the private sector, but during the end of the nineteenth century and first half of the twentieth century its provision was taken over by municipal and later national state electricity suppliers, at which point electricity increasingly became considered as a public service.[3] The liberal wave of privatization policies in the 1980s that began in Northern countries and spread to developing countries restructured the electricity industry and reintroduced the private sector, but often resulted in only partial privatizations (Victor/Heller 2007).

Electricity services, like other network industry services such as water supply and telecommunications, have been of great political interest to governments and politicians, for reasons ranging from the importance of ensuring the provision of these services to the public (i.e. a form of social contract), to the importance of electricity security to economic growth, and the high capital investment costs and associated possibility of job creation, political patronage and corruption (Victor/Heller 2007: 1). In the context of Asian NICs, construction and maintenance of electricity systems have been promoted by the government as a priority for national economic development. Yet, this 'national' economic development has disproportionately benefited politically-connected industrial elites and their networks (Hildyard/Lohmann/Sexton 2012). Actors in the incumbent electricity regime, who are bound together by mutual dependencies, act to maintain regime stability and resist change. They include established business and state enterprises, supportive state agencies, policymakers, unions and politicians. Aside from considerations of politics and vested interests, there are a number of attributes of the electricity sector that lock in the incumbent regime, including high capital costs, political visibility, network monopoly effects, technological stasis, and daunting regulatory tasks (Victor/Heller 2007: 2).

Finally, in ST studies there has recently been an effort to unpack in greater detail how technical systems have implications for the practices of everyday life and its reproduction (Shove/Walker 2010). In the context of electricity systems, this means consideration not only of sociotechnical practices of supply, but also those of demand. Shove/Walker (2014: 41) observe "Whereas theories of practice highlight basic questions about what energy is for, these issues are routinely and perhaps necessarily obscured by those who see energy as an abstract resource that structures

or that is structured by a range of interlocking social systems". Thus, everyday practices of electricity use are important considerations to understand how regimes and niches become embedded (or entrenched), and how (or whether) energy transitions occur (Smith/Voß/Grin 2010: 443).

39.2.4 Role of Civil Society in Electricity Transitions

Amongst state agencies and enterprises, firms and civil society groups, networks exist that promote different visions for electricity systems. These partnerships—of differing degree of affiliation and asymmetrical power relations—may either seek to maintain and stabilize the incumbent regime, or promote alternative pathways. For example, Hess (2014) explores the formation, strategies and power asymmetries of broad coalitions of actors and how they shape the US energy sector, namely: the incumbent regime seeking to maintain its position; (often) grassroots coalitions, including social movements, seeking transition to a more sustainable regime; a 'countervailing industry mobilization' that support grassroots coalitions with financial and political resources around shared interests; and the multifaceted role of the state (Hess 2014).

Smith (2012) proposes that the MLP perspective helps social movement theory broaden its scope of analysis from political systems to sociotechnical regimes (table 39.1). Smith (2012: 180) asks "What visions do civil associations hold, and what roles do they play in transitions processes?" Smith (2012: 190) stresses, however, that civil society—whether unsettling regimes, nurturing niches, or shaping societal values—are "not amendable to herding and corralling" and thus it is unrealistic to anticipate diverse civil society activity as constituting a "coordinated transition management". Instead, he emphasizes that it is the diversity of civil society that is one of its strengths, including ensuring that electricity system transitions do not lose sight of principles of justice.

39.2.5 Conceptual Contribution

As a heuristic framework (Geels 2011: 34), ST and MLP can offer new conceptual insights into the emergence of Thailand's electricity production–consumption system, and opportunities for a transition to sustainability. A significant number of studies have analysed electricity systems from an ST and MLP perspective but mainly in an OECD-country context (Markard/Raven/Truffer 2012). Few have examined

---

3   The author appreciates the insight of an anonymous reviewer in raising this point.

Table 39.1: Civil society activity in relation to sustainable electricity transitions. **Source:** The author, adapted from Smith (2012: 189).

MLP domain	Types of civil society activity
Sociotechnical landscape	Awareness raising; social pressure
Unsettling existing sociotechnical regime	Consumer boycotts; protest and lobbying; standards and counter-expertise
Aspired-to sociotechnical regime	Community aspirations; plural visions in civil society
Technological niches	Grassroots innovation; green consumption; citizen science

electricity systems in Asian NICs, an area to which this chapter contributes (Geert/Loorbach 2012). Responding to knowledge gaps identified by Geels (2011; 2014) and Smith/Voß/Grin (2010: 445), the chapter also highlights the active resistance of the incumbent regime to change, and the role and strategies of civil society groups in destabilizing it, whilst at the same time promoting alternative pathways (Smith 2012). Finally, in exploring the interaction between the incumbent electricity regime and its actors—and those who would like to change it—, the chapter adopts a political economy approach and explicitly considers the actors involved within decision-taking processes and the relative distribution of political power, so contributing towards a nascent political economy turn in MLP literature (Geels 2014).

39.3 Emergence and Embedding of Thailand's Incumbent Electricity Regime

Since the 1960s, Thailand has been transformed from a predominantly agrarian to an industrializing, urbanizing society, where until the 1980s the country was a weak developmentalist state which subsequently increasingly liberalized. Thailand is presently mainland South East Asia's largest economy, and has been classified as an upper-middle-income country by the World Bank since 2011. Rapid economic growth came in the 1980s as the country shifted towards an export-orientated economy, infused with *foreign direct investment* (FDI) from Japan. The country's economic growth has been dependent upon—and as a political priority has shaped—the construction of a national electricity system fuelled predominantly by large-scale fossil-fuelled technologies, and to a lesser extent by large hydropower dams. Reflecting Thailand's development pathway, however, the country has experienced escalating challenges, including high levels of economic, social and political inequality, an oligarchic political structure, and widespread environmental degradation (UNEP/TEI 2007; UNDP 2010).

Thailand has regularly faced political crisis, and this has once again escalated since 2005 leading to the most recent military coup d'état in May 2014.

This section maps out the emergence and progressive embeddedness of Thailand's electricity regime. Two broad phases are identified: the construction of a centralized national power system (1950–1980; 39.3.1); and the partial privatization of this system (1980–present; 39.3.2).[4] Several researchers have described the evolution of Thailand's electricity sector in detail, including Wattana/Sharma/Vaiyavuth (2008), Greacen/Greacen (2004), Foran (2006; 2013) and Sulistiyanto/Xun (2004). This section furthers these analyses by examining the electricity system's emergence through the lens of ST and MLP with a focus on landscape and regime scales and guided by the electricity regime typology of Smith (2012:193–195) (table 39.2). Particular attention is paid to the politics of resistance of the incumbent regime during the second phase. The role played by civil society groups is also introduced, and then expanded upon in section 39.4.

39.3.1 Establishment of a Development State-Led Sociotechnical Regime (1950–1980)

In 1932, Thailand transformed from an absolute to a constitutional monarchy, and this was followed by almost five decades of predominantly military and elite bureaucratic rule with only brief periods of representative democracy (Phonpaichit/Baker 2012). During this period, the aristocratic, senior bureaucratic and merchant oligarchic elites from the time of the absolute monarchy yielded to accommodate rising military and new business elites. The foundation of Thailand's national electricity system was laid in the

---

4   Wattana/Sharma/Vaiyavuth (2008) provide a useful detailed chronology of Thailand's electricity sector's evolution as: early days (1884–1949); industry establishment (1950–79); foundation for privatization (1980–89); first steps in electricity reform (1990–97); and proposal for market-oriented reform (1998–2006).

Table 39.2: Evolution of Thailand's electricity regime. **Source:** Table structure adapted from Smith (2012: 193–195).

Sociotechnical dimension[a]	Establishment of a development state-led sociotechnical regime (1950–1980)	Partial privatization of sociotechnical regime (1980–present)
'Guiding principles'	Electricity is a public good produced by the state utility for socio-economic development; electrification linked to nation-building, modernity, and bringing the benefits of 'development'	Electricity produced according to regulated market principles by the state utility and private enterprises; electrification and energy security required for rapid export-orientated economic growth
'Favoured technologies'	Large-scale technologies (lignite coal-fired plants; hydropower dams); centralized production with transmission through a national grid	Increased dependency on technologies fuelled by imported natural gas (combined-cycle gas turbines); still general commitment to large-scale projects and centralized system; some niche spaces emerge for energy conservation and renewable energy generation
'Industrial structure'	Vertically integrated. Dominated by *state-owned enterprises* (SOEs).	Remains vertically integrated. Increased private sector role in generation at large, small and very small scales; independent regulator since 2008; increasing electricity imports from neighbouring countries
'User relations and markets'	SOEs as monopoly generator and distributor of electricity, guided by a weak developmentalist state. Electricity consumers as passive recipients. Cost-plus arrangement in terms of EGAT investment, yet electricity prices low.	Electricity consumers generally remain passive, but increasingly aware of issues around energy including the *Power Development Plan* (PDP) and renewable energy. Cost-plus arrangements for EGAT remain in place, but limited competition introduced with *independent power producers* (IPPs).
'Policy and regulations'	Utilities essentially self-regulating. Policies on electricity and energy fragmented. Little concern for broader social, environmental and governance issues.	A period of policy flux from state monopoly to *enhanced single-buyer* (ESB) market regulations. Creation of an energy regulatory commission in 2008. Economic efficiency, social, environmental and governance issues rising up the policy agenda.
'Knowledge'	Expert engineering knowledge dominates policy development, planning, and operation	Expert engineering knowledge continues to dominate, but challenged by counter-knowledge related to social and environmental impacts of projects, and governance principles for electricity planning.
'Culture'	Cheap and reliable electricity perceived as important to economic development and Thailand's modernization. The electricity system also as a source of patronage and corruption.	Thailand's modernization and urbanization underpinned by cheap and reliable electricity. Ownership of electricity production increasingly contested, including between centralized versus decentralized models and role of state versus private sector.

a) Sociotechnical dimensions are flagged in the analysis by being place in 'single quotation marks'.

1950s and 1960s, shaped by this landscape (Greacen 2004: 129).

As the cold war escalated, so Thailand's relationship with Western aid agencies grew closer, in particular with the World Bank and the United States. In 1961, during a period of martial law, the government announced its first five-year National Economic Development Plan with advice from the World Bank aimed at transforming Thailand from an agricultural to an industrial country under a market economy; at this time the dominant development paradigm informed by the success of the Marshall Plan in Europe and Rostow's notion of economic take-off was for large-scale state-led development. Thailand pursued a weak development state model where the role of the government was to invest public expendi-

ture in basic infrastructure to support the private sector—including in large-scale electricity generation and rural electrification (Wattana/Sharma/Vaiyavuth 2008: 42). Some, however, have suggested that Thailand was closer to an authoritarian state rather than a developmental one (Siriprachai 2012).

The establishment of a national electricity infrastructure entailed significant 'industrial restructuring'. With World Bank guidance, as concessions granted to over 200 small cooperative-, municipal- and privately-owned concessions ended in the 1950s, the government did not renew them. Instead, the Government brought the concessions under their control. With borrowing from private-sector lenders and concessionary lending and technical advice from USAID and the World Bank, Thailand built a series of large dams and lignite-fired power plants, together with a national high-voltage transmission network (Foran 2006:13-15). These 'favoured technologies' (lignite-fired power stations, hydropower) reflected the domestic availability of resources, before natural gas that could be used as a fuel was discovered in the early 1980s. In 1968, EGAT, a *state-owned enterprise* (SOE), was established to be responsible for electricity generation and transmission,[5] alongside the earlier-created *Provincial Electricity Authority* (PEA) (1960) and the *Metropolitan Electricity Authority* (MEA) (1958) which are SOEs responsible for rural and urban distribution respectively. Overall, this was a move to consolidate, vertically integrate, and standardize the 'industry's structure', and also to bring the industry under the control of the state. These early infrastructure investments and institutional arrangements established the centralized system and cost-plus[6] organizational model that shapes the electricity system regime to this day.

Whilst in the early 1960s less than two per cent of Thailand's population had access to electricity, this had increased to over eighty per cent by 2000 (Grea-

cen 2004: 127, 144). As a 'guiding principle', not only was electricity central to the country's industrialization and economic growth strategy, but it was also viewed as a public good. Universal and affordable electricity became a promise of modernity by the state to the people, which, given the massive public investment and for some the social and environmental cost, also served as a justification for expectations of self-sacrifice (Williams/Dubash 2004). Electricity generation and provision delivered by the state was integral to the process of nation-building and was a symbol of development delivered. In terms of 'knowledge' (and its associated power relations), electricity provision was largely viewed as an administrative and technical exercise to be undertaken by the state, reflecting the prevailing global development paradigm of electricity system design, construction and operation.

During this period, EGAT in particular, but also PEA and MEA, became very powerful politically. These SOEs were 'effectively self-regulating' towards attaining the ends of meeting electricity demand for economic growth (Greacen/Greacen 2004: 519; Foran 2006: 17). Little concern was paid to "competition and profitability, environmental and social constraints, and governance issues such as transparency, accountability and public participation" (Williams/Dubash 2004: 413). There was a general atmosphere of 'grow now and clean up later', with implications for electricity production (Angel/Rock 2009: 232). More broadly, there was accelerating consumption of resources and production of pollution and waste. Environmental concerns—often raised by civil society groups and affected communities—emerged gradually in the late 1970s and grew in the late 1980s. Significant environmental legislation was first created in Thailand in 1975 and reformed in the early 1990s (Harashima 2000), although it was often weakly enforced. Contested projects have included the Mae Moh lignite-fired power station in Lampang province, northern Thailand (Boonlong 2011), and various dams such as the Sirindhorn dam in Ubon Ratchatani province, north-east Thailand (Blake 2013; Missingham 2003).

During this period of rapid growth, EGAT was located within the prime minister's office.[7] With privileged access in the government structure, EGAT emerged as the country's largest SOE with access to large amounts of development funds (Smith 2003). Thus, EGAT was also "regarded by politicians as a vehi-

---

5 Greacen (2004: 130) notes that the earliest large generation projects in the 1950s and 1960s were initially "set up as 'independent' state-owned enterprises at the behest of the World Bank in order to ensure that World Bank loans would not be deposited directly into the Thai national Treasury".

6 A cost-plus regulatory model allows for a fixed rate of return (i.e. profit) based on expenditure, and globally has been a common model for regulated monopoly utilities. It provides a strong incentive for the rapid expansion of infrastructure, but also carries the risk of over-investment given that all costs—including excessive ones—are ultimately passed on to the consumer (Greacen/Footner 2006: 23).

---

7 The PEA and MEA, meanwhile, were established under the Ministry of the Interior.

cle for patronage in appointments and awarding contracts" (Smith 2003: 281). EGAT's long-established well-connected political influence shaped its ability to muster resistance against later attempts at privatization. Meanwhile, at least until the 1970s, during this period of fledgling democracy in Thailand, military rather than elected government was more common, and civil society groups were little active on the electricity sector.

39.3.2   Partial Privatization of Electricity Regime (1980–Present)

From the mid-1970s, following protests by students, workers and farmers, there were lengthening periods of elected government—still punctuated by military coups—as democratic institutions became increasingly embedded.[8] Business owners became elected as *members of parliament* (MPs), displacing bureaucrats and generals from Parliament; in the process politics—via oligarchic networking– became more directly linked to the interests of private business and power relations between these elite groups partly shifted towards the latter (Phongpaichit/Benyaapikul 2013: 35).

In the late 1980s and early 1990s, Thailand's economy boomed, growing at eight to nine per cent a year as a result of massive FDI inflows, in particular from Japan, and growth in export of manufactured goods. At the same time, the government increasingly liberalized Thailand's economy. The Asian financial crisis severely affected Thailand in 1997, and recovery only began in 2000 although at a lower rate of growth than before (Phongpaichit/Baker 2008). The global financial crisis (2008–9), a major flood in 2011, and political unrest in 2010 and since 2013 have all affected growth since, and hence also the electricity sector coupled to it. Some economists consider Thailand caught in a 'middle-income trap', where it faces a significant challenge to transform from an industrializing economy based on cheap labour, exploitation of natural resources, and imported technology via FDI and transnational corporations, to an economy that can compete with advanced economies through producing value via knowledge creation and innovation

(Phongpaichit/Benyaapikul 2013); indicatively, in contrast to Korea and Japan, as well as China and India, very few globally competitive multinational companies have emerged from Thailand. The pathway set by Thailand's economic model of development has also been related to the country's contemporary environmental, social and political challenges.

Meanwhile, in 1997, following growing protests by social movements and now with an established and vocal NGO sector, Thailand passed a new 'people's' constitution. These social movements, Phonpaichit/Baker (2012: 85) write, "focused on specific issues, particularly growing competition over resources of land and water, declining agricultural prices, corruption and over-centralization". At the same time, the Asian financial crisis challenged the old oligarchic elites, and opened the door to Thaksin Shinawatra's *Thai Rak Thai* (TRT) party and a new era of populist politics in Thailand (Phonpaichit/Baker 2012; Walker 2012). Ultimately, this led from 2005 onwards to an intense 'politics of colour' and entrenched political deadlock, and ultimately to two military coups in September 2006 and May 2014.

Thailand's incumbent electricity regime has been fundamentally shaped by this economic, social and political 'landscape' and reconfigured power relations. With rapid economic growth, electricity consumption rose, and this was further bolstered by 'policy principles' for a commitment to nationwide electrification, and a pricing system that made electricity attractive over other fuels to the manufacturing and services sectors (Wattana/Sharma/Vaiyavuth 2008: 44). Thailand's electricity system peak capacity grew elevenfold from 2,838 *megawatts* (MW) in 1982 to 32,600 MW in 2012 (Greacen/Greacen 2004; EPPO 2013). Yet, as democratic space expanded, controversy also erupted with increasing regularity over the environmental and social costs of individual projects and the procedures for electricity 'policy-making and planning.'

The 'landscape' for the incumbent regime's partial privatization was laid in the 1980s with a series of pro-business governments. Thailand had experienced a public sector debt crisis from 1978 to 1981 during the second global oil price shock,[9] compounded by inflationary pressures coupled with stagnant economic growth (i.e. stagflation) in OECD countries affecting

---

8   Thailand has witnessed since 1932 twelve successful military coups and nine attempted ones, and even during periods of democracy the military continues to play a pivotal, if often covert, role in Thai politics: Nicholas Farrelly, "Counting Thailand's coups", at: <http://asia-pacific.anu.edu.au/newmandala/2011/03/08/counting-thailands-coups/> (31 May 2015).

---

9   The second oil price shock tripled Thailand's fuel import bill, constituting thirty per cent of all imports by 1982, even as natural gas was at that time coming online (Foran 2006, citing Phongpaichit/Baker 1995; Greacen/Greacen 2004).

export demand. Thailand's electricity sector particularly struggled, as its rapid expansion in the late 1960s and 1970s had been debt-financed; furthermore, an emphasis on supply-side-led expansion (rather than energy conservation) also created perceptions of capital shortage (Foran 2006: 41). The government entered into a structural adjustment programme from 1981 to 1985 with the World Bank and *International Monetary Fund* (IMF), who had realigned themselves towards a neo-liberal development paradigm; loan conditions of the World Bank and the IMF included commitments to privatize SOEs, and for the electricity sector to raise prices (ultimately by two and a half times as much). Yet EGAT and its union resisted and ultimately defeated their privatization (Greacen/Greacen 2004).

By the late 1980s, Thailand's economy had recovered, and the country began to experience power shortages. EGAT, however, was still burdened by high levels of foreign-sourced debt, servicing of which constituted over half of its budget (Greacen/Greacen 2004). In 1992, the pro-market National Energy Policy Council chaired by the prime minister, and its secretariat the *National Energy Policy Office* (NEPO), tried to bring together a fragmented series of energy 'policies' within one entity (Wattana/Sharma/Vaiyavuth 2008). It also sought to address power shortages through 'restructuring the industry' by launching an *Independent Power Producers* (IPPs) programme in 1994. There were subsequent plans for a competitive power pool electricity market for generation and privatization of retail distribution, which remained unfulfilled. As EGAT also strengthened its technical capacity ('knowledge') for planning, it introduced least-cost planning practices. Thailand's *National Economic and Social Development Board* (NESDB), meanwhile, increased its 'regulatory' scrutiny of EGAT's *Power Development Plans* (PDPs) that it prepared (Foran 2006: 19). Power shortages also sparked EGAT's first concern for energy conservation, catalysed by the NGO *International Institute for Energy Conservation* (IIEC), signifying a shift in planning 'culture' (see Foran 2006; 39.4.2).

NEPO permitted EGAT to sign several *Power Purchase Agreements* (PPAs) with IPPs on a 'take-or-pay' basis, thus allowing entry of large private-sector actors into Thailand's electricity generation. EGAT established a subsidiary, the *Electricity Generating Company* (EGCO), to operate two of its most profitable plants as IPPs whilst maintaining a forty-five per cent share in the company, and began negotiating contracts with other IPPs. These 'policies' were rein-

forced by pressure from the World Bank and IMF, alongside the apparent availability of international private capital seeking profitable returns in developing countries. Greacen (2007) notes that the IPP programme, whilst contributing to meeting Thailand's electricity demand, has presented a number of risks to IPPs, including delays due to electricity demand gluts, community opposition, and political and policy/regulatory uncertainty, as well as risks to electricity consumers in Thailand who have had to pay for unused generation capacity (39.3.3).

At the same time, the *Small Power Producers* (SPP) programme, launched in 1992, allowed an additional role for the private sector, either selling to EGAT or directly to nearby industry. The SPP programme purchases electricity from either *combined heat and power* (CHP) or renewable private sector generation projects of up to 90 MW. Thailand was the first country in Asia to adopt such a programme,[10] which was modelled on the US *Public Utilities Policies Act* (PURPA) 'regulations' (Greacen 2007). As of 2009, the capacity of SPPs was 1,962 MW, representing 6.7 per cent of Thailand's total capacity (EGAT 2010).

As EGAT resisted NEPO's attempt to unbundle generation, transmission and distribution, in 1997 Thailand was hit by the Asian financial crisis (Smith 2003). The crash of the economy reduced electricity demand, whilst the collapse of the Thai baht left EGAT struggling with its foreign-denominated debt. The 'take-or-pay' IPP contracts signed by EGAT were also left in a precarious position, and the government subsequently renegotiated these (Greacen 2007). An economic adjustment package offered by the IMF required further 'policy change' towards privatization; EGAT was required to sell assets, including a sixty-five per cent share in its just-built, profitable Ratchaburi gas-fired plant (Smith 2003).

Following the Asian financial crisis, Thaksin Shinawatra's *Thai Rak Thai* (TRT) government which came to power in 2001 redefined the direction of Thailand's electricity 'industry restructuring' (as well as many other functionings of the government). Having established a new Ministry of Energy in 2002 and redesignated NEPO as the *Energy Policy and Planning Office* (EPPO) with significantly reduced powers, TRT

10 World Bank "Retoolkit Case Study: Small Power Producers in Thailand", at: <http://siteresources.worldbank.org/EXTRENENERGYTK/Resources/5138246-1238175210723/Thailand0Small0Power0Producer0Program0.pdf> (31 May 2015).

shelved plans to create a competitive power-pool electricity market and replaced it with an *enhanced single-buyer* (ESB) model, in which EGAT owned approximately fifty per cent of the generation capacity and a hundred per cent of the transmission. Wattana/Sharma/Vaiyavuth (2008: 47) observe that the ESB model was quite similar to the previous single-buyer model, thus maintaining many traits of the existing electricity regime. TRT's approach de-emphasized market competition within the electricity sector, and promoted EGAT as a 'national champion.' A greater priority for TRT was to corporatize EGAT as a public company on the *Stock Exchange of Thailand* (SET), reflecting TRT's economic policy of expanding the SET, building Thailand's domestic market, and projecting influence into neighbouring countries. The SET listing, however, was blocked in Thailand's Supreme Administrative court in 2006 by a coalition formed of EGAT's labour union and civil society consumer groups concerned about the absence of an independent energy regulator. Subsequent to the court case, the Energy Industry Act, B.E. 2550 (2007) was passed (under a military-appointed government), which established the *Energy Regulatory Commission* (ERC) reshaping 'user relations' (Wattana/Sharma/Vaiyavuth 2008; Wisuttisak 2012).

As a result of these waves of partial-privatization, EGAT's share in generation dropped from eighty-nine per cent in the late 1980s to forty-six per cent in 2012 (EPPO 2013). Meanwhile, 'favoured technology' had shifted towards combined-cycle gas turbines fuelled by natural gas, which had become available domestically and via import from Myanmar. The claimed aims of the IPP programme were to reduce EGAT's investment burden and the cost of power generation. Wattana/Sharma/Vaiyavuth (2008: 45) conclude, however, that although IPP bidding was competitive, it appeared that cartels were formed to push up bidding prices, and thus any reduced costs in production were not passed on to consumers but rather remained with the companies and their shareholders. Conflicts of interest were also noted; Wattana/Sharma/Vaiyavuth (2008: 50) write "Some of the business-orientated politicians with dual roles—as citizens' representatives and as executive directors of companies—played a part in promoting the privatization of the industry".

The corollary of the partial privatization of Thailand's electricity sector is the growing role of the private sector in decision-making on power projects; this includes not only IPPs but also construction companies and commercial banks, among others (Middleton/Matthews/Mirumachi 2015). Many of Thailand's

IPPs and SPPs, as well as the major commercial banks that fund them, are listed on the Stock Exchange of Thailand (SET). For these actors, return on investment and minimization (or redistribution) of investment risks are key criteria by which power projects are financed and thus built. For example, the controversial 1,285 MW, US$3.5 billion Xayaburi Dam on the Mekong River's main stream in northern Laos (see also 39.4.2.1), now under construction, is owned by a predominantly Thai consortium with financing from Thai commercial banks. The project signed a PPA with EGAT to export ninety-five per cent of its power to Thailand. When the Laos government announced its final approval of the project in November 2012, the share price of the lead developer, the Thai construction company Ch. Karnchang, hit a twenty-one-month high, unsurprisingly revealing the stock market incentives for listed IPPs.[11] Merme/Ahlers/Gupta (2014) warn that such strict market logic may undermine a power project's long-term commitment to environmental sustainability and local livelihoods, or displace these costs from the private developer to the state, as is highly likely to be the case with the Xayaburi Dam (Matthews 2012; Middleton/Matthews/Mirumachi 2015). Meanwhile, Phongpaichit/Benyaapikul (2013) flag up that EGAT's role as both state utility and major investor in private affiliates, such as Ratchaburi and EGCO (which also holds a 12.5 per cent share in the Xayaburi Dam), creates a potential conflict of interest as the organization becomes a blurred semi-public, semi-private entity.

In the 1990s, some initial domestic concern (reflecting also a global concern) for renewable energy, energy efficiency, and demand-side management moved up the 'policy' agenda within the incumbent electricity regime (see 39.3.3 and 39.4). This was catalysed by both collaborative and adversarial relationships with NGOs (see 39.4.2). An increasingly vocal civil society also sought to challenge individual projects, including fossil-fuel-fired projects and hydropower dams that still remained as 'favoured technologies', as well as to influence EGAT's planning process. In total, this reflects the emergence of a "small sustainability agenda" in pursuit of cost effectiveness and environmental consideration, although Foran (2006: 4) argues that "Thailand's electricity planning, and its overall industry structure, impede sustainable energy

---

11 "Ch Karnchang hits 21-mth high on Xayaburi dam nod"; in: *Reuters*, 6 November 2014, at: <http://www.reuters.com/article/markets-thailand-stocksnews-idUSL3E8M61E520121106> (31 May 2015).

futures". Foran (2006: 4) further observes that the privatization debate in the 1990s and 2000s insufficiently addressed who plans and strategizes the electricity system, and that:

> Of all the agencies involved, EGAT plays a major role in shaping the details of what appears in the PDP, particularly plant size, fuel source, and location. These conditions prevailed in the 1980s, at the time Pak Mun was identified as a potential addition to the Thai power system. They prevail today. The continuity surrounding the PDP process is remarkable considering the dynamism surrounding EGAT (Foran 2006:5).

Whilst preparation of the PDP has been a closed-door process, since 2007 a slight (but imperfect) increase in transparency and public participation has emerged, with public hearings held during the 2010 PDP preparation process (Foran 2013) and more limited ones for the 2015 PDP. Thailand's PDP process has been criticized by civil society groups and critical academics for emphasizing supply-side options, in particular large-scale centralized technologies, downplaying the potential for renewable small-scale technologies and distributed systems, and not integrating demand-side planning, including energy efficiency and demand-side management (Greacen/Greacen 2012). Thus, even as countervailing 'knowledge' of civil society advocacy coalitions increasingly challenged mainstream discourses, EGAT's technical 'knowledge' continued to predominate, and constructive discussion about any actual technical and economic constraints and how they might be overcome has been limited.

It is of note that the circumstances, processes, industry structure, and outcomes of partial electricity sector reform in Thailand parallel the experience of other emerging economies that have incumbent electricity regimes. These include: the significant role of debt and financial crisis as a context for (partial) reform; the creation of an (enhanced) single-buyer model rather than full privatization of distribution; the prioritization of a limited number of (politically connected) IPPs to meet immediate generation demand that seems politically and technically easier, and the use of long-term PPAs rather than a competitive generation market, guaranteeing revenues; the relatively weak role of independent regulation; and, overall, the continued strong presence of the state (Victor/Heller 2007).

Thailand has also experienced the emergence of what Victor/Heller (2007: xvii) term 'dual firms' that are owned jointly between SOEs and private-sector actors. In other emerging economies, including China, India and South Africa, Victor/Heller (2007:

xvii) observe that dual firms "thrive in the murky middle ground between the old state-dominated system and a fully open and competitive private marketplace," and this captures the character of EGCO and Ratchaburi. They are well connected politically, yet relatively efficiently managed, and act to protect the partially privatized regime and their privileged status within it (Victor/Heller 2007: 289–290). The limited number of actors within the regime facilitates policy negotiation internal to the regime, which outsiders—including critical NGOs and civil society groups—find difficult to influence, reflecting overall power relations between these actors.

39.3.3   Thailand's Current Electricity System and Challenges

In terms of the current structure of the industry, of the total installed capacity of 32,600 MW in 2012, EGAT generates 46 per cent; IPPs generate 39 per cent; SPPs generate 8 per cent; and 7 per cent is imported from Lao PDR and exchanged with Malaysia (EPPO 2013: 89). The maximum peak demand in 2012 was 26,121 MW. The figures for fuel type are: natural gas fuels 67 per cent; coal/lignite fuels 20 per cent; domestic hydropower fuels 5 per cent; oil fuels 1 per cent; and electricity import/exchange (principally hydropower) fuels 7 per cent. By sector, the largest consumers of electricity were industry (45 per cent), followed by residential (23 per cent) and commercial (17 per cent) (EPPO 2013: 93).

Thailand faces a particular challenge in terms of long-term fuel supply. At present, seventy per cent of Thailand's electricity generation is fuelled by natural gas, of which (as of 2006) twenty-seven per cent was imported from Myanmar (Nakawiro/Bhattacharyya/Limmeechokchai 2008). As Thailand's domestic gas supplies could potentially be exhausted by 2025 (Sutabutr 2010, cited in Meerow/Baud 2012: 21), and opposition to further coal-fired power stations and hydropower remains staunch, as does proposals for nuclear power, EGAT faces a difficult dilemma in continuing a business-as-usual model without encountering civil society and community opposition (Nakawiro/Bhattacharyya 2010). Recognizing these challenges, and based on Thailand's 2010 Power Development Plan, Kamsamrong/Sorapipatana (2014) argue that a renewable energy scenario for Thailand is possible, which would strengthen energy security through dependence on domestic fuel sources, whilst also reducing CO_2 emission intensity (see also Greacen/

Greacen 2012). However, the cost per unit of electricity in the 2010 PDP would increase by fourteen per cent.

On the other hand, at present Thailand's electricity system has an excess of generation capacity; in 2015, the reserve margin[12] was twenty-five per cent, and with several new projects contracted to come online in the next couple of years this could increase to as much as thirty-five per cent over the next decade.[13] EPPO and EGAT have claimed that an unexpectedly weak economy has led to unanticipated low growth in electricity demand, whilst civil society groups, frustrated that these costs are ultimately passed on to consumers, claim that the creation of overcapacity is a systemic flaw in the incentives and oversight of the current cost-plus electricity regulations (39.3.1) and power planning model (39.4.2.1).

Climate change (as a 'landscape' factor) has also risen up the 'policy' agenda, creating pressure for change in the electricity system. For civil society groups, this has led to a push for energy conservation and renewable energy (see 39.1.4). EGAT, meanwhile, whilst incorporating these concerns into its so-called 'Green PDP' (EGAT 2010), has also responded by promoting 'clean coal technology', more large-scale hydropower dams, and a nuclear power station.

Another challenge is created by the institutional disjunctures, not unique to Thailand, between electricity planning and those agencies related to water management and food production (Middleton/Dore 2015). Since 2008, there has been growing discussion about the water–energy–food nexus globally and in South East Asia as a policy and research agenda, although to date this is yet to be extensively translated into national policy and practice (Middleton/Allouche/Gyawali et al. 2015).

At the time of writing, Thailand's most recent Power Development Plan is the PDP 2010 revision 3, approved in December 2011 (EPPO 2012).[14] It anticipates a total system capacity growth of 52,256 MW by 2030, almost double that of 2010, although this growth is contested by civil society groups (Greacen/Greacen 2012). Guided by an Alternative Energy Development Plan (2012– 2021), the PDP proposes that "total capacity of renewable energy will be

around 20,546.3 MW (or 29 percent of total generating capacity in the power system)", although this includes a significant proportion of large hydropower plants whose 'renewable' credentials (in the sense of broad-based sustainability and social justice) are contested. This strategy reflects a concern for energy security, in particular fuel diversification, and a reduction in dependence on natural gas. Meanwhile, the Twenty-Year Energy Efficiency Development Plan 2011–2030 proposes a twenty-five per cent reduction in energy intensity within twenty years.

39.4 Role of Civil Society in Sustainable Electricity Transition in Thailand

This section discusses how civil society has acted to transform the 'landscape' in which the incumbent electricity regime exists (39.4.1), to unsettle the existing 'regime' (39.4.2) and to imagine a new one (39.4.3), and how new 'niches' have been created (39.4.4). The analysis is structured according to Smith's (2012: 189) typology of civil society activity in relation to sustainable energy transitions (see table 39.1).

39.4.1 Landscape Transformation

Thailand's 1997 People's Constitution—since replaced, following a military coup, by a new Constitution in 2007[15]—was a fundamental shift in landscape (39.3.2) that reconfigured Thailand's political system, including recognizing many human rights, and creating a Constitutional Court, an Administrative Court, a National Counter Corruption Commission, and a National Human Rights Commission. Articles[16]

---

12 'Reserve margin' reflects the percentage of excess capacity relative to maximum annual peak demand in the system.

13 "Officials to tackle surplus in future electricity supply"; in: Bangkok Post, 29 April 2015, at: <http://www.bangkokpost.com/business/news/544859/officials-to-tackle-surplus-in-future-electricity-supply> (31 May 2015).

14 On 14 May 2015, Thailand's National Energy Policy Committee approved the PDP 2015. Full details were not available at the time of writing, but the plan anticipates a growth in generation capacity from 37,612 MW in 2015 to 70,410 MW by 2036 ("Public hearing held on the Energy Ministry's PDP"; in: Thai PBS, 28 April 2015, at: <http://englishnews.thaipbs.or.th/public-hearing-held-on-the-energy-ministrys-pdp> (31 May 2015)); and a reduction in the proportion of natural gas as a fuel from sixty-seven per cent to forty per cent, to be replaced by coal, hydropower and renewable sources ("National Energy Policy Committee approves Thailand's power development plan (PDP 2015)", in: media release by the Royal Thai Government, 14 May 2015, at: <http://www.thaigov.go.th/index.php?option=com_k2 &view=item& id=91997:91997&Itemid=398&lang=en> (31 May 2015)).

allowed for the right to access information and to hold public hearings (Articles 56 and 57), and the right to public participation (Article 67); the latter is significant given that Thailand's *Enhancement and Conservation of the National Environmental Quality Act, NEQA* 1992, that predates the 1997 and 2007 constitutions and provides the law on *Environmental Impact Assessment* (EIA), does not detail requirements for public participation.

These mechanisms to counterbalance the power of the state have been framed by often contentious debate about democracy and development in Thailand, incorporating public interest issues such as economic, social and political (in)equality, and environmental protection versus development. These 'landscape' shifts have challenged (and been shaped by) the incumbent electricity regime, including in terms of transparency, participation and accountability, and they also provide some opportunity for emergent niches (Smith/Voß/Grin 2010: 441). For example, article 67 states that people have the right to ask for and participate in a *Health Impact Assessment* (HIA), which was translated into rules and procedures following a constitutional court ruling—brought by civil society—in December 2009; power development plans and large power projects are subject to a HIA (National Health Commission Office Thailand 2010: 12). In another example, as mentioned above (39.3.2), opponents of EGAT's listing on SET won their case in Thailand's Supreme Administrative Court in 2006. These entitlements under the law are legitimized and reinforced as they are exercised with regard to cases in the electricity sector.

Some civil society groups have also conducted awareness-raising campaigns about the impact of consumerist lifestyles in Thailand, perhaps the most high-profile of which have related to climate change, for example the activities of the Thai Climate Justice Network.[17] Whilst Thailand has made important steps in reducing material poverty and increasing *gross domestic product* (GDP), its ecological footprint is rising;[18]

Thailand's carbon intensity—CO_2 emissions per unit of GDP—are significantly higher than neighbouring Cambodia and Laos, as well as greater than some other large industrial countries in Asia such as Japan.[19] According to the International Energy Association, for the period 2011 to 2035, carbon intensity will decrease by 1.4 per cent per year on average, whilst per-capita emissions will rise from 36 per cent to 90 per cent of the OECD average over the same period (IEA 2013).

39.4.2 Unsettling the Incumbent Electricity Regime

Since the 1990s, a diverse range of civil society groups has sought to unsettle Thailand's existing electricity regime at scales ranging from individual projects to the PDP itself (Foran 2013). Not all civil society, however, is seeking to unsettle the incumbent regime. EGAT's union has maintained a close alignment with EGAT, staunchly resisting efforts to privatize EGAT in order to protect members' jobs and the benefits that EGAT provides for its employees. On the other hand, when interests have been aligned, EGAT's union has also partnered with consumer groups and NGOs, most notably when the Thai Rak Thai party sought to corporatization EGAT in 2006 (see 39.3.2); whilst EGAT's union opposed the corporatization in general and sought to maintain a minimum generation capacity of at least fifty per cent of the total system for EGAT, consumer groups and NGOs disagreed with the corporatization in the absence of an independent regulator.

39.4.2.1 Challenging the Incumbent Regime Through Resistance

Since the 1990s, community protests—supported by a range of NGOs—emerged around numerous projects proposed by EGAT and IPPs, including the Pak Mun and Nam Choan hydropower dams (Foran/Manorom 2009; Hirsch 1998) and coal-fired power plants in Prachub Khiri Khan province and the Mae Moh project in Lampang province (Hildyard/Lohmann/Sexton 2012;

---

15 The new constitution was approved in October 2006. At the time of writing (May 2015), the 2006 constitution had been repealed following another military coup in May 2014. In July 2014 an interim constitution was enacted, with a new constitution under preparation. Meanwhile, martial law was mostly lifted in April 2015, although many restrictions on political freedoms remain in place.

16 Carried over from the 1997 into the 2006 constitution.

17 See Thai Climate Justice website, at: <http://www.thai-climatejustice.org/> [in Thai] (28 May 2015).

18 See at: <http://www.gms-eoc.org/gms-statistics/overview/ecological-footprint> (28 May 2015).

19 According to World Bank Indicators (see at: <http://data.worldbank.org/indicator/EN.ATM.CO2E.PP.GD> (28 May 2015)), CO_2 emissions (kg per PPP $ of GDP) for 2010-2014 are: 0.4 in Thailand; 0.1 in Cambodia and Laos; 0.2 in Indonesia and the Philippines; 0.4 in Vietnam, Malaysia and South Korea; and 0.3 in Japan.

Greenpeace 2005). The case of Mae Moh, for example, has been the subject of a decade-long court case for remedy and restitution.[20] Whilst it has been claimed that EGAT was a relatively early adopter of EIA, partly due to the strong influence of the World Bank (Shepard/Ortolano 1997), numerous other researchers have highlighted the shortcomings of such assessment processes so far in Thailand (ADB 2010; Boonlong/Farbotko/Parfondry et al. 2011; Friend/Pradubsuk/Badenoch/ et al. 2011).

In the case of the proposed private coal-fired power plants in Prachub Khiri Khan in the 1990s, for example, EGAT signed a PPA before holding hearings or conducting an EIA. International NGOs supported local opposition "by pointing to the conflict of interest between the government's investment in private projects, and its regulation of those projects' rates of return" (Ryder 1997, cited in Foran 2006). Meanwhile, others pointed out that the power was surplus to requirements due to the impact of the Asian financial crisis. As Thailand has shifted to power-import projects from neighbouring countries, transnational campaigns have also emerged, for example around the Nam Theun 2 and Theun Hinboun Dams in Laos, and the Yandana gas pipeline and proposed dams on the Salween River in Myanmar (Middleton 2012). These have challenged EGAT as the electricity buyer, as well as the host project government, project developers and financiers.

A recent example of a transnational campaign is the Xayaburi Dam (see 39.3.2). Project proponents argue that the Xayaburi Dam would contribute towards Thailand's energy security and generate cheap electricity, and that the FDI and project revenues would bring development to Laos. Those opposing the project, including various civil society groups, emphasize that the project will displace 2,100 people and that more than 200,000 people located near the dam would experience a negative impact on their livelihoods, both within Laos and in neighbouring countries. Civil society strategies to challenge the project have included: challenging the intergovernmental process hosted by the Mekong River Commission; direct protests including peace walks along the Mekong River, in front of the lead company's headquarters, and at various government agencies; consumer boycotts against Thai banks; public petitions; and media

coverage (International Rivers 2014; Matthews 2012). A range of counter-expertise has been invoked, including legal interpretation,[21] scientific assessment of project documents (Hirsch/Hogan/Lanza et al. 2011), and alternative ways of valuing the river, ranging from ecological economic assessments (Costanza/Kubiszewski/Paquet et al. 2011) to local knowledge (Herbertson 2012). The project is currently a case before the Supreme Administrative Court in Thailand brought by Thai riparian communities against the Thai government agencies involved, including the Ministry of Energy, benefiting from the 1997 'landscape' changes–and seeking to expand them, given that the project is located in neighbouring Laos.[22]

From the late 1990s, Thai NGO civil society groups have also sought to challenge the power planning process itself, seeking to make it more transparent and accountable (Greacen/Palettu 2007; Foran 2013). Electricity planning in Thailand has been enshrouded in a discourse of expert knowledge–and the power relations that that entails–which in turn has supported the incumbent electricity regime (Foran 2006). Since the 1980s, EGAT's power planning has become more technically sophisticated, including least-cost planning, load forecasting, and determining reserve capacity (Foran 2006). Yet counter-expertise has challenged assumptions within EGAT's PDP (see 39.4.3). For example, a 2006 study by Greenpeace showed that twelve of the last thirteen power-demand estimates by EGAT had been overestimates, resulting in over-investment in generation capacity (Greacen/Footner 2006). A combination of factors is likely to have contributed to this track record, including: a tendency to over forecast Thailand's GDP growth rate, which is a fundamental assumption in the long-term PDP, and hence demand growth; risk perception of planners towards demand-side management and energy efficiency measures in the face of the need to maintain a stable electricity supply; the moral hazard of cost-plus regulations;[23] and the existing interests and politics of the incumbent electricity regime.

Civil society has sought also to open up the electricity planning process to more participation, transpar-

ency and accountability, citing the broader 'landscape changes' and associated entitlements. For example, under a wider World Resources Institute initiative, a consortium of Thai organizations researched a benchmarking report that assessed electricity governance performance with regard to policy process, regulatory process, and environmental and social considerations, and placed Thailand in a comparative perspective against nine other emerging economy countries (Sukkumnoed/Greacen/Limstit et al. 2006). The report and policy work surrounding it both contributed to blocking EGAT's corporatization in 2006, and helped shape the subsequent law that established the Energy Regulatory Commission (WRI/EGI/Prayas Energy Group n.d.).

39.4.2.2 Challenging the Incumbent Regime Through Cooperation

Some civil society groups have sought to cooperate with EGAT to reform its practices. For example, the rise of Thailand's energy conservation agenda is linked to the catalytic work of the *International Institute for Energy Conservation* (IIEC), a technically-orientated NGO with its headquarters in the US. In the early 1990s, IIEC proposed a US$179 million energy conservation programme to EGAT, PEA and MEA, that was taken up and implemented. IIEC formulated its proposal on the basis that investment in *demand-side management* (DSM) and *energy efficiency* (EE) was the least-cost option for Thailand. In tracing the origin of the programme and its impact, Foran (2006: 28) observes that there was a "good rapport" between EGAT and IIEC.

Yet energy conservation also presented a number of challenges to EGAT, such that its full potential has not been exploited (Foran 2006: 27–32; Foran/du Pont/Parinya/ et al. 2010). IIEC proposed a new approach to PDP preparation based on the principles of *Integrated Resources Planning* (IRP), namely least-cost planning that optimizes both the supply side and the demand side. EGAT's senior management and planners, however, perceived interventions to change user behaviour as risky with regard to ensuring electricity system reliability in contrast to building new

supply, and thus continued to pursue a business-as-usual approach that privileged the expansion of capacity. Such nationally-scaled framing of electricity systems—including of aggregated demand—renders invisible local-scaled practices surrounding electricity consumption, including its micro-politics (Smits 2012), and how the preferences of users are shaped through broader consumer society preferences and practices (Shove/Walker 2014) (39.2.3).

39.4.3 Imagined Alternative Sociotechnical Regime

Civil society has also unsettled the incumbent electricity regime through imagining and practising alternatives. At the community scale, for example, groups resisting EGAT's plans for two large-scale coal-fired power plants in Prachub Khiri Khan province sought to reframe the concept of development. The power stations were part of the Southern Seaboard development plan that proposes industrial steel production in the region. They envision

> a just provincial level programme for defence of local subsistence and prosperity through rice, coconut and pineapple cultivation, local marketing, small fisheries, tourism, and wind and other non-fossil energy sources (Sureerat 2010, cited in Lohmann/Hildyard 2013:14).

They reimagine energy production as locally produced and at an appropriate scale for their area, rather than meeting 'national' energy demand; this reflects an often-found 'politics of scale' tension between local- and national-level priorities and the discourses (and power inequalities) that frame them (Sneddon 2003). In another example, the *Appropriate Technology Association* at its energy ashram in Nakorn Ratchasima Province researches, promotes and puts into practice appropriate technologies related to rural development.[24] It was created by an early-retired engineering professor from Chulalongkorn University in Bangkok, and those visiting the ashram can learn about a range of methods by which to produce energy sustainably.

Other civil society groups have worked to create different PDPs from EGAT's plans. In 2004, in the context of the opposition to the corporatization of EGAT, civil society groups under the auspices of the National Economic and Social Advisory Council developed an "Alternative PDP" that was presented to the Senate Committee on Public Participation (Permpongsachar-

---

23 It has been pointed out by numerous critics that EGAT's cost-plus investment arrangement is a disincentive to investment in electricity-saving measures, as profit cannot be made by reducing electricity sales; in contrast, it incentivizes over-investment, as well as creating unnecessary social and environmental costs (Foran 2006: 31; Greacen/Footner 2007).

24 Appropriate Technology Association website; at: <http://www.ata.or.th/th/index.php> (28 May 2015).

oen 2004). Since then, two more complete studies have been prepared, in 2006 (Greacen/Footner 2006) and in 2012 (Greacen/Greacen 2012). These studies highlight the limitations of existing electricity planning and its governance, and propose plans whereby Thailand could meet its energy needs through energy conservation, renewable energy, and refurbishing existing power stations. They also propose improved practices for planning, namely IRP, and additional decision-making criteria that internalize environmental and societal costs. Whilst EGAT has not officially responded to these plans, as credible counter-expertise they have empowered community groups to challenge the business-as-usual approach.

39.4.4   Electricity Niche Development

Civil society groups also play a role in nurturing niches (Seyfang/Smith 2007; Smith 2012). As an example in Thailand, this section focuses on the emergence of the *Very Small Power Producer* (VSPP) programme and the role of civil society, approved by the Thai Cabinet in 2002 and expanded in 2006. The internationally-applauded programme has allowed for the distributed production of electricity from renewable energy systems, and has been argued to increase the resilience of Thailand's electricity system (Meerow/Baud 2012).

The origin of the VSPP programme can be traced back to a community micro-hydropower project in Mae Kampong village, Mae On district, Chiang Mai province, northern Thailand (Smits 2012; Greacen 2004), and the activities of a small number of researchers, civil society groups and progressive government staff in EPPO and EGAT (Brouwer 2012). Briefly, three micro-hydro schemes of twenty to forty kilowatts have been built in Mae Kampong village in 1983, 1988 and 1994. The projects were built as a partnership between the community and the government's *Department of Alternative Energy Development and Efficiency* (DEDE), resulting in a strong sense of community ownership (Smits 2012). Importantly, even when PEA's grid electricity reached the village in 2000, the community preferred to maintain the micro-hydro system as a cooperative alongside it, partly because it enhanced their image as an 'environmentally friendly forest community' and thus supported an ecotourism project also implemented by the villagers (Smits 2012). The micro-hydro projects, in other words, are linked to the village's culturally-valued ecological identity (cf. Smith 2010).

In 2001, a PhD researcher working with the community, Christopher Greacen, began to consider how it might be technically possible to connect one of the micro-hydro projects to PEA's grid. At the same time, Cheunchom Sangarasri Greacen, a staff member at EPPO, explored how a regulatory framework might enable this arrangement.[25] According to Brouwer (2012: 4), over 2001:

> Working closely with the utility companies and regulators, and operating without public pressure, lobbying, op-eds or media coverage, Chris and Chom saw Cabinet approval for the VSPP rules in less than a year. Their strategy was to work collaboratively with the authorities (government regulators), and to establish allies in the sector with the biggest influence on the process (utilities).

Thus, catalysed by this groundbreaking work emerging from Mae Kampong, in 2007 one of the village's micro-hydro projects was synchronized to sell to PEA's grid, benefiting from the VSPP programme it helped create and earning the community approximately US$1,000 per month.[26]

Thailand's VSPP regulations are drawn from net-metering rules that were already in operation in the US at the time of drafting, and are also based on the existing Small Power Producers regulations passed in Thailand in 1992 (Greacen 2007). The first-phase VSPP regulations, approved in 2002, allowed projects of up to 1 MW to connect to the grid, thus assuaging the concerns of EGAT's engineers regarding distributed generation sources creating grid instability. The 2006 VSPP modifications included an adder feed-in tariff (i.e. a subsidy) and allowed for projects of up to 10 MW, including co-generation units (Greacen 2007).

The VSPP projects have challenged Thailand's business-as-usual electricity regime, in that most contributing renewable energy systems are owned by small- and medium-scale businesses[27] rather than EGAT or large IPP companies, thus diversifying the ownership of gen-

---

25 Christopher and Cheunchom Greacen went on to create the NGO energy think tank Palang Thai in 2002 (Foran 2006), which continues to promote the VSPP programme.

26 Unfortunately, after six months operation, sales to PEA were halted due to a disagreement over the sharing of revenues between the village and the sub-district authority (Smits 2012).

27 Since 2014, community groups—in hybrid governance arrangements with the state and private sector—have sought to benefit from the VSPP programme, albeit on a small scale at present (On 2015).

eration capacity. On the other hand, at the time of the VSPP programme's development, EGAT was facing pressure to privatize, and thus EGAT's permitting a greater (but still comparatively small) role for the wider private sector could also be viewed as a minor compromise that actually bolstered the incumbent electricity regime. As Brouwer (2012) writes, interviewing Christopher Greacen:

> the VSPP regulations were politically very 'nicely aligned, because they were consistent with private sector participation in the power sector in the sense that they would enable more customer-owned generators. The utilities could give back a little bit by making a concession on this while they were fighting against [utility privatization]'.

