Global Environmental Change and Sustainability Transition

Over the past three to four decades, global change research communities across the world have been analysing the dramatic global environmental changes related to increasing fossil fuel consumption, accelerated resource use and a growing world population. The international global environmental change research programmes initiated during this time by the *International Council for Science* (ICSU), often in cooperation with the *International Social Science Council* (ISSC) and relevant UN partners, have made major contributions to our understanding of these processes, and to the complex interlinkages between natural and human systems underlying them.

Yet despite the wealth of scientific knowledge produced, and notwithstanding national and global policy efforts, including UN conferences and international agreements, we have only taken small steps—at best— towards the kind of sustainable development called for back in 1986 in the Brundtland Report *Our Common Future* and in *Agenda* 21, adopted at the first summit in Rio de Janeiro in 1992. Our failure to act and the growing exposure to threats this has generated now mean we face the urgent and immensely challenging task of accelerating transformations to a sustainable, peaceful and just world.

In 2015, the world community agreed on an ambitious set of new commitments to end and, indeed, transform, unsustainable business-as-usual policies and practices towards global socio-economic development. At three high-level meetings in the context of the United Nations, governments took remarkable steps forward in the quest for effective solutions to an integrated global agenda of ending poverty, ensuring social and economic development, and protecting our planet. Three new international agreements were adopted: the 2030 *Agenda for Sustainable Development*, including a set of seventeen *Sustainable Development Goals* (SDGs); the *Paris Climate Agreement*; and earlier in the year the *Sendai Framework for Disaster Risk Reduction*.

The hard work of implementing the goals of these agreements—particularly by national policymakers and practitioners—cuts across the substantive issues addressed and is widely accepted as demanding an integrated, multisector, multi-stakeholder approach within which science has a central role to play. This places a significant new demand on the scientific community: to be more immediately impactful, more effective in making a difference to real-world problems by contributing transformative solutions to a series of interconnected challenges, from poverty eradication to food production for a growing world population, from addressing global financial crises and growing levels of social discontent to managing the looming global water crisis and providing sustainable energy for all. And with this demand comes the challenge to change: to work in ways that most scientists have not been trained to work in, and more often than not, are not supported or rewarded for working in.

Taking science into the so-called 'solutions space' calls not only for a reinvigorated interdisciplinarity, one that takes collaboration across the natural, social, human, medical and engineering sciences to a deeper, more meaningful level in which the collective strengths of disciplines are brought to bear on the framing of problems as much as they are on the production of new research insights. It also calls for the kind of boundary-spanning work (and skills) that enables scientists to engage with other knowledge partners—decision-makers, practitioners, business leaders and citizens—in the co-design and co-production of knowledge, policy and practice.

Solutions-oriented science that is global, inter- and transdisciplinary in nature is increasingly supported at the international level, most notably perhaps by initiatives such as *Future Earth*, a global platform for sustainability research established and now governed by an alliance of international organizations including ICSU and the ISSC (see <http://www.futureearth.org>).

This volume on *Sustainability Transition and Sustainable Peace* shares the Future Earth vision. It makes a timely and important contribution to our understanding of the leading role that science can—and must—play in shaping humanity's future on planet Earth.

Paris, France   23 April 2016

Heide Hackmann
Executive Director
International Council for Science (ICSU)

Climate Change and Sustainable Development Goals

This *Handbook of Sustainability Transition and Sustainable Peace* appears at a particularly timely juncture. In December 2015 the global community came together to reach the Paris Agreement on climate change, more far-reaching than many had dared hope. Three months earlier, world leaders adopted the 2030 Agenda for Sustainable Development, comprising seventeen Sustainable Development Goals to end poverty, protect the planet and ensure prosperity for all. Climate action is one of the seventeen, but in fact all of them are affected one way or another by climate change.

2016 therefore is the year that the world begins a process of implementation of these vital agreements. Never before have so many countries sought to undertake such ambitious goals in the economic and development spheres. Decision-making in a changing world benefits from iterative risk management; the experience of implementing these agreements will be a rich field for researchers in a range of disciplines in the coming years, and policymakers will benefit from their findings. The IPCC too can also contribute, in its coming reports, by assessing the research of the academic community addressed by this Handbook.

The tasks faced by the world and analysed by the Handbook are not to be underestimated: decarbonization, dematerialization, changes in consumption patterns and waste, the restoration of environmental and ecosystem services, the recovery of soils and integrated water management. These are the challenges of the twenty-first century.

One of the key difficulties we face is the multidisciplinary nature of the tasks we have set ourselves. At its simplest this comes down to the apparent conflict between protecting the environment and tackling climate change while ensuring that development continues to lift people out of poverty. I say apparent, because the IPCC has shown that climate (and hence environmental) policy can be profitably mainstreamed into countries' development agendas. Indeed, the mutually reinforcing rather than contradictory nature of development and environmental policy is the essence of what we mean by sustainability.

The potential tension does not lie only between economy and ecology. The IPCC has shown how climate-related hazards exacerbate other stressors, often with negative outcomes for livelihoods, especially for people living in poverty. Climate change impacts can exacerbate poverty in rich and poor countries, and indirectly increase risks of violent conflicts in the form of civil war and inter-group violence by amplifying well-documented drivers of these conflicts such as poverty and economic shocks. By worsening droughts and water shortages, climate change can add to pressures encouraging people to migrate. In other words, climate change and the other sustainable development goals in general have a powerful bearing on peace and human security.

By linking the four social science research areas of peace studies, security studies, development studies and environmental studies, the Handbook makes a welcome contribution to an integrated assessment of these issues. As the IPCC focuses increasingly on solutions in future assessments we too will look increasingly at these areas. In its assessments of the policy response to climate change as well as the causes and impacts, the IPCC aims to be policy-relevant but never policy-prescriptive. But even in a policy-neutral framework, there is a need for a comprehensive, integrated and urgent response. This Handbook provides rich source of insights and information to students and policymakers as they confront these challenges.

Seoul/Geneva   27 April 2016

Hoesung Lee
Chairman
Intergovernmental Panel on Climate Change (IPCC)
The Larger Challenge

Sustainability and security, the foci of this collection, are critical themes of a larger drama now unfolding on the global stage. With threads of connectivity binding people and planet into a single community of fate, a profound historical transition is under way. We have entered the *Planetary Phase of Civilization*,[1] with the outcome indeterminate and contested. Our trajectory in the twenty-first century will depend to a significant degree on the choices we make, or fail to make, now and in the pivotal years ahead. The overarching challenge is to shape a flourishing planetary civilization.

The global future is inherently uncertain, but this much seems clear: the current course will take us helter-skelter into a time of troubles, even calamity. Anachronistic twentieth-century mindsets and institutions—the state-centric political order, growth-driven economies, environmental insensitivity, and consumer culture—are ill-suited to twenty-first-century realities. The gap between the 'is' of the world today and the 'ought' of a civilized tomorrow is a breeding ground for myriad perils best understood as various expressions of a common phenomenon: the disruptive coalescence of one, planet-encompassing social–ecological system.

Emerging conditions in the Planetary Phase demand a new development paradigm, a *Great Transition* centred on the well-being of people and nature in our interdependent, fragile world. With the stakes high and political leadership feeble, a zeitgeist of apprehension is on the rise, bringing fear for the future, despair, and even fatalism. At the same time, antidotes to self-fulfilling pessimism and passivity—social vision and collective action—are gaining traction. Twin motives—necessity and desire—propel the movement for a *Great Transition*: the need to mute looming dangers and the hope for a civilized future. At a fundamental level, the moral imperative to pass on a liveable world resonates with the instincts for survival and empathy that lie deep in the human psyche.

Needless to say, these spurs for deep change confront powerful counterforces, namely, vested interests, institutional inertia, and cultural tenacity. And less noble human impulses—greed, dominance, complacency—too often best the better angels of our nature. Still, despite such resistance and distraction, change is afoot, even in the mainstream where policy reforms are actively pursued, and where the 2015 UN Sustainable Development Goals provide an aspirational framework for guiding further effort. But incrementalism will not suffice: scattershot tweaks to conventional development leave intact the deep drivers of systemic stress.

---

1 The ideas of the *Planetary Phase* and *Great Transition* were introduced in Paul Raskin, Tariq Banuri, Gilberto Gallopín, Pablo Gutman, Allen Hammond, Robert Kates, and Rob Swart: *Great Transition: The Promise and the Lure of the Times Ahead* (Boston: Tellus Institute, 2002), at: <http://www.tellus.org/tellus/publication/great-transition-the-promise-and-lure-of-the-time-ahead>. The *Great Transition Initiative*, an international network devoted to elaborating the framework, publishes scholarship on the theory and practice of global transformation (see: <www.greattransition.org>).

Transformative change entails cultivation of values and institutions consonant with the exigencies and potentialities of the *Planetary Phase*. The expansion of the human project encourages a corresponding expansion of human consciousness to embrace humanity-as-a-whole and its place in the ecosphere, as well as a revised understanding of what constitutes a good life and a good society. Ultimately, the hope for a *Great Transition* correlates with the waxing of a new suite of values—human solidarity, quality of life, and an ecological sensibility—and the waning of the conventional triad of individualism, materialism, and domination of nature.

Each value demarcates a vital domain of strategic action. The concern for human solidarity supports efforts to establish an egalitarian social contract, eradicate poverty, strengthen popular democracy, and cultivate the identity and practice of global citizenship. The emphasis on quality of life inspires initiatives to limit workweeks and foster lifestyles rich in creativity, recreation, relationships, community, spirituality, and other dimensions of a well-lived life. An ecological sensibility motivates endeavours to protect and heal the earth, including advancing the sustainable development agenda, which calls for moving beyond unfettered capitalist growth toward regenerative economies that maintain human impacts within the environmental boundaries of a finite planet.

These values and strategies are emerging as a potent cultural and political influence. The critical uncertainty is whether the forces for a *Great Transition* will mobilize with sufficient speed, scale, and coherence. This question of social agency—Who will change the world?—needs a plausible answer. The myopic concerns of government and business render them poor candidates to lead the way. Civil society holds more potential. Indeed, in recent decades, countless global and local movements and organizations have weighed in on a full spectrum of issues, an eruption of citizen energy that has spread popular awareness, conducted important research, and mounted action campaigns. Much has been achieved, but piecemeal victories have not scaled up to a systemic change of direction. Organizational and conceptual fragmentation has stifled civil society's potential, slicing the integral challenge into a thousand arenas and turfs with no unifying conceptual framework or social vision.

Our pressing task now is to weave disparate efforts into an integrated planetary praxis that can attract and engage widening circles of concerned citizens. Such a 'global citizens movement' is the critical actor for a *Great Transition*, but remains missing from the global stage. Nevertheless, history shows that popular movements arising from widespread grievance and offering a path to rectification can, after a period of slow development, reach a critical mass, then quickly coalesce. Thus, advancing an inclusive and plural global movement towards its tipping point has become a frontline project for shaping a civilization worthy of the name.

In times of social stability, visionaries of a better world can be dismissed, with some justification, as quixotic dreamers. In transformative moments, business-as-usual thinkers are the utopians, and the prophets of 'another world' the pragmatists. If today's generations prove too hidebound to accept the necessity of deep change or too cynical to think such change possible, the legacy could well be a century of decline. Hence, it is urgent but not too late to join together in a new planetary praxis for meeting the larger challenge: building the community of Earth.

- **Figure 15.6:** IHDP's new governance structure. **Source:** IHDP's Strategic Plan 2007–2015, p. 30.

In chapter 16 *Marit Sjovaag* used material from the publications on *The Limits of Growth* with the permission of Jørgen Randers, who was a co-author of all studies.
- **Figure 16.1:** Causal diagram of the World3 model. **Source:** Jørgen Randers presentation material; he also granted permission to use this figure.
- **Figure 16.2:** Causal diagram for the 2052 study–changes from the World Model marked in red. **Source:** Jørgen Randers presentation material; he also granted permission to use this figure.
- **Figure 16.3:** World State of Affairs, 1970–2050. **Source:** Randers (2012: 232). Permission to use this figure was granted by the author.

In chapter 17 *Mark Swilling* used previously published figures and a table of which he is a co-author; material by UNEP's International Resource Panel of which he has been a member and which are in the public domain; and material by close colleagues who granted their permission.
- **Figure 17.1:** Global metabolic rates and incomes (1900–2005), and income. **Source:** Fischer-Kowalski and Swilling (2011: 12).

- **Figure 17.11:** Largest net exporters and importers by material composition of net trade in 2010. **Source:** Fischer-Kowalski, Dittrich, Eisenmenger et al. (2015).
- **Figure 17.12:** Growth in production of minerals, 1845-2010. **Source:** Mudd (2009), cited in International Resource Panel Working Group on Global Metal Flows (2013).
- **Figure 17.13:** Computer Chip Elemental Contents. **Source:** Quoted in a Powerpoint presentation by Tom Graedel, November 2013, Stellenbosch University.
- **Figure 17.14:** Agricultural inputs relative to crop yields (1961–2009). **Source:** FAO data compiled by Schutz, cited in Bringezu, Schutz, Pengue et al. (2014).
- **Figure 17.15:** Cereal yields by selected world regions (1961-2011). **Source:** FAO data cited in Bringezu, Schutz, Pengue et al. (2014).
- **Figure 17.16:** High and low estimates of net and gross expansion of agricultural land, 2005-2050. **Source:** Bringezu, Schutz, Pengue et al. 2014–note: for detailed references to the sources of data cited here, see original diagram in this report.
- **Figure 17.17:** Number of people living in water-stressed areas in 2030, by country type. **Source:** UNEP (2011), cited in Urama (2015).
- **Table 17.1:** Increases in Annual Water Demand, 2005- 2030. **Source:** McKinsey (2009), cited in Urama (2015).

In chapter 18 *Czeslaw Mesjasz* developed a figure and several tables based on his own research.
- **Figure 18.1:** Areas and elements of sustainability description and analysis (three/four pillars). **Source:** Own research based upon Adams (2006) and Goodland.
- **Table 18.1:** General definitions of 'sustainability'. **Source:** The author's own research.
- **Table 18.2:** General definitions of 'sustainable development'. **Source:** The author's own research.
- **Table 18.3:** Levels of analysis of sustainability. **Source:** Riley (1992).
- **Table 18.4:** Definitions of sustainability in specific socio-economic domains. **Source:** The author's own research.

In chapter 20 *Mike Hodson, Simon Marvin and Philipp Späth* designed a figure based on their own research:
- **Figure 20.1:** Scalar interrelationships in transitions activities and chains of intermediary spaces. **Source:** The authors.

In chapter 23 *Juan Antonio Le Clercq* developed the following figures and tables based on Mexican sources that are in the public domain:

- **Figure 23.1:** Legislative process concerning climate change in Mexico (1992–2012). **Source:** Information from the Chamber of Deputies, the Senate and the *Legislative Information System* (SIL); at: <diputados.gob.mx/>; <senado.gob.mx/>; and <sil.gobernacion.gob.mx/>.
- **Figure 23.2:** Climate change bills by topic (2006–2012). **Source:** Information from the Chamber of Deputies, the Senate and the *Legislative Information System* (SIL); at: <diputados.gob.mx/>; <senado.gob.mx/>; and <sil. gobernacion.gob.mx/>.
- **Figure 23.3:** Climate change legislative policy calls by topic (1992–2012). **Source:** Based on information from the Chamber of Deputies, the Senate and the *Legislative Information System* (SIL); at: <diputados.gob.mx/>; <senado.gob.mx/>; and <sil.gobernacion.gob.mx/>.
- **Figure 23.4:** Mexican climate policy (2006–2012). **Source:** Information presented in the 4th and 5th National Communications to the UNFCCC (INE: National Institute of Ecology; CICC: Interministerial Commission on Climate Change).
- **Figure 23.5:** Proposed reform for climate regulation in environmental law. **Source:** Information from the legislative project to reform the environmental law (LEEGEPA) approved by Congress (25 April 2012); CICC: Interministerial Commission on Climate Change).
- **Figure 23.6:** Climate change law structure. **Source:** Ley General de Cambio Climático (NSCC: National Strategy on Climate Change; INECC: National Ecology and Climate Change Institute; CICC. Interministerial Commission on Climate Change; C3: Advisory Council on Climate Change).
- **Table 23.1:** Climate policy instruments, objectives and goals (2006–2012). **Source:** Information from PND (2007–2012), ENACC (2007) and PECC (2009).
- **Table 23.2:** Alternative models in the legislative discussion on climate change 2010–2012: **Source:** Information from the National Communications and Legislative Information System (SIL); at: <sil.gobernacion.gob.mx/>.

In chapter 24 *Audley Genus* added a figure and table he developed himself.
- **Figure 24.1:** A discourse-institutional analytical framework. **Source:** The author.
- **Table 24.1:** Discursive legitimation strategies underpinning institutional pillars (rules). **Source:** The author.

In chapter 25 *Jan Jonker and Linda O'Riardon* designed three figures based on their own sources or inspired by selected cited texts by colleagues:
- **Figure 25.1:** The value creation logic behind conventional business models. **Source:** The authors.
- **Figure 25.2:** Process NBMs. **Source:** The authors, based on Shafer, Smith and Linder (2005) and Simanis and Hart (2009).
- **Figure 25.3:** Value creation process NBMs. **Source:** The authors, based on Simanis and Hart (2009).

In chapter 26 *Sylvia Lorek* added a box based on her own research. For the three figures and two tables she obtained the permission of the copyright holders.
- **Box 26.1:** Green Growth and De-growth. **Source:** The author.
- **Figure 26.1:** The Environmental Space Concept. **Source:** Spangenberg (1995).
- **Figure 26.2:** Possible pathways to sustainable consumption from overconsumption. **Source:** Brunner and Urenje (2012).
- **Figure 26.3:** Possible pathways to sustainable consumption from under-consumption. **Source:** Brunner and Urenje (2012).
- **Table 26.1:** Sustainable World Population at Different Consumption Levels. **Source:** Assadourian (2010).

- **Table 26.2:** Examples of enabling mechanisms for sustainable consumption. **Source:** Lebel/Lorek 2010.

In chapter 27 *Hongmin Chen* summarized her research in three boxes, developed three figures and added two tables based on Chinese official and scientific sources that are partly in the public domain.

- **Box 27.1:** Top 1000 Enterprises Energy Conservation Programme. **Source:** NDRC (2006a, 2011).
- **Box 27.2:** China's Carbon Emissions Trading Pilots. **Source:** Zheng (2014); Wilkening, Kachi (2014); Wu, Shi, Xia et al. (2014).
- **Box 27.3:** Project "Energy-saving Products Benefiting the Public". **Source:** MFPRC (2013).
- **Figure 27.1:** MSW treatment by type in China (2004–2010). **Source:** NBS (2014).
- **Figure 27.2:** Household Waste Sorting at Different Stages in Shanghai. **Source:** Huang (2014).
- **Figure 27.3:** Regional Distribution of Per Capita GDP in mainland China in 2013 (104 US dollars). **Source:** NBS (2014).
- **Table 27.1:** Development of Seven Pilot Carbon Trading Schemes in China. **Source:** Zheng Shuang (2014); International Carbon Action Partnership Region; at: <https://icapcarbonaction.com>.
- **Table 27.2:** Development of three types of NGOs in China. **Source:** Website of the Ministry of Civil Affairs, <www. mca.gov.cn>.

In chapter 28 *Philipp Schepelmann, René Kemp and Uwe Schneidewind* developed one figure (28.8) based on their own research and added two maps (figure 28.1) and six photos (figures 28.2–28.7) that are licensed under Wikimedia Commons and based on public sources.

- **Figure 28.1:** Germany, the State of North Rhine–Westphalia and the Ruhr Area. **Sources:** Locator map of the Ruhr District, Germany (TUBS Own work). Licensed under Creative Commons Attribution-ShareAlike 3.0 via Wikimedia Commons; Ruhr District (Ruhr) with all cities with more than 50,000 inhabitants (Threedots (Daniel Ullrich))— Own work. Licensed Regionalverband under Creative Commons Attribution-ShareAlike 3.0 via Wikimedia Commons.
- **Figure 28.2:** View of the city of Gelsenkirchen, to the right the former coal mine, today centre of the Nordstern Parks—view from a former slag heap in the city of Essen. **Source:** Hans-Jürgen Wiese—Own work. Licensed under Creative Commons Attribution-ShareAlike 3.0 via Wikimedia Commons.
- **Figure 28.3:** River Emscher in the Ruhr district near Herne and Herten. **Source:** Arnoldius—Own work. Licensed under Creative Commons Attribution-ShareAlike 2.5 via Wikimedia Commons.
- **Figure 28.4:** Wastewater treatment plant Deusen at the river Emscher. **Source:** Tbachner—Own work. Licensed under Creative Commons Attribution-ShareAlike 3.0 via Wikimedia Commons.
- **Figure 28.5:** Heritage of the IBA Emscher Park at night: Furnace No. 5 at the Landscape Park Duisburg North. **Source:** Tuxyso—own work. Licensed under Creative Commons Attribution-ShareAlike 2.5 via Wikimedia Common.
- **Figure 28.6:** The river Emscher beside the Landscape Park Duisburg. **Source:** DerHexer—own work. Licensed under Creative Commons Attribution-ShareAlike 3.0 via Wikimedia Commons.
- **Figure 28.7:** UNESCO World Heritage Site Zeche Zollverein in Essen. **Source:** Thomas Wolf—own work. Licensed under Creative Commons Attribution-ShareAlike 3.0 via Wikimedia Commons.

- **Figure 28.8:** Main phases and elements of NRW sustainability transition. **Source:** The authors.

In chapter 29 *Belinda Yuen* and *Asfaw Kumssa* summarized their own research in three boxes (29.1–29.3), added six of their own photos (figure 29.1–29.6) for which they own the copyright, and in table 29.1 used data from the United Nations Population Division that are in the public domain.
- **Box 29.1:** Cairo: Africa's Megacity. **Source:** The author.
- **Box 29.2:** Africa's Path to Green Growth. **Source:** The author.
- **Box 29.3:** National Strategy for Green Growth, South Korea. **Source:** The author.
- **Figure 29.1:** A hotel in the slums of Nairobi, Kenya. **Source:** Authors.
- **Figure 29.2:** Rising traffic congestion in Nairobi city, Kenya. **Source:** Authors.
- **Figure 29.3:** Squatter settlement in Metro Manila, the Philippines. **Source:** Authors.
- **Figure 29.4:** Lack of proper solid waste disposal creates an environmental problem in Jakarta, Indonesia. **Source:** Authors.
- **Figure 29.5:** Salt pan barren land being transformed into the Sino-Singapore Tianjin eco-city. **Source:** Authors.
- **Figure 29.6:** Turning waste to recreation land at Semakau, Singapore. **Source:** Authors.
- **Table 29.1:** Urbanization Levels, 1950–2050. **Source:** United Nations, 2012: *World Urbanization Prospects: The 2011 Revision* (New York: United Nations Population Division, Department of Economic and Social Affairs).

In chapter 30 *Gregory Trencher* and *Xuemei Bai* summarized their own research in one box (30.1) and in three tables (tables 30.1-30.3) and designed seven figures (figures 30.1–30.7) based on their own findings.
- **Box 30.1:** Method. **Source:** The authors.
- **Figure 30.1:** Urban systems targeted (n = 15 cases). **Source:** The authors.
- **Figure 30.2:** Types of internal actors (n = 15 cases). **Source:** The authors.
- **Figure 30.3:** Types of external actors (n = 15 cases). **Source:** The authors.
- **Figure 30.4:** Number of external actor types involved (n = 15 cases). **Source:** The authors.
- **Figure 30.5:** Factors motivating partnership formation (n = 15 cases). **Source:** The authors.
- **Figure 30.6:** Mechanisms (n = 15 cases). **Source:** The authors.
- **Figure 30.7:** Barriers and negative factors (n = 13 cases). **Source:** The authors.
- **Table 30.1:** List of partnerships (n = 15). **Source:** The authors.
- **Table 30.2:** Summary of key roles, motivations and potential barriers. **Source:** The authors.
- **Table 30.3:** Overview of Urban Reformation Programme for the Realization of a Bright Low-Carbon Society. **Source:** The authors.

In chapter 31 *Cecilia Tortajada* and *Martin Keulertz* used one figure based on sources from NASA, and in two tables summarized data provided by international organizations that are in the public domain or may be used for scientific purposes without permission.
- **Figure 31.1:** Satellite-based estimates of groundwater depletion in India. **Source:** I. Velicogna, University of California, Irvine; at: <http://www.nasa.gov/topics/earth/features/india_water.html>.
- **Table 31.1:** Regional production and consumption of biofuels, 2011. **Source:** Adapted from HLPE (2013). This information is originally from the US Energy Information Administration/International Energy Statistics, available at: <http://www.eia.gov/>.
- **Table 31.2:** Global water use for energy production in the New Policies Scenario by region (bcm). **Source:** OECD/IEA (2012).

In chapter 32 *Úrsula Oswald Spring* summarized in two tables (32.1–32.2) a survey that was conducted by CRIM/UNAM under her guidance; developed twelve figures based on her own research and on official Mexican sources (figures 32.1–32-3, 32.6–32.13); adapted a figure by Bohle (figure 32.4) and used a photograph taken by Civil Protection, Yautepec that is in the public domain.

- **Figure 32.1:** Location of the study area in the central part of Mexico. **Source:** The author.
- **Figure 32.2:** Location of the study area with municipalities. **Source:** The author.
- **Figure 32.3:** Complexity of the river basin. **Source:** The author.
- **Figure 32.4:** Dual vulnerability. **Source:** Adapted by the author from Bohle (2002).
- **Figure 32.5:** Flood over bridge in the centre of Yautepec. **Source:** Photograph taken by Civil Protection, Yautepec, during the 2010 flood.
- **Figure 32.6:** Part of the Didactic Map of the Yautepec River Basin. **Source:** The author.
- **Figure 32.7:** Multiple risks in the YRB. **Source:** Survey (CRIM/UNAM 2011–2013).
- **Figure 32.8:** Main disasters occurring in the YRB. **Source:** Survey (CRIM/UNAM 2011–2013).
- **Figure 32.9:** Environmental destruction in the YRB. **Source:** Survey (CRIM/UNAM 2011–2013).
- **Figure 32.10:** Dealing with increasing risks in the YRB. **Source:** Survey (CRIM/UNAM 2011–2013).
- **Figure 32.11:** Identity in the YRB (two possible answers). **Source:** Survey (CRIM/UNAM 2011–2013).
- **Figure 32.12:** Income distribution of a peasant household. **Source:** Oswald Spring/Serrano Oswald/Flores Palacio et al. (2014: 343), based on data from SIAP [Statistics from the Ministry of Agriculture].
- **Figure 32.13:** Arenas, agendas, actors and activities of vulnerability and livelihood. **Source:** The author.
- **Table 32.1:** Representative survey in the Yautepec River Basin (YRB). **Source:** Field research (CRIM/UNAM 2010–2013).
- **Table 32.2:** Land use changes in the YRB. **Source:** Field research (CRIM/UNAM 2010–2013).

In chapter 33 *Monica de Andrade* summarized her own research in three tables (33.1–33.3).
- **Table 33.1:** Characterization of sustainability transitions in Brazil: structural changes at local level (landscape level). HD = Hydroelectricity. **Source:** The author.
- **Table 33.2:** Timeline of main policy interventions in Brazil and their impacts on health and the ecosystem, together with their social and economic aspects. **Source:** The author.
- **Table 33.3:** Transition of heath indicators in Brazil. **Source:** The author.

In chapter 34 *Jürgen Scheffran* and *Rebecca Froese* used the following boxes, figures and chapters based on the sources provided below for which no permission was needed. For Figure 34.1 and Table 34.2 permission was granted by Elsevier.
- **Box 34.1:** Aspects of technology transfer and learning in low-carbon development. **Source:** Adapted and condensed from: Lema, Iizuka and Walz (2015).
- **Box 34.2:** Public-Private Partnership for Electricity from Peanut Shells in Senegal. **Source:** Assembled by the authors.
- **Box 34.3:** China-Zambia South-South Cooperation on Renewable Energy Technology Transfer. **Source:** Assembled by the authors.
- **Box 34.4:** Mechanisms for Technology Transfer. **Source:** Assembled from <http://unfccc.int/ttclear/templates/render_cms_page?TTF_home>.
- **Box 34.5:** Solar Home Systems for Bangladesh. **Source:** Assembled by the authors.

- **Box 34.6:** Barriers to technology transfer and investment. **Source:** Based on Santarius/ Scheffran/Tricarico 2012.
- **Box 34.7:** Clean Power from the Desert–Concentrated Solar Power (CSP). **Source:** Assembled by the authors.
- **Figure 34.1:** The process of technology transfer. **Source:** Adapted from Karakosta, Doukas, Psarras (2010), with the permission of Elsevier.
- **Figure 34.2:** Innovation Chain. **Source:** Adapted and modified from Grubb (2004) and Tomlinson, Zorlu, Langsley (2008).
- **Figure 34.3:** Global New Investment in Renewable Power and Fuels, Developed and Developing Countries, 2004-2013. **Source:** Adapted from REN 21 (2014).

- **Figure 34.5:** FDI inflows, global and by group of economies, 1995-2013 and projections, 2014-2016 in billions of dollars. **Source:** Adapted from UNCTAD FDI-TNC-GVC Information System, FDI/TNC database; at: <www.unctad.org/fdistatistics> (WIR 2014).
- **Figure 34.6:** Estimates of financing for mitigation technologies. **Source:** Adapted from UNFCCC (2009).
- **Table 34.1:** Gaps between actual and required climate finance. **Source:** Authors' representation, data from EC (2015).
- **Table 34.2:** Relative importance of particular types of financial flows to technology transfer pathways for different actors. **Source:** Adapted from Karakosta, Doukas, Psarras (2010), with the permission of Elsevier.
- **Table 34.3:** Current investments, investment needs and gaps, and private sector participation in key SDG sectors in developing countries. **Source:** Adapted from WIR 2014; at: <www.unctad.org/fdistatistics>.
- **Table 34.4:** Summary of actions and incentives for the public and private sectors in the developed and developing countries. **Source:** Adapted from Santarius, Scheffran, Tricarico (2012: 50).

In chapter 35 *Karlson 'Charlie' Hargroves* summarized his joint research with colleagues in table 35.1, designed five figures (35.1-35.5) based on his own research (35.3) and joint research with colleagues (35.1–35.2, 35.4), and adapted a methodology used by colleagues (35.5) for the purpose of his own research.
- **Figure 35.1:** Waves of Innovation. **Source:** Hargroves/Smith (2005).
- **Figure 35.2:** Gross Domestic Product vs. Estimated Environmental Costs (billions) for the United States of America from 1950 to 2004. **Sources:** Smith, Hargroves and Desha (2010), with data reinterpreted by K. Hargroves from Talberth, Cobb and Slattery (2006).
- **Figure 35.3:** Schematic of Key Elements of Carbon Structural Adjustment. **Source:** Hargroves (2014).
- **Figure 35.4:** Whole of Society Approach to Sustainable Development. **Source:** Hargroves and Smith (2005).
- **Figure 35.5:** A method for the prioritization of efforts based on the likely impact on greenhouse gas emissions and the likely willingness to adjust in the area of focus. **Source:** Adapted by K. Hargroves from an adaptation by K. Hargroves and C. Desha of the CBSM Methodology (McKenzie-Mohr/Smith 1999).
- **Table 35.1:** Examples of cost-effective reductions in carbon intensity in various sectors that deliver strong economic multipliers. **Source:** von Weizsäcker, Hargroves, Smith, Desha and Stasinopoulos (2009).

In chapter 36 *Britta Rennkamp* and *Radhika Perrot* summarized their research in two tables (36.1–36.2).

- **Table 36.1:** Overview of the framework for analysis of Wind Energy Technology Drivers and Barriers. **Source:** The authors based on Bergek, Jacobsson, Carlsson et al. (2008).
- **Table 36.2:** Synthesis of the results. **Source:** The authors.

In chapter 37 *Lucy Baker* used a table (37.1) for which written permission was granted by the copyright holders; for the figure (37.1) she used data which are in the public domain.
- **Figure 37.1:** Total envisaged capacity 2030 under policy-adjusted IRP 2010. **Source:** Author's own elaboration using data available from DoE (2011a:17).
- **Table 37.1:** The DoE technical task team. **Source:** McDaid, Austin and Bragg (2010: 5). Permission was granted.

In chapter 38 *Eduardo Viola* and *Larissa Basso* summarized official data that are in the public domain in two tables (38.1–38.2).
- **Table 38.1:** Domestic energy production and domestic energy supply by source 2003–2012 (103 tep (toe)). **Source:** Author's elaboration based on: *Balanço Energético Nacional—séries completas* 1970–2012; at: <https:// ben.epe.gov.br/BENSeriesCompletas.aspx> (12 January 2014).
- **Table 38.2:** UHEs in the Amazon region (Amazon basin and Tocantins-Araguaia basin). **Source:** Author's elaboration, based on data from *Agência Nacional de Energia Elétrica—Banco de Informações sobre Geração*; at: <http://www.aneel.gov.br/aplicacoes/capacidadebrasil/GeracaoTipoFase.asp?tipo=1&fase=3>, and *Programa de Aceleração do Crescimento—PAC*; at: <http://www.pac.gov.br/energia/geracao-de-energia-eletrica/br/30> (26 July 2014). PCHs and UHEs under study or not found on any of the government websites above are excluded from the table.

In chapter 39 *Carl Middleton* compiled two tables adapted from a publication by a British colleague with his permission (39.1–39.2).
- **Table 39.1:** Civil society activity in relation to sustainable electricity transitions. **Source:** The author, adapted from Smith (2012: 189).
- **Table 39.2:** Evolution of Thailand's electricity regime. **Source:** Table structure adapted from Smith (2012: 193-195).

In chapter 40 *Roeland J. in 't Veld* developed two figures to illustrate his own research.
- **Figure 40.1:** The emergence of the knowledge democracy concept. **Source:** The author.
- **Figure 40.2:** Old and new forms coexist and influence each other. **Source:** The author.

In chapter 41 *Sander Happaerts* summarized his own research findings in two boxes (41.1–41.2).
- **Box 41.1:** Transitions in the European Commission's Roadmaps. **Source:** The author.
- **Box 41.2:** Resource efficiency and Europe 2020: the back story. **Source:** The author.

In chapter 42 *Úrsula Oswald Spring, Hans Günter Brauch,* and *Jürgen Scheffran* included the following figures:
- **Figure 42.1:** System approach to natural and anthropogenic factors of global environmental change. **Source:** Oswald Spring (2016), based on data from Rockström, Steffen, Noone et al. (2009).
- **Figure 42.2:** Transition to sustainability. **Source:** Oswald Spring (2016).
- **Figure 42.3:** From diagnosis to remedy: Sustainability Transition and Sustainable Peace: **Source:** Hans Günter Brauch (2016), with many suggestions from Úrsula Oswald Spring.

Part I   Moving towards Sustainability Transition

1 Sustainability Transition and Sustainable Peace: Scientific and Policy Context, Scientific Concepts and Dimensions

Hans Günter Brauch[1] and Úrsula Oswald Spring[2]

Abstract

This Handbook links together four social science research programmes—peace studies, security studies, development studies and environmental studies—which have had only limited exchanges on sustainable development, human security and sustainable peace. The Handbook connects these three concepts within the *research paradigm* of 'sustainability transition'. This research paradigm focuses on a large-scale and long-term transformative change of the dominant carbon-intensive development path by addressing the causes of global environmental and climate change. There has been an exponential increase in GHG emissions since the 1950s and a rapid destruction of biodiversity and ecosystem services. These texts can be used in graduate seminars in different scientific disciplines and research programmes and in new transdisciplinary degree programmes. The texts foster longer-term proactive strategies and policies and specific measures to realize two policy goals, 'sustainable development' alongside and contributing to a 'sustainable peace', as the possible result of a large-scale transition of the systems of production, consumption, and governance.

Among the key questions in this Handbook are a) whether *business-as-usual* policies and the growing number of climate-induced natural hazards that threaten the survival of millions of people pose threats to international peace and security; b) whether anticipative learning and a forward-looking discourse on long-term transformative changes may contribute to sustainable development and address new dangers to international peace and security in a preventive manner; and c) what lessons may be drawn from the violent consequences of the industrial revolution and used to promote a long-term transformative change towards sustainable development with sustainable peace.

This chapter consists of eight parts. After a brief sketch of opposing scientific and political visions (1.1.), the purpose and objectives of the Handbook are highlighted (1.2.) and a survey (1.3) reviews the challenges posed by global environmental change: population growth, the impacts of climate change, loss of biodiversity, soil erosion and desertification, water scarcity and stress, food scarcity and hunger, and gender implications. It addresses the impacts of different economic development paths (1.4), through integrating the results of global research programmes, of their linkages and their assessment by the IPCC, and through the nexus debates between the fields of water, food and energy security (1.5). The three key concepts of sustainable development, sustainability transition and sustainable peace are introduced (1.6), the evolution of different approaches to sustainability transition is reviewed, the debates on ecosystem restoration, green growth and decarbonization are noted, and six dimensions of the research on 'sustainability transition' are outlined (1.7). The last section introduces the ten parts of this Handbook and offers an overview of its 40 peer-reviewed contributions (1.8).

Keywords: Anthropocene, biodiversity, business-as-usual, climate change, cornucopian perspectives, decarbonization, development paths, food, gender, global environmental change, human security, hunger, soil, sustainable development, sustainable peace, sustainability transition, water.

1.1 Introduction and Overview of the Chapter

This *Handbook on Sustainability Transition and Sustainable Peace* follows the *Global Environmental and Human Security Handbook for the Anthropocene*, which focused on the reconceptualization of security (Brauch/Oswald Spring/Grin et al. 2009; Brauch/Oswald Spring/Mesjasz et al. 2008, 2011). In the latter's concluding chapter Oswald Spring and Brauch

(2011) argued that in the Anthropocene humankind faces two alternative visions and policy strategies:

- *Business-as-usual* (BAU) in a Hobbesian world. Here economic and strategic interests and actions dominate and may lead to a major crisis for humankind, inter-state relations and nature.
- The need for a *transformation* in cultural, environmental, economic and political relations.

Scheffran, Brzoska, Brauch et al. (2012) examined the possible consequences of the *first* alternative and showed, by addressing climate change as a 'threat multiplier', that in the case of no action it might lead to "dangerous climate change" (UNFCCC 1992; Schellnhuber/Cramer/Nakicenovic et al. 2006). This volume deals with the second alternative: 'sustainability transition' that may serve as a sustainable alternative. It would avoid the negative consequences of climate change for human, national and international security (Brauch 2014). Both visions address different coping strategies for this century for *global environmental change* (GEC) and climate change:

- In the first vision, *cornucopian perspectives* or *business-as-usual* suggest technical fixes and the defence of economic, strategic and national interests, with the adaptation and mitigation strategies that are affordable for industrialized countries.
- In the alternative vision of a comprehensive transformation of the global economy, *Politik* (as politics, policy and polity), economics, society and culture, a *sustainable perspective* requires effective new strategies and policies. Their goal should be decarbonization, dematerialization, reduction of the water and environmental footprint, and global cooperation and solidarity. These would contribute to a sustainable peace with more global equity and social justice.

The consequences of both scientific visions and policy perspectives are:

- The first vision—with minimal reactive adaptation and mitigation strategies—would increase the probability of dangerous global changes in the environment, water, food and climate (IPCC 2013/2014), and there would be linear and chaotic changes in the earth system.
- The sustainability perspective requires a change in *culture* (thinking on the human–nature interface), *world views* (thinking on systems of rule, e.g. democracy vs autocracy, on domestic priorities and policies, and on inter-state relations in the world), *mindsets* (the strategic perspectives of policymakers), and new forms of national and global sustainable *governance* (Oswald Spring/Brauch 2011).

This alternative vision addresses the need for a "transition to [a] much more sustainable global society" (Raskin/Banuri/Gallopin et al. 2002), aimed at peace, freedom, cooperation, care, material well-being and environmental health. Changes in technology, financing and management systems alone will not be sufficient, but "significant changes in governance, institutions and value systems" are needed, resulting in a new major transformation after "the stone age, early civilization and the modern era". These alternative strategies should be "more integrated, more long-term in outlook, more attuned to the natural dynamics of the Earth System and more visionary" (Steffen/Sanderson/Tyson et al. 2004: 291–293).

Taking up this second vision and coping strategy, this Handbook tries to bridge different research programmes in the social sciences, especially environmental studies and ecology, but also sociotechnological perspectives (Grin/Rotmans/Schot 2010), peace and gender studies. It addresses the following questions:

- What are the possible conceptual relationships between a manifold *process* of 'sustainability transition' and the *normative goal* of a 'sustainable peace'?
- Will this long-term transformative process towards sustainability contribute to a more peaceful world or to new forms of violence and war?
- How could global participative governance and solidarity avoid critical tipping points in the Earth and human systems?

2   Prof. Dr. Úrsula Oswald Spring, full-time Professor/Researcher at the *National Autonomous University of Mexico* (UNAM) in the *Regional Multidisciplinary Research Center* (CRIM); email: <uoswald@gmail.com>.

There have been two previous technical revolutions: the *Neolithic and agricultural revolution* (10,000 BP to 6,000 BP) resulted in the formation of states, urbanization, warfare, and religious-ideological control; the *industrial revolution* (since 1750 AD) resulted in a continuing process of scientific and technical innovation that led to the industrialization of warfare (with millions of casualties both among soldiers and the civilian population), billions of poor and hungry people, gender discrimination, and an extreme concentration of wealth in very few hands.

It is at present impossible to answer the question of whether this long-term transformative process aiming at the realization of the *sustainable development goals* (SDG) will contribute to a more peaceful world, a world where peace goes beyond domestic or internal peace and becomes peace among ethnic groups, cultures, gender and religions and nations: peace with nature, with equity and with equality in the Anthropocene.

However, by addressing this linkage and the possible consequences of the process of 'sustainability transition', an endurable peace within society, states and the nations of the globe can be put on the scientific and policy agenda.

The next section highlights the purpose and objectives of this Handbook (1.2). This is followed by a survey (1.3) of the challenges posed by global environmental change. These necessitate a long-term process of sustainability transition in this century because of the silent transition in earth history from the Holocene to the Anthropocene (1.3.1). This has created many challenges caused by severe physical and societal impacts in the twentieth and twenty-first centuries brought about by multiple interactions between the human and earth systems (1.3.2). The section on GEC and its physical and societal impacts (1.3.3) offers a diagnosis—based on the most recent reports by international organizations and regimes—on *population change*, as a major driver for the rising demand for environmental services, food and manufactured goods (1.3.4), on *climate change* impacts and policy responses (1.3.5), on *loss of biodiversity* (1.3.6), on *soil degradation, erosion and desertification* (1.3.7), on *water degradation, scarcity, and stress* (1.3.8), and their joint impacts on *food scarcity and hunger* (1.3.9), as well as on the *gender impacts of global environmental and climate change* (1.3.10).

The next two sections address the impacts of different economic development paths (1.4). It integrates the results of four global research programmes (WCRP, IGBP, DIVERSITAS, IHDP) and their link-

ages. These have been addressed by the ESSP and Future Earth (1.5), and their peer-reviewed research results have been assessed by the *Intergovernmental Panel on Climate Change* (IPCC), with a special focus on human security (1.5.1), and on nexus debates between water, food and energy security (1.5.2).

The sixth section briefly introduces three key concepts of this Handbook: sustainable development, sustainability transition and sustainable peace (1.6), with a special focus on the etymology of the terms and concepts 'sustainable' and 'sustainability' (1.6.1), on transition and transformation (1.6.2), and on different concepts of peace, such as ahimsa, peace with nature, and sustainable peace (1.6.3).

In section seven, the alternative approach to sustainability transition will be reviewed (1.7). The section examines its origins and conceptual evolution in North America and Europe (1.7.1), especially the early US debate (1970s onwards) on sustainability transition (1.7.2), and looks at a Dutch scientific research initiative dating from 2005 (1.7.3), and a German scientific advisory report on a 'Social Contract for Sustainability'(1.7.4). This advisory report put this approach on the policy agenda, thus enriching other policy debates on green growth and decarbonization that had been launched by international organizations and governments (1.7.5). All these debates produced feedback for an emerging new research paradigm in the social sciences (1.7.6), and this has been addressed in at least six dimensions of the research on 'sustainability transition' (1.7.7): the spatial (1.7.7.1), scientific (1.7.7.2), societal (1.7.7.3), economic (1.7.7.4), political (1.7.7.5), and cultural (1.7.7.6) dimensions of sustainability transition.

The last section introduces the ten parts of this Handbook and offers an overview of its 40 peer-reviewed contributions (1.8), examining the move towards sustainability transition (1.8.1), the target of sustainable peace (1.8.2), and meeting the challenges of the twenty-first century, e.g. demographic imbalances, rise in temperature, and the climate–conflict nexus (1.8.3). This is followed by a review of different efforts to initiate research into global environmental change, the limits to growth, and the decoupling of growth and resource needs (1.8.4), as well as through developing theoretical approaches on sustainability and transitions (1.8.5), and analysing national debates on sustainability in North America (1.8.6). In the areas of policy development and implementation, the next sections address preparing transitions towards a sustainable economy and society, and production and consumption and urbanization (1.8.7), examining sus-

tainability transitions in the water, food and health sectors from Latin American and European perspectives (1.8.8), and preparing sustainability transitions in the energy sector (1.8.9). The last part discusses issues of international, regional and national governance in achieving sustainability transition (1.8.10).

1.2   Purpose and Objectives of this Book

Scientifically this Handbook links the four distinct research programmes of peace, security, development and environmental studies, each with their specific goals. Only limited bilateral scientific exchanges have occurred in the past, e.g. between peace and security, and between development and environment, with the aim of promoting sustainable development (WCED 1987), human security (UNDP 1994; CHS 2003) and sustainable peace (see Brauch, chapter 9 in this volume).

The Handbook connects these three scientific concepts and policy goals with the *research paradigm* of 'sustainability transition'. This focuses on socio-technological, socio-economic and societal as well as political processes of a large-scale and long-term transformative change of the dominant carbon-intensive development path. It does this by addressing the specific causes of global environmental and climate change, and the exponential increase in *greenhouse gas* (GHG) emissions and their concentration in the atmosphere since the end of World War II.

Given the enormity of the challenges facing humankind, and the powerful opposition of the industrial and business sectors affected, as well as the deeply anchored consumer society, Clark, Crutzen and Schellnhuber (2004) have called for a *new scientific revolution* (Kuhn 1962), with a change in world view, similar to the 'Copernican Revolution' (Copernicus, Kepler, Galilei, Giordano Bruno et al.) of the fifteenth century that faced violent opposition from the Catholic Church and its inquisition process. Clark, Crutzen and Schellnhuber (2004) have suggested a new world view of 'sustainability' and proposed a "New Social Contract for Sustainability" (WBGU 2011; Pagliani/ Bonini, 2011; Mancebo/Sachs 2015).[3]

3   UNITAR, Ethos Institute: "Leading International Thinkers Call for New Social Contract", High-level expert panel in Rio de Janeiro, 23 June 2012; at: <https://www.unitar.org/leading-international-thinkers-call-new-social-contract> (23 February 2016).

From the perspective of the *social and political sciences*, multiple theoretical and empirical approaches are presented in this Handbook:

- different notions of *time* in geology, chemistry (Crutzen) and history (Braudel, Kosellek), and of the different duration of processes of transformation, transition and change triggered by 'structure-creating events' (Brauch 2016, chapter 9 in this volume);
- *conceptual theory* by reviewing the evolution (conceptual history) of the changing meanings of the four key political concepts of peace, security, development and environment, and of the three linkage concepts of sustainable development, human security and sustainable peace (see chapter 9 by Brauch);
- from *human geography* (human dimension of global environmental change, see chapters 2 by Dalby and 15 by Ehlers) and *physical geography* or 'geoecology' (Huggett 1995) and anthropology (chapter 14 by Arizpe, Price and Worcester);
- from *scientific breakthroughs* and *sociotechnological* approaches, histories and processes of technological innovations (see chapter 35 by Hargroves);
- from *systems* and *complexity theory* (chapters 13 by Scheffran and 18 by Mesjasz), by addressing the linkages between the earth system and human systems in an era of direct human intervention into nature;
- a.) from theories of *governance* (chapter 40 In 't Veld, and 41 by Happaerts), from local to state and international levels, addressing multiple actors and the three different notions of *Politik* or *politique* as *politics* (process), *policy* (field) and *polity* (norms, legal and regulatory framework).

These new research paradigms and programmes often need to overcome narrow disciplinary approaches and to move to transdisciplinary research designs, both between the different disciplines in the natural sciences, as with *Earth System Science* (ESS) and *Earth Systems Analysis* (ESA), and within the social sciences, as with *sustainability science* (Kates, Clark et al.), but they also need to link the natural and social sciences, e.g. as a *political geoecology* (Brauch/Dalby/ Oswald Spring 2011). Understanding and researching individual cases, as well as strategies, policies and specific measures for sustainability transition, requires such a multidisciplinary or 'consilience' approach (Wilson 1998).

The Handbook provides texts that may be used in graduate seminars in different scientific disciplines

(anthropology, economics, engineering, geography, history, law, political science, sociology, etc.), in research programmes for development studies, environmental (ecology, sustainability) studies, and peace and security studies, but also in new inter- and trans-disciplinary degree programmes, e.g. those in ESS, ESA, geoecology, and transition studies. The Handbook challenges the tendency towards overspecialization of research and knowledge and encourages more holistic thinking in order to facilitate communication between scholars and between scientists and policymakers.

Politically the texts in this Handbook promote longer-term proactive strategies and policies but also shorter-term and specific measures that aim to realize the two complementary policy goals of 'sustainable development' that contributes to 'sustainable peace', as a possible result of a large-scale transition of the systems of production, consumption and governance, both of supply and demand. Two chapters discuss how a process of sustainability transition may foster or endanger the goal of sustainable peace (chapters 9 by Brauch and 13 by Scheffran).

Which peace dividends might a sustainability transition generate, e.g. by countering the prospects of resource conflicts over oil, gas and coal through improvements in energy efficiency and through switching from fossil to renewable energy sources? Which dangers to peace, security and development might be generated by opposition from those industries that are negatively affected by such a transition? These processes focus primarily on unilateral local and national action to reduce GHG emissions, irrespective of global norms and obligations, and on realizing the innovations of these systems, even if the multilateral environment and climate diplomacy remains as paralysed as it has been since 2009 up to the adoption of the Paris Agreement in December 2015.

These changes in the international order differ from the sociotechnical perspective on "the dynamics of transitions", for which Geels and Schot (2010: 11–12) identified five characteristics:

- Transitions are co-evolution processes that require multiple changes in sociotechnical systems and configurations. ...
- Transitions are multi-actor processes, which entail interactions between social groups such as businesses, firms, different types of user groups, scientific communities, policymakers, social movements and special interest groups.

- Transitions are radical shifts from one system or configuration to another. The term 'radical' refers to the scope of change, not to its speed....
- Transitions are long-term processes (40–50 years); while breakthroughs may be relatively fast (e.g. 10 years), the preceding innovation journeys through which new sociotechnical systems gradually emerge usually take much longer (20–30 years).
- Transformations are macroscopic. The level of analysis is that of the 'organizational fields'.

The *Handbook on Sustainability Transition and Sustainable Peace* offers a collection of original peer-reviewed texts by leading scholars from many disciplines that introduce both themes and address their linkages. Both authors and audience are international and the aim is the generation of 'transformative knowledge', with the goal of changing policies towards achieving the dual goal of sustainable development with sustainable peace.

The Handbook examines the impacts of possible 'threat minimizers' through sustainable development policies for international peace and human security (UN 2009a). It emerged from two workshops in Yautepec, Mexico in September 2012 and in San Francisco in April 2013[4] and from a winter school at Chulalongkorn University in Bangkok in December 2013. These addressed possible linkages between scientific discourses and policy debates on global environmental and climate change, on the international, national and human security impacts of climate change issues, on sustainable peace, and on long-term transformative change towards sustainable development. Among the key questions that were addressed in these meetings and which are discussed in the Handbook are:

- Might *business-as-usual* policies that fail to address the challenges posed by global environmental change and the growing intensity of climate-induced natural hazards and disasters threaten the survival of millions of people during this century and pose serious threats to international peace and security?
- Might anticipative learning and a forward-looking public and global discourse on the necessary long-term transformative changes contribute to sustain-

---

4   These workshops are documented with abstracts, Powerpoint presentations and podcasts at: the Yautepec workshop: <http://afes-press-books.de/html/sustainability_ workshop_programme.htm>, and San Francisco Workshop: <http://afes-press-books.de/html/workshop_ SanFrancisco.htm>.

able development and thus address the new dangers to international peace and security in a preventive manner?

• What general policy lessons can be drawn from the violent consequences of the industrial revolution (during the nineteenth century) and the third technical revolution (during the twentieth century) for a long-term transformative change towards sustainable development?

The *Handbook on Sustainability Transition and Sustainable Peace in the Anthropocene* presents a collection of innovative texts written by invited distinguished authors. The Handbook addresses scholars, policymakers and students and may be used across the world for university seminars in environmental studies (sustainability and sustainability transition), development studies, peace and security studies, and international studies. John Grin (see chapter 4 in this volume; Grin/Rotmanns/Schot 2010, 2011), one of the initiators of the sustainability transitions studies discourse, has outlined sustainability transition theory and offered an overview and assessed its gradual evolution:

> The transition perspective on promoting sustainable development recognizes a need for not merely new societal practices, but changes in the structures in which these practices are embedded, and which have co-evolved with earlier practices ('the regime'). This contribution presents insights on the dynamics of sustainable transitions, developed within the context of the Dutch KSI programme (2005-2010), and identifies issues for further research. Three perspectives have been most central to the programme: (i) the sociotechnical approach, primarily rooted in STS [sociotechnological studies] and empirically grounded in historical case studies; (ii) the complex adaptive systems approach, grounded, through action research, in on-going transitions, and (iii) the governance approach, rooted in political science and sociology. I will discuss these approaches as well as two other ones, and indicate some of the main research findings form the KSI programme. For each approach, I will also present the associate governance concepts that translate the theoretical understanding of transitions into prescriptions for shaping them.[5]

Sustainable Peace is a normative goal that aims at 'peace with nature', based on a sustainable development process that has been used in the context of development and peace, and to a lesser extent in environmental studies (Coleman/Deutsch 2012; Oswald Spring/Brauch/Tidball 2014). Alongside negative, positive, cultural and engendered peace, 'sustainable peace' has been recently introduced as one of five con-

ceptual pillars of an emerging 'peace ecology' (Oswald Spring/Brauch/Tidball 2014):

> *Sustainable peace* refers to the manifold links among peace, security and the environment, where humankind and the environment as the two key parts of global Earth face the consequences of destruction, extraction and pollution. ... The sustainable peace concept includes also the processes of recovering from environmental destruction, reducing the human footprint in nature through a less carbon-intensive—and in the long term possibly carbon-free and increasingly dematerialized production processes that future generations may still be able to decide on their own resources and development strategies.

This Handbook suggests linking the goal of achieving sustainable development through sustainable production and consumption with international cooperative multilateral political strategies for achieving international peace and security. It is argued that the possible peace dividends of *sustainability transition* (ST) strategies may reduce future energy resource conflicts (over scarce oil) and the negative consequences of a BAU approach for global environmental and climate change (Oswald Spring 2008, 2009; Oswald Spring/Brauch 2011).

A key research question of this book is to what extent political strategies aimed at achieving the goal of sustainable development through a gradual process of sustainability transition may reduce the probability of resource conflicts and the security consequences of climate change if policies of *business-as-usual* and a Hobbesian mindset prevail.

To be able to understand the global environmental changes humankind is expected to face during this century, and to be able to create a broad public societal and political awareness in order to create a consensus and political support for proactive coping strategies, a shift from disciplinary to inter- and transdisciplinary as well as to transformative approaches is needed in both the natural and social sciences. This may require a new epistemic community aiming at 'consil-

ience' (Wilson 1988) in science and closer horizontal cooperation in policy-making.

Proactive coping strategies have been difficult and suboptimal in the past, but they have become essential for understanding and coping with these challenges of developing knowledge about and policies on these complex linkages. Approaches aiming at transformative social science and at developing new knowledge about sustainability transition and its impact on sustainable peace are important tasks for the knowledge sector in universities and research institutes as well as for education and the media.

1.3 The Global Environmental Context

The world faces economic crises, population growth, climate change, water scarcity and pollution, soil depletion, erosion and desertification, food crises, urbanization with slum development, rural–urban and international migration, physical and structural violence, gender, race and ethnic discrimination, youth unemployment, a growing loss of ecosystem services, and an increasing number of resource conflicts. The interaction of these multiple crises may result in extreme outcomes, especially for vulnerable people living in risky places, and may reduce human, gender and environmental security and peace (HUGE; see chapter 8 by Oswald Spring in this volume).

This global environmental context has gradually changed since the agricultural and industrial revolution, but over the last fifty years the survival of Earth and humankind has been more intensively threatened. Scientists only began to be aware of this global environmental change in the 1970s, which is when the scientific discourse began, initially in the natural sciences and from the 1990s also in the social sciences. This process has been referred to as *scientization*. In the late 1980s, the political debate and international negotiations (*politicization*) started, with Gro Harlem Brundtland's concept of sustainability (WCED 1987) and at the *United Nations Conference on the Environment and Development* (UNCED) in 1992 in Rio de Janeiro. The global outcome was the signing of the *United Nations Framework Convention on Climate Change* (UNFCCC) and the *Convention on Biological Diversity* (CBD); adoption of a mandate for the *United Nations Convention to Combat Desertification* (UNCCD) that was signed only in 1994.

Global environmental change is wider than climate change. The term refers to the transformation produced by human beings in the ecosphere, which affects the hydrosphere (the combined mass of water found above, on and under the surface of the planet), the atmosphere (the layer of gases surrounding the surface), the biosphere (the global ecological system where all living beings exist), the lithosphere (the outer layer of the Earth) and the pedosphere (the soil) (see chapter 2 by Dalby; NRC 1999; Oswald Spring 2016).

Changes in the natural system are the result of modifications in agricultural production, of rapid urbanization processes, and of population growth (Oswald 2011). Furthermore, unsustainable productive processes are polluting natural resources and creating health threats for human beings, as well as endangering ecosystems (Elliott 2011). The energy, transportation and production sectors have polluted heavily due to their use of fossil fuels (IEA 2014). In addition, changes in land use and deforestation are reducing the capture of *carbon dioxide* (CO_2) (IPCC 2014a; 2014b). For these reasons, the emissions from *greenhouse gases* (GHG) have increased exponentially (IPCC 2013). In addition, a globalized financial system, unequal credit access, current patterns of consumption and production, and an uneven level of access to resources are also contributing to environmental change. Irrational behaviour has also produced poverty, hunger, and inequality among regions and social groups (Wilkinson/Pickett 2009).

In Earth and human history, drastic changes have gradually occurred since the industrial revolution (1780–1870). Such changes have taken place especially over the last five decades, because of the intensive use of fossil energy; the rapid increase in GHG emissions into the atmosphere; pollution, warming, and acidification of the seas; massive changes in land use, population growth, and an accelerated process of urbanization. The Anthropocene represents a new geological epoch that is changing the history of Earth. Bond, Showers, Cheseby et al. (1997) define it as "the most recent manifestation of a pervasive millennial-scale climate cycle operating independently of the glacial–interglacial climate state". This concept is useful for understanding the transformative negative effects of human activity on the global planet, on its ecosystem services, and on humankind itself. Nevertheless, human agency also has the potential for positive change.

Nobel laureate Paul J. Crutzen claimed in February 2000, during an IGBP meeting in Cuernavaca, that "we are in the Anthropocene" (Moore III 2000; Crutzen/Stoermer 2000). Crutzen (2002) links these changes with the environmental changes induced and produced predominantly by human intervention. The

'Anthropocene' is a term widely used since to denote the present time interval, in which many geologically significant conditions and processes are profoundly altered by human activities. These include changes in erosion and sediment transport associated with a variety of anthropogenic processes, including colonization, agriculture, urbanization, population growth, poverty, inequality (Oxfam 2016), and global warming.

The chemical composition of the atmosphere, oceans and soils has been altered, with significant anthropogenic perturbations of the cycles of elements such as carbon, nitrogen, phosphorus, sulphur, various metals, and emergent pollutants in water and soil (Cortés/Calderón 2011). Environmental and human conditions generated by these perturbations include global warming, ocean acidification, the spreading of oceanic 'dead zones', and biosphere destruction on both land and sea. This has resulted in habitat loss, predation, species invasions, and physical and chemical changes, and has also led to socio-economic changes, with greater inequality, poverty and misery among socially vulnerable groups, together with gender discrimination and violence.

1.3.1   "We are in the Anthropocene"

In the natural and social sciences six historical times (Brauch 2016) may be distinguished. These have triggered multiple contextual changes of different duration: a) *cosmic time* in modern physics and astronomy, that is beyond any human influence; b) *geological time* in contemporary earth sciences; c) the *technical time* of the Neolithic and industrial revolutions that have triggered the change in geological time with the 'silent transition' from the Holocene to the Anthropocene. The French historian Braudel (1969, 1972) distinguished between *three times* in human history: d) *structural time* (e.g. of international order); e) *cyclical time* (e.g. of the government of presidents and prime ministers); and f) the short *time of historical events*. Such historical events (e.g. revolutions, coups, elections, disasters) may trigger changes in governments (cyclical time) or even of international order (structural time, e.g. the Russian revolution of 1917 or the fall of the Berlin Wall in 1989).

Since the industrial revolution a long series of technical inventions, e.g. by Watt, Edison, Curie, Bell, Daimler, Benz, Ford, Röntgen, Zuse, Lederberg, Müller, with indirect intervention into the earth system by humans, has resulted in fundamental changes: the accumulation of CO_2 and the destruction of the ozone layer, biodiversity, soil and water. During the

twentieth century several major changes in international order occurred. Two resulted from global (1919, 1945) and regional wars (Korea, Indochina, Algeria, Angola, Uganda, Liberia, Congo, Iraq, Afghanistan, Yugoslavia, etc.), and military *coups d'état* (Chile, Argentina, Bangladesh, Myanmar, Ghana, Chad, Fiji, etc.). The others were the outcome of liberation struggles (independence of India, Pakistan, Vietnam, African nations) or were peaceful changes (the disintegration of the Soviet Union, which was not a victory for the West (Schweitzer 1994) but the result of a 'learning' (Grunberg/Risse-Kappen 1992) by the new Soviet leadership). Others were related to interventions by the UN Security Council or regional peace bodies (the African Union), some of them with unintended outcomes.

Geologists and Earth scientists use a "*geological time scale*" (GTS) approved by the "International Commission on Stratigraphy" (Cohen/Finney/Gibbard 2012; Gradstein/Ogg/Schmitz 2012). In 2008 the international Commission on Stratigraphy set up a study group "to make the Anthropocene a formal unit of geological epoch divisions", with the goal of reaching a decision by 2016 (Waters/Zalasiewicz/Williams et al. 2014).[6]

With the end of several wars of independence, e.g. the Vietnam War (1975), and of the cold war (1989), a peaceful regional and global transition of the structure, strategies and international politics in the Westphalian sovereignty-based system of nation states resulted. The 'silent' transition from the Holocene[7] to the 'Anthropocene' is more profound, however. The fundamental change from the '*Holocene*' to the '*Anthropocene*' is caused by increasing human interventions in the Earth processes, but there is no agree-

---

6   See the Working Group on The 'Anthropocene', *International Commission on Stratigraphy* (ICS); at: <http://quaternary.stratigraphy.org/workinggroups/anthropocene/>; see also the most recent "Newsletter of the Anthropocene Working Group", September 2014; at: <http://quaternary.stratigraphy.org/workinggroups/anthropo/anthropoceneworkinggroupnewslettervol5.pdf>. The convenor of this working group is Dr. Jan Zalasiewicz (University of Leicester, UK).

7   The Holocene started with the end of the glacial period about 12,000 years ago. This marked the beginning of great civilizations in the Mediterranean, China, India, Egypt, Mesopotamia and Meso-America. The 'Holocene' is a period of geological transition, when a dramatic environmental change took place, with a major rise in sea level as a result of the melting of the huge ice sheets that covered large areas in the northern hemisphere.

Figure 1.1:   Atmospheric CO2 at Mauna Loa Observatory.**Source**: National Oceanic and Atmospheric Administration (NOAA)—Monthly Data for Atmospheric CO_2 from 1958 until December 2015; at: <http://www.esrl.noaa.gov/gmd/ccgg/trends/full.html> (30 January 2016).
ment on when the 'Anthropocene' actually began. Crutzen initially named the Industrial Revolution as the starting point, while others pointed to the end of World War II, after which greenhouse gas concentrations increased exponentially due to the rapid increase in the burning of oil and natural gas (figure 1.1). But Crutzen (2006: 17) argued that since humankind "will remain a major geological force for many millennia", it is necessary "to develop a world-wide accepted strategy leading to sustainability of ecosystems against human induced stresses", and that this will be "one of the greatest tasks of [hu]mankind, requiring intensive research efforts and wise application of the knowledge".

After the Industrial Revolution the CO2 concentration in the atmosphere rose from about 279 ppm in 1750 to 315 ppm in 1958. But from 1958 to November 2015, CO2 concentration increased to 400.38 ppm.[8] While from 1750 to 1958 CO2 concentration rose by 36 ppm, from 1958 to 2015 it increased by 85 ppm.

___

8   See "Weekly Data-Atmospheric CO2"; at: <http://co2 now.org/Current-CO2/CO2-Now/weekly-data-atmospheric- co2.html> (2 December 2015), and at: <http://www.esrl.noaa.gov/gmd/ccgg/trends/global.html# global> (30 January 2016).

NOAA noted that "for the past ten years (2005–2014), the average annual rate of increase is 2.11 parts per million (ppm). This rate of increase is more than double the increase in the 1960s".

1.3.2   Changing Interactions between the Human and Earth System in the Anthropocene

The 'silent transition' in earth history from the Holocene to the Anthropocene is the result of multiple interactions between the human and earth systems. Humankind has for the first time directly interfered in nature and has triggered physical effects in the global climate system. This has resulted in small-onset a) temperature rise, b) precipitation change, c) extreme weather events, and d) slow-onset sea-level rise. To analyse these interactions, the PEISOR model (figure 1.2) was developed by Brauch (2005: 16; 2007: 28; 2009: 76). It was inspired by several similar pressure–response models produced by international organizations (OECD 2001; EEA, UNCSD) to securitize GEC issues from an environmental security perspective. This model combines five stages:

Figure 1.2: The PEISOR model. **Source**: Brauch (2009: 76); Brauch and Oswald Spring (2009: 9).

Pressure	Effect	Impact	Societal Outcome	(Policy) Response
Causes of *Global Environmental Change (GEC)*	Socio-economic interaction Environmental scarcity, degradation and stress	Natural and human-induced hazards	Individual choice *(survival dilemma)* Societal response	National and international political process, state, societal and economic actors and knowledge

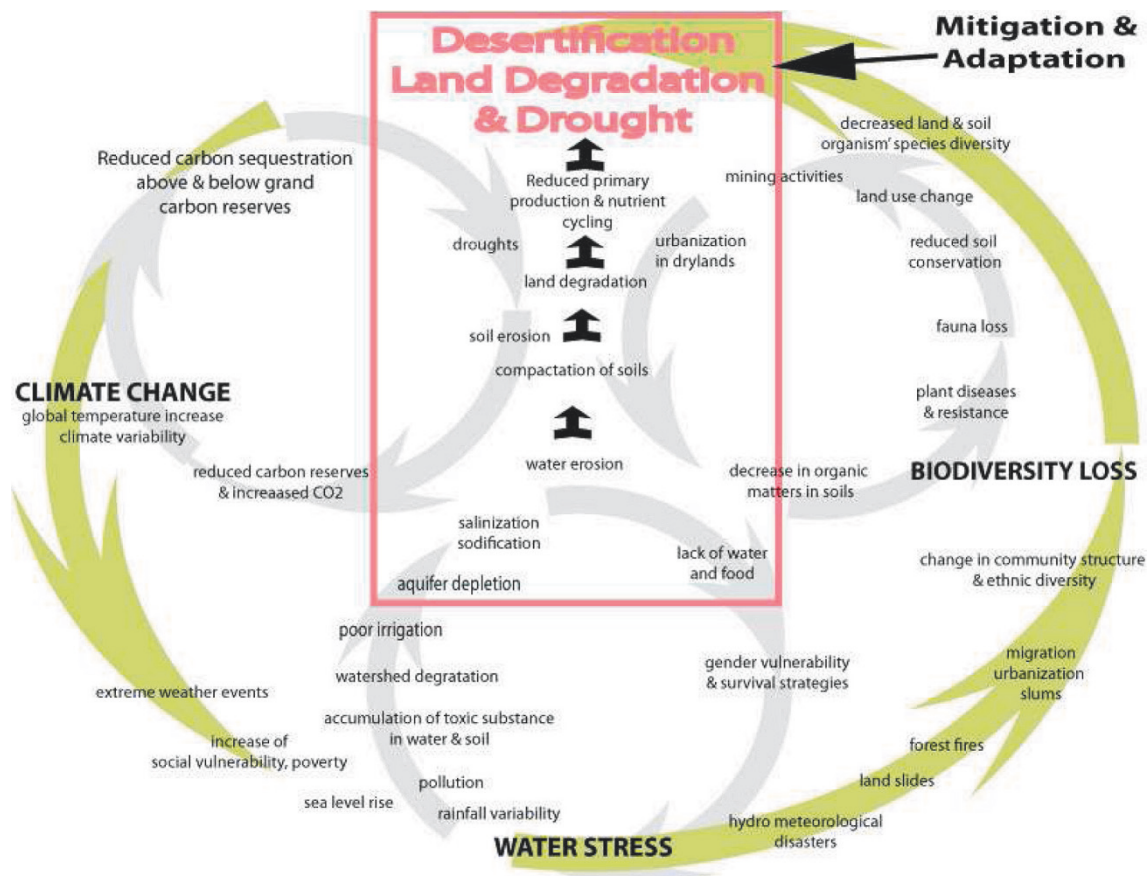
- *P (pressure)* refers to the eight drivers of global environmental change;
- *E* to the *effects* of the interactions on environmental scarcity, degradation, and stress;
- *I* to the extreme *impacts* of human-induced and climate-related natural hazards;
- *SO* to *societal outcomes*: forced migration, slums, crises, conflicts or state failure;
- *R* to the *response* of all stakeholders.

In the PEISOR model, 'Pressure' refers to the eight factors contributing to GEC. They often interact in a non-linear or chaotic way and impact on earth and human systems. The political and societal contexts may affect the socio-economic processes that contribute to anthropogenic environmental degradation or to resource scarcity that may result in environmental stress. Four factors are key drivers of the human system (population, rural systems and agriculture, urbanization, industry and services, and the socio-economic development process), and these affect the 'environmental quartet' of the earth system: climate change (air) (1.3.5), biodiversity (1.3.6), water (1.3.7) and soil (1.3.8).

Figure 1.2 illustrates GEC and the complex interactions and feedbacks between the earth and human systems needed to understand the impact of climate change, water stress and biodiversity loss on *desertification, land degradation and drought* (DLDD). In figure 1.3 the three small cycles with the factors determining climate change, water stress and biodiversity loss each have different effects on DLDD. The wider cycle representing GEC describes the often chaotic interrelations between the earth and human systems and their possible societal outcomes.

1.3.3 Global Environmental Change and its Physical and Societal Impacts in the Twentieth and Twenty-First Centuries

During the twenty-first century, the relationship between the causes and severe societal outcomes of GEC and climate change may result in environmentally-induced massive and forced movements of people, hunger- and famine-induced protests, and small-scale societal violence. It may also possibly result in violent conflicts within and between countries. These

Figure 1.3: Environmental Quartet: DLDD, Climate Change, Water Degradation and Biodiversity Loss. **Source**: The figure was developed by Úrsula Oswald Spring based on MA (2005: 17) and designed by Guillermo A. Peimbert, UNAM/CRIM, Mexico.


may pose numerous security dangers, and these have increasingly been addressed by governments and international organizations (Brauch 2002, 2009; WBGU 2008; Gleditsch 2012; Scheffran/Brzoska/ Brauch et al. 2012; IPCC 2014a; see chapter 12 by Ide, Link, Scheffran and Schilling; chapter 13 by Scheffran).

While a number of natural scientists had hypothesized on the linkages between the burning of hydrocarbons and an increase of the greenhouse gases in the atmosphere from the nineteenth century onwards (e.g. Tindall, Arrhennius in 1896 et al.), the concept of *global environmental change* and associated research in the natural sciences has gradually emerged from the 1970s onwards (IGBP, WCRP, DIVERSITAS) and in the social sciences from the 1990s (IHDP, chapter 14 by Arizpe/Price/Worcester and chapter 15 by Ehlers). In 1988 the *World Meteorological Organization* (WMO) and the *United Nations Environment Program* (UNEP) established jointly the IPCC and this was endorsed by the *United Nations General Assembly* (UNGA). The role of the IPCC is to assess

on a comprehensive, objective, open and transparent basis the scientific, technical and socio-economic information relevant to understanding the scientific basis of risk of human-induced climate change, its potential impacts and options for adaptation and mitigation.

1.3.4 Demographic Change and Urbanization in the Twenty-First Century

During the twentieth century world population increased threefold, while water use rose sixfold (Steffen/McNeill/Crutzen 2007: 617; Steffen/Grinevald/ Crutzen et al. 2011: 843). The interdependence of technological change, agricultural change (the green revolution with improved seeds and today transgenic seed, irrigation, chemical fertilizers, pesticides, and heavy agricultural machinery), cheap energy, and medical improvement (antibiotics) has resulted in a rapid growth in population worldwide (see chapter 10 by Zlotnik), while birth control, reproductive health for women, and contraception have been limited due to

cultural (patriarchy), religious (Christianity, Islam, Buddhism) and social obstacles (poverty, illiteracy, lack of hygienic conditions, public health or medical attention).

The medium variant of the *United Nationa Population Division*'s (UNPD) 2015 Population Revision (2015: 7) projection indicated that a global population of 7.349 billion in 2015 would increase to 9.725 billion in 2050 and reach 11.213 billion by 2100. Most of this growth will take place in the poorest developing countries. The highest increase is forecast for Africa, where the population rose from 133 million in 1950 to 1.186 billion in 2015 and is projected to rise further to 2.478 billion by 2050 and to 4.387 billion by 2100, representing 25 per cent of the global population in 2050 and 39 per cent by 2100 (UNPD 2015: 9). The Asian continent was the most populated region and in 2015 held 4.93 billion of a global total of 7.349 billion people; this figure is projected to rise in 2050 to 5.267 billion and to fall to 4,889 billion by 2100. For North America, population is projected to grow from 358 million in 2015 to 433 million by 2050 and to about 500 million by 2100, while the projected increase for Latin America will be more modest, from 634 million in 2015 to 784 million in 2050, after which it will decline to 721 million by 2100. Only for Europe is a continuous decline projected: from 738 million in 2015 to 734 million in 2030, to 707 million in 2050, and to 646 million by 2100 (UNDP 2015: 7).

Most of this population growth will occur in urban areas. While in 1950 only 30 per cent of the world's population was urban, by 2014 about 54 per cent were residing in an urban context and the projections indicate 66 per cent by 2050. The turning point from rural to urban population was in 2007.

From an occidental view, Eric Hobsbawn (1962: chapter 11) insisted that "urban development in our period [1789-1848] was a gigantic process of class segregation, which pushed the new labouring poor into great morasses of misery outside the centres of government and business and the newly specialized residential areas of the bourgeoisie. The almost universal European division into a 'good' west end and a 'poor' east end of large cities developed in this period." The developing countries could not avoid this segregation process and today the *United Nations Population Fund* (UNFPA) (2012) has stated that informal slum settlements suffer "disproportionately from disease, injury, premature death, and the combination of ill-health and poverty entrenches disadvantage over time" (UNFPA 2012).

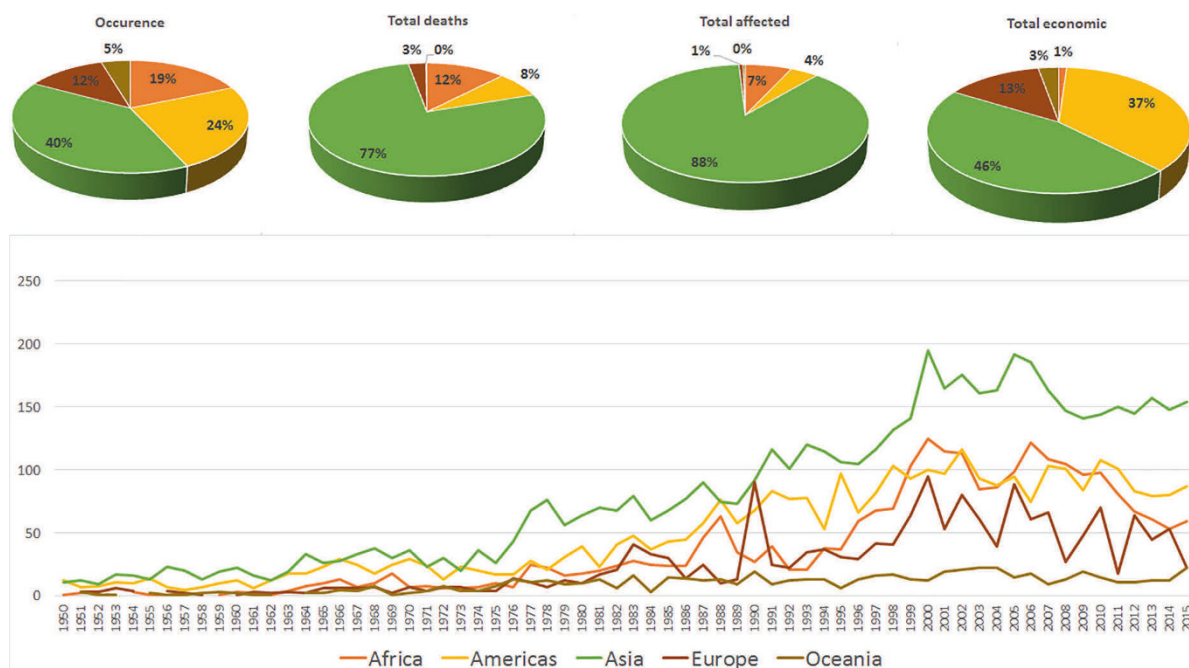
In the cities in the developed world, urbanization follows a general pattern of immigration into downtown areas. Most of the impoverished city centres have also exhibited a concentration of human activities and settlements around the so-called 'peripheralization of the core'. Henderson (2002) argued that urbanization in developing countries resulted in very high levels of concentration of people in megacities. Since 1995 an enormous change in cities has occurred globally and today almost half of the world's population lives in big cities, which is also where future growth will mainly occur (Cohen 2006). These megacities create enormous socio-economic, environmental and cultural challenges. This excessive concentration of people has created traffic congestion and air, water and soil pollution. Lack of city planning and management is often combined with corruption, increasing health threats and reducing the quality of life.

1.3.4.1 Impacts of Population Growth and Urbanization

The results are urban heat islands and a lack of safe food, drinking water, drainage systems and sewage treatment plants. Gasoline with lead and a lack of parks and green areas are other additional threats to health and well-being. The eutrophication of water and rain leaches all type of pollutants to aquifers, rivers and seas and has damaged large areas of agricultural land and marine ecosystems (Cortes/Calderón 2011). Nevertheless, planned urban development may also create new environmental opportunities. Land use is concentrated, provision of services is cheaper, food is widely available and increasingly produced even on roof and vertical gardens. Public transport systems often replace private cars, reducing air pollution. Furthermore, parks and green cities are promoting new models of urban settlement and job opportunities. But in poor megacities the absence of job opportunities, food scarcity and escalating poverty may also become a 'threat multiplier'. When good governance is absent and corruption and liberalizing reforms limit the state resources, then public insecurity, organized crime and insurgency could destroy existing development strategies and prevent people's survival.

1.3.4.2 Anthropogenic Global Environmental Change

Projected population growth, the change in hygienic conditions, developments in urbanization, and the increase in or lack of income means that from now until 2100 there will be an increase in the demand for

Figure 1.4: Reported natural disasters by continent (1950–2015). **Source**: D. Guha-Sapir, R. Below, Ph. Hoyois - EM-DAT: The CRED/OFDA International Disaster Database – <www.emdat.be> – Université Catholique de Louvain - Brussels - Belgium, The figures were published in: CRED Crunch, No. 30, January 2013:"Natural disasters in Asia" (Brussels: CRED: 1). Permission of the authors was granted on 14 March 2015. The authors are grateful to Régina Below for updating the figure from 1950-2010 to 1950-2015.


water, food, energy, housing, industrial goods, and public services. Global environmental change has directly affected many natural processes, such as a) climate change—with a rise in temperature, changes in precipitation, extreme weather events (droughts, storms, floods, forest fires, heatwaves) and a rise in sea level; b) loss of biodiversity due to deforestation, changes in land use, land grabbing and industrial and urban development; c) soil degradation, related to the overuse of agrochemicals, inadequate irrigation systems, erosion and desertification; and d) water scarcity, degradation and pollution due to the interaction of population growth, industrial, urban and agricultural pollution, and poor soil and ecosystem management. Confronted with these multiple environmental stressors, humankind can not only destroy but also has the capacity to restore and recover the natural resources and ecosystem services affected.

1.3.5 Climate Change Impacts and Policy Responses

Since the first Report of the IPCC in 1990, scientists have warned that climate change is a 'threat multiplier', which exacerbates other threats to social and natural systems. The existing dual vulnerabilities (Bohle 2001, 2002; Oswald Spring 2013) caused by environmental challenges (posed by GEC and climate change) and social threats (globalization, poverty, violence) have increased the risks that extreme events (figure 1.4) are transformed into disasters.

1.3.5.1 Physical and Societal Impacts of Anthropogenic Climate Change

The physical impacts of anthropogenic climate change include storms, floods, droughts, landslides, forest fires, sea-level rise, changes in precipitation, and extreme temperatures. It places additional burdens on the poorest countries because of their lack of human and financial resources, thus further constraining development paths. In response to these environmental challenges, the IPCC (2014a) has proposed positive interaction between adaptation, mitigation and sustainable development, both within and across regions, social actors, and governmental scales. Mitigation efforts could cause risks to environmental resources and drain financial resources from development priorities, including the alleviation of poverty.

But there are also numerous co-benefits, such as improved air quality and reduced energy and water

consumption in urban areas through a greening of cities and from a recycling of water, by shifting to sustainable agriculture and forestry. All these initiatives could contribute to the recovery of ecosystems for carbon storage and other ecosystem services, and also to the enhancement of energy security.

1.3.5.2 Towards Climate-Resilient Pathways and Sustainable Development

Strategies aimed at climate-resilient pathways and sustainable development may contribute to mitigation by reducing GHG emissions and increasing the adaptation and resilience of the people affected. They may simultaneously improve livelihoods and socio-economic well-being, and enhance effective environmental management. Successful implementation depends on policies and cooperation at all levels, where all stakeholders are constructively involved. Usually engineering and technological options are the most common responses; sometimes they are tied together with disaster risk management and water management.[9]

Most assessments of adaptation activities are limited to an analysis of impacts, vulnerabilities, and adaptation planning, primarily from a top-down perspective, where the processes and multiple effects of actions are rarely assessed. Most adaptation policies recognize the value of social, institutional, and ecosystem-based measures and of common enabling factors. The IPCC (2014a) emphasized that these factors should include effective institutions and governance, innovation and investments into environmentally sound technologies and infrastructure, sustainable livelihoods and behavioural and lifestyle changes.

Other global risks of climate change are concentrated in urban areas, due to heat stress, extreme precipitation, inland and coastal flooding, landslides, air pollution, drought, and water scarcity affecting people, assets, economies, and ecosystems. In developing countries the lack of essential infrastructure and services as well as living in flood-prone and highly exposed regions and in poor quality housing increases the vulnerability and exposure of the poor. Inundations due to rapid-onset tropical storms and floods as well as sea-level rise pose risks to the territorial integrity of small island states and to countries with extensive coastlines. Furthermore, changes in sea ice, in shared water resources, and pelagic fish[10] stocks may

increase conflicts between states. Robust national and intergovernmental institutions can enhance cooperation and manage many of these rivalries peacefully.

Integrated policy responses are especially relevant for a) energy planning and implementation; b) interactions between water, food, energy and biological carbon sequestration; and c) urban planning. These integrated policies provide substantial opportunities for enhanced resilience, reduced emissions, and more sustainable development. These policies require financial and economic support from industrialized states for poor developing countries and especially for low-income groups and vulnerable communities. According to the IPCC (2014a), the effectiveness of adaptation may be further enhanced by transparent governance structures, adequate institutional and human capacities, and partnerships with local governments and organized stakeholders or directly exposed social groups.

1.3.5.3 Towards the Paris Agreement

In this complex situation and given the increasing impacts and threats posed by the physical and societal impacts of climate change, the twenty-first *Conference of the Parties* (COP 21) of the *United Nations Framework Convention on Climate Change* (UNFCCC, 1992) took place in Paris in November and December 2015. Its aim was to negotiate and to adopt a new legally binding agreement that would supersede the Kyoto Protocol (1997) to the UNFCCC, which expired in 2012.

After the failure of COP 15 in Copenhagen (2009), the Paris conference was to agree among the member countries of the UNFCCC on a drastic reduction of GHG emissions that would stabilize the "increase in the global average temperature to below 2°C above pre-industrial levels by reducing emissions to 40 gigatonnes or to 1.5°C above pre-industrial levels by reducing to a level to be identified in the special report". The specific measures were to be identified in an IPCC Report in 2018 "on the impacts of global warming of 1.5°C above pre-industrial levels and related global greenhouse gas emission pathways" (Decisions adopted at COP 21).[11]

The resulting "Paris Agreement"[12] was prepared and approved by 196 participating ministers from state parties, who had submitted their *Intended Nationally*

---

9   The role of science and engineering and the technological dimension will be discussed in more detail in the concluding chapter by Oswald Spring, Brauch and Scheffran.

10 See at: "What are pelagic fish?"; at: <http://oceanservice.noaa.gov/facts/pelagic.html> (2 March 2016).

11 See at: <http://unfccc.int/resource/docs/2015/cop21/eng/10a01.pdf> (9 March 2106).

Determined Contributions (INDC) prior to COP 21. It was agreed that this legally binding agreement would enter into force by 2020.

But these proposed INDCs would stabilize the global average temperature at much higher than 3°C above pre-industrial levels by 2100 (FCCC/CP/2015/7). They are insufficient to reduce GHG emissions and certainly would not realize the general target adopted by the same representatives of the state parties.

However, after procedural matters related to the adoption (1-11), the "II. Intended Nationally Determined Contributions" (12-21) are welcome, the "III. Decisions to Give Effect to the Agreement" listed under 'mitigation' (22-41), 'adaptation' (42-47), 'loss and damages' (48-52), 'finances' (53-65), 'technology development and transfer' (66-71), 'capacity building' (72-84), 'transparency of action and support' (85-99), 'global stocktake' (100-102), 'facilitating implementation and compliance' (103-104) and 'final clause' (105) rely exclusively on voluntary actions. The same applies to the "IV. Enhanced Action Prior to 2020" (106-133). The role of "V. Non-Party Stakeholders", especially of "civil society, the private sector, financial institutions, cities and other subnational authorities" is welcomed.

Although the Paris Agreement will be a legally binding international treaty—once it has been ratified by the required number of states—that will succeed the Kyoto Protocol (1997), it avoids any legally binding obligations in quantitative reduction for the state parties and sanctions in the case of lack of implementation. It is a collection of good intentions that "in enhancing the implementation of the Convention, including its objective, aims to strengthen the global response to the threat of climate change, in the context of sustainable development and efforts to eradicate poverty", with the goal of "holding the increase in the global average temperature to well below 2°C above pre-industrial levels and to pursue efforts to limit the temperature increase to 1.5°C above pre-industrial levels" (Article 2). It referred to what state parties 'shall' and 'should' do but not what they 'have to' or 'must' do to achieve these goals.

Article 6 recognized "that some Parties choose to pursue voluntary cooperation in the implementation of their nationally determined contributions". Although the states established in Article 7 "the global goal on adaptation of enhancing adaptive capacity, strengthening resilience and reducing vulnerability to climate change, with a view to contributing to sustainable development and ensuring an adequate adaptation response in the context of the temperature goal referred to in Article 2", it was only stated that "each Party shall, as appropriate, engage in adaptation planning processes and the implementation of actions".

Also on "loss and damages" (Art. 8) and on financial support of "developed country parties ... to assist developing country Parties with respect to both mitigation and adaptation in continuation of their existing obligations under the Convention" (Art. 9) no specific legally binding commitments for state parties were adopted. In Art. 10 the "Parties share a long-term vision on the importance of fully realizing technology development and transfer in order to improve resilience to climate change and to reduce greenhouse gas emissions", while in Art. 11 "Capacity-building ... should enhance the capacity and ability of developing country Parties ... [to take] effective climate change action". However, according to Art. 27 "no reservations may be made to this Agreement". Developed countries are committed to provide financial and technological support for developing countries and others are invited to help on a voluntary basis. They "should continue to take the lead in mobilizing climate finance from a wide variety of sources, instruments and channel" (Art. 9) and they are voluntarily committed to provide 100 billion dollars annually from 2020 onwards as a floor. This *burden sharing* is complemented with a *review mechanism* each five years from 2023 on, where each country is "updating and enhancing" (Art. 14) their pledges. The third mechanism is a *recognition of the needs* of vulnerable countries for adverting, minimizing and addressing losses due to climate change. A financial compensation for "loss and damage" (Art. 8) brought up by affected countries was not accepted by industrialized countries. Developed country parties should continue to take the lead by undertaking economy-wide absolute emission reduction targets. Developing country parties should continue enhancing their mitigation efforts, and are encouraged to move over time towards economy-wide emission reduction or limitation targets in the light of different national circumstances.

This achievement was the result of more than twenty-three years of international collective action in the framework of the UN. 'Informal informals' held by bodies such as the G7, G20, OECD, OPEC, and small groups of delegates tried to remove the brackets which denoted disagreements on the text. When no progress was achieved, the conference chair, French

---

12 See at: <http://unfccc.int/files/meetings/paris_nov_2015/application/pdf/paris_agreement_english.pdf> (9 March 2016).

foreign minister Laurent Fabius turned to 'indaba' (Barry 2012). This is a Zulu tradition for discussing and negotiating disputes between groups of elders, which was also used in Durban in 2011 to achieve the outcomes of COP 17. In France this procedure consisted of groups of up to eighty delegates whose task was to overcome the disagreements; the final agreement was then accepted by consensus. Paul Bodnar, the US National Security Council's director of energy and climate change observed: "Very rarely do you get to a moment like that and feel completely that what the world had been looking for was achieved in this particular meeting,"[13] Outside the hall fifty thousand people were waiting. After sleepless nights during the negotiation marathon, when they heard about the success they produced a 'Mexican wave'.[14]

There was much criticism from scientists and social movements. Kumi Naidoo from Greenpeace insisted: "The Paris agreement is only one step on a long road and there are parts of it that frustrate, that disappoint me, but it is progress. The deal alone won't dig us out of the hole that we're in, but it makes the sides less steep."[15] The differences between the developed countries who were doing enough to control GHG emissions and the threshold countries, such as China and India, who should do more, were not resolved. There is an agreement that industrialized nations are responsible for the cumulative emission of GHG since the start of the industrial revolution and that China is now the largest emitter, followed by the US, the twenty-eight countries of the European Union, India, Russia, Indonesia, Brazil, Japan, Canada and Mexico. These ten emitters accounted for 68 per cent of all GHG, have 60 per cent of the population in 2011 and produce 74 per cent of *gross domestic product* (GDP) worldwide (World Resource Insti-

tute).[16] There is also agreement that these GHGs—mainly *carbon dioxide* (CO_2)—are warming up the atmosphere and that global GHG emissions should peak as soon as possible, and fossil fuels, including those used for electricity generation, should be eliminated by 2050, thus realizing a decarbonization.

During the Paris conference new alliances emerged, such as the "Carbon Pricing Leadership Coalition"[17] with seventy-four countries, twenty-three subnational governments and more than a thousand companies committed to putting a price on carbon. President Obama launched "Mission Innovation", by which twenty countries agreed to double research and development spending on clean energy technologies over the next five years.[18] Bill Gates promoted the "Breakthrough Energy Coalition", with twenty-eight of the world's wealthiest people providing funding for clean energy technologies.[19]

Finally, the signatories of the Paris Agreement agreed that climate change is closely intertwined with several *Sustainable Development Goals* (SDG),[20] including gender, water, food and health security, where gender equity (tool 7), the empowerment of the vulnerable, climate-intelligent agriculture and nutrition (Oswald Spring 2016) may increase crop yields and improve the income of small-scale farmers, especially in rain-fed and mountain agriculture.

1.3.6   Biodiversity Loss

Gibbs, Ruesch, Foley et al. (2010) indicate that in the tropics between 1980 and 2000 about fifty-five per cent of pristine forest and twenty-eight per cent of disturbed[21] forest were cleared for new agricultural land. This deforestation represents a 'criminal biodiversity loss' affecting crucial ecosystem services, which are

providing food, water, energy, wood, biomass, oxygen and fibre; *supporting* the nutrient cycle, the carbon, nitrogen, sulphur cycle, acting as a biodigestor of waste, and removing naturally different toxins; *regulating* climate, water, waves, and controlling floods, winds and storms; and *offering cultural services* of material and immaterial goods and the patrimony of humanity (MA 2005, 2005a, 2005b).

Human activities, especially in the Anthropocene, have seriously affected Earth's biodiversity. Current extinction rates are a thousand times greater than fossil extinction rates were, and are projected to increase in future to ten times more than the current rate, that is, ten thousand times greater than fossil extinction rates (MA 2005, 2005a, 2005b). This ecological footprint is seriously affecting biocapacity and ecosystem services. During the last four decades many countries, including some of the most biodiverse states (India, China, Mexico, US, Indonesia, Cambodia, Vietnam), have destroyed their natural capital and have created today a bio-debt, which is unable to restore naturally their biodiversity and ecosystem services. The WWF notes that "10,000 representative populations of mammals, birds, reptiles, amphibians and fish, have declined by 52 per cent since 1970" (WWF 2014).[22]

Biodiversity is a cornerstone of developed and developing economies. The *Convention on Biological Diversity* (CBD),[23] as a global agreement, addresses all aspects of biological diversity: genetic resources, species, and ecosystems with their services. It was signed in 1992 in Río and has nearly universal membership, with 196 parties.[24] Two decades later at Rio+20, the 'Strategic Plan' proposed an integrated methodology, where biodiversity was incorporated in economic and social policies. The 'Strategic Plan' (known also as 'Aichi Biodiversity Targets') adopted a long-term vision with five goals, twenty targets, and different tools and mechanisms, able to implement, monitor, review and evaluate achievements.

The five goals address the mainstreaming of biodiversity into other sectors, reducing the pressures on biodiversity, improving the status of biodiversity, enhancing the benefits to all from biodiversity and ecosystem services, and providing for a participatory process of implementation.[25]

This transdisciplinary approach integrates the social, economic and environmental aspects of the SDG, represents a global commitment by all parties and is a flexible national framework for policies that provide mechanisms for monitoring, review and evaluation.

Without healthy conservation of biodiversity, livelihoods, ecosystem services, and natural habitats, food security can be severely compromised. The *Global Biological Outlook* 4 (GBO-4)[26] "finds that reducing deforestation rates have been estimated to result in an annual benefit of US$183 billion in the form of ecosystem services. In addition, many households in developing countries, especially in Asia, derive as much as 50-80 per cent of annual household income from non-timber forest products" (GBO-4 2014: 7). In the UN General Assembly, those countries who were convinced by the economic, environmental and cultural importance of biodiversity declared the years 2011-2020 as the UN Decade on Biodiversity. The *Strategic Plan for Biodiversity* 2011–2020 was adopted in 2010 at the tenth meeting of the *Conference of the Parties to the Convention on Biological Diversity* (CBD).[27]

The 'Nagoya Protocol on Access to Genetic Resources and the Fair and Equitable Sharing of Benefits Arising from their Utilization to the Convention on Biological Diversity'[28] is the second agreement after Cartagena's 'Protocol on Biosafety'.[29] The Nagoya Protocol is a supplementary agreement that was adopted on 29 October 2010 in Nagoya, and entered into force on 12 October 2014, by when seventy-one parties had ratified it (CBD 2011a).

---

21 A disturbed forest or a secondary forest is a "forest that has been logged and has recovered naturally or artificially. Not all secondary forests provide the same value to sustaining biological diversity, or goods and services, as did primary forest in the same location. In Europe, secondary forest is forest land where there has been a period of complete clearance by humans with or without a period of conversion to another land use. Forest cover has regenerated naturally or artificially through planting"; at: <https://www.cbd.int/forest/definitions.shtml> (26 February 2016).

The *Global Environment Facility* (GEF) is the international funding mechanism which supports parties in implementing the Convention and the Strategic Plan. The parties have identified and used different additional innovative domestic and international financial resources, and member states have emphasized national priorities and addressed the way they may contribute to the achievement of the SDGs (CBD 2015). National SDG agendas were promoted among the parties to improve their CBD goals.

Five goals were agreed with the aim of achieving the proposed conserved, restored, maintained and evaluated biodiversity with its ecosystem services by 2050 (CBD 2011c):

> Goal A: Address the underlying causes of biodiversity loss by mainstreaming biodiversity across government and society; Goal B: Reduce the direct pressures on biodiversity and promote sustainable use; Goal C: Improve the status of biodiversity by safeguarding ecosystems, species and genetic diversity; Goal D: Enhance the benefits to all from biodiversity and ecosystem services; Goal E: Enhance implementation through participatory planning, knowledge management and capacity building (CBD 2011b: 1).

Both at the local and national levels, legal terms were included into the national SDG plans. Scientifically there are still discussions regarding the monitoring process and national goals that are sometimes in conflict with global ones, such as extractivism[30] from mines and oil in natural protected areas in Latin America, or land grabbing in Africa.

The *National Biodiversity Strategies and Action Plans* (NBSAP) are trying to translate the global goals into national priorities, which must represent the interests of all ministries.[31] Some countries have been able to create an inter-ministerial or inter-agency committee to improve mainstreaming and integration (CBD 2015). Nevertheless, high profits from mines and oil made by private investors are causing them to pressure governments not to adhere to the CBD convention and its additional protocols. But there are also scientists who are concerned about the protocol. They experience many obstacles in their work for the prevention of diseases and in their conservation activ-

ities, including the imprisonment of researchers. The national history museums are afraid of limits to maintaining their biological collections and to the interchange among institutions, due to the greater legal certainty and transparency for providers and users. Finally, the Protocol must address the illegal trafficking of wild and especially threatened plants and animals, which has become a profitable business controlled by organized crime.

During studies for the preparation of the sixth report of the *Global Environmental Outlook* (GEO-6),[32] experts found that *Latin American and Caribbean* (LAC) countries contain an important proportion of Earth's natural wealth. The absence of environmental planning, the extraction and transformation of raw materials, population growth together with unsustainable urbanization and consumption patterns have degraded biodiversity, soils, water and air and affected ecosystem services, while pollution and toxic emissions have worsened human health and caused conflicts over land and water use.

1.3.7 Soil Degradation, Erosion and Desertification

From the land that is free of ice only 46.5 per cent is in a natural state. Of the remainder, 38.6 per cent is used for agricultural activities and 14.9 per cent has been eroded and occupied by urban, rural and industrial settlements, mines, dams, railways and roads, or is used for plantations (Leb Hooke 2015). Reducing the human footprint on the environment requires the sustainable use of soil, water and air and the encouragement of biodiversity (MA 2005, 2005a, 2005b). *Integrated water resources management* (IWRM) includes the conservation of forests, soils and riverbeds, the restriction of wind and water erosion, strengthening of the slopes and the reforesting of cleared areas. This lets the rain infiltrate into aquifers and the topsoil remains in the mountain areas.

Soil organic matter (SOM) is crucial for carbon sequestration. SOM is a biogeochemical mixture of organic matter that is in the process of decomposition. Due to microbial degradation and mineralization to CO_2 (and methane (CH_4) in anaerobic environments), the majority of plant litter and compounds added to soil remain for a relatively short time (from a few days to a few years). However, in high perennial tropical forests SOM could stay for millennia and

31 See at: <https://www.cbd.int/nbsap/introduction.shtml> (20 February 2016).

32 See at: <http://www.unep.org/geo/> (20 February 2016).

deforestation could produce an abrupt process in the biogeochemical composition of the tropical soil, leaking the stored carbon to the atmosphere. Water is also essential for adequate microbial activity in soils, as in drier soils the rates of decomposition decrease. But flooded soils have lower amounts of organic matter. A high level of precipitation or intensive wind may produce wind or water erosion, with intensive loss of the natural fertility of soils. Healthy soils support plant growth and provide nitrogen, phosphorous, potassium, calcium, magnesium, sulphur and different trace elements (FAO 2016b).

The causes of land degradation—and in its extreme form, desertification—are massive deforestation, overgrazing of fragile savanna soils, overuse of agrochemicals, use of heavy machinery, bad irrigation practices, lack of soil protection, monocultures, and wind or water erosion. One of the most important effects of soil deterioration is desertification, defined by WWF (2015)[33] as being "characterized by the droughts and arid conditions the landscape endures as a result of human exploitation of fragile ecosystems. Effects include land degradation, soil erosion and sterility, and a loss of biodiversity, with huge economic costs for nations where deserts are growing".

Nkonya, Gerber, Baumgartner et al. (2016) estimated that the overall cost of land degradation per year amounts to US$300 billion. Soil degradation affects 3.2 billion people and thirty per cent of the surface of Earth. Of this, forty-six per cent is related to land use changes at a cost of US$231 billion—equivalent to 0.41 per cent of global GDP—and fifty-four per cent is related to the loss of ecosystem services. Deterioration of the natural soil fertility alone accounts for an annual loss of US$15 billion or 0.07 per cent of global GDP.

The most severely affected region is sub-Saharan Africa, followed by Latin America and the Caribbean. In Latin America, Mexico and Argentina suffer worst, due to severe soil deterioration. Land use has undergone significant change during the last century. Between 1900 and 2000, natural forests and mountain areas decreased from 70.1 per cent to 46.5 per cent; crop land increased from 27.2 per cent to 46.5 per cent; and urban areas from 2.7 to 6.9 per cent (UNCCD 2015: 6). In relation to GEC and climate change, there is an emission gap which requires urgent action to achieve sustainable land management, ecosystem and wetland restoration, climate-smart agriculture, agroforestry, and land use and urban planning to reduce not only environmental costs, but also the threat of disasters. UNCCD (2015) suggested restoring twelve million hectares of degraded land every year to help close the remaining emission gap. This was discussed in Paris and may amount to 25 per cent by 2030.

Soil erosion basically affects the upper layer of fertile soil. Half of the topsoil on Earth has been lost during the last 150 years. Soil quality is further affected by compaction, loss of soil structure, nutrient degradation, and soil salinity, which in extreme cases could result in processes of sodification.[34] From the 'green revolution' of 1950 onwards, agrochemicals have been massively used, increasing atmospheric pollution and GHG (CO_2, N_2O), as well as water and ocean eutrophication, and causing serious risks to human health. The *Food and Agriculture Organization of the United Nations* (FAO) (2016b) has examined global trends in soil management and their effects on ecosystem services as far as supply is concerned, where land use change, decreased water availability and biodiversity, decreased soil saturation and increased biomass have had the most important impacts. As far as regulation of supply is concerned, water storage capacity, decreased filtration capacity and carbon sequestration have suffered losses, while from the cultural aspect, there have been impacts on landscape, with decreased natural and recreational potential.

Figure 1.5 (UNCCD 2015) shows the cycle by which deteriorating soils produce a loss in ecosystem services and decreased mitigation and adaptive capacities, which are further worsened by the poor management of land resources. Further effects are related to *climate change* (CC) and biodiversity losses, where invasive species, diseases, loss of habitat and changes in species abundance are increasing existing land degradation and therefore affecting different ecosystem services. Figure 1.5 also points to linkages among the three Rio agreements of 1992 on climate change (UNFCCC), biodiversity (CBD) and land degradation (UNCCD). It is these linkages that are aggravating GEC and CC, where deterioration in soils increases the impacts of disasters, especially during extreme events, such as drought, floods, landslides, and loss of resource management.

1.3.8   Water Degradation, Scarcity and Stress

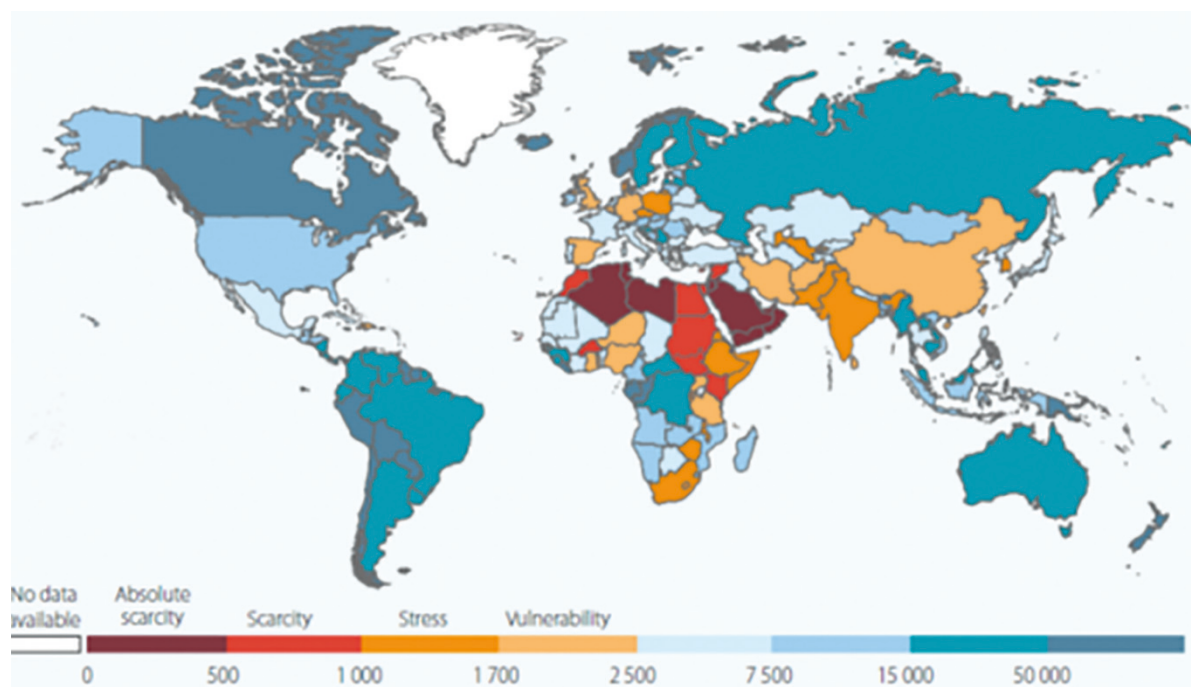
Water accessibility, use and management is crucial for everybody in daily life, as well as for food and industrial production. Only recently there have been concerns about the crucial role of ecosystem services and the loss and pollution of water. Clean water is vital for human health, yet still one out of six people does not have access to safe water and 2.5 billion people lack basic sanitation facilities, while large-scale corporate agribusiness consumes seventy per cent of the fresh water on Earth. Ban Ki-moon argued in the introduction to UN Water (2015):

> Water flows through the three pillars of sustainable development–economic, social and environmental. Water resources, and the essential services they provide, are among the keys to achieving poverty reduction, inclusive growth, public health, food security, lives of dignity for all and long-lasting harmony with Earth's essential ecosystems.