Despite the apparent success of the VSPP programme and Thailand's Ten-Year Alternative Energy Development Plan (39.3.3), challenges remain for the widespread scaling-up of renewable energy. Tongsopit/ Greacen (2013: 440) point out that one "major impediment" is that Thailand has six separate long-term national energy plans which are neither integrated nor coordinated. Meanwhile, whilst the adder feed-in tariff programme as first implemented between 2007 and 2010 was, according to Tongsopit/Greacen (2013: 441), "systematic and transparent", since then loopholes have been exploited whereby private companies have bid for solar VSPP PPAs with the intent to resell the PPA rather than develop the capacity themselves. The government's response has been to create a new Management Committee and evolve rules since 2010 which have been criticized as lacking transparency and also as slowing down investment in renewable energy (see also Meerow/Baud 2013). Other controversies have also emerged, for example the local pollution impacts of some poorly-managed biomass projects under the VSPP programme (Yoo 2013).

39.5 Conclusion: Towards Decentralizing and Democratizing Electricity

This chapter has applied a Sustainability Transition and Multilevel Perspective lens to explain the creation and resistance to change of Thailand's incumbent electricity regime, which was first a state monopoly and since the 1980s has evolved into a partially-privatized structure. This chapter has conceptualized the incumbent regime not as monolithic but as a coalition of actors (pursuing their interests) including the state utility, its labour unions, and various 'dual-firm' IPPs,

thus adopting an explicitly political economy approach. The chapter has contributed to sparse literature on sustainability transition in Asia's NICs, and in particular on how Thailand's political economy has shaped the electricity regime's establishment and embedding, and its resistance to change that combines economic, institutional, cultural and political factors, with technical lock-ins and historical pathway dependencies.

Changes in the structure of the incumbent electricity regime have been shaped by shifts in 'landscape'. These shifts include those at the global scale (changing development paradigm from developmentalist state to neo-liberalism, global economic crisis and Thailand's exposure to it as an export-orientated economy, and climate change) and at the national scale (increasingly embedded democratic institutions, and a growing role for civil society). Regarding the latter, these political spaces have been widened as civil society groups have sought to claim, utilize, and thus legitimize them—and have been closed as elites have sought to reduce the role of progressive civil society groups. It may be noted that not only has reform of the electricity sector regime been shaped by these landscape level shifts, but the electricity sector has also constituted an important theme within broader political movements seeking landscape shifts in the first place. Incremental reforms, some of which have originated in niches, have been accommodated by the incumbent regime, including the growing contribution of distributed renewable energy generation and energy conservation, the creation of an independent regulator, and a small increase in civil society participation and accountability of the power planning process.

The chapter has emphasized in particular the role of civil society in shaping the incumbent electricity regime. Civil society groups have adopted a range of strategies to unsettle the regime, including opposing problematic projects, advocating for progressive policy, and proposing alternative plans, values and visions for Thailand's electricity sector. In the past two decades there has been a significant growth in contestation and deliberation about how electricity should be produced, how decisions should be taken around it, and how implications for ecological sustainability and justice should be internalized. Whilst significant power asymmetries exist, there is now somewhat more debate between government agencies with civil society. They have drawn upon independent state agencies, such as the justice system and the Thai National Human Rights Commission, to counterbalance the power of the state (Middleton 2012), and their existence reflects 'landscape' level shifts. Civil society is evi-

dently a source of reflexivity in Thailand's electricity sector (Grin/Rotmans/Schot 2010, cited by Smith 2012).

The ST approach and MLP has helped explain why the structure of the incumbent electricity regime has remained relatively intransient, despite the argued-for benefits of electricity sector reform (Greacen/Greacen 2012), and from the perspective of ongoing broader environmental, social and political challenges in Thailand (Phongpaichit/Benyaapikul 2013). Transformation towards sustainability in Thailand, therefore, is a long-term challenge. Drawing insight from sustainability transition management literature (Verbong/Loorbach 2012), some strategies and policies to steer Thailand's incumbent electricity regime in the direction of sustainability include:

- The importance of building long-term and broad coalitions formed of civil society, government reformers, academics, and media (amongst others) that can counterbalance the political influence of the incumbent electricity regime, and that can support the emergence of green niches.
- Expand and maintain political space (or 'transition arenas') and support more deliberative processes that increase the responsiveness of the incumbent

regime, and in particular government agencies (EGAT; Ministry of Energy), to public interest concerns. Adopting IRP practices can integrate supply-side and demand-side multi-criteria least-cost planning. Governance and planning tools such as strategic environmental assessment and (transboundary) environmental impact assessment can also be employed, through which deliberation can occur (Middleton/Dore 2015).
- Build upon landscape pressures to destabilize unsustainable aspects of the incumbent electricity regime. Landscape pressures range from international expectations for sustainability transition towards renewable energy and energy conservation in the context of climate change to utilizing (and thus reinforcing) relatively recent independent state agencies such as the Administrative Courts, the Thai National Human Rights Commission, and the Energy Regulatory Commission.
- Acknowledge and support the legitimate role of civil society in its diverse forms, ranging from local community groups to progressive NGOs, as regime watchdogs and advocates, and as niche innovators.

40 Governance of Sustainable Development in Knowledge Democracies—Its Consequences for Science

Roeland Jaap in 't Veld

Abstract

Governance is the way in which a society organizes decision-making. Advanced societies turn into knowledge democracies where the relationships between politics, media and science intensify and change continuously. The concept of knowledge democracy embraces participatory democracy besides representative democracy, the rise of social media besides corporate media, the emergence of transdisciplinary trajectories besides classical disciplinary science with complex interactions that also change. The quest for sustainable development takes place within knowledge democracies, where sustainability covers economic, social and ecological issues, whose governance is complex. The future direction and content of sustainable development depend on uncertain future determinants such as technological innovation and the evolution of social values. The precautionary principle as a powerful moral imperative has its limitations. The multidimensional nature of sustainability requires integration and a recognition of a multilevel, multiscale, multidisciplinary character. Development refers to change, transitions and transformations. Governance of sustainable development has to cope with complex dynamics. Governance that furthers transitions focuses on the interaction between representative and participatory democracy, and the optimalization of the contribution of science. This chapter addresses the specific consequences for science, in particular the organization of science, relating both to disciplinary research and transdisciplinarity.

Keywords: Sustainable development, knowledge democracy, science, transdisciplinarity.

40.1 Introduction

Sustainable development can be described as a normative notion presenting the preferred evolution of society. The realization of sustainable development demands change in many domains. These changes can be described as transformations or transitions. Governance presents in a normative manner how a society organizes its decision-making. Governance of sustainable development has specific characteristics dependent on its complexity. This chapter concentrates on the necessary changes in the organization of science as an essential component of the governance of sustainable development.

Representative parliamentary democracy is an essential part of governance. Representation gradually became the predominant mechanism by which the population at large, through elections, provided a body with a general authorization to take decisions in all public domains for a certain period of time. Representative parliamentary democracy became the icon of advanced nation states.

The recent decline of representative parliamentary democracy has been noted by many authors (Castells 1996, 2009; Dahrendorf 2002). Media politics destroys the original meaning of representation. The evolution of political parties to marketeers in the political realm destroys their capacity for designing consistent broad political strategies. Like willow trees they move with the winds of the voters' supposed preferences. Volatility therefore has increased. *This is dramatic, because important challenges like sustainable development demand consistent policies over a longer time period.*

The debate on the future of democracy has not yet led to major innovations in advanced societies in Europe. Established political actors try to tackle populism with trusted resources: a combination of anti-populist rhetoric and adoption of the populist agenda. Some media have tried to become "more

populist than populists themselves", almost always at the expense of analytical depth. The development in different parts of the world points to various directions: in parts of South America city government is characterized by remarkable citizens' participation, while in Asia the rule of law is introduced without classical democracy in influential nations. Meanwhile, the Internet and the evolution of social media provide for a drastic change in the rules of the game. A better-educated public has wider access to information, and selects it increasingly itself, instead of relying on media filters by classical media. Moreover, citizens themselves have become prosumers (simultaneously producing and consuming): they utilize social media as consumers but also produce YouTube pictures at home.

At the national level, representative democracy must find new ways of interacting with various forms of bottom-up participatory democracy. The relationships between corporate, top-down media and politics have considerably changed due to the rise of social media because politicians may utilize social media to directly communicate with voters, reducing their dependence on the top-down media. The corporate media are no longer the sole necessary intermediaries between politicians and voters.

But people get also tired of social media, because the latter produce information of different quality, increasing the costs of finding trustworthy information and producing confusion and ambiguity. In most social media no editor exists. There is no selection of information on the basis of quality to enable consumers to minimize their costs of searching.

The crucial combination of a network society and media politics (Castells 1996, 2009) provides new problems and tensions. The political agenda is increasingly filled with so-called wicked problems, characterized by the absence of consensus both on the relevant values and on the necessary knowledge and information. Uncertainty and complexity prevail. Wicked problems cannot be 'solved' in a classical way but it is possible to live with them (Hajer 2003, 2005; Hoppe 2008, 2010; Meuleman 2013). *Sustainable development is characterized by the presence of major wicked problems.*

In general contemporary societies experience an increasing intensity and speed of reflexive mechanisms (In 't Veld, 2009, 2010, 2012). In a more or less lenient political environment reflexive mechanisms cause overwhelming volatility of bodies of knowledge about social systems. As all available knowledge is utilized to facilitate reflexive processes, their result might establish new relationships undermining existing knowledge. Social reality has thus become unpredicta-

ble in principle. Both knowledge and information are increasingly volatile and are surrounded by uncertainty.

In their introductory chapter to *Reflexive Governance to Sustainable Development*, Voß and Kemp (2006) deal with reflexivity and distinguish between first- and second-order reflexivity. First-order reflexivity "refers to how modernity deals with its own implications and side effects, the mechanism by which modern societies grow in cycles of producing problems and solutions to these problems that produce new problems. The reality of modern society is thus a result of self-confrontation" (Voß/Kemp 2006: 6). Second-order reflexivity concerns "the cognitive reconstruction of this cycle". It "entails the application of modern rational analysis not only to the self-induced problems but also to its own working, conditions and effects".

The relationships between science and politics demand new designs in an environment of media politics, wicked problems and reflexivity. Jasanoff's (2003, 2004) classical theory on boundary to cope with existing gaps between science and politics is now widely accepted among experts. The underlying insight is that scientific knowledge by its very structure never directly relates to action, because it is fragmented, partial, conditional and immunized. This observation applies to both mono- and multidisciplinary knowledge. Translation activities are always necessary to utilize scientific knowledge for policy purposes.

The literature on transdisciplinary research is dominated by process-directed normative studies. The key concept of transdisciplinarity should be defined as the trajectory in a multi-actor environment from a political agenda and existing expertise to a robust, plausible perspective for action. Thus, in the terminology of Voß and Kemp we mainly deal with second-order reflexivity.

We try to explore the relationships between disciplinary research and transdisciplinarity further, and to come up with several recommendations for the future organization of science.

40.2   Sustainable Development

The concept of sustainability deals with three key dimensions of human societies, the economic, social and ecological dimensions, as the three P's: people, planet, profit. This implies that multiple changes are relevant regarding sustainable development, not only ecological dynamics.

Statistics indicate that on average human beings live longer and in better health than ever before, but the pursuit of happiness relates to more than statistics. Our values concerning distributive justice urge us to pay attention to differences. Many normative environmental perspectives are formulated in terms of threats that require immediate action. While increasing wealth appears to reduce the willingness to accept risks of wealthy people (Beck 2003, 2009), these threats are shaped as extreme risks.

Humankind is now able to cause irreversible change that partially diminishes the options of future generations. The normative insight derived from this principle is formulated as the precautionary principle, which leads to the norm that we should abstain from action that reduces the choice among valuable future options.

The reconciliatory character of sustainable development raises specific questions for judgment about changes that lead to improvement in two dimensions but to a deterioration in the third. Until now we have lacked a satisfactory interdimensional measuring rod in order to evaluate this type of changes. This deficiency is serious because as a consequence we are unable to provide convincing criteria to judge policy options in a comparative manner. In real-life situations Pareto-optimal solutions are exceptions. The remembrance of the slow death of welfare economics as an academic subdiscipline should warn us: the inability of welfare economics to formulate convincing policy recommendations in cases of non-Pareto-optimal situations appeared to be the main cause of its death (In 't Veld 1975).

Many different dialogues on sustainable development occur simultaneously. It functions as a unifying concept because its vagueness breeds a consensus that might be later used. It is an asset if it triggers action. On the other hand, if sustainable development is everything, maybe it is nothing. Although—or maybe because—the concept is so vague, it has overwhelming appeal on political agendas and in programmes and dialogues.

Sustainable development is a container notion. The use of the singular form fits holistic viewpoints. The supporters of these viewpoints speak about *the* climate, *the* earth, *the* emissions, *the* planetary boundaries (Meuleman 2013; In 't Veld 2011), which are all at stake, and disasters threaten. Such constructs enable us subsequently to deal with a global challenge that should be addressed in a well-coordinated manner. Thus, the normative construction of the problematique leads to a specific line of argumentation on

governance. Once again it appears that framing is normative. The supporters of this view may be found in international organizations that make continuous efforts to produce consensus on internationally binding agreements to prevent disasters. Basic metaphors like the exhaustion of the earth and planetary boundaries are then very useful.

However, people do not experience *the* climate but a climate in the neighbourhood. They pursue a good life according to their own values and in many cases try to find a satisfactory relationship with the surrounding nature. Their visible world is not abstract or systemic but specific and concrete. Likewise, until a few years ago, climatologists distinguished many different climates.

Entrepreneurs make attempts to design and apply more sustainable technologies. They act in a specific environment too, not in an abstract universe. Not just perceptions are context-bound but also acceptable ways of dealing with problematic issues.

Thus, major discrepancies may exist here between the systemic world and daily life. Those who recognize the twofold framing of sustainable development will prefer multiple politics and policies on different scales, with both top-down and bottom-up influence.

The Western world has developed environmental policies during the last half century. In the international realm younger nation states, often former colonies, more recently also become aware of the disagreeable side effects of economic growth. They want to counterbalance these effects in their own manner. However, in the diplomatic arena they are continuously confronted with urgent calls to participate in bargaining processes on treaties with the former colonial powers. These partners now urge dramatic reductions of emissions and the like. Quotas for a certain future year are symbols of urgency. The young nation that is coping with the need for reduction of backwardness in technologies and is just starting to think about clean technologies will not feel inspired by the short-term limits set by others. It will experience those as unnatural.

Cultural diversity should be recognized both as a component of sustainability and as a complicating factor that prohibits progress in reaching consensus on collective action. A society needs a certain cohesion that is produced as a moral order, based on consensus about some fundamental values and norms. Culture within a society also implies the sharing of some common substantial and relational values. A society consists of configurations that possess a specific culture but—as observed earlier—this leads to outside walls (In

't Veld, 2009; Teisman 2009). Thus, tensions arise. In particular the tensions between emerging identities on one side, accompanied necessarily by outer walls, and the need for cohesion and collective action on the other will never disappear. Thus, shaping governance is walking a high wire.

We should argue that both biodiversity and cultural diversity are components of sustainability. We may mourn the loss of a language somewhere on this globe and the loss of a species. But our general attitude towards cultural diversity in daily practice is far more critical than towards biodiversity. We do not believe that each culture is intrinsically good. On the contrary, some cultures are horrifying to many. As sustainability also implies the economic and social dimension, we realise that "diversity always is a bedfellow of inequality" (Van Londen in De Ruijter 2011: 14). Inequality might be a threat to sustainable development. So our attitude towards cultural diversity is ambiguous. In other terms, we do not embrace the precautionary principle for culture. *The full recognition of cultural diversity as a major component of sustainability delivers a strong argument against uniform global governance of transitions and transformations.*

According to the concept of second modernity (Beck 1997, 2006), it is probable that from the tense relations between emerging opposites variety increases. Striving at sustainable development urges us to take these tensions fully into account when dealing with governance.

Because sustainable development is a long-range trajectory, with considerable uncertainty and lack of forecasting options, the notion of resilience is crucial: like Noah we can act sensibly without any certainty about future events by answering the question of how to avoid a disaster, *in casu* by building an Ark. Nowadays, for instance, it is uncertain which theory about climate change is the right one, but once the theory that allies climate change to carbon emissions is there, the justification of measures to reduce emissions can be based on the resilience norm: in order to avoid disasters we have to take into account the feasible theoretical viewpoints irrespective of our beliefs.

We should realise in accordance with the view of Grunwald (2004), Grin (2006) and others that the plurality of notions of sustainable development and their normative origins and connotations lead to the necessity to consider the recommendable knowledge-producing and policy-making processes as reflexive. In Grunwald's terminology: "The normative character of the imperative of sustainability, its inseparable connection with deep-rooted societal structures and val-

ues, the long-term nature of many relevant developments, as well as the often necessary inclusion of societal groups and actors, result in specific demands on scientific problem-solving contributions. Research for sustainable development is a particularly marked type of post-normal science (Funtowitz/Ravetz 1993: 151)". Therefore we argue that dealing with reflexivity and transdisciplinarity are necessary once we strive for sustainable development.

40.3   Knowledge Democracy

Representative democracy has been a successful governance concept for societies (In 't Veld, 2010). During the last two centuries, several forms of representative constitutional democracy developed at the national level and democracy is recommended by Western and most Southern political leaders as the preferred system of rule.

In the twentieth and twenty-first centuries parliamentary democracy, politics and media have become more interdependent; policies are increasingly funded in science, but at the same time science relies on public resources, which is why the linkages between politics and science have intensified. There have been large cognitive and emotional investments in current democratic institutions. As a consequence the stability of these institutions is embraced. Resistance to change has been considerable. But exogenous and endogenous developments threaten the continued success of representative parliamentary democracy.

The recent decline in acceptance, legitimacy and effectiveness of representative parliamentary democracy has been noticed by many authors (In 't Veld 2009, 2010). Three intertwining simultaneous developments have taken place on the macro-, meso- and micro-level of societies, with important effects. On the micro-level of the individual citizen, the classical assumption of a consistent individual position, based on an ideologically-based consistent value pattern, has disappeared. Separate values prevail but the glue of a focal ideological principle often no longer exists. Fragmentation of values has resulted in individualization and uniqueness but also in the impossibility of being represented for all different purposes by a single actor such as a member of parliament. None of the values cherished by an individual may be unique, but the combination probably is. The preference of individuals to be partially represented by a *non-governmental organization* (NGO) per value-domain is therefore no mistake, but a logical evolution. On the

meso-level the development of political parties to marketeers who try to optimize their future votes in the political realm destroys their capacity to design broad and consistent political strategies. And on the macro-level media politics dominate. As a consequence the epicentre of politics has shifted from parliament to the media. Media can handle personalities better than programmes.

Personalities instead of programmes become the major focus for selection and therefore the voters choose personalities. In the attempt to maximize their votes, political parties are keen to use the media, as it is only possible to actually 'sell' personalities through mass media. This of course significantly increases the structural dependence of politicians on the mass media. The classical function of democracy of protecting the people against tyranny and random or arbitrary action by rulers is endangered by stressing personalities over programmes. But media politics destroy the original meaning of representation.

We now envisage a world where representative democracy is enhanced with participatory democracy, in which social media are added to classical corporate top-down media, and in which disciplinary science is increasingly accompanied by transdisciplinary trajectories. The evolutionary patterns at each corner of the triangle are not without tensions: the institutions towards the centre of the triangle feel threatened by the younger ones at the edges. Each corner in the triangle is prone to profound change, as indicated in the second-order relationships:

- the bottom-up media not only supplement the classical media, but compete with them;
- participatory democracy is complementary to representative democracy but is also seen as a threat to it;
- transdisciplinary research designs are not only a bridge between classical science and the real world but also produce deviant knowledge and insights, which may challenge the disciplinary viewpoints.

The Internet, better education and other societal changes have made knowledge accessible to many more people than in the past. This leads to an abundance of knowledge and information that needs to be interpreted. It also leads to different types of knowledge: not only scientific knowledge appears to be relevant, but also citizens' knowledge. This is a huge challenge for policymakers, for scientists and for the media. Politics is not just about how knowledge can be selected for political decisions, but also about how democratic decision-making processes should change in order to incorporate the different types of knowledge adequately.

Moreover citizens themselves have become prosumers: any citizen may produce a YouTube picture that is world-famous within two days.

The classical media suffer from the new ones: not only in a commercial sense, but also because of the influence of the new media. We call the new media the bottom-up media in order to distinguish them from the classical top-down media. This distinction does not imply that the top is more powerful than the bottom. An increasing series of empirical counter-proofs is available. Many new media do not have an editor: nobody accepts the obligation to select the rubbish from the trustworthy materials. The developments within and with the media are confusing. Our capacity to observe and to interpret adequately seems to be deficient. Information and knowledge of very different origins are available within a second but it is hard to judge quality. As usual in second modernity the top-down media do not disappear altogether but develop innovative strategies, accepting Internet options and modes of cooperation with social media. The social media are in the process of discovering their own deficiencies, and in some cases organize a revival of editorial functions. The 'wicked' character of many problems on the political agenda sheds a fascinating light on the complexities caused by the interaction of top-down and bottom-up media.

Both contribute to the agenda-setting of politics. The top-down media operate in structural interdependency with politics. The expression 'media politics' refers to this interdependency. The bottom-up media are to a considerable degree independent from both the top-down media and politics. Participation in decision preparation and -making may be invited by public authorities, but uninvited participation also occurs, in particular with support from bottom-up media. It is too early to draw consolidated conclusions on this development: it is fluid, fast and reflexive, and also unpredictable.

The current global economic situation raises new, very challenging questions that are mainly about the institutional frameworks of today's societies. It is therefore time for a transition to a new concept that concentrates on institutional and functional innovation. As the industrial economy has been combined with mass democracy through universal suffrage and later by the rise of mass media, one might suggest that the logical successor is a new type of governance, to be called 'knowledge democracy'.

Which challenges and threats are we facing? How will parliamentary and new direct forms of democracy mix, and which roles will knowledge play in the transition towards a knowledge democracy? The crucial combination of a network society and media politics provides new problems and tensions. Today policy-making in many instances is evidence- or knowledge-based, providing both legitimacy and effectiveness, according to its supporters. Effectiveness is assured as the knowledge concerns true statements about the relationships between political interventions and their societal effects. The argument runs thus: according to them, legitimacy is enhanced when the policies are based on 'objective' truth. It is easy to undermine this belief.

Scientific research is a specific form of research, aimed at the creation or accumulation of scientific knowledge. Classical scientific research is performed within disciplines, specialized branches of science with specific theories and methodologies. A discipline studies an aspect of reality, not reality itself. A disciplinary methodology consists of several approved conditions under which truth claims are accepted.

This mono-disciplinary knowledge is methodologically formalized in a particular way: for example it is subject to peer review. It is often put into a rule-based form, such as: 'A implies B' in a particular set of circumstances, whenever these circumstances occur. Such an assertion is known as a hypothesis. 'The more a child participates in sports, the less likely the child is to turn to drugs', is a statement which could originate from empirical research and which probably applies to white families in European cities since 1990, but not to rural areas in Colombia. And why should this statement be true in the future? Scientific knowledge is therefore by definition both fragmented and conditional. Its scientific value depends on the correct application of the agreed methodology. Scientific knowledge requires validity, and methodology protects against criticism. This is called 'normal research'.

It is difficult to integrate different areas of scientific knowledge because scientific knowledge is by its very nature fragmented. And its conditional character means that in order to apply the knowledge in real-world situations, it is necessary to verify whether the relevant characteristics of the situation in which the original study was performed have been complied with. Regarding the future, this question can never be definitively answered. This means that every application of social scientific knowledge for the purpose of policy implies an element of risk.

If a policymaker—in the course of preparing policy proposals—wishes to apply an assertion which is based on a rule, such as 'for every X, under condition Y: A implies B', she/he first has to verify:

- 'Is the X that I am talking about the same X as in the assumption?'
- 'Are the conditions which I am faced with the same as the Y in the assumption?'
- 'Is there really an A in my situation?'
- 'Will the implication still apply at the time when the policy is implemented?'

In particular the last question is a nasty one because the consciousness of reflexivity urges us to wonder whether the drug dealers might have reflected upon the research results too, and might have ensured for themselves a position on the boards of the sports clubs.

This implies that applying scientific knowledge in policy does not always and should not follow the accepted route of meeting the methodological requirements which applied when the knowledge in question was developed. The application of scientific knowledge in a political and governmental context is an exercise in uncertainty, partly based on suppositions, and it also requires competences other than scientific ones, such as social intelligence and well-developed social intuition. It appears necessary to link scientific knowledge to other types of insights without detracting from its relevance and usefulness. Combining knowledge from different scientific disciplines and mixing it with other insights is an opportunity to try to maintain the relevance and usefulness of such knowledge in the relevant application. Multi-, inter- and transdisciplinary developments in research are in full swing. Anyone who realizes this cannot fail to be impressed by the speculative nature of many elements of the methods used. The precision of a great deal of scientific knowledge very soon gets lost in these methods. Robust concepts are often unrefined. As Silvio Funtowicz has repeatedly explained, this image of evidence-based policies based on 'sound' knowledge is not adequate according to the advanced science model (Funtowicz/Ravetz 1991, 1992, 1993). Let us now state that knowledge about social systems is by definition volatile as a consequence of the reflexivity we discuss below. The predominant position of 'wicked problems' on political agendas as indicated earlier is the main reason that linear problem-solving strategies cannot be used. Wicked problems cannot be solved, but they can be managed. In many cases interactive processes are part of effective management.

Today's societies are characterized by the increasing intensity and speed of reflexive mechanisms. We define reflexive mechanisms as events and arrangements that bring about a redefinition of the action perspectives, the focal strategies of the groups and people involved, as a consequence of mindful or thoughtful considerations concerning the frames, identities, and the underlying structures of themselves as well as other relevant stakeholders. Defined in this manner, reflexivity has to do with a particular kind of learning potential. Reflexive systems have the ability to reorient themselves and adapt accordingly based on available self-knowledge.

Reflexive mechanisms in a more or less lenient political environment cause the overwhelming volatility of bodies of knowledge related to social systems. As all available knowledge is utilized to facilitate reflexive processes, the result of such processes might establish new relationships that undermine the existing knowledge. Social reality has then become unpredictable in principle. The efficacy of reflexive mechanisms is furthered by institutional arrangements that enable individual liberty and tolerance.

It is necessary to develop this notion of reflexive learning further because it is of utmost importance for the design of an advanced way of thinking on policy-making: we should realize that a social theory of any kind may never be used to create policy measures without an additional research effort on the specific issue. Such an effort should include the question of whether it is probable or plausible that the theory is already undermined by reflexive reactions in or around the target group of the measure. This latter effort will never deliver results with an absolute truth claim. So uncertainty is overwhelmingly present there too. The policy dialogue will then be characterized by different layers of uncertainty, and so by a discussion about the impact of the different layers of uncertainty too.

Evidence-based policy-making as a normative concept probably bears some relevance when it concerns the application of a physical, chemical or biological scientific theory. But it becomes a hazardous pretention if the decision support comes from a theory in the social sciences for the reasons just explained. Thus, the fashionable approach towards evidence-based policies in social domains should be moderated in a more modest and thoughtful framework.

Knowledge democracy could become an emerging concept with political, ideological and persuasive meaning. The concept of knowledge democracy is meant to enable a new focus on the relationships between knowledge production and dissemination, the functioning of the media and our democratic institutions.

The media are far from neutral or passive. The illusion that they are a neutral mirror of reality belongs to a forgotten past. We have already shed light on the relationships between politics and media. Media create realities; they also produce knowledge, and moreover report on citizens' knowledge. They are the reporters on scientific findings but also competitors of scientists. The same goes for the relationships between media and citizens.

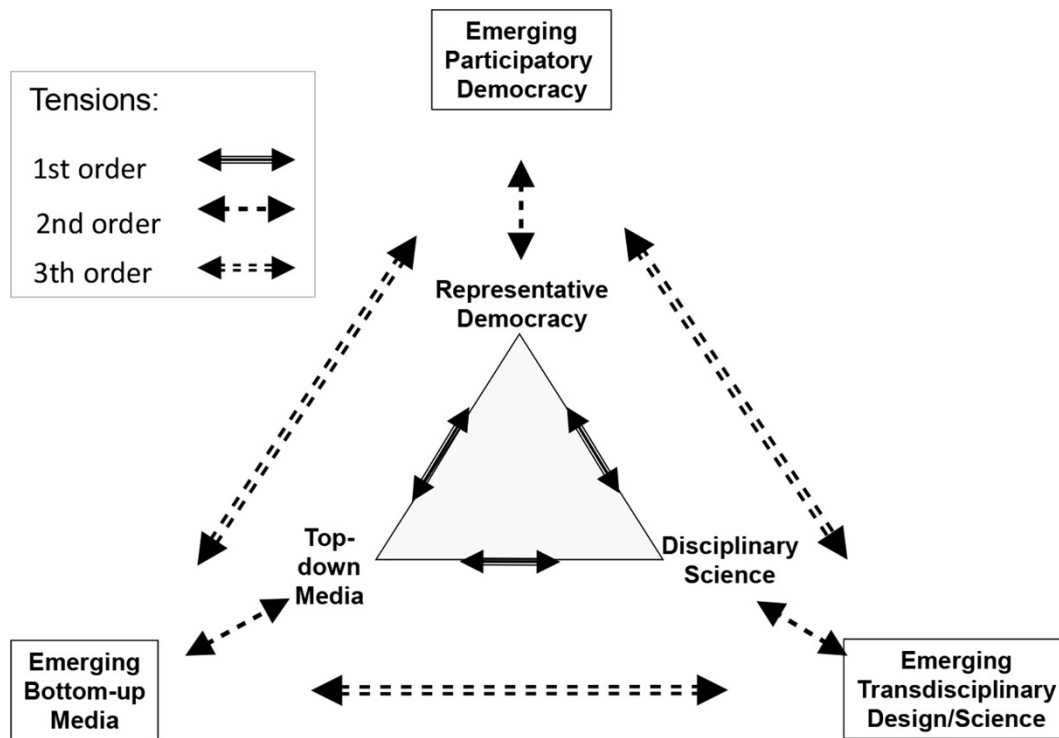
Moreover, citizens utilize social media independently from authorities either in order to mobilize support for ideas, or to attack existing policy theories. Science is involved in fierce competition, in continuous marketing efforts in order to gain support for viewpoints based upon research and aiming at the acquisition of public resources for further research.

Advocacy coalitions between the proponents of a certain policy theory, the scientific representatives of related scientific theoretical viewpoints, and sympathetic NGOs and citizens' initiatives are born, live and disassemble later on.

40.4   Transdisciplinarity

Much valuable scientific work has been performed on the relationships between science and politics, in order to answer the last question at least partially. Jasanoff (1990, 2003, 2004, 2005) and others have argued that it would be wise to design an independent boundary function in order to foster the quality of the translation (Jasanoff/Martello 2004). The classical theory of boundary work in order to master the existing gaps between science and politics is nowadays widely accepted among experts. The underlying insight is that scientific knowledge by its very structure never directly relates to action, because it is fragmented, partial, conditional and immunized. This observation is valid for both mono- and multidisciplinary knowledge. So translation activities are always necessary in order to utilize scientific knowledge for policy purposes. Pohl, Scholz, Nowotny, Regeer, Bunders and many others have explored this vast domain and developed the concept of transdisciplinarity in a number of variations. The literature on transdisciplinary research is dominated by process-directed normative studies (see Bunders in In 't Veld 2010).

Many authors suggest that transdisciplinary research is just a specific category of scientific research, characterized by the acceptance of some normative

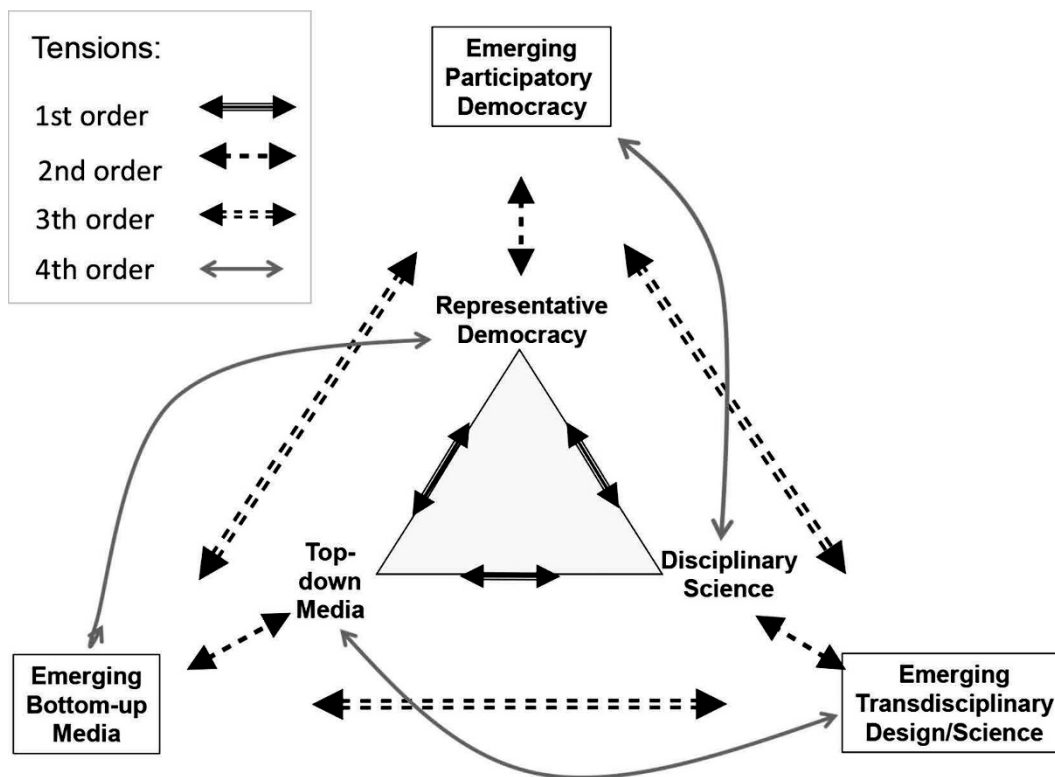
Figure 40.1: The emergence of the knowledge democracy concept. **Source:** The author.


base for scientific reasoning. Here another viewpoint is defended: it appears clear that the core concept of transdisciplinarity is to be defined as the trajectory in a multi-actor environment, a trajectory that in due course leads from two sources: a political agenda and existing scientific expertise, to an acceptable robust, plausible perspective for action. This trajectory bears the character of a communicative and argumentative process (In 't Veld 2013). Its character is design. Funtowicz's later models contain both solutions and caveats on this thorny road (Funtowicz/Ravetz 1991, 1992, 1993).

Figure 40.1 illustrates the twofold relationships between the corners of the triangle. The original, inner institutional framework was fit for the application of the fruits of disciplinary science, in order to solve rather simple policy problems within the framework of representative democracy. Society was ordered clearly in terms of ideological patterns, and classical top-down media fulfilled their roles. The first-order relationships show this picture. The second-order relationships describe the evolution of each corner. As a consequence of that evolution we are confronted with tensions, threats and opportunities around the outer corners of the triangle that are indicated in the third-order relationships.

As we may observe, the outer points of the extended triangle also strengthen and stimulate each other. Transdisciplinarity nears participatory democracy, and social media play crucial roles in large-scale communication processes. So the tensions relate mainly to the inside–outside relations in the triangle while the stimuli relate to the outer point of the corners. Hardly any empirical research is available yet.

Figure 40.2 shows some of the relations between each inner and each outer corner. This type of relation also has far-reaching consequences for the governance of sustainable development in knowledge democracies. These fourth-order relations might prove to be very diversified: for instance, bottom-up media might be utilized by representative democracy but also cause conflicts as shown in the case study on vaccination. Citizens initiatives might internalize the fruits of disciplinary science, but this might also cause application problems. Top-down media might organize transdisciplinary trajectories, but they could prove to be boomerangs for those media themselves. In any society, a wide diversity of actors possesses relevant knowledge concerning important societal problems. In a knowledge democracy both dominant and non-dominant actors could and maybe should have equal access and ability to put this knowledge forward in the process of solving societal problems. We have

Figure 40.2: Old and new forms coexist and influence each other. **Source:** The author.


already explained why disciplinary knowledge on its own is not fit to solve broader societal problems.

During the past centuries the tendency towards specialization has dominated in science, destroying the practical meaning of the *homo universale*, and leading to more and more disciplines and subdisciplines. Sometimes innovation was brought about by new combinations of those, called multidisciplinary or interdisciplinary cooperation or even mergers.

According to the earlier terminology, transdisciplinary research developed during the 1980s and early 1990s. Multidisciplinary and interdisciplinary research then can be placed on a continuum between monodisciplinary research and transdisciplinary research. Thompson Klein, Grossenbacher-Mansuy, Häberli et al. (2001: 7) at the start of this century defined transdisciplinarity as:

> A new form of learning and problem-solving involving co-operation between different parts of society and science in order to meet complex challenges of society. Transdisciplinary research starts from tangible, real-world problems. Solutions are devised in collaboration with multiple stakeholders.

So she already states that cooperation and mutual learning are key notions in transdisciplinary trajectories.

We observe, following Bunders and Regeer (2010), that in the scholarly literature the core of transdisciplinary research is most often presented as a shared set of principles. Principles differ from theories, methods, tools and conditions because they refer to the attitudes of the researcher-participant; the researcher is said to perform genuine transdisciplinary research as long as he or she acknowledges and acts in accordance with the intention of these principles. These principles relate to process demands such as joint problem definition, orientation towards robust action perspectives, and so on. As such, a set of principles describes the intentions that guide the researcher in choices he or she has to make for the design of the project or programme, that is, the choice of methods, tools and the sequence of these. In other words, 'the approach' is the manner in which the issue at stake is addressed. This is in line with the widespread convention of labelling specific realizations of transdisciplinary research as 'approaches'.

If one concentrates on the essentials of transdisciplinarity as communication and argumentation, the demands for specific attitudes and even principles concerning the other participants besides researchers are as crucial. The policymakers will tend to accept those scientific viewpoints that are closely related to

the predominant policy theory, if present. They should, however, develop a certain willingness to open up to other scientific insights because the aim of the exercise could be to end up with resilient proposals, having answered the question of how to avoid disasters. This demands a sophisticated degree of reflexivity on their part.

Once all participants are touched by the need for mutual adapting, learning and the common goal of a resilient design, the transdisciplinary process could really be successful. Considering the existing literature, one might observe that these conditions are seldom fulfilled.

40.5 Agenda for the Future Organization of Science

Transitions and transformations are major changes that may contribute to sustainable development. There is an impressive number of studies available, also represented in this volume, on the character of these phenomena, under different names such as transformation theory, transition theory, etc. Above we argued that transdisciplinarity is a promising approach to tackling the wicked problems that emerge as we aim for sustainable development. Our analysis of knowledge democracies leads to specific questions about the organization of science in society in order to enable the coexistence of disciplinary research and transdisciplinarity.

In general, assuring the independence of scientific disciplinary research becomes more complicated as the interdependencies between politics, media and science become so intense and numerous. Reflexive mechanisms also considerably complicate the reactions of the public at large to scientific findings: the *Intergovernmental Panel on Climate Change* (IPCC) consensus on the causes of climate change irritated a large proportion of political actors and media so intensely that the support for sustainable policies declined. Each actor is involved in the interdependencies and turmoil of knowledge democracies: there is no outsider position available!

So consciousness of incompatible relations should increase. Scientific activities are performed by numerous organizations, by government and enterprises, by NGOs and by individual researchers, and most of all by specialized organizations devoted to research such as universities. One might say that society at large becomes a research institute.

Governments stimulate and finance research in order to further national competitive positions and innovation, and to contribute to an attractive cultural climate. The belief is widespread that expenditure on research and development causes economic progress without causing damage to other dimensions of societal evolution. Inside government the allocation of scarce resources to specific fields and objectives often leads to conflicts between the innovators on the one hand and the gatekeepers of academic excellence on the other. The latter defend the ideal of meaningful accumulation of knowledge while the former accentuate the need for applicability of scientific insights. Systematically of course both are complementary in nature, but the practice of budgeting in most cases is not adapted to that nature. These conflicts are reproduced nowadays within universities.

As the problematique of sustainable development bears a long-term, multilevel, complex character, the consistency and stability of science policies are of the utmost importance, but so also is free access to scientific sources for local and regional public authorities and citizens' initiatives. This is an essential characteristic of the governance of sustainable development.

In Europe, the scientific infrastructure is primarily connected to national decision-makers. Innovation, however, mainly originates in local and regional communities, so free access is necessary in order to strengthen the nature of participatory democracy.

Growing tensions surround the well-established prototype of the Humboldtian university with its accent on funding disciplinary research—at a distance from society—which is executed in absolute autonomy and 'disinterest'. This university will not show much sympathy for involvement in transdisciplinary trajectories. Academic excellence is here defined as excellence according to academic peers. The idea that there is more 'between heaven and earth' than disciplinary science alone, even in the realm of knowledge production, may be hard to digest for Humboldtian scientists.

The tradition of the American university—our reference concerns among others the University of California, Harvard and MIT—demonstrates a quite different picture: here the assignment of the university as an institution that considers itself obliged to render services to society—besides performing basic research—is rooted in centuries of institutional value formation.

European nation states have developed advisory bodies and semi-autonomous agencies in order to perform boundary work between the worlds of science and politics. If knowledge democracy is accompanied by an increasing degree of populism, political hostility

to these intermediaries grows fast, as can be seen now in Denmark, the Netherlands and France.

The wicked character of the sustainability problem necessitates transdisciplinarity, but political conflicts are often fought out here by playing two-level games. As the political controversy may lead to a dead end, an attractive strategy might be to accuse the knowledge source of the opponent of lack of trustworthiness. As the scientific experts are not present in the political arena, this type of indirect accusation will not stimulate the willingness of scientists to participate in transdisiplinary trajectories.

We foresee that in advanced societies the quantitative dimensions of research activities will still increase considerably, because a large proportion of the population will be capable of creating new knowledge, and productive activities will become still more knowledge-intense. As a consequence, transdisciplinarity

and participatory democracy will become more closely interwoven.

The competences of scientists who are successful in transdisciplinarity are concentrated around empathy, and more on specific insights into the specific rationality of politicians.

Adequate governance arrangements in order to ensure acceptable equilibria between different modes of knowledge production demand redesign of the external and internal organization of scientific institutions.

More fundamentally, one could come up with an organizational logic that stimulates peaceful coexistence between the different research orientations in universities and the like that have just been mentioned. The organization of science is a focal issue in the pursuit of sustainable development.

41 Discourse and Practice of Transitions in International Policy-making on Resource Efficiency in the EU

Sander Happaerts[1]

Abstract

For a number of years now, 'transitions' has been the new buzzword in international policy-making. The emergence of an international transitions discourse is linked to debates on the green economy and a low carbon society, and is manifested within the UN system as well as in EU discussions. Does the apparent political appeal of a concept that introduces fundamental changes mean more than the superficial use of the word 'transition'? And how far is it also translated into policy? This chapter analyses international policy initiatives from the perspective of sustainability transitions, with the aim of moving towards a better understanding of the potential role of international policy-making in current and future transitions. A case study of the European Commission's policy initiatives on resource efficiency demonstrates a remarkably strong awareness of transitions thinking, consistently integrated into the discourse with the intention of creating a sense of urgency and convincing other actors of the need for fundamental change. Furthermore, transitions thinking has served as the inspiration for a number of principles, goals and instruments, such as the European Resource Efficiency Platform.

Keywords: EU, green economy, international organizations, public policy, resource efficiency, sustainability transitions.

41.1 Introduction

For some years now, 'transitions' has been the new buzzword in international policy and politics. The concept refers to a strand of thinking that advocates fundamental changes in the main societal systems (food, mobility, housing, etc.) in order to overcome persistent problems such as climate change or resource scarcity. It is explicitly linked to the overall goal of sustainable development, and can be considered as a new way of thinking in sustainability science (Dedeurwaerdere 2013). Transitions thinking assumes that persistent problems, rooted as they are in our prevailing modes of production and consumption, can only be overcome when deep innovations are realized in societal systems ('system innovations'), by means of profound changes to the dominant structures, practices, technologies, policies, lifestyles, etc. (Kemp/Rotmans 2005).

Recently, various gradations of a 'transitions discourse' have been permeating international policy documents (Audet 2014; Happaerts 2014). Such a discourse, that borrows frames and assumptions from the academic transitions literature to promote certain transformative 'pathways' out of contemporary crises, is for instance observed in policy initiatives by international agencies in the framework of the 'green economy' (e.g. OECD 2010; UNCSD 2012; UNEP 2011; 2014). Transitions have also become an essential part of the language of recent EU initiatives in the field of climate policy and related issues. In these EU initiatives, the transitions discourse is strongly linked to the systemic character and the long-term time horizon of the societal transformations needed to overcome per-

sistent problems (e.g. Council of the EU 2009; European Commission 2011b; EEA 2014).

The emergence of such an international discourse inevitably means that certain actors will appropriate it in order to influence policies and practices. Consequently, Audet (2014: 47) indicates that scholars should focus on how the appropriation of transition in international discourses might influence future transitions. In a similar vein, this chapter starts from the observation that a transitions discourse is emerging at the level of international agencies. The chapter aims at, first, gaining a better understanding of what such a discourse means in specific cases and, second, assessing whether it also influences the policy-making practices of those agencies. This could contribute to an evaluation of the potential role of international policy-making in current and future transitions and, ultimately, to better substantiating the multi-scalarity of transitions (see Hansen/Coenen 2013).

This chapter moves towards better knowledge of the role of international policy-making by conducting in-depth, exploratory research in one case study, proceeding in two steps. First, the discourse of the case is analysed by looking into how sustainability transitions are framed. Policy framing refers to the process of interpreting a concept and of giving meaning to a problem. It involves the use of available knowledge and information in order to select, name, emphasize or organize certain aspects of a policy problem (Daviter 2007; Schön/Rein 1994). In a policy context, framing takes the form of 'problem-setting stories', which are told to persuade others in policy debates, and to shape the preferred policy solutions (Hajer/Versteeg 2005; Mazey/Richardson 1997; Peters/Hoornbeek 2005). The importance of policy framing cannot be overestimated (Hajer 2000: 287). The particular way in which a policy problem is framed has important consequences for the solutions that can be chosen for it and can already imply who will be responsible for that solution, thus limiting the policy choices that actors can make (Hajer/Versteeg 2005: 178; Peters/Hoornbeek 2005: 82–85; Rochefort/Cobb 1994: 4). As a second step, the chapter looks at whether and how the transitions discourse influences policy-making, by studying the precise policy content. In policy analysis, policy content is commonly broken down into different components (Heichel/Pape/Sommerer 2005; Howlett 2009). This chapter focuses on three such components: the stated principles that guide policy-making, the policy goals, and the instruments chosen to attain those goals. The case study is guided by two research questions: how are transitions framed in the

discourse of international policy initiatives, and to what extent does transitions discourse influence policy-making at the level of principles, goals and instruments?

The next section offers theoretical and conceptual background. In order to explore what sort of influence transitions can be expected to have on policy-making, the most significant policy implications of transitions thinking are elaborated. Before turning to the case study, a subsequent section is dedicated to the link between sustainability transitions and the green economy, as it has been observed that the emergence of a transitions discourse in international policy-making is closely related to that issue. Afterwards, the in-depth analysis of one case study is presented, namely, the EU's recent policy initiatives on resource efficiency. Findings and a future research agenda are laid out in a final section.

41.2   Sustainability Transitions and International Policy-making

41.2.1   The Concept of Sustainability Transitions

In the theoretical literature on sustainability transitions (building upon earlier traditions such as innovation and technology studies and complex systems theory), transitions are presented as a new solution to the problems of sustainable development. Those problems are said to be 'persistent', mainly because they are deeply embedded in societal structures, and for this reason are difficult to manage or steer (Loorbach 2007).[2] Examples are climate change, the scarcity of certain resources, and the housing and food needs of a growing world population. Because of their specific characteristics, persistent problems will not be solved by regular or short-term policy-making, incremental institutionalism or market mechanisms (Geels 2010; Meadowcroft 2011: 71). As persistent problems are rooted in existing structures, they require a fundamental change in the dominant institutions, policies and lifestyles that shape societal systems. Such fundamental changes are called *transitions*—or *sustainability transitions* when their fundamental goal of achieving

---

2   The characterization of persistent problems bears strong similarities to the 'wicked problems' defined in the policy literature (Rittel/Webber 1973), but it adds the specific perspective of sustainable development and the different layers of complexity that distinguish that policy issue from others (cf Lafferty 2004: 12).

sustainable development is underlined. The assumption that such fundamental changes are needed distinguishes transitions thinking from other paradigms such as ecological modernization theory, which hold to a more incremental type of change based upon technological innovation and increased efficiency within existing institutions.

Most transition theorists use the *multilevel perspective* (MLP) as a common tool to analyse changes in societal systems. Their research has demonstrated that transitions are the result of the interaction (or 'co-evolution') of phenomena taking place at three levels: the *landscape* (the exogenous societal and material environment that encompasses social, political and economic values and trends, shocks, etc.), the *regime* (the dominant setting of the societal system, containing elements of technology, industry, markets, consumer preferences, science, culture and policy) and the level of *niches* (where new rules, technologies, behaviour and so on are developed that deviate from the regime) (Geels/Schot 2010; Geels 2011). Developments at the landscape level can put pressure on the regime and trigger innovations in niches which ultimately cause the regime to adjust. But many other patterns of change (or inertia) are envisaged (Geels/Schot 2007).

The trajectory of transitions can be idealized as an S-curve with four consecutive phases: *predevelopment* (in which only minor changes occur or are prepared), *take-off* (where the change process gains momentum), *acceleration* (in which the change becomes structural and visible) and *stabilization* (where a new dynamic equilibrium of the societal system is reached) (Rotmans/Loorbach 2010: 126). But not all initiated transitions end in a new dynamic equilibrium; other outcomes are possible too. Authors describe the risks of a *lock-in* (when attention is paid only to making existing structures more efficient, rather than changing them), a *backlash* (when the exclusive focus on one part of the solution causes unexpected side-effects) or a *system breakdown* (when no fundamental changes are initiated and the persistent problems eventually cause the sociotechnical system to collapse) (van der Brugge/Rotmans 2007: 254–56).

41.2.2   Policy Implications of Sustainability Transitions

Transitions have been observed to occur spontaneously. The endeavour to deliberately influence or steer them, usually in a sustainable direction, is called *transition governance* (Paredis 2013). It involves a large-scale societal effort, in which the role of governmental policies is limited but essential. Little has been written about the consequences of sustainability transitions for policies (Paredis 2013).[3] This is surprising, both because sustainability transitions are unlikely to proceed in a desirable direction if regular policies are not at least altered, and because the implementation of a transitions approach will have a great impact on policies. From a study of the transitions literature, at least five major policy implications of sustainability transitions can be deduced.

First, a transitions perspective implies that the policy focus moves away from traditional policy sectors towards the core societal systems that shape contemporary production and consumption patterns. In the literature these are called 'sociotechnical systems'. They are organized around essential societal needs (such as feeding and sheltering people, moving around goods and persons, caring for people, etc.) and consist of three main components. The *structure* is the material infrastructure, the technologies, the different kinds of institutions and the associated economic reality of a sociotechnical system. A system's *culture* contains the principal images, values and paradigms. And the *practices* denote the 'normal' behaviour and routines within a system (Rotmans/Loorbach 2010). To achieve a transition, changes need to happen in all these components. This requires specific consultation and coordination instruments but also demands a systemic approach that goes far beyond the principle of horizontal policy integration advocated by the sustainable development paradigm (Happaerts/Bruyninckx 2014).