In 2014 UN Water recommended five policies: (i) WASH [access to water, sanitation and hygiene]; (ii) water resources; (iii) water governance; (iv) water quality and wastewater management; and (v) water-related disasters.

Water is analysed generally for its environmental, social, and economic impacts. The link between water and ecosystem services, especially wetlands and mangroves, is still under-recognized. Water is also crucial for safe food production, healthy forests, sustainable agriculture, and urban planning, and reduces human and material losses during any disaster. An integrated focus on ecosystems for development and water protection and conservation should be relevant in decision-making and environmental planning. Evaluation of ecosystem services assesses the trade-offs between water conservation, adaptation to more extreme climate events, and safe drinking water.

The social aspect of water is related to poverty and marginalization with a cross-cutting gender under-

Figure 1.6:   Total renewable water resources, cubic metres per capita (2013). **Source**: UN Water (2015: 12).


standing. Women are generally responsible for water supply, which is critical for the well-being and health of the family. Clean water reduces water-related illnesses and better hygienic conditions improve well-being. At the household level subsistence food production is crucial to overcoming chronic undernourishment, especially for children under five years. Inequality within and between countries is a key factor in underdevelopment and lack of the basic services of safe water, improved sanitation and healthy food supply. Water is ubiquitous in any productive process and clean water reduces costs in health and loss of working hours. Investments in water facilities increase opportunities for businesses and enable self-sustained small enterprises. Clean water and sewage treatment plants depend on the available technology and trained people to operate these facilities. There exists a wide range of technologies, and depending on the number of people to be served and the financial possibilities they range from the household to big cities. Dispersed settlements may increase the costs of providing basic water and sewage facilities. Nevertheless the impact on social and environmental assets compensates for the financial investment, but also represents a basic human right.

The UN Water Report (UN 2015: 4) estimates that "by 2050, agriculture will need to produce 60 per cent more food globally, and 100 per cent more in developing countries". The water footprint is high in agri-culture (Hoekstra 2011) and requires 1,021 litres of water for every litre of milk; 17,196 litres for 1 kg of chocolate and 15,415 litres for 1 kg of beef. Energy production is also water-intensive and additional energy demand will increase the stress on freshwater resources and cause conflicts with existing water users. Increasing solar, geothermal, and wind energy reduces the demand from the cooling systems of thermal power plants. Manufacturing industry is estimated to increase by 400 per cent between 2000 and 2050 but water and energy-efficient productive processes will save fresh water. Some multinational enterprises are already moving their production chain to water-rich countries.

The water demand is expected to increase in all sectors and climate change will further threaten the water supply. The *UN Water Report* (UN 2015: 11) estimates that with a BAU scenario there will be a global water deficit of forty per cent. Figure 1.6 shows renewable water resources per person in 2013, with North Africa and the Arabian Peninsula threatened by absolute water scarcity; Sudan, Kenya and Ghana by water scarcity; and India, Pakistan, Zimbabwe, Myanmar, Tajikistan, Poland, the Czech Republic, the Horn of Africa, and South Africa by water stress. Several of these water-stressed countries are currently involved in armed conflicts and water scarcity is increasing the risks of political instability.

To reduce water conflicts, several transboundary water basins are globally managed through collaboration (the Nile, Mekong, Danube, etc.), but no legal agreements exist that would provide long-term sustainable management of shared aquifers. Big cities are depleting their aquifers in an unsustainable way and often lack of sanitation pollutes green and blue water. The *World Economic Forum* (WEF 2016) has analysed the economic, geopolitical, environmental, societal and technological risks. At the centre is a profound water crisis, which could produce food crises, profound social instability, large-scale involuntary migration, state collapse and massive unemployment and underemployment.

This complex risk scenario is further threatened by climate change impacts and extreme weather events. The IPCC (2014a) assessed that the *Palmer Drought Severity Index* (PDSI) for 1900 to 2002 has drastically changed, and that the cumulative deficit due to precipitation is affecting surface land moisture. Global estimates suggest a probability of 29.5 per cent of longer dry periods, 42.4 per cent of irregular rainfall; of 15.03 per cent in insufficient rain for crops; and of 13.06 per cent in extreme rainfall. This global prediction especially affects rain-fed agriculture, which still provides most food worldwide.

1.3.9 Food Scarcity and Hunger

Food scarcity is of global importance. In 2015, about 850 million people went hungry. By 2050 the world must feed another two billion inhabitants, especially in the poorest countries. In addition, greater prosperity in China, India and other developing countries has increased the demand for meat, milk and eggs, and animals are fed mainly on cereals, in competition with a vegetarian diet[35] and inflating the price of grains (GHI 2014, 2015). Since 1960, the green revolution has meant that modern agriculture employs mechanization, irrigation and agrochemicals. This has increased productivity at the expense of depletion of the aquifers and soils. Genetically modified seeds now promise pest control, but have affected human health and have not increased productivity (Velázquez 2015). Modern agriculture emits more greenhouse gases (GHG) than all means of transport taken together, especially methane from livestock and rice production, nitrous oxide (N_2O) emitted from fertilized

fields, and CO_2 as a result of deforestation for agriculture and ranching (IPCC 2013).

Although 53.5 per cent of primal vegetation has been modified by human activities, more than half of the food produced is still grown organically in home gardens, often by women (FAO 2015; IPCC 2014). Most of the grain from modern agriculture is used for animal feed (FAO 2013b) and transformed into biofuels (Ren21 2014).

Mexico is the birthplace of the so called 'green revolution', an agricultural model using improved or transgenic seeds, massive agrochemicals, mechanization and irrigation. This causes groundwater pollution and abatement especially in the drylands all over the world (Oswald Spring 2011). This model is globally conceived as the 'productive model' of agriculture (Land/Heaseman 2004). The *United Nations Environment Programme*'s (UNEP) GEO-5 report, Gibbs, Ruesch, Foley et al. (2010) and the WWF (2014) have stated that according to this model, and especially because of change in land use from pristine forest to agriculture, intensive agrochemical production modes, and genetically modified organisms, a total of fifteen out of twenty-four ecosystem services have deteriorated (MA 2005). The effects on ecosystems and their services with this 'resource intensive model', aggravated by extensive food subsidies, were further accelerated by the impacts of climate change (IPCC 2013). Particularly in the most affected regions in the South, international organizations and governments have begun to promote adaptation, changes of crop and different seeds to increase the level of resilience in agricultural production.

Because of the increasing changes in food intake, as well as obesity, researchers have included in their models the process of nutrition, access to safe, nutritional and culturally acceptable food for a healthy life, and the permanent local availability of food at reasonable prices. A key issue in 2008 was the increase in the price of basic food. This caused the number of hungry people on the planet to increase to more than one billion. The situation was partially aggravated by drought, by speculation on basic grains in the stock markets, and by the massive use of these grains for biofuel. By 2015, the FAO (2016a) estimated that 800 million people were still chronically undernourished, and 161 million children under five years of age were stunted in their growth;[36] this may result in brain damage and thus affect their future lives (Álvarez/Oswald Spring 1985). Two billion people lack the essential micronutrients for a healthy life, and more than 500 million are obese.

---

35 A calorie of beef requires ten calories of grain; and a vegetarian diet could feed more people.

Increases in population, income and urbanization, and free trade agreements, have made the situation more complex. Together with increases in the price of food, they have driven changes in the demand for food and the demand for feed. In addition, in industrialized countries subsidies for biofuel and livestock have distorted international grain prices, and financial capital has been used to speculate on basic food staples (De Schutter 2014). Both biofuels and ranching have exacerbated the competition for land, water, and food investment. Since 2011, half of the corn produced has been used for ethanol (biofuel) in the US (REN21 2015: 44). These structural phenomena in food production have been further challenged by the impacts of climate change. Transdisciplinary researchers have linked the food system with global environmental change, gender studies and health impacts. The bridges between the social and natural sciences have played a crucial role. Eriksen (2010) synthesized the empirical evidence and showed that the trade-offs of an integrated food system are often context-specific and differ at different scales, and that climate conditions and changes also play a crucial role.

The IPCC (2014a) identified the following as key factors in the decline in food security: the loss of rural livelihood and income; the deterioration in terrestrial and inland water ecosystems; the deterioration in marine and coastal ecosystems; and food insecurity and the breakdown of regional food systems. Prospective models indicate current and future impacts on water availability and supply, food insecurity, and a deterioration in agricultural income. Drylands especially may suffer from shifts in the areas where food and non-food crops are produced. The FAO (2016a: 4) has developed a scheme of cascading effects of climate change on food and nutrition that includes physical, biological, biophysical, socio-economic, livelihood and health factors. Interactions between natural and social factors, changes in food culture, and economic deprivation are further aggravated by climate change impacts, disasters and land degradation. These affect above all the most vulnerable of the poorest countries in Africa, Asia and Latin America. The fifth assessment report of the IPCC (2013, 2014) mentions co-benefits from mitigation, adaptation and preventive behaviour at the national and local levels.

Such behaviour would guarantee food security and healthy nutrition for the most vulnerable people, mostly women and girls.

1.3.10 Gender Impacts of Global Environmental and Climate Change

GEC and CC are not gender-neutral. Socially determined discrimination and conditions of exclusion have limited access to strategic goods, land, education, and health care (Ímaz/Blazquez/Chao et al. 2014). For millennia, the elimination of women from decision-making processes has made them invisible and prevented their equal participation in productive processes. These structural factors, deeply embedded in the patriarchal system and characterized by authority, exclusion, discrimination, exploitation and violence, have also affected justice and human rights. These historical and socially constructed processes also affect values of solidarity and cultural identity (Serrano Oswald 2014). The sources of threats towards women have developed over thousands of years, influenced by patriarchal institutions (Folbre 2006), religious controls (Jaspers 2013), and the totalitarian exercise of power. MacKinnon (1987) claimed that the distinction between women and men is a not just a difference of sexes, but of powerlessness and power. Nevertheless, Judith Butler (1990) criticized the sex/gender distinction and showed that the socially constructed order upholds current power relationships.

This long-term discrimination has been exercised through violence, and this has affected more vulnerable women and girls and has often threatened their survival in disasters (Fordham 1999; Oswald Spring 2008) and wars. Women's bodies were often made into a battlefield (Hynes 2004). During the past millennia the evolution and consolidation of patriarchy has changed and become regionally differentiated. Nevertheless, there are some common dominant factors: ideological control mechanisms around the world have both sociobiological and social constructivist explanations. Ecofeminists (D'Eaubonne 1974; Mies 1986; Warren 1997) believe that similar power relationships between dominance, greed, exploitation, and violence have been the cause of GEC, CC and the destruction of biodiversity. In this context, the international feminist agenda has emphasized the need for a transverse gender perspective for strategies and actions of mitigation, adaptation and disaster risk reduction, where all types of discrimination against women are eliminated. UNEP recognizes that GEC

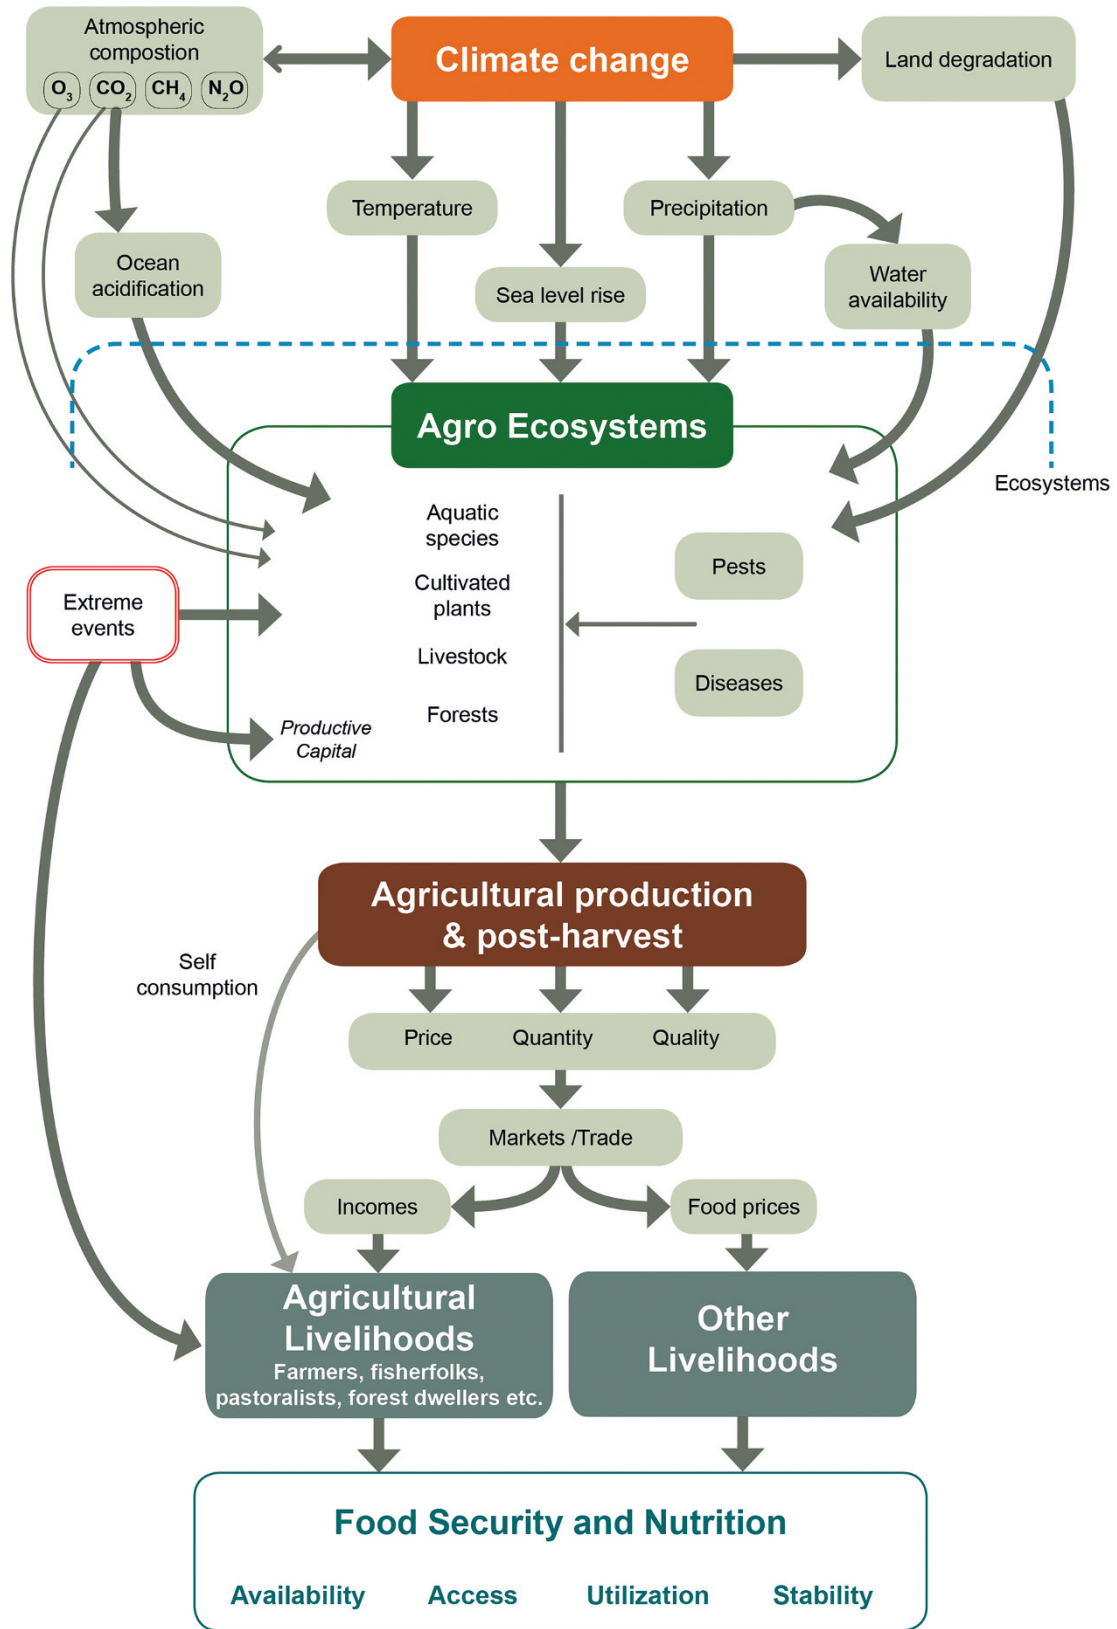
36 UNICEF defines stunted growth as "moderate and severe—below minus two standard deviations from median height for age of reference population", at: <http://www.unicef.org/infobycountry/stats_popup2.html> (26 February 2016).

Figure 1.7: Cascading effects of climate change on food security and nutrition. **Source**: FAO (2016a: 4).


and CC are environmental, technological, social and economic issues, but that they are primarily political and development concerns where gender equality is crucial. The identification of different gender processes in water, food, livelihood, technology and disasters also opens up challenges for collective processes that may create a different qualitative growth, with equality, equity, sustainability and safety for all, men and women.

Traditionally women were always involved in food production, as paid agricultural workers, in the transformation and cooking of food, and in local markets for agricultural and food products. Nevertheless, the modern productive system has made the work of women invisible. Furthermore, modern agriculture is only evaluated in terms of the use of heavy machinery, agrochemicals and large land resources. The IPCC (2014) stated that, especially in developing countries, most of the food is directly produced by women, mostly using positive carbon sequestration processes, reuse and recycling of waste, and the protection of soil, health, and biodiversity. Forests, oceans and soils are crucial for climate mitigation and water capture. People's different capabilities depend on gender, ethnic, age, and social class. This means that governments, international institutions, and social movements need to revise their approaches to vulnerability, risk, prevention, adaptation and resilience.

1.4   Impacts of Different Economic Development Paths

These changes in the global environment have been caused by anthropogenic climate change, loss of biodiversity, processes of soil erosion, degradation and desertification, and processes of water degradation, scarcity and stress. The changes have been facilitated by an increase in the consumption of cheap fossil energy sources (coal, oil and gas). This has emerged slowly since the industrial revolution and has rapidly increased since the end of World War II (1945), and has further intensified since the end of the cold war (1990).

The dominant Western economic development path of *business-as-usual* (BAU) relies on high economic growth rates and uncontrolled financial transaction and accumulation processes. It became globalized with the adoption of state capitalism in China (inspired by Deng Xiaoping's reforms in the 1980s) and the collapse of state communism in the early 1990s. The industrial revolution first emerged in Eng-

land against the background of the British capitalist system. In the early twentieth century, and especially after 1919, the US replaced Great Britain as the leading world economy. After World War II, the US opted for an active role in economic, political and military world leadership. It was instrumental in setting up and initially controlling the Bretton Woods institutions (World Bank, IMF), the United Nations and regional organizations (OAS), the *World Trade Organization* (WTO), and a system of military alliances (e.g. NATO).

Particularly since the end of the cold war, economic neo-liberalism–influenced by the 'Consensus of Washington'–became the dominant global economic doctrine driving globalized financial processes and markets (Notz 2015). Neo-liberalism had been promoted since the early 1970s and 1980s by neo-liberal economic theories and economists (e.g. the Chicago school of Milton Friedman) and implemented by the economic policies of Margaret Thatcher in the United Kingdom and Ronald Reagan in the United States.

Neo-liberalism means the privatization of public services, state-owned property and banking systems, deregulation, a reduction in governmental spending and public subsidies, economic liberalization, and wage containment (Strahm/Oswald Spring 1990; Stiglitz 2010; Kotz 2015). The World Bank and IMF reinforced this policy with a structural adjustment policy applied to highly indebted countries.

In the dominant development path, nature became an object of exploitation. However, from the 1960s environmental movements and from the 1970s national (ministries, agencies, parties, *non-governmental organizations* (NGOs)) and international environmental institutions (UNEP, environmental regimes) addressed the negative consequences that were resulting in the anthropogenic processes of GEC, CC, desertification and water scarcity, degradation and stress.

The materialization of ecosystem services and natural resources has also existed in the state socialist system of the Soviet Union (1917–1991), in the People's Republic of China (since 1949), in Eastern Europe (1945–1989), and in selected communist developing countries (Vietnam, North Korea, Cuba, et al.). The environmental impact of socialist development strategies was largely ignored. With the disintegration of the Soviet Union, the transition of former socialist and communist countries in Eastern Europe to a market economy, economic growth, production and international trade were at the centre of new development strategies. In 2007, China became the largest emitter

of GHG, producing 15 per cent of global cumulative GHG emissions (US: 16 per cent; EU: 12 per cent; Russia: 6 per cent).[37] In 2014, China emitted 7.4 tonnes of CO_2 per capita, overtaking the average of the twenty-eight states of the EU (6.69 tonnes of CO_2 per capita).[38]

With the neo-liberal 'Washington Consensus',[39] global inequality within and inequity among countries has increased from the early 1990s onwards. Stiglitz (2010) has analysed the impacts of faith in the free market and globalization and has shown that the 'great recession' started in 2008 and produced massive unemployment, poverty and a global crisis in so-

called 'American Capitalism'. The richest country in the world had lived beyond its capacity and low interest rates, due to lax regulations in their own country, caused the mortgage bubble. Stiglitz (2010: 21) argued that the crisis became global because "nearly a quarter of US mortgages had gone abroad" and European financial institutions suffered from these toxic mortgages. Banks, car producers and numerous companies

39 The International Monetary Fund (IMF), the World Bank and the US Treasury Department imposed ten economic policy prescriptions to stabilize macro-economically the countries affected by economic crises. John Williamson coined the term 'Washington Consensus' in 1989. This forced developing countries in particular to achieve: a disciplined fiscal policy that would avoid a large fiscal deficit in relation to their GDP; reduction of subsidies and reorientation of public spending towards pro-growth and pro-service investments (private education, health care, infrastructure); a broadening of the tax base through tax reforms; market-determined interest rates; competitive exchange rates; liberalization of imports and elimination of trade protections through trade liberalization; openness to foreign investments and free capital flows; privatization of state enterprises; deregulation of norms that restrict international competition, especially in financial institutions; and legal security for private property rights.

collapsed when suppliers went bankrupt. The American government bailout supported businesses generously, while "low-income workers who had to work hard all their life and had done nothing wrong had to take a wage cut, but not the million-dollar-plus financiers who had brought the world to the brink of financial ruin" (Stiglitz 2010: 43).

The outcome is shown in figure 1.8. The richest 1 per cent of people owned 48 per cent of global wealth in 2014.[40] Of the remaining 52 per cent, the richest 20 per cent leave only 5.5 per cent of global wealth for the rest—80 per cent—of the world's population. Thus the 'Washington Consensus' permitted the richest eighty people in the world to accumulate wealth at a rate even faster than in the past, while the wealth of poor people has decreased. Today these eighty people own more than the whole of the bottom fifty per cent of the world's population. Their income has increased rapidly over the last year and grew especially fast after the crisis of 2008, while poor people lost purchasing power.

This inequality is socially constructed and could potentially be overcome with specific policies. Oxfam (2016) proposed that governments should work for their citizens and tackle extreme inequality; promote women's equality and women's rights; adopt a higher and progressive tax burden on financial capital and income; implement free public services and universal social protection by 2020; reorient R&D towards public health services; invest in development finance to promote the integration of poor people; and close international financial and tax loopholes (tax havens).

The abolition of the ten mandates of the Washington Consensus could be added, as well as a reduction in differences of terms of trade between raw materials and manufactured products; the elimination of agricultural subsidies in industrial countries, which are destroying the food supply in poor countries because of an imposed policy of comparative advantage; land-grabbing and extractive industries; corruption and lobbying of politicians; patents and TRIPs (*trade-related aspects of intellectual property rights*); reinvestment of military and arms spending in development projects and equity; reduction of debts for poor countries, and so on.

1.5　　Integrating the Global Trends

In the scientific realm, different international efforts have addressed the complex linkages between the four global research programmes (WCRP, IGBP, DIVERSITAS, IHDP). In 2002, the *Earth Systems Science Partnership* (ESSP) emerged from a conference in Amsterdam (2001) and a decade later the *Future Earth Initiative*[41] of the *International Council of Science* (ICSU) succeeded the ESSP and its four research programmes; and the *Global Research Forum on Sustainable Production and Consumption* (GRF-SPaC)[42] emerged from meetings in Rio de Janeiro in June 2012.[43]

1.5.1　　The IPCC: Climate Change Impacts for Human Security

So far the direct effect of the four key physical effects of climate change (temperature increase, precipitation change, sea-level rise and increase in extreme events) on security issues (migration, conflicts and wars) is contested (IPCC 2014a, chapter 12; Scheffran/Brzoska/Brauch et al. 2012; Gleditsch 2012). In its assessment of the peer-reviewed social science literature on climate change and human security, the IPCC (2014a) concluded (see box 9.1 in chapter 9 by Brauch):

- *Climate change will have significant impacts on forms of migration that compromise human security (high agreement, medium evidence). ...*
- *Mobility is a widely used strategy to maintain livelihoods in response to social and environmental changes (high agreement, medium evidence). ...*
- *Some of the factors that increase the risk of violent conflict within states are sensitive to climate change (medium agreement, medium evidence). ...*

40　In 2014 1,645 people were listed by Forbes as billionaires. About 30 per cent are US citizens, 85 per cent are aged over fifty and 90 per cent are male (Oxfam 2016: 5).

41　See: <http://www.icsu.org/future-earth/> and: <http://www.icsu.org/future-earth/who>. Future Earth builds on the existing global environmental change programmes (Diversitas, IGBP, IHDP, WCRP and ESSP).

42　See: <http://grf-spc.weebly.com/> and its research agenda: <http://grf-spc.weebly.com/research-agenda.html>.

43　This problem will be discussed in more detail in the concluding chapter by Oswald Spring, Brauch and Scheffran.

- *People living in places affected by violent conflict are particularly vulnerable to climate change (high agreement, medium evidence). ...*
- *Climate change will lead to new challenges to states and will increasingly shape both conditions of security and national security policies (medium agreement, medium evidence)....*

The future impact of climate change on human, national and international security will depend on the success of international diplomatic political efforts to freeze and reduce greenhouse gas emissions, dematerialize the extraction of raw materials, recover ecosystem services, forests, wetlands, and mangroves, protect fresh water, and recover desertified soils.

At the national level, initiatives towards a rigorous application of *Nationally Appropriate Mitigation Actions* (NAMAs) and *Intended Nationally Determined Contributions* (INDCs), and for the protection and restoration of natural areas, climate-smart agriculture and a sustainable economy may counter GEC and CC and conserve the planet for present and future generations.

1.5.2 The Scientific and Political Nexus Debates

With its Risk Report, the *World Economic Forum* (WEF 2011) started a discussion on the security nexus between *water, energy, and food* (WEF), but without including biodiversity. This Forum is an important meeting place for global policy debates between political leaders and the global business elite, who represent multinational corporations and major financial, productive, commercial, and entertainment institutions.

In an early nexus paper the WEF (2011) had adopted a traditional national security approach (Oswald Spring 2016) and ignored the widening, deepening and sectorialization of security (Buzan/ Wæver/de Wilde 1998; Brauch/Oswald Spring/Grin 2009). Their nexus approach between *water, energy and food* security reflected the traditional assumptions of a *business-as-usual* strategy.

It ignored a sustainable nexus between *water security* (WS), *energy security* (ENS), *food security* (FS) and *biodiversity security* (BS) from an *environmental* (ES) and *human security* (HS) perspective. Such a HS approach is based on the four pillars of *freedom from fear* and *freedom from want* (UNDP 1994, CHS 2003), *freedom to live in dignity* (Annan 2005) and *freedom from hazard impacts* (Bogardi/Brauch 2005; Brauch/Scheffran 2012).

1.6 Three Key Concepts: Sustainable Development, Sustainability Transition and Sustainable Peace

The key concepts for this book of 'sustainable' and 'sustainability' (1.6.1) and of 'transition' and 'transformation' (1.6.2), the research programme on 'sustainability transition' (1.6.3), and the meanings and uses of 'sustainable peace' (1.6.3) in the humanitarian and scientific community will be introduced here.

1.6.1 Term and Concept: 'Sustainable' and 'Sustainability'

The adjective 'sustainable', '*sustentable*', '*nachhaltig*' and the noun 'sustainability' have been widely used globally since 1987 in the ecological debate about a preferred development path. The word 'sustainability' is derived from the Latin *sustinere* (*tenere*, to hold; *sub*, up). According to the *Shorter Oxford English Dictionary* (Oxford 2002: 3129), the verb 'sustain' means "1. support the efforts, conduct or cause of (a person); support (a cause or course of action)...; 2. keep (a person, the mind, spirit, etc.) from failing or giving way; 3. cause to continue in a certain state; maintain at the proper level or standard; [and] 4. maintain or keep going continuously (an action or process)..." The adjective 'sustainable' has these meanings: "1. Supportable, bearable; 2. able to be upheld or defended; 3. able to be maintained at a certain rate or level (of economic activity....)." The *Compact Oxford Dictionary of Current English* (Oxford 2002a: 1160) applies the term 'sustainable' to "industry, development or agriculture, avoiding depletion of natural resources". These dictionaries do not include or define separately 'sustainability'.

The German adjective '*nachhaltig*' means "long-enduring, strong" and emerged in the eighteenth century from the noun '*Nachhalt*', indicating "something that is retained for times of distress" (Der Große Duden, volume 7, Etymologie, 1963: 460). The development of the political term 'sustainable development' is reflected in the twenty-first and latest edition of the *Brockhaus Enzyklopädie* (2006, volume 19: 233-237), where the historical roots of the concept are traced to Hans Carl von Carlowitz (1665-1714), who used it in forestry. During the nineteenth century '*Nachhaltigkeit*' or 'sustainability' was used as a principle in forestry, of countering the overuse of wood and guaranteeing a continual supply.

The Club of Rome in its Report *The Limits to Growth* (Meadows/Meadows/Randers et al. 1972;

see chapter 16 by Marino below) used the word 'sustainable' to describe the desirable 'state of global equilibrium'. A report by the *International Union for the Conservation of Nature* (IUCN 1980) included a reference to sustainable development as a global priority. The 'Brundtland Report' (1987) offered the first widely recognized definition of sustainable development as "development that meets the needs of the present without compromising the ability of future generations to meet their own needs". This report contextualized sustainable development within the concept of the 'needs' of the world's poor and "the idea of limitations imposed by the state of technology and social organization on the environment's ability to meet present and future needs" (WCED 1987).

The goal of 'sustainable development' was operationalized in the context of justice, of globalization, of anthropocentric assumptions whose aim was to contribute to securing human existence, and of societal productiveness, while maintaining the possibility of development and action. The key term pointed to *areas of action* (energy, mobility/transportation, construction/living, agriculture/forestry, leisure/tourism, technological development, gender, financing of social systems, ageing population, education/knowledge, development policy), *conflict potentials* (cause of new conflicts, strong vs weak sustainability), and *strategies for implementation* (resource productivity, ecological structural change, resource management, sustainable consumption patterns). Since the first *UN Conference on Environment and Development* (UNCED) in 1972 in Stockholm, the concept of sustainability has been integrated as a joint ecological and development idea, and it was introduced as a political guideline in the Brundtland Commission Report (WCED 1987).

Since the 1980s sustainability has been used in the context of "human sustainability on planet Earth ... as a part of the concept sustainable development..." by the Brundtland Commission (WCED 1987). This Report further stated that "the concept of sustainable development provides a framework for the integration of environment policies and development strategies–the term 'development' being used here in its broadest sense. The word is often taken to refer to the processes of economic and social change in the Third World. But the integration of environment and development is required in all countries, rich and poor. The pursuit of sustainable development requires changes in the domestic and international policies of every nation" (WCED 1987: 3).

Several pillars of sustainability are usually distinguished, the three classic ones being economy, society and environment (UN Millennium Declaration 2000). To these some experts have added 'the next generation' (Brundtland Commission 1987; WCED 1987) as a fourth pillar, and 'politics' (Earth Charter 2000), or 'culture' (Plumwood 2002; Head, Trigger, Mulcock 2005) as a fifth, while others have embedded the economy and society within the environment. The Brundtland concept was later criticized as being arbitrary, an ideological delusion, a utopian hope and a mere illusion.

Agenda 21 was the practical approach to sustainable development. It referred to "four domains of economic, ecological, political and cultural sustainability". Sustainability improves "the quality of human life while living within the carrying capacity of supporting eco-systems". Furthermore, "sustainability implies responsible and proactive decision-making and innovation that minimizes negative impact and maintains balance between ecological resilience, economic prosperity, political justice and cultural vibrancy to ensure a desirable planet for all species now and in the future".

In the social sciences, numerous definitions, research paradigms and programmes have been developed since 1987, when sustainable development was used by policymakers both as a road map and an action plan for achieving sustainability. Sustainability envisions a desirable future state for human societies where living conditions and resource use continue to meet human needs without undermining the 'integrity, stability and beauty' of natural biotic systems. The concept addresses the "concern for the carrying capacity of natural systems with the social, political, and economic challenges faced by humanity".

The *Organization of American States* (OAS), UNEP and the Government of Peru (2001) identified potential conflicts between the concepts of development and sustainability. After the Rio Summit in 1992, the three Rio Conventions on climate change, biodiversity and desertification were not universally implemented, as a few large industrialized countries were unable to ratify them (US) or later withdrew (Canada). Two decades later, at Rio+20 (in June 2012), the governments adopted a more modest and legally non-binding document, "The future we want", which was a step towards the *Sustainable Development Goals* (SDGs).

The *Earth Charter* (1992) called for the "building of a just, sustainable, and peaceful global society in the 21st century". *Agenda* 21, adopted at UNCED in Rio de Janeiro in June 1992, identified information,

Figure 1.9: The Sustainable Development Goals adopted by the UN in 2015: **Source**: UN; at: <http://www.un.org/sustainabledevelopment/sustainable-development-goals/> (23 February 2016).

integration, and participation as three key goals of sustainable development and as the key task of the *UN Commission on Sustainable Development* (UNCSD). In June 2012, the Rio+20 Conference launched a process to develop *Sustainable Development Goals* (SDGs, see figure 1.9) based on the *Millennium Development Goals*. In the Rio+20 outcome document (2012), member states agreed on ten requirements that these SDGs should comply with.[44] On 25–27 September 2015, the SDGs were adopted by the UN Summit on the post-2015 development agenda.[45]

Sustainable Development Goal 16 "is dedicated to the promotion of peaceful and inclusive societies for sustainable development, the provision of access to justice for all, and building effective, accountable institutions at all levels".[46] Among its twelve key targets are:

- Significantly reduce all forms of violence and related death rates everywhere
- End abuse, exploitation, trafficking and all forms of violence against and torture of children

- Promote the rule of law at the national and international levels and ensure equal access to justice for all
- By 2030, significantly reduce illicit financial and arms flows, strengthen the recovery and return of stolen assets and combat all forms of organized crime
- Substantially reduce corruption and bribery in all their forms
- Develop effective, accountable and transparent institutions at all levels
- Ensure responsive, inclusive, participatory and representative decision-making at all levels
- Broaden and strengthen the participation of developing countries in the institutions of global governance
- By 2030, provide legal identity for all, including birth registration
- Ensure public access to information and protect fundamental freedoms, in accordance with national legislation and international agreements
- Strengthen relevant national institutions, including through international cooperation, for building capacity at all levels, in particular in developing countries, to prevent violence and combat terrorism and crime
- Promote and enforce non-discriminatory laws and policies for sustainable development.

However, in the short-term targets there is no reference to 'sustainability transition' as a process to

---

44 See: <https://sustainabledevelopment.un.org/topics/sustainabledevelopmentgoals> (10 February 2015).
45 See: "UN Sustainable Development Platform"; at: <https://sustainabledevelopment.un.org/> (23 February 2016).
46 See: <http://www.un.org/sustainabledevelopment/peace-justice/> (23 February 2016).

achieve a 'sustainable peace', nor is this term even mentioned. Thus the concept lacks an action component to promote sustainable peace among nations, regions, and people.

In their theoretical introduction to "transitions to sustainable development", Grin, Rotmans and Schot (2010: 2) used a definition by Meadowcroft (2000: 73), where sustainable development aims at "promoting human well-being, meeting the basic needs of the poor and protecting the welfare of future generations (intra- and intergenerational justice), preserving environmental sources and global life-support systems (respecting limits, integrating economics and environment in decision-making, and encouraging popular participation in development processes".

1.6.2   Terms and Concepts: Transition and Transformation

The word 'transition' derives from the two Latin words '*trans*' (beyond) and '*ire*' (go) and has been used in many disciplines in the natural sciences (geology, genetics, medicine), social sciences (political science, psychology, sociology, anthropology, economics) and humanities (music, painting, sculpture). According to the *Shorter Oxford English Dictionary* (Oxford 2002: 3129) 'transition' means "1. action or process of passing or passage from one condition, action, or place, to another; change"; 2. passage in thought, speech, or writing from one subject to another...; 4. passage from an earlier to a later stage of development or formation ...". The *Longman Dictionary of Contemporary English* (1995: 1537) defines 'transition' as "the act or process of changing from one form or state to another".

The term 'transformation' originates from the Latin verb '*transformare*' or 'to transform' and it is used in mathematics, physics, chemistry, hydrodynamics, medicine, genetics, soil science, linguistics, political science, law, military affairs and management. According to the *Shorter Oxford English Dictionary* (Oxford 2002: 3327), 'transformation' means "1. action of changing in form, shape, or appearance; metamorphosis; 2. a complete change in character, nature etc.; ... 6. natural change of form in a living organism; metamorphosis ...".

In the twenty-first (2006) and latest edition of the *Brockhaus Enzyklopädie* 'transition' is mentioned as a concept in molecular genetics as a form of point mutation. The nineteenth edition (1993) of the *Brockhaus Enzyklopädie* (1993, volume 22: 311–312) recognized 'transformation' as a concept in mathematics,

medicine, molecular biology, linguistics, and in economics and politics for the fundamental change of the economic, political and societal system or a state. After the collapse of the communist states of Eastern Europe, the concept was used for the transition from a planned to a market economy.

The twenty-first (2006, volume 27: 660–665) edition of *Brockhaus Enzyklopädie* distinguished 'transformation', 'transformation function', 'transformation society' and 'transformation curve'. Accordingly the transformation concept was used in mathematics, physics, medicine, molecular biology, linguistics, and for political and economic issues as in "system transformation and transformation societies". Here 'transformation society' refers to a concept in political and social science and economics relating to "processes and steering problems of societal change in the context of ... interaction of fundamental political, economic, social and cultural changes". These transformation processes focus on political institutions, political culture, value systems, changes in the economic order, and fundamental changes in societal living together and social structure, as well as changes in ways of life, behavioural patterns and value preferences. This concept assumes that such a transformation may be planned and steered.

Karl Polanyi's book *The Great Transformation* (1944) examined the great social and political upheavals England experienced during the industrial revolution with the rise of the market economy and the modern nation state "as the single human invention he calls the 'market society'". The debate on 'transformation societies' was inspired by the theories of Durkheim and Max Weber on 'social change' and it was rekindled after 1990 by the transformation processes taking place in post-communist countries. Since the mid-1990s the prevailing 'transition' or 'transformation research' schemes in political and social science have analysed past changes induced by industrialization (W. F. Ogburn; K. Mannheim), modernization (T. Parsons; W. W. Rostow), and the collapse of the Soviet Union, focusing on the transition of state-socialist political, economic and societal systems towards Western 'neo-liberal' market economies (v. Beyme/Offe 1995; Merkel 1996).

1.6.3   Ahimsa, Peace with Nature and Sustainable Peace

The English word 'peace' comes from the Latin '*pax*', while the Greek '*eirene*', the Hebrew '*shalom*', and the Arabic '*salaam*' mean 'peace with justice', while

the Hindi '*ahimsa*' adds the ecological dimension. 'Ahimsa' means 'not to injure', cause no injury, do no harm, and also involves the concept of nonviolence, which according to Jainism, Hinduism, and Buddhism is to be applied to all living beings–including all animals. "The concept reached an extraordinary status in the ethical philosophy of Jainism. Mahatma Gandhi popularized the term, and he strongly believed that the principle of *ahimsa*, of 'cause no injury', includes one's deeds, words, and thoughts" (Oswald Spring 2008).

In *Wege zum Frieden mit der Natur* ('Ways to peace with nature') Klaus Michael Meyer-Abich (1984) suggested an applied philosophy of nature for environmental policy. For Meyer-Abich (1979, 2003), "peace with nature" is both a domestic and an international task, where human behaviour has to be brought back in line with the wholeness of nature, where increasing hazards and disasters are an expression of the disharmony and lack of peace of humankind with nature. 'Peace with nature' has been called a goal of many initiatives.[47]

'Sustainable peace' is a value-oriented concept that has been used by development NGOs and in the social sciences in development and peace studies, including peace psychologists (chapter 6 by Deutsch/Coleman; chapter 7 by Coleman). Connie Peck (1998: 22–23) introduced the concept into the post-cold war debate on preventive diplomacy and on conflict prevention both as a 'vision' and as a policy programme for conflict prevention. In the conflict prevention and transformation literature, 'sustainable' was primarily used as a synonym for a 'lasting' or 'enduring' peace, without addressing 'peace with nature' (see chapter 9 by Brauch in this volume).

1.7   Alternative Approach to Sustainability Transition

1.7.1   Origins and Conceptual Evolution since the 1970s

The debate on 'sustainability transition' emerged first in the US in the 1970s and was taken up in a report by the US Academy of Science (NRC 1999; see chapter 21 by Twig Johnston in this volume; Raskin/Banuri/Gallopin et al. 2002). It has looked forward to the processes of a long-term system transformation necessary to contain and reduce the effects of the dominant *business-as-usual* paradigm and to reduce GHG emissions through both *multilateral* quantitative emission reduction obligations and *unilateral* transformations.

From 2005, a specific 'sustainability transition' research paradigm emerged from the *Dutch Knowledge Network on Systems Innovation and Transition* (KSI)[48] and from the Amsterdam Conference in 2009 where the *Sustainability Transition Research Network* (STRN)[49] was founded. This particular approach will be presented below, together with other considerations focusing on long-term transformations in culture, values, behaviour and lifestyle.

The UNFCCC and its Kyoto Protocol did not achieve their goals because of the lack of political will to implement them (Brauch 2012), and the "Paris Agreement" (2015) is based exclusively on voluntary commitments (INDC). For these reasons, unilateral bottom-up strategies to reduce both GHG emissions and energy efficiency will be an important coping strategy for facing the impacts of global environmental and climate change.

47 "Make peace with nature" is also the name of a TV show by David F. Surber on WKRC–TV, Channel 12, Cincinnati, Ohio, US; at: <http://www.makepeace-withnature.org/>; see also the "Peace With Nature Initiative" by Costa Rica's former president, Oscar Arias Sanchez; at: <http://www.wegefoundation.com/peace-with-nature-initiative/>; "Pax Natura—Peace with Nature"; at: <http://www.paxnatura.org/> (23 February 2016.

48 For KSI see for details: <http://www.ksinetwork.nl/home>; on its participants: <http://www.ksinetwork.nl/what-is-ksi/participants> and publications: <http://www.ksinetwork.nl/output/publications>; see also Routledge Studies in Sustainability Transition: <http://www.routledge.com/books/series/RSST/>

49 For STRN, see: <http://www.transitionsnetwork.org/>; reference list of ST literature: <http://www.transitions-network.org/files/Reference%20list%20to%20transition%20publications.pdf>. STRN has held conferences in Amsterdam (2009), Lund (2011), Copenhagen (2012) Zürich (2013), Utrecht (2014), Brighton (2015), and Wuppertal (2016); selected results are published in: *Journal on Environmental Innovation and Sustainability Transition*; at: <http://www.journals.elsevier.com/environmental-innovation-and-societal-transitions/>.

1.7.2 Evolution of the US Debate on Sustainability Transition

From the mid-1970s and the late 1990s there have been several initiatives aiming at 'sustainability transition'. The *Tellus Institute*, which was founded in 1976, was an early pioneer of sustainability transition research. Kates (2001: 15325) noted "an effort to re-engage the scientific community around the requirements for a sustainability transition" in the US during the 1990s. This sought "a transition towards a state of sustainable development", which "was studied as a series of interlinked transitions, as a process of adaptive management and social learning, and as a set of indicators and future scenarios". This effort was influenced by "the widespread perception that the continuation of current trends in both environment and development would not provide for the desired state of sustainable development. To the extent that transitions represent breaks in such trends, there was growing interest in identifying the needed or desired transitions in the relationship between society and the environment."

In a first major conceptualization of 'sustainability transition', Speth (1992) specified five "inter-linked transitions (demographic, technological, economic, social and institutional) as collective requirements for a sustainability transition". He proposed "a transition towards technologies that were environmentally benign and reduced sharply the consumption of natural resources, and the generation of waste and pollutants. For the economy, the desired transition was towards one in which prices reflected their full environmental costs. A social transition would move towards a fairer sharing of economic and environmental benefits both within and between countries." As a fifth process, he proposed "a transition in the institutional arrangements between governments, businesses and people that would be less regulation-driven and more incentive-led, less confrontational and more collaborative."

In addition to these approaches, US Nobel Laureate Gell-Mann (1994) "suggested an ideological transition towards a sense of solidarity that can encompass both the whole of humanity and the other organisms of the biosphere and an informational transition that integrates disciplinary knowledge and disseminates it across the society." In order to study these necessary transitions they jointly organized "a major, albeit uncompleted, research effort known as the '2050' project (World Resources Institute, Brookings Institu-

tions, Santa Fe Institute) that sought to track these transitions and understand their interactions".

Kates (2001) noted two different approaches by the US National Academy of Sciences in its report *Our Common Journey: A Transition toward Sustainability* (NRC 1999), and a process of social learning (Social Learning Group 2001). The NRC's research agenda was "based on both current scientific understanding and the requirements of an emerging sustainability science". The report "identified concrete goals and appropriate next steps to accelerate major transitions underway or needed in each sector" and tried "to integrate global and local perspectives to shape a 'place-based' understanding of the interactions between environment and society; and initiate focused research programs on a small set of understudied questions that are central to sustainability transition".

A fourth group focused on long-term scenarios of alternative pathways to transition "about how the global system might unfold". These scenarios reflected "current trends and reform proposals, various forms of social and environmental breakdown, and more fundamental transitions or transformations (Raspin/Gallopin/Gutman et al. 1998, Hammond 1998)". The NRC (1999) report concluded that

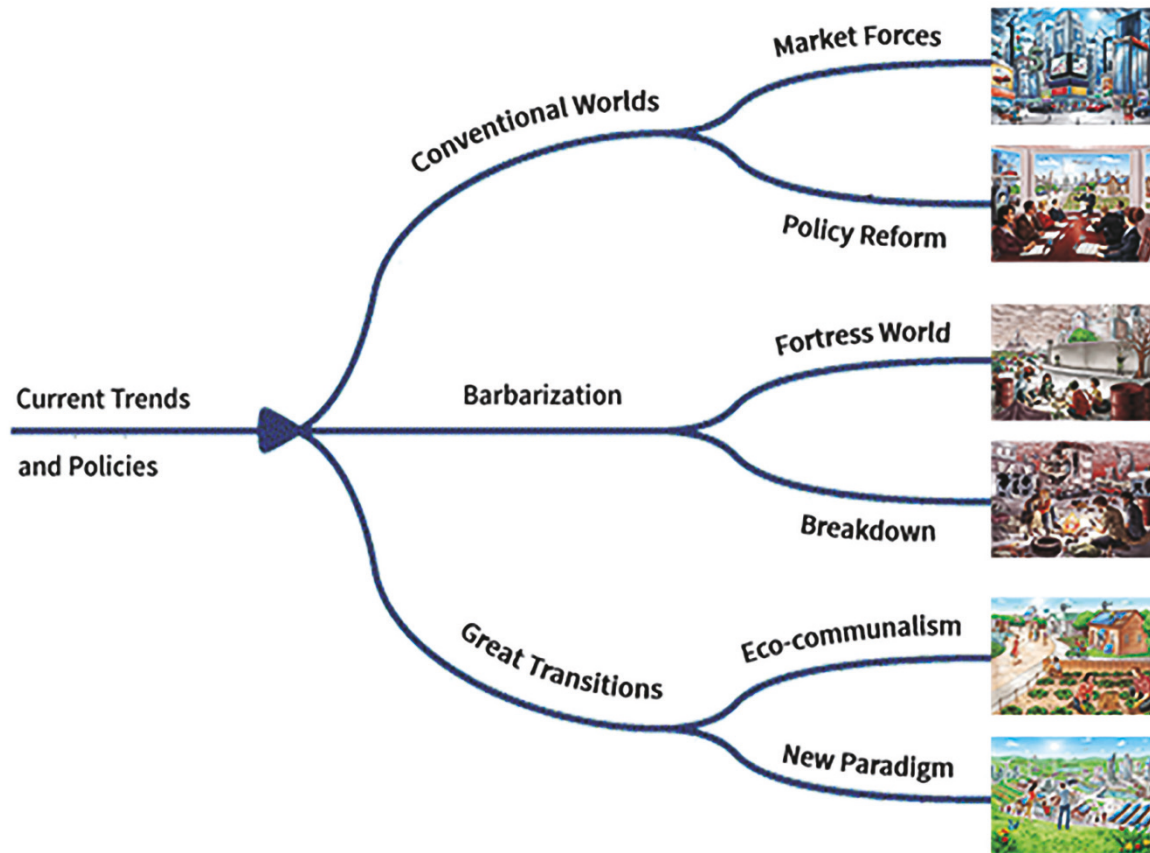
> although the future is unknowable a successful transition toward sustainability is possible over the next two generations. This transition could be achieved without miraculous technologies or drastic transformations of human societies. What will be required, however, are significant advances in basic knowledge, in the social capacity and technological capabilities to utilize it, and in the political will to turn this knowledge and know-how into action (Kates 2001: 15328).

The Tellus Institute focuses on "global scenarios, planetary phase of civilization, sustainable development, climate change, eco-efficiency, globalization, information technology", and since 2005 it has addressed

> a *Great Transition* to a sustainable, just, and liveable global civilization. To attain this vision, the world must navigate toward ways of producing, consuming, and living that balance the rights of people today, future generations, and the wider community of life. The prospects for such a transition rest with the ascendance of new values, a planetary consciousness, and a sense of global citizenship. These aims will lie at the heart of the Institute's program of research, education, and network-building in the coming years.[50]

---

50 For Tellus, see at: < http://www.tellus.org/about/> (11 February 2015).

Figure 1.10: The three major scenarios and six alternative pathways of a global transition. **Source**: Tellus' Gobal Transition Initiative; at: <http://www.greattransition.org/explore/scenarios> (11 February 2015).


This *Great Transition Initiative* (GTI) coordinates a global network ... [and] spreads the message that a future of enriched lives, global solidarity, and a healthy planet is possible if the citizens of the world join in a vast cultural and political mobilization for change. ... It builds on the ground-breaking work of the international *Global Scenario Group*. With ... over 400 participants from over 40 countries, GTI ... reach[es] out to those seeking greater understanding of global challenges and a positive framework for addressing them.[51]

In 2014, Paul Raskin, the Tellus President, distinguished three global models (figure 1.10): *Conventional Worlds* (business-as-usual), a model which assumes structural continuity of present trends and actors, *Barbarization* (worst case), which assumes "a deluge of instability swamps society's adaptive capacity, leading to a general global crisis and the erosion of civilized norms", and *Great Transitions*, that imagines "how the imperatives and opportunities of the

Planetary Phase might advance more enlightened aspirations", envisioning the new values of "human solidarity, quality-of-life, and an ecological sensibility" instead of "individualism, consumerism, and domination of nature", and aiming for "institutions that support democratic global governance, well-being for all, and environmental sustainability".

Raskin argued (see also his foreword to this book) that at present: "Great Transition precursors announce themselves ... in a rising cosmopolitan consciousness, civil society campaigns, and expanding subcultures seeking more responsible and fulfilling lifestyles." But while the technological feasibility may be easier, changing the cultural and political assumptions is more difficult. He claimed that "the Planetary Phase, by unravelling old patterns and mindsets and urging new ones, opens opportunities for creative social transformation" by fostering "the idea of global citizenship", which "carries both psychological and juridical meanings". But he cautioned that "intergovernmental institutions, transnational corporations, and big civil society organizations are unlikely candidates

for the role of change agent", and hoped that "the natural change agent for a Great Transition would be a vast and inclusive movement of global citizens".[52]

The Great Transition Scenario distinguishes two pathways: "Ecocommunalism" and "New Paradigm". While the first incorporates "the green vision of bioregionalism, localism, face-to-face democracy, small technology, and economic autarky ... [with the] emergence of a patchwork of self-sustaining communities from our increasingly interdependent world seems implausible", the GTI embraces the "New Sustainability Paradigm", which "sees globalization not only as a threat but also an opportunity to construct a planetary civilization rather than rely on the incremental forms of Conventional Worlds or retreat into local-

ism. It envisions the ascendance of new categories of consciousness—global citizenship, humanity-as-whole, the wider web of life, and the well-being of future generations—alongside democratic institutions of global governance".[53]

1.7.3   The Dutch Scientific Research Initiative

A totally different approach to sustainability transition emerged from a large research project by the *Dutch Knowledge Network on Systems Innovation and Transition (*KSI) in the Netherlands, in which eighty-five researchers participated (2005–2010). Grin, Rotmans and Schot (2010) combined "three perspectives on transitions to a sustainable society: complexity the-

ory, innovation theory, and governance theory". The authors

> seek to understand transitions dynamics, and how and to what extent they may be influenced. ... They do so from the conviction that only through drastic system innovations and transitions it becomes possible to bring about a turn to a sustainable society to satisfy their own needs, as inevitable for solving a number of structural problems on our planet, such as the environment, the climate, the food supply, and the social and economic crisis. Among other things this implies that our world has to overcome the undesirable side effects of the ongoing 'modernization transition', which began around 1750. However, the transition to sustainability has to compete with other developments, and it is uncertain which development will gain the upper hand. In *Transitions to Sustainable Development* the authors ... closely address the need for transitions, as well as their dynamics and design (Grin/Rotmans/Schot 2010: xvii–xix).

A new discourse on 'sustainability transition' has evolved since 2009 within the *Sustainability Transition Research Network* (STRN).[54] It focuses on sustainability problems in the energy, transport, water and food sectors from different scientific perspectives on the ways

> in which society could combine economic and social development with the reduction of its pressure on the environment. A shared idea among these scholars is that due to the specific characteristics of the sustainability problems (ambiguous, complex) incremental change in prevailing systems will not suffice. There is a need for transformative change at the systems level, including major changes in production, consumption that were conceptualized as 'sustainability transitions'.[55]

The STRN defined transitions research as a "new approach to sustainable development" that

> is also developing its own core set of questions and theories. Major research efforts ... have advanced knowledge of transitions to sustainability, particularly in the field of a broad understanding of how major, radical transformations unfold and what drives them. ... Technical changes need to be seen in their institutional and social context, generating the notion of 'socio-technical (s-t) systems', which are often stable and path dependent, and therefore difficult to change. Under certain conditions and over time, the relationships within s-t systems can become reconfigured and replaced in a process that may be called a system innovation or a transition.

The STRN argued that

> transitions to sustainability may ... be strongly context specific. ... It is ... of great interest to explore the varied governance challenges that transitions to sustainability imply in different contexts ... from ... industrial transformation, innovation and socio-technical transitions; integrated assessment; sustainability assessment; governance of SD (political science); policy appraisal community; researchers working on reflexive governance; the resilience community; the ecological economics community; groups of energy-, environment- and sustainability-modelers; and a core sustainability transitions community. ... Research is organized around seven themes: (a) synthesizing perspectives and approaches to transitions; (b) governance, power and politics; (c) implementation strategies; (d) civil society, culture and social movements in transitions; (d) firms and industry; (e) geography of transitions; (e) modelling of transitions.

The STRN defined its mission as coordinating its scientific capacity "towards the production of foresight reports on strategic sustainability policy questions, ... to support the development of a sustainability transitions research community internationally, and provide an independent, authoritative and credible source of analysis and insight into the dynamics and governance of sustainability transitions".[56]

Their multilevel perspective on transitions was influenced by Geels's (2002: 1263) model that distinguished between technological niches, the sociotechnological regime and landscape developments that start with ... interrelated and mutually reinforcing technological innovations in 'niches'. Such multiple events initially face opposition in the respective socio-technical regime, and once they are overcome they often result in a structural change by exploiting windows of opportunity, and lead to changes in the landscape (figure 1.11).[57]

57 The *Environmental Innovation and Sustainability Transitions* (EIST) Journal "offers a platform for reporting studies of innovations and socio-economic transitions to enhance an environmentally sustainable economy and thus solve structural resource scarcity and environmental problems, notably related to fossil energy use and climate change." See the 'Environmental Innovation and Sustainability Transitions' (EIST) Journal at: <http://www.journals. elsevier.com/environmental-innovation-and-societal-transitions/>.

1.7.4 A German Scientific Advisory Report on a 'Social Contract for Sustainability'

The research focus of KSI and of the STRN influenced a policy report by the *German Advisory Council on Global Change* (WBGU 2011) on a 'Social Contract for Sustainability' (2011). This report argued that the transformation to a low-carbon society requires that we

> not just accelerate the pace of innovation; we must also cease to obstruct it. ... We must also take into account the external costs of high-carbon (fossil energy-based) economic growth to set price signals, and thereby to provide incentives for low-carbon enterprises. Climate protection is ... a vital fundamental condition for sustainable development on a global level.

The WBGU (2011: 93) report adapted Geels's model and added several megatrends in both the earth system (climate, biodiversity, land degradation, water, raw materials) and the human system (development, democratization, energy, urbanization, food), where innovative changes in the regime may directly affect the megatrends. The report argued that the realization of a low-carbon economy and society is overcoming the many barriers and exploiting the favourable factors (WBGU 2011: 6). The WBGU report stated that "... a low-carbon transformation can only be successful if it is a common goal, pursued simultaneously in many of the world's regions" (WBGU 2011). It discussed (WBGU 2011: 5) the global "remodelling of economy and society towards sustainability as a 'Great Transformation'. Production, consumption patterns and lifestyles in all of the three key transformation fields must be changed in such a way that global greenhouse gas emissions are reduced to an absolute minimum over the coming decades, and low carbon societies can develop."

The transformation towards a climate-friendly society requires that many existing change agents lead to a "concurrence of multiple change" (Osterhammel 2009), which "can trigger historic waves and comprehensive transformations". This transformation aims at a low-carbon society that starts with the decarbonization of energy systems, where "the proactive state and the change agents are the key players". Within the next decade, they should jointly initiate a transformation towards a sustainable energy path. This transformation should permit a major decarbonization of the economy by 2050, avoiding both a rebound effect and a climate crisis.

To achieve a major transformation towards a low-carbon economy and society, the WBGU proposed specific measures for the energy sector, land-use changes and global urbanization that could accelerate and extend the transition to sustainability. The WBGU Report suggested that "research and education are tasked with developing sustainable visions, in co-operation with policy-makers and citizens; identifying suitable development pathways, and realizing low-carbon and sustainable innovations". The WBGU argued "that transformation costs can be lowered significantly if joint decarbonization strategies are implemented in Europe. The transformation also represents a great chance for Europe to make innovation-driven contributions to a globalization process that has a viable future" (WBGU 2011).

A report by the *International Social Science Council* (ISSC 2012: 16) on *Transformative Cornerstones of Social Science Research for Global Change* defined transformation as "a process of altering the fundamental attributes of a system, including in this case structures and institutions, infrastructures, regulatory systems, financial regimes, as well as attitudes and practices, lifestyles, policies and power relations". It argued that the necessary additional social science research will contribute to producing change by calling "for an additional response to global change and to climate change; additional to and building on the enduring focus in this field on adaptation and mitigation; ... a critical questioning of the systems and paradigms that have created climate change and on which climate change rests".

So far all the studies on sustainability transition in North America–by the Tellus Institute, by Speth, Kates and the NRC–and more recently in Europe–by the KSI, STRN and WBGU–and those by the ISSC have not addressed the possible linkage of the suggested transitions–including those of the past–to questions of international and national peace and security. This leads to the second key goal of this Handbook: 'peace with nature' or 'sustainable peace'.

1.7.5 Policy Debates on Green Growth and Decarbonization

UNEP (2011, 2014), OECD,[58] the EU and several governments have promoted an alternative vision and outlined alternative policies for a global green deal, green growth, and a decoupling of economic growth from energy consumption. These policy proposals were partly taken up by the European Commission

---

58 See publications on: "Green growth and sustainable development", at: <http://www.oecd.org/greengrowth>.

Figure 1.12: EU GHG emissions towards an 80 per cent domestic reduction (1990 = 100 per cent). **Source**: EU (2011b: 5).
and the European Council in its longer-term goals and policy papers on climate change, its energy (EU 2011), resource (see chapter 41 by Happaerts below, EU 2011c, 2011d) and transport policies[59] (EU 2011a), and in its "Roadmap for moving to a competitive low carbon economy in 2050" (EU 2011b).[60] In this Roadmap the European Commission addressed the goal "of reducing greenhouse gas emissions by 80–95 per cent by 2050 compared to 1990". Based on these goals, the EU's Roadmap outlined milestones with "policy challenges, investment needs and opportunities in different sectors".

The Commission projected the necessary GHG reductions for key sectors (table 1.1). The modelling analysis assumed that "the switch to domestically produced low carbon energy sources will reduce the EU's average fuel costs by between €175 billion and €320 billion per year" (EU 2011: 11–12). The study further assumed that "in 2050, the EU's total primary energy consumption could be about 30 per cent below 2005

levels" and it argued that "without action the oil and gas import bill could instead double compared to today, a difference of €400 billion or more per annum by 2050, the equivalent of 3 per cent of today's GDP" (EU 2011: 12).

Table 1.1: Sectoral reductions. **Source**: EU (2011b: 6).

GHG reductions compared to 1990	2005	2030	2050
Total	-7%	-40 to -44%	-79 to -82%
Sectors			
Power (CO_2)	-7%	-54 to -68%	-93 to -99%
Industry (CO_2)	-20%	-34 to -40%	-83 to -87%
Transport (incl. CO_2 aviation, excl. maritime)	+30%	+20 to -9%	-54 to -67%
Residential and services (CO2)	-12%	-37 to -53%	-88 to-91%
Agriculture (non-CO_2)	-20%	-36 to -37%	-42 to -49%
Other non-CO_2 emissions	-30%	-72 to -73%	-70 to -78%

The Commission's Roadmap study for moving towards a low-carbon economy indicated

59 See "White paper 2011: Roadmap to a Single European Transport Area—Towards a competitive and resource efficient transport system", at: <http://ec.europa.eu/transport/themes/strategies/2011_white_paper_en.htm>.
60 European Commission, Climate Action, "Roadmap for moving to a low-carbon economy in 2050"; at: <http://ec.europa.eu/clima/policies/roadmap/index_en.htm>.

that a cost effective and gradual transition would require a 40% domestic reduction of greenhouse gas emissions compared to 1990 as a milestone for 2030, and 80 per cent for 2050. ... With existing policies, the EU will achieve the goal of a 20 per cent GHG reduction domestically by 2020. ... Deep reductions in the EU's emissions have the potential to deliver benefits in the form of savings on fossil fuel imports and improvements in air quality and public health. ... The Roadmap gives ranges for emissions reductions for 2030 and 2050 for key sectors (EU 2011b: 14).

The Commission planned to use this Roadmap for sector-specific policy initiatives and longer-term funding considerations on how EU funding could support necessary instruments and investments for the transition to a low-carbon economy. Three years later, on 23 October 2014, the European Council agreed that

- the domestic 2030 greenhouse gas reduction target [should be] at least 40 per cent compared to 1990 together with the other main building blocks of the 2030 policy framework for climate and energy. ... This 2030 policy framework aims to make the European Union's economy and energy system more competitive, secure and sustainable and also sets a target of at least 27 per cent for renewable energy and energy savings by 2030.
- The framework presented will drive continued progress towards a low-carbon economy. It aims to build a competitive and secure energy system that ensures affordable energy for all consumers, increases the security of the EU's energy supplies, reduces our dependence on energy imports and creates new opportunities for growth and jobs.
- The 2030 framework ... also takes into account the longer-term perspective set out by the Commission in 2011 in the Roadmap for moving to a competitive low-carbon economy in 2050, the Energy Roadmap 2050 (EU 2011) and the Transport White Paper (EU 2011a). These documents reflect the EU's goal of reducing greenhouse gas emissions by 80–95 per cent below 1990 levels by 2050 as part of the effort needed from developed countries as a group.[61]

By the end of 2015, at COP 21 in Paris, a majority of state parties agreed on legally binding voluntary commitments as defined by the member countries themselves. They would reduce their GHG emissions in the decades to come. Moreover, they would fully implement these commitments by moving gradually towards a low-carbon economy and by realizing a sustainability transition in the energy and production sectors and adopting national policies that supported sustainable consumption by their citizens. However, no global targets and no sanctions were approved.

While the EU, UN, UNEP and OCED have suggested a transition towards a green economy, so far only very few countries have initiated detailed policy programmes aiming at a sustainable energy transition (e.g. Germany,[62] the UK,[63] France,[64] Austria, Denmark and Japan).[65] As major producers of solar panels and of wind power, China,[66] India,[67] Mexico (see chapter 23 by Le Clercq)[68] and many other OECD and threshold countries have also adopted major energy transition laws and policies.

The *International Renewable Energy Agency* (IRENA) argued in its Roadmap for a Renewable Energy Future (IRENA 2016: 23) that to move towards

a 2°C goal the global share of renewables would have to double by 2030 what would require "a six-fold increase".

Both the Roadmaps of the EU for moving to a low-carbon economy by 2050 and of IRENA for realizing a *Renewable Energy Future* by 2030 are model projections that do not imply any binding legal obligations. Rather, policy decisions and their subsequent full implementation into national policies are needed.

The fossil and nuclear energy industries and the car and highway lobbies have attacked the IPCC as a key messenger by supporting the campaign of climate critics. In the US Congress, they have succeeded in blocking all major climate bills proposed by the Obama Administration.[69] The tar sand lobby in Canada (Dalby 2016) and the fracking industry in the US have invested heavily in new fossil technologies and supported policies to prevent legal obligations by not ratifying the Kyoto Protocol in US or by withdrawing from it in Canada (in December 2011).

The weak performance and implementation of quantitative GHG emissions reductions will most severely affect the highly socially and environmentally vulnerable developing and least developed countries. These have already seen the highest number of deaths and people affected. The economic losses from climate-induced hazards and health impacts were highest in developed countries, because of insurance. It is projected that many countries with a continuing high level of population growth and a high level of people below the poverty line will also have a low level of resilience and limited capabilities for adaptation and mitigation during the twenty-first century.

1.7.6   Towards a New Research Paradigm in the Social Sciences

Both the scientific discourse and the policy debates have closely interacted. While the policy debate since the publication of the Brundtland Report (1987) has partly triggered funding for new scientific institutions and research projects, the scientific debate has since moved much further from developing an approach to zero growth, to a reduction of the overuse of nature and the recuperation of ecosystem services that are

essential for humans and nature. While natural scientists (Clark/Crutzen/Schellnhuber 2004) have called for a 'second Copernican revolution in science' and the development of a new scientific world view and a new sustainability paradigm, in the social sciences several approaches to 'sustainability research' exist:

- the '*sociotechnical approach*' of sociologists and historians who examine technical innovations (inventions, breakthroughs and setbacks) in their specific national political, economic and societal contexts with the aim of drawing generalizable *lessons from past long-term transformative innovation processes* for the necessary transition to sustainable development;
- the '*empirical approach*' of *policy analysis* that observes and assesses ongoing processes of sustainability transition, i.e. of discussion, planning, steering and implementation of processes of energy transition or change ("*Energiewende*");
- '*discourse analysis*', that reviews and interprets scientific discourses, and the societal and political debates of multiple actors;
- '*constraint analysis*', that analyses systemic (mindset), technical (laws of physics, status of innovation), ideological (e.g. cornucopian, Hobbesian), and interest-driven (lobbies of affected industries and trade unions) obstacles to strategies and policies aiming at sustainability transition.

Besides these numerous scientific approaches to analysing strategies, policies and measures that aim at processes of 'sustainability transition' with the goal of realizing a sustainable development path, the debate is taking place in many scientific disciplines and thus several dimensions may be distinguished, among them, besides the historical or *temporal* dimension, *spatial*, *scientific, societal, economic, political* and *cultural* dimensions, which will not be dealt with in detail in this multidisciplinary Handbook.

1.7.7   Dimensions of Research into 'Sustainability Transition'

The emerging research and publications on 'sustainability transition' have focused on spatial (1.7.5.1), scientific (1.7.5.2), societal (1.7.5.3), economic (1.7.5.4), political (1.7.5.5), and cultural (1.7.5.6) dimensions.

1.7.7.1   The Spatial Dimension of Sustainability Transition

Within the evolving discourse on sustainability transition, the proposal by Coenen, Benneworth and

---

69 Naomi Klein: "Capitalism vs. the Climate—Denialists are dead wrong about the science. But they understand something the left still doesn't get about the revolutionary meaning of climate change", in: *The Nation*, 28 November 2011; at: <http://www.thenation.com/article/164497/capitalism-vs-climate> (25 January 2014).

Truffer (2010, 2012) of a spatial dimension[70] was more limited. They argued that "an explicit analysis of the geography of transitions contributes to the extant transitions literature in a variety of ways. Firstly it provides a contextualization and reflection on the limited territorial sensitivity of existing transitions analysis". Coenen and Truffer (2012: 1) claimed that "environmental innovations and sustainability related initiatives have received increasing attention in the recent economic geography and regional studies literature". They suggested future research should combine both traditions in sustainability-related research in regional studies. They distinguished between two trends in sustainability transition studies: a focus on a) the *technological innovation systems* (TIS) *approach* and b) a focus on the *multilevel perspective* (MLP); both rely on innovation and technology studies (Coenen/Diaz Lopez, 2010).

Coenen and Truffer (2012: 8) noted that the emerging sustainability transitions research is still "nascent and partially immature" and lacks a specific geographic or spatial dimension. They reviewed forty-seven papers that had appeared in the *Journal of Regional Studies* since 1993 and which referred explicitly to sustainability concerns. Some focused on "assessing and quantitatively measuring the state of sustainable development in regions", while others "highlighted the interdependence of sustainable regional development with natural resources and ecosystems" or submitted "conceptually and theoretically programmatic contributions" that focused on "a) ecological modernization and regulationist approaches, b) industrial ecosystems and, c) what can be considered as the most prominent thread in regional studies, the development of a framework to analyse policy processes that help shape 'sustainable regions'", including regional aspects of sustainable production and consumption. Coenen and Truffer (2012: 8) concluded that

> the major weaknesses being that technologies and sectoral (trans-)formation processes rarely receive very explicit consideration. Either there is a strong focus on institutional change at the expense of technological

change, regional production structures at the expense of consumer and citizen related processes or alternatively a strong but singular focus on (experimental) policies for regional sustainability. The complementarities between regional studies and transitions studies therefore warrant some further scrutiny.

However, regional studies usually only look at the lower level of the geographical scale, while international relations address the more abstract level of the relations among states, societies and economies, thus linking international with transnational relations, including negotiations towards achieving policy declarations on decarbonization of the economy and a shift towards green growth. The discussion on 'sustainability transition' has so far primarily focused on the micro-level of socio-economic and societal and technological innovations, and has not addressed the impacts of strategies and policies within a business-as-usual world view or mindset and an alternative sustainability perspective on international peace and security (see chapter 2 by Dalby and chapter 20 by Hodson/Marvin/Späth in this volume).

To simplify, a continuation of the present trend in the consumption of fossil fuels (coal, oil, gas) will not only raise the level of GHG emissions but also increase the demand for these non-renewable energy sources and increase their price, and may result in military conflicts over access to and control of hydrocarbons, especially in the Middle East. What policy scenarios and strategies are foreseeable whose strategies, policies and measures are oriented towards long-term transformative change towards sustainable development, and may enhance the prospects for international cooperation, peace with security and a long-term vision of a positive or sustainable peace?

1.7.7.2　Scientific Dimension of Sustainability Transition

The development of new scientific and technological knowledge is crucial for initiating processes that call for multiple transitions towards sustainability. In "Science for Global Sustainability: Toward a New Paradigm", Clark, Crutzen and Schellnhuber (2004: 3) provided the conceptual context for the Dahlem Workshop on "Earth Systems Science and Sustainability" (2003). They pointed to "the need for harnessing science and technology in support of efforts to achieve the goal of environmentally sustainable human development in the Anthropocene". They noted the great transformation during the twentieth century that had resulted in an increase of cropland by a factor of two, of world population by a factor of

---

four, water use by a factor of eight, energy use by a factor of 16 and industrial output by a factor of 40 (based on McNeill 2000, 2009). They discussed both the opportunities and challenges in facing and coping with the impacts of GEC and CC. These were addressed in the Amsterdam Declaration (2001) that called for the *Earth System Science Partnership* (ESSP) that has evolved during the past decade (Leemans/Rice et al. 2011), until it was replaced by *Future Earth* in 2012.

They considered earth systems science as a key promoter of such a transition, which requires a change in the scientific world view and orientation that recognizes that sustainable development is a knowledge-intensive activity. They pointed to a growing consensus "that management systems for a sustainability transition need to be systems for adaptive management and social learning". In conclusion, they suggested "A New Contract for Planetary Stewardship" linking science and society. This resulted in 2011 in the WBGU Report "A Social Contract for Sustainability".

From the perspective of international relations, ecology and geography this may require a readiness from the natural sciences to bring international and peace and security considerations into their analysis, as well as a readiness from the social sciences to consider the results of ESS and ESA in their own analyses. This has stimulated Brauch, Oswald Spring and Dalby (2011) to call for a new "Political Geoecology for the Anthropocene". The scientific discourse on 'sustainability transition' must be broadened from its narrow initial focus as it has evolved since the Amsterdam conference in 2009 towards a wider scope that comprises all the dimensions of 'sustainability transition'.

1.7.7.3   Societal Dimension of Sustainability Transition

Political, economic and societal strategies for 'sustainability transition' cannot be implemented against the wishes, values and preferences of the people concerned. Such a long-term and global transformative change requires not only 'hard' changes in the production, energy and transportation systems and in human settlements and habitats, but also many 'soft' changes in human values, belief systems, world views and mindsets. The societal dimension of the discourse on sustainability transition has so far focused on the changes needed in human values, perception and behaviour that would result in new lifestyles, ways of life and patterns of consumption.

Ingelhart's (1977, 1998) work on value change addressed the emergence of post-materialist values since 1945. These have resulted in an "increasing power of new social movements ... as the expression of a wider cultural value change (Inglehart 2008)" (cited in WBGU 2011: 69). However, this value change and the global contextual change since 1989 has not affected the prevailing world view in US society and the mindset of its policymakers in the US Congress. While during the fifth wave of the *World Value Survey* (WVS 2010), close to eighty per cent of the US population saw global warming, or the greenhouse effect, as serious or very serious, President Obama failed to get any climate change legislations adopted in either house of the US Congress or with the Supreme Court (2016) (Klein 2011). This is a clear indication of the high volatility of these WVS and demonstrates that it hardly mattered politically, given the strong economic and ideological interests of climate change opponents and sceptics.

For a behavioural change towards sustainability transition a temporary change in public preferences and attitudes is not sufficient. Rather, fundamental changes in human behaviour are needed, with major changes in lifestyles and consumptive preferences and patterns. This would result in a lower ecological footprint and in a reduction of individual carbon emissions. However, this cannot be achieved by changes only on the demand side. It also requires major changes on the supply side with regard to green and renewable energy systems, public and low-carbon transport systems and products with a much lower carbon footprint.

New social movements and political parties may contribute to creating both awareness of and positive political frameworks for a change in the lifestyles and the preferred way of life of a majority of the people. Thus, changing the 'soft' human and societal side of 'sustainability transition' may be as difficult if not even more difficult than changing the sociotechnological framework on which most research is so far focused. The WBGU (2011: 78–79) argued that

> for the transformation of economy and society towards sustainability, the political, economic and technological path dependency is also a significant barrier (Liebowitz/ Marjolis 1995; Pierson 2004). An existing system of institutions (norms, contracts negotiating and decision-making modi, etc.), but also of technologies and infrastructures, can hinder far-reaching social changes. ... In politics and the economy, path dependent processes and developments frequently result in mistakes becoming the established norm, and the continued absence of learning effects. Individual and political decision-mak-

ers, as well as the public, are led by crisis management routines that were developed for past problem cases. Clinging to past thought and action patterns can lead to an 'objective' pressure to change, which merely results in modification, rather than transformation of the status quo, delaying the replacement of the fossil-nuclear energy system with a sustainable energy system even further.

While new scientific results and new publicly shared knowledge does not change values, attitudes, preferences or behaviour, the enduring change of these soft factors requires simultaneous changes in the hard factors of the economic system and production and consumption processes, as well as in the policy process.

1.7.7.4   Economic Dimension of Sustainability Transition

According to the IPCC's (2011) *Special Report on Renewable Energy Sources and Climate Change Mitigation* and the WBGU's (2011: 119) assessment, "the sustainable potential of renewable energies is fundamentally sufficient to provide the world with energy". The IPCC (2011: 15) stated that: "There are multiple pathways for increasing the shares of RE [*renewable energy*] across all end-use sectors." This applies to the transportation, building and agricultural sectors and requires long-term integration efforts including "investment in enabling infrastructure; modification of institutional and governance frameworks; attention to social aspects, markets and planning; and capacity building in anticipation of RE growth".

The IPCC (2011) argued that "historically, economic development has been strongly correlated with increasing energy use and growth of GHG emissions, and RE can help decouple that correlation, contributing to sustainable development (SD)." Renewables can also make a significant contribution to global mitigation efforts, given that "a significant increase in the deployment of RE by 2030, 2050 and beyond is indicated in the majority of the 164 scenarios reviewed" in the IPCC's *Special Report on Renewable Energy Sources and Climate Change Mitigation* (SRREN). The IPCC argued that "individual studies indicate that if RE deployment is limited, mitigation costs increase and low GHG concentration stabilizations may not be achieved". Also "a transition to a low-GHG economy with higher shares of RE would imply increasing investments in technologies and infrastructure".

As fossil fuels are the major cause for the increase of GHG emissions in the atmosphere, an increase of RE is a necessary but not sufficient policy for coping with GHG emissions. A gradual and comprehensive decarbonization of the economy requires major improvements in energy efficiency and a great transformation in many economic sectors that may be opposed by economic financial and labour interests representing the old sectors.

The WBGU Report (2011) also proposed an intensification of policies of sustainable production and consumption and major initiatives in buildings, living and land-use planning, in mobility and communication and in food; this would require both climate-compatible agricultural management and a change in dietary habits.

Initiating sustainable transformation in cities with the highest energy growth potential can become a major force for innovation and investment in new infrastructure. This requires new governance actors (Corfee-Morlot/Kamal-Chaoui/Donovan et al. 2009) who can reduce traffic by a "spatial integration of urban functions", thus "achieving a high quality of life for inhabitants". Further, "energy infrastructure integration (CHP [*combined heat and power*] technology, heating and cooling systems, smart grids, electromobility, etc.) can benefit considerably from the spatial density" (WBGU 2011: 173). While "land-use systems cannot become completely emissions-free", "a significant contribution from land use" is needed, including "stopping deforestation and switching to sustainable forest management, as well as the promotion of climate-friendly agriculture and dietary habits" (WBGU 2011: 173).

FAO (2013a) has proposed a climate-smart agriculture, fishery and forestry, which includes the recovery of ecosystems, ecosystem services, organic agriculture, protection of seed diversity, local and regional marketing, and sustainable food patterns. FAO (2015) stated that, worldwide, half of the food is lost as waste in the whole cycle of production, transformation, marketing, and consumption. "Without accounting for GHG emissions from land use change, the carbon footprint of food produced and not eaten is estimated to 3.3 Gtonnes of CO_2 equivalent: as such, food wastage ranks as the third top emitter after US and China. Globally, the blue water footprint (i.e. the consumption of surface and groundwater resources) of food wastage is about 250 km³, which is equivalent to the annual water discharge of the Volga river, or three times the volume of lake Geneva. Finally, produced but uneaten food vainly occupies almost 1.4 billion hectares of land; this represents close to 30 percent of the world's agricultural land area" (FAO 2013b: 6)

Figure 1.13: Total annual anthropogenic GHG emissions by groups of gases 1970–2010. **Source:** IPCC (2014d: 9).
Working Group 3 of the Fifth Assessment Report of the IPCC[71] concluded in its "Summary for Policymakers" (2014: 8–9) that: "CO2 emissions from fossil fuel combustion and industrial processes contributed about 78% of the total GHG emission increase from 1970 to 2010, with a similar percentage contribution for the period 2000–2010" (figure 1.13) and "about half of cumulative anthropogenic CO2 emissions between 1750 and 2010 have occurred in the last 40 years". Furthermore, "annual anthropogenic GHG emissions have increased by 10 GtCO2eq between 2000 and 2010, with this increase directly coming from energy supply (47%), industry (30%), transport (11%) and buildings (3%) sectors".

To counter these trends, the IPCC's WG 3 assessed several "mitigation pathways and measures in the context of sustainable development". They argued that "mitigation scenarios in which it is likely that the temperature change caused by anthropogenic GHG emissions can be kept to less than 2°C relative to pre-industrial levels are characterized by atmospheric concentrations in 2100 of about 450ppm CO2eq". However, to reach this target would include "substantial cuts in anthropogenic GHG emissions by mid-century through large-scale changes in energy systems and potentially land use" (IPCC 2014d: 12). But "delaying mitigation efforts beyond those in place today through 2030 is estimated to substantially increase the

difficulty of the transition to low longer-term emissions levels and narrow the range of options consistent with maintaining temperature change below 2°C relative to pre-industrial levels" (IPCC 2014d: 14). The IPCC agreed that "mitigation scenarios reaching about 450 to about 500 ppm CO2eq by 2100 show reduced costs for achieving air quality and energy security objectives, with significant co-benefits for human health, ecosystem impacts, and sufficiency of resources and resilience of the energy system" (IPCC 2014d: 16) and that "mitigation scenarios reaching around 450 ppm CO2eq concentrations by 2100 show large-scale global changes in the energy supply sector" (IPCC 2014d: 18).

Working Group WG 3 of IPCC AR5 also noted the high relevance of soft factors, for example: "[e]fficiency enhancements and behavioural changes, in order to reduce energy demand compared to baseline scenarios without compromising development, are a key mitigation strategy in scenarios reaching atmospheric CO2eq concentrations of about 450 to about 500 ppm by 2100" and "behaviour, lifestyle and culture have a considerable influence on energy use and associated emissions, with high mitigation potential in some sectors, in particular when complementing technological and structural change" (IPCC 2014d: 22).

For the IPCC, "decarbonizing (i.e. reducing the carbon intensity of) electricity generation is a key component of cost-effective mitigation strategies in achieving low-stabilization levels (430–530ppm CO2eq); in most integrated modelling scenarios, decarbonization hap-

---

71 See at: <http://www.ipcc.ch/pdf/assessment-report/ar5/wg3/ipcc_wg3_ar5_summary-for-policymakers.pdf>.

pens more rapidly in electricity generation than in the industry, building, and transport sectors". The IPCC suggested replacing "coal-fired power plants with modern, highly efficient natural gas combined-cycle power plants or combined heat and power plants", while increasing reliance on bioenergy may imply "challenges and risks" (IPCC 2014d: 22).

In the transport sector, "technical and behavioural mitigation measures for all transport modes, plus new infrastructure and urban redevelopment investments, could reduce final energy demand in 2050 by around 40% below the baseline" (IPCC 2014d: 23) and in the building sector: "lifestyle, culture and behaviour significantly influence energy consumption in buildings", and "the energy intensity of the industry sector could be directly reduced by about 25% compared to the current level through the wide-scale upgrading, replacement and deployment of best available technologies, particularly in countries where these are not in use and in non-energy intensive industries" (IPCC 2014d: 25).

In *Agriculture, Forestry and Other Land Use* (AFOLU) the IPCC saw "the most cost-effective mitigation options in forestry are afforestation, sustainable forest management and reducing deforestation, with large differences in their relative importance across regions. In agriculture, the most cost-effective mitigation options are cropland management, grazing land management, and restoration of organic soils" (IPCC 2014d: 26). With regard to human settlements and urbanization, "the largest mitigation opportunities ... are in rapidly urbanizing areas where urban form and infrastructure are not locked in, but where there are often limited governance, technical, financial, and institutional capacities" (IPCC 2014d: 28).

In discussing the financial aspects, the IPCC argued that "in many countries, the private sector plays central roles in the processes that lead to emissions as well as to mitigation. Within appropriate enabling environments, the private sector, along with the public sector, can play an important role in financing mitigation" (IPCC 2014d: 31). *Working Group* (WG) 3 of the IPCC concluded that "policy linkages among regional, national, and sub-national climate policies offer potential climate change mitigation and adaptation benefits" that can "be established between national policies, various instruments, and through regional cooperation" (IPCC 2014d: 32).

1.7.7.5 Political Dimension of Sustainability Transition

The political dimension of 'sustainability transition' has been extensively discussed and many approaches,

analysis and proposals have been submitted so far. Grin (2010: 223) suggested that the transition to sustainable development can no longer rely on centralized government institutions of political administrative steering, given the "more prominent role of the interactions between the state, market, and society". He argued that a governance perspective "allows us to consider transition management, strategic niche management and interrelated processes in the real world".

Grin (2010: 237) reviewed the contemporary processes of institutional change in modern societies with regard to a) structural changes affecting the polity and dealing with institutional transformations between the four key actors: state, market, society and science; b) structural changes in innovative systems relating to the development and use of new technologies, and c) the emergence of new, often transnational, arrangements for corporate governance.

This perspective lacks an analysis of the transformation of international politics of peace and security that compares the international, regional and global impacts of a continuation of *business-as-usual* policies and of the sustainability paradigm. Based on the first three levels, Grin (2010: 247) argued that "at the regime level, major processes of transformations go on in the institutions of state, market, civil society and knowledge, and their mutual alignment."

Grin interpreted these changes as the result of two processes resulting from: a) "influences on the regime from landscape-level trends, such as globalization, individualization, Europeanization and the politicization of side effects, as well as derived trends such as privatization and liberalization;" and b) the responses to "the challenges these practices have come to face during the past two decades as a consequence of feedback processes."

A different approach was taken by Roeland J. in 't Veld (2011: xv; see chapter 40 in this volume). He suggested decision-makers in politics, business, science, civil society and the media should create governance arrangements beyond traditional borders; "sustainability requires transgovernance", where action is based on thinking: a) beyond classical governance style and towards a culturally sensitive meta-governance for sustainable development; b) beyond disciplinary scientific research, towards more transdisciplinarity.

These studies by Grin (2010) and in 't Veld (2011) link the intensive scientific debate on global environmental and climate governance to the process of sustainability transition. Other studies have addressed governance aspects and perspectives of sustainability transition (Loorbach 2007). Governance aspects were

also discussed prior to the Rio+20 summit but no proposals for international governance for sustainability transition, e.g. the upgrading of UNEP from a programme to a specialized agency, were adopted in its outcome document.

1.7.7.6   The Cultural Dimension of Sustainability Transition

While many studies of sustainability transition have focused on technological innovation in the relevant industrial sectors, especially energy, and on governance aspects, the societal and cultural dimension has been less prominent. Myles (2012) found a deep cultural transition was needed in the British army and Morrow, Rothwell, Burford et al. (2013) inquired into the cultural dimension of transition for overseas medical staff in the UK.

In the social sciences there has been an intensive debate on postmodern values and value changes (Inglehart 1977) and on changes of attitudes and preferences towards sustainability (Raskin/Banuri/Gallopin et al. 2002; Leiserowitz/Kates/Parris et al. 2006). The WBGU used values as "a shared perception of something worth striving for", where cultural values refer "to something that has evolved socioculturally, something that exists independent of individuals". It stated that "attitudes relate to certain objects, people (groups), ideas, and ideologies, or specific situations" (Häcker/Stapf 1994). In contrast to short-term intentions and long-term value systems, attitudes "represent evaluations and action tendencies with regard to attitude objects, and are usually stable over the medium term", while opinions are understood as "verbalizations of attitudes and values".

The WBGU (2011: 77) argued that various barriers prevent "value systems from impacting on behaviour, at both individual and social or structural level", and that a change in behaviour requires "a material and cognitive basis". A transition towards sustainability is structurally constrained by the prevailing path dependence, as well as the high level of carbon infrastructure and its political and electoral influence on decision-makers in parliaments and in the executive sector.

Analysis of the so-called soft aspects of sustainability transition, e.g. of the constraints, obstacles and barriers to a change in opinion, attitudes, value systems and behaviour, requires the expertise of not only sociologists, social psychologists and anthropologists, but also of political scientists. It should include an analysis of cognitive perceptual and evaluative barriers created by the established traditional world views of

scientists and the mindsets of policymakers (Oswald Spring/Brauch 2011).

1.8   Structure of this Handbook and its Contributions

The sixty authors of this Handbook are citizens of or work in eighteen different countries from all five continents. They come from *or* work in Africa (3, all from South Africa); the Americas (16): Brazil (3), Canada (1), Mexico (5), and the US (7); Asia (5): China (2), Singapore (2) and Thailand (1); Australia (3); and Europe (33 *or* 43): particularly Belgium (1), France (1), Germany (21), Ireland (2), Norway (1), Poland (1), Sweden (1), the Netherlands (7), and the United Kingdom (8). Three-fifths of them are male and two-fifths female.

The authors were trained or are working in the following scientific disciplines:

- *Anthropology* (3): Lourdes Arizpe, Twig Johnson and Úrsula Oswald Spring;
- *Climate Studies* (6): Sophie Adams, Rebecca Froese Hans Joachim Schellnhuber, Carl-Friedrich Schleussner, Olivia Maria Serdeczny, and Simon Dalby;
- *Demography* (2): Hongmin Chen and Hania Zlotnik;
- *Development Studies* (4): Sophie Adams, Lucy Baker, Asfaw Kumssa and Carl Middleton;
- *Ecology and Environmental Studies* (9): Úrsula Oswald Spring, Philipp Schepelmann, Monica de Andrade, Philipp Späth, Bonno Pel, Belinda Yuen, Sander Happaerts, Cecilia Tortajada and Gregory Trencher;
- *Economics* (11): Karoline Augenstein, Audley Genus, Jan Jonker, Flor Avelino, Sylvia Lorek, Czeslaw Mesjasz, Linda O'Riordan, Ilona Magdalena Otto, Uwe Schneidewind, Mike Hodson and Hongmin Chen;
- *Engineering* (3): Karlson 'Charlie' Hargroves, Carl Middleton and Martin Keulertz;
- *Geography* (8): Simon Dalby, Eckart Ehlers, Peter Michael Link, Simon Marvin, Jürgen Scheffran, Janpeter Schilling, Rebecca Froese and Martin F. Price;
- *Philosophy* (3): Claudia Köhler, Bonno Pel, Olivia Maria Serdeczny and Úrsula Oswald Spring;
- *Physics* (4): John Grin, Czeslaw Mesjasz, Jürgen Scheffran and Hans Joachim Schellnhuber;
- *Political Science* (13): Karoline Augenstein, Hans Günter Brauch, John Grin, Juan Antonio Le

Clercq, Radhika Perrot, Britta Rennkamp, Marit Sjøvaag, Carolyn M. Stephenson, Eduardo Viola, Mike Hodson, Larissa Basso, Tobias Ide and Lucy Baker;

- *Psychology* (2): Coleman, Morton Deutsch, and Úrsula Oswald Spring;
- *Sociology* (3): Flor Avelino, Claudia Köhler and Sir Robert Worcester;
- *Sustainable Development* (5): Sander Happaerts, Roeland J. in 't Veld, Mark Swilling, Mike Hodson and René Kemp; and
- *Urban Studies* (3): Xuemei Bai, Belinda Yuen and Shivant Jhagroe.

The book reflects a methodological pluralism and several chapters aim for a transdisciplinary and transformative approach. All chapters in this Handbook have been peer-reviewed, and the book is organized into ten parts.[72]

1.8.1   Moving towards Sustainability Transition

Simon Dalby (CIGI Chair in the Political Economy of Climate Change at the Balsillie School of International Affairs and Professor of Geography and Environmental Studies at Wilfrid Laurier University, Waterloo, Canada) argues in chapter 2, "Contextual Changes in Earth History", that human activities have changed the parameters of the Holocene so much that we now live in the Anthropocene. Studies in earth system science suggest that sustainable development and plans for transitions to a sustainable peace must consider the possibility of rapid phase shifts in the biosphere. Constraining human activities to ecological boundaries in the earth system is key to sustainability, but rapid shifts may be coming. Sustainability planning must think beyond national security and recognize that human actions are shaping the future of the planet and are changing the geopolitical context. Adopting the perspective of a geopolitical ecology focusing on global economic production rather than only on environmental protection is key to the future if planetary stewardship of the Anthropocene is to be successful.

In chapter 3, "Paradigm and Praxis Shifts: Transitions to Sustainable Environmental and Sustainable Peace Praxis", *Carolyn Stephenson* (Associate Professor of Political Science at the University of Hawaii at Manoa and affiliate faculty member in its Matsunaga Institute for Peace, US) claims that the paradigms of both sustainable environmental practice and sustainable peace practice have rapidly diffused in past decades, but unevenly across time and space, across regions, and within countries. Until recently, researchers in environmental studies and peace studies have often ignored each other. Cooperation between them is a significant change. This chapter reviews the paradigms of sustainable environment and sustainable peace as an incomplete engagement with each other.

John Grin (Professor at the Department of Political Science of the University of Amsterdam, The Netherlands) introduces in chapter 4 on "Transition Studies: Basic Ideas and Analytical Approaches" different approaches to (i) understanding and (ii) shaping transition dynamics. He distinguishes among three key approaches: 1) A *socio-technical approach*, with the multi-level perspective as its main concept, and strategic niche management as its governance concept; 2) A *complex (adaptive) system based approach*, using the concept of transition patterns, with transition management as its governance concept; 3) A *governance approach*, which has elaborated the politics of transition dynamics, with reflexive design as the core of its approach to shaping transition. Further, work based on the social theory of practice have helped to bring in consumption practices into transition theory, and an approach focusing on innovation systems has helped to understand how different arrangements may become interconnected so as to produce a transition.

In chapter 5, "Transformative Science for Sustainability Transitions", *Uwe Schneidewind* (President of the Wuppertal Institute for Climate, Environment, Energy and Professor for Sustainable Transition Management at the University of Wuppertal), *Mandy Singer-Brodowski* (scientific coordinator of the Center for Transformation Research and Sustainability at the University of Wuppertal) and *Karoline Augenstein* (research fellow at the Wuppertal Institute for Climate, Environment, Energy) (all from Germany) argue that sustainability transitions require a knowledge production that contributes actively to the Grand Challenges of twenty-first-century societies. In their view, scientific institutions play a key role in the transformation towards sustainability and peace. A 'transformative science' is needed that not only analyses processes of transformation, but also actively supports and accelerates them. Drawing from the German science system, they introduce the concept of 'transformative science' and its implications for (1) the methodologies of transdisciplinary and transformative

---

72 The summaries of the chapters are based on condensed abstracts written by the authors.

research, (2) institutional capacity-building for facilitating such a research approach, and (3) the national science systems and national science policies that will enable this new mode of knowledge production.

1.8.2   Aiming for Sustainable Peace

The second part of the book addresses sustainable peace and includes two chapters on the use of this concept in peace psychology, from a gender perspective and in its environmental dimension as peace with nature. In chapter 6, *Morton Deutsch* (E. L. Thorndike Professor and director emeritus of the Morton Deutsch International Center for Cooperation and Conflict Resolution (MD–ICCCR) at Teachers College, Columbia University, US) and *Peter T. Coleman* (Professor of Psychology and Education at Columbia University at Teachers College and The Earth Institute and who teaches courses in Conflict Resolution, Social Psychology, and Social Science Research; Director of the Morton Deutsch International Center for Cooperation and Conflict Resolution (MD–ICCCR) at Teachers College, Columbia University, US) introduce "The Psychological Components of a Sustainable Peace", based on the introductory chapter of their book (Coleman/Deutsch 2012), They enhance the understanding of sustainable peace by supplementing the standard approach of studying the prevention of destructive conflict, violence, war and injustice with the equally important investigation of the promotion of the basic conditions and processes conducive to lasting peace. In addition to addressing the pervasive realities of oppression, violence and war, peace requires us to understand and envision the alternatives we wish to construct.

In chapter 7, "The Essence of Peace? Toward a Comprehensive and Parsimonious Model of Sustainable Peace", *Peter T. Coleman* (Columbia University, US) highlights the basic commonalities of a "harmonious sustainable peace", summarizes the main components of sustainable peace, presents a sketch of a more parsimonious model of sustainable peace informed by dynamic systems theory and dynamic minimalism, and outlines an agenda for future study and education in this area

In chapter 8, "Development with Sustainable-Engendered Peace: A Challenge during the Anthropocene", *Úrsula Oswald Spring* (Research Professor at the *National Autonomous University of Mexico* (UNAM) in the *Regional Multidisciplinary Research Center* (CRIM) in Cuernavaca, Mexico) examines the evolution of the concept of peace from a negative

towards a positive, sustainable, and engendered concept, with reference to long-term violence, embedded in the patriarchal system and characterized by authoritarianism, exclusion, discrimination, exploitation, and violence. These threats are consolidated by patriarchal institutions, religious controls, self-identified beliefs and social representations, and totalitarian exercise of power affecting natural resources and human development. The chapter explores the concept of a sustainable-engendered peace, attempts to understand the links to patriarchy and its war system, and explores the potential for a holistic and cosmopolitan peace that may challenge the root causes of violence and destruction.

In chapter 9, "Sustainable Peace in the Anthropocene: Towards Political Geoecology and Peace Ecology", *Hans Günter Brauch* (Privatdozent (Adj. Prof.) at the Faculty of Political Science and Social Sciences, Free University of Berlin (ret.) and chairman of *Peace Research and European Security Studies* (AFES-PRESS, Germany) conceptualizes possible linkages between the 'sustainability transition' research paradigm and the rethinking of peace, security, development and the environment or ecology since 1990. With the transition from the Holocene to the Anthropocene the threat to the survival of humankind has changed. We are now the threat due to the increase in our burning of hydrocarbons and the accumulation of greenhouse gases in the atmosphere. This new threat cannot be countered with traditional military strategies any longer but requires a long-term transformative change of our economy with its production and consumption and of the energy, transportation, agricultural and housing sectors towards a low-carbon economy that would be the result of a process of a transition to sustainability. Such a long-term transformative change can avoid climate-induced and resource-scarcity-driven violent conflicts. This chapter recommends the development of possible linkages between sustainable development, human security and sustainable peace in the context of a political geoecology and a peace ecology. There is a need for more conceptual, theoretical and empirical research on the possible linkages between peace studies and ecology, that takes into account the changed human and environmental conditions in the Anthropocene. The added value is to sensitize the research on 'sustainability transition' to reflect on the impact of its realization on sustainable peace and human security.

1.8.3 Meeting the Challenges of the Twenty-First Century: Demographic Imbalances, Temperature Rise and the Climate–Conflict Nexus

In chapter 10, "Population imbalances: Will they continue over the rest of the century?", *Hania Zlotnik* (consultant and former director of the United Nations Populations Division, US/Mexico) states that current population dynamics vary markedly between countries. In 2010, forty-six per cent of the world's population lived in countries with below-replacement fertility, while nineteen per cent lived in countries with such high fertility that their combined populations are likely to double by 2050. The remaining thirty-five per cent lived in countries where fertility levels had declined considerably but where the potential for continued population growth remains high. Both population momentum and long-standing differences in population dynamics between these groups of countries are expected to continue in the medium term. Reducing population imbalances by the end of the century requires that the high-fertility countries accelerate the reduction of fertility to reach below-replacement levels before 2100.

In chapter 11, "The Challenge of a 4°C World by 2100", *Hans Joachim Schellnhuber* (Director of the *Potsdam Institute for Climate Impact Research* (PIK), Germany), *Olivia Maria Serdeczny* (research analyst at *Climate Analytics*, Germany), *Sophie Adams* (research analyst at *Climate Analytics*, from Australia), *Claudia Köhler* (Personal Executive Advisor to the Director, PIK, Germany), *Ilona Magdalena Otto* (researcher at PIK, Germany), and *Carl-Friedrich Schleussner* (climate scientist with *Climate Analytics*, Berlin and PIK, Germany) argue that our understanding of the earth system and the climate change impacts expected in the coming decades is developing at a rapid pace. They argue that we need to take into account the different degrees of vulnerability not only across but also within nation states. The ramifications of non-linear impacts and their uneven distribution are likely to be deleterious to the stability and well-being of our societies. If we wish to understand the challenges associated with a 4°C world, such a world needs to be imagined.

In chapter 12, "The climate–conflict nexus: Pathways, regional links and case studies", *Tobias Ide* (head of the research field Peace and Conflict at the *Georg Eckert Institute* in Braunschweig, Germany), *P. Michael Link* (postdoctoral scientist at the *Research Group Climate Change and Security* (CLISEC), Insti-tute of Geography, University of Hamburg, Germany), *Jürgen Scheffran* (professor at the Institute of Geography and the *Center for Earth System Research and Sustainability* (CEN), Germany, head of CLISEC in the CliSAP Cluster of Excellence, Hamburg University, Germany), *Janpeter Schilling* (Associate at International Alert in London, postdoctoral researcher with CLISEC at Hamburg University, Germany) claim that the role of climate change as a potential cause of violent conflict has been debated in the scholarly and policy communities for years. They review the most recent quantitative and qualitative literature and find that research on the issue has produced little consensual findings so far. Further, they discuss major theoretical, conceptual and empirical issues and describe possible pathways linking climate change to violent conflict. They analyse the climate–conflict nexus in different world regions and present three qualitative case studies: in north-western Kenya, the Nile Basin, and Israel/Palestine. They see possible reasons for the lack of scientific consensus in the difficulties existing approaches have in adequately capturing the complex links between climate change, vulnerability, and violent conflict.

In chapter 13, "From a Climate of Complexity to Sustainable Peace: Viability Transformations in the Anthropocene", Jürgen Scheffran (see above, Germany) argues that in an increasingly interconnected climate of complexity, the stabilization of human–environment interactions is a major challenge in international relations that demands the integration of complexity science with global governance. This chapter highlights several cases of complex crises where cascading events have affected international stability. Climate change is considered as a risk multiplier which disturbs the balance between natural and social systems and amplifies the consequences through complex impact chains that affect the functioning of critical infrastructures and supply networks; intensify the nexus of water, energy and food; lead to production losses, price increases and financial crises in other regions through global markets; undermine human security, social living conditions and political stability; and trigger or aggravate migration movements and conflict situations. An integrative framework of human–environment interaction is used to analyse destabilizing developments, tipping elements and cascading risks, as well as concepts of resilience, viability and sustainable peace.

1.8.4 Initiating Research on Global Environmental Change, Limits to Growth, Decoupling of Growth and Resource Needs

The next four chapters deal with international efforts to initiate research on global environmental change, on the 'Limits to Growth', and on a decoupling of economic growth from resource needs. In chapter 14, *Lourdes Arizpe* (Professor, Regional Center for Multi-disciplinary Research, National Autonomous University of Mexico), *Martin F. Price* (Professor, Director of the *Centre for Mountain Studies* (CMS), Perth College, *University of the Highlands and Islands* (UHI), Scotland, UK), and *Sir Robert Worcester* (Emeritus Chancellor of the University of Kent, Visiting Professor and Honorary Fellow at the London School of Economics, UK) document "The first decade of initiatives for research on the Human Dimensions of Global (Environmental) Change (1986–1995)". They present and discuss the emergence of initiatives for research on the human dimensions of global change up to the 1996 launch of the *International Human Dimensions Programme on Global Environmental Change* (IHDP). In 1990, *International Social Science Council* (ISSC) launched the *Human Dimensions of Global Environmental Change Programme* (HDP), identifying seven broad research topics. Simultaneously various related national and regional research initiatives emerged.

In chapter 15, "From HDP to IHDP: Evolution of the International Human Dimensions of Global Environmental Change Programme (1996–2014)", *Eckart Ehlers* (Professor emeritus, Bonn University, Germany) reviews as a process of maturation of social science research the challenges of climate and global environmental change that became part of the *Earth System Science Partnership* (ESSP) and in 2015 were fully integrated into the Future Earth initiative.

In chapter 16, "From the Limits to Growth to 2052", *Marit Sjovaag* (political scientist working on climate policy, Norway) summarizes the content of and the debate around the 'Limits to Growth' and its updates, from 1972 until 2012. The chapter presents the background and political context to the original 1972 study, and follows the debate on the four books. The methodology of systems analysis is briefly introduced and the analyses are presented, as are the reactions from academia and political and economic interests. The chapter addresses the research questions of why the debate around the 'Limits to Growth' became so polarized, and how the original scenarios have

been updated over the last four decades. The chapter concludes with Randers' forecast (2012) for the next forty years.

Finally, in chapter 17, "Preparing for Global Transition: Implications of the Work of the International Resource Panel", *Mark Swilling* (Professor of Sustainable Development, School of Public Leadership, University of Stellenbosch, South Africa) briefly describes the establishment of the *International Resource Panel* (IRP) by UNEP in 2007 as a panel of scientific experts. In his review of the IRP's activity he uses a material flow analysis perspective, as the primary focus of the IRP is on global resource use and potential alternatives. The notion of a 'third great transformation' is deployed to suggest that the work of the IRP is documenting the endgame of the industrial socio-metabolic regime. Three clusters of reports are addressed: (a) global resource perspectives, with special reference to decoupling rates of economic growth from rates of resource use by focusing on the importance of resource productivity; (b) nexus themes, including cities, food, trade, and GHG mitigation technologies; and (c) specific resource challenges with respect to two clusters of issues, metals and ecosystem services. He concludes that a resource-use perspective adds to an understanding of the unsustainability of the current global system, complementing the outputs of climate science on the effects of anthropogenic carbon emissions and ecosystem science on the implications of biodiversity degradation. The IRP anticipates the possibility of a more resource efficient socio-metabolic order but it has not yet addressed the dynamics and modalities of transition from an institutional and macro-economic perspective.

1.8.5 Developing Theoretical Approaches to Sustainability and Transitions

In the next three chapters, an economist from Poland (Czeslaw Mesjasz), three political scientists from the Netherlands (B. Pel, Flor Avelino and S. S. Jhagroe), and three geographers from the UK and Germany (Mike Hodson, Simon Marvin and Philipp Späth) present different theoretical approaches to sustainability and transitions.

In chapter 18, "Sustainability and Complexity: A Few Lessons from Modern Systems Thinking", *Czeslaw Mesjasz* (Associate Professor, Faculty of Management, Cracow University of Economics, Poland) argues that sustainable development, sustainability and sustainability transition are associated with the growing complexity of sociopolitical and ecological systems and

their interactions. The chapter identifies and assesses the applications of the concepts deriving from complexity studies to the discourse on sustainability and sustainable development and on related terms. Its main hypothesis is that a sophisticated language dealing with complexity and applied in the narratives about sustainability and related ideas requires profounder clarification so as to provide new insights concerning the description, explanation of causal links, prediction, normative approach and influence on societal phenomena.