Sustainability transitions ultimately aim at fundamental changes within the core sociotechnical systems, which is a significant policy challenge. Not only do changes need to happen at the combined level of structure, culture and practices, they also need to be deep and fundamental (e.g. Loorbach/Lijnis Huffenreuter 2013). This stands in contrast with regular policy (Paredis 2013), which is usually of an incremental nature: policies are usually aimed at making existing systems more efficient or at improving specific aspects of their functioning. However, with system innovation being the purpose of sustainability transitions, an incremental improvement of an incumbent

---

3   Looking at specific approaches to transition governance, the picture is more nuanced. For example, see Loorbach (2007) on the policy implications of Transition Management, and Schot and Geels (2008) for the policy implications of Strategic Niche Management.

system is unlikely to lead to a fundamentally new system. Rather, policies will need to destabilize the existing system and stimulate a different constellation, in order to eventually "replac[e] established ways of doing things, as well as their structural embedment" (Voß/Smith/Grin 2009: 278). But it is not because incrementalism is the wrong approach for transitions that radical revolutions are the only alternative. Of essential importance is the difference between *incremental* change and *gradual* change. A transition can materialize in a stepwise approach, as long as each step, no matter how small, is aimed at destabilizing the incumbent regime and constructing a new one (or, in less radical language, fundamentally changing that regime). The reason is that transition policies must avoid a lock-in. Regular, incremental policies are based on the pre-established structure, culture and practices of the regime—including infrastructure, financial mechanisms, and networks of people and organizations—and continuously reinforce them, making innovation ever more difficult and thus 'trapping' society in suboptimal outcomes (Meadowcroft 2009: 329). According to Geels (2013), policies and institutional changes in support of transitions are especially required in the take-off phase, when fundamental changes have been prepared in niches and need to be supported and scaled up.

Third, one of the essential features of transitions thinking is its long-term perspective. Again, this clashes with regular policies, which have a short-term orientation (Loorbach 2007). Similarly, in policy studies only scarce attention has been given to long-term policy design (Voß/Smith/Grin 2009). Rather, experts in policy studies have described why long-term policies are rare. Because of electoral cycles and uncertainty, among other things, it is assumed that long-term policies are difficult to implement in democratic societies (EEA 2011; Hendriks 2009: 334; Lempert/Popper/Min et al. 2009; Sprinz 2012). The popularity of long-term planning has, however, been increasing again (Voß/Smith/Grin 2009). Especially within the field of environmental policy and policy analysis, reflections can be found on how to tackle long-term policy challenges such as climate change (Sprinz 2009). Knowledge of different policy designs and of facilitating and impeding factors is growing (EEA 2011; Lempert/Scheffran/Sprinz 2009; Underdal 2010). Some years ago the European Commission issued a number of 'road maps' in climate policy and related areas, that define 2050 as their long-term time horizon (see box 41.1). These initiatives are punctuated with a transitions discourse (see section 40.1). It

is thus argued that the renewed popularity of long-term policy planning is associated with the salience of a transitions discourse. Similarly, Voß, Smith and Grin (2009: 294) claim that the transitions framework offers opportunities for long-term policy design, and Meadowcroft (2009: 325) mentions the adoption of a long-term perspective as one of the most promising features of transitions thinking. As change processes leading from one system state to an entirely new system state, transitions typically take a generation or longer (Loorbach/Frantzeskaki/Thissen 2011: 76). If one wants to manipulate the direction or the sustainable character of such transitions, a vision is needed of what the intended system state looks like. Moreover, transition paths to achieve a systemic change should be evaluated against that long-term vision. If not, they are likely to lead to a lock-in of the system. The design of a long-term policy should thus structure the current, short-term and mid-term activities of political actors (Voß/Smith/Grin 2009: 291).

A fourth policy implication is the 'reflexive' character of long-term transition policies, as opposed to a rational and unidirectional conceptualization of planning (Voß/Smith/Grin 2009). Reflexive governance processes accept the uncertainty of policy choices and their effects. A reflexive perspective furthermore sees a constant interaction between policies and broader societal changes (Voß/Smith/Grin 2009). The different policy focus that emerges as a consequence of this reflexivity also assumes a more reflexive view on policy monitoring. Transition policies therefore accept experimenting and learning as principal drivers of change, as systematic learning activities should continuously lead to policy adjustments (Bussels/Happaerts/Bruyninckx 2013).

Making policy processes more reflexive is not necessarily the exclusive task of governments. Other actors, such as research institutes or civil society organizations should also contribute to knowledge-building and reflexivity (Meadowcroft 2009: 336). This points to a more general policy implication of transitions, the involvement of a broad group of stakeholders. Not only do policies account for merely a fraction of transition governance (see above), but the paradigm also demands that such governmental policies are developed in close cooperation with different types of non-governmental stakeholders, in the participatory tradition of sustainable development (Meadowcroft 2009: 325; van der Brugge/Rotmans 2007: 261). This involvement is not limited to the implementation phase but should be incorporated in policy formulation and during the formation of long-term

---

Box 41.1: Transitions in the European Commission's Roadmaps. **Source**: The author.

In 2011, the European Commission published a number of 'road maps' in the environmental domain. They defined 2050 as a long-term time horizon, something new in EU policy-making. The overview of the road maps given below demonstrates how this policy innovation followed on from the EU's climate agenda.

- In order to reach the global goal of limiting global warming to 2° Celsius, the European Council decided in October 2009 that the EU should aim for an 80 to 95 per cent reduction of greenhouse gases by 2050 (compared to 1990 levels). This decision supplemented the previously agreed EU climate and energy objectives for 2020 with a long-term dimension. The Commission's newly created Directorate-General (DG) Climate Action then elaborated the long-term goal by issuing the *Roadmap for Moving to a Competitive Low Carbon Economy in* 2050. It proposed a way of sharing efforts to reduce emissions among different sectors and policy domains between 2011 and 2050 (European Commission 2011b).
- Other DGs followed with similar road maps for the same time horizon. DG Environment prepared the *Roadmap to a Resource Efficient Europe*, which is the main case study of this chapter (European Commission 2011a).
- DG Energy drafted the *Energy Roadmap* 2050, in which different scenarios for Europe's energy use are

elaborated based upon different assumption of decarbonization, and thus only partly based on DG Climate Action's road map (European Commission 2011d).

These road maps are not legally binding decisions or legislative proposals. They appear under the form of Communications, non-binding documents adopted by the European Commission without a Treaty basis. They are intended to communicate the Commission's position on a particular issue to the other institutions, the public and other stakeholders, and as such are not different from documents issued by other international agencies. Communications also promote the policy options that the Commission considers desirable to deal with that issue (Krämer 2012). With these documents, the Commission actually anticipates legislative proposals that it might formulate in following years. Communications are thus meant to develop societal and political support for its intentions with regard to future policies (Delreux/Happaerts 2016).

Although not always bearing the name of 'road map', other Commission Communications adopted in the same period have the same characteristics. For example, the *White Paper on Transport* also looks to 2050 and refers to long-term climate targets (European Commission 2011e). Likewise, the EU's *Seventh Environment Action Programme* frames the EU's environmental challenges in a 2050 vision (European Commission 2012c).

---

visions that will guide transition policies. The difficulty of this final implication for policy-making is illustrated by the critiques of the democratic deficit of specific transition processes (Hendriks 2009).

41.2.3   Transitions at an International Scale

It has been observed by previous scholars that a significant part of the transitions literature has a 'bottom-up bias': a built-in tendency to focus on bottom-up dynamics, on local experiments, or on processes taking place within economic or technological niches (Jørgensen 2012: 999; Lauridsen/Jørgensen 2010: 487). This bias is currently being challenged by a growing field of studies on the geography of transitions looking more closely at the spatial context of transitions and at the interactions between multiple scales (Hansen/Coenen 2013; Raven/Schot/Berkhout 2012), but it is still in need of remedy. One of the remaining issues is that few analyses of transition governance pay substantive attention to international politics and policy (exceptions include Lauridsen/Jørgensen 2010; Nilsson 2012; van der Brugge/Rotmans 2007). Most case studies use a national or subnational level of observation (Raven/Schot/Berkhout 2012). If they do include

international policy-making in their analyses, it is often underexposed or too easily categorized as an exogenous (stimulating or inhibiting) factor or as a 'kitchen sink' variable of change (Happaerts/Bruyninckx 2012).

Transitions are nevertheless essentially international phenomena. Indeed, the persistent problems of sustainable development have a transboundary character and, as a consequence, the systemic changes that are needed to overcome them are international challenges, manifested at a regional or even a global scale. While niches can be localized (Hansen/Coenen 2013), the sociotechnical systems and the patterns of production and consumption that shape them are increasingly globalized. Transition studies therefore need to take account of the globalized character of economic, technological and regulatory structures (Meadowcroft 2005: 490–91). At the same time, the literature's lack of attention to international policy initiatives stands in contrast with the burgeoning transitions discourse that permeates those initiatives (see section 41.1), making them additionally interesting to investigate from a transitions perspective.

The transitions literature is thus in need of, on the one hand, a better conceptualization of the interna-

tional scale and, on the other, more attention to international policy initiatives (both by adopting an international level of observation and by involving such initiatives more systematically in case studies in general). This chapter hopes to contribute to that second challenge by conducting an exploratory case study of one particular steering initiative. The intention of the case study is to increase the scholarly community's understanding of the potential role of international policy-making in transitions, which, ultimately, should also bring us closer to a better conceptualization of the international scale in transition studies.

41.3   Sustainability Transitions and the Green Economy

Many of the instances where a transitions discourse can be seen emerging are international initiatives in the context of the green economy (Audet 2014). This is a concept that became popular in the sustainable development debate of the end of the 2000s (Happaerts/Bruyninckx 2014), and especially after the eruption of the global financial and economic crisis in 2008. In an attempt to redefine the crisis as an opportunity for sustainable development, UNEP's Green Economy Report proposed investing heavily in the greening process of a number of key sectors, in order to create jobs, eradicate poverty and support the transition to a low carbon, resource-efficient and socially inclusive economy (UNEP 2011). Other actors launched similar proposals, such as the OECD's Green Growth strategy (OECD 2011). A number of studies have analysed the content of different green economy proposals (Althaus 2013; Bina 2013; Ferguson 2014; Jänicke 2012). When compared to sustainable development—the concept that dominated environmental and development debates in previous decades—the green economy at first glance seems to offer some opportunities for a bigger impact on policy. It has a certain appeal for governments, because it justifies the priority they intuitively accord to economic development. Optimistically, it could thus be more easily integrated into governments' main economic policies and lead to concrete improvements (Ferguson 2014). But, on the other hand, a number of the important policy principles of sustainable development appear to have been overlooked by applications of the green economy concept, such as North–South equity and intergenerational solidarity (Althaus 2013; Onestini 2012). Another risk is that a purely instrumental view of the environment is adopted, as a 'capital

stock' which offers resources and ecosystem services, and which absorbs waste (Happaerts/Bruyninckx 2014).

Although the choice of the green economy as one of the main themes of the Rio+20 conference (the UN Conference on Sustainable Development held in 2012 in Rio de Janeiro, Brazil) appeared to denote a consensus among states to put the economy at the centre of attention at a time of global economic crisis, some transition scholars invoke that same crisis as a favourable occasion for sustainability transitions. Loorbach and Lijnis Huffenreuter (2013) claim that the landscape shocks brought about by that crisis inevitably led to structural systemic changes. Those changes, of course, do not necessarily head in a sustainable direction. That is why the green economy should be seized as an opportunity to propel sustainability transitions (Loorbach/Lijnis Huffenreuter 2013). Geels (2013) agrees, although he deduces from public discourse and investments that the window of opportunity for sustainability transitions is by now much smaller than at the beginning of the crisis, so before the green economy had gained its most popularity.

If the crisis is not seized as an opportunity for sustainability transitions, it could be because behind the green economy, despite its transitions discourse, are ideas closer to ecological modernization theory than to transitions thinking. Indeed, the emphasis on technological innovation as a driver of change and on the decoupling of economic growth from environmental impact (UNEP 2014), to name just two examples, corresponds with the key assumptions of ecological modernization (cf Bina 2013). One of the core differences between the two theoretical paradigms is the depth of change envisaged. The path to a green economy promoted by international organizations such as UNEP and OECD is situated somewhere between radical change and business as usual (Bina 2013: 1033–34), and embraces the idea of transitions while steering clear of its fundamental ambitions. Bina (2013) demonstrates "an uneasy balance" between wanting to change and effectively reconfirming the incumbent sociotechnical regimes, as green economy policies target incremental, technology-driven changes towards a more efficient and cleaner economy. Moreover, the dominant economic paradigm, with its focus on sustained growth, is not questioned, while it is acknowledged that the market mechanisms, so prominent in that paradigm, need fixing (Bina 2013: 1034–37). Based upon these horizontal findings, the transitions discourse of the green economy at best suggests tentative support for transitions in international policy-making.

But more detailed analysis, for which the case study presented in this chapter is a first step, is needed in this field.

41.4   The Case of Resource Efficiency in the EU

The case study that was selected for this study consists of a recent steering initiative at the level of the EU in the area of resource efficiency. Although the EU is not a global organization, non-legislative initiatives by the European Commission can be taken as a case of policy-making initiatives by international agencies that potentially play a role in stimulating transitions and influencing other levels of governance and other scales of societal action. In other words, although the EU is hardly comparable to other international organizations and obviously has a direct influence on national policy-making in various ways, it also produces a body of soft law, general guidance and other types of steering initiatives (e.g. Commission Communications, see box 41.1) which have a potential impact equal to that of the OECD, the IEA, UN bodies or other international agencies. The initiative that serves as our case study, the *Roadmap to a Resource Efficient Europe*, falls in that category, and touches upon a topic that is extremely relevant for sustainability transitions.

The international transitions discourse is manifested in a number of thematic areas, including natural resource use (e.g. UNEP 2014). Resources are central to the major global production and consumption patterns, which are at the core of many persistent problems of sustainability. As the extraction, production and consumption of materials are necessary for the provision of buildings, transport, energy and food, materials have a vital link to the main sociotechnical systems. At the global level, initiatives for a more sustainable use of natural resources have tried to address the multiple environmental impacts that materials generate throughout their life cycle. UNEP, the OECD and G8 have taken the issue to heart. A horizontal analysis indicates that those international initiatives were boosted by two recent events (Happaerts 2014: 32–33). First, sharp rises in commodity prices in the second half of the 2000s, a phenomenon closely linked to the outbreak of the economic crisis, pitchforked the issue of raw materials and their perceived scarcity to the highest ranks of geopolitics. It fundamentally heightened the level of governmental intervention concerning raw materials, and signified a break with an era in which the efficient or more sustainable use of natural resources was purely an environmental affair. Second, the economic advantages of sustainable resource use are prominently promoted in green economy strategies (see above), as it offers both ecological gains and economic savings in win-win scenarios for various sectors.

In this context, the concept of 'resource efficiency' was endorsed by several actors in 2010 and gave a new impetus to the debate (Happaerts 2014). This concept attempts to link the economic and geopolitical concerns about commodity prices and resource scarcity with an environmentally motivated concern for the responsible use of natural resources. At the same time, it presents itself as an integrating concept: a more efficient use of resources allows connections with a broad spectrum of environmental problems (such as climate change, biodiversity and waste) and provides an effective solution to several forms of environmental impact (such as air, soil and water pollution).

Also in the EU, resource efficiency became a central policy concept. While the EU has been taking action on natural resources since the beginning of the 2000s, mainly from an environmental policy point of view (with waste and product policies as the predecessors of a genuine resource policy), the economic crisis brought the EU to focus on the economic governance of raw materials. Subsequently, the defining moment for resource efficiency was the formulation of seven 'flagship initiatives' within Europe 2020 (European Commission 2011f), the EU's main socio-economic strategy and the successor of the Lisbon Strategy. Resource efficiency is now the number one priority of the EU's environmental policy (Potočnik 2010, 2012). Moreover, with its inclusion in Europe 2020, it achieved a political position in the EU unprecedented by any other initiative proposed by DG Environment (see box 41.2). The Commission first issued a general Communication about the flagship initiative (European Commission 2011f), and then established an interdepartmental task force led by DG Environment to draft the *Roadmap to a Resource Efficient Europe* (European Commission 2011a).

The *Roadmap*, its accompanying documents, and the EU discourse on the *Roadmap* form the case study of this chapter. The analysis is based on a thorough document analysis, on nine interviews with European and national policy officials and on non-participant observation at two informal workshops of EU member states on resource efficiency (April 2012, Brussels and November 2012, Berlin).

Box 41.2: Resource efficiency and Europe **2020**: the back story. **Source**: The author.

The development of Europe 2020 coincided with the start of the second Barroso Commission and with a significant institutional shift in EU environmental policy-making. Since 2010, climate change has come under the newly created DG Climate Action within the European Commission (Schoenefeld 2014). Previously, climate change was arguably the chief policy-making issue of DG Environment, for instance because the EU took a leadership role in global climate change discussions until 2009 (Bäckstrand/Elgström 2013). As a consequence, when Janez Potočnik took office as the new European Commissioner for the Environment in 2010, he had to look for a new 'grand story' if he wanted to play a prominent role within the Commission, after his 'loss' of climate change. It is suggested that Potočnik connected several policy streams to create a window of opportunity for 'resource efficiency' to become a major policy priority of the European Commission (Happaerts 2014). Those streams were the existing waste and product policies of the EU, in which natural resources had become increasingly prominent since the early 2000s, and the focus on raw materials within the industrial policy. Potočnik was explicitly looking for an issue that had the chance to weigh on the EU's economic agenda in times of crisis. Linked to the perception of scarcity of raw materials and to the problem of European competitiveness, resource efficiency was such an issue.

41.4.1 Policy Framing

Following the first research question, this chapter assesses how and under which conditions the concept 'transitions' is used in the discourse of the *Roadmap*, and the *Roadmap*'s policy framing is studied. The three main European institutions frequently use the word 'transition' in the context of the *Roadmap*. The concept either stands alone or appears in combination with 'resource efficiency' (Council of the EU 2011; European Commission 2010, 2011f, 2011a; European Parliament 2012), 'green economy' (Council of the EU 2011: 4; European Commission 2011a: 3, 8, 22), or 'low carbon economy' (European Commission 2011c: 11, 22; 2011a: 8, 14). The Commission defines a transition as "a fundamental transformation within a generation—in energy, industry, agriculture, fisheries and transport systems, and in producer and consumer behaviour" (European Commission 2011a: 2), and the terms 'transition' and 'transformation' are used interchangeably in the policy discourse (European Commission 2011c: 24; 2011a: 4). The *Roadmap* systematically stresses its long-term perspective and that it will take a generation to achieve the transition (European Commission 2011a: 2).

Sociotechnical systems and system innovation are also referred to in the EU's resource efficiency discourse. The Commission calls for "a significant transition in energy, industrial, agricultural and transport systems" (European Commission 2011f: 3). The Council states that the shift towards resource efficiency "will require, in addition to technological innovation, innovation at the level of our socio-economic system, i.e. new governance models, new business and education models, new consumption patterns, and lifestyles geared towards the sustainable management of resources" (Council of the EU 2011: 5). Awareness of the other possible outcomes of a transition trajectory is equally manifested in the discourse. The Commission adopts the explicit wording of "lock-ins" of sociotechnical systems when it refers to market distortions, to Europe's technological and knowledge systems, to prevailing institutions or to dominant production and consumption patterns (European Commission 2011c: 20–23; 2011g: 14-16, 18, 28, 34, 54, 56; 2011a: 4, 10). In a single instance, the Commission warns against the risk of "systemic collapse" when current resource use persists (European Commission 2011c: 6).

Another manifestation of the transition discourse is the explicit reference to transition governance. The *Roadmap* expresses the ambition to "[p]repar[e] th[e] transformation in a timely, predictable and controlled manner" (European Commission 2011a: 2) and mentions the use of 'transition paths' (European Commission 2010). Referring to the historical development of transition governance in the Netherlands (see above), the Commission advances the example of the "Dutch government['s] ... 'transition management' as national policy" (European Commission 2011c: 28).[4]

Although the Commission defines a transition as a fundamental transformation, and although interviewees stress the Commission's awareness that incremental changes are not enough for a transition, it is unclear from the discourse how fundamental the proposed

---

4 The concept of sustainability transitions and the ensuing 'transition management' approach were developed in the Netherlands in the context of the Fourth National Environmental Policy Plan (Ministerie van VROM 2001). As a policy concept, it was afterwards diffused to other jurisdictions, with the Flanders region in Belgium as the first testing ground for transition management (Paredis 2008).

changes are considered to be, as Commission documents have a tendency to be cautious and avoid radical wording. This is illustrated by the references to the concept of decoupling, an important principle of the *Roadmap*. While the goal of decoupling economic growth from resource use is frequently mentioned (European Commission 2011f: 5; 2011a: 2; European Parliament 2012: §7), it is unclear whether the aim is to achieve absolute decoupling (i.e. economic growth continues while resource use decreases) or relative decoupling (i.e. resource use continues to increase, but less intensively than economic growth). The Commission only mentions absolute decoupling in a staff working document that contains background analyses and trends of resource use (see also European Commission 2010, 2011g: 96), but interviews demonstrate that a lack of consensus within the Commission prevents the explicit promotion of absolute decoupling of resource use. Although it is never formally confirmed, the Commission's discourse on 'efficiency' and 'doing more with less' goes much more in the direction of relative decoupling. The Council of Environment Ministers is in that regard more ambitious than the Commission, when it calls for "absolute decoupling of growth from resource use and negative environmental impacts" (Council of the EU 2011: 6; see also Council of the EU 2012: 4, 6).

In the policy framing of resource efficiency, the EU's resource problem is very clearly an economic one. The *Roadmap* stresses different forms of scarcity that follow a rising demand for a number of resources at a global scale and a volatility of resource prices (European Commission 2011c: 3-4; 2011f: 2; 2011a: 2–3). Besides global economic trends, the *Roadmap* deals with market distortions or systemic construction errors within Europe. These are situated in three domains. First, the EU addresses the problem of externalities (such as pollution or waste) that are not reflected in the price of resources. As a consequence, signals of scarcity are not perceived, and unsustainable exploitation and inefficient consumption are promoted (European Commission 2011c: 20; 2011a: 2, 4–5, 9–11, 23). Second, the *Roadmap* deprecates the exclusive orientation of financial markets towards short-term interests, whereas the long-term gains of resource efficiency are not sufficiently rewarded (European Commission 2011c: 19; 2011a: 20). In a working document of the European Parliament, it is argued that this "vested interest focussed on short-term economic gains needs to be defied" (European Parliament 2011). Third, a related distortion is the unfamiliarity of investors with the returns of resource efficiency, which functions as an obstacle for sustainable investments (European Commission 2011a: 9, 12, 20). Besides an economic problem, the transition towards resource efficiency is also presented as a policy problem, and explained as the result of policy failures and inconsistencies, e.g. inefficient subsidies (European Commission 2011c: 20-22; 2011a: 9-11; Potočnik 2011). Finally, although the *Roadmap* is an initiative of DG Environment, environmental problems take a back seat in the framing of economic policy. Only limited attention is given to the pressure of the EU's extensive resource use on ecosystems and to its contribution to climate change (European Commission 2011c: 4-6; 2011a: 2). The same goes for social and demographic changes (European Commission 2011c: 2). Moreover, when problems related to environment, energy or health are invoked, they are framed as economic problems and expressed in, for instance, the loss of working days (e.g. European Commission 2011a: 14).

The solution to the resource problem is also framed as an economic story. The EU sees a significant role for itself in what it calls "transforming the economy" (European Commission 2011a: 23). The *Roadmap* proposes a number of adjustments that can be made in the system's policy framework (of which the EU controls a significant part) in order to eliminate the distortions and construction errors of the market framework. The solutions for a new policy framework mostly revolve around the principle of 'getting the prices right'. Policies must create economic opportunities, offer the right incentives for investments, reward innovation and resource efficiency, and ensure security of supply. The way to do this is on the one hand by implementing policies that promote product redesign and increased reuse, recycling and substitution of materials, and on the other by improving coherence among existing policies which "shape our economy and our lifestyles" (European Commission 2011a: 2). An improved policy framework, in short, offers long-term certainty to businesses and investors about the future policy direction of Europe, which is aimed at resource efficiency. The Commission systematically emphasizes the economic advantages of resource efficiency, such as less dependence on imports and increased competitiveness (European Commission 2011a: 4, 6, 8, 10-11, 19-20), more growth, profit and jobs (European Commission 2011a: 2, 4-5, 8, 10, 20), opportunities for businesses to capitalize on the commercialization of their innovations and to use waste as a resource, and savings for consumers (European Commission 2011a:

2, 4–6). With all these economic benefits, the *Roadmap to a Resource Efficient Europe* is presented as a guidebook to a way out of the economic crisis.

To conclude, the appearance of a discourse on transitions in the EU's resource efficiency policy is more than the sporadic mention of the word 'transition', but a systematic use of several concepts central to transitions thinking. Interviews confirm that some of those who wielded the pen in the writing of the *Roadmap* (including Dutch and Flemish EU officials, see footnote 4) are very aware of the framework of sustainability transitions, and deliberately positioned the EU's efforts for resource efficiency within that framework.[5] They are conscious of the importance of such a discourse and indicate that they see it as an important strategy for creating awareness and pushing for a sense of urgency and the idea that fundamental changes are necessary. Furthermore, the *Roadmap*'s framing of economic policy suggests a firm belief in the market's ability to steer itself, provided that policies offer the right incentives. The EU's confidence in the functioning of improved market mechanisms should come as no surprise and can partly be explained by the fact that the EU's weight in and influence on national policies is strongest with regard to the internal market. In several domains, the European Commission tends to invoke internal market tools as the legal basis of policy proposals (e.g. Pollack/Shaffer 2005: 331). As early as the recession of the late 1970s, the EU's environmental policies were framed as economic measures (Delreux/Happaerts 2016, Lenschow 2005: 307, 12).

41.4.2   Principles

Following the second research question, the case study now assesses to what extent transitions thinking permeates the content of the EU's resource efficiency policy, measured at the level of principles, goals and instruments. An analysis of the *Roadmap* shows that a number of principles that are rooted in transitions thinking are strongly embedded in the policy initiative. Those include a fundamental observation about the unsustainability of our current system, a systemic approach, a long-term approach and the new paradigm of a circular economy. However, a number of

other principles that give shape to the *Roadmap*— decoupling, getting the prices right, monitoring and participation—appear focused on the optimization of the sociotechnical system instead of on a fundamental renewal of it.

As a first fundamental principle, the *Roadmap* departs from the observation that current patterns of resource use are unsustainable (European Commission 2011a: 2), thus implying that business as usual is not an option. The *Roadmap* then advances a systemic approach to suggest solutions to alter the EU's resource use. It does so by consistently coupling resource efficiency to other major domains and European policies (e.g. energy, agriculture, industry, transport). Even though concrete measures in those domains are not always elaborated, the *Roadmap* proposes to take land use impacts into account in all policies, to move from energy-efficient policies (e.g. for buildings) to resource-efficient policies, and to integrate resource efficiency into the European Semester, among other examples. Besides its systemic approach, the long-term approach embedded in the *Roadmap* also fits well with a transitions perspective. The strategy is built on the idea that current practices must be aligned with the long-term gains of sustainable resource use, even though that means short-term investments and costs incurred by or clashes with normal market practices (European Commission 2011a: 6, 20). The most visible expression is the formulation of the vision for 2050. A final principle that highlights a systemic transition is the idea of a circular economy. Although not a new concept, this has recently become a popular buzzword in the governance of resources (e.g. Ellen MacArthur Foundation 2012) and is increasingly used by the EU to frame the transition towards sustainable materials management (European Commission 2012b, 2014, 2015). The principle is used in the *Roadmap* to advance certain ideas and approaches that suggest a move towards a new materials system based on closed material loops, e.g. turning waste into a resource or adopting life-cycle approaches.

The *Roadmap* rests on four other principles that suggest a change in the EU's resource use, but which appear to avoid rather than support a fundamental renewal of the system. The first one is decoupling. As stated above, the principle is interpreted as relative decoupling, meaning that the main focus is on efficiency and that decreasing resource use is a secondary issue. The second principle is 'getting the prices right', the dominant image of the economic policy framing of the *Roadmap* (see above). It is linked to the idea that consumers will make more resource-effi-

---

5   The interviewees also indicate that those same officials intended to integrate the discourse on transitions in the 2005 Thematic Strategy on the Sustainable Use of Natural Resources (European Commission 2005), but that it was impossible at that time.

cient choices if they are properly informed and if taxes and product prices reflect the real environmental costs and the true value of natural capital. The two principles of decoupling and correct prices are oriented towards optimizing the current system of resource use, which according to the EU is characterized by market failures, rather than towards a real innovation of that system. Another principle that is strongly present in the *Roadmap* is monitoring. While transitions thinking promotes a reflexive form of monitoring, the *Roadmap* focuses narrowly on the development of indicators to measure the EU's progress towards resource productivity. A similar assessment is made with regard to participation, a final principle of the *Roadmap*. While the EU strongly invests in the involvement of all relevant stakeholders (member states, business, civil society, etc.), this participation is only invoked for the development of the resource efficiency indicators, a very narrow aspect of the governance of the initiative.

In conclusion, a number of principles suggest that the EU makes an attempt at intervening in the culture of the sociotechnical system, i.e. the prevailing images, values and paradigms of resource use in the EU. A point of departure assuming that the current system is unsustainable, the emphasis on a long-term, systemic approach and the new paradigm of a circular economy are clearly intended to achieve a necessary "shift in mindset" (European Commission 2011a: 20). However, the elaboration of some other principles, such as decoupling and the internalization of external costs, shows that the *Roadmap* tends to aim at an optimization of the current system, i.e. making current resource use much more efficient, rather than striving for a fundamental renewal of that system.

41.4.3   Goals

As a Commission Communication, the *Roadmap to a Resource Efficient Europe* sets out policy goals that are aimed at shaping EU policies in the years to come (see box 41.1). In the *Roadmap*, goals are formulated at three levels: long-term (2050), medium-term (2020) and short-term. The long-term vision contains the EU's long-term goals for resource efficiency in a condensed form (European Commission 2011a: 3). It is relatively vague and certainly not ambitious enough for some, but its main merit is that it exists, and thus integrates a long-term perspective into the policy process. The *Roadmap* is the only one of Europe 2020's flagships that looks beyond 2020, but it joins a recent

trend of other Commission road maps that depart from a long-term vision (see box 41.1).

The vision is translated into eighteen 'milestones' or mid-term goals to be reached by 2020. The milestones relate to the 'key issues' and governance aspects identified by the *Roadmap*.[6] Some correspond to 'hard goals' (e.g. environmentally harmful subsidies are phased out by 2020) or figured targets (e.g. water abstraction remains below twenty per cent of available resources), while others remain very vague (e.g. transport will use less and cleaner energy). Interviewees reveal that most milestones were formulated according to different resources rather than sectors to avoid creating the perception that DG Environment would encroach upon other domains (e.g. agriculture, fisheries, transport, construction, etc.). Nevertheless, the Commission found that the milestones were the object of the bulk of the criticism that the *Roadmap* received from member states and other actors, as they were too vague for some or too ambitious for others.

Short-term actions are formulated for each milestone. Those actions, around a hundred in total, are proposals for what either the Commission or the member states (or a combination of the two) will or should do between 2012 and 2020. About half of the actions involve the implementation, evaluation or (partial) improvement of existing policies, while only a fifth deal with new policy measures (the rest consisting of vague goals related to research or the promotion of certain issues). The Commission defends the inclusion of so many actions related to existing policies, arguing that many subsectors already have targets, and that the actions formulated by the *Roadmap* can help those targets to be reached by exploiting synergies between subsystems (European Commission 2011c: 24). Interviews show that the formulation of the actions was even harder than the definition of the milestones, which is why they are the most similar to incremental policy-making.

---

6   These are: 'sustainable consumption and production' (two separate milestones), 'turning waste into a resource', 'supporting research and innovation', 'environmentally harmful subsidies and getting the prices right' (containing one milestone on subsidies and one on taxation), 'ecosystem services', 'biodiversity', 'water', 'air', 'land and soils', 'marine resources', 'addressing food', 'improving buildings', 'ensuring efficient mobility', 'new pathways to action on resource efficiency', 'supporting resource efficiency internationally' and 'improving the delivery of benefits from EU environmental measures'.

The analysis of the policy goals reveals that, following the strong discourse on transitions in the *Roadmap*, the long-term and systemic approach is translated into a long-term vision for a resource-efficient Europe and a number of strategic goals covering a wide array of fields important for resource use. However, the more concrete and immediate the policy goals become, the more they deviate from fundamental transformations and suggest an approach based on incrementalism and improved business as usual. The *Roadmap* thus demonstrates a firm sense of urgency but little willingness to make fundamental choices right away.

41.4.4   Instruments

As a broad strategy proposed by the Commission, the *Roadmap* does not create radically new instruments. It does, however, lay out a spectrum of governance strategies that should be used to achieve a more resource-efficient Europe. Those strategies include addressing markets and prices, promoting new business models and production patterns, stimulating innovation, integrating life-cycle thinking, adequately informing consumers, boosting knowledge and information-sharing, and developing indicators.

Three types of instruments are particularly promoted. First, the Commission attributes a significant role to the instruments pertaining to the internal market and the EU's new competences with regard to 'economic governance'. Exactly those instruments give the EU the "sufficient scale of influence" needed for the transition (European Commission 2010). For instance, the Commission wants to integrate resource efficiency objectives into the European Semester (European Commission 2011a: 11, 19, 21). Its preference for using market-based instruments is explained by the weight of the EU's internal market tools (see above).

A second type is information instruments. This refers to the work on indicators, but also to the proposed measures with regard to product footprinting and other informational tools (e.g. European Commission 2011a: 7). The preference for information instruments demonstrates that the Commission realizes that it is the best placed institution for the monitoring of the transition towards resource efficiency in the EU, and that it can partially influence the transition by developing indicators. The focus on indicators can also be explained by the common criticism of the Lisbon Strategy, Europe 2020's predecessor, concerning the lack of concrete targets and indicators (Natali 2010; Steurer/Berger 2011). This time, the Commis-

sion wants to actively monitor the progress of Europe 2020. Furthermore, some authors have stated previously that working on indicators is popular because it is less threatening than actually intervening for change (Kemp/Parto/Gibson 2005: 21).

While the formulation of the *Roadmap* rested on unprecedented intra-Commission consultation, a third type of instrument is used to encourage the cooperation of specific stakeholders during the implementation process. Several of the short-term actions call for the establishment of platforms and partnerships for specific topics. The most prominent proposal was the launch of an *EU Resource Efficiency Transition Platform* (European Commission 2011a: 21). This is an explicit reference to the 'transition arenas' that the Dutch government used for its transition policy (European Commission 2011c: 28). The platform was formally established in June 2012, under the name *European Resource Efficiency Platform* (EREP).[7] It was a high-level consultation group, composed of Commissioners, MEPs, environment ministers, international organizations and representatives of different stakeholder groups, that presented recommendations, after a series of meetings, on the implementation of the *Roadmap* and on further action. These recommendations focused, for instance, on setting targets for resource productivity, promoting non-financial company reporting, phasing out environmentally harmful subsidies, and developing instruments for SMEs (EREP 2013, 2014).

The *Roadmap* thus contains at least one instrument that is explicitly derived from transitions thinking. But in general, the *Roadmap* mostly relies on market-based instruments and on information instruments. Rather than developing new instruments, it refers to a significant degree to already existing policies and measures, thus supporting an incremental approach.

41.5   Conclusions

The strong transitions discourse in the EU's resource efficiency policy, a case of a broader trend of emerging transitions thinking in international policy initiatives for the green economy, suggests the political appeal of a concept that demands fundamental

---

7   According to interviews, the choice was eventually made to give the platform a shorter name for communication purposes, and because the concept of 'transition arenas' is not well known in government circles apart from in the Netherlands and Belgium.

changes in our way of life. Indeed, the case study points out that the adoption of a transitions discourse was a deliberate choice by policy officials, who saw in transitions thinking the appropriate framework to strengthen the awareness that deeper societal changes are needed to achieve a shift towards a more sustainable use of natural resources. In the broader context of international green economy policies, it is hypothesized that the attraction of transitions thinking lies in its strong wording of deep change, in its comprehensive systems approach and in its focus on a number of principles and assumptions that differentiate regular policy-making from a more radical approach. However, the analysis of the case's policy framing indicates that the choice for an economic framing limits the scope of policy choices, focusing almost exclusively on improved market dynamics. The case also confirms the tendency to adopt a very instrumental view of the environment, as was observed with regard to green economy policies.

The analysis furthermore points out that the EU's resource efficiency policy experiences a real impact from transitions thinking, demonstrating that the adoption of the transitions discourse is more than a change of terminology. A number of policy components informed by this discourse are in line with transitions thinking. The long-term horizon is the most significant manifestation of such influence, and could be seen as a very meaningful policy innovation in the EU. However, while these policy components are symptoms of a significant change in the mindset of EU policy-making circles, the analysis confirms that the changes envisaged fall short of a true transition. Confirming previous observations concerning international green economy policies, the *Roadmap* seems situated between radical change and business as usual.

In conclusion, the underlying theoretical assumption about the nature of change in the policy initiative analysed is not fully in line with transitions thinking. The adoption of a long-term, systemic perspective and the awareness of the need for fundamental changes clash with the organizations and routines of EU policy-making, which are not at all oriented towards profound changes, whether radical or gradual. Rather, the EU's resource efficiency policy is built predominantly on incremental policy-making, guided by the conviction—which is at odds with transitions thinking—that an improvement in market-oriented policies will be enough to realize a fundamental societal change. The findings from this case study are in agreement with Meadowcroft (2009: 336), who states that transition governance in practice logically looks more

like regular policy-making than like theoretical transition governance. The real innovation is that these international policy initiatives have embraced the concept of transitions in the first place. From the perspective of the transitions framework, that could mean two things. A first possibility is that the transition towards sustainable materials management in Europe in still at the predevelopment phase, where the adoption of a transitions discourse is applied to facilitate upcoming changes, but where policies and institutional modifications in support of fundamental changes have not yet been put in place. A second possibility is that, despite the adoption of a number of the key principles of sustainability transitions, the policies conducted under that denominator are actually leading to a lock-in of the current system.

Future research should focus on at least three questions in order to deepen the understanding of the potential role of international policy-making in sustainability transitions. First, scholars should assess to what extent transitions thinking and related principles are permeating EU policies, including in a less visible way and independently of a transitions discourse. The example of regional policy, where in the context of Europe 2020 regions are encouraged to aim for transformative innovation rather than reactive or incremental innovation (European Commission 2012a), suggests that other EU policy processes are also moving in the direction of fundamental and systemic changes. Second, a detailed analysis of additional cases, exceeding the scope of the EU, is needed to corroborate the findings of this case study and to integrate them into a more universal framework. Third, from the perspective of multilevel governance, research needs to delve into the question of how international policy initiatives oriented towards transitions can be linked to bottom-up processes of innovation. Some of those processes are propelled by ambitious national and subnational governments, and such front-runners are likely to become a model for diffusion when their ideas are picked up at the international level (cf Jänicke 2013).

Chapter 42 **Sustainability Transition with Sustainable Peace: Key Messages and Scientific Outlook**

Úrsula Oswald Spring, Hans Günter Brauch, and Jürgen Scheffran

42   Sustainability Transition with Sustainable Peace: Key Messages and Scientific Outlook

Úrsula Oswald Spring[1], Hans Günter Brauch[2], and Jürgen Scheffran[3]

Abstract

This chapter presents the key messages of this *Handbook on Sustainability Transition and Sustainable Peace found in the previous texts by the sixty authors, arranged into ten parts. They focus on I)* moving towards sustainability transition; II) aiming for sustainable peace; III) meeting the challenges of the twenty-first century: demographic imbalances, temperature rise and the climate–conflict nexus; IV) initiating research on global environmental change, the limits to growth, and the decoupling of growth and resource needs; V) developing theoretical approaches to sustainability and transitions; VI) analysing national debates about sustainability in North America; VII) preparing transitions towards a sustainable economy and society, production and consumption and urbanization; VIII) examining sustainability transitions in the water, food and health sectors from Latin American and European perspectives; IX) preparing sustainability transitions in the energy sector; and X) relying on international, regional and national governance for strategies and policies leading towards sustainability transition.

This chapter proposes moving from disciplinary perspectives towards a transdisciplinary and anticipatory transformative approach. It points to research deficits and maps future research needs on 'sustainability transition', on 'sustainable peace', and on the linkages between both discourses, so that we can move from knowledge to action, and towards governance strategies, policies and measures aiming at *Sustainability Transition with Sustainable Peace*. Four examples are used to briefly illustrate this transformative scientific approach towards proactive policies. The first examines the sustainable energy transition achievable by moving from fossil fuels to enhancing energy efficiency and to renewables; this would grant access to energy for up to twelve billion people by 2100, while GHG emissions would be reduced. The second proposes a shift from resource- and carbon-intensive agriculture and a high degree of waste in the food sector to *climate-smart agriculture* with less waste. The third and fourth examples address proposed changes to different lifestyles in industrialized countries, and a shift in values as suggested, for example, by the Kingdom of Bhutan (Gross Happiness Index) and by indigenous people in Bolivia (Pachamama) and Chiapas. These alternatives may not be globally acceptable but they indicate that new viable pathways are needed that will lead towards a sustainable and peaceful world, and enable us to move beyond a continuation of the unsustainable Western way of life based on abundance and waste in consumption and production.

Keywords: Anthropocene, business-as-usual, climate-smart agriculture, complexity, decarbonization, global environmental change, interdisciplinary, lifestyles, multidisciplinary, sustainable development, sustainable peace, sustainability transition, transdisciplinary, transformative.

42.1   Introduction

This concluding chapter summarizes the key messages of the sixty authors in the ten parts (42.2). It goes on to stress the need to move from a disciplinary perspective towards a transdisciplinary and anticipatory and transformative approach (42.3), by pointing to research deficits and mapping future research needs on 'sustainability transition', on 'sustainable peace', and on the linkages between both discourses (42.4). In this way it will be possible to move from knowledge to action, and towards strategies, policies and measures aiming at *Sustainability Transition with Sustainable Peace* (42.5).

42.2   Key Messages of the Book in the Ten Parts

The *Handbook on Sustainability Transition and Sustainable Peace* examines in ten parts: moving towards sustainability transition (42.2.1); aiming for sustainable peace (42.2.2); meeting the challenges of the twenty-first century: demographic imbalances, temperature rise and the climate–conflict nexus (42.2.3); initiating research on global environmental change, the limits to growth, and the decoupling of growth and resource needs (42.2.4); developing theoretical approaches to sustainability and transitions (42.2.5); analysing national debates about sustainability in North America (42.2.6); preparing transitions towards a sustainable economy and society, production and consumption and urbanization (42.2.7); examining sustainability transitions in the water, food and health sectors from Latin American and European perspectives (42.2.8); preparing sustainability transitions in the energy sector (42.2.9); and relying on transnational, international, regional and national governance for strategies and policies leading towards sustainability transition (42.2.10).

42.2.1   Moving towards Sustainability Transition

In the introductory chapter, *Hans Günter Brauch* (Germany) and *Úrsula Oswald Spring* (Mexico) addressed the global context, the scientific concepts, the evolution of a new research paradigm, and the dimensions of the debate on sustainability transition and their linkages with sustainable peace. The Handbook links research on sustainable development, human security and sustainable peace with 'sustaina-

bility transition', focusing on the long-term transformative change from a carbon-intensive development path by addressing the causes of global environmental and climate change. The texts foster research on longer-term proactive strategies and policies in order to realize 'sustainable development' with 'sustainable peace', resulting from a transition of the systems of production, consumption, and governance. The Handbook addresses the key questions of whether business-as-usual policies and the growing number of climate-induced natural hazards pose threats to international peace and security; whether anticipative learning about long-term transformative changes might contribute to sustainable development and prevent new security dangers; and what lessons may be drawn from the violent consequences of the industrial revolution for a long-term transformative change towards sustainable development. After a brief sketch of opposite visions, the purpose and objectives of the Handbook were highlighted and a survey reviewed the challenges posed by global environmental change driven by population growth: climate change, biodiversity loss, soil erosion and desertification, water scarcity and stress, food scarcity and hunger, and gender. The survey integrated the results of global research programmes, of their linkages and their assessment by the IPCC, and on the nexus debates between water, food and energy security. Three key concepts—sustainable development, sustainability transition and sustainable peace—were introduced, the evolution of different approaches to sustainability transition were reviewed, the debates on green growth and decarbonization were noted, and six dimensions of the research on 'sustainability transition' were presented.

Simon Dalby (Canada), in chapter 2, "Contextual Changes in Earth History: From the Holocene to the Anthropocene: Implications for Sustainable Development and for Strategies of Sustainable Transition", recontextualized peace and sustainability for the Anthropocene. Taking an earth systems science perspective, he examined ecological phase shifts, boundaries, thresholds and tipping points, and multiple system stressors in the context of planetary boundaries. He placed the debate on 'sustainable transitions' in a rapidly changing future caused by global environmental change and reviewed the implications for contextualizing sustainable peace beyond national security by taking into account geopolitical contexts from the perspective of political geoecology and of the creation of the Anthropocene. Dalby's key conclusions were: 1. Production is a key consideration in understanding and constructing our future and integral to a

sustainable transition that will be shaped by decisions of community executives, where global cooperation is a key component. 2. Territorial strategies to 'green' some societies by outsourcing the production of energy- and pollution-intensive industries to others do not solve problems. 3. Authority over ecological processes necessitates deeper action than state territorial strategies of rule. 4. This new geography of connection in the globalized economy, and the possibilities of commodity chain governance, suggest that traditional assumptions of state-based national security are insufficient frameworks for governance. 5. This becomes more urgent if the earth system discussion is engaged, precisely because assumptions of a stable ecological context for humanity can no longer be taken for granted. 6. The future struggle for peace will be carried out in rapidly changing ecological and social conditions. Any transition from consumption-based extractive modes of economy to a sustainable one will take place during dramatic ecological change. 7. Strategies linking development and sustainability must consider ecological phase shifts if earth system boundaries are further transgressed. 8. Planning is more difficult if humanity is making the future of the planetary system as well as its own economic and social future. 9. This requires a transition to new ways of thinking about economics and politics if peaceful human societies are to be created as the next phase of the Anthropocene.

Carolyn Stephenson (US) examined, in chapter 3, "Paradigm and Praxis Shifts: Transitions to Sustainable Environmental and Sustainable Peace Praxis", transitions in paradigms and praxis, a sustainable environment in environmental studies, sustainable peace and peace studies, and the beginning of convergence between sustainable environment and sustainable peace in the 1970s, with a special focus on Kenneth Boulding (1966, 1970, 1978, 1983). She focused on conceptualizing peace in the context of UNESCO's 'culture of peace' and the rethinking of peace by the Nobel Peace Prize committee, on concepts of security, especially of human security, and on the UN debate that led to the Sustainable Development Goals. Stephenson's key concluding messages were: 1. Sustainability transitions may offer important contributions to peace and environmental studies in systems thinking. 2. While the environment has changed over millennia, transitions to environmental sustainability must acknowledge the importance of the environment for humankind. 3. Human beings have played a detrimental role in the health of the environment, and in environmental protection. 4. A key maxim is the

precautionary principle, where threats of serious damage and lack of full scientific certainty should be no reason for postponing measures to prevent environmental degradation. This principle could be important for peace and human rights. 5. A transition to an expanded concept of our human community would improve our work on both peace and the environment.

In chapter 4 on "Transition Studies: Basic Ideas and Analytical Approaches" John Grin (The Netherlands) offered a concise introduction of different approaches to (i) understanding and (ii) shaping transition dynamics: 1) A *socio-technical approach*, with the multi-level perspective as its main concept, and strategic niche management as its governance concept; 2) A *complex (adaptive) system based approach*, using the concept of transition patterns, with transition management as its governance concept; 3) A *governance approach*, which has elaborated the politics of transition dynamics, with reflexive design as the core of its approach to shaping transition and he reviewed the literature based on the social theory of practice. Grin concluded that the *sociotechnical approach* has yielded transition pathways that enable discussion of possible patterns of interaction between these levels. The *complex systems approach* offers more analytical insight into the underlying mechanisms, summarized in various types of transition patterns that underlie the sociotechnical pathways. The *governance theory based* approach has added an understanding of how the 'politics' of transitions are part of transition dynamics—thus yielding new insight into both transition dynamics and its politics. He argued that *social practice theory* has contributed insight into the agency in the embedded practices which shape transition dynamics, including the under-emphasized agency of users and consumers. Further development of these approaches and their relations may be both used in and informed by emerging research on new objects and units of analysis, which has expanded from societal domains, such as energy, agrifood, mobility, water management and health care, to cities and regions. Recently transition research has become aware of the role of place and space in all the approaches, which shapes regime-niche dynamics for all units of analysis; the governance and social practices approaches have highlighted the importance of proper analysis of the interaction between local, embedded, practices and globalization; and place and space are obviously particularly important when studying regions or cities. A final trend concerns the increasing attention paid to non-developed countries; this may help develop the theoretical

approaches, as novel contexts mean a more varied empirical basis: comparison of European with non-European cases may shed new light on the former as they may reveal how far regime dynamics is intertwined with the development of the capitalist welfare state, or how (reflexive) modernization takes different forms in different places.

In chapter 5, "Transformative Science for Sustainability Transitions", *Uwe Schneidewind*, *Mandy Singer-Brodowski*, and *Karoline Augenstein* (Germany) reviewed the need for and definition of 'transformative science', the methodological challenges of transformative research given the status quo of transdisciplinary science. They suggested moving from transdisciplinary to transformative research, and discussed the institutional challenges of a transformative science that could achieve institutional self-transformation and a 'new governance of science' by shifting from science policy to governance of science if civil society were given a larger role. Their main messages were: 1. As humanity is facing massive challenges, the key role of science in sustainability transitions has hardly been recognized. 2. 'Transformative science' has catalysed necessary processes through suitable forms of knowledge production. Transformative science is based on debates about transdisciplinary/transformative research and places emphasis on the aspirations of scientists to intervene in complex systems and to carry out research in real-world laboratories. It focuses on the problem dimensions of sustainability science and aims for an institutional change as the framework condition for sustainability science. Transformative science focuses on the whole science system, which faces massive transformations. 3. Building on the 'governance of science' approach, they argued for non-hierarchical forms of organization in science, where external actors play an important role. 4. In the context of sustainability transitions, science system transformations require reflection on the institutional conditions for a broadening and a quality enhancement of sustainability sciences as a whole. 5. They sketched out such change processes for the German science system and showed how processes of reform have prepared the ground. Although this case cannot be generalized, structural similarities may exist in other cases. 6. This was illustrated for global initiatives, such as the Future Earth programme and the global change research agenda of the International Social Science Council.

42.2.2   Aiming for Sustainable Peace

The four chapters in this second part examined sustainable peace from the perspective of peace psychology (chapters 6 and 7) and with a focus on patriarchy (chapter 8) and on the linkages between peace and nature, especially in the context of the emerging concepts of a political geoecology and peace psychology (chapter 9).

Morton Deutsch and *Peter T. Coleman* (US), in chapter 6, encouraged other psychologists to sensitize citizens, scientists and public officials to the psychological components of peace. They proposed thirteen elements in a sustainable peace process: 1. *Effective cooperation* on pressing international issues and at the interpersonal level on religious concerns, sexual relations, political views, lifestyles, etc.; 2. *Constructive Conflict Resolution* at the interpersonal, intergroup and international level; 3. *Social Justice* that distinguishes between injustice and oppression in order to enhance constructive conflict resolution; 4. *Power and Equality* in order to raise awareness of hidden discriminative relationships and to overcome confrontation by negotiation, in order to promote a successful peace process; 5. *Human Needs and Emotions*, in order to fulfil basic human needs and overcome apathy, fear, depression, humiliation, rage, and anger; 6. *The Psychodynamics of Peace*, to be achieved by emphasizing the interdependence between internal and external conflicts; 7. *Creative Problem-Solving* to bring in imagination, freedom and abilities to create new possibilities and capacities for problem-solving; 8. *Complex Thinking*, achieved by overcoming dichotomies between different regional experiences and integrating opposed alternatives to give unexpected results; 9. *Persuasion and Dialogue* as mutual processes where the parties listen to one another with mutual respect and equality; 10. *Reconciliation* of conflicting parties by encouraging them to cooperate with the support of third parties; 11. *Education*, by transmitting and discussing the psychological components of peace through cooperative learning, training in conflict resolution, constructive use of controversy, creation of dispute resolution centres and the development of awareness of human rights and social justice; 12. *Norms for Policy*, as being crucial for sustainable peace, where psychological principles and activism help change norms and policies towards processes of a sustainable peace; and 13. *The Practice of Sustainable Peace*, fostered by cognitive, affective, behavioural, structural, institutional, spiritual, and cultural elements. The authors concluded that "decision-

making within the individual as within the nation can entail a struggle among different interests and values for control over action. Internal structure and internal process, while less observable in individuals than in groups, are characteristic of all social units".

In chapter 7, *Peter T. Coleman* (US) analysed the essence of sustainable peace, highlighting the basic commonalities and synthesizing its main components by using a model of dynamic systems theory and minimalism. He outlined an agenda for future study and education that moves beyond destructive conflict, violence or war towards sustainable peace solutions. Instead of a simple, linear model of cause-and-effect he proposed a more complex, holistic model of sustainable peace that would integrate ecological, biological, psychological, social, economic, and other structural forces, promote transdisciplinary collaboration and foster sustainable peace through multiple perspectives and approaches. These processes go beyond short-term outcomes (peace treaties, agreements, etc.) and establish positive conditions for communities. Through communication and local, regional, and global networks, partnerships between both science and policy/practice should emerge to support these processes. His proposed initiatives included developing basic theory and research into sustainable peace with its fundamental conditions and processes. Applied frameworks should include empirically-tested theoretical models to foster peace and to enable the teaching of graduate, multidisciplinary, theory-and-practice courses on sustainable peace, using transdisciplinary approaches. He suggested a data-based index for annual reporting on state and regional levels of sustainable peace. The business and academic communities could develop comprehensive methodologies beyond early warning and violence prevention, and measure processes of sustainable peace. Coleman proposed an annual theory–practice–policy forum, where policymakers, peace practitioners and scholars would meet and cooperate on translating research into practice. This would require a common language with an integrative platform for transdisciplinary communication and coordination that would contribute to a new paradigm across scientific disciplines.

Úrsula Oswald Spring addressed a sustainable-engendered peace as a challenge in the Anthropocene. She examined different peace concepts, from the Neolithic and agricultural revolutions to the twenty-first century, such as negative, positive, structural, sustainable, and cultural peace, noting that none included long-term violence, authoritarianism, exclusion, discrimination or exploitation, all of which are deeply embedded in the patriarchal system. In agreement with Betty Reardon she argued that a sustainable peace requires overcoming patriarchy, militarism and injustice through: 1. the adoption of a holistic, gender-equal and feminist perspective; 2. a fundamental change in the occidental world view to include feminist values at all levels of society, in the public domain and in government; 3. a shift from national security towards human and gender security; and 4. an increasing global self-awareness of the people, especially the most vulnerable. She argued that this sustainable-engendered peace includes 'power-from-within', leading to a preference for change and to a commitment to action. Such a peace starts from a positive understanding of power and encourages new forms of action to overcome all types of oppression. This concept encourages a process of empowerment in order to overcome systemic violence, economic oppression, socio-economic marginalization, lack of autonomy in decision-making, cultural imperialism and environmental destruction. This peace is based on diversity in a world with numerous ethnic, religious, cultural, and social groups. The integration of traditional and modern knowledge may offer new approaches for dealing with conflicts and new ways of promoting equality and solidarity. From a radical feminist perspective, she criticized the current world view arising from greed, exploitation, violence, and oppression. Her peace paradigm is based on a different world view that is inclusive, just, participative, and equal, and focuses on a holistic, cosmopolitan, ethically oriented approach with the clean management of natural resources, ecosystem services, and safe food. This transformative approach may overcome the patriarchal system through education, peace-building, mediation, and negotiation aimed at an ethnically-oriented, gender-sensitive, religiously diverse and just society.

In chapter 9, "Sustainable Peace in the Anthropocene: Towards Political Geoecology and Peace Ecology", *Hans Günter Brauch* (Germany) argued that policymakers favouring a transformation towards a low-carbon society will face opposition. A sustainability transition in the energy and transport sectors would reduce energy costs and dependence on fossil energy imports from unstable regions. At least two peaceful outcomes of such a transition process may be assumed: the probability of energy resource conflicts would be reduced; and climate wars, dangerous climate change and tipping points would become unlikely. Preventing these conflicts would become a diplomatic strategy towards sustainable peace. Brauch's messages were: 1. Humankind has interfered in nature

and the earth system, causing it to move towards the Anthropocene. 2. This transition requires a scientific revolution for sustainability. 3. The social sciences must reconceptualize research programmes on peace, security, development and environment. 4. Irrespective of multilateral global climate diplomacy, strategies for a 'sustainability transition' must have an economic rationale. 5. Such strategies may contribute to 'sustainable development' with 'human security' and 'sustainable peace'. 6. Two research programmes, 'political geoecology' and 'peace ecology,' may contribute to a new scientific paradigm. 7. 'Political geoecology' adds a 'political' dimension to physical geography. 8. 'Peace ecology' links environmental and peace studies. 9. 'Sustainable peace in the Anthropocene' requires a rethinking of peace, focusing on 'peace with nature'. 10. The 'sustainability revolution' requires a *transformation* of global cultural, environmental, economic and political relations, replacing the dominant strategy of business-as-usual in a Hobbesian world that may lead to a major crisis for humankind.

42.2.3　Meeting the Challenges of the Twenty-First Century: Demographic Imbalances, Temperature Rise and the Climate–Conflict Nexus

The four chapters of the third part (chapters 10–13) assessed the key challenges and obstacles for sustainability transitions and possible ways of addressing them. These include demographic and population imbalances (chapter 10), the consequences of global warming in a 4°C world (chapter 11), the climate–conflict nexus (chapter 12), and the transformation from complex climate risk cascades to viability and sustainable peace in the Anthropocene (chapter 13).

In chapter 10, "Population imbalances: Will they continue over the rest of the century?", *Hania Zlotnik* (Mexico/US) analysed variations among countries in current population trends, which are expected to continue in the medium term. This will maintain today's population imbalances and produce a high potential for marked population growth during this century, especially in some of the world's poorest countries. According to the most recent estimates of fertility levels, 62 countries (19 per cent of the world population in 2014) had high fertility; another 64 countries (35 per cent of the world population) had intermediate fertility, and 75 countries (46 per cent of the world population) had low fertility. Zlotnik's key messages were: 1. Current population imbalances result from different trends in the reduction of fertility. Clear dif-

ferences exist between the countries of high fertility, intermediate fertility and low fertility in terms of contraceptive use, which is lowest in the high-fertility countries and highest in the low-fertility countries. 2. Given the differences in levels and trends of fertility that already exist between the countries, their influence cannot be erased in the medium term. 3. If the high-fertility countries could achieve the reductions of fertility projected by the low variant while all other countries followed the medium variant, the world might witness the beginning of population stabilization by the end of this century. 4. If the world population is to remain below ten billion by the end of this century, there is an urgent need to accelerate the reduction of fertility in the countries that still have high fertility levels, and that countries with intermediate levels of fertility continue to reduce them. 5. The use of modern contraception is the major immediate means of reducing fertility, especially in the high-fertility countries, where the unmet need for contraception remains high, especially among low-income groups, but also in the intermediate-fertility countries. 6. Increasing use of modern contraception seems feasible but requires sustained support for family planning, especially considering that the number of women of reproductive age in intermediate-fertility countries will increase over the next two decades. 7. In both the high-fertility and the intermediate-fertility countries, the unmet need for contraception is projected to decline between 2010 and 2030, while in the intermediate-fertility countries, the decline in unmet need is slower, but for the high-fertility countries it is faster than in the past. 8. Groups of countries will still leave a substantial proportion of women of reproductive age with an unmet need for contraception in 2030, especially in the high-fertility countries where, as fertility declines and increasing numbers of women wish to reduce their fertility, the demand for contraception will likely grow faster than the capacity to meet it.

In chapter 11, *Hans Joachim Schellnhuber*, *Olivia Maria Serdeczny*, *Sophie Adams*, *Claudia Köhler*, *Ilona Magdalena Otto* and *Carl-Friedrich Schleussner* (Adams Australia; all others Germany) focused on "The Challenge of a 4°C World by 2100". Recognizing the limitations of our understanding, they addressed processes that are scarcely or not at all reflected in current assessments of global warming, including critical thresholds and tipping points in the earth system, suggesting that the risk of crossing such thresholds might be much greater than previously thought. The overall effect of climate impacts has been determined in large part by the patterns of capital and commodity flows

and the degree of complexity in social networks. Another decisive factor driving the nature and scale of impacts and impact cascades and human vulnerability is future socio-economic development. The authors' main messages were: 1. Climate change acts as a multiplier on other environmental and social stressors, further increasing the vulnerability of the poor and those already disadvantaged. In a 4°C world the negative impacts of increasing temperatures and changing rainfall patterns on human sectors interact in non-linear and complex ways and have the potential for cascading impacts that affect the stability and well-being of societies. 2. Different degrees of vulnerability need to be taken into account across and within nation states when the risk of complex and abrupt impacts combines with the direct effects of unprecedented heat extremes and asymmetric sea-level rise. 3. Cumulative effects can be mediated and shaped by societal developments, including population and economic growth, which in turn affect and are affected by changes in climate. Climate change will likely widen the divide between rich and poor, or between more and less resilient populations. 4. Impacts projected for ecosystems, agriculture, and water supply in the twenty-first century could lead to large-scale displacement of populations, with manifold consequences for human security, health and economic and trade systems. 5. Given the intricate complexity of the earth system, impacts may also occur in a non-linear manner, significantly exacerbating the challenge for precautionary risk reduction and other adaptation measures. 6. Adaptation policy-making and planning needs to find ways of minimizing the risks associated with the impacts of climate change, both expected and unexpected. 7. The safest course for humanity is to avoid the unexpected rather than to prepare for it, and mitigating climate change remains the safest bet for the lives and well-being of present and future generations.

In chapter 12, *Tobias Ide*, *P. Michael Link*, *Jürgen Scheffran* and *Janpeter Schilling* (Germany) investigated "The climate–conflict nexus: Pathways, regional links and case studies". They reviewed the most recent quantitative and qualitative literature, assessed empirical, theoretical and conceptual issues, and analysed case studies. Their key conclusions were: 1. Research on the climate-vulnerability-conflict nexus has produced few consensual findings and remains disputed. 2. Depending on the spatial and temporal scales of data, large-N studies differ regarding the impacts of increasing temperatures, precipitation variability and extremes, lower freshwater availability, soil degradation, and natural disasters on the onset of violent conflict. 3. Qualitative studies also provide no clear picture: climate change in combination with other political, social, and economic trends seems to influence the intensity of pastoralist violence in northwestern Kenya, unlike the Nile Basin where coordinated efforts by the major riparian states have been able to avoid increasing conflict. 4. In Israel and Palestine, confrontational discourses and asymmetric power structures are more important for the course of the conflict than availability of water, which is predicted to decline due to climate change. 5. Possible reasons for the lack of scientific consensus may include difficulties in capturing multiple complex links in theoretical and empirical research on the dependent and independent variables. 6. Shortcomings also exist regarding methodology and the availability and quality of data sets, e.g. the onset of civil war at the country level with an annual temporal resolution is more likely driven by other factors than the persistence of communal violence at administrative unit levels with a monthly temporal resolution. 7. As climate change progresses, the relevance of conflict over adaptation, mitigation and geoengineering increases, while violent conflict in (peri-)urban areas may become more likely. 8. The potential impacts of climate change on societal stability could erode institutions, and this might trigger a downward spiral of violent conflict and environmental degradation, while violent conflict affects the environment negatively. 9. The debate on climate change and (violent) conflict is relevant for the debate on sustainability transitions and sustainable peace: to realize a sustainable world characterized by low CO_2 emissions and small ecological footprints, stable, reliable and accountable institutions are needed. 10. Research is needed on the climate–cooperation nexus, e.g. how climate change can facilitate cooperation and reconciliation between rival groups who adapt to common threats such as storms, floods or droughts.

In chapter 13, "From a Climate of Complexity to Sustainable Peace: Viability Transformations in the Anthropocene", *Jürgen Scheffran* (Germany) investigated major challenges in international relations caused by an increasingly complex and interconnected world. Occurring across different scales, this demands the stabilization of human–environment interactions and the integration of complexity science with global governance. Scheffran discussed cases of complex crises where climate change can be considered as a 'risk multiplier' that disturbs the balance between natural and social systems and amplifies the consequences

through complex impact chains. He used an integrative framework of human–environment interaction to analyse destabilizing developments, tipping elements and cascading risks, as well as concepts of resilience, viability and sustainable peace. His conclusions were: 1. Climate change can act as a 'risk multiplier' where the consequences are amplified through complex impact chains that affect the functioning of critical infrastructures and supply networks; intensify the nexus of water, energy and food; lead to production losses, price increases and financial crises in other regions through global markets; undermine human security, social living conditions and political stability; and trigger or aggravate migration movements and conflict situations. 2. Affected systems need to develop strategies to tackle the problems, including climate mitigation and adaptation; building resilient societal structures; cultivation of diversity and flexibility; social networks that facilitate the exchange of knowledge, income and other resources; new capabilities for disaster management, crisis prevention and conflict resolution; arms control, non-proliferation and disarmament; regional security concepts, crisis prevention, conflict resolution and confidence-building; and innovative institutional frameworks and legal mechanisms. 3. To avoid a cycle of violence and support, a transition towards a cycle of cooperation with new concepts of anticipative and adaptive governance is required, based on the concepts of resilience, viability and sustainable peace. To influence critical decision points and adjust actions towards human security, social resilience and societal stability, 'win-win' solutions can help in resource sharing and risk management; new social and political structures and institutions; and rules and regulations. The viability concept can serve as a guiding framework for transition and transformation processes towards a viable world.

42.2.4 Research on Global Environmental Change, The Limits to Growth, and Decoupling and Resource Needs

In the fourth part, Lourdes Arizpe, Martin F. Price and Sir Robert Worcester, together with Eckart Ehlers, reviewed the emergence of the human dimension of global environmental change, Marit Sjovaag analysed four reports by the authors of *The Limits of Growth* (1972–2012), and Mark Swilling assessed the work of the *United Nations Environment Programme*'s (UNEP) *International Resource Panel*.

In chapter 14 on "The first decade of initiatives for research on the Human Dimensions of Global (Environmental) Change (1986–1995)", *Lourdes Arizpe* (Mexico), *Martin F. Price* (UK), and *Sir Robert Worcester* (UK) analysed the institutional framework, the emerging social science issues on global change, and the initial steps towards a research programme on the human dimension of global (environmental) change between 1990 and 1995. Their main messages were: 1. Between 1986 and 1995 scientists from the natural and social sciences, politicians and members of the public recognized the rapid changes in the biophysical and human systems of our planet, with climate change and development as key drivers. 2. From the scientific perspective a critical need for new ways of thinking, data, and approaches to research emerged, requiring collaboration across disciplines with a new conceptualization of research problems, agreements on measurement, and time to learn to work together. 3. New research strategies developed on the *human dimension of global environmental change* (HDGEC), within the ISSC's (International Social Science Council) research framework and in its subsequent implementation. 3. This was one of many international initiatives concerning HDGEC, while much research was carried out by individuals and groups within and across disciplines at the local, subnational and national levels. 4. In the next two decades, substantial advances occurred as a result of these initiatives.

Eckart Ehlers (Germany), in chapter 15, examined the "Evolution of the International Human Dimensions of Global Environmental Change Programme (1996–2014)" by moving from HDP to IHDP (1995–1996) and offering an overview of the activities of the IHDP (1996–2014) in its search for stability and sustainability. He assessed IHDP's new mission and organizational restructuring and its transformation into a scientific programme. In an outlook, he examined the GEC research within the new 'Future Earth' initiative. Ehlers' key messages were: 1. IHDP fulfilled its mission and paved the way for a new understanding of the interactions between nature and societies. 2. The results from IPCC and the postulate of the Anthropocene are milestones of a new interpretation of the interactions between society and nature. 3. IHDP participated in developing these new paradigms. 4. Humans have changed the Earth in fundamental ways, and as a result stronger commitments are needed from the social science community to cope with these threats to Planet Earth. 5. IHDP and its projects have raised awareness and expanded the consciousness of the causes and consequences of climate and environmental change through supporting a

new 'sustainability science' and highlighting its responsibility for society and its well-being. 6. While for millennia, humanity faced the threat of nature, now nature is threatened by humankind. 7. A Nobel Prize Laureate symposium on global sustainability called for new ways of thinking and a new alliance between nature and society, and for new forms of social–ecological systems of research into global change. 8. The symposium proposed a 'new social contract for global sustainability', with a shift of perception from people and nature to interdependent social–ecological systems. 9. Humankind needs a 'social–ecological' innovation and technologies that work more directly for social justice, the alleviation of poverty, environmental sustainability, and democracy. 10. IHDP has contributed to meeting these challenges.

In chapter 16, "From The Limits to Growth to 2052", *Marit Sjovaag* (Norway) reviewed the debate on *The Limits to Growth* and its updates from 1972 to 2012. She assessed *The Limits to Growth–A System Dynamic Analysis of Planet Earth* (1972) and analysed its key concepts and methodology, its scientific approach and messages, and the immediate reactions to its publication. She examined the update *Beyond the Limits* (1993) and the 30-Year Update (2002), including the reactions to these reports, as well as the fourth report, 2052–*A Global Forecast for the Next Forty Years* (2012); she also reviewed further resources. Sjovaag's key messages were: 1. Major industrial interests saw their wealth and fortunes threatened. Economists and politicians found their world view questioned. The population saw economic growth as the safest option for meeting their needs. 2. In 1972, the report's messages were radical and its plea for a sustainable development path threatened the established economic, political and industrial elites. 3. The report was not the only environmental message that caused hostility. 4. The updates were presented in different lights, emphasizing 'hope' and 'love' (1992), and 'doom and gloom' (2004). The authors chose different strategies to engage the world in a debate about where we are heading. 5. Three decades later, Graham Turner showed that the model offered a good description of reality. 6. The global UN-based governance system has been unable to produce a globally binding GHG emission reduction treaty in the forty years since 1972. 7. The four books concentrated on the 'physical' variables of human development and its global effect, while discussions on security and social development were absent. The reports assumed that resource shortages might lead to social unrest, but did not carry out a closer causal

analysis. 8. The '2052' book included superficial discussions on quality of life. There was no discussion of how the political process can solve *social* problems caused by climate change. 9. *The Limits to Growth* pointed to two stories about how global governance failed to take action to prevent the challenges highlighted in the 1970s, and it incited debate, raised ethical questions and spurred on a search for deeper knowledge of our world.

In chapter 17, "Preparing for Global Transition: Implications of the Work of the International Resource Panel" (IRP), *Mark Swilling* (South Africa) contextualized the activities of the IRP, gave an overview of its work, reviewed global resource perspectives, addressed the nexus themes by discussing city-level decoupling, GHG mitigation technologies, food systems and trade, examined specific resource challenges posed by metals, land-use and soils, and water, and discussed the implications of the IRP's work for global transition thinking. Swilling's key messages were: 1. In this assessment long-wave theories of transition were used for understanding its relevance for anticipatory science. 2. The IRP's work suggests that it is unlikely that the industrial epoch can continue relying on the continuous increase in the consumption of natural resources. 3. Elements in its reports could be woven into a more robust and systematic conception of transition: the types of decoupling in the *Decoupling 2 Report*, the dietary and land-use changes in the *Land and Soils Report*, the key role of cities in the *City-Decoupling Report*, and the unintended consequences of a transition to clean energy, to give a few examples. 4. Three broad conclusions flow from this analysis: a) The IRP's reports support the notion that future well-being must be decoupled from rising rates of resource use. This requires a fundamental restructuring of prevailing modes of production and consumption. b) The IRP's work reveals the futility of naïve assumptions on what is attainable in a sustainable world of over nine billion people, mostly living in cities. Anticipatory science must show that this cannot continue. A world of over nine billion people without poverty may well need what was extracted in 2000. c) The IRP's work on resource limits and potentials must be integrated into a wider holistic theory of economic development.

42.2.5 Developing Theoretical Approaches to Sustainability and Transitions

In the fifth part, in chapter 18 Czeslaw Mesjasz addressed linkages between sustainability and com-

plexity, deriving lessons from modern systems thinking. In chapter 19, Bonno Pel, Flor Avelino and S. S. Jhagroe developed critical approaches to transitions theory, while in chapter 20, Mike Hodson, Simon Marvin and Philipp Späth investigated inter-scalar dynamics in the differentiated geographies of low-carbon transitions, with examples from the UK.

In chapter 18, *Czeslaw Mesjasz* (Poland) addressed "Sustainability and Complexity: A Few Lessons from Modern Systems Thinking". He identified and assessed the applications of concepts derived from complexity studies in the discourse on transition to sustainability and sustainable development, which are associated with the growing complexity of ecological and socio-political systems, and of their interactions. This includes a clarification of the terminology of complexity and related narratives to provide new insights into causal links as well as prediction, the normative approach, and influence upon societal phenomena. The author came to several conclusions and recommendations concerning sustainability, sustainable development and transition management: 1. Complexity cannot be defined in a precise way, and thus its meaning emerges in intersubjective exchange. Applications in sustainability and sustainable development may vary, beginning with loosely defined metaphors and analogies, and ending with various attempts at operationalization. 2. In many cases, the terms associated with complexity theory are misused in discussions about sustainability, where their vague meanings are applied as a kind of decoration, adding a 'scientific value' to the discourse. 3. Well-thought-out use of those concepts would contribute to a better understanding of the fast-changing modern world, and should lead to the development of more effective policy measures. 4. Sustainability transition and transition management are based upon ideas drawn from complexity theory and complexity science which relate to phenomena, processes, names and mathematical models for studying the complexity of natural and social phenomena with a set of simple descriptions, explanations and predictions, including ideas such as adaptation, the edge of chaos, learning, and self-organization. 5. It is a challenge to identify and stimulate the process of self-organization among the reflexive and self-reflexive members of an *autopoietic* social system which is described metaphorically as being at the edge of chaos. 6. A methodological toolbox should be open, but at the same time, any ideas and methods, before inclusion, should be tested for their conceptual and cognitive validity as well as for their applicability. The development of sets of indicators

for sustainable development is the first step in this direction

In chapter 19, *Bonno Pel* (Belgium), *Flor Avelino* (The Netherlands), and *S. S. Jhagroe* (The Netherlands) developed "Critical Approaches to Transitions Theory". The authors showed how transitions theory has started to gain currency among both policymakers and researchers, and a process of institutionalization and mainstreaming is increasingly being established. At the same time, transitions theory remains controversial and questions have been raised about the theorization of agency and transformation dynamics, particularly about the normative assumptions underlying intervention strategies. Key issues discussed were: 1. Critical approaches to transitions theory are guided by a constructive attitude that reflects distinctly 'critical' elements and avoids polemical juxtapositions between critical and uncritical transitions approaches. 2. Key questions are addressed through a historical comparison with the critical-theoretical project initiated by Marx, Horkheimer, Adorno and others to diagnose the social problems of its time and to articulate corresponding remedial strategies. 3. Critical transitions theory runs into various internal contradictions, provides useful insights, and is well equipped to deal with critical-theoretical paradoxes, but also displays tendencies towards relapsing into pitfalls. 4. The relapse into objectivism and ivory tower critiques, into fortification and scientization, and the negligence of the normative assumptions underlying transitions diagnoses and remedies, seems to be the flip side of the aspiration towards transitions science, where transitions theory is somewhat uprooted from its origins in the humanities. 5. There have been considerable developments towards a more emphatically critical transitions theory, with many recent advances that take direct issue with the paradoxes discussed. 6. The existence of repertoires such as transition management, strategic niche management and the technological innovation systems framework shows how transitions theory is strongly dedicated to the development of remedies. 7. The critical-theoretical legacy reminds us that transitions theory too is shaped by the prevailing social conditions of its time.

In chapter 20, *Mike Hodson* (UK), *Simon Marvin* (UK) and *Philipp Späth* (Germany) investigated "Subnational, Inter-Scalar Dynamics: The Differentiated Geographies of Governing Low-Carbon Transitions—With Examples from the UK". Taking as a starting point the *Multilevel Perspective* (MLP), and distinguishing niche, regime and landscape levels, the authors improved the analytical understanding of low-

carbon transitions at and in between multiple geographical scales, particularly 'below' a national level. They set out a range of spatial levels relevant to transition activity, and explicitly identified different, yet coexisting and interacting, scales of low-carbon transition activity in the UK. Their key results were: 1. The MLP approach offers tools for thinking through institutional and technological conditions and rules through which regimes reproduce or change over time. 2. Activities that contribute to a transition (electricity systems, heat and buildings, mobility systems, food systems, etc.) have effects of different spatial reach, and are connected with a wide range of socially constructed spaces. 3. From a geographical perspective, both spaces (e.g. cities, regions, neighbourhoods) and scales (the city scale, the regional scale) are continually being made, negotiated and remade; transition activities are defined on national, urban, hyperlocal and even smaller scales. 4. Coalitions are tightly linked to the space of the national state, promoting a view of the primacy of markets in low-carbon transitions and the need for effective political coordination of institutions to shape low-carbon transitions. 5. Their chapter illustrated the ways in which political-economic institutional configurations have shaped a particular low-carbon response at UK national level, mediated landscape pressures and set conditions for regime reproduction/reconfiguration and niche activities. 6. The literature on sociotechnical niches shows how, why and the extent to which hyperlocal spaces are 'protected' and the limits of geographical protection where national and local priorities may differ. 7. Scalar transition activity works on one dimension to promote top-down low-carbon activity or alternatively bottom-up activity.

42.2.6 Analysing National Debates about Sustainability in North America

In the North American geopolitical context Twig Johnson, Simon Dalby and Juan Antonio Le Clercq analysed for the US, Canada and Mexico the constraints for sustainability transition.

In chapter 21, "Policy, Politics and the Impact of Transition Studies", *Twig Johnson* (US) addressed US interests in linking research and political action as a key challenge for transition studies. Following the publication of *Our Common Journey: A Transition toward Sustainability* (NRC 1999), a contested presidential election and the terrorist attacks of 9/11 totally changed the political arena for a sustainability transition. Several universities and research centres

working on sustainability studies shifted to interdisciplinary research and teaching, while others established new courses, launched a transdisciplinary approach, and founded new academic journals. The award of the Nobel Prize for Chemistry for work on the depletion of the ozone layer (1995) and of the Nobel Peace Prize to the IPCC and Al Gore (2007), as well as the increasing number of disasters from extreme weather events, put pressure on the US government, which failed to react to this but rather securitized terrorism. The high level of support for environmental issues by the Clinton administration was replaced during the Bush administration with hostility and the suppression of research results. During the Obama administration, multinational insurance companies maintained the pressure because of the increasing costs of disaster payments, but the Republican-controlled Congress together with many lobbyists continued to block a radical decarbonization. The problem-solving policies oriented towards sustainability have shifted to the states, municipalities, the people affected, scientists, engineers and educational institutions, as well as to *non-governmental organizations* (NGOs) and some corporations, who pointed out the potential for job creation and innovation in a decarbonized and sustainable economy, where water, soil, biodiversity, health, food and population growth were all addressed.

In chapter 22, "Geopolitics, Ecology and Stephen Harper's Reinvention of Canada", *Simon Dalby* (Canada) examined the consequences of Harper's policies. Harper promoted a geopolitical foreign and domestic policy approach based on energy exports, with the aim of making Canada an energy superpower. This neo-liberal approach prioritized the market, since its key objectives were wealth and job creation. His conservative government withdrew from the Kyoto Protocol, dropped some regulations concerning environmental standards, and pushed for a carbon-intensive economy. Dalby found that six lessons could be learnt: 1) Activists for a sustainable world in Canada and elsewhere generally ignore politics. 2) They primarily focus on narrow technical environmental matters and assume that legislation can protect nature in the long term. 3) They forget that "power has also slipped away from states as they become enmeshed in complicated international trade agreements where foreign companies have the rights to sue governments trying to initiate social and environmental regulations deemed a challenge to corporate profits". 4) Dalby argued that governance driven by the market is often only a chimera resulting in business-as-usual, rising

inequality and social unrest. Profit-driven policies cause long-term market failures and threaten the future of Earth. The biosphere and human well-being should not be exclusively managed by market forces. 5) In a globalized world economy, environmental and climate governance of countries, provinces, cities, social organizations, corporations and international institutions, which are often based on competing values, require cooperation and negotiation of common interests towards sustainability. 6) Dalby questioned the ontological premise of competition as the sole way of reaching sustainable futures, and stressed inter- and intra-generational equity, cooperation and care about nature and humans as a different geopolitical postulate for promoting sustainability globally.

In chapter 23, "Regime Change, Transition to Sustainability and Climate Change Law in México", *Juan Antonio Le Clercq* (Mexico) argued that "the environmental governance perspective points to a relationship between the quality of institutional design, regime interplay and effectiveness in dealing with global challenges". He asked why parliament had opted for this model of regulation for a governance regime, and whether this law would have an impact on Mexico's environmental policy and lead to a sustainable transition. The law required the government to establish an inter-ministerial commission whose objectives should reflect the goals of the National Development Plan (2007–2012) and be linked to a sustainable human development approach for mitigating GHG. The law required an *Inter-Ministerial Commission on Climate Change* (ICCC) to develop binding strategic guidelines including a diagnosis of environmental challenges; to formulate a hundred objectives and reportable goals on adaptation and mitigation; and to promote a voluntary register of emissions from the private sector. The decision in favour of a climate regime permitted the creation of a national climate policy with only minimal modifications of the existing environmental law. Climate policy instruments alone did not grant an effective mitigation and adaptation process, and after the government changed, climate policy was downgraded. The government of Peña Nieto adopted a constitutional change that allowed the privatization of hydrocarbons, and during the first three years of his government GHG emissions increased by twenty-eight per cent. In December 2015 (during COP 21 in Paris) the Law of Energy Transition was approved by Congress, and this facilitated investment in renewable energy and moves towards a more sustainable energy future in Mexico. This adoption of an energy regime not only weakened the Law on Cli-

mate Change but slowed down Mexico's transition toward a sustainable future.

42.2.7 Preparing Transitions towards a Sustainable Economy and Society, Production and Consumption and Urbanization

Part seven deals with the economic and societal dimensions of preparing sustainability transitions. Its seven chapters cover the discourse-institutional perspective (chapter 24); new business models relating to transactions and interactions (chapter 25); and sustainable consumption (chapter 26). Case studies focus on sustainable consumption and production in China (chapter 27); the eco-restructuring of the Ruhr as an example of a managed transition (chapter 28); the transition towards sustainable urbanization in Asia and Africa (chapter 29); and university partnerships in urban sustainability experiments, with evidence from Asia (chapter 30).

Audley Genus (UK) provided, in chapter 24, a review of "Sustainability Transitions: A Discourse-Institutional Perspective", based on diverse contributions concerning the role of language and institutional arrangements. Addressing the complex web of activities and actors in the transition process, the author presented a framework for a cross-disciplinary conversation on sustainability transitions, neo-institutional theory, and critical discourse analysis. Potential insights were considered from a discourse-institutional perspective in an attempt to improve understanding of the problems involved, the issues at stake, and the implications for policy and practice. The author's key conclusions were: 1. It is essential to embed or reproduce pro-environmental or unsustainable values and actions; the role of language in substantiating the status quo and in 'carrying' institutional change; and the role of firms, citizens/consumers and academic researchers as agents of institutional change or inertia, or as catalytic intermediaries. 2. Some contributors have developed combined discourse-institutional frameworks, highlighting how the discourse of 'ecology' has 'disciplined' the debate about nature in the Netherlands, leading to new and 'enduring policy practices'. 3. Several contributions highlighted different types of factors and actors in (un)sustainable patterns of production and consumption and the (in)effective governance of environmental sustainability-related science and technology; others highlighted the potential or marginalization of certain actors, such as NGOs and citizens, in grass-roots social movements. 4. Con-

ceptual issues apply to the definition of the types of institutions that may be significant to transition governance and innovation as well as to a more explicit analysis of the carriers, mechanisms and processes of institutionalization, non-institutionalization or de-institutionalization of arrangements, norms and cultures. 5. Earlier contributions have lacked a comprehensive treatment of specific *texts*, practices and their social conditions which together (re)produce the institutional reality of governance in a sustainability transition.

In chapter 25, *Jan Jonker* (The Netherlands/France) and *Linda O'Riardon* (Ireland/Germany) studied "New Business Models: Examining the Role of Principles Relating to Transactions and Interactions". Recognizing the signals that current economic ideas no longer function, they found that new ways of organizing are emerging with relevance for sustainability. The results of exploratory research, based on a series of interviews, demonstrate the relevance of *new business models* (NBMs) to create 'multiple value(s)' regarding the task of organization and the organizing entities. The empirical evidence is combined with theoretical underpinnings to explore the nature, features and functioning of NBMs. The authors' main results may be summarized as: 1. The world lives in a time of great transition, which is rapidly changing the conventional practice of merely economic business models. 2. Early NBMs can be generally categorized into different streams based on the practice of sharing, trading, and creating. 3. At the interface of connecting, community-building and cooperation, renewal, innovation, and thus NBMs come into existence. 4. The ability to connect increasing social and economic values, such as nature, care, attention, and money. 5. These connections create new consortia and constituent configurations of parties. 6. While money no longer predominates as the only means of trade, economic traffic is based on 'exchanging and satisfying' needs; having 'access to' the means of production becomes more important than actually owning them. 7. It is only possible to organize such an economy cooperatively based on long-term commitment where securing trust in relations via collaboration is a necessary condition. 8. Almost all of the models under investigation included activities to create an experience or a community or both that has to do with combining a product or products with a service or services.

Chapter 26, "Sustainable Consumption", by *Sylvia Lorek* (Germany) drew key arguments from the literature on sustainability research. As an early concept, 'environmental space' embedded sustainable con-

sumption within natural and social boundaries, and considered floor and ceiling as well as the space itself, its size and how to share it. She described various possible paths of transition to environmental space starting from overconsumption and under-consumption. Providing a more detailed analysis of the concepts of both 'green growth' and 'de-growth', the chapter distinguished between strong and weak sustainable consumption, and outlined some enabling mechanisms for sustainable consumption. The author's key arguments were: 1. Human consumption is embedded in the boundaries of natural systems but shaped by economic, societal and cultural structures. 2. The concept of environmental space helps us to visualize how the consumption level of countries, regions or individuals can be unsustainable if it exceeds upper and lower limits. 2. The limits often have not been clearly formulated, nor are there concrete suggestions about how to reach the safe operating space and what the best pathways are to achieving sustainable consumption; this is debated. 3. Green growth pathways rely on the transformative capacity of the economic system and respect consumer sovereignty. 4. (Global) consumption patterns that recognize these conditions do not necessarily remain within environmental limits and so characterize a weak sustainable consumption path. 5. De-growth paths demand shrinking economic activities, investment in research, and policies that lead to a change of systemic structures, 6. A development favouring sustainable consumption and 'sustainable shrinking' would require enabling mechanisms, framing conditions for the economy, strong sustainable consumption governance, and convincing research to show that it does not lead to adverse consequences, such as the collapse of economic or social security systems, and that it is completely different from austerity or recession situations.

In chapter 27, *Hongmin Chen* (China) explored "Sustainable Consumption and Production in China" as a primary way of addressing the constraints on economic development caused by a large population, severe resource scarcity, environmental pollution and ecological degradation. China's consumption has grown rapidly, in particular among the middle class and because of the shift to a consumption-driven economy. This increases the need for *sustainable consumption and production* (SCP) as a national strategy for economic and social development that can decouple economic development from environmental degradation. The key messages were: 1. SCP is still facing crucial challenges as extensive economic growth, uneven development, imbalanced expenditure between

consumption and investment, and rising inequality in income, accompanied by overconsumption, are challenging the coordination of development and protection and is thus aggravating problems of resources and environment. 2. Weak capacities for scientific and technological innovation and underdevelopment of non-governmental organizations in China leave the government as the main player in SCP, although long-term capacity for the improvement of SCP lies mainly in markets, independent technical innovation in enterprises, and extensive social participation by civil society. 3. SC has not received as much attention as SP from the government and the public because of the relatively low proportion of consumption in the GDP expenditure structure. 4. China's further reforms are expected to lift institutional barriers, and to include the optimization of fiscal and tax systems, adjustment of the performance evaluation system, transition of government functions, expansion of market spaces and social forces, and the construction of the rule of law. 5. With great efforts, China has made achievements in SP in some regions, especially improvements to production efficiency where the pace of improvements appears inadequate to offset the rapid increases in consumption. 6. SCP has not been clearly established as a development strategy in China, where it should be conducted more systematically and efficiently and better integrated in order to reduce duplication of effort and minimize conflicts. 7. Energy-saving and environmental protection policies and practices include the adjustment of the industrial structure, promotion of a circular economy and clean production, the Energy Conservation and Emission Reduction Project, green procurement, and progress in waste management.

In chapter 28, *Philipp Schepelmann* (Germany), *René Kemp* (The Netherlands) and *Uwe Schneidewind* (Germany) presented "The Eco-restructuring of the Ruhr Area as an Example of a Managed Transition", demonstrating the importance of regional actors and factors, alongside external stimuli. Since the decline of the coal and steel industries was associated with major job losses, the Ruhr district has been in transition for four decades. The chapter provides a narrative of a real-world laboratory for ecological modernization which became revitalized by investments and projects. The chapter offered relevant lessons for transition management: 1. The managed transition consisted of three phases: a) After Willy Brandt's promise of blue skies, pollution control and policies for nature conservation helped to establish an eco-industry (1961–1990). b) Starting with the IBA

Emscher Park, came the ecological reconstruction, clean-up and urban revitalization of the Ruhr district (1989–2015). c) The sustainable energy transition initiated regional innovation policies, supported by state and national energy programmes (2010 onwards). 2. The transition frame is the yet unfinished socio-economic structural change away from coal mining and heavy industries, together with growing environmental awareness and protection, building on existing regional energy clusters and infrastructures. 3. The region achieved economic strengths in the leading markets of resource efficiency and sustainable consumption, above the share for Germany and the state of North Rhine-Westphalia, taking advantage of the German *Energiewende*. 4. The eco-restructuring confirms many elements of transition management: a vision shared by most actors, platforms for strategic thinking, special innovation projects acting as stepping stones for transition processes, and special transition institutions. 5. Institutional entrepreneurs follow different agendas: air quality for health reasons, environmental amenities, preserving industrial heritage, quality of places, labour in the Ruhr area and halting depopulation. 6. The importance of transition showcases and real-world experiments to build a constituency behind a product (firms, researchers, public authorities) was noted. 7. It is difficult to determine the role of flagship projects in the transition when success depends on factors like the proximity of cooperative actors in the state. 8. Regional actors and city governments are more cooperative and result-oriented than national ministries. 9. Ecological restructuring and energy transition have top-down and bottom-up elements, where state authorities support innovation policy for regional specialization, while national authorities and the European Commission are funders of ecological restructuring projects.

Belinda Yuen (Singapore, China) and *Asfaw Kumssa* (Kenya, Sweden) analysed, in chapter 29, "Transition towards Sustainable Urbanization in Asia and Africa", two of the world's least urbanized but fastest urbanizing regions, where cities are engines of growth, with high population densities, congestion, expansion of slums, infrastructure shortages and environmental degradation. As rapid urbanization continues, how Africa and Asia manage the urban transition affects urban economic efficiency and greenhouse gas footprints. This chapter compared the urbanization patterns and transitions of both regions and discussed challenges and opportunities for sustainable urbanization. Major lessons highlighted were: 1. To abandon business-as-usual practices that impede economic

growth and efficiencies, lead to social and environmental risks, and ignore the realities of climate change and resource scarcity, African and Asian cities have to act towards sustainable urbanization in a way that is more inclusive, resilient and ecologically efficient. 2. Various Asian and African cities have begun sustainable urbanization with greener growth and economic prosperity, including regulation; green building, research and technology; and business and community energy-saving and emission-reduction. 3. Cities need to invest in infrastructure and to focus on pro-poor and greener growth strategies to reduce poverty, create jobs and improve living conditions. 4. Municipal governments and urban authorities should mainstream policies leading towards energy saving, fewer sprawls and climate-resilient infrastructure, that address drainage, flood control, housing, sanitation, transport and water distribution systems. 5. Rather than focusing on single pathways to sustainable futures, the transition is a complex and negotiated process allowing for some levels of failure and opportunities to learn. 6. An institutional and policy framework will mutually reinforce sustainable infrastructure and the management of natural assets, economic growth, the conservation of resources and the resilience of livelihoods in changing urban circumstances and at different stages of development. 7. Such effort needs to build collaboration among different urban actors (government, private sector, NGOs, people) to identify policies suitable to local conditions and needs.

In chapter 30, *Gregory Trencher* (USA, Canada) and *Xuemei Bai* (Australia, China) studied "The Role of University Partnerships in Urban Sustainability Experiments: Evidence from Asia". Starting from the observation that Asian research universities are forming cross-sector partnerships and implementing sociotechnical experiments for urban sustainability, the authors examined fifteen cases from Singapore, Japan, Hong Kong and Korea for knowledge co-production and urban sustainability experiments. They found common attributes (focus areas, actors, motivations and mechanisms) and investigated functions, motivations, barriers and significance of roles by differing societal sectors. Their key findings were: 1. University partnerships addressing urban sustainability are dominated by technical approaches, with numerous R&D platforms and competitive funding schemes privileging the engineering and physical sciences, although the capacity of technocentric approaches to reform lifestyles and trigger societal transformations to sustainability is limited. 2. Since human aspects are

significant barriers in sustainability experiments (for example, time restraints, lack of unity, poor management and leadership), and since the human and societal dimensions are crucial for the co-design and co-production of knowledge, more funding opportunities for the social sciences and humanities are needed to engage university actors and civil actors in social innovation-orientated sustainability experiments. 3. The ability of partnerships to tackle complex social issues and trigger societal transitions is often constrained by existing research projects and institutional capacities, and calls for interdisciplinarity in sustainability partnerships to address potential tensions and obstacles. 4. University partnerships demonstrate a promising capacity to generate knowledge, technologies, tools and societal transformations for advancing urban sustainability, and potentially serve as 'umbrellas' or 'portfolios' for societal experiments and interventions (i.e. protected spaces or 'niches' of innovation). 5. There is a wealth of mechanisms (e.g. knowledge management, governance and planning, technology transfer or economic development, technical demonstrations and experiments, reform of the built and natural environment, sociotechnical experiments) to co-produce knowledge, co-implement experiments and magnify societal impacts by the transfer of lessons.

42.2.8 Examining Sustainability Transitions in the Water, Food and Health Sectors from Latin American and European Perspectives

In the twentieth century, international politics focused on hydrocarbons. During the summit in Rio de Janeiro in 1992 an understanding emerged of the complex linkages among energy, soil, water, biodiversity and ecosystem services and population growth and land use changes due to rural, urban and productive processes.

Cecilia Tortajada (Mexico/Singapore) and *Martin Keulertz* (Germany/US) argued in chapter 31, "Future global water, food and energy needs", that "scarcity, pollution, mismanagement and misallocation of natural resources will impact every sector on which humankind depends for survival. In a globalized economy with increasingly free movement of commodities and financial and human capital, a poor understanding of the most pressing issues and their interconnectedness and interdependences will cause irreparable damage to the Earth and its billions of people: a clear case of *fait accompli*." The Millennium

Ecosystem Assessment (MA 2005) claimed that the changes in ecosystem services could produce non-linear, chaotic, unpredictable and often irreversible tipping points in the environment. Water is crucial for life and most productive processes, especially for agriculture and food production, which still consume seventy per cent of global water. The nexus between water, food and energy links the productive, service and domestic sectors, promotes or inhibits socio-economic development, and creates well-being and health globally. As there can be no peaceful development with empty stomachs and chronic undernourishment, both authors argued that water, energy and food security is "at the heart of the development challenges of the twenty-first century". In the past these resources were globally abundant and their use was considered free. At present both drastic environmental deterioration and economic globalization are threatening not only these three resources and their security, but could also directly affect the survival of humankind through polluted water and food scarcity. Population growth, increased demands for hygiene and new productive processes require more water, food and energy and thus put pressure on ecosystem services. Scarce and polluted resources also require different forms of international and local collaboration that involve all stakeholders. The authors concluded that "getting decision-makers to overcome silo thinking is key to achieving new policy outcomes. It is indeed the mega-challenge of our time."

In chapter 32, "Sustainability Transition in a Vulnerable River Basin in Mexico", *Úrsula Oswald Spring* (Mexico) analysed climate impacts in the context of increased organized crime in Central Mexico. Abrupt slopes, numerous affluents, high population density in the floodplain, laissez-faire politics, illegality, governmental corruption, and public insecurity have produced high levels of dual environmental and social vulnerability. Using survey data, she examined the risks perceived by the people and how they reduced their socio-economic and security risks. She explored cooperation between people and different levels of government in extreme events, and asked how the management of disaster risk reduction could be enhanced, the social tissue be reinforced, and the impact of criminal acts be avoided. For dealing with these complex emergencies, she suggested that a sustainable transition process requires the linking of socio-economic, political, environmental, judicial, cultural and psychological factors to develop adaptation and resilience from the bottom up. She proposed a new governance model, where the political arena needs to be changed at the local level from vulnerability to human and gender security. Human security for the people requires freedom from fear, want and hazard impacts, as well as freedom to live in dignity. Empowerment, equality, and equity are key mechanisms for establishing this new arena. She proposed that all stakeholders should develop a common agenda, with new activities and agents to change this complex emergency into sustainable livelihood and well-being for the most vulnerable people, including women and girls. Oswald Spring concluded that the transition to sustainability in the Yautepec river basin began with a common problem analysis involving crucial stakeholders and a desirable future vision including short-, middle- and long-term agendas for social (equality), economic (development), and gender (equity) issues.

In chapter 33, *Monica de Adrade* (Brazil) examined "Sustainability Transition in the Health Sector in Brazil". Brazil faces demographic, environmental and climate problems aggravated by migration and globalization. To address these challenges, over the past two decades the government of Brazil has developed multisectorial and universal public policies, whose objectives are universal health care, zero hunger, family health, and conditional cash transfer for extremely poor people. This has improved the indicators of extreme poverty, hunger, under-five mortality, maternal health, infectious and vector diseases, and primary education. During the last two decades Brazil has changed: the traditional epidemiological pattern of a poor country has given way to the modern diseases of industrialized countries, and cardiovascular diseases, cancer and traffic accidents now dominate. She linked environment policies to health issues, such as biofuel, hydro-energy, solar power plants, and the reduction of deforestation in the Amazon Basin, with a reduction in forest burnings and smoke emissions. These policies are combined with better urban planning and the promotion of public transport, and this has improved air quality. She showed that the health infrastructure and services are insufficient because of inadequate financial support. Efficiency, quality and the optimal use of investments may consolidate the achievements in the health sector and promote the transition process in Brazil. This requires a drastic reduction of income inequality and intersectorial collaboration between health, education and social development. This would optimize existing resources and support a sustainability transition through new investment in the Brazilian health and social sector.

42.2.9 Preparing Sustainability Transitions in the Energy Sector

Chapters 34 to 39 in part nine discuss the issues of sustainable energy transformation (Jürgen Scheffran and Rebecca Froese), low-carbon transition (Karlson Hargroves), wind energy technology transitions in India, Brazil and South Africa (Britta Rennkamp and Radhika Perrot), sustainability transitions and the politics of electricity planning in South Africa (Lucy Baker), Brazilian policies and the politics of energy and a low-carbon green economy (Eduardo Viola and Larissa Basso), and sustainable electricity transition in Thailand and the role of civil society (Carl Middleton).

In chapter 34, *Jürgen Scheffran* and *Rebecca Froese* (Germany) focused on "Enabling Environments for a Sustainable Energy Transformation: The Diffusion of Know-How, Technologies and Innovations in Low-Carbon Societies". The chapter started from the assumption that a sustainability transition addressing global warming and access to energy requires the diffusion of innovations, investment and learning to support transformation processes, including new technologies, products and infrastructures, as well as new social rules, norms and interactions. Their major conclusions included: 1. Developing North–South transitions into green economies requires an enabling environment for the innovation and dissemination of climate-friendly energy systems, including financial support, smart governance, and new social rules and norms in order to develop the economic, sociopolitical and technological capacities of all countries. 2. Key elements are the international diffusion of know-how, investments and technologies to establish market-creation mechanisms, including production capacities, the demand for low-carbon goods and international cooperation between business and government to adapt technologies to local contexts in a low-carbon society. 3. New market opportunities arising from changes in consumer behaviour could be tapped, including markets for organic food, goods produced under responsible practices (fair trade, no child labour, fair treatment of workers), and low-carbon products. 4. Governments can take up various policies to encourage investment in low-carbon and energy efficient production and transportation systems, including public procurement of low-carbon products and technologies; energy performance standards or mandatory energy labelling schemes; renewable portfolio standards; blending mandates for alternative fuels; taxes for high-emission technology or tax incentives for green electricity; tendering procedures for green electricity or green certificate systems; and feed-in tariffs. 5. Technology increasingly flows through private networks of information and assessment services, management consultants, financial firms, lawyers and accountants as well as through technical specialist groups. 6. Due to the failure of top-down and technology-centred approaches, participatory approaches involving community institutions, local public agencies, consumer groups, industry associations and NGOs are essential for successful technology transfer. 7. Multi-level interactions, social learning and institutions can help adapt technologies to local contexts.

In chapter 35, "Considering a Structural Adjustment Approach to the Low-Carbon Transition", *Karlson Hargroves* (Australia) argued "that the scale and pace of economy-wide changes required to significantly reducing greenhouse gas emissions are akin to … the application of *structural adjustment programmes* (SAPs) in developing countries". His key question was: "How can lessons from structural adjustment programmes inform the low-carbon transition, and how can a strategic approach be developed to deliver carbon structural adjustment?" After discussing the low-carbon transition (35.2) and efforts towards creating low-carbon economic multipliers (35.3), Hargroves examined the impacts of structural adjustment programmes (35.4), efforts towards harnessing structural adjustment mechanisms for carbon management (35.5), and a proposed carbon structural adjustment road map (35.6). His key messages were that "economy-wide adjustments to key structures [involving] multiple actors across society" are needed that could deliver "sustained economic growth, job creation, and poverty eradication". He proposed a reassessment "of the policy and industrial strategy used to achieve development", arguing that "efforts to achieve a low-carbon transition will need to be balanced with the level of embedded infrastructure in each economy", as a transition of "the economy to a low greenhouse gas emissions future [requires] sophisticated strategies". He proposed that a '*carbon structural adjustment*' may be needed "as a solution to unsustainable development", and that we should draw "on lessons learned … to progress the sustainable development and climate change response agendas, and merge this knowledge into an economy-wide structural change agenda". He recommended "six key areas for carbon structural adjustment, namely standards and codes, government requirements, taxation and subsides, investment and procurement policies, professional accreditation requirements, and education programme accreditation and requirements". He

suggested that for each action we should consider "its likely 'Carbon Impact Factor', and the likely 'Willingness to Adjust'".

In chapter 36, "Drivers and Barriers to Wind Energy Technology Transitions in India, Brazil and South Africa", *Britta Rennkamp* (Germany/South Africa) and *Radhika Perrot* (South Africa) provided a framework for the analysis of drivers and barriers to successful technological development (36.2), and applied it to wind energy technology innovation in three countries (36.3). They concluded that different combinations of the seven TIS (*technological innovation systems approach*) functions predominated in these countries, where each function might be crucial for the success or failure of a wind energy innovation system. Knowledge diffusion, entrepreneurial activities, experimentation, and resource mobilization were locked in to each country's existing knowledge, industrial structures and institutions. This induced positive externalities and initiated a process of legitimation within each country. They had a 'powerful' technological trajectory in common, based on fossil fuels, or large-scale hydropower in the case of Brazil, and this impeded switching from one trajectory to an alternative. The authors concluded that Brazil and India had succeeded in catching up because major companies had accumulated innovation capabilities independently of public policy incentives, thus speeding up the development of wind technology systems, while South Africa had had to start almost from scratch. They described a partnership with a company in a mature wind energy market that could trigger the transfer of knowledge and technology. While in Brazil a combination of resource mobilization, entrepreneurial experimentation and knowledge diffusion had led to innovation capabilities, in India there was a combination of entrepreneurial experimentation, influence in the direction of search, and knowledge diffusion from foreign joint ventures. Another crucial innovative factor was the enabling environment, for example, market size and trade barriers, where joint ventures stimulated knowledge creation and entrepreneurial experimentation and influenced the direction of search and eventually legitimation.