In chapter 19, "Critical Approaches to Transitions Theory", *Bonno Pel* (postdoctoral researcher, *Centre d'Études du Développement Durable*, *Université Libre de Bruxelles*, Belgium), *Flor Avelino* (researcher and lecturer, DRIFT, Erasmus University Rotterdam, the Netherlands), and *Shivant Jhagroe* (PhD researcher, Eindhoven University of Technology, The Netherlands) argue that since its emergence as a theory of sustainability transformation, transitions theory has attracted both policymakers and researchers. As transitions approaches become established in research and policy, a process of institutionalization can be witnessed. Yet notwithstanding this mainstreaming, transitions theory continues to be controversial. Questions have been raised about its theorization of agency and transformation dynamics, and especially about the normative assumptions underlying its intervention strategies. There are repeated calls for 'critical approaches' to transitions theory. This contribution explores these, guided by a constructive attitude. The argument starts from the consideration that transitions theory harbours distinctly 'critical' elements: What are the critical contents of transitions theory? How can the critical contents of transitions theory be retained and developed further? These questions are answered through a historical comparison with the critical-theoretical project as initiated by Marx, Horkheimer and Adorno, amongst others. As with transitions studies, this project was meant to diagnose the social problems of its time, and to articulate corresponding remedial strategies. It ran into various internal contradictions, however, and these provide useful insights for the further development of critical transitions. The main conclusion is that transitions theory is well equipped to deal with these critical-theoretical paradoxes, but also displays tendencies towards relapsing into the pitfalls.

In chapter 20, *Mike Hodson* (Research Fellow, University of Manchester, *Sustainable Consumption Institute* (SCI) and *Manchester Institute of Innovation Research* (MIoIR), UK), *Simon Marvin* (Direc-

tor, Urban Institute and Professor, Department of Geography, Sheffield University, UK) and *Philipp Späth* (who heads a research project on Smart EcoCities, Institute of Environmental Social Sciences and Geography, Albert-Ludwigs-University Freiburg, Germany) address "Sub-national, Inter-scalar Dynamics: The Differentiated Geographies of Governing Low-Carbon Transitions—With Examples from the UK" with the aim of improving the analytical understanding of low-carbon transitions at and in between multiple geographical scales, particularly 'below' the national level. Taking the *Multilevel Perspective* (MLP) as their starting point, they show that it offers tools for thinking through the institutional and technological conditions and rules through which regimes reproduce or change over time. But it is not well equipped to facilitate the study of transitional dynamics as they unfold in space. The chapter sets out several levels on a spatial scale and activities that are relevant to transition activity but with which the MLP so far engages only partially. The chapter explicitly identifies very different, yet coexisting, scales of transition activity that aim at low-carbon transitions in the UK. It demonstrates the possibilities of attributing different spaces and levels to particular transition activities on a geographical scale and highlights the dynamics between these scaled activities. It initiates debate on the 'appropriate' mechanisms for dialogue 'between' governance levels and differently scaled transition activities.

1.8.6 Analysing National Debates on Sustainability in North America

The next three chapters by Twig Johnson (US), Simon Dalby (Canada) and Juan Antonio Le Clercq (Mexico) offer three case studies on aspects of national debates and policies in the three *North American Free Trade Agreement* (NAFTA) countries.

In chapter 21, "Policy, Politics and the Impact of Transition Studies", *Twig Johnson* (Writer/Consultant, Kingston, Massachusetts, US) argues that transition studies are undertaken in a variety of contexts and at various levels of society. Researchers hope and in some cases expect that their studies will be used to address challenges to sustainability transition. The relationship between research and effective action poses a challenge that transition studies must address. As part of an effort to study the different contexts in which sustainability transition studies have developed, Johnson discusses a 1999 report by the US National Research Council (NRC), *Our Common Journey: A*

Transition toward Sustainability (NRC 1999). The study was begun in 1996 during the Clinton and Gore administration. Sustainable development and environment were high on their list of priorities. The time seemed ripe for looking at ways in which science could better support US policy efforts to transition to sustainability. It was the best of times. Shortly after publication (December 1999) the political climate changed radically, especially after the 9/11 terrorist attacks. Johnson reviews this study and related efforts to address the sustainability transition challenge fifteen years since its publication.

In chapter 22, "Geopolitics, Ecology and Stephen Harper's Reinvention of Canada", *Simon Dalby* (see above, Canada) analyses the impact of the election to power of the Conservative Party in Canada in 2006 with a vision of the world that was much more competitive than previous Liberal or earlier conservative visions. Dalby interprets this as an attempt to reinvent Canada as a player in a world of competitive geopolitics rather than as a good citizen in a shared biosphere. Foreign and domestic policy have been shaped by this new view, and this has led to the abrogation of the Kyoto protocol. Since Canada is an energy superpower and oil exporter, it has also led to substantial attacks by the government on environmental science and regulatory processes, as these might obstruct resource company projects. What is being sustained in this process is a vision of Canada antithetical to what in most parts of the world would be considered sustainable. The lessons to be learnt for sustainable transitions are many, most notably the importance of thinking carefully about conventional politics and the dangers of narrowly-cast nationalist and populist attacks on environmental policies and sustainability initiatives.

In chapter 23, "Regime Change, Transition to Sustainability and Climate Change Law in México", *Juan Antonio Le Clercq* (professor, International and Political Sciences Department, *Universidad de las Américas, Puebla* (UDLAP), Mexico) examines the creation of the Climate Change Law in Mexico as a governance regime, where the legislative deliberations oriented towards creating the Climate Change Law between 2005 and 2012 are understood as a pathway to a sustainable transition. The chapter discusses the principal elements of Mexican climate policy and identifies three competing alternatives for climate legislation in 2012. The chapter argues that the energy sector limits the possibilities for a sustainable transition in Mexico.

1.8.7 Preparing Transitions towards a Sustainable Economy and Society, Production and Consumption and Urbanization

In part seven, chapters 24 to 30 deal with "Preparing Transitions towards a Sustainable Economy and Society, Production and Consumption and Urbanization". In chapter 24, "Sustainability Transitions: A Discourse-Institutional Perspective", *Audley Genus* (Professor, Small Business Research Centre, Kingston University, Kingston upon Thames, UK) addresses the complex web of activities and actors necessary for the transition to sustainability. He reviews various contributions, with a concern for the role that language and institutional arrangements play in related developments, in order to improve the understanding of the problems involved, the issues at stake, and the implications for policy and practice. He presents a framework for a discussion of sustainability transitions, neo-institutional theory, and critical discourse analysis by drawing on neo-institutional theory and critical discourse analysis on different factors and actors implicated in (un)sustainable patterns of production and consumption and the (in)effective governance of environmental sustainability-related science, technology and other phenomena. He considers potential insights from a discourse-institutional perspective and the progress that has been made using this approach.

In chapter 25, "New Business Models: Examining the Role of Principles Relating to Transactions and Interactions", *Jan Jonker* (Professor of Sustainable Entrepreneurship, Nijmegen School of Management, Radboud University Nijmegen and Chaire d'Excellence Pierre de Fermat, Toulouse Business School in Toulouse (France), The Netherlands) and *Linda O'Riardon* (Professor of Business Studies and International Management, Director of the *KompetenzCentrum for Corporate Social Responsibility* (KCC), FOM University of Applied Sciences in Essen, Germany) claim that our current economic ideas no longer function and that sustainability concerns are often central. They present the results of exploratory research initiated by Radboud University Nijmegen into *new business models* (NBMs). Their study focuses on business models that create so-called 'multiple value(s)', a way of organizing that focuses not just on organization between organizing entities. This approach generates social and ecological as well as economic value. For this research, a series of interviews was conducted in order to gain insight into the phenomenon of NBMs and to combine this fresh

empirical evidence with theoretical underpinnings from previous scholarship. This data was then used to explore the field and discover the nature of NBMs, their features, and how they function in (micro-)practice.

In chapter 26, "Sustainable Consumption", *Sylvia Lorek* (head, *Sustainable Europe Research Institute* (SERI) Germany e.V.) offers key arguments from the sustainable consumption literature. The chapter introduces 'environmental space' as an early concept which embedded sustainable consumption within natural and social boundaries. It explains why a floor as well as a ceiling for the environmental space has to be considered and reflects on the space itself, its size and how to share it. Various possible paths of transition to reach the environmental space from a position of over- and under-consumption are linked to various schools in sustainability research. Lorek emphasizes the need for a detailed analysis of the concepts of 'green growth' and 'de-growth'. Relating these concepts to sustainable consumption research and politics, she distinguishes between strong and weak sustainable consumption, and outlines enabling mechanisms for sustainable consumption.

In chapter 27, "Sustainable Consumption and Production in China", *Hongmin Chen* (Associate Professor, Department of Environmental Science and Engineering and researcher, Fudan Urban Environmental Management Research Center and Fudan Tyndall Center, all at Fudan University, Shanghai, China) states that the increasing problem of severe resource scarcity, environmental pollution and ecological degradation has become a great constraint on economic development in China. *Sustainable consumption and production* (SCP), as a primary way to decouple economic development from environmental degradation, has been undertaken in China with energy-saving and environmental protection policies. She discusses the main practices of SCP, including the adjustment of the industrial structure, the promotion of a circular economy and clean production, the Energy Conservation and Emission Reduction Project, green procurement, and progress in waste management. Though China has made some achievements in SCP, it still faces serious challenges.

In chapter 28, "The Eco-restructuring of the Ruhr Area as an Example of a Managed Transition", *Philipp Schepelmann* (acting director, Research Group for Material Flows and Resource Management, Wuppertal Institute for Climate, Environment and Energy, Germany), *René Kemp* (Professor of innovation and sustainable development, *International Centre for*

Integrated Assessment and Sustainable Development (ICIS), Maastricht University and professorial fellow, UNU–MERIT, The Netherlands), and *Uwe Schneidewind* (see above, Germany) present the eco-restructuring of the Ruhr area as a remarkable case of a managed transition, bringing out the importance of regional actors and factors alongside external stimuli. The evidence in support of the authors' hypothesis of a managed transition in the Ruhr district is: (i) the vision of blue skies above the Ruhr, (ii) the reconstruction of the Emscher river system, and (iii) the emerging energy transition. The ongoing transition of the Ruhr district requires further analysis which the authors plan to undertake. The chapter provides a first attempt at offering an evidence-based narrative of a region as a real-world laboratory for ecological modernization.

In chapter 29, "Transition towards Sustainable Urbanization in Asia and Africa", *Belinda Yuen* (Lee Kuan Yew Centre for Innovative Cities, Singapore University of Technology, Singapore) and *Asfaw Kumssa* (Chief Technical Advisor, Office of the United Nations Resident Coordinator's Office, Nairobi, Kenya) show that both continents are the world's least urbanized regions. But they are fast urbanizing; eighty per cent of the world's projected urban growth to 2050 is expected to take place in Africa and Asia. Even though cities in Africa and Asia are increasingly recognized as engines of growth, they are sites of extremely high population density, congestion, informal housing and the concomitant expansion of slums and squatter settlements, infrastructure shortages and environmental degradation. As rapid urbanization continues, how Africa and Asia manage the urban transition will not just affect urban economic efficiency but will also define their greenhouse gas footprint. They compare the urbanization of both regions and discuss the challenges and opportunities for transition towards sustainable urbanization.

In chapter 30, "The Role of University Partnerships in Urban Sustainability Experiments: Evidence from Asia", *Gregory Trencher* (Assistant Professor in Environmental Science and Policy, Clark University, US) and *Xuemei Bai* (Professor of Urban Environment and Human Ecology, Fenner School of Environment and Society, Australian National University, Australia) argue that university-driven partnerships and experiments for advancing urban sustainability are flourishing across the globe. Responding to drivers such as calls for stakeholder engagement in research, tangible social and economic contributions, and government funding incentives, Asian research universi-

ties are forming cross-sector partnerships and implementing various sociotechnical experiments. The authors examine the role of university partnerships in knowledge co-production and the implementation of urban sustainability experiments in industrialized Asian nations. By examining fifteen cases from Singapore, Japan, Hong Kong and Korea, they highlight common attributes and investigate the functions, motivations, barriers and significance of the roles assumed by different societal sectors. A case study from the University of Tokyo illustrates these attributes in context.

1.8.8 Examining Sustainability Transitions in the Water, Food and Health Sectors from Latin American and European Perspectives

The next three chapters, in part eight, examine sustainability transitions in the water, food and health sectors from Latin American and European perspectives. In chapter 31, "Future global water, food and energy needs", *Cecilia Tortajada* (Senior Research Fellow, Institute of Water Policy, Lee Kuan Yew School of Public Policy, Singapore) and *Martin Keulertz* (postdoctoral research associate, Department for Agricultural and Biological Engineering, Purdue University in Indiana, US) argue that if present trends continue, it is unlikely that increasingly overused ecosystems will meet global water, food and energy needs. Scarcity, pollution, mismanagement and misallocation of natural resources will impact every sector on which humankind depends for survival. In a globalized economy with increasingly free movement of commodities and financial and human capital, a poor understanding of the most pressing issues and their interconnectedness and interdependences will cause irreparable damage to Earth and its people. This is a challenging context for global development, and to understand and manage the interdependencies between the various sectors and their global impact will require comprehensive planning and policy implementation, institutional resilience, partnerships across economic sectors, and innovation in development in order to sustainably manage resources in the wake of population growth and climate change.

In chapter 32, "Sustainability Transition in a Vulnerable River Basin in Mexico", *Úrsula Oswald Spring* (see above, Mexico) examines a transition process that is greatly affected by climate change, social deterioration and the drugs war. The Yautepec River Basin in Central Mexico is particularly prone to climate impacts because of its abrupt slopes, numerous

affluents, and a high population density in its floodplain, which is frequently exposed to the impacts of hurricanes. Taking laissez-faire policies, illegality, government corruption, and public insecurity into account in a region with high levels of dual vulnerability (environmental and social), and which is subject to extreme events, the chapter reviews the constraints on the process of transition towards sustainability, especially when the goals of the people and government are not the same. People organize themselves to increase public security and to reduce the impacts of extreme events which directly affect their lives and livelihoods, while the government promotes a wide infrastructure. The study examines the risks perceived by the people and the ways in which they reduce these risks of extreme events. The transition process requires an integration of numerous social, economic, political, environmental, judicial, cultural and mental factors. These will help to develop processes and resilience from the bottom up to deal with this complex emergency, as well as to force the different levels of government to enhance the human security of the people.

In chapter 33, "Sustainability Transition in the Health Sector in Brazil", *Monica de Andrade* (Health Promotion Graduate Program, University of Franca, Brazil) analyses the dynamic and the forces influencing political, sociotechnical and cultural features. The aim of her study is to identify transition in health in a Brazil facing globalization, demographic, migration, environmental and climate change effects and inequities. Brazil has improved its capacity to formulate, implement, monitor and evaluate multisectoral and universal public policies in the last twenty years, with the implementation of universal health care and conditional cash transfers. These policies have resulted in the improvement of the health indicators of extreme poverty and hunger, under-five mortality, maternal health, infectious diseases, and primary education coverage. Since the frequency of extreme weather events has been increasing globally and in Brazil cardiovascular diseases are a leading cause of death, the consequences for health systems must be considered. Mortality due to traffic accidents has also increased, despite policy efforts and restrictive laws, overwhelming health services and public financial resources.

1.8.9 Preparing Sustainability Transitions in the Energy Sector

The six chapters in part nine examine "Preparing Sustainability Transitions in the Energy Sector". *Jürgen Scheffran* (see above, Germany) and *Rebecca Froese*

(Research Assistant, CLISEC, Hamburg University, Germany) argue in chapter 34, "Enabling Environments for a Sustainable Energy Transformation: The Diffusion of Know-How, Technologies and Innovations in Low-Carbon Societies", that a sustainability transition requires transformation processes and innovations in different fields, including new technologies, products and infrastructures as well as new social rules and norms. Greening the economy rests on the rapid and effective dissemination of climate-friendly technologies, in particular of renewable and efficient energy systems. A high level of finance and smart governance are required in this process in order to involve the economic and technological capacities of all countries. Within this progression, the international diffusion of know-how, investments and technologies needs to be strengthened in order to build up production capacities and the demand for low-carbon goods. Furthermore, business and government actors have to establish international cooperation so that they can adapt technologies to the local context and support the transformation towards a low-carbon society.

In chapter 35, "Considering a Structural Adjustment Approach to the Low-Carbon Transition", *Karlson Hargroves* (Postdoctoral Fellow, Curtin University, Perth, Australia) raises a range of questions about how to effectively transition economies to low-carbon operation over the coming decades as the world comes to grips with the need to significantly reduce greenhouse gas emissions. Increasing pressure is now being felt across a range of sectors to reduce emissions, in particular carbon-related fuel consumption, and this is leading to autonomous emissions reduction efforts—typically ad hoc and business-led. However, in order to meet the ambitious targets for the reduction of greenhouse gas emissions now set by the world's largest economies, a structural adjustment approach may be needed, and this needs to be effectively underpinned and appropriately expedited at an economy-wide level. Hargroves introduces key lessons from structural adjustment programmes for the low-carbon transition and how the willingness to adjust structures of the economy to deliver low-carbon outcomes can be increased.

Britta Rennkamp (researcher, Energy Research Centre and fellow, African Climate and Development Initiative, University of Cape Town, South Africa) and *Radhika Perrot* (senior researcher, *Mapungubwe Institute for Strategic Reflection* (MISTRA), Johannesburg, South Africa) examine, in chapter 36, "Drivers and Barriers to Wind Energy Technology Transitions

in India, Brazil and South Africa", by analysing actors and institutions that have played a role in the development and diffusion of wind energy technologies, from a *technological innovation systems* (TIS) perspective. They introduce innovation capabilities, the enabling environment and policy-independent strategies as the main drivers for the development of TIS. Their aim is to contribute to improving the understanding of drivers of and barriers to innovation relevant to successful transitions towards cleaner technologies and less carbon-intensive economies.

In chapter 37, "Sustainability Transitions and the Politics of Electricity Planning in South Africa", *Lucy Baker* (research fellow, Science Policy Research Unit, University of Sussex and visiting fellow, Energy Research Centre, University of Cape Town; UK) shows that after decades of cheap, abundant coal-fired electricity, from which large international mining and energy conglomerates and wealthy households have benefited disproportionately, South Africa is experiencing a supply-side crisis. In 2011, the country's first *integrated resource plan for electricity* (IRP) was promulgated after a prolonged consultation process throughout 2010. This plan anticipates that renewable energy will constitute twenty per cent of installed generation capacity by 2030, and that this will deliver approximately nine per cent of supply. Coal will retain the greatest share alongside a potential yet currently uncertain nuclear sector. She examines electricity governance in South Africa and the highly politicized policy-making process for IRP in which vested interests have played a major role; and considers the extent to which IRP has facilitated a low-carbon transition.

In chapter 38, "Low Carbon Green Economy: Brazilian Policies and Politics of Energy, 2003–2014", *Eduardo Viola* (Full Professor, International Relations at the University of Brasília and senior researcher, *Brazilian Council for Scientific Research* (CNPQ), Brazil) and *Larissa Basso* (PhD candidate, University of Brasília and researcher, *Brazilian Federal Agency for Support and Evaluation of Graduate Education* (CAPES), Brazil) argue that achieving sustainability is complex. A low-carbon green economy is introduced as a good paradigm for guiding policy-making towards respecting these boundaries; it includes the objective of the decarbonization of energy systems in order to mitigate climate change. The authors show how Brazilian energy policies and politics evolved from 2003 to 2014, and they identify an upward and downward trend in the production of energy from low-carbon sources and a stable trend in energy efficiency. They

conclude that Brazil has not yet embraced the low-carbon green economy even though significant forces are promoting it, while powerful political forces are opposed.

In chapter 39, "Sustainable Electricity Transition in Thailand and the Role of Civil Society", *Carl Middleton* (lecturer, *MA in International Development Studies* (MAIDS) Program and Deputy Director for International Research, *Center for Social Development Studies* (CSDS), Faculty of Political Science, Chulalongkorn University, Bangkok, Thailand) explains the creation and resistance to change of Thailand's centralized and fossil-fuel-intensive electricity regime through a Sustainability Transition and Multilevel Perspective lens, with an emphasis on the sector's political economy (actors, interest, power). The incumbent electricity industry has evolved from a state-owned monopoly to a partially-privatized industry dominated by the state utility and several large independent power producers, and is increasingly shaped by the sector's financialization. Middleton's analysis demonstrates how important global landscape shifts articulate with the sector's domestic political economy, including a shifting global development paradigm from a developmentalist state to liberal market principles, as well as the impact of waves of global economic crises.

1.8.10   International, Regional and National Governance towards Sustainability Transition

In chapter 40, "Governance of Sustainable Development in Knowledge Democracies—Its Consequences for Science", *Roeland J. in 't Veld* (UNESCO Professor of Governance and Sustainability at Tilburg University, The Netherlands) claims that governance is the way in which a society organizes decision-making. Advanced societies turn into knowledge democracies where the relationships between politics, media and science intensify and change continuously. He argues that the quest for sustainable development takes place within knowledge democracies, where sustainability covers economic, social and ecological issues, whose governance is complex. The future direction and con-

tent of sustainable development depend on uncertain future determinants such as technological innovation and the evolution of social values. The multidimensional nature of sustainability requires integration and a recognition of a multilevel, multiscale, multidisciplinary character. Development is about change, transitions and transformations. Governance of sustainable development has to cope with complex dynamics. Governance that furthers transitions focuses on the interaction between representative and participatory democracy, and the optimization of the contribution of science. He addresses the specific consequences for science relating both to disciplinary research and transdisciplinarity.

Sander Happaerts (European Commission, Brussels and part-time assistant professor, Leuven International and European Studies, University of Leuven, Belgium) argues in chapter 41, "Discourse and Practice of Transitions in International Policy-Making on Resource Efficiency in the EU", that for several years, 'transitions' has been the new buzzword in international policy-making. The emergence of an international transitions discourse is linked to debates on the green economy and a low-carbon society, and is manifested in the UN system and in EU discussions. Happaerts analyses international policy initiatives from the perspective of sustainability transitions, with the aim of moving towards a better understanding of the potential role of international policy-making in current and future transitions. A case study of the European Commission's policy initiatives on resource efficiency demonstrates a strong awareness of transitions thinking, consistently integrated into the discourse with the intention of creating a sense of urgency and convincing other actors of the need for fundamental change. Furthermore, transitions thinking has served as the inspiration for several principles, goals and instruments, such as the European Resource Efficiency Platform.

In the concluding chapter, Úrsula Oswald Spring (Mexico), Hans Günter Brauch (Germany), and Jürgen Scheffran (Germany) summarize the key messages of this book and offer suggestions for future research on sustainability transition and sustainable peace.

2   Contextual Changes in Earth History: From the Holocene to the Anthropocene — Implications for Sustainable Development and for Strategies of Sustainable Transition

Simon Dalby[1]

Abstract

Human activities have changed many of the key parameters of the Holocene geological epoch of the recent past so much that we now live in the Anthropocene. New perspectives in earth system science suggest that sustainable development and plans for transitions to a sustainable peace now have to consider the possibilities of rapid phase shifts in the biosphere. Constraining human activities to within a safe operating space defined by key ecological boundaries in the earth system is key to sustainability but planning has to recognize that rapid shifts may be coming. The implications of this suggest that sustainability planning has to think beyond notions of national security and recognize that human actions are shaping the future configuration of the planet and hence changing the geopolitical context. Adopting a perspective of geopolitical ecology with a focus on global economic production rather than only on traditional ideas of environmental protection is key to the future if planetary stewardship of the Anthropocene is to be successful.

Keywords: Anthropocene, Earth System Science, ecological phase shift, Holocene, sustainable development, Planetary Boundaries, Planetary Stewardship, political geoecology, safe operating space.

2.1   Earth History and Sustainable Development

Discussions about peaceful transitions to a sustainable society are driven by an often-implicit understanding that humanity ought to live in a planetary system that is at least broadly similar to the geological circumstances of the last ten thousand years.[2] Geologists and Earth system scientists usually call this period the Holocene. It provided the ecological conditions that facilitated the emergence of human civilization. Now recent research into the earth system, and a growing recognition of the sheer scale of human transforma-tion of many environments, suggests that the assumption of a relatively stable geological context for humanity is at best misleading, and at worst a dangerous failure to think carefully about the new context that humanity is creating for itself in the new epoch driven by human actions, this new epoch of the Anthropocene.

If rapid ecological change accelerates in the next few decades, as all indications are that it will, then rapid adaptations to new circumstances have to be part of the planning for transitions to more sustainable modes of life. Sustainable peace strategies must consider the possibility of rapid and unexpected ecological phase shifts. If peace is to prevail these will have to be lived through without major powers resorting to military action in attempts to deal with at least some of the consequences of environmental and social disruptions. This is the key implication that arises from juxtaposing discussions of peace, transitions and sustainable development with the new insights into geological and ecological sciences.

2.1.1   Formulating Sustainable Development

The *World Commission on Environment and Development* (WCED), chaired by Gro Harlem Brundtland, popularized the phrase 'sustainable development' in its widely cited report *Our Common Future*. The famous definition at the beginning of the second chapter of the report reads: "Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (WCED 1987: 43). This has become the standard definition of one of the most widely used terms in contemporary international politics.

The authors of *Our Common Future* went on to elaborate on the definition, stating that it involved two key concepts. The first is "the concept of 'needs', in particular the essential needs of the world's poor, to which overriding priority should be given" (WCED 1987: 43). The second concept is "the idea of limitations imposed by the state of technology and social organization on the environment's ability to meet present and future needs" (WCED 1987: 43). But the authors went on to emphasize that the social and the physical are inextricably interconnected. "Even the narrow notion of physical sustainability implies a concern for social equity between generations, a concern that must logically be extended to equity within each generation" (WCED 1987: 43). How to do this is not exactly easy; claims to inter-generational and intra-generational equity persist in discussions of sustainable development, but the dramatic trajectory of economic change since the Brundtland Report was published a generation ago has apparently not operated on the report's principles despite the repeated invocation of the term 'sustainable development'.

Bluntly put, the term was at best a compromise. It was an attempt to incorporate Northern concerns with environment with Southern concerns about development. Fifteen years after Indira Gandhi called poverty the worst kind of pollution at the United Nations Conference on the Human Environment in Stockholm, the necessity of dealing with rapid environmental change and with impoverishment in many parts of the world required that some compromise between development and environmental protection be articulated in international forums. At the time, alarm about the depletion of stratospheric ozone and concerns about industrial accidents—with Chernobyl and Bhopal very much on people's minds—was coupled with worries about deforestation and the limited possibilities of expanding agricultural production.

Ozone depletion in particular made it clear that some environmental vulnerabilities were in fact widely shared and some sense of global cooperation was necessary to deal with these matters.

Southern leaders were adamant that Northern environmental issues should not be used as a method for constraining what they saw as essential Southern economic growth (Kjellen 2008). Given that most of the big environmental problems of the time were caused by Northern activities, simple matters of justice required that those who had caused the problems be the ones to pay for the solution. Where ozone depleting substances were a problem, Southern leaders insisted that Northern economies help provide technological alternatives to compensate for what they portrayed as foregone development opportunities. Such principles linking environment to development have subsequently been key to much of the diplomatic discussions about aid and development. More recently, these themes have been key to international discussions of climate change where technology transfer and development aid are part of the negotiations under the rubric of common but differentiated responsibilities (Brunee/Streck 2013). This terminology has become the taken-for-granted language for discussing many international political matters, not just obviously and immediately 'environmental' matters.

This has more recently been complemented by attempts to reconfigure economies and societies in ways that are more obviously 'sustainable' in that they reduce energy and resource use and hence put less pressure on ecological systems. They remain key themes in the more recent scholarly discussions of sustainable transitions (Grin/Rotmans/Schot 2010) and policy-oriented documents focusing on innovations necessary for global governance (WGBU 2011). The growing recognition in at least some states, and European ones in particular, that de-carbonizing energy supplies is key to dealing with climate change is linked to a recognition that development cannot be equated with economic growth as traditionally understood. Ever larger appropriation of resources to feed increased material production is anathema to serious attempts to think about sustainability and further disrupts the livelihoods of many of earth's poorer peoples (Nixon 2011). Coupled with new measurement metrics, only most obviously the notion of an ecological footprint that calculates the amount of land surface needed for each economic or social entity to be at least carbon-neutral, such strategies attempt to dramatically increase efficiencies and recycle materials. They also attempt to limit the extraction of new

resources from fields, forests and mines while simultaneously trying to deal with questions of global justice (Sachs/Santarius 2007).

2.1.2 Sustainability in the Anthropocene

Given the scale of the changes already caused by humanity, earth system scientists are now suggesting that we live in a new geological epoch, one commonly called the Anthropocene following Paul Crutzen's (2002) popularization of the term. There are complicated technical discussions about when the Anthropocene might have started, related to which ecological functions of the system are defined as the most important (Ruddiman 2005), and scepticism on the part of at least some geologists as to whether this is a useful formulation for solving scientific questions in stratigraphy (Autin/ Holbrook 2012). The most commonly accepted view is that the Anthropocene began with the industrial revolution and the growth of the use of fossil fuels, first coal and subsequently petroleum and natural gas (Steffen/Crutzen/McNeill 2007). Steam power was key to the industrial revolution period, both as a source of industrial power and as a mode of locomotion that rapidly connected parts of the global economy and greatly facilitated the extraction of resources and the spread of commercial agriculture.

While this changed many aspects of the global system, starting in the aftermath of the Second World War the global economy began what is now called a period of "great acceleration" (Steffen/Grinewald/ Crutzen/McNeill 2011). Powered by an increasing use of petroleum in addition to the coal use, mass consumption economies grew rapidly, first in the United States, Europe and Japan. Subsequently, the rise of Asian economies–in Korea, Singapore and elsewhere–extended this pattern, with China in particular adopting a capitalist-driven consumption model of 'development' in the 1980s. India too has joined the race to consume. Carbon dioxide in the atmosphere has risen rapidly so that it is now present in quantities unknown in the geological history not only of the Holocene, since the last ice age, but back through previous ice ages and interglacial periods stretching back at least 800,000 years.

In earth system science terms, what comes next is a matter for humanity to decide. A 'planetary stewardship' would seem to be the desirable next phase of the Anthropocene. But if the earth system is to be sustained in something roughly approximating Holocene conditions, many things will have to change, not least

the understandings at beginning of environment' and humanity's place 'in it'. In the terms of international relations, what should be secured to facilitate a sustainable earth is rather different from what has been seen as essential until very recently; geopolitics can no longer operate on the assumption that the 'playing field' of international politics is a given (Hommel/ Murphy 2013). The key point about the Anthropocene perspective is that climate change and other ecological changes are remaking the context of international politics (Dalby 2014).

2.1.3 Recontextualizing Peace and Sustainability

To fill in some of the details for recontextualizing geopolitics in these terms, this chapter first looks to the discussions of earth system science and how the current geological situation is understood. Considerable caution is needed in invoking this particular scientific view of present circumstances; science is not unrelated to attempts to govern human affairs, and the political implications of attempting to see the earth as a whole are not trivial (Lovbrand/Stripple/Wiman 2009). Nonetheless, insofar as environmental contexts are part of the larger considerations of peace and sustainability in coming decades, the earth system science perspective provides a contextualization that distances analysis from an undue focus on states and demands an engagement with the specific material contexts of vulnerability in an innovative way that makes it difficult to avoid the key issues of the politics of security (Dalby 2009). The larger engagement between humanities, social and natural sciences that has often been bypassed by disciplinary foci on one or the other is in urgent need of engagement, and earth sciences provide an especially productive way to link environmental change to history (Hornborg/McNeill/ Martinez-Alier 2007) as well as to a wider range of humanities scholarship (Palsson/Szerszynski/Sörlin et al. 2012). Insofar as peace is to be linked to sustainability, such intellectual conversations are simply essential; these frameworks are increasingly being used to discuss innovative development policies as well as climate adaptations (Pisano/Berger 2013; Raworth 2012).

While earth system science cannot provide a blueprint for a sustainable future, it has developed a loose framework for what is called a 'safe operating space' for humanity in light of key ecological functions of the biosphere. The chapter reviews these prior to returning to the questions of what is needed in terms of transitional strategies and how international security

needs to be rethought if a sustainable earth is to be produced in coming generations. In the words of the unofficial report to the United Nations Conference on the Human Environment in Stockholm in 1972, there is "Only One Earth" (Ward/Dubos 1972). How we think about it is now rather different from that early environmental view of what needs to be done, not least because we have recently come to understand humanity as a geological-scale actor in the earth system. While earth system science does not provide answers to the key political questions facing humanity, it does provide a framing of the options that is increasingly influential (Dalby 2013a).

The rest of this chapter argues that, whatever the finer points of transition and peace strategies engaging sustainability, they all now have to be considered in light of these new insights into the new geological circumstances that humanity is creating for future generations. The chapter first turns to earth system science and the discussion of phase shifts, tipping points and the key question of the boundaries of a safe operating space for humanity in the earth system. These boundaries involve more than climate change that gets most contemporary attention; it is important to consider other ecological changes that humanity is making if the context for sustainability is to be adequately formulated. Later sections of the chapter emphasize that notions of stewardship and transitions have to be understood in light of these new global ecological understandings. The final section suggests that any consideration of peaceful transitions or sustainability now has to include both a recognition that any proposed transition involves decisions about what kind of ecology its strategies imply and, crucially, that rapid ecological change may be the context in which the transitions happen. Any plans for a transition to a new less rapacious mode of economy will also have to include thinking about how to peacefully cope with rapid and sometimes unanticipated ecological change. Earth system science has profound implications for how social sciences now understand their task (Schellnhuber/Crutzen/Clark et al. 2004); taking these seriously is essential for all strategies for economic sustainability.

2.2   Earth System Science

Human actions are often viewed as external drivers of ecosystem dynamics; examples include fishing, water extracting, and polluting. Through such a lens the manager is an external intervener in ecosystem resilience. However, many of the serious, recurring problems in natural resource use and environmental management stem precisely from the lack of recognition that ecosystems and the social systems that use and depend on them are inextricably linked. It is the feedback loops among them, as interdependent social–ecological systems, that determine their overall dynamics and sustainability (Folke/Jansson/Rockström et al. 2011: 722).

With much more attention now placed on the question of sustainability, and given increasing concerns regarding a wide range of large-scale ecological changes and climate change in particular—well beyond the concerns in *Our Common Future*—the possibilities of transitioning to a sustainable mode of economic life on the part of developed economies extend the conceptual framework of sustainable development further. Earth system sciences have emphasized how difficult it is to clearly define the parameters of 'physical sustainability' while also confirming the necessity of understanding social considerations as an essential part of the biosphere. The planet is 'under pressure' from widespread human activities (Steffen/Sanderson/Tyson et al. 2004). While in the 1970s environmentalists had often looked to the discussion of "the limits to growth" in terms of pollution and resource availability (Meadows/Meadows/Randers/Behrens 1972, 1974), now the earth system science literature nuances these matters by looking to a more wide-ranging series of boundaries to what has been called the "safe operating space" for humanity (Rockström/Steffen/Noone et al. 2009a, 2009b). Climate change in particular has raised questions about how we might now understand 'physical sustainability' given that human actions are already changing some of the key parameters of the biosphere.

This is a profound shift in understanding of humanity's place in the larger cosmological ordering of things. Just as astronomy's proofs that the earth orbited the sun rather than the other way round shook human conceptions profoundly as modern science began its investigations, now earth system sciences are making clear that the planet is not a given stable context into which humanity was recently added, but rather a dynamic system that humanity is now profoundly and rapidly changing. 'Physical sustainability' is not a stable given context for humanity; human systems are actively shaping the future geology of the planet, directly altering terrestrial ecosystems and indirectly changing many other aspects of the biosphere, and need to be contextualized that way in any serious thinking about how to address the needs of future generations (Ellis 2011). We are in this new epoch of the Anthropocene, one where human actions are leaving traces in the sedimentary record in

many remote places, a geomorphological footprint as it were of the age of humanity (Brown/Tooth/Chiverrell et al. 2013). These actions may yet leave a distinctive geological footprint on the history of the planet (Clark 2012). Even if the geological legacy we leave may not be this epochal when viewed from millions of years in the future, the rapidly changing context is more than enough to raise profound questions for societal stability and with it human security in coming decades (Scheffran/Brzoska/Brauch et al. 2012).

2.2.1 Ecological Phase Shifts

> As a result of the enormous complexity of the system as a whole, it is not possible to predict the outcomes of rapidly increasing human pressures on the Earth System, but it is clear that thresholds have been or are being reached, beyond which abrupt and irreversible changes occur. These changes will affect the basic life-support functions of the planet (UNEP 2012: 210).

In earth system science terms, the current transformations that humanity has set in motion amount in some accounts to an approaching phase shift in how the biosphere functions (Barnosky/Hadly/Bascompte et al. 2012). Ecological thresholds have either already been crossed or are in danger of being crossed with the consequence that ecosystems will likely operate in new and potentially unpredictable ways (Huggett 2005).

> The shift from one state to another can be caused by either a 'threshold' or 'sledgehammer' effect. State shifts resulting from threshold effects can be difficult to anticipate, because the critical threshold is reached as incremental changes accumulate and the threshold value generally is not known in advance. By contrast, a state shift caused by a sledgehammer effect—for example the clearing of a forest using a bulldozer—comes as no surprise. In both cases, the state shift is relatively abrupt and leads to new mean conditions outside the range of fluctuation evident in the previous state (Barnosky/Hadly/Bascompte et al. 2012: 52).

These shifts can occur at various scales, and while the overall effect may be global, it is important to emphasize that the cumulative effects of many small changes may cross thresholds at larger scales.

> In the context of forecasting biological change, the realization that critical transitions and state shifts can occur on the global scale, as well as on smaller scales, is of great importance. One key question is how to recognize a global-scale state shift. Another is whether global-scale state shifts are the cumulative result of many smaller-scale events that originate in local systems or instead require global-level forcings that emerge on the planetary scale and then percolate downwards to cause changes in local systems. Examining past global-scale state shifts provides useful insights into both of these issues (Barnosky/Hadly/Bascompte et al. 2012: 53).

Those past events suggest that the current transition is more rapid than previous dramatic changes in the earth system, the most recent of which was the transition from the last ice age.

While transitions happen very quickly relative to the fairly stable states that precede them, the pace of human adaptation of numerous aspects of the biosphere may be unprecedented. "Global-scale forcing mechanisms today are human population growth with attendant resource consumption, habitat transformation and fragmentation, energy production and consumption, and climate change. All of these far exceed, in both rate and magnitude, the forcings evident at the most recent global-scale state shift, the last glacial–interglacial transition" (Barnosky/Hadly/Bascompte et al. 2012: 53) which gave rise to the geological period of the Holocene. This is one of the worrisome factors in our present circumstances: there are few clear geological analogies to draw upon to anticipate how the earth system will respond to the new forcing mechanisms humanity has created.

However, the question of whether there are global tipping points that will mean the earth system in total will rapidly tip into some new format is disputed, and much remains to be studied on potential linkages between different drivers of system change (Hughes/Carpenter/Rockström et al. 2013). Brook, Ellis, Perring et al. (2013) suggest that for at least four of the main drivers a phase shift in the immediate future is unlikely at least for terrestrial ecosystems.

> Our examination of the evidence suggests that four principal drivers of terrestrial ecosystem change—climate change, land use change, habitat fragmentation, and biodiversity loss—are unlikely to induce planetary-scale biospheric tipping points in the terrestrial realm. Criteria that would increase the likelihood of such a global-scale tipping point—homogeneity of response over space at a short timescale, interconnectivity, and homogeneity of a causative agent across space—are not met for any of these drivers. Instead, terrestrial ecosystems are likely to respond heterogeneously to these variable forcings and, with a few exceptions, show limited interconnectivity" (Brook, Ellis, Perring, et al. 2013: 399-400).

In part this is because humanity has already transformed so much of the terrestrial ecosystem that there is not a natural state that might tip in terms of land use. All of which makes the case for great caution in predicting global ecological consequences of further changes. It also emphasizes the key point that ecological change is highly geographically variable in

the earth system and human vulnerabilities are dependent on this and the increasingly artificial circumstances in which most of us live (Dalby 2009).

The most worrisome dimension to all this is not that the world will gradually change as a result of human activities, but that the earth system will be rapidly changed in ways that are not conducive to human flourishing. This may happen if the whole earth system enters a rapid phase of non-linear change that results in a new relatively stable configuration, but one very different from that so far familiar to human societies. While this may be unlikely in the immediate future, and some of the earlier concerns about rapid change may have been exaggerated (Committee on Understanding and Monitoring Abrupt Climate Change and its Impacts 2013), exactly how many ecosystems will respond to accelerating climate change is a crucial unknown (Hughes/Carpenter/Rockström et al. 2013). The Anthropocene presents us with a new set of questions concerning the cumulative consequences of human actions, and possible interactions among them, that are key to any discussion of what kind of future we may be creating. The question of the Anthropocene as posed by Rockström, Steffen, Noone et al. (2009a) is nothing less than "What are the non-negotiable planetary preconditions that humanity needs to respect in order to avoid the risk of deleterious or even catastrophic environmental change at continental to global scales?"

2.2.2   Boundaries, Thresholds and Tipping Points

Such 'planetary preconditions' are not easy to establish, not least because ecological matters rarely work in simple linear processes. They often have very considerable abilities to function while key drivers of important facets vary considerably. Many are resilient too, being able to bounce back after serious disruptions. Not all ecosystems function in patterns that are immediately obvious and they are sometimes interconnected over distances in ways that are hard to clearly analyse. Many have threshold values that, once surpassed, lead to systems changing dramatically as they cross a "tipping point" (Lenton/Held/Kriegler et al. 2008). In the case of the global ecosystem, human and ecological systems are so interconnected and enmeshed that they now have to be considered together if any discussion of sustainability is to make sense. "Because ecosystems are variable, one must focus on the risk, not the certainty, of exceeding an objectively defined target or threshold" (Bennett/Car-

penter/Cardille 2008: 132). Calculating such things is rarely easy, but clearly many earth scientists are convinced that some boundaries have already been crossed, and others may well be in the next few decades, with consequences that are potentially disastrous to the contemporary modes of human existence.

More specifically, ecological change has to be understood in terms of potential non-linearities, thresholds, and tipping point responses to stresses that drive systems in particular ways.

> Ecosystem attributes such as species abundance or biological carbon sequestration can respond in three (stylized) ways to biotic and abiotic drivers. The first type of response is characterized by being consistently proportional to the magnitude of the driver, thus exhibiting a 'smooth response' pattern, where no single critical point can be determined. In the second class of ecosystem change, the response, at some critical level of forcing, is amplified by internal synergistic feedbacks and thus becomes nonlinear in relation to the driver, changing the slope of the response curve. The third class similarly involves nonlinearity, but exhibits hysteresis, in which at least two stable states exist, implying limited reversibility. The term tipping point applies to the second and third class of ecosystem change and refers specifically to the inflection point or threshold at which the ecosystem response becomes nonlinear or the rate of change alters steeply (Brook/Ellis/Perring et al. 2013: 397).

Rapid and unpredictable change is what worries most political decision-makers: the potential for drastic disruptions to increasingly artificial social-ecological systems is what has stimulated seemingly endless invocations of environmental security since the Brundtland Commission explicitly raised concerns that environmental disruptions could potentially cause military conflict (Floyd/Matthews 2013). Such considerations have become all the more urgent because scientific evaluations of current transformations are identifying thresholds in many systems.

> Theoretical or empirical evidence of tipping points, manifesting on decadal to centennial time scales, exists at local and regional scales for many subsystems of the Earth system, including the cryosphere, ocean thermohaline circulation, atmospheric circulation, and marine ecosystems. In the terrestrial biosphere, tipping points involve ecosystem attributes such as species abundance or carbon sequestration responding nonlinearly and potentially irreversibly to proximate drivers like habitat loss or climate change (Brook/Ellis/Perring et al. 2013: 396).

The interconnected nature of these suggests very clearly that any attempt to think carefully about sustainability, and strategies for transitions towards more

sustainable human systems, will face fraught interpretive tasks in terms of the science. These will be just as fraught as potential governance arrangements if in the next few decades humanity seriously tries to shape a functional biosphere for future generations.

2.2.3   Multiple System Stressors

All of this is made more complicated by the simple but unavoidable point that multiple stressors are working simultaneously on most systems.

> In a related area of concern, we are struggling conceptually with how to propose robust boundaries for issues that are spatially distributed heterogeneously around the world. Part of the answer relates to the potential geographic specificity of process and function—the primary concern is not the physical intervention in the structure itself. Thus for instance, deforesting the equatorial/tropical Amazon basin really might be more of a planetary cause for concern than land use change over an equivalent area elsewhere, not because of what it materially consists of nor the area involved, but because of the interplay of that particular patch of vegetation with the processes influencing global water and energy balance (Cornell 2012: 2).

Thus, while global boundaries are suggestive, specific ecosystems in particular places matter and trying to ascertain which of these are most important in terms of ecological function is not easy, although it is essential for earth system governance (Bierman 2012).

To even think in such terms requires a conceptual shift from modern notions of a nature external to humanity that provides the environmental context for humanity, to formulations that understand at least the affluent fossil-fuel-powered part of humanity as a key ecological actor in what effectively are geological processes. Such considerations suggest that humanity itself be understood in geological terms given the scale of its actions, a discussion that has given rise to various prior formulations of present times in geological terms before science settled on the informal use of 'the Anthropocene' in the last decade (Davis 2011). What is also clear is the relative novelty of major human interventions in the biosphere, although on closer examination the question of when humanity started to have a noticeable impact on the biosphere and which impact is most important turns out to be very complicated (Ruddiman 2005). Nonetheless, what is clear is that human actions are now transforming the biosphere and the concern is that unless great care is taken not to cross crucial thresholds, we may change it in ways that threaten human civilization profoundly. Not crossing key thresholds in the biosphere is a key part of any strategy that aims to transition from current economic practices to ones that remain safely within the planetary operating space (Rockström/Steffen/Noone et al. 2009a).

2.3   Planetary Boundaries

> Industrial human systems, in just two centuries, have already introduced at least three clearly novel biospheric processes: the use of fossil energy to replace biomass fuel and human and animal labour, revolutionizing human capacity for ecosystem engineering, transport and other activities; the industrial synthesis of reactive nitrogen to boost agro-ecosystem productivity; and, most recently, genetic engineering across species (Ellis 2011: 1013).

In attempting to provide at least a preliminary answer to questions about how far such transformations can be taken while keeping essential biospheric processes working in more or less the conditions humanity is familiar with, Rockström, Steffen, Noone et al.'s (2009a) formulations of a safe operating space for humanity suggest that nine planetary boundaries need to be especially carefully monitored (see figure 3.1). While these are obviously not precisely definable technical measures, they are postulated as conditions short of those that might plausibly be thresholds that, if crossed, might shift ecological conditions from the present desirable state into one much less desirable from the human point of view. Thresholds are defined in terms of coupled human natural systems and non-linear transitions, and the example given is the recent unanticipated retreat of Arctic ice caused by anthropogenic global warming (2007 was a year of especially dramatic reduction in the Arctic Ocean ice cover).

Given the complexity of earth system processes, such simple definitions are very difficult to operationalize in terms of practical metrics. "Some Earth System processes, such as land use change, are not associated with known thresholds at the continental to global scale, but may, through continuous decline of key ecological functions (such as carbon sequestration), cause functional collapses, generating feedbacks that trigger or increase the likelihood of a global threshold in other processes (such as climate change)" (Rockström/Steffen/Noone et al. 2009b). While these may occur at smaller scales (in particular biomes), they may become a matter of global concern when aggregated if their occurrence is widespread. Determining the boundaries prior to such thresholds is not easy and depends on judgments in the face of numerous uncertainties.

Figure 2.1: Planetary Boundaries for a Safe Operating Space for Humanity. **Source:** Stockholm Resilience Centre: "Azote Images"; at: <http://www.stockholmresilience.org/21/research/research-programmes/planetary-boundaries.html>.
With such caveats carefully noted, the Rockström team identified nine boundaries to a safe operating space for humanity about which they are especially concerned. Three of these are systemic processes at the planetary scale, namely, climate change, ocean acidification, and stratospheric ozone depletion. While the first two are processes with global-scale thresholds, in the case of stratospheric ozone this is less clear. The other boundaries deal with aggregated processes from local and regional changes. The associated thresholds here are less clear in the case of global phosphorous and nitrogen cycles, atmospheric aerosol loading, freshwater use, and land use change. Biodiversity loss and chemical pollution are also listed: they are clearly slower processes than the others and lack obvious global-scale thresholds. From such categorizations, climate change and ocean acidification, both of which are predominately caused by the accumulation of carbon dioxide due to human use of fossil fuels, as well as deforestation, are the immediate cause for concern, being both planetary processes and ones that are happening quickly. All the others listed matter as well, as they are important parts of the life support systems for humanity even if there is no way to establish precise thresholds yet. Even more complicated is that these processes interplay and connect in numerous ways; changes in one may cause other processes to cross boundaries.

The initial planetary boundaries framework was updated and extended in 2015 (Steffen/ Richardson/ Rockström et.al 2015). The new version added updates to the initial scientific estimates, and added an additional discussion of what they termed "novel entities" a category that encompasses the new products of industrial civilization which has added numerous new things to the biosphere, the consequences of which are at least so far less than clear. The revised formulation also emphasized the geographical diversity of boundaries, noting that some boundaries are transcended in some regions, but not elsewhere, a matter that makes the framework more precise, but adds difficulty to the task of aggregating the local boundaries into global calculations. Johan Rockström (Rockström and Klum 2015) at least argues that it is still possible to have a civilization based on abundance within these revised planetary boundaries; but critics are doubtful whether there is the necessary clarity concerning what needs to be done to stay within the climate change boundary in particular (Anderson 2015).

2.3.1   Climate Change

The most high-profile theme in the discussion of the Anthropocene is climate change: the body of science related to this topic is now huge. The consensus, widely adopted at the Copenhagen climate negotiations in 2009, is that any warming above 2 degrees Celsius is to be avoided as it will be dangerously disruptive. What is less clear is the long-term level of carbon dioxide in the atmosphere that will keep the climate below this threshold. Concentrations reached 400ppm briefly in 2013, and while environmental activists suggest that perhaps 350ppm is the maximum level that should be maintained in the long run—approximately the level when *Our Common Future* was written—there are as yet few serious suggestions as to how the atmosphere can be brought back to such a level, one already reached after the first few decades of the great acceleration. With the Arctic Ocean ice cap already melting and warming the northern hemisphere as a result of increased albedo, one of the positive feedbacks that concerns climate science is clearly already in operation. Enhanced methane emissions from melting northern permafrost also suggest accelerated warming in this region. The trend to ever-greater emissions of carbon dioxide from combustion and further destruction of forests suggests rapid climate change. Considerations of rapid climate change are now part of the scenario planning exercises for the future (Anderson/Bows 2011) and increasingly a

matter of concern to financial planners who have belatedly begun to consider the consequences of climate system disruptions (Potsdam Institute 2012; see the chapter by Schellnhuber et al. in this volume).

In terms of the boundary debate, climate is one of the key potential drivers that might cross significant tipping points this century with potentially serious disruptions to human systems. Lenton, Held, Kriegler et al.'s (2008) summary suggested that Arctic Sea Ice, the Greenland Ice Sheet, the Atlantic Thermohaline Circulation, the West Antarctic Ice Sheet, the El Nino–Southern Oscillation, Indian Summer Monsoon, Sahara/Sahel and West African Monsoon, Amazon forest dieback, and possible Boreal forest dieback were all contenders for major changes as a consequence of accelerating climate change. While this is far from encompassing the whole earth system, these components are substantial parts of it and they raise the alarm about potential climate security risks very clearly, especially as the monsoons are key to feeding much of Asia and Africa. But as Lenton's (2013) subsequent investigation of environmental shocks makes clear, all this change also matters in human terms: as a matter of how vulnerable people are in particular places and, related to that, a matter of institutional preparedness—or the lack thereof—in particular societies. All this is especially important because, despite repeated warnings that this boundary is one that humanity is on track to transcend, some key scientists are warning that scientific projections of what is needed to prevent global heating, are still not being taken anything like seriously enough by politicians (Anderson 2015).

2.3.2   Ocean Acidification

One of the so-called 'carbon sinks' that removes carbon dioxide from the atmosphere is the ocean where the gas is absorbed in surface waters. But this process is itself a matter with profound ecological consequences.

> Nearly one third of the carbon dioxide released by anthropogenic activity is absorbed by the oceans. But for this fact, current atmospheric CO2 concentrations would be higher than they already are. However, CO uptake lowers the pH and alters the chemical balance of the oceans, in particular the solubility of calcium salts. This phenomenon is called ocean acidification, and is occurring at a rate faster than at any time in the last 300 million years (Gillings/Hagan-Lawson 2014: 3).

The solubility of calcium salts is a key factor in the success of coral reefs and other marine creatures

dependent on shells; if the water is too acidic, coral skeletons or shells may dissolve and cause reefs to stop functioning and shellfish to die. The ecosystem consequences of this phenomenon and other disruptions of marine life may be crucial to the future of the biosphere:

> In the final analysis, protection of the ocean may be more important than protection of atmosphere or land because it stores more carbon, mediates climate variability and provides essential ecosystem services (Gillings/ Hagan-Lawson 2014: 4).

This point is especially important given the obviously global dimensions to the oceans. Despite the large-scale implications of shifts in oceanic functions, they frequently remain a low priority for environmentalists whose focus is on terrestrial systems, which are perceived as more immediately a matter of human experience. Indeed, the focus on 'greening' things in environmental politics and the formulation of 'green' policies suggests a focus on chlorophyll that is key to growing plants. But the earth system perspective and a focus on Anthropocene life suggests that, given the importance of the atmosphere, oceans, and ozone layer, a focus on blue formulations, following from oxygen in ozone and in water in particular, might be more appropriate. Correcting this inherent 'terrestrial bias' is one of the key implications of earth system thinking.

2.3.3   Stratospheric Ozone Depletion

If there is a success story in global environmental management and international cooperation, it is clearly the Montreal Protocol and its subsequent additional amendments and extensions (Benedick 1991). These mandated the end to the production of *chlorofluorocarbons* (CFCs) and the gradual reduction of the use of other halocarbons. While they remain in the atmosphere and will for decades more as they gradually decay, the annual ozone holes over the poles are not increasing, although in 2014 detection of new chemicals in the atmosphere in small quantities raised concern about the efficacy of this regime (Laube/Newland/Hogan et al. 2014). Coincidentally, the reduction in CFCs in the atmosphere has been a useful climate change measure given their potency as greenhouse gases. While other chemicals such as nitrous oxides will still have some detrimental effects on ozone levels in the stratosphere, the immediate danger of removing the essential ultraviolet filter from the upper atmosphere, something essential to terrestrial life, has been removed.

However, while this success is worth emphasizing, so too is the point that the combination of easily identifiable dangers, the availability of technical replacements for the outlawed gases, and the relative simplicity of the technical issues allowed for a relatively rapid evolution of policy. Likewise, financial compensation to Southern states for difficulties they might have encountered in making the transition was forthcoming and was not a prohibitive cost to signatories to the agreements. But this regime, frequently invoked as a model for dealing with other 'global' environmental matters, and a prominent part of the discussions about climate change in particular, may not be a good fit for more complicated issues where numerous technologies operate and where substitutions are much more difficult to identify and implement (Hoffman 2005).

2.3.4   Phosphorous and Nitrogen Cycles

One of the keys to the rapid transformation of rural landscapes has been the availability of artificial fertilizers that have, when coupled with tractors and other farm machinery, facilitated industrial-scale monoculture farming. While the fossil fuel 'subsidy' to natural systems has boosted productivity dramatically in the so-called 'green revolution', it has done so by disrupting rural social systems and ecologies and by dramatically increasing the circulation of nitrogen and phosphorous through the biosphere. "Nitrogen flux through the biosphere is primarily a biological process, while phosphorus availability arises slowly through geological weathering. Humans sidestep the phosphorus bottleneck by mining and distribution of fertilizer onto agricultural lands, thus inadvertently increasing the flow of phosphorus into the oceans" (Gillings/ Hagan-Lawson 2014: 5). Eutrophication and other ecological disruptions result from the addition of artificial fertilizers into aqueous environments; ocean anoxic events that have caused large-scale die-offs may have been caused by phosphorous being washed into the ocean.

However, the boundary on this ecological change is distant when considered at a global scale despite the fact that phosphorous run-off rates may be significant for some coastal waters. An important consideration with managing phosphorous is that it is geographically heterogeneous: while the application of fertilizers in some places may have eutrophication effects on terrestrial waterways, phosphorous deficiencies elsewhere limit ecosystem productivity. This means that a global boundary for phosphorous is very difficult to calculate even if specific ecosystems have

transcended boundary conditions (Carpenter/Bennett 2011). Nitrogen pollution also has regional effects but as yet does not seem to be close to any global threshold (Vries/Kros/Kroeze/Seitzinger 2013). The nitrogen cycle is more complicated to assess as, in the form of nitrous oxide, it is an important greenhouse gas and hence also counts as part of the climate change calculations.

2.3.5 Atmospheric Aerosols

Combustion of fossil fuels, and in particular their inefficient combustion, leads to particulate matter and various chemicals in the atmosphere that have numerous effects (Tsigaridis/Krol/Dentener et al. 2006). These have been of particular concern recently in terms of their immediate pollution effects in Asia and the possible effects global warming may have on disrupting the Asian monsoon, the key rainfall pattern that supplies agricultural systems in the region with water, thus helping feed a large portion of the human population (Kitoh/Endo/Kumar et al. 2013). Ironically, aerosols also act as cooling agents in the atmosphere, shading the ground from sunlight. This effect is clearly visible in studies of the consequences of volcanic eruptions and has become one of the proposed ideas for geoengineering to artificially cool the planet in coming decades if climate change becomes an immediately hazardous phenomenon. As such, aerosols are both pollution and a health hazard but also potentially an artificial sunshade, if practical attempts to cool the planet are undertaken. Hence the great difficulty in assessing the total impact of aerosols on global heating as well as other related human effects.

2.3.6 Freshwater Use

Human activities divert large quantities of surface and ground water for farming, industrial use, as well as for basic human needs such as drinking, bathing, cooking, and household use, making discussions of water security for humanity very complicated indeed (Grey/Garrick/Blackmore et al. 2013). Potable water is key to basic hygiene and disease prevention and, as such, a key dimension to human functioning in many increasingly artificial ecosystems. Water supplies are both a matter of 'natural' supply (as in rain and snow), but also, given the extensive plumbing systems that now supply cities in particular, very much a matter of artificial hydrology. Many rivers no longer flow all the way to their estuaries due to the volume of water diverted en route. Groundwater aquifers are also being pumped dry in many places. While this may not have many direct ecological effects beyond the locations where aquifers feed water springs and hence provide water for ecosystems and human use, the effects matter once the water is depleted and the unsustainable activities dependent on that water source have to be discontinued.

Climate change may alter rain and snow patterns, causing droughts and forcing ecosystems and farming arrangements into new configurations. The California drought emergency of 2014 suggests difficult political choices concerning the allocation of remaining water supplies. Such decisions regarding prioritization have practical, social and philosophical implications for the communities and actors affected. Water is an essential part of human politics, contested and used in numerous ways that defy easy categorization, but an unavoidable necessity in all human activities no matter how humans try to govern its use (Linton 2010). It is clear that human use of fresh water is rapidly increasing due to food cultivation requirements in particular. As such, governance issues will be an important part of sustainability transitions. "This indicates that the remaining safe operating space for water may be largely committed already to cover necessary human water demands in the future" (Rockström/Steffen/Noone et al. 2009b: 16).

2.3.7 Land Use Change

Humanity cleared land for agricultural purposes throughout much of the Holocene period. Indeed, part of the argument that the Anthropocene started long before the industrial revolution is related to the release of methane from agricultural activities (Ruddiman/ Vavrus/Kutzbach/He 2014). The scale of the transformations that have already taken place are such that ecologists have suggested that traditional classifications of the world's large geographical designations of natural areas in terms of biomes now needs to be updated with the addition of various "anthromes" (Ellis/Goldewijk/Siebert et al. 2010). Deforestation reduces carbon sink capabilities at least in forests where trees do not decay quickly and return their carbon to the atmosphere. The albedo of bare land is very different from that of a tree canopy. Forests' water retention functions also affect other hydrological functions. Clearly terrestrial land cover is key to many ecological matters and it is very hard to aggregate these into any one meaningful global threshold.

That said, humanity is already using much of the most fertile parts of the planet's land surface and we

will need to implement many changes in how land is used if the ecological footprint of agriculture is to be reduced while its efficiency is simultaneously increased to feed a still-growing population (Foley/Ramankutty/ Brauman et al. 2011). Part of the concern about land use change is the question, "Can a threshold for habitat clearance effects on biodiversity be defined on a global scale?" (Brook/Ellis/Perring et al. 2013: 399). The answer would seem to be negative not least because "thresholds are deeply context dependent" and "tipping points might differ between scales" (Brook/Ellis/Perring et al. 2013: 399). Beyond that, it is also worth emphasizing again that, given the diversity of terrestrial land cover, it is unlikely that terrestrial ecosystems will universally respond to a global tipping point crossing some other boundary; they are more likely to react heterogeneously in the event of major disruptions.

2.3.8   Biodiversity Loss

The huge changes to landscapes, including deliberate land clearing as well as inadvertent habitat disruption, in combination with hunting and fishing, has already led to the extinction of many species. The rates of extinction are much greater than the normal background rates of species disappearance in the geological record, suggesting that we are living through the sixth global extinction event in the planet's history (Kolbert 2014). While many species have disappeared, other artificial species, such as farm animals, have expanded greatly. These, however, are dependent on human systems and not a replacement for the diverse species that make up 'natural' ecosystems. The rate of extinction is the key consideration: the alarming pace of extirpation has been driven by most of the other ecological processes in addition to direct human predation on particular species. Given the diversity of species in tropical rainforests, many of them with very limited geographical ranges, forest clearing is an especially damaging human activity in terms of reducing species diversity. Further complicating efforts to stem biodiversity loss, conservationists warn that assuming that these ecosystems have already been radically disrupted may undercut important conservation efforts that can still protect many species, especially in tropical areas less immediately susceptible to climate change playing out more intensely in polar regions (Caro/Darwin/Forrester et al. 2012).

While possible food and pharmaceutical derivatives may be being destroyed, the large concern is that unknown future possibilities for life are being pre-

cluded. In the very long run, the planet will no doubt replenish life forms, but humanity faces an impoverished range of life forms in the centuries ahead. It is important to note that not all species are equally important in ecosystem function: removing "top predators and structurally important species such as corals and kelp, results in disproportionately large impacts on ecosystem dynamics" (Rockström/Steffen/Noone et al. 2009b: 15). As such, while an overall reduction in the rate of extinction by several orders of magnitude is needed to push biodiversity loss to a level within the safe operating space, specific species may have a disproportionate effect on particular ecosystems and their functioning. It consequently becomes clear that managing the global scale must be balanced with micro-scale interventions.

The overall pattern of biodiversity loss in comparison to previous mass extinction events is not clear (Condamine/Rolland/Morlon 2013), even if the trend in particular places due to 'sledgehammer' clearing effects frequently is observable and better understood. This remains the case in the updated version of the planetary boundaries framework where matters of biodiversity loss are nuanced by dealing with them in terms of biosphere integrity, and focusing on functional and genetic diversity in specific biomes (Steffen/ Richardson/Rockström et.al 2015). The lack of clarity about baselines in terms of species numbers and extinction rates remains a measurement problem in terms of the precise location of the boundary even if the trajectory of rapid extinction is clear.

2.3.9   Chemical Pollution

While pesticides were a central driver in the rise of environmentalism in the United States in particular, inspired by Rachel Carson's book *Silent Spring*, other forms of industrial pollution have long been a problem both for ecosystems and as a direct cause of human health issues. Recent smog events in China are reminiscent of the situation in London sixty years earlier when the death of thousands as a result of smog caused by coal fires finally led to comprehensive efforts to reduce smoke. Many of the environmental campaigns of the 1960s and 1970s in the developed world led to technological innovations that removed pollutants from smokestacks and effluent pipes. Ecological modernization provided numerous technical fixes to pollution problems but only rarely led to more fundamental social change. With the rise of globalization, industrial production frequently moves to states with less rigorous regulations, effectively out-

sourcing pollution rather than permanently and directly addressing the problem. Of great concern are the very low-level toxic substances that may have effects on particular species and thus alter whole eco-systems indirectly. These include such substances as endocrine-disrupting chemicals. Where the thresholds on such activities might be is not yet clearly known.

2.3.10   Boundary Priorities

The most immediate concerns are with atmospheric greenhouse gases. Nonetheless, as Rockström and colleagues emphasize, the nine factors identified as safe operating space boundaries interact and intercon-nect in complicated ways. It is worth remembering that chlorofluorocarbons, the most obvious cause of stratospheric ozone depletion, are also powerful green-house gases. The regime to curtail their production is effectively also an agreement to deal with climate change even if it is not designed explicitly to do this! Crossing one boundary may have many serious and unpredictable consequences for others: this simple but difficult point is key to any serious consideration of how to facilitate transitions to sustainability. Sus-tainability usually implies a fairly stable context for humanity but, as the earth system science analyses briefly summarized here suggest, in the present context sustainability of societies has to be considered in terms of the rapidly changing context for humanity and the simple fact that societies have been changing rapidly as rural transformations and urbanization interact.

Viewed as a totality, the planetary boundaries per-spective suggests that humanity has effectively taken its own fate into its hands in terms of the future con-figuration of the planetary system. However, while we have clearly crossed the boundaries in terms of biodi-versity loss, the artificial production of nitrogen in the atmosphere, and climate change, it appears that human action has at least halted the dangerous trend of ozone depletion and limited it to the areas within the high-altitude polar vortex wind systems. Although depletion will remain a problem until at least the mid-dle of the current century, given the existing inventory of ozone depleting substances already released, it is important to remember that the boundary has not been crossed nor does it seem likely that this will hap-pen given the widespread agreement that chlorofluor-ocarbons and related chemicals are too dangerous for more than very limited use. Dealing with this bound-ary has been relatively easy given that the components necessary for a solution were practical and political opposition to agreements was relatively weak. Other

boundaries are much more difficult to deal with, even if it is clear where they might be and how close we are coming to some of the thresholds.

2.4   Planetary Stewardship for a Sustainable Earth?

Implied but rarely spelled out in the discussion of sus-tainable development is the assumption that the plan-etary conditions inherited from the Holocene are essential for future generations to meet their needs. The discussion presupposes that the baseline condi-tion of the planet is one given by the Holocene parameters that facilitated the emergence of human civilization and that the planetary boundaries are effectively guard-rails beyond which humanity should not venture. Sustainable development is about eco-nomic change while effectively maintaining Holocene conditions, ones that are presumably the optimal state for humanity. The extraordinary growth in human numbers and associated increase in economic activity over the last half-century of the great acceleration have been powered by the extraction and combustion of fossil fuels. This process has reversed the long-term ecological pattern of life sequestering carbon from the atmosphere, and effectively made industrial humanity a new geological force in the planetary system. Con-straining the further expansion of these activities and planning to reduce the carbon dioxide levels in the atmosphere to something approaching pre-industrial levels is key to most policies of transition to a sustain-able future. However, the very awkward assumption about this formulation is that it presupposes precisely what current processes of unsustainable development have started to fundamentally change:

> Environmentalist traditions have long called for a halt to human interference in ecology and the Earth system. In the Anthropocene, the anthropogenic biosphere is per-manent, the legacy of our ancestors, and our actions as human systems a force of nature, making the call to avoid human interference with the biosphere irrelevant. The implication is clear; the current and future state of the terrestrial biosphere is up to us, and will be deter-mined by human systems of one form or another, whether it is the momentum of our past or new path-ways we are able to achieve in the future (Ellis 2011: 1027).

It is abundantly clear that decisions about human eco-nomic activities are now central to constructing the future of the planet and instrumental in determining whether key boundaries will be crossed. Preventing these transgressions while simultaneously working

back to levels within the boundaries in terms of nitrogen and climate change, as well as drastically reducing the rate of loss of biodiversity, is key to any transition to a human condition that lives within the safe operating space. The alternative requires a transition to a very different configuration of the biosphere, one impossible to predict precisely but, given the phase shifts already looming, one very different from the conditions that have given rise to human civilization. The implicit assumption in juxtaposing transitions and a peace that can be sustained is that ecological changes will not be so drastic or so quick that major powers resort to military force in attempts to control the human consequences of the disruptions.

In Steffen, Persson, Deutsch et al.'s (2011) terms, the next phase of the Anthropocene requires planetary stewardship, a complex matter of global governance that will require numerous social innovations if the earth is to be kept within a safe operating space loosely analogous to Holocene conditions. While production of chlorofluorocarbons and other ozone-depleting substances has largely ceased due to international cooperation, this has occurred despite a remarkable amount of foot-dragging on the part of specific sectors of some economies, notably strawberry producers in California, reluctant to give up their particular mode of soil sterilization (Gareau 2013). The larger lesson of this case is the necessity of thinking in terms of how humanity produces things, and how these processes are governed. Phasing out the use of ozone-depleting substances emphasizes that merely regulating the use of substances is not enough for at least some of the planetary boundaries; prohibition of certain activities may be required, and that, in turn, is a matter of global governance where industrial corporations as well as state governments must be involved in determining production priorities.

Looking further ahead, it is clear that decisions about such things as the continued production of coal-powered electricity generation stations are matters of industrial policy that have global consequences. If climate boundaries are not to be yet further transcended, then thinking in terms of the political economy of energy systems is essential to future planetary governance. But this is more than a matter of governments regulating some detrimental environmental consequences of economic activity; it is about production decisions and, quite literally, *who* decides *what* gets made. While there is a wide diversity of economic decision-making authorities currently operating, the neo-liberal modes of letting markets make such decisions seem unlikely to constrain the use of fossil fuels

quickly enough to begin reducing carbon dioxide emissions any time soon, even if they do focus attention on how markets might work as governance mechanisms (Newell/ Paterson 2010). The climate boundary has been breached and the larger patterns of the great acceleration suggest that this trajectory is not likely to change quickly despite repeated, although as yet limited, efforts to restrict emissions under the *United Nations Framework Convention on Climate Change* (UNFCCC).

This has in turn raised the question of geoengineering, attempting to artificially manipulate the global climate to at least temporarily mask the effects of elevated levels of greenhouse gases (Hamilton 2013). However, as the discussion of the other planetary boundaries emphasizes, dealing with just one facet of boundary crossing, such as the failure to cope with rapidly rising greenhouse gases, needs to take into consideration other facets of the earth system. As one of the leading proponents of experimenting with climate engineering technologies is keen to emphasize, while artificial sulphate aerosol use may be feasible as a method of "solar radiation management", it will not address the major issue of ocean acidification—hence, reducing emissions of carbon dioxide must remain the priority for global environmental politics (Keith 2013).

The implications of such considerations are profound. While arguments for a transition to a sustainable future suggest that rapidly reducing the disruptions to the natural arrangements that humanity has known since the end of the last ice age approximately ten millennia ago are essential, it is no longer the case that this future will occur in the given circumstances implied by the invocation of physical sustainability. The assumption built into environmental concerns through the discussion of the limits to growth in the 1970s, the 1980s discussions of sustainable development, and subsequently through the initial formulations of the UNFCCC in the 1990s is that the planet ought to be kept in more or less the configuration that has so far nurtured civilization. This is implied in the formulation of 'physical sustainability' in *Our Common Future*, and spelled out clearly in the formulation of avoiding dangerous human interference with the climate system that is the key operant phrase in the UNFCCC.

But all this is very new in human affairs. "At the first major global environmental governance conference—the 1972 Stockholm Conference on the Human Environment—none of the major earth system challenges that we discuss today was on the agenda. And

this was merely forty years ago. Hardly anybody talked then about ozone depletion, climate change, desertification, or the mass extinction of species" (Biermann 2012: 9). Given these novel circumstances, it is hardly surprising that humanity does not have institutions, much less governance structures, to effectively deal with such issues. However, as other chapters in this book suggest, such structures are now urgently necessary, and need to be formulated so that warfare is precluded as an adaptive mechanism, both because it will make other adaptations more difficult and, in the event of major weapon use, add yet further unpredictable perturbations to the earth system. In the words of the German Advisory Committee on Climate Change, a United Nations 2.0 is needed, a new structure whose purpose "... would be to take the planetary guard rails into account as a guiding principle that governs all UN actions, the pursuit of which would guarantee the protection of climate and environment in order to stabilize the Earth system as much as peace, security and development" (WGBU 2011: 316). While this remains an aspiration, the speed of current ecological changes make thinking about new habits of cooperation to deal with coming transformations a crucial part of any transition strategy.

2.5 Sustainable Transitions in a Rapidly Changing Future

Most of the ideas about mitigating climate change, the predominant emphasis in climate discussions until relatively recently, epitomized by the UNFCCC, have either implicitly or explicitly assumed that the Holocene condition is the optimal biospheric arrangement for humanity. Given the patterns of agricultural activity at the moment, taking advantage of most of the temperate humid biomes to grow crops using petroleum-powered industrial production systems is not surprising, but it is important to note that the assumption that this is how the social organization of food production ought to be, or that extensive monocultures of grain are the only way to feed humanity in the long run, are simply that: assumptions. If these systems are not optimal, then perhaps other ecological possibilities open up and new ways of feeding, fuelling, and housing humanity may be possible. Thinking in these terms makes it clear that sustainable development strategies need to operate in ways that do not foreclose such possibilities for future generations; a flexible interpretation of future needs is a crucial component of such policies.

Many of the ecological ideas that structure thinking about environmental strategies also presume some form of stability, or at least a notion of homoeostasis as the desirable state toward which policy should direct human activity. The last generation of ecological management thinking has drawn heavily on notions of resilience, as well as the frameworks of panarchy and non-linear changes (Gunderson/Holling 2001). Earlier assumptions of stable ecosystems and ecological transitions back to a climax condition following disruptions have not been entirely abandoned, but ecological thinking is now clearly much more complicated than visions built upon simplistic assumptions of a stable nature disrupted by human economic activity. Even in arguments about resilience, however, it is clear that the assumptions of stability are integral to subsequent 'bounce back' strategies after a major disruption. Policies using such thinking usually postulate a given relatively stable situation which, after facing disruption, can return to more or less the situation prior to the disruption.

However, as the growing awareness of the sheer scale of the human transformation of the biosphere becomes clear and the failure of humanity to curb the use of fossil fuels in particular ensures at least some climate change is inevitable, policy is frequently turning to questions of how to adapt to these new circumstances. In Bangladesh, where poor people are especially vulnerable to flooding and storms moving up from the Bay of Bengal, adaptation is the order of the day. Flood shelters and rebuilding coastal mangrove forests are necessary tools for dealing with rising sea levels and inundations. In such states there is limited choice in terms of policy; they have done little to cause climate change and can do little to change the global energy mix that is accelerating the process. What sustainability and the transition to it might mean in such changing circumstances suggests that the most important aspect of sustainability is the flexibility to adapt to new circumstances as they arise. How to make social systems that can change quickly without disruptions, social breakdown, or the use of organized coercion is not easy but it is key to any serious attempt to link peace with sustainability.

The clear implication to be drawn from earth system science is that such questions are in need of immediate scholarly attention. "These are admittedly huge tasks, but are vital if the goal of science and society is to steer the biosphere towards conditions we desire, rather than those that are thrust upon us unwittingly" (Barnosky/Hadly/Bascompte et al. 2012: 57). Sustainable development implies that economic

transitions to modes of industrial activity that do not exceed the parameters of the conditions inherited from the Holocene are key to maintaining a relatively stable biosphere, the *sine qua non* for future generations being able to supply their own needs.

But if some of those key parameters have already been exceeded, as the discussion of planetary boundaries suggests, then what kind of transition is needed to peacefully move to what kind of future must be much more carefully deliberated. Nature can no longer be taken for granted as some sort of given context for humanity; the Anthropocene discussion makes it clear that the future of humanity and whether that future is peaceful or not depends on much more than traditional discussions of the causes of war. Now humanity it shaping its context in novel ways, and that too has to be a key part of any discussion of transitions to new modes of economy and life.

2.6 Implications for Contextualizing Sustainable Peace

Focusing on the insights of earth system science and the clear understanding that humanity is shaping the future in ways that are much more profound than has been understood until very recently requires that social scientists and policymakers interested in thinking through both strategies of sustainable development and peaceful modes of transition to more ecologically benign economic modes of human life now have to incorporate at least four key themes in their work. These are: a notion of security very different from cold war versions; a recognition that geopolitical contexts are changing; a perspective on political geoecology; and, crucially, a focus on economic production rather than just on environmental protection as key to the next phase of the Anthropocene.

2.6.1 Beyond National Security

We are currently on track for a much warmer world, one where ecological disruptions are inevitable (Anderson/Bows 2011). The potential for human conflict caused by these disruptions to undo the economic progress and improvements in human welfare made in recent generations is a key part of the logic of sustainable development spelled out in *Our Common Future*. Indeed, this is the logic that underpins the whole discussion of environmental security even if the empirical evidence on the small scale repeatedly suggests that environmental change does not directly

cause violence (Theisen/Holtermann/Buhaug 2011; O'Loughlin/Witmer/Linke et al. 2012). But larger-scale ecological phase shifts might present the world system with much greater disruptions than small-scale rural displacements and agricultural failure in specific regions. Transitions to sustainability that focus on the complexity of social change in particular parts of the world are important, but how particular places play a part in shaping the overall configuration of the future matters greatly (Grin/Rotmans/Schot 2010). Planning for these in advance rather than relying on force to try to deal with some of the disruptions is now key; it requires a move towards policies for global human security.

Nonetheless, much of the recent literature that links climate change to security persists with traditional American formulations wherein instabilities in distant parts of the world are understood as potential threats, whether through terrorism or violence spilling over from conflict zones. More specifically, climate change has been formulated as a threat enhancer or 'multiplier' implying that related policies are essential in preventing future conflicts (CNA 2007; Campbell/Gulledge/McNeill et al. 2007; UN 2009). The necessity of dealing with climate change is specified as key in these formulations but what is threatening in terms of security is defined in terms of political instabilities in peripheral areas, not the disruptions caused by the global economy. Recent attempts to think through the practicalities of environmental insecurity by focusing on water and climate change suggest that structural inequalities in the global economy and political discrimination are more important immediate drivers of conflict if not interstate war (Zografos/Goulden/Kallis 2014). This key finding links back to the initial WCED (1987) formulations of sustainable development that insist that matters of equity are key to sustainable development that is peaceful.

More recently, as numerous institutions and governments start to come to terms with the fact that some climate change is inevitable, policy questions about how to adapt to changing circumstances are coming to the fore (Dalby 2013b). But now adaptations themselves are causing further environmental transformations. States are buying or leasing land in other states to ensure supplies of food in future, leading to further displacements of peoples to make way for plantations and commercial farming arrangements. These trends add to land use transformations and, in some cases, chemical pollution that put stress on existing ecosystems. Extending the modern agricultural development model that has already caused

dramatic disruptions to many ecosystems may just accelerate environmental change; these systems need innovations as part of a larger effort to rethink global governance in terms of planetary boundaries (Galaz/Biermann/Crona et al. 2011). Such policies have 'backdraught' effects that need to be considered in terms of unanticipated consequences of trying to deal with climate change while ignoring other aspects of environmental change (Dabelko/Herzer/Null et al. 2013). Attempts to adapt to climate change have consequences in terms of how landscapes are remade: such changes need to be thought of in those terms if earth system analysis is to be worked into policy considerations.

2.6.2   Changing Geopolitical Contexts

This has international repercussions in terms of trade and the international flows of investment that shape how one state impacts another's ecology. All of this emphasizes decisions about what is being made, and how, rather than discussions of protecting an environment that has already been transformed many times over: this is the context for twenty-first century geopolitics. A further extension of this point is that the geopolitical rivalries of the present are frequently being played out in the arcane details of trade negotiations (Wang/Gu/Li 2012). Who will write the rules on technological standards related to new generations of energy technologies now matters, and here the mostly neglected dimension of geopolitics in discussions of sustainable transitions needs to be engaged directly (Markand/Raven/Truffer 2012). How what gets produced in future will also quite literally shape the planetary ecology of the future.

Understanding that geopolitics is no longer a simple matter of military rivalry but a matter of shaping the technological future to the short-term advantage of the rule-writers—with long term implications for how the biosphere is shaped—is crucial to linking earth system thinking to matters of geopolitics. This becomes even more important where discussions of possible geoengineering experiments enter the discussion (Galaz 2012; Luke 2010; Humphreys 2011) as a contribution to attempts to keep the planet's climate within a safe operating space. The related point is that environmental changes have already transformed the terrain of great power rivalry; nineteenth-century assumptions about the given context of politics are no longer tenable premises for serious political discussion (Hommel/Murphy 2013).

2.6.3   The Perspective of Political Geoecology

Thinking about the point that nature is no longer the given context for humanity in terms of international peace and security requires a very different approach from that of traditional geopolitics, with its attendant focus on territorial states and their rivalries as key to war and peace. Thinking in terms of a 'political geoecology' of human actions at the global scale shaping the future global context, rather than taking it for granted, is now key to any notion of a sustainable peace if serious consideration is to be given to ensuring that climate and other ecological disruptions do not trigger violent policy responses (Brauch/Dalby/Oswald Spring 2011). A geopolitical imagination of competing territorial states as what is most important in human affairs is simply out of date as the premise for either policy prescription or academic analysis. While states may still write many of the rules for international trade, and as such are still a key institution in shaping the future, understanding geopolitics in these terms is now much more important than traditional discussions of elite military rivalries and struggles to dominate the planet.

While technical details of trade arrangements may be important in the shaping of the future, so too are the cities and towns in which the majority of us now live. The Anthropocene has also been about the urbanization of humanity and the construction of increasingly large artificial environments of concrete and asphalt. The commodities and resources that are extracted often at great distance in rural hinterlands supply these consumption spaces, spaces that also function as centres of political innovation in many ways (Magnusson 2011). How cities are rebuilt and governed to simultaneously reduce their carbon footprint and make them less vulnerable to extreme events will matter greatly in coming decades. But as Naomi Klein (2014) has ruefully noted, thinking about practical ways to green cities and building sensible public transit systems, communal green spaces, and local food systems has not been a priority among many political movements. If members of such movements and communities were thinking seriously about the artificial landscapes of the present, these considerations should certainly be prioritized.

Even more important is to think about how suburban sprawl, which is so dependent on automobiles and uses large amounts of energy very inefficiently, can be reworked with ecological principles in mind. Likewise, informal solutions to the huge challenges of urbanization in the global South that take ecological

issues seriously also present possibilities for adaptation that improve the lot of residents of the new cities there (Robertson 2012). All of this urbanization is dependent on the integration of the global economy which is in turn shaping the life chances of people in the new cities of our time, and hence producing new geopolitical circumstances that make old imperial struggles to gain colonies or zero sum games to directly control agricultural territories increasingly anachronistic. Struggles over economic activity are now shaping national policies as well as city strategies; the task for a political geoecology is think through these interconnections as they shape the increasingly artificial habitats of the future.

2.6.4 Producing the Anthropocene

Thinking in these terms makes it clear that production—quite literally *what* humanity is making—is a key consideration in understanding and constructing our future; getting that clearly in focus is integral to a sustainable transition (Harris 2012). The Anthropocene will be shaped by decisions taken both by community planners and executives in boardrooms who decide which commodities will be made and how they will be produced. It makes a big difference if new electrical systems are powered by solar panels or coal-burning power stations. If automobile manufacturers stop making gasoline-powered cars in favour of other propulsion systems, this too will have all sorts of ramifications for climate and other ecological changes. Global cooperation on such matters is a key component for transitions to sustainability.

In part, this point also relates to where they are produced. Territorial strategies to 'green' some societies by outsourcing the production of energy- and pollution-intensive industries to less regulated societies, an accusation frequently levelled at European states,

do not solve problems when viewed in earth system terms. Authority over ecological processes necessitates deeper action than state territorial strategies of rule, especially when territorial arrangements for such policies as emissions trading quotas and ecological offsets are involved. Outsourcing pollution may satisfy some limited state-based counting methods, but it is not an ecologically sensible strategy if more than short term geographically-specific spaces are considered. This new geography of connection in the increasingly globalized economy, and the possibilities of commodity chain governance also suggest that the traditional assumptions of state-based national security are insufficient frameworks for governance in the next phase of the Anthropocene.

All of which becomes ever more pressingly urgent if the earth system discussion is engaged precisely because assumptions of a stable ecological context for humanity can no longer be taken for granted. Peace is a condition to be struggled for but the struggle will be carried out in future in ecological and social conditions that are rapidly changing. Any strategy of transition from present consumption-based extractive modes of economy to ones that can be sustained in the long run have to recognize that this transition will happen against the backdrop of dramatic ecological change. Strategies that link development and sustainability now have to factor in the possibilities of ecological phase shifts if the earth system boundaries are further transgressed in the next few decades. This makes planning more difficult, but also emphasizes the fact that humanity is making the future of the planetary system as well as its own economic and social future. They are but two sides of the same coin, a matter requiring a transition to new ways of thinking about economics and politics if peaceful human societies are to be created as the next phase of the Anthropocene.

3   Paradigm and Praxis Shifts: Transitions to Sustainable Environmental and Sustainable Peace Praxis

Carolyn M. Stephenson[1]

Abstract

The diffusion of both paradigms of sustainable environmental practice and sustainable peace practice has quickened in the last thirty to forty years, but has occurred unevenly across time and space, across regions, and even within individual countries and subregions of countries. Some disciplines have been more hospitable to one or the other. In large part, until recently, environmental studies has not found peace issues relevant, nor peace studies environmental issues. The beginning of the coming together of these paradigms and their practice is a significant change. This chapter examines the evolution of the separate paradigms of sustainable environment and sustainable peace, and their gradual but as yet incomplete engagement with each other. It also examines texts at the level of global governance, particularly at the United Nations, with respect to the same issues, asking how and why UN and other documents and conceptualizations in the 1970s have increasingly begun to reflect the linkages between these issues.

Keywords: Environmental security, human security, international environmental studies, peace studies, spaceship earth, stable peace, sustainable development, sustainable peace.

3.1   Transitions in Paradigms and Praxis

While there has developed a somewhat technical literature in transitions, especially sustainability transitions, this paper relies on the ordinary everyday meaning of the term, in the belief that it may be useful to speak political and social science in a way that can be comprehended by ordinary people, especially if one is trying to change paradigms and praxis of the general population. Since much of the work on sustainability transitions has focused especially on environmental sustainability, this work will place more emphasis on the development of work on sustainable peace, and on the development of peace studies as a field, as well as on the interrelationships between peace studies and environmental studies.

In 1949 Aldo Leopold published, posthumously, *A Sand County Almanac* and, within it, "The Land Ethic". He argued that ethics has extended, in "a process of ecological evolution", from relations between individuals to the relation between the individual and society, and that this needs to expand to a societal ethic on "man's relation to land" (202–3). "All ethics so far evolved rest upon a single premise: that the individual is a member of a community of interdependent parts"(203). "The land ethic simply enlarges the boundaries of the community to include soils, waters, plants, and animals, or collectively: the land" (204). Leopold was both a game manager and an advisor on conservation to the United Nations. This extension of ethics can be observed in the fields of both peace studies and environmental studies, but it is not yet complete in either. The linkage of paradigm to praxis was evident in Leopold's life and work and there are attempts, in both peace and environmental studies, to make such linkages and to enlarge the size of the community. Yet there is no real epistemic community that includes scholars in both peace studies and environmental studies, even within the social sciences. There are primarily different journals, different organizations or sections of organizations, different schools. Linkage of concerns over international

1   Prof. Dr. Carolyn M. Stephenson, Associate Professor of Political Science at the University of Hawaii at Manoa and affiliate faculty member in its Matsunaga Institute for Peace; Email: <cstephen@hawaii.edu>.

peace and security with concerns over sustainable environment and development is an important step in linkages between paradigms and praxis in both these fields. The development of a paradigm inclusive of the concerns of both fields could well improve praxis as well.

This chapter examines the early historical development of the fields of international environmental studies and peace studies, including both conceptual and institutional changes.[2] It looks first at the academic fields of international environmental studies and the various conceptual waves of peace studies, and then the beginnings of convergence of the fields, especially as exemplified by Kenneth Boulding. It then looks at global governance contributions to sustainable environment and sustainable peace, incorporating in particular work on the Culture of Peace, the Nobel Peace Prize, the evolution of concepts of security, and the Millennium and Sustainable Development Goals, concluding that the convergence has progressed but remains incomplete.

3.2   Sustainable Environment and Environmental Studies

Environmental studies as a field of social science research really had its beginnings in the 1960s, and began to emerge in earnest in the 1970s. Early emphases included simply recognition of the physical and

2   *Editor's comment*: There is a rich literature that covers the more recent scientific discussion on environmental studies and peace research and their emerging linkages, including environmental peacemaking (Conca/Dabelko 2002) and peace ecology (Amster 2014; Oswald Spring/Brauch/Tidball 2014; Brauch/Oswald Spring/Bennett et al. 2016); see e.g. the previous reviews of the state of the scientific debate in previous volumes of this Hexagon Book Series on *Human and Environmental Security and Peace* (HESP) that may be easily accessed at: <http://www.afes-press-books.de/html/hexagon.htm>; see also the three volumes of the *Ecology and Peace Commission* (EPC) of IPRA in the *SpringerBriefs on Environment, Security, Development and Peace* (ESDP), at: <http://www.afes-press-books.de/html/SpringerBriefs_ESDP.htm>. Older texts by pioneers of peace and ecology studies are also included in the *SpringerBriefs on Pioneers in Science and Practice* (PSP); at: <http://www.afes-press-books.de/html/SpringerBriefs_PSP.htm>. The websites on the books in these three book series offer references and links to the state of the global scientific discussion on these linkages. See also many recent references in chapters 1-2, 6-9 and in the concluding chapter of this book.

biological environment as part of the environment of international politics, as well as concerns over the harm being done by humans to the environment, the dangers of increases in world population, notions of resource scarcity and the limits to growth, and the idea of the environment as a commons. Harold and Margaret Sprout brought considerations of the environment into the study of international relations in their 1962 textbook *Foundations of International Politics*. That their work was regarded as pivotal by the international studies community was confirmed by the naming of the International Studies Association's Environmental Studies Section annual book award in their name. The year 1962 also saw the publication of Rachel Carson's *Silent Spring*, which warned of the dangers of pesticide pollution, and awoke an environmental movement against DDT.

Garrett Hardin's essay on the "Tragedy of the Commons", in the December 1968 issue of *Science,* was a part both of the emerging literature on the dangers of world population growth to the environment and the emerging approach of looking at the world as a commons. Paul and Anne Ehrlich's works on population stressed and popularized the dangers of population growth, characterizing it as *The Population Bomb* (Ehrlich 1968; Ehrlich/Ehrlich 1970). While Ehrlich's use of the word "bomb" was clearly related to the dangers of nuclear proliferation that were beginning to be recognized in that period leading up to the development of the 1970 Nuclear Non-Proliferation Treaty, his analogy to the enormity of the nuclear bomb did not carry through to an analysis of the linkages between population and war. Hardin's approach to the "tragedy of the commons" was controversial, as he advocated "mutual coercion mutually agreed upon" to curb population growth. But his reconceptualization of the commons as an area of joint decision-making as related to population and the environment led to a burgeoning literature on common property resource regimes, much of it in disagreement with his original thesis. Elinor Ostrom's 1990 work *Governing the Commons* argued against Hardin's logic of the necessity of coercion and for the possibility of cooperative action in governing fisheries and other common property resource regimes. Her work was awarded the Nobel Prize in Economic Science in 2009.

The series of books that began with the Club of Rome reports on the limits to growth also included population as a limiting factor (see chapter by Slovaag Marino in this volume), but added into their MIT-based computer modelling the factors of resources,

food output per capita, industrial output per capita, and pollution, stressing the interlinkages between these factors and subcategories of each of the factors.

Donella and Dennis Meadows, Jorgen Randers and William Behrens's 1972 *The Limits to Growth* models stressed the dangers that would be likely to result from the interactions of these factors. War, however, was not one of the factors considered. While there was praise for the systematic global modelling in the book, there was scepticism about the conclusions. The book, however, did inform the analysis at the UN's 1972 Stockholm Conference on the Human Environment, which helped to put the issue of environment on the global agenda. Mesarovic and Pestel's 1974 *Mankind at the Turning Point,* the second report to the Club of Rome, carried further the analysis on limits to growth by disaggregating the world into ten regions with very different streams of development. When Meadows and Randers in 1992, at the time of the Rio "Earth Summit", the UN Conference on Environment and Development, updated their findings in the new book, *Beyond the Limits,* they were able to answer their critics with a resounding clarity that in fact, things were in fact worse than they had originally stated (see chapter 16 by Marino in this vol.).

Kenneth Boulding, economist and peace researcher, was also an early pioneer in thinking about global environmental limits. In his 1966 article "The Economics of the Coming Spaceship Earth", he argued that we needed to proceed from the paradigm of unlimited resources in a "cowboy economy" to a paradigm recognizing that the earth has more the limits of a spaceship. In his 1968 book *Ecodynamics*, he advocated a systems approach to the environment. Among the limits Boulding saw, however, were not only population but also rising inequality.

Several other books were significant in advancing the focus on resource scarcity, William Ophuls, in his 1977 *Ecology and the Politics of Scarcity: Prologue to a Theory of the Steady-State*, argued that "man and nature" were "on a collision course", and that industrial man was rapidly exceeding the earth's carrying capacity. He argued that our thinking needed to be changed toward a theory of the steady-state economy either by teaching or by coercion, i.e. the development of law. Ophuls also argued for the necessity of a new paradigm. This emphasis on changing the patterns of consumption was later followed up by the work of Princen (2005).

Another influential work was E. F. Schumacher's *Small is Beautiful: Economics as if People Mattered*, first published at the time of the oil/energy crisis in 1973. Schumacher argued that the dehumanization of the economic system, as it grew larger and larger, would harm the provision of human needs, and that the furtherance of economic growth was not the be-all and end-all of politics. In the face of the expansion of what would become the *European Union* (EU), he argued that local production might put economic control back into the hands of people. He argued the importance, not so much of the tenet "small is beautiful", but of the need for things to be done at the level appropriate to that activity, some small, some medium, some large. His emphasis on subsidiarity, that things should be done at the lowest level at which they could, ultimately became a principle that was adopted—albeit not quite in the same sense as Schumacher conceptualized it—by the EU, where it is currently interpreted in different ways by different countries, with the UK holding that this means that the EU itself should not take on what states can do, and Germany going further, holding that this principle goes even further down, and that sometimes this means that sub-units of states should hold primary responsibility.

If one looks at the development of education in environmental studies, one can go back to the development of what were originally schools of forestry. The New York State College of Forestry was founded at Cornell in 1898, the Yale Forest School in 1900, and the SUNY College of Environmental Science and Forestry at Syracuse in 1911. But the original emphasis did not fit so much with Leopold's land ethic; this was forestry for human consumption, not forestry for the sake of forests. It was only with the rise of environmental concerns in the early 1970s that educational institutions focusing on the broader issues of environment were formed. Among the most significant were the School of Public and International Affairs at Indiana, under the influence of Lynton Caldwell, and the renamed Yale School of Forestry and Environmental Studies, both created in 1972.

Also very early on, many of the international organizations which remain significant in environmental issues were formed, before many of the peace organizations we will examine below. The *International Council of Scientific Unions* (ICSU), now the International Council for Science, was created in 1931. The *International Union for the Conservation of Nature* (IUCN) was formed in 1948. The Environmental Studies Group was formed within the International Studies Association (ISA) in 1974, but there was little overlap between either the initial or the present membership of that and the Peace Studies Section of ISA.

Intellectually, one could go back even further to the work of Thomas Malthus, whose 1798 *Essay on the Principle of Population* began the emphasis on the problem of population growth that was later continued by Hardin, Ehrlich and others mentioned above. Malthus argued that there are different ratios for the increase of population and food, with population growing in a geometric ratio and food an arithmetic ratio, that thus population will exceed the food supply, also that the checks on human population, primarily the food supply and famine, epidemic disease, and war, do not have much effect on the size of populations. Interestingly enough, he does raise some of the questions of inequality, including the inequality of women and men, that later came to concern peace studies and to be significant in understanding the relationships between gender, population, development and peace. Again, however, Malthus was concerned with the social system, not with the environment for environment's sake.

3.3 Sustainable Peace and Peace Studies

The origins of peace research could be judged to be as far back as Thomas Hobbes's *Leviathan* (1651) or even Plato or Thucydides. Hobbes's characterization of war as originating from the combination of the greed and equality of human beings, with the solution being a social contract dependent on the creation of authoritative institutions, has been a thread in both realist and idealist strands of peace research ever since. The Lockean claim of the right of revolution against the tyranny of authoritarian institutions has been a second important strand. Yet the origins of peace research as a separate field of inquiry are probably better traced only within the twentieth century. Elsewhere this author (Stephenson 2008) has argued that there have been three primary waves of peace studies worldwide since its beginnings between the world wars, a) a first wave consisting of research on the causes of war and conditions of peace; b) a second wave on peace education and critical peace research; and c) a third wave dealing with the institutionalization of peace research and education, with those waves intermingling with each other and with waves from other related fields in the period after the end of the cold war and 9/11.[3]

In what might be called the first wave of peace studies, which ran roughly 1945 to the late 1960s, the quantitative study of war was the primary focus. The work of US political scientist Quincy Wright and UK (Quaker) physicist Lewis Richardson looked at the causes of war over the long term, with Richardson in particular finding that homogeneity among states did not preclude arms races and war. Together with the socio-cultural theories of Pitrim Sorokin, these works revolutionized the emerging field of international relations. Peace research institutes were first established in this period, among them the *Institut Français de Polémologie* (1945), the Center for Conflict Research and David Singer's *Correlates of War Project* at the University of Michigan (1957), the *Peace Research Institute Oslo* (PRIO, originally 1957, independent in 1966), and the *Stockholm International Peace Research Institute* (SIPRI, 1966). Significant journals included the *Journal of Conflict Resolution* (1957) and the *Journal of Peace Research* (1964). Organizations included the 1959 *Lancaster Peace Research Centre/ Richardson Institute*, the 1963 *Conference* (now *Council*) on *Peace Research in History*, and the 1964 *International Peace Research Association* (IPRA).

The second wave of peace studies, roughly 1970 to the late 1980s, focused primarily on the development of peace education in the US and on critical peace research in Europe. The first undergraduate peace studies programme in the US, at Manchester College, established in 1948, was joined by many others, including the first chair in peace studies at Colgate in 1971, along with the first chair in the UK at Bradford in 1973. Uppsala (Sweden) began the *Department of Peace and Conflict Research* in 1971. Other research institutes were founded: the *Tampere Peace Research Institute* (TAPRI, in Finland) in 1970, and the Peace Research Institute Frankfort, also 1970, as the first of the German peace research institutes. In 1970 IPRA added its *Peace Education Commission* (PEC). Regional organizations were formed: the *Canadian Peace Research and Education Association* (CPREA) in 1966, the *Consortium on Peace Research, Education and Development* (COPRED) in the US in 1970 (which became the Peace and Justice Studies Association in 2001), and the *Asian Peace Research Association* (later the *Asia-Pacific Peace Research Association*, or APPRA) in 1974; the First *Latin American Conference on International Relations and Peace*

---

3   A fuller version of this argument can be found in Stephenson (2008: 1534–1548). This chapter is available for download at: <http://www.sciencedirect.com/science/article/pii/B9780123739858001306>. For a conceptual overview of the evolution of peace studies, see also Stephenson (2010: 5579-5603).

Research was held in 1994 (CLAIP). Surprisingly, Europe, although a center of peace research, did not form a regional organization until the late 1980s. The *European Peace Research Association* (EUPRA) began in 1988, and held its first conference in 1991. The *African Peace Research and Education Association* began in 2000. Critical peace research began especially at the Peace Research Institute Oslo, where Johan Galtung was then located, and where he put forth the ideas that peace was more than the absence of war and direct violence, and included the presence of social justice, or the absence of structural violence (1969, 1971). He termed these two kinds of peace 'negative' and 'positive peace', terms that had been used earlier by Martin Luther King in much the same way. Galtung's conceptualization of peace revolutionized the field. It was criticized especially by Kenneth Boulding (1977), who argued that while justice was essential for peace, conceptual clarity required that one not be defined in terms of the other.

The third wave of peace studies, roughly during the 1980s, saw considerable institutionalization of peace studies at the national and international levels, especially in government funded institutes. These included: the *University for Peace* (UPEACE, whose establishment was approved by UN General Assembly Resolution 35/55 of 5 December 1980) in Costa Rica, the *Canadian Institute for Peace and International Security* (1984-1992), the *Peace Research Centre at Australian National University* (1984-1994), the *US Institute of Peace* (1984), the *Copenhagen Peace Research Institute* (1985-2005), and the *Scientific Research Council on Peace and Development* in the USSR (1979). New journals included *Negotiation Journal* (1985), *Peace Review* (1989), and *Security Dialogue* (1992, renamed from the earlier *Bulletin of Peace Proposals*). While the instigation for much of this was expanded peace activism, especially the anti-nuclear movements that developed in the early 1980s, some of the field narrowed a bit to focus on nuclear war and international security.

At the same time, peace studies also began to focus not only on the causes of war and conditions of peace, as well as on structural violence, but also on peaceful processes that might serve as alternatives to war. Two important fields that could be seen either as subfields of peace studies or as intersecting with it were conflict resolution and nonviolent action. Conflict resolution practice emerged primarily in the domestic and local arena, but was later reinvigorated by the work on peacemaking, peacekeeping and peacebuilding that came with the UNs *Agenda for Peace* in 1992. The

Hewlett Foundation in the US was instrumental in advancing research on both the theory and practice of conflict resolution, first funding the *Program on Negotiation* at Harvard (1983) and then many other universities from 1984 to 2004. Fisher and Ury's book *Getting to Yes* and the many sequels established principled negotiation as a key approach to conflict resolution. The Institute for *Conflict Analysis and Resolution* at George Mason University established the first M.S. in conflict resolution in 1982, later expanding to a Ph.D. as well, while the *Kroc Institute* at Notre Dame, begun in 1986, focused its M.A. in peace studies more broadly. The study of nonviolent action, which had received its initial energy from Gene Sharp's landmark three-volume *Politics of Nonviolent Action* (1973) and his *Program on Nonviolent Sanctions in Conflict and Defense* at Harvard (to 2005), received new energy from the creation of the *Einstein Institution* in 1983. The field of nonviolence studies continued to expand with the PBS TV series and book by Ackerman and DuVall on *A Force More Powerful* (2001) and their foundation of the *International Center on Nonviolent Conflict* (ICNC) in 2002. Most recently, the award-winning *Why Civil Resistance Works* (2011) by Chenoweth and Stephan has further deepened research in this area, as has the Roberts and Ash book *Civil Resistance and Power Politics* (2011), the result of an important conference at Oxford that linked theory and case studies in many regions of the world. However, although there were social movements using nonviolent action to deal with environmental conflicts, such as the Chipko movement in India, the anti-dam movement, and the rubber tappers in Brazil, the use of nonviolent action for environmental goals was not highlighted by most researchers focusing on nonviolent action. Other peace researchers focused on integrating these various sets of methods in the hope of leading toward a system that would provide alternatives to war. One of the first conferences attempting to integrate alternative methods for international security was COPRED's 1979 annual meeting, which resulted in an edited book (Stephenson, 1982).

What might either be characterized as a fourth wave of peace studies, or as a spreading out and commingling of earlier waves, occurred in the aftermath of the bombings of the World Trade Center in New York City and the Pentagon in Washington DC on 11 September 2001. The consolidation of US power that had occurred especially in the decade after the end of the cold war had challenged all of the fields concerned with the international system.

While many who study or comment on international relations argue that the world changed after both the end of the Cold War and 9/11, most of those in the field of peace studies see the same fundamental issues and structures continuing to challenge us. Ethical issues around peace, power, violence and justice came to the forefront of the field again. The democratic peace hypothesis that began with Kant's work received new attention. International law and organization were studied both as conservative structures which promote and maintain the interests of the powerful, and as liberating structures which promote human rights, justice, peace and a clean environment. The role of sanctions and of other various forms of intervention in the prevention of genocide, war crimes and crimes against humanity and the promotion of human rights were debated and researched. Additional attention went to the role of smart, focused sanctions, and to the role of post-conflict transitional justice mechanisms, with debates over the relative effectiveness of punishment mechanisms like the International Criminal Court versus reconciliation mechanisms like South Africa's Truth and Reconciliation Commission. The reconceptualization of security begun by feminists and alternative security researchers in the 1970s, and taken up by more conventional political elites during the 1980s, expanded to bring the concept of human security into centre focus following UNDP's *Human Development Report* (HDR 1994), the *Report of the Commission on Human Security* (CHS 2003) and the *Human Security Report* (2005).

A development strain has always linked peace studies to international relations. With the development of peacebuilding as a major subfield in conflict resolution, examination of the linkages between war and violent conflict, development, justice issues, and various forms of intervention has become a central focus of study linking all three fields, as well as linking them to security studies. Two new peacebuilding journals, the *Journal of Peacebuilding and Development* in 2002 and *Peacebuilding* in 2013, emerged. This has long been a focus at Bradford, perhaps the premier peace studies programme. In contrast, however, the linkages between environment, development, and conflict, while studied intensively in certain parts of the field of peace studies, for example at PRIO, have not been central to the field.

3.4 Beginnings of Convergence in Sustainable Environment and Sustainable Peace

Choucri and North (1972) argued that the emphasis on the study of crises in international relations needed to be supplemented with the study of the dynamics of competition and conflict in the longer run. This included the study of the impact of population growth, technology and resources. They argued that it was important for a policymaker to know whether population growth or growth in technology was more likely to influence conflict outcomes, but that since such variables are not very much manipulable in the short term, policymakers tend to ignore them. Their basic proposition was that "differential rates of population growth in combination with differential rates of technological growth contribute to international competition and sometimes to conflict…" (Choucri/North 1972: 83) They argued that:

> the demands and specialized capabilities of a society combine multiplicatively to produce what might be called lateral pressure. This amounts to a tendency to undertake activities farther and farther from the original boundaries of the society, to acquire some degree of influence or control over a wider extent of space or among a larger number of people (Choucri/North 1972: 90).

Their research focused especially on the major powers during the period 1870–1914. While this research did not deal with the issue of environment as we conceive of it today, the concern with population growth, harkening back to Malthus's hypothesis, was a predecessor to later work on environment, conflict and security. While Choucri and North's work was seen as significant in international studies, it was never really picked up in peace studies.

Attention began to be given to environmental issues within the framework of peace research and peace education in the late 1980s and early 1990s. The first issue of the Five College Program on Peace and World Security's *PAWSS Perspectives on Teaching Peace and World Security Studies* focused on "Peace and the Environment: Making the Connections in the Classroom" (1990). Drawing on the expertise of those in environmental studies, the issue argued for integrating environmental concerns into peace and international relations courses. Ake Bjerstedt of the University of Malmö, Sweden, School of Education, who served as Executive Secretary of the *International Peace Research Association's Peace Education Commission* (IPRA/PEC), edited "Peace, Environment

and Education", which served as the newsletter for PEC during the period beginning in 1990. While environment was a concern of some, it was not an overriding concern of the field. It was not integrated widely into peace studies courses at that time, and a quick perusal of the issues of *Peace, Environment and Education* shows only a few issues with a focus on environment.

The argument was put forward in the 1980s that it was important to integrate environmental concerns into the concept of security. With the publication of the *World Commission on Environment and Development*'s (WCED 1987) *Our Common Future*, the concepts of both sustainable development and environmental security came into currency in both policy and academic circles. Many had by then called for the redefinition of security to include environmental security. Among the earliest was Lester Brown (1977). Others included Richard Ullman (1983) and Arthur Westing (1986). Jessica Matthews (1989) also argued that security needed to be redefined to include environmental security. Sverre Lodgaard (1990) stated that the concept of environmental security "conveys a message that environmental problems have a legitimate claim for status as military problems have".

Critical environmental studies scholars found problems with the concept of environmental security, arguing that a focus on security marginalizes concerns over environmental justice. Simply adding in environmental problems as a security threat is incompatible with the basic requirements of solving environmental problems. Some scholars, such as Barry Buzan, Ole Wæver, and Jaap de Wilde (1998) of the Copenhagen School, have argued that "securitization" of the environment would lead to inappropriate policy choices. Dan Deudney (1990) also critiqued the concept of environmental security, arguing that the security discourse is a discourse of militarism incompatible with an environmental ethic. The structures developed for national security rely on violence, which is of little use in dealing with environmental problems. Dalby has provided a comprehensive overview of the problems of environmental security conceptualization and policy (2002). Later work began to focus not only on the potential for conflict, but also on that of cooperative responses to scarcity (Ronnefeldt 1997).

Thomas Homer-Dixon (1994), then Chair of the Peace and Conflict Studies Program at the University of Toronto, and researchers in the Project on Environmental Change and Acute Conflict began systematic case study research on the relationships between environmental scarcity, population growth, depletion and degradation of resources, unequal access to resources and violent conflict. Finding relationships in the developing world, and hypothesizing that scarcity would become more acute, he predicted that states' inability to deal with environmental problems would lead them to fragment or become more authoritarian. Robert Kaplan (1994) in *The Atlantic Monthly*, drawing on Homer-Dixon's research and arguing against Huntington's "clash of civilizations" thesis, cited evidence that scarcity, crime, overpopulation, tribalism, and disease were destroying our social fabric and bringing about anarchy, especially in West Africa, but in other regions as well.

There continues to be a lack of agreement on the conceptualization of environmental security. Most treat environmental security as meaning security for humans, or states, from environmental problems; only a few base their conceptualization on security for the environment. This has been especially true as environmental security has been incorporated into national defence thinking; for example, as the US Department of Defense established the Deputy Under Secretary of Defense for Environmental Security in 1993. If one returns to Aldo Leopold's argument in "The Land Ethic" about the expansion of the community as a tenet of ecological evolution, perhaps a solution to the debate over the utility of the concept of environmental security might be its expansion to include security both for the environment itself and for all people in the international system, thus overcoming the narrowness of the traditional concept of national security.

The *Peace Research Institute Oslo* (PRIO) was one of the first to embark on research into the possible relationships between environment, especially resource scarcity and degradation, and conflict. Early research concluded that there was not good evidence of any past relationship between water and armed conflict. However, Peter Gleick of the Pacific Institute made important arguments on the relationships between fresh water and conflict (1993). He also provided a comprehensive look at freshwater resources and a database on water and conflict (2009). Nils Petter Gleditsch (1998), in a critique of the literature on armed conflict and the environment, citing scarce resources as a source of armed struggle, and evaluating the argument that environmental degradation would increase scarcity and therefore contribute to an increase in armed struggle, concluded that there had been little systematic study on these issues. He identified a number of problems in the literature, among them lack of conceptual clarity, neglect of significant

variables, and questions about the direction of causality.

PRIO has continued its work on the examination of the relationships between environment and conflict. Gleditsch introduced a special issue of the *Journal of Peace Research* (2012) on climate change and conflict. Among the works included were articles by Bergholt and Lujala on climate-related natural disasters, economic growth, and armed civil conflict, Bernauer and Siegfried on climate change and international water conflict, Slettebak on climate-related natural disasters and civil conflict, and a number of articles on specific conflicts in various regions. To its credit, the issue included conflicting viewpoints, and also focused on the role of institutions in mitigating or resolving such conflicts. Others have also taken up the issues of the relationships between climate change, water and conflict, including Scheffran, Brzoska, Kominek and Link (2012) and Carter and Veale (2015).

Another significant area of convergence was the development of environmental peacemaking and environmental peacebuilding. Significant academic work began in the 1980s, with Larry Susskind's 1980 *Breaking the Impasse* focusing on the use of dispute resolution in public disputes. Bacon and Wheeler published their *Environmental Dispute Resolution* text in 1984. Gail Bingham reviewed a decade of experience with environmental dispute resolution in 1986. Drawing on the beginnings of this work, and on Conca and Dabelko's (2002) environmental peacemaking work, which made the case for environmental peacemaking, including case studies in different world regions, both theory and practice further developed after the turn of the century. Both UNEP and UNDP developed programmes focusing on environmental peacebuilding in war-torn or conflict regions. Carius published Environmental Peacebuilding in 2006 and Conca and Wallace an article on UNEP's work in 2009.[4]

3.5   Kenneth Boulding—The Exception

One of the very few exceptions to the lack of attention given to the environment in peace studies and to peace and security in environmental studies was Kenneth Boulding, an economist who is generally regarded as one of the founders of the field of peace

---

4   The website <www.environmentalpeacebuilding.org> provides other useful links to much of this work.

studies. Boulding (1910–1993) was both economist and ecologist.

Among the books for which Kenneth Boulding was most widely recognized were his books *The Image* (1956) and the *Conflict and Defense* (1962). *The Image* represented Boulding's attempt to show a single thread running through the diverse academic disciplines "to produce something like a general theory" (Boulding 1956: 139). In *Conflict and Defense* (1962), rooted in game theory, Boulding puts forward a general theory of conflict ranging from the individual, through economic and industrial–organizational, to the international level, focusing especially on the dangers of international conflict, and concluding with approaches to conflict resolution and control.

It has been argued that Boulding actually laid the foundations of ecological economics in his book *A Reconstruction of Economics* (1950). Robert Scott (2015) argues in his new biography of Boulding that "Many people (including me) think *Reconstruction* was Boulding's most underappreciated work" (Scott 2015: 66). Boulding (1966) was far ahead of either economics or peace studies when in 1965 he first spoke of earth as a spaceship, characterizing in his classic article "The economics of the coming Spaceship Earth" the "cowboy economy" as a more open system and the "spaceman economy" as the more closed system which would need to be the economy of the future. In *Ecodynamics*, employing an evolutionary perspective, and seeing the world and universe as a "total system of interacting parts" (Boulding 1978: 31), he argued for a "more accurate image of the future" (Boulding 1978: 373). Among the limits to growth he saw the rise of world inequality and the necessity for population control. Several chapters also foreshadow his threefold conceptualization of power.

In his *Stable Peace* (1978a), Boulding spoke of the continuum of war and peace, rather than seeing them as diametrically opposed. He argued that we can move back and forth between stable war, unstable war, unstable peace, and stable peace, with the goal being to move to more stable peace. But Boulding also elaborated on a more complex conceptualization of power itself in his *Three Faces of Power* (1989). He argued not only for the carrot-and-stick dichotomy, but also argued that what he termed social power was an equally prevalent mode of power in human life, including in international relations. Boulding argued that political-military power was primarily destructive power, based on threat, while economic power was primarily productive, based on exchange, and social power was primarily integrative, based on the power

of love. He argued both that society, including international society, is primarily reliant on social or integrative power, and that we would all be better off if we continued to move society further in that direction by reliance on less coercive forms of power.

Boulding's work on the development of general systems theory and his later work on 'human betterment' framed an understanding of both the dynamics of power and peace and of ecodynamics. Yet his work on peace was read primarily by peace studies scholars, and his work on environment by environmental studies scholars. Very few made the linkages he made. The work of this book begins to follow that lineage.

3.6 Global Governance, Sustainable Environment and Sustainable Peace

In some ways, it can be argued that the institutions of global governance have done more to incorporate the areas of sustainable environment and sustainable peace than have the academic fields of environmental studies and peace studies. In a number of multilateral and other forums, conceptualization of peace and security, for whatever reasons, began to link environment and development issues to traditional peace issues. Among these were the Culture of Peace programme in UNESCO, the Nobel Peace Prize, the series of commissions on changing concepts of security, and the Millennium Development Goals, which by 2015 morphed into the Sustainable Development Goals. The final documents from the series of UN conferences that began with the 1972 UN Conference on the Human Environment in Stockholm, the food and population conferences in Rome and Bucharest in 1974, the International Women's Year Conference in Mexico City in 1975, and carrying through to their follow-on conferences in 1992, 1994, and 1995, also began to reflect the linkages between war, peace, food, population, gender, and the environment.

3.6.1 Conceptualizing Peace: the Culture of Peace

Peace studies began to examine and incorporate the concept of a "culture of peace", although this was done primarily within UNESCO and the United Nations rather than in academia. The Seville Statement on Violence, drafted by natural and social scientists during the UN International Year for Peace in 1986, foreshadowed the work that was begun at UNESCO in the early 1990s. UN work on the culture of peace was furthered by UN General Assembly resolution 52/15 of 20 November 1997, by which it proclaimed the year 2000 as the "International Year for the Culture of Peace", and its resolution 53/25 of 10 November 1998, by which it proclaimed the period 2001–2010 as the "International Decade for a Culture of Peace and Non-Violence for the Children of the World". The General Assembly adopted the Declaration on a Culture of Peace on 13 September 1999, and the Programme of Action on a Culture of Peace in General Assembly resolution 53/243 of 6 October 1999. The Programme defined eight domains of action:

- a culture of peace through education
- sustainable economic and social development
- respect for all human rights
- equality between women and men
- democratic participation
- understanding, tolerance and solidarity
- participatory communication and the free flow of knowledge
- international peace and security.

All of these areas of work have been incorporated into peace studies, and many into more conventional work in international relations as well. What is significant about the Culture of Peace framework, however, is that it highlights the interrelationships between each of the domains of a culture of peace. One of the links between paradigms of sustainable development and sustainable peace is found in the section on Sustainable Economic and Social Development, which links a culture of peace to both environmental sustainability and gender equality.

There appears to be a reciprocal relationship between sustainable economic and social development and gender equality. This domain of the Culture of Peace combines the importance of traditional economic development, as well as social or human development, and concern with the protection of the environment. The environment vs. development debate that came about with the first UN Conference on the Human Environment in Stockholm in 1972, over whether the South had the right to destroy their environment in the course of development, as the North had done, resulted in the Brundtland Commission's 1987 popularization of the term "sustainable development". Sustainable development, defined by the Commission as "development that meets the needs of the present while not compromising the rights of future generations", incorporated the view that, if development did not pay attention to environmental protec-

tion, it would not be sustainable (WCED 1987). We will examine both the development side and the environment side of this conceptualization.

Many of the measures of economic as well as social and human development are highly correlated with gender equality. Women's basic literacy improves the chances of child immunization and reduces under-five child mortality. Two measures of gender empowerment, female education, and lifetime exposure to employment, appear to increase the probability of contraceptive use, reducing family size, which in turn seems to improve child survival rates, especially for girl children. While the relationships are complex, improvements in gender equality appear to lead to improvements in health and well-being both at the level of the family and that of the society (Kabeer 1999). Research also suggests that in societies where more than thirty per cent of the legislators are female, there is a greater emphasis on social and human development concerns such as health and education. Gender equality also appears to be positively related to many of the Millennium Development Goals adopted by the UN in 2000, including especially the reduction of infant and maternal mortality.

Second, there are also linkages between women and the environment. Women, in many societies, are the drawers of water and the hewers of wood; their approaches to consumption are key in determining environmental sustainability. There are clear links between gender and land distribution, biodiversity, and water management (UNEP 2004). The Women's Environment and Development Organization, today one of the primary women's NGOs, was founded in 1991 to link and to show the linkages between gender and environmental concerns. The Green Belt Movement was founded in 1977 by Kenyan Wangari Maathai, who received the 2004 Nobel Peace Prize for her work on the intersection of the issues of democracy, environmental protection and restoration, human rights, and especially women's rights.

3.6.2 Conceptualizing Peace: The Nobel Peace Prize

While the Nobel Peace Prize is not strictly peace research, the diversity of its awards can also be seen as a fertile source of theorizing on the relationships of the conditions of peace. One of the ways in which the general public becomes aware of the conceptualization of peace is the annual awarding of the Prize. Within peace research, there has been a small strain of solid historical research on the Prize. Alfred Nobel, a

Swede and the inventor of dynamite, created the Nobel Prizes to be awarded "to those who, during the preceding year, shall have conferred the greatest benefit on mankind", with the award divided into five equal parts, including one part to the person who shall have done: "the most or the best work for fraternity between the nations, for the abolition or reduction of standing armies and for the holding and promotion of peace congresses".[5]

In 1895, shortly before his death, while Norway and Sweden were under common governance (until 1905), and Norwegian liberals were working for self-governance, he decreed that the prize for champions of peace was to be awarded by a committee of five persons to be elected by the Norwegian Storting. Since the first Nobel Peace Prize was awarded in 1901, divided between Jean Henri Dunant, founder of the International Committee of the Red Cross, and Frederic Passy, founder of the first French peace society, Nobel Peace Prizes have been awarded to persons and institutions who represent a wide variety of conceptualizations of peace.

Over the course of the 1997–2007 decade the Nobel Peace Prize broadened further, being awarded to both governmental and non-governmental individuals and institutions; and in 2004 and 2007 environmental work was added, when the Nobel Peace Prize was awarded to Wangari Maathai (2004) and to the *Intergovernmental Panel on Climate Change* (IPCC) and Albert Arnold (Al) Gore, Jr. (2007).[6]

The Prize's conception of peace has always been broad. Within that decade alone, it included awards for efforts to ban weapons, find a peaceful solution to the Northern Ireland conflict, provide humanitarian assistance, promote democracy and human rights, promote reconciliation in divided societies such as South and North Korea, work for a more organized and peaceful world, find peaceful solutions to conflicts, work for democracy and human rights (especially women's rights), contribute to sustainable development, democracy and peace, prevent nuclear energy from being used for military purposes, create economic and social development through microcredit, and build up and disseminate knowledge about man-made climate change. The awarding of the Peace Prize to Wangari Maathai for her development of the

Green Belt Movement in Kenya and her advancement of environment, women, and democracy was a significant broadening of the notion of peace.

The October 2007 announcement of the award of the Prize to the United Nations' *Intergovernmental Panel on Climate Change* (IPCC) for its work on the science of global warming and to Al Gore for his publicizing of the issue, particularly through the documentary "An Inconvenient Truth", was contested immediately from various political positions. The most common criticism of the 2007 Nobel award appears to have been that environmental issues do not fall within the province of an award for peace. Certainly environmental issues were not specified in Nobel's will, but neither were they recognized as important on their own at the turn of the century. Today it is clear that there are many important linkages between environmental problems and peace, as there are between peace and justice. The Nobel citation said that the IPCC and Gore had emphasized "the processes and decisions that appear to be necessary to protect the world's future climate, and thereby reduce the future threat to the security of mankind".

In the peace research community, another criticism was that the Prize has often tended to reward government-related rather than grassroots work. This presages the question of peace research's independence from or integration with government, and whether it should serve the needs of government or civil society and, as a derivative argument, whether it should or should not accept support from government. This relates as well to the arguments in international relations as to who are to be seen as the actors in international relations, only states, as realists argue, or also civil society actors including non-governmental organizations, as liberal institutionalists have argued in putting forward the concepts of transnational relations and complex interdependence (Keohane/Nye 2001). These debates, in addition to the positive peace/negative peace debates, have been central in framing the development of peace research and peace studies. Similar debates have arisen over the concept of environmental security, a part of the evolving debate both in peace studies and even more so in environmental studies.

3.6.3 Evolving Concepts of Security

The traditional concept of security developed at the time of the peace of Westphalia in 1648, with the idea of nation-state sovereignty, backed up by the balance of power. This can be contrasted with the development of concepts of international security, which came along with the development of multilateral security institutions (Brauch/Oswald Spring/Grin et al. 2009; Brauch/Oswald Spring/Mesjasz et al. 2008, 2011).

First, the concept of 'collective security' came about with the League of Nations in 1919, failed when the League of Nations failed in stopping aggression, but came back stronger under the United Nations in 1945 when the UN Charter in articles 2.3 and 2.4 said that "all nations shall settle their international disputes by peaceful means" and "refrain in their international relations from the threat or use of force against the territorial integrity or political independence of any state". Collective security is backed up by enforcement. If any nation violates that ban against the use of force, the UN under Chapter VII can enforce action upon it by either non-military (article 41) or military (article 42) sanctions.

A step backward toward national security was 'collective defence' under the alliances of the NATO Pact in 1949 and the Warsaw Pact in 1955. Collective security was based on the idea that an attack on one was an attack on all but this, again, was still based on the use of force.

A somewhat more interesting concept is that of 'common security'. Common security came about with the Brandt Commission in 1980, which focused on North–South issues and economic security and presaged human security. After that the *Independent Commission on Disarmament and Security Issues* (Palme Commission 1982) brought about the concept of 'common security', in the context of nuclear war. The Palme Commission defined common security as the notion that you couldn't have a victory in nuclear war and therefore security had to be mutual, and that the implications of that are that you have to reduce military budgets.

Of all of this series of evolving concepts of security, only the Brundtland Commission's work addressed environmental issues. The World Commission on Environment and Development in 1987 talked about the concept of 'environmental security' and their report *Our Common Future* publicized the notion of sustainable development, the notion that you couldn't have development unless you took account of the environment.

Japan's 1983–84 Defence White Paper introduced the concept of *comprehensive security*, including traditional national self-defence, but also introduced access to food and access to energy as security issues and talked about the use of development aid as a security mechanism as well. While there was no men-

tion of environmental security, the issues of access to food and energy intersected with the scarcity issues encountered in environmental studies.

3.6.4   Human Security

The concept of human security was introduced in the *Human Development Report* (HDR) in 1994 and was then taken up by the Commission on Human Security that ran from 2001 to 2003 and issued its report, *Human Security Now*, in 2003, with Sadako Ogata and Amartya Sen as primary authors. It was funded by the government of Japan and the Rockefeller Foundation and a number of other groups. It followed on from the concept introduced in the *Human Development Report* 1994. The *Commission on Human Security* (CHS) defined human security in the following way: "to protect the vital core of all human lives in ways that enhance human freedoms and human fulfilment".

To the Commission, human security meant protecting fundamental freedoms, freedoms that are the essence of life. It meant protecting people from critical, severe and pervasive threats and situations. It meant using processes that build on people's strength and aspirations. It meant creating political, social, environmental, economic, military and cultural systems that together give people the building blocks of survival.

Human security in its broader sense embraces far more than the absence of violent conflict, building on the *Human Development Report's* conceptualization. It is security based on people, individual security rather than state security, though both of these argue very much that these are complementary and not different. It talks about protecting people in cases of violent conflict but also about empowering people, and so it refers to a number of different aspects: protecting people in violent conflict, protecting people from the proliferation of arms, protecting the security of "people on the move", working to provide minimum living standards everywhere, prioritizing universal access to basic health care, empowering all people with universal basic education.

This particular report focused on the broad concept of human security. There is a big debate in the field as to whether the concept should be broad and essentially include development and human rights, or whether it should still be focused narrowly and involve protection from direct threats of violence.

On the other hand, the *Human Security Report* (2005) that came out of the Liu Institute in Vancouver, Canada, funded by the government of Canada and others, adopted the narrow concept of human security. They decided to focus on threats based on violent conflict, and to talk also about some of the indirect effects of those, like refugees and disease, but to focus largely on the threat of war and other factors that involve human violence. The *Human Security Report* focuses on wars: both inter-state wars, which have reduced considerably, and intra-state wars, which have actually been increasing, as well as on genocide, on the violence that comes with crime, on political repression, on terrorism, on human rights abuse, particularly the kind that kills people, and on the displacement that comes with wars and also the disease that often comes with wars.

As with the concept of environmental security, there has been much criticism of human security. One of the first and most cited critics is Roland Paris (2001). There continues to be disagreement on what human security is, with 21 comments on the subject published in a special issue of *Security Dialogue* in 2004. While the concept of human security certainly broadened the concept of security itself, it did little to incorporate environmental security or environmental issues.

3.6.5   From the Millennium Development to the Sustainable Development Goals

The *Millennium Development Goals* (MDGs), adopted by world leaders at the UN's Millennium Summit in September 2000 and reaffirmed at the World Summits in September 2005 and 2010, followed on from the conceptualization of human security, although they did not make the explicit linkages between development and peace and security, nor even include peace. The MDGs, however, did explicitly include environmental issues, although only in Goal 7. Intended to be achieved by 2015, the MDGs stressed the interconnectedness of all goals.

Following on from the many UN Decades of Development, beginning in 1961, and the conceptualization of human development in 1970 and human security in 1974 by the UN Development Programme, as well as from the series of UN conferences on environment, food, population, and women beginning in the 1970s, the MDGs explicitly included a focus on ensuring environmental sustainability in Goal 7: "Ensure environmental sustainability." By this time the environment had made it onto the world agenda, although the linkages between war, peace, gender, population, environment and development were still not always explicitly addressed. As these goals morphed

into the seventeen *UN Sustainable Development Goals (SDGs),* adopted in 2015 to be accomplished by 2030, the concept of sustainable development publicized by the Brundtland Commission in 1987 became an even stronger part of our way of thinking.[7]

The SDGs continued many of the MDGs, but this time eleven goals explicitly addressed issues of sustainability (Goals 2, 6 (which was a target in the MDGs), 7, 8, 9, 11, 12, 13, 14, 15, and 17). A notable integrative innovation was goal 16, which explicitly linked peace and the environment, reading: "Promote peaceful and inclusive societies for sustainable development, provide access to justice for all and build effective, accountable and inclusive institutions at all levels." But sustainable development may well be an oxymoron; development, over the long term, may not be sustainable, particularly if it includes the connotation of growth, as in Goal 8. Attention to the values of environment may mean not developing the fossil fuels now accessible rather than exploiting them.

3.7   Conclusions

While the conceptualization of 'sustainability transitions' (Brauch, chapter 1 in this volume) may be an important contribution both to the fields of peace studies and environmental studies, it may also be important to consider this in the light of systems

thinking. Boulding's work on the development of systems theory and that of the *Limits to Growth* project continue to be important here. Systems evolve; though they may exist in equilibrium at any one point in time, the equilibrium is likely to evolve also with the introduction of step-level functions that change any of the basic conditions. Stability is unlikely over time. Sustainability suggests stability. The environment has been changing over millennia, and will continue to change. The question may not so much require transitions to environmental sustainability as simply to acknowledge the importance of the environment, both to human society and on its own. This implies acknowledgment of the detrimental role human beings have played with respect to the health of the environment, and a commitment to a transition to protecting the environment.

Whether the concept 'sustainability transitions' best captures this may be debated. Among the key maxims toward environmental protection is the precautionary principle put forward by the UN in the 1992 Rio Declaration, and earlier in climate change and other negotiations, that: "Where there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation." The adoption of a precautionary principle with respect to peace and human rights could also be important. A transition to an expanded concept of our human community would improve our work both on peace and the environment. We can come back to Aldo Leopold's dictum: the evolution of human ethics has involved the expansion of our understanding of community, and the adoption of a "land ethic" would be an important transition in our ethical development.

4   Transition Studies: Basic Ideas and Analytical Approaches

John Grin[1]

Abstract

As a background to later contributions, this chapter provides a concise introduction to different approaches to (i) understanding and (ii) shaping transition dynamics:

1. A *sociotechnical approach*, with the multilevel perspective as its main concept, and strategic niche management as its governance concept;
2. A *complex (adaptive) system-based approach*, using the concept of transition patterns, with transition management as its governance concept;
3. A *governance approach*, where the politics of transition dynamics are examined, with reflexive design as the core of its approach to shaping transition.

In addition, work based on the social theory of practice has helped to bring consumption practices into transition theory, and an approach focusing on innovation system has helped to explain how different arrangements may become interconnected so as to produce a transition.

Keywords: Sociotechnical transitions, multilevel perspective, strategic niche management, complex adaptive systems, transition management, reflexive governance, reflexive design, power, legitimacy.

4.1   Introduction: Rationale and Nature of Transitions and the Scope of Transition Studies

Transitions may be *defined* as profound societal transformations in that they involve changes in both multiple, interacting societal practices and the institutional, structural and discursive structures in which these are embedded. The *rationale* for transition studies lies in particular diagnosis of persistent societal problems—problems that appear to resist potential solutions, such as the depletion of specific resources, continued greenhouse gas emissions, and flooding in river flow areas. Central to that diagnosis is the presumption, well-rooted in evolutionary economics and sociology, *science and technology studies* (STS) and social theory, that the definitions of societal problems, the practices that tend to be used to deal with them, and societal structures themselves co-evolve with each other, meaning that the evolution of each over time co-shapes the evolution of the other two. If problem definitions that are fundamentally novel become dominant, a call for fundamentally different practices may result. These are often not well served by incumbent structures. This may generate inertia, and lead to a more fertile ground for resistance to transformative practices than acceptance of them. As a result, such innovative practices may be difficult to establish, may easily fall back into normality, or may not survive in the long run.

This in a nutshell is why such 'novel type' problems may be so persistent, and why in transition studies persistent problems are seen as providing a rationale for a transition (Grin/Rotmans/Schot 2010: 1–5). From that key point of departure the two main research questions follow: how may transition dynamics be understood, and how may they be shaped so as to deal with persistent problems?

Transition studies has its intellectual roots in work by many scholars from a variety of fields, most notably STS (*science and technology studies*) and innovation studies, and the field of complex systems studies

1   John Grin (The Netherlands) is a full Professor in Policy Science, in particular of System Innovation, in the Department of Political Science, University of Amsterdam, and Co-Director of the Programme Group Transnational Configurations, Conflicts and Governance, Amsterdam Institute for Social Science Research (AISSR); email: <j.grin@uva.nl>.

and socio-ecological system studies (Smith/Voß/Grin 2010; Grin 2008). These strands of work were stimulated by a global sense of urgency concerning climate change and other sustainability problems, and by programmes like the *International Human Dimensions Programme on Global Environmental Change* (IHDP). Transition studies as a field received a major boost when Dutch scholars were fortunate enough to get a major research programme funded, the *Dutch Knowledge Network on System Innovations and Transitions* (KSI, 2005–2010). This five-year programme (Rotmans/Schot/Grin 2004) comprised eighty-five researchers, including thirty-eight PhD students, at eight Dutch universities and at TNO, a Dutch *Great Technological Institute* (GTI); they collaborated with some 750 transition practitioners in several dozen transition projects, some of which had been established by KSI.[2]

Normal, healthy academic routines of critical scrutiny were applied to novel strands of research, and KSI spent ten per cent of its 22 million budget on internationalization. As a result, important exchanges took place with scholars from a host of other countries who had been working, in their own ways, on transitions or related themes; these scholars began to critically scrutinize the Dutch approaches. A series of international workshops, together with sessions at major conferences, special issues of scholarly journals and so on helped to improve and further develop original theorizing, and added important new themes and modes of theorizing. This also helped to overcome the field's original Eurocentric focus (e.g. Berkhout/Angel/Wieczorek 2009; Berkhout/Verbong/Wieczorek 2010). KSI also initiated a transition journal (*Environmental Innovation and Sustainability Transitions, EIST)*[3] as well as a book series with Routledge.[4] At present, the field counts more than thousand scholars from all continents, assembled in the *Sustainability Transitions Research Network* (STRN),[5] founded at the first international transitions conference in Amsterdam in 2009. They meet at the annual conferences organized by STRN as well as during sessions at other academic conferences, and frequently undertake internationally collaborative pro-

jects. By now a vast, global literature has evolved (Markard/Raven/Truffer 2012; Chappin/Ligtvoet 2014). Lessons from and for practitioners are being exchanged.[6]

This chapter seeks to introduce the approaches included in the original KSI programme. While these are primarily those based on the sociotechnical (4.2), complex system (4.3) and governance theory (4.4) approaches, in section 4.5 we will briefly discuss two other approaches, focusing on social practices and technical innovation systems respectively.

The objective of this chapter is to provide a background to the following chapters by discussing some of the main concepts and insights that were developed at the cradle of the field. For each of the approaches the chapter will describe (i) how it conceives of transition dynamics and on the basis of what theoretical ideas, and (ii) which governance concept it proposes. While some recent research which further develops these original concepts will be discussed in the next sections, many other recent lines of research will not be discussed. The most important ones will be briefly indicated in the final section, however.

4.2   The Sociotechnical Approach and Strategic Niche Management

The first approach is the *sociotechnical approach*. It focuses on the interactions of the practices and objects of social, economic and technological innovation with each other and with incumbent sociotechnical systems. The central concept it proposes for mapping and understanding transition dynamics is the *multilevel perspective* (MLP), which has become a core notion in transition studies more generally.

4.2.1   Understanding Transition Dynamics

This approach is rooted in STS, evolutionary theory and the 'contextual history' of technology. One seminal source of the MLP is a major study by Rip and Kemp (1998), which seeks to contribute to a better understanding of how, and under what conditions, deliberate technical change can contribute to dealing

with climate change. It begins by reviewing the bodies of literature on large technical systems, innovation system approaches, evolutionary theories, actor network theory, and the tradition of the social construction of technology. The authors then organize their findings into a two-dimensional scheme (Rip/Kemp 1998: 339). Along one axis, 'configurations that work' gradually merge into structuring entities and, eventually, 'seamless webs' that provide even stronger structuration. The other axis indicates scope. At the meso-level, there are regimes defined as "the rule-set or grammar embedded in a complex of engineering practices, production process technologies and product characteristics, skills and procedures, ways of handling relevant artefacts and persons, ways of defining problems–all of them embedded in institutions and infrastructures" (Rip/Kemp 1998: 338).

Usually, innovations will be shaped by the incumbent regime. However, the regime is not static, but may change, partly under the influence of its linkages to innovations at the micro-level and (changes at) the landscape level. On the basis of these findings, the authors claim that "to understand and explain technical change, a combination of economic and sociological theory is necessary" (Rip/Kemp 1998: 356). While no single explanation may be sensibly given, it is crucial to note path dependencies and irreversibilities as major factors in technical change.

A second seminal source of the MLP sheds more specific light on the potential of change beyond the incumbent regime. Drawing on a vast empirical basis of studies of the development of technology in the Netherlands in the nineteenth century (for an English summary volume of the Dutch book series, see Schot/Rip/Lintsen 2010), Johan Schot (1998) observes that in many cases, the development of technology appears to follow established patterns. Theoretically guided by a range of evolutionary theories, he explains this by pointing out that the development of technology is structured by a *technological regime,* which combines "the rules embedded in engineering practices (cognitive structuring) with the rules following from the embodiment of a given set of technologies in specific production and consumption patterns" (Schot 1998: 190). In some cases, however, regime shifts appeared to take place, especially when the efforts of interested parties coincided with favourable exogenous ('landscape') developments. Under such conditions, a niche may be formed: "a limited and local alliance (network) between the party that produces the new technology and the party that uses it (the sponsor)" (Schot 1998: 193), which protects

technologies under development from the incumbent regime. These niches create links between variation and selection, contributing to *quasi-evolution*.

Crucial in this connection is the finding that actors' expectations are not only a source of new technical options (variation), but also a "guiding force in the process of technological development" and "the development and articulation of expectations gradually improve the definition of the technology and the environment in which it is supposed to function" (Schot 1998: 196). Such dynamics of expectations and articulation in niches, formed by change agents under favourable exogenous conditions, may contribute to regime change, especially when constructive interference may be brought about between niche innovations, changes or instabilities in the regime, and landscape developments. This point has been further developed by Frank Geels (2005). Building upon earlier work as well as on a wide variety of literatures, concerning for instance the role of users and the role of increasing returns in innovation processes, he develops and employs a more detailed version of the MLP. The three levels are considered as a 'nested hierarchy', with an increasing degree of structuration from the niche level to the landscape level (Geels 2005: chapter 3). Drawing upon a set of case studies, he then (Geels 2005: 246-279) reconfirms and adds analytical accuracy to the claims of the MLP that transitions occur through interlinkage and interaction between developments at the three levels, and that they often involve multiple technologies (cf. figure 1.11, in this volume). Van Driel and Schot (2005) have interpreted this as interferences between changes occurring at different scales of time (Braudel 1980).

At that stage, the MLP had become a relatively well-developed heuristic framework, yielding the following insights on transition dynamics. First, its most central claim is that regime shifts occur through interlinkage and interaction between multiple developments at the three levels. Second, and more precisely, in this connection, other crucial insights are that this requires

- the *creation of niches*, locations that are actively protected against part of the influence of the existing regime; and
- *strategic action* in the sense of creating linkages to overcome inertia through connecting dynamics at all three levels.

Subsequent work by Schot, Geels and collaborators has produced several dozen case studies. These have yielded detailed accounts of the mechanisms through

Box 4.1: Possible transition pathways according to Geels and Schot (2007: 54–76).

- *Reproduction pathway*: in the absence of landscape pressure, the regime is likely to remain dynamically stable.
- *Transformation pathway*: if there is moderate landscape pressure at a time when niche innovations have not yet been sufficiently developed, then regime actors will respond by modifying the direction of the development path and innovation activities.
- *De-/re-alignment pathway*: if landscape change is divergent, large and sudden, then increasing regime problems may lead to erosion. This then creates space

for the emergence of multiple niche innovations that co-exist and compete for attention and resources. Eventually a new dominant core for realignment of a new regime emerges.
- *Substitution pathway*: if there is substantial landscape pressure at a point when niche innovations have developed sufficiently, then these will break through and replace the existing regime.
- *Reconfiguration pathway*: niche innovations are initially adopted in the regime to solve local regime.

which transitions and system innovations unfold–including the role of outsiders, the importance of policy support, the role of the market mechanism, the role of wide cultural visions and promises, and the importance of strategic games and competition throughout. Also, based on this body of case studies, a typology has been developed for transition pathways through which interlinkage and interaction may occur (Geels/Schot 2007; Schot/Geels 2010). These pathways differ from each other in two dimensions: the nature of landscape influences (continuing pressure on incumbent regime; a disruptive effect, hyper-turbulence, an avalanche effect, or a specific shock effect) and the degree of development of niche innovations. Five proposed pathways are summarized in box 4.1.

4.2.2   Shaping Transition Dynamics

Following their understanding of transition dynamics, Rip and Kemp state two crucial questions about how those dynamics are shaped are: "how to increase the chances for better path dependencies (…[and]) how to identify and realize transition paths from the present situation to a more desirable one" (Rip/Kemp 1998: 371). The authors emphasize the need to use the model as a heuristic device, which can guide, but not replace, contingent analysis. At the core of their ideas is their proposal that governance should be seen as a matter of the 'modulation' of ongoing dynamics within and between the three levels. They draw attention to the need to develop the perspective so as to take into account normative goal-setting, power asymmetries and strategic action, as well as to diagnose the course contemporary industrial societies are taking.

The sociotechnical approach has drawn on earlier work on strategic niche management (Schot/Hoogma/Elzen 1994; Kemp/Schot/Hoogma 1998; Weber/Hoogma/Lane et al. 1999; Hoogma/Kemp/Schot et al. 2002; Truffer/Metzner/Hoogma 2004) as

a basis for shaping transition dynamics in a way that draws strongly on experiments. In *strategic niche management* (SNM), novelties are able to develop within a niche that protects them from the adverse influences of the regime and provides helpful structural conditions not prevalent in the regime. Importantly, a niche must be understood as an analytical construct: a segment of the market with relatively interested consumers and helpful supply chains may be supported by a tax exemption or by government-funded research.

In much early work on SNM, a niche was understood more or less as an incubator, nurturing a premature novelty until it was strong enough to enter the normal world, through processes of learning, network formation and the shaping of expectations, and taking place within and between niche experiments. Later, Smith and Raven (2012) proposed and elaborated three functions: shielding, nurturing and empowerment.

Another limitation of early work was that much less attention was paid to the question of how the novelty could eventually help to fundamentally change the world. That problem has been addressed by later research. Elzen, Geels, Hofman et al. (2004) have proposed the *Sociotechnical Scenario* approach. Scenarios may provide guidance for the development of niche experiments and their connection to changes at the regime and landscape levels. They should be designed such they are both sustainable for a specific set of actors and attainable in the sense that their realization may build on ongoing changes at the regime and landscape levels. This kind of analysis has been used in different fields, including car mobility (Marletto 2014) and energy (Foxon/Hammond/Pearson 2010; Verbong/Geels 2012). Along similar lines, Raven (2005, 2006) has explicitly situated SNM in ongoing multilevel dynamics. Thus the capacity of niche experiments to contribute to regime change is

understood as co-determined by the ways in which they interact with ongoing changes at the regime and landscape levels. Smith (2007) has proposed the concept of translation (from actor network theory) to theorize the agency involved in bringing about such connections. In later work, Raven and others (Raven 2007; Raven/Verbong 2007, 2009; Raven/Verbong/ Schilpzand et al. 2011) have elaborated this understanding so as to comprise the dynamic interaction between niche experiments and multiple regimes, a key issue as many transitions involve the reordering of 'systems' (e.g. biofuel implies the emergence of a system reconnecting elements from the energy and agriculture systems). Amongst many other findings, such work reveals on the one hand additional difficulties in reconciling experiments with two different regimes, and on the other, more opportunities for strategically operating agents to alternately draw on elements from different regimes. Schot and Geels (2008) have synthesized this and other work, seeing SNM as a form of reflexive governance (Grin 2006), and proposing a new version of SNM, where niches facilitate sustainable innovation journeys in which the internal and external dynamics of niches are deliberately connected. Seyfang and Haxeltine (2012) have added other drivers of dynamics, most notably group (identity) formation.

Other important work has been done, for example, focusing on better understanding the internal dynamics of niches in bringing about protection (Ulmanen/Verbong/Raven 2009; Ulmanen 2013; Boon/Moors/Meijer 2014), and on the specific nature of 'grassroots' niches, rooted in civil society (Seyfang/Hielscher/Hargreaves et al. 2014).

4.3 The Complex Systems Approach and Transition Management

4.3.1 Understanding Transition Dynamics

The second approach to explaining sustainability transitions (Rotmans/Loorbach 2010) has been inspired by two strands of systems theory in particular. In the first, *integrated assessment*, systems are depicted as comprising mutually interacting sociocultural, economic and physical stocks and flows (Rothman/Robinson 1997; cf. Pahl-Wostl 2002; Weaver/Jansen/van Grootveld et al. 2008). At any specific moment in time, the system may be characterized by its stocks. These stocks change relatively slowly compared to their own volume. Relatively rapid changes may occur

through flows, associated with ongoing socio-economic and natural processes. This depiction involving stock flow and agents is of obvious use in conceptualizing the basic notion of sustainable development as involving the closing of substance cycles.

The second body of theory involves *complex adaptive systems* (CAS) theory (Gunderson/Holling 2002; Holland 1996). Compared with more traditional systems theory, it adds the possibility of adaptation through (complex, non-linear) responses to external (e.g. 'landscape', in MLP terms) perturbations. Under normal conditions, when changes in the environment are moderate at most, the system maintains a particular dynamic equilibrium of stocks, flows and agents (an 'attractor'). This is due to an internal structure which emerges over time from processes at a lower or higher level of aggregation. Attractor and associate structure are the CAS depiction of the regime. In the case of stronger external perturbations, agents will induce non-standard responses, through a constant stream of self-reinforcing changes in flows and agent behaviour—this is how a niche may be represented in CAS terms). In specific circumstances this may bring the system into a different state of dynamic equilibrium, centring its dynamics on a different attractor. This transformative change from one dynamic system equilibrium to another, involving a change in the deep structure of the system, constitutes a transition. Systemic adaptability and resilience may also be seen as intrinsic features of sustainable development.

Following this understanding of niche and regime, De Haan and Rotmans (2011; cf. Haxeltine/Whitmarsh/Bergman et al. 2008) have developed a typology of 'transition patterns'—basic modes of transition dynamics, understood as interactions between the niche and regime levels and involving an intermediate level: the niche-regime. The basic patterns are listed in box 4.2. Compared with the transition pathways that have resulted from the sociotechnical approach, the 'niche to niche-regime' and 'niche-regime to regime' patterns form two steps in a process in which regime changes gradually result from changes at the niche level, with the niche-regime as a key element. The main difference is its analytical nature (Grin/Marijnen 2011). Sociotechnical pathways, derived from historical analysis, follow in more or less phenomenological terms the process of (re-, de-)alignment. They thus relate relatively clearly to everyday terms. CAS patterns take a more abstract perspective, providing insight into the underlying systemic causation in terms of stocks, flows and agents. Patterns may be

---

Box 4.2: Different transition patters. **Sources**: Rotmans and Loorbach (2010: 137–139), and De Haan and Rotmans (2011).

- A 'niche to niche-regime' pattern, where niches emerge, cluster and form a niche-regime which starts to undermine the incumbent regime.
- A 'niche-regime to regime' pattern, in which the niche is absorbed or combined with the incumbent regime,

which thus evolves into a new regime.
- A 'regime to niche-regime' pattern, in which a massive change at the landscape level induces regime change through significant landscape changes, or competition from niches and niche-regimes.

---

analytically related to core notions of sustainable development.

4.3.2   Shaping Transition Dynamics

Associated with and rooted in this (complex) system understanding of transition dynamics, *Transition Management* (TM) has been proposed as a governance concept for transitions (Rotmans/Kemp/van Asselt 2001; Loorbach 2007; Kemp/Loorbach/Rotmans et al. 2009; Rotmans/Loorbach 2010). A key point of departure is the idea that the actor (alliance) that seeks to deliberately influence a system towards a desirable transition is bound, in and through doing so, to become part of the system. Even if we initially conceive of such action as an external intervention, as such it will provoke a (complex) response from the system, partly unforeseen. The steering agent, who has already become part of the web of causation, can do little better than make her next move informed by that response, and the awareness that that move will draw her even further into the system (Van der Brugge/Van Raak 2007). This, in essence, is the notion of self-governance: the governing system essentially is part of the system to be governed (Loorbach 2007: 175). As Rotmans and Loorbach (2010) point out, the methodological implication is that action research may play a key role in both developing the theoretical understanding of transition dynamics and in shaping and promoting transitions in actual contexts. This has led researchers in this tradition to develop ways of analysing transition dynamics, in order to be able to monitor their progress as a basis for learning (Van der Brugge 2009; Taanman 2014).

Transition Monitoring is one of the four key activities, mutually related in a dynamic, iterative mutual way, that co-constitute TM. It gathers insights into the dynamics and (desired and undesired) progress of a second activity–performing transitions experiments–as inputs into the other two activities: the development of visions, and the structuring of strategic problems, the development of a transition agenda and the derivation of associated transition paths. These take

place in a so-called transition arena, composed on the basis of the idea of selective participation: a critical mass of 'front runners', visionary thinkers and entrepreneurial actors complement regime actors with a certain openness to change.

There is no fixed order for undertaking these activities. The major Dutch governmental Energy Transition programme started with problem structuring. It then involved visioning, agenda-building and the defining of tracks. For each track a set of experiments was then defined (Rotmans/Loorbach 2010: 180-199). But the Transition Programme on Long-Term Care, for instance, started with existing, relatively radical experiments and helped them to 'transitionize' (Van den Bosch/Neuteboom forthcoming). In both cases, subsequent programme evolution comprised a wide set of different relations between the four core activities, with demands for accountability and funding, monitoring activities, and an emphasis on experimentation and external feedbacks as the main drivers.

When explained in detail (Loorbach 2007, 2010; Rotmans/Loorbach 2010: 140-159), TM has been underpinned by principles derived from complex adaptive system theory. For instance, the idea of emergence translated into creation niches as a structural context that may nurture novel practices, around which further structures may develop. The principle of focusing on front runners is based on the idea that they, by connecting experiments to exogenous changes, may promote what is called in CAS dissipative structures, i.e. (regime) structures that lose energy to the environment. Simultaneously, they may develop novel visions that provide guidance to distributed practices, yielding a novel attractor in the system: the principle of promoting radical change through small, interconnected steps.

Through such correspondences between CAS and TM, transition management may, generically as well as in specific cases, be developed further on the basis of modelling (Haxeltine/Whitmarsh/Bergman et al. 2008) in ways that are still being further developed (De Haan/Ferguson/Adamowicz et al. 2014; Holtz/Alkemade/de Haan et al. 2015). Other recent work on

transition management focuses on more detailed understanding of specific aspects, such as the role of agency (Brown/Farrelly/Loorbach 2013; Rauschmayer/Bauler/Schäpke 2015), urban transition labs (Nevens/Frantzeskaki/Gorissen et al. 2013) and partnerships in TM (Frantzeskaki/Wittmayer/Loorbach et al. 2014). There is also work applying it to novel domains, such as the financial crisis (Loorbach/Lijnis-Hüffenreuter 2013) and Agenda 21 (Wittmayer/van Steenbergen/Rok et al. 2015), as well as work which focuses more on particular places, like cities, than on a domain (Wittmayer/van Steenbergen/Rok et al. forthcoming).

4.4 Reflexive Governance and Reflexive Design

4.4.1 Understanding Transition Dynamics

The final approach to transition studies is the governance approach (Grin/van de Graaf/Vergragt 2003; Grin 2010; see also Voß/Bauknecht/Kemp 2006; Avelino 2009, 2011). This designation may be somewhat confusing, given that the two approaches described in the preceding two sections also discuss the governance of transitions (the second central question in this chapter). This third approach is nevertheless so called as it has its home base in governance studies. It differs from both the sociotechnical and the complex systems approaches in how the answers to the questions that guide this chapter (how to understand and how to shape transitions) are related. In the sociotechnical approach, the second question was answered by discussing strategic niche management, a governance concept derived from MLP-based theory on transition dynamics. In the second approach, the answers to both questions are derived from complex systems theory, while methodologically, the further development of either informs the other.

The governance approach draws substantially on results of studies of transition dynamics from both other approaches (especially MLP insights into transition dynamics, and the notion of adaptation in CAS), but opens them up from the governance question. Basically, this requires a dual vision of the dynamics of transition: iterating between a helicopter view and the perspective of a performing, situated actor. This is because the essence of governance is in the interaction between context and agency; the art of governance is thus in skilfully employing dual vision, like a person wearing Google glasses. Moreover, as we will see, it is an insight into this relationship which enables us to understand, unlike with both other approaches, the politics evoked by transitions as part and parcel of transition dynamics, thus opening up new ways of dealing with such politics.

To develop such a dual vision, several points of departure are needed. First, structuration theory is used to understand how the agency involved in transitions depends on the structural context (Grin/van de Graaf/Vergragt 2003; cf. Grin 2006). While niche and regime are both sets of practices and associated structures, it is stressed that the regime may also been seen as structuring niche practices. Regular practices are, by definition, privileged by the incumbent regime, while niche practices may face inertia as the regime tends to 'draw' them back into regular practices, and does not offer proper rules and resources. This means that there is little support for their development, while actors resisting those niche practices may be better served by the regime (Roep/van der Ploeg/Wiskerke 2003; Grin/van de Graaf/Vergragt 2003; Grin/Felix/Bos et al. 2004; Bos/Grin 2008; Geels 2014). While TM acknowledges the inertia and resistance it may encounter, the governance approach offers opportunities for a more fine-grained, anticipatory analysis.

Second, transition dynamics is explicitly situated in the real world, i.e. in the context of ongoing long-term ('landscape') trends such as Europeanization, individualization and the politicization of side effects, and their interaction with the practices and structures of various societal domains. Regarding structure, attention is drawn to the nature of the four key institutions of modern society (market, state, civil society and knowledge) and their mutual alignments in various arrangements: the market system, the governance system and the innovation system. These institutions and their mutual alignment (together designated the 'institutional rectangle') have co-evolved with dominant practices and therefore differ between domains. Yet it is possible to discern some more or less generic trends (Grin 2010: 237–248), such as the changing/increasing role of civil society in the innovation system (the societization of science and technology since the 1970s), the governance system (in the wake of the emergence of the new social movements) and the market system (e.g. partnerships between NGOs and firms). This has led to less rigid, pre-given functional differentiation, making practices more contingent upon contextual agency. A second generic trend is re-spatialization of these systems due to globalization and Europeanization: the locus of activities has become not just the context, but also the outcome of

agency, which may more or less strategically choose between a variety of venues (see also Späth/Rohracher 2010, 2012, 2014; Hodson/Marvin 2010).

Within the governance approach, such developments are an important part of the helicopter view implied in the dual vision. As such, they acquire additional meaning when understood against the backdrop of modernization theory, especially the versions espoused by Beck (1997) and Giddens (1991). From this perspective, transitions essentially become a matter of (1) redirecting the co-evolution of structure and agency towards (2) an orientation which goes beyond the control-mode orientation characterizing 'first' or 'simple' modernity (Beck 1997), as well as beyond the categorizations and identities of the 'emancipatory politics' of that era (Giddens 1991), and takes sustainable development as a normative orientation. This has to be achieved (3) amidst the turbulence of a variety of exogenous trends in the real world, as discussed above.

Crucial in the process of re-orientation is reflexivity, understood as what Voß and Kemp (2006) have called 'second-order reflexivity.' While 'first-order reflexivity' captures the unconscious and unintended, 'reflex-like', consequences (side effects and risks) of early modernization processes, second-order reflexivity is about self-critical and self-conscious reflection on the processes of modernity. It evokes a sense of agency, intention and change. Here actors reflect on and confront not only the self-induced problems of modernity, but also the approaches, structures and systems that reproduce them (Grin/Felix/Bos et al. 2004; Stirling 2006). It is this emphasis on reflexivity that turns this approach into a form of reflexive governance (Voß/Bauknecht/Kemp 2006).

4.4.2   Shaping Transition Dynamics

Crucial to shaping transitions in this approach is that changes at the level of practice and the regime inform each other. Niche practices central to SNM need regime changes in order to develop and spread. Conversely, regime changes undertaken to promote novel practices need to be accompanied by experiments at the practice level to determine whether they work out well or need to be adapted: a central element of TM. While direct interaction between agents working to achieve change at the two levels is important and elaborated in this 'dual-track governance', intermediaries may also play a pivotal role (Grin 2006, 2010). Research into care farming (the therapeutic use of farming practices) has shown that the embedding of

these intermediaries into one or more regimes is a crucial influence on their effectiveness (Hassink/Hulsink/Grin 2014; Grin 2014). These insights into three different kinds of 'governance work', all in their own way requiring a dual vision, have been deepened on the basis of three different strands of planning theory, focusing on the design of local practices, the shaping of such practices through the adaptation of their structural embedding, and the interconnecting of 'local' and 'global' changes (Grin 2010).

A key aspect of the governance of transitions are its politics, including *powering*. The lack of an adequate conception of power in early versions of the sociotechnical and complex system approaches has been rightly criticized by a variety of authors, who have pointed out that there are a priori grounds for expecting (i) resistance from incumbent actors (Meadowcroft 2007: 308); (ii) inertia from the incumbent regime (Meadowcroft 2005: 488–489); and (iii) competing processes of change (associated with e.g. liberalization or Europeanization), which may or may not help to promote a transition towards a particular, desired direction (Shove/Walker 2007: 767; Meadowcroft 2005: 490). Others have raised the question of how transitions may be influenced in a situation of distributed power (Meadowcroft 2007: 308–312).

Fundamental to addressing this shortcoming is the realization (Grin 2010) that power is not only a quality of actors and their interaction per se. Power is also embedded in structure, something that Arts and Van Tatenhove (2004) have called 'dispositional power.' Transitions by their nature involve structural change, due both to changes in practice and to *longue durée* trends at the MLP's 'landscape' level (which thus also embodies power—structuring power, as Arts and Van Tatenhove call it). Therefore, transition dynamics may as much shape power dynamics as the other way around—in fact, they may be seen as implied in each other. As a corollary, the more fruitful question about power in transition becomes: how may power dynamics and transition dynamics reinforce each other over time?

This opens up novel perspectives on 'powering' in transitions. For example, *longue durée* trends do not determine transition dynamics, but may be key to it since agents may strategically draw upon them in order to interfere in that interaction. Thus, while it has often been claimed that globalization and liberalization by their very nature work against sustainable development, the achievement of the MacSharry reforms in the EU's agricultural policy (Grin/Marijnen 2011) has been analysed as a counter-example, in

which EU commissioner MacSharry strategically drew upon these trends to push for a structural change in the common agricultural policy. Similarly, then minister Mansholt drew on post-war inclinations towards 'Americanization' to promote the modernization of Dutch agriculture, 1945-1970 (Grin 2012). Stirling (2014) has recently argued that contemporarily there seems to be a window of opportunity for a transition to a non-fossil energy regime.

Hoffman has further developed this understanding of powering as part and parcel of transition dynamics, and significantly advanced the point theoretically, framing transitions as intertwined processes of creativity and powering. Inertia and resistance comprise powering and provoke creativity, which in its turn may help open up novel modes of powering. Creativity and powering are understood in relational terms, i.e. the work of creativity and powering is conceived as relating innovative practices to structural elements in relevant fields, while simultaneously adapting these practices to these fields (Hoffman 2013; Hoffman/Loeber forthcoming).

We may conceive of legitimization in a similar way. As Hendriks and Grin (2007) have shown, legitimization often arises in and through the contestation occurring at the interfaces between transition practices and the spheres in which they are embedded. And legitimization too may be understood as relating a novel practice to resources embedded at the regime level (Hassink/Hulsink/Grin 2014).

Seeing and exploiting opportunities for reconnecting practices, regimes and landscape trends involves second-order reflexivity. As we have seen, this may arise from the confrontation between transition practices and a nearby regime. Yet proposals have also been developed within the governance approach for more deliberate instances of the designing of both visions and practices. This has been called (Grin/Felix/Bos et al. 2004) reflexive design or reflexive interactive design (Bos/Groot Koerkamp 2009). It has been epistemologically grounded (Bos 2008) and further developed through practical experience (with actual societal impact) in the area of livestock systems (for an overview of this evolution, see Bos/Grin 2012). Its micro-dynamics have been analysed in terms of how to shift from a perspective rooted in past experience towards one putting a 'different future' centre stage (Lissandrello/Grin 2011). Schuitmaker (2012) has developed a method for identifying which structural regime elements need to change by analysing barriers in transition practices from the perspective of a historical–critical analysis of the regime (Schuit-

maker 2012). Inghelbrecht (2016) has explored how the results of reflexive design exercises may be written into material designs.

The governance approach has thus strongly drawn on the two other approaches' theorizing of the dynamics of transitions, but at the same time added conceptual starting points for understanding the politics of such dynamics, and translated this into proven methods for shaping transitions. By now, this more accurate political understanding is being developed both for the MLP-based sociotechnical approach (e.g. Geels 2014; Raven/Kern/Verhees et al. forthcoming) and for transition management, where the early work by Avelino (2009, 2011) and Kern (Kern/Howlett 2009; Smith/Kern 2009) has now been joined by, for example, Brown/Farrelly/Loorbach et al. (2013), Frantzeskaki/Wittmayer/Loorbach et al. (2014), Voß (2014) and Wittmayer/van Steenbergen/Rok et al. (forthcoming). Apart from its place in these three original approaches, the politics of transitions has become an object of study in and of itself (e.g. Seyfang/Haxeltine 2012; Pel/Teisman/Boons et al. 2012; Jørgensen 2012; Goulden/Bedwell/Rennick-Egglestone et al. 2014; McGuirk/Bulkeley/Dowling 2014; Pesch 2015; Avelino/Grin/Jhagroe/Pel forthcoming).

4.5 The Social Practice Theory and Technical Innovation System Approaches

While, as has just been implied, a range of new approaches has emerged by now, two other approaches emerged simultaneously with the three just discussed. The first is *social practice theory* (Shove/Pantzar 2005; Spaargaren/Martens/Beckers 2006). It seeks to fill two important gaps (Shove/Walker 2007; Spaargaren/Oosterveer/Loeber 2012) in MLP theorizing: the lack of properly accounting for agency, and the reduction of consumption to one dimension of the regime of a system defined by its supply side, thus analytically excluding the possibility of change (co-)caused by changes in consumption. Recognizing that agency should be understood not individually, as rational choice theory would, but as social and embedded, the proponents of this approach listed above have sought to address both shortcomings through bringing into transition theory the concept of social practices, i.e. everyday practices (such as cooking, laundering, getting the children to school), as they are typically and habitually performed in society. In a seminal article, Reckwitz (2002) has

pointed out that such practices bring together, in a particular way, heterogeneous elements such as bodily and mental activities, knowledge and skills, financial resources, material artefacts, and so on. Showering, for instances, brings together things as different as particular standards of cleanliness, a particular bathroom design, a water supply infrastructure, and particular soaps (Shove 2004).

Spaargaren, Oosterveer and Loeber (2012) have connected to Grin's (2010) understanding of the MLP as depicting different levels of structuration of practices and integrated the notion of embedded social practices into the MLP. This introduces as part of the regime objects like refrigerators, intermediary infrastructures like (globalizing) retail firms, and (induced by individualization and cultural globalization) a diversity of lifestyles (Spaargaren/Oosterveer 2010). This approach was used as an analytical framework in an edited volume on transitions in the area of food in OECD countries, and led to a variety of theoretical contributions (Spaargaren/Loeber/Oosterveer 2012). In addition to a wider understanding of the regime, as just exemplified, it also demonstrates different methods of interaction between consumer niche practices and the regime, as well as interactions between the practices of consumption, retailing and production. Such insights may well be developed into an extension of the typology of transition pathways discussed in section 4.2. While the volume's analyses make clear that there is a gross power differential between consumers and retailers, there are also interesting examples of how critical consumers may, eventually, make a difference.

Shove and Walker (2010) provide a thoughtful analysis of how the London Traffic Congestion Zone Scheme has affected citizens' practices of going to work, taking children to school, and so on. In complex ways, the agency of consumers and the complex interference between different practices may yield (partly unintended) patterns, in addition to attempted interventions. In this finding resonate notions like self-organization and emergence, from the complex systems approach to transitions (4.3), which thus may be expanded to better account for the everyday practices of consumers or citizens.

The second approach is the *technical innovation system* approach. A central idea in this approach is that technical innovation requires an adequate innovation system to support the functions needed to nurture a sociotechnical innovation. These functions, derived from Jacobsson and Johnson (2000) and further elaborated by Hekkert, Suurs, Negro et al. (2007:

426–427), are: entrepreneurial activities, knowledge development, knowledge diffusion, guidance of the search, market formation, resource mobilization, and creation of legitimacy. It should be understood that 'innovation system' in this literature focuses on a specific technology, while what was called 'innovation system' in the previous section fulfils similar functions, but on the level of a particular domain, where it is part of the regime.

Rooted, like the sociotechnical and complex system approaches, in evolutionary theory, a basic assumption is that more fundamental innovations, like those involved in a transition, may often not be embedded in an appropriate innovation system. In such cases, so-called 'systemic instruments' (Smits/ Kuhlman 2004) may play important roles: platforms situated in between the institutions of state, market and society, and that bring about the structural connections between the elements needed to support innovation functions. Wieczorek (2014) has contributed to the further development of the notion of a system instrument by elaborating how structural system deficits and systemic problems can be related, so as to inform the design of system instruments.

Hekkert, Suurs, Negro et al. (2007) stress that innovations entail many interactions between these functions, and they mention two 'virtuous cycles' of functions that often occur. One motor driving such virtuous cycles is entrepreneurial action for better structural conditions. Another motor is driven by the 'guidance of the search' function. These are the engines that may drive the emergence and transformation of innovation systems. Meanwhile, empirical studies (e.g. Suurs/Hekkert 2009; Negro/Alkemade/ Hekkert 2012; Gabaldon-Estevan/Hekkert 2013) have yielded significant insight into the driving mechanisms.

From the approaches to transition studies discussed above, the sociotechnical approach is obviously closest to the technical innovation system approach, as both have a sociotechnical focus. Reviews of the relationship between these two conceptualizations (Bergek/Hekkert/Jacobsson 2008; Bergek/Hekkert/ Jacobsson et al. 2015; Markard/Truffer 2008) agree that a *key difference* between the two is that the technical innovation system approach has an individual technology as a focus, and sees the system as comprised of those elements needed for that specific technical innovation, while the sociotechnical approaches focus on the transformation of a system that will fulfil a particular societal need (like food or energy) or, in later work, serve a particular place (like a region or

city). A key point that hitherto has remained unclear is the nature and dynamics relationship between innovation system and regime. While in particular more recent work on technical innovation systems (e.g. Bergek/Hekkert/Jacobsson et al. 2015; Markard/Wirth/Truffer 2016) pays significant attention to their interaction with 'context', the nature of that context remains under-theorized, comprising both 'regimes' (explicitly understood as in MLP literature), and other elements (like legal systems) that in MLP theory would be included under the 'regime'. Also, the dynamics of that context is much less theorized than in MLP-based literature. There seems little interest in integrating insights on, for example, transition pathways, or in an understanding of the differences in temporal scales involved in (slow) changes in the incumbent structural context, the latter's day-to-day impact on innovative practices, and the way in which very slow changes in the wider context ('landscape' in MLP terms) may affect direct structural context.

Yet this literature furnishes an important understanding of the micro-dynamics of building a proper innovation system around a technical innovation, that is, into how a niche-regime may emerge and/or niche experiments may induce regime change. In addition, these insights may be of wider significance: it seems that it is possible to understand regime-building in similar terms—in a wider sense around innovations of a primarily non-technical nature (Hassink/Hulsink/Grin 2016). In order to fully benefit from this contribution to understanding the dynamics and shaping of transitions, such insights should firstly be seen as relevant to the work involved in creating or connecting to new structural elements while drawing on existing ones, and secondly be integrated with MLP theory, including its understanding of pathways.

4.6   Concluding Reflections

In the preceding sections, the three main approaches to transition studies were reviewed. In terms of the first guiding question, they share a portrayal of transitions as interactions between experiments, regime changes and exogenous trends. The sociotechnical approach, empirically rooted in historical case studies, has yielded transition pathways that enable discussion of possible patterns of interaction between these levels in more or less everyday terms. The complex systems approach has generated a more analytical insight into the underlying mechanisms, summarized in various types of transition patterns that underlie the soci-

otechnical pathways. Further conceptual integration would probably promote further development of either. The third, governance theory based, approach draws on these insights while adding an understanding of how the 'politics' (powering, legitimization) of transitions are part and parcel of transition dynamics—thus yielding new insight into both transition dynamics and its politics.

Social practice theory has contributed insight into the agency in the embedded practices which shape transition dynamics, including the previously under-emphasized agency of users and consumers. It can, and should, be better integrated into the MLP. Technical innovation systems theory has a lot to offer in terms of insight into the drivers of transition patterns; this too should be further explored in future research.

Further development of these various approaches and their relations may be both used in and informed by emerging research into novel objects (the financial crisis, the circular economy, the transformation of the welfare state, etc.) as well as novel units of analysis—the unit of analysis of transition research (Grin 2008) has expanded from consisting of mainly societal domains, such as energy, agrifood, mobility, water management and health care, to also including, for example, cities or regions. These relatively recent strands of research may offer novel insights into these original approaches.

Another more recent development in transition research is an increasing awareness of the role of place and space in all five approaches discussed above (Smith/Voß/Grin 2010; Coenen/Raven/Verbong 2010; Truffer/Coenen 2012; Raven/Schot/Berkhout 2012; Wieczorek/Raven/Berkhout 2015; Hansen/Coenen 2015). Places and connections shape regime-niche dynamics for all units of analysis; the governance and social practices approaches have highlighted the importance of proper analysis of the interaction between local, embedded, practices and globalization; and place and space are obviously particularly important when studying regions or cities.

The critical debate about the approaches discussed above may increase over the next few years. Work from about 2008 onwards owes a lot to such criticism, and the debate is still proving useful for further theoretical development (Avelino/Grin/Jhagroe et al. forthcoming). A final ongoing trend concerns the increasing amount of attention being paid to non-developed countries (e.g. Patankar/Patwardhan/Verbong 2010; Vreugdenhil/Taljaard/Slinger 2012; Fatimah/Raven/Arora 2015; Jolly/Raven 2015; Pant/Adhikari/Bhattarai 2015—and many chapters in this

volume). Such studies may help to further develop the various theoretical approaches, not only because novel contexts mean a more varied empirical basis, but also because comparison of European with non-European cases may shed new light on the former—they may, for instance, reveal how much regime dynamics is intertwined with the development of the capitalist welfare state; or how (reflexive) modernization takes different forms in different places. All in all, transition studies is here to stay for a while, and for good reasons.

5   Transformative Science for Sustainability Transitions

Uwe Schneidewind[1], Mandy Singer-Brodowski[2] and Karoline Augenstein[3]

Abstract[4]

Sustainability Transitions require a knowledge production that contributes actively to the Grand Challenges of twenty-first-century societies. Scientific institutions play a key role in this domain in the transformation towards sustainability and peace. Against this background a Transformative Science is needed: a mode of science that not only analyses processes of transformation, but also actively supports and accelerates them. This chapter will introduce the concept of Transformative Science and its implications for (1) the methodologies of transdisciplinary and transformative research, (2) institutional capacity-building for facilitating such a research approach, and (3) the national science systems and national science policies that enable this new mode of knowledge production. The case of the German science system is introduced to describe an ongoing science system transition with special regard to the role of civil society organizations.

Keywords: Transformative science, science system transition, transformative research, transdisciplinarity, governance of science, civil society participation, Wuppertal Institute[5].

5.1   Need for and Definition of 'Transformative Science'

The concept of transformative science is closely connected to international debates about the 'Great Transformation' (WBGU 2011) or the 'grand challenges' announced by the EU (Reid/Chen/Goldfarb et al. 2010). The meaning of this concept and the new role it assigns to science and academia can only be fully comprehended against the background of these debates. Humanity in the twenty-first century is faced with massive upheaval and the challenge of guaranteeing a good life for nine billion people. Planetary boundaries (Rockström/Steffen/Noone et al. 2009) have been discovered that set clear limits for resource-intensive economies, for political systems that are not adequately oriented *towards* social welfare for all, and for the carefree continuation of today's lifestyles and

---

1   Prof. Dr. Uwe Schneidewind is president of the Wuppertal Institute for Climate, Environment and Energy and Professor for Sustainable Transition Management at the University of Wuppertal; Email: <uwe.schneidewind@wupperinst.org>.

2   Mandy Singer-Brodowski is a research fellow at the Wuppertal Institute for Climate, Environment and Energy and a founding member of the German network for student initiatives in sustainability; Email: <mandy.singer-brodowski@wupperinst.org>.

3   Karoline Augenstein is a research fellow at the Wuppertal Institute for Climate, Environment and Energy; Email: <karoline.augenstein@wupperinst.org>.

5   The Wuppertal Institute for Climate, Environment and Energy was founded in 1991, when decision-makers around the world became aware of global climate change caused by humankind as a new global challenge. For more than twenty years now, the Wuppertal Institute has undertaken research and developed models, strategies and instruments for transitions to a sustainable development at local, national and international level. Sustainability research at the Wuppertal Institute focuses on resource-, climate- and energy-related challenges and their relation to economy and society. Special emphasis is put on analysing and stimulating innovations that decouple economic growth and wealth from natural resource use. The overall research focus is on transition processes towards sustainable development. Scientific research towards this end combines its approaches to generate practical and actor-oriented solutions. An overview of current projects of the Wuppertal Institute can be found at: <http://wupperinst. org/en/projects/>.

---

patterns of consumption. The *German Advisory Council on Global Change* (WBGU) therefore claims in its flagship report *World in Transition* that a "great transformation towards a decarbonized society" is needed:

> Adding together all of these challenges involved in the transformation to come, it becomes clear that the upcoming changes go far beyond technological and technocratic reforms: the business of society must be founded on a new 'business basis'. *This is, in fact, all about a new global social contract for a low-carbon and sustainable global economic system* (WBGU 2011: 1).

At the international level, momentum is currently created by the UN's *Sustainable Development Goals* (SDGs). On the one hand, these address the slow progress towards more sustainable development (e.g. in the context of international climate negotiations about a binding agreement) and identify key fields of action. On the other hand, the SDGs serve as a new narrative that describes the necessary change processes; they offer a comprehensive framework for coordinating sustainable development efforts and strategies at regional, national and international levels, and for integrating them in a shared vision of a globally just and much less resource-intensive world society.

The emergence and steady growth of new fields of research, such as transition studies and related approaches focusing on a better understanding of complex system innovations, can also be explained as a phenomenon in this broader context. Current transformation challenges require radical change in infrastructures, institutions and lifestyles, and these have to be dealt with by different sectors and societal subsystems at different but interrelated levels.

In this transformation challenge, science and science policy plays a central—while often underestimated—role. Over the past years, science policy has come to be equated with innovation policy (Martin 2012) and this has contributed to the generation of unrestrained economic growth and the development and diffusion of technologies that have often caused severe and harmful side effects for society and the environment (Beck 1992). Therefore, achieving sustainable development crucially depends on the kind of knowledge that is produced in modern societies. Meeting the key societal challenges of today demands socially robust knowledge that can be applied under diverse, uncertain and unforeseeable conditions. The term *mode-2 science* (Nowotny/Scott/Gibbons 2001) emerged at the turn of the millennium and captures a new mode of scientific knowledge production, which facilitates and argues for a pluralization of the places

where relevant knowledge is produced and of actors involved in the production of knowledge. A central claim in this debate is that a 're-contextualization' (Rip 2011: 5) of science in society is needed in order to accommodate the increasing demand for participation by non-scientific stakeholders and the growing complexity of knowledge production in the age of reflexive modernity.

In this context, transformative science is understood as a mode of science that not only analyses processes of transformation but also actively contributes to them: by developing new methodological approaches, and by explicitly focusing on the institutions shaping scientific knowledge production and science policy at the level of (national) science systems. The concept builds on successful experiences in the field of sustainability science, which has been established in the academic sphere from the early 2000s onwards (e.g. Clark/Dickson 2003; Kates/Clark/Corell et al. 2001). The WBGU has introduced the term 'transformative research' in its flagship report and defines it as research that analyses "transformation processes with regard to their causes, conditions and development" (WBGU 2011: 373) and actively contributes to "transformation processes through specific innovations in the relevant sectors" (WBGU 2011: 373).

Transformative research aims not only at delivering analyses of complex and sustainability-related systems but also at supporting transformational changes in sustainability transitions (Wiek/Ness/Schweizer-Ries et al. 2012). This transformational agenda goes back to the beginnings of the debate about sustainability science (Clark/Dickson 2003: 8059), but in the practice of carrying out sustainability research it is confronted with many challenges (Wiek/Ness/Schweizer-Ries et al. 2012). For instance, engaging an extended peer community for research processes in post-normal science, as suggested by Funtowicz and Ravetz (1993: 752ff.), or concrete user engagement in sustainability research (Talwar/Wiek/Robinson 2011) require a completely new understanding of the role of researchers in the process of knowledge production (Wittmayer/Schaepke 2014). Researchers aiming at participatory knowledge production in complex und uncertain systems and transition processes (Loorbach/Frantzeskaki/Thissen 2011) will need a whole range of new competencies.

Building on strategies of 'transformative research' and introducing the broader concept of 'transformative science' highlights the crucial fact that knowledge production in a transformative mode is always embedded in the institutional context of the established sci-

The German Advisory Council on Global Change (WBGU 2011) distinguishes four transformative pillars of the knowledge society:

- *Transformation research* focuses on "the basic principles, conditions and progression of transformation processes" (WBGU 2011: 351).
- *Transformative research* "supports transformation processes in practical terms", e.g. by developing relevant technological and social innovations, applying methods for facilitating inter- and transdisciplinary research processes, and by actively including non-academic stakeholders (WBGU 2011: 351f.).
- *Transformation education* "makes the findings of transformation research available to society" (WBGU 2011: 352).
- *Transformative education* encourages changes in actual social practices and focuses on creating awareness of concrete options for action and solution approaches (WBGU 2011: 352).
Typification of transformation research and education.

ence system, and this influences and bounds this specific quest for new forms of knowledge production.

Transformative science is not limited to research and education that focuses on analysing sustainability challenges and relevant systems; it goes beyond systems analysis and aims at catalysing and supporting transformation processes towards sustainable development through suitable forms of knowledge production and transfer. Consequently, the concept of transformative science has massive implications for (1) methodologies of transdisciplinary and transformative research, (2) institutional capacity-building for facilitating such a research approach in the field of sustainability science, and (3) national science systems, where this type of institutional change is the subject of controversial debate.

With regard to the methodological challenges discussed in the first part of this chapter, transformative research refers to the discourse on transdisciplinarity, which focuses on the development of research designs suitable for addressing sustainability-oriented research questions. A key aspect is the methodologically robust integration of the different forms of knowledge of different actors and stakeholders. Basic principles of transdisciplinary research have been adopted by global science programmes, such as Future Earth, by introducing concepts of 'Co-Design' and 'Co-Production' of knowledge, which explicitly provide a new role for non-scientific actors.

In addition, transformative science focuses on the institutional dimension regarding the places where knowledge is traditionally produced and reflects on the impact institutional structures have on the science–society interface. An institutional perspective is crucial because inter- and transdisciplinary research approaches have been faced with substantial barriers over the past years. Establishing such approaches requires institutional capacity-building that goes beyond project-based funding (Lyall/Fletcher 2013). In contrast to the methodological issues, the institutional dimension of the change envisaged in the science system remains understudied so far and will be discussed in the second part of the chapter.

Furthermore, the concept of transformative science is at the core of the political controversies that emerge when science actively assumes responsibility for societal developments. A number of controversial issues appear in this debate, for instance, the role of academic freedom versus the societal responsibility of academia, university autonomy versus university management, academic excellence versus transdisciplinarity, fostering innovation and ethics. Tensions in these fields are increased by the demands of external actors (e.g. civil society organizations) for a more open science system. By including a perspective on these issues, transformative science is positioned in the context of new theories of the governance of science, and the focus is explicitly on these negotiation and inter-

action processes. In the third part of this chapter, a discussion of these issues will be presented for the case of the German science system.

5.2 Methodological Challenges of a Transformative Research

A more detailed elaboration of the concept of 'transformative science' has to start by outlining transformative research, which is deeply intertwined with the discourse of transdisciplinarity and the basis of 'transformative science'.

Transformative research takes as its starting point various societal transformation challenges in the context of urban transitions, transitions to sustainable energy and transport systems, dealing with resource scarcity and the pressures caused by unlimited economic growth. The complexity of such transition processes can be illustrated by the example of the German energy transition ('Energiewende'), i.e. the nuclear phase-out and restructuring process of the entire German energy system, oriented towards increased energy efficiency and the development of renewable energies: This transformation not only includes the substitution of traditional technology but also supports social innovations between the affected stakeholders (companies, decision-makers, users etc.).

The energy transition is a typical example of a complex problem, in the sense that the object of study can hardly be separated from its context (Scholz/Lang/Wiek et al. 2006: 228). Such problems are deeply embedded in a complex system (Scholz/Tietje 2002). Most sustainability challenges can be described as 'wicked problems' which do not fit the disciplinary logic of academic problem definitions. Against the background of global unsustainable developments such as climate change, the term 'super-wicked problems' has been recently introduced. 'Super-wicked problems' are characterized by four key features: "time is running out; those who cause the problem also seek to provide a solution; the central authority needed to address them is weak or non-existent; and irrational discounting occurs that pushes responses into the future" (Levin/Cashore/Bernstein et al. 2012: 124). The urgent need to address these super-wicked problems using scientific approaches underlines once again the need for a transformational research agenda.

Nevertheless, transformative research basically draws on the methods developed in the field of transdisciplinary sustainability science, which emerged as a distinct field of research around the turn of the millennium (Clark 2007).

Transdisciplinarity can be defined as "a reflexive, integrative, method-driven scientific principle aiming at the solution or transition of societal problems and concurrently of related scientific problems by differentiating and integrating knowledge from various scientific and societal bodies of knowledge. This definition highlights the need for transdisciplinary research to comply with the following requirements: (a) focusing on societally relevant problems; (b) enabling mutual learning processes among researchers from different disciplines (from within academia and from other research institutions), as well as actors from outside academia; and (c) aiming at creating knowledge that is solution-oriented, socially robust (cf., for example, Gibbons 1999), and transferable to both scientific and societal practice." (Lang et al. 2012: 26f.).

This quotation summarizes the state of the art of the debate about transdisciplinarity and it shows that disciplinary approaches of defining relevant aspects of a broader research question and suitable methods for addressing these remain the core of good scientific practice. However, it is imperative that different disciplinary perspectives are connected and related to each other early in the research process, in order to be able to gain a comprehensive understanding of complex problems—and to cultivate a much deeper appreciation for the approaches and methods of other disciplines. In the case of transdisciplinary research processes, non-academic stakeholders are integrated as well, in order to provide relevant practical and transformation knowledge. Roland Scholz coined the simple yet ambitious phrase "disciplined interdisciplinarity in transdisciplinary processes" (Scholz 2011: XVII), which captures the central idea of the whole endeavour.

Thus, a disciplinary approach remains the essential starting point for transdisciplinary and transformative research. However, since sustainability science has to cope with complex systems and transitions processes, characterized by huge uncertainties and ambiguity (Kates/Clark/Corell et al. 2011, 641), there is an additional need for (1) cooperation in interdisciplinary teams and (2) participatory involvement of affected stakeholders (Loorbach/Frantzeskaki/Thissen 2011: 80f.). The basic idea is that such an approach leads to the production of socially robust knowledge.

5.2.1 Status Quo of Transdisciplinary Science?

An important milestone for transdisciplinary research was the conference "Transdisciplinarity: Joint Problem Solving among Science, Technology and Society" held in Zürich in 2000 (Klein/Grossenbacher-Mansuy/Häberli et al. 2001), which stimulated an intensive debate on the value, goals and processes of transdisciplinary research.

In transdisciplinary research processes, non-scientific actors are ideally integrated into all stages of a research process, i.e. from the formulation of the research question and the selection of methods to the discussion of findings and results. The basic aim is to arrive at a shared identification and systematization of the problem that is to be studied, and to ensure a continuous feedback process between researchers and non-scientific actors throughout the research process and the subsequent up-scaling of results (Hirsch Hadorn/Biber-Klemm/Grossenbacher-Mansuy et al. 2008). Following Jahn, Bergmann and Keil (2012: 7f.), this requires an integration of the perspectives of both actor groups at three levels:

1. at an epistemic level, the different kinds of knowledge (scientific knowledge and practical knowledge) of the involved actors need to be integrated;
2. at a social-organizational level, the varying interests and activities of involved actors need to be integrated;
3. at a communicative level, the different (professional) languages and forms of expression of the involved actors need to be integrated, in order to arrive at a shared understanding of the problem, the research process and the results; this also needs to be expressed in some form of language conversion.

The three levels of integration show that transdisciplinary knowledge production requires organizational framework conditions that facilitate cooperation between researchers and non-scientific actors at eye level. At the same time, creating acceptance and the conditions for epistemological pluralism and reflexivity is a central aim of institutional change for sustainability-oriented knowledge production (Miller/Munoz-Erickson/Redman 2011: 188f.). Researchers who have been successful in current science systems for a considerable amount of time have to develop this kind of reflexivity, because otherwise they tend to rely on their academic routines and action strategies (e.g. using highly specialized professional languages), making communication with non-scientific stakeholders extremely difficult.

Discourses on transdisciplinarity have gained substantial momentum over the past ten to fifteen years. Important impulses have been created by the discussion of suitable quality criteria for this new mode of science. Quality criteria have been defined for the different phases of a transdisciplinary research process: "problem identification and systematization, participative generation of solution-oriented and compatible knowledge, re-integration and application of the generated knowledge" (Vilsmaier/Lang 2014: 101). Most experts in the field of transdisciplinary research (Jahn 2008; Lang/Wiek/Bermann et al. 2012) have defined similar quality criteria for the different phases of the research process.

Most recently, the idea of transdisciplinarity has gained a prominent position in the redefinition of 'Global Change Research'. In the newly constituted programme of Future Earth Science, the concepts of Co-Design of research questions and processes and Co-Production of knowledge play a key role. The discourse on transdisciplinarity has successfully entered the field of science and science policy.

However, an overview of transdisciplinary research projects shows that there is still a large gap between the aspirations of an ideal-typical transdisciplinary sustainability science and the reality of actual research projects: "there is a gap between 'best practice', transdisciplinary research as advocated, and transdisciplinary research as published in scientific journals" (Brandt/Ernst/Gralla et al. 2013: 5). Furthermore, transdisciplinary research is currently still a niche discipline in the science system as a whole. The academic mainstream is firmly based on traditional disciplinary quality criteria. Central questions thus remain: what institutional framework conditions are needed to facilitate transdisciplinary research, and what are the differentiation criteria delineating the boundaries between transdisciplinary research and transformative science?

5.2.2 From Transdisciplinary Research to Transformative Research

The outline of the basic principles of transdisciplinary research presented above (cf. also Jahn/Bergmann/Keil 2012; Lang/Wiek/Bermann et al. 2012) shows that a new relationship between researchers and non-scientific actors is central. This new relationship is built on the acceptance of the different epistemological backgrounds of the involved scientific and non-scientific research partners and it aims at the generation of knowledge that is socially robust and solution-ori-

ented. The concept of transformative research further stresses this aspiration: it contributes to the generation of different forms of knowledge and actively catalyses concrete transformation processes.

In addition to the principles of knowledge integration developed in the field of transdisciplinary research, a central element of transformative research is active intervention in a specific field of research. Such an interventionist character is described by the WBGU in its conceptualization of transformative research:

> It supports transformation processes in practical terms through the development of solutions and technical and social innovations, including diffusion processes in economy and society, and opportunities for their acceleration, and demands, at least in part, systemic perspectives and inter- as well as transdisciplinary procedure methods, including stakeholder participation (WBGU 2011: 351f.).

The aim of transformative research is to actively generate impulses for change in society and to intervene in concrete transformation processes by scientific means and in the course of a research process. It contributes to an Experimental Turn in the social sciences, which has been observed in political science as a "significant change in perspective" (Morton/Williams 2010: 3) towards a focus on experiments as a suitable method for studying causality in complex real-life settings (Greenberg/Shroder 2004). This experimental turn includes a move away from abstract modelling approaches that are independent of specific contexts and introduces a new focus on analysing systems through 'real-world experiments' (Groß/Hoffmann-Riem/Krohn 2005). The aim of real-world experiments is to identify characteristic patterns in transformation processes and to generate 'pattern languages', which provide orientation to concrete actors involved in transformation processes (Schneidewind/Singer-Brodowski 2014: 73).

The interventionist character of transformative research also requires a more explicit focus on (sectoral) societal subsystems and on catalysing, accompanying, analysing and reflecting on complex system innovations in these systems. In this way, an active contribution to transformation processes is generated. Knowledge generated in these types of research processes is socially and scientifically robust. From a methodological point of view, this research mode is similar to the field of 'action research'. Together with the focus on societal systems, this makes research in real-world laboratories a suitable strategy (cf. Schneidewind/Scheck 2013).

However, the interventionist character of transformative research is a controversial issue in the field of transdisciplinary research, because it implies a redefinition of the role of science in society, where science is no longer just a provider of objective and neutral knowledge to politics, economy and society. Mittelstraß stresses that transdisciplinary research is in fact a new 'scientific and research principle', but that it does not have a direct impact on scientific standards of rationality (2003: 22). Jahn, Bergmann and Keil (2012: 2) also stress that transdisciplinarity is a "research approach, not a theory, methodology or institution". Nonetheless, the institutional consequences of transdisciplinarity 'between mainstreaming and marginalization' are spelled out clearly: "the true challenges of transdisciplinary collaboration are underestimated and [that] those who take them seriously become marginalized" (Jahn/Bergmann/Keil 2012: 1). Yet still, the necessity of associated forms of institutional change is only hinted at. A discussion of the institutional consequences of a new mode of sustainability science expands the focus of transformative research and calls for developing a broader notion of transformative science.

5.3 Institutional Challenges of a Transformative Science

It has been shown that, in principle, transdisciplinary research is possible and it has developed fruitfully over the past years as regards methods and fields of application. However, why has its diffusion in actual research practice and across concrete research projects been relatively slow? It is argued here that this is mainly due to the lack of a focus on an institutional perspective. In order to facilitate inter- and transdisciplinary as well as transformative research, new institutional framework conditions in universities and other scientific organizations are needed. A number of arguments are relevant in this context:

1. Transdisciplinary and transformative research is in conflict with the established disciplinary organization of science. A brief look at the field of science studies shows that the science system follows a distinct logic of functioning which is detrimental to transdisciplinary and transformative aspirations: scientific communities can be described in terms of epistemic communities that tend to develop within disciplinary boundaries and focus on specialization within their specific fields of research. They withdraw from non-scientific perspectives, from the

political regulation of science and thus also from societal expectations (cf. e.g. Gläser/Lange 2007: 441). "The autopoietic nature of disciplines assures their perennial and, in principle, their unlimited regeneration, growth and differentiation" (Weingart 2014: 163). Efforts towards the establishment of transdisciplinary and transformative research thus remain an uphill battle, if they do not explicitly include an institutional perspective, because they are in conflict with the deep structural principles of scientific communities. The disciplinary organization of science (especially within universities) limits the possibilities for designing research projects that are motivated by concrete societal challenges from the outset.

2. A closely connected argument is related to established reputation-building and qualification mechanisms in the science system, which is firmly placed within the disciplinary logic of academia. Over the past decades, scientific impact has emerged as the key criterion for assessing the quality of research as well as of individual researchers. Science policy instruments are also geared towards increasing scientific impact—together these factors prove to be a disincentive for engaging in transdisciplinary research. Scientists focusing on transdisciplinary research early in their career face major barriers in their further academic career. Therefore, identifying measurable indicators of societal impact (e.g. Bornmann 2013) are decisive for the further development of sustainability science. Additionally, institutional framework conditions need to be established within universities (specific research groups, institutes, faculties) that offer a protected space for discussing societal quality criteria for transdisciplinary research and developing career pathways in accordance with such criteria.

3. Adopting a perspective on real-world problems that guides the research process and organizing research based on transdisciplinary and transformative principles questions the self-conception of science and individual researchers. Tensions emerge in the related debates about autonomy versus freedom of research and lead to massive controversies in the realm of science policy. It can safely be assumed that scientific self-conceptions represent the most prominent barriers to institutional change because they touch upon the issue of freedom of research, which is argued to be at risk where science focuses more explicitly on societal challenges. It is feared that science as a whole will be increasingly politicized (Shinn 2002), if

external expectations are entering the safe haven of academia. A common accusation thus centres on the 'normativity' of transdisciplinary and transformative research. However, this criticism in fact applies to any field of research that avoids making inherent norms and values transparent and hides behind seemingly 'objective' data. Again, the field of science studies provides an important contribution to this debate, showing that social negotiation processes within science have always shaped the generation of new (and only allegedly objective) knowledge (Felt/Nowotny/Taschwer 1999: 136ff.). A crucial example in this context is the current state of economic research, which has focused on objective calculations and thereby failed to predict dramatic developments during the financial crisis, and up until now has ignored substantial foundations of economic activity, such as natural capital, which are not included in common economic models and calculation methods. In contrast, transdisciplinary and transformative research make different forms of knowledge (e.g. the target knowledge of societal stakeholders regarding desirable futures) explicit and integrate it into a cooperative research process—in this way being fully transparent and thus complying with the most fundamental requirement of good scientific practice (Schneidewind/Singer-Brodowski 2014: 380). While debates about normativity and academic freedom are often avoided in the sustainability science community, they are a central element in the concept of transformative science.

A final reason for the slow development of transdisciplinary research over the past years has to do with the lack of 'transformative' infrastructures, i.e. the arenas in which sustainability scientists can discuss such fundamental questions and at the same time have the opportunity to develop new methods for and approaches to a more interventionist research process. The decisive impact of favourable structural conditions can be shown for the case of the Leuphana University of Lüneburg, where the foundation of the Faculty of Sustainability has allowed for the integration of approaches from the natural and social sciences. As a result, the Faculty of Sustainability has not only emerged as an important think tank in the German field of sustainability science, it also plays an important role in the education of a new generation of young scientists thinking and working in a transdisciplinary fashion.

Transformative science calls for an institutional revolution if it is to contribute to the mainstreaming

of sustainability science. This distinguishes transformative science from other concepts (post-normal science, action research, intervention research, transdisciplinary research), because they call for an alternative form of doing research (for sustainability) and the changing roles and competencies of researchers in the concrete research processes. However, they lack a perspective on the institutional framing, which is needed to provide additional space and resources for transformative research, as well as suitable incentives and structures, which reduce the risk for sustainability researchers of being permanently overburdened.

The necessary institutional change depends not only on the various academic institutions themselves (universities, non-university research institutes, departmental research in government ministries, that should enable research processes across single disciplines and in cooperation with non-academic stakeholders), but also on those agencies shaping the framework conditions for academic knowledge production, such as administrative agencies, scientific policy advisors and other relevant political authorities (that are called to facilitate these non-conventional research approaches with a focus on a societal impact). Finally, change is needed at the deeper level of implicit routines, self-conceptions and paradigms in the science system, which has been shaped by the institutional framework conditions.

Transformative science actively contributes to societal transformations towards sustainable development and is itself subject to a continuous transformation process, where new interrelations between specific national or regional science systems and other societal subsystems are forged. This affects also the level of the curriculum and higher education, which should be oriented more towards societal challenges and foster education for sustainable development.

The interplay of change towards transformative science approaches and the related institutional change has been defined in terms of a mode-3 science (Schneidewind/Singer-Brodowski 2014: 103ff.). It builds on the concept of mode-2 science (Nowotny/Scott/Gibbons 2001) and further develops it as a concept of continuous self-reflexion of science and an opening-up of the science system with a view to societal transformation challenges. Mode-3 science is further based on the concept of third-order change or higher-order learning as developed in system theory (Sterling 2003: 127 ff.), which goes beyond the reflection of implicit routines during learning processes, and conceptualizes epistemic change, "a corrective change in the system of alternatives from which choice is made" (Bateson 1972: 293). This type of change can be fostered by actively including civil society actors, because civil society organizations can function as an external corrective with a critical perspective on the 'blind spots' in the science system. Defining transformative science in terms of mode-3 science includes basic principles such as "plurality, heterodox thinking and inclusion of civil society. At the same time the normal-science-mode is not negated but transcended" (Schneidewind/Singer-Brodowski 2014: 123).

Sophisticated approaches to delineating a mode-3 knowledge production have described it in terms of an advancement of the triple helix (i.e. the interplay of science, politics and industry) to a quadruple helix that also includes civil society (Carayannis/Campbell 2012). "The Mode 3 Knowledge Production System architecture focuses on and leverages higher order learning processes and dynamics that allow for both top-down government, university and industry policies and practices and bottom-up civil society and grassroots movements initiatives and priorities to interact and engage with each other towards a more intelligent, effective, and efficient synthesis" (Carayannis/Campbell 2012: 3).

Mode-3 science places academic knowledge production in a context of societal challenges and broadens the set of relevant scientific actors to also include civil society, and it discusses the related institutional implications with regard to relevant forms of knowledge, scientific organizations and quality criteria for research.

5.4 Achieving Institutional Self-transformation: Towards a 'New Governance of Science'

5.4.1 From Science Policy to Governance of Science

A focus on institutional mechanisms is instructive with regard to the science system as a whole, and especially in the context of its political framework conditions. The way in which political framework conditions for a specific field of research have developed is regularly discussed, particularly by researchers as the concerned parties who have to react to new emphases in research funding programmes. Apart from this, these issues have been analysed in the field of 'science policy research', where the political steering processes of the science system are studied. Relevant questions in this field deal with issues of the

effectiveness of science policy, science policy as innovation policy (Martin 2012), and the changing role of steering committees. New science policy instruments have internationally contributed to a strengthening of decision-making power by university boards and thus to greater flexibility and responsiveness towards external demands (Jansen 2010: 47). Science policy research also studies the changing interplay between industry, politics and science, i.e. the triple-helix model (Etzkowitz/Leydesdorff 2000).

Based on the current state of research in the field of science studies, it can be shown that the science system is confronted with dynamic change processes and shifting boundaries, where new demands are voiced by industry or civil society actors and media penetration is increasing. These changing conditions also have a massive impact on science policy itself, as well as on research carried out in this field. "These transformations require ... a fundamental change in perspective in science policy: from traditional 'science-policy making' to the 'governance of science' which is currently taking shape" (Grande/Jansen/Jarren et al. 2013: 19, translation by authors).

In general, a governance approach provides a perspective on negotiation processes and the interdependencies of actors in a specific field. Governance theories adopt a social science perspective and analyse patterns of handling interdependencies between actors (Schimank 2007: 29). The term governance depicts the interplay of "all co-existing forms of collectively regulating societal issues: from the institutionalized self-regulation of civil society, to the different kinds of interaction between public and private actors, and the sovereign actions of state actors" (Mayntz 2003: 72, translation by the authors). The following characteristics of governance approaches are identified by Grande, Jansen, Jarren et al. (2013: 20, translation by authors):

1. 'Emphasis on non-hierarchical forms of providing public goods,
2. a critical perspective on the nation state as the exclusive provider of public goods,
3. a non-hierarchical integration of private actors in the provision of public goods,
4. the complexity of political action in a world of blurred boundaries and, following from this,
5. the 'necessity of coordination (of action) and, beyond that, of cooperation (between different actors)'.

The governance debate has over the past years spread out into an increasingly differentiated field. A promi-

nent strand of research has developed around the concept of reflexive governance, which describes governance processes and policy analyses as "interlinked with and open to feedback from broader social, technological and ecological changes, both in terms of innovative action and structural change" (Voß/Smith/Grin 2009: 280). The field of transition studies has also built on the concept of governance (Chappin/Ligtvoigt 2014: 717) and explicitly emphasizes the importance of reflexive approaches.

The theoretical positioning of transformative science in a context of 'governance of science' emphasizes a move away from top-down steering processes; it takes up the impulses from science politicians and statistically analyses their effects. The theoretical approach of science governance includes a more diverse set of actors and external demands (e.g. by civil society) in its analyses, since they have begun to influence academic knowledge production (Jansen 2007).

The role of civil society as an increasingly active agent in science policy shows the value of such a broadened perspective. In current discussions of science policy and in the field of science studies, the analysis of negotiation processes and the handling of interdependencies between researchers and civil society actors play only a minor role. In the following section, the case of Germany shows the increase in dynamics caused by the more active involvement of civil society organizations in science policy.

5.4.2 The Role of Civil Society in the Governance of Science

Organized civil society has not entered the field of science policy as an independent stakeholder so far. Apart from a few exceptions, theoretical analyses of civil society as a stakeholder in the field of science policy are hardly to be found (Wehling/Viewhöver 2013). At the same time, civil society organizations do play a key role in fostering societal transformation processes. However, they can only fulfil this role adequately if they can rely on scientific expertise in sustainability-related challenges.

Transfer of knowledge and expertise has traditionally worked well in specific cases in Germany, where civil society organizations such as the large environmental associations were well connected with academic partners in specific types of universities. "Together with the growing environmental movement, a large number of reform universities were founded in the 1970s. In these universities, controversially discussed issues such as environmental protection played an

important role and many professors were appointed who focused on research questions close to the concerns of environmental associations" (Schneidewind/Singer-Brodowski 2014: 309). Such a pattern of transferring knowledge between civil society and science has not been broadly diffused beyond the issue of environmental protection throughout the science system as a whole, but this is nonetheless a valuable example of successful cooperation.

This type of close cooperation deteriorated with the changes in the science systems sketched above. "The generation of professors appointed in the 1970s is resigning. Many of their professorships are not reappointed or with severely changed denominations. Environmental associations suddenly experience the ... results of a self-reducing science system that solely focuses on inner-academic disciplinary expertise" (Schneidewind/Singer-Brodowski 2014: 309). Pressing questions voiced by civil society are not matched with sufficient amounts of research funding. Therefore, the large environmental associations, such as BUND,[6] have published their own science-political position papers over the past few years (e.g. BUND 2012). These position papers highlight the discrepancies between the funding priorities of the Federal Ministry of Education and Research and the research questions that, from the perspective of civil society, are decisive for achieving sustainable development: for instance, instead of spending billions of euros on technological innovation and the development of e-mobility, research projects should rather focus on the development of new concepts of mobility.

Another large environmental association in Germany, NABU,[7] has intensively dealt with the science-political strategy of the German government in the field of 'bio-economy' and has, in 2011, published a study on the specific focus of the research programme on 'bio-economy', worth two billion euros (NABU 2011). The study showed that the adopted research strategy focuses almost exclusively on technological solutions and basically ignores the position of civil society. NABU is also the first environmental

association that has established among its staff the official position of an advisor for research and science policy, whose task it is to integrate the different policy fields within NABU with the field of science policy.

The various science-political activities of the German environmental associations have increasingly emerged as an important catalyst for a more sustainability-oriented science policy (similar initiatives at an international level are presented in box 5.2). In this way, they support the role of other large stakeholders, such as the independent sustainability research institutes and students, who are actively involved in the transformation of the science system and of universities. In 2012, concerted activities resulted in the foundation of a common platform, 'Forschungswende' ('Research Transition'), which independently voices their demands, such as the integration of civil society issues in the conceptualization and calls for new research programmes. These demands were taken up in the coalition agreement of the new German Government (2013 – 2017). Organized civil society has thus become established as an important new player in the field of science policy and its participation demands have contributed to an opening-up of science policy towards the great societal challenges. Such initiatives are not limited to environmental lobby groups but also include stakeholders in other fields directly and personally affected by (a lack of) research, such as patient associations and consumer organizations (cf. Wehling 2012). Ober (2014) argues that involving civil society actors can contribute to a democratization of science policy, because the increasing tendency to make science-political decisions in expert commissions that are not democratically elected has led to an exclusion of citizens in this policy field.

Including civil society in science policy can develop an additional potential. Wehling and Viehöver (2013) describe a double participation of civil society in science. On the one hand, it can offer welcome contributions in agenda-setting processes, which often play a role in politically sensitive fields (e.g. nuclear technology, genetic engineering) and where civil society involvement can contribute to greater societal acceptance of new technologies. On the other, it can also offer "unwelcome civil society participation", for instance, in cases where patient organizations successfully demand research on rare diseases and through continuous lobbying achieve the establishment of new research programmes. It is argued that "civil society organizations can play an important role for the governance of science, especially when they proactively and in self-organized ways contribute to the

6 Friends of the Earth Germany (Bund für Umwelt und Naturschutz Deutschland, BUND) is an environmental NGO with currently more than 480,000 members and supporters in Germany. More information can be found at: <http://www.bund.net/ueber_uns/bund_in_english/>.

7 The *Nature and Biodiversity Conservation Union* (Naturschutzbund Deutschland, NABU) is one of the oldest environmental associations in Germany with currently more than half a million members and supporters (see at: <http://www.nabu.de/en/nabu/>).

Box 5.2: Global Efforts towards Transformative Research and Civil Society Participation. **Source:** The authors.

'Future Earth' is a global research programme and coordinating platform for inter- and transdisciplinary research on transformations towards sustainable development. It was launched by the UN (including UNESCO, UNEP, and UNU), the *International Council for Science* (ICSU), the *International Social Science Council* (ISSC), and the Belmont forum of funding agencies. It is not only a platform for connecting scientists; its explicit aspiration is to generate knowledge together with societal partners in co-design and co-production processes. For more information see: <http://www.futureearth. org>.

The ISSC has developed a global social science research agenda on global environmental change: *The Transformative Cornerstones of Social Science Research for Global Environmental Change* (see chapter 14 by Arizpe/Price/ Worcester in this volume). This agenda originates from the idea that co-designing research processes and co-producing knowledge together with civil society is imperative for addressing sustainability challenges in a solution-oriented way and for achieving actual societal impact. It also calls for institutional change in the global science system, since there are no adequate funding structures for this type of research (see at: <https://igfagcr.org/sites/default/files/ news/issc_transformative_cornerstones_report.pdf>).

---

development and design of research and technology" (Wehling/Viehöver 2013: 213, translation by authors).

Thus, external demands by civil society can be included in theoretical analyses in the field of the governance of science—in contrast to research approaches with a more traditional focus on science policy—and the concrete impact of civil society on the science system as a whole can be studied in theoretically differentiated ways. Furthermore, a governance approach is suitable for capturing all the relevant negotiation and interaction processes that have an impact on the science system. In this context, the demands for participation and the necessary processes play an important role. A perspective on the science system and science policy against the background of the century's major challenge of achieving sustainable development can be captured in terms of 'governance of science' as a comprehensive concept that is close to reality and that facilitates the analysis of the complex interdependencies in the science system. Transformative science is positioned in this exact context.

5.5 Conclusion

Humanity is facing massive challenges. The important role of science in contributing to sustainability transitions is so far only partially being recognized. This chapter has introduced the concept of transformative science, which aims at catalysing the necessary processes through suitable forms of knowledge production. The concept of transformative science emerges from three specific strands of thought:

1. Transformative science is based on debates about transdisciplinary/transformative research and emphasizes the aspirations of scientists to inter-

vene in complex systems and adopt a new mode of research carried out in real-world laboratories.

2. Transformative science not only focuses on the problem dimensions of sustainability science, but also adopts a perspective on the necessity for institutional change, in order to build the framework conditions for better sustainability science.

3. Transformative science also focuses on the science system as a whole, which is itself facing massive transformations. Building on theoretical approaches of the 'governance of science', it argues for non-hierarchical forms of organization in science and the acceptance of external actors (such as organized civil society), which are playing an increasingly important role in national science policy.

Change processes that have contributed to an opening-up of the science system have briefly been sketched for the case of the German science system (Schneidewind/Augenstein 2012). Science system transformations, in the larger context of transitions to sustainability, require a process of reflection on the institutional conditions for a broadening and a quality enhancement of sustainability sciences as a whole. A science system transition presents a complex challenge, but it is not a lost cause. The German example shows how reform processes extending over twenty years have prepared the ground. Even though the German case cannot be directly compared with other countries, it can be assumed that structural similarities can be observed in other cases. This has been illustrated by examples of global initiatives such as the Future Earth programme and the global change research agenda of the International Social Science Council.

Part II   Aiming at Sustainable Peace

6   The Psychological Components of a Sustainable Peace: An Introduction

Morton Deutsch and Peter T. Coleman

Abstract

The purpose of The Psychological Components of a Sustainable Peace, a book edited by Peter Coleman and Morton Deutsch (Coleman & Deutsch, 2012), is to enhance understanding of sustainable peace by supplementing the standard approach of studying the prevention of destructive conflict, violence, war and injustice with the equally important investigation of the promotion of the basic conditions and processes conducive to lasting peace. For in addition to addressing the pervasive realities of oppression, violence and war, peace requires us to understand and envision what alternatives we wish to construct. Recognizing the ultimate need for multidisciplinary frameworks to best comprehend and foster sustainable peace, we hoped to elicit what contemporary psychology might have to contribute to such a framework. This chapter provides a brief historical and conceptual context for the many fine scholarly chapters that follow in The Psychological Components of a Sustainable Peace (Coleman/Deutsch 2012).[1]

Keywords: Sustainable peace, war prevention, cooperation, conflict resolution, social justice, power, needs and emotions, psychodynamics, creative thinking, reconciliation

6.1   Introduction

William James, the first peace psychologist, was a most distinguished scholar and also an insistent public voice on issues of war and peace. He was deeply opposed to imperialism and the war fever with which it was associated. He was at one time the vice president of the Anti-Imperialist League, and he published articles and letters in newspapers as well as making many speeches against the Monroe Doctrine, the Spanish-American War, the colonization of the Philippines and Cuba, and so forth (Perry 1948).

James was opposed to war but he admired the heroic and courageous actions associated with the military. For James, the appeal of war and the military did not come primarily from people's negative predispositions, but from their desire to face challenge and adversity and, in so doing, to realize their potentials in such virtues as fidelity, cohesiveness, tenacity, and heroism. In his famous paper, *The Moral Equivalent of War* (James 1917), he sought to articulate how the manly virtues associated with the military and war could find expression in the midst of a pacific civilization and thus be a moral substitute for war. This chapter takes a different orientation than that of James and much of psychological writings related to issues of war and peace. Their focus has mainly been on what psychological theory and research can contribute to the very important concern, *the prevention of war.* *The Psychological Components of a Sustainable Peace* (Coleman/Deutsch 2012) is concerned with what psychological theory and research can contribute to the promotion of a *harmonious, sustainable peace.*

Underlying this orientation is our belief that promoting the ideas and actions which can lead to a sustainable, harmonious peace can not only contribute to the prevention of war, but will also lead to more positive, constructive relations among people and nations and to a more sustainable planet. This chapter has

---

1   This chapter was first published as the introductory chapter by the authors, in: Coleman, Peter T.; Deutsch, Morton (Eds.): *Psychological Components of Sustainable Peace. Series: Peace Psychology Book Series* (New York: Springer 2012). The permission to include this text was granted by Springer in Heidelberg in 2013. The text has been updated and the most recent scientific literature has been added by the authors.

three brief sections: (1) Psychological contributions to the prevention of war and violent, destructive conflicts; (2) The nature of a sustainable, harmonious peace; and (3) The psychological components of a sustainable, harmonious peace.

6.2 Psychological Contributions to the Prevention of War and Violent, Destructive Conflicts

6.2.1 Debunking the Inevitability of War

One of the earliest and most important contributions of psychologists and other social scientists was to debunk the myth that war was inevitable because of mankind's innate aggressiveness. As early as 1945, the Society for the Psychological Study of Social Issues published a book, *Human Nature and Enduring Peace* (Murphy 1945), which included a statement endorsed by the leading psychologists of that time, "If man can live in a society which does not block and thwart him, he does not tend to be aggressive; and if a society of men can live in a world order in which the members of the society are not blocked or thwarted by the world arrangements as a whole, they have no intrinsic tendency to be aggressive" (Murphy 1945: 20).

On 16 May 1986 a multinational and multidisciplinary group of scientists, organized by David Adams (a psychologist), issued the *Seville Statement on Violence,* which was subsequently adopted by UNESCO on 16 November 1989. The statement was designed to refute "the notion that organized human violence is biologically determined". The statement contains five core ideas. These ideas are:

1. It is scientifically incorrect to say that we have inherited a tendency to make war from our animal ancestors.
2. It is scientifically incorrect to say that war or any other violent behaviour is genetically programmed into our human nature.
3. It is scientifically incorrect to say that in the course of human evolution there has been a selection for aggressive behaviour more than for other kinds of behaviour.
4. It is scientifically incorrect to say that humans have a 'violent brain'.
5. It is scientifically incorrect to say that war is caused by 'instinct' or anysingle motivation.

The statement concludes: "Just as 'wars begin in the minds of men', peace also begins in our minds. The same species who invented war is capable of inventing peace. The responsibility lies with each of us" (Adams/Barnett/Bechtereva et al. 1990).