In chapter 37, "Sustainability Transitions and the Politics of Electricity Planning in South Africa", *Lucy Baker* (UK) defined a 'just' transition to sustainability (37.2), offered an analytical framework for sociotechnical transitions (37.3), examined the challenges of electricity governance (37.4), reviewed South Africa's electricity sector in context (37.5), and discussed the politics of electricity planning (37.6). She concluded that South Africa's minerals–energy complex still retains a key role in decision-making processes in electricity policy, and that the role of politics in the relationship between energy and industry is central because energy-intensive users are also the country's major coal mining enterprises and have vested interests in both supply and demand. She further argued that in order to meet the needs of the country's energy-intensive export-oriented growth trajectory, South Africa's IRP (*Integrated Resource Plan* for electricity) has simultaneously permitted a low-carbon niche, supported the expansion of the incumbent coal-based regime, and facilitated the potential introduction of nuclear energy. Despite plans for significant diversification in the electricity mix, Baker noted that demand is still projected to increase significantly, although much more slowly than projected; this reduces the possibility of a transition to sustainability due to a fundamental disconnect between the creation of a lower-carbon electricity mix and industrial demand. She further claimed that while the IRP will facilitate a renewable energy niche, its ability to address issues of energy poverty and access to energy for the poor is limited. She stated that this plan will not deal with the consumption-led model of economic growth or the high levels of national socio-economic inequality in consumption and access to power, and she concluded that any claims of a transition to sustainability and its governance and policy must be evaluated from a holistic perspective, including social, economic, environmental, financial and technological factors.

In chapter 38, "Low-Carbon Green Economy: Brazilian Policies and the Politics of Energy, 2003–2014", *Eduardo Viola* and *Larissa Basso* (Brazil) reviewed the debate on a low-carbon green economy (38.2), discussed the Brazilian energy matrix and its transformations (38.3), examined Brazilian energy policy and politics (38.4), and criticized crony capitalism and short-term thinking as major stumbling blocks to a low-carbon green economy (38.5). They concluded that Brazil had not so far adopted the low-carbon green economy model, and that the share of non-renewable energy sources had increased during the last decade, because of a lack of long-term policies towards renewables. Two opposite trends dominated Brazil's energy policy: while from 2003 to 2007 the share of renewables increased, from 2007 to 2014 it declined due to new deep offshore oil reserves and the use of oil prices as a policy tool to maintain higher rates of economic growth. Energy efficiency remained underdeveloped because a lack of policy, with no clear direc-

tion towards decarbonization because crony capitalism opposed investment in energy efficiency and renewable energy sources. In Brazil, energy security depends on cost-effective long-term quality and reliability of the supply and the transmission systems. The authors claimed that Brazil lacks strategic planning from government policies down to household budgets and that measures often simply respond to urgent problems and create contradictory situations. The authors concluded that only with quality education, transparency, accountability and rules that challenge privileges in Brazilian society can a sense of community and belonging, still absent in Brazilian society, develop.

In chapter 39, "Sustainable Electricity Transition in Thailand and the Role of Civil Society", *Carl Middleton* (UK/Thailand) examined the role of civil society in Thailand's sustainable electricity transition (39.2), analysed the emergence and embedding of Thailand's incumbent electricity regime (39.3) and the role of civil society in sustainable electricity transition (39.4), and discussed efforts towards decentralizing and democratizing electricity (39.5). Taking a multilevel perspective, Middleton explained the emergence and opposition to change of Thailand's electricity regime, which since the 1980s has been transformed from a state monopoly into a partially-privatized structure. Taking a political economy approach, he analysed Thailand's energy regime as a coalition of actors, including the state utility, its labour unions, and various independent power producers. Structural changes had been caused by shifts in 'landscape' at the global and national scales. While civil society groups supported the changes, elites had tried to limit their role. Incremental reforms were accommodated by the regime, including the growing contribution of distributed renewable energy generation and energy conservation, the creation of an independent regulator, and a small increase in civil society participation and accountability of the power planning process. Middleton argued that civil society groups had challenged the regime, opposed problematic projects, advocated a progressive policy, and proposed alternative plans, values and visions for Thailand's electricity sector. In his view, "the ST approach and MLP has helped explain why the structure of the incumbent electricity regime has remained relatively intransient, despite the argued-for benefits of electricity sector reform, and from the perspective of ongoing broader environmental, social and political challenges in Thailand". Reviewing the sustainability transition management literature, he pointed to strategies and policies that could

transform Thailand's incumbent electricity regime in the direction of sustainability.

42.2.10 Relying on Transnational, International, Regional and National Governance for Strategies and Policies Leading Towards Sustainability Transition

In chapter 40, "Governance of Sustainable Development in Knowledge Democracies—Its Consequences for Science", *Roeland J. in 't Veld* (The Netherlands) examined sustainable development, knowledge democracy, transdisciplinarity, and an agenda for future science organization. He argued that transdisciplinarity contributes to tackling the 'wicked' problems of sustainable development, and that knowledge democracies address the organization of science in society. Independent disciplinary scientific research becomes more complicated given the growing interdependencies between politics, media and science. Reflexive mechanisms complicate the reactions of the public to scientific findings. Scientific activities are performed by many organizations, governments and enterprises, by NGOs and individual researchers, and by specialized research organizations, such as universities. Governments stimulate and finance research to further national competitive positions and innovation, and to contribute to an attractive cultural climate. As sustainable development is long-term, multilevel and complex, consistent and stable science policies have free access to scientific sources for local and regional public authorities and citizens' initiatives. Innovation originates in local and regional communities, so free access is necessary for participatory democracy. The Humboldtian university is not interested in transdisciplinary trajectories, while the American university has rendered services to society based on centuries of institutional value formation. European nation states developed advisory bodies and semi-autonomous agencies to perform boundary work between science and politics. If a knowledge democracy is accompanied by populist tendencies, political hostility to these intermediaries grows fast. Sustainability problems necessitate transdisciplinarity but political conflicts are fought by playing two-level games. As the political controversy may lead to a dead end, an attractive strategy is to accuse the knowledge source of the opponent of a lack of trustworthiness. This indirect accusation will not stimulate the willingness of scientists to participate in transdisciplinary trajectories. In advanced societies the quantitative dimensions of research activities will increase, as large proportions of the popula-

tion create new knowledge and productive activities become more knowledge-intense. Transdisciplinarity and participatory democracy are more closely interwoven. Scientists who are successful in transdisciplinarity have insights into the rationality of politicians. Adequate governance arrangements for acceptable equilibria between different modes of knowledge production make necessary a redesign of the external and internal organization of scientific institutions. Peaceful coexistence between different research orientations in universities, and the organization of science, are focal issues for sustainable development.

Finally, in chapter 41, "Discourse and Practice of Transitions in International Policy-Making on Resource Efficiency in the EU", *Sander Happaerts* (Belgium) examined sustainability transitions and international policy-making, focusing on policy implications, the green economy, and resource efficiency in the EU. Happaerts' key messages were: The transitions discourse in the EU's resource efficiency policy demands changes in our way of life. With this discourse policy officials wanted to strengthen awareness that deeper societal changes are needed to achieve a more sustainable use of natural resources. In the context of international green economy policies, transitions thinking puts the emphasis on deep change and a comprehensive systems approach, and its principles and assumptions differ from a radical approach. Its economic framing limits the policy choices and focus on improved market dynamics. This discourse on the EU's resource efficiency policy is more than a change of terminology, and many policy components show that transitions thinking as symptoms of a change in the mindset of EU policy-making circles remains below the level of a true transition. The adoption of a long-term, systemic perspective and the awareness of the need for fundamental changes clash with the organization and routines of EU policy-making, which resist radical change. EU policy is built predominantly on incremental policy-making. Transition governance looks more like regular policy-making than theoretical transition governance. In the transition towards sustainable materials management in Europe, policies and institutional modifications for fundamental changes are not yet in place. Future research should address three questions about international policy-making in sustainability transitions. Scholars should assess whether transitions thinking is permeating EU policies. The example of regional policy suggests that other EU policy processes are also moving towards fundamental and systemic changes. Additional cases beyond the EU are needed to integrate the author's

case study into a universal framework. From the perspective of multilevel governance, research needs to address how such international policy can be linked to bottom-up processes of innovation. Some are propelled by ambitious national and subnational governments, and they are likely to become a model for diffusion when their ideas are picked up at the international level.

42.3 From Disciplinary, Multi-, Inter- and Transdisciplinary Approaches towards Transformative and Anticipatory Science

The linkages between sustainability transition and sustainable peace require bridge-building between different scientific disciplines in the natural and social sciences and different research programmes of political science: on the one hand between environmental and development studies, especially those that focus on sustainable development, and on the other between peace and security studies. This requires a fundamental shift from narrow disciplinary and programme-specific approaches to *multi- and interdisciplinary perspectives* as well as *transdisciplinary and transformative research designs and policy proposals*.

Each discipline has its specific epistemology, its premises and its methods of generating new knowledge. As the problems and issues that need to be examined scientifically become more complex, multidisciplinarity offers a first step in analysing complex problems from different disciplinary perspectives. These multidisciplinary studies rely on the methodologies of their respective disciplines.

The Swiss scholar Jean Piaget[4] who worked simultaneously in different disciplines, e.g. in developmental psychology, cognitive theory and genetic epistemology, pioneered a new transdisciplinary scientific approach, which resulted in educational reforms. Piaget promoted communication among different disciplines, and in the 1960s he proposed using the term 'interdisciplinary'. He applied interdisciplinarity to pedagogic units or modules in order to integrate knowledge from different disciplines. This interdisciplinary approach was taken up by new approaches and fields, such as bioengineering and brain sciences.

Brauch, Dalby and Oswald Spring (2011) suggested the creation of a 'political geo-ecology' for the Anthropocene by linking the 'geoecology' approach of physical geography (Huggett 1995) with the 'politi-

cal' dimension of the human security approach within political science and peace and security studies. The goal was to sensitize social scientists to take the results of the natural and earth sciences on global environmental change into account and to ask natural scientists to bring the political and security dimensions into their research paradigms and teaching on *Earth Systems Science* (ESS) and *Earth Systems Analysis* (ESA). Within the social and political sciences, Oswald Spring, Brauch and Tidball (2014) proposed a 'peace ecology' approach that would encourage bridge-building research and discourse between two parallel research programmes, each of which often ignored the results of the other (see chapter 3 by Stephenson).

Given the complexity of the Anthropocene, of global environmental change and of resource scarcity, several research centres and think tanks proposed transdisciplinarity as a new scientific approach to overcome the narrow disciplinary boundaries of specialized subfields and epistemic schools of knowledge creation. Darbellay (2015: 165) has argued that

> the increasing interest in ITD [inter- and transdisciplinarity] reflects a growing awareness of the multidimensional complexity of research contexts and objects and, hence also, of societal issues that require the greater synergization of institutionalized disciplinary skills. Today, the implementation of this type of approach responds to a need within the community of researchers, who must provide answers on a daily basis to theoretical and practical questions that are highly complex and not reducible to a single disciplinary point of view.

For Hirsch Hadorn, Hoffmann-Riem, Biber-Klemm et al. (2008) and Jaeger and Scheringer (1998), transdisciplinarity refers to "the cause of the present problems and their future development (*system knowledge*)"; to

the "values and norms ... [to] be used to form goals of the problem-solving process (*target knowledge*)"; and to "how a problematic situation can be transformed and improved (*transformation knowledge*)". They argue that "transdisciplinarity requires adequate [ways of] addressing ... the complexity of problems and the diversity of perceptions of them, that abstract and case-specific knowledge are linked, and that practices promote the common good" (Hirsch Hadorn/Hoffmann-Riem/Biber-Klemm et al. 2008; Pohl/Hirsch Hadorn 2007; Jaeger/Scheringer 1998; Mittelstrass 2003; Brand/Schaller/Völker 2004).

While "*multidisciplinarity* draws on knowledge from different disciplines but stays within their boundaries" (Choi/Pak, 2006), a definition of transdisciplinary and interdisciplinary research[5] states:

> *Transdisciplinary Research* is defined as research efforts conducted by investigators from different disciplines working jointly to create new conceptual, theoretical, methodological, and translational innovations that integrate and move beyond discipline-specific approaches to address a common problem. *Interdisciplinary Research* is any study or group of studies undertaken by scholars from two or more distinct scientific disciplines. The research is based upon a conceptual model that links or integrates theoretical frameworks from those disciplines, uses study design and methodology that is not limited to any one field, and requires the use of perspectives and skills of the involved disciplines throughout multiple phases of the research process.

In short, *transdisciplinarity* refers to a research strategy that establishes a common research objective that crosses disciplinary boundaries. The goal is to create a holistic approach by addressing complex problems that require close cooperation between several disciplines, such as brain or cancer research or issues of global environmental change, where medical, behavioural, environmental, economic and political sciences work together. Funtowicz and Ravetz (1993) argued that "transdisciplinarity can help determine the most relevant problems and research questions involved" (Funtowicz/Ravetz 1993, 2003).

Holistic system analysis (Güvenen 2015) also contributed to *transdisciplinary* research, which includes all possible aspects and focuses on the interaction among different elements. *Transdisciplinarity* takes a structural approach (Nicolescu no/year) and distinguishes between different levels of analysis. The surrounding conditions facilitate dynamic adjustment of undesirable disturbers. Of particular interest is a sys-

---

4   Jean Piaget and Barbara Inhelder (1969) argued that meta-thinking and behaviour are not simply acquired from the outer world but emerge from within, in relation to the outside. His constructivism is embedded in social, economic, environmental, political, gender and cultural structures. According to Piaget's epistemology the development of a child's knowledge came about through understanding of the chronological sequences and the structural interrelations among each of these processes, their advances and sometimes also their regressions. He used empirical data to show how a simple structure becomes more complex, then global, and how this generalizable structure may permit a sustainable transition process. From this epistemology comes the idea of complex structures, processes, and social interactions, where a sustainable-engendered peace may help overcome greed, social differentiation, discrimination, and violence.

5   "Definitions"; at: <http://www.hsph.harvard.edu/trec/about-us/definitions/> (4 February 2016).

temic dissipative and self-regulating approach, based originally on Ilya Prigogine and the thermodynamic understanding of processes (Prigogine/Stengers 1977: 184) and Haken's (1983) *Synergetics*.

These 'dissipative and open systems' operate outside and mostly far from thermodynamic equilibrium in a setting where energy and matter are exchanged. Prigogine characterized the 'dissipative structures' with the spontaneous appearance of anisotropy[6] or symmetry-embracing processes, where complex and often chaotic structures interact and create unpredictable new system formations. These dissipative systems are part of a permanent dynamic process which creates a new equilibrium among the existing structures and substructures, but also among the flows at different levels. The outcomes are permanently changing processes and new structures, which are far from equilibrium but able to maintain some dynamic functionality within the global system.

Niklas Luhmann (1991) applied dynamic system analysis to sociology and used the term 'autopoiesis', which originally described and explained the nature of a living system (Maturana 1996, e.g. a biological cell consisting of various biochemical components such as nucleic acids and proteins which are organized and bound in a cell nucleus). Luhmann's term 'autopoiesis' refers to the complexity of dynamic systems which interact with the complexity of the environment. Luhmann insisted on the radical nature of the concept and assessed five key characteristics: autonomy, emergency, operative closure, self-structuration and autopoietic reproduction. These elements are essential for the analysis of new risks and uncertainties caused by changes in the environment and social behaviour in the Anthropocene.

In chapter 5, Uwe Schneidewind, Mandy Singer-Brodowski, and Karoline Augenstein proposed moving from a 'transdisciplinary' approach to a 'transformative science', while in chapter 17 Swilling suggested an 'anticipatory science'. The concept of

'transformative research' or 'science' has been used since the 2000s for a new approach that cuts across the dominant scientific paradigms. The US National Science Board (2007) adopted the following working definition of 'transformative research': "[it] involves ideas, discoveries, or tools that radically change our understanding of an important existing scientific or engineering concept or educational practice or leads to the creation of a new paradigm or field of science, engineering, or education. Such research challenges current understanding or provides pathways to new frontiers".

Building on this approach, in *World in Transition–A Social Contract for Sustainability*, the WBGU (2011: 21–23, 321–356) referred to "four transformative pillars of the knowledge society": 'transformation research' and 'transformation education', as well as 'transformative research' and 'transformative education'. It proposed (2011: 21) that 'transformation research' should "specifically addresses the future challenge of transformation realisation" by exploring "transitory processes in order to come to conclusions on the factors and causal relations of transformation processes" and should "draw conclusions for the transformation to sustainability based on an understanding of the decisive dynamics of such processes, their conditions and interdependencies. ... Transformative research supports transformation processes with specific innovations in the relevant sectors and it should encompass, for example, "new business models such as the shared use of resource-intensive infrastructures, and research for technological innovations like efficiency technologies" by aiming at a "wider transformative impact". Uwe Schneidewind and Mandy Singer-Brodowski (2013) and Maja Göpel (2017) have developed this transformative approach further for climate policy and for research on sustainability transition.

The International Social Science Council (ISSC 2012: 21–22) in its report on the *Transformative Cornerstones of Social Science Research for Global Change* identified six cornerstones: 1) historical and contextual complexities; 2) consequences; 3) conditions and visions for change; 4) interpretation and subjective sense-making; 5) responsibilities; and 6) governance and decision-making. The report concluded that

> the transformative cornerstones framework speaks to the full spectrum of social science disciplines, interests and approaches—theoretical and empirical, basic and applied, quantitative and qualitative. By not fashioning a global change research agenda around a substantive

---

6   According to *Encyclopedia Britannica* at: <http://global.britannica.com/science/anisotropy>, '*anisotropy*' refers in physics to "the quality of exhibiting properties with different values when measured along axes in different directions. Anisotropy is most easily observed in single crystals of solid elements or compounds, in which atoms, ions, or molecules are arranged in regular lattices. In contrast, the random distribution of particles in liquids, and especially in gases, causes them rarely, if ever, to be anisotropic. A familiar example of anisotropy is the difference in the speed of light along different axes of crystals of the mineral calcite."

focus on concrete topics—water, food, energy, migration, development, and the like—the cornerstones are not only inclusive of many social science voices but, perhaps most importantly, show that climate change and broader processes of global environmental change are organic to the social sciences, integral to social science preoccupations, domains par excellence of social science disciplines. ... The transformative cornerstones of social science function not only as a framework for understanding what the social sciences can and must contribute to global change research. They function as a charter for the social sciences, a common understanding of what it is that the social sciences can and must do to take the lead in developing a new integrated, transformative science of global change.

The seventh conference of the *Sustainability Transitions Research Network* (STRN) in September 2016 will take as its theme "Exploring Transition Research as Transformative Science". Contributions have been invited that "[focus] on the conceptual and methodological challenges of transformative science, i.e. research that is actively involved in societal transformation processes". The speakers are invited "to reflect on the challenges and lessons learned in concrete research projects, on theoretical contributions advancing our understanding of transitions, and on the role of science and scientists involved in transitions to sustainability".[7]

Various initiatives by the US National Science Board (2007), the ISCC (2012), and the STRN (2016) have called for a new scientific paradigm in research into both global environmental change and sustainability transitions. The policy dimension should be included in the research design, by moving from knowledge creation to action, to policy initiatives, development and implementation.

These efforts are still highly dependent on the top-down efforts of governments and multinational enterprises. In the South, meanwhile, many excluded stakeholders have for decades put into practice a transformative education, e.g. by implementing the pedagogy of liberation inspired by Paulo Freire (1970, 1975). These excluded social groups promote transformative processes from their daily situation of marginalization, violence and exclusion, and promote sustainable livelihoods not for elites, but for wider social groups (Benavenides 2015; Silvia/Tavares 2015).

42.4 Need for Research: Deficits and Mapping

There have been few systematic intellectual exchanges between the early US pioneers on sustainability transitions such as the Tellus Institute in Boston, the suggestions by Speth (1992) and the Report of the NRC (1999), and the *Dutch Knowledge Network on Systems Innovations and Sustainability Transition* (2005–2010) that has since influenced the sociotechnological debate in the social sciences in Europe. Both approaches largely excluded the demand side, the values, preferences and behaviour of human beings as customers and citizens.

We need to integrate the contributions of the different disciplines on the spatial, scientific, economic, societal and cultural dimensions of sustainability transition into a wider and more holistic approach. The report on a *Social Contract for Sustainability* (WBGU 2011) took the earth systems and the global economic and social megatrends (chapter 1) into account as well as changing values (chapter 2), stages of the great transformation (chapter 3), and its technical and economic feasibility (chapter 4), as well as transformation governance (chapter 5) and the agents of transformation (chapter 6), including 'transformative science' and education (chapter 7). This approach was taken up by UNDP and was discussed by scholars from developing countries in June 2012 in Rio de Janeiro. So far, most approaches have been top-down and not bottom-up and have often involved only policymakers, opinion leaders in society, scientists and a few businesspeople. However, there have also been many grassroots movements calling for slow growth or 'degrowth' strategies (<http://www.degrowth.org/>), primarily for the industrialized countries.

In both the top-down and bottom-up approaches and initiatives, there has been no relationship between the call for sustainability transition and the normative goal of a sustainable peace and processes of conflict resolution and negotiation. The root causes of exploitation, discrimination, violence, neo-colonialism, and authoritarian leadership have been ignored. Greed has prevailed and since the 1970s has resulted in a rising level of social inequality and the accumulation of wealth by the top one per cent of the population, the super-rich. So far, only a few modest efforts by governments and social movements in Africa, Asia, Latin America, Europe and Australia have begun to link the transition process with sustainable peace initiatives.

---

7 See at: <http://www.ist2016.uni-wuppertal.de/fileadmin/ist2016/Call_for_Papers_IST_ 2016.pdf> (6 February 2016).

Research on 'sustainable peace' exists in the context of peace psychology (see chapters 6 and 7 by Coleman and Deutsch), and of conflict prevention and conflict and post-conflict peace-building, but it scarcely exists in the context of environmental problems, nor is there a focus on 'peace with nature'. An attempt to widen this narrow approach was made by Oswald Spring in chapter 8 by bringing in the debates on the root causes of violence with gender and patriarchy, and in chapter 9 by Brauch, who discussed the concept in the context of GEC in the Anthropocene. Since the 1990s the ecumenical movement has been calling for justice, peace and the preservation of creation, and more recently Pope Francis issued *Laudato Si* (2015), an encyclical on the environment. This is the first papal statement on the issue directed not just to the Catholic church but to "all people of good will".

So far hardly any research results exist on linking the process of 'sustainability transitions' with the normative goal of a 'sustainable peace'. The emerging debate on climate change and security (Gleditsch 2012; Scheffran/Brzoska/Brauch et al. 2012) in the Anthropocene (Dalby 2007, 2009, 2013, 2014, 2015, 2016; Brauch 2009) and on the nexus between water, food, energy and biodiversity security (Oswald Spring 2016) has crossed the boundaries between researchers working on GEC and those who work on security, both from a narrow military perspective and on human security from a liberal security and peace research perspective.

Only a few scholars have addressed the linkages between environmental and peace studies (Kenneth Boulding in the 1960s and 1970s; Conca 2002; Amster 2014; Oswald Spring/Brauch/Tidball 2014 and the other authors of the IPRA's *Ecology and Peace Commission* (EPC)). However, so far there is no systematic conceptual, theoretical, empirical and scenario research that addresses the possible consequences and impacts of strategies, policies and measures aiming at 'sustainability transition' on international relations, on international and national security or on 'sustainable peace'.

Robert W. Kates and Thomas M. Parris (2003: 8062) discussed "Long-term Trends and a Sustainability Transition" and found "10 classes of trends, which makes them complex, contradictory, and often poorly understood". They argued that "each class includes trends that make a sustainability transition more feasible as well as trends that make it more difficult. Taken in their entirety, they serve as a checklist for the consideration of global trends that impact place-based sustainability studies."

Using the NRC (1999) report, Kates and Parris (2003: 8062) added "material related to peace, security, and globalization" and described "10 major classes and 26 long-term global and regional trends that make a sustainability transition more feasible as well as more difficult". They indicated a "paradox of sustainable development [that] lies in the need to meet human needs through growing affluence and economy and the threat to the planet that such affluence poses through rapid and growing consumption". In their view, sustainability transition "reflects a process of globalization or interconnectedness, emerging forms of governance, and changing institutions and values" (Kates/Parris 2003: 8063). They argued that "favourable shifts in investment, income, and job opportunities in some parts of the interconnected world are accompanied by the loss of jobs elsewhere, unpredictable withdrawals of capital, and a deepening divide in needed skills and innovation, all adding new sources of instability for the world."

The post-development agenda called the *Sustainable Development Goals* (SDG) promotes, in its goal 16, 'Peace and Justice': peaceful and inclusive societies with access to justice for all and the building of institutions that are accountable, inclusive, effective and equal for all citizens, regardless of gender, race, caste, social class or age. Pisano, Lepuschitz and Berger (2014: 23) noted that the UN Secretary-General's High-Level Panel of Eminent Persons on the Post-2015 Development Agenda proposed

> that two out of 'five transformative shifts' for the Post-2015 agenda should consider to (a) *build peace and effective, open and accountable institutions for all* (with responsive and legitimate institutions that encourage the rule of law, property rights, freedom of speech and the media, open political choice, access to justice, and accountable government and public institutions), and (b) *forge a new global partnership* that involves governments but also other stakeholders, including people living in poverty, civil society and indigenous and local communities, multilateral institutions, local and national government, the business community, and academia.

Without taking up this suggestion, they reviewed the "sustainability transition initiatives undertaken in six EU member states (Austria, Belgium, Finland, France, Germany, and [The] Netherlands)" but without discussing the prospective impacts of these sustainability transitions initiatives on European and international peace and security. Nevertheless, all the attempts mentioned basically addressed processes of decarbonization but did not go further to processes of dematerialization, the recovery of ecosystem services, or resource recovery. The peace dividend was overlooked.

42.5   From Knowledge to Action: Sustainability Transition with Sustainable Peace

There is little or no scientific knowledge about the possible consequences and impacts of global and national strategies, policies and measures dealing with national and international peace and security or achieving the goal of sustainable peace with increased global equity and social justice. Policy-relevant considerations on the linkages between "Sustainability Transition with Sustainable Peace" are even scarcer.

How can we move from knowledge to action to achieve 'sustainability transition' with 'sustainable peace' in the Anthropocene? 'Anticipatory' and 'transformative' research and science mean integrating a 'proactive policy perspective' into research design. There must be a shift away from the dominant policy perspective of business-as-usual. This leads to ignoring the challenges and postponing action (or to non-action) and calls for 'reactive policies' of adaptation by technical and military means. In this way the aim is to contain the causes instead of addressing them in a sustainable scientific way and developing a process of 'anticipatory' sustainability transition.

However, this alternative paradigm and vision has almost totally ignored the dimension of international peace and security. A proactive policy perspective requires a systematic analysis of the constraints and opposed political and societal actors at national and local levels. This should include, for example, businesses and workers involved in the fossil fuel industries, especially in coal, natural gas and oil and in the fossil fuel and nuclear energy sectors.

Apart from global climate change, losses in biodiversity and increased levels of soil degradation and desertification and degradation, scarcity and stress of water have received less scientific attention; similarly, there is less public awareness of these issues and they are accorded a much lower political priority. For all these sectors both 'anticipative' scientific research and 'proactive' policy activities are needed.

The systemic model shown in figure 42.1 presents an analysis of natural and anthropogenic impacts on the earth system. There are several doubts about the impacts of chemical pollution and so new research is needed in order to obtain safe scientific data. The greatest impact on the earth system, following data provided by Rockström, Steffen, Noone et al. (2009), is loss of biodiversity, and this affects flora and fauna, ecosystem services, soil composition and food production, but also the mitigation for climate change.

The nitrogen flow is another threat. Together with other national and international institutions the FAO (2013) has promoted a soft approach to agriculture. They encourage the composting of organic waste and nitrogen fixation of microorganisms from the air to the soil (*Azospirillum*, *Rhizobium*), as well as a association of crops and mixed farming.

The melting of glaciers is a further danger. Schellnhuber and Martin (2014) argued that the ice shields of the Antarctic and of Greenland, as well as other glaciers, could trigger dangerous tipping points, while in the Indian subcontinent, in parts of China and in the Andes progressive melting of glaciers (Painter 2007) has occurred. This may create threats from glacier break-ups, as well as leading to a lack of drinking water for people who depend exclusively on meltwater.

As discussed in the introductory chapter, climate change (IPCC 2013, 2014a, 2014b), soil erosion, loss of natural fertility and desertification, and loss of phosphorous may seriously impact on food production (FAO 2016). This poses a threat to an ever-increasing population with changing dietary habits and calling for more meat and dairy products.

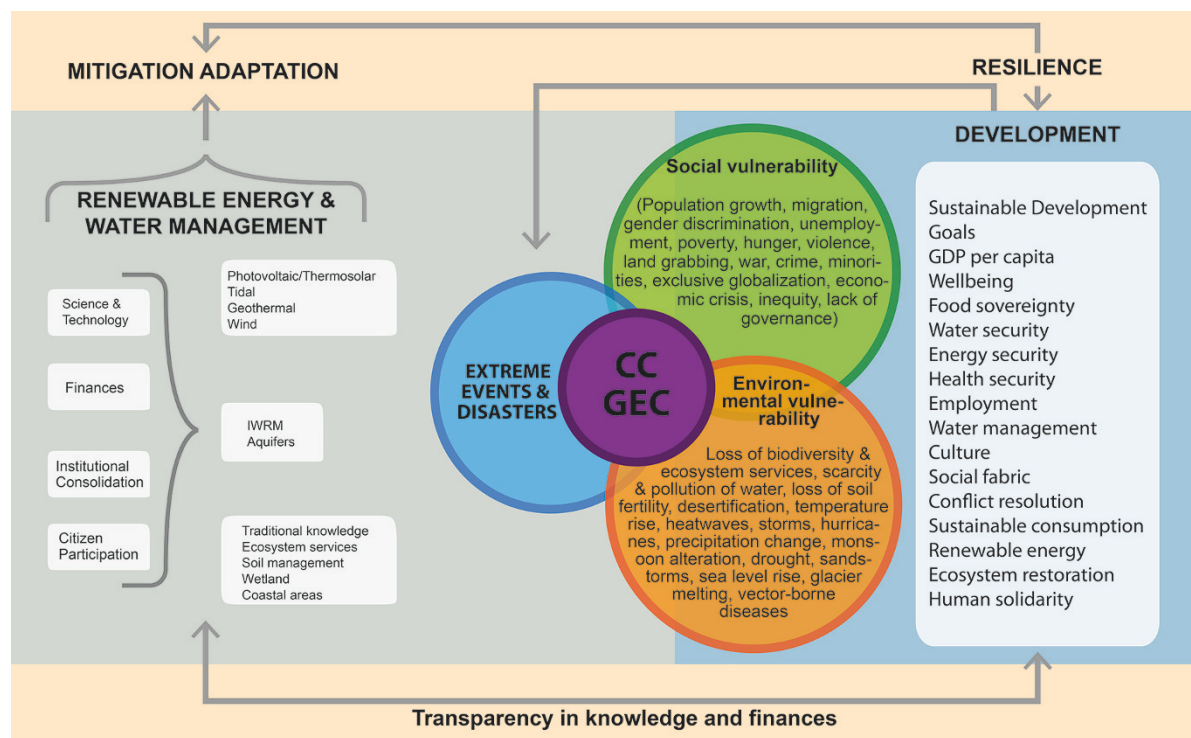
Finally, lack of water and increasing pollution has become another serious threat. Some conflicts are related to drought, lack of pasture for pastoralists, and lack of water facilities (e.g. in the Sahel countries, as also in Kenya, Sudan, etc.). During the last century, the world's population increased threefold and water use sixfold, partly because of changing habits of hygiene, but also because of massive water pollution from mining and oil extraction. In dryland areas, electricity production has caused serious threats to survival, further exacerbated by climate change and extreme events. The anthropogenic impacts of global environmental change and extreme events, together with business-as-usual behaviour with respect to natural resources, have put pressure on the natural cycles of nitrogen, phosphorous, sulphur, and dioxide.

Resource management has become more complex because of GEC. It now includes alternative approaches to managing water and energy, the restoration of ecosystems, and the recovery of depleted soils (figure 42.2). If 'transformative' science and progressively 'dematerialized' technologies can be implemented, effective strategies, policies and measures of mitigation and adaptation may emerge, and sufficient financial support, effective governmental and societal institutions, and active participation by citizens and stakeholders may come about. Social and environmental vulnerability could be reduced, and the resil-

Figure 42.1: System approach to natural and anthropogenic factors of global environmental change. **Source:** Oswald Spring (2016), based on data from Rockström, Steffen, Noone et al. (2009).
ience and the well-being of all social groups could be strengthened. While GEC and CC have already become 'threat multipliers', extreme weather events and disasters could destroy the development path of many poor countries (IPCC 2012), creating hunger, causing death, and impelling affected people to migrate (Oswald Spring 2012; Oswald Spring/Serrano Oswald/Estrada Álvarez et al. 2014).

Nevertheless, with a solid development path which is human-oriented and takes the most vulnerable into account, new threats could be better managed through disaster risk reduction ((McBean/ Ajibade 2009), and water, food, energy, health and sanitary security. It will be possible to restore and maintain the social tissue, create employment, consolidate transparent institutions, and maintain or recover essential ecosystem services.

Finally, there is the question of how 'sustainability transition' with 'sustainable peace' may be achieved in the Anthropocene by moving from knowledge to action. The above analysis has not specifically addressed the international, security and peace aspects. It was argued in the introduction that a process of sustainability transition may make two conflict

Figure 42.2: Transition to sustainability. **Source:** Oswald Spring (2016).


constellations less likely: resource conflicts and climate-induced violent confrontations.

Peace is not a stable process and there are different approaches to a sustainable-engendered peace. There cannot be worldwide peaceful behaviour if water, food, energy and well-being are not available to the 9.5 billion of people forecast for 2050 and the twelve billion in 2100. However, the SDGs adopted in 2015 as a global pathway to achieving these goals will remain a paper tiger unless governments can persuade their elites to implement them as targets at national and local levels. This requires effective national policies to reduce poverty and social inequality. Mahatma Gandhi said "the world has enough for everyone's need, but not enough for everyone's greed".

A major change is needed in the prevailing mindset, from favouring a business-as-usual approach towards supporting more sustainable behaviour and culture. It requires, first of all, peaceful negotiations at international, national and local levels on the use and efficient management of scarce resources to give reduced environmental footprint. This may result during this century in a decarbonized, dematerialized sustainable world with constructive human relations and care and solidarity for the most vulnerable. However, this means that scientists need to integrate 'transformative' perspectives in their research designs that will

contribute to 'proactive' knowledge, and policymakers need to have the courage to move from mere policy declarations to proactive policies that will produce the desired results.

This transformative scientific approach towards proactive policies cannot be systematically developed here. Rather, just four examples will be offered for a sustainable energy transition: firstly, moving from fossil fuels to enhancing energy efficiency and to renewables so there can be access to energy for up to twelve billion people by 2100 while GHG emissions can be reduced (42.5.1); secondly, shifting from resource- and carbon-intensive agriculture and a high degree of waste in the food sector to climate-smart agriculture with a lower level of waste (42.5.2). The third and fourth examples address proposed changes to totally different lifestyles in industrialized countries (42.5.3), and a shift in values as suggested, for example, by the kingdom of Bhutan (Gross Happiness Index) and by indigenous people in Bolivia (Pachamama) and Chiapas (42.5.4). These alternatives will not be globally acceptable but they indicate that a continuation of the Western way of life based on abundance and waste in consumption is not sustainable for a global population reaching twelve billion people in the year 2100.

42.5.1 From Fossil Fuels to Renewable Energy Sources

The *International Energy Agency* (IEA 2014) has estimated that the global demand for energy will double by 2050 and that this requires the investment of US$2.5 trillion per year for the next twenty years. Electricity is currently responsible for a quarter of global GHG emissions. To achieve these development goals and to produce electricity for everybody on Earth, while simultaneously reducing GHG emissions to the ambitious goal adopted in the 'Paris Agreement' (2015), that is, limiting the increase in global average temperature to 1.5°C above pre-industrial levels by 2100, requires a sustainable energy transition and similar transitions in other sectors (figure 42.3). Fossil energy sources (coal, oil, gas) must gradually be replaced by renewables (solar, wind, etc.) by 2050, and there must be a progressive decarbonization of the whole energy, transportation, heating and cooling sectors and of the global economy as a whole by the end of the twenty-first century.

The UN Environment Programme (UNEP 2015) has forecast the many co-benefits of a sustainable energy transition towards renewable and clean energy; impacts on ecosystems will be reduced, especially eutrophication and acidification. Human health will also benefit from the limiting of particles, toxicity, and GHG emissions. Furthermore, the use of many resources such as concrete, metals, energy intensity, water use, and land use may be reduced and the resources reused; all this will contribute to a process of dematerialization.

The year 2014 was the first year in four decades that saw a 'decoupling' of global economic growth from an increase in carbon dioxide emissions (UNEP 2011, 2014; see also chapter 17 by Swilling). This encouraging sign may be a turning point in countering the worst outcomes of GEC and CC. The rapid increase in renewable energy sources in developing countries (led by China, India et al.) may offer the 1.3 billion people without access to electricity the possibility of obtaining energy in a decentralized way that is cheaper than through the traditional centralized electricity grid. There are still ninety million African children who have no access to electricity at school and who cannot do their homework after sunset. The economic, social and personal benefits of electrification based on clean energy may overcome regional inequalities and promote health and education across gender and ethnic barriers, as well as increasing

income and well-being and thus contributing to social equity.

Sustainable Development Goal (SDG) 7 does not just refer to energy; it also promotes development with new tools. Electricity also permits better communication through the use of mobile phones. This facilitates the purchase of solar units and the development of microfinance and micro-insurance, and provides new customers with the possibility of living in a safer world. Health, emergency and risk warnings can now easily reach billions of people.

Oil rents from the exploitation and export of oil and gas have resulted in a high level of economic growth and development in countries that export fossil energy. Their fossil fuels are increasingly used to meet their rising domestic energy demand. Many oil-exporting countries in the Gulf have invested significantly in renewable energies, especially in solar and wind energy (IRENA 2016).[8]

Against the background of a dramatic decline in oil prices and a substantial increase in energy consumption worldwide, the use of renewable energy has also increased in developing countries, and energy efficiency has improved. In 2013, "renewable energy provided an estimated 19.1% of global final energy consumption. ... Traditional biomass, used primarily for cooking and heating in remote and rural areas of developing countries, accounted for about 9%, and modern renewables increased their share slightly over 2012 to approximately 10.1%". From the 10.1 per cent of modern renewables: 4.1 per cent comes from biomass, geothermal and solar heat; 3.9 per cent from hydroelectricity; 1.3 per cent from biomass, solar, geothermal and wind power; and 0.8 per cent from biofuel. Most of the global final energy consumption (78.3 per cent) came from fossil energy, with 2.6 per cent from nuclear (REN21 2015: 27).[9]

About 58.5 per cent of net additions to global power capacity came from wind, solar *photovoltaic* (PV) and hydropower (REN21 2015: 30). In late 2014, "renewables comprised an estimated 27.7 per cent of the world's power generating capacity, enough to supply an estimated 22.8 per cent of global electricity, with hydropower providing about 16.6 per cent" (REN21 2015: 30). Energy support policies and subsi-

dies for fossil fuels and nuclear power are still limiting the present growth of renewable sources and their cost-competiveness. The development of energy storage systems for all sectors also supports the use of renewables .

The transition to renewable energy sources has already created more than 7.7 million renewable energy jobs globally by 2014, including 2.5 million jobs in solar photovoltaics, 1.5 million in large hydropower, and one million in wind energy (figure 42.4).[10] The majority of the jobs have moved from Europe (1.2 million) and the US (724.000) to Asia, especially to three BRIC countries: China (3.390.000), Brazil (934.000) and India (427.000), two of which China and India have very high GHG and CO_2 growth rates. With 1.6 million jobs in the solar photovoltaic industry, China's share of the world's solar manufacturing capacity amounts to seventy per cent, and it has become the world leader for jobs in wind power, solar heating and cooling, small and large hydropower, biomass and biogas. The *International Renewable Energy Agency*

(IRENA) has forecast that India's renewable energy workforce may add about one million jobs to the workforce by 2022, while Japan, Malaysia, Korea, and Bangladesh are also expanding their share of green jobs, primarily from wind energy and solar PV manufacturing. In the US, the number of coal miners has declined from 784,621 in 1920 to 80,209 in 2013, while annual production per miner increased from 0.84 (1920) to 15.01 (2000) and has since declined to 12.25 (2013).[11] From 1920 to 2000, the productivity per miner rose eighteen fold.

Biofuel jobs are concentrated in feedstock supply, with 1.8 million (Brazil, US, South East Asia), and half the one million jobs in wind have been created in China. China has also become the world leader in solar heating and small hydropower; most of the 1.5 million jobs in large hydropower have also been created in China.

In the US, the *Energy Information Agency* (EIA 2015: 40) has projected the future energy mix of the US from 2013 to 2040. Its reference case model pro-

MSW/LFG stands for municipal solid waste and landfill gas.

jects that the share of natural gas will increase from 27 per cent to 31 per cent and of renewables from 13 to 18 per cent, while the share of nuclear energy is projected to decline from 19 to 16 per cent, and of coal from 39 to 31 per cent; other liquid fuels may account for one per cent (figure 42.5). According to this official US assessment, renewables would account only for a modest share of the energy mix. The EIA (2015) has also analysed the evolution of renewables in the generation of electricity. Figure 42.5 projects an important increase in wind and solar energy by 2040, less for geothermal and biomass, and a steady figure in the case of hydropower.

Renewables also have an important impact on human and environmental health. During 2015 improvements were achieved in the storage and sequestration of GHG emissions: chemical absorption of CO_2 from flue gas (post-combustion), physical adsorption from synthesis gas (pre-combustion), and the combustion of fossil fuels with pure oxygen producing CO_2 and water are mechanisms for capturing and storing carbon dioxide. Life-cycle GHG assessments have shown that PV and wind energy have comparatively the lowest impacts of GHG emissions, and these emissions will continue to decline between now and 2050. The impacts of ionizing radiation, photochemical oxidant formation, particulate matter formation, human toxicity, and ozone depletion are also the lowest in renewable energies. This offers co-benefits for human health and health care (REN 21 2015:24), as well as for the environment and for ecosystem ser-

vices. Renewables, a carbon-free and dematerialized economy, waste reduction and recycling help realize a different way of life based on a different world view, one that calls for deep changes in culture and its relationship with the environment and with ecosystem services. A transformation is also needed in the relationships between human beings; greed, exploitation, violence and discrimination need to be replaced by solidarity, confidence, care, commitment and mutual responsibility for others, especially for the vulnerable, but also for the environment.

42.5.2   From Agribusiness and Hunger to a Sustainable and Equitable Livelihood

Despite the MDGs of 2000, by 2015 the level of global hunger had remained quite high (GHI 2105). The FAO (2013), IPCC (2014a) and other international and national institutions have called for an agriculture with drastic reductions in the carbon, water, soil, biological and ecosystem service footprints (Torquebiau 2016). Confronted with the complexity of climate change, FAO (2011a) developed the concept of '*climate-smart agriculture*' (CSA). This refers to "agriculture that sustainably increases productivity, resilience (adaptation), reduces/removes greenhouse gases (mitigation), and enhances the achievement of national food security and development goals" (FAO, 2016a: 548). CSA is not a new agricultural system or a different set of practices.

CSA shares with sustainable development and green economy objectives and guiding principles. It aims also for food security and contributes to preserve natural resources. As such, it has close links with the concept of sustainable intensification, which has been fully developed by FAO for crop production (FAO 2011b) and is now being extended to other sectors and to a food chain approach (FAO 2013a: 27).

CSA reduces carbon emissions and pollution, enhances energy and resource efficiency, reduces the water footprint and losses in biodiversity and ecosystem services, and promotes the restoration of soils and forests. FAO (2016b) widened the concept and integrated the whole food chain into it, including waste management and losses in field, harvest, staple and market.

This new approach to a safe food system also needs to be regionally consolidated to diminish the carbon footprint for transport. It should use organic production processes to restore soils that have suffered a drastic decline through the use of agrochemicals. It should promote local market structures and food transformation. The IPCC (2014a) also stated that half of the world's food is produced by women or small-scale farmers, usually in orchards, while highly technological agriculture uses massive amounts of fossil energy, depletes soil and water, and produces basically grains for biofuel and livestock. A climate-smart agriculture can not only reduce up to thirty-two per cent of GHG emissions related to modern agriculture and change in land use, but it may also improve the local food system, restore soils, compost organic waste, reduce transport, limit the carbon footprint nationally and locally, recover ecosystems and improve the livelihood of poor people.

Pretty (2006) suggested integrating biological and ecological processes, with the goal of improving the nutrient cycle. Organic agriculture can increase crop yields by up to seventy-nine per cent. When combined with agroforestry, aquaculture, mixed farming, rainwater harvesting, water retention during the rainy season and soil conservation, these practices can restore natural environments, recover human health, restore ecosystem services and improve food quality for consumers, at affordable prices. Biofertilizers naturally fix nitrogen from the air to the soil and regenerate impoverished soils, while biopesticides efficiently combat pests. Nitrogen fixation from the air to the soil (*Azospirillum, Rhizobium*), organic fertilization, mixed agriculture, rotation of crops and soils, and biopesticides not only reduce production costs, but also open new markets for organic food products and help the restoration of soils and the recovery of eco-system services. These interlinked processes minimize non-renewable inputs that harm the environment, conserve and save water, and reduce production costs. Fewer agrochemicals also mean that natural and human health is protected. Links between science and modern technology, together with traditional knowledge and practices, facilitate adaptation everywhere, improve environmental security, promote sustainable development, and limit the need for migration and survival strategies.

A different approach to the environment, economy, labour and social interactions challenges the present processes of globalization and the powerful role of multinational enterprises (Scholte 2005). It aims at human security instead of greed and financial accumulation. Hunger, undernourishment and obesity create a vicious circle along with ignorance, poverty, disease, dependency and cultural discrimination.

Locally-based food production, also called 'food sovereignty', reduces the dependence of national governments on the world economy and on short-term investments, and inhibits speculation on food staples. Food sovereignty increases national savings, creates local jobs and develops creativity, science and technology; in addition, it has positive effects on health and well-being. A skilled labour force finds local jobs, and this stimulates the internal market and reduces foreign investment and restrictions on social development imposed by the IMF, the World Bank and the *World Trade Organization* (WTO). Productive systems that are stable at the local and regional level reduce dependence on international trade and prevent the cultural homogenization of consumerism. They reinforce local productive niches and increase regional food security and food sovereignty (Oswald Spring 2009). A healthy economy produces savings and reduces international debt and high-interest payments. This may also allow the use of public funds for the development of infrastructure, for education, and also for adaptation and resilience-building measures.

Positive linkages between a safe environment, restored ecosystem services, a healthy population and cultural diversity also allows the creation of new political arenas, in which a participative society can contribute to an agenda of sustainable well-being. Corrupt public actors can be viewed critically, and corruption itself countered more effectively, as public activities are reoriented to the well-being of the people, including the mitigation of the impacts of GEC. Such postmodern governance (see chapter 41 by in t' Veld.) may reorient the relationships between science, the mass media, and the government.

No longer will a small global oligarchy of the super-rich and powerful national economic and political elites benefit most. This has been widely documented as a reason for the rapid increase in social inequality since the 1970s, as wealth is concentrated in fewer and fewer hands. People and opinion leaders need to develop a totally different political and economic mindset and a new societal and scientific world view (Oswald Spring/Brauch 2011). Society needs to develop, adopt and implement new goals inspired by the SDGs and should aim at a new praxis based on an understanding of the underlying processes driving the present processes of GEC and CC.

42.5.3 Alternative Lifestyle Activities and Projects

In the industrialized countries a number of authors, social movements and NGOs have put the case for alternative values and promoted a more sustainable lifestyle. In the context of its *Education for Sustainable Development* (ESD), UNESCO focused on sustainable lifestyles alongside ten other themes.[12] In the framework of its programme on sustainable consumption, UNEP has also addressed the theme of sustainable lifestyles, which it defines as

> rethinking our ways of living, how we buy, what we consume and how we organize our daily lives. It is about transforming our societies and living in balance with our natural environment. All our choices and actions ... —on energy use, transport, food, waste and communication— contribute to sustainable lifestyles. For sustainable lifestyles to be part of our cultures and societies and become part of our everyday lives, they must be enabled and developed at all levels, through the social and technical systems and institutions that surround us. These include efficient infrastructures, services and products, such as efficient public transport systems, and by individual choices and actions to help minimize the use of natural resources, emissions, wastes and pollution while supporting equitable socio-economic development and conserving the Earth's life support systems within the planet's ecological carrying capacity.[13]

With the support of Sweden, UNEP has launched several projects to examine and promote sustainable lifestyles in the context of the Marrakech *Task Force on Sustainable Lifestyles*,[14] including the *Global Survey on Sustainable Lifestyles*, among other key projects.