Another myth that has been debunked is that there are no peaceful societies. Much work by anthropologists has demonstrated the existence of many peaceful societies, large as well as small. Some excellent books about peaceful societies are: Fry (2006), *The Human Potential for Peace: An Anthropological Challenge to Assumptions about War and Peace,* Howell and Willis (1989) *Societies at Peace: Anthropological Perspectives,* and Kemp and Fry (2004) *Keeping the Peace: Conflict Resolution and Peaceful Societies around the World.*

6.2.2 Psychology and the Prevention of War

After the end of World War II, stimulated by the development of nuclear weapons, the emergence of the United Nations, and the development of the Cold War between the Soviet Union and the United States, a significant number of psychologists began to become active in applying psychology to the prevention of war. Such psychologists as Ed Cairns, Leila Dane, Joseph de Rivera, Morton Deutsch, Daniel Druckman, Ronald Fisher, Susan Fiske, Jerome Frank, Irving Janus, Herbert Kelman, Paul Kimmel, Evelin Lindner, Susan McKay, Susan Opotow, Charles Osgood Dean Pruitt, Ann Sandon, Milton Schwebel, Ervin Staub, Richard Wagner, Michael Wessels, Ralph White, and many others were very active in writing papers, giving talks, and participating in conferences with citizen groups as well as with officials from the US State and Defense Departments. They wrote about: motivations and misperceptions which led to war; such processes as 'autistic hostility', 'self-fulfilling prophecies', and 'unwitting commitments' that perpetuate destructive conflicts; they analysed and criticized the psychological assumptions involved in 'nuclear deterrence'; they considered processes for reducing tension and hostility such as mediation and GRIT (the *graduated reduction in tension*); they identified 'groupthink' which, in tense situations, limits the alternatives of interpretation and action available to the group; they identified the conditions which give rise to destructive rather than constructive resolution of conflict; they analysed current international hostilities such as the Cuban Missile Crisis and the Vietnam War in terms of how psychological factors affected their development and course. Scholars from other disciplines (political science, economics, sociology, law, etc.) often participated with psychologists in multidisciplinary books

and conferences; most notably Andrea Bartoli, Jacob Bercovitch, Kenneth and Elise Boulding, Roger Fisher, Mary Parker Follett, Johan Galtung, Ted Gurr, Robert Jervis, Debra Kolb, Victor Kremenyuk, Louis Kriesberg, Jean Paul Lederach, Chris Mitchell, Robert Mnookin, Linda Putnam, Anatol Rapaport, David Riesman, Harold Saunders, Thomas Schelling, Gene Sharp, Larry Suskind, William Ury, and William Zartman.

They wrote about such topics as: arms control and disarmament; non-physical methods of disarmament; economic steps toward peace; East and West; military defence; reducing international tensions; building a world society; international cooperation and the rule of law, ethnic conflicts, and negotiation and mediation.

6.2.3 Modern Peace Psychology

With the end of the Cold War, the break-up of the Soviet Union, and the dissolution of the pro-Soviet Eastern Bloc during the 1980s, the attention of Western peace psychology became less focused on preventing war between the United States and the Soviet Union. As Christie, Tint, Wagner et al. (2008: 542) point out:

> The focal concerns of post-Cold War peace psychology have become more diverse, global, and shaped by local geohistorical contexts in part because security concerns are no longer organized around the U.S.–Soviet relationship. For example, countries aligned with the Global South and developing parts of the world tend to associate peacebuilding efforts with social justice, in part because political oppression and the unequal distribution of scarce resources diminish human well-being and threaten survival. In geohistorical contexts marked by deeply divisive intractable conflicts and oppositional social identities, such as the conflicts in Northern Ireland, the Middle East and parts of Africa, research and practice often focus on the prevention of violent episodes through the promotion of positive intergroup relations. In the West, the research agenda is dominated by efforts to more deeply understand and prevent terrorism.

During the Cold War, but especially afterwards, not only were there many psychological articles and workshops aimed at psychological intervention into specific violent conflicts, whether at the international, intergroup, or interpersonal levels; there was also much psychological work to develop theory that might improve psychologically based interventions. Galtung's (1969) important distinctions between direct and structural violence provides useful distinctions between much of the early and more recent work of psychologists concerned with issues of peace,

conflict, and violence. Structural violence is embedded in the values, social norms, laws, social structures, and procedures within a society or community which systematically disadvantage certain individuals and groups so that they are poorer, sicker, less educated, and more harmed than those who are not disadvantaged. Much of the early work was focused on direct violence; on the causes and conditions which give rise to aggression and physical violence. More recent work has often been concerned with the bidirectional relationship between conflict and social injustice (structural violence).

The literature and contributions to the modern fields of peace psychology and conflict resolution have grown so large that no summary will be presented here. However, in a number of recent books there are excellent presentations and summaries of this work. They include: Christie, Tint and Wagner et al. et al. (2001); Blumberg, Hare and Costin (2007); Deutsch, Coleman and Marcus (2006); Fisher (1990, 1997); Kriesberg (2006); Lederach (1994, 1997); Pruitt and Kim (2004).

In a book of essays on preventing World War III (Wright/Evan/Deutsch 1962), Quincy Wright, a distinguished historian, wrote:

> A world society capable of settling international disputes and preventing war is possible, and without such a society the maintenance of peace in the shrinking world will be increasingly difficult. The basic problem in preventing World War III is, therefore, thebuilding of such a society. Observation of the history of groups merging into supersocieties indicated that such a development normally proceeds through four stages which mayconsiderably overlay. They are (1) the establishment of *communication* and trade amongindependent groups; (2) the process of *acculturation* through mutual borrowing of technologies and syntheses of values; (3) the emergence of common cultural standards andtechniques, inducing *cooperation* to maintain norms, achieve goals, and promote common interests in the developing culture; and (4) the increase of the efficiency of such cooperation by the establishment of a central *organization* with authority to recommend, guide, or even compel appropriate action, at first by the component groups and eventually by individuals.

Similarly, in the foreword to the important book, *Building Peace: Sustainable Reconciliation in Divided Societies* (Lederach 1997), Richard Solomon, President of the United States Institute of Peace, offered this image:

> Sustainable peace requires that long-time antagonists not merely lay down their arms but that they achieve profound reconciliation that will endure because it is sustained by a society-wide network of relationships and

mechanisms that promote justice and address the root causes of enmity before they can regenerate destabilizing tensions (Solomon 1997: ix).

We agree with Wright and Solomon that a sustainable world peace will require the building of such a society imbued with such mechanisms and relationships. Below, we stress what we consider to be the psychological requirements of such a society.

1. A strong sense of positive interdependence among the units composing the greater society. They should feel as well as believe that the units are so linked that they "sink or swim together". Such common bonds are most prevalent in societies organized around cross-cutting structures, where members of different ethnic groups play, work, and socialize together (LeVine/Campbell 1972; Varshney 2002).

2. A strong sense of global, as well as local, patriotism and loyalty. Their sense of identity is strongly linked to the global as well as their local community. Such phrases as 'Irish American', 'Jewish American', and 'Italian American' indicate the possibility of such dual or multiple identities.

3. The sharing of such basic common values as recognition that all human beings despite differences or disagreements have the right to be treated with respect, dignity, and justice as well as to have their basic needs fulfilled. The United Nations Universal Declaration of Human Rights, adopted by the United Nations General Assembly on 10 December 1948, is a much fuller statement of these basic values.

4. Mutual understanding, which is fostered by the freedom to be informed as well as the freedom to communicate and by the ability to have the message being communicated expressed or translated so that it is mutually understood by the sender and receiver of the messages. Quick, accurate computer translation of different languages may become a substitute for a common, universal language.

5. A sense of fair recourse. Inevitably, conflicts between people and between groups will occur and experiences of injustices and even oppression will arise. When such problems develop, the presence of fair and efficient means of recourse goes a long way in decreasing the probability that they will culminate in either criminal or political forms of violence (Gurr 2000). Of course, history is filled with instances of the opposite, where unmet needs combined with a limited sense of recourse

have resulted in extraordinary episodes of violence, revolution and human suffering.

6. Social taboos against the use of violence to solve problems. The biggest single predictor of spikes in violence in Western society is the presence of international wars (Gurr). There are similar correlations to be found between incidents of local ethno-political violence and the normalization of violence as a legitimate method of communal problem-solving, as well as between experiences of domestic abuse as a child and the perpetration of domestic abuse as an adult. In contrast, anthropological research has documented the central importance of social taboos against violence for fostering more internally and externally peaceful societies (Fry 2006).

These six psychological requirements constitute a set of basic building-blocks for fostering a harmonious, sustainable peace. No one aspect would be sufficient, nor would the presence of all six necessarily be adequate. However, the more that a society invests in each of these components, the more they will decrease the prevalence of destructive conflict and the more they will increase the probability that peaceful relations will be sustained.

6.3 The Psychological Components of a Sustainable Peace

Below, we characterize briefly what we consider to be key psychological components; these were shown to the contributors as we invited their contributions. Individual chapters address these components as the distinguished contributors see fit. The chapters do not exhaust the potential contributions of psychological theory and research to the development of a sustainable peace, nor do they cover what other disciplines (e.g. economics, political science, sociology, international relations, history, the physical and biological sciences) can contribute to the development of a sustainable peace. Their aim is to stimulate other psychologists to make further contributions and to inform educated citizens and public officials as well as other social scientists of existing and potential psychological contributions to this area of knowledge.

The key psychological components discussed in *The Psychological Components of a Sustainable Peace* (Coleman/Deutsch 2012) are:

1. *Effective Cooperation* At the international level, the developmental of harmonious peaceful rela-

tions among nations will require effective cooperation in dealing with such issues as climate change, proliferation of weapons of mass destruction, pandemics of contagious diseases, global economic development, failed states, and so on. Similarly, in interpersonal relations such as marriages, if a couple is unable to cooperate effectively on matters that are central to their identities whether these be religious concerns, sexual relations, political views, economic relations, lifestyles, child-raising or in-laws, it will be difficult for them to have a harmonious, peaceful marriage. Much research has been done on the conditions which give rise to successful cooperation and to its effects (see Johnson/Johnson 2005; Deutsch 2006, 2011).

2. *Constructive Conflict Resolution*
Among extended relations of all sorts–whether at the interpersonal, intergroup, or international levels–it is inevitable that conflict will arise. Some of the conflicts are not central to the relationship and may persist and be mainly ignored without harming the relationships. Other conflicts which threaten the well-being or identity of one or more of the participants in the relationship cannot be suppressed or ignored without harming the involved parties and their relationship. How such conflicts are resolved–constructively or destructively–is critical in determining whether harmonious, cooperative relationships will persist and be strengthened or will deteriorate into bitter, hostile relations.

During the past several decades, there has been extensive theoretical and research investigation of the effects of constructive and destructive processes of conflict resolution as well as of the conditions which give rise to each process (for summaries, see for instance Deutsch/Coleman/Marcus 2006; Bercovitch/Kremenyuk/Zartman 2009). There is also a growing literature of useful, practical, advice in how to manage conflict (see e.g. Moore 1996; Gottman/Silver 1999; Schneider/Honeyman 2006; Thompson 2008).

3. *Social Justice*
Relationships that are just foster effective cooperation and constructive conflict resolution. Injustice and oppression, on the other hand, foster and are fostered by destructive conflict. Similarly, effective cooperation is inhibited or destroyed by injustice and oppression.

It is useful to make a distinction between *injustice* and *oppression*. Oppression is the experience of repeated, widespread, systemic injustice. It need not be extreme and involve the legal system (as in slavery, apartheid, or the lack of the right to vote) nor violent (as in tyrannical societies). Harvey (1999) has used the term 'civilized oppression' and Sue, Capodilupo, Torino et al. (2007) the term 'micro aggression' to characterize the everyday processes of oppression in normal life. Civilized oppression "is embedded in unquestioned norms, habits, and symbols, in the assumptions underlying institutions and rules, and the collective consequences of following those rules. It refers to the vast and deep injustices some groups suffer as a consequence of often unconscious assumptions and reactions of well-meaning people in ordinary interactions which are supported by the media and cultural stereotypes as well as by the structural features of bureaucratic hierarchies and market mechanisms" (Young 1990: 41).

There is an extensive literature dealing with overcoming injustice and oppression which is too extensive to present here. The main themes are: *Awakening the Sense of Injustice; Persuasion Strategies for Changing Oppression; Relationships and Power Strategies for Change* (see Deutsch 2006, for more elaboration).

4. *Power and Equality*
The distribution of power, the equality or inequality of the parties involved in any relationship, plays a critically important role in determining the characteristics of the relationship. For instance, Adam Curle (1971), a mediator working with ethnic conflicts in Africa in the 1960s and 1970s, observed that as conflicts moved from unpeaceful to peaceful relationships, their course could be charted from one of relative inequality between the groups to relative equality. He described this progression toward peace as involving four stages. In the first stage, conflict was 'hidden' to the lower-power parties because they remained unaware of the injustices that affected their lives. Here, any activities or events resulting in conscientization (erasing ignorance and raising awareness of inequalities and inequities) moved the conflict forward. An increase in awareness of injustice led to the second stage, confrontation, when demands for change from the weaker party brought the conflict to the surface. Under some conditions, these confrontations resulted in the stage of negotiations, which were aimed at achieving a rebalancing of power in the relationship in order for those in low power to increase their capacities to address their basic needs. Successful negotiations moved the conflicts to the final stage of sustainable peace,

but only if they led to a restructuring of the relationship that addressed effectively the substantive and procedural concerns of those involved.

5. *Human Needs and Emotions*

Neither effective cooperation, constructive conflict resolution, nor social justice is likely when basic human needs are unsatisfied. Maslow (1954) has identified the basic human needs as: physiological, safety, belongingness and love, esteem, and self-actualization. Frustration of these needs lead to diverse emotional consequences such as apathy, fear, depression, humiliation, rage, and anger. These emotions are not conducive to effective cooperation, constructive conflict resolution, or any other psychological component of a harmonious, sustainable peace. The view that the frustration of one's needs is purposeful and unjust gives rise to intense feelings of humiliation which Lindner (2006) has described as the 'nuclear bomb of emotions'.

6. *The Psychodynamics of Peace*

From Freud on psychodynamic theorists have been interested in how individual and group psychodynamics have contributed to constructive, peaceful, or destructive, violent relationships at the international as well as interpersonal levels. The psychodynamic approach emphasizes the interdependence between internal conflicts and external conflicts. Thus, internal conflict between a socially prohibited desire (e.g. desire for homosexual contact) and guilt feelings may lead to anxiety and such defence mechanisms against anxiety as projection where the struggle in yourself is denied and is projected on to or attributed to another.

External conflict can also give rise to internal conflict. Psychodynamic approaches also emphasize the importance of understanding how the past and development of an individual, group, or society play a critical role in forming self-identity, as well as the values, symbolic meanings, attitudes, and predispositions to behaviour.

7. *Creative Problem-Solving*

Betty Reardon, a noted peace educator, once said, "The failure to achieve peace is in essence a failure of imagination" (pers. comm.). The freedom and ability to imagine new possibilities as well as the capacity to select judiciously from these possibilities what is novel, interesting, and valuable (Simon 2001) are central to creative problem-solving. The conditions which foster the freedom and ability to create novel and valuable solutions not only are conditions in the problem-solver (individual or group), but also are in conditions in the social context which affects the problem-solver. Creative problem-solving is necessary to overcome the obstacles which block effective cooperation and the impasses which hinder constructive conflict resolution.

8. *Complex Thinking*

Simple thinking is directed at the here-and-now and, often, has an 'either/or' quality. It does not take into account the future or past or what is occurring in different locales and remote places, nor that solutions to problems often involve the integration of apparently opposed alternatives and the creation of new alternatives. At the international level such problems as climate change, depletion of basic resources, worldwide economic recession, terrorism, and weapons of mass destruction require the ability to think of the future as well as of the past, to think globally as well as locally. Similarly, in married couples such issues as college tuition for one's children, retirement income, care for elderly parents, and maintaining the positive in marital relations require complex thinking.

9. *Persuasion and Dialogue*

As Ledgerwood, Chaiken and Gruenfeld (2006) have pointed out: "Persuasion is distinct from coercion in that persuasion is influence designed to change people's minds, whereas coercion involves influence designed to change people's behaviours (with little regard for whether they have actually changed their minds)." Lasting change is more likely to result from persuasion than coercion.

Persuasion involves communication by a *source* of a *message,* through a *medium,* designed to *reach* and influence a *recipient.* Whether the recipient will be persuaded by the message is a function of the characteristics of each of the foregoing elements as well as the characteristics of the relationship between the source and the recipient. Sustainable, harmonious peaceful relations require the mutual ability to persuade one another. Without this ability, a convergence of values, information, and actions as well as mutual satisfaction of needs is not likely to occur.

Dialogue, unlike persuasion, is not unilateral. It is a mutual process in which the interaction parties openly communicate and actively listen to one another with mutual respect and a feeling of mutual equality. Each communicates what is important and true for her without derogating what is true and important for others. They seek to learn together and to find common meaning by exploring the

assumptions underlying their individual and collective beliefs. Dialogue is a collaborative and creative process in which the participants are open to change as they seek common ground and mutual understanding.

10. *Reconciliation*

After destructive conflicts in which the conflicting parties have inflicted grievous harm (humiliation, destruction of property, torture, assault, rape, murder) on one another, the conflicting parties may still have to live and work together in the same communities. This is often the case in civil wars, ethnic and religious conflicts, gang wars and even family disputes that have taken a destructive course. Consider the slaughter that has taken place between Hutus and Tutsis in Rwanda and Burundi (Staub 2012); between blacks and whites in South Africa; between the 'Bloods' and 'Crips' of Los Angeles; the Protestants and Catholics in Northern Ireland; and among Serbs, Croats and Muslims in Bosnia. Is it possible for forgiveness and reconciliation to occur under such conditions? If so, what fosters these processes? Recently, a considerable psychological literature has emerged in response to this question (see Lederach 1997, 2002, 2003, 2005).

After bitter destructive conflict, it can be expected that reconciliation will be achieved, if at all, after a slow process with many setbacks as well as advances. The continuous and persistent help and encouragement of powerful and respected third parties is often necessary to keep the reconciliation process moving forward and to prevent its derailment by extremists, misunderstandings or harmful actions by either of the conflicting parties. The help and encouragement must be multifaceted. It must deal not only with the social-psychological issues addressed so well in this volume, but also, justly, with such institutions as the economic, political, legal, educational, health care and security, whose effective functioning is necessary for a sustained reconciliation.

11. *Education*

One of the most important things that educators can do to foster each of the psychological components discussed above is to exemplify these components in their own behaviour in and out of the classroom and also in the pedagogy, curricula, and organizational functioning of the school. To achieve these objectives will require changes in the education and training of school personnel, particularly teachers and administrators, as well as new requirements in the hiring of school personnel.

In recent years, it has been increasingly recognized that schools have to change in basic ways if we are to educate children so that they are for rather than against one another, so that they develop the ability to resolve their conflicts constructively rather than destructively and are prepared to live in a peaceful world. This recognition has been expressed in a number of interrelated movements: cooperative learning, conflict resolution, and education for peace. In our view, there are several key components in these overlapping movements: cooperative learning; conflict resolution training; the constructive use of controversy in teacher subject matters; the creation of dispute resolution centres in the schools; and development of knowledge of and a commitment to human rights and social justice. Students should also acquire, at the appropriate age level, substantive knowledge in such fields as political science, international relations, arms control and disarmament, economic development, the global environment, and world trade, fields which are also important to world peace, together with other substantive knowledge and skills necessary to function as responsible adults. They should also become informed and sensitized to the many injustices that exist globally as well as locally so that they can be intelligently active in bringing about social change.

12. *Norms for Policy*

Psychological principles play a central role in the development of policies and norms that support sustainable peace, where peace is defined comprehensively to include the prevention and mitigation of episodes both of direct violence and structural violence. Sustainable peace requires changes at the level of norms and policies and psychologically-informed principles and activism have played a role in changing policies and/or norms. Some potential examples can be found in research and activism/practice that created: (a) a climate that made the Oslo Accords possible; (b) a movement that led to the removal of secrecy clauses from the Truth and Reconciliation Act, thereby making some of the testimony public; (c) serial dramas that have been used to change norms in regard to intergroup relations; and (d) emancipatory agendas that have increased voice and representation among the oppressed throughout Latin America.

13. *The Practice of Sustainable Peace*

Peace is never achieved, but rather is a process that is fostered by a variety of cognitive, affective, behavioural, structural, institutional, spiritual, and

7   The Essence of Peace? Toward a Comprehensive and Parsimonious Model of Sustainable Peace

Peter T. Coleman

Abstract

This concluding chapter has four sections. First, it highlights the basic commonalities in the discussion of the construct of a "harmonious sustainable peace". Second, it offers a summary of the main components of sustainable peace. Third, it presents a sketch of a more parsimonious model of sustainable peace informed by dynamical systems theory and dynamic minimalism. Finally, it outlines an agenda for future study and education in this area

Keywords: Sustainable peace, commonalities, a parsimonious model, dynamic systems theory, research education.

> *For every thousand pages published on the causes of war,*
> *there is less than one page directly on the causes of peace.*
>
> *Historian Geoffrey Blainey (1988)*

The purpose of developing the book *The Psychological Components of a Sustainable Peace* (Coleman/ Deutsch 2012) was to achieve three main objectives. First, to enhance our understanding of sustainable peace by supplementing the standard approach of studying the *prevention* of destructive conflict, violence, war and injustice with the equally important investigation of the *promotion* of the basic conditions and processes conducive to lasting peace. For in addition to addressing the pervasive realities of oppression, violence and war, peace requires us to understand and envision what alternatives we wish to construct. Second, in the context of this new inquiry, we hoped to help clarify and better specify the meaning of *sustainable peace*. Third, with respect to the ultimate need for multidisciplinary frameworks to best comprehend and foster sustainable peace, we hoped to elicit what contemporary psychology might have to contribute to such a framework.

The good news is that through their many excellent chapters, the contributors to *The Psychological Components of a Sustainable Peace,* edited by Coleman and Deutsch (2012) have helped make great progress toward meeting the three objectives; identifying a wide variety of factors at different levels of analysis associated with the promotion of peace. However we are now left with an embarrassment of riches. The seventeen chapters which constitute *The Psychological Components of a Sustainable Peace* (Coleman/ Deutsch 2012) offer a vast array of psychosocial conditions and processes which have been linked to sustainable peace. While a critical first step, this bounty of information leaves us with a rather cluttered state of understanding. Therefore, this concluding chapter from *The Psychological Components of a Sustainable Peace* (Coleman/Deutsch 2012) will attempt to offer a synthesis of the research and ideas presented in the book. It has four sections. First, it returns to the discussion of the meaning of a harmonious, sustainable peace broached in the introduction, and highlights the basic commonalities of the construct that underlie the many aspects of peace described in the chapters of the book. Second, it offers a brief summary of the main components of sustainable peace presented in the book, organized within a nested, multi-level framework. Third, it offers a sketch of a more parsimonious model of sustainable peace, informed by dynamical systems theory (Nowak/Vallacher 1998) and dynami-

cal minimalism (Nowak 2004), which conceptualizes the effects of the many component parts on the probabilities of stable dynamics of destructive conflict and peace. And finally, it outlines an agenda for future study and education in this area.

7.1   The Meaning of Sustainable Peace Revisited

Peace is both complicated and simple. For example, a search of the *Thomson Reuters Web of Knowledge* database on articles published in English since 2000 with 'peace' in the their title reveals over forty terms distinguishing different types or aspects of peace (see table 7.1). This is more than a matter of semantics. Peace can differ in a variety of ways, including by level (interpersonal to international to global peace), direction (internal and external peace), durability (from fragile to enduring peace), source or conditions (peace through coercion, democratic participation, economic incentive, etc.), type (negative, positive and promotive peace) and scope (local to global peace).

Table 7.1: Types and components of peace. **Source**: Thomson Reuters web of knowledge database 2000–2011.

Agonistic peace	Movable peace
Armed peace	Negative peace
Capitalist peace	Nuclear peace
Cold-warm peace	Overt peace
Commercial institutional peace	Partial peace
Democratic peace	Peace-building
Durable peace	People's-civil peace
Enduring peace	Perpetual peace
Feminist peace	Positive peace
Fragile peace	Post-liberal peace
Global-world peace	Precarious peace
Hegemonic peace	Realistic peace
Holistic Gaia peace	Relative peace
Holistic Inner Peace	Republication peace
Holistic intercultural peace	Sustainable peace
Hybrid peace	Technological peace
Imperfect peace	Tyrannical peace
Kantian peace	Uneasy peace
Lasting peace	Unqualified peace
Liberal peace	Virtual peace
Monadic peace	Dynamic-static peace

This vision of sustainable peace narrows the focus of our discussion somewhat, although even this type of peace can still differ by level, direction, source, type and scope, and these differences affect the nature of the facilitating and inhibiting conditions associated with them. For example, the psychological conditions conducive to holistic inner peace are likely to differ dramatically from the conditions which foster sustained international peace.

Nevertheless, all forms of sustainable peace share some basic underlying qualities, reflecting a relative absence of destructive conflict, tension and violence and a presence of constructive conflict, harmony and well-being. Therefore, building on Boulding (1978), we define *sustainable peace* as existing in a state where the probability of using destructive conflict and violence to solve problems is so low that it does not enter into any party's strategy, while the probability of using cooperation and dialogue to promote social justice and well-being is so high that it governs social organization and life.

Thus, the many factors, conditions and processes related to peace presented in the chapters of *The Psychological Components of a Sustainable Peace* by Coleman and Deutsch (2012) can be understood in the context of their relative effects on (1) decreasing probabilities for destructive conflict, violence and injustice and (2) increasing probabilities for promotive peace. They are summarized below.

7.2   A Nested Model of the Psychosocial Components of Sustainable Peace

The psychosocial components from chapters 1 to 17 in the book *The Psychological Components of a Sustainable Peace* (Coleman/Deutsch 2012), where this text was first published, are summarized briefly and organized below by level (micro, meso and macro) and by *orientation* (prevention of destructive conflict or promotion of sustainable peace; see table 3.1 in Coleman 2012a). Micro-level components include those involving individuals; meso-level are those within families, schools, organizations and communities; and macro-level those involving policies and institutions of societies, states and the international community. Many of the factors associated with preventing destructive conflict may also be necessary for promoting positive relations, and vice versa. However they are each categorized here as oriented toward where they are most commonly employed.

Each of the factors presented can operate in isolation, but typically is nested within a communal system of interlacing forces which affect the relative probabilities of destructive conflict and peace. Whether components operate at higher macro-levels or lower micro-levels will affect the rate and scope of their impact (Klein/Kozlowski 2000). Of course, the probabilities of maintaining a culture of constructive conflict and peace increase considerably when multiple factors are operating and aligned across levels. Exactly how best to operationalize this, however, is highly dependent on the particulars of the local situation.

7.3   Micro-level Factors (Prevention of Destructive Conflict)

Individuals, particularly when acting in concert, are key agents in processes of transforming and preventing conflict. Of course, exceptional leaders such as Mahatma Gandhi, Martin Luther King, Nelson Mandela, and the recent Liberian Nobel Laureate Leymah Gbowee can have a disproportionate impact on conflict resolution and prevention (Disney/Gbowee 2012). However, as many of the chapters suggest, destructive conflict is most likely to be mitigated when all individuals in a society adopt and internalize the following components:

- Awareness of the causes, consequences and escalatory tendencies of destructive conflict and violence.
- Moderately high levels of self-monitoring, restraint and regulation of internal impulses for destructive or violent acts.
- Satisfaction of basic human needs including physiological needs, safety and dignity.
- Values, attitudes, skills and behaviours supporting non-violence.
- Moderate levels of tolerance for uncertainty.
- High levels of tolerance for and openness to difference.
- capacity for forgiveness.

7.4   Micro-level Factors: Promotion of Sustainable Peace

Individuals also play a foundational role in increasing the probabilities for sustainable peace. They increase when individuals in a society adopt and internalize the following:

- Recognition of the interdependence of all people, similar and different, local and global.
- A strong self-transcendent value orientation committed to the welfare of others and society, with a sufficient self-enhancement orientation to mitigate individual resentment.
- A healthy balance of openness to change *and* conservatism, responsive to changing times and circumstances.
- Values, attitudes, skills and behaviours promoting cooperation and trust.
- Knowledge, attitudes and skills for constructive conflict resolution.
- Higher levels of integrative, emotional, behavioural and social identity complexity.
- Capacities for tolerance, humanization, realistic empathy (understanding how a situation looks to someone else) and compassion for members of one's in-groups and out-groups.
- An appreciation of environmental stewardship and equitable sharing of the earth's resources among its members and with all human beings.
- Language for peace: a large lexicon for all aspects of cooperative and peaceful relations and sufficient use of such terms to foster automaticity.
- A strong sense of global identity with a concrete understanding of the steps that need to be taken locally to act as a global citizen.

7.5   Meso-level Factors: Prevention of Destructive Conflict

Some scholar-practitioners suggest that mid- or meso-level factors play a disproportionate role in determining community dynamics related to conflict, as these forces are situated between both micro and macro forces and thus have an important mediating effect between, for instance, governance and policy and individual beliefs, values and behaviour (Dugan 1996; Lederach 1997; Kriesberg 1999). Some of the meso-level factors relevant to conflict prevention and mitigation identified by our contributors include:

Social taboos against corporal punishment and other forms of violence in the home, schools, workplace and public spaces.

Norms of gender equity and equality in the home, schools and the workplace. Early access to peace education and multicultural tolerance programs in preschool, elementary and middle school.

Opportunities for peaceful sublimation of aggression through competitive or extreme sports, occupations, creative arts, etc.

Functional and accessible venues for constructive, non-violent action to seek recourse and address perceived injustices and other harms.

Strong norms for procedural and distributive justice in schools, workplaces, marketplaces, and elsewhere in the community.

7.6 Meso-level Factors: Promotion of Sustainable Peace

With regard to increasing the probabilities for fostering and sustainingpeace,the following mid-level components were identified as critical:

- Strong norms valuing and nurturing children.
- Early socialization of children oriented toward mutual care and nurturance.
- Cross-cutting structures fostering common interests, activities and bonds across different ethnic and religious groups.
- Structures of cooperative task, goal and reward interdependence in schools, workplaces, and politics.
- Programs and workshops in constructive conflict resolution and creative problem-solving for children, adults, parents and leaders of schools, businesses and politics.
- Shared, accurate and transparent collective memories of past events, conflicts and relationships between groups.
- Common use of peaceful language in popular media and normal daily discourse.
- Strong emphasis on both local and superordinate identities at the ethnic, communal, national and global levels.

7.7 Macro-level Factors: Prevention of Destructive Conflict

Conditions, mandates, regulations and processes operating at the macro-level have the paradoxical effect of being the most distant from individual-level behaviours and yet influencing these behaviours most rapidly once implemented (Klein/Kozlowski 2000). And although what our leaders do and say at this level may often seem to not have a major impact on our day-to-day lives, they can have a substantial symbolic effect on us as well as significantly alter the social con-

ditions in which our conflicts take place. Thus, our contributors rightly identified the following macro-level factors as important to the prevention and mitigation of destructive conflict.

- Recognition and understanding of the inordinately strong salience of threat and tendencies towards inequality and competition in many societies across the globe.
- Established national political and social institutions that ensure the implementation and follow-through of negotiated settlements.
- Well-coordinated early warning systems operating through local governments and NGOs networked locally, regionally and globally for efficient communication.
- Use of crisis-mapping: an open-source platform for collecting and plotting local cell phone accounts of the commission of violent atrocities to inform the international community of emerging crises in a timely manner.
- Use of the internet and other social technologies to mobilize broad non-violent movements for social justice and corporate responsibility.
- Coordination between local governments, civil society and international organizations to prevent violent conflict.
- Well-functioning global organizations and institutions such as the United Nations, the International Criminal Courts, Interpol, and the Universal Declaration of Human Rights.
- Developing awareness and knowledge of the Dilemma of the Commons and how to overcome it.

7.8 Macro-level Factors: Promotion of Sustainable Peace

Finally, chapters of the book *The Psychological Components of a Sustainable Peace* by Coleman and Deutsch (2012) also identified these important influences for promoting and maintaining a state of sustainable peace:

- A societal idea of peace that includes an ethic of interethnic unity, care and nurturance of others, which is as strong (or stronger) as the view of peace as something that need be secured and defended.
- Societies that define themselves as internally and externally peaceful.

- A transcultural elite with shared norms of tolerance, cooperation, and creative problem-solving, who model for all the efficacy and value of constructive, non-violent action.
- National governance structures tending towards egalitarianism and democracy.
- A strong community of global citizens engaged locally in initiatives fostering global citizenry and addressing shared global concerns (climate change, poverty, etc.).
- Political and business ethics that are in harmony with nature and environmental stewardship.
- Institutions which reflect and uphold self-transcendent values.
- Gender parity with a proportional number of women in the highest positions of leadership in business, politics and the military.
- Use of the internet and other social technologies to mobilize broad social movements for humanitarian works and global peace.
- Strong communications, trade, and cultural and civilian exchanges between nations
- Peace-mapping: an open-source platform for collecting and plotting local cell phone accounts of nations.the commission of peaceful and humanitarian acts to inform and inspire other potential 'third-siders'.
- The establishment of peace parks: natural parks located at the borders between disputing nations where development and use of the parks are offered as superordinate goals.

These multiple factors operating across three levels together constitute a system of sustainable peace, distinguishing such communities and societies from those locked in systems of dominance and destructive conflict. The question then becomes, can we conceptualize how these systems develop, stabilize and change, and how groups and communities can move from one to the other?

7.9   A Dynamical-Minimal Model of Sustainable Peace

In Cultures of Peace: The Hidden Side of History, Elise Boulding (2000) points out that our warlike culture is accompanied by a concurrent culture of peace. This is the view we have taken in this book: that all communities and societies inflicted by destructive conflict and war have a latent potential for peace, and that societies at peace often harbour a latent potential for hostilities. For instance, in Islands of Agreement:

Managing Enduring Armed Rivalries (2007<XREF>), Gabriella Blum describes the many examples of cooperation and exchange operating in the context of long-enduring armed rivalries such as between India and Pakistan, Greece and Turkey, and Israel and Lebanon. These havens of cooperation in the context of enmity effectively reduce suffering and loss and allow mutually beneficial exchanges to take place, and are evidence of the latent potential for peace inherent in all societies, even those currently engulfed by war. On the other hand, if we examine the current state of Northern Ireland, we see a somewhat fragile state of peace and often hear the rumblings of what could once again become a dynamic of violence. Both potentials exist.

The trick then is not to simply be able to move from one state (war) to the other (peace) constructively. In fact the international community has got quite good at this, seeing a dramatic increase in the number of wars ending through negotiation rather than through unilateral military victory. In fact, these numbers have flipped since the end of the Cold War, with today twice as many wars ending through negotiation as through military victory (Mason/Crenshaw/McClintock et al. 2007). Incredibly, from 1988 to 2003, more wars ended through negotiation than had in the previous two centuries (United Nations 2004). After peaking in 1991, the number of civil wars had dropped by roughly forty per cent by 2003 (United Nations 2004). This indicates that local, regional and international peacemakers have an increasing positive impact in peace mediation and transitions to systems of peace.

However, over twenty-five per cent of the wars ended through negotiations relapse into violence within 5 years (Suhrke/Samset 2007). In some cases, such as in Rwanda and Angola, more people were harmed and died after peace agreements were ratified by the parties and then failed (Stedman et al. 2002). And these failed-peace states seem to begin a new downward spiral. States with civil wars in their history are far more likely to experience renewed violence (Mason/Crenshaw/McClintock et al. 2007). And the longer such conflicts last, the greater the chances of recurrence of war (Collier 2000). Thus, the priority focus today should fall on sustainability—how to increase the probabilities that once societies transition to peace, they will be able to remain there and navigate the many challenges to peace that can accompany its implementation and maintenance.

A new theoretical approach to understanding and promoting sustainable peace is informed by the

efforts of a multidisciplinary research team working to apply insights and methods from complexity science to understanding peace (see Nowak/Bui-Wrzosinska/Vallacher/Coleman 2012 and Coleman/Bui-Wrzosinska/Vallacher et al. 2006; Coleman/Vallacher/Nowak et al. 2007; Coleman/Hacking/Stover et al. 2008; Coleman/Vallacher/Nowak et al. 2011; Nowak/Vallacher/Bui-Wrzosinska et al. 2006; Vallacher/Coleman/Nowak et al. 2010). They suggest that qualitative differences in the dominant patterns of social behaviour (such as those found in peaceful societies versus hostile or warring societies) can be accounted for by a few basic factors. Accordingly, their research attempts to identify, from scholarship and practice, the fundamental factors that promote sustained peaceful dynamics in communities or, put another way, that make societies immune to prolonged destructive or violent conflict.

The basic model centres on the concept of *attractor*, a concept from applied mathematics. In a dynamical system composed of many parts or 'elements', an attractor is a relatively stable state or pattern of behaviour that coordinates or integrates the elements (see Nowak and Vallacher 1998). In a mental system, an attitude or a belief functions as an attractor if it integrates and provides common meaning for different events, memories, and pieces of information, even if these mental 'elements' by themselves might be interpreted in very different ways. In a social system (e.g. a group or society), an ideology functions as an attractor if it provides a shared reality and frame of reference for collective action, even if the members of the group or society each have divergent needs and interests. Metaphorically, an attractor 'attracts' the system's elements to a common state or pattern, providing coherence and stability in the face of new and confusing experiences (e.g. ambiguous information, unexpected events). Once a system is governed by an attractor, it actively resists threats that would change the way the elements (e.g. thoughts, individuals) are organized. From a dynamical perspective, then, attempts to challenge a person's firmly held attitude or a group's ideology are likely to backfire, strengthening rather than weakening the attractor, and thus may intensify rather than reduce antagonism and violence in a situation characterized by conflict (see Staub 2012 for a more detailed discussion of attractor properties and dynamics).

Research on attractors has found that groups (e.g. communities, gangs, societies) typically have more than one attractor governing the way they think about and behave toward other groups. This means that hos-

tile and destructive interaction patterns between groups may coexist with the potential for peaceful interactions between such groups. At any one time, however, only one attractor (e.g. negative) is likely to manifest, with the other attractors (e.g. positive) virtually invisible to observers, or even to the participants themselves.

The existence of *latent attractors* suggests that under the right conditions, the groups may demonstrate a sudden and dramatic change in their thoughts, feelings, and actions vis-à-vis one another. Thus, the interactions within a community can move from one manifest attractor (such as peace) to another previously latent attractor (such as war), sometimes even in response to a rather minor incident that triggers the latent pattern of thought, feeling, and action. This scenario of *nonlinear change* is evident both in sudden outbreaks of group violence in situations of relative peace (such as has occurred in Northern Ireland) and in sudden outbreaks of peace in situations of protracted conflict (such as occurred in the 1990s in Mozambique after sixteen years of civil war). Recognition that the current state of communal life can coexist with other potential but latent patterns of interaction (each with differing degrees of 'attracting' power) underlies an ambitious research agenda and provides the foundation for the following set of recommendations for promoting sustainable peace.

7.9.1 Be Aware That War and Peace Potentials Can Coexist

As the attractor landscape in figure 7.1 indicates, groups and communities typically hold the potential for dramatically different types of interaction patterns simultaneously. One attractor may capture the state of the system for extended periods of time (as is seen during protracted periods of conflict). However, this does not mean that peace-building initiatives (peace education, dialogue groups, intergroup cultural exchanges, common community projects, etc.) during this period are for naught. Here, the idea of *latent attractors* provides an important new perspective for understanding peace. In this view, the malignant thoughts, feelings, and actions characterizing a group's dynamics during conflict represent only the most salient and visible attractor for the group.

Particularly if there is a long history of interaction with the out-group, there may be other potential patterns of mental, affective, and behavioural engagement vis-à-vis members of the out-group, including those for positive relations. With this in mind, identi-

Figure 7.1:   A dynamical system with two attractors corresponding to constructive relations (*A*) and destructive relations (*B*).
fying and reinforcing latent (positive) attractors, not simply disassembling the manifest (negative) attractors, should be the aim of conflict prevention in service of sustainable peace. In other words, in addition to attempts at achieving *negative peace* (an end to destructive conflict and violence), and the goal of *positive peace* (establishing fair systems of opportunity and justice) we must also strive to enhance *promotive peace*—the establishment of strong attractors for positive, constructive social relations. These objectives can be accomplished by implementing many of the initiatives summarized in the above multi-level framework.

7.9.2   'Reverse Engineer' Negative, Destructive Attractors

When conflicts do arise, the most obvious need is to quell any violence and contain actively destructive processes. This is often done by introducing police support, peacekeeping troops, or other forms of regional or international military interventions. However, even when systems de-escalate and appear to return to a state of peace, the potential for destructive interactions (destructive attractors) still exists. It is important, then, that we work actively to deconstruct and dismantle the negative attractors.

In generic terms, the deconstruction of an attractor entails focusing on the elements comprising the pattern of behaviour rather than focusing on the pattern itself. In the context of conflict, this means calling attention to specific actions, events, and pieces of information without noting their connection to the pattern in which they are embedded. When decoupled in this fashion, the lower-level elements may become reconfigured into an entirely different pattern (e.g. a positive view of the out-group and a benign or peaceful interaction pattern). The important point is this: attacking the pattern itself is likely to intensify rather than weaken the pattern because of the tendency for attractors to resist change, so one should focus instead on isolating elements and thereby weakening or eliminating the reinforcing feedback loops among

them. The chapters in the book *The Psychological Components of a Sustainable Peace* edited by Coleman and Deutsch (2012) present a variety of ways in which this can be accomplished in real-world settings, including: *introducing negative feedback loops (early-warning systems, cross-cutting structures, international monitoring, etc.); institutionalizing more nuanced, alternative conflict narratives (through media, textbooks, official accounts, etc.); and limiting the pervasive spread of conflict by allowing movement of the parties.*

7.9.3   Increase Complexity for Peace

Research has also shown that constructive social relations are characterized by relatively high levels of cognitive, emotional, behavioural, and structural complexity (see Nowak/Bui-Wrzosinska/Vallacher/Coleman 2012). Such complexity is advantageous when groups face problems or conflicts with other groups. As conflicts intensify, there is a strong tendency for the parties' thoughts, feelings, and behaviours to become more simple and black and white (which is evidence of strong attractor dynamics). If the conflict spreads to the community level and persists, then we see the same polarization occur in social networks, groups, and institutions. However, communities and groups who maintain more complex cross-cutting (intergroup) structures and social networks, who hold more complex (multiple group) social identities, and who display more complex cognitive, emotional, and behavioural (adaptive) patterns, have been found to be more tolerant of out-groups, display less violence when conflicts spark, and engage in a more constructive manner when conflicts become difficult. Thus, *sustainable peace requires structures and processes that foster increased contact and complexity.*

7.9.4   Increase Movement for Peace

The findings from research support the basic idea that peace is associated with movement (Bartoli et al. 2010). When people and groups get trapped in narrow attractors for social relations, whether in patterns of destructive conflict, oppressor-oppressed dynamics, or even in patterns of isolation and disengagement from others, their well-being tends to deteriorate and their level of resentment tends to build. These traps may be constituted by physical structures such as segregated spaces, or by social-psychological constraints such as norms, attitudes and ideologies. When trapped in such a well, people can be creative

at becoming ever more destructive, oppressed, independent, etc., which acts to deepen the attractor and makes it less likely they will be able to escape its pull. Of course, any pattern of behaviour may be functional in certain situations; a destructive orientation fits very well in times of armed conflict. But these patterns can become dominant and pervasive, so that when the current situation changes, or when people move to different situations, it is critical for people to *adapt*—to take up different patterns of behaviours that are appropriate to the varied situations they face. From this perspective, *sustainable peace requires the establishment of conditions that allow for movement and adaptation.* At times, even 'jiggling' the system—almost random movement—can break patterns and restore flexibility.

7.9.5 Peace is Associated with a Sufficient yet Tolerable Rate of Movement toward Justice

Decades of research on the psychology of justice has found that movement is also central to justice and peace. First, a sense of relative deprivation has been found to be a fundamental source of ethno-political conflict and instability in otherwise peaceful communities. This is the injustice felt when people experience a gap in what they feel their group deserves and what it can achieve, in comparison to similar groups. This experience is typically triggered by change—shifts in the status quo that affect what groups expect, what they can get, and with whom they compare themselves. However, it is the need for procedural justice, or the sense that there exist fair processes for the allocation of goods and for recourse against grievances, that has been shown to be critical to addressing injustice, even more so than actually receiving fair outcomes. Furthermore, the rate at which justice is achieved is also critical. Peace scholars have found that minority groups who feel that the channels for fair recourse are blocked or too unresponsive are more likely to revolt (Gurr 2000). However, they have also found that when particular minority groups ascend to justice and equal treatment very rapidly, this can raise the aspirations, envy, and resistance of other groups (including those in power), and thus destabilize communities (Gurr 2000; Lederach 1997). Thus, procedures of justice that provide a sufficiently steady response to the grievances of all stakeholders are a necessary condition for sustainable peace.

7.9.6 Foster Repellors for Violence

Anthropological research summarized by Fry and Miklikowska (2012) has shown that communal taboos against violence have existed for the bulk of human history, and were a central component of our ancestors, the prehistoric nomadic hunter-gatherer bands. Indeed, a key characteristic of peaceful societies, both historically and in the contemporary world, is the presence of non-violent values, norms, ideologies, and practices. Although non-violent norms are practised in many communities around the globe, they are often overwhelmed by more violent ideologies, messages, and social modelling. There are a wide-variety of parenting and educational methods for fostering more non-violent, pro-social attitudes and skills in children, such as violence-prevention, tolerance, cooperative learning, conflict resolution, and peace education curriculum, to name just a few. However, sustainable peace will require a much more concerted effort to teach non-violent values, norms, and practices to young people and to better limit exposure of youth to gratuitous forms of violence and to destructive social modelling by adults and public leaders.

7.9.7 Realize that Peace is never Achieved

Peace is a dynamic process, not an outcome. It requires a set of fair processes and procedures that allow all stakeholders to negotiate for their needs and rights, in order to create unity out of diversity. Indeed, peace initiatives uninformed by an ongoing process of reading feedback are destined to do more harm than good. Research has found that the most effective decision-makers are those who are able to continually adapt; by remaining open to feedback, they can reconsider their decisions and alter their course if necessary (Dorner 1996). These leaders make more, not fewer, decisions as their plans unfold, and ultimately are able to enhance the well-being of the communities with which they work. Thus, effectiveness comes from flexibility not rigidity. In this way, we can work to increase the probabilities that peace will emerge and be sustained.

7.10 Conclusion: An Agenda for Sustainable Peace

Today, very few scholars study peace. However, the few that do tell us that today there are approximately eighty societies worldwide who could be categorized

as having low levels of internal aggression, and seventy societies who are peaceful in their relations with other groups and communities in their regions (Fry 2006). Unfortunately, our understanding of such groups, and of the conditions that foster pro-social relations, is extremely limited. There is often an unarticulated assumption in research on war and conflict that a thorough understanding of the problem of destructive conflict will provide insight into conditions and processes which foster and sustain peace. This assumption has been found by researchers to be unfounded and incorrect (see Gottman/Murray/Swanson et al. 2002; Losada 1999; Losada/Heaphy 2004). Destructive conflict and peace are not end points of a single dimension but rather often coexist as separate dimensions. It is clearly time to champion the study of peace in its own right. In dynamical-systems terms, the coexistence of malignant and (potential) peaceful possible relations is tantamount to the coexistence of two attractors constraining the dynamics of the parties to a conflict. Although effort should be devoted to the deconstruction of the negative attractor, attention should also be devoted to strengthening the positive attractor for intergroup relations. There may be little immediate effect of fostering opportunities for positive relations between the groups, but such efforts plant the seed for a possible transformation should conditions change in a way that destabilizes existing mental, affective, and behavioural patterns.

If such a seed is not planted, it cannot take root even if the negative attractor is somehow discredited or otherwise destabilized. A dynamical system does not change unless it has a new space to occupy. A latent attractor essentially represents a new space for intergroup relations.

Therefore, the approach to the study of sustainable peace we advocate includes the following components:

• Movement beyond the primary focus on destructive conflict, violence and war (problems) to the equally important study of sustainable peace *(solutions)*.
• Movement away from simple, linear models of cause-and-effect toward more complex, *holistic* models of sustainable peace situated within constellations of ecological, biological, psychological, social, economic, and other structural forces.
• An enhanced capacity to work collaboratively across a variety of disciplines to better understand and foster sustainable peace through *multiple perspectives* and complementary approaches.

• A shift in emphasis away from achieving particular short-term outcomes (peace treaties, agreements, etc.) toward establishing and maintaining the conditions for *sustainable* peace processes in communities over time.
• An enhanced capacity to communicate and build *partnerships* from science to policy/practice and from policy/practice to science. The establishment of local, regional, and global *networks* of support and information on best practices for increasing the probabilities of sustainable peace.

What is required at this stage is an investment in a concerted effort to bring together scholars, practitioners, and policymakers from a variety of disciplines to work to understand sustainable peace beyond the level of case-based descriptions, to get at the essence of their underlying dynamics. This could include initiatives such as:

• *Support for the development of basic theory and research on sustainable peace*. There are few scholars conducting basic research on the fundamental (necessary and sufficient) conditions and processes for sustainable peace (Doug Fry and Marta Miklikowska are exceptions). However, it is critical that the applied frameworks which inform practice be informed by basic, sound, empirically-tested theoretical models, in order to foster peace most effectively.
• *Graduate-level, multi-disciplinary, theory-practice courses on sustainable peace*. Courses which involve a core group of faculty from different disciplines that are committed to working together to weave and develop the ideas and practices of sustainable peace. These courses could move from basic theory through applied models to strategies and tactics for intervention, and it is vital that we involve academics and UN/NGO practitioners and policymakers as guest lecturers on the course.
• *The development of a data-based index for annual reporting on state and regional levels of sustainable peace*. This project could build of off the Global Peace Index and other such resources (FAST International, International Crisis Group, Human Security Report) and could involve the business and academic communities in developing a comprehensive methodology (beyond early warning and violence prevention) for measuring and reporting on sustainable peace worldwide. This initiative could be informed by such initiatives as the Gross National Happiness Index (Yones 2006), the eight bases of a Culture of Peace (UN Resolu-

Figure 7.2:   A nested model of the psychological components of sustainable peace.

	Prevention of Destructive Conflict	Promotion of Sustainable Peace
Micro-Level Factors	• Awareness • Self-monitoring, restraint and regulation • Satisfaction of basic human needs • Values, attitudes, skills and behaviors supporting non-violence. • Tolerance for uncertainty. • Tolerance for and openness to difference. • A capacity for forgiveness.	• Recognition of the interdependence of all people • A strong self-transcendent value orientation • A healthy balance of openness to change and conservatism • Values, attitudes, skills and behaviors promoting cooperation and trust. • Knowledge, attitudes and skills for constructive conflict resolution. • Higher levels of integrative, emotional, behavioral and social identity complexity. • Capacities for tolerance, humanization, realistic empathy and compassion. • An appreciation of environmental stewardship and equitable sharing • Language for peace • A strong sense of global identity
Meso-Level Factors	• Social taboos against corporal punishment and other forms of violence • Norms of gender equity and equality in the home, schools and the workplace. • Early access to peace education and multicultural tolerance programs • Opportunities for peaceful sublimation of aggression • Functional and accessible venues for constructive, non-violent action to seek recourse and address perceived injustices and other harms. • Strong norms for procedural and distributive justice	• Strong norms valuing and nurturing children. • Early socialization of children oriented toward mutual care and nurturance. • Cross-cutting structures fostering common interests, activities and bonds across different ethnic and religious groups. • Structures of cooperative task, goal and reward interdependence • Programs and workshops in constructive conflict resolution and creative problem-solving . • Shared, accurate and transparent collective memories of past events, conflicts and relationships between groups. • Common use of peaceful language in popular media and normal daily discourse. • Strong emphasis on both local and superordinate identities.
Macro-Level Factors	• Recognition and understanding of the salience of threat and tendencies towards inequality and competition in many societies across the globe. • Established national political and social institutions that ensure the implementation and follow-through of negotiated settlements. • Well-coordinated early warning • Use of crisis-mapping • Use of the internet and other social technologies to mobilize broad non-violent movements for social justice and corporate responsibility. • Coordination between local governments, civil society and international organizations to prevent violent conflict. • Well-functioning global organizations and institutions	• A societal idea of peace that includes an ethic of interethnic unity • Societies that define themselves as internally and externally peaceful. • A transcultural elite with shared norms of tolerance, cooperation, and creative problem-solving. • National governance structures tending towards egalitarianism and democracy. • A strong community of global citizens • Political and business ethics that are in harmony with nature and environmental stewardship. • Institutions which reflect and uphold self-transcendent values. • Gender parity. • Use of the internet and other social technologies to mobilize broad social movements for humanitarian works and global peace. • Strong communications, trade, and cultural and civilian exchanges between nations. • Peace-mapping • The establishment of peace parks

tion A/RES/52/13), the Peace Scale (Klein/Goertz/ Diehl et al. 2008), and the Universal Declaration of Human Rights. Another possible step would be to develop a dynamical computational model with variables from multiple disciplines that have been shown to predict violence and peace and then try to keep a 'Violence Watch' as well as a 'Peace Watch' on countries by plugging data in to see if we can identify nations susceptible to outbreaks of violence and outbreaks of peace (latent attractors).

An annual theory-practice-policy forum on sustainable peace. There is currently a need for an annual gathering of policymakers, peace practitioners and scholars, where leading-edge research on sustainable peace could be translated and provided to policymakers. Collaborative, multidisciplinary work of this nature requires a common language based on an integrative platform to facilitate communication and coordination across the legendary disciplinary and theory-practice divides. Theapproach of dynamical systems, a scientific paradigm widely employed across scientific disciplines, provides such a platform.

8 Development with Sustainable-Engendered Peace: A Challenge during the Anthropocene

Úrsula Oswald Spring[1]

Abstract

This chapter examines the evolution of the peace concept from its understanding as a negative concept towards a positive, structural, sustainable, and engendered peace. The concept of a 'sustainable-engendered peace' refers to the structural factors related to long-term violence, deeply embedded in the patriarchal system and characterized by authoritarianism, exclusion, discrimination, exploitation and violence. This dominant social structure affects values such as equity, equality and justice, and often even threatens the survival of individuals and social groups. Further, this dominant system has also concentrated the wealth of earth within a small group of oligarchs who manage multinational enterprises. The sources of threats have been consolidated over thousands of years by patriarchal institutions, religious controls, self-identified beliefs and social representations, and totalitarian exercise of power, and have also affected natural resources. Faced with these global threats, the chapter explores the potential of the concept of a sustainable-engendered peace, and attempts to reach an understanding of the deeply anchored links to patriarchy and its war system that are related to the physical, social and cultural threats of the dominant values and behaviour in the Anthropocene. The text also explores the potential for a concept of holistic and cosmopolitan peace that can challenge the root causes of violence and destruction, and it discusses the goal of just and equal power structures for human beings and nature.

Keywords: Sustainable development, sustainable-engendered peace, Anthropocene, peace concept, patriarchy, civilization, empowerment, equity, values, cultural identity.

8.1 Introduction

This chapter examines[2] the evolution of the peace concept from negative (UN Charter 1947) towards a positive peace (Galtung 1967) where structural (Galtung 1968), environmental (Conca 1994; Oswald Spring 2008), and engendered peace elements (Oswald Spring/Brauch/Tidball 2014; Oswald Spring 2004) are integrated in a diversified culture of peace (Boulding 2000). A 'sustainable-engendered peace'

explores the structural factors related to long-term violence, which are deeply embedded in the patriarchal system (Mies 1968; Reardon/Snauwaert 2015a, 2015b).

Over thousands of years, patriarchy has developed a complex system of power, exploitation and control, where economy, politics, wars, culture, religious beliefs, identity, and psychosocial roots have been adapted to historical and regional differences. The dominant factors of this system are authoritarianism, control, violence, exclusion, discrimination, exploitation, and concentration of wealth. The reference object refers to all people with no power or limited access to power at the global and local level, such as women, the indigenous, youth, the elderly, the unemployed, the poor, etc. (Calva 2012a, 2012b, 2012c). The values at risk are established gender relations (Lagarde 1990; Lamas 1996), deeply rooted in the dominant social representations of gender (Jodelet 1991; Serrano Oswald 2010), which are manipulated by an oligarchy (Stiglitz

1 Prof. Dr. Úrsula Oswald Spring, full-time Professor/Researcher at the *National University of Mexico* (UNAM) in the *Regional Multidisciplinary Research Center* (CRIM); email: <uoswald@gmail.com>.

2 I want to express my sincere thanks for the creative comments I received from Betty Reardon, Hans Günter Brauch, and from three anonymous peer reviewers. They helped to strengthen the arguments; however, any errors are my own responsibility. I am also grateful to Mike Headon for his careful English revision.

2010; Yiamouyiannis 2013) and reinforced by religious fundamentalism, hierarchical churches (Gutiérrez 2013), and schools (Gramsci 1975, 1998). This social structure affects values such as equity, equality, solidarity, justice (Truong/Gasper/Handmaker et al. 2014), cultural identity (Arizpe 2015, Serrano Oswald 2014) and often even the survival of individuals and social groups (Oswald Spring 1994). The sources of threats have been consolidated over thousands of years by patriarchal institutions (Folbre 2006), religious controls (Jasper 2013), and the totalitarian exercise of power (Held 2004).

Nevertheless, today not only humanity as a whole, but even the survival of the planet itself are threatened by an aggressive exploitation of natural resources, including mining, oil extraction, and the exploitation of timber (UNEP 2012; Crutzen 2011). Further, a small oligarchic global elite has imposed patterns of production that deplete and pollute natural resources (Westing 2013) and create a wasteful and unequal consumerism (MA 2005), precarious livelihoods, and corporate production patterns (Ellis 2003). Monopolized finances, unequal terms of trade, a consumerist propaganda worldwide and an unequal control of resources (UN/DESA 2015, Calva 2012a, 2012b) dominate these global environmental changes (Brauch/Oswald Spring/Mesjasz et al. 2008, 2011; Brauch/Oswald Spring/Grin 2009).

Faced with these deeply-rooted global threats, this chapter addresses the following research questions: how may the widened concept of a 'sustainable-engendered peace' provide a deeper understanding and new conceptual tools so that alternatives may be proposed for a transition to sustainable development? How may a sustainable-engendered peace cope with and overcome the present economic structure and power structure and the global threats to the survival to humankind and planet Earth in the era of the Anthropocene (ISSC 2013)?

The chapter starts with definitions of the 'Anthropocene' (Crutzen 2002; 2011), of 'structural peace' (Webel/Galtung 2007), of a 'culture of peace' (Boulding 2000, 2016; UNESCO 2000), and of 'sustainable development' (Brundtland 1987). Then it explores the emergence, history and adaptation of patriarchy from its origins until today. It shows how this socio-economic, military and political system of organization could develop from a decentralized village structure to monarchies, slavery, colonialism, feudalism, capitalism, and neo-liberalism, and produce an economic oligarchy based on a symbolic relation with militarism and the war system (Reardon 1996; Reardon/Snau-

waert 2015a, 2015b). It analyses the structural elements that limit the sustainable development of humankind in the present unequal and unsustainable globalized world and explains the threats emanating from the production and consumption process for both humankind and planet Earth. Section 8.4 explores the potential of the concept of 'sustainable-engendered peace', a concept that will help in the analysis of patriarchy and its war system, which are related to the physical, socio-economic and cultural threats of dominant values and behaviour in the Anthropocene. In the final section, the chapter discusses critically the research question and explores the potential for a sustainable-engendered peace. The conclusion proposes an integrated negative, positive, structural, cultural, engendered, and sustainable peace. This holistic and cosmopolitan shift requires a change to the root causes of economic monopoly, violence and destruction in order to move towards just and equal economic and power structures that can nurture both human beings and nature.

8.2 Conceptual Definitions: Global Environmental Change, Anthropocene, Structural Peace, Culture of Peace, Sustainable-Engendered Peace and Development

8.2.1 Global Environmental Change

Global environmental change (GEC) is wider than *climate change* (CC). The term refers to the transformation produced by human beings in the ecosphere and that affects the hydrosphere, the atmosphere, the biosphere, the lithosphere and the pedosphere (Brauch/Oswald Spring/Mesjasz et al. 2008, 2011; Brauch/Oswald Spring/Grin 2009). Changes in the natural system are the result of numerous changes in systems of agricultural production, of a rapid urbanization process, and of population growth–the human population tripled during the last century, but water consumption increased sixfold (Oswald 2011). Further, unsustainable productive processes are polluting natural resources and creating health threats for human beings, as well as endangering ecosystems (Elliott 2011). The energy, transportation and production sectors have consumed increasing amounts of fossil fuel (IEA 2014), and in addition deforestation is reducing the capture of CO_2 (IPCC 2013, 2014a,

2014b, 2014c, 2014d). The emissions from greenhouse gases (IPCC 2013) have increased exponentially. Together with changes in land use, the intensive use of chemical fertilizers and pesticides in agriculture (FAOSTAT 2013), water pollution, deforestation and unsustainable waste production and management, both natural and human systems have seriously deteriorated. Finally, a globalized financial system, unequal credit, patterns of consumption and production, and an uneven level of access to material and immaterial resources are leading contributors to GEC.

8.2.2   Concept of the Anthropocene

Paul Crutzen (2002) proposed the idea of the Anthropocene. This concept relates to the environmental changes produced, predominantly by human intervention and corporate enterprises, in the earth system since the industrial revolution, but especially during the last five decades, because of the intensive use of fossil energy, the rapid increase in greenhouse gas emissions into the atmosphere, the pollution and warming of the seas, and an accelerated process of urbanization. The Anthropocene is a new geological epoch that is changing the earth history of the Holocene, it is defined as "the most recent manifestation of a pervasive millennial-scale climate cycle operating independently of the glacial-interglacial climate state" (Bond/Willima/Maziet et al. 1997). This concept is useful for understanding the transformative negative effects of human activity on the planetary ecology, but this chapter supports the argument that human agency also has a positive potential for change. It is precisely the dominant patriarchal global order that is limiting human choice and agency. By choosing peace actions that lead towards an envisioned political, social, economic and cultural transformation, a sustainable-engendered peace paradigm may open ways for new socio-economic orders, which will transform the present exploitation of humanity and earth into equal, peaceful and sustainable behaviours.

8.2.3   Structural Peace and Globalization

Quincy Wright ([1942] 1965²: 1090) had already distinguished between 'negative peace', defined as the absence of war, and a dynamic understanding of peace. This involves political, social, cultural and technological aspects and "the conception of positive peace ... [that] encroaches upon many established conceptions and interests". Wright (1965: 1093) argued that if it "is to be realized, peace must be

accepted not merely in symbols and myths but also in personalities and cultures".

Galtung (1967, 1968) distinguished between 'negative peace' (absence of physical or personal violence, reduction of arms or a state of non-war) and 'positive peace' (absence of structural violence, repression, discrimination, class conflicts and injustice). The lack of a 'structural peace' limits the full potential of human beings or of nations and is often related to institutional racism and sexism, where women and girls especially are discriminated (Anttila-Hughes/Hsiang/Hsiang 2013) and underpaid (Truong/Gasper/Handmaker et al. 2014).

A sustained peacebuilding process needs to address these root causes of social and physical conflict and discrimination. The present system of unequal access to natural and social resources has aggravated the structural imbalance (Stiglitz 2007). The World Bank (2014) has indicated that the very richest became wealthier during and after the financial crises of 2008, while among the majority of the world population many lost their well-being, their jobs and their income. 'Structural peace' means equity in economic terms, well-being in social interactions, and equality and lack of discrimination at the personal, family, social, regional and international levels. Senghaas (1997) proposed five conditions among nations to achieve a lasting peace: positive interdependence, symmetry of interdependence, homology, and entropy, together with common softly-regulating institutions that are able to promote a 'civilisatory hexagon'. Peacekeeping and its supervision can be considered a civilising project. His civilisatory hexagon consists of six elements: the disarmament of citizens, the rule of law, democratic participation, social justice, a culture of constructive conflict, and interdependencies and control of emotions (Senghaas 1997; 2013).

On the other hand, a 'destructive globalization' (Woodward 2000) is increasing the differences between poor and rich in North and South (Howell 2007). Globalization means the international integration of raw materials, products, services, finances, and knowledge through a free-market system (Calva 2012a, 2012b). In theoretical terms, there should be no limits to this trade in merchandise, people and ideas. The South has opened its borders and its trade; nevertheless, the industrialized countries have imposed increasing controls, subsidies and limits on their economic and human interchanges.

Militarized borders (Schomerus/de Vries 2014), the brain drain (Tigau 2012), *trade-related aspects of intellectual property rights* (TRIPs), protection by pat-

ents, and commercial or non-commercial barriers bring disadvantages for the poorer countries. This *business-as-usual* or neo-liberal system has widened the gap not only between industrialized and developing countries, but also between social classes inside the industrialized countries. Ideologically, it has strengthened a global world view of consumerism, fashion, trademarks, violence and fake modernity, where cultural diversity is subsumed into the monopolized market system with a single goal: to create a unique system of dominance or a hegemony controlled by transnational enterprises (Calva 2012a, 2012b, 2012c) and supported by the remaining superpower.

Nevertheless, structural peace has not focused sufficiently on the essential 'gender apartheid' of the global corporate economy. This system includes various forms of violence against women that have become corporately organized. Frequently human trafficking, sweatshops and the arms trade are business of the same corporation. However, all this money obtained illegally from organized crime, tax evasion, unequal terms of trade, and so on is laundered in the same corporate global financial system.

8.2.4   A Culture of Peace and International Institutions

The concept of a 'culture of peace' includes a diverse set of values, traditions, behaviours, attitudes and ways of life with respect for life on earth and for human beings (UNESCO 2002). Conflicts between human beings, communities and states should be managed through conflict resolution, where discriminative social representations and violence are ended through negotiation that can lead to win-win conditions for all those involved. In this positive sense, a 'culture of peace' should promote peacebuilding education (Reardon/Snauwaert 2015a, 2015b) in order to deepen the dialogue and increase cooperation between races, genders and ages. The existence of two concepts, peace and culture, has also created tensions. Groff and Smoker (1995) insisted that the wider understanding of culture must include symbols, rituals, heroes and values, but the crucial issue of an integrated culture of peace is related to shared values, including relationships with others, with nature, and with God. A culture of peace has a visible and a hidden dimension of culture, both of which influence the peacebuilding process.

Declaration 53/243A on a 'Culture of Peace' was accepted by the UN General Assembly in September 1999. It is based on the United Nations Charter, the constitution of UNESCO, and the Universal Declaration of Human Rights. This Declaration was launched just when the cold war had ended, but many violent conflicts were still going on and an intensive trade in weapons still taking place. The declaration is based on nine principles:

1. Respect for life, the ending of violence and promotion and the practice of non-violence through education, dialogue and cooperation;
2. Full respect for the principles of sovereignty, territorial integrity and political independence of states and non-intervention into matters which are essentially within the domestic jurisdiction of any state, in accordance with the Charter of the United Nations and international law;
3. Full respect for and promotion of all human rights and fundamental freedoms;
4. Commitment to peaceful settlement of conflicts;
5. Efforts to meet the developmental and environmental needs of present and future generations;
6. Respect for and promotion of the right to development;
7. Respect for and promotion of equal rights and opportunities for women and men;
8. Respect for and promotion of the right of everyone to freedom of expression, opinion and information;
9. Adherence to the principles of freedom, justice, democracy, tolerance, solidarity, cooperation, pluralism, cultural diversity, dialogue and understanding at all levels of society and among nations; fostered by an enabling national and international environment that itself fosters peace.

In the year 2000 the United Nations (UN Resolution A/RES/52/15) launched an "International Decade for a Culture of Peace and Non-violence for the Children of the World (2001–2010)". The goal is to "create a 'grand alliance' of existing movements that unites all those already working for a culture of peace in its eight domains of action", of which UNESCO became the "Focal Point for the International Year for the Culture of Peace (UN Resolution E/1997/47) and lead agency for the Decade (UN Resolution A/55/47)".[3]

Despite all these efforts, no peace dividend was realized at the end of the cold war. Instead, exclusive globalization, greed for natural resources, exploitation of the labour force (ILO 2014), violence (Mies 1986) and injustice (Truong/Gasper/Handmaker et

al. 2014; Fraser 1994) have prevented such a 'culture of peace'.

While a culture of peace has been embraced by some civil society organizations, it is poorly understood in terms of acknowledging the deep psychosocial roots in patriarchy of the culture of violence and the war system. The UN Charter lays claim to a commitment to equality between men and women, but the basic document on the *Conference of Parties* (COP) Declaration lacks gender awareness. It is precisely the term "respect for" instead of "acting towards" that permits continued resistance to specific policies for achieving that equality on the basis of culture.[4]

Rather, a 'culture of war' has prevailed, a culture that was intensified during 2014 with the centenary of the start of World War I, the seventy-fifth anniversary of the German attack on Poland that resulted in World War II, and the twenty-fifth anniversary of the fall of the Berlin Wall. These events triggered some peaceful changes: the reunification of Europe and other parts of the world, such as South East Asia, and a peaceful expansion of both the *European Union* (EU) and of the *Association of Southeast Asian Nations* (ASEAN), involving former opponents in a bipolar world as new partners.

8.2.5   Sustainable Development in the Era of the Anthropocene

There are many definitions of 'sustainable development', with many of them based on the Brundtland Report (1987): "Development that meets the needs of the present without compromising the ability of future generations to meet their own needs". It includes well-being and quality of life in the present, but with an intergenerational approach that looks to future generations.

This definition includes several conflicts: clean air for people or polluted air so that businesses can make high profits. We also need to define which level of needs we are talking about —basic or luxurious. We must also take the long term into account. Meeting the needs of the future we want (UN 2012) depends on how well we are able to balance social, economic, environmental and cultural goods in the present. For example, are we able to tackle the threats of GEC and CC today by reducing the emissions of greenhouse gases, by reorganizing the processes of production, extraction and urbanization, and by conserving forests and jungles (ISSC 2013)? How can people balance household needs with industrial growth and the productive use of labour? How can humankind improve equity through participative involvement, empowerment, social mobilization and cultural preservation without creating failed states and an anoxic environment? How can humanity allow ecosystem services to function and restore biodiversity and clean air, soil and water, when natural resources are being extracted for industrial activities (Willaarts/Garrido/Llamas 2014)?

Finally, there is also the problem of the territorial ownership of resources (often located in the South), and the necessity of negotiating prices that are just and not only promote the conservation of existing resources but also lead to integrated development for everyone. As the deterioration in natural resources has shown, the paradigm of sustainable development is a benchmark but not a reality in the present system of production (Lelé 1991; The Great Debate Schools Programme 2011). When the ongoing processes of development between 1980 and 2005 are compared, there is no sustainability: resource intensity was reduced by twenty-five per cent, population increased by forty per cent, extraction of raw material increased by fifty per cent, and global *gross domestic product* (GDP) augmented by as much as 125 per cent (SERI 2010).

Our ecological footprint in 2014 was equivalent to the depletion of 1.5 planets (WWF 2014), even though we have only one that has favourable conditions for human life. In the distant past, fossil records show that for every thousand mammals, only one became extinct. The current extinction rate is a thousand times greater than the fossil record, and the future is expected to be ten times more destructive still than the present (MA 2005). During the last six decades of the Anthropocene in hand of multinational enterprises, nine million km^2 of soil (an area roughly the size of China) were moderately degraded and three million km^2 were severely degraded, losing their original biological function. We know that healthy soil is a basic precondition for living organisms (FAO 2012). All these data provoke the following questions: what are the obstacles to a sustainable and peaceful future for humankind and for nature? What violent system

lies behind the concentration of natural and economic goods that is capable of destroying both humankind and nature?

8.3   History and Adaptation of Patriarchy: A Structural Impediment to Equity

In the European tradition, the term and concept of 'patriarchy' emerged from Latin (*patriarchia*) and Greek (*πατριάρχης*) roots and is widely used in the contemporary social sciences. Etymologically, the *Shorter Oxford English Dictionary* (52002, vol. 2: 2122) defines 'patri-' as a combinatory form that refers in anthropology and sociology to a "social organization defined by male dominance or relationship through the male line". It defines 'patriarch' in contemporary British English as: "1 The male head or ruler of a family or tribe...; 2 (Ecclesiastical) An honorific or official title given to a bishop of high rank ... 3 (A person regarded as) the father or founder of an institution, tradition, science, school of thought etc.; 4 A man or thing which is the oldest or most venerable of a group; esp[ecially] the oldest man in a village or neighbourhood; a veteran, a grand old man". 'Patriarchy' is defined in the same dictionary as a "patriarchal system or society or government; rule by the eldest males of a family; a family, tribe, or community so organized", and 'patriarchalism' as a "patriarchal rule or government", while 'patriachate' is "the position or office of patriarch; the jurisdiction of a patriarch; the residence of a patriarch". The German term 'Patriarchalismus' refers in economic sociology to the unlimited dominance of men in the family, tribe or society.[5]

From an American perspective, for *Webster's Third New International Dictionary* (2002: 1656) 'patriarchy' refers to a "social organization marked by the supremacy of the father in the clan or family in both domestic and religious functions, the legal dependence of wife or wives and children, and the reckoning of descent and an inheritance in the male line; a society so organized".

Originally, the term 'patriarchy' was understood as a system of society or government, where the father or the oldest male is the head of the family and descent and heritage is traced through the male line (Silverblatt 1987; Federici 1999; Meillassoux 1981). This means that the social structure of living is patrilocal and inheritance is patrilineal. These definitions describe a situation, but lack any analysis, which explains when the change from cooperation to exploitative patriarchy occurred among humans and what the structural elements and social relations were that favoured it. The following structural, functional, and diachronic analysis may help to deconstruct this long-term pattern of violence and exclusion.

Feminists (Reardon/Snauwaert 2015a, 2015b; Hartsock 1983, 1996; Young 1992) have analysed patriarchal structures and found that the social structure is male-dominated; for example, the most powerful roles in all sectors of society are held by men and the least valued by women (Lagarde 1990). A second hypothesis is that powerful men control the social structure because they consider that they are the only ones able to exert functions of control, and therefore women need male control, supervision, and protection. The control functions are often reinforced by violence, discrimination and exclusion. This division of labour and power has produced social values and male and female roles and social norms. Males generally work outside, are providers, and perform economic and political activities: they are the *homo sapiens*, while the work of women is devalued and 'made invisible'. Women are traditionally confined to the interior of their houses in order to care for the family, and they take on the role of being-for-others as *homo domesticus*.

Benett (2006: 54) argued that "Patriarchy might be everywhere, but it is not everywhere the same, and therefore patriarchy, in all its immense variety, is something we need to understand, analyse, and explain". It is precisely this variety and diversity which allows the present androgenic world to be overcome in different cultural contexts where power is exercised through control, oppression and the exploitation of nature and human beings. In order to deepen the understanding of the concept of an 'engendered peace', a paradigm without violence, control and destruction, it is crucial to understand the origin and process of consolidation of patriarchy, as well as the inherent power structure within which patriarchy developed and was consolidated.

8.3.1   Origin and Emergence of Patriarchy

During the first phase of the Neolithic and the initial agricultural revolution, social organization changed drastically, due to a fundamental change in the method of food supply. In place of hunting and gathering, humans began to domesticate some of the basic food items, such as millet in Africa and China some 10,000 years BP[6] (Lu/Zhang/Liu et al. 2009; Colledge 2007). Genetic evidence from rice shows that rice originates from a single domestication in the Pearl River valley in China between 13,500 and 8,200 BP (Huang/Kurata/ Wei et al. 2012). Wheat originated from the wild *emmer* and was first cultivated in the Levant as early as 11,600 BP. Heun, Schäfer-Pregl, Klawan et al. (1997) used DNA to identify the earliest wheat where *einkorn* was found on a site near the Karacadag Mountain Range, in modern Turkey. Maize was found to have grown around 8,700 BP in the Balsas river valley of Mexico (Ranere/Piperno/Holst et al. 2009) and was transformed from *teocinte* to the present cob of corn.

The long period of experimentation, including failures and adaptation, with these basic food crops required knowledge and cooperation among family members, regardless of their sex. Archaeologists and anthropologists agree that in this early phase of the agricultural revolution social groups had a better chance of survival when they cooperated. Goddesses and gods protected humans from natural catastrophes and there was no formal system of family relationship between men and women. Smaller or larger human groups lived together, and fertility and reproduction were at the centre of interest, since they provided a sufficient labour force for agricultural activities. The people transferred their agricultural knowledge to the next generation, which developed it further. The preservation of food was crucial, especially in extreme climate conditions. In cold climates, meat and fish were frozen on the ice, and in tropical climates food was dried in the sun. Later the food staple was improved and was fermented, pickled, cured, canned, and transformed into jam and jelly (Zerzan 2010).

The earliest human lifestyle (hunting and gathering) and later independent rural economic units in agricultural and pastoral settlements (8,000 BP) required a high level of collaboration between men and women (Federici 2004). Female fertility was crucial for the survival of these agricultural societies, and sexual promiscuity and group marriage were common (Morgan 1881). Goddesses symbolized the ruthless fertility of nature, and sexual regulations were progressively introduced to avoid incest (Malinowsky 1929). Human populations increased as each of these processes was able to improve conditions of food and life, and technologies progressed slowly. The leap forward occurred with the invention of plough, irrigation and flood control, so that in warmer climates several harvests could be produced each year.

With the domestication of food crops and livestock, technological improvements, better methods of conservation and especially with irrigation, a food surplus allowed food to be accumulated within productive units. Scientists agree that this important innovation began in Mesopotamia (Adams 1965). People in the hills were threatened by food scarcity and hunger and migrated from the mountains to the floodplain. However, these valleys between the Euphrates and the Tigris were often flooded and then later dried out. To overcome these arid climate conditions, the people built and maintained irrigation systems for villages. Around 3,500 BP villages grew into larger communities (Neugebauer 1993). Neighbouring food-scarce communities often attacked these cities. The situation of rural villages also changed drastically, with violent invasions by male hordes from the eastern steppes (del Valle 1993), and later different tribes occupied particular territories, although they were often driven out by poor climatic conditions.[7]

To find protection, Sumeria people organized themselves into larger cities, which represented small independent countries surrounded by agricultural areas. Each city had its own ruler and the irrigated farmland provided people with different sorts of food. Society became socially differentiated and people specialized in specific activities. Disputes over water became so intense that they led to armed conflicts, the military was created, and arms were produced to deal with internal conflicts and to protect the city against foreign invaders. The citizens built walls and dug moats outside the city to prevent ene-

---

6 BP = "Before Present" (used in archaeological dating for prehistory; "Present" is taken as 1950 CE). For historical dates, and to avoid a Eurocentric cultural approach, this chapter uses BCE and CE rather than BC and AD.

7 The wild Germanic tribes from Central and Northern Europe (Vandals, Goths, Langobards and others) brought the Roman Empire down; later the nomadic pastoralist Huns invaded southeastern Europe; there is archaeological evidence of Olmec expansion as far as Guatemala, and in China stronger dynasties conquered weaker ones.

mies from entering and to protect their people within the walls (Arnold 2004). Groups of men were trained for both attack and defence, and a social class of soldiers emerged in order to defend wealth in urban settlements. These armies were not just defensive but also invaded neighbouring cities and other kingdoms and towns, and stole goods, women and technological knowledge from them. Successive conquests of smaller regional cultures strengthened the regional dominance of an ethnic group. Slowly, greater kingdoms and empires were established which were better equipped militarily, and the division of labour was consolidated. Power was concentrated in the hands of a powerful king who ruled over his subjects and slaves. Women were successfully eliminated from decision-making and the exercise of power, and disappeared inside their houses. Violent conquest was a crucial ingredient of this patriarchal expansion, led by men and controlled by male armed forces.

Ideologically, fertility goddesses were replaced by male gods (the Sumerian Ishkurthe, who held supreme power, or Enki, the god of fresh water and male fertility, the Greek Zeus, the Meso-American Quetzalcoatl, etc.) and later by the religious control of one male father god (in the Jewish, Christian and Muslim religions). This ideological shift further diminished the role of women. They were confined to the house, their fertility controlled by a husband, and their labour was considered unproductive. This 'gender blindness' took away the highly visible efforts of women, because they did not fit the preferred patriarchal paradigm. Fathers gained authority over women, children and property, based on institutions of male rules and privileges that meant female subordination and expropriation. Patriarchy is thus closely related to gender roles, which are socially constructed and which generate norms through habits, costumes, violence and repression. With the historical evolution of societies, the division of labour became more diversified (Reilly 2010). Goods, including women, were traded first in local and regional markets, and later long-distance market structures were established during the great empires of Egypt, Meso-America, Inca, China and India (Meillasoux 1981; Hoodfar 1997; Silverblatt 1987).

Patriarchy includes therefore polity, religious belief, political economy, social discrimination, sexual control, and women's loss of power in decision-making processes. The origins of the political dimension of patriarchy, which has existed through all stages of the consolidation of political structures, included a war system to reinforce and consolidate the political system (see table 8.1).

In the beginning of patriarchy, the king further reinforced his legitimacy and took on the attributes of a divine supreme being. This king as God at the summit of the civil and religious hierarchy reigned over the city-state. The belief that patriarchy is part of the 'natural order' or 'ordained' by God has been invoked by fundamentalists from the majority of religious traditions and by the economic elite. Human coexistence was regulated by social rules that clearly discriminated against women and girls. The origins of patriarchy are also linked with a process of primitive accumulation, with social stratification, and with a hierarchical system of rule reinforced by religious fundamentalist beliefs. The first document carved in stone was the Hammurabi code of 1754 BP. This code contains 282 laws, which organized all aspects of life in the city-kingdom. The code distinguished between free men and slaves and is based on the punishment philosophy of 'an eye for an eye, a tooth for a tooth'. One-third of the code addressed issues of family relationships, household, inheritance, divorce, paternity and sexual behaviour. Women were clearly discriminated against and oppressed by this code. After marriage, a women's sexuality became the property of her husband, and adultery by women was punished by the death penalty. Female slaves belonged to their master. Girls from higher classes had to remain virgins until their marriage, and inheritance was patrilineal. This code is the first written evidence of patriarchal relationships in an agricultural society (table 8.1).

Similar processes occurred in Greece, Egypt, China, Meso-America and the Roman Empire, and widened the scope of patriarchy. Goddesses were successively replaced by male gods and later often by one dominant and vindictive male god. During the past 4,000 to 5,000 years these initial patriarchal relationships were transformed and have shown a tremendous capacity to adapt to different systems of rule (e.g. king as God, city-kingdoms, monarchies, slavery colonialism, republics, autocracies, communism, liberal democracy), economic systems (slavery, feudalism, mercantilism, capitalism, socialism, neo-liberalism), and processes (barter, conquest, piracy, interchange, market). Nevertheless, during these thousands of years of evolution, patriarchy also adapted to regional and social differences, even though its basic roots continue to be violence, discrimination, domination, exploitation, and oppression in household and society, in short, a system of waging war in order to maintain the dominant power relationships. Its verti-

cal structure integrated cultural and ritual elements into its system of rule in Mesopotamia, China, Meso-America, the Roman Empire, and later in the European conquest of Asia, America, and Africa. It replaced the traditional legal forms of social coexistence and imposed worldwide a single system of rule controlled by Bretton Wood: the International Monetary Fund, the World Bank and the World Trade Organization. Within these patriarchal social representations and exercises of power, empires, feudalism, conquest, monarchies, mercantilism, capitalism, and socialism emerged and laid the basis for the current neo-liberal globalization at the hands of corporate enterprises, international legal support (Serrano 2013), and military control by the US.

In the mid-twentieth century a postmodern globalization emerged that is largely influenced and controlled by neo-liberal multinational oligarchies, authoritarian governments and hierarchical structured and exclusive religions. The state of law has developed an independent system of rule divided between the executive, the legislative and the judiciary branches of government at the national level. Nonetheless, international treaties and normative systems of operation have been inefficient when leading states and domestic political forces or interests have opposed them and tried to block or constrain such changes in the systems of operation (Diehl/Ku/Zamora 2003). All legal international frameworks have largely reflected occidental interests and have replaced the original tribal or indigenous community norms and rules in the southern hemisphere (Bartra 2012). The global interests of a transnational oligarchy (Lander 2011), supported by hegemonic governments, represent the present patriarchal system, where warfare, the corporate economy and political power determine the present neo-liberal process of globalization.

With this historical construction of gender differentiation of male-ness and women-ness (Mies 1986), together with the glass ceiling for women, patriarchy spread from within the family structure up to the level of the kingdom, e.g. in the Greek democracy, the Roman Empire, in feudalism, mercantilism and capitalism (Reardon/Snauwaert 2015a, 2015b). In England in the seventeenth century, Robert Filmer developed the political theory of "Patriarcha" for the kingdom and compared the *paterfamilias* with the king. The origin of patriarchy preceded the institution of private property (Engels 1940 [1884]), and goes back to the earliest establishment of cities in the river valleys of the Jordan, the Euphrates and Tigris, the Nile, and the Indus (more than 3,000 years BCE). Similar conditions were found a thousand years later in the cities of Meso-America and China. These urban processes were consolidated in a similar way among regions, people, and social developments. Vertical relationships of rule, with labour specialization, class distinction, social hierarchies, kingship, priests, writers, artisans and the military, thus a clear division of labour, characterized the goal of an unequal appropriation of the surplus. Without any doubt, the productive work of women was essential to maintaining society, but women's power structures and processes of decision-making were systematically devaluated and obscured.

Undoubtedly, during the last millennia the evolution and consolidation of patriarchy has changed and become differentiated regionally. Nevertheless, there are some common dominant factors: the ideological control mechanisms around the world have both socio-biological and social constructivist explanations. While the first uses genetics and biology to explain male control, the second focuses on socially constructed gender roles, which have changed over time, could change further, and must be abolished in order to allow the creation of an engendered security and peace. Anthropologists have suggested that most hunter-gatherer and early agricultural societies were egalitarian and cooperative between genders (Hughes/Hughes 2001). Following social and technological innovations (irrigation, cities, technology), social stratification, fatherhood, and sexual control over women and girls became dominant (Kraemer 1991).

In economic terms, Hartmann (1976) locates the interrelationship between patriarchy and female subordination at the material level, where the control of women's labour, in both the private and public spheres, is in the hands of men. Today the reduction in the purchasing power of wages obliges an increasing number of families to have two incomes. Usually, job segregation by gender means that "economic class differences and patriarchal social control are maintained. Job segregation and the wage differential tend to keep women connected to and partially dependent on men, so that even though we have a high divorce rate, the practice of marriage is perpetuated" (Hartmann 1976: 147) and therefore so is the concept of reproduction.

Table 8.1: Rise and adaptation of patriarchy in different socio-economic contexts. **Source:** The author.

Type of society	Era	Activities	System of Rules	Goals	Ideology, faith	Adaptation to risks	Gender relations
Neolithic and agricultural revolution	8000–3000 BCE	hunting, gathering, pastoralism, subsistence agriculture, millet in China (5000 BCE)	emerging rules against incest	subsistence, survival, cooperation among humans	fertility cult, goddesses, Mother Earth as archetype, protecting gods, stone carving, painting of caves	migration due to climate variability, lack of resilience, survival strategies,	equality, equity, cooperation, participation in labour and local rule, control of incest
Centralized god-state (Babylonia) China: Liangzhu dynasty (3400–2250 BP)	3000–50 BCE	crop development, livestock, agriculture with irrigation & aquaculture, handicraft, division of labour, military, writing on stone	paterfamilias, monarchy with god-kings, legal written rules of social behaviour, slaves	subsistence, territorial expansion, kingdoms, elite, social stratification, slaves, improvement of agricultural technologies (plough, irrigation, flood defences)	king as god, absolutism, Buddha, evaluation of cultural expressions, one male god (Judaism)	gods, goddesses, migration, invasion, army, militarized defences, protected settlements, women are turned invisible	women submissive to husbands, central male power, control of virginity of girls and sexuality of women, complex societal hierarchies, castes, slaves, discrimination, sanctions against women
Slavery, Xia dynasty (1600–1050 BCE); Shang dynasty (1700–1046 BCE), Zhou dynasty (1046–256 BCE), Mayan kingdoms	3000 BCE - 1772 CE	household productive activities (mines, plantations), rural villages and emergence of towns	monarchy, state with senate (Greece), empires in China and Meso-America, political entities and mandate of heaven; written laws and clear social rules	labour force, free service, exploitation of slaves and women, territorial expansion	master, dominance, private, public and state property	buy freedom (bail-out) with money or service, escape, struggle	patriarchal violence exclusion, control, rape, discrimination
Roman Empire	27 BCE–476 CE	market institutions, global commerce, conquest	empire with senate, protection of citizens within the *limes*, laws and social rules	territorial expansion, conquest, control, *pax romana*	male gods, one father god, expansion of Christianity and Buddhism	war outside *limes*, emergence of democratic institutions and division of power	patriarchal patrilineal patrilocal discrimination
Feudalism, Inca, Aztec, Chinese empires, European monarchies	9th–15th century CE	lords, vassal fiefs, agriculture, wars, recognition and protection by monarch	religious and civil authorities, kingdoms, dynasties, cities, lords, tributes, written law and personal agreements	reciprocal legal and military obligation, individual states, monarchies, original accumulation	one male father god, Christianity, Occidentalism, Confucianism in China, Buddhism in S, SE and NE Asia, Hinduism in India and Nepal	ceremonies agreements protection, alliance, migration, wars, military, exploitation, renting land	patriarchal patrilineal patrilocal discrimination against women, burning of witches
Conquest	15th–19th century CE	control of market in natural resources and products, exploitation of mines, food products, and natural resources	empires, kingdoms, lords, absolutism, colonization, occidental laws and customs imposed in colonies	colonies, gold, territorial expansion, raw material, land, new food products, medicinal herbs	dominant Catholic church, one male father god destruction of traditional beliefs and cultures	war, military, destruction of autochthonous cultures, ideological and religious control, colonial control	patriarchal patrilineal patrilocal, genocide, rape, discrimination, violence

Type of society	Era	Activities	System of Rules	Goals	Ideology, faith	Adaptation to risks	Gender relations
Mercantilist capitalism	17th–18th century CE	market partially coordinated, exploitation, trade	emergence of nation states, trade rules and consolidation of trade routes, Westphalian peace agreement (1648)	government monopoly with private investments	one male father god, goods	production and distribution toward market forces, violence, respect for internal differences of states	patriarchal patrilineal patrilocal, extended families, exploitation, discrimination, violence, exclusion, women and child labour
From commercial to labour capitalism	1750–1930 CE	industrial revolution, proletariat, labour unions	division of rules (executive, legislative, judicial), trade unions	paid labour force, proletariat, oil, GHG, resource scarcity, repression of any opposition	one male father god, money, class struggle	exploitation urbanization, laws agreements, poverty, migration, hunger, Red Cross	patriarchal patrilineal small families, female and child labour, exploitation, discrimination, individualism
Socialism–Marxism	1848 (1917) CE – present	state-organized economy, social welfare, education, militarization, Eastern bloc, bureaucracy, a one party state	USSR and Chinese Communist Party, economy planned by the state, Supreme Soviet, central committee, democratic centralism, Warsaw Pact, massive famine, repression	bureaucratic centralized economy, scarcity of basic goods, high level of military expenditure, technological improvement	social equality, proletariat, party elite, socialism, atheism, cold war, representative wars in the South and East	education, social welfare, military warfare, Warsaw Pact equality of labour (men–women), women's emancipation in labour system	patriarchal small family under state control, female political participation, gender discrimination, glass ceiling for women, violence, party hierarchy
From industrial to state capitalism and social capitalism	1930–1980 CE	national sovereignty, control of capital by the state, taxes, redistribution of some income, economic blocs	welfare state, division of rules (executive, legislative, judicial), UN Charter, human rights, NATO, US dominance, Bretton Wood organizations	protection of labour force, trade, and finances; equality, resource abuse, pollution, scarcity, science and technology	one male father god, capitalism, welfare state, cold war, independence movements in India, Africa and Asia	welfare state, pensions, social security, militarization, military warfare, feminist groups, anti-war movements	patriarchal patrilineal small family, female suffrage, some redistribution of wealth, support of female labour force, housewifization, subordination, inequality
Neo-liberalism, internationalization of finance, globalization of markets, fashion, consumerist culture, superpower military control, business-as-usual	1980 CE –present	financial and market control, privatization, lack of social protection, globalization, liberalization, deregulation, FTA, financial crises, youth unemployment, military and police control, illegal activities (drugs, arms, human trafficking), money laundering, emerging countries, BRICS	Hegemonic world order, military interventions, division of power (executive, legislative, judicial) systems, small government with large security sector, global oligarchy with multinational enterprises, binding agreements, Washington Consensus (IMF, World Bank, WTO), NATO, structural adjustment policy	economic crises, laissez-faire, free market, globalization and deregulation of financial markets, unemployment, increase of poverty and hunger, development of productive forces, R&D, innovation, resource exploitation, GEC, climate change, ideological domination, massive global consumerism	one male father god, money and economic totalitarianism, elite, poverty, oligarchy with governmental legitimization, social consciousness, risk perception, horoscope	informal labour force, migration, poverty, resource wars: oil, mines, water, social conflicts, warfare and economic organizations (e.g. OECD, EU, ASEAN, NAFTA, BRICS and other economic associations for cooperation and disaster risk reduction, urbanization, horoscope, massive tourism, human rights groups, feminists, alternative media	patriarchal, patrilineal small family, individual violence, incipient female political participation, discrimination, glass ceiling, but also women's and civil rights movements in the US, empowerment, resistance, power-from-within, self-subjugation, contraception, solidarity, peace building, ecofeminism

Edholm, Harris and Young (1972) distinguish three forms of the concept of reproduction: 1. social reproduction that includes the reproduction of the total conditions of production; 2. the reproduction of the labour force, and 3. biological reproduction. This distinction helps to combat the Marxist emphasis on the importance of the economy for reproduction, and to understand that patriarchy goes far beyond the rise of capitalism. Various feminists have defined the evolution of this dominant social system, which can be found globally in different temporal and spatial frameworks, as patriarchy. It is "the power of the fathers: a familial–social, ideological, political system in which men—by force, direct pressure, or through ritual, tradition, law and language, customs, etiquette, education, and the division of labour, determine what part women shall or shall not play, and in which the female is subsumed under the male " (Benett 2006: 55).

Maria Mies (1986) asks why the exploitation and oppression of women are not only accidental phenomena but an intrinsic part of the systems that have controlled women throughout thousands of years of humanity and its evolution, and why such a brutal system could not be overthrown with modernity. She insists that capitalism cannot function without patriarchy and that the "struggle against all capitalist–patriarchal relation ... [means that we] have to extend our analysis to the system of accumulation on a world scale, the world market or the international division of labour" (Mies 1986: 39). How did this happen?

These brief summaries are an attempt to explain in general terms how patriarchy emerged and became a global archetype of male and female roles and behaviours, which are culturally embedded in order to support an unequal, exploitative, violent and destructive system of rules. A crucial requirement related to the consolidation of patriarchy worldwide is to understand the manifest and hidden power relations, which enabled minority social groups to accumulate power and wealth at the cost of the majority. This basic system of patriarchy evolved and created the potential for further development and greater consolidation. Different social systems emerged, but all of them reinforced a system where power and wealth were concentrated in a minority of male leaders at the cost of the majority. The present oligarchic system of neo-liberal control, where a small number of corporate enterprises dominate the world economy, is the historical result of patriarchy consolidated through different economic and political processes such as slavery, feudalism, colonialism, and capitalism.[8]

While economic factors are the basis of any social system and they are crucial to understanding the consolidation of patriarchy worldwide in the past and the present, it is existing power combined with violence, war, conquest, ideological superiority and religious belief that has permitted this sophisticated dominant system of rule. The global arena is today one of neo-liberal globalization, where Margaret Thatcher could insist that 'TINA': "there is no alternative". The next chapter reviews these power relations from a feminist point of view.

8.3.2   Feminist Analysis of Power Relations

Most feminist theories try to explain women's subordination by analysing the intersections between sexism, racism, heterosexism, and ethnic and class oppression, while Marxist feminists include economic domination. Ecofeminists believe that similar power relationships between dominance, greed, exploitation, and violence (D'Eaubonne 1974; Mies 1986; Warren 1997) cause environmental destruction. Other approaches envision the possibility of overcoming such subordination through both individual and collective resistance, and through empowerment. Allen (1998, 1999, 2008, 2011), Hartsock (1983, 1996), and Young (1992) have analysed the concept of power as a central element in understanding this subordination and in discovering the limits to and potential for a sustainable-engendered peace and worldview.

Adrienne Rich (1976) gazes into the fissure that separates modern women's link to maternity and the "theories, ideals, archetypes, descriptions" of the patriarchal culture that is replacing this relationship. "All human beings are born of women therefore all have a connection to motherhood, more fundamental than tribalism or nationalism ... [But patriarchal culture] has created images of the archetypal Mother, which reinforce the conservatism of motherhood and convert it to an energy for the renewal of male power". Rich insists that art should evoke in its cultural scope "rape and its aftermath ... marriage as economic dependence ... the theft of childbirth from women ... laws regulating contraception and abortion

---

8   The development of capitalism in Britain destroyed most domestic production and forced women, men and children into the factory system. Similar processes occurred in Latin America, Asia and Africa, where rapid urbanization was a result of rural-urban migration in order to improve income and to obtain better services in the cities, although the outcome was shantytowns.

... the absence of social benefits for mothers". This archetype is charged with patriarchal elements, such as rape, violence, and submission. The active role of women is visible in neither society nor peacebuilding.

There are four different approaches to analysing power relations. The first relates to the exercise of 'power-to' in the traditional way of Thomas Hobbes, who understood the concept as power-to "obtain some future apparent good" (Hobbes 1985 [1641]: 150). Max Weber added 'power-over': "the probability that one actor within a social relationship will be in a position to carry out his own will despite resistance..." (Weber 1978: 53). Michel Foucault developed this approach in his analysis of institutions of control. He affirmed that "if we speak of the structures or the mechanisms of power, it is only insofar as we suppose that certain persons exercise power over others" (Foucault 1983: 217). It was Hannah Arendt who understood power as "the human ability not just to act but to act in concert" (Arendt 1970: 44). In her sense, power is the capacity to act, although she states that "power springs up between men when they act together and vanishes the moment they disperse" (Arendt 1958: 200). Lukes also defined power also as a possibility when he affirms that power "is a potentiality, not an actuality—indeed a potentiality that may never be actualized" (Lukes 2005: 69).

The fourth way of understanding power is as a systemic conception where power is seen as "the ways in which given social systems confer differentials of dispositional power on agents, thus structuring their possibilities for action" (Haugaard 2010: 425), and precisely this type of power is able to promote an engendered-sustainable peace. This systemic conception highlights the ways in which "historical, political, economic, cultural, and social forces enable some individuals to exercise power over others, or inculcate certain abilities and dispositions in some actors but not in others" (Allen 2001: 3). The systemic approach goes back to Weber's understanding as 'power-over'. Feminists are interested in understanding the gender-based relationships of domination and subordination, and how women could empower, and then how such relations could be generalized in the whole of society. In a liberal feminist approach, power is understood as a resource oriented towards a positive social good ('power-to'). Okin found that in the distribution "between husbands and wives of such critical social goods as work (paid and unpaid), power, prestige, self-esteem, opportunities for self-development, and both physical and economic security, we find socially

constructed inequalities between them, right down the list" (Okin 1989: 136).

This approach is underlain by a broader social, cultural, institutional and structural context in which power relations are organized. Young (1990) focused on the relationship of domination, understood as oppression, patriarchy and subjection. She considered power to be a special 'power-over' relation, which is unjust and illegitimate. She was inspired by Simone de Beauvoir (1974), who understood power as domination or oppression. Beauvoir recognized that women are partly responsible for this power oppression by submitting to the status of the 'Other' in order to avoid the anguish of authentic existence. From a radical point of view, MacKinnon (1987: 123) insisted that "women/men is a distinction not just of difference, but of power and powerlessness. ... Power/powerlessness is the sex difference".

Judith Butler (1990) and other critics of the sex/gender distinction think that sex differences or gender differences are socially constructed in order to maintain the existing relationships of power. Economic and political power within the family is thus concentrated in the hands of husbands or dominant male figures and supports the system of private property and patrilineal heritage. Frye (1983) compares this male domination to a master/slave relationship, and she defines oppression as "a system of interrelated barriers and forces which reduce, immobilize, and mould people who belong to a certain group, and effect their subordination to another group (individually to individuals of the other group, and as a group, to that group)" (Frye 1983: 33).

In the case of historical materialism, feminists have criticized Marxism because of its lack of understanding of gender. Young (1990: 21) went behind the dual systems theory: women's oppression arises from two distinct and relatively autonomous systems. "The system of male domination, most often called 'patriarchy', produces the specific gender oppression of women; the system of the mode of production and class relations produces the class oppression and work alienation of most women". She proposed an authentic feminist historical materialism in which she identified five types of oppression: economic exploitation, socio-economic marginalization, lack of power or autonomy over one's work, cultural imperialism, and systematic violence (Young 1992: 183–193).

Hartsock understood that the dominant group, such as men and the ruling class or oligarchy, is the one carrying out the analysis of power. She is concerned with "(1) how relations of domination along

lines of gender are constructed and maintained and (2) whether social understandings of domination itself have been distorted by men's domination of women" (Hartsock 1983: 1). Patricia Hill Collins (2002) proposed the concept of "interlocking systems of oppression" where racial, gender, and class-based subordination are intertwined. Foucault (1977) influenced radical feminists, although Bartky (1990: 65) criticizes him because he did not understand that disciplinary practices are gendered due to the fact that women's bodies are rendered more docile than the bodies of men. "[I]t is women themselves who practise this discipline on and against their own bodies ... The woman who checks her make-up half a dozen times a day to see if her foundation has caked or her mascara run, who worries that the wind or rain may spoil her hairdo, who looks frequently to see if her stockings have bagged at the ankle, or who, feeling fat, monitors everything she eats, has become, just as surely as the inmate in the Panopticon, a self-policing subject, a self committed to relentless self-surveillance. This self-surveillance is a form of obedience to patriarchy" (Bartky 1990: 80). Butler notes that subjection is a paradoxical form of power. It has an element of domination and subordination. She writes: "if, following Foucault, we understand power as forming the subject as well as providing the very condition of its existence and the trajectory of its desire, then power is not simply what we oppose but also, in a strong sense, what we depend on for our existence and what we harbour and preserve in the beings that we are" (Butler 1997: 2). Fraser (1989) insisted that the normative notions (autonomy, legitimacy, sovereignty) are themselves effects of modern power, and Hartsock (1990) claimed that the deeper analysis of power can be performed only from the standpoint of the dominated, exploited and subordinated.

From an analytical feminist viewpoint, Cudd (2006: 21–23) understood oppression as "an objective social phenomenon". She mentioned four conditions: 1) the group condition, which states that individuals are subjected to unjust treatment because of their (ascribed) membership; 2) the harm condition, where individuals are systematically and unfairly harmed due to such membership; 3) the unjustified coercion condition of the harms; and 4) the privilege condition, which states that such coercive, group-based harms count as oppression only when there exist other social groups who derive a reciprocal privilege or benefit from that unjust harm.

Confronted with these different approaches, feminists from various theoretical backgrounds have reconceptualized power as the capacity to empower and therefore to transform oneself, others and social conditions. These feminists understand power not as 'power-over' but as 'power-to'. On the other hand, Wartenberg (1990) argues that this transformative power is a type of 'power-over', but one distinct from domination because it permits the empowerment of those over whom power is exercised. Miller insisted that women's perspective on power takes a different approach: "there is enormous validity in women's not wanting to use power as it is presently conceived and used. Rather, women may want to be powerful in ways that simultaneously enhance, rather than diminish, the power of others" (Miller 1992: 247–248). Therefore, for Hoagland, "power-from-within" is "the power of ability, of choice and engagement. It is creative; and hence it is an affecting and transforming power but not a controlling power" (Hoagland 1988: 118).

Hartsock (1983: 226) took the view that male power relations established over thousands of years "should allow us to understand why the masculine community constructed ... power, as domination, repression, and death, and why women's accounts of power differ in specific and systematic ways from those put forward by men ... such a standpoint might allow us to put forward an understanding of power that points in more liberatory directions". Years before, Hannah Arendt had rejected the command–obedience model of power and had insisted on "the human ability not just to act but to act in concert" (Arendt 1970: 44). Her understanding of power brings together individual empowerment with a focus on community or collective empowerment, which is also the key to the understanding of resistance by all oppressed groups, including indigenous peoples, racial groups, and minorities. The question that remains for the creation of a sustainable-engendered peace is then, how can this transforming power be used to overcome patriarchy, the war system, and human and environmental destruction?

While the hopes of women and other vulnerable groups suffered a backlash from the dominant structures, after World War II independence movements in Asia and Africa challenged imposed colonial structures. In the US, women's and civil rights movements changed the most discriminative behaviours and produced a social consciousness of social and political processes. In Japan and the USSR women left their homes to join what the government called 'the war effort'. In the global South,[9] the lives of women remained mostly unchanged, although the dictatorships in Latin America presented women with the possibility of

fighting against military repression and for their disappeared children and grandchildren.

The 'pill' and other modes of contraception gave women—and not only in the North—more control over their fertility and a sense of autonomy that fed into the women's movement. Issues of health and social costs were transferred to the South, where women were used as human guinea pigs—as an uneducated market, they became victims of the promotion of formula baby milk, while the rest of the world returned to breastfeeding for the sake of their children's health. Immigrant women from the South were also increasingly used as cheap household labour with little or no rights. While Betty Friedan's (1963) rallying cry against the 'feminine mystique' allowed women to put limits on 'housewifization' and 'domesticity', the differences worldwide are enormous.

All these analytical and practical reflections have challenged the constructed self-discipline and internalization of gender roles in most societies, although the enemy —corporate power based on patriarchy— is immense. None of the advances made in women's empowerment could halt the progress of the neo-liberal model, where patriarchy has developed an almost perfect model of exclusion, concentration of wealth, exploitation, discrimination and violence. A common struggle involving both men and women to defeat this corporate power requires global empowerment and a social pact without patriarchal relations. This change will simultaneously produce an economic, environmental, cultural and ideological restoration of dignity and respect for humans and nature. Only the transformation of these deeply embedded patriarchal structures will be able to overcome thousands of years of consolidation and perfection of patriarchy and the present-day inhuman corporations. This change to the roots of the system will also open the way to a sustainable-engendered peace for South and North, women and men, the elderly and children.

---

9 There is no doubt that the economic and social conditions of women worldwide are very different and the different phases of the evolution of patriarchy and later capitalism have left a large population of men and women, the elderly and children bereft of the basic requirements of life. The present chapter tries to overcome the occidental approach that sees the Western rise of capitalism as the key reason for the exploitation of human beings and nature. The text focuses on the root causes of violence, which began thousands of years ago and through the consolidation of neo-liberalism culminated in a system of exclusion.

8.4 Engendering Sustainable Peace and Security by Transforming Patriarchy and its War System

Through this conceptual review, patriarchy can be seen to be understood historically as being imposed on women through violence (via conquest, spoliation, rape and feminicide), discrimination (by laws and rules), subordination (through economic and sexual control), hierarchy (by the notion of paterfamilias, today represented by the global oligarchy), inequality (in education, income, leisure and political power), through exclusion (patrilineal and patrilocal inheritance and exclusive globalization), and through social representations (constructed self-discipline and internalization of gender roles).

As Burton (2013) maintained, during the agricultural revolution and the consolidation of god-cities, motherhood was bereft, fertility goddesses abandoned, and reproduction shut away into the private sphere. This spoliation of motherhood has given rise to gender inequalities not only among women, but also among men with less power (the indigenous, the unemployed, youth and the elderly). Together with discrimination, it has limited opportunities for employment, education and art, and undermined solidarity because of the dominant individualistic values that have been imposed by the Western value system. The same mechanisms that were used for the oppression of women were employed in the destruction of Mother Earth. In the past, humanity depended directly on ecosystem services for its survival, although there were fewer humans on earth. The pressure on soil, water, air and biodiversity was less. Through the processes of industrialization, the massive use of fossil energy, the exponential growth of population, and the wasteful consumerist society, during the last six decades earth history has moved from the Holocene to an era called by Crutzen (2002) the Anthropocene. Patriarchy has destroyed nature through the same mechanisms as it has done with women, changing the face of the earth by producing a global environmental change.

On the social side, the *information technology* (IT) revolution after World War II gave women a new hope that they might empower and overcome the patriarchal structures. Many women and also men thought that the integration of the three revolutions (agricultural, industrial and IT) would allow women and socially vulnerable people to get rid of backward, feudal and patriarchal relationships. However, what actually happened was that the structures of dominance were consolidated as the neo-liberal patriarchy

transformed women into housewives. These new social arrangements also increased the establishment of nuclear/small families, where children and especially the elderly lack space because of small living-spaces. This *housewifization* (Mies 1986) affects not only women and family relationships, but also male labour and especially youth.[10] Since 2008, most countries have lost incomes and jobs during the latest financial crisis; poverty has grown, and the anorexic state, because of earlier massive processes of privatization, is unable to balance monopolized capital, the needs of the people and the needs of jobless workers.

There is no doubt of the consolidation of the present neo-liberal system by a market economy, globalization, liberalization, deregulation, privatization, and free trade agreements. Selective World Bank investments, the structural adjustment policy of the International Monetary Fund, and the regional and global treaties of free trade agreements under the jurisdiction of the World Trade Organization with TRIPs have created a billon hungry people (mostly children), three billion people without safe water and improved sanitation, and fifty-eight corporate multinational oligarchs which own half the wealth on earth (UNDP 2014: 21).

Therefore a key question is how the embedded system of patriarchy can be transformed. Betty Reardon (1985) looked into the deep fear-based psychological dynamics that underlie the symbiotic relationship between patriarchy and the war system: "I continue to insist [that] ... the oppression of women and the legitimation of coercive force which perpetuates war, the two major pillars of patriarchy, are mutually dependent conditions..." [Reardon 1985:98]. In the same book she insists that "... militarism and militarization [are] the bastions and bulwark of patriarchy" (cited in Reardon 2015a: 74). She actively worked for peace education and linked it with peacekeeping, peace-making and peacebuilding, and with Agenda 21, thus promoting an agenda of conflict reduction and resolution and an agenda for development and for restoring the environment.

To achieve a sustainable peace she listed four basic transformations needed to overcome patriarchy, militarism and injustice:

1. The general adoption of a feminist, holistic, gender-equal perspective.

2. A fundamental change in worldview, which includes the widespread inclusion of feminist values in all levels of society, including the public domain and government.
3. Shifting the concept of security from national security to human security, and a cosmopolitan ethic.
4. A widespread increase in self-awareness among the population (Snauwaert 2015: XVI).

Combining this with Young's proposal we may include in the concept of a sustainable-engendered peace the reduction of economic exploitation, global policies to overcome socio-economic marginalization, training for increased power or autonomy over one's own work, the eradication of cultural imperialism, and the eradication of systematic violence. Ecofeminists also draw attention to the relationship between patriarchy and the plundering of natural resources: "there are important connections between how one treats women, people of colour, and the underclass on one hand and how one treats the nonhuman natural environment on the other" (Warren 1997: XI). An engendered peace requires the healing of the environment through a massive reduction in fossil energy and greenhouse gas emissions, a full recycling of all materials, and a systematic restoration of all ecosystems and renewable natural resources.

8.4.1 Transition to a Sustainable-Engendered Peace

The analysis presented above has described the development of at least five thousand years of patriarchy and the complexity of embedded power relations from the family to the global level. In addition, awareness is growing that conflicts and post-conflict situations have different implications for women and men. There have been few efforts at international and government levels to propose gender-sensitive policies. This comes partly from a lack of gender knowledge, but also demonstrates the continuing resistance to losing small benefits from the patriarchal system. A third problem is the lack of money available for gender-sensitive peace efforts, as most of the money is used internationally for UN peacekeeping forces, who have limited opportunities to promote a stable peace as their task is oriented towards the maintenance of a negative peace. Their modes of action are militarized and the UN operates under the dominant patriarchal state paradigm. Their troops have been among the perpetrators of sexual violence against women and have often failed to protect the vulnerable (Ruanda).

---

10 Unemployment rates among youth are extremely high, especially in South Africa (53.6%), Libya (50.8%), Spain (57.3%), Greece 58.4%, and Croatia (51.5%), to mention only those countries with the highest unemployment rates on earth (ILO 2014).

It is difficult to promote an engendered peace when in the recent history of any conflict–but also during so-called times of peace–women and girls have been the victims of sexual violence and torture carried out to express domination along gender lines, as well as to humiliate the male enemy. Arendt (1979) distinguishes between the space of appearance, as a space of political freedom and equality, constructed by citizens through the medium of speech and persuasion, and the space of the common world. The second is a shared and public human world with institutions, agendas, and actors, which provides a relatively stable environment for activities. Both spaces are essential for the consolidation of citizenship, and hence essential for a change in the dominant power relationships. Arendt insists that the recovery of a common and shared world will reactivate a mode of citizenship where individuals and groups can establish relationships of support, reciprocity and solidarity. It is precisely in the common space where collective ideas can emerge and group preferences are strengthened. It is in this space where gender-sensitive practices and peacebuilding can be developed.

There have been many movements worldwide that have achieved major political goals without arms and through non-violent activities. There was Gandhi's non-violent movement for India's independence; the Civil Rights movement in the US against racism; the ending of apartheid in South Africa and the construction of a rainbow democracy; the Velvet Revolution in Czechoslovakia that overcame authoritarianism; and the fall of the Berlin wall and the reunification of both Germanies. There is also the interesting case of Costa Rica, a country that abolished its army in 1948 and invested the savings in education and public health. Today it is the country with the highest Human Development Index and the lowest crime rate in Latin America (UNDP 2014).

Worldwide there is a growing concern about environmental and social deterioration, as a result of the current process of neo-liberal globalization. Most of these efforts occur in isolation, sometimes through leadership struggles. A systemic process is still lacking where first a collective thinking emerges, then a readiness to act, and later a process of judgement, which is necessary, as Hannah Arendt argued, for efficiency in the common space and for achieving goals through peaceful means. This means that first of all it is necessary to design an agenda for combating patriarchy from a clearly gender-equal perspective. This means equal salaries for equal work and making visible unpaid household work and caring activities, which are mostly carried out by women. The revalorization of household and caring activities is needed to produce a more just distribution of the unpaid workload at the household level (Parvin/Bélanger 1996). At the local level, all types of discrimination and oppression in jobs, public spaces, and the media must be made known and prosecuted at law. At the regional, national and international levels, there is the need for a rigorous assessment together with an adjustment of all legal frameworks towards gender equality, with clear guidelines for a policy of equity and equality. This includes the abolition of the military and of warfare.

In the second phase, young people and the alternative media can promote a worldview where feminist values are anchored at all levels of society, including in the public domain and in government. In the third phase, there should be a shift at national and international levels from the narrow militaristic view of security to human security (UNDP 1994) and a "widespread increase in self-awareness among the population" (Snauwaert 2015: XVI), where the environment, sustainability, and gender security (Oswald 2013) are key values.

8.4.2 Engendering a Sustainable Peace: Imagining the Possible

Thousands of years of written and institutional woman-hating activities have limited the understanding of how harmonious relations between nature, humankind, and gender might be achieved. Violence, authoritarianism, discrimination, and exclusion have not only affected the environment, but also limited democracy and gender equity, and increased risks for both men and women (Beck 2009, 2011). "The patriarchal culture of control and domination is the root of all social and ecological violence. It corrupted the original unity of man and woman and is now corrupting the unity between humanity and the human habitat" (Burton 2013). Peace and security were conceived within a male-dominated system and conceptual evolution is imbued with these patriarchal biases. For this reason, Serrano Oswald (2009) noted that security and peace must be engendered in conceptual terms to overcome the underlying prejudices.

A transition to a sustainable-engendered peace requires an ethical framework and a clear strategy for change (Grin/Rotman/Schot 2010). The current method of reaching a holistic peace is seen as a step-by-step procedure through international organizations, governments, social movements, and *non-governmental organizations* (NGOs). This may be too slow to

achieve the goal, as environmental and social conditions are deteriorating so fast that the traditional diplomatic way may be too late to transform thousands of years of oppression and violence into a sustainable-engendered peace. Disasters tripled between 2000 and 2009 compared with their number between 1980 and 1989. About eighty per cent of this increase is climate-related, and greenhouse gases have risen above 400 ppm. Since 1990, extreme events that resulted in disasters have affected about 217 million people yearly. Time and the speed of change are becoming crucial variables in changing the paradigm of patriarchy to a sustainable-engendered peace.

Facing this reality, most feminists propose a more radical way, where a cultural change in worldview and mindset is necessary in order to overcome the present system of patriarchal oppression (Oswald/Brauch 2011). This means a change in the globally organized way of life and changes in values, norms, beliefs, institutions and productive processes, and also requires the human-oriented development of science and technology. It means a collective learning process, one which is not based on the so-called 'natural laws' of patriarchy where women are invisible, but one which understands that discrimination, violence, and exploitation are socially constructed and follow hegemonic power interests. To defeat patriarchy, deeply anchored structures and mechanisms of control must be demolished. As Simone de Beauvoir argued and Frye (1983) emphasized, there are not just external factors of control, but also internal ones, which have created a system of articulated barriers and forces that are able to immobilize people. As Hannah Arendt stressed, there are also social cognition processes, which are able to overcome the deep structures of violence and empower groups of people to promote holistic and complex sustainable change.

Finally, the difference in the public response to the fourth and fifth *Intergovernmental Panel on Climate Change* (IPCC) assessment reports (IPCC 2007, 2007a, 2007b, 2013, 2014a, 2014b, 2014c, 2014d), greater awareness, and protest marches (for example, in New York in September 2014) are social indicators for change. More and very severe extreme events (IPCC 2012), increasing financial costs, and a loss of life and livelihood have persuaded people to get rid of the present system of exploitation and destruction of the environment and human beings. A radical change towards sustainability and equity in the management of earth is required (Conca 1994). It is exactly greater knowledge about power structures, better communication about world disasters, and global solidarity

that are opening new ways to move away from Margaret Thatcher's TINA (there is no alternative) to the TAMA (there are many alternatives) of ecofeminists.

8.5   Some Initial Conclusions

Returning to the research question, a widened concept of sustainable-engendered peace may offer a deeper understanding of the historical development of patriarchy, the destruction of the environment, and the power relations and economic interests intrinsic to both processes. Women have powerful ways of enhancing rather than diminishing the power of others. This means that a sustainable-engendered peace is a 'power-from-within', which leads first to a preference for change and later to a commitment to action. A sustainable-engendered peace starts from a positive understanding of power, which will lead to new actions to overcome all types of oppression, including self-subjugation. The concept of a sustainable-engendered peace focuses on a process of empowerment, primarily to overcome systemic violence, economic oppression, socio-economic marginalization, a lack of autonomy in decision-making, cultural imperialism and environmental destruction. Figure 8.1 shows how the different elements of peace, such as negative, positive, sustainable, cultural, structural and engendered peace may produce feedback to and solid bases for a process of empowerment.

The first step is to overcome the narrow concept of military security and promote policies aimed at human security, defined as freedom from fear, freedom from want, freedom from hazard impacts, and freedom to live in dignity within a state of law (Brauch/Oswald Spring/Mesjasz et al. 2008, 2011; Brauch/Oswald Spring/Grin et al. 2009). It also begins to make visible the existing harmony among gender relations, generations, races and classes, as well as the solidarity and the gift economy that exist between all human beings (Vaughan 2007). The gift from nature through ecosystem services is another starting point for understanding that sustainability is vital to living well for both present and future generations. Present and future generations need a healthy environment with plenty of resources for a dignified livelihood; especially taking into account that the world population is still growing and that by 2050 we may reach ten billion.

The concept of diversity is crucial in a world with numerous ethnic, religious, cultural, and social groups. The integration of traditional and modern knowledge

Figure 8.1: Sustainable-engendered peace with cultural diversity. **Source**: The author.
from all over the world may offer new ways of dealing differently with approaching conflicts (Oswald Spring 2004), but will especially offer new ways of promoting equality.

Wilkinson and Pickett (2010) have shown that countries with fewer internal levels of difference have the longest life expectancy and the lowest rates of violence. This means that the redistribution of wealth will also offer rich people better conditions of life than the present concentration of wealth with widespread violence. There are enough resources on earth to grant each world citizen an adequate quality of life

and the ability to live with dignity. Finally, numerous oppressive mechanisms at global level are limiting the development of the largest part of world society. These subordinated groups could achieve greater equity and empowerment among women, races, classes, ethnic groups and religions. Link(age)s, feedbacks, and reinforcements among all these factors may promote greater personal and collective self-awareness, which is crucial to understanding and taking action towards a peaceful and sustainable transition.

The *United Nations Environment Programme* (UNEP 2011) has promoted a new sustainable policy

called the "green economy", designed to overcome local resource problems. It integrates holistic approaches from different theoretical positions such as ecofeminism, postmodernism, ecology, peace movements, green politics and parties, anti-globalization movements, and anarchists. The proposed "green economy" encourages an economic future with renewable energy, green buildings, sustainable transport systems, water, waste and land management, with soil restoration and food sovereignty that includes subsistence agriculture mostly in the hands of women (Bennholdt-Thomsen/Faraclas/Werlhof 2001; Oswald Spring 2009).

From a feminist, holistic, and gender-equal perspective, feminist values are deeply embedded at all levels of society, and this could be realized by governments and the business community. A paradigm shift towards a sustainable-engendered peace would include pathways to negotiate agreements and to promote actions for change. All these efforts together may be able to transform the present worldview based on greed, exploitation, violence, and oppression, and to promote a fundamentally different worldview that is inclusive, just, participative, and equal. This new feminist paradigm, as suggested in this chapter, focuses on a globally holistic, cosmopolitan, ethically oriented, sustainable-engendered peace with clean natural resources and safe food (Bennholdt-Thomsen/ Mies 1999). This shift may help overcome the patriarchal system and achieve an ethnically-oriented, gender-sensitive, religiously diverse and just society. If the root causes of violence and destruction in world society are transformed, the environment is provided with

an opportunity to recover its crucial natural processes and to continue to offer clean resources such as water, air, soil, and biodiversity. A different way of managing the earth will enable the environment to deliver the crucial ecosystem services that provide, regulate, support, and create cultural benefits for humans and nature.

A radical understanding of justice will allow us to move from the narrow conception of military security to an integrated human, gender and environmental security, a HUGE security (Oswald Spring 2009) and peace—a holistic peace—, where opportunities to care about nature and other human beings are created. Actions based on bottom-up initiatives supported by policies of equity and mechanisms of redistribution of wealth from the top down may offer the most vulnerable people alternatives for empowerment and self-awareness. This sustainable-engendered peace paradigm includes a holistic approach that will allow us to understand that life on earth and among humans is interrelated and interdependent. From this point of view, more just and more equal power structures may enable civil society to restructure global and local societal arenas and to educate and train actors to promote the societal values of

> love, genuine caring for others, fairly sharing all that is available to the group; and empowerment, helping group members to achieve fulfilment, cooperation and maturity—making together for mutual fulfilment. Feminism is profoundly transformational, for it calls for fundamental changes in personal values and human relationships as well as in structures and systems (Reardon 1980: 14).

9   Sustainable Peace in the Anthropocene: Towards Political Geoecology and Peace Ecology

Hans Günter Brauch[1]

Abstract

This chapter attempts to conceptualize possible and plausible linkages between the emerging 'sustainability transition' research paradigm and the conceptual debate on a rethinking of peace, security, development and the environment or ecology, within the context of four research programmes carried out since the end of the Cold War. Within the framework of a shift in earth history from the Holocene to the Anthropocene during the past sixty years, the threat to the survival of humankind has fundamentally changed. No longer are 'others' the threat, but 'we' are, due to the exponential increase in the burning of hydrocarbons and the resulting accumulation of greenhouse gases in the atmosphere. This new anthropogenic threat can no longer be countered with traditional military strategies and means. In the twenty-first century, there needs to be a long-term transformative change towards a low-carbon economy, in production and consumption, and in the energy, transportation, agricultural and housing sectors. Only thus can dangerous climate change and chaotic tipping points in the climate system be avoided. Such a low-carbon economy should be the result of a transition to sustainability, necessitating not just sociotechnical changes but changes in perception, values, behaviour and lifestyles. Such a long-term transformative change to sustainability may possibly prevent two types of conflicts: climate-induced violent conflicts, and those driven by resource scarcity. On the conceptual level, this chapter suggests possible linkages that may be developed in the Anthropocene between sustainable development, human security and sustainable peace in the context of both a *political geoecology*—between the natural and social sciences—and a *peace ecology*—between peace, security, development and environmental studies. Its key message is the need for more conceptual, theoretical and empirical research into possible linkages between peace studies and ecology that takes into account the changed human and environmental conditions in the framework of the Anthropocene. The added value is to sensitize research on 'sustainability transition' so that it reflects on the impact of its realization on sustainable peace and human security.

Keywords: Anthropocene, sustainability transition, peace, security, development, ecology, environment, sustainable development, human security, sustainable peace, political geoecology, peace ecology, avoidance of resource and climate conflicts.

9.1   Introduction[2]

Since the mid-twentieth century, a fundamental change in earth history has occurred, brought about by humankind's intervention into nature and the Earth System through the massive consumption and burning of fossil energy sources. Now, "we are in the Anthropocene", as Paul J. Crutzen stated at a conference in Cuernavaca in late February 2000.[3] At about the same time Hans Joachim Schellnhuber (1999) called for a 'second Copernican revolution' and William C. Clark contributed to the NRC Study (1999) *Our Common Journey. A Transition towards Sustainability* (Johnson 2016, in this volume).

In May 2003, during a Dahlem workshop on "Earth Systems Analysis for Sustainability" William C.

Clark, Paul J. Crutzen and Hans Joachim Schellnhuber (2004: 1) spoke of "the extraordinary revolution in our understanding of the Earth System that is now underway". They called for a "new paradigm aiming at sustainability" and a "new contract between science and society", calls prompted by "the urgent need to harness science and other forms of knowledge in promoting a worldwide sustainability transition that enhances human prosperity while protecting the Earth's life-support systems and reducing hunger and poverty". Clark, Crutzen and Schellnhuber (2004: 24) summarized their observations in this statement:

> We are currently witnessing the emergence of a new scientific paradigm that is driven by unprecedented planetary-scale challenges, operationalized by transdisciplinary centennium-scale agendas, and delivered by multi-scale co-production based on a new contract between science and society.

These insights have emerged gradually since 1896, when the Swedish physicist Svante Arrhenius hypothesized a linkage between the burning of hydrocarbon energy sources (coal, oil, gas) and the accumulation of greenhouse gases in the atmosphere. It was seventy-five years until this hypothesis was taken up by natural scientists in the early 1970s; climate change then became a recognized scientific issue, and formed a major research objective for four international scientific programmes (*scientization*).[4]

In the late 1980s, issues of global environmental change became political problems. For example, in December 1988 the IPCC was established and a mandate for the negotiation of the Rio conventions (1992) was approved by the UN General Assembly (*politicization*). Since 2000, the possible security impacts of global environmental change and climate change have been addressed by policymakers and scientists, that is, they have been *securitized* (Brauch 2002, 2009; Gleditsch 2012; Scheffran/Brzozka/Brauch et al. 2012; Scheffran/Brzoska/Kominek et al. 2012; Salehyan 2014; chapter by Ide/Link/Scheffran et al. in this volume).

Since the end of World War II, in the policy-oriented social sciences, four research fields have evolved: a) *security studies*, b) *peace studies* or *peace research*, c) *development studies* and d) *environmental studies* or *ecology*. There has been only limited scientific exchange between them, especially between peace studies and environmental studies (chapter 3 by Stephenson in this volume).[5] The linguistic and conceptual evolution of these four key guiding concepts has been discussed previously in the framework of a 'conceptual quartet' (Brauch 2009).

The study of issues raised by global (environmental and climate) change has gradually emerged since the mid-1980s, through four global research programmes. Only one, IHDP, which focused on the

---

3   On the history of the 'Anthropocene' concept, see Steffen, Grinevald, Crutzen and McNeill (2011); for an overview of the public debate, see: Ellis, Erle, 2013: "Anthropocene", in: *Encyclopedia of Earth*; at: <http://www.eoearth.org/view/article/150125>. The term was first used by Crutzen and Stoermer (2000); Paul J. Crutzen (2002, 2012, 2016) independently reinvented and popularized it. Crutzen has explained, "I was at a conference where someone said something about the Holocene. I suddenly thought this was wrong. The world has changed too much. So I said: 'No, we are in the Anthropocene.' I just made up the word on the spur of the moment. Everyone was shocked. But it seems to have stuck." (Stoermer as cited at: <http://en.wikipedia.org/wiki/Anthropocene> (12 Nov. 2015).

---

4   See the *World Climate Research Programme* (WCRP), which was set up in 1980 (Church, Asrar, Busalacchi et al. 2011); the *International Geosphere–Biosphere Programme* (IGBP) in 1986 (Noone, Nobre, Seitzinger 2011); DIVERSITAS followed in 1991 and modified in 2002 (Walther, Larigauderie, Loreau 2011); and IHDP in 1996 (*von* Falkenhayn, Rechkemmer, Young 2011; see chapter 14 by Arizpe, Price, Worcester and chapter 15 by Ehlers in this volume).

5   This list of area-specific research programmes is not comprehensive and many issue-specific research paradigms and programmes have also emerged, such as globalization and migration research, technology assessment and sociotechnical innovations; and many theory-specific approaches, such as systems and complexity theory.

"international human dimensions" of global change, had a social science focus, and only one of its many projects on *Global Environmental Change and Human Security* (GECHS) addressed 'human' security issues (Barnett/Matthew/O'Brien 2008; Sygna/O'Brien/Wolf 2013).[6] These discussions were evaluated for the first time by the IPCC (2014, II, chapter 12) in its fifth assessment report (for a critique, see Gleditsch/Nordas 2014). As systematic research on GEC and peace issues has hardly emerged so far,[7] one goal of this chapter is to inspire more innovative research of a bridge-building nature in the years to come.

Since the nuclear age began, with the development and deployment of nuclear and hydrogen weapons, massive use of such weapons would have been unable to act as a defence and could only have destroyed the areas to be defended (von Weizsäcker 1972). Crutzen and Birks (1982) argued that a big nuclear war could cause a 'nuclear winter'; this challenged the views of some US civilian nuclear strategists, who argued that wars using nuclear weapons could be fought and won (Gray/Payne 1980) in Central Europe. While during the Cold War, when a nuclear doomsday was being discussed, the perceived enemy was always the 'other' superpower (e.g. a war between East and West) or nuclear nation (Pakistan vs. India), in the Anthropocene the threat to human survival has fundamentally changed from the 'other' to 'us'.

'We' have become the major threat to our own survival. This threat is no longer posed by the 'other' through 'weapons of mass destruction' but by our consumptive behaviour and our use of 'fossil energy sources' that has resulted in an exponential increase in greenhouse gases (Brauch 2016, 2016a). The impact of the 'we' can be measured by the exponential increase in greenhouse gas concentration. This rose from between 260 and 279 ppm during the Holocene (the last 12,000 years) to 405 ppm in early 2015, with an increase of 90 ppm since 1958 (315 ppm) alone. This threat is not posed by weapons but by our unsustainable production and consumption patterns. It has spread rapidly from the industrialized to the developing threshold countries, who between 1990 and 2015

have increased their CO_2 emissions by 50 to 250 per cent (Brauch 2016b).

Between 2005 and 2010, a new research paradigm, 'sustainability transition', was developed by the *Dutch Knowledge Network on Systems Innovations and Transitions* (KSI), using "complex systems analysis, a socio-technical ... and a governance perspective" (Grin/Rotmans/Schot 2011: xvii). This Handbook aims to examine possible conceptual linkages between the proposed 'sustainability transition' paradigm, which is an *analytical concept*, and the primarily *normative debate* on 'sustainable peace'. So far, the conceptual linkages between a *process* of 'sustainability transition' and the *goal* of a 'sustainable peace' have not been systematically addressed.

Global research into 'sustainability transition' has been discussed at the annual conferences of the *Sustainability Transition Research Network* (STRN) since 2009 in Amsterdam,[8] while as a normative concept 'sustainable peace' is being used and addressed in UN circles (UN Women;[9] UNU [Keating/Knight 2004]) and by NGOs that focus on development (Busumtwi-Sam 2002), peacebuilding (Sending 2010) and conflict resolution (Peck 1998) and post-conflict situations (Roeder/Rothchild 2005). However, it has hardly been addressed in the framework of ecological, environmental and global change problems (Oswald Spring/Brauch/Tidball 2014).

This chapter attempts to contribute to the debate on conceptual bridge-building between 'peace research' and 'environmental studies' in general, and on the narrower assumed linkages between the impacts of GEC and GCC for humankind and its security and the process of 'facing' and 'coping' with those impacts through a process of 'sustainability transition' with the goal of avoiding conflict (Galtung's 'negative peace') and of achieving a 'sustainable peace' (Galtung's positive peace with justice). One long-term policy goal of such a 'sustainability transition' is a "low-carbon global economy", and this was endorsed in June 2015 by the heads of states and governments of the G7 in Elmau (Germany):

9   See UN Women at: <http://www.unwomen.org/en/what-we-do/peace-and-security> (1 December 2015).

> We commit to doing our part to achieve a low-carbon global economy in the long-term including developing and deploying innovative technologies striving for a transformation of the energy sectors by 2050 ... To this end we also commit to develop long term national low-carbon strategies.[10]

This 'long-term' policy goal has been analysed in many publications by the OECD[11] and the UNEP.[12] The UNEP's International Resource Panel[13] has called for a 'decoupling' of sustainable economic growth from an increase in fossil energy consumption and in GHG emissions. This requires a better understanding of the concepts that influence scientists and policymakers who address problems of 'sustainable development' (WCED 1987), as well as a better understanding of 'green growth' and of a transition towards a 'low-carbon' economy and society during the twenty-first century.

According to the Summary for Policymakers of the Synthesis Report of the Fifth Assessment Report (AR5) of the *International Panel on Climate Change* (IPCC 2014: 1,4,6–7), there is general agreement among scientists and policymakers:

> Human influence on the climate system is clear, and recent anthropogenic emissions of greenhouse gases are the highest in history. Recent climate changes have had widespread impacts on human and natural systems. ... Warming of the climate system is unequivocal, and since the 1950s, many of the observed changes are unprecedented over decades to millennia. The atmosphere and ocean have warmed, the amounts of snow and ice have diminished, and sea level has risen. ... Anthropogenic greenhouse gas emissions have increased since the pre-industrial era, driven largely by economic and population growth, and are now higher than ever. This has led to atmospheric concentrations of carbon dioxide, methane and nitrous oxide that are unprecedented in at least the last 800,000 years.

This assessment supports Crutzen's claim that "we are now in the Anthropocene". The effects of this change in earth history caused by human interventions into the earth system have been observed, and they are gradually being understood by scientists and policymakers and by the population at large:

> Their effects, together with those of other anthropogenic drivers, have been detected throughout the climate system and are *extremely likely* to have been the dominant cause of the observed warming since the mid-20th century. ... In recent decades, changes in climate have caused impacts on natural and human systems on all continents and across the oceans. Impacts are due to observed climate change, irrespective of its cause, indicating the sensitivity of natural and human systems to changing climate. ... Changes in many extreme weather and climate events have been observed since about 1950. Some of these changes have been linked to human influences, including a decrease in cold temperature extremes, an increase in warm temperature extremes, an increase in extreme high sea levels and an increase in the number of heavy precipitation events in a number of regions.

Empirical evidence from the observed security impacts of climate change is still limited, and the linkage is contested among social scientists (Burke/ Miguel/Satyanath et al. 2009; Hsiang/Burke/Miguel 2013; Buhaug 2010, 2014; Bernauer/Böhmelt/Koubi 2013; Theisen/ Gleditsch/Buhaug 2013); however, the strategic, military[14] and intelligence community (NIC 2008, 2012, 2012a) has taken into account considerations of climate in planning their medium- and long-term postures, so that they will be able to protect their infrastructure and operate their forces under these changed conditions.

Policymakers and science advisers in the UK have argued that, as a consequence of these assumed and projected impacts on security, humankind may face two new and closely related security threats during this century—from the impact of climate change and from declining resources. British Defence Secretary John Reid and Sir David King, a former science adviser to Prime Minister Tony Blair, mentioned the dual challenge of climate-induced and scarcity-driven violent resource conflicts. On 28 February 2006, John Reid warned, in a speech at Chatham House:

> that global climate change and dwindling natural resources are combining to increase the likelihood of violent conflict over land, water and energy. Climate

change, he indicated, 'will make scarce resources, clean water, viable agricultural land even scarcer'—and this will 'make the emergence of violent conflict more rather than less likely'.[15]

Sir David King claimed in 2004 that during the twenty-first century climate-induced conflicts will be a bigger threat than terrorism;[16] in 2009 he argued that the US intervention in Iraq in 2003 was primarily driven by energy security concerns, given the reliance of the US "on foreign oil from unstable states".

> 'Unless we get to grips with this problem globally, we potentially are going to lead ourselves into a situation where large, powerful nations will secure resources for their own people at the expense of others.' ... 'I went into the White House in 2001 to persuade them that de-carbonising their economy was the way forward. I didn't get much shrift at that time. What I can tell you is that, if I had managed to persuade the government of America that investing (instead of going into Iraq) in de-carbonising their economy with roughly a tenth of [the estimated $3 trillion the US spent on the war], they would have managed it.' ... King summed up by saying that with growing population and dwindling resources, fundamental changes to the global economy and society were necessary.[17]

In the aftermath of the dual natural geophysical hazard (an earthquake triggering a tsunami) that hit Fukushima on 11 March 2011 and caused the meltdown of several nuclear reactors, the 'cheap' answer to anthropogenic climate change—by moving to nuclear energy—was challenged. This had a negative effect on German politics, and a few months later the German government decided to move out of nuclear energy. Meanwhile Japan—after a temporary shutdown of most of its reactors—only three years later, during the Abe administration, resumed the use of its nuclear reactors for electricity production.

The reaction of society and of the political world to the scientific assessments of the IPCC and the hydro-meteorological hazards triggered by both climate change and by geophysical natural disasters has been significantly different in the major democracies. Australia, New Zealand, Spain, Canada, Portugal, Japan and the US all missed their national reduction targets under the UNFCCC's Kyoto Protocol. On the other hand, Russia, all the former Socialist countries, the UK, Germany, the EU, France and Italy stuck to their commitments and even over-performed, for different reasons.[18] So far, only the twenty-eight EU countries have agreed on a joint strategy aiming at a low-carbon economy and society by 2050 (EU 2011; Brauch 2016: see chapter 42 by Happaerts in this volume); but at least the goal was endorsed by the US President and by the prime ministers of Japan and Canada during the G8 conferences between 2007 and 2011.

Is there a linkage between the two perceived new security threats and the fundamental transformation of the economy and society suggested by the proponents of the 'sustainability transition' research paradigm, with the normative goal of a sustainable peace? The observed anthropogenic changes in the earth's climate system have triggered physical impacts (temperature increase, sea-level rise, precipitation changes and increases in extreme weather events) and societal outcomes (migration, crises and conflicts), and these have increasingly posed environmental challenges that may become 'human' and also 'national' and 'international' security problems and concerns' (Brauch 2002, 2009; WBGU 2008; UNSG 2009; Scheffran/Brzoska/Brauch et al. 2012; Gleditsch 2012, IPCC 2014). This anthropogenic change in earth history (Steffen/Grinevald/Crutzen et al. 2011) requires a reconceptualization of the four key concepts of peace, security, development and environment, as well as of the linkages between 'sustainable development' (WCED 1987), 'human security' (UNDP 1994; CHS 2003) and 'sustainable peace' (Peck 1998), in the framework of the Anthropocene.

A heuristic research question is whether and to what extent a transition towards sustainability may—in some future scenarios—help prevent the two related climate-induced and resource scarcity-driven violent

conflicts (as suggested by Sir David King) and whether such a process may thus be beneficial for achieving the goal of sustainable peace in the Anthropocene. Since our experience is that the two previous agricultural and industrial revolutions have resulted in a revolution in warfare and more deadly conflicts (Brauch 2016), such a thought experiment is necessary so that the context of the research on sustainability transitions can be broadened in order to take 'peace and security' considerations in the Anthropocene into account.[19]

This chapter is structured in ten parts. After this introduction, the Anthropocene is framed in the context of historic times (9.2), and the dual thesis is developed that we are both the 'threat' but also the 'solution', if we can aim for policy constellations that prevent new environmental and climate conflicts from occurring (9.3). After a brief summary of the conceptual quartet (9.4), the linkages between these four key concepts are discussed as 'sustainable development' (9.5), 'human security' (9.6), and as 'sustainable peace' in the Anthropocene (9.7). These conceptual considerations are further explored in the framework of two new proposed scientific approaches: a wider 'political geoecology' (9.8) and a 'peace ecology' (9.9). The chapter finally offers hypothetical considerations on linkages between 'sustainability transition' and 'sustainable peace' in the Anthropocene (9.10).

---

19 In a comment to an earlier draft of this chapter Kalevi Holsti argued that the author wants "to marry peace research with environmentalist thought in order to provide a conceptual framework for developing systematic thought about 'sustainability transition'. ... The road to sustainability transition is blocked by traditional Hobbesian security thinking, by continued blockage of meaningful GHG-emission reduction policies, by subsidies to oil and other carbon industries, by lack of political will, by industry lobbies, and the like." Holsti is "somewhat more pessimistic ... on future possibilities" noting that most of the literature ignores "the demand side of the equation". He claims that our epoch is dominated by the philosophy of possessive individualism", where "we focus on the consequences of this philosophy rather than its causes". And he continues "the optimists argue that technological advances can resolve the incompatibility between our prevailing definitions of the 'good life' and its consequences on the biosphere. ... The other sources of international conflict seem to be much stronger."

9.2 Historical Times: We are Living in the Anthropocene

In the natural and social sciences six historical times are distinguished. These have triggered numerous contextual changes of different duration. Elsewhere, the author has examined past long-term transformations, turning points and transition processes, focusing specifically on the Anthropocene (Brauch 2016). In earth and human history, five historical times may be distinguished. This argument is inspired by Braudel's (1969, 1972) three historical times: the history of structures, of repetitive cycles and of events, as well as by Crutzen's reference to the Anthropocene.

As has been argued elsewhere, the peaceful global change of 1989 was not a victory for the military superiority of the West (Schweitzer 1994), but rather the result of a 'learning' (Grunberg/Risse-Kappen 1992) by the new Soviet leadership that triggered unintended results (Brauch 2016). Since the end of the Cold War, 'transition studies' has emerged in political science, focusing on the transition of state socialist political, economic and societal systems towards Western 'neoliberal' market economies (Wolfgang Merkel 1996).

However, the discourse on 'sustainability transition' fundamentally differs from that on 'transition studies'. It addresses transformations in scientific, societal, economic, and political systems, together with a radical cultural transformation that can prevent catastrophic changes in climate, soil and water and major losses in biodiversity. The 'industrial revolution' and the many technological innovations led to a major human intervention into the earth system with an exponential increase in *greenhouse gases* (GHG) in the atmosphere, something that had not occurred in millions of years of climate variability (IPCC 1990, 1996, 2001, 2007, 2013).

The emerging scientific debate on 'sustainability transition'[20] addresses the many needs to reduce GHG emissions. There are both *multilateral* obligations to reduce emissions quantitatively, and a need for *unilateral* transformations. But since the UNFCCC and its Kyoto Protocol did not achieve their goals, due to a lack of political will to implement these obligations (Brauch 2012), unilateral strategies to reduce both GHG emissions and energy intensity[21] have become more important as a coping strategy for facing the impacts of global environmental and climate change. (see chapter 1 on the outcome of COP 21 in Paris).

Taking a sociotechnical perspective on "the dynamics of transitions", Geels and Schot (2010: 11–12) described five characteristics of transitions:

- Transitions are co-evolution processes that require multiple changes in sociotechnical systems and configurations. ...
- Transitions are multi-actor processes, which entail interactions between social groups such as businesses, firms, different types of user groups, scientific communities, policymakers, social movements and special interest groups.
- Transitions are radical shifts from one system or configuration to another. The term 'radical' refers to the scope of change, not to its speed....
- Transitions are long-term processes (40–50 years); while breakthroughs may be relatively fast (e.g. 10 years), the preceding innovation journeys through which new sociotechnical systems gradually emerge usually take much longer (20–30 years).
- Transformations are macroscopic. The level of analysis is that of the 'organizational fields'.

In Geels' and Schot's view, Braudel's historical times offer a general heuristic "for studying long-term processes, multi-causality, co-evolution, lateral thinking, anti-reductionism, patterns, context and the use of different time scales" (Geels/Schot 2010: 15). In their dynamic model they distinguish between *niches*, where the radical innovations occur; the sociotechnical *landscape* that offers the exogenous context; and the middle level of the sociotechnical *regime*, where the innovations have to succeed and overcome multiple obstacles.[22]

This Dutch research project influenced a policy report from the *German Advisory Council on Global Change* (WBGU 2011) on a 'Social Contract for Sustainability' (2011). This argued that the transformation to a low-carbon society requires an 'accelerated pace of innovations' but there is also a need to overcome the hurdles, including cutting subsidies for fossil energy sources and making use of favourable trends in society. "Sustainable development means more than climate protection [and] include[s] many other natural resources, such as fertile soil and biological diversity". The WBGU (2001:93) adapted Geels's model and added several megatrends in both the Earth System (climate, biodiversity, land degradation, water, raw materials) and the Human System (development, democratization, energy, urbanization, food), where innovative changes in the regime may directly affect the megatrends. The WBGU report stated that

> [t]he transformation into a sustainable society requires a modern framework to allow ... almost nine billion people to lead 'the good life', both in terms of living with each other, and living with nature: a new *Contrat Social* ... [that] represents a special agreement between science and society. ... It is also about a new culture of democratic participation. ... A low-carbon transformation can only be successful if it is a common goal, pursued simultaneously in many of the world's regions. Therefore, the social contract also encompasses new ways of shaping global political decision-making and cooperation beyond the nation state.[23]

The WBGU (2011: 5) discussed the global "remodelling of economy and society towards sustainability" with the goal of changing "production, consumption patterns and lifestyles in all three key transformation fields ... in such a way that global greenhouse gas emissions are reduced to an absolute minimum over the coming decades, and low carbon societies can develop." The social dynamics for a change in the direction of climate protection requires *a knowledge-based strategy*, a *proactive state* to establish a relevant framework aiming for structural change by guaranteeing the implementation of climate-friendly innovations, and it also counts on the *cooperation of the international community* and on global governance

20 See the Sustainability Transition Research Network (STRN); at: <http://www.transitionsnetwork.org/> (22 January 2015), which focuses on sustainability problems in the energy, transport, water and food sectors from different scientific perspectives on the ways: "in which society could combine economic and social development with the reduction of its pressure on the environment. A shared idea among these scholars is that due to the specific characteristics of the sustainability problems (ambiguous, complex) incremental change in prevailing systems will not suffice. There is a need for transformative change at the systems level, including major changes in production, consumption that were conceptualized as 'sustainability transitions'."

21 According to a Special Report by *The Economist* on Energy and Technology (17 January 2015), China had the highest increase in the consumption of fossil energy but also the highest decline in energy intensity between 1990 and 2012 and spent over $56 billion on renewables in 2013, more than all of Europe.

structures as the indispensable driving force for the transformation (WBGU 2011: 5-6).

Both the Dutch project and the WBGU Report (2011) avoided any contextualization of their theoretical approach and their policy proposal in the international foreign and security context and there was no discussion of the two related concepts of 'human security' and 'sustainable peace' in the Anthropocene era of earth history.

9.3 Not 'They' but 'We' are the Threat and Solution

In strategic studies, the 'other' country, with its military forces, economic potential and ideological attractiveness, was perceived as 'the threat'. With globalization and the emergence of 'new wars' (Kaldor 1999, 2002, 2012, 2013) with an 'asymmetric' and often 'invisible' opponent in the form of terrorists, drug cartels, or organized crime, this logic has not changed during the US-led 'war on terror'. But with the emergence of the global debate on the security implications of global environmental and climate change, a totally different type of threat has been identified, where human beings as producers and consumers pose a threat that cannot be defeated by military means. Georg Boomgarden (2007), a state secretary of the German foreign ministry, argued:

> 'If we ask ourselves who the enemy is in climate change, using the concepts of classic security policy, we must conclude that we are turning nature itself into an enemy'. ... 'And with this enemy, neither deception nor deterrence is going to be of any use. The later we adapt, the greater the cost will be'. ... Avoiding security-relevant cataclysms of global extent required the course to be set today. The time window for possibly irreversible processes to occur as a result of global temperatures rising by more than two degrees compared to pre-industrial days was about to close.

The *German Advisory Council on Global Change* (WBGU 2008) argued in a previous report on *Climate Change as a Security Risk* that "without resolute counteraction, climate change will overstretch many societies' adaptive capacities within the coming decades. This could result in destabilization and violence, jeopardizing national and international security to a new degree". But a positive outcome may also be possible if the international community "recognizes climate change as a threat to humankind and soon sets the course for the avoidance of dangerous anthropogenic climate change by adopting a dynamic and globally coordinated climate policy".

The report described probable new conflict constellations "as typical causal linkages at the interface of environment and society, whose dynamic can lead to social destabilization and, in the end, to violence": a) climate-induced degradation of freshwater resources; b) climate-induced decline in food production; c) climate-induced increase in storm and flood disasters; and d) environmentally-induced migration. The WBGU identified "six key threats to international security and stability which will arise if climate change mitigation fails": 1) a possible increase in the number of weak and fragile states as a result of climate change; 2) risks to global economic development; 3) risks of growing international distributional conflicts between the main drivers of climate change and those most affected; 4) the risk to human rights and the industrialized countries' legitimacy as global governance actors; 5) the triggering and intensification of migration; and 6) the overstretching of classic security policy. In the WBGU's view, "climate policy ... becomes preventive security policy, for if climate policy is successful in limiting the rise in globally averaged surface temperatures to no more than 2°C relative to the pre-industrial value, the climate-induced threat to international security would likely be averted".

When the Norwegian Nobel Committee awarded the Nobel Peace Prize of 2007 to both the IPCC and to Al Gore it justified its choice by stating:

> Extensive climate changes may alter and threaten the living conditions of much of mankind. They may induce large-scale migration and lead to greater competition for the earth's resources. ... There may be increased danger of violent conflicts and wars, within and between states. ... The Norwegian Nobel Committee is seeking to contribute to a sharper focus on the processes and decisions that appear to be necessary to protect the world's future climate, and thereby to reduce the *threat to the security of mankind*.

In its Fifth Assessment Report (AR5), the IPCC (2014) assessed the literature on climate change and human security (Gleditsch 2015; Brauch 2016).

In the Anthropocene, with the intervention of humankind into the earth system and into nature, 'we are the threat' that is posed by 'our' economic behaviour and by the prevailing production, transportation and consumption processes that rely heavily on the burning of hydrocarbons for the production of our food, goods and services and for our movement.

If 'we are the threat', then a sustainable peace policy in the Anthropocene has to address these multiple causes that are unrelated to classic security considerations. Such a 'sustainable peace' policy must deal with the obstacles to policies that aim for a sustainability

transition or a great transformation of major economic sectors; but it must also address our values, perceptions, world views, and mindsets, all of which influence our economic, societal, political and consumptive behaviour. It also requires major changes in our agricultural, economic, housing, transportation, and environmental policies, with the aim of a gradual dematerialization and decarbonization of the energy and other key economic sectors that have been major producers of greenhouse gases. This challenges the Hobbesian thinking that relies on military solutions whose aim is the control of those regions and countries that have the largest reserves of fossil energy sources.

9.4 'Conceptual Quartet' in the Anthropocene: Peace—Security—Development—and the Environment

Of the four concepts of a 'conceptual quartet' (Brauch 2008), peace and security are key goals of the UN Charter. 'Development' and 'environment' were added to the political agenda in the 1950s and 1970s. While these concepts have been widely used in the social sciences, systematic conceptual analyses of these concepts and their linkages are rare.

In the Anthropocene there is a need to reconceptualize these four key concepts and the related linkage concepts of 'sustainable development' (1987), 'human security' (1994) and 'sustainable peace' (1998). These three linkage concepts are considered as conceptual pillars of two proposed research programmes of a "political geoecology" and of a "peace ecology" under the specific conditions of the Anthropocene, the new era of earth history we have silently entered.

9.4.1 The Peace Concept

The English word 'peace' originates from the Latin 'pax'. The German word 'Frieden' indicates a 'condition of quietness, harmony, resolution of warlike conflicts', and in Russian 'mir' means both 'peace' and 'the world'. While the Greek *eirene*, the Hebrew *shalom*, and the Arab *salām* all imply 'peace with justice', the Hindi *ahimsa* adds the ecological dimension.[24]

Plato argued that war and conflicts should be avoided within the *polis*. Aristotle stressed that all political goals can only be realized under conditions of peace, and war is only acceptable as a means for the defence of the polis. During the Roman period, 'pax' was closely tied to law and contracts, where the

pax Romana relied on subjugation under the emperor in exchange for protection against external intruders. Besides 'peace within the state' that was achieved through its monopoly of the means of force, 'peace between and among states' has been a major concern of international law since the sixteenth century. Authors have still considered war a legitimate means for the realization of interests between states (*ius ad bellum*), while calling for constraints during war (*ius in bello*). In his treatise for an *eternal peace* (1795), Kant proposed a ban on war itself and developed a legal framework for a permanent peace based on six preliminary and three definite articles that called for a democratic system of rule, a league of nations, and respect for human rights.

After World War I, the Kantian tradition influenced the creation of the League of Nations, while after World War II, the United Nations gained teeth with the Security Council. However, during the Cold War a bipolar power system dominated, with nations relying on military alliances instead of on the 'collective security' of the UN Charter. With the end of the Cold War, 'new wars' emerged as resource, ethnic, and religious conflicts, primarily within states but also as pre-emptive wars. During the 1990s proposals for a new international order were gradually replaced by power-driven concepts of preventive wars and the 'war on terror'.

Detached from these political contexts, peace has been defined as a 'basic value' and as a 'goal of political action', as a situation of non-war, or as a utopia of a just and sustainable world. Galtung (1967, 1968, 1969; Galtung/Fischer 2013) distinguished between 'negative peace' (absence of physical or personal violence) and 'positive peace' (absence of structural violence, repression, and injustice), taking into account the methods of "economic exploitation and/or political repression in intra-country and inter-country class relations". He distinguished negative, indifferent and positive relations that often result in *negative peace* (absence of violence, cease-fire, indifferent relations) or *positive peace* (harmony).[25]

In the UN Charter of 1945, the 'concept of peace' is noted as its key mission in Art. 1,1: "to maintain

---

24 For a discussion of the "meanings of peace" that includes the philosophical debate in China (including Lao Tzu, Confucius, Mo Tzu), and in Buddhist, Hindu, and Judaeo-Christian thinking with the goal of "achieving positive peace", see Webel, Barash ([2]2008), part IV on "Building Positive Peace", in a chapter on "Ecological Well-Being" (397–418); see also Oswald Spring (2008a).

international peace and security", and "to take effective collective measures for the prevention and the removal of the threats to the peace, and for the suppression of acts of aggression or other breaches of the peace", as well as peaceful conflict settlements. Wolfrum (1994: 50) pointed to both narrow and wide interpretations of peace in the UN Charter. In Art. 1(2) and 1(3) the Charter uses a wider and more positive peace concept when it calls for the development of "friendly relations among nations" and for "international cooperation in solving international problems of an economic, social, cultural, or humanitarian character." In chapter VI on the Pacific Settlement of Disputes, Art. 33 uses a 'negative' concept of peace that is "ensured through prohibitions of intervention and the use of force" (Tomuschat 1994: 508). In Chapter VII of the UN Charter dealing with "Action with Respect to Threats to the Peace, Breaches of the Peace, and Acts of Aggression", in Art. 39, a 'negative' concept of peace dominates, with a reference to "the absence of the organized use of force between states". In the framework of Chapter IX on "International Economic and Social Cooperation", Art. 55 (3) refers to "universal respect for, and observance of, human rights and fundamental freedoms." It has been suggested that "the right of self-determination, to peace, development, and to a sound environment" (Partsch 1994: 779) should be incorporated as "human rights of the third generation" (Vasak 1984: 837).

Thus, in the UN Charter of June 1945, a narrow or 'negative' concept of peace has been at the centre with a few direct references to 'positive' aspects to be achieved by 'friendly relations among nations', and by 'international cooperation'. The 'positive peace' concept indicates peaceful social and cultural beliefs and norms, the presence of economic, social and political justice and a democratic use of power including non-violent mechanisms of conflict resolution. 'Sustainable peace' or 'peace with nature' was added later to the debate in the UN.

Inspired by the 'ahimsa' concept, Mahatma Gandhi's thinking had a significant impact on Arne Næss's

(1973, 1986, 1989) environmental philosophy and his 'deep ecology', and on Schumacher's (1999) 'small is beautiful' philosophy. Within peace research, only a few scholars addressed environmental challenges, among them Kenneth and Elise Boulding.[26] In *The Economics of the Coming Spaceship Earth* (1966, 1970),[27] Kenneth Boulding used the symbol of cowboys arguing that the world of unlimited resources is coming to an end, and in *Ecodynamics* (1978)[28] he combined evolutionary biology, ecology, peace research and Keynesian, socio- and environmental economics (Khalil 1996). Later, Boulding (1983) developed his concept of the 'empty niche' in biology, societal evolution and artefacts, biological catastrophes, ecological and human interactions, social ecosystems and finally, evolutionary economics. Elise Boulding co-edited a book on climate change (Chen/Boulding/Schneider 1983) and linked peace to ecology, insisting that there is no true peace without ecological links, respect for nature and human ecology (Morrison 2005). The concepts of 'environmental peacebuilding' (Conca 2002) and 'peace ecology' (Kyrou 2007; Oswald Spring/Brauch/Tidball 2014; Amster 2014) later contributed to this bridge-building.

In the US peace research and international relations community Patrick M. Regan (2014) and Paul F. Diehl (2016), in their presidential addresses to the Peace Studies Society (2013) and the International Studies Association (2015), called for "Bringing peace

---

25 Johan Galtung commented on an earlier draft: "To me both sustainable peace and environment are guided by two basic deep structures: diversity and symbiosis; hence very dynamic. To impose one culture, Western, one structure, capitalism will lead to the collapse of both; cultures-structures in partnership and species, abiota and biota in symbiosis will lead to higher complexity, evolution—that then has to be watched but is promising. What I read seems to me very compatible with these simple propositions."

26 Russell Boulding, the oldest son of Elise and Kenneth Boulding, wrote to this author on 10 February 2015 that the oldest comment of his father on environmental issues "was his poem *A Conservationist's Lament; The Technologist's Reply* which he wrote during the ... 1955 symposium on *Man's Role in Changing the Face of the Earth*. [His] 1966 paper *Economics of the Coming Spaceship Earth* is probably the most often cited paper ..., but he laid some theoretical foundations for an approach to sustainable economics in *A Reconstruction of Economics* (Boulding 1950) and even earlier critiques of mainstream economic theory. ... Robert Scott's [2015] biography ... discuss[es] the 1950 book and also the 1966 paper and its significance/impact on the development of ecological economics. ... Scott notes that [his] first actual reference to Spaceship Earth was in a speech given in May 1965 titled *Earth as a Space Ship* presented to the Committee on Space Sciences and Washington State University. [In] April 1965 he presented a paper *Economics and Ecology* at a Conservation Foundation Conference on "Future Environments in North America" (1966).

back in" and for "Looking beyond war and negative peace", thus returning to suggestions put forward by Quincy Wright (1942, 1954) and Johan Galtung (1964, 1967, 1985, 2012) decades earlier. Neither Regan nor Diehl addressed environmental challenges, nor did they try to recontextualize peace in the framework of the Anthropocene.

Environmental issues were not discussed in Peter Wallensteen's (2015) book on *quality peace*, but he mentioned climate change twice, writing about the present post-Cold War period as "a time that soon will be described as an imprudent spending spree before the Great Global Climate Crisis, similarly to how the 1920s is now seen as the irresponsible period before the Great Depression" (p. 61) and as a source of new cooperation over dwindling resources, arguing that scarcity may give rise not only to conflict but also to cooperation (p. 193).[29]

In the framework of the 'silent transition' in earth history from the Holocene to the Anthropocene, the peace concept must be reconceptualized, and the goals of peace studies and peace research courses and degrees must be developed further so that they can reflect on the impacts of our own productive and consumptive behaviour as a cause of global environmental change and thus also of its potential violent consequences. The normative goal of 'peace with nature' in a process of transition towards more sustainable development strategies of decarbonization and dematerialization must be addressed. The first step is one of agenda-setting.

9.4.2   The Security Concept

The reconceptualization of security in the twenty-first century[30] has gradually evolved since the end of the East–West conflict (1989–1991) and has been influenced by the end of the Cold War, processes of globalization, and the emerging impacts of global environmental change. Since the late 1970s, an expanded concept of security has been discussed in academia (Krell 1981; Buzan 1983). In the policy debate, the 'security concept' has gradually widened since the late 1980s. Ullman (1983), Mathews (1989) and Myers (1989, 1993) put environmental concerns on the US national security agenda. Since the 1990s, many European governments have adopted an extended concept of security.

Buzan, Wæver and de Wilde (1998) distinguished between wideners and traditionalists, focusing on the primacy of a narrow military concept of security (Walt 1991; Chipman 1992). The Copenhagen School (Wæver 1995, 1997; Buzan/Wæver/de Wilde 1998) distinguished five dimensions (military, political, economic, societal and environmental) and five referent objects or levels of analysis (international, regional, national, domestic groups, individual). But they did not review the sectorialization of security (Brauch 2009a) from the perspective of national, international and human security (Brauch 2009). Others referred to five vertical levels of security analysis: global or planetary (Steinbruner 2000), regional (Buzan/Wæver 2003), national (Tickner 1995), societal (Møller 2003; Wæver 2008) and human (UNDP 1994; CHS 2003) security.

In the post-Cold War era, within the UN, NATO and the EU, different security concepts have coexisted: a state-centred political and military concept, and an extended security concept with economic, societal, and environmental dimensions, while some countries have adhered to a narrow concept of national security that emphasizes the military dimension.

Although since the Westphalian order (1648)—and especially since the nineteenth century—the key security 'actor' has been the 'state' (Holsti 1991, 2016), it has not necessarily been the major 'referent object', which is often referred to as 'the people', whose survival is at stake. A major debate has evolved since the late 1980s over whether the state as the key referent object ('national security') should be extended to include the people (individuals, humankind) as 'human security'. Buzan (1991) distinguished between the international, state and individual levels of analysis and emphasized the inherent tension between the latter two, but he remained critical of the human security approach (Buzan 2004a).

While the classical means and instruments of a narrow security policy have remained the prerogative of the military and diplomacy, in the EU this classical *domaine réservé* of the nation state is changing with common policies and strategies, and increased common voting in international institutions (UN, OSCE). In many international regimes (food, climate, desertification), the EU is a full member alongside its twenty-eight member states. Its common *European Foreign*

For an overview of the debate on the reconceptualizing of security, see Brauch (2005, 2008, 2009a, 2011, 2012), and from a peace research perspective, see Albrecht and Brauch (2008).

and Security Policy (CFSP) and *Security and Defence Policy* (ESDP) have affected the traditional national military and diplomatic leverage.

Within international organizations sector-specific security concepts are widely used, such as 'environmental security', 'food security', 'global health security', 'energy security', and 'livelihood security'. The drivers of the theoretical security discourse and the centres of conceptual innovation have shifted away from the United States. During the 1980s, conceptual thinking on 'alternative security' in Europe searched for alternatives to mainstream deterrence doctrines and nuclear policies (Weizsäcker 1972; Brauch/Kennedy 1990, 1992, 1993; Møller 1991). By 2008, discourses on security were no longer a primarily American social science (Crawford/Jarvis 2001; Hoffmann 2001). The American national security concept was challenged by alternative security experts in Europe from the 1970s onwards and also by new national perspectives during the 1990s, when geopolitics re-emerged in southern Europe (France, Italy, Spain) and elsewhere. Since 1990, new centres of conceptual innovation have emerged and new journals on security problems have been launched.

- In Europe, *Aberystwyth*, *Paris*, and *Copenhagen* are associated with critical 'schools' of security theory (Wæver 2004).
- The *human security concept* was promoted by Mahub ul Haq (UNDP 1994), and developed further by the *Human Security Commission* (CHS 2003) co-chaired by Sadako Ogata and Amartya Sen.
- Civil society organizations in South Asia developed the concept of *livelihood security.*
- International organizations introduced the sectoral concepts of *energy*, *food*, *water*, *health*, and *soil security.*
- In the US, Canada and Switzerland the *environmental security* concept and research into it developed during the 1990s.
- The *Earth System Science Partnership* (ESSP) and its four programmes: IHDP (*International Human Dimensions Programme*), IGBP (*International Geosphere–Biosphere Programme*), WCRP (*World Climate Research Programme*) and *Diversitas* resulted in global scientific networks that are addressing new security problems.

These new centres of conceptual innovation challenged the narrow state-focused security concept of realists during the Cold War. But the world view of experts working on war, security and strategic studies still determines the political mindsets of decision-makers in the post-Cold War era (Albrecht/Brauch 2008). From 1989, in environmental security research, three phases have been distinguished (Dalby/Brauch/Oswald Spring 2009) and a fourth phase has been suggested (Oswald Spring/Brauch/Dalby 2009).

In the Anthropocene, the new era of earth history, the goals of the security concept must again be reconceptualized and the tasks of security policy must be redefined. If the 'other' nation, its weapons and ideologies are not the 'sole' or 'major' threat to the survival of humankind any longer and 'we' have become a new non-military threat to our own survival, security must increasingly reflect on these new challenges besides the traditional threats and those associated with the 'new wars' and 'terrorism' of the post-Cold War era.

Simon Dalby[31] has pioneered the debate on a reconceptualization of security in the Anthropocene, which implies for him that:

> We have to shift our understanding of the human place in the cosmos to one of us as an active agent in remaking the biosphere, not a passive spectator in environmental matters. Threats to modernity are internal, generated by fossil fueled modes of economy, not by distant peripheral 'others' with evil intentions. Anthropocene security has to start from this reversal of traditional geopolitical premises and think how urban civilization can be quickly rebuilt so we can all live well without burning things to do so, and before we disrupt the climate system to such an extent that civilization can't cope.[32]

Addressing, understanding, facing and coping with the new anthropogenic causes of insecurity requires major scientific and political efforts. However, national and international politics are increasingly influenced by a revival of nationalist ideologies and radical fundamentalist religious belief systems and ideologies that are being exploited by terrorist groups who want to re-establish an Islamic State in a new caliphate in Syria and Iraq, and in parts of Africa. Hence security in the Anthropocene must analyse traditional threats, those posed by the 'new wars', and also long-term human-induced environmental challenges triggered, caused or influenced by human interventions into the Earth system during the Anthropocene.

9.4.3   The Development Concept

The concept of 'development' is defined as "1. the act or process of growing or developing; 2. the product of developing; 3. a fact or event, especially one that changes a situation; 4. an area of land that has been developed" (McLeod 1985: 305). The *Shorter Oxford English Dictionary* ([5]2002: 662) adds: "Economic advancement or industrialization. In economics, development is defined as a synonym for economic growth. The term is also used for the improvement of the living conditions that includes besides the standard of living also social indicators, and aspects of distribution (income, public goods, and infrastructure)".

Ake (1993: 239–243) stated that after World War II, development theory emerged during decolonization as a variant of modernization theory. However, these theories "were at best heuristic devices" that were "too general and too vague to be taken seriously as scientific theories and paradigms" because "their major concepts could not be operationalized and their empirical referents were unclear". Toye (1996: 212–215) observed that by 1965 "prolonged and steady increase of national income" was identified as an indicator of economic development. It is accompanied by rapid population growth due to declining mortality, longer life expectancy, rapid urbanization, and improved standards of literacy and education. The identification of these indicators has been criticized if the distribution of income remains unequal and if the population majority remains impoverished. Some have claimed that "indicators of economic growth and structural change must be complemented by indicators of improvement in the quality of everyday life for most people". Sen (1981, 1984, 1994, 1999, 2000, 2000a) argued that distribution of income should be complemented by a fair distribution of entitlements to food, shelter, clean water, clothing and household utensils. These definitions excluded environmental factors contributing to and constraining economic development, especially natural hazards and disasters.

The policy goals of development differed between the industrial (OECD, G7, G8) and developing countries (G77 and China). During the Cold War, in a bipolar world, these goals were closely associated with economic systems. The goals differed on import-substitution or export-led industrialization, and capital- or labour-intensive strategies. Stallings (1995) used this concept primarily for economic development, i.e. for growth and equity of distribution. He pointed to five new elements in the new international context for development since 1990: "the end of the Cold War, new relations among advanced capitalist powers, increased globalization of trade and production, shifting patterns of international finance, and new ideological currents" (Stallings 1995: 2).

Decolonization and global competition between rival systems and modes of production predominated during the Cold War where development aid was an instrument of global strategic policy—the geo-strategic and geo-economic importance of developing countries was rewarded with economic and military assistance. Development assistance was supplied by governments, the EU, international organizations, financial institutions (e.g. the World Bank Group, the EIB) and development banks (Asian, African, Latin American and Islamic development banks), and by non-governmental economic, societal, and humanitarian organizations. Since 1990, development assistance from OECD countries as a percentage of their GDP has dropped. There was no peace dividend after the end of the Cold War and the geo-strategic importance of several developing countries declined, as did the security-motivated economic aid, and this contributed to weak, failing or failed states.

Development research emerged after World War II as an objective of social and political science that focused on the preconditions for and features of development processes, especially the economic, social, political and cultural factors that enhance or restrain development. Later the goals of development and the causes of underdevelopment were added. Two main theories of modernization emerged, to be used by scientists in OECD countries, and critical approaches were influenced by theories of imperialism, *dependencia*, self-reliance, and autocentric development.

With the end of the Cold War a crisis in development theories was noted (Boeck 1995: 69–80). Development theories and strategies for poverty eradication, and social and sustainable development are linked to the state, market, community, and civil society (Kothari/Minougue 2002: 1–15).

During the 1950s and 1960s most development experts stressed 'economics first' through investment-driven economic development strategies with a focus on industrialization. Since 1980, the focus has shifted to poverty and development and a basic human needs approach (Boserup 1970; Sen 1981; W. Arthur Lewis and Richard Jolly;[33] Burton 1998[34]). This was reflected in an upgrading of poverty eradication programmes, but until 1985 there was no emphasis on issues of governance, development of social capital, or institution-building and capacity-building for self-reliance. During the 1990s there was a gradual shift to

agriculture, gender issues, and participatory community development so that people were put first, as reflected in the Human Development Reports, which introduced 'human security' (UNDP 1994) as a complement to 'human development'.

With the concept of 'sustainable development', the Brundtland Commission (WCED 1987) has initiated a global scientific and political debate that has reflected on the impacts of economic development on the environment (see section 9.5 below; chapters 1 and 18 by Mesjasz). With the emergence of global environmental and climate change as major human challenges from 1988 and on through the 1990s and since 2000, in the Anthropocene era of earth history, the scope of the debate on sustainable development has narrowed to green growth, green economy, dematerialization, and decarbonization aiming at a low-carbon economy resulting from a process of sustainability transition.

9.4.4   The Environment and Ecology Concept

In English dictionaries the terms 'environment' and 'ecology' have been given many different meanings. The definition of 'ecology' in the *Shorter Oxford English Dictionary* (⁵2002: 789) is: "1. The branch of biology that deals with organisms' relations to one another and to the physical environment in which they live; (the study of) such relations as they pertain to a particular habitat or a particular species; also human ecology; 2. The political movement that seeks to protect the environment, esp[ecially] from pollution." According to *Webster's Third New International Dictionary* (2002: 720) 'ecology' is: "1. a branch of science concerned with the interrelationship of organisms and their environments especially as manifested by natural cycles and rhythms, community development and structure, interaction between different kinds of organisms, geographic distributions, and population alterations; 2. the totality or pattern of relations between organisms and their environment; 3. human ecology."

While the term 'environment' has many meanings, the scientific concept has been more specific. The *Encyclopaedia Britannica* (1998, IV: 512) has defined

'environment' as: "the complex of physical, chemical, and biotic factors that act upon an organism or an ecological community and ultimately determine its form and survival". Aspects of the natural environment of human beings are covered in that work under *atmosphere*, *hydrosphere*, *biosphere*, and *geosphere*.

The concept of ecology has been developed by many scientists from different disciplines and world regions, in part using observations of indigenous cultures in the Americas, China, India and the Middle East, where knowledge of the uses and dangers of plants and animals is crucial for human survival and cultural development. According to Ellen (1996: 207), the concept of ecology "has been centrally concerned with the concept of adaptation and with all properties having a direct and measurable effect on demography, development, behaviour and [the] spatio-temporal position of an organism." *Human ecology* is used in human geography, urban sociology and anthropology. Ellen stated that "the other major impact of ecological concepts in the social sciences has been in the relation of political environmentalism, and to environment and development. ... Increasing attention is also being paid to the cultural construction of nature, indigenous technological knowledge, the management of collectively owned resources, and environment history" (Ellen 1996: 208).

Vladimir Vernadsky (1926) defined the biogeochemical cycles as the sum of all ecosystems. Arthur Tansley (1935) described an interactive system between living things and their environment and ecology, and from this he created a science of ecosystems that was crucial for the development of ecology as a modern systems science. Odum (1953, 1975, 1977, 1998) defined ecology as the study of the linkages of organisms and of groups of organisms with their environment and of their structure and functions (Nentwich et al. 2004: 1). The concept of ecology was used in biology chiefly in terms of 'autoecology' and 'synecology', as 'population ecology', as 'community ecology' and as 'systems ecology', and in physical geography as 'landscape ecology' (Troll 1968) or 'geoecology' (Huggett 1995, 2000). The ecology concept was initially related to the biophysical sciences and only after World War II was the concept used in the social sciences and the humanities. In the *Encyclopedia of Global Environmental Change*, Munn (2002a: xi, xiv) wrote:

> In the 1960's, the scientific community began to use the word *environment* in this new non-specialist sense. ... In the ensuing decades, the world community has come to see the 'environment' in many different ways, as a

life-support system, as a fragile sphere hanging in space, as a problem, a threat and a home. ... In the 1970's and 1980's; ... *global environmental change* acquired a popular currency. ... Another vital insight began to emerge about 1980: the inescapably interlinked nature of these many environmental changes. ... Thus, the term *global environmental change* has come to encompass a full range of globally significant issues relating to both nature and human-induced changes in the Earth's environment, as well as their socio-economic drivers.

Fleming (2002, II: 290), writing on the environment, distinguished between *abiotic* (climate, minerals, soil, sunlight, water) and *biotic* (organisms) factors that are linked by "the flow of energy and the cycling of nutrients". Lovelock (1975, 1979, 1986, 1988, 1992), in cooperation with Margulis (1974, 1974a), expressed the complicated physical, chemical, and biological processes that maintain life on earth in the *Gaia hypothesis*, which claims "that the entire range of living matter on Earth defines the material conditions needed for its survival, functioning as a vast organism ... capable of modifying the biosphere, atmosphere, oceans, and soil to produce the physical and chemical environment that suits its needs" (Oxford 1998).

From an international relations perspective, Ronald Mitchell (2002: 500–516) focused on a) agenda-setting, b) policy formulation, and c) policy implementation and effectiveness and policy evolution and social learning. For the analysis of national and international environmental governance and regime formation, all three stages of the policy process are relevant. On environmental issues, especially on population growth and resource constraints, two opposite traditions have evolved (Kennedy 1992; Gleditsch 2003):

- a *pessimist* or *Neo-Malthusian view*, stimulated by Malthus's *Essay on Population* (1798) that stresses the limited carrying capacity of the Earth to feed the growing population;
- an *optimist* or *Cornucopian view* that believes an increase in knowledge, human progress, and breakthroughs in science and technology can cope with these challenges.

These two *ideal type* positions have dominated the environmental debate since the Club of Rome's *Limits of Growth* (Meadows/Meadows/Randers et al. 1972; Meadows/Meadows/ Randers 1982, 2004; chapter by Marino in this volume) and Lomborg's (2001) *Skeptical Environmentalist* (Gleditsch 2003). Rayner and Malone (2002, V: 109–123) pointed to a descriptive vs. an interpretative tradition in social science analyses of global environmental change. While the *descriptive tradition* relies on quantitative methods

"of tracing stocks and flows of social data through time and space", using methods and models from the natural sciences, the interpretive tradition tries "to understand motivations, ideas, and values". But both are essential for research, e.g. descriptive approaches "have revealed much what would happen under various scenarios of climate change", while "interpretive approaches can provide value-oriented parameters as a basis for choosing among candidate policies".

In the social sciences, the analysis of issues of global environmental changes and of human–nature relationships (Glaeser 1995, 2002: 11–24) are polarized between epistemological idealism and realism, or between *social constructivism* and *neo-realism*. The *neo-idealist orientation* has highlighted two aspects: a) the uncertainty of scientific knowledge and claims; and b) the attempt to explain the scientific and public recognition of environmental change as influenced by political and historical forces (Rosa/Dietz 1998). Glaeser calls for a combination of the strongholds of both positions, i.e. for a critical analysis of the assumptions and models of the natural scientists and of their inherent interests.

Within the scientific discipline of international relations, the analysis of problems of global environmental change has been pursued from different theoretical or practical orientations. Paterson (2000: 5) distinguished between six basic positions: a) *liberal institutionalism*, b) *realism*, c) *eco-authoritarianism*, d) *eco-socialism* (Pepper 2002: 224–225), e) *social ecology* (Pepper 2002a: 484) and f) *deep ecology* (Pepper 2002b: 211), to which one may add g) *ecofeminism* (Warren 2002: 218–224). These all differ on perceived causes and appropriate responses.

Several ideologies have been distinguished: *ecocentrism* "that centres on and prioritizes the whole planetary ecosystem", reflecting a *biocentric* focus on the biosphere, and *Gaiacentric* that focuses on the Earth as one living system. Homer-Dixon (1999: 28–46) distinguished between *neo-Malthusians* (biologists, ecologists); *economic optimists* (economic historians, neoclassical economists, agricultural economists); and *distributionists* (poverty, inequality, misdistribution of resources).

Paelke (2002: 49–61) distinguished two waves in the establishment and institutionalization of environmental politics: a) the early environmental movement with an often apocalyptic and apolitical dimension that focused on pollution and global sustainability concerns, and b) a second wave with "the re-emergence of conservationist and biodiversity concerns". Mostafa Tolba (2002: 1–13) noted eight trends in the

national and international responses of industrialized countries to environmental problems: a) the inclusion of environmental impacts into sectoral policies; b) an increase in cross-sectoral policies; c) the replacement of a reactive approach to pollution control by a preventive one; d) a growing interest in economic instruments as incentives to energy and pollution control; e) the promotion of energy efficiency, energy conservation, and environmentally sound processes in industry, transport and domestic environments; f) the recognition of the international, and often regional, nature of many environmental problems; g) increased public information and participation; and h) better environmental science and monitoring (Tolba 2002: 5).

Since the 1960s and 1970s many new governmental and non-governmental institutions have been set up, and an increasing number of environmental laws and regulations have been adopted in OECD countries. The developing countries have followed this pattern "but with a different range of concerns and on a different time-scale" (Tolba 2002: 8), with a primary focus on land and freshwater management and food production. While for them development is crucial "to improve the quality of life, eliminate poverty and support the infrastructure needed in order to deliver the health care, education and other institutions essential to the national future", many countries have prepared national conservation strategies.

International environmental regimes and institutions have gradually evolved since the end of World War II within the framework of the UN. In 1948 the IUCN (World Conservation Union) was founded by state and non-governmental members to protect natural areas and species. The decision at the Stockholm Conference (1972) to set up the *UN Environment Programme* (UNEP) in Nairobi and the adoption of the Agenda 21 and of several environmental regimes at the *United Nations Conference on the Environment and Development* (UNCED) in Rio in 1992 were major steps towards international responses.

It has been argued above that in the Anthropocene a reconceptualization of these four basic concepts of the 'conceptual quartet' is needed. As well as this, a reframing of the research programmes on the environment and ecology and a reformulation of environmental policies may be necessary. This would proactively address the causes of global environmental change and its projected consequences. This would then make it less likely that these new environmental challenges will present security threats in the decades ahead.

This will be discussed below in the context of the three established concepts, scientific goals and policies of 'sustainable development' (9.5), 'human security' (9.6) and 'sustainable peace' (9.7).

9.5 Moving From Sustainable Development to a Long-Term Transformation to Sustainability Transition

Since the UN Conference on the Human Environment in Stockholm (1972), many representatives of developing countries have called for 'additional' funding by the North to deal with the global environmental issues caused by the industrialized nations. While the debate between modernization and critical theories of development has excluded the environment, since the late 1980s controversies between proponents of sustainable development and neoclassical modernization and critical theories of development have increased.

The concept of 'sustainable development' was politically introduced—fifteen years later—in the Brundtland Report (1987: 8) that defined it as meaning "to ensure that it meets the needs of the present without compromising the ability of future generations to meet their own needs". Sustainable development was understood as "a process of change in which the exploitation of resources, the direction of investments, the orientation of technological development, and institutional change are made consistent with future as well as present needs" (Brundtland 1987: 9). 'Sustainable development' combines two key concepts: of needs, in particular the essential needs of the world's poor, to which overriding priority should be given; and the idea of limitation imposed by the state of technology and social organization on the environment's ability to meet present and future needs (Brundtland Report 1987: 43).

For the Brundtland Commission, "sustainable development is a process of change in which the exploitation of resources, the direction of investments, the orientation of technological development; and institutional change are all in harmony and enhance both current and future potential to meet human needs and aspirations". Their report calls for a 'sustainable development' path, necessitating "a concern for social equity between generations, a concern that must logically be extended to equity within each generation". Since the publication of the Brundtland Report in 1987, sustainable development has become

the key concept guiding both policy and scientific debates over the past nearly three decades.

The UNCED conference in June 1992 in Rio de Janeiro resulted in the signing of the *UN Framework Convention on Climate Change* (UNFCCC) and of the *UN Convention on Biodiversity* (CBD) and the adoption of Agenda 21 and of a mandate for negotiating a *UN Convention to Combat Desertification* (UNCCD). The *United Nations Commission on Sustainable Development* (CSD) was to ensure effective follow-up of UNCED by reviewing progress in the implementation of Agenda 21 and of the Rio Declaration on Environment and Development and by providing policy guidance for the *Johannesburg Plan of Implementation* (JPOI) at the local, national, regional and international levels.

In 2000 a summit meeting of the *United Nations General Assembly* (UNGA) in New York adopted the Millennium Declaration, with eight *Millennium Development Goals* (MDG) to be achieved by 2015. Goal 7 focused on ensuring 'environmental sustainability' (UN 2011: 50). The UN 2005 World Summit Outcome Document refers to the "interdependent and mutually reinforcing pillars" of sustainable development as economic development, social development, and environmental protection.[35]

The *UN Conference on Sustainable Development* (UNCSD or Rio+20) in June 2012 adopted a 'legally non-binding outcome document', *The Future We Want*, calling for a green economy in the context of *sustainable development* (SD) and poverty reduction, an institutional arrangement for SD, and a framework for action and follow-up (UNGA 2012). It was proposed to develop a set of *Sustainable Development Goals* (SDGs), guidelines on green economy policies, a ten-year framework on sustainable consumption and production[36] which would include guidelines on *green economic policies*, and a ten-year framework for sustainable consumption and production.

The SDGs defined in a report by an intergovernmental committee of experts on sustainable development financing, together with other documents, were adopted at the UN Summit on 26 September 2015 by heads of state and government and high representatives,[37] in a document entitled *Transforming our world: The 2030 Agenda for Sustainable Develop-*

ment. In the policy debate at the UN General Assembly during the *UN Summit on Sustainable Development 2015* (25–27 September 2015):

> Climate change was repeatedly stressed as an existential threat that jeopardizes hard-won development gains and undermines efforts for future sustainable development. Without addressing climate change, achieving the 2030 Agenda and the other SDGs will not be possible. Its negative impacts are putting at risk the potential for progress in the economic, social and environmental areas. … The transition to renewable energy sources was underscored as particularly important, while improving the efficiency of energy and natural resources.[38]

Among the interactive dialogues, one dealt with "Fostering sustainable economic growth, transformation and promoting sustainable consumption and production" and stressed the need for the "economies … to undertake structural and technological transformation in order to attain higher technological intensity, greater value added and productivity and full integration in international trade". It was further argued that: "economic growth must be decoupled from environmental degradation and combat climate change to protect future generations. Accelerating a real shift towards more sustainable lifestyles will require changing how we consume and use valuable resources".[39]

The seventeen SDGs "with 169 associated targets" include a "transformational vision" of "a world in which every country enjoys … sustainable economic growth and decent work for all", where "consumption and production patterns and use of all natural resources … are sustainable". The SDGs are general policy guidelines for a process of sustainability transition and call for "access to affordable, reliable, sustainable and modern energy for all" (goal 7); "sustain-

able economic growth" (goal 8); "inclusive and sustainable industrialization and ... innovation" (goal 9); "sustainable consumption and production patterns" (goal 12); and a "global partnership for sustainable development" (goal 17).

Goal 12, "sustainable consumption and production patterns", includes "implement the 10-year framework of programmes on sustainable consumption and production" (12.1), so that it will be possible by 2030 to achieve "the sustainable management and efficient use of natural resources" (12.2), "encourage companies ... to adopt sustainable practices and to integrate sustainability information into their reporting cycle" (12.6), and "support developing countries to strengthen their scientific and technological capacity to move towards more sustainable patterns of consumption and production" (12a), and to "rationalize inefficient fossil-fuel subsidies that encourage wasteful consumption by removing market distortions" (12c).

Global climate governance has been paralysed due to the failure of the *Conference of Parties* since Copenhagen (COP 15, 2009) to adopt a legally binding post-Kyoto climate regime. At the political level several OECD states have failed to implement their legal obligations under the UNFCCC and the Kyoto Protocol (1990–2012) and to adopt a post-Kyoto regime (Brauch 2012). The Durban outcome "included a decision by Parties to adopt a universal legal agreement on climate change as soon as possible, and no later than 2015".

Democratic governance is not relevant for distinguishing the different climate performance of the G7/G8 and G20 countries. An implementation gap exists among democracies between EU countries (leaders) and large OECD countries in North America and in the Asia–Pacific region (laggards) with legally binding reduction obligations.

Among the G20 countries different strategies towards a long-term transformative change to sustainability can also be observed. During the G20 summit in Antalya on 15-16 November 2015 their leaders were more constrained than the G7 had been in Elmau (May 2015) recognizing "that actions on energy, including improving energy efficiency, increasing investments in clean energy technologies and supporting related research and development activities will be important in tackling climate change and its effects" without calling for decarbonization. They supported a move "to adopt a protocol, another legal instrument or an agreed outcome with legal force under the UNFCCC that is applicable to all Parties".[40]

During the Anthropocene it is necessary to move beyond declaratory national policy statements and international agreements with limited implementation and to adopt binding national policies with economic incentives, with the aim of moving towards a gradual sustainable transformation of the national and global economy towards a low-carbon economy, especially of an energy sector that relies heavily on fossil fuels.

In the Anthropocene, 'sustainability transition' is both a scientific concept and a research programme and paradigm. It also refers to a policy process that aims for a long-term transformative change of policies, the economy, society and science. As Clark, Crutzen and Schellnhuber (2004: 2-3) argued, 'sustainability' is "a normative concept regarding not merely what *is*, but also what *ought to be* the human use of the Earth (Kates 2001)". They noted that "while the goal of environmentally sustainable development in the Anthropocene was generally recognized", its implementation has largely failed since the Johannesburg summit (2002) and at Rio II (2012), where no legally binding commitments were adopted.

The US National Academy of Science claimed in 1999 that "a successful transition toward sustainability is possible over the next two generations", with "significant advantage in knowledge, in the social capacity and the technical capabilities to utilize it, and in the political will to turn this knowledge into action" (NRC 1999: 160; Johnson 2016).

While our scientific knowledge and technical capabilities have significantly progressed since 1999, in the context of the Bush Administration's 'war on terror' from 2001 onwards there was a return to a military agenda driven by Hobbesian power rationales, with new wars in Afghanistan (1991), Iraq (2003), Libya (2011) and Syria (2013). At the same time the environmental and global change agenda was partly disputed, ignored or downgraded. Not surprisingly, billions of US dollars and euros have been spent since the mid-1990s and especially since 9/11 on these wars and their humanitarian consequences. Global military expenditure in constant US dollars has increased again since 1997, and since 2008 it has reached its highest level since the end of the Cold War in 1989 (figure 9.1).

Three of the G7 countries failed to achieve their goals under the *Kyoto Protocol* (KP) and many devel-

oping and threshold countries (China, India) totally ignored the goals of the UNFCCC that they had endorsed, and increased their GHG and emissions by up to 250 per cent between 1990 and 2014 (Brauch 2016a). At COP 15 of the UNFCCC in Copenhagen (1999) and at the Rio II Summit (2012), there was a lack of political will to act decisively to meet the recognized, declared and endorsed challenges that face humankind in the Anthropocene, among both major industrialized countries and rapidly developing threshold countries. Most industrialized countries have also failed to meet their declared commitments to spend 0.7 per cent of their GNP on development aid. The humanitarian crisis—with millions of war refugees and distressed migrants—facing Europe in autumn 2015 was partly driven or influenced by Western 'wars' in the Balkans, in Afghanistan and in the MENA region.

While the 'political will' has often been lacking since the start of the twenty-first century, scientific research, knowledge and discourse on the problems of global environmental and climate change have progressed significantly, as Clark, Crutzen and Schellnhuber (2004:15) have pointed out: "the Anthropocene crisis forces humanity to manage consciously a transition toward sustainable use of the Earth". However, the hopes they put in the proposal of the NRC (1999) that a sustainable development could be achieved over two generations have not yet been realized. They called for a new Copernican revolution, a new paradigm for sustainability and a new 'social contract'

between science and society for planetary stewardship (Clark/Crutzen/Schellnhuber 2004: 23-24).

The WBGU (2011: 1-2) took up the proposal for *A Social Contract for Sustainability* aiming at a "low-carbon and sustainable global economic system" and it stated that

> One key element of such a social contract is the 'proactive state', a state that actively sets priorities for the transformation, at the same time increasing the number of ways in which its citizens can participate, and offering the economy choices when it comes to acting with sustainability in mind. The social contract also encompasses new forms of global political will formation and cooperation.

The WBGU used this concept for its call "for the transformation towards sustainability...as an analogy to the emergence of the industrialised societies during the course of the 19th century", following Karl Polanyi's (1944) analysis in his *Great Transformation* that described the embedding of "the uncontrolled market dynamics and innovation processes into a constitutional state, democracy and the creation of the welfare state". The WBGU stated (2011: 8) that this idea:

> refers to the necessity of humankind taking collective responsibility for the avoidance of dangerous climate change and other dangers to the planet. ... This needs a voluntary capping of the usual options for economic growth in favour of giving the people in those parts of the world already suffering the consequences of our irresponsible behaviour, and particularly future generations, room to manoeuvre. For another, the transforma-

tion needs a powerful state, counterbalanced by extended participation on the part of its citizens.

The WBGU report was discussed during an international symposium in Berlin in May 2012 where Chancellor Angela Merkel argued that "the two crucial elements ... must ... be ... switching to renewables, and dealing more efficiently with energy and the resources we have." She stressed that her government "decided to raise the proportion of renewables in our overall energy consumption to sixty per cent by 2050. For electricity consumption, that figure is to be eighty per cent." Merkel concluded that "sustainability needs to become a central tenet in every area of our lives."[41] At the G7 meeting in Elmau (Germany), the heads of major industrialized countries called for a legal instrument to be adopted at COP 21 in Paris, which

> should enable all countries to follow a low-carbon and resilient development pathway in line with the global goal to hold the increase in global average temperature below 2°C. ... In order to incentivize investments towards low-carbon growth opportunities we commit to the long-term objective of applying effective policies and actions throughout the global economy.[42]

The key challenge in the years ahead will be whether the agreements adopted at COP 21 will be implemented by all major contributors to the rapidly rising GHG and CO2 concentrations in the atmosphere. The 'rationale' of the research on 'sustainability transition' is that these changes should occur nationally and regionally, e.g. within the EU, irrespective of international commitments, and that a creative scientific and investment climate must be created such that sustainable niches and changes in the regime and the landscape will occur globally and become as competitive as wind power and increasingly photovoltaics have done since 1990.

The gradual shift from the normative goal of '*sustainable development*' (SD) towards an analytic concept and policy process of '*sustainability transition*' (ST) requires a reframing of the social science agenda, including the four key programmes of security, peace, development and environmental studies, as well as of the courses offered and existing degree programmes

(see below, section 9.8). In the context of the Anthropocene, the many related scientific and political concepts of green growth, green economy, low-carbon economy, dematerialization, decarbonization and decoupling must be discussed and developed further.

Prior to this recent debate on 'sustainability transition' and peace, Scheffran (1997, 1998, 1999, 2011) analysed multiple linkages between "peace and sustainable development" where he discussed the linkages between economic growth and violent conflicts, the consequences of resource scarcity, and between sustainable development and the limits of satisfying human needs. As a step towards sustainable peace, Scheffran suggested moving from a negative towards a positive linkage (see also chapter 34 by Scheffran/Froese and chapter 13 by Scheffran in this volume).

9.6   Adopting a Human Security Approach

After the end of the Cold War 'human security' emerged as a new security concept that shifted the focus from the 'state-centred' perspectives of national, international and global security to a 'people-centred' or 'human-centred' security.[43] Before 1989, a few scholars had already called for a human security approach (Westing 1989, 1989a, 2013). After UNDP (1994) had launched the concept of human security, the traditional narrow understanding of military and political security was widened to include economic, societal and ecological security dimensions, as well as deepened to include human and gender security. As a result, its reference objects changed from sovereignty and territory to human beings and humankind. The values at risk shifted to identity, sustainability and survival, while the sources of threats changed from other states to global environmental change, globalization and financial crises. Some expanded the human security discourse to the environmental dimension and to interactions between the individual and humankind as a cause and victim of global environmental change (Brauch 2005, 2008a, 2009).

Since the late 1990s two different concepts have existed in the political realm. While Canada, Norway and the European members of the *Human Security Network* (HSN) preferred a narrow concept that

43   This section relies on previous texts by this author (Brauch 2005, 2005a, 2009a) and a co-authored chapter (Brauch/Scheffran 2012), with the permission of the co-author.

focused on 'freedom from fear' and dealt with humanitarian initiatives and human rights, Japan opted for a wider concept that included the human development agenda, with 'freedom from want'. In the social sciences, several proponents of a narrower concept of human security (Mack 2004, 2004a, 2005; Krause 2004, 2004a, 2008, 2008a; MacFarlane/Khong 2006) were opposed to including development and environment policy.

In the social sciences, the concept has been widely discussed in political science, international relations, and especially in *development studies* (Picciotto/Olonisakin/Clarke 2007; Ulbert/Werthes 2008) and *peace studies* (Tadjbakhsh/ Chenoy 2006; Thakur 2006/2007) and to a lesser extent in *environmental studies* (Page/Redclift 2002; Dodds/Pippard 2005) and *security studies* (Dannreuther 2007; Booth 2005, 2007), where many realists ignored this discourse (Kolodziej 2005). It has also been discussed in geography (Lonergan 1999; Bohle/O'Brien 2007), in international law (von Tigerstrom 2007), in education (Nelles 2003), in philosophy (Fabra Mata 2007), in theology (Eisen 2008), and in the health sciences (Leaning 2009). Human security has been discussed in relation to *national* (urdevic-Lukic 2004), *international* (Dannreuther 2007) and *global security* (Stoett 1999), as well as in the field of sectoral security concepts, including water, food, health, and livelihood security (Bohle 2009).

Human security requires a fundamental shift in thinking on security. It addresses different policy requirements and needs, with horizontally integrated political coping strategies where the role of development and environment policies is vital, and the mission of the military changes from fighting wars to *protecting* the people against genocide and natural hazards; society and social movements should *empower* people to build resilience and to enhance their coping capacities. Human security concepts and agendas enhance societal groups and knowledge-based scientific epistemic communities as new *securitizing actors* that can put global environmental and climate change on national and international policy agendas.

Within international relations, the concept of human security has remained controversial. While many realists and the strategic studies community, as well as 'state-centred' peace researchers, have rejected the human security concept, authors with liberal and constructivist perspectives and from peace research have rallied behind it. Uvin (2004, 2008) used the concept as a "conceptual bridge between the ... fields of humanitarian relief, development assistance, human

rights advocacy, and conflict resolution" (Owen 2004). For Hampson (2004), human security gives voice to the politically marginalized, while Acharya (2004) interpreted it as a response to the globalizing of international policy, and for others, human security is a response to genocide and the limits of sovereignty that can justify humanitarian interventions.

Thomas and Tow (2002, 2002a) distinguished general human security 'threats' such as hunger and disease, and specific ones, such as "single actions that have an immediate effect on the safety or welfare of victims and demand immediate remedy", to which 'peacekeeping' emerges as a major response along with peace enforcement measures. They argued that human security could be considered "a valid paradigm for identifying, prioritizing and resolving emerging transnational security problems", and that it offers ways to respond to these challenges by "safeguarding and improving the quality of life" for individuals and groups.

Owen (2004) suggested combining UNDP's (1994) wide definition with a threshold-based approach. He argued that "human security is the protection of the vital core of all human lives from critical and pervasive environmental, economic, food, health, personal and political threats", regardless of whether people are affected by floods, communicable disease, or war. Rather, all those threats would be included "that surpass a threshold of severity [and] would be labelled threats to human security" (2004).

Khagram, Clark and Raad (2003: 107–135) discussed both environmental threats (and their impacts on human survival, well-being and productivity) and environmental opportunities for human security. Environmental change can have direct and immediate effects on well-being and livelihoods, it can also impact on health, economic productivity and political instability. Environmental threats can affect "individuals, families, communities, social organizations, identity groups (women, children), diasporas, governments and biological species". Also, a single environmental threat "can have potentially adverse effects at multiple scales from the household to the planetary". On the other hand, environmental protection, cooperation and peacemaking can improve human security.

Mary Kaldor (2007: 182–187) who headed the *Study Group on Europe's Security Capabilities* (Kaldor 2004; Glasius/Kaldor 2005) argued that "it includes both civilian and military elements; it offers a way to act, a set of principles for crisis management." In order to put the concept into practice she suggested five principles (as both ends and means)

for the implementation of human security "in a continuum of varying degrees of violence that always involve[d] elements of both protection and reconstruction:" 1) the primacy of human rights; 2) legitimate political authority; 3) multilateralism; 4) the bottom-up approach; and 5) a regional focus. Kaldor (2007: 190–191) claimed that even after new wars have been stabilized, "individuals still experience high levels of physical insecurity as a consequence of high crime rates, high human rights violations and high levels of violence against women." She suggested that a human security approach "would aim both to stabilize conflicts and address the sources of insecurity." This requires public security based on the rule of law and effective law enforcement. The implications of this for international organizations are an expanded international presence, new human security forces, and a legal framework.

The economic and social priorities for conflict prevention include: a) combining humanitarian and development assistance; b) creation of legitimate employment and self-sustaining livelihoods; c) institution-building, including the rule of law; d) attention to the importance of infrastructure and public works; e) education and social services; and f) generating tax revenues. She concluded that a human security approach could benefit development by: a) "providing the conditions (physical safety, rule of law and sustainable institutions) that are integral to development; b) focusing on human development and strengthening weak institutions; and c) stressing the needs of individuals and communities" (Kaldor 2007: 193–195).

There has been an intensive scientific discourse on human security concepts and issues among and with scholars from developing countries, in Latin America (Neff 2003; Palma 2003; Kornblith 2003; Bonilla 2003; Lopez 2003; De Lombaerde/Norton 2009; Rojas Aravena 2009; Singh 2009), in South Asia (Ariyabandu/Fonseka 2009; Chari/Gupta 2003, 2003a; Abdus Sabur 2003, 2009; Bajpai 2000, 2003, 2004, 2005; Najam 2003, 2003a), in South East Asia (Othman 2009; Wun'Gaeo 2009), in Japan (Shinoda 2009), in Africa (Hendricks 2008; Goucha/Cilliers 2001; Naidoo 2001; Hussein/Gnisci/Wanjiru 2004; Mulongo/Kibasomba/Njeri Kariri 2005; Mutesa/Nchito 2005 Mpagala/Lwehabura 2005; Mataure 2005; Ngoy Kaungulu 2005; Correira de Barros 2005; Mlambo 2005; Dzimba/Matooane 2005; Poku/Sandkjaer 2009), and in the Arab world (Chourou 2005, 2009).

The human security concept has also been widely debated in Africa. On the political level the debate on human security was triggered by a *conference on security, stability, development and cooperation* (CSS-DCA) in Kampala in 1991 where five hundred African politicians and leaders adopted the Kampala Document that formed the basis for the comprehensive security agenda of the African Union. The human security concept influenced the *New Partnership for Africa's Development* (NEPAD 2001) and the adoption of a *Common African Defence and Security Policy* (2004). However, there was disagreement on the policy priorities for achieving its aims (Hendricks 2008: 137-142).

In June 2001, the *Institute for Security Studies* (ISS) in Pretoria hosted UNESCO's regional conference on *Peace, Human Security and Conflict Prevention in Africa* (Goucha/Cilliers 2001: vi-vii). This addressed: a) promoting human capacity-building in the member states of the region; b) helping African countries to establish a strategy for the prevention of HIV/AIDS and other contagious diseases; c) mobilizing and acting as a catalyst for international cooperation in support of initiatives by African Member States; and d) promoting the active participation of communities and representatives of civil society in the planning and implementation of development programmes.

This selective review of definitions of human security and of threats for human security, as well as of areas of relevance for human security issues, documents both the diversity and the lack of a clear consensus. This last has hindered communication with policymakers and their efforts to move from declaratory statements to concrete policy initiatives and actions. And so after two decades the conceptual discourse remains inconclusive and the definition of human security being used depends on the approach and preferences of the respective author. In the policy and scientific debate on human security, environmental security problems have been mostly ignored.

Kofi Annan argued (2005) that human security should be based on the three pillars of 'freedom from want' (human and sustainable development agenda), 'freedom from fear' (the traditional peace and security agenda) and 'freedom to live in dignity' (democracy, rule of law and human rights agenda). Bogardi and Brauch (2005; Brauch 2005, 2005a, 2009) suggested a fourth conceptual pillar, 'freedom from hazard impact', which would be brought about by reducing the vulnerability and enhancing the coping capabilities of societies confronted with natural and human-induced hazards, through empowering people and enhancing their resilience.

Box 9.1: Excerpts of chapter 12 on "Climate change and human security" by the IPCC, WG II. **Source**: IPCC (2014).

- *Climate change will have significant impacts on forms of migration that compromise human security (high agreement, medium evidence).* Some migration flows are sensitive to changes in resource availability and ecosystem services. Major extreme weather events have in the past led to significant population displacement, and changes in the incidence of extreme events will amplify the challenges and risks of such displacement. Many vulnerable groups do not have the resources to be able to migrate to avoid the impacts of floods, storms and droughts. ... Migrants themselves may be vulnerable to climate change impacts in destination areas, particularly in urban centres in developing countries ...
- *Mobility is a widely used strategy to maintain livelihoods in response to social and environmental changes (high agreement, medium evidence).* ... Expanding opportunities for mobility can reduce vulnerability to climate change and enhance human security ...
- There is insufficient evidence to judge the effectiveness of resettlement as an adaptation to climate change. *Some of the factors that increase the risk of violent conflict within states are sensitive to climate change (medium agreement, medium evidence).* The evidence on the effect of climate change and variability

on violence is contested ... Although there is little agreement about direct causality, low *per capita* incomes, economic contraction, and inconsistent state institutions are associated with the incidence of violence ... These factors can be sensitive to climate change and variability. Poorly designed adaptation and mitigation strategies can increase the risk of violent conflict ...

- *People living in places affected by violent conflict are particularly vulnerable to climate change (high agreement, medium evidence).* Evidence shows that large-scale violent conflict harms infrastructure, institutions, natural capital, social capital and livelihood opportunities. Since these assets facilitate adaptation to climate change, there are strong grounds to infer that conflict strongly influences vulnerability to climate change impacts ...
- *Climate change will lead to new challenges to states and will increasingly shape both conditions of security and national security policies (medium agreement, medium evidence).* Physical aspects of climate change, such as sea level rise, extreme events and hydrologic disruptions, pose major challenges to vital transport, water, and energy infrastructure ...

These four pillars of a wide concept of human security match four different human security agendas that were addressed by the UN member states during the two thematic discussions on human security on 22 May 2008 and on 14 April 2011.[44] UN Secretary-General Ban Ki-Moon (UNSG 2009) proposed in his report on *Climate change and its possible security implications* "several 'threat minimizers', ... [to] lower the risk of climate-related insecurity. ... Accelerated action at all levels is needed to bolster these threat minimizers". The daily survival problems of a few billion people, their social vulnerability, and their physical exposure to climate change are creating additional dangers for human security.

In his Human Security report of 2010, the Secretary-General applied the human security concept to "Climate change and the increase in the frequency and intensity of climate-related hazard events". A *policy-focused human security approach* to climate change prioritizes the climate-induced security threats

that humankind will *face* during the twenty-first century. Its task is to develop policies for coping better with the human security impacts of climate change by measures of mitigation, adaptation and resilience-building to *protect* and to *empower* the people affected. 'Freedom from Hazard Impact' requires a proactive environmental strategy for implementing the Rio Conventions. It requires a close cooperation between those agencies working on the global environmental change and the hazard agenda (early warning, disaster response, disaster preparedness, resilience building and reduction of social vulnerability).

In its fifth Assessment Report (AR5), the IPCC (2014) for the first time assessed social science literature on the human security impacts of climate change (box 9.1). Gleditsch and Nordas (2014) commented critically on the report, pointing to the lack of a consensus in the scientific community on the linkage between climate change and war (Nordas/Gleditsch 2013).

This IPCC assessment of the social science literature requires that the environmental and the climate change dimension of human security and its fourth conceptual pillar of 'Freedom from Hazard Impact' should be taken up in the debates in the UN General

---

44 The following section is based on the author's presentation at this meeting and on his background paper, accessible at: <http://www.afes-press-books.de/html/hexagon_05_PressConf_Presentations.htm#NY2>.

Assembly and in the discussions of the UN Security Council as well as in future reports from the UN Secretary-General (2009, 2010, 2012) on both human security and climate change. So far, these have treated both as two separate policy issues. In the social sciences and especially in peace, security, development and environmental studies, these observed linkages need more emphasis in conceptual, theoretical, and empirical research.

Simon Dalby is one of the very few scientists who work on security (see chap. 2 in this volume) and human security in the Anthropocene. "How we respond to these changes will be at the heart of what security means in the coming decades; how we think about linking ecological change and what we feel is important enough to need securing will soon shape future human prospects profoundly" (Dalby 2013a: 28). He argues that "security thinking needs to be substantially updated to be relevant to the new era of the Anthropocene" (Dalby 2013a: 28), in terms of what future is to be secured and which challenges must be contained, including the "increasing severity of hazards" (Dalby 2013a: 30) and the highly vulnerable urban infrastructure. Human security in the Anthropocene is, for Dalby, "a matter of what we choose to make, build and use. It is about investment decisions, only most obviously in terms of energy choices and transportation modes" (Dalby 2013a: 32). And he indicates that "The shift from a perspective that takes rival territorial states as the key to global order to one that looks to low carbon modes of economy providing basic needs for all the world's people is dramatic" (Dalby 2013a: 32).

9.7   Developing Sustainable Peace Further

'Sustainable peace' is a value-oriented and idealist concept that has been used by development NGOS and IGOs and in the social sciences in development and peace studies, especially by peace psychologists (chapter 6 by Deutsch/Coleman; chapter 7 by Coleman). In her book on *Sustainable Peace*, Connie Peck (1998: 22–23) introduced this concept into the post-Cold War debate on preventive diplomacy and on conflict prevention both as a 'vision' and as a 'policy programme' for conflict prevention, She argued that

> the twin concepts of sustainable development and sustainable peace could provide a full, and more focused and acceptable agenda for conflict prevention. ... The search for sustainable peace will therefore need to be

based on the establishment of the rule of law (a rights-based approach) and the institutionalization of problem solving (an interest-based approach) to replace violent conflict (a power-based approach).

Peck linked 'sustainable peace' and 'sustainable development' to 'human security', stating that

> sustainable peace is dependent upon addressing human security needs through the development of a fair process that can foster and maintain that security. Assistance in the creation of sustainable peace must therefore be based first on a thorough understanding of human security needs at the local level, and second on knowledge about how these might be best addressed through appropriate institutional and structural mechanisms (Peck 1998: 225).

Deutsch and Coleman have discussed above (chapter 6) "what psychological theory and research can contribute to the promotion of a *harmonious, sustainable peace*". The purpose of their book (Coleman/Deutsch 2012) was to enhance the "understanding of sustainable peace by supplementing the standard approach of studying the *prevention* of destructive conflict, violence, war and injustice with the equally important investigation of the *promotion* of the basic conditions and processes conducive to lasting peace."

Following Solomon (1997: ix), Deutsch and Coleman stated that: "Sustainable peace requires that long-time antagonists not merely lay down their arms but that they achieve profound reconciliation that will endure because it is sustained by a society-wide network of relationships and mechanisms that promote justice and address the root causes of enmity before they can regenerate destabilizing tensions". They argued that "a sustainable world peace will require the building of such a society" and they outline ... the "psychological requirements of such a society".

Coleman defined "sustainable peace as existing in a state where the probability of using destructive conflict, oppression and violence to solve problems is so low that it does not enter into any party's strategy, while the probability of using cooperation, dialogue and collaborative problem-solving to promote social justice and well-being is so high that it governs social organization and life", a definition which he elaborated for peace education.[45]

In a World Bank study, Lie, Malmin, and Gates (2007) discussed 'sustainable' or 'durable' peace in the context of 'post-conflict justice', while Lederach (1998)

---

45 Peter Coleman, "The Missing Piece in Sustainable Peace"; at: <http://blogs.ei.columbia.edu/2012/11/06/the-missing-piece-in-sustainable-peace/> (15 Nov. 2015).

proposed building sustainable peace "beyond violence". The UN Secretary-General in his 2001 report on conflict prevention argued that "effective conflict prevention is a prerequisite for achieving and maintaining sustainable peace, which in turn is a prerequisite for sustainable development".[46] In a similar direction the activities of the Department for Peacekeeping Operations (DPKO) "are designed to support peaceful transitions towards the building of sustainable peace in post-conflict environments" (Pampell/Sen 2005).

The Advanced Consortium on Cooperation, Conflict and Complexity (2015)[47] at Columbia University produced an expert survey report on *The Sustainable Peace Mapping Initiative: What is Sustainable Peace?* which concluded that among the seventy-four scholars there was "no clear consensus... on the definition of key elements associated with sustainable peace", but some points of convergence:

> All ... respondents either defined peace as the presence of processes and conditions for preventing *negative, destructive* dynamics and outcomes (violence, war, injustice, exclusion etc.), as the presence of processes and conditions promoting more positive, constructive dynamics and outcomes (mutual respect, cooperation, justice, harmony, environmental sustainability etc.), or as a combination of both (AC4 2015: 9).

The authors of the expert survey took four components into account in their working definition of sustainable peace: "*dynamic processes*, *positivity* and *negativity*, *systemic context* and *sustainability*", and proposed a

> working definition of sustainable peacefulness as *a set of dynamics that result in a high probability of robust patterns of constructive interactions between stakeholders and communities and a low probability of destructive interactions. Such dynamics establish and are established by a robust, enabling, and self-perpetuating context of peacefulness* (AC4 2015: 10–11).

The authors distinguished six thematic categories: 1) well-being, 2) quality of relations, cooperation and interdependence, 3) conflict management and resolution, 4) access to resources, equality, and human security, 5) institutional capacity and governance, and 6)

violence, non-violence and security. For the purpose of our own analysis the fourth is most relevant; the participants associated it with "freedom of speech, access to information, economic opportunities, access to healthcare, and education, social protection, arts, freedom of religion, social and income inequalities, environmental protection, [and] public goods provision", which corresponds with the definition of human security as freedom from fear and want.

In a proposal for a "systems-based applications of sustainable peace", Coleman, Burns, Fisher-Yoshida and Fisher (2015) noted that for many policymakers sustainable peace is elusive; for some it means

> a stable, long-lived peace that is associated with the preservation of the status quo through adequate security and protection from outside influence. For others, sustainability in the context of peace is associated with adaptation and renewal—a creative-adaptive peace—which recognizes that all social systems are in flux and progress through multiple states or stages over time (AC4 2015: 1).

Coleman, Burns, Fisher-Yoshida et al. (AC4 2015a: 1) argue that for decades peace research "has primarily studied the pathologies of war, violence, aggression and conflict" and only few researchers have studied peace "as a positive state". They deplore the fact that, so far, "interdisciplinary approaches are limited, and [a] comprehensive review of the scientific contributions across disciplines is yet to be undertaken. As a result, the complexity, multidisciplinarity, dynamism, and sustainability of peace are not well understood."

However, Peck, Deutsch and Coleman and most texts on sustainable peace have often ignored environmental challenges and their possible consequences for new types of conflict during the Anthropocene. This theme has therefore been underexplored, and conceptual, theoretical and empirical research is needed to develop the concept of a sustainable peace in the Anthropocene.

The respondents to the expert survey did not contextualize 'peace' in the context of 'peace with the environment' and the 'silent transition' to the Anthropocene that has not yet been socially constructed by most political scientists, international relations experts and peace researchers. Moving towards 'sustainability transition' may be conceived as the positive, creative-adaptive cooperative peace initiative that helps to contain or even prevent new causes of distress migration, conflict and, in the worst and most unlikely case, of wars to emerge. It requires shifting resources from the 'war system' to sustainable development, more equality, economic opportunities, and justice (Oswald 2008).

9.8   Conceptualizing an Emerging Political Geoecology

In the Anthropocene a rethinking of the relationship between humankind and nature, including the political realm and the social sciences, is needed, and it will make geopolitical approaches in the Hobbesian tradition obsolete.[48] In the Anthropocene, the old spatializations of international political, strategic and economic relations as 'geopolitics', 'geostrategy' and 'geoeconomy' have been primarily power- and interest-based and were partially ideologically legitimated. The ideas of many of these spatializations can be traced to the writings of Thomas Hobbes and to the pioneers of geopolitics and geostrategy: Kjellén (1917/1924), Mackinder (1904, 1905, 1918), Mahan (1890, 1897), Haushofer (1932). But these scientific and political approaches are unable to cope with the new environmental security problems posed by issues of global environmental change during the Anthropocene.

Instead of these Hobbesian spatializations of international political, strategic and economic relations, that totally ignore the environmental dimension and issues of global environmental change, a new concept of a *political geoecology* was developed. Geopolitics, geostrategy and geoeconomics have understood space as 'territory', as a component of national sovereignty, and have ignored the environment. But several approaches from the natural sciences, such as Lovelock's 'Gaia hypothesis', Edward O. Wilson's (1998, 1998a) 'consilience', Huggett's (1995) 'geoecology', and the 'earth systems analysis' approach (Schellnhuber/Wenzel 1998; Steffen/Sanderson/Tyson et al. 2004) have ignored politics.