The European 'social platform' on *Sustainable Lifestyles* 2050 (SPREAD), a project funded by the EU (2011-2012), addressed four key questions: "What is a sustainable lifestyle? What will a sustainable future mean for the way we live, move, and consume? How do we know if our lifestyles are sustainable or not? How can our aspirations for continuous life improvements be enabled sustainably (within one planet)?"[15] The SPREAD project gave rise to four working groups who considered: a) sustainable moving, b) sustainable living, c) sustainable consuming and d) sustainable society. It developed a "roadmap of action strategies" for "different societal actors, including 2012–2050 pathways to enable sustainable living across Europe by 2050". SPREAD distinguished four visions: i) economies for dense communities; ii) the convenience of trust; iii) entrepreneurial and self-aware society, connected wealth; and iv) happy sharing communities.[16] The project developed four scenarios for sustainable lifestyles (2012-2050): 1) Singular Super Champions; 2) Governing the Commons; 3) Local Loops; and 4) Empathetic Communities.[17]

These four alternative scenarios for a gradual transition of lifestyles in Europe between 2012 and 2050 (figure 42.6) were stimulated by a conceptual

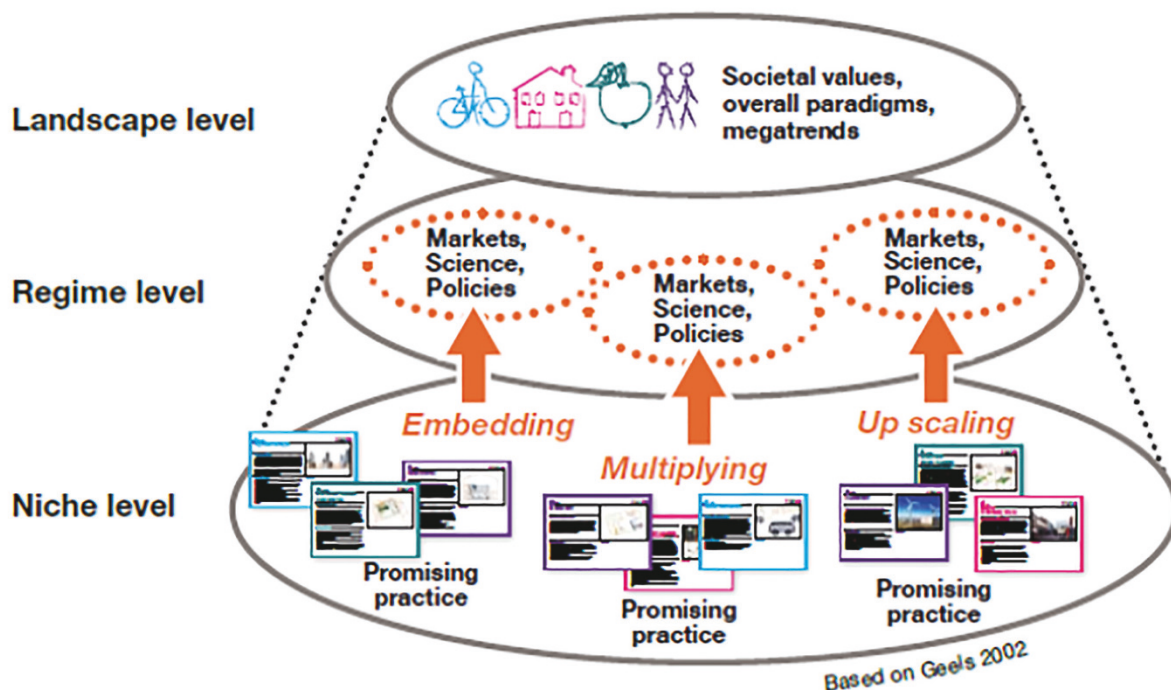
	Singular Super Champions	Governing the Commons	Local Loops	Empathetic Communities
Education	Embedded into everyday life and practices, lifelong. Instead of short cycles in the beginning of life. Individualized and commodified. Basis of welfare provision.	The main focus of education is on peer-to-peer skill-sharing. Learning by doing is emphasized in iterative ways. Pandemic technology enables instant feedback loops, which accelerate sharing of knowledge. Focus on informal education where classrooms do not exist.	Education is about transmitting and sharing skills. Craftsmanship and specialisation are promoted through mutual teaching and problem-based learning.	Education and learning are problem-based and collaboration-driven.
Work	Human resources highlight work. Talent is concentrated in global organisations. Entrepreneur vs. super talented multinational class.	People's sources of income have fragmented. Comprehensive use of skills are valued. Everyone has something to offer to society.Key words describing work include micro-tasks, crowdsourcing and being useful to one's peers.	Work is characterised by engagement with issues and collaboration within and among guilds. Needs met by applying design thinking and formulating local solutions.	Work happens collaboratively in hubs and people learn through asking for input from colleagues. Hands-on work is highly valued. Work is neighbourhood-based and aims at contributing to the community.
City	10-15 highly urbanised metropolises in Europe. Extremely dense. Lots of new infrastructure. New specialised areas of excellence.	Cities are based on already existing infrastructure. Office and school buildings have been converted into flats and public spaces. Urban experiences are enriched by augmented reality. People find personalised solutions to fulfil their needs and aspirations on bot the physical and virtual layers.	Cities are multicentred and formed into their own loops. Guilds working and living in the loops lay their own strong characteristics on their loops.	Village infill form sprawl to farm village. Parking lots are turned into places of food production. The public space gains great significance. Villages within cities are key elements of the urban fabric.
Health	Preventative public healthcare. Rational diets. Selfdiagnosis.	Peer-to-peer network support is characteristic of both preventative and reactive health care. Public funding is provided for health-care cooperatives. A wide variety of healthy lifestyles have become routinised. Digital feedback tools are used by everyone.	Work places provide health-care and skilled doctors. There are basic rights that all regions agree to prioritise with regard to health-care.	Paradigm of quality over quantity characterises the health-care system. This means that the meaningfulness of a person's lifespan is seen as more important than the amount of years lived. Local administration prioritises health-care and healthy living. Every municipality has a hospital. Healthy-living-circles share preventative knowledge locally.
Living	Location compensates size of the flat. New materials and design. Price drives density.	People live in small flats and work in new office lofts. The digital layer is key to ovide people with quality in their lives. Smart homes, austere furniture and digital services characterise domestically.	Living in the loops is characterised by shared spaces, existing infrastructure and co-working spaces. Guild members often live in the same neighbourhood.	Farming opportunities raise property values. People live in shared apartments and make use of shared spaces.
Food	Price and health efficient diet. Large scale organic production.	Food production and distribution are managed by global food systems and smart food storage mechanisms are in place. A multitude of diets are offered and energy intake is reduced. Vegetable choices and synthetic meats form differentiations in diets.	Food production and distribution are marked by locality, minimised transportation and neighbourhood canteens. Energy used for food production is optimised.	Growing food in urban farming circles meets local food demand. Food transportation needs are very low. In addition to production, high importance is also placed on food quality, and distribution.
Mobility	New rail systems within and between metropolises. Personalized rapid transport systems. Smart mobility solutions. High prices.	Mobility is greatly reduced by the use of digital tools. Commuting has become unnecessary and the construction of new traffic infrastructure has become unnecessary. Smart public transit and car and ride sharing are the main forms of transport.	Transportation is about walkability and cycling. Existing infrastructure is optimised. Intercity mobility is needed less and services are home-delivered. Local tourism and long vacations are favoured by people.	Local mobility is emphasised and less road space is devoted for private vehicles. Old and new infrastructure is adapted to cycling.
Consuming	Meanings and symbols get consumed more than products. Education and self-projected me. Price mechanism.	3D-printing personalises consumption. Material consumption is reduced by using modular appliances, which enable do-it-yourself (DIY) repair and upgrade of products. High degrees of appliance personalisation, virtual consumption and recyclable generic materials form new design and producer cultures, helping to reduce the overall number of appliances.	Consumption drivers include a mass quest to reduce the overall volume of appliances needed through sharing schemes and replacement services. Products are made with high-quality local materials and design. Availability of foreign goods is limited. All products are repairable.	Consumption is geared towards meeting people's basic needs. Sharing, swapping and renting succeed private ownership.
Economy	Large multinational firms. Efficiency. Competition. Eco-industrial revolution. Standardised transparent data.	Micro-tasks characterise economic organisation. New businesses are created in and by data-rich environments. Open source, open data and free distribution of information drive new innovation. Personal optimisation, DIY, peer services and manufacturing are drivers of the new economy.	The economy is based around local user-centric adaptations and efficient local clustering.	The economy is organized around the self-sufficiency of small units. Food production is prioritised. Experimentation happens on the local level and high value is given to community activities.
Sense of security	From technological progress. Transparency. Surveillance. Individual choices. Thought leaders.	Sense of security is heightened by membership in peer-to-peer communities. Democratised data empowers people. Easy access to services, products and global knowledge-bases promotes equality. Personalised appliances and direct participation increase a sense of belonging and security.	Sense of security is generated through guilds and understanding of how the system, i.e. the closed cycles, work. People identify themselves primarily as part of their work communities.	Sense of security is generated by communities, closed circles, cooperatives as well as by health and food circles. PPP-systems guarantee participation and sense of ownership in public and social affairs.
Leisure time	Investing in own education and training.	Leisure time is formed around a multitude of digital interactions. Home consumption, high quality household capabilities and digital crowd experiences are the main ways of spending free time.	People have outsourced their housework in order to be able to maximise their inputs in work communities. Leisure time is mostly spent with guild members.	Leisure time is mostly public and used for social activities, e.g. in gardening circles. Vacations provide time for self-reflection.

Figure 42.7: How to spread sustainable lifestyles. **Source:** SPREAD: *Scenarios for Sustainable Lifestyles–From Global Champions to Local Loops* (Wuppertal: 2013), based on Geels (2002).


model based on Geels (2002; see figure 42.7) that distinguished the three levels of niche, regime and landscape change (see figure 1.11 in chapter 1 by Brauch/Oswald Spring); it was deeply influenced by the Dutch approach to sustainability transition (Grin/Rotmans/Schot 2010).

Many grass-roots initiatives and research groups in the *Organisation for Economic Co-operation and Development* (OECD) countries have promoted alternative sustainable lifestyles since the end of the Cold War, for example, in the US (*The Global Stewards*[18]), the UK (Sustainable Lifestyle Research Group[19]), France (Voluntary Simplicity Movement[20]), Germany

(De-Growth Movement[21]), Spain (Research & Degrowth[22]). These have been supplemented by economic movements (e.g. in Mexico, on the economics of solidarity (Cadena 2009) and the Peasant University of the South (UNICAM, on subsistence agriculture[23]) and in developing countries (Bangladesh: Yunus Centre;[24] India: Ashok Khosla;[25] Brazil: MST,[26]

as well as intellectual leaders (Samir Amin (2014, 2014a)[27]). Completely different ways of life have been developed in the kingdom of Bhutan and proposed by indigenous people in Bolivia and in Chiapas (Mexico).

42.5.4   Alternative Indigenous World Views and Mindsets

Both biocentric world views and the dominant socio-political and economic mindset that promotes business-as-usual development paths and strategies reflect a 'cornucopian' (Gleditsch 2003) understanding of the economy, society, the environment and culture. In the Anthropocene, human beings, especially the top one per cent of the moneyed elite, exploit all the existing natural, human, political and cultural resources, often understood as natural, human, political and cultural capital (Bourdieu 1983). Earth and society may face challenges to their survival during this century as a result of this dominant and homogenized mindset, a mindset that is reinforced on a daily basis by a mass media that promotes consumerism and ignores the potentially catastrophic societal outcomes of this cornucopian world view. But not everybody has adopted the business-as-usual ideology.

For the people of Bhutan a 'gross national happiness index'[28] expresses a different approach and a guiding principle for a good life, where nature and human beings live together in harmony and peace, and where diverse traditions and rules open the way to cultural diversity, the defence of Mother Earth and the protection of the 'Pacha Mama'.[29]

Alternative lifestyles have at their centre the goal of a sustainable peace within a sustainability transition process that aims for a decent and good life and not just a better consumerist way of life. These lifestyles combine ideas of complementarity and try to counter the destruction of nature and humankind. They accept unity in diversity, prioritize life within community, respect the natural cycle of nature and promote the recovery of the wisdom of the elderly. This post-modern understanding recovers the deep indigenous knowledge of 'cosmovisions'[30] and their traditions, where the Western paradigm of development is decolonized and the diversity of pluricultural integration of society permits the understanding of a biocentric world view, where harmony with nature and its ecosystem services respect simultaneously the intrinsic rights of nature and social rights.

In Mexico, the indigenous Zapatista movements proposed a shell or 'caracol'[31] model of sustainability, where they organized their way of life based on values, norms, institutions and productive processes which include the development of modern science and technology. Through formal and informal processes they transmit their knowledge and wisdom and integrate new scientific achievements. They reinforce their own structures of power, where society controls the mechanisms of power, and where they rotate authority and obey the community ('mandando obediciendo': directing obeying) for their necessities. Their period of authority is limited to one year and they are not paid for their social service, but the community provides the daily necessities for them and their families.

In analytical terms this cultural product of an indigenous society, which was exposed during hundreds of years of colonialization to exploitation, discrimination and violence, has developed new structures of power sharing since 1994, which are deeply internalized and perceived by the people as natural. Their cognition process legitimizes thoughtful structures of beliefs and behaviours, where nature and

25 Ashok Khosla is the founding director of "Development Alternatives: eco-solutions for people and the planet" in New Delhi, India, see at: <http://www.devalt.org/GoverningPersonDetail.aspx?Gid=1> and co-chair of UNEP's resource panel; see at: <http://www.unep.org/resourcepanel/PanelMembers/Ashok/tabid/794042/Default.aspx> (6 March 2016).

(Eds.): *Dress and Gender: Making and Meaning* (New York/Oxford: Berg): 145–163; Molinie, Antoinette, 2004: "The Resurrection of the Inca: The Role of Indian Representations in the Invention of the Peruvian Nation", in: *History and Anthropology*, 15,3: 233–250.

30 See: Adamson, Joni: "Indigenous Literature", in: Garrard, Greg (Ed.), 2014: *The Oxford Handbook of Ecocriticism* (Oxford: Oxford University Press).

31 The Zapatista movement proposed the shell model on 15 February 2010; see <http://enlacezapatista.ezln.org.mx/2010/02/15/gobierno-autonomo-zapatista-caracteristicas-antisistema-politico-mexicano/> or its general website < http://enlacezapatista.ezln.org.mx/>.

community interact in a complex interdependence and where individuals and social actors, institutions and regimes have transformed a business-as-usual approach or a cornucopian world view to a complex sustainable interaction between the biological and human systems.

This is just an example of a totally different and slow way of moving towards a cultural transformation within small groups of indigenous people. These changes resulted not simply from social nonconformity, but also from a longer learning process, where these social groups analysed all the different types of development processes proposed by governments, enterprises and other social groups—indigenous people, mestizos, *non-governmental organizations* (NGOs), and *civil society organizations* (CSOs). In this process identity patterns and social representations were recreated, and the deep sustainable biological–human system was anchored into their culture, later objectivized and then assimilated and transferred into local or regional policy.

A key process was the sharing of cultural and material products, which consolidated the social cohesion and at the same time limited internal social stratification. Besides this, extreme hydro-meteorological events have reinforced the process of solidarity among the affected and their capacity for sharing scarce resources among the most vulnerable communities. Their new world view is based on a way of life which is mostly carbon-free and dematerialized, where waste is recycled and consumption oriented towards renewable production and consumption.

This fundamentally different indigenous world view links the transition to sustainability with the recovery of crucial ecosystem services and the environment. The changes in mindset from a patriarchal business-as-usual approach is embedded in a daily transformation of the understanding and exercise of non-authoritarian authority, economy, society and environment. A critical approach to incipient social stratification processes and mechanisms has the function of limiting it. Interest-driven political and economic interests are controlled by participative governance and collective decision-making to protect the most vulnerable and the environment. It includes a sustainable peace-building process that is focused on a sustainable culture in their radically alternative world view, mindset and system of governance.

These different approaches from Bhutan, Bolivia and the Zapatista movement in Chiapas in Mexico are deeply culturally embedded in their respective cosmovisions and religious beliefs. However, they do not offer a solution for highly industrialized modern societies in the OECD world and for the elites and upper and middle classes in many economic threshold countries and also in most parts of the developing world.

Abbreviations

10YFP	10-Year Framework of Programmes	CAPES	Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (Brazilian Federal Agency for Support and Evaluation of Graduate Education)
AA	Auswärtiges Amt (Federal Ministry for Foreign Affairs, Germany)		
ABEE	Associação Brasileira para Eficiência Energética (Brazilian Association for Energy Efficiency)	CAS	complex adaptive systems
		CBD	UN Convention on Biodiversity
AC^4	Advanced Consortium on Cooperation, Conflict and Complexity	CC	climate change
		CCL	Ley General de Cambio Climático (Climate Change Law), Mexico
AD	Anno Domini	CCS	carbon capture and storage
ADB	Asian Development Bank	CCSP	Climate Change Science Programme
AfDB	African Development Bank	CCT	conditional cash transfer
AFES-PRESS	Peace Research and European Security Studies	CDA	critical discourse analysis
		CDM	clean development mechanism
AFOLU	Agriculture, Forestry and Other Land Use	CE	circular economy
AGF	Advisory Group on Climate Change Financing	CE	Common Era
		CEA	Comisión de Agua (State Water Agency, Morelos, Mexico)
AHDR	American Human Development Report		
ANEEL	Agência Nacional de Energia Elétrica (Brazilian Electricity Regulatory Agency)	CEN	Center for Earth System Research and Sustainability
ANT	actor network theory	CEO	Chief Executive Officer
APEC	Asia–Pacific Economic Cooperation	CER	Certified Emissions Reductions
APESS	The Anthropocene: Politik–Economics–Society–Practice (book series)	CERC	US–China Clean Energy Research Center
		cf	confer (compare)
APPRA	Asia–Pacific Peace Research Association	CFCs	chlorofluorocarbons
APREA	African Peace Research and Education Association	CFL	compact fluorescent lamp
		CFSP	European Foreign and Security Policy
AR5	Fifth Assessment Report of the IPPC	CH$_4$	methane
ASEAN	Association of Southeast Asian Nations	CHP	combined heat and power
		CHS	Commission on Human Security
BAU	business-as-usual	CICC	Comisión Intersecretarial de Cambio Climático (Interministerial Commission on Climate Change), Mexico
BC	Before Christ		
BCE	Before Common Era		
Bha	billion hectares	CIDA	Canadian International Development Authority
BICC	Bonn International Center for Conversion		
BTL	Beyond the Limits	CIESIN	Centre for International Earth Science Information Network
BNDES	Brazilian Development Bank		
BP	Before Present	CIGI	Centre for International Governance Innovation (Waterloo, Ontario, Canada)
BP	A supermajor oil and gas companies with headquarters in London		
		CIM	climate-induced migration
BRIC	Brazil, Russia, India, China	CISEN	Centro de Investigación y Seguridad Nacional (Centre for Investigation and National Security), Mexico
BRICS	Brazil, Russia, India, China, South Africa		
BRISE	the 14 largest 'emerging' economies		
BS	biodiversity security	CLAIP	Latin American Council on Peace Research
BSD	Board on Sustainable Development		
Bt	billion tonnes	CliSAP	Cluster of Excellence, Hamburg University, Germany
BTL	Beyond the Limits		
BUND	Bund für Umwelt und Naturschutz Deutschland (Friends of the Earth Germany)	CLISEC	Research Group Climate and Security
		CMM	coal mine methane
		CMS	Centre for Mountain Studies, Perth College, Scotland
C3	Consejo Consultivo de Cambio Climático (Advisory Council on Climate Change)		
		CNA	Center for Naval Analyses
CAFE	Corporate Average Fuel Economy		

CNPq	Brazilian Council for Scientific and Technological Development	DECC	Department of Energy & Climate Change (UK)
CO_2	carbon dioxide	DEDE	Department of Alternative Energy Development and Efficiency, Thailand
CO_2e	carbon dioxide equivalent		
COCOM	Coordinating Committee on Multilateral Export Controls	DEFRA	Department for Environment, Food and Rural Affairs (UK)
CONAGUA	Comisión Nacional de Agua (National Water Commission, Mexico)	DEG	Deutsche Investitions- und Entwicklungsgesellschaft (German Investment and Development Society)
CONPET	Programa Nacional da Racionalização do Uso dos Derivados do Petróleo e do Gás Natural (National Programme of Rational Use of Oil and Natural Gas By-products), Mexico	DG	Directorate-General
		DHI	DHI Water & Environment (Private) Limited
		Diversitas	(international research programme on biodiversity science)
COP	Conference of the Parties	DLDD	desertification, land degradation and drought
COP 15	Conference of the Parties of the UNFCCC, Copenhagen (2009)		
		DNA	deoxyribonucleic acid
COP 19	Conference of the Parties of the UNFCCC, Warsaw (2013)	DoE	Department of Energy (South Africa)
COP 21	Conference of the Parties of the UNFCCC, Paris (2015)	DPKO	Department for Peacekeeping Operations of the United Nations
COPRED	Consortium on Peace Research Education and Development	DPR	Detailed Project Report
		DRDO	Defence Research and Development Organization
COPRI	Copenhagen Peace Research Institute		
CP	Cleaner Production	DRIFT	Dutch Research Institute for Transitions
CPA	Cleaner Production Audit	DRM	disaster risk management
CREATE	Campus for Research Excellence and Technological Enterprise	DRR	disaster risk reduction
		DSM	demand-side management
CRED	Centre for Research on the Epidemiology of Disasters (Université Catholique de Louvain, Belgium)	DTU	Danmarks Tekniske Universitet (The Technical University of Denmark)
CRIM	Center for Regional Multidisciplinary Studies (of UNAM, in Mexico)	EC	European Commission
		ECA	Export Credit Agency
CSA	climate-smart agriculture	ECER	energy conservation and emissions reduction
CSA	Carbon Structural Adjustment		
CSD	United Nations Commission on Sustainable Development	ECO	Energy Company Obligation
		EE	energy efficiency
CSDS	Center for Social Development Studies, Faculty of Political Science, Chulalongkorn University, Bangkok, Thailand.	EEA	European Environment Agency
		EF	ecological footprint
		EFM	environmentally-forced migration
CSIR	Council for Scientific and Industrial Research)	EG/LV	Emschergenossenschaft/Lippeverband (planning association of the region of Emscher and Lippe in North Rhine–Westphalia, Germany)
CSO	civil society organization		
CSP	concentrated solar power		
CSR	corporate social responsibility	EGAT	Electricity Generating Authority of Thailand
CT	critical theory	EGCO	Electricity Generating Company
CUHK	City University of Hong Kong	EHS	environment and human security
CUT	Central Única dos Trabalhadores (Association of Independent Trade Unions), Brazil	EIA	environmental impact assessment
		EIA	US Energy Information Agency
		EIB	European Investment Bank
CvJO	Centre for Young Entrepreneurship	EIST	Environmental Innovation and Sustainability Transitions
C-WET	Centre for Wind Energy Technology		
		EIUG	Energy Intensive Users Group
DAFF	Department of Agriculture Forestry and Fisheries	EMC	environmentally-weighted material consumption
DANIDA	Danish International Development Agency	Em-DAT	Emergency Disasters Database (of the Centre for Research on the Epidemiology of Disasters at the Catholic University of Louvain, Brussels)
DBZ	Development Bank of Zambia		
DC	direct current		
DDT	dichloro-diphenyl-trichloroethane		

ENACC	Estrategia Nacional de Cambio Climático (National Strategy on Climate Change), Mexico		G20	Group of twenty (most important industrial and threshold states)
ENIGH	Encuesta Nacional de Ingresos y Gastos de los Hogares (National Survey of Household Income and Expenditure), Mexico		G7	Group of seven (major industrialized countries: Canada, France, Germany, Italy, Japan, UK, US)
ENS	energy security		G8	Group of eight (major industrialized countries: Canada, France, Germany, Italy, Japan, Russia, UK, US)
ENSO	El Niño Southern Oscillation			
EoLRR	end-of-life recycling rate		GACGC	German Advisory Committee on Global Change
EOM	Equal Opportunity Model			
EOP	end-of-pipe		GBO	global biological outlook
EPA	Environmental Protection Agency		GCC	global climate change
EPC	Ecology and Peace Commission of IPRA		GCCP	natural gas combined cycle power
EPC	Energy Performance Certificate		GCF	Green Climate Fund
EPE	Empresa de Pesquisa Energética (Brazilian Federal Energy Planning Company)		GCM	General Circulation Model
			gCO$_2$e/kWh	grams of carbon dioxide equivalent per kilowatt-hour
EPPO	Energy Policy and Planning Office		GCP	Global Carbon Project
ERC	Energy Regulatory Commission		GCRP	Global Change Research Program
EREP	European Resource Efficiency Platform		GCTE	Global Change and Terrestrial Ecosystems
ERU	emission reduction unit		GDI	Gender-Related Development Index
ES	environmental security		GDP	gross domestic product
ES	environmental space		GEC	global environmental change
ESA	Earth Systems Analysis		GECAFS	Global Environmental Change and Food Systems
ESB	enhanced single-buyer			
ESD	Education for Sustainable Development		GECHH	Global Environmental Change and Human Health
ESDP	European Security and Defence Policy			
ESDP	European Spatial Development Perspective		GECHS	Global Environmental Change and Human Security
ESG	Earth System Governance			
ESGP	Earth System Governance Project		GEDA	Gujarat Energy Development Agency
ESS	Earth System Science		GEF	Global Environmental Facility
ESSC	Earth System Science Committee, NASA		GEO	Global Environmental Outlook
ESSP	Earth System Science Partnership		GEO 4	Global Environment Outlook 4
ETS	emissions trading system		Gg	gigagrams
EU	European Union		Gg/y	gigagrams per year
EU–28	European Union (with its 28 member states)		Gha	global hectares
			GHG	greenhouse gases
EUPRA	European Peace Research Association		GHI	Global Hunger Index
EV	electric vehicle		GIM	Global Impact Model
EW–MFA	economy-wide material flow analysis		GLADA	Global Assessment of Land Degradation and Improvement
FAG	Forest Advisory Group		GLASOD	Global Assessment of Human-Induced Soil Degradation
FAO	Food and Agriculture Organization of the United Nations			
			GLP	Global Land Project
FAOSTAT	Statistics Division of the Food and Agriculture Organization		GMP	genetically modified organism
			GNH	Gross National Happiness
FAST	Frühanalyse von Spannungen und Tatsachenermittlung (Early Analysis of Tensions and Fact Finding)		GNI	gross national income
			GNP	gross national product
			GONGO	government-organized non-governmental organization
FDI	foreign direct investment			
FE	Future Earth		GOP	Grand Old Party (Republican Party of the USA)
FHP	Family Health Programme (Programa Saúde da Família), Brazil			
			GPI	genuine progress indicator
FiT	Feed-in Tariff		GPP	green public rocurement
FRONTEX	European Agency for the Management of Operational Cooperation at the External Borders		GPTI	Grupo Permanente de Trabalho Interministerial (Permanent Group for Interministerial Work), Brazil
FS	food security			
FYP	Five-Year Plan			

GRF–SPaC	Global Research Forum on Sustainable Production and Consumption
GRIT	graduated reduction in tension
GTC	global technology company
GTI	Great Technological Institute
GTI	Great Transition Initiative
GTS	geological time scale
GTZ	Agency of German Technical Cooperation
GVC	global value chain
GW	gigawatt
GWEC	Global Wind Energy Council
GWP	global warming potential
GWSA	Global Warming Solutions Act
GWSP	Global Water Systems Project
ha	hectares
HD	hydroelectricity
HDGCP	Human Dimensions of Global Change Programme
HDGEC	Human Dimensions of Global Environmental Change
HDI	Human Development Index
HDP	Human Dimensions of Global Environmental Change Programme
HDR	Human Development Report
HFCs	hydrofluorocarbons
HIA	Health Impact Assessment
HIV/AIDS	Human immunodeficiency virus/Acquired immune deficiency syndrome
HIVA	Onderzoeksinstituut voor Arbeid en Samenleving (Research Institute for Work and Society)
HLPE	High Level Panel of Experts
HNR	Human–Nature Relationships
HPI	Happy Planet Index
HS	human security
HSN	Human Security Network
HUGE	human, gender and environmental (security)
HVDC	high voltage direct current
IAD	Institutional Analysis and Development (framework)
IAEA	International Atomic Energy Agency
IBA	Internationale Bauausstellung (International Building Exhibition)
ICCC	Interministerial Commission on Climate Change
ICIS	International Centre for Integrated Assessment and Sustainable Development, Maastricht University, The Netherlands
ICNC	International Center on Nonviolent Conflict
ICSHP	International Centre on Small Hydro Power
ICSU	International Council of Scientific Unions (now International Council for Science)
ICT	information and communication technology
ICT	integrated circuit technology

IDC	International Development Cooperation
IDCOL	Infrastructure Development Company Limited
IDDRI	Institute for Sustainable Development and International Relations
IDGEC	Institutional Dimensions of Global Environmental Change
IDMC	Internal Displacement Monitoring Centre
IDRC	International Development Research Centre
IEA	International Energy Agency
IFIAS	International Federation of Institutes for Advanced Study
IGBP	International Geosphere-Biosphere Programme
IGO	international governmental organization
IHDP	International Human Dimensions Programme on Global Environmental Change
IHOPE	Integrated History of People on Earth
IIASA	International Institute for Applied Systems Analysis
IIEC	International Institute for Energy Conservation
IISD	International Institute for Sustainable Development
ILO	International Labour Organization
IMF	International Monetary Fund
IMTA	Instituto Mexicano de Tecnología del Agua (Mexican Institute of Water Technology)
INAMPS	Instituto Nacional de Assistência Médica da Previdência Social (National Administration for Medical Assistance and Social Welfare), Brazil
INDC	Intended Nationally Determined Contributions
INE	Instituto Nacional de Ecología (National Institute of Ecology, Mexico)
INECC	Instituto Nacional de Ecología y Cambio Climático (National Institute of Ecology and Climate Change), Mexico
INEGI	Instituto Nacional de Estadísticas y Geografía e Informática (National Institute for Statistics and Geography), Mexico
INPS	Instituto Nacional de Previdência Social (National Social Security Administration), Brazil
IOM	International Organization for Migration
IPCC	Intergovernmental Panel on Climate Change
IPP	Independent Power Producer
IPR	intellectual property rights
IPRA	International Peace Research Association
IRENA	International Renewable Energy Agency
IRG	integrated risk governance
IRP	integrated resources planning
IRP	International Resource Panel
ISA	International Sociological Association
ISA	International Studies Association

ISDR	international strategy for disaster reduction		LUCC	Land Use and Land Cover Change
ISEW	Index of Sustainable Economic Welfare		LULUCF	Land Use, Land Use Change and Forestry
ISFH	Institut für Friedensforschung und Sicherheitspolitik an der Universität Hamburg (Institute for Peace Research and Security Studies at the University of Hamburg)		MA	Millennium Ecosystem Assessment
			MAB	Man and the Biosphere Programme, UNESCO
ISI–MIP	Intersectoral Impact Model Intercomparison		MAD	mutually assured destruction
			MAIRS	Monsoon Asia Integrated Regional Study
ISRO	Indian Space Research Organisation		MAS	Mutually Assured Survival
ISS	Institute for Security Studies in Pretoria (South Africa)		MDB	Multilateral Development Bank
			MDGs	Millennium Development Goals
ISSC	International Social Science Council		MD–ICCCR	Morton Deutsch International Center for Cooperation and Conflict Resolution
IT	industrial transformation			
IT	information technology		MEA	Metropolitan Electricity Authority
ITD	inter- and transdisciplinarity		MENA	Middle East and North Africa
IUAES	International Union of Anthropological Sciences.		MEP	Member of the European Parliament
			MFPRC	Ministry of Finance of the People's Republic of China
IUCN	International Union for the Conservation of Nature		MEVs	micro-electric vehicles
			Mha	million hectares
I-WEC	Isivunguvungu Wind Energy Converter		MIIT	Ministry of Industry and Information Technology
JI	Joint Implementation		MIoIR	Manchester Institute of Innovation Research
JPOI	Johannesburg Plan of Implementation			
JTC	JTC Corporation		MISTRA	Mapungubwe Institute for Strategic Reflection
kg	kilogram		MIT	Massachusetts Institute of Technology
kg/cap	kilogram per capita		MJ	megajoules
KLSC	Knowledge, Learning and Societal Change		MLG	multilevel governance
km/l	kilometres per litre		MLP	multilevel perspective (on sociotechnical transitions)
km²	square kilometre			
KP	Kyoto Protocol		MME	Ministério de Minas e Energia (Ministry of Mines and Energy), Brazil
KSI	Dutch Knowledge Network on Systems Innovations and Transitions			
			MNES	Ministry of Non-Conventional Energy Sources
kt	kilotonne			
KU Leuven	Katholieke Universiteit Leuven (Catholic University of Leuven)		MNRE	Ministry of New and Renewable Energy
			MNRES	Ministry of New and Non-Conventional Energy Sources
LANUV	Landesamt für Natur, Umwelt und Verbraucherschutz NRW (environment agency of North Rhine–Westphalia, Germany)		MP	Member of Parliament
			MRI	Mountain Research Initiative
			MRV	monitoring, reporting, verification
LCA	light combat aircraft		MST	Movimento dos Trabalhadores Rurais Sem Terra (Landless Workers' Movement), Brazil
LCD	low-carbon development			
LCEA	Low-Carbon Economic Area		MSW	municipal solid waste
LCHRS	Low-Carbon Housing Retrofit Strategy		Mt	megatonne
LCR	Local Content Requirement		MtCO₂	megatonnes of carbon dioxide
LCR	low-carbon and climate-resilient		MTCR	Nuclear Suppliers Group or the Missile Technology Control Regime
LDC	least developed country			
LED	light-emitting diode		MVMC	Metropolitan Valley of Mexico City
LEGEEPA	Ley General del Equilibrio Ecológico y La Protección al Ambiente (General Law on Ecological Equilibrium and Protection of the Environment), México		MW	megawatt
			MWh	megawatt hour
			N₂O	Nitrous Oxide
LETS	Local Exchange Trading System		NABU	Naturschutzbund Deutschland (Nature and Biodiversity Conservation Union)
LM	Lunderskov Moebelfabrik			
LOICZ	Land-Ocean Interactions in the Coastal Zone		NAFTA	North American Free Trade Agreement
			NAL	National Aerospace Laboratories
LTG	Limits to Growth		NAMA	Nationally Appropriate Mitigation Actions (in the context of UNFCCC)

NAS	National Academy of Sciences		PDSI	Palmer Drought Severity Index
NASA	US National Aeronautics and Space Administration		PEA	Provincial Electricity Authority
NATO	North Atlantic Treaty Organization		PEC	Peace Education Commission of IPRA
NBFI	non-bank financial institution		PECC	Programa Especial de Cambio Climático (Climate Change Special Programme), Mexico
NBI	Nile Basin Initiative			
NBM	new business model		PEISOR	pressure, effect, impact, societal outcome and response model
NBS	National Bureau of Statistics			
NBSAP	National Biodiversity Strategies and Action Plans		PERN	Population–Environment Research Network
NDRC	National Development and Reform Commission		PIK	Potsdam Institute for Climate Impact Research and Climate Analytics
NEPAD	New Partnership for Africa's Development		PJSA	Peace and Justice Studies Association
NEPO	National Energy Policy Office		PLO	Palestinian Liberation Organization
NERSA	National Energy Regulator South Africa		PND	Programa Nacional de Desarrollo (National Development Programme), Mexico
NESDB	National Economic and Social Development Board		PPA	Power Purchase Agreement
NETL	National Energy Technology Laboratory		PPCDAm	Plano de Ação para a Prevenção e o Controle do Desmatamento na Amazônia Legal (Action Plan for the Prevention and Control of Deforestation in the Legal Amazon), Brazil
NGO	non-governmental organization			
NHDR	National Human Development Report			
NIC	National Intelligence Council			
NIC	newly industrialized country		ppm	parts per million
NIMBY	not in my backyard		PPP	purchasing power parity
NOAA	US National Oceanic and Atmospheric Administration		PRD	Partido de la Revolución Democrática (Revolutionary Democratic Party), Mexico
NPC	The National People's Congress		PRI	Partido Revolucionario Institucional (Institutional Revolutionary Party), Mexico
NPO	not-for-profit organization			
NRC	US National Research Council		PRIF	Peace Research Institute Frankfurt
NRDC	Natural Resources Defense Council		PRIO	International Peace Research Institute in Oslo (Norway)
NRF	National Research Foundation			
NRR	net reproduction rate		PRO	public research organization
NRW	North Rhine–Westphalia		PROCEL	Programa Nacional de Conservação de Energia Elétrica (National Electrical Energy Conservation Programme), Brazil
NSI	national system of innovation			
NSM	Nijmegen School of Management			
NTU	Nanyang Technological University		PROINFA	Programa de Incentivo às Fontes Alternativas de Energia Elétrica (Alternative Energy Sources Incentive Programme), Brazil
NUS	National University Singapore			
OAS	Organization of American States			
ODI	overseas development assistance		PSP	Poznan Strategic Program on Technology Transfer
OECD	Organisation for Economic Co-operation and Development			
OEM	original equipment manufacturer		PSP	Springer Briefs in Science and Practices (book series)
OIC	observed irreducible complexity		PSR	pressure-state-response
OPEC	Organization of the Petroleum Exporting Countries		PT	Partido dos Trabalhadores (Labour Party, Brazil)
OSCE	Organization for Security and Co-operation in Europe		PT	Partido del Trabajo (Labour Party, Mexico)
			PURPA	Public Utilities Regulatory Policies Act
PAHSEP	Pioneers in Arts, Humanities, Science, Engineering, Practice (book series)		PV	photovoltaics
			PVEM	Partido Verde Ecologista de México (Green Ecological Party of Mexico)
PAN	Partido Acción Nacional (National Action Party) country?			
PAWSS	Peace and World Security Studies		R&D	research and development
PAYGO	pay-as-you-go		RAST	resource abundance and scarcity threshold
PBE	Programa Brasileiro de Etiquetagem (Brazilian Labelling Programme)		RCEP	Regional Comprehensive Economic Partnership
PCH	Pequena Central Hidrelétrica (Small Hydroelectric Plant)		RCP	representative concentration pathways
			RD&D	research, development and deployment
PDP	Power Development Plan		RE	renewable energy
			REA	Rural Electrification Authority

REDD+	Reducing Emissions from Deforestation and Forest Degradation in Developing Countries and the Conservation, Sustainable Management of Forests and Enhancement of Forest Carbon Stocks policy		SNM	strategic niche management
			SOE	state-owned enterprise
			SOM	climate model simulation
			SOM	soil organic matter
			SP	sustainable production
			SPP	small power producer
REIPPPP	Renewable Energy Independent Power Producer Procurement Programme		SPREAD	European 'social platform' on Sustainable Lifestyles 2050
REN 21	Renewable Energy Network for the 21st Century (c/o UNESCO)		SPREAD	Scenarios for Sustainable Lifestyles–From Global Champions to Local Loops
RHI	Renewable Heat Incentive		SREX	Special Report on Managing the Risks of Extreme Events and Disasters to Advance Climate Change Adaptation (IPCC)
ROW	the rest of the world			
RTD	Research and Technological Development			
RVR	Regionalverband Ruhr (regional association of municipalities of the Ruhr district, Germany)		SRREN	Special Report on Renewable Energy Sources and Climate Change Mitigation (IPCC)
			ST	sustainability transition
SAP	Structural Adjustment Programme		START	System for Analysis, Research and Training
SAR	Special Administrative Region		STI	science, technology and innovation
SC	Scientific Committee		STRN	Sustainability Transition Research Network
SC	State Council		STS	science and technology studies
SC	Sustainable Consumption		SuMMa	Policy Research Centre on Sustainable Materials Management
SCI	KompetenzCentrum for Corporate Social Responsibility, University of Applied Sciences in Essen, Germany		SUS	Sistema Único de Saúde (Unified Health System), Brazil
SCI	Sustainable Consumption Institute, University of Manchester		SYR	Synthesis Report
SCOPE	Scientific Committee on Problems of the Environment, ICSU		t/cap	tonnes per annum per capita
			TAMA	there are many alternatives
SCORAI	Sustainable Consumption Research and Action Initiative		TAPRI	Tampere Peace Research Institute
			TC	triangular cooperation
SCP	sustainable consumption and production		tce	tonnes of coal equivalent
SD	sustainable development		tep	tonelada equivalente de petróleo (tons of oil equivalent, in Portuguese)
SDG	Sustainable Development Goal			
SDSN	Sustainable Development Solutions Network		TINA	there is no alternative
			TIS	technological innovation systems approach
SEGOB	Secretaría de Gobernación (Ministry of the Interior), Mexico		TM	transition management
			TMR	total material requirements
SEMARNAT	Secretaría de Medio Ambiente y Recursos Naturales (Mexican Ministry of the Environment and Natural Resources)		TNA	technology needs assessment
			TNC	transnational corporation
			TNEB	Tamil Nadu Electricity Board (India)
SERC	Structural Engineering Research Centre		TNEP	The Natural Edge Project
SERI	Sustainable Europe Research Institute		TNO	Nederlandse Organisatie voor Toegepast Natuurwetenschappelijk Onderzoek (Netherlands Organisation for Applied Scientific Research)
SES	social–ecological systems theory			
SET	Stock Exchange of Thailand			
SHS	solar home systems			
SIAP	Sistema de Información Agropecuario (System of Information for Agriculture and Livestock), Mexico		toe	tonnes of oil equivalent
			TPP	Trans-Pacific Partnership
			TRIP	trade-related aspects of intellectual property rights
SIDS	small island developing states			
SIL	Sistema de Información Legislativa (Legislative Information System) Mexico		TRT	Thai Rak Thai
			TSB	Technology Strategy Board
SIN	Sistema Interligado Nacional (National Interconnected System), Brazil		TT	transitions theory
			TTIP	Transatlantic Trade and Investment Partnership
SIPRI	Stockholm International Peace Research Institute			
			TUM	Technical University of Munich
SME	small and medium-sized enterprise		TUPADO	Turkana Pastoralist Organization
SNCC	Sistema Nacional de Cambio Climático (National Climate Change System) Mexico		TWA	tolerable windows approach

TWAS	Third World Academy of Science
UAEM	Universidad Autónoma del Estado de Morelos (Autonomous University of the State of Morelos, Mexico)
UCDP	Uppsala Conflict Data Programme
UDLAP	Universidad de las Américas, Puebla
UGEC	Urbanization and Global Environmental Change
UHC	universal health care
UHE	Usina Hidrelétrica (Hydroelectric Plant)
UHI	University of the Highlands and Islands, Scotland, UK
UK	United Kingdom
UN	United Nations
UNAM	Universidad Nacional Autónoma de México (National Autonomous University of Mexico)
UNCCD	United Nations Convention to Combat Desertification
UNCED	United Nations Conference on Environment and Development
UNCSD	United Nations Commission on Sustainable Development
UNCSD	United Nations Conference on Sustainable Development (or Rio+20) in June 2012
UNCTAD	United Nations Conference on Trade and Development
UNDESA	United Nations Department of Economic and Social Affairs
UNDP	United Nations Development Programme
UNECA	United Nations Economic Commission for Africa
UNEP	United Nations Environment Programme
UNESCAP	United Nations Economic and Social Commission for Asia and the Pacific
UNESCO	United Nations Educational, Scientific and Cultural Organization
UNFCCC	United Nations Framework Convention on Climate Change
UNGA	United Nations General Assembly
UNHCR	United Nations High Commissioner for Refugees
UNICAM	Peasant University of the South
UNICEF	United Nations Children's Fund
UNIDO	United Nations Industrial Development Organization
UNODC	United Nations Office on Drugs and Crime
UNPD	United Nations Population Division
UNSC	United Nations Security Council
UNSG	United Nations Secretary-General
UNU	United Nations University
UNU–EHS	United Nations University–Environment and Human Security Institute
UNU–MERIT	United Nations University–Maastricht Economic and Social Research Institute on Innovation and Technology

UNWR	United Nations Water Report
UPEACE	University for Peace
US	United States of America
USA	United States of America
USAID	United States Agency for International Development
USD	United States dollar
USIP	United States Institute of Peace
USSR	Union of Soviet Socialist Republics
UV	ultraviolet
VIABLE	Values and Investments in Agent-Based Interaction and Learning for Environmental Systems
VKT	vehicle kilometres travelled
VSPP	very small power producer
WAPOR	World Association for Public Opinion Research
WASH	water access, sanitation and hygiene
WB	World Bank
WBCSD	World Business Council for Sustainable Development
WBGU	Wissenschaftlicher Beirat Globale Umweltveränderungen (German Advisory Council on Global Change)
WCED	World Commission on Environment and Development
WCR	World Climate Research Programme
WEF	World Economic Forum
WEG	wind energy generator
WFE	water, food, and energy security nexus
WFE	World Federation of Engineering Organizations
WG	Working Group (of the IPCC)
WHO	World Health Organization
WIPO	World Intellectual Property Organization
WIR	World Investment Report
WMO	World Meteorological Organization
WMR	Wirtschaftsförderung Ruhr (economic development agency of the Ruhr district, Germany)
WS	water security
WSSD	World Summit on Sustainable Development, Johannesburg (2002)
WTO	World Trade Organization
WVS	World Value Survey
WWF	Worldwide Fund for Nature (also known as World Wildlife Fund)
YHDR	Young Human Dimensions Researchers
YRB	Yautepec River Basin (Mexico)
ZESCO	Zambia Electricity Supply Corporation Limited

Biographies of Editors

Hans Günter Brauch (Germany), Dr. phil. habil., Adj. Prof. (Privatdozent) at the Faculty of Political and Social Sciences, Free University of Berlin (1990–2012); since 1987 chairman of *Peace Research and European Security Studies* (AFES-PRESS). He is editor of the *Hexagon Book Series on Human and Environmental Security and Peace* (HESP), of the *Springer Briefs in Environment, Security, Development and Peace* (ESDP), of the *SpringerBriefs on Pioneers in Science and Practice* (PSP); of *Pioneers in Arts, Humanities, Science, Engineering, Practice (PAHSEH)* and of *The Anthropocene: Politik–Economics–Society–Science (APESS)* with Springer International Publishing. He has been visiting professor of international relations at the universities of Frankfurt am Main, Leipzig, Greifswald, and Erfurt; research associate at Heidelberg and Stuttgart universities, and a research fellow at Harvard and Stanford Universities. He has taught at the Free University of Berlin (1990–2012), at Sciences Po (Paris, 2010–2012), at the *European Peace University* (EPU, Schlaining, Austria), at the *National Autonomous University of Mexico* (UNAM), at the *National University of Malaysia* (UKM), Malaysia (2010, 2012), and in autumn and winter 2013/2014 he was a visiting professor at Chulalongkorn University in Bangkok, Thailand. He has published on security, armament, climate, energy, and migration, on Mediterranean issues and on sustainability transition in English and German, and his work has been translated into Chinese, Spanish, Greek, French, Danish, Finnish, Russian, Japanese, Portuguese, Serbo-Croat, and Turkish. *Publications*: His books include: (co-author with H. v. d. Graaf, J. Grin, W. Smit): *Militärtechnikfolgenabschätzung und präventive Rüstungskontrolle*, 1997; *Klimapolitik der Schwellenstaaten: Südkorea, Mexiko und Brasilien; Osterweiterung der Europäischen Union. Umwelt- und Energiepolitik der Tschechischen Republik*, 2000. Books in English, Spanish, Greek, Turkish and Chinese: (co-ed. with D. L. Clark): *Decision-making for Arms Limitation–Assessments and Prospects*, 1983; (ed.): *Star Wars and European Defence–Implications for Europe: Perceptions and Assessments*, 1987; (co-author with R. Bulkeley): *The Anti-Ballistic Missile Treaty and World Security*, 1988; (ed.): *Military Technology, Arma-ments Dynamics and Disarmament*, 1989; (co-ed. with R. Kennedy): *Alternative Conventional Defense Postures in the European Theater*, vol. 1: *The Military Balance and Domestic Constraints*, 1990; Vol. 2: *Political Change in Europe: Military Strategy and Technology*, 1992; Vol. 3: *Military Alternatives for Europe after the Cold War*, 1993; (co-ed. with H. J. v. d. Graaf, J. Grin; W. Smit): *Controlling the Development and Spread of Military Technology*, 1992; (co-ed. with A. Marquina): *Confidence Building and Partnership in the Western Mediterranean. Tasks for Preventive Diplomacy and Conflict Avoidance*, 1994; *Energy Policy in North Africa (1950–2050). From Hydrocarbon to Renewables*, 1997; (co-ed. with A. Marquina, A. Biad): *Euro-Mediterranean Partnership for the 21st Century*, 2000; (co-ed. with A. Marquina): *Political Stability and Energy Cooperation in the Mediterranean* (2000); *Liberalisation of the Energy Market for Electricity and Gas in the European Union: a Survey and implications for the Czech Republic*, 2002; (co-ed. with P. Liotta, A, Marquina, P. Rogers, M. Selim): *Security and Environment in the Mediterranean. Conceptualising Security and Environmental Conflicts*, 2003; *Environmental Dimension of Human Security: Freedom from Hazard Impact*, 2005; *Threats, Challenges, Vulnerabilities and Risks in Environmental and Human Security*, 2005; (co-ed. with Ú. Oswald Spring, C. Mesjasz, J. Grin, P. Dunay, N. Chadha Behera, B. Chourou, P. Kameri-Mbote, P. H. Liotta): *Globalization and Environmental Challenges: Reconceptualizing Security in the 21st Century*, 2008; (co-ed. with Ú. Oswald Spring, J. Grin, C. Mesjasz, P. Kameri-Mbote, N. Chadha Behera, B. Chourou, H. Krummenacher): *Facing Global Environmental Change: Environmental, Human, Energy, Food, Health and Water Security Concepts* (2009); (co-ed. with Ú. Oswald Spring): *Reconceptualizar la Seguridad en el Siglo XXI* (2009); (co-author with Ú. Oswald Spring: *Securitizing the Ground–Grounding Security* and: *Seguritizar la Tierra–Aterrizar la Seguridad* (Bonn: UNCCD, 2009); (guest co-ed. with Ú. Oswald Spring and M. Aydin of a special issue of: *Uluslararasi Iliskiler / International Relations*, 5,18 (Summer) Special Issue on "Security" (2009): (co-ed. with Ú.Oswald Spring, C. Tsardanidis and Y. Kinnas: Greek translation of 7 chapters, vol. 3: *Globalization and Environmental Challenges*, in: *Agora*, Spring 2010; *Climate Change and Mediterranean Security: International, National, Environmental and Human Security Impacts for the Euro–Mediterranean Region during the 21st Century–Proposals and Perspectives*. Papers IEMed No. 9 (Barcelona: IE, 2010); (co-ed. with Oswald Spring, Mesjasz, Grin, Kameri-Mbote, Chourou, Dunay, Birkmann), *Coping with Global Environmental Change, Disasters and Security–Threats,*

Challenges, Vulnerabilities and Risks (2011); (co-ed with Scheffran, Brzoska, Link, Schilling), *Climate Change, Human Security and Violent Conflict: Challenges for Societal Stability* (2012); with Aydin, Celikpata, Oswald Spring, Polat (Eds.): *Uluslararasi Iliskilerde Catismadam Güvenige* (2012); co-ed. with Oswald Spring, Tidball (Eds.): *Expanding Peace Ecology: Security, Sustainability, Equity and Peace: Perspectives of IPRA's Ecology and Peace Commission* (2014); co-ed. with Oswald Spring, Serrano Oswald, Estrada Álvarez, Flores Palacios, Ríos Everardo, Ruíz Pantoja, Lemus Ramírez, Estrada Villareal, Cruz: *Vulnerabilidad Social y Género entre Migrantes Ambientales* (Cuernavaca: CRIM, DGAPA-PAPIIT-UNAM, RETAC-Conacyt, 2014); co-ed. with Grimwood (Ed.): *Jonathan Dean: Pioneer in Détente in Europe, Global Cooperative Security, Arms Control and Disarmament* (2015); co-ed. with Oswald Spring, Mesjasz, Grin, Cheng (Eds.): [in Chinese] *Globalization and Environmental Challenges: Reconceptualizing Security in the 21st Century* (2015); co-ed. with Oswald Spring, Mesjasz, Grin, Cheng (Eds.): [in Chinese]: *Facing Global Environmental Change: Environmental, Human, Energy, Food, Health and Water Security Concepts* (2015); co-ed. with Oswald Spring, Mesjasz, Grin, Cheng (Eds.): [in Chinese] *Coping with Global Environmental Change, Disasters and Security—Threats, Challenges, Vulnerabilities and Risks* (2015); co-ed. with Oswald Spring, Bennett, Serrano: *Addressing Global Environmental Challenges from a Peace Ecology Perspective* (2016); co-ed. with Oswald Spring, Serrano, Bennett: *Regional Ecological Challenges for Peace in Africa, the Middle East, Latin America and Asia Pacific* (2016).

Address: PD Dr. Hans Günter Brauch, Alte Bergsteige 47, 74821 Mosbach, Germany.