The specific goal of a 'political geoecology' is to bring in politics, and especially peacebuilding and widened security issues (Dalby 2009, 2009b), and to outline a policy vision for the twenty-first century that aims for a sustainable peace (Brauch/Oswald Spring 2009a; Oswald 2009). Political geoecology was introduced as a new concept for research and teaching that links the approaches in physical and human geography with those of other social sciences. This requires a political dimension that moves from 'anticipatory knowledge' to 'proactive action' inspired by a political geoecology, with guidelines for a cooperative environ-

mental policy in the Anthropocene. The environment is not external to the human enterprise, because we are part of the earth.

With their proposed 'political geoecology for the Anthropocene', the authors want to launch a debate among scholars in the natural and social sciences. The old geopolitical and geostrategic research and policy debates were unaware of environmental issues, while the new research programmes in physical geography on 'geoecology' ignored 'politics', that is, the fields, processes, institutions, and legal frameworks that are needed for the implementation of sustainable development. The proposed perspective of a 'political geoecology for the Anthropocene' aims for a long-term global cooperative political strategy in a multilateral context. This requires a rethinking of one of the key goals of the UN Charter, "to maintain international peace and security", to include the new challenges humankind faces in the twenty-first century, and to develop a new strategy for a sustainable peace based on a gradual decarbonization of the global economy that can cope with the impacts of global environmental change.

The proposed new approach of a political geoecology combines the necessary *political orientation* with a *spatial focus* that combines different scales by implementing the many visions, perspectives and programmes for a sustainable development, so that both the linear projections of 'dangerous climate change' and the possible chaotic tipping points in the earth system are prevented from becoming reality. These new security dangers do not differentiate between countries, and they cannot be countered by military superiority.

Security policy in the Anthropocene requires primarily non-military instruments, and it also needs a gradual reallocation of scarce resources to be used for strategies of adaptation and mitigation that address the impacts of GEC and global and regional climate change. Purely technical solutions are bound to fail if there is no comprehensive political strategy for a progressive global green economy and no change in human lifestyles and social responsibility.

The cooperation between natural scientists working on geoecology and those working on programmes on *earth systems science* (ESS) addressing issues of global environmental change and climate change has not been easy. By adding a 'political dimension' to spatially sensitive 'geoecology' Brauch, Dalby and Oswald Spring (2011) call on the natural sciences to bring in perspectives from the policy sciences, and call

---

48 This chapter relies on previous work by the author (Brauch 2003) and on a co-authored chapter (Brauch, Dalby, Oswald Spring 2011), where this concept was developed further and discussed in detail. Some text is used here with the permission of the co-authors.

on the social sciences to reflect the new knowledge produced in the natural sciences.

As a result of linking 'ecology' as a scientific concept with the normative ethical, political and scientific goal of 'peace', scientific analysis must be broadened, as must be action-oriented political thinking and associated strategies, policies and measures to achieve peace, with its different features of a 'negative', 'positive', 'cultural', an 'engendered' and a 'sustainable peace'. Peace ecology should be conceptualized in relation to its five key pillars, embracing peace, security, equity, gender and sustainability.

9.9   Conceptualizing an Emerging Peace Ecology

Since the 1990s, environmental security research has shifted from environmental scarcity, degradation and conflict to the dangers posed by global environmental and climate change (Sygna/O'Brien/Wolf 2013). With the direct impacts of humans upon ecosystems in the Anthropocene (Crutzen 2002, 2011) and with the progressive securitization of issues of GEC during the past decade, these anthropogenic changes are increasingly threatening human lives and livelihoods. Worldwide, the destruction of key ecosystem services, the pollution of air, water and soil, land use change and extreme events are creating new 'anthropogenic challenges' for humankind, although these do not pose the threat of violent conflict and war.

Conca (1994: 20) suggested an "environmental agenda for peace studies" and a discussion on whether "ecologically desirable futures include concerns for peace and justice". He argued that it is not enough "to place 'sustainable development' and 'ecological security' alongside peace or social justice as 'world-order values'" but that scholars must ask whether "not only their formal definitions, but also their metaphorical and institutional associations, further the purposes of peace, justice, and community". Conca (2002: 9) fundamentally challenged a core premise of the debate on environmental (in)security and conflict by asking "whether environmental cooperation can trigger broader forms of peace defined as a continuum ranging from the absence of violent conflict to the inconceivability of violent conflict" by also addressing "problems of structural violence and social inequality" and by "building an imagined security community" based on peaceful conflict resolution.

Christos N. Kyrou (2007) introduced the concept of 'peace ecology'[49] as an "integrative, multi-contextual,

and case sensitive approach in identifying resources for conflict and violence transformation" with as its goal "to include issues of conflict analysis and peacebuilding" in environmental studies. Peace ecology calls philosophically for "peace with nature" (Meyer-Abich 1979, 2003), both a domestic and an international task where human behaviour has to be brought back into line with the wholeness of nature, where increasing hazards and disasters are an expression of the disharmony and absence of humankind's peace with nature.

How humans respond to these new threats to their survival depends not only on the world view of the scientists but also on the mindset of the elites. Business-as-usual prevails when the political, economic and military elites are unwilling or unable to act to address the root causes of GEC and climate change.

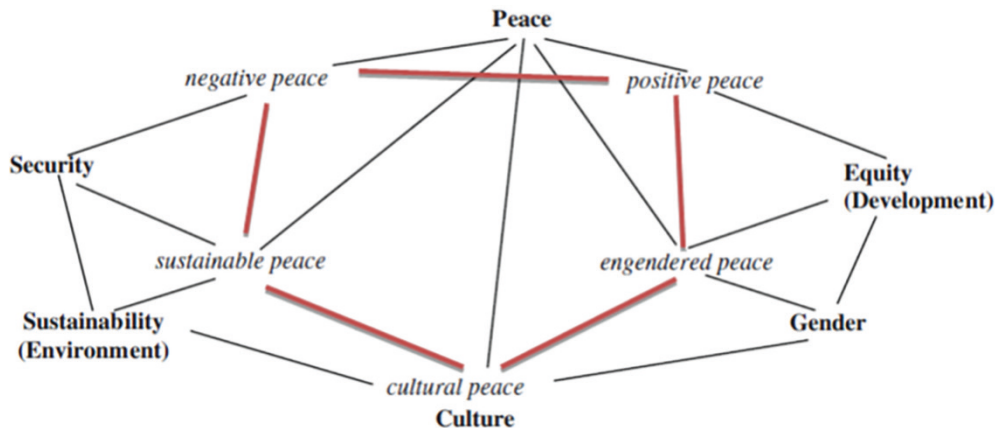
Peace ecology in the Anthropocene was conceptualized by Oswald Spring, Brauch and Tidball (2014: 18-19) within the framework of six conceptual pillars: peace, security, equity, sustainability, culture and gender, where *negative peace* (non-war) is defined by the linkages between peace and security, while for the relationship between peace and equity the concept of *positive peace* is defined by peace with social justice and global equity; for interactions between peace, gender and environment the concept of *cultural peace* was proposed, and for the relations between peace, equity and gender the concept of an *engendered peace* was suggested.

These five pillars of peace ecology point to different conceptual features of peace. The classic relationship between 'international peace and security' in the UN Charter refers only to a narrow *negative peace* without war and violent conflict. It aims for the prevention, containment and resolution of conflicts and violence and the absence of 'direct violence' in wars and repression. To achieve peace with equity or *positive peace* requires the absence of 'structural violence'. This is achieved by overcoming social inequality, discrimination, marginalization and poverty where there is no access to adequate food, water, health or educational opportunities.

Sustainable peace involves the manifold links between peace, security and the environment, where humankind and the environment as the two interdependent parts of global Earth face the consequences of destruction, extraction and pollution (Oswald Spring 2008). The concept of sustainable peace also includes

---

49 This section partly relies on a previous co-authored chapter (Oswald Spring, Brauch, Tidball 2014), with the permission of the two co-authors.

Figure 9.2: Five Pillars of Peace Ecology and their four linkage concepts of negative, positive, cultural and engendered peace. **Source:** Oswald Spring, Brauch and Tidball (2014: 19).


the processes of recovering from environmental destruction, reducing the human footprint in ecosystems through less carbon-intensive processes, and in the long term possibly carbon-free and dematerialized production, so that future generations may still decide on their own resource and development strategies.

Policies aiming for 'sustainability transition' are thus part of a positive strategy that addresses possible new causes of instability, crises, conflicts and in the worst case even war. These causes may be either the scarcity of fossil energy sources or the possible security consequences of anthropogenic global environmental and climate change, either of which may be triggered by linear trends as well as by chaotic tipping points (Lenton/Held/Kriegler et al. 2006).

The relation between peace, the environment and gender may result in *cultural peace*. *Cultural peace* facilitates the creation of peace in the minds and actions of humankind. It socializes people so that religious and social discrimination can be overcome, by establishing human rights granted equally to all people. This will enable them to develop the ability to negotiate solutions to present and future conflicts peacefully and to share political, economic, social and cultural powers. The rights also respect different ecosystems, by taking into account their vulnerability to human actions.

Finally the links between peace, equity and gender introduce an *engendered peace*, creating relations between men and women, children, young people and elderly people based on equity. This will build up the capacity for negotiation, exchange, sharing, bargaining and developing tools, where the most vulnerable are empowered through development processes, non-violent conflict management, and disaster risk reduction (see chapter 8 by Oswald Spring in this volume). For Amster (2015)

peace ecology is more than merely a conceptual synthesis of peace and ecology. In essence, it contemplates the ways in which the same environmental processes that often drive conflict—e.g. resource depletion, anthropogenic climate change, food and water shortages—can also become opportunities for peaceful engagement. ... When confronted with a crisis ... recent research [argues] that people are actually more likely to cooperate than they are to compete, and that instances of violence in such situations are the exception rather than the norm (e.g. Solnit 2009). ... People around the world who strive to manage scarce essential resources (as with sensitive watersheds) often find that their mutual reliance on the resource transcends even profound cultural and political differences—and in some cases even warring parties have found ways to work together positively on such issues. Informed by schools of thought including *social ecology* ... and *deep ecology*, peace ecology is concerned equally with the human–human and human–environmental interfaces as they impact the search for peace at all levels (Amster 2015: 8-9).

Amster (2015: 143ff.) reviewed different concepts of and approaches to environmental cooperation, the concepts of *environmental dispute resolution* (Caplan 2010), *environmental peacemaking* (Conca/Dabelko 2002; Ali 2007, 2009) and *environmental peacebuilding* (Ecopeace 2016). However, he did not frame his argument in the context of the Anthropocene, nor did he discuss issues of sustainability transition or of the long-term global transition and transformation of the national and global economies that needs to be achieved through strategies aiming at a gradual decarbonization and dematerialization of the economy.

9.10   Sustainability Transition with Sustainable Peace

This concluding section focuses on possible interrelations between the research paradigm of a 'sustainability transition' and the goal of 'sustainable peace'. According to Geel's model, sociotechnological innovations emerge from small niches, and they often face major opposition within society (sociotechnical regime) from coalitions of special interest groups, business representatives and policymakers, who would lose from these innovations. This process will only succeed if new coalitions of societal, economic and political actors can successfully overcome opposing interests before these innovations can succeed globally (landscape). Globally successful innovations must take external factors—both earth systems and global economic and social megatrends—into account. However, both the DKI (Grin/Rotmans/Schot 2010) and the WBGU (2011) have not yet reflected on the implications for peace and security.

The two major technical revolutions in earth history have both resulted in technical and strategic revolutions and in more violent warfare. During the two world wars the total mobilization and militarization of technological innovations resulted in between 7,750,919 and 15 million deaths in World War I[50] and between 50 and 85 million deaths in World War II—if those who died from war-related famine and diseases are included[51]—and in more than 50 million deaths since 1945.[52]

The initial question was whether a long term transformative change towards sustainability —as in the aftermath of the Neolithic and the industrial revolutions—might result in a 'higher form of killing' or whether this transformation would foster more cooperative forms of multilateral cooperation and conflict resolution and peacebuilding. No definite answer is possible because future political constellations, decisions and events cannot be predicted.

However, different scenario outcomes may be assumed:

- A pessimist or *worst-case scenario* that assumes that—given the present global and national economic, political and societal power structures—such a major change in human and state behaviour is unforeseeable and that new technological innovations will be absorbed by the military, resulting in new revolutions in warfare.

- An optimist or *best-case scenario* assumes that a 'sustainability transition' to a low-carbon economy may foster the realization of a utopian vision of a global peaceful order, where war and patriarchy (Oswald Spring, chapter 8) must be overcome before a lasting, eternal or 'sustainable peace' in the Kantian tradition can prevail.

- A *pragmatic scenario* combines features of both the pessimist and the optimist scenarios and assumes that the behaviour of human beings and their interest in wealth, power and domination are unlikely to change. But sociotechnical innovations and a new scientific revolution towards sustainability (Clark/Crutzen/Schellnhuber 2004) will fundamentally change the world view of scientists and partly change the mindset of policymakers. Whether such a 'sustainability transition' might lead to a more peaceful and cooperative international order is an open question that cannot be scientifically answered.

Only this third *pragmatic* scenario will be discussed, from a pragmatic 'Grotian perspective' (Bull 1977; Bull/Kingsbury/Roberts 1992; Dean 2008, 2014) on

---

50 The figures for WWI differ: The American *Public Broadcasting System* (PBS) estimated a total number of deaths for all conflict parties as 8,528,831, of wounded as 21,189,154, and of prisoners and missing as 7,750,919, amounting to a total number of casualties of 37,466,904; at: <https://www.pbs.org/greatwar/resources/casdeath_pop.html>; a similar figure was offered by: <http://www.historylearningsite.co.uk/world-war-one/world-war-one-and-casualties/first-world-war-casualties>; according to Wikipedia for World War I, estimates of total deaths range from 9 million to over 15 million; at: <https://en.wikipedia.org/wiki/World_War_I_casualties>, based on Matthew White, Source List and Detailed Death Tolls for the Primary Megadeaths of the Twentieth Century: <http://necrometrics.com/20c5m.htm>.

51 The figures for WW II differ even more: Wikipedia offers a total for military deaths of between 21 and 25,5 million, of civilian deaths between 29 and 30,5 million, and of civilian deaths due to war-related famine and diseases of between 19 and 28 million, amounting to a total of 70 to 85 million; at: <https://en.wikipedia.org/wiki/World_War_II_casualties>; another source estimates 20,858,800 military deaths, 20,858,800 civilian deaths and 48,231,700 total deaths; at: <http://warchronicle.com/numbers/WWII/deaths.htm>.

52 The Worldmapper claimed that 51 million people were killed in wars between 1945 and 2000; at: <http://www.worldmapper.org/display.php?selected=287> (19 November 2015); see Max Roser, 2015: "War and Peace after 1945"; in: *OurWorldInData.org;* at: <http://ourworldindata.org/data/war-peace/war-and-peace-after-1945/> (19 November 2015).

Figure 9.3: Battle death rate in state-based conflicts by type (1946–2013) by Max Roser. Annual worldwide battle deaths per 100,000 people. **Source**: PRIO battle deaths dataset (1946–2007) and data provided by Steven Pinker for 2009 and later (based on UCDP and PRIO). peace and security issues. A 'sustainability transition' towards a low-carbon industry challenges the old carbon-based industry, energy utilities, and the highway and car transportation lobbies whose economic interests would be negatively affected. Since 2007 these industries have been major sponsors of climate change critics (Klein 2011) and of their aggressive campaign against the IPCC. They have significantly changed public opinion about climate change issues in the US, Canada and Australia, where politicians who supported their economic interests have been successful.

Powerful interest groups in the primary exporting countries of coal, oil and natural gas have countered the debates on global climate change and the arguments for a decarbonization of the economy, while countries that import from fossil energy sources (e.g. the EU, but also China and India) have increasingly relied on renewable energy sources (wind, solar) for electricity.[53]

The global capacity of wind power has risen from 48 GW (2004) to 370 GW (2014) and of solar PV from 3.7 GW (2004) to 177 GW (2015), and global new investment in renewable power and fuels in both developed and developing countries increased from US$45 billion to US$270 billion between 2004 and 2014 (figure 9.4, 9.5, 9.6). While both new fossil energy sources and renewables may counter resource conflicts, only the latter may avoid the negative security consequences of the physical effects of anthropogenic climate change.

As a 'decoupling of growth from energy consumption' (UNEP 2014; von Weizsäcker 2014) is possible if there is an energy efficiency improvement of a factor 4, 5 or 10 (von Weizsäcker/Lovins/Lovins 1997; von Weizsäcker/Hargroves/Smith et al. 2009; von Weizsäcker 2014) and through a replacement of fossil fuels with renewable energy sources, dependence on energy imports will gradually decline and resource wars may

be less likely. This is a declared goal of the EU's roadmap for a low-carbon economy by 2050 (EU 2011b; Brauch 2016a).

Policymakers who favour a transformation of the economy towards a low-carbon society will face major and well-funded opposition. So far only the European Union (EU 2011, 2011a, 2011b, 2011c, 2011d; Hap-

paerts in this volume; Brauch 2016) and a majority of its twenty-eight countries have favoured such a strategy. Both the European Commission and the Council have argued that a sustainability transition in the energy and transport sector as the result of an efficiency revolution and a gradual replacement of fossil with renewable energy sources would significantly reduce both energy

Figure 9.6: Global new investment in renewable power and fuels, developed and developing countries (2004–2014). **Source:** REN 21 (2015); at: <http://www.ren21.net/status-of-renewables/global-status-report/>.
costs and dependence on imports of fossil energy sources from unstable regions such as the Middle East. This would not only decouple economic growth from energy consumption but possibly also from dependence on contested regions.

At least two peaceful outcomes of such a transition process towards a low-carbon economy and society can be assumed with some plausibility:

1. Climate wars would become highly unlikely if the causes of this threat could be countered by a major global reduction in the consumption of fossil energy and thus a stabilization of GHGs in the atmosphere. This would make dangerous climate change and tipping points unlikely. Preventing this new type of violent conflict in highly vulnerable climate hot spots would represent a global diplomatic strategy that fosters a sustainable peace (Brauch 2002; WBGU 2008; Scheffran/Brzoska/Brauch et al. 2012; IPCC 2014).

2. For those countries that adopt and implement such a long-term transformative change towards sustainability in the energy, production, transportation, housing and agricultural sectors, their dependence on a scarce supply and rising energy prices from contested regions would decline. This would reduce the pressure to intervene militarily in order to guarantee access to and transportation of these

energy sources and to prevent their economy from collapsing. A second major beneficial outcome would be that classical resource conflicts, especially over oil and gas and other scarce strategic minerals, might be reduced (Klare 2001, 2012).[54]

Combining both challenges, Michael T. Klare (2013) argued: "Two nightmare scenarios—a global scarcity of vital resources and the onset of extreme climate change—are already beginning to converge and in the coming decades are likely to produce a tidal wave of unrest, rebellion, competition and conflict."[55]

The probable reduction of the likelihood of old 'resource conflicts' and the avoidance of new 'climate conflicts' through economic transformation towards sustainability would by itself not change the international order. It could, however, possibly foster new political coalitions of those countries who could invest in concrete projects that might result in such a dual

---

54 Stephen Kinzer: "America's next security threat: resource wars—This century's clashes will be conflicts over access to food, water, and energy", in: *Boston Globe*, 31 August 2014.

55   See Klare (2013); on this dual linkage, see also Leggett (2001, 2005, 2005a), Homer-Dixon (2006); and Lovins, Datta, Bustness et al. (2005).

decoupling of many highly vulnerable countries situated in climate change hot spots.

Thus, a sustainability transition towards a low-carbon economy by reducing the probability of two types of conflicts might foster policy strategies that aim for a more sustainable peace with more human security, where freedom from the impacts of climate-induced hazards would also be more likely. This linkage between the three new policy goals of a 'sustainable development' with 'human security' and 'sustainable peace' would draw basic lessons from the security implications of the Anthropocene, where 'we' have become the threat to the survival of humankind and only 'we' as part of humankind itself can offer a solution to the consequences of human intervention into the earth system.

These conceptual considerations have suggested the contextualization of the 'sustainability transition paradigm' and policy strategies for a 'low-carbon economy' as a sustainable peace goal within a human security strategy, as Sir David King (UK) has suggested. As only 'we' can offer the solutions to the impact of human interventions into the earth system it is crucial to bring sustainable peace considerations into the mainstream of conceptual thinking and policy action that aims for a long-term transformative change towards a low-carbon economy with high energy efficiency during this century.

The ten key messages of this chapter[56] are:

1. During the twentieth century humankind has for the first time significantly interfered in nature and the earth system and has silently moved as a result of multiple anthropogenic interventions—especially during the past sixty years—from the Holocene to the Anthropocene (Crutzen 2002, 2011; Crutzen/Brauch 2016), a new era of earth history.

2. This silent transition requires a "Second Copernican Revolution" (Schellnhuber 1999) with the emergence of a new 'scientific paradigm' aiming at sustainability and a new 'social contract for sustainable development' (Clark/Crutzen/Schellnhuber 2004; WBGU 2011) that can be advanced through a process of 'sustainability transition'.

3. This means that during the twenty-first century, the policy-focused social sciences must rethink and reconceptualize the key concepts of, and the design of research programmes on, peace, security, development and the environment, including their cultural contexts.

4. Irrespective of the outcome of multilateral global climate diplomacy and of the adoption of climate treaties and their implementation, unilateral national and regional strategies aiming at a 'sustainability transition' in key economic sectors (energy, transportation, production and consumption, urbanization and housing, agriculture and forestry with water and soil management) are needed; they must be based on economic incentives and rationales.

5. A strategy that aims for a 'sustainability transition' towards a low-carbon economy may contribute to the realization of the triple goal of 'sustainable development' with 'human security' and 'sustainable peace' by reducing the probability of conflicts over energy, other non-renewable resources (fossil fuels, minerals) and renewable resources (including water and arable soil), and caused by the physical and societal impacts of climate change.

6. The two suggested multidisciplinary scientific research programmes of a 'political geoecology' and of a 'peace ecology' in the Anthropocene may contribute to the development of a new sustainability revolution (Oswald Spring/Brauch 2011) with a new science paradigm aiming for sustainability.

7. The goal of the proposed 'political geoecology' is to add to the 'geoecology' paradigm used in physical geography the 'political' dimension, including issues of peace and security, while sensitizing policy-oriented social scientists for new knowledge generated by scholars in earth system sciences and geoecology.

8. The proposed 'peace ecology' paradigm will link environmental and peace studies by addressing both the negative consequences of pollution and global environmental change and also the opportunities created by 'environmental peacemaking' and 'sustainability transition', within the framework of the *Sustainable Development Goals* (SDGs) in the Anthropocene.

9. Both research paradigms and approaches, when they are developed and discussed, must take the specific framework of the 'Anthropocene' fully into account. 'Sustainable peace in the Anthropocene' requires a rethinking of this 'normative concept' that is widely used for conflict prevention and post-conflict peacebuilding, focusing also on 'peace with nature'.

10. The proposed 'sustainability revolution' requires a *transformation* of global cultural, environmental,

---

56 This summary has benefitted from critical comments by Ursula Oswald Spring, based on a joint publication.

economic and political relations (Oswald Spring/ Brauch 2011: 1487ff.). This must replace the dominant vision and strategies of *business-as-usual* in a Hobbesian world where economic and strategic interests and behaviour predominate. Such Hobbesian interests and behaviour may possibly lead to a major crisis for humankind in inter-state relations, where the survival of the vulnerable is put at risk. If this happens, Earth as a habitat for humans and ecosystems will be destroyed.

In the dominant vision of *business-as-usual* a *cornucopian perspective* predominates that suggests primarily technical fixes (geoengineering) and the defence of economic, strategic and national interests in a way that only OECD countries can afford. The alternative vision requires a *sustainable perspective* based on global equity and social justice. The first vision with its minimal reactive strategies will most likely increase the probability of 'dangerous climate change' (Schellnhuber/Cramer/Nakicenovic et al. 2006) with both linear and chaotic changes in the climate system and their sociopolitical consequences. For Oswald Spring and Brauch (2011), the sustainability perspective

requires a change in *culture* (thinking on the human–nature interface), *world views* (thinking on systems of rule, e.g. democracy vs. autocracy, on domestic policies and inter-state relations), *mindsets* (the strategic perspectives of policymakers) and new forms of national and global *governance*.

This alternative vision identifies the need for a "new paradigm for global sustainability" (Clark/ Crutzen/Schellnhuber 2004), for a "transition to [a] much more sustainable global society" (Raskin/ Banuri/Gallopin et al. 2002), aimed at peace, freedom, material well-being and environmental health. Changes in technology and management systems alone will not be sufficient, but "significant changes in governance, institutions and value systems" are needed. These alternative strategies should be "more integrated, more long-term in outlook, more attuned to the natural dynamics of the Earth System and more visionary" (Steffen/Sanderson/Tyson et al. 2004: 291–293) and should take planetary boundaries into account (Rockström/Kulm 2015; see chapter 4 by Dalby).

Part III   Meeting Challenges of the 21ˢᵗ Century: Demographic Imbalances, Temperature Rise and the Climate-Conflict Nexus

10   Population Imbalances: Their Implications for Population Growth over the Twenty-first Century

Hania Zlotnik[1]

Abstract

Current population dynamics vary markedly among countries. In 2010, 46 per cent of the world population lived in countries with below-replacement fertility, whose populations are experiencing rapid population ageing and will likely decrease in the future. In sharp contrast, 19 per cent of the world population lived in countries with such high fertility that their combined populations are likely to double by 2050 and to keep growing over the rest of the century. The remaining 35 per cent lived in countries where fertility levels had declined considerably since their peak but where the potential for continued population growth over the medium term remains high. Owing to both population momentum and the long-standing differences in population dynamics between those groups of countries, these diverse population trends are expected to continue over the medium term, thus maintaining today's population imbalances and producing a high potential for marked population growth over the course of this century, especially in some of the world's poorest countries. Reducing those population imbalances by the end of the century and achieving the stabilization of the world's population requires that the high-fertility countries accelerate the reduction of fertility so that it reaches below-replacement level before 2100.

Keywords: Below-replacement fertility, population ageing, population dynamics. population growth, population imbalances, population momentum.

10.1   Introduction

In 2014, as governments debate which goals they are to adopt to spur sustainable development between 2015 and 2030 (United Nations 2014a), the world population continues to grow, having reached 7 billion in 2011 and being poised to reach 8 billion between 8 and 12 years from now (that is, between 2022 and 2026). Crucially, the earlier that 8th billion is reached, the more likely it is that the world population will add several additional billions by the end of the century. Because most of the people who will be alive over the next twelve years have already been born, the exact moment at which the next billion is reached depends mostly on how many children are born over the next few years. That is, fertility trends are the main determinant of population increases and, because of the multiplicative nature of population growth, small changes in global fertility now and in the immediate future can have a major impact on the long-term potential for further population growth.

Although the rapid population growth that the world has experienced since 1950 has been accompanied by improvements in the standard of living and the quality of life of the majority of the world population, it is becoming increasingly clear that the planet is under stress because of human activity and that ensuring better livelihoods for future generations poses many challenges. Thus, attaining universal food security by mid-century, a basic goal to ensure future well-being, may be feasible but is far from certain. The need to increase the global food supply by at least 70 per cent to be able to feed the nine billion people expected to inhabit the Earth by 2040 requires intensifying the use of existing agricultural land, particularly in the populous countries of Asia, and extending the land under cultivation in many of the world's least developed countries where population growth is expected to be the fastest (Butler and Dixon 2012;

---

1   Dr. Hania Zlotnik is an independent consultant and was Director, Population Division, Department of Economic and Social Affairs, United Nations Secretariat (2005–2012); Email: <hania.zlotnik@hotmail.com>.

West et al, 2014). Achieving those changes while simultaneously reducing the deleterious effects of agriculture on global warming and water quality and reducing water use will demand large additional investments in agriculture and the judicious use of technology. Expanding access to clean energy is another daunting task that has just started and that is still progressing too slowly to meet the needs of the rapidly growing populations of the developing world.

These and other challenges are all scaled up by population numbers and will be more difficult to meet the larger the population becomes. Yet intergovernmental and even expert discussions about how to attain a sustainable future rarely consider future population numbers as a factor subject to modification. Because policymakers usually focus on the short term and changes in population dynamics usually take time to have a significant effect on overall population numbers, the need to modify current population dynamics is often disregarded.

This chapter, by focusing on the long-term implications of changes in population dynamics, shows that, if the world population is to remain below 10 billion by the end of this century, there is an urgent need to accelerate the reduction of fertility in the countries that still have high fertility levels, and it is also necessary that the countries with intermediate levels of fertility continue reducing them. According to the most recent estimates of fertility levels, referring to 2005–2010, 62 countries, accounting for 19 per cent of the world population in 2014, had high fertility; another 64 countries, accounting for 35 per cent of the world population, had intermediate fertility, and a further 75 countries, representing 46 per cent of the world population, had low fertility.

Analysis of past trends shows that the high-fertility countries of today have had, on average, higher fertility levels than the rest since 1950 and, although their levels of mortality in childhood have declined substantially, their fertility has declined very slowly. Therefore, even though they account for just 19 per cent of today's population, their population is increasing rapidly and may grow to represent 43 per cent of the world population in 2100 even if their fertility declines at a moderate pace in future. Because most of the high-fertility countries are low-income or lower-middle-income countries, they are the least well prepared to satisfy the basic needs of rapidly growing populations. In contrast, the most prosperous or rapidly growing economies are those of countries whose fertility has reached low levels and whose overall population is likely to decrease during this century, so that

by 2100 they may account for 28 per cent of the world population, down from 46 per cent today.

Past trends reveal that such 'population imbalances', meaning the marked differences in population dynamics that over the long run change the regional distribution of the world population, have been at play since at least 1950. However, the expectation has been that population trends will converge so that all countries will eventually achieve a state of low fertility and low mortality that, aside from producing a world population that changes very slowly, would also contribute to improve human well-being by maximizing longevity and facilitating higher investments in the human capital of each child. Yet, in view of developments over the past two decades, one may question whether that convergence will actually occur and, if it does, how rapidly it will be achieved. Considering the number and characteristics of the countries that continue having high fertility, there is greater uncertainty today than just two decades ago about whether convergence will happen. By exploring the consequences of a delayed convergence, this chapter provides evidence that should prompt those interested in sustainability to advocate a sustained and well-funded effort to accelerate the reduction of fertility in high-fertility countries through the promotion of a smaller family norm and the uptake of voluntary family planning in countries where still too many children are born and too many die from preventable causes.

10.2   The Demographic Transition as the Rationale for Convergence

By any standards, world population trends changed dramatically during the second half of the twentieth century. The reductions of mortality that had started in the more advanced countries in the nineteenth century expanded rapidly to the developing world particularly after 1950 as better nutrition, improved sanitation and modern medical interventions successfully controlled or treated the most deadly infectious and parasitic diseases that were endemic in those countries. Plummeting infant and child mortality coupled with fertility levels that remained high resulted in accelerated population growth. However, with the expanded adoption of family planning and the use of modern contraceptives, fertility eventually declined also, sometimes very rapidly and often to unprecedentedly low levels. By the end of the twentieth century, most developed countries and an increasing number of developing countries were experiencing

levels of fertility so low that, if maintained for a generation or more, they would lead to decreasing populations.

These developments have led demographers to develop a model of demographic change known as 'the demographic transition'. In the 1950s, this model provided a stylized description of the changes in fertility and mortality trends that took place as populations passed from a state where both mortality and fertility were high and population growth was low to one where both mortality and fertility were low and population growth would again be very low. According to the demographic transition, mortality would decline first while fertility remained high until people realized that, because of improved child survival, it was no longer necessary to have so many children in order to achieve the number of adult children they desired. That realization would prompt people to reduce their fertility and, as mortality continued to decline, fertility would drop further until once more fertility levels would counterbalance mortality and the natural increase of the population would reach zero. By the 1990s, noting that many populations were completing the demographic transition not by reaching a balance between fertility and mortality but rather by overshooting the fertility decline and ending in a stage where fertility was too low to counterbalance mortality, demographers modified the original description of the last stage of the transition by recognizing that it could produce not an unchanging population with zero population growth but rather a decreasing population.

By 2014, changes in fertility and mortality trends consistent with the demographic transition had taken place in all countries in the world. In every country, mortality is currently lower today than it was in the 1950s and fertility has also declined with respect to the peak level it attained after 1950. However, the pace of mortality and fertility reductions as well as their timing has varied considerably among countries. Currently, countries that are most advanced in the demographic transition are characterized by having very low fertility and low mortality. Those that are the least advanced still have relatively high fertility levels. The rest have advanced in the path to low fertility but have not yet reached the very low levels that characterize the last stage of the demographic transition. Consequently, those three groups of countries have today different population profiles and different prospects for future population change. Countries with low fertility have rapidly ageing populations and, if their populations are not decreasing already, expect to experience population reductions in the future. Countries with high fertility still have young populations that are growing fast and have a high potential for future population increases. The rest are experiencing moderate rates of population growth and have moderately ageing populations but their future hinges on whether or not they complete the demographic transition by reaching very low fertility levels. These differences in current population dynamics are at the root of the population imbalances that characterize world population today and are likely to remain a feature of the world population over the next four or five decades at least. Furthermore, developments over those decades will determine whether there is any chance for those imbalances to start waning during the second half of this century as the fertility and mortality of all countries converge to low levels.

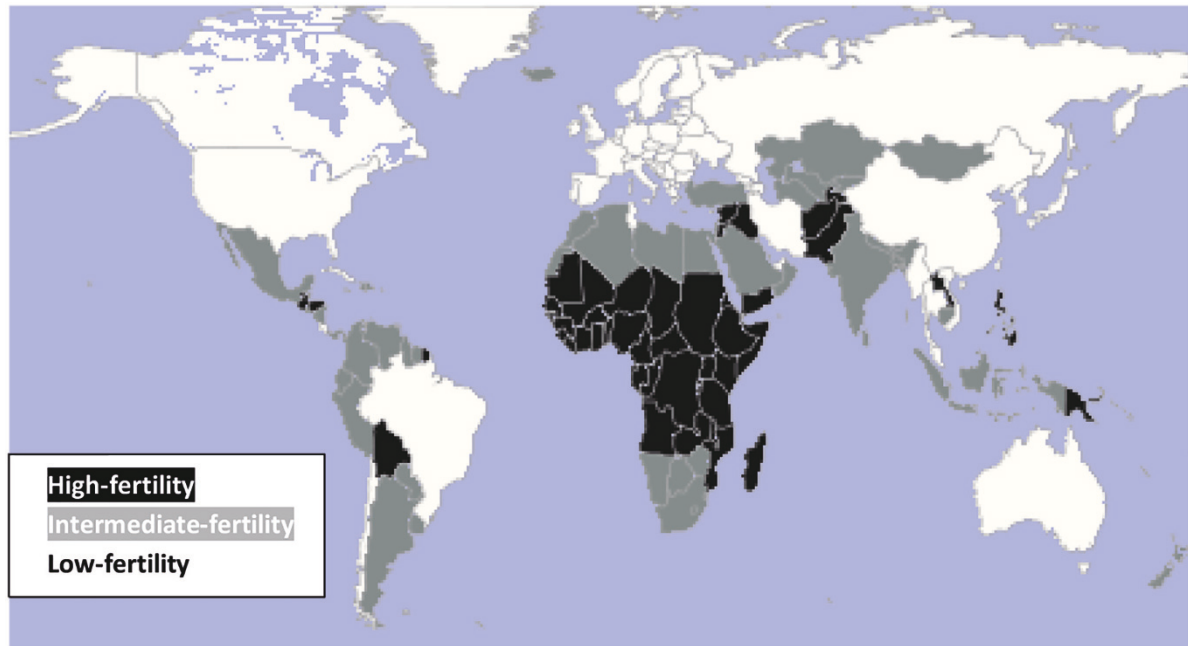
10.3 Classifying Countries into Three Groups According to Their Net Reproduction Rates

The countries of the world can be classified into three groups according to their fertility levels. The classification used in this chapter is based on the value of the *net reproduction rate* (NRR) for each country. NRR is a measure of the reproductive potential of a population. It takes into account both the overall level of fertility of a country (that is, a country's total fertility[2]) and the level of mortality during the first 25 or 30 years of life. NRR indicates the average number of daughters expected to survive to the mean age at childbearing that a cohort of women would have by exact age 50 were those women to experience from exact age 15 onwards the age-specific fertility rates observed during a given period without being subject to mortality. The *United Nations Population Division* (UNPD) estimates NRR for the 201 countries[3] that had at least 90,000 inhabitants[4] in 2010 (United Nations 2013a). In the majority of those 201 countries,

---

2 Total fertility is a measure of the level of fertility in a population. Total fertility is the average number of children a hypothetical cohort of women would have at the end of their reproductive period if they were subject during their whole lives to the fertility rates of a given period and if they were not subject to mortality. It is expressed as children per woman.

3 The term 'countries' is used here to encompass also areas that are dependent territories but whose data are reported separately from that of the country from which they depend.

Figure 10.1: Map displaying the high-fertility, intermediate-fertility and low-fertility countries.


fertility and mortality have been the major components of past population change.

A net reproduction rate of 1.0 daughter per woman indicates that every woman of reproductive age is eventually replaced by a daughter who survives to an age where she herself may have a child. Therefore, when NRR = 1.0, the population is on track to 'replace itself' and fertility is said to be at 'replacement level'.[5] When NRR is higher than 1.0 daughter per woman, the current level of fertility is higher than it needs to be to counterbalance the current level of mortality and, therefore, the population is poised to increase from generation to generation and fertility is said to be 'above replacement level'. When NRR is lower than 1.0 daughter per woman, the reverse holds, that is, the current level of fertility is not sufficient to counteract the current level of mortality and, therefore, the population is poised to decrease from generation to generation. In this latter case, fertility is said to be 'below replacement level'.

Estimates of NRR referring to the period 2005–2010 have been used to classify the 201 countries with estimates available into three groups. The *high-fertility countries* are those with an NRR equal to or higher than 1.5 daughters per woman, that is, they are countries whose most recently measured fertility and mortality levels, if maintained, would lead to an increase of at least 50 per cent between one generation and the next. The second group of countries, denominated *intermediate-fertility countries*, are those whose NRR in 2005–2010 varies from 1.0 daughter per woman to just under 1.5 daughters per woman. Lastly, the *low-fertility countrie*s are those whose NRR is below 1.0 daughter per woman, that is, their fertility is below replacement level. If an NRR below 1.0 daughter per woman is sustained over a period of a generation or more, the population will decrease.

According to the above classification, in 2005–2010, 62 countries[6] had high fertility levels, 64 had

---

4   The United Nations Population Division does not produce estimates of the components of population change for countries with fewer than 90,000 inhabitants, and that is why they cannot be included in the analysis presented here. In 2010, 32 countries or areas had fewer than 90,000 inhabitants each and their joint population amounted to approximately one million. Because of their small populations, in many of those countries migration is a very important component of population change.

5   Since NRR depends on both the level of fertility and that of mortality, 'replacement level' fertility varies according to the level of mortality: the higher the probability of dying before age 30, the higher total fertility needs to be to assure that a daughter survives to the age of reproduction. When mortality is low, a total fertility of around 2.10 children per woman is usually sufficient to ensure replacement and that number is often described as 'replacement-level fertility'. When mortality is high, however, replacement-level fertility can be much higher, sometimes amounting to values well above 3 children per woman.

Table 10.1: Distribution of countries and population among the high-fertility, intermediate-fertility and low-fertility groups. **Source**: Derived from United Nations (203a).

Region	Total	Number of countries			Percentage		
		High-fertility countries	Intermediate-fertility countries	Low-fertility countries	High-fertility countries	Intermediate-fertility countries	Low-fertility countries

Oceania	0,01	0,01	0,00	0,00	84	16	0

intermediate fertility levels[7] and 75 had low fertility levels[8] (see table 10.1). Most of the developed countries[9] (98 per cent) have below-replacement fertility levels and are classified as low-fertility countries. Only two developed countries, Iceland and New Zealand, had intermediate-fertility levels in 2005–2010 and both had fertility close to replacement level. Among developing countries, 32 (20 per cent) had below-replacement fertility, including two of the most populous countries: Brazil and China. Ninety per cent of the low-fertility countries are high-income or upper middle-income countries according to the World Bank's classification.

The remaining 144 developing countries are equally divided among the high-fertility and the intermediate-fertility countries. In Africa, the majority of countries had high fertility levels in 2005–2010 (72 per cent). In developing Oceania, half of the countries belonged to the high-fertility group. High-fertility countries are less common in Asia, where they account for 22 per cent of the total, and in Latin America and the Caribbean, where they account for just 11 per cent. Nevertheless, all developing regions still have significant numbers of countries maintaining high fertility. Ninety per cent of the high-fertility coun-

---

6   *High-fertility countries:* Afghanistan, Angola, Benin, Bolivia, Burkina Faso, Burundi, Cameroon, Central African Republic, Chad, Comoros, Congo, Côte d'Ivoire, Democratic Republic of the Congo, Djibouti, Equatorial Guinea, Eritrea, Ethiopia, Federated States of Micronesia, French Guiana, Gabon, Gambia, Ghana, Guatemala, Guinea, Guinea-Bissau, Honduras, Iraq, Jordan, Kenya, Lao People's Democratic Republic, Liberia, Madagascar, Malawi, Mali, Mauritania, Mayotte, Mozambique, Niger, Nigeria, Pakistan, Papua New Guinea, Philippines, Rwanda, Samoa, Sao Tome and Principe, Senegal, Sierra Leone, Solomon Islands, Somalia, South Sudan, State of Palestine, Sudan, Syrian Arab Republic, Tajikistan, Timor-Leste, Togo, Tonga, Uganda, United Republic of Tanzania, Vanuatu, Yemen and Zambia.

7   *Intermediate-fertility countries:* Algeria, Antigua and Barbuda, Argentina, Bahrain, Bangladesh, Belize, Bhutan, Botswana, Brunei Darussalam, Cambodia, Cape Verde, Colombia, Dominican Republic, Ecuador, Egypt, El Salvador, Fiji, French Polynesia, Grenada, Guadeloupe, Guam, Guyana, Haiti, Iceland, India, Indonesia, Israel, Jamaica, Kazakhstan, Kiribati, Kuwait, Kyrgyzstan, Lesotho, Libya, Maldives, Mexico, Mongolia, Morocco, Namibia, Nepal, New Caledonia, New Zealand, Nicaragua, Oman, Panama, Paraguay, Peru, Qatar, Réunion, Saint Vincent and the Grenadines, Saudi Arabia, Seychelles, South Africa, Sri Lanka, Suriname, Swaziland, Turkey, Turkmenistan, United States Virgin Islands, Uruguay, Uzbekistan, Venezuela, Western Sahara and Zimbabwe.

tries are low-income or lower middle-income countries according to the World Bank's classification.

Intermediate-fertility countries are mostly concentrated in Asia and in Latin America and the Caribbean where they account for 42 per cent and 58 per cent of the countries respectively. Among countries in developing Oceania, half had intermediate fertility in 2005–2010 and so did a quarter of those in Africa. India, the most populous country in the world, is among the intermediate-fertility countries, as are Indonesia, Bangladesh, Mexico and Egypt (in order of population size). Those five countries account for 75 per cent of the population of all intermediate-fertility countries. Sixty-three per cent of intermediate-fertility countries are high-income or upper-middle-income countries, according to the World Bank's classification, and 9 per cent are low-income countries.

In 2014, 46 per cent of the world population lived in low-fertility countries, 35 per cent in intermediate-fertility countries and 19 per cent in high-fertility countries (table 10.1). The populations of low-fertility and intermediate-fertility countries are highly concentrated in just a few countries. As just noted, five countries account for 75 per cent of the 2.5 billion people living in the intermediate-fertility countries. Among the 3.4 billion people living in the low-fertility countries, 75 per cent live in just nine countries of which the most populous are, in order of population size, China, the United States, Brazil, the Russian Federation and Japan. In comparison, the 1.4 billion people living in high-fertility countries are less concentrated in a few populous countries given that 17 countries are needed to account for 75 per cent of their overall

population. The most populous among them are: Pakistan, Nigeria, the Philippines and Ethiopia, in order of population size.

10.4   Past Trends in Total Fertility and Under-five Mortality[10]

Although the three groups of countries defined above were determined on the basis of a synthetic measure of reproductive potential (the net reproduction rate) referring to 2005–2010, it turns out that the three groups have had quite different trends in total fertility and under-five mortality[11] since at least 1950. That is, their current differences are not only the result of diverging trends since 1950 but reflect also long-standing differences that have been more persistent than expected. In particular, the high-fertility countries have, as a group, consistently had higher fertility and higher mortality in childhood than the other two groups. In 2005–2010, one in every ten children born in the high-fertility countries would die before age five. Nevertheless, that probability of dying was two-thirds lower than it had been in the early 1950s, a reduction that in many other countries has been sufficient to trigger a major reduction of fertility. Therefore, the slow fertility decline observed among the high-fertility countries is unlikely to be mainly a response to the persistence of high childhood mortality.

Another development of note relates to the continued decline of total fertility among the low-fertility countries, a group that reached replacement-level fertility in the early 1990s but continued to see its fertility drop, so that it has been below-replacement level since at least 1995. Such a sustained fertility decline has meant that, rapid as the reduction of fertility has been in the intermediate-fertility countries, their fertility has still not 'caught up' with that of the low-fertility countries. Furthermore, the convergence of the fertility of the two groups, if it happens at all, may still take several decades, a period over which the population

---

8   *Low-fertility countries*: Albania, Armenia, Aruba, Australia, Austria, Azerbaijan, Bahamas, Barbados, Belarus, Belgium, Bosnia and Herzegovina, Brazil, Bulgaria, Canada, Channel Islands, Chile, China, Costa Rica, Croatia, Cuba, Curaçao, Cyprus, Czech Republic, Democratic People's Republic of Korea, Denmark, Estonia, Finland, France, Georgia, Germany, Greece, Hong Kong, Hungary, Iran, Ireland, Italy, Japan, Latvia, Lebanon, Lithuania, Luxembourg, Macao, Malaysia, Malta, Martinique, Mauritius, Montenegro, Myanmar, Netherlands, Norway, Poland, Portugal, Puerto Rico, Republic of Korea, Republic of Moldova, Romania, Russian Federation, Saint Lucia, Serbia, Singapore, Slovakia, Slovenia, Spain, Sweden, Switzerland, Taiwan, Thailand, The Former Yugoslav Republic of Macedonia, Trinidad and Tobago, Tunisia, Ukraine, United Arab Emirates, United Kingdom, United States and Viet Nam.

9   Developed countries include all the countries in Europe plus Australia, Canada, Japan, New Zealand and the United States.

---

10   All population estimates and projections cited in this chapter were derived from the 2012 *Revision* of *World Population Prospects* prepared by the Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat in New York (United Nations 2013a). Calculations of the relevant indicators for the groups of countries used in this chapter were made by the author.

11   Under-five mortality is the probability of dying between birth and exact age 5. It is expressed as number of deaths per 1,000 births.

Figure 10.2: Trends in total fertility for the three groups of countries considered, 1950–2010. **Source**: Derived from United Nations (2013a).
of the intermediate-fertility countries will continue to increase.

10.4.1   Trends in Total Fertility

In 1950–1955, total fertility among the high-fertility countries averaged 6.70 children per woman, 0.76 children higher than the 5.96 children per woman estimated for the intermediate-fertility countries, which, in turn, surpassed the total fertility of the low-fertility countries (4.26 children per woman) by 1.70 children per woman. The large difference between the total fertility of the intermediate-fertility countries and that of the low-fertility countries was to be expected because the latter group includes nearly all developed countries, the vast majority of which had experienced major reductions of fertility since the late nineteenth century. Thus, although many of them had experienced a 'baby boom' during the 1950s and early 1960s, their average total fertility was a low 2.83 children per woman in 1950–1955.

More remarkable is the difference between the total fertility of the high-fertility and the intermediate-

fertility countries in the early 1950s, since there was no reason to expect that their past experience would have differed so markedly at the early stages of the demographic transition. Also remarkable is the difference in the timing of the fertility decline in the high-fertility and the intermediate-fertility countries. Thus, whereas in the group of intermediate-fertility countries average total fertility began to decrease between 1960-1965 and 1965-1970, that of the high-fertility countries started to decline ten years later, between 1970-1975 and 1975-1980. Furthermore, during the 35 years following peak total fertility, the high-fertility countries saw their total fertility decline, on average, by 0.5 children per decade, whereas in the intermediate-fertility countries the decline averaged 0.8 children per decade. That is, the fertility decline in the high-fertility countries has been significantly slower than in the intermediate-fertility countries (figure 10.2). Consequently, by 2005-2010, total fertility in the intermediate-fertility countries was 56 per cent lower than at its peak, averaging 2.6 children per woman in 2005-2010, whereas that of the high-fertility countries averaged 4.96 children per woman in 2005-2010 and had

declined by just 26 per cent from its peak value of 6.79 children per woman in 1970–1975.

The sharp decline in fertility achieved by the intermediate-fertility countries since 1965 brought them closer to the low-fertility countries by 2005–2010 but, remarkably, their total fertility of 2.6 children per woman still surpassed by 0.9 children per woman that of the low-fertility countries, which averaged 1.7 children per woman in 2005–2010. Indeed, the low-fertility countries had recorded an almost equally rapid reduction of fertility as the intermediate-fertility countries, averaging a reduction of 0.7 children per decade during the 35 years following their peak fertility level. In addition, the total fertility of the low-fertility countries had kept on falling even after reaching replacement level with the result that they had maintained, as a group, below-replacement fertility since at least 1995.

In sum, as of 2005–2010, the differences in fertility levels between the three groups of countries considered were remarkable, with the high-fertility countries having, on average, a total fertility of nearly 5 children per woman as a result of consistently higher fertility since 1950, a late onset of the fertility decline and a slow pace of fertility reductions. The intermediate-fertility countries, with an average total fertility in 2005–2010 of 2.6 children per woman, had, as a group, recorded major and rapid reductions of fertility but were, nevertheless, still far from achieving the low levels characterizing the low-fertility countries, whose total fertility averaged a low 1.7 children per woman. As this chapter will show, future prospects for stopping population growth hinge on the eventual convergence of all countries to low fertility levels similar to those already attained by the group of low-fertility countries.

10.4.2   Trends in Under-Five Mortality

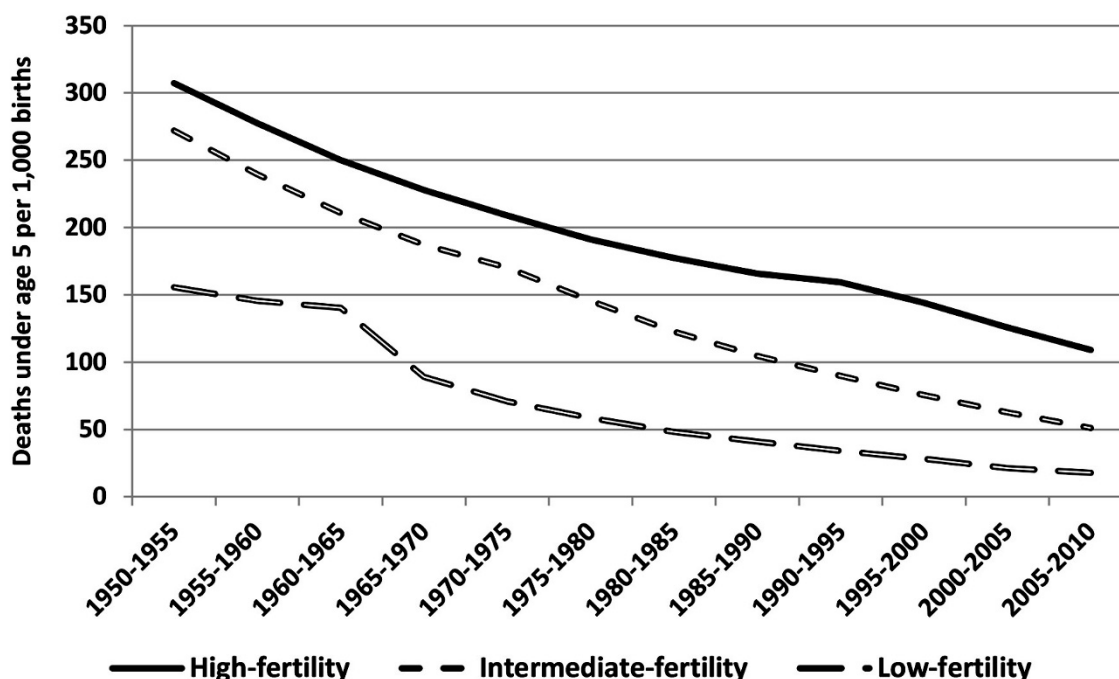
Trends in childhood mortality have also been distinct for the three groups of countries considered. The high-fertility countries have consistently had the highest mortality under age five since 1950 and although it has dropped by nearly two-thirds, their under-five mortality was still a high 109 deaths under age 5 per 1,000 births in 2005–2010. Under-five mortality was high for the intermediate-fertility countries in the 1950s, but lower than in the high-fertility countries (272 vs 307 deaths under age 5 per 1,000 births in 1950–1955). Since then, the under-five mortality of the intermediate-fertility countries has dropped by more

than 80 per cent, reaching 51 deaths per 1,000 births in 2005–2010.

Under-five mortality was markedly lower for the low-fertility countries in the 1950s being, at 156 deaths under age 5 per 1,000 births, about half what it was in the high-fertility countries at that time. Yet its decline has been even steeper than that achieved by the intermediate-fertility countries, so that its level in 2005–2010, at 18 deaths per 1,000 births, is lower by 88 per cent than what it was in 1950–1955.

Interestingly, the decline in fertility in the intermediate-fertility countries started when their average under-five mortality was higher than it was in the high-fertility countries when their own fertility started to decline and, in both cases, under-five mortality was high when fertility began to decrease (at 187 and 177 deaths under age 5 per 1,000 births, respectively). In 1985–1990, when the under-five mortality of the intermediate-fertility countries stood at 105 deaths per 1,000 births, their total fertility was 4.04 children per woman, 0.9 children below the total fertility in the high-fertility countries (4.96 children per woman) in 2005–2010, when the under-five mortality of the latter group was 109 deaths under age 5 per 1,000 births. That is, similar levels of under-five mortality have been associated with higher fertility in the high-fertility countries than in the intermediate-fertility countries indicating that there is not an automatic and tight relationship between declining mortality in childhood and declining fertility and that factors other than the reduction of mortality are hindering rapid reductions in fertility in the high-fertility countries.

Because the reduction of under-five mortality has been faster in the intermediate-fertility countries than in the high-fertility countries, by 2005–2010 the under-five mortality of the former was closer to that of the low-fertility countries, although it had been closer to that of the high-fertility countries in the 1950s (figure 10.3). In the high-fertility countries, the slow decline in under-five mortality between 1980 and 2000 owes much to the impact of the HIV/AIDS epidemic on the highly affected countries that are members of that group. Therefore, as in the case of fertility, convergence in the levels of under-five mortality among the three groups considered is still in the future and, especially in the case of the high-fertility countries, the gap between their under-five mortality and that of the other groups will likely take decades to close.

Figure 10.3: Trends in under-five mortality for the three groups of countries considered, 1950–2010. Source: Derived from United Nations (2013a).


10.4.3 Consequences of Past Fertility and Mortality Trends

Differences in past fertility and mortality trends among the three groups of countries considered have produced major differences in population growth rates that, in turn, have given rise to the population imbalances described earlier in the chapter. Despite their higher mortality, the persistence of high fertility in the high-fertility countries has produced a very high rate of annual population growth, which peaked at 2.84 per cent in 1977 and is still a high 2.42 per cent in 2014. The intermediate-fertility countries also reached a peak annual growth rate of 2.36 per cent in 1977 but it has since declined to an estimated 1.22 per cent in 2014, still far from zero but declining at a good pace. The most remarkable change has occurred among the low-fertility countries, whose annual growth rate peaked at 1.83 per cent in 1967 and is now a low 0.5 per cent per year and declining fast.

Another source of population imbalances are differences in the extent of population ageing experienced by the different groups of countries considered. The speed of the fertility decline and its starting point determine the speed of population ageing, that is, of the increasing concentration of the population at adult ages at first and then at older ages. The best

overall indicator of population ageing is the median age of the population, that is, the age that divides the population into two equal parts, with half the population being younger that the median age and half being at the median age or older.

At the start of the demographic transition, decreases in mortality and the increases in fertility that sometimes accompany them produce increasing numbers of surviving children and, therefore, lead to a rejuvenation of the population as the proportion of people in the younger ages increases. Such rejuvenation produces a decreasing median age. However, once fertility starts to decline, its reduction eventually leads to decreasing numbers of children being born and thus triggers population ageing, reflected in an increasing median age.

As expected, between 1950 and 2010, the median ages of the three groups of countries considered declined at first and eventually started to increase. In the low-fertility countries, the median age declined from 25.7 years in 1950 to 23.9 in 1970 and in the intermediate-fertility countries, it dropped from 20.9 to 18.9 years over the same period before it began to increase. In contrast, in the high-fertility countries the median age declined for 40 years, from 19.1 years in 1950 to 17.4 years in 1990. By 2010, the median age for the low-fertility countries had risen to 35.5 years, that

of the intermediate-fertility countries to 25.7 years and the one for the high-fertility countries to 18.8 years.

Population imbalances relative to the population age structure were already evident in the 1950s, when the low-fertility countries had an older population than the intermediate-fertility countries and the latter an older one than the high-fertility countries. Furthermore, those differences have become starker over time, with the median age of the low-fertility countries increasing faster than that of the intermediate-fertility countries (by 48 per cent from 1970 to 2010, as compared to 36 per cent over the same period in the intermediate-fertility countries). Population ageing has been slowest in the high-fertility countries, whose median age rose by a mere 8 per cent since 1990. Furthermore, the median age of the high-fertility countries was lower in 2010 than it had been in 1950.

In view of these trends, although the populations of all three groups of countries are ageing, a convergence of the shape of their age distributions is not expected to occur soon. The population of the low-fertility countries, which is already far advanced in the ageing process, will continue to have a rapidly growing older population. That of the intermediate-fertility countries is poised to enter a phase of rapid ageing, caused by their rapid fertility decline, whereas the population of the high-fertility countries will remain relatively young. Furthermore, provided their fertility decline continues or accelerates, the high-fertility countries will soon enter a phase where their rising proportions of persons of working age have the potential to boost economic growth provided they can be productively employed (Bloom/Canning/Sevilla 2003).

One way of gauging the potential economic impact of the age distribution of a population is to consider the ratio of the number of persons of working age (usually considered to be those aged 15 to 64) to the number of children (persons under age 15) and the number of elderly persons (those aged 65 years or over). That indicator is known as the 'support ratio' and, although it does not reflect the actual number of producers or workers in a population relative to the dependants in the population, it is a useful indicator of the relative size of the number of potential workers to the number of potential dependants. For the three groups of countries considered, the support ratio has always been highest for the low-fertility countries as a group, having reached a minimum of 1.44 potential workers per dependant in 1965 and increased to 2.39 potential workers per dependant in 2010. The support ratio for the intermediate-fertility countries also

reached a minimum in 1965, at 1.18 potential workers per dependant, and then rose to 1.83 in 2010. The lowest support ratio corresponds to the high-fertility countries where a minimum of 1.07 potential workers per dependent was reached in 1990, a value that has since increased to 1.21 in 2010.

These trends in the support ratio confirm that, owing to their early and sustained reduction of fertility, the low-fertility countries have had a more favourable age distribution since 1950 than the other two groups of countries. In the intermediate-fertility countries, the age distribution has become more favourable to economic growth since 1965 but it has yet to reach a support ratio above 2, let alone the 2.39 that the low-fertility countries had in 2010. In the high-fertility countries, the persistently young age distribution has been a drag rather than a boost for the economy because of the high child dependency burden it implies. Hence, although their support ratio has started to increase, unless their fertility decline accelerates, the high-fertility countries may never reach a support ratio of 2 potential workers per dependant.

10.5 The Future of Fertility and its Implication for Future Population Trends

Differences in the past fertility trends experienced by the three groups of countries considered have major implications for future population trends. The high-fertility countries are expected to continue having higher fertility and higher mortality than the rest and to continue experiencing rapid population growth for some time. The key questions regarding these countries are whether and when their fertility will drop to replacement level or below. The sooner their fertility reaches replacement level, the sooner their fast population growth will be curbed and the smaller their peak population will be. Alternatively, the slower their fertility decline is in future, the larger their population will become. As this section will show, a variety of population projections indicate that the high-fertility countries of today are very likely to be the major contributors to future population growth at the global level.

For the intermediate-fertility countries, the key questions are whether and when their fertility will drop below replacement level. If it does so within the next few decades, their contribution to overall population growth over the rest of the century will be moderate. The slower this group is in reaching below-replacement fertility, the more it will contribute to

future population growth and the higher their peak population will be.

Lastly, the low-fertility countries, whose average fertility has been below replacement level since 1995, are expected to continue having below-replacement fertility until 2100. The key questions in this case are whether the overall fertility of this group will increase over the century and whether it will remain below replacement level until 2100. If the total fertility of the low-fertility countries remains at or close to the low level it has already reached, their overall population will decrease markedly by 2100. A slowly increasing fertility that remains below replacement level will slow down the contraction of their population but, unless their fertility increases above replacement level, their population will decrease, therefore contributing to moderate global population growth.

The different projection variants and scenarios produced by the United Nations Population Division as part of the most recent set of official United Nations population estimates and projections (United Nations 2013a) will be used to explore the implications of future fertility trends for the three groups of countries considered.

10.5.1 The United Nations Projection Variants and Scenarios

In the official United Nations population projections, the 'medium-fertility variant' is the reference for the preparation for other projection sets. For a given country, its future fertility path is derived using stochastic simulations of future fertility paths that take account of past fertility trends in that country and of the pattern and variability of fertility trends in all other countries since 1950. The medium variant therefore reflects a central path informed by all the data available on fertility change since 1950.

The medium variant is the basis for deriving two other variants, namely, the 'high-fertility' and 'low-fertility' variants, that allow an assessment of the sensitivity of population projections to small changes in projected fertility. The high-fertility variant (also called 'high variant', for short) projects, for each country, a total fertility that remains half a child above the total fertility projected by the medium variant during the projection period (2010 to 2100). The low-fertility variant (also called 'low variant', for short) projects, for each country, a total fertility that remains half a child below that projected by the medium variant over the projection period.

The United Nations Population Division also prepares a number of 'scenarios', that is, projections aimed to answer 'what-if' questions. Two of those scenarios are considered here. The first, called the 'no-change scenario', illustrates what would happen if fertility and mortality were to remain constant in each country at the level they had in 2005–2010. This scenario provides a useful basis on which to judge whether the most recently estimated fertility and mortality levels, if maintained indefinitely, could lead to future population numbers that may be 'sustainable'.

The second scenario of interest is the 'instant-replacement scenario', which shows what would happen if each country were to attain and maintain replacement-level fertility immediately after 2010, when the projections start. Therefore, this scenario projects the total fertility[12] of each country in such a way that it produces an NRR that remains constant at 1.0 daughter per woman during the projection period (that is, from 2010 to 2100). Demographic theory predicts that a population that maintains replacement-level fertility over lengthy periods and whose mortality stops changing reaches eventually a stationary state where both its size and age distribution remain constant. In the instant-replacement scenario, no country reaches the stationary state by 2100, partly because mortality is projected to keep on decreasing over the rest of the century. Nevertheless, for countries with fertility above replacement level, the instant-replacement scenario provides a measure of the minimum population increase that one would expect if current and future generations of reproductive age had only the number of children necessary to replace themselves.

The rest of this section will focus on fertility trends and their implications for future population growth based on the results of the different projection variants and scenarios just described. Table 10.2 displays the total fertility levels estimated for 2005–2010 and those projected for 2045–2050 and 2095–2100 by the different projection variants and scenarios for the three groups of countries considered. Table 10.3 shows the population size of those three groups of countries as of 2010 and as projected to 2050 and 2100 according to the same projections.

---

12 Under low mortality conditions, a total fertility close to 2.10 children per woman usually implies an NRR of 1.0 daughter per woman. Therefore, that level of total fertility is often considered to indicate that fertility is at replacement level. However, when mortality is high or moderate, replacement level will be reached at higher levels of total fertility, as the instant-replacement scenario shows.

Table 10.2: Current and projected total fertility for different projection variants, 2005–2010, 2045–2050 and 2095–2100 (children per woman). **Source:** Derived from United Nations (2013a).

Group	2005-2010	No-change scenario	High variant	Medium variant	Instant-replacement scenario	Low variant
				2045-2050		
High-fertility countries	4,96	5,20	3,47	2,98	2,18	2,50
Intermediate-fertility countries	2,60	2,62	2,39	1,89	2,12	1,39
Low-fertility countries	1,68	1,71	2,29	1,80	2,08	1,30
				2095-2100		
High-fertility countries	4,96	5,50	2,59	2,10	2,10	1,62
Intermediate-fertility countries	2,60	2,64	2,34	1,84	2,09	1,34
Low-fertility countries	1,68	1,77	2,39	1,89	2,07	1,39

Group	2010 Population (billions)	No-change scenario	High variant	Medium variant	Instant-replacement scenario	Low variant
					Projected population (billions)	
				2050		
High-fertility countries	1,2	3,5	3,2	2,8	1,9	2,5
Intermediate-fertility countries	2,4	3,6	3,7	3,3	3,3	2,8
Low-fertility countries	3,3	3,1	4,0	3,5	3,9	3,1
Total	**6,9**	**10,2**	**10,9**	**9,5**	**9,0**	**8,3**
				2100		
High-fertility countries	1,2	13,0	6,8	4,7	2,1	3,1
Intermediate-fertility countries	2,4	4,9	5,0	3,1	3,6	1,8
Low-fertility countries	3,3	2,1	4,8	3,0	4,2	1,8
Total	**6,9**	**19,9**	**16,6**	**10,9**	**9,9**	**6,7**

10.5.2 Future Fertility and its Implications for Population Size

10.5.2.1 The High-Fertility Countries

According to all the projection variants and scenarios considered, the high-fertility countries are expected to maintain the highest fertility among the three groups of countries considered over the whole projection period. Of particular interest are the results of the no-change scenario for the high-fertility countries. In that scenario future fertility remains constant for each country at the level it had in 2005–2010, but for groups of countries total fertility under the no-change scenario rises because the countries with higher fertil-

ity gain weight within each group. Thus, for the high-fertility countries, total fertility in the no-change scenario increases by slightly more than half a child between 2005–2010 and 2095–2100, passing from 4.96 children per woman to 5.50 children per woman by century's end. This increasing fertility results in accelerated population growth, which yields a population of 13 billion for the high-fertility countries alone in 2100. Such a huge number of people, were it to materialize, would undoubtedly prevent the attainment of a sustainable future in the high-fertility countries of today and would very likely impose heavy constraints on the sustainability of the world population as a whole. These results indicate that the current lev-

Table 10.4: Population in 2010 and ratio of the projected population in 2050 and 2100 to the population in 2010 for different projection variants and for the three groups of countries considered. **Source**: Derived from table 10.3.

Group	2010 Population (billions)	Ratio of projected population to 2010 population				
		No-change scenario	High variant	Medium variant	Instant-replacement scenario	Low variant
				2050		
High-fertility countries	1,2	2,8	2,6	2,3	1,5	2,0
Intermediate-fertility countries	2,4	1,5	1,6	1,4	1,4	1,2
Low-fertility countries	3,3	0,9	1,2	1,1	1,2	0,9
Total	**6,9**	**1,5**	**1,6**	**1,4**	**1,3**	**1,2**
				2100		
High-fertility countries	1,2	10,6	5,5	3,8	1,7	2,6
Intermediate-fertility countries	2,4	2,0	2,1	1,3	1,5	0,8
Low-fertility countries	3,3	0,6	1,5	0,9	1,3	0,5
Total	**6,9**	**2,9**	**2,4**	**1,6**	**1,4**	**1,0**

els of fertility and mortality in the high-fertility countries are not sustainable.

The high variant produces the next largest population for the high-fertility countries in 2100. Under that variant, the average total fertility of the group declines slowly, passing from 4.96 children per woman in 2005–2010 to 3.47 children per woman in 2045–2050 and to 2.59 children per woman in 2095–2100. Hence, according to the high variant, the total fertility of the high-fertility countries remains well above replacement level over the projection period and leads therefore to robust population growth. Thus, their overall population increases from 1.2 billion in 2010 to 6.8 billion in 2100, implying that by century's end the high-fertility countries would have a population nearly as large as that of the whole world in 2010. That is, if the total fertility of the high-fertility countries declines in future as slowly as projected in the high variant, they alone could add more than 5 billion inhabitants to the Earth.

According to the medium variant, whose assumptions about future fertility and mortality trends are derived from all the information available on past trends of fertility and mortality change, the total fertility of the high-fertility countries declines more rapidly than in the high variant, but still not as fast as the medium variant projections prepared in the late 1990s had forecast (United Nations 2000). Thus, their fertility drops from 4.96 children per woman in 2005–2010 to 2.98 children per woman in 2045–2050 and to 2.10

children per woman in 2095–2100, meaning that it reaches replacement level only towards the end of the century. Such a prolonged decline to replacement level leads to a significant increase in the population of the high-fertility countries, which reaches 4.7 billion in 2100. Yet, this total is 2.1 billion lower than that projected under the high variant and although it represents almost a quadrupling of the population of the high-fertility countries between 2010 and 2100 (table 10.4), it implies that their population growth rate would be well on the way of reaching zero in the early decades of the twenty-second century if they were to maintain low fertility from 2100 onward.

If the high-fertility countries managed to reduce their fertility faster than in the medium variant, they might approach the path set by the low variant, according to which their fertility declines from 4.96 children per woman in 2005–2010 to 2.50 children per woman in 2045–2050 and reaches a low 1.62 children per woman in 2100. Thus, under the low variant, the fertility of the high-fertility countries drops below replacement level during the second half of this century and reaches a very low level towards its end. Such a path of fertility decline results in a more moderate population increase compared to that in the medium variant, with the population of the high-fertility countries rising from 1.2 billion in 2010 to a peak of 3.2 billion in 2093 and then declining slowly to 3.1 billion in 2100. Hence, under the low variant, the overall population of the high-fertility countries would increase

just about two and a half times between 2010 and 2100 instead of nearly quadrupling as in the medium variant (table 10.4).

As already noted, the high-fertility countries still have a young population, therefore their potential for future population growth is high because the current and future generations of potential parents are large. The instant-replacement scenario provides an indication of the minimum increase that might be expected in the high-fertility countries because of both their youthful age distribution and the projected decline of mortality. According to the instant replacement scenario, the total fertility of the high-fertility countries would need to drop from 4.96 children per woman in 2005–2010 to 2.42 children per woman[13] in 2010–2015 in order to reach replacement level immediately and it would then decline in response to declining mortality until it reached 2.10 children per woman in 2095–2100. Under those conditions, the population of the high-fertility countries would increase by just 0.9 billion between 2010 and 2100, to reach 2.1 billion at century's end. This increase can be interpreted as the minimum likely to occur in the high-fertility countries provided their mortality continues to decline.

In sum, depending on the speed of future fertility declines in the high-fertility countries, their population may vary over a relatively wide range in 2100, from a high of 6.8 billion as projected in the high variant to a low of 2.6 billion as projected in the low variant. The results of the no-change and the instant-replacement scenarios are not considered realistic. Nevertheless, the no-change scenario shows that the continuation of current levels of fertility and mortality in the high-fertility countries would lead to a very large population by century's end and suggest that, were high population growth to continue in those countries, it would very likely prevent the attainment of sustainability. The instant-replacement scenario indicates that, at a minimum, the high-fertility countries will add nearly another billion people to the world population by 2100.

Among the three groups of countries considered and in all the projections discussed, except for those associated with the instant-replacement scenario, the high-fertility countries make the largest contribution to world population growth during 2010–2100.

---

13 Their current replacement level is higher than 2.10 children per woman because the high-fertility countries still have relatively high mortality, especially in childhood. As their mortality declines, so will their replacement-level fertility.

Hence, the future increase of the world population depends highly on what happens in the high-fertility countries and, in turn, their future population growth hinges on the path they follow to achieve low fertility. It is important, therefore, to support policies and programmes that contribute to accelerate the reduction of fertility in those countries.

Given the significant and rapid fertility decline that has already occurred in the rest of the world (that is, among the 81 per cent of the population living in the low-fertility and the intermediate-fertility countries), the sense of urgency that prevailed in the 1960s and 1970s about the need to curb population growth has disappeared. For at least the past twenty years, the expectation has been that the countries lagging behind in reducing fertility would follow the path of their predecessors almost automatically. Yet the expected rapid declines in fertility have failed to materialize and recent evidence suggests that, instead of declining, total fertility levels in some high-fertility countries may be stalling if not increasing. Furthermore, the case for reducing fertility to moderate population growth and increasing the chances of achieving sustainability is complicated by the fact that, with their youthful populations, the high-fertility countries are very likely to experience rapid population growth over the next few decades even if their fertility declines precipitously. Thus, the projections to 2050 produce a relatively narrow range of variation for their overall population, ranging from 2.5 billion in the low variant to 3.2 billion in the high, with the medium variant producing a population of 2.8 billion. Only by extending the projection horizon can one grasp the big difference that accelerating or delaying the reduction of fertility can make over the long run. As the projections shows, the higher the population size the high-fertility countries have by mid-century, the more likely they will be to add several billion people to the world population by 2100.

10.5.2.2 The Intermediate-Fertility Countries

The intermediate-fertility countries, as a group, have achieved success in reducing fertility. However, with an average total fertility of 2.60 children per woman in 2005–2010, they still have some way to go to reach low fertility. Furthermore, encompassing 35 per cent of the world's population, they still have considerable potential to add a few billions to the world population over this century. Thus, if their fertility were to remain constant at the level it had in 2005–2010 and their mortality remained unchanged, the no-change scenario shows that their population could double by

2100, rising from 2.4 billion in 2010 to 4.9 billion by century's end (table 10.3). These results suggest that the continued reduction of fertility in the intermediate-fertility countries is still necessary to avoid the increasing demands that a doubling of their population would place on the environment.

The high variant illustrates what would happen if the fertility of the intermediate-fertility countries failed to decline to below-replacement level and remained, instead, slightly above replacement level until 2100.[14] Even relatively small positive deviations from replacement level accompanied by declining mortality result in significant population growth over the long run, so that the population of the intermediate-fertility countries reaches 5 billion in 2100 under the high variant, a number higher than that projected by the no-change scenario because the latter does not incorporate a reduction of mortality.

In the medium variant, the total fertility of the intermediate-fertility countries is projected to fall below replacement level in 2030–2035 and to remain at below-replacement level thereafter, so that by 2045–2050 it would be at 1.89 children per woman and it would further decline to 1.84 children per woman by 2095–2100. This trend in fertility reduces their potential for continued population growth, leading to an overall population increase of just 0.9 billion between 2010 and 2065 (from 2.4 billion in 2010 to 3.3 billion in 2065) when their population starts decreasing to reach 3.1 billion in 2100. That is, between 2010 and 2100, the medium variant projects that the population of the intermediate-fertility countries would have increased by just 0.7 billion people.

That small increase compares favourably with the increase projected under the instant-replacement scenario where the total fertility of the intermediate-fertility countries remains at replacement level instead of dropping below that level as it does in the medium variant. That trend in fertility coupled with declining mortality produces an increasing population for the intermediate-fertility countries, which reaches 3.6 billion in 2100, a figure half a billion higher than that projected under the medium variant.

In contrast, the low variant, by projecting very low fertility levels for the intermediate-fertility countries (below 1.50 children per woman after 2035), reduces

their overall population by a fourth: from 2.4 billion in 2010 to just 1.8 billion in 2100.

In sum, although the intermediate-fertility countries still have the potential of experiencing sustained population growth if their total fertility does not fall below replacement level over the next few decades, their already moderate fertility levels ensure that such potential is also moderate. In comparison with the high-fertility countries whose population is very likely to nearly quadruple or more, that of the intermediate-fertility countries might at most double by the end of the century. Nevertheless, because of their large current population, the intermediate-fertility countries are expected to make, as a group, the second largest contribution to world population growth among the three groups of countries considered. Only if their fertility were to fall below 1.5 children per woman and remain at such low levels during most of the century would they contribute to a net reduction of the world population by 2100.

Although it is generally expected that the total fertility in the intermediate-fertility countries will continue to fall, it is by no means certain that it will or that all countries in that group will reach below-replacement levels soon or at all. In India, for instance, a significant proportion of the population continues to have high fertility and, if such high levels are maintained, they may slow down the national fertility decline or even reverse it. In other countries, the successful programmes that accelerated the reduction of fertility have been dismantled or are no longer getting the financial and public support that was such an important factor in ensuring their effectiveness. These developments may slow down or even prevent further fertility reductions and make it more likely that the intermediate-fertility countries would continue to add to the world population long after the end of the century.

10.5.2.3 The Low-Fertility Countries

In contrast to the other two groups, the group of low-fertility countries is projected to have an increasing total fertility in almost every scenario and projection variant, excepting only the low variant. For this group of countries the importance of achieving a sustained, even if small, increase in total fertility over the long run is underscored by the results of the no-change scenario which, by maintaining fertility and mortality constant for each country at the low levels reached in 2005–2010, produces a 2100 population of just 2.1 billion, nearly one-third lower than the population that the low-fertility countries had in 2010 (3.3 billion).

---

14 It remains about half a child above replacement level until 2030 and about a quarter of a child above replacement level after 2045, varying between 2.72 to 2.32 children per woman over the projection period.

In contrast with the sharp population reduction produced by the maintenance of recent levels of low fertility coupled with unchanging mortality, the medium variant projects a small decrease in the population of the low-fertility countries by assuming that their total fertility increases from 1.68 children per woman in 2005–2010 to 1.80 in 2045–2050 and then to 1.89 children per woman in 2095–2100. Such a modest increase in fertility, coupled with declining mortality, is sufficient to prevent a rapid reduction of the population, producing an overall population of 3.0 billion in 2100, down from 3.3 billion in 2010.

Because the low-fertility countries already have below-replacement fertility, they constitute the only group for which the instant-replacement scenario produces an increasing population. Thus, were their total fertility to increase immediately to replacement level, rising to 2.18 children per woman in 2010–2015 and then declining to 2.07 children per woman toward the end of the century as mortality decreases, their population would increase from 3.3 billion in 2010 to 4.2 billion in 2100.

An even larger population increase would occur if the fertility of the low-fertility countries were to follow the path projected by the high variant whose total fertility increases from 2.11 children per woman in 2010–2015 to 2.39 in 2095–2100. That is, under the high variant the fertility of the low-fertility countries would not only remain well above replacement level but would also increase over time. That trend produces a population that rises steadily from 3.3 billion in 2010 to 4.8 billion in 2100.

In contrast with the other projections for the low-fertility countries, the low variant projects a declining total fertility until 2050 and a very slight increase thereafter. The result is a total fertility that remains well below 1.5 children per women until 2100 and leads to a sharp reduction of the population: from 3.3 billion in 2010 to 1.8 billion in 2100.

Because the low-fertility countries, as a group, accounted for 46 per cent of the world population in 2010, their potential for future population growth or decline is of considerable significance for world population trends. Given that below-replacement fertility has been a feature of virtually all the low-fertility countries for at least two decades and the measures to increase fertility adopted by countries that have been concerned about the persistence of low fertility have generally not resulted in large increases, it is expected that the low-fertility countries as a group will maintain below-replacement fertility over the foreseeable future and, consequently, that their overall population will

decrease eventually, thus contributing to counterbalance the population growth expected to occur in other countries. Nevertheless, as the results of the different projections described above indicate, the increase in total fertility needed to prevent the population of the low-fertility countries from decreasing is small by historical standards and may not be beyond the realm of possibility especially if the total fertility of China, the world's most populous country, were to increase in future.

10.5.2.4 Implications of the Different Projections for World Population Size

According to the medium variant, which is the one most commonly used as reference, the world population would increase from 7.2 billion in 2014 to 9.5 billion in 2050 and further to 10.9 billion in 2100. By 2100, according to this variant, the population of both the low-fertility and the intermediate-fertility countries would be decreasing slowly whereas that of the high-fertility countries would still be growing. Furthermore, because of the rapid growth of their population over the rest of the century, the high-fertility countries would account in 2100 for 43 per cent of the world population, up from the 19 per cent in 2014. Partly because of this expansion, the projected population growth in the high-fertility countries at the end of the century would more than counterbalance the decline in the other two groups of countries so that the world population would still have the potential of continuing to increase after 2100. Thus, according to the medium variant, the relatively slow reduction of fertility projected for the high-fertility countries coupled with their declining mortality would lead to population increases not only sufficient to counterbalance the population reductions projected in the low-fertility countries, which account for 46 per cent of the world population today, but also large enough to dominate future population growth at the world level.

Further evidence that rapid population growth in a small proportion of the world population can not only counterbalance population decreases in a major part of the population but also surpass the growth in the intermediate-fertility countries, which constitute 35 per cent of today's world population, is provided by the no-change scenario. According to that scenario, the population of the low-fertility countries decreases by 0.2 billion between 2010 and 2050, while that of the intermediate-fertility countries rises by 1.2 billion and that of the high-fertility countries increases by 2.3 billion. Clearly, the potential decreases in the

46 per cent of the world population that lived in the low-fertility countries in 2014 is no match for the huge potential increases in the rest of the population and, especially, for those projected for the 19 per cent of the population that still has high fertility.

As already noted, in order to moderate the expected population growth in the high-fertility countries, their fertility would have to follow a path closer to that projected under the low variant, which projects their total fertility falling below replacement level by 2065–2070. If the high-fertility countries managed to follow the low variant while the other two groups followed the medium variant, the world population would increase from 7.2 billion in 2014 to 9.2 billion in 2050, reach a peak of 9.6 billion around 2075 and decline thereafter to 9.3 billion in 2100. Indeed, the world population might reach a peak over this century if it were possible to achieve an accelerated reduction of fertility in the high-fertility countries of today and if the fertility of the intermediate-fertility countries would drop below replacement level over the next few decades.

In comparison with the results of the medium variant, those produced by the high variant are sobering. If fertility were to remain just half a child above that projected by the medium variant for each country, the world population in 2100 would reach 16.6 billion, more than doubling today's population. According to the high variant, the population of the high-fertility countries alone would reach 6.8 billion by 2100, equivalent to the size of the world population in 2010 and representing more than a five-fold increase with respect to the population that the high-fertility countries had in 2010.

In sum, if the world population is to remain within manageable limits, it is imperative for the high-fertility countries to reduce their fertility at least as fast as and preferably faster than projected in the medium variant. It is also necessary for the intermediate-fertility countries to reach below-replacement fertility as soon as possible and for all countries to maintain below-replacement fertility for a long time after they reach it in order to counterbalance the high potential for continued growth that large populations with favourable age distributions have.

How likely are these changes to be realized? In the past, actions taken by governments, non-governmental organizations and the international community have facilitated and contributed to spur and accelerate the social and behavioural changes leading to lower fertility. However, over the past two decades, the attention and funding being invested in providing peo-ple with the means and the social support that they require in order to have only the children they desire and no more have not kept up with the growth of population and the increasing demand for family planning services. Therefore, many countries, especially those having low average incomes and suffering from poor governance, are unlikely to experience soon the changes necessary to reduce fertility. Even in countries with better governance where fertility levels remain high, the focus of key actors on other pressing issues has meant that the challenge of reducing population growth through the achievement of lower fertility ranks low on the governments' development agenda. Hence, the chances of achieving rapid reductions of fertility in those countries also seem low. These conclusions, however, are based on purely qualitative assessments. Can quantitative methods be brought to bear on the issue?

Recently, the United Nations Population Division has issued the second version of a set of probabilistic projections that include, for the first time, probabilistic projections for groups of countries (United Nations 2014b). The groups used by the United Nations do not include the three groups considered in this chapter. Nevertheless, the probabilistic projections for some world regions provide useful insights into the uncertainty surrounding future outcomes. The United Nations probabilistic projections have the advantage of being data-driven, that is, their future variability is modelled using estimates of variability derived from data on the trends experienced since 1950 and therefore allow a purely quantitative assessment of the probability of projected trends.

Future developments in sub-Saharan Africa are considered here as a good representation of what may happen in the high-fertility countries as a whole. In 2014, 93 per cent of the population of sub-Saharan Africa lived in high-fertility countries and they constituted 65 per cent of the population in all high-fertility countries. The probabilistic projections for sub-Saharan Africa show that the 80 per cent confidence interval for its population in 2100 ranges between 3.13 billion and 4.7 billion. Given that the population of sub-Saharan Africa was 0.83 billion in 2010, those results imply that there is a 90 per cent probability that the population of that region will nearly quadruple by the end of the century (be multiplied by a factor of 3.7, to be exact). Since the 95 per cent confidence interval for the population of sub-Saharan Africa in 2100 ranges from 2.82 billion to 5.30 billion, there is almost a certainty that its population will at least triple by 2100. These results suggest that, in view of past

trends, the probability that the high-fertility countries may follow a low-fertility path such as that embodied by the low variant is virtually nil. This conclusion is consistent with the qualitative assessment made above on the basis of the low priority that reducing fertility has today on the development agenda.

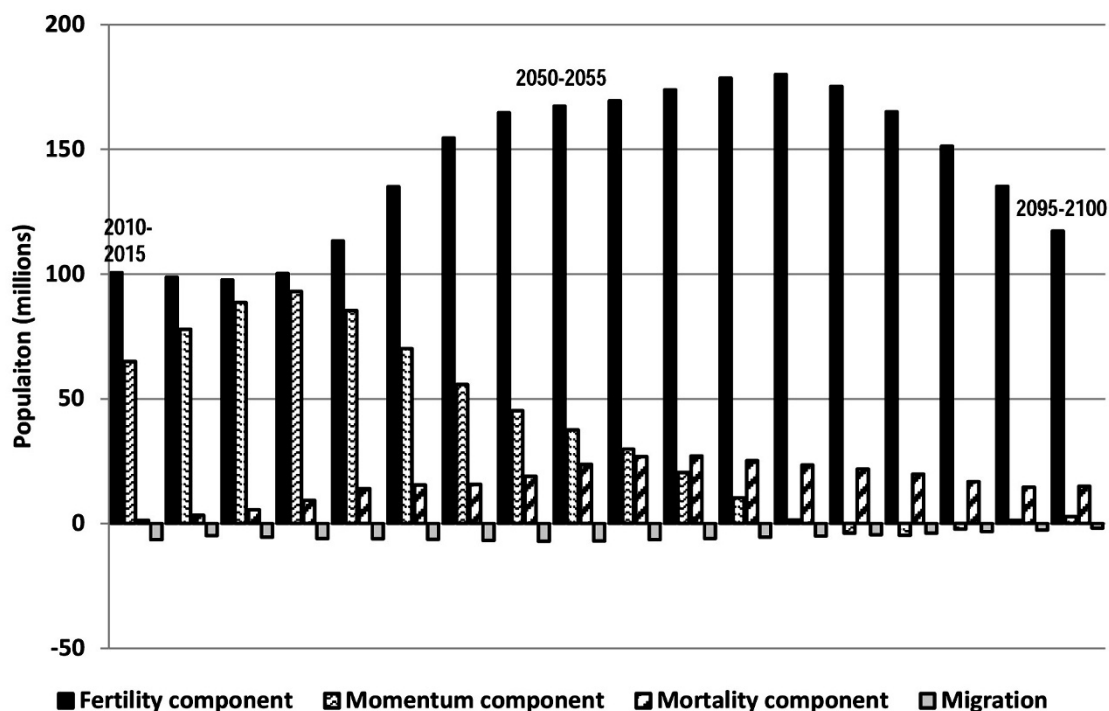
There is no ideal region to represent the intermediate-fertility countries, since they are distributed among all developing regions. However, Southern Asia, which includes India, the most populous country with an intermediate fertility level, is a region where 88 per cent of the population lives in countries with intermediate fertility and where that population accounts for 59 per cent of the overall population of the intermediate-fertility countries. According to the probabilistic projections, the population of Southern Asia, which rose to 1.7 billion in 2010, has an 80 per cent probability of being between 2.10 billion and 2.55 billion in 2050, indicating that the region still has a significant potential for continued population growth over the medium term. Yet depending on the path the population takes over the next few decades, that potential may decrease during the second half of this century, as indicated by the fact that the 80 per cent confidence interval for the 2100 population of Southern Asia ranges from 1.6 billion to 2.9 billion in 2100, with a median value of 2.20 billion. That is, there is more than a 50 per cent probability that the population of Southern Asia will be higher in 2100 than it was in 2010, with a 50 per cent chance of surpassing 2.20 billion by century's end. These findings are congruent with the analysis presented earlier about the prospects for future population growth in the groups of intermediate-fertility countries. That group may also today almost be certain of seeing their population increase by 2050 and have a greater than even chance of having a larger population in 2100 than they had in 2010. Yet, depending on the path the intermediate-fertility countries follow over the next few decades, they also have a substantial chance of experiencing a population reduction before the end of the century.

Two regions will be taken as representative of the low-fertility countries: Eastern Asia and Europe, in both of which virtually all the population lived in low-fertility countries in 2014. Eastern Asia, which includes China, accounted for 48 per cent of the population of the low-fertility countries in 2014 and Europe accounted for a further 22 per cent. The probabilistic projections for both regions confirm that it is very unlikely that their populations will be larger in 2100 than they were in 2010. For Eastern Asia, whose population in 2010

was 1.6 billion, the 95 per cent confidence interval for the population projected to 2100 ranges from 0.8 billion to 1.6 billion, implying that the probability of having a population higher than 1.6 billion in 2100 is a low 2.5 per cent. For Europe, whose population in 2010 amounted to 0.74 billion, the 95 per cent confidence interval for 2100 ranges from 0.55 billion to 0.74 billion, implying again that the chances of experiencing a population increase over the long run are slim. These findings confirm the general expectations that experts have about the persistence of low fertility in the countries that have attained it and reflect the trends observed since 1950. Yet a word of caution may be in order: those trends do not reflect properly the moderate increases in fertility experienced by developed countries during the 'baby boom' because, by starting in 1950, they exclude data on the low fertility levels that developed countries had reached in the 1930s and 1940s. At the time it occurred, the 'baby boom' was unexpected and caught experts by surprise. Hence, especially in the case of the low-fertility countries, one must bear in mind that unexpected events may occur even if their probability of occurrence is low. Furthermore, it bears underscoring that the low-fertility countries would benefit from small increases in fertility that would prevent a too precipitous decrease in population size and moderate somewhat population ageing.

For the world as a whole, the probabilistic projections produce a 95 per cent confidence interval for the 2050 population ranging from 9.0 billion to 10.1 billion and for the 2100 population from 9.0 billion to 13.3 billion. These ranges of variation are significantly narrower than those suggested by the low and high variants, which are: 8.3 billion to 10.9 billion in 2050 and 6.7 billion to 16.6 billion in 2100. The narrow intervals produced by the probabilistic projections result from the nature of the random processes that mix countries following different projection paths, whereas the low and high variants impose similar paths, if not to all countries, at least to those in the three groups of countries distinguished in this chapter. The probabilistic projections indicate that it is very unlikely that the world population will fall below 9 billion over the course of this century but it is also unlikely that it will rise above 13.3 billion. However, for the world population not to rise above this level, it is necessary for all regions to follow fertility paths that are well below that of the high variant.

Interpreting the results of the probabilistic projections is difficult for at least two reasons. First, any single future path has theoretically a zero probability of

Figure 10.4: Components of future population change in high-fertility countries, medium variant, 2010–2100. **Source**: Derived from United Nations (2013b).


being realized. Second, except for the median path, which corresponds to the medium variant, there is no way of relating the results of a probabilistic path to the fertility and mortality levels that generated it. For instance, the combination of fertility and mortality trends that would produce the population path generated by the upper limit of the 95 per cent confidence intervals for future population size are not known. Therefore, it is useful to refer to the results of the deterministic projections discussed earlier to assess the types of changes in fertility that would produce outcomes within the confidence limits yielded by the probabilistic approach. In the case of the probabilistic projections for the world as a whole, in order for the population to remain below 13.3 billion as projected, the future fertility of most countries and especially of the high-fertility countries would have to remain well below that projected in the high variant. That is, the results of the probabilistic projections are not 'predictions': they will not be realized automatically. They indicate that, if past experience could be replicated, outcomes within the confidence interval range could be achieved. It is important to stress, therefore, that past experience includes political and financial commitments that were successful, in many instances, in generating the voluntary behavioural changes necessary to reduce fertility.

10.6   The Components of Future Population Change in the Medium Variant

As fertility declines, there is at first a greater concentration of the population in adult ages and, among women in particular, in the reproductive ages. Such a distribution is favourable to the maintenance of population growth because, even if women reduce on average the number the children they bear, the increasing numbers of women bearing children ensure that the number of children born remains high and, consequently, the population keeps on growing. The effect of the age distribution in maintaining or accelerating population growth is known as 'population momentum'. The United Nations Population Division has recently produced a report providing estimates of the future contribution of population momentum to the projected population trends under the medium variant (United Nations 2013b). The report distinguishes the contribution of four distinct components of population change: fertility, mortality, net migration and population momentum. Calculation of these components for the three groups of countries considered shows remarkable differences between them (figures 10.4, 10.5 and 10.6).

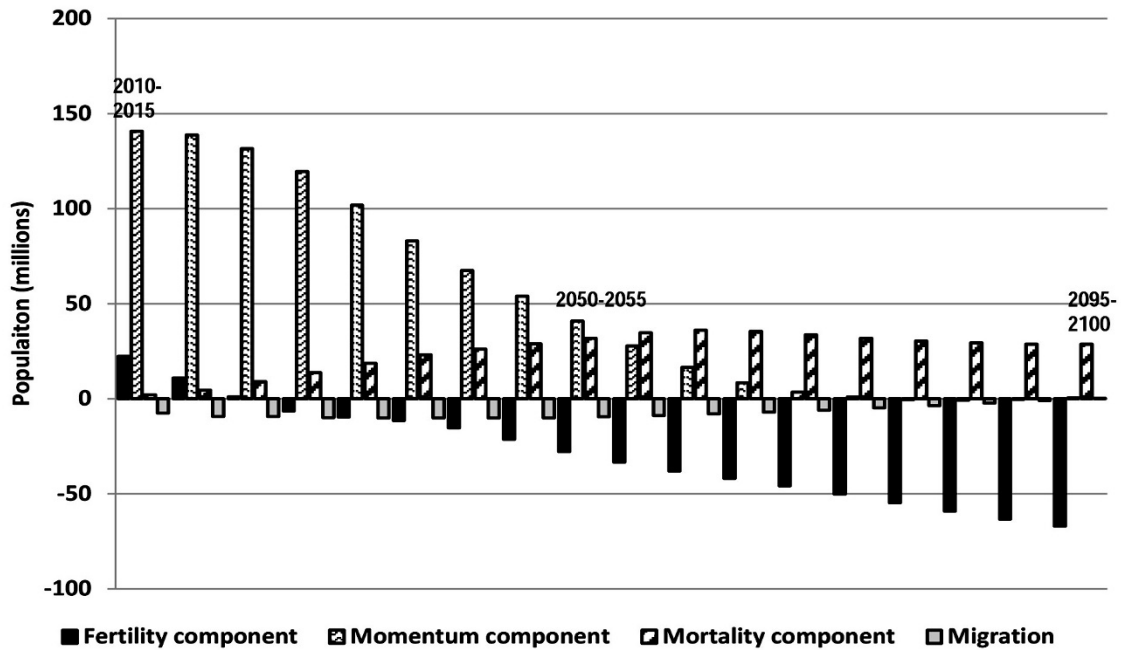
Figure 10.5: Components of future population change in intermediate-fertility countries, medium variant, 2010–2100.
Source: Derived from United Nations (2013b).


Figure 10.6: Components of future population change in low-fertility countries, medium variant, 2010–2100. **Source**: Derived from United Nations (2013b).
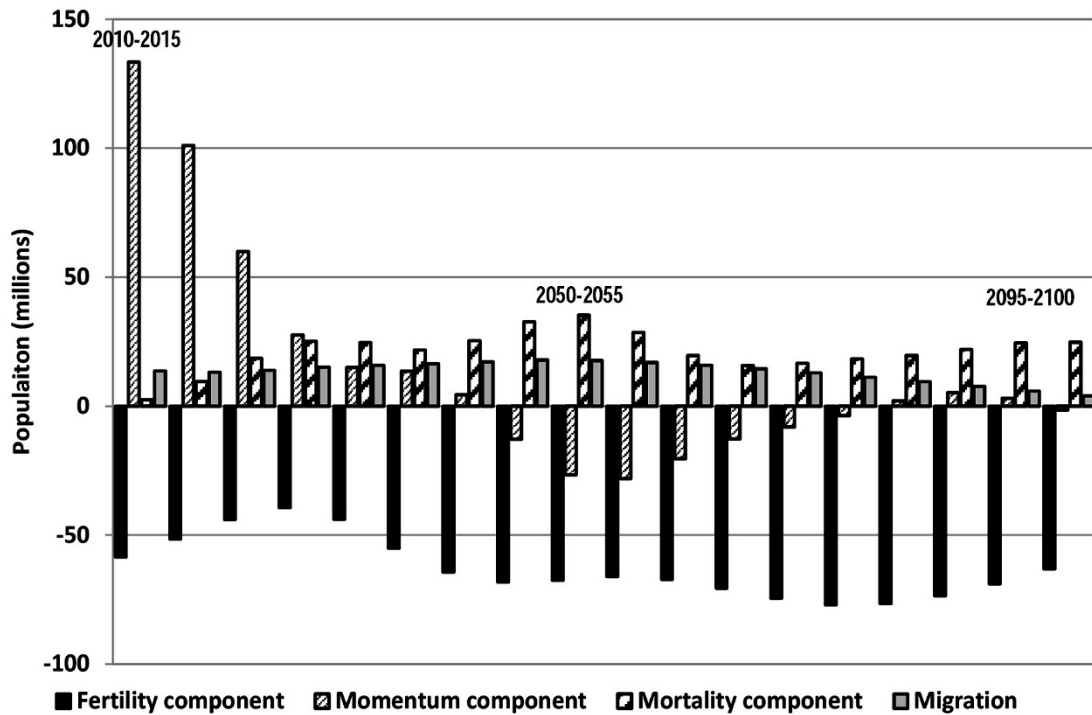

In the high-fertility countries, fertility is by far the major component of population change but population momentum makes an important contribution to population growth, especially before 2050. After 2050, the fertility contribution is dominant.

In the intermediate-fertility countries, population momentum is the major component of population change until about 2050 and fertility is the major component thereafter, but fertility contributes then to population reductions rather than to population growth because, after 2050, the total fertility of the intermediate-fertility countries remains below replacement level in the medium variant.

In the low-fertility countries, population momentum is still making a major contribution to population growth but will not do so for long. After 2025, the contribution of population momentum is small and, even as soon as 2020, population momentum is not sufficient to counteract completely the negative contribution of below-replacement fertility. From 2030 onward, that negative contribution dominates the components of population change and is reinforced between 2045 and 2080 by a smaller but significant negative contribution of population momentum. It is noteworthy that the group of low-fertility countries is the only one for which the contribution of net migration remains positive during the whole projection period. However, it is small and insufficient to counteract the negative contribution of low fertility.

These results reinforce the conclusions derived from considering the different projection variants and scenarios: the high-fertility countries have the highest potential for continued growth driven mainly by the continuation of relatively high, even if declining, fertility. The population of the intermediate-fertility countries also has considerable potential for future growth but, because that growth comes mostly from population momentum, that potential drops markedly by mid-century. Hence, provided their fertility falls below replacement level by 2035–2040, as projected in the medium variant, the contribution of fertility to population change in the intermediate-fertility countries will be largely in the negative direction after 2050, thus counteracting any tendency to population growth.

Lastly, the low-fertility countries can still expect to experience population growth driven by population momentum over a decade or so. Beyond 2025, however, population momentum will not be sufficient to counteract the negative contribution of below-replacement fertility to population change in the low-fertility countries. Therefore, unless their total fertility increases to replacement level or above, their overall population will decrease.

10.7   Future Population Ageing

Population ageing results primarily from declining fertility, although decreasing mortality at adult and older ages also contributes to it. Because every country in the world has already experienced some reduction of fertility, all populations today are ageing and, as discussed in section 10.4.3 above, population ageing is most advanced in the low-fertility countries, less so in the intermediate-fertility countries and has barely started in the high-fertility countries. Since all the projection variants and scenarios considered in this chapter, with the sole exception of the no-change scenario, project further fertility reductions for the high-fertility and the intermediate-fertility countries, their projected populations under those variants are sure to continue ageing. For the low-fertility countries, several variants project fertility increases which will slow down population ageing.

Table 10.5 shows the values of the median age estimated for 2010 and projected according to different projection variants and scenarios to 2050 and 2100. In all projection variants and scenarios the future population of the high-fertility countries remains younger than that of the intermediate-fertility countries and this one, in turn, remains younger than the population of the low-fertility countries. The no-change scenario produces the lowest median age for the high-fertility and intermediate-fertility countries in both 2050 and 2100, but at the cost of major increases in population size, especially in the case of the high-fertility countries whose population by 2100 would increase more than tenfold with respect to 2010 (table 10.3). The high variant produces the next lowest set of median ages, which do not surpass age 40 even for the low-fertility countries but at the cost of marked increases in population size. The low-fertility countries, for instance, would have to increase their population by about 50 per cent by 2100 to prevent their median age from rising above 40 years, and for the high-fertility countries, the population would have to increase more than fivefold to prevent the median age from rising above 31 years.

The instant-replacement scenario provides a useful standard against which to judge the performance of other variants because, by maintaining fertility at replacement level for nearly a century, by 2100 it approaches the age distribution of a population that is close to experiencing zero population growth. That is, the results of the instant-replacement scenario may be thought as indicative of the minimum degree of ageing that the population would experience in order

Table 10.5: Median age in 2010 and according to different projection variants in 2050 and 2100 for the three groups of countries considered. Source: Derived from United Nations (2013a).

Group	2010 Median age (years)	No-change scenario	High variant	Medium variant	Instant-replacement scenario	Low variant
				2050		
High-fertility countries	18,8	19,6	23,4	25,5	33,8	28,2
Intermediate-fertility countries	25,7	31,8	33,1	37,6	36,9	42,5
Low-fertility countries	35,5	44,8	39,7	45,4	40,2	50,8
				2100		
High-fertility countries	18,8	18,8	30,9	35,6	38,9	41,4
Intermediate-fertility countries	25,7	31,8	38,0	45,4	41,3	54,7
Low-fertility countries	35,5	44,5	39,5	47,1	43,6	56,6

Table 10.6: Support ratio (population aged 15–64 over population under age 15 plus the population aged 65 or over) in 2010 and according to different projection variants in 2050 and 2100. **Source**: Derived from United Nations (2013a).

Group	Support ratio in 2010	No-change scenario	High variant	Medium variant	Instant-replacement scenario	Low variant
				2050		
High-fertility countries	1,21	1,23	1,52	1,70	2,22	1,92
Intermediate-fertility countries	1,83	1,79	1,77	1,98	1,88	2,21
Low-fertility countries	2,39	1,64	1,44	1,51	1,48	1,56
				2100		
High-fertility countries	1,21	1,17	1,69	1,80	1,60	1,85
Intermediate-fertility countries	1,83	1,72	1,49	1,41	1,46	1,19
Low-fertility countries	2,39	1,58	1,36	1,26	1,35	1,05

to get to a stationary state. For the intermediate-fertility countries, the instant-replacement scenario produces a median age that is about 4 years lower than that produced by the medium variant (41.3 years vs 45.4 years) and that difference is similar for the low-fertility countries (43.6 years vs 47.1 years). Yet, to attain those lower median ages, the joint populations of the intermediate-fertility and the low-fertility countries would have to increase by an additional 1.7 billion by 2100.

For the high-fertility countries, the medium variant produces a lower median age than the instant-replacement scenario because the former maintains a higher fertility for the high-fertility countries during most of the projection period. Consequently, reducing the median age of the high-fertility countries by 3.4 years with respect to that projected in the instant-replacement scenario requires an increase of their 2100 pop-

ulation by 2.6 billion (the difference between the population in 2100 projected by the medium variant and that projected by the instant-replacement scenario).

The many examples cited above show that slowing population ageing can be achieved only by accommodating the higher population growth resulting from higher fertility. Such an unavoidable trade-off makes it imperative that societies adapt to population ageing since it is unlikely that ever-growing populations will prove to be sustainable. Furthermore, the initial stages of population ageing have beneficial aspects. The support ratio, for instance, increases when the proportion of the population in the working ages rises. As table 10.6 shows, the support ratio for the high-fertility countries is projected to increase according to every variant that projects declining fertility and it increases more rapidly the faster and sharper the decline in fertility. From that perspective, following the fertility

path associated with the low variant would bring about the most beneficial changes to the high-fertility countries and would have the advantage of limiting their population growth more than in the medium variant.

The support ratio for the intermediate-fertility countries is already high and is projected to increase at least until 2050 in the medium variant, the low variant and in the instant-replacement scenario, but will then decline considerably. That is, after 2050, the beneficial changes in the age distribution associated with declining fertility would have run their course in the intermediate-fertility countries and their population would enter the final stage of population ageing. Yet, if the intermediate-fertility countries follow the medium variant, their support ratio by 2100 will not be less than it had been before their fertility started declining and it will be qualitatively different from what it was in the 1960s because a higher proportion of the 'dependent' population will consist of older people than it did in the 1960s. In comparison with children, who are real 'dependants' because they require care and services and are generally not allowed to engage in productive activities in modern societies, people aged 65 or over may remain productive, continue to engage in the labour force and be likely to have accumulated savings that will prevent them from being fully dependent on transfers. Appropriate policies and institutions will be necessary to promote the accumulation of savings for use after retirement but there is increasing evidence that older people do not fit the traditional 'dependent' mould.

As for the low-fertility countries, because they are already in the last stage of population ageing and the process is accelerating, they are projected to see a sharp decline in their support ratio in all projection variants and scenarios. They all indicate that the most rapid decline of the support ratio in low-fertility countries will likely occur over the next four decades. Beyond 2050, their support ratio would continue to decline but more slowly. By 2100, the low-fertility countries would have the lowest support ratio among the three groups considered. In the medium variant, the support ratio for low-fertility countries is projected to be 1.26 potential workers per dependant in 2100, low by historical standards but still higher than 1.0. The no-change scenario, which projects lower fertility for the low-fertility countries than the medium variant, produces a higher support ratio (1.58 potential workers per dependant) because it maintains mortality constant at the level it had in 2005–2010 and therefore fewer people survive to advanced ages by 2100 than according to the medium variant. If the mortality reductions projected by the medium variant are real-

ized, it is to be hoped that such rising longevity may be accompanied by healthier and more productive lives beyond age 65.

10.8   The Persistence of Population Imbalances

The projection results presented thus far provide ample reasons to conclude that current population imbalances will continue to shape the population dynamics of the world over the next four or five decades. The population of the high-fertility countries will continue to grow and is likely to double by mid-century. Whether it keeps on increasing rapidly thereafter depends in great measure on how fast their fertility levels decline from now to 2050. The persistence of high fertility in the past has meant that the population of the high-fertility countries still has a young age distribution with high numbers of children under age 15. Therefore, their support ratio is low but is starting to increase. The more rapid the reduction of fertility that the high-fertility countries achieve in future, the faster their support ratio will grow, increasing its potential to boost their economic growth.