Úrsula Oswald Spring (Mexico), full time Professor/Researcher at the *National University of Mexico* (UNAM) in the *Regional Multidisciplinary Research Center* (CRIM), she was national coordinator of water research for the *National Council of Science and Technology* (RETAC-CONACYT), first Chair on Social Vulnerability at the *United National University Institute for Environment and Human Security* (UNU–EHS); founding Secretary-General of El Colegio de Tlaxcala; General Attorney of Ecology in the State of Morelos (1992–1994), National Delegate of the Federal General Attorney of Environment (1994–1995); Minister of Ecological Development in the State of Morelos (1994–1998). She was President of the *International Peace Research Association* (IPRA, 1998–2000), and General Secretary of the Latin-American Council for Peace Research (2002–2006). She studied medicine, clinical psychology, philosophy, anthropology, ecology, and classical and modern languages. She obtained her PhD from the University of Zürich (1978). For her scientific work she received the Premio Sor Juana Inés de la Cruz (2005), the Environmental Merit in Tlaxcala, Mexico (2005, 2006), and the UN Development Prize. She was recognized as Women Academic of UNAM (1990 and 2000); and Women of the Year (2000). She works on nonviolence and sustainable agriculture with groups of peasants and women and is President of the Advisory Council of the Peasant University. She has written fifty-two books and more than 379 scientific articles and book chapters on sustainability, water, gender, development, poverty, drug consumption, brain damage due to undernourishment, peasantry, social vulnerability, genetically modified organisms, bioethics, and human, gender, and environmental security, adaptation, resilience, climate-induced migration, peace and conflict resolution, democracy and processes of negotiation. Among her major publications are: (co-author with Rudolf Strahm): *Por esto somos tan pobre* (translated into 17 languages, 1.5 million copies); *Unterentwicklung als Folge von Abhängigkeit* (Berne: Lang, 1978); *Mercado y Dependencia* (México, D.F.: Ed. Nueva Imagen, 1979); *Piedras en el Surco* (México, D.F.: UAM-X, 1983); *Campesinos Protagonistas de su Historia: la Coalición de los Ejidos Colectivos de los Valles del Yaqui y Mayo, una Salida a la Cultura de la Pobreza* (México, D.F.: UAM-X, 1986); *Estrategias de Supervivencia en la Ciudad de México* (Cuernavaca: CRIM/UNAM, 1991); *Fuenteovejuna o Caos Ecológico* (Cuernavaca: CRIM/UNAM, 1999); *Peace Studies from a Global Perspective: Human Needs in a Cooperative World* (ed.) (New Delhi: Mbooks, 2000); (co-author with Mario Salinas): *Gestión de Paz, Democracia y Seguridad en América Latina* (México, D.F.: UNAM–CRIM/Coltlax, Böll, 2002); *El recurso agua en el Alto Balsas* (ed.) (México: IGF, CRIM/UNAM, 2003); *Soberanía y Desarrollo Regional. El México que queremos* (ed.) (México, D.F.: UNAM, 2003); *Resolución noviolenta de conflictos en sociedades indígenas y minorías* (ed.) (México, D.F.: CLAIP, IPRA & Böll Fundation, COLTLAX, 2004); *El valor del agua: una visión socioeconómica de un conflicto ambiental* (COLTLAX, CONACYT, 2005); *International Security, Peace, Development, and Environment*, Book 39: *Encyclopaedia on Life Support Systems* (ed.) (Paris: UNESCO—EOLSS, UK, online); *Gender and Disasters* (Bonn: UNU–EHS, 2008); (co-ed. with H. G. Brauch, C. Mesjasz, J. Grin, P. Dunay, N. Chadha Behera, B. Chourou, P. Kameri-Mbote, P. H. Liotta), 2008: *Globalization and Environmental Challenges: Reconceptualizing Security in the 21st Century* (translated into Chinese); (co-ed. with H. G. Brauch, J. Grin, C. Mesjasz, P. Kameri-Mbote, N. Chadha Behera, B. Chourou, H. Krummenacher (translated into Chinese), 2009: *Facing Global Environmental Change: Environmental, Human, Energy, Food, Health and Water Security Concepts*; (co-ed. with H.G. Brauch): *Reconceptualizar la Seguridad en el Siglo XXI*, 2009; (co-author with H. G. Brauch: *Securitizing the Ground–Grounding Security* and *Seguritizar la Tierra–Aterrizar la Seguridad* (Bonn: UNCCD), 2009; (guest co-ed. with H. G. Brauch and M. Aydin of a special

issue of *Uluslararasi Iliskiler / International Relations*, 5,18 (Summer) Special Issue on "Security", 2009: (co-ed. with H. G. Brauch, C. Tsardanidis and Y. Kinnas: Greek translations of 7 chapters, vol. 3: *Globalization and Environmental Challenges*, in: *Agora*, Spring 2010; (co-ed. with H. G. Brauch, C. Tsardanidis and Y. Kinnas): Greek translations of chapters, vol. 4: Facing Global Environmental Change, in: *Agora*, Summer, 2010; *Retos de la investigación del agua en México* (ed.), 2011, CRIM-UNAM, CONACYT, México; *Water Research in Mexico*, Springer Verlag, Berlin; *Coping with Global Environmental Change: Disaster and Security* (co-ed. with H. G. Brauch, C. Mesjasz, J. Grin, P. Dunay, N. Chadha Behera, B. Chourou, P. Kameri-Mbote, P. Dunay, J. Birkman) 2011 (translated into Chinese: 应对全球环境变化、灾难及安全 —— 威胁、挑战、缺陷和风险); "Can health be Securitized?", *Human evolution* 2012, 27 (1–3), 2015, pp. 21–29; "Vulnerabilidad social en eventos hidrometeorológios extremos: una comparación entre los huracanes Stan y Wilma", *SocioTam*, 2012, 22 (2) (July–Dec), pp. 125–145.; "Forced migration, climate change, mitigation and adaptive policies in Mexico. Some functional relationships", *International Migration,* 2013 (co-author with I. Sánchez, G. Díaz et al.); "Water security and national water law in Mexico", *Earth Perspectives*, 2013: vol.1, núm. 7: 1–15. "Dual Vulnerability among Female Household Heads", *Acta Colombiana de Psicología,* 2013: 16(2), pp. 19–30; *Vulnerabilidad Social y Género entre Migrantes Ambientales,* (co-author with S. E. Serrano, Adriana. Estrada, F. Flores, M. Ríos, H. G. Brauch, T. E. Ruíz, C. Lemus, Ariana Estrada, M. Cruz), 2014, CRIM, DGAPA–UNAM, Cuernavaca; *Expanding Peace Ecology: Security, Sustainability, Equity and Peace*, 2015, (co-ed. with H. G. Brauch, K. G. Tidball) Berlin, Springer Verlag; "Human Security", 2014, (co-author with N. Adger et al.), *Fifth Assessment Report, IPCC, WG 2*, Cambridge University Press, Cambridge, pp. 755–791; "Cambio Climático, Salud y Género", 2014, (co-author with A. R. Moreno, O. Tena, in: M. Ímaz et al. (eds.). *Cambio climático, miradas de género*, México, UNAM, pp. 85–136; *América Latina en el Camino hacia una Paz Sustentable: Herramientas y Aportes*, 2015: (co-ed. with S. E. Serrano, D. de la Rúa) ARP, FLACSO, CLAIP, Guatemala; *México ante la Urgencia Climática: Ciencia, Política y Sociedad* (co-ed. with X. Cruz, G. C. Delgado), 2015, CCEIICH, CRIM, PINCC, UNAM; "Water Security: Past, Present and Future of a Controversial Concept", 2015, (co-author with J. Bogardi, H. G. Brauch), in: *Handbook on Water Security*, C. Pahl-Wostl, A. Bhaduri, J. Gupta (eds.), Edward Elgar, Cheltenham, pp. 38–58; "Seguridad humana", in C. Gay, C. Ruiz (eds.), 2015: *Reporte Mexicano de Cambio Climático GRUPO II Impactos, vulnerabilidad y adaptación*, PINCC–UNAM, pp. 183–210.

John Grin (The Netherlands) is a Full Professor in Policy Science, in particular of System Innovation, Dept. of Political Science, University of Amsterdam, and Co-Director (with Marieke de Goede) of the Programme Group Transnational Configurations, Conflicts and Governance, Amsterdam Institute for Social Science Research (AISSR). A physicist by training (MSc 1986, VU University Amsterdam) he gained a PhD (1990) on defence technology assessment. He is driven by a profound, life-long interest in the relationships between knowledge, technology, society and policy. He is particularly interested in understanding the 'politics' of knowledge and technology and ways to analyse them; and in the intertwining between the two. He co-established and was co-director of the transdisciplinary *Dutch Knowledge Network for System Innovations and Transitions* (KSI; <www.ksinetwork.nl>), in which some hundred researchers of ten different universities cooperate on major changes towards a sustainable society. From 2006 to 2009 he was scientific director of the Amsterdam School for Social Science Research (ASSR; at: <www.assr.nl>). He co-edited special issues of the journals *Policy Sciences* (vol. 43[2009], no. 4) and *Research Policy* (vol. 39 [2010], no. 4) on transitions, and he published (co-author with Jan Rotmans, Johan Schot): *Transitions to Sustainable Development. New Directions in the Study of Long Term Structural Change (*New York: Routledge, 2010). Earlier (co-)authored books include (with Hans Günter Brauch, Henk van de Graaf, Wim Smit): *Militärtechnikfolgenabschätzung und Präventive Rüstungskontrolle. Institutionen, Verfahren und Instrumente* (Münster: LIT, 1997); and *Military-technological choices and political implications. Command and control in established NATO posture and a non-provocative defence* (Amsterdam: VU University Press–New York: St. Martin's Press, 1990); (co-ed. with Wim A. Smit, Lev Voronkov): *Military-technological innovation and stability in a changing world. Politically assessing and influencing weapon innovation and military research and development* (Amsterdam: VU University Press, 1992); (with Henk van de Graaf, Rob Hoppe): *Technology assessment through interaction: A guide* (Den Haag: SDU, 1997). His edited volumes include (with Armin Grunwald): *Vision Assessment: Shaping Technology in 21st century society. Towards a repertoire for Technology Assessment* (Heidelberg: Springer, 2000); (co-ed. with Brauch, Oswald Spring, Mesjasz, Dunay, Chadha Behera, Chourou, Kameri-Mbote, Liotta, 2008): *Globalization and Environmental Challenges: Reconceptualizing Security in the 21st Century* (Springer); (co-ed. with Brauch, Oswald Spring, Mesjasz, P. Kameri-Mbote, Chadha Behera, Chourou, Krummenacher, 2009): *Facing Global Environmental Change: Environmental, Human, Energy, Food, Health and Water Security Concepts* (Springer), (co-ed. with Brauch, Oswald Spring, Mesjasz, Kameri-Mbote, Chourou, Dunay, Birkmann: *Coping*

with Global Environmental Change, Disasters and Security—Threats, Challenges, Vulnerabilities and Risks, 2011); (co-ed. with Brauch, Oswald Spring, Scheffran (Eds.): *Handbook on Sustainability Transition and Sustainable Peace*, 2014). Some key journal articles and book chapters on transitions are Niki Frantzeskaki, Wil Thissen, John Grin: "Drifting between transitions. Lessons from the environmental transition around the river Acheloos Diversion project in Greece", in: *Technological Forecasting and Social Change,* 102 (January 2016): 275-286; Andrew Switzer, Luca Bertolini, John Grin, 2015: "Understanding transitions in the regional transport and land-use system: Munich 1945-2013", in: *Town Planning Review*, 86,6: 699-723; Vanja Karadzic, Paula Antunes, John Grin, 2014: "Adapting to environmental and market change: Insights from Fish Producer Organizations in Portugal", in: *Ocean & Coastal Management,* 102, Part A: 364-374 ; Jan Hassink, Wim Hulsink, John Grin, 2014: "Farming with care: the evolution of care farming in the Netherlands", in: *NJAS–Wageningen Journal of Life Sciences*, 68,7: 1-11; Vanja Karadzic, John Grin, Paula Antunes, Marija Banovic, 2014: "Social learning in fish producers' organizations: how fishers perceive their membership experience and what they learn from it", in: *Marine Policy*, 44: 427-437; Andrew Switzer, Luca Bertolini, John Grin, 2013: "Transitions of Mobility Systems in Urban Regions: A Heuristic Framework", in: *J. Environmental Policy and Planning*, 15,2: 141-160 (JIF 1,421; SCI 1,316); Jan Hassink, John Grin, Wim Hulsink, 2013: "Multifunctional Agriculture Meets Health Care: Applying the Multi-Level Transition Sciences Perspective to Care Farming in the Netherlands", in: 'Sociologia Ruralis, 53,2: 223-245; John Grin, 2012: "The politics of transition governance in Dutch agriculture. Conceptual understanding and implications for transition management", in: *Int. J. Sustainable Development*, 15, 2:72-89 (SCI 0,297); Vanja Karadzic, Paula Antunes, John Grin, 2012: "'How to learn to be adaptive?' An analytical framework for organizational adaptivity and its application to a fish producers organization in Portugal", in: *Journal of Cleaner Production*, 45: 29-37; Boelie Elzen, Marc Barbier, Marianne Cerf, John Grin, 2012: "Stimulating transitions towards sustainable farming systems", in: Ika Darnhofer, David Gibbon, Benoit Dedieu (Eds.) (2012). *Farming Systems Research into the 21st century: The new dynamic* (Berlin etc.: Springer): 431-455; John Grin, 2012: "Between governments, kitchens, firms and farms: the governance of transitions between societal practices and supply systems", in: Spaargaren, Gert, Anne Loeber, and Peter Oosterveer (Eds.), 2012: *Food Practices in Transition. Changing Food Consumption, Retail and Production in the Age of Reflexive Modernity.* (London: Routledge): 35-56; John Grin, Johan Schot, Jan Rotmans, 2011: "On patterns and agency in transition dynamics: Some key insights from the KSI programme", in: *Environmental Innovation and Societal Transitions*, 1,1: 76-81; John Grin, Esther Marijnen, 2010: "Global Threats, Global Changes and Connected Communities in the Agrofood system", in: (co-ed. with Brauch, Oswald Spring, Mesjasz, Grin, Kameri-Mbote, Chourou, Dunay, Birkmann, 2011): *Coping with Global Environmental Change, Disasters and Security—Threats, Challenges, Vulnerabilities and Risks*): 1005-1018.

Address: Prof. Dr. John Grin, Dept. of Political Science, University of Amsterdam P.O. Box 15578, 1001 NB Amstedam, Netherlands.

Jürgen Scheffran (Germany) is Professor at the Institute of Geography and the *Center for Earth System Research and Sustainability* (CEN) of the University of Hamburg in Germany and head of the *Research Group Climate Change and Security* (CLISEC) in the Cluster of Excellence *Integrated Climate System Analysis and Prediction (CliSAP)*. Until summer 2009 he held faculty positions at the Departments of Political Science and Atmospheric Sciences at the *University of Illinois at Urbana-Champaign* (UIUC) where he also was a researcher in the *Program in Arms Control, Disarmament and International Security* (ACDIS), the *Center for Advanced BioEnergy Research* (CABER) and the *Energy Biosciences Institute* (EBI). After his PhD in physics at Marburg University he held various research positions in the *Interdisciplinary Research Group Science, Technology and Security* (IANUS) at Technical University Darmstadt, the *Potsdam Institute for Climate Impact Research* (PIK) and as a Visiting Professor at the University of Paris (Pantheon-Sorbonne). At all these locations he taught more than fifty different courses on a wide range of topics, and attracted project funding from a number of funding organizations, e.g. *Deutsche Forschungs-Gemeinschaft* (DFG), *German Academic Exchange Service* (DAAD), *Federal Ministry for Education and Research* (BMBF), European Commission, COST Action, VW Foundation, Berghof Foundation, Heinrich Böll Foundation, Federal Environmental Agency, US Department of Energy, UIUC Environmental Council, Critical Initiatives for Research and Scholarship, MacArthur Foundation, Ploughshares Fund, Vattenfall Europe, BP. Besides CliSAP and CLISEC, participation in recent projects includes the ConflictSpace project, the Renewable Energy Initiative and related projects on bioenergy at UIUC, the EuTRACE assessment of climate engineering, and the COST Action on climate change and migration. Research and teaching interests include: climate change and energy security; natural resources, land use, environmental conflict and human migration; rural-urban interaction and the water-energy-food nexus; complex systems analysis, agent-based modelling and human–environment interactions; transformation and sustainability science; technology assessment, and arms control and international security. He has served as a consultant to the United Nations, the Technology Assessment Bureau of the German Parliament, and the Federal Environmental Agency, and he was part of the German delegation to the climate negotiations in New Delhi in 2002

(COP-8). He has published more than twenty books and more than 300 articles in journals and books, is co-editor of *Wissenschaft und Frieden (Science and Peace)*, and has co-edited special issues of the journals *Complexity, Foreign Policy Analysis, Earth System Dynamics, Migration and Development*. Recent books include: (co-ed. with Brzoska, Brauch, Link, Schilling): *Climate Change, Human Security and Violent Conflict: Challenges for Societal Stability* (2012); (co-ed. with Khanna, M., Zilberman, D.): *Handbook of Bioenergy Economics and Policy* (Heidelberg etc.: Springer, 2010); (co-ed. with Blaschek, H., Ezeji, T.): *Biofuels from Agricultural Wastes and Byproducts* (Ames, Iowa: Wiley/Blackwell, 2010); (co-ed. with Mascia, P. N., Widholm, J.): *Plant Biotechnology for Sustainable Production of Energy and Co-Products* (Heidelberg etc.: Springer, 2010); (co-ed. with Kropp, J.): *Advanced Methods for Decision Making and Risk Management in Sustainability Science* (New York: Nova Science, 2007); (co-ed. with Billari, F., Fent, T., Prskawetz, A.): *Agent-Based Computational Modelling in Demography, Economic and Environmental Sciences* (Heidelberg etc.: Springer/Physica, 2006); (co-ed. with Johnke, B., Soyez, K.): *Abfall, Energie und Klima. Wege und Konzepte für eine integrierte Ressourcennutzung* (Erich Schmidt Verlag, Berlin: 2004); (co-author with Ott, K; Klepper, G. M., Lingner, S., Schäfer, A., Sprinz, D.): *Reasoning Goals of Climate Protection. Specification of Article 2 UNFCCC* (Berlin: Umweltbundesamt, 2004); (co-ed. with Hummel, M., Simon, H.-R.): *Konfliktfeld Biodiversität* (Münster: agenda, 2002); (co-ed. with Bender, W., Hagen, R., Kalinowski, M.): *Space Use And Ethics* (Münster: agenda, 2001); (co-ed. with Zoll, R., Ackermann, H., Melsheimer, O.): *Energiekonflikte: Problemübersicht und empirische Analysen zur Akzeptanz von Windkraftanlagen* (Münster: LIT Verlag); (co-author with Abid, M., Schilling, J., Zulfiqar, F.): "Climate change vulnerability, adaptation and risk perceptions at farm level in Punjab, Pakistan", in: *Science of The Total Environment*, 547 (2/2016): 447–460; (co-author with Shu, K., Schneider, U.): "Bioenergy and Food Supply: A Spatial-Agent Dynamic Model of Agricultural Land Use for Jiangsu Province in China", in: *Energies*, 8,11 (11/2015): 13284-13307; (co-author with Gioli, G., Hu-

go, G., Máñez Costa, M.): "Human mobility, climate adaptation, and development. Introduction to special issue", in: *Migration and Development* (2015); (co-author with Schilling, J., Locham, R, Weinzierl, T., Vivekanada, J.): "The nexus of oil, conflict, and climate change vulnerability of pastoral communities in northwest Kenya", in: *Earth System Dynamics*, 6,2 (11/2015): 703-717; (co-author with Schäfer, M. S.; Penniket, L.): "Securitization of media reporting on climate change?", in: *Security Dialogue*, 10/2015; (co-author with Rodriguez Lopez, J. M., Rosso, P., Delgado, D.): "Remote Sensing of Sustainable Rural-Urban Land Use in Mexico City", in: *Journal Interdisciplina*, 3,7 (2015): 1-20; (co-author with Link, P. M., Brücher, T., Claussen, M., Link, J. S. Biographies of the Authors of Forewords

Heide Hackmann (a dual citizen of South Africa and Germany) has been Executive Director of the *International Council for Science* (ICSU) since March 2015, following eight years as Executive Director of the *International Social Science Council* (ISSC) from 2007 to 2015. She was born in South Africa, read for an MPhil in contemporary social theory at the University of Cambridge, UK, and completed her PhD in Science and Technology Studies at the University of Twente, Netherlands in 2003. She has worked as a science policymaker, researcher and consultant in the Netherlands, Germany, the United Kingdom and South Africa. Her career in science policy dates back to the early 1990s, when she worked at the Human Sciences Research Council in South Africa. From 2004 until 2007 she was Head of the Department of International Relations and National Quality Assurance and Director of CO–REACH (an EU-funded multilateral initiative for the Coordination of Research between Europe and China) at the *Royal Netherlands Academy of Arts and Sciences* (KNAW). She is a member of several international advisory committees, including the Scientific Advisory Board of the Potsdam Institute for Climate Impact Research in Germany, and co-chairs the UN's ten-member group supporting the *Technology Facilitation Mechanism* (TFM) on the Sustainable Development Goals.

ICSU is a non-governmental organization with a global membership of national scientific bodies (121 members, representing 141 countries) and International Scientific Unions (31 members). It mobilizes the knowledge and resources of the international scientific community to strengthen international science for the benefit of society. The ISSC was established by the United Nations Educational, Scientific and Cultural Organization (UNESCO) in 1952. The ISSC represents the social, behavioural, and economic sciences at a global level, and aims to bring the best social science to bear on the biggest social challenges of our times. As Executive Director of the International Social Science Council she strengthened ISSC's activity profile, membership base and financial position, and forged strong links with the International Council for Science through key partnerships. These include the Integrated Research on Disaster Risk programme and the Science and Technology Alliance for Global Sustainability, the consortium of international organizations that founded Future Earth, the new global research initiative on global sustainability that also coordinates inputs from the international scientific community on key policy processes at the United Nations. Hackmann also led the launch of the World Social Science Forums and spearheaded the development of a new series of World Social Science Reports. She initiated a new global social science research funding and coordination programme on Transformations to Sustainability, which was launched in March 2014 as a major contribution to Future Earth. Her major co-authored publications include: Heide Hackmann, Susanne C. Moser, Asuncion Lera St. Clair: "The social heart of global environmental change", in: Nature Climate Change, 4 (2014): 653-655; Peter P. J. Driessen, Jelle Behagel, Dries Hegger, Heleen Mees, Lisa Almesjö, Steinar Andresen, Fabio Eboli, Sebastian Helgenberger, Kirsten Hollaender, Linn Jacobsen, Heide Hackmann, Jörg Knieling, Corrine Larrue, Björn Ola Linnér, Orla Martin, Karen O'Brien, Saffron O'Neill, Marleen van Rijswick, Bernd Siebenhuener, Catrien Termeer, Aviel Verbruggen: "Societal transformations in the face of climate change", Working Paper, December 2013; Wolfram Mauser, Gernot Klepper, Martin Rice, Bettina Susanne Schmalzbauer, Heide Hackmann, Rik Leemans, Howard Moore. "Transdisciplinary Global Change Research: the co-creation of knowledge for sustainability", in: Current Opinion in Environmental Sustainability (July 2013); Gisli Palsson, Bronislaw Szerszynski, Sverker Sörlin, John Marks, Bernard Avril, Carole Crumley, Heide Hackmann, Poul Holm, John Ingram, Alan Kirman, Mercedes Pardo Buendía, Rifka Weehuizen: "Reconceptualizing the 'Anthropos' in the Anthropocene: Integrating the Social Sciences and Humanities in Global Environmental Change Research", in: Environmental Science & Policy (April 2013); Karen O'Brien, Jonathan Reams, Anne Caspari, Andrew Dugmore, Maryam Faghihimani, Ioan Fazey, Heide Hackmann, David Manuel-Navarrete, John Marks, Riel Miller, Kari Raivio, Patricia Romero-Lankao, Hassan Virji, Coleen Vogel, Verena Winiwarter: "You say you want a revolution? Transforming education and capacity building in response to global change", in: Environmental Science & Policy (April 2013); Gisli Palsson, Bronislaw Szerszynski, Sverker Sorlin, John Marks, Bernard Avril, Carole Crumley, Heide Hackmann, Poul Holm, John Ingram, Alan Kirman, Mercedes Pardo Buendia, Rifka Weehuizen: "Challenges of the Anthropocene: Contributions from Social Sciences and Humanities for the Changing Human Condition", in: Environmental Science & Policy (January 2013); W. V. Reid, D. Chen, L. Goldfarb, H. Hackmann, Y. T. Lee, K. Mokhele, E. Ostrom, K. Raivio, J. Rockström, H. J. Schellnhuber, A. Whyte: "Earth System Science for Global Sustainability: Grand Challenges", in: Science (November 2010); Heide Hackmann, Arie Rip: "Priorities and quality incentives for university research: A brief international survey: Countries studied: Australia, Belgium, Germany, Switzerland, UK" (January 2000); H. Hackmann, P. J. D. Drenth, J. J. F. Schroots: "Evaluating for Science: Processes & Protocols" (Amsterdam: ALLEA, 2004).

Address: Dr. Heide Hackmann, Executive Director, International Council for Science (ICSU), 5 rue Auguste Vacquerie, 75116 Paris, France.

Hoesung Lee (Republic of Korea) is the Chair of the Intergovernmental Panel on Climate Change (IPCC). He is a professor of economics of climate change, energy and sustainable development at Korea University's Graduate School of Energy and Environment in the Republic of Korea. He serves on various boards including as executive member of the Korean Academy of Environmental Sciences; a member of the Asia Development Bank President's advisory board, a council member of the Global Green Growth Institute and an editorial board member of UK-based journal *Climate Policy*. Hoesung Lee has published extensively in the field of energy and climate change. He was the founding president of the Korea Energy Economic Institute and the former president of the International Association for Energy Economics. Professor Lee has been involved in the IPCC in various capacities including as Vice-Chair and Working Group III Co-Chair since its Second Assessment Report of 1992. He obtained a bachelor's degree in economics at Seoul National University in 1969 and received his PhD in economics at Rutgers University (USA) in 1975. Among his major publications are: (co-authored with Jin-Gyu Oh): "Mitigation initiatives: Korea's experiences", in: *Climate Policy*, 2,2-3 (2002); (with Dennis Eklof): "Refining in the Far East: Its Potential and Constraints", in: *The Energy Journal*, 15 (1994); (Ed.): *The Role of Technology Transfer in Coping with Global Warming: The Case of Korea* (Seoul: Korea Energy Economics Institute, 1993); "Energy outlook and environmental implications for Korea", in: *Energy*, 16,11-12 (1991); "Korea's energy outlook", in: *Energy*, 6,8 (1981); (with Paul Davidson, Laurence H. Falk): "Oil: Its Time Allocation and Project Independence", in: *Brookings Papers on Economic Activity*, 2 (1974): 411-448; (with E. Haites): "Review of IPCC Working Group III Findings on the Impacts of Energy Policy Options on GHG Emissions", in: *Wiley Interdisciplinary Review: Energy and Environment*, 1,1 (2012); (with J. Oh): "Integrating Climate Change Policy with a Green Growth Strategy: the Case of Korea", in Bryce Wakefield (Ed.): *Green Tigers: The Politics and Policy of Climate Change in Northeast Asian Democracies*, Asia Program Special Report (Washington DC: Woodrow Wilson International Center for Scholars, 2010); (with J. Byrne et al.): "Electricity Reform at a Crossroads: Problems in South Korea's Power Liberalization Strategy", in: *Pacific Affairs*, 77,3 (Fall 2004); (with F. Toth, M. Mwandosya, C. Cararro et al.): "Decision-making Frameworks", in: IPCC [B. Metz and O. Davidson] (Eds.): *Climate Change 2001: Mitigation, IPCC Third Assessment* Report, Working Group III (Cambridge: Cambridge University Press, 2001): 601-688; (with Robert T. Watson, John A. Dixon, Steven P. Hamburg, Anthony C. Janetos, Richard H.

Moss et al.): *Protecting Our Planet–Securing Our Future* (United Nations Environment Programme, US National Aeronautics and Space Administration, World Bank, 1998); "Approaches to differentiation for advanced developing countries", in: M. Peterson, M. Grubb (Eds.): *Sharing the Effort: Options for Differentiating Commitments on Climate Change* (London: Royal Institute of International Affairs, 1996): 77-82; IPCC [P. Bruce, E. Haites] (Ed.): *Economics and Social Dimensions of Climate Change: IPCC Second Assessment Report* 1995 (Cambridge: Cambridge University Press, 1996); (with Z. Dadi, Y. Jung, J. Wisniewski, J. Sathaye): "Greenhouse Gas Emissions Inventory and Mitigation for Asia and Pacific Countries", in: *Ambio*, 25,4 (June 1996): 220-228.

Address: Prof. Dr. Hoesung Lee, Chairman, IPCC, c/o World Meteorological Organization, 7bis Avenue de la Paix, C. P. 2300, CH-1211 Geneva 2, Switzerland.

Paul Raskin (United States of America) is the founding President of the Tellus Institute, Boston, Massachusetts, and Director of the Great Transition Initiative. Born in Chicago in 1942, he was raised in California, receiving a BA in physics and philosophy in 1964 from the University of California, Berkeley, where his senior thesis was supervised by philosopher of science Paul Feyerabend. He earned a PhD in theoretical physics from Columbia University in 1970, and taught at university level, becoming Chair of an interdisciplinary department at the State University of New York at Albany in 1974. In 1976, he co-founded the Tellus Institute, a non-profit research and policy organization, where he has directed an interdisciplinary team working on environmental, resource, and development issues throughout the world. He also founded the US Centre of the Stockholm Environment Institute in 1989, the Global Scenario Group in 1995, and the Great Transition Initiative (GTI) in 2003. The overarching theme of Dr. Raskin's research has been the development of scientifically-based visions and strategies for a transformation to resilient and equitable forms of social development. Toward this larger aim, his research has spanned issues (energy, water, climate change, ecosystems, and sustainable development) and spatial scales (local, national, and global). He has conceived and built widely-used models for integrated scenario planning for energy (LEAP), fresh water (WEAP), and sustainability (PoleStar). His recent research and writing has centred on formulating and analysing long-range, integrated global and regional scenarios, and, in particular, the requirements for a 'Great Transition' to a sustainable, just, and liveable future. Dr. Raskin has published widely, and served as a lead author for the US National Academy of Science's Board on Sustainability, the Intergovernmental Panel on Climate Change, the Millennium Ecosystem Assessment, the Earth Charter, and UNEP's Global Environment Outlook. In 1995, he convened the Global Scenario Group (GSG) to explore alternative futures and their implications for contemporary values, choices, and actions. The GSG's 2002 valedictory essay–*Great Transition: The Promise and Lure of*

the Times Ahead–became the point of departure for the Great Transition Initiative that Dr. Raskin launched in 2003 and continues to direct, which engages an eminent network of hundreds of international scholars and activists in research, publications, and public outreach. His publications include: *Great Transition: The Promise and Lure of the Times Ahead* (Boston: Stockholm Environment Institute, 2002); "Contours of a Resilient Global Future", in: *Sustainability*, 6 (2014): 123-135; "The Century Ahead: Searching for Sustainability", in: *Sustainability*, 2,8 (2010): 2626-2651; "World Lines: A Framework for Exploring Global Pathways", in: *Ecological Economics*, 65,3 (2008): 461-470; "Scenes from the Great Transition", in: *Solutions*, 3,4 (2012): 11-17; "Global Scenarios: Background Review for the Millennium Ecosystem Assessment", in: *Ecosystems*, 8 (2005): 133-142; "Imagine All the People: Advancing a Global Citizens Movement", in: *Development*, 54 (2011): 287-290; "Future", in: Willis Jenkins (Ed.): *Encyclopedia of Sustainability: The Spirit of Sustainability* (Great Barrington, MA: Berkshire, 2010); "Planetary Praxis: Rhyming Hope and History", in: Stephen R. Kellert; James Gustave Speth (Eds.): *The Coming Transformation: Values to Sustain Human and Natural Communities* (New Haven: Yale University, 2009); "The Problem of the Future: Sustainability Science and Scenario Analysis", in: *Global Environmental Change*, 14 (2004): 137-146; *Global Environmental Outlook Scenario Framework* (Nairobi: United Nations Environment Programme, 2002); *Global Sustainability: Bending the Curve* (London: Routledge, 2002); *Halfway to the Future: A Reflection on the Global Condition* (Boston: Tellus Institute, 2002); *Bending the Curve: Toward Global Sustainability*. Second Report of the Global Scenario Group (Stockholm: Stockholm Environment Institute, 1998); "Windows on the Future: Global Scenarios and Sustainability", in: *Environment Magazine*, 40,3 (April 1998): 6-11; "Global Energy, Sustainability and the Conventional Development Paradigm", in: *Energy Sources*, 20 (1998): 363-383; *Water Futures: Assessment of Long-Range Patterns and Problems Perspectives* (Stockholm: Stockholm Environment Institute–United Nations, 1997); *Branch Points: Global Scenarios and Human Choice* (Stockholm: Stockholm Environment Institute, 1997). See his recent Tellus publications at: <http://www.tellus.org/tellus/author/paul-raskin>.

Sophie Adams (Australia) has a background in Development Studies and works with the German organization *Climate Analytics*. She is currently based in Sydney, Australia, and is completing doctoral research on community participation in climate change policy-making.

Address: Ms Sophie Adams, School of Social Sciences, Morven Brown Building, The University of New South Wales, Sydney, Australia.
Email: <s.m.adams@unsw.edu.au>.

Monica de Andrade (Brazil) holds a PhD and a Master's in Ecology and Natural Resources and diplomas in Biological Sciences. She is based at the Health Promotion Graduate Programme, University of Franca, Brazil, responsible for research projects about the role of environmental hazards on human health, including correlation between deforestation and emergent diseases, extreme weather and water-related diseases and cardiovascular disease. Since 2006, she has been advisor on more than twenty Master's theses. She has also worked as a consultant for national organizations and is a Visiting Professor at the University of Costa Rica. Recent publications include: "The role of land use and land cover changes in epidemiology of Hantaviruses in Minas Gerais, Brazil"; "The role of land use and land cover changes in epidemiology of Brazilian Spotted Fever in São Paulo, Brazil"; "The impacts of natural disasters on Brazilian public health. Dry eye as an environmental disease".

Lourdes Arizpe (Mexico) received an MA from the National School of History and Anthropology in Mexico in 1970; a PhD in Anthropology from the London School of Economics and Political Science, UK, in 1975; and an Honorary Doctorate from the University of Florida at Gainesville in 2010. She is a professor at the Regional Center for Multidisciplinary Research of the National University of Mexico. Her early anthropological studies were focused on migration, gender, rural development, and the human dimensions of environmental change. Professor Arizpe received a Fulbright grant in 1979 and a John F. Guggenheim grant in 1981. Elected President of the International Union of Anthropological and Ethnological Sciences in 1988, she became a member of the United Nations Commission on Culture and Development in 1990 and soon afterwards was designated Assistant Director General for Culture at UNESCO 1994-98. As President of the International Social Science Council 2004-2008, and the Academic Faculty of the Global Economic Forum at Davos, Switzerland 2000-2004, she participated in projects to further policy-oriented studies on culture and sustainability. At the United Nations Institute for Research on Social Development, she was Chair of the Board 2005-2011 and a member of the United Nations Committee for Development Policy of the Economic and Social Council (ECOSOC). Her major studies were published in three volumes by Springer-Verlag in 2014-15 and may be consulted at <http://www.afes-pressbooks. de/html/SpringerBriefs_ ESDP06.htm> and <http://www. afes-press-books.de/html/SpringerBriefs_PSP_Arizpe. htm>.

Karoline Augenstein is a Research Fellow at the Wuppertal Institute for Climate, Environment and Energy. Her background is in political science and economics. She completed her BA in European Studies at the University of Maastricht and her MA in Sustainability Economics and Management at the University of Oldenburg. Since 2010, she has worked as scientific assistant to the management board at the Wuppertal Institute and in 2014 completed her PhD at the University of Wuppertal. Her main research interest is in sustainable system innovations in various fields, narrative approaches in sustainability transitions research, and concepts of transdisciplinary research for sustainability. Among her publications on this theme are: Schneidewind, Uwe; Singer-Brodowski, Mandy; Augenstein, Karoline, 2016: "Sustainability and Science Policy", in: Heinrichs, Harald et al. (Eds.): *Sustainability Science*, Springer Science, Dordrecht, 149-160; Schneidewind, Uwe; Augenstein, Karoline, 2012: "Analyzing a transition to a sustainability-oriented science system in Germany", in: *Environmental Innovation and Societal Transitions*, 3: 16-28.

Address: Dr. Karoline Augenstein, Wuppertal Institute for Climate, Environment and Energy, Döppersberg 19, 42103 Wuppertal, Germany.

Xuemei Bai (Australia/China) is a Professor of Urban Environment and Human Ecology at Fenner School of Environment and Society, Australian National University. She obtained her bachelor's degree in science from Peking University, and her Master's in engineering and PhD from the University of Tokyo. Prior to joining ANU, she worked at ecology and environmental research institutes in Japan and at CSIRO in Australia, and was a Visiting Professor at Yale University for two years. Her current research interests include: drivers and impacts of urbanization, cities as complex social ecological systems, evolution of urban environment and urban systems, urban metabolism, cities and climate change, and system innovation and sustainability transition/transformation, as well as broader Anthropocene futures and the sustainability agenda. She is a member of the Science Committee of Future Earth, and served as a vice chair of the International Human Dimensional Programme of Global Change (IHDP). She serves on the editorial board of several international journals including *Current Opinion of Environmental Sustainability*; *Sustainability Science*; *Environment, Computer, Environment and Urban Systems*; etc. Selected academic journal publications include: "Realizing China's Urban Dream" (2014), in: *Nature*, 509: 158–160; "Landscape Urbanization and Economic Growth" (2012), in: *Environmental Science & Technology*, 46,1: 132–139; "Plausible and Desirable Futures in the Anthropocene" (2015), in: *Global Environmental Change*, <doi:1 0.1016/ j.gloenvcha.2015.09.017>; "Urban Sustainability Experiments: Patterns and Pathways" (2012), in: *Environmental Science & Policy*, 13: 312–325; "Global Change and the Ecology of Cities" (2008), in: *Science*, 319: 756–760.

Address: Prof. Dr. Xuemei Bai, Fenner School of Environment and Society, College of Medicine, Biology and Environment, Frank Fenner Building, The Australian National University, Canberra 2601, Australia.

Lucy Baker (United Kingdom) is a Research Fellow in the Science Policy Research Unit at the University of Sussex and a Visiting Fellow at the Energy Research Centre, University of Cape Town. Between 2013 and 2015 Lucy was a Research Fellow in the School of Global Studies, University of Sussex on an ESRC-funded project, *Rising powers and the low carbon transition in Southern Africa*. Lucy's areas of research include: the political economy of energy; electricity policy in South Africa; sociotechnical transitions; and low-carbon development in low- and middle-income countries. Lucy holds a PhD in *The political economy of sociotechnical transitions in South Africa's electricity sector* from the University of East Anglia, UK, an MSc in Development Studies from the School of Oriental and African Studies, and an MA in Hispanic Studies and French from the University of Edinburgh. Prior to joining academia she worked for ten years in the fields of environment, development and human rights as a policy officer and campaigner with non-governmental organizations Amnesty International, Oxfam and the Bretton Woods Project. A native speaker of English, she is fluent in Spanish, Portuguese and French.

Address: Dr. Lucy Baker, Science Policy Research Unit, University of Sussex, Sussex House, Falmer, Brighton, BN1 9RH.
Contact details: <L.H.Baker@sussex.ac.uk>.

Larissa Basso (Brazil) is currently a PhD candidate in International Relations at the University of Brasília and a researcher at the *Brazilian Federal Agency for Support and Evaluation of Graduate Education* (CAPES). She is also a member of the *Brazilian Research Network on International Relations and Climate Change* (Redeclim). She holds Bachelor of Laws–LLB (2003) and Master's in International Law–LLM (2008) degrees from the University of Sao Paulo, and an MPhil in Environmental Policy (2010) from the University of Cambridge. She is also a Graduate Teaching Assistant in the Institute of International Relations, University of Brasília, and an Attorney-at-Law since 2004 (legal consulting and litigation). She has researched extensively on international trade and development; since 2009, her main research interests are sustainable development, environmental governance, and climate change and global energy governance in the transition to low-carbon development.

Address: Ms Larissa Basso, Institute of International Relations, University of Brasília (Campus Darcy Ribeiro, Caixa Postal: 04306, CEP: 70904-970, Brasília – DF, Brazil).

Hans Günter Brauch (Germany), Privatdozent (Adj. Prof.) at the Faculty of Political Science and Social Sciences, Free University of Berlin (ret.), since 1987 chairman of *Peace Research and European Security Studies* (AFES-PRESS). See *Biographies of editors*.

Hongmin Chen (China) holds a PhD in population, resources and environmental economics. She is an associate

professor in the Department of Environmental Science and Engineering at Fudan University and a researcher in the Fudan Urban Environmental Management Research Center and Fudan Tyndall Center. Her research interests focus on the transformation towards a low-carbon society. Her current research covers a range of topics including trade-embodied CO2 emissions and high-emission groups and their role in accelerating the transition towards a low-carbon society. Recent publications include: *Energy and Environmental Impacts of China's International Trade: A Research on Embodied Flows* (in Chinese, Shanghai: Fudan University Press, 2011); (co-authored with Xingyi Dai et al.): 2050 *Shanghai Low Carbon Development Roadmap Report* (in Chinese, Beijing: Science Press, 2011); "Development and Prospect of Personal Carbon Trading Research", in: *China Population, Resources and Environment*, 24, 9 (2014): 30–36; (with Yanni Zhu and Miaojing Lu): "Identification and Analysis of High-Emission Commuter Groups in Shanghai" (in Chinese), in: *Resources Science*, 36,7 (2014): 1469–1477; (with Miaojing Lu): "Review of the Inequality of Carbon Emissions" (in Chinese), in: *Resources Science*, 35,8 (2013): 1617–1624; (with Jing Chen): "Energy Consumption Differences in Different Income Groups: The Case Study of Shanghai" (in Chinese), in: *Population and Development*, 18,4 (2012): 30-38.

Address: Dr. Hongmin Chen, 220 Handan Road, Department of Environmental Science and Engineering, Fudan University, 200433, Shanghai, China.

Peter T. Coleman (USA) holds a PhD in Social/Organizational Psychology from Columbia University and is a Professor of Psychology and Education at Columbia University with a joint appointment at Teachers College and The Earth Institute and teaches courses in Conflict Resolution, Social Psychology, and Social Science Research; Director of the *Morton Deutsch International Center for Cooperation and Conflict Resolution* (MD–ICCCR) at Teachers College, Columbia University; Chair of Columbia University's *Advanced Consortium on Cooperation, Conflict, and Complexity* (AC4); research affiliate of the *International Center for Complexity and Conflict*, The Warsaw School for Social Psychology in Warsaw, Poland. He currently conducts research on optimality of motivational dynamics in conflict, power asymmetries and conflict, intractable conflict, multicultural conflict, justice and conflict, environmental conflict, mediation dynamics, and sustainable peace. In 2003, he became the first recipient of the Early Career Award from the American Psychological Association, Division 48: Society for the Study of Peace, Conflict, and Violence. He has edited: *Handbook of Conflict Resolution: Theory and Practice* (2000; 2006; 2014); *The Five Percent: Finding Solutions to Seemingly Impossible Conflicts* (2011); *Conflict, Justice, and Interdependence: The Legacy of Morton Deutsch* (2011); *Psychological Components of Sustainable Peace* (2012); *Attracted to Conflict: Dynamic Foundations of Destructive Social Relations* (2013); and *Making Conflict Work: Harnessing the Power of Disagreement* (2014). He has authored over seventy journal articles and chapters, and is a member of the United Nation Mediation Support Unit's Academic Advisory Council, a founding board member of the Leymah Gbowee Peace Foundation USA, and a New York State certified mediator and experienced consultant.

Address: Prof. Peter T. Coleman, Director, *Morton Deutsch International Center for Cooperation and Conflict Resolution*; Professor of Psychology and Education. Program in Social-Organizational Psychology, Department of Organization and Leadership, Teachers College, Columbia University, Box 53, 525 West 120th Street, New York, NY 10027, USA; Co-Director, Advanced Consortium for Cooperation, Conflict, and Complexity (The Earth Institute at Columbia University), New York, NY, USA.

Simon Dalby (Canada/United Kingdom/Ireland), Professor, formerly at Carleton University, is now CIGI Chair in the Political Economy of Climate Change at the Balsillie School of International Affairs and Professor of Geography and Environmental Studies at Wilfrid Laurier University, Waterloo, Ontario. He is author of *Creating the Second Cold War* (Pinter 1990), *Environmental Security* (University of Minnesota Press, 2002) and *Security and Environmental Change* (Polity, 2009). His articles have appeared in various scholarly journals including *Alternatives, Antipode, Australian Journal of International Affairs, Contemporary Security Policy, Geoforum, Geopolitics, Global Environmental Politics, Global Policy, Intelligence and National Security, International Politics, Political Geography, Society and Space* and *Studies in Political Economy*.

Address: Prof. Simon Dalby, Balsillie School of International Affairs, 67 Erb Street West, Waterloo, ON N2L 6C2, Canada.
Email: <sdalby@gmail.com>.
Website: <http://www.balsillieschool.ca/people/simon-dalby>.

Morton Deutsch (USA) is E. L. Thorndike Professor and Director Emeritus of the *Morton Deutsch International Center for Cooperation and Conflict Resolution (*MD–ICCCR) at Teachers College, Columbia University. He studied with Kurt Lewin at MIT's Research Center for Group Dynamics, where he obtained his PhD in 1948. He is well-known for his pioneering studies in intergroup relations, cooperation–competition, conflict resolution, social conformity, and the social psychology of justice. His books include *Interracial Housing, Research Methods in Social Relations, Preventing World War III: Some Proposals, Theories in Social Psychology, The Resolution of Conflict, Applying Social Psychology*, and *Distributive Justice*. His work has been widely honoured by the Kurt Lewin Memorial Award, the G. W. Allport Prize, the Carl Hovland Memorial Award, the AAAS Socio-Psychological Prize, APA's Distinguished Scientific Contribution Award, SESP's Distinguished Research Scientist Award, and the Nevitt Sanford Award. He is a William James Fellow of APS. He has also received lifetime achievement awards for his work on conflict management, cooperative learning, peace psychology, and applications of psychology to social issues. In addition, he has received the Teachers College Medal for his contri-

butions to education, the Helsinki University medal for his contributions to psychology, and the doctorate of humane letters from the City University of New York. He has been president of the Society for the Psychological Study of Social Issues, the International Society of Political Psychology, the Eastern Psychological Association, the New York State Psychological Association, and several divisions of the American Psychological Association. It is not widely known, but after postdoctoral training, Deutsch received a certificate in psychoanalysis in 1958 and conducted a limited practice of psychoanalytic psychotherapy for more than twenty-five years.

Address: Prof. Morton Deutsch, *Morton Deutsch International Center for Cooperation and Conflict Resolution.* Professor of Psychology and Education. Program in Social-Organizational Psychology, Department of Organization and Leadership, Teachers College, Columbia University, Box 53, 525 West 120th Street, New York, NY 10027, USA.

Eckart Ehlers (Germany) received his PhD (1965) and his Habilitation (1970) in geography from the University of Tübingen. After appointments as Professor of Geography in Gießen (1970–1972) and Chair of the Department of Geography in Marburg (1972–1986), he accepted an offer from the University in Bonn in 1986, where he retired as Professor Emeritus in 2004. In 1996 the *Deutsche Forschungsgemeinschaft* (DFG) appointed him as chair of the newly-created *Nationales Kommittee für Global Change Forschung* (NKGCF), a position he held until 2002. Internationally, he served as Secretary General and Treasurer of the *International Geographical Union* IGU (1992–2000), as Chair of the *International Human Dimensions of Global Environmental Change Programme* IHDP (1996–1999), and as a member of the Scientific Steering Committee of START between 2007 and 2013. Since 2007 he has been on the Board of Trustees of the *International Foundation for Science* (IFS) in Stockholm. He is a member of *Academia Europaea* and Senior Fellow at the *Center for Development Research/Zentrum für Entwicklungsforschung* (ZEF) at the University of Bonn. In 2008, he published: *Das Anthropozän. Die Erde im Zeitalter des Menschen*, summarizing his plea for interdisciplinarity and integrative research with a specific focus on the interrelationships between nature and society.

Address: Prof. Dr. Eckart Ehlers (Em.), ZEF, Walter-Flex-Str. 3, 53113 Bonn, Germany.

Rebecca Froese (Germany) is a Research Assistant in the *Research Group on Climate Change and Security* (CLISEC) at Hamburg University and a Master's student in the programme "Integrated Climate System Sciences" at the Cluster of Excellence "Integrated Climate System Analysis and Prediction" (CliSAP) at Hamburg University. She com-

pleted her bachelor's degree in Geoscience at the University of Bremen and at the University of Victoria, Canada, focusing on geochemistry, oceanography and climatology. After graduating in 2013 she spent six months in Brazil, working as an intern for the GIZ (German Society for International Development). Currently she is writing her Master's thesis on the topic of climate-proof development cooperation.

Address: Ms Rebecca Froese, Grindelberg 7, 20144 Hamburg, Germany.
Email: <rebecca.froese@studium.uni-hamburg.de>.

Audley Genus (United Kingdom), Professor at the Small Business Research Centre, Kingston University, Kingston Hill, Kingston upon Thames, has research interests in the areas of innovation and entrepreneurship, technology policy, and new approaches for stimulating 'green' innovation in firms and communities. Current projects include an investigation into the nature of institutional innovation and entrepreneurship in community energy initiatives and the emergence of permaculture-inspired small firms. Audley publishes regularly in high-impact journals such as *Research Policy* and *Technological Forecasting and Social Change* and has published three single-authored books. He is currently working on a book entitled *Sustainable Consumption: Design, Innovation and Practice*, to be published by Springer in 2016. Audley is a member of the editorial board of *Technology Analysis and Strategic Management* and a member of the *European Association for the Study of Science and Technology* (EASST), the *British Academy of Management*, and the *Sustainable Consumption Action Research Initiative*.

Address: Prof. Audley Genus, YTL Professor of Innovation and Technology Management, Small Business Research Centre, KHBS410 Kingston Business School, Kingston University, Kingston Hill, Kingston upon Thames, Surrey, KT2 7LB, UK.
Email: <a.genus@kingston.ac.uk>.
Website: <http://business.kingston.ac.uk/staff/professor-audley-genus>.

John Grin (The Netherlands) is Professor at the Department of Political Science of the University of Amsterdam and was scientific director to the *Amsterdam School for Social Science Research* (ASSR). See *Biographies of editors*.

Sander Happaerts (Belgium) was until September 2014 research manager for environmental policy and sustainable development at HIVA (*Research Institute for Work and Society*), University of Leuven, Belgium. He is also a part-time Assistant Professor at Leuven International and European Studies, University of Leuven, Belgium. His expertise is situated in the fields of sustainable development, transitions and sustainable materials management. Between 2007 and 2011, Sander conducted PhD research into governance for sustainable development. His PhD was awarded in the Thesis Competition of the EU Committee of the Regions. He

has published extensively on the sustainable development policies of subnational governments, on their embedding in national and international governance, and on symbolic politics. In 2010, he held a Visiting Fellowship at the *Université du Québec à Montréal* (UQÀM, Canada), where he became the Social Responsibility and Sustainable Development Research Chair. After completing his chapter, he took up a position at the European Commission. The information and views set out in this chapter are those of the author and do not reflect the official opinion of the European Commission.

Address: KU Leuven, Leuven International and European Studies, Parkstraat 45 box 3600, 3000 Leuven, Belgium
Email: <sander.happaerts@kuleuven.be>.
Website: <http://soc.kuleuven.be/lines>.

Karlson 'Charlie' Hargroves (Australia) holds a Bachelor of Engineering degree and has a PhD in low-carbon transitions and carbon structural adjustment. He is an internationally renowned sustainability transitions researcher, strategist and author, who has co-authored five books, numerous chapters and papers, and delivered over fifty keynote presentations and guest lectures around the world. His first book, 'The Natural Advantage of Nations', won the Australian Banksia Award for Environmental Leadership, Education and Training in 2005, and the two published in 2010 were ranked among the 'Top Forty Sustainability Books' in the world that year by the Cambridge Programme for Sustainability Leadership (with 'Cents and Sustainability' ranked fifth and 'Factor 5' ranked twelfth). He is a Senior Research Fellow at the *Curtin University Sustainability Policy* (CUSP) Institute, working with Professors Peter Newman and Dora Marinova, and is the Sustainable Development Fellow at the University of Adelaide. He has a focus on low-carbon transitions and works on a series of national and international projects and publications. He is a full member of the Club of Rome. He lives in Adelaide and he and his wife, Stacey, have two children, Grace and Tyson. Recent related publications include: (with Desha): *Higher Education & Sustainable Development: A Model for Curriculum Renewal* (London: Earthscan/Routledge Publishing 2014); (with Smith and Desha): *Cents and Sustainability: Securing Our Common Future through Decoupling Economic Growth from Environmental Pressure* (London: Earthscan/Routledge Publishing 2010); (with von Weizsäcker, Smith, Desha and Stasinopolous): *Factor 5: Transforming the Global Economy through 80% Increase in Resource Productivity* (London: Earthscan/Routledge Publishing 2010); (with von Weizsäcker, de Larderel, Hudson, Smith, and Rodrigues): *Decoupling 2: Technologies, opportunities and policy options* (Nairobi/Paris: UNEP 2014).

Address: Karlson 'Charlie' Hargroves, Curtin University, Perth, Australia.

Mike Hodson (United Kingdom) is Research Fellow at the University of Manchester, where he is based jointly in the *Sustainable Consumption Institute* (SCI) and the *Manchester Institute of Innovation Research* (MIoIR). Mike was previously Senior Research Fellow at Salford University, where he spent a decade in the *Centre for Sustainable Urban and Regional Futures* (SURF) working in the area of urban and regional governance and transitions. He has published and presented widely on this research agenda. His developing research interests are at the interface of systemic transitions and territorial transitions and the ways in which relationships between the two are, are not and can be organized.

Address: Dr. Mike Hodson, Sustainable Consumption Institute (SCI) & Manchester Institute of Innovation Research (MIoIR), Harold Hankins Building, Room 8.15, University of Manchester, Manchester M13 9PL, United Kingdom.
Email: <michael.hodson@mbs.ac.uk>
Website: <http://www.sci.manchester.ac.uk/people/dr-mike-hodson>.

Tobias Ide (Germany) is Head of the research field Peace and Conflict at the *Georg Eckert Institute* in Braunschweig and associated researcher in the *Research Group Climate Change and Security*, University of Hamburg. His research on the links between environmental change, resource scarcity, conflict and cooperation has been published in *Global Environmental Change* and *Political Geography*, among other places. He has received various grants from the German Research Foundation (DFG) and the German Environmental Foundation (DBU) for his research.

Address: Dr. Tobias Ide, Celler Straße 3, 38114 Braunschweig, Germany.
Email: <ide@gei.de>.
Website: <http://www.gei.de/en/staff/dr-tobias-ide.html>.

Roeland J. in't Veld (The Netherlands) is UNESCO Professor of Governance and Sustainability at Tilburg University and teaches in postgraduate education. Previously, he was professor at eight European universities (1977-2010). He chaired the National Council on Spatial, Nature and Environmental research in the Netherlands (1999-2009), as well as a project at the *Institute for Advanced Sustainability Studies* (IASS) in Potsdam (2010-2011). He has served as a World Bank and OECD consultant, and as a Director-General for Higher Education. He was Chief Strategist in the Airport Region Haarlemmermeer (2012-2013), and carried out scenario studies on the future sustainable development of the region. He is dedicated to efforts to further social innovation in the Tilburg Region, in particular in the fields of participatory democracy and private–public partnerships. Some of his past positions include supervision both in the private sector (IBM) and the public sector (National Railways Infraprovider). His research focuses on democracy theory, the interface of science and politics, and foresight studies. He is involved in transdisciplinary research on sustainable development and argues that fundamental change towards sustainability demands improvements in the functioning of democratic institutions. He is author, co-author and editor of about thirty books and 110 papers and articles on public choice theory, educational economics, cost-benefit analysis, boundary work and political theory. Recently he has published *Kennisdemocratie* (Den Haag: SDU, 2010), *Knowledge Democracy* (Heidelberg: Springer,

2011) and two chapters in *Transgovernance* (Heidelberg: Springer, 2013).

Address: Prof. Dr. R. J. in't Veld, Waterbieskreek 40, 2353 jh, The Netherlands.
Email: <roelintveld@hotmail.com>.
Website: <www.roelintveld.nl>.

Shivant Jhagroe (The Netherlands) is a researcher at the Eindhoven University of Technology. Shivant graduated in Public Administration and History, and completed his doctoral thesis at the Erasmus University Rotterdam (DRIFT). His (forthcoming) dissertation examines the politics of urban sustainability transitions. His current project studies the transformation of domestic energy practices in the context of smart homes and energy technologies. Shivant's research interests include sustainability transitions, environmental politics, critical urban studies, political philosophy and STS.

Address: Shivant Jhagroe, MSc, MA, Faculty of Industrial Engineering and Innovation Science, Eindhoven University of Technology (TIS). De Rondom 70, 5612 AP Eindhoven, The Netherlands. Room IPO 2.07.
Email: <s.s.jhagroe@tue.nl>.

Twig Johnson (USA) received his MA in 1971, his MPhil in 1974 and his PhD in 1977 in Anthropology from Columbia University, taught in the Anthropology Departments of Queens College, City University of New York and the University of Maine, and spent two years as a Visiting Scientist at *Massachusetts Institute of Technology* (MIT). He has served as a Peace Corps Brazil Volunteer (1964-66) and as its Country Director (1977-78). US Governmental service included Chief of the Studies Division in the US Agency for International Development's Policy and Program Coordination Bureau and Director of Environment and Natural Resources in its Global Bureau. At the UN, he was the Chief of Evaluation for UNICEF. With the *Worldwide Fund for Nature* (WWF) he served as Regional Director for Latin America and as Vice President of WWF/US for Latin America. He also served on the Brazil/World Bank/G8 International Advisory Group for the Amazon. At Earthwatch he was Director of the Center for Field Research. He served on US delegations to UNCED and WCSD as well as taking part in numerous preparatory meetings. In the Policy and Global Affairs Division of the *National Research Council* (NRC), he was responsible for developing a programme on Science, Technology and Sustainability.

Address: Twig Johnson, Writer/Consultant, 29 Wapping Road, Kingston, Massachusetts, 02364 USA.
Email: <twigjohnson@gmail.com>.

J. (Jan) Jonker (The Netherlands/France) is a professor of Sustainable Entrepreneurship at the Nijmegen School of Management at Radboud University Nijmegen. Since 2014 he has also held the Chaire d'Excellence Pierre de Fermat at the Toulouse Business School in Toulouse (France). His research focuses on the interface of sustainability, (new) business models, and transitions. He is the author of the 'green' bestseller *Duurzaam Denken Doen* [*Thinking and Acting in a Sustainable Way*] (Deventer: Kluwer, 2011) and

Werken aan de WEconomy [*Working on the WEconomy*] (Deventer: Kluwer, 2013), among other books, and has recently published *Nieuwe Business Modellen* [*New Business Models*] (The Hague: Academic Service, 2014). As a follow-up to these previous projects, he is now working on a system of Hybrid Banking (see the Dutch website <www.nieuwebusinessmodellen.info>). Dr. Jonker ranked five years in a row (between 2010 and 2014) in the Dutch daily paper *Trouw*'s Top 100 as one of the most influential 'green' people in the Netherlands. In order to keep in touch with everyday practice, he also works as a management consultant, his motto being 'practise what you preach'. According to Dr. Jonker, over the next few years sustainable and responsible entrepreneurship and identifying how to realize fundamental change by organizing in different ways will continue to increase in significance.

Address: Prof. Dr. J. Jonker, Nijmegen School of Management, Radboud University, PO Box 9108, 6500 HK Nijmegen, The Netherlands.
Email: <j.jonker@fm.ru.nl>.
Website: <www.ru.nl/fm>.

René Kemp (The Netherlands) is Professor of Innovation and Sustainable Development at the *International Centre for Integrated Assessment and Sustainable Development* (ICIS) of Maastricht University and a Professorial Fellow of UNU-MERIT. He is a multidisciplinary researcher interested in real-life problems. He has published in innovation journals, ecological economics journals, policy journals, transport and energy journals, and sustainable development journals. He is advisory editor of *Research Policy*, editor of *Sustainability Science* and editor of *Environmental Innovation and Societal Transitions*. His work on technological regime shifts, strategic niche management and sustainability transitions is foundational to the field of sustainability transition studies. He currently works on resource efficiency, transformative social innovation and urban labs.

Address: Prof. Dr. René Kemp, ICIS, Maastricht University, and UNU-MERIT, Boschstraat 24, 6211 AX Maastricht, The Netherlands.
Email: <rkemp@maastrichtuniversity.nl> and <Kemp@merit.unu.edu>.
Website: <http://unu.edu/experts/rene-kemp.html#profile>.

Martin Keulertz (Germany/USA) is a postdoctoral research associate in the Department for Agricultural and Biological Engineering at Purdue University in Indiana (United States). He is part of the core water-energy-food nexus team around Prof. Rabi Mohtar (Texas A&M). Prior to joining Purdue, he received his PhD from King's College, London; in it he analysed the role of water resources in foreign direct investment in African agriculture. During his PhD research, he carried out fieldwork in fifteen MENA and SSA countries to empirically investigate the risks and opportunities of FDI in agriculture. Martin has published several peer-reviewed articles in journals, books and conference proceedings. In 2012, Water International selected his co-authored article on the role of corporates in global 'virtual water' trade as paper of the year. He further led the editing process of the *Handbook of Land and Water Grabs in Af-*

rica: foreign direct investment and food and water security published by Routledge in 2013 and the special issue on The water–food–energy–climate nexus in global drylands in the *International Journal of Water Resources Development* in 2015. His research interests centre around the water–energy–food nexus with reference to the West Asia/North Africa region, 'virtual water', the impact of global economic change on global agricultural trade and food systems, and sub-Saharan African agriculture and water accounting methods.

Address: Dr. Martin Keulertz, Department for Biological and Agricultural Engineering, 225 South University Street, West Lafayette, IN 47907, USA.
Email: <mkeulert@purdue.edu>.
Website: <http://wefnexus.tamu.edu/511-2/>.

Claudia Köhler (Germany) studied sociology and philosophy and earned her MA at Potsdam University in 2004. Since 2008 she has been employed at the *Potsdam Institute for Climate Impact Research* (PIK). Her previous positions were at the Max Planck Institute and the German Institute for International and Security Affairs.

Address: Ms Claudia Köhler MA, Potsdam Institute for Climate Impact Research, Telegraphenberg A 31, P.O. Box 601203, D-14412 Potsdam, Germany.
Email: <koehler@pik-potsdam.de>.
Website: <https://www.pik-potsdam.de/members/ckoehler>.

Dr. Asfaw Kumssa (Sweden) is a Chief Technical Advisor at the Office of the United Nations Resident Coordinator's Office in Nairobi, Kenya. Dr. Kumssa has over twenty years of experience in the field of development studies. Prior to his appointment with the UN Resident Coordinator's Office, Dr. Kumssa, served for sixteen years as the Coordinator of the United Nations Centre for Regional Development Africa Office (UNDESA's Project Office) in Nairobi, Kenya. While in UNCRD, he undertook training-cum-research activities, advisory services, and information exchange related to local and regional development, and assisted African countries in designing and implementing effective and innovative local and regional development policies to address their socio-economic needs and problems. Prior to that, Dr. Kumssa worked as a Regional Economic Development Planner in Nagoya, Japan for four years. From 1992 to 1994, Dr. Kumssa served as an Adjunct Professor of Global Political Economy and Development Economics at the University of Denver, Colorado, USA. Dr. Kumssa holds a PhD and an MA in International Studies, specializing in International Economics (University of Denver, CO, USA); and an MSc in National Economic Planning (Odessa Institute of National Economy, Ukraine). From 1984–1986 he also studied economics at Stockholm University, Sweden. He has published a number of books and articles in the field of urban and regional planning; climate change; globalization; capacity-building and distance training; human security and conflict; refugee issues; police corruption; social development; transitional economies; and other development related subjects.

Address: Dr. Asfaw Kumssa, Office of the United Nations Resident Coordinator's Office in Nairobi, Kenya.

Email: <asfaw.kumssa@undp.org>.

Peter Michael Link (Germany) is a postdoctoral scientist at the *Research Group Climate Change and Security* (CLISEC) at the Institute of Geography of the University of Hamburg, Germany. His main research interest is the numeric modelling of societal and economic impacts of climate change in different regions of the world. He has published numerous journal articles and several edited volumes on the climate change and conflict nexus and on coastal and marine geography. Michael Link is also Speaker of the Working Group on Coastal and Marine Geography of the German Geographical Society and currently a board member of the Coastal and Marine Specialty Group of the American Association of Geography.

Address: Dr. Peter Michael Link, Grindelberg 7, 20144 Hamburg, Germany.
Email: <michael.link@uni-hamburg.de>.
Website: <http://clisec.zmaw.de/Dr-Peter-Michael-Link.868.0.html>

Sylvia Lorek (Germany) holds a PhD in consumer economics diploma in household economics and nutrition (Oecotrophologie) and in economics. The combination of these different disciplines provides her with the tools - the individual micro-economic and the societal macroeconomic perspective - for a well-founded analysis of the contexts in which the scientific and societal discourses about sustainable consumption take place. She is based at the *Sustainable Europe Research Institute* (SERI) and is head of SERI Germany e.V. Here she has worked on studies and as consultant for national and international organizations und institutes. She is also engaged in civil society organization (CSO) activities dealing with sustainable consumption at national, European and global levels. Among other roles,

she is a leading functionary at the *Sustainable Consumption Research and Action Initiative* (SCORAI) in Europe and the Global Research Forum on Sustainable Production and Consumption. Recent publications include: *Towards Strong Sustainable Consumption Governance* (LAP Publishing, Saarbrücken; 2010); *Sustainable Production and Consumption Systems* (co-edited with Lebel and Daniel; Springer, Dordrecht 2010); *Strong Sustainable Consumption Governance—Precondition For A Degrowth Path?* (with Fuchs, 2013); and *Sustainable consumption within a sustainable economy—beyond green growth and green economies* (with Spangenberg, 2014), both published in the *Journal of Cleaner Production*.

Address: Dr. Sylvia Lorek, SERI, Schwimmbadstr. 2e, 51491 Overath, Germany.
Email: <sylvia.lorek@seri.de>.
Website: <http://www.seri.de>.

Simon Marvin (United Kingdom) is Director of the Urban Institute and a Professor in the Department of Geography, Sheffield University. He is interested in developing both conceptual and empirical understanding of the changing relations between sociotechnical networks and urban contexts. To date, he has played major roles within urban research towards addressing important questions surrounding telecommunications, infrastructure and mobility, sustainability and infrastructure, smart, interdisciplinary urban research, and, most recently, cities, systemic transitions, energy and low carbon, climate change and ecological security.

Address: Professor Simon Marvin, Urban Institute, The University of Sheffield, 219 Portobello, S1 4DP, United Kingdom.
Email: <s.marvin@sheffield.ac.uk>.
Website: <http://www.sheffield.ac.uk/urbaninstitute/our-people>.

Czeslaw Mesjasz (Poland), Dr habil., Associate Professor, Faculty of Management, Cracow University of Economics, Cracow, Poland. His research interests include applications of systems approach in management and in international relations, conflict resolution and negotiation, corporate governance, international management, and the links between economics and security. From 1992 to 1996 he was the convener of the Defence and Disarmament Commission of IPRA (*International Peace Research Association*). In 1991-1992 he received a NATO Democratic Institutions Fellowship. In 1992-1993 he was a Visiting Research Fellow at the *Centre for Peace and Conflict Research* in Copenhagen (later COPRI). From 2010 to 2014 he was Secretary of the Research Committee Sociocybernetics (RC51) of the International Sociological Association. He has published some 250 items—two books in Polish, and papers and book chapters in Polish, English, Chinese and Turkish on management, security and related areas. Among his major publications are: "Applications of Systems Modelling in Peace Research", in: *Journal of Peace Research*, 25,3, 1988. He is a co-editor and co-author of the Hexagon Series. His most recent publications are: (co-ed. with Brauch, Oswald Spring, Grin, Kameri-Mbote, Chourou, Dunay, Birkmann): *Coping with Global Environmental Change, Disasters and*

Security—Threats, Challenges, Vulnerabilities and Risks, (Berlin–Heidelberg–New York: Springer, 2011); and "Complex Systems Studies and Terrorism", in: Fellman, Bar-Yam, Minai (Eds.): *Conflict and Complexity. Countering Terrorism, Insurgency, Ethnic and Regional Violence* (New York: Springer, 2015).

Address: Assoc. Prof. dr habil. Czeslaw Mesjasz, Cracow University of Economics, Pl-31-510 Kraków, ul Rakowicka 27, Poland.
Email: <mesjaszc@uek.krakow.pl>
Website: <http://kpz.uek.krakow.pl/portal/pl/user/43> and <http://www.afes-press.de/html/mesjasz_en.html>.

Carl Middleton (United Kingdom/Thailand) is a lecturer on the *MA in International Development Studies* (MAIDS) programme and Deputy Director for International Research in the *Center for Social Development Studies* (CSDS) in the Faculty of Political Science, Chulalongkorn University, Bangkok, Thailand. Before joining the MAIDS programme in 2009, he spent eight years working with international and local civil society organizations throughout the Mekong Region. His research interests are the politics and policy of the environment in South East Asia, with a particular focus on environmental justice and the political ecology of water and energy. He graduated from the University of Manchester, UK, with a bachelor's degree in Civil Engineering, and a Doctorate in Environmental Chemistry. Among his major publications are: Middleton, Carl; Elmhirst, Rebecca; Chantavanich, Supang (Eds.), 2016: *Living With Floods in a Mobile Southeast Asia: A Political Ecology of Vulnerability, Migration and Environmental Change* (London: Earthscan); Middleton, Carl; Dore, John, 2015: "Transboundary Water and Electricity Governance in Mainland Southeast Asia: Linkages, Disjunctures and Implications", in: *International Journal of Water Governance* 3,1: 93-120; Middleton, Carl; Allouche, Jeremy; Gyawali, Dipak; Allen, Sarah, 2015: "The Rise and Implications of the Water-Energy-Food Nexus in Southeast Asia through an Environmental Justice Lens", in: *Water Alternatives* 8,1: 627-54; Middleton, Carl; Matthews, Nathanial; Mirumachi, Naho, 2015: "Whose Risky Business?: Public–Private Partnerships (PPP), Build-Operate-Transfer (BOT) and Large Hydropower Dams in the Mekong Region", in: Matthews, Nathanial; Geheb, Kim (Eds.), 2015: *Hydropower Development in the Mekong Region: Political, Socio-economic and Environmental Perspectives* (London: Earthscan): 127-152; Smits, Mattijs; Middleton, Carl, 2014: "New arenas of engagement at the water governance–climate finance nexus? An analysis of the boom and bust of hydropower CDM projects in Vietnam", *Water Alternatives* 7,3: 561-583.

Address: Carl Middleton, Deputy Director for International Research, *Center for Social Development Studies* (CSDS), Faculty of Political Science, Chulalongkorn University, Henri Dunant Road, Bangkok, 10330, Thailand.
Email: <carl.Chulalongkorn@gmail.com>.

L. (Linda) O'Riordan (Germany/Ireland) is a Professor of Business Studies and International Management and Director of the *KompetenzCentrum for Corporate Social Re-*

sponsibility (KCC) at the FOM University of Applied Sciences in Germany. Dr. O'Riordan researches and writes with a focus on responsible management and sustainable entrepreneurship via an inclusive approach to organizing business in society. She has led an edited book on CSR, *"New Perspectives on Corporate Social Responsibility: Locating the Missing Link"*, and her work has been published in peer-reviewed international journals such as the *Journal of Business Ethics*. Dr. O'Riordan lectures mainly at MBA level but also to undergraduate students in subjects such as Business Strategy, Corporate Governance and CSR, International Management, Management Consulting and Problem-Solving. She is a general manager by background, with a PhD from the University of Bradford, UK. Previous to her academic role, she gained business and consultancy experience from working in industry. Some of her past employers include Accenture, UCB–Schwarz Pharma, and the Government of Ireland (Bord Bia), as well as apprenticeship positions during her studies in Ireland at the Irish Telecom Company, Dublin (now Eircom), and the Bank of Ireland, Cork. Her qualifications include a bachelor's degree in Business Studies from the University of Limerick, Ireland, as well as an MBA and a Master's in Research from the University of Bradford in the UK.

Address: Professor Dr. Linda O'Riordan, FOM University of Applied Sciences, Leimkugelstraße 6, 45141 Essen, Germany.
Email: <linda.oriordan@fom.de>.

Úrsula Oswald Spring (Mexico), Research Professor at the National University of Mexico (UNAM), in the Regional Multidisciplinary Research Center (CRIM) in Cuernavaca. See *Biographies of editors.*

Ilona Magdalena Otto (Germany) is a researcher at the *Potsdam Institute for Climate Impact Research* (PIK). She obtained a PhD in resource economics at Humboldt University, Berlin, where she teaches climate management and advanced research methods. In her research she investigates coordination mechanisms for the provision of public and common resources such as biodiversity and water. She is interested in combining different research methods and approaches to assess the socio-economic impacts of climate change.

Address: Dr. Ilona Magdalena Otto, Potsdam Institute for Climate Impact Research, Telegraphenberg A 31, P.O. Box 601203, D-14412 Potsdam, Germany.
Email: <ilona.otto@pik-potsdam.de>.
Website: <https://www.pik-potsdam.de/members/banaszak/>.

Bonno Pel (The Netherlands) is a postdoctoral researcher at the *Centre d'Etudes du Développement Durable* of the *Université Libre de Bruxelles* (Belgium). After graduating in environmental planning and sociopolitical philosophy at the University of Amsterdam, he completed a dissertation on system innovation in-the-making at the Erasmus University of Rotterdam in 2012. Bonno specializes in the governance and politics of system innovations and transitions,

with a specific interest in mobility issues. Currently he is researching social innovation processes in the context of societal transformations.

Address: Dr. Bonno Pel, Institut de Gestion de l'Environnement et d'Aménagement du Territoire (IGEAT), Room DB.6.250, Université Libre de Bruxelles, 50 avenue FD Roosevelt, 1050 Bruxelles, Belgique.
Email: <Bonno.Pel@ulb.ac.be>.
Website: <http://igeat.ulb.ac.be/fr/equipe/details/person/bonno-pel/>.

Radhika Perrot (South Africa) is senior researcher at the *Mapungubwe Institute for Strategic Reflection* (MISTRA) in South Africa. She is currently based in Johannesburg, and is completing doctoral research on firm innovation in alternative energy systems, from UNU–MERIT, the Netherlands. She has researched and worked on various issues and topics around renewable energy, including feed-in policies and sociotechnological factors behind solar PV, wind and hydrogen-fuel cells innovation, and understanding market competition and firm strategies in industry and global markets. Radhika has authored and co-authored a number of articles, book chapters, and media articles on innovation, green economy, sustainable energy and technologies, and climate change.

Address: Ms Radhika Perrot, MISTRA, PostNet Suite 586, Private Bag X29, Gallo Manor, Johannesburg 2052, South Africa.
Email: <radhika.perrot@gmail.com>.
Website: <www.mistra.org.za>.

Martin F. Price (United Kingdom) has been Director of the *Centre for Mountain Studies* (CMS) at Perth College, University of the Highlands and Islands (UHI), UK since 2000; since 2009, Chairholder of the UNESCO Chair in Sustainable Mountain Development; and since 2013, Adjunct Professor at the University of Bergen, Norway. He has a PhD in Geography from the University of Colorado at Boulder and was appointed Professor of Mountain Studies by UHI in 2005. He worked previously at the University of Oxford; the University of Bern, Switzerland; and the National Center for Atmospheric Research, USA. The primary emphasis of his research has been on mountain people and environments; he has acted as a consultant on mountain issues to many international organizations. In 2012, the King Albert I Memorial Foundation awarded him the King Albert Mountain Award: the citation states that "Martin Price, with his exceptional knowledge and his editorial competence, has played a vital role for the mountains of the world". Further emphases of his work have been on interdisciplinary research and the human dimensions of global (environmental) change, beginning with his experience as the Secretary of the International Social Science Council's Standing Committee on the Human Dimensions on Global Change in 1989–90, which produced the first global framework for research on this topic. See his publications at: <http://www.perth.uhi.ac.uk/subject-areas/centre-for-mountain-studies/staff/professor-martin-price>.

Address: Prof. Martin F. Price, Director, Centre for Mountain Studies, Perth College, University of the Highlands and

Islands (UHI), Crieff Road, Perth, PH1 2NX, UK.
Email: < Martin.Price.perth@uhi.ac.uk >.

Britta Rennkamp (Germany/South Africa) is a researcher at the Energy Research Centre and Fellow at the African Climate and Development Initiative, University of Cape Town. She holds a PhD in Science and Technology Policy from the University of Twente, the Netherlands, and a Master's Degree in Latin American Studies from University of Cologne, Germany. Prior to joining the University of Cape Town, Britta worked at the interface of technological innovation and social development in international cooperation for *German International Cooperation* (GIZ) in Brazil. After her return to Germany, she worked as a researcher at one of Europe's leading think tanks on international development, the *German Development Institute* (DIE) in Bonn, for four years. Her research focuses on policy analysis of climate technology, climate change mitigation, and poverty eradication in developing countries. Previous work has analysed renewable energy and nuclear programmes, carbon taxation, and green industrial and innovation policies. She has published various papers and book chapters on the overall question of integrating policies on emissions reductions, energy supply and development in Africa and Latin America.

Address: Britta Rennkamp, PhD, Energy Research Centre, University of Cape Town, Private Bag X3, 7701 Cape Town.
Email: <britta.rennkamp@uct.ac.za>.
Website: <http://www.erc.uct.ac.za>.

Jürgen Scheffran (Germany) is Professor at the Institute of Geography and the *Center for Earth System Research and Sustainability* (CEN), Germany, and Head of the *Research Group Climate Change and Security* (CLISEC) in the CliSAP Cluster of Excellence, Hamburg University. See *Biographies of Editors*.

Hans Joachim Schellnhuber (Germany) has been Director of the *Potsdam Institute for Climate Impact Research* (PIK) since he founded the institute in 1992. He is Professor of Theoretical Physics at the University of Potsdam and External Professor at the Santa Fe Institute, USA, and is Co-Chair of the *German Advisory Council on Global Change* (WBGU). Schellnhuber has authored, co-authored or edited around 300 articles and over fifty books in the fields of condensed matter physics, complex systems dynamics, climate change research, Earth System analysis, and sustainability science. Among his major publications are: (with Coumou, D.; Petoukhov, V.; Rahmstorf, S.; Petri, S., 2014): "Quasi-resonant circulation regimes and hemispheric synchronization of extreme weather in boreal summer", in: *Proceedings of the National Academy of Sciences of the United States of America (PNAS)*, 111, 12331; (with Menck, P.; Heitzig, J.; Kurths, J., 2014): "How Dead Ends Undermine Power Grid Stability", in: *Nature Communications*, 5; (with Rahmstorf, S., 2006): *Der Klimawandel. Diagnose, Prognose, Therapie* (München: C.H. Beck); (with Lenton, T.M., 2007): "*Tipping the scales*. Nature Reports", in: *Cli-

mate Change*, 1, 97; (with Lenton, T.; Held, H.; Kriegler, E.; Hall, J.; Lucht, W.; Rahmstorf S., 2008): "Tipping elements in the Earth's climate system", in: *PNAS*, 105: 1786-1793; (2008): "Global warming: Stop worrying, start panicking?", in: *PNAS*, 105: 14239-14240; (with Hall, J.; Held, H.; Dawson, R.; Kriegler, E., 2009): "Imprecise probability assessment of tipping points in the climate system", in: *PNAS*, 106: 5041-5046; (with Hofmann, M., 2009): "Ocean acidification affects marine carbon pump and triggers extended marine oxygen holes", in: *PNAS*, 106: 3017-3022; (Ed.): "*Tipping Elements in Earth Systems Special Feature*", in: *PNAS*, 106, 20561-20621.

Address: Prof. Dr. Dr. h.c. Hans Joachim Schellnhuber, Potsdam Institute for Climate Impact Research, Telegraphenberg A 31, P.O. Box 601203, D-14412 Potsdam, Germany.
Email: <director@pik-potsdam.de>.
Website: <http://www.pik-potsdam.de/institute/director>.

Philipp Schepelmann (Germany) is Acting Director of the Research Group for Material Flows and Resource Management at the Wuppertal Institute for Climate, Environment and Energy. His academic work focuses on societal and political conditions for successful ecological transition in multilevel governance systems. In particular he explores the use of scientific evidence for steering social and technological innovations in the right direction such as narratives, heuristics, indicators, and appraisal procedures.

Address: Dr. Philipp Schepelmann, Wuppertal Institute for Climate, Environment and Energy, Döppersberg 19, 42103 Wuppertal, Germany.
Email: <philipp.schepelmann@wupperinst.org>.
Website: <http://wupperinst.org/kontakt/details/wi/c/s/cd/89/>.

Janpeter Schilling (Germany) is a Postdoctoral Fellow in the research group Climate Change and Security (CLISEC) at Hamburg University. He is also an Associate at International Alert in London. His previous roles include: Programme Officer in Environment, Climate Change and Security at International Alert, Postdoctoral Research Fellow in Environmental Security at Colgate University in New York, and Research Associate at Hamburg University, where he received his PhD in Geography. Janpeter Schilling has published several journal articles and book chapters on climate change, vulnerability, adaptation, resilience and conflict.

Address: Dr. Janpeter Schilling, Grindelberg 7, 20144 Hamburg, Germany.
Email: <janpeter.schilling@uni-hamburg.de>.
Website: http://clisec.zmaw.de/index.php?id=869

Carl-Friedrich Schleussner (Germany) is a climate scientist currently with *Climate Analytics*, Berlin and the *Potsdam Institute for Climate Impact Research*. He earned a PhD in climate physics, under the supervision of Anders Levermann at the Potsdam Institute for Climate Impact Research, on the stability of the North Atlantic Ocean current system, and he is working on a variety of climate-related topics including stability analysis of tipping elements, cou-

pled socio-ecosphere systems and the Amazonian rainforest.

Address: Dr. Carl-Friedrich Schleussner, Climate Analytics, Friedrichstr 231 - Haus B, 10969 Berlin, Germany.
Email: <carl.schleussner@climateanalytics.org>.
Website: <http://www.climateanalytics.org/the-team/dr-carl-friedrich-schleussner>.

Prof. Dr. Uwe Schneidewind (Germany) is President of the Wuppertal Institute for Climate, Environment, Energy, and Professor of Sustainable Transition Management at the University of Wuppertal. He is a member of the Club of Rome and of the Steering Group of the Sustainability Transitions Research Network. He has been a member of the German Advisory Council on Global Change (WBGU) since 2013. His latest book, "Transformative Wissenschaft" (Transformative Science), analyses the status of sustainability science in the German science system. Among his major recent publications on this theme are: Schneidewind, Uwe; Singer-Brodowski, Mandy; Augenstein, Karoline, 2016: "Sustainability and Science Policy", in: Heinrichs, Harald et al. (Eds.): *Sustainability Science*, Springer Science, Dordrecht, 149–160; Schneidewind, Uwe; Singer-Brodowski, Mandy, 2014: *Transformative Wissenschaft. Klimawandel im deutschen Wissenschafts- und Hochschulsystem* (Marburg: Metropolis); Schneidewind, U. (2013); "Transformative Literacy. Rahmen für den wissensbasierten Umgang mit der 'Großen Transformation'"; in: *GAIA* 22:2, 82–86; Schneidewind, Uwe; Augenstein, Karoline, 2012: "Analyzing a transition to a sustainability-oriented science system in Germany", in: *Environmental Innovation and Societal Transitions*, 3: 16–28.

Address: Prof. Dr. Uwe Schneidewind, President of the Wuppertal Institute for Climate, Environment and Energy, Döppersberg 19, 42103 Wuppertal, Germany.
Email: <uwe.schneidewind@wupperinst.org>.
Website: <http://wupperinst.org/home/>.

Olivia Maria Serdeczny (Germany) earned her MA in Philosophy at the Freie Universität Berlin and currently works as a research analyst at *Climate Analytics*. From 2010 to 2013 she worked as a research analyst for Professor Schellnhuber at the German Advisory Council on Global Change to the Federal Government and at the Potsdam Institute for Climate Impact Research. In 2012 and 2013 she coordinated and co-authored two reports commissioned by the World Bank on climate impacts in a 4°C world.

Address: Olivia Serdeczny, Climate Analytics, Friedrichstr 231 – Haus B, 10969 Berlin, Germany (affiliated to Potsdam Institute for Climate Impact Research, Telegraphenberg A 31, P.O. Box 601203, D-14412 Potsdam, Germany).
Email: <olivia.serdeczny@climateanalytics.org>.
Website: <http://www.climateanalytics.org/the-team/olivia-serdeczny>.

Mandy Singer-Brodowski (Germany) studied educational science at the University of Erfurt and was a founding member of the nationwide network for student initiatives in sustainability in Germany. She was also a member of the German national committee for the implementation of the UN "Decade of Education for Sustainable Development".

She has worked at the Wuppertal Institute for Climate, Environment and Energy from 2012 till 2015. In 2015 she completed her PhD at the Leuphana University of Lüneburg, where she is also a lecturer. At the moment she is scientific coordinator of the Center for Transformation Research and Sustainability at the University of Wuppertal. Her main interests in research are the development of student competency in sustainability projects and transformative learning. Among her major recent publications on this theme are: Schneidewind, Uwe; Singer-Brodowski, Mandy; Augenstein, Karoline, 2016: "Sustainability and Science Policy", in: Heinrichs, Harald et al. (Eds.): *Sustainability Science*, Springer Science, Dordrecht, 149-160; Schneidewind, Uwe; Singer-Brodowski, Mandy, 2014: *Transformative Wissenschaft. Klimawandel im deutschen Wissenschafts- und Hochschulsystem* (Marburg: Metropolis).

Address: Dr. Mandy Singer-Brodowski, Center for Transformation Research and Sustainability (TransZent), University of Wuppertal, Bendahler Str. 31, 42285 Wuppertal, Germany.
Email: <singer@uni-wuppertal.de>.
Website: <http://www.transzent.uni-wuppertal.de/home.html>.

Marit Sjøvaag (Norway) is a political scientist whose main research interest is climate policy both in Norway and internationally. She holds a PhD from the London School of Economics and Political Science. She has also studied mathematics and natural sciences in Oslo, Tromsø and Caen, France, and management and social sciences at the Norwegian Business School and at Sciences-Po, Paris. In the period 2008–2011 she was responsible for the annual Status Report on the implementation of climate policies in Norway at the Norwegian Business School's Center for Climate Strategy. She has written and taught on climate policy, regulatory regimes and democratic processes, and aims to contribute to the transition to a low-carbon society. She currently works with energy and climate issues both in Norway and in an international context, for the environmental organization Bellona. Among her major publications are: (with Nils Erik Bjørgo, Torgeir Ericson, Per Arild Garnåsjordet, Håkon Karlsen, Jørgen Randers, Daniel Rees): *People's opinion of climate policy—Popular support for climate policy alternatives in Norway*, CICERO working paper 2012: 03; *The Study of the European Union from Outside: European Integration Studies in Norway and Iceland 1990–2010*; (with Kjell A. Eliassen, Eirikur Bergmann): in: Eliassen, K.A.; Bindi, F. (Eds.): *Analyzing European Union Politics* (Bologna: Il Mulino).

Address: Dr. Marit Sjøvaag Marino, Bellona, Maridalsveien 17B, 0175 Oslo; and: Boks 2141 Grünerløkka, 0505 Oslo, Norway.
Email: <marit@bellona.no> and <sjovaag@aol.com>.
Website: <http://bellona.org/employee/marit-sjovaag-marino>.

Philipp Späth (Germany) was Assistant Professor at the chair group of environmental governance in the Faculty of the Environment and Natural Resources at Albert-Ludwigs University, Freiburg. He now heads a research project on Smart EcoCities funded by the German Research Foundation (DFG) in the same institute. Trained as a geographer

and political scientist, he obtained a PhD in Science and Technology Studies in 2009. His research is on urban environmental governance, with a particular focus on the governance of sociotechnical change in multilevel governance systems, with the German Energiewende being a primary example. From 2003 to 2009 he was senior researcher at the Inter-University Research Centre for Technology, Work & Culture (IFZ) in Graz, Austria. From 1997 to 2003 he worked as a practitioner in renewable energy projects in Freiburg, Germany. He has published in *Urban Studies, Research Policy, Energy Policy, Transportation Reviews* etc.

Address: Dr. Philipp Späth, Institute of Environmental Social Sciences and Geography, Albert-Ludwigs University Freiburg, Tennenbacherstr. 4, D-79106 Freiburg, Germany.
Email: <spaeth@envgov.uni-freiburg.de>.
Website: <https://www.envgov.uni-freiburg.de/mitarbeiterinnen/philippspaeth-en/>.

Carolyn M. Stephenson (USA) is Associate Professor of Political Science at the University of Hawaii at Manoa, and affiliate faculty member in its Matsunaga Institute for Peace. With a BA from Mt. Holyoke and an MA and PhD from Ohio State, she taught previously at Colgate, where she was Director of Peace Studies. Her current research is on alternative security systems, the role of NGOs at the UN on environment and disarmament, and the UN role in the development of women's rights. Among her major publications are: "Alternative International Security Systems: An Introduction", and "Alternative Methods for International Security: A Review of the Literature"; in: Stephenson, Carolyn (Ed.), 1982: *Alternative Methods for International Security* (Washington DC: University Press of America); "NGOs and the Principal Organs of the United Nations"; in: Taylor, Paul; Groom, A. J. R. (Eds.), 2000: *The United Nations at the Millennium: The Principal Organs* (London: Continuum): 271–294; "Gender Equality and a Culture of Peace"; in: de Rivera, Joseph (Ed.), 2008: *Handbook for Building Cultures of Peace* (New York: Springer): 123–137; "Peace Research/Peace Studies: a Twentieth Century Intellectual History"; in: Denmark, Robert E. (Ed.), 2010: *The International Studies Encyclopedia* (Oxford, UK: Blackwell): 5579–5603; "Women Leaders in the Peace/Anti-War Movements"; in: O'Connor, Karen (Ed.), 2010: *Gender and Women's Leadership*, Volume I (Thousand Oaks, CA: Sage): 279–289.

Address: Prof. Carolyn M. Stephenson, Political Science Department, Saunders 640, 2424 Maile Way, University of Hawaii at Manoa, Honolulu, HI 96825, USA.
Email: <cstephen@hawaii.edu>.

Mark Swilling (South Africa) is Professor of Sustainable Development in the School of Public Leadership, University of Stellenbosch <www.sopmp.sun.ac.za> and Academic Director of the Sustainability Institute <www.sustainabilityinstitute.net>. He is responsible for a Master's and doctoral programme in Sustainable Development delivered at the Sustainability Institute in Stellenbosch, South Africa. He also heads up the TSAMA Hub, a new Centre for the transdisciplinary study of sustainability and complexity at Stellenbosch University <www.tsama.org.za>. The TSAMA Hub hosts a transdisciplinary doctoral programme that involves

collaboration between seven of Stellenbosch University's Faculties. Professor Swilling obtained his PhD from the University of Warwick in 1994. He co-authored with Eve Annecke: *Just Transitions: Explorations of Sustainability in an Unfair World* (Tokyo: United Nations University Press, 2012), runner-up in 2013 for the Harold and Margaret Sprout Award for best environmental governance book. He is also a member of UNEP's International Resource Panel, which addresses the challenge of global transition to more sustainable production and consumption, and he has specific responsibility for coordinating the Cities Working Group.

Address: Professor Mark Swilling, School of Public Leadership, Stellenbosch University, Private Bag X1, Matieland, 7602, South Africa.
Email: <Mark.Swilling@spl.sun.ac.za>.
Website: <www.sopmp.sun.ac.za>.

Cecilia Tortajada (Mexico/Singapore) is a Senior Research Fellow, Institute of Water Policy, Lee Kuan Yew School of Public Policy, National University of Singapore, Singapore. The main focus of her work at present is on the future of the world's water, especially in terms of water, food, energy and environmental security through coordinated policies. She has been an advisor to major international institutions such as FAO, UNDP, JICA, ADB, OECD and IDRC, and has worked in countries in Africa, Asia, North and South America and Europe on water and environment-related policies. She is a member of the OECD Initiative in Water Governance and is engaged in independent studies on the Corporate Social Responsibility of major multinational corporations. She is a past President of the International Water Resources Association (2007–2009) and Editor-in-Chief of the *International Journal of Water Resources Development*. Recent publications include: (co-edited with Biswas, 2015): "*Water Security, Climate Change and Sustainable Development*" (Heidelberg: Springer); (co-authored with Hering, J. G., D. L. Sedlak, A. K. Biswas, C. Niwagaba, and T. Breu, 2015): "The need for local perspectives", in: *Science*; (co-authored with Muller, M., A. K. Biswas, and R. Martin-Hurtado, 2015): "Building Water Security: The Role of Infrastructure in the Anthropocene", in *Science*; (co-edited with Wegerich and Warner, 2014): "'Dark' Side of Water Governance", in: *International Journal of Water Governance*; (co-authored with Joshi and Biswas, 2013): *The Singapore Water Story, Sustainable Development in an Urban City State* (London: Routledge).

Address: Dr. Cecilia Tortajada, IWP, LKYSPP, 469C Bukit Timah Road, Oei Tiong Ham Building, Singapore 259772.
Email: <cecilia.tortajada@gmail.com>.
Website: <http://lkyspp.nus.edu.sg/iwp/>.

Gregory Trencher (USA) holds a PhD in Sustainability Science and is currently an Assistant Professor in Environmental Science and Policy at Clark University. His main field of research examines innovative cases of collaboration between universities, government, industry and civil society to drive societal transformations towards sustainability. In parallel, his research also analyses approaches, impacts and barriers of innovative policies implemented in various C40 cities to advance the energy efficiency of existing commer-

cial buildings. This is conducted with the Tokyo Metropolitan Government Bureau of Environment and C40 Cities Climate Leadership Group London. He recently held a Visiting Assistant Professor appointment at the University of Tokyo Graduate School of Frontier Sciences. Recent publications include: "Policy innovation for building energy efficiency and retrofitting: Approaches, impacts and challenges in ten C40 cities" (submitted to *Local Environment*); "Implementing sustainability co-creation between universities and society: Potential models, challenges and strategies" (submitted to *Sustainability Science*); "The role of students in the co-creation of knowledge and societal transformations towards sustainability: Experiences from Lund, Tokyo and Ohio", in: Leal Filho, W.; Brandli, L. (Eds.): *Engaging Stakeholders in Education for Sustainable Development at the University Level* (Berlin: Springer, 2016); "*University partnerships for co-designing and co-producing urban sustainability*" in: *Global Environmental Change* (2014), 28: 153-165; "Beyond the third mission: Exploring the emerging university function of co-creation for sustainability", in: *Science and Public Policy* (2014), 41,2: 151-179.

Address: Ass. Prof. Dr. Gregory Trencher, Clark University, Department of International Development and Environment. 950 Main Street, Worcester, 01610 Massachusetts, USA.
Email: <gtrencher@clarku.edu>.
Website: <https://www.clarku.edu/faculty/facultybio.cfm?id=992>.

Eduardo Viola (Brazil) has been a Full Professor of International Relations at the University of Brasília since 1993 and senior researcher of the Brazilian Council for Scientific Research (CNPQ) since 1986. He holds a PhD in Political Science from the University of Sao Paulo (1982) and has postdoctoral training in international political economy from the University of Colorado at Boulder. He has also been the coordinator of the *Brazilian Research Network on International Relations and Climate Change* (Redeclim) since 2009. Dr. Viola has been Visiting Professor in several first-rank international universities, among them Stanford, Colorado at Boulder, Notre Dame, Texas at Austin, Amsterdam, Campinas, San Martin and Buenos Aires. He has also taught for some years at the Rio Branco Institute, the Brazilian school for diplomatic training. Prof. Viola has published five books, more than seventy articles in journals and more than forty book chapters on issues of globalization and governance, democracy and democratization in South America, Brazilian foreign policy, international environmental policy and politics and international political economy of climate change. He has published in Portuguese, English, Spanish, French and Italian in thirteen countries. He has more than 2,700 citations in Google Scholar.

Address: Prof. Dr. Eduardo Viola, Institute of International Relations, University of Brasília (Campus Darcy Ribeiro, Caixa Postal: 04306, CEP: 70904-970, Brasília – DF, Brazil).
Email: eduviola@gmail.com.

Sir Robert Worcester (United Kingdom) is Emeritus Chancellor of the University of Kent, and is Visiting Professor and Honorary Fellow at the London School of Economics, Visiting Professor and Fellow of King's College London, Honorary Professor at Warwick University and Adjunct Professor at the University of Kansas. He was Senior Vice President of the International Social Science Council, UNESCO and is Past President of the World Association of Public Opinion Research. Sir Robert was the co-editor and co-founder of the *International Journal of Public Opinion Research* with Professors Elisabeth Noelle-Neumann and Seymour Martin Lipset. In 2015 he was Chairman of the 800th Anniversary Commemoration Committee of the Magna Carta Trust.

Address: Sir Robert Worcester, Allington Castle, Maidstone, Kent, ME16 0NB, UK.
Email: <rmworcester@yahoo.com>.
Website: <http://www.kcl.ac.uk/sspp/departments/icbh/people/worcester/index.aspx>; <http://magnacarta800th.com/magna-carta-today/membership-of-the-magna-carta-800th-committee/>; <http://www.kent.ac.uk/politics/about-us/staff/members/worcester.html>.

Belinda Yuen (Singapore) is with the Lee Kuan Yew Centre for Innovative Cities, Singapore University of Technology and Design. She is a qualified urban planner. Her academic qualifications include: BA (Hons), MA (Town & Regional Planning) and PhD (Environmental Planning). Aside from master planning practice, Belinda has extensive research and publication in spatial planning and urban policy analysis, most recently on planning liveable, sustainable cities. She has been elected President, Singapore Institute of Planners (2005–08) and Vice-President, Commonwealth Association of Planners (South East Asia) (2006–08; 2010–12). Belinda has served on various Singapore urban planning committees, including as Planning Appeals Inspector, and on international advisory committees including the International Advisory Board of the United Nations Global Research Network on Human Settlements (2008–11); United Nations Commission on Legal Empowerment of the Poor Working Group; and on the editorial boards of international journals including *Asia Pacific Planning Review*; *Regional Development Studies*; *Cities*; *Journal of Planning History*; and *Journal of Comparative Asian Development*. She has been a Juror, Shaikh Khalifa Bin Salman Al Khalifa Habitat Award, 2008–2009, and science reviewer of various international multidisciplinary research programmes.

Address: Singapore University of Technology and Design, Singapore.
Email: <Belinda_yuen@sutd.edu.sg>.

Hania Zlotnik (Mexico/US) is currently an independent consultant. She retired in early 2012 from the post of Director of the Population Division of the United Nations. She joined the Division in 1982 and worked previously as Chief of the Mortality and Migration Section and Chief of the Population Estimates and Projections Section. Before joining the United Nations, she served as research associate for the Committee on Population and Demography of the US National Research Council. She holds a PhD in Statistics and Demography from Princeton University and is a graduate of the *Universidad Nacional Autónoma de México*

(UNAM). Her work has spanned the field of demography, covering the analysis of fertility, mortality and migration with especial emphasis on their quantitative aspects. She has prepared manuals on demographic estimation techniques and on the collection of international migration statistics. She has edited or written reports published by the United Nations on a variety of topics, including international migration and development, female migration, levels and trends in urbanization, population distribution and migration, population ageing, health and mortality, and population estimates and projections. Recent publications include: "Population ageing in the context of globalization", in: Diego Sánchez González and Vicente Rodríguez Rodríguez (Eds.): *Environmental Gerontology in Europe and Latin America* (New York: Springer, 2016): 45-72; (with David Bloom; Emmanuel Jimenez): *Seven Billion and Growing: A Twenty-First Century Perspective on Population* (Geneva: World Economic Forum, 2012); "International migration and population ageing", in: *Global Population Ageing: Peril and Promise* (Geneva: World Economic Forum, 2012): 97-102; "Does population matter for climate change?", in: José Miguel Guzmán et al (Eds.): *Population Dynamics and Climate Change* (New York: UNFPA–London: IIED, 2009): 31-44. She has contributed texts to volumes 1 and 5 of the Hexagon Book Series.

Address: 78-06 Kew Forest Lane, Forest Hills, NY 11375, USA.
Email: <hania.zlotnik@hotmail.com>.

Hexagon Series on Human and Environmental Security and Peace (HESP)

This book series includes monographs and edited volumes that cross scientific disciplines and develop common ground among scientists from the natural and social sciences, as well as from North and South, who are addressing common challenges and risks for humankind in the 21ˢᵗ century.

The 'hexagon' represents six key factors contributing to global environmental change—three *nature-induced* or supply factors: *soil*, *water* and *air* (atmosphere and climate), and three *human-induced* or demand factors: *population* (growth), *urban systems* (habitat, pollution) and *rural systems* (agriculture, food). Throughout the history of the earth and of *Homo sapiens* these six factors have interacted. The supply factors have created the preconditions for life, while human behaviour and economic consumption patterns have contributed to its challenges (increase in extreme weather events) and led to fatal outcomes for human beings and society. The series covers the complex interactions among these six factors and their often extreme and sometimes fatal outcomes (hazards/disasters, internal displacement and migrations, crises and conflicts), as well as the crucial social science concepts relevant for their analysis.

Further issues relate to three basic areas of research: the approaches and schools of environment, security, and peace, especially in the environmental security realm and from a human security perspective, will be addressed. The aim of this book series is to contribute to a fourth phase of research on environmental security from the perspective of normative peace research and human security. In this series, the editor welcomes books by natural and social scientists, as well as by multidisciplinary teams of authors. The material should address issues of global change (including climate change, desertification, deforestation), and its impacts on humankind (natural hazards and disasters), on environmentally-induced migration, on crises and conflicts, together with cooperative strategies to cope with these challenges either locally or within the framework of international organizations and regimes.

From a human-centred perspective, this book series offers a platform for scientific communities dealing with global environmental and climate change, disaster reduction, human, environmental and gender security, and peace and conflict research, as well as for the humanitarian aid community and the policy community in national governments and international organizations.

The series editor welcomes brief concept outlines and original manuscripts as proposals. If they are considered of relevance, these proposals will be peer-reviewed by specialists in the field from the natural and the social sciences. Inclusion in this series will also require a positive decision by the publisher's international editorial conference. Prior to publication, the manuscripts will be assessed by the series editor and external peer reviewers.

SpringerBriefs in Environment, Security, Development and Peace

Editor:
Hans Günter Brauch, *AFES-PRESS, Mosbach, Germany*

SpringerBriefs in Environment, Security, Development and Peace (ESDP) present concise summaries of cutting-edge research as well as innovative policy perspectives. The series focuses on the interconnection of new and nontraditional global environmental and development challenges facing humankind that may pose dangers for peace and security in the Anthropocene era of earth history. SpringerBriefs in ESDP publish monographs as well as edited volumes of topical workshops that are peer-reviewed by scholars from many disciplines and from all parts of the world. SpringerBriefs in ESDP will give more "voice" and "visibility" to scientists and innovative political thinkers in developing countries.

The books will be published 8 to 12 weeks after acceptance. Featuring compact volumes of 50 to 125 pages (approx. 20,000–55,000 words), the series covers a wide scope of policy-relevant issues from policy-oriented, to professional and academic perspectives.

SpringerBriefs in ESDP address the "conceptual quartet" among the four research research programmes in the social sciences focusing on *Environment, Security, Development and Peace* as well as the "consilience" between the natural and the social sciences that try to initiate debates and to provide multi-, inter- and transdisciplinary knowledge relevant for coping with the multiple projected impacts of global environmental change.

- Timely reports of state-of-the art analyses (e.g. from earth systems science or analysis, geoecology) and policy assessments dealing with the global challenges facing humankind in the 21st century
- SpringerBriefs in ESDP bridges between new research results offering snapshots of hot and/or emerging topics, literature reviews and in-depth case studies

Briefs will be published as part of Springer's eBook collection, with millions of users worldwide. In addition, Briefs will be available for individual print and electronic purchase. Briefs are characterized by fast, global electronic dissemination, standard publishing contracts, easy-to-use manuscript preparation and formatting guidelines, and expedited production schedules.

Interested? Please send your proposal to:

PD Dr. habil. Hans Günter Brauch

Alte Bergsteige 47, 74821 Mosbach, Germany

hg.brauch@onlinehome.de

Your proposal should consist of the following items: Title, Author(s) information, Abstract, 5 Keywords (would be used when searching your topic on Google or Amazon), Manuscript delivery date, estimated number of pages, concise outline (ca. 200 words), Table of contents. Please allow 1–2 months for the peer review process.