At the other extreme, the low-fertility countries are already advanced in the process of population ageing and their low fertility, which remains below replacement level, will likely produce a decreasing population at some point during the coming two or three decades. The period of most rapid population ageing will also occur during the coming four decades. By 2050, the support ratio of the low-fertility countries as a group is likely to have fallen by about a third from its 2010 level but changes thereafter will depend on how much mortality declines at older ages and whether fertility continues to rise while remaining below replacement level. The median age of the low-fertility countries, which was 35.5 years in 2010, will probably rise to 45 years or higher by mid-century. By adapting to a decreasing and ageing population, the countries in this group will make a major contribution to the eventual stabilization of world population and set the example for countries that are still far from reaching below-replacement fertility.

As for the intermediate-fertility countries, they have, as a group, an average total fertility sufficiently close to replacement level that if, as projected in the medium variant, it attains replacement level and goes below it over the next three or four decades, their population will grow mainly because of population momentum until 2050. Consequently, the intermedi-

ate-fertility countries appear likely, as a group, to add about a billion to the world population by 2050 unless their fertility drops below replacement level much earlier. Although the intermediate-fertility countries still have a relatively young population, with a median age of 25.7 years, it is ageing more rapidly than that of low-fertility countries did and will likely have a median age well above 40 years by 2050. Their support ratio, which stood at 1.83 potential workers per dependant in 2010, seems likely to change little by 2050, perhaps increasing slightly if their fertility continues to fall, but it is projected to decline significantly thereafter as population ageing continues and the period with below-replacement fertility lengthens. Provided the total fertility of intermediate-fertility countries does not stall at levels above replacement, by the end of the century their population would share similar traits with that of the low-fertility countries and the major imbalances remaining then would be those between the high-fertility countries of today and the rest.

One scenario that would reduce markedly the population imbalances prevalent today among the three groups of countries considered would be that combining the medium variant for the low-fertility and the intermediate-fertility countries with the low variant for the high-fertility countries. Under that combination, the three groups of countries would have below-replacement fertility by the end of the century and their populations would be declining. Each group of countries would account for about a third of the world population, which would total 9.3 billion. All three groups of countries would have median ages above 41 years, though the high-fertility countries would still have a younger population than the intermediate-fertility countries and these, in turn, would have a lower median age than the low-fertility countries. The high-fertility countries would have a more advantageous support ratio than the rest, with 1.85 potential workers per dependant and it would be decreasing slowly. Realizing this type of convergence over the course of this century is feasible even if it may seem unlikely given the trends followed by the high-fertility countries in the recent past. The more reason, therefore, to concentrate effort and support in promoting the reduction of fertility in the high-fertility countries of today, especially in the ways discussed below.

10.9 Concluding Thoughts: What Will it Take for the Changes Projected to Happen?

Population projections are not predictions and though they provide elements to judge how much current population dynamics need to change in order to realize particular outcomes, their realization is not automatic. This chapter has stressed that future population growth and prospects depend crucially on the path that future total fertility takes, particularly in today's high-fertility countries. Among the proximate determinants of fertility change, the level of contraceptive use among women subject to the risk of childbearing is a key one. Demographers consider that women aged 15 to 49 who are married or in a stable union represent the main group of women at risk of childbearing. The percentage of those women using contraception at a particular point in time is a measure of contraceptive prevalence. It is possible to distinguish between women who use the most effective contraceptive methods (usually denominated 'modern methods') and those who use traditional methods whose effectiveness in preventing pregnancy is lower. Therefore, contraceptive prevalence can be measured with respect to all methods or just taking into account the women using modern methods.

A measure indicative of how well the need for contraception is being satisfied is the 'unmet need for contraception'. This measure is calculated as the percentage of women aged 15 to 49, who are married or in union, who are not pregnant or sterile and who do not wish to become pregnant soon or do not wish to have another child ever but who are not using any method of contraception. The unmet need for modern contraception includes women who are using a traditional method of contraception among those having an unmet need for contraception.

Table 10.7 shows the estimated and projected levels of contraceptive prevalence and unmet need among women in the three groups of countries considered. These estimates were derived from the set of country estimates produced by the United Nations Population Division (United Nations 2013c, 2013d; Alkema/Kantorova/Menozzi/Biddlecom 2013). The latter are based on a set of observations that are incomplete (not all countries have the required data at every point in time) and subject to a variety of errors. Therefore, the country estimates and those for the groups considered here should be taken as indicative of trends and differences but should not be interpreted too strictly. Nevertheless, the estimates pre-

Table 10.7: Estimates and projections of contraceptive prevalence and unmet need for contraception for the three groups of countries considered, 1970–2030. **Source:** Derived from United Nations (2013c, 2013d).

Group	Percentage of women aged 15-49 who are married or in union					
	1970	1980	1990	2000	2010	2030
	Using a method of contraception (any method)					
High-fertility countries	6	9	14	22	29	47
Intermediate-fertility countries	15	32	45	54	60	66
Low-fertility countries	53	64	72	78	78	76
	Using a modern method of contraception					
High-fertility countries	2	4	8	15	21	38
Intermediate-fertility countries	10	25	38	47	53	59
Low-fertility countries	36	52	64	72	73	72
	With an unmet need for contraception					
High-fertility countries	28	28	28	27	25	20
Intermediate-fertility countries	27	25	20	16	14	11
Low-fertility countries	17	12	9	7	6	7
	With an unmet need for modern contraception					
High-fertility countries	31	33	34	35	33	28
Intermediate-fertility countries	32	32	27	23	21	18
Low-fertility countries	34	24	17	13	11	11

sented in table 10.7 show that clear differences exist between the high-fertility, the intermediate-fertility and the low-fertility countries in terms of contraceptive prevalence and unmet need for contraception. For all time points, contraceptive prevalence is lowest in the high-fertility countries and highest in the low-fertility countries. Conversely, unmet need for contraception is highest in the high-fertility countries and lowest in the low-fertility countries. Although such differences were to be expected, it is important to stress that the estimates of contraceptive prevalence and unmet need for contraception presented here were derived independently from the estimates of total fertility discussed earlier in this chapter.

According to table 10.7, just 22 per cent of women aged 15-49 who were married or in union were using some method of contraception in 2010 in high-fertility countries and the percentage using a modern method was a low 15 per cent. Although both these levels were higher than they had been in 1970, contraceptive prevalence in high-fertility countries had increased very slowly between 1970 and 1990 and, although it increased more rapidly after 1990, its speed of change between 1990 and 2010 was moderate at best. This experience contrasts with that of the intermediate-fertility countries whose level of contraceptive prevalence in 2010 had reached 60 per cent, having

increased very fast between 1970 and 1990, when it attained 45 per cent, and increasing at a more moderate pace between 1990 and 2010, although still faster than in the high-fertility countries after 1990.

In low-fertility countries, contraceptive prevalence was already high in 1970 (at 53 per cent) although there was room to increase the use of modern contraceptive methods since only 36 per cent of women of reproductive age who were married or in union were using them. Over the next 20 years, the use of modern methods in low-fertility countries nearly doubled and overall contraceptive prevalence increased to 72 per cent. That is, by 1990 nearly 3 out of every 4 women of reproductive age who were married or in union in low-fertility countries were using some method of contraception and by 2010 that same proportion was using a modern method of contraception.

These past trends in contraceptive use are congruent with the changes in total fertility experienced by each group of countries. Because projected levels of future contraceptive prevalence are available, one may consider whether they can guide action to achieve the fertility reductions embodied by the population projections considered earlier in this chapter. The projected levels of contraceptive prevalence to 2030 are derived by taking account exclusively of past trends in contraceptive prevalence in each country, trends in

countries in the same region and those in all countries. They are obtained, therefore, independently of projections of future fertility. Consequently, it is not certain that the projected levels of contraceptive prevalence will necessarily lead to the total fertility levels projected under, for instance, the medium variant. However, a comparison of the level of fertility experienced by the intermediate-fertility countries in 1990 at the time when their contraceptive prevalence was 45 per cent suggests that the projected level of contraceptive prevalence of 47 per cent in 2030 for high-fertility countries may be sufficient to reduce fertility as projected by the medium variant. Assuming that to be the case, it will be necessary for high-fertility countries to accelerate the uptake of contraceptive use and, in particular, to expand the use of modern contraceptives during 2010–2030 if the projected contraceptive prevalence is to be attained by 2030. Moreover, the projected increase in contraceptive prevalence needs to occur even as the number of women of reproductive age in high-fertility countries increases rapidly as a result of the high fertility levels of the past.

Although achieving a contraceptive prevalence of 47 per cent and a prevalence of modern contraceptive use of 38 per cent over the next 15 years in high-fertility countries should be feasible based on the experience of intermediate-fertility countries, those levels are unlikely to be achieved without serious commitment from governments, non-governmental organizations and the international community to support family planning in the high-fertility countries. Experts have noted that since the mid-1990s, that support has waned (Cleland/Bernstein/Ezeh et al. 2006), but recent efforts by private donors to galvanize support for family planning are expected to make a difference. Bongaarts, Cleland, Townsend et al. (2012) provide an overview of changing perspectives about the effectiveness of family planning programmes and describe strategies to reduce barriers to the use of contraception in low-income countries, such as those included in the group of high-fertility countries considered here.

In the case of the intermediate-fertility countries, increasing contraceptive prevalence from 60 per cent in 2010 to 66 per cent in 2030 and the use of modern contraception from 53 per cent in 2010 to 59 per cent in 2030 seems feasible in view of past experience. Nevertheless, achieving those goals requires sustained support for family planning, especially considering that the number of women of reproductive age in intermediate-fertility countries will be increasing over the next two decades. It is of concern that several countries in this group, after having successfully expanded contraceptive use and reduced fertility, have been reducing their support for family planning both in financial terms and in terms of commitment to the provision of services. If those changes make fertility stall at current levels, the potential for sustained population increases in intermediate-fertility countries may become a reality.

In both the high-fertility and the intermediate-fertility countries, unmet need for contraception is projected to decline from 2010 to 2030. In the intermediate-fertility countries, the decline in unmet need is slower than it has been in the past, but for the high-fertility countries it is faster than in the past. Furthermore, the projected reduction of unmet need in both groups of countries still leaves a substantial proportion of women of reproductive age with an unmet need for contraception in 2030. That is to be expected, especially in the high-fertility countries where, as fertility declines and increasing numbers of women wish to reduce their fertility, the demand for contraception will likely grow faster than the capacity to meet it. Furthermore, as the existence of a significant level of unmet need for contraception in the low-fertility countries suggests, even when contraceptive use is high, some unmet need will remain unsatisfied.

To sum up, current population imbalances are to a large extent the result of different trends in the reduction of fertility among countries. The use of contraception, particularly modern contraception, is the major immediate means of reducing fertility. Given the stark differences in levels and trends of fertility that already exist between the high-fertility, the intermediate-fertility and the low-fertility countries, their influence cannot be erased over the medium-term future. However, if those imbalances are to diminish over the long run, it is necessary to accelerate the transition to low fertility in the high-fertility countries and ensure that the intermediate-fertility countries reach below-replacement levels of fertility over the coming two or three decades. To do so, a key strategy is to expand contraceptive use, especially in the high-fertility countries where the unmet need for contraception remains especially high. Continuing to support and facilitate access to modern contraception, especially among low-income groups, is also necessary in the intermediate-fertility countries. If the high-fertility countries could achieve the reductions of fertility projected by the low variant while all other countries followed fertility paths close to those projected by the medium variant, the world might witness the beginning of population stabilization by the end of this century.

11   The Challenge of a 4°C World by 2100

Hans Joachim Schellnhuber, Olivia Maria Serdeczny, Sophie Adams,
Claudia Köhler, Ilona Magdalena Otto and Carl-Friedrich Schleussner[1]

Abstract

As evidenced by the Fifth Assessment Report of the IPCC, our understanding of the Earth System and the climate change impacts expected in the coming decades is developing at a rapid pace. Contributing to this progress, the first ever Inter-Sectoral Impact Model Intercomparison *(ISI-MIP)* has helped to paint a clearer picture of potential impacts at different levels of global mean warming. However, along with such advances the limitations of our understanding become more apparent. A number of processes are scarcely or not at all reflected in current assessments of the risks associated with significant levels of warming. These include critical thresholds in the Earth system which, once breached, can give rise to non-linear impacts. Recent insights from West Antarctica indicate that we have already 'tipped' several large glacier systems there, suggesting that the risk of crossing such thresholds might be much greater than previously thought. Also excluded from a sectoral perspective are the intricate interdependencies between systems and the potential for an initial impact to cascade into a chain of impacts, or for impacts to occur simultaneously and interact in complex ways. Finally, we need to take into account the different degrees of vulnerability not only across but also within nation states. The ramifications of non-linear impacts and their uneven distribution are likely to be deleterious to the stability and well-being of our societies and will, we hope, never be realized. However, if we wish to understand the challenges associated with a 4°C world[2], such a world needs to be imagined.

Keywords: 4°C World, non-linearity, social vulnerability, cascading impacts, intersectoral hotspots, thresholds, tipping elements, uncertainty, complex systems.

11.1   Introduction

A scenario in which global mean temperature reaches 4°C above pre-industrial levels by the end of the century constitutes a real risk. Current policies would lead us to a warming of 3.7°C above pre-industrial levels by 2100, with about a 40% chance of exceeding 4°C by that time (climateactiontracker.org). What this means for the livelihoods, welfare and security of future generations remains highly uncertain. However, research on climate change impacts is progressing rapidly and our understanding of the implications of high emission scenarios continues to deepen.

Although we are not able to project future impacts with the precision that policymakers might hope for, we now know enough to build a picture of a 4°C world and some of the risks that it will entail. For example, as analysed in Schellnhuber/Hare/Serdeczny et al. (2012, 2013), projections from five bias-corrected general circulation models (Hempel/Frieler/Warszawski et al. 2013) indicate a severe increase in the frequency and intensity of extreme heat in a 4°C world. Heatwaves of unprecedented magnitude—five standard deviations outside the historical norm—are

---

2   The term '4°C world' is used as shorthand for an increase of 4°C in global mean temperature above pre-industrial levels by the end of the century.

Figure 11.1: The IPCC's Working Group II Assessment: *A global perspective on climate-related risks.* The colour shading indicates the additional risk due to climate change when a temperature level is reached and then sustained or exceeded. Undetectable risk (white) indicates no associated impacts are detectable and attributable to climate change. Moderate risk (yellow) indicates that associated impacts are both detectable and attributable to climate change with at least *medium confidence*, also accounting for the other specific criteria for key risks. High risk (red) indicates severe and widespread impacts, also accounting for the other specific criteria for key risks. Purple shows that very high risk is indicated by all specific criteria for key risks. Temperatures on the left are given for the baseline period 1986–2005 and above pre-industrial levels on the right. **Source:** IPCC Summary for Policy Makers, Working Group II (2014: 13).
expected to affect 60 per cent of the global land area by the end of the century. Today's extremes, like the Central European heatwave of 2010, would be the new normal, affecting 80 per cent of the surface. Rainfall patterns would be amplified with decreases of up to 30 per cent during the dry season and increases of up to 30 per cent in the wet season projected for South Asia (Schellnhuber/Hare/Serdeczny et al. 2012, 2013). Sea-level rise poses another severe risk, particularly to coastal populations at low latitudes. Semi-empirical projections of regional sea-level rise indicate that sea-level rise at tropical and subtropical locations will be up to 20 per cent higher than the global mean, reaching 1.2 m in the Western Pacific

(Schellnhuber/Hare/Serdeczny et al. 2012, 2013). It is clear that these risks pose enormous obstacles to human development and security (German Advisory Council on Climate Change 2007). That climate change will hit the poorest hardest is now widely accepted. But climate change impacts are not confined to the developing world, and indeed climate change is expected to also threaten the more comfortable ways of life of the industrialized regions of the world. Based on a common understanding of shared responsibility for present and future generations, the challenge of climate change requires no less than a global transformation towards sustainability (German Advisory Council on Climate Change 2011).

Box 11.1: The Inter-Sectoral Impact Model Intercomparison Project (ISI-MIP)

The *ISI-MIP*-Project is a community-driven modelling effort and the first intercomparison of climate impacts to bring together several sectors expected to be affected by climate change: agriculture, water, ecosystems, human health (malaria) and coastal infrastructure. The project aims to quantitatively assess global climate impacts at different stages of global warming using a consistent setting. It is based on earlier impact model comparisons and helps to identify research gaps as well as to provide robust results on societally relevant climate impacts. ISI-MIP's core element is a public data archive, which is driven by the motivation to create transparency and to lead to model improvement. Based on the quantitative analysis of intermodel variations, the project also aims to estimate uncertainties for *General Circulation Models* (GCMs) as well as for *Global Impact Models* (GIMs). ISI-MIP aims to initiate a continuous process of coordinated improvement of impact modelling and assessment that involves the entire scientific community. In this sense, ISI-MIP pursues a dual purpose: that of facilitating the process of understanding and of model development within the research community.

In the following we provide an outline of the challenges humanity could be faced with in a 4°C world. We begin with a brief overview of projections of climate change impacts in a number of sectors of particular importance to society. The results are derived from scientific publications based on the first Inter-Sectoral Impact Model Intercomparison Project (ISI-MIP; see box 11.1; Warszawski/Frieler/Huber et al. 2013). In light of the uncertainties associated with climate change projections, we then review the literature to discuss some of the 'known unknowns' that have emerged in recent research—those risks that at present remain inadequately captured in modelling exercises and that require further investigation. These include the potential for 'tipping points' in the Earth system and human sectors, as well as for complex interactions between impacts, all of which could have substantial adverse consequences for the human populations inhabiting a 4°C world.

In this discussion we investigate some of the key risks as identified by the Second Working Group of the Intergovernmental Panel on Climate Change (see figure 11.1). Based on expert judgment, five areas of emergent risks of climate change and its societal impacts indicate how risks mount with increasing global mean temperature. These areas include the distributional aspect of impacts as well as risks related to large-scale singular events. While our chapter cannot provide a detailed understanding of those key risks that societies will be faced with in a 4°C world, it does illustrate the scope of the challenge both for scientists to advance our understanding and for policymakers to act even in conditions of uncertainty.

11.2 Sectoral Impact Estimates Derived from ISI-MIP

In order to study the differences between warming scenarios of a 1, 2, 3 and 4 °C temperature rise above pre-industrial levels, the *Inter-Sectoral Impact Model Intercomparison Project* (ISI-MIP) brought together thirty research teams from twelve countries involved in the assessment of climate impacts in multiple sectors (Warszawski/Friend/Ostberg et al. 2013). In the first project phase, the researchers compared 28 impact models across five different sectors within the consistent setting provided by the ISI-MIP modelling protocol (see box 11.1). The sets of climate data used were derived from five climate simulations, each simulating four *Representative Concentration Pathways* (RCPs) (Hempel/Frieler/Warszawski et al. 2013). The results of this interdisciplinary exercise allow for a better understanding both of the differences between low and high warming scenarios and of the remaining research gaps and the main sources of the uncertainty that hamper climate impact projections. Seemingly paradoxically, a model comparison such as this increases the range of results, and the results therefore appear less sharp than those of a single simulation. At the same time, however, the results become more reliable compared to the results of just one simulation. Some of the key insights of the first fast-tracked phase, including for the water and agricultural sectors, are presented below.

11.2.1 Sectoral Results

Changes in precipitation patterns due to climate change pose threats to human populations through both increased risk of direct water scarcity and associated agricultural impacts. Drought conditions and extreme precipitation and flood events are also hazardous to human lives and livelihoods. The ISI-MIP

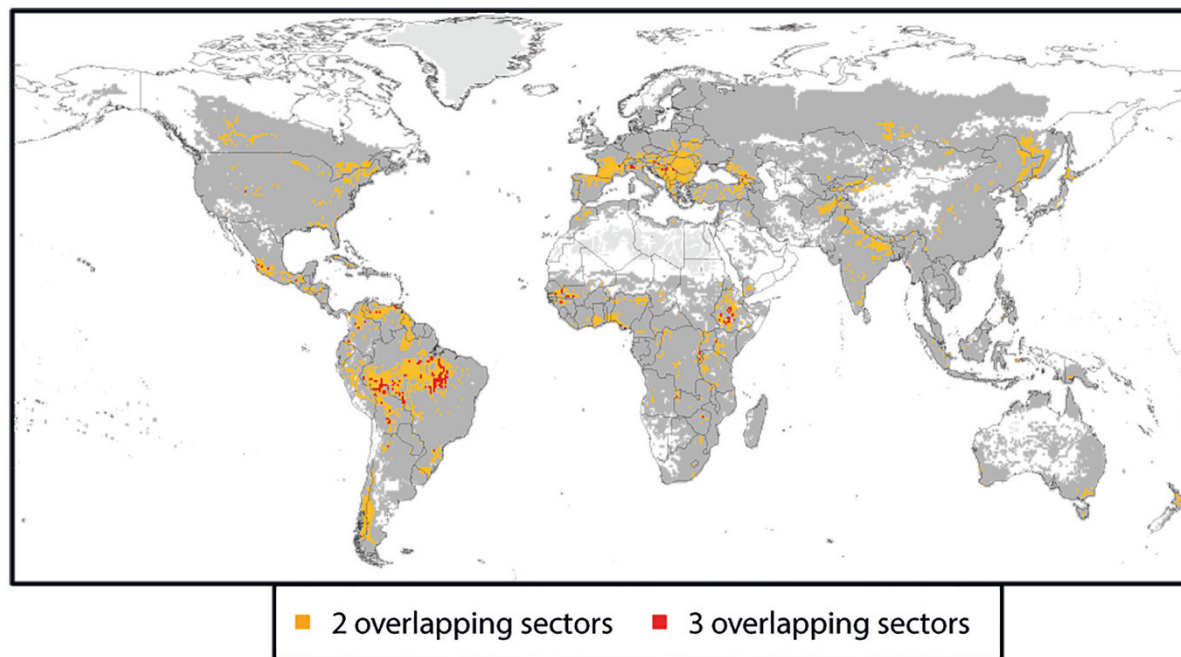
results for the water sector published in Schewe/ Heinke/Gerten et al. (2013) focus on the impacts of climate change on water resources and availability. Although population change accounts for the larger part of the overall change in water scarcity, climate change significantly increases the number of people at risk: a warming of approximately 2.7°C above pre-industrial levels is projected to expose an additional 15 per cent of the global population to a severe decrease in water resources. The number of people living with absolute water scarcity (<500 m3 per capita per year) is expected to grow by another 40 per cent compared with a scenario without climate change. The study shows that the greatest increase in water scarcity could occur at a warming of 2–3°C above pre-industrial levels. At 3°C warming, 10 out of 100 people would be affected by absolute water scarcity—compared to one to two people per 100 people today. Significant regional differences appear: while water availability in the Mediterranean region, the Middle East, the southern USA and southern China decreases, it is projected to increase in southern India, western China and parts of East Africa. Increasing drought conditions are likely to place affected populations under immense pressure. According to Prudhomme/Giuntoli/Robinson et al. (2013), as warming approaches 4°C drought conditions are expected to deteriorate in the Americas, large parts of tropical and southern Africa, the Mediterranean region, south-east China and Australia. Overall, an increase in drought conditions is projected for 40 per cent of all land area analysed in nearly half of all simulations of a 4°C world used in the study. Minor changes or decreased drought conditions are found only in northern Canada, north-east Russia, the Horn of Africa and parts of Indonesia.

With its high exposure and strong dependence on rainfall, agricultural productivity is particularly vulnerable to climate change. Rosenzweig/Elliott/Ruane et al. (2013) bring together and compare the results of seven crop models within the frameworks of the Agricultural Model Intercomparison and Improvement Project, and ISI-MIP. Despite strong variation across models, overall results show a robust negative trend of 50 per cent decreases in yield for important crops such as wheat and maize in the tropics in a scenario roughly corresponding to a 4°C world. The response is stronger if the uncertain CO_2 fertilization effect is not taken into account. The authors stress that while higher latitudes are expected to see increases in yields, important soil properties in these regions are understudied and add another factor of uncertainty to projections and another risk to global food production.

A risk analysis of ecosystem shifts under climate change by Warszawski/Friend/Ostberg et al. (2013) aggregates changes in the biochemical ecosystem state as a proxy for the risk of ecosystem changes at different levels of global warming. The main result shows a risk for 5-19 per cent of the naturally vegetated land surface at 2°C of global warming above 1980–2010 levels. The area at risk of severe changes is projected to grow as global mean temperature rises, approximately doubling for a warming of between 2°C and 3°C and reaching a median value of 35 per cent of all naturally vegetated land surface at approximately 4°C warming. Some regions characterized by exceptional biodiversity coincide with those found to be at risk of severe ecosystem changes, such as the montane grass and shrublands of the Tibetan Plateau Steppe, and several moist forest regions, such as the Guayanan Highland moist forests of South America. The authors identify strong divergence in results across models, with discrepancies in the globally aggregated level of risk of ecosystem change and its geographical distributions resulting from the diversity of modelling approaches and their respective sensitivities to climate change and increasing CO_2 concentrations. Overall, however, there is agreement within the model ensemble regarding the increasing risk of severe change on a global scale under all warming scenarios considered.

11.2.2   Climate Impact Hotspots

According to the analysis provided by Piontek/ Müller/Pugh et al. (2013), every tenth person lives in a place on Earth that can become a hotspot of unrestrained climate change. With increasing global mean temperature, the risk of overlapping impacts grows and leads to higher adaptation pressure. Within the ISI-MIP framework, Piontek/Müller/Pugh et al. (2013) define hotspots as regions of multisectoral exposure, where metrics in two or more sectors indicate severe change from average conditions. In order to identify such hotspots, the authors analyse data across a range of impact areas including agriculture, malaria, water resources and ecosystems. They find that following the strict assessment criteria (climate and impact model agreement of at least 50 per cent), overlapping of multisectoral impacts starts at 3°C warming above the mean temperature of the 1980–2010 period, with at least two of the four impact sectors overlapping at 4°C. The most prominent hotspot is the southern Amazonian Basin, which is affected by impacts in three areas: agricultural yields, ecosystems,

Figure 11.2: Multisectoral hotspots of impacts for two (orange) and three (red) sectors, where at least fifty per cent of climate and impact model combinations agree on the threshold crossing in each sector for a global mean temperature change of up to 4.5°C above 1980–2010. Regions in light grey are regions where no multisectoral overlap is possible at all because of data and assessment restrictions. Dark grey shading shows areas where at least ten per cent of climate and impact model combinations agree on the given threshold crossing. **Source:** Piontek/Müller/Pugh et al. (2013).


and river discharge (see figure 11.2). The second largest hotspot identified is southern Europe, as this region is expected to experience pressures in water resources and ecosystems. A further region at high risk of multiple impacts is the Ethiopian Highlands, where malaria extension, crop yield reduction and ecosystem change are projected to coincide. Similarly, northern regions of Africa are expected to be affected by either reductions in discharge and crop yields or by crop yield reduction and ecosystem change. Where impacts in different sectors overlap they increase exposure, will likely lead to interaction between impacts, and most certainly will compound adaptation pressures.

Critically, loosening the strict criteria to 10 per cent agreement between climate and impact models in order to include a worst-case scenario substantially increases the area at risk of overlap between multisectoral climate impacts (dark grey areas in figure 11.2). Areas at risk cover most of the global land area, with the exception of the high northern latitudes, the Sahara, and individual areas in Australia and China. In particular the exception of the Arctic from a worst-case assessment indicates that this assessment is limited to the sectors in question and does not capture

impacts such as cultural loss and health impacts other than malaria, which have both already been observed in high-latitude northern regions (e.g. Crate 2008). Integrating further sectors into this analysis would thus likely lead to a different, albeit not more optimistic picture of climate impacts.

11.3 Critical Thresholds, Cascading Impacts and Sectoral Interactions within Human Systems

The analysis outlined above provides an important indication of the risks arising from multiple impacts occurring in one location. Particularly in cases in which such impacts are experienced simultaneously, they would place enormous pressure on affected populations. Over the last decade or so the scientific community has been developing conceptual approaches and models that reflect the interactions and positive feedbacks that can occur between natural and societal systems (e.g. Brauch 2007). Agent-based models also allow for a better understanding of societal responses to changes in climatic conditions (e.g. Smith 2014).

However, climate impact modelling exercises for the most part do not capture potential interactions between impacts, as well as the ways in which climate change impacts can influence and be influenced by non-climatic factors and processes such as urbanization and environmental degradation. Current assessments also tend to not be able to capture the significance of critical thresholds within human sectors, beyond which the scale of impacts grows non-linearly and adaptation may no longer be possible. There is also a possibility that an initial impact can trigger a series of impacts across multiple sectors or different parts of the globe—particularly given the interconnectedness of today's world. Such dynamics, which could lead to abrupt, non-linear or potentially irreversible changes within sectors, with significant consequences for human populations, are illustrated with examples in this section. While the overall damage of climate impacts will be strongly shaped by societal developments and the state of readiness in the face of large-scale environmental change, a comprehensive risk assessment needs to incorporate the possible ways in which climate impacts may unfold to affect societies. Some of these are illustrated in the following examples.

11.3.1   Non-linearities Associated with Critical Thresholds within Sectors

Responses to rising temperatures can be abrupt if critical system thresholds are crossed. Such thresholds are likely to exist not only in components of the Earth system (discussed below in section 11.5), but also in human sectors such as agriculture and health care. While modelling development in individual impact sectors is currently under way (e.g. Rosenzweig/Jones/Hatfield et al. 2013), the processes underlying non-linear responses within individual sectors are typically not yet represented in climate impact projections.

One such potential non-linear response has been found in agriculture. Observations point to threshold behaviour in the growth of important crops including maize, wheat, soya, and cassava. When exposed to extreme temperatures or drought conditions during critical growth periods, plant development can be severely inhibited, leading to substantive yield losses. Non-linear temperature effects on these crops have been identified in several regions of the world, including the United States, Africa, India and Europe. For example, in the USA, significant non-linear effects have been observed when local temperature rises above 29°C for corn, 30°C for soybeans, and 32°C for cotton (Schlenker/Roberts 2009). In South Asia, the

upper temperature sensitivity threshold for current cultivars of rice is 35-38°C and of wheat is 30-35°C (Wassmann/Jagadish/Sumfleth et al. 2009). Further factors exacerbating the risk of non-linear effects include inhibited plant growth due to increasing salinity in deltaic regions, the spread of pests and diseases, declines in pollinators associated with habitat loss, and increasing pesticide use (Potts/Biesmeijer/Kremen et al. 2010; Wassmann/Jagadish/Sumfleth et al. 2009). Most current crop models do not account for the interaction of such factors with climatic changes (Warren 2011) and their net impact remains a considerable uncertainty associated with a warming of 4°C.

Critical thresholds may also exist in social systems, beyond which climatic pressures produce rapid, unforeseen and unprecedented effects. However, they are not well understood. Archaeological studies indicate that natural disasters can cause significant social and cultural shifts—through mass migration and economic and political upheaval—in instances in which the effects of the disaster make existing ways of life untenable (Riede 2013). It is plausible that present institutions could similarly be pushed beyond their capacity to maintain normal operation when faced with multiple unprecedented pressures from climate change impacts. For example, various stresses on human health, such as heatwaves, malnutrition, reduced quality of drinking water due to salt water intrusion and the spread of vector-borne diseases, could overburden health care systems to the point that coping with given stresses is no longer possible. The long-term repercussions remain unclear. Alternative means of coping are likely to be developed by those affected, including migration to more secure locations; however, the human and cultural costs of such changes are likely to be high.

11.3.2   Non-linearities Due to the Interaction of Impacts

Most model-based climate impact studies present results for individual natural or human systems. However, as global mean temperature rise approaches 4°C, it can be expected that impacts will more frequently coincide with one another and interact. Such interactions could produce a combined effect on human populations that is greater than the sum of the first-order impacts.

Interactions could occur between multiple impacts within a single sector, or between impacts across different sectors. For example, productivity in the agricultural sector could be severely undermined by a combi-

nation of direct impacts associated with changing temperature and precipitation patterns and indirect climate change impacts resulting from the expansion of weeds and invasive species (Potts/Biesmeijer/Kremen et al. 2010). An example of how impacts within the agricultural sector might interact with impacts in other sectors is that of the repercussions of a large shock to agricultural production following an extreme weather event such as extreme temperatures, drought or flooding. The resulting risk of malnutrition could significantly compound the health impacts associated with a possible concurrent outbreak of transmittable disease or heat stress (WHO 2009). In such a scenario the human costs could be considerable and very likely greater than in a scenario of agricultural impacts only.

Importantly, interactions between climate change impacts would occur against a backdrop of non-climatic pressures on natural and human systems. In effect, climatic factors interact with non-climatic pressures. The latter, which include population growth and environmental degradation, will influence the nature and scale of the ultimate repercussions of climate change for populations. Declining agricultural productivity along with a simultaneous increase in demand may, for example, lead to an expansion of agricultural area at the cost of natural ecosystems and the ecosystem services on which some people depend. Further, adaptation measures in one sector may exacerbate impacts in another—for example, if dam construction impedes the resilience of natural ecosystems (Warren 2011). However, the outcome of these interactions is highly uncertain, given the contingency and complexity of factors involved.

11.3.3   Non-linearities Due to Cascading Impacts

It is becoming increasingly apparent as research progresses that climate change impacts can produce many indirect effects. In other words, an initial impact can set off a chain of further impacts, which tend to not be taken into account in climate impact assessments. Such cascading impacts present another layer of risk to be integrated into a comprehensive understanding of the challenges of 4°C of warming by 2100.

For example, the impacts of climatic changes and extreme events on critical physical infrastructure or goods traded in international markets can ripple through the economy, leaving their mark well beyond the initial point of impact. This could occur as a result of damage to seaports from impacts including sea-level rise, more intense tropical cyclone activity, higher storm surges, severer river flooding, and altered wave regimes, with consequent effects on the supply chain (Becker/Acciaro/Asariotis et al. 2013). Another example is that of the long-term economic and welfare effects of damage to transport infrastructure due to a severe flooding event in Mozambique in 2000. Road connections between the capital Maputo and the rest of the country, along with the railway line to Zimbabwe, were destroyed for nearly a year. According to Chinowsky/Arndt (2012), this caused per capita economic growth to decline to the slowest growth rate in two decades. Economic growth rebounded when the primary north-south road link was repaired in 2001. Further, linkages between infrastructure systems can cause impacts in one to echo throughout others. For example, disruptions to wastewater treatment could increase flood losses due to contaminated floodwaters and decrease availability of cooling water for power generation (Kirshen/Ruth/Anderson 2007).

Similarly, impacts on production sites and distribution networks of widely traded goods can reverberate across the globe. Based on data collected by Lenzen/Kanemoto/Moran/Geschke (2012), Levermann/Clark/Marzeion et al. (2014) estimate that for receiving countries the knock-on effects of the cessation of exports by the country of origin may well exceed the direct economic damages. For example, six per cent of the US economy relies on imports from the Philippines. It would thus be directly affected if all Philippine exports ceased in the wake of a catastrophic weather event such as a tropical cyclone. However, indirect effects—mainly through the channels of retail trade—could resonate throughout the wider US economy, of which 21 per cent is calculated to be affected. Similarly, extreme events expose the market's susceptibility to weather-related production shocks. When coal exploration was put on hold in Queensland, Australia, following the combined effects of heavy rainfall and Cyclone Yasi in 2010–11, coking coal prices rose by 25 per cent the following year (Levermann 2014).

11.4   The Differential Social Impacts of Climate Change

The overall effect of climate impacts will be determined in large part by the patterns of capital and commodity flows and the degree of complexity in social networks. Another decisive factor driving the nature and scale of impacts and impact cascades and human vulnerability to them is future socio-economic development. While its trajectory remains uncertain, it

is becoming increasingly clear that socio-economic development itself will be negatively affected by the impacts of climate change.

The ways in which climate change will affect human development and efforts to alleviate poverty are increasingly receiving research attention. Although there are as yet few studies which fully capture and quantify the socio-economic repercussions of a global mean warming of $4°C$, it is apparent that climate change impacts have the potential to impede practically all aspects of human life and threaten long-term development goals. Climate change acts as a multiplier on other environmental and social stressors, further increasing the vulnerability of the poor and those already disadvantaged (see chapter by Ide/Link/Scheffran/Schilling in this volume). It is therefore considered likely that climate change will widen the divide between rich and poor, or between those populations that are generally more resilient and those that are less so.

11.4.1 Differential Social Vulnerability

Social vulnerability has been defined by Füssel (2012), following Blaikie, Cannon, Davis et al. (1994) and Adger and Kelly (1999), as the inadequate capacity of individuals, groups or communities to cope with and adapt to external stress placed on their livelihoods and well-being. This is determined by the availability of resources and by the capacity of individuals and groups to call on these resources. A complex set of characteristics influence a person's vulnerability, including initial well-being and health; livelihood circumstances and qualifications; capacity and willingness of individuals to minimize risks to themselves and their property; the forms of hazard preparedness provided by society and the availability of public services (e.g. disaster relief, shelters); and social and political networks and institutions (e.g. people's right and capacity to express their needs; see also Brauch 2011; Cannon/Twigg/Rowell 2003).

Marginalized and disadvantaged social groups and individuals are therefore often more vulnerable to the impacts of climate change than others (Warner/Erhart 2009). Accordingly, a wide range of literature reports that those people that are disadvantaged in society due to their age, gender, or ethnicity are among those most vulnerable to negative climate change impacts (e.g. Blaikie/Cannon/Davis et al. 1994; WHO 2009; Mearns/Norton 2010; FAO 2013; Wang/Otto/Lu 2013). This includes marginalized groups and individuals in middle- and high-income countries (e.g. Sti-

vers 2007; Napier/Mandisodza/Andersen et al. 2006; Vandentorren/Bretin/Zeghnoun et al. 2006).

In this context we use the term 'differential social vulnerability' to refer to the varying degrees of adverse effect that different individuals and social groups in one location may suffer from the climate stressors they are exposed to. Critically, patterns of differential vulnerability to climate change impacts have the potential to shape future patterns of inequality across the globe and within regions. For example, children, women and the elderly are generally expected to be more affected by negative health impacts related to the transmission of diseases and pathogens, increase of diarrhoeal and respiratory illnesses, under- and malnutrition, and heat stress (WHO 2009, 2012; EACC Synthesis World Bank Group 2010; Reyburn/Kim/Emch et al. 2011; UN Habitat 2011). The inhabitants of Small Island Developing States and low-lying areas are particularly vulnerable to the salinization of fresh water and arable land as well as to the impacts of storm surges (WHO 2009). Indigenous groups in the Arctic region may suffer a decrease in food sources and severe cultural impacts as reduced sea ice causes the animal populations on which they depend to decline, affecting their hunting and food-sharing cultures (Bronen 2008; ACIA 2004; Crowley 2010). Ethnic minorities often work outdoors in sectors such as construction and agriculture and tend to have few income alternatives. As they receive inadequate protection by labour law and trade unions, they have been identified as being particularly prone to dangerous working conditions, including exposure to heat stress (Vásquez-Léon 2009; Hanna/Kjellstrom/Bennett et al. 2011; Aw 2010). Urban populations are more vulnerable to increased temperatures due to a combination of higher inner-city temperatures, high population density, and inadequate sanitation and freshwater services (WHO 2009).

Although vulnerability and poverty are not synonymous, they tend to coincide. Indeed, it is clear that the poorest people in any given community are often disproportionately affected by environmental stressors such as disasters, particularly over the long term (Shepherd/Mitchell/Lewis et al. 2013). Recent trend analysis shows that poverty will be increasingly concentrated in particular areas in the future (Shepherd/Mitchell/Lewis et al. 2013). Such locations tend to be those in which people are most vulnerable to climate-related stressors as economic and political forces confine the poor to living in high-risk landscapes (Warner/Erhart 2009). For example, Amarasinghe/Samad/Anputhas (2005) show that in Sri Lanka the

poorest households are located in dry areas where small-sized agricultural holdings depend on rain-fed production and where income diversification opportunities are scarce due to the large distance from roads and cities. Similarly, the urban poor are expected to be among the most vulnerable groups to the impacts of climate change, due to the location of many cities in coastal areas as well as an increasing trend towards urbanization. Urbanization often drives urban migrants into informal settlements, which tend to be located in areas most prone to extreme weather, such as steep slopes or alluvial plains. They also lack basic services and infrastructure, such as waste collection and sanitation, and this can increase the prevalence of transmittable disease. In addition, as the urban poor are the net buyers of food, they are particularly vulnerable to increases in food prices following climate-induced production shocks and declines (Hein/Metzger/Leemanns 2009; Kumssa/Jones 2010; Smit/Parnell 2012; McMichael/Montgomery/Costello 2012).

11.4.2 The Potential of Climate Change to Exacerbate Vulnerability

Climate change impacts can affect people in multiple ways and with long-lasting effects. The channels through which extreme weather events, for example, can impact upon populations and economies include death and disability, sudden loss of income, depletion of assets, loss of public infrastructure, and macroeconomic shocks (UNDP 2007; Shepherd/Mitchell/Lewis et al. 2013). As for the multifarious changes to their lives and lived surroundings, many of the critical impacts on the poor cannot be measured in economic terms. These include degradation or loss of ecosystem services and social networks, which in some cases, particularly in developing countries, may in fact be of greater consequence than economic losses (UNFCCC 2013). Where there is inadequate capacity to recover, these impacts can place people in an ever more vulnerable position in the face of future impacts. This can lead to a cycle of losses and maladaptive strategies including divestment of productive assets such as livestock, exchange of land for food, and the sale of firewood, leading to increased deforestation (UNDP 2007). Particularly detrimental to human resilience in the face of climate change are consecutive disasters that do not allow enough time for societies and households to recover.

Climate change impacts such as droughts and extreme storms carry the potential to push vulnerable households beyond an observed threshold at which they fall into a poverty trap (Carter/Little/Mogues/Negatu 2007). This makes them acutely vulnerable to further impacts, effectively preventing recovery and impeding economic growth and human development in the longer term. Climate-related impacts on food availability, for example, may lead to long-term setbacks in areas such as health, education and future employment opportunities for children in those households that are unable to avoid the detrimental effects of malnourishment, stunting, and missed schooling (Shepherd/Mitchell/Lewis et al. 2013).

Social and economic asset endowments largely determine the capacity of a household or individual to withstand shocks, with the likelihood of impoverishment decreasing as household prosperity rises (Little/Stone/Mogues et al. 2006). There appears to be no clear threshold, but at an income of more than US$4 per day, the risk of falling into poverty has been shown to be greatly reduced (Shepherd/Mitchell/Lewis et al. 2013). Insofar as climate change threatens to cause people to fall into poverty, it can be seen as a threat to human development and the advances in poverty alleviation made in recent years.

Climate change also has the potential to influence broad social processes and trends that are driven by non-climatic factors. For example, there are strong indications that climate extremes as well as ongoing negative climate change impacts on water availability and food production are contributing to population movements in sub-Saharan Africa (Chaves/Koenraadt 2010) and South East Asia (Marks 2011; Warner 2010; World Bank 2010). Recent studies based on household surveys show that climate events may account for approximately 6–12 per cent of current levels of migration in North Africa and the Middle East (Grant/Burger/Wodon 2014). Indeed, the role that weather patterns play in such dynamics could increase in the future as climate conditions continue to deteriorate. The poorest migrants—those lacking the social networks and resources to go through formal migration procedures—may choose life-threatening escape channels. These include so-called 'boat people', who are at risk of trafficking, crime, and death (Murray/Williamson 2011; Düvell 2012). As a consequence of population movements, migrants can be exposed to the risks associated with informal settlements, as outlined above. In their new locations they may also face tensions across ethnic identities and political and legal restrictions as well as competition and limitations to access to land (Tacoli 2009).

To sum up, those people who are initially the most vulnerable to climate change are made all the more vul-

nerable by climate change. This could cause resilience to be progressively degraded. The relatively less vulnerable parts of the world, on the other hand, would be less affected by this feedback loop. In this way, climate change has the potential to drastically deepen inequality across the world.

11.5　(In)Stability of Earth System Components

Climate change may interact with several large-scale components of the Earth system in a non-linear way. Due to the complex nature of these systems their response to increasing global mean temperature may be highly amplified by internal dynamics and in some cases even lead to regime shifts. The human consequences of such major perturbations are still little understood. This means that their integration into a comprehensive climate risk assessment is still for the most part lacking.

11.5.1　The El Niño Southern Oscillation

One large-scale component of the Earth system of high societal relevance is the *El Niño Southern Oscillation* (ENSO), which is expected to be affected by and interact with anthropogenic climate change. The ENSO is the dominant mode of natural variability of the Earth climate system and consists of irregular warm (El Niño) and cold (La Niña) sea-surface patterns in the central Pacific Ocean. Anomalous, El Niño-type conditions are related to disastrous flooding events in Latin America on the one hand and droughts in Australia and large areas of South East Asia on the other, and can have far-reaching effects on Atlantic hurricane activity and the global monsoon system (see e.g. Donnelly/Woodruff 2007; Kumar/Rajagopalan/Hoerling et al. 2006).

Additionally, the ENSO affects the global heat budget as it strongly alters ocean heat uptake in the Pacific. In fact, the recent 'hiatus' decade of slowed global warming has been related to the absence of strong El Niño events and a corresponding increase in ocean heat uptake (Balmaseda/Trenberth/Källén 2013; Meehl/Arblaster/ Fasullo et al. 2011; Rahmstorf/Foster/Cazenave 2012).

Given its socio-economic importance and possible growing future impacts, short-term prediction of ENSO evolution is a crucial, albeit challenging, scientific task. Based on an analysis of the network of teleconnections of the El Niño basin with the surrounding Pacific Ocean, Ludescher/Gozolchiani/Bogachev et al. (2013) have developed a new forecasting scheme for the occurrence of El Niño events. While predictions have to date been limited to approximately six months, the method introduced by Ludescher/Gozolchiani/Bogachev et al. (2013) allows a robust twelve-month forecast and thus enables adaptation in, for example, the agricultural sector in advance of potential ENSO related climatological extremes.

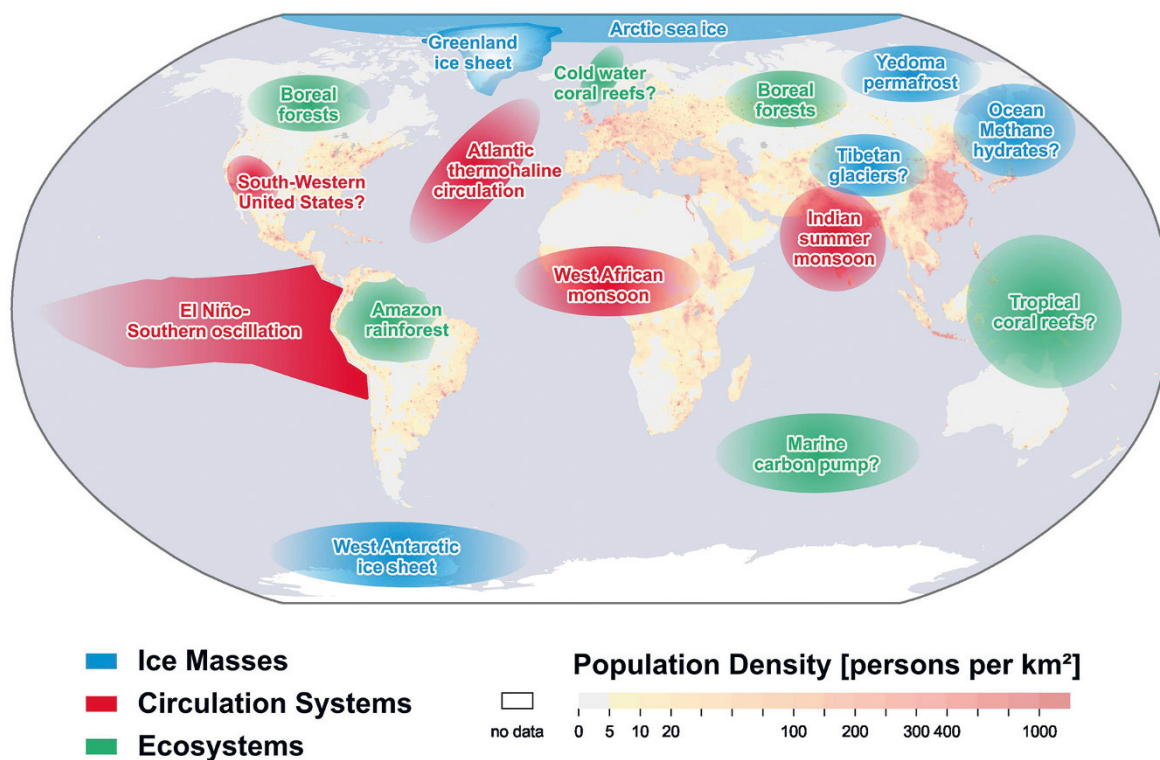
As natural ENSO variability both temporally and spatially is very large, the last IPCC report remained inconclusive about future ENSO evolution (Collins et al. 2013). Recent model intercomparison studies, however, reveal a trend towards more extreme El Niño events over the twenty-first century (Cai/Borlace/Lengaigne et al. 2014; Power/Delage/Chung et al. 2013).

11.5.2　The Indian Monsoon

Palaeoclimatological records provide evidence that the Indian monsoon system has undergone abrupt transitions in the past that might have been the result of a regime shift in the underlying moisture-advection feedback (Levermann/Schewe/Petoukhov/Held 2009; Schewe/Levermann 2012). While such dramatic shifts are not projected for the twenty-first century, increases in absolute rainfall and in the number of monsoon failure events are projected. An increase in the interannual variability of the Indian monsoon may further pose a risk to agricultural productivity patterns which are highly adapted to the timing of monsoon rainfall (Menon/Levermann/Schewe et al. 2013). Thus, the monsoon circulation may become less reliable and potentially more extreme, which represents a serious risk for agriculture and the hydrological cycle in South East Asia.

11.5.3　The Amplification of Planetary Waves

An increase in the frequency of climatological extremes, both warm and cold, has been observed in the Northern Hemisphere. This might be related to a weakening of the zonal mean jet stream as well as quasi-resonant amplification of planetary waves in the Northern Hemisphere jet stream (Petoukhov/Rahmstorf/Petri/Schellnhuber 2013). Under such quasi-resonant conditions, the amplitude of these planetary waves—their longitudinal extension—is enhanced, which leads to uncommon northward (southward) penetration of warm (cold) air masses. At the same time, the planetary waves that normally meander around the

Figure 11.3: Schematic mapping of tipping elements of the Earth system and populations density. **Source:** Schellnhuber, pers. comm., after Lenton, Held, Kriegler et al. (2008).


globe become quasi-stationary, which can lead to persistent extreme weather conditions over several weeks.

Stationary wave patterns have been observed in connection to severe flooding events in central Europe, heatwaves in Russia and the US, as well as cold winters in central Europe and the US over the last decade. Additionally, quasi-resonant amplification could translate into extremes occurring simultaneously over the Northern Hemisphere.

The role of climate change in the recent increase in occurrence of such events has not been conclusively established. However, a decreased temperature gradient between the subtropics and the polar regions is favourable to the establishment of quasi-resonant conditions. During the last decade, we have seen a dramatic loss in Artic sea-ice accompanied by a strong warming signal in the Arctic region (Cowtan/Way 2013), and it might be that this loss is partially responsible for the increase in mid-latitude extreme events over the same period (Coumou/Petoukhov/Rahmstorf et al. 2014; Petoukhov/Semenov 2010; Tang/Zhang/Francis 2013). While evidence is growing that this phenomenon might be responsible for a variety of recent weather extremes, the resolution of state-of-the-art General Circulation Models is too low to cor-

rectly resolve it, which means that future Northern Hemisphere mid-latitude climate extremes may potentially be underestimated.

11.5.4 Tipping Elements

The three examples outlined above illustrate the importance of considering the non-linear responses of large-scale components of the climate system to anthropogenic interference. In addition, a variety of these components may show self-amplifying dynamics that can lead to system-immanent regime shifts. These are the so-called "tipping elements" of the climate system (Lenton/Held/Kriegler et al. 2008, depicted in figure 11.3), which include ecosystems such as the Amazon rainforest and parts of the cryosphere such as the Greenland and West Antarctic ice sheets.

Moisture recycling, that is, the re-evaporation of precipitated water, over the Amazon rainforest is a crucial part of the climate of South America, where in some regions more than 70 per cent of the moisture that precipitates is of continental origin (van der Ent/Savenije/Schaefli et al. 2010). While a critical threshold of annual precipitation exists below which tropical rainforests are unlikely to persist (Hirota/ Holmgren/

Nes et al. 2011; Malhi/Aragão/Galbraith et al. 2009), the extent of evaporation depends on the vegetation type and is considerably higher for rainforest than grassland or pasture, thus providing a self-sustained positive feedback. As the Amazon rainforest is critically endangered by deforestation and increasing drought risk due to climate change (Prudhomme/ Giuntoli/Robinson et al. 2013), there is a risk of disruption to the self-sustaining hydrological processes, resulting in large-scale Amazon dieback as a consequence of anthropogenic interference (Davidson/Araújo/ Artaxo et al. 2012; Malhi/Aragão/Galbraith et al. 2009).

Sea-level rise poses substantial risks to the lives and livelihoods of growing coastal populations. Irrespective of short-term projections for future sea-level rise, palaeo-evidence as well as ice-sheet modelling suggest an equilibrium global sea-level rise of approximately 2.3 m per degree of warming over the next millennia (Levermann/ Clark/Marzeion et al. 2013). A non-linear reaction of the Greenland and West Antarctic ice sheets to warming ocean and atmospheric temperatures may significantly contribute to this rise. The total ice volume of the Greenland ice sheet corresponds to 7 m of sea-level rise. The ice sheet rests nearly fully on bedrock above sea level, and its elevation, as well as the albedo feedback, will positively amplify melting induced by climate change . As the ice sheet starts to melt, elevation decreases and thus the temperature at the ice sheet's surface rises. At the same time, the melting ice sheet covers less and less land area, which changes the local surface albedo and thus changes absorbed radiation. Given these two dominant feedbacks, the critical threshold for the Greenland ice sheet is estimated at between 0.8°C and 3.2°C global mean temperature rise above the pre-industrial temperature, with a best estimate of 1.6°C (Robinson/ Calov/Ganopolski 2012). Recent insights about the bed topography of the ice sheet reveal that about 88 per cent of total ice discharge from Greenland into the ocean is channelled through deeply incised submarine glacial valleys (Morlighem/Rignot/Mouginot et al. 2014). This indicates that the Greenland ice sheet is more sensitive to oceanic melt than previously thought, suggesting a higher degree of sensitivity in the tipping dynamics of the ice sheet.

An even more dramatic picture emerges for the mostly marine West Antarctic ice sheet, which rests on bedrock below sea level. Increased sub-ice-shelf oceanic melting underneath the floating ice shelves fringing the Antarctic coast can potentially destabilize the ice sheet and lead to rapid disintegration. Recent evidence from observations and numerical model sim-

ulations indicate that such a destabilization is already under way for several large glacier systems in West Antarctica (including the Pine Island and Thwaites glaciers, see: Favier/Durand/Cornford et al. 2014; Joughin/ Smith/Medley, 2014; Rignot/Mouginot/Morlighem et al. 2014). Such a disintegration of these glacier systems would contribute about one metre or more to global sea-level rise on multi-centennial timescales and may potentially contribute to a destabilization of the whole West Antarctic ice sheet equivalent to about 4 m global sea-level rise. Additionally, the Wilkens basin in East Antarctica (about 3-4 sea-level equivalent, see: Mengel/Levermann 2014) was recently identified as being prone to marine ice-sheet instability as well.

The non-linear and potentially self-amplifying responses of elements in the Earth system may lead to severe impacts for centuries to come. Impact analyses of future climate change tend to focus on gradual, quasi-linear changes, which may alone lead to severe socio-economic impacts (Schellnhuber/Hare/Serdeczny et al. 2012), and the non-linear responses of large-scale climate components to anthropogenic perturbations are rarely taken into account (Lenton/Ciscar 2012). However, the self-amplifying nature of the responses of many of these systems may represent an at least equally significant threat to humanity, as they can neither be controlled nor easily reversed by future generations. While the assessment of such critical tipping points is not a trivial task, the recent alarming results from West Antarctica illustrate the risks posed by interference with these systems at levels of warming already experienced. In the light of these post-IPCC deadline insights, the IPCC assessment of the climate risk posed by "large-scale singular events" (see figure 11.1, high risk assessed above 3°C warming) seems to be far too optimistic.

11.5.5 Concluding Remarks

Climate change impacts do not occur in a vacuum. The negative impacts of increasing temperatures and changing rainfall patterns on human sectors can be expected to interact with each other or cascade into potentially far-reaching chains of impacts. These cumulative effects will be mediated and shaped by societal developments including population and economic growth, which in turn affect and are affected by climatic changes. Impacts projected for ecosystems, agriculture, and water supply in the twenty-first century could, for example, lead to large-scale displacement of populations, with manifold consequences for human security, health and economic and trade systems. While

each of these sectors has been the subject of research, researchers do not fully understand the wide-ranging and concomitant consequences for society which appear to be increasingly likely with higher levels of warming. Given the intricate complexity of the Earth system, impacts may also occur in a non-linear manner, significantly exacerbating the challenge for precautionary risk reduction and other adaptation measures. As the world warms towards 4°C above pre-industrial levels, the risk of complex and abrupt impacts increases to combine with the direct effects of unprecedented heat extremes and asymmetric sea-level rise.

Important sectoral model development is under way and the research community continues to fill in the picture of what a 4°C world would look like. While this will with time help to ameliorate our lack of knowledge, there will never be full certainty. In light of this, adaptation policy-making and planning needs to find ways to minimize the risks associated with climate change impacts both expected and unexpected. The safest way forward for humanity, however, is to simply avoid rather than to attempt to be prepared for the unexpected. Mitigating climate change remains our safest bet for the lives and well-being of present and future generations.

12 The Climate-Conflict Nexus: Pathways, Regional Links, and Case Studies

Tobias Ide, P. Michael Link, Jürgen Scheffran and Janpeter Schilling[1]

Abstract

The role of climate change as a potential cause of violent conflict has been debated in the scholarly and policy communities for several years. We review the most recent quantitative and qualitative literature and find that research on the issue has produced little consensual findings so far. Further, we discuss major theoretical, conceptual and empirical issues and describe possible pathways linking climate change to violent conflict. To illustrate these issues, we analyse the climate-conflict nexus in different world regions and present three qualitative case studies in north-western Kenya, the Nile Basin, and Israel/Palestine. We find that possible reasons for the lack of scientific consensus may be the difficulties of existing approaches to adequately capture the complex links between climate change, vulnerability, and violent conflict.

Keywords: Climate change, environment, violence, conflict, pathways, Kenya, Nile Basin, Israel, Palestine.

12.1 Introduction

Climate change caused by human activities such as the emission of greenhouse gases is likely to cause an overall worldwide increase in the number and/or intensity of drought conditions, heatwaves, floods, and other natural disasters,[2] with important regional variations (IPCC 2013; see chapter 11 in this volume by Schellnhuber/Serdeczny/Adams et al.). Failure to apply far-reaching mitigation and adaptation measures is likely to cause reduced freshwater availability, increased food insecurity, biodiversity loss, infrastructure destruction, a reduction of economic growth, poverty, non-voluntary migration, and increased stress on health systems (IPCC 2014). Those already poor and marginalized will be affected most severely by climate change and its impacts on biophysical and social systems (see chapter 11 in this volume by Schellnhuber/Serdeczny/ Adams et al.). The impacts of current and future climate change are aggravated by rapid population growth (see chapter 10 in this volume by Zlotnik), poverty, large-scale land acquisitions by foreign investors, and similar processes of resource appropriation by the rich and powerful (Cotula 2012; Houdret 2012).

Climate change is increasingly seen as a threat to several dimensions of security, including human security (Brauch/Scheffran 2012). Since at least 2007, the possible implications of climate change and its consequences for peace, conflict, and security have received the attention of researchers, think tanks, and policymakers alike. In the same year, the IPCC and Al Gore received the Nobel Peace Prize for their efforts to mitigate climate change. The Nobel Prize Committee (2007) explained its decision as follows: "Extensive climate changes may alter and threaten the living conditions of much of mankind. They may induce large-scale migration and lead to greater competition for the earth's resources [...]. There may be increased danger of violent conflicts and wars, within and between states." In the same year and again in 2011, the UN Security Council discussed the issue of climate

2   The term natural disasters in this chapter is used to refer to natural hazards (potential geo- or biophysical threats) which become active and negatively influence a humanitarian crisis.

change. And very recently, the CNA Military Advisory Board (2014: 2)[3] warned that "in many areas, the projected impacts of climate change [...] will serve as catalysts for instability and conflict". Are such claims justified by the scientific literature? Recently, a meta-study by Hsiang et al. (2013: 1) found "strong causal evidence linking climatic events to human conflict" (see also Hsiang/Burke 2014). This conclusion was heavily criticized (Buhaug 2014; Buhaug/Nordkvelle/ Bernauer et al. 2014). Other reviews of the literature could not detect any scientific consensus on the relationship between climate change and violent conflict (Ide/Scheffran 2014; Scheffran/Brzoska/Kominek et al. 2012a; Theisen/Gleditsch/Buhaug 2013). Mixed results were also presented in the fifth assessment report of the IPCC (2014), particularly in chapters 12 and 19 (Gleditsch/Nordås 2014).

The debate on climate change and (violent) conflict is highly relevant for the debate on sustainability transitions and sustainable peace. In order to realize a sustainable transition towards a world characterized by low CO2 emissions, a small ecological footprint and a strong role for democracy, stable, reliable and accountable institutions are necessary. The possible adverse impacts of climate change on societal stability could erode the development of such institutions, and this might trigger a downward spiral of violent conflict and environmental degradation (UNEP 2009). Similarly, violent conflict, especially within states, is known to have net negative effects on the environment (Reuveny/Mihalache-O'Keef/Li 2010). On the other hand, recent studies suggest that if the impacts of adverse environmental changes on conflict are adequately handled, they can facilitate cooperation and reconciliation between rival groups and contribute to sustainable peace (Ide/Scheffran 2014; Scheffran 2011; Streich/Mislan 2014; see chapter 13 in this volume by Scheffran).

The aim of this chapter is to give the reader an overview of the current academic debate on the possible link between climate change and violent conflict and to highlight the complexity of the issue by addressing conceptual and empirical perspectives. In the next section, we discuss major theoretical and conceptual issues in the research on the nexus between climate change and violent conflict (12.2). Afterwards, the results of qualitative and quantitative empirical

research on possible climate-conflict links are evaluated for possible pathways and world regions (12.3). We then illustrate the theoretical issues and causal pathways discussed by presenting the findings of three qualitative case studies (12.4). Each of these studies was conducted in a region that is widely perceived to be a hot spot of climate change and conflict, namely north-western Kenya (12.4.1), the Nile River Basin (12.4.2), and Israel/Palestine (section 12.4.3). Finally, a conclusion is drawn (12.5).

12.2   Conceptual Considerations on the Nexus of Climate Change and Violent Conflict

As in many other social science research fields, the literature on climate change and (violent) conflict does not use its core concepts and variables in a standardized manner (Salehyan 2014). Climate change is commonly defined as "a statistically significant variation in either the mean state of the climate or in its variability, persisting for an extended period (typically decades or longer)" (IPCC 2001), while climate itself refers to the average patterns of meteorological variables such as temperature and precipitation over a long period of time. But empirical studies operationalize climate change in many different ways, ranging from monthly and annual changes (often compared with long-term averages or trends) to climate processes that take place over decades and even centuries (Buhaug/Nordkvelle/Bernauer et al. 2014). In terms of their dependent variable, most studies on climate change and conflict focus on the reciprocal use of direct, physical violence against humans, typically resulting in at least one fatality and including the state as a party (Scheffran/Ide/Schilling 2014). Some scholars use wider definitions of violence as dependent variables, ranging from small-scale, non-lethal communal violence (and sometimes even baseball disputes) to full-blown civil and inter-state wars (Hsiang/Burke/ Miguel 2013). Forms of structural violence as well as genocide have so far been largely absent in the research on climate change and conflict (Zimmerer 2014).

In this chapter, we define conflict broadly as a process in which at least two social groups perceive their respective interests as contradictory and undertake actions in order to enforce or articulate these interests (Baron 1990; Dietz/Engels 2014). Conflicts can catalyse positive societal change. However, if differences in interests cannot be overcome or at least mediated, tensions increase, pushing parties in conflict

towards extreme actions such as the use of violence. When at least one of these social groups uses direct, physical violence in order to articulate or enforce its interests, the conflict is considered to be violent (Bonacker/Imbusch 2010: 83–87).

Climate change is often conceived as a "threat multiplier" (e.g. Buhaug/Theisen 2012: 51; Johnstone/Mazo 2011: 11; Njiru 2012: 520). This metaphor is used to make the point that if there are no pre-existing conditions favourable to violent conflict onset (i.e. factors that climate change can multiply), then the implications of climate change for societal stability and violent conflict will not be significant. Such factors include, inter alia, population growth, livelihood insecurity, increased demand and unequal distribution of resources, pre-existing social, ethnic, or religious tensions, and the lack of political legitimacy of governments (Carius/Tänzler/Winterstein 2006; Dixon 2009).

From an actor-centred approach, two main causal mechanisms are relevant for the potential links between climate change and violent conflict. In order to start, perpetuate, or join a violent conflict, individuals and social groups must have both the motivation and the capability or opportunity to do so (Scheffran/Ide/Schilling 2014; Scheffran/Link/Schilling 2012). Motivations may be relevant if climatic changes (higher temperatures, prolonged droughts, or more intense storm events) negatively affect the availability of key resources such as food, land, water, or income. The resulting competition for these resources can take place along pre-existing cleavages and escalate into violence (Homer-Dixon/Blitt 1998). If certain social groups are more strongly affected by natural disasters than others or receive less post-disaster support, relative deprivation can increase grievances and facilitate their violent escalation (Berrebi/Ostwald 2011; Nel/Righarts 2008). Similarly, resource scarcity can lead people to migrate, causing tensions over scarce resources or identity conflicts in the receiving area (Reuveny 2007). Regarding capability and opportunity, climate change may reduce tax revenues due to its negative impact on economic growth and instead increase the amount of money that a state has to spend on infrastructure and disaster relief because of extended damage caused by disasters. Hence, climate change may weaken already fragile states, making them an easier target for rebel groups and reducing their capacity to prevent communal violence (Kahl 2006). Furthermore, climate change potentially reduces recruitment costs for fighters. If, for instance, resource scarcity and natural disasters lead to lower yields and lower incomes, the opportunity costs for people to join a conflict group

decline (Barnett/Adger 2007). Climate change may also diminish the capacity to fight, e.g. by limiting resource abundance, destroying military infrastructure or restricting the mobility of rebel forces (Adano/Dietz/Witsenburg et al. 2012; Salehyan/Hendrix 2014).

One of the main deficits in the literature on the effects of climate change and violent conflict is the absence of a theoretical basis that would take into consideration the complexities of these issues. One promising approach is to represent the relationship between climate change and violent conflict within a comprehensive framework that allows the integration of the environmental and societal conditions of violent conflict, as well as quantitative and qualitative factors (for a comprehensive analysis see Scheffran/Battaglini 2011; Scheffran/Link/Schilling 2012). In particular, the degree of vulnerability is important in determining the conflict potential of climate change (Ide/Schilling/Link et al. 2014). Vulnerability is defined here as the "predisposition to be adversely affected" (IPCC 2012: 32) by climate change and can be broken down into three factors: i) exposure to climate change, ii) sensitivity to climate change, and iii) adaptive capacity (Adger 2006; IPCC 2007a). Exposure to climate change concerns the frequency and intensity of extreme weather events, the variability of weather parameters such as temperature and precipitation, cloud and wind patterns, and long-term changes in such parameters. These changes act as stressors on natural systems and human societies, which may have direct or indirect impacts on natural resources and related infrastructure (e.g. soil and water, ecosystems, agriculture and land use, forests and biodiversity, energy and economic systems, networks, and infrastructures) that are important for human livelihood, well-being, and survival (IPCC 2014).

Sensitivity is "the degree to which a system is modified or affected by perturbations" (Adger 2006: 270). For instance, a region in which a large percentage of the population depends on rain-fed agriculture is more sensitive to more intense/frequent droughts (as a consequence of climate change) than a region characterized by a strong tertiary sector. Furthermore, vulnerability critically depends on adaptive capacity and how people actually respond to climate stress. Some responses can help adapt and minimize the risks, others may cause new problems, e.g. through mitigation risks, maladaptation, forced migration, or climate engineering (Maas/Scheffran 2012; Scheffran/Cannaday 2013; Tänzler/Maas/Carius 2010). For existential threats the spectrum of responses may be restrained,

making non-legal and violent acts more likely, but these could also force people to work together to improve their chances for survival, e.g. through risk reduction, strengthening resilience, and improving sustainability (Feil/Klein/Westerkamp 2009).

Vulnerability and conflict affect each other, implying that the climate-conflict link is not a one-way street. Considering the regional exposure to climate change and violent conflict, there are countries that are sensitive to both violent conflict and future climate change. A comparison of the number of deaths from natural disasters and battle-related deaths in the past shows that both are highest in countries with a low human development index (Scheffran/Brzoska/Kominek et al. 2012b). Inhabitants of these countries already experience increased threats to their lives and health that undermine human development. If climate change adds to these risks and vulnerabilities, it can augment humanitarian crises and aggravate existing conflicts without directly causing them. Thus, it can be argued that violent conflict has a devastating effect that makes societies also more vulnerable to climate change. In turn, climate change can undermine social stability, which increases vulnerability to violent conflict (Scheffran/Ide/Schilling 2014).

While theoretical considerations can help to structure and assess the complex climate-conflict nexus, it is essential to examine in more detail the potential pathways between climate change and violent conflict as well as the regionally specific conditions. To distinguish facts from fiction it is essential to analyse the empirical state of the art and the research deficits, and to make an in-depth assessment of pathways and regional conditions for selected case studies.

12.3   State of the Art

12.3.1   Pathways and Quantitative Evidence

In the research on climate change and conflict, qualitative single-case and quantitative large-N studies are the dominant methods. A few studies have made efforts to explore the middle ground between them and concluded that environmental stress is related to violent conflict, but only under very specific conditions (Bretthauer 2014; Ide 2015). Quantitative large-N studies are currently the most widely accepted methodological approach in the research on climate change and violent conflict, although they face severe problems regarding the quality of their data sets and their ability to capture complex human-nature interac-

tions (Bernauer/Böhmelt/Koubi 2012; Detges 2014; Ide/Scheffran 2014; Scheffran/Brzoska/Kominek et al. 2012a; Vivekananda/Schilling/Smith 2014). While some recent studies suggest a link between water scarcity and military inter-state disputes (Devlin/Hendrix 2014; Hensel/Mitchell/Sowers 2006; Tir/Stinnett 2012), climate change is unlikely to have an impact on inter-state wars in the short to middle term (Gleditsch/Furlong/Hegre et al. 2006; Wolf/Yoffe/Giordano 2003). Regarding intra-state violent conflict, more studies are available but there is less consensus. Particular attention has been paid to the degradation of freshwater resources, the decline in food production, increasing storm and flood disasters, and environmentally-induced migration (Scheffran/Battaglini 2011; WBGU 2008). In the following, we discuss the degree of consensus among quantitative studies on the six pathways connecting climate change and violent conflict. The pathways are structured along the physical impacts of climate change and include higher temperatures, reduced precipitation, more precipitation extremes, lower freshwater availability, land degradation, and climate-related natural disasters (see table 12.1).

12.3.1.1   Temperature Changes

Higher temperatures are suspected of increasing the risk of violent conflict onset because they aggravate water scarcity (through evaporation and the melting of glaciers) or crop failure (through heat and water stress). Several studies in social psychology indicate "that in many settings hot temperatures cause increases in aggression" (Anderson 2001: 37), which may escalate into conflict via spirals of violence or an increased preparedness to fight (Anderson/DeLisi 2011). However, the empirical link between higher temperatures and violent conflict remains disputed, as can be observed in table 12.1. Burke, Miguel, Satyanath et al. (2009) claim a strong link between higher temperatures and more violent conflict but the robustness of their findings has been subject to controversy (Buhaug 2010; Hsiang/Meng 2014). Existing empirical evidence does not allow us to draw clear or universal conclusions on the relationship between higher temperature and violent conflict. Such a link would be quite indirect and is therefore hard to support by qualitative evidence. We are not aware of any concrete empirical cases that justify a significant temperature–violence link. There are some studies that claim a strong and direct link between colder temperatures and war for long historical periods (Tol/Wagner 2010; Zhang/Brecke/Lee et al. 2007) but these studies

Table 12.1: Central findings of large-N studies on possible pathways connecting climate change to violent conflict. **Source:** Expanded from Ide/Scheffran 2014).

Pathway	Increases the risk of violent conflict significantly	Does not significantly increase the risk of violent conflict
higher temperatures	(Burke/Miguel/Satyanath et al. 2009) (Hsiang/Meng/Cane 2011) (Landis 2014) (Maystadt/Ecker 2014) (O'Loughlin/Witmer/Linke et al. 2012) (O'Loughlin/Linke/Witmer 2014) (Yeeles 2015)	(Buhaug 2010) (Couttenier/Soubeyran 2013) (Koubi/Bernauer/Kalbhenn et al. 2012) (Salehyan/Hendrix 2014) (Theisen 2012) (Wischnath/Buhaug 2014)
reduced precipitation	(Bohlken/Sergenti 2010) (Couttenier/Soubeyran 2013) (Ember/Adem/Skoggard et al. 2012) (Fjelde/von Uexkull 2012) (Hendrix/Glaser 2007) (Hendrix/Salehyan 2012) (Hsiang/Meng/Cane 2011) (Maystadt/Ecker 2014) (Miguel/Satyanath/Sergenti 2004) (Raleigh/Choi/Kniveton 2015) (Raleigh/Kniveton 2012) (von Uexkull 2014)	(Buhaug 2010) (Buhaug/Theisen 2012) (Brückner/Ciccone 2010) (Miguel, Edward; Satyanath et al. 2009) (Koubi/ Bernauer/Kalbhenn et al. 2012) (Meier/Bond/Bond 2007) (Nel/Righarts 2008) (O'Loughlin/Witmer/Linke et al. 2012) (O'Loughlin/Linke/Witmer 2014) (Salehyan/Hendrix 2014) (Theisen 2012) (Theisen/Holtermann/Buhaug 2012) (Wischnath/Buhaug 2014) (Witsenburg/Adano 2009) (Yeeles 2015)
more precipitation extremes	(Hendrix/Salehyan 2012) (Raleigh/Kniveton 2012)	(Koubi/Bernauer/Kalbhenn et al. 2012) (O'Loughlin/Linke/Witmer 2014) (Wischnath/Buhaug 2014)
lower freshwater availability	(Gizelis/Wooden 2010) (Hauge/Ellingsen 1998) (Raleigh/Urdal 2007)	(Couttenier/Soubeyran 2013) (Hendrix/Glaser 2007) (Salehyan/Hendrix 2014) (Theisen 2008)
land degradation	(Biermann/Petschel-Held/Rohloff 1998) (Esty/Goldstone/Gurr et al. 1999) (Hauge/Ellingsen 1998) (Raleigh/Urdal 2007) (Theisen 2008)	(Hendrix/Glaser 2007) (Rowhani/Degomme/Guha-Sapir et al. 2011)
climate-related natural disasters	(Berrebi/Ostwald 2011) (Besley/Persson 2011) (Drury/Olson 1998) (Hsiang/Meng/Cane 2011) (Nardulli/Peyton/Bajjalieh 2015) (Nel/Righarts 2008)	(Bergholt/Lujala 2012) (Ghimire/Ferreira/Dorfman 2015) (Omelicheva 2011) (Slettebak 2012)

focus on the pre-industrial and pre-globalization era and are therefore of limited relevance for violent conflicts in the twentieth and twenty-first centuries.

12.3.1.2 Precipitation Reductions

Lower precipitation is associated with a lower availability of water and a lower availability of food due to crop failure. Lack of these resources can stimulate grievances and provide opportunities for violent

behaviour as discussed in section 12.2. Table 12.1 indicates that the majority of large-N studies find no link between precipitation reduction and violent conflict onset. However, five recent and methodologically advanced studies do detect such a link (Ember/ Adem/Skoggard et al. 2012; Fjelde/von Uexkull 2012; Hendrix/Salehyan 2012; Raleigh/Kniveton 2012; von Uexkull 2014). The debate continues. This is especially the case since many of the studies of precipitation and violence have problems interpreting their

results in a meaningful way. To give an example: for Kenya, both Theisen (2012) and Witsenburg and Adano (2009) find that violent conflicts occur primarily in regions and time periods with above-average rainfall. But this does not necessarily support their conclusion that low precipitation and the associated scarcity of pasture and water are unrelated to violent conflict. From the perspective of spatial theory, one would expect people who are negatively affected by reductions in precipitation to migrate into wetter areas and to compete for the remaining resources there (Detges 2014; Rutten/Moses 2014). Similarly, during wetter periods opportunity structures are more favourable for violent cattle raids: cattle are strong, vegetation for hiding and labour surplus are available, rain washes away tracks etc. But that does not exclude the possibility that these raids become necessary in the first place due to the need to restock herds after a severe drought (Schilling/Opiyo/Scheffran et al. 2014).

12.3.1.3 More Precipitation Extremes and Increased Precipitation Variability

For many regions (e.g. northern and eastern Africa) climate models do not necessarily predict an absolute decrease in precipitation, but rather an increase in precipitation variability. This means that instances of heavy rainfall, which may cause floods, landslides, or crop failure, alternate with longer periods of very little rainfall. The potential consequences of such alternating climate patterns include a reduced ability for anticipatory planning (e.g. of stockpiling, sowing, or infrastructure work), an increase in food, water, economic, and cultural insecurity, increased grievances as well as a weakening of the state, and a reduction of opportunity costs for violence. Social scientists have reacted to this discussion and investigated whether more rainfall extremes increase the risk of violent conflict. However, research on this issue is very recent and has so far not produced unambiguous results, as can be deduced from table 12.1.

12.3.1.4 Freshwater Availability

Earlier studies on environmental change, resource scarcity, and violent conflict also focus on freshwater scarcity, which can be caused by climate change as well. However, the degree of scientific consensus on the link between water scarcity and violent conflict is limited, as table 12.1 indicates. Most data on water scarcity are also not exogenous to socio-economic variables such as level of development, resource management

practices, or population size, and are usually only available at a national level. In contrast, many recent studies use subnational administrative areas or grid cells as the unit of analysis. This makes it even harder to draw causal inferences from studies on freshwater scarcity and violent conflict (Koubi/Bernauer/Kalbhenn et al. 2012; Meierding 2013).

12.3.1.5 Land Degradation

With the conflict relevance of land degradation, there seems to be the greatest degree of scientific consensus. Five out of seven statistical studies find a link between land degradation and violent conflict onset. The existence of such a link is also claimed by various qualitative studies, which emphasize a link between land/soil degradation, land scarcity, the political instrumentalization of the related grievances, and violent conflict (e.g. Homer-Dixon/Blitt 1998; Kahl 2006). However, four out of the five studies detecting a correlation between soil degradation and violent conflict use the criticized GLASOD data set (Benjaminsen 2008), while the most recent study using a more comprehensive land degradation indicator is unable to confirm the existence of such a link (Rowhani/Degomme/Guha-Sapir et al. 2011). Furthermore, Fearon (2010) and Urdal (2005) find no correlation between per capita cropland scarcity and violent conflict. Per capita cropland scarcity may be a particularly appropriate operationalization since resource scarcity is the supposed mediating mechanism between land degradation and violent conflict, while even a high level of land degradation may be unproblematic if the affected area is sparsely populated.

12.3.1.6 Climate-related Natural Disasters

Natural disasters can destabilize societies with weak economies, mixed political regimes, and pre-existing conflicts. The hypothesized links between natural disasters and climate change are well summarized by Bhavnani (2006: 38):

> Natural disasters in general contribute to conflict because they create competition for scarce resources, exacerbate inequality with the unequal distribution of aid, change power relationships between individuals, groups, and the organizations that serve them, and can create power vacuums and opportunities for warlords to usurp power.

However, table 12.1 indicates a lack of consensus on the link between climate-induced natural disasters and violent conflict. Nearly all of these studies rely on the EM-DAT database (CRED 2014). To be recorded by

EM-DAT, a natural disaster must either cause at least ten fatalities, affect at least a hundred people, cause the declaration of a state of emergency, or cause a call for international assistance. This again raises concerns with regard to endogeneity. Strong states with a wealthy population are less likely to experience violent conflict (Dixon 2009) and they can often also cope better with natural disasters, thus reducing the number of events EM-DAT registers for such countries.

12.3.1.7 Other Pathways

There are no quantitative studies on the link between environmental or climate change-induced migration and violent conflict, presumably because of inadequate or incomplete data (Reuveny 2008). Recent studies suggest considering migration as an adaptive response to climate change that includes the development of capabilities of migrant networks (Black et al. 2011; Scheffran/Marmer/Sow 2012). There is wide agreement in the literature that low economic growth, which is predicted to be a consequence of climate change (IPCC 2014), increases the risk for violent conflict onset (Dixon 2009; Hegre/Sambanis 2006). However, explicit quantitative tests have so far only provided weak support for this pathway (Koubi/Bernauer/Kalbhenn et al. 2012). Finally, climate change is also likely to contribute to food insecurity (IPCC 2014). Several recent empirical studies suggest that higher food prices increase the risk of riots and other forms of violent conflict events (e.g. Rowhani/Degomme/Guha-Sapir et al. 2011; Hendrix/Haggard 2015; Raleigh/Choi/Kniveton 2015; Smith 2014; Wischnath/Buhaug 2014b). However, Sneyd/Legwego/Fraser (2013) show that such forms of violence are triggered by a complex set of political and economic factors rather than by higher food prices alone.

12.3.2 The Climate-Conflict Nexus in Different World Regions

Several regions have emerged as focal points of the qualitative debate on climate change and conflict in recent years, each of which has vulnerabilities specific to itself (Scheffran/Battaglini 2011; WBGU 2008):

a.) Middle East: In early 2011, large protests against the regimes in Egypt, Libya, and Tunisia marked the beginning of the 'Arab Spring'. Some analysts consider rising food and especially bread prices as an important cause of these protests, especially in Egypt. Price spikes were caused by, among other factors, extreme droughts in Russia (Egypt's largest wheat supplier) and China, the world's largest wheat consumer and producer (Johnstone/Mazo 2011; Sternberg 2012). Gleick (2014) recently argued that an exceptional drought in important agricultural regions from 2006 to 2010 fuelled grievances and the protests that escalated into the Syrian civil war. Other researchers remain sceptical and point to political mismanagement as the key reason for the humanitarian crisis succeeding the Syrian drought (de Châtel 2014). The impact of climate change on the Nile (Link et al. 2012) and the Israeli–Palestinian conflict (Brown/Crawford 2009; Feitelson/Tamimi/Rosenthal 2012) is also frequently discussed.

b.) East Africa: The role of drought in causing violent conflict between pastoral groups, or between pastoral and sedentary groups, is also intensely debated for Ethiopia, Kenya, Tanzania, and Uganda. While some studies conclude that such a link exists (Ember/Adem/Skoggard et al. 2012; Schilling/Opiyo/Scheffran 2012; Temesgen 2010), others remain skeptical (Adano et al. 2012; Benjaminsen/Maganga/Abdallah 2009; Eaton 2008; see also 12.4.1). The ethno-political violent conflict in western Sudan is sometimes considered to be "the world's first climate war" (Faris 2007). However, most researchers agree that drought-induced livelihood insecurities, grievances, and migration patterns were at best one among several causes of the civil war in Darfur (Scheffran/Ide/Schilling 2014; Selby/Hoffmann 2014). Other assessments even conclude that the years preceding the onset of violent conflict in 2003 were unusually wet (Brown 2010; Kevane/Gray 2008).

c.) West Africa: In the northern regions of Nigeria, more frequent and/or intense droughts have caused a southward migration of pastoralist groups, and this has contributed to livelihood or cultural conflicts with sedentary farmers in the receiving regions (Nyong/Fiki/McLeman 2006; Obioha 2008). Similar conflict dynamics are described for Mali, although their link to climate change remains disputed (Benjaminsen/Ba 2009; Benjaminsen/Alinon/Buhaug et al. 2012). Other studies focus on the conflict relevance of land tenure systems in Cameroon (Gausset 2007) and food price spikes in Burkina Faso (Engels 2014).

d.) Central Asia: Irrigated agriculture is of great importance in many central Asian states. The water for irrigation is mainly extracted from large rivers (e.g. Syr Darya, Amu Darya), whose flow is likely to be reduced in the long run by glacial melt-

ing. The resulting water scarcity has the potential to worsen already existing international and inter-communal tensions in this ethnically heteroge-neous and in parts politically unstable region. However, the relevance of water for the dynamics of (violent) conflict in central Asia has been chal-lenged (Bernauer/Siegfried 2012; Bichsel 2009; de Martino/Carlsson/Rampolla et al. 2005; Sehring/Giese 2011).

Other potential climate conflict hot spots include North Africa (Schilling/Freier/Hertig et al. 2012), South Asia (Wischnath/Buhaug 2014), Latin America (Stark/Guillén/Brady 2012), and the Pacific (Weir/Virani 2011). However, more in-depth research on these regions is necessary. Following our review of the qualitative and quantitative evidence in this section, we now present in-depth qualitative analyses of three conflict hot spots and assess how the dynamics of (possible) disputes are influenced by climate change.

12.4   Case Studies

In order to illustrate the conceptual and empirical points above and to complement the extensive discus-sion of the quantitative literature with further qualita-tive evidence, we now discuss the existence and rele-vance of a potential climate-conflict nexus for three case studies. In order to maximize the insights gained, we choose three areas that are quite different with regard to their location, the actors involved, the means of conflict, and the level of violence. Turkana (Kenya) is characterized by frequent armed violence between non-state pastoralist groups, while the disputes about water from the Nile are carried out non-violently between the riparian states. The Israeli–Palestinian conflict cannot be clearly characterized as either intra- or inter-state. It has also experienced, at least in recent years, high levels of structural violence and the erratic use of direct, physical violence. All three cases are also frequently discussed as potential climate security hot spots (Brown/Crawford 2009; O'Loughlin/Witmer/Linke et al. 2012; Piontek 2010; WBGU 2008).

12.4.1   Turkana (Kenya)

Turkana, located in north-western Kenya, is among the country's poorest and economically and politically most marginalized administrative Districts (UNDP 2006, 2010). The dominant livelihood is pastoralism, which is well adapted to the semi-arid to arid climate. Most of the rainfall is received during the 'long rains'

between March and May and the 'short rains' between October and December (McSweeney/New/Lizcano 2008). Because of the region's strong depen-dence on rain-fed water and pasture resources and the parallel occurrence of violent conflict between pastoral groups, the media tend to draw direct links between drought and conflict in Turkana. In response to the drought of 2009, the Guardian (2009) for example announced "the first climate change conflicts". Scien-tific studies on pastoral conflict in Kenya suggest that matters are more complex while at the same time acknowledging that climate-influenced resource avail-ability plays a role in pastoral conflicts (Campbell/Dalrymple/Rob et al. 2009; Mkutu 2008; Schilling/Opiyo/Scheffran et al. 2014; Temesgen 2010; Theisen 2012; Witsenburg/Adano 2009). However, the impor-tance of environmental changes and particularly of global climate change as a conflict driver varies across studies. Several studies (Campbell/Dalrymple/Rob et al. 2009; Ember/Adem/Skoggard et al. 2012; Erik-sen/Lind 2009; Meier/Bond/Bond 2007; Mkutu 2008; Njiru 2012; Omolo 2010; Temesgen 2010) stress that climate-related and climate-unrelated resource scarcity is a conflict driver while others associate a higher level of violence with more rainfall and hence increased resource availability (Adano/Dietz/Witsen-burg et al. 2012; Eaton 2008; Theisen 2012; Witsen-burg/Adano 2009). In contrast, it is undisputed that the Turkana engage in violent conflict with other groups and particularly with the Pokot of Kenya and Uganda (Mkutu 2006; Schilling/Opiyo/Scheffran 2012). These conflicts mostly articulate themselves through violent livestock thefts called 'raids' and direct attacks on individuals and even villages (Schil-ling/Opiyo/Scheffran 2012). Between 2006 and 2009 the local non-governmental organization *Turkana Pastoralist Organization* (TUPADO) recorded 592 raid-related deaths in Turkana (Schilling/Opiyo/Scheffran 2012; TUPADO 2011).

Over the past fifty years Kenya has experienced a warming of 1°C, which is well above the global aver-age (IPCC 2007b). Local ground measures from the meteorological station in Lodwar suggest that the temperature increase is even stronger in Turkana (Schilling/Opiyo/Scheffran et al. 2014).

Precipitation data for the past fifty years show no clear trend for Kenya (Eriksen/Lind 2009; Tutiempo 2011). However, the proportion of rain falling in heavy rainfall events has increased (McSweeney/New/Lizcano 2008). Some authors (e.g. Mude/Bar-rett/Carter et al. 2009) argue that the frequency of droughts has increased in northern Kenya. For Tur-

Figure 12.1: Overview of the case study areas. **Source:** The authors.

Case studies — Israel and Palestine — Nile Basin States — Turkana (Kenya)

kana, Opiyo, Wasonga, Nyangito et al. (2014) find that the occurrence of extreme droughts has increased since the 1990s. While climate projections for eastern Africa are less reliable than for other parts of Africa (IPCC 2013; Klehmet 2009), the majority of models suggest a strong increase in temperature and rainfall variability (IPCC 2007b, 2013; Schilling/ Opiyo/Scheffran et al. 2014). Both trends are likely to increase the drought frequency and possibly also the severity of droughts.

While droughts have the potential to significantly decrease herds on occasion, the increased rainfall variability is likely to decrease the predictable availability of water and pasture in general. Increased drought risk and fewer reliable resources are likely to affect the pastoral conflicts over water, pasture, land, and territory. Based on interviews with members of the Turkana and Pokot communities and an analysis of raiding records and climate data, Schilling, Opiyo, Scheffran et al. (2014) have developed the *Resource Abundance*

and Scarcity Threshold (RAST) hypothesis, which suggests that droughts increase the pressure to compensate own livestock losses through raiding. But the raiding to restock is mostly conducted in and around the rainy seasons because the raided animals are healthier, they can travel longer distances, and raiders find cover in the higher vegetation. In contrast, raiding during dry seasons is only conducted when a certain threshold of resource scarcity is reached. During this time, raiding serves the purpose of gaining or securing control over scarce pasture and water resources rather than restocking. The RAST hypothesis hence suggests that climatic changes have and are likely to continue to aggravate the violent conflicts between the Turkana and the Pokot.

However, this conclusion does not mean that climate change is an actual cause of conflict. Political and economic marginalization, including the limitation of pastoral movement and the inability of the central government to provide security for the pastoral communities in northern Kenya, are key conflict causes that are then exacerbated by climate-related resource scarcities (Schilling/Opiyo/Scheffran 2012; Schilling/Opiyo/Scheffran et al. 2014). Recently, major oil reserves have been found in the conflict zone between the Turkana and the Pokot (Tullow 2014). While oil exploitation has aggravated pastoral conflicts in Sudan (Chavunduka/Bromley 2011), it is too early to tell if oil is not only driving global climate change but also local conflicts in Turkana.

12.4.2   Nile River Basin

The Nile River Basin is a region with a cultural history that dates back to the fourth millennium BCE. Since then it has served as a lifeline for the entire region. As there are no other water sources, riparians are often critically dependent on the Nile waters, particularly in Egypt which, together with Sudan, Ethiopia, and Uganda, is the key player in the Nile Basin when it comes to the sharing of the waters of the river. The balance of power that can be observed today is the result of a long set of developments in the past that cemented Egypt's dominance in the area. However, this dominance is challenged by the other riparians of the Nile who are economically developing quickly. In conjunction with a continued strong population increase in the region and progressing climate change (IPCC 2013), there is a distinct possibility that conflicts may erupt over the distribution of the limited Nile waters among the riparians. On the other hand, there are basin-wide efforts to cooperate on water issues, and

these have led to the formation of the *Nile Basin Initiative* (NBI) (Peichert 2003). Here, we want to address the boundary conditions that govern the distribution of this scarce resource among the many riparians.

Current disputes in the Nile Basin about water allocation are based on the historic asymmetry between the downstream country Egypt, which can be considered the hydro-hegemon (Cascão 2009; Zeitoun/Warner 2006) of the basin, on the one side, and the upstream states on the other side. Hydro-hegemony rests on three pillars: the location of the country, its military, economic, ideational, political, and bargaining power, and its exploitation potential. Even though Egypt's location far downstream puts it at a disadvantage, it is the dominant country when it comes to power and exploitation potential. This status of Egypt has grown historically and is based on the extensive external support it has received from Great Britain in colonial times and from other countries in subsequent decades, e.g. for the construction of the Aswan High Dam (Allan 2009; Link/Piontek/Scheffran et al. 2012; Piontek 2010). Egypt is highly dependent on the Nile waters since there are practically no other sources of renewable water in the country (Schilling/Freier/Hertig et al. 2012; Waterbury 1979). Consequently, it has a strong interest in preserving its 'historic' rights to the river's water in treaties.

The two fundamental treaties initially governing the water allocation of the Nile date back to 1929 and 1959. The first was a treaty between the United Kingdom, Egypt, and Sudan, and institutionalized "the Egyptian belief in 'natural and historic rights' to the Nile water" (Cascão 2009: 245). An adjustment was necessary because of the construction of the Aswan High Dam in 1959. The resulting agreement implicitly left no water to the upstream countries of the Nile. Therefore, this treaty manifested a strong division between the upstream and downstream regions of the Nile Basin (Waterbury 1979).

Since the beginning of the twenty-first century, there have been extensive efforts by all riparians to overcome this division and to foster cooperation. The NBI has become an institutional framework for many cooperative projects (Mekonnnen 2010). Furthermore, a Cooperative Framework Agreement was negotiated and signed by the upstream countries Ethiopia, Uganda, Rwanda, and Tanzania, followed by Kenya (Al Masry/Al Youm 2010). With the signature of Burundi in February 2011 as the sixth country, the ratification of the agreement now could proceed despite Egypt's and Sudan's continued opposition (World Politics Review 2011). This development high-

lights the upstream countries' increasing emancipation and their challenge to Egypt's status as hydro-hegemon. In addition, the Arab Spring that has triggered considerable political change in Egypt since 2011 has created the opportunity to alter the Egyptian approach towards regional integration and cooperation over the Nile waters. Also, the independence of South Sudan in July 2011 has the potential of influencing upstream–downstream relations by possibly leading to new coalitions.

Current struggles for adequate water allocation schemes in the Nile Basin occur in the wake of large challenges regarding demographic and socio-economic development, which steadily increase the pressure on the Nile as a water resource, while there is no basin-wide agreement on Nile water use yet and a situation of low-level conflict remains (Cascão 2009). Under these circumstances, climate change imposes an additional pressure on water resources and augments the effects of other current challenges that could possibly trigger conflict and social destabilization (Goulden/Conway/Persechino 2009; Kim/Kaluarachchi 2009). One important issue resulting from altered temperature and precipitation patterns is the changed agricultural yield (Agrawala/Moehner/El Raey et al. 2004; Müller/Cramer/Hare et al. 2011). Agriculture is likely to become even more dependent on irrigation, which in turn reduces the possibilities of allocating the water to other purposes. Therefore, measures need to be taken to offset this higher vulnerability; one possibility is the sharing of benefits from water use among riparians instead of sharing the water itself (Rahman 2013). However, this appears to be difficult to achieve because of lack of political will to cooperate and differences in socio-economic backgrounds among the riparians.

So even without altered environmental conditions due to climate change, the chances for cooperation among riparians are already hard to assess. The additional influence of climate change on cooperation in the Nile Basin is still uncertain (Kim/Kaluarachchi 2009; Link/Piontek/Scheffran et al. 2012). This has to do with the fact that it is not yet clear how climate change will affect the water availability in the basin in the future. Climate models disagree on whether the overall water availability in the Nile will increase or decrease or whether merely the variability of precipitation will increase. The key area for the water supply of the Nile Basin is the Ethiopian highlands (Kim/Kaluarachchi 2009). This makes it hard to define adequate measures to increase the adaptive capacity of the region. Also, the riparians' actions may be guided by short-term political considerations despite the fact that effective climate change adaptation is likely contingent on strong cooperation. Reduced water availability may increase vulnerability, conflict, and barriers to cooperation but simultaneously presses riparians to cooperate for the most efficient use of the available water (Solomon 2014). And there is hope that in the long run cooperation will prevail, as it is much more likely in transboundary watersheds than conflict (Wolf 1998; Yoffe/Wolf/Giordano 2003). In contrast, the short-term impact of changing environmental conditions on the riparian relations is likely to result in an enhanced securitization of water. This would lead to increased distrust among the riparians (Stetter/Herschinger/Teichler et al. 2011) and is thus a threat to basin-wide cooperation as it emphasizes unilateral action rather than joint efforts (Link/Piontek/Scheffran et al. 2012).

In addition to water allocation issues, Egypt is potentially exposed to and adversely affected by another kind of climate change impact: sea level rise. Some of the coastal zones of Egypt are artificially protected, and large parts of the coast rely on natural protective measures. Nonetheless, some of the low-lying areas are hardly protected and thus highly vulnerable (Frihy/El-Sayed 2013; Link/Kominek/Scheffran 2013). Already, a moderate increase in sea level can cause extensive economic damage (Dasgupta/Laplante/Murray et al. 2011) and force millions of people to adapt or relocate, particularly in metropolitan areas such as Alexandria (El Raey 1997). The current state of Egyptian coastal protection is insufficient to counter the expected future rise in sea level in the eastern Mediterranean (Dasgupta/Laplante/Meisner et al. 2009).

For this reason, coastal protection should become a more important issue on the agenda of the country (Elsharkawy/Rashed/Rached 2009), but the current political instability in Egypt actually causes environmental protection to be often disregarded in comparison with civil rights and economic development (Dasgupta/Laplante/Meisner et al. 2009). Also, coastal protection necessitates cooperation at all administrative levels and an increase in civil awareness (Malm 2013), both of which are aspects that are far from being realized (Link/Kominek/Scheffran 2013). All in all, the multiple facets of climate change will place a significant burden on the adaptive capacities of the riparians of the Nile Basin. It will take a joint cooperative effort to effectively deal with these challenges as failures of states would result in increased basin-wide conflict.

12.4.3   Israel–Palestine

The Middle East in general and Israel/Palestine in particular has often been characterized as a region in which climate change has the potential to worsen existing tensions and to create new ones (e.g. Amery 2002; Brown/Crawford 2009; Scheffran/Battaglini 2011). In general, the dispute between Israel and Palestine is a political conflict (Moore/Guy 2012). However, the conflict has a water dimension as well. Water has been a contested issue in past Israeli–Palestinian negotiations and it is indeed one of the few issues on which no final agreement could be reached during the peace process in the 1990s (Lautze/Reeves/Vega et al. 2005). Water distribution between both sides is also highly unequal and disputed. According to the 1995 Oslo II agreement between the government of Israel and the *Palestinian Liberation Organization* (PLO), Israel is allowed to withdraw 912 million cubic metres of water per year (MCM/y) from the shared mountain and coastal aquifers. Palestinians are only entitled to withdraw 253 MCM/y (Zeitoun 2008: 48, see below for a per capita estimate). Furthermore, Palestinians have no access to the River Jordan at all.

Due to the ongoing Israeli military occupation of the West Bank and the legal framework established by the Oslo II accord, the Israeli administration can block the development of water infrastructure or the increase of well extraction quotas in the West Bank (Selby 2003). It frequently uses this right among other reasons because it is the lower riparian with regard to the mountain aquifer shared between Israel and the West Bank (Selby 2013). Regarding the heavily overexploited coastal aquifer shared between Israel and the Gaza Strip, Israel is the upper riparian. Altogether, fresh water availability per capita is approximately four times higher in Israel than in Palestine and the gap is even larger for agricultural water. Consequently, many Palestinians have to survive with less than the 100 litres per day recommended by the *World Health Organization* (WHO) (Daoudi 2009).

Israel and Palestine experienced unusually little rainfall during the first decade of the twenty-first century when compared with historical records. After two very wet years in 2012 and 2013, a major drought hit the region again in early 2014. Climate models suggest that temperatures in the region will rise; this is one of the factors contributing to the region's vulnerability. Rainfall will become less predictable and more erratic, although it is not clear yet whether the absolute amount of precipitation will increase or decrease. Salt water intrusion into the coastal aquifer is expected due to sea level rise, which will cause a further decrease of the already poor quality of Gaza's only water source. However, most experts agree that climate change is unlikely to cause tremendous changes to the regional water quality or quantity before 2030 (Feitelson/Tamimi/Rosenthal 2012; Messerschmid 2012).

Several analysts predict that a decrease in water availability and quality will worsen existing water-related grievances and tensions and thus contribute to the escalation of the Israeli–Palestinian conflict. Based on the above discussion, we cannot deny this possibility. But it is important to emphasize that the Israeli–Palestinian water conflict is not primarily based on the physical scarcity of water as a resource. The amount of water available in the region has increased considerably in recent years due to ambitious Israeli seawater desalination and wastewater recycling programs (Aviram/Katz/Shmueli 2014; Feitelson/Rosenthal 2012; Fischhendler/Dinar/Katz 2011). Similarly, virtual water can be and is imported in large quantities in the form of food (Shuval 2007). In spite of these developments the water conflict did not de-escalate but rather became fiercer (Selby 2013). This is the case because confrontative discourses and the unequal power structures are the major drivers of the Israeli–Palestinian water conflict.

In the dominant Israeli discourse, the water resources of the region are considered limited although the overall water availability can be increased through technological measures. Water is also perceived as essential because of its importance for agriculture, which is strongly linked to the Zionist ideas of settling the land, making the desert bloom, and forming a secure and self-sufficient Jewish homeland. Furthermore, water is securitized in the sense that giving up control over the region's water resources is unthinkable in the dominant Israeli discourse, mainly because Israel considers itself to be surrounded by enemies (Fröhlich 2012; Lipchin 2007). In the dominant Palestinian discourse, exactly this Israeli control over water resources is constructed as an existential threat. Water is perceived to be intrinsically tied to land and without control over sufficient land/water resources a viable Palestinian state is considered impossible. According to the dominant Palestinian discourse, water scarcity in the region is not natural but politically induced by unfair Israeli policies (Daoudi 2009; Fröhlich 2012). These contradictory and rather confrontative discursive constructions of the same physical water reality are a major driver of the Israeli–Palestinian water conflict. However, this symbolic confrontation does not take place in a vacuum. Rather, Israel is the domi-

nant military and economic power in the region and its depiction of the regional water situation is internationally much more accepted (Zeitoun 2008). On the national as well as on the international level, the costs for the Israeli government of maintaining the highly unequal water distribution and governance are rather low. Israel is likely to benefit from this situation, e.g. through higher water availability and political support by settler groups (Messerschmid 2012).

In summary, water is certainly an important although not the most important factor in the Israeli–Palestinian conflict while climate change is likely to aggravate the regional water situation. The main drivers of the water conflict, however, are not physical resource scarcity and declining water quality but confrontative discourses and asymmetric power and incentive structures. The potential of climate change to act as a threat multiplier in the Israeli–Palestinian conflict is thus rather limited. These findings also highlight the importance of considering factors such as discourses, identities, and power structures as crucial elements of vulnerability vis-à-vis climate change and violent conflict (Adger/Dessai/Goulden et al. 2009; Jabri 1996).

12.5 Conclusion

The links between climate change and violent conflict remain disputed. Depending on the spatial and temporal scales and the data sets used, large-N studies provide different and at times opposing conclusions regarding the possible impacts of higher temperatures, less precipitation, larger precipitation extremes, lower freshwater availability, soil degradation, or natural disasters on violent conflict onset. Qualitative studies also provide no clear picture. This also holds true for the cases presented in this chapter. Climate change in combination with several other political, social, and economic trends seems to influence the intensity of pastoralist violence in north-western Kenya. Such a nexus has not yet manifested in the Nile Basin although it will take coordinated efforts by the major riparian states to adapt to climate change in order to avoid increasing conflict in the future. With regard to water in Israel and Palestine, it can be said that confrontational discourses and asymmetric power structures are much more important for the course of the conflict than the amount of water physically available, which is predicted to be reduced due to climate change.

Possible reasons for this lack of scientific consensus may be the difficulties of existing approaches to adequately capture the complex links between climate change vulnerability and violent conflict in theory and to operationalize them in empirical research. Particularly the different operationalizations of the dependent variables (onset or incidence of civil war, armed conflict, or social violence) and the independent variables, and the different units of analysis (countries, administrative units, or grid cells spatially, and decades, years, or months temporally) require nuanced and tailor-made theoretical approaches (Landis 2014; Salehyan 2014). The onset of civil war at the country level with an annual temporal resolution, for instance, is very likely to be driven by other factors and dynamics than the persistence of communal violence on the administrative unit level with a monthly temporal resolution. Other important issues include the poor availability and quality of data sets and deficits regarding the development and combination of adequate methodological approaches (Ide/Scheffran 2014; Selby 2014). However, it is also possible that the existence and nature of a climate-conflict nexus may vary within short time periods and geographically at the local level, so that general conclusions on the issue are hardly possible. And finally, as climate change progresses, the relevance of conflict over climate change adaptation and mitigation measures (Dabelko/Herzen/Null et al. 2013) and of geoengineering (Maas/Scheffran 2012) increases, while the consequences of climate change for violent conflict in (peri-)urban areas (Saha 2012) and the impact of high-impact non-linear events may become more likely (see chapter 11 in this volume by Schellnhuber/Serdeczny/Adams et al.). These issues are far from being understood in detail. The possible links and interactions between climate change and violent conflict will continue to be an important issue in scientific as well as in policy debates. In order to allow the readers to better keep track of these debates, box 12.1 provides an overview of the websites we consider most relevant in this research field.

Finally, we think it is important to mention the growing literature on environmental peace (Ide/Scheffran 2014), environmental peacemaking (Conca/Dabelko 2002), disaster diplomacy (Kelman 2012), and natural resource management (Ratner/Meinzen-Dick/May et al. 2013). This research suggests that the predicted impacts of climate change can under certain circumstances provide incentives for social groups to overcome their differences and cooperate in order to cope with and adapt to common threats such as storms, floods, or droughts. Not much is known about this climate-cooperation nexus yet. However, it provides additional reasons that with progressing climate change we are not necessarily heading towards a

13   From a Climate of Complexity to Sustainable Peace: Viability Transformations and Adaptive Governance in the Anthropocene

Jürgen Scheffran[1]

Abstract

In an increasingly interconnected climate of complexity, the stabilization of human–environment interactions is a major challenge in international relations and demands the integration of complexity science with global governance. This chapter highlights several cases of complex crises where cascading events affect international stability. Climate change is considered as a risk multiplier which disturbs the balance between natural and social systems and amplifies the consequences through complex impact chains that affect the functioning of critical infrastructures and supply networks; intensify the nexus of water, energy and food; lead to production losses, price increases and financial crises in other regions through global markets; undermine human security, social living conditions and political stability; and trigger or aggravate migration movements and conflict situations. An integrative framework of human–environment interaction is used to analyse destabilizing developments, tipping elements and cascading risks, as well as concepts of resilience, viability and sustainable peace. Whether climate stress fuels a cycle of violence or climate policy drives a transition towards a cycle of cooperation and sustainable peace depends on the human and societal responses. Strategies for viability transformations and adaptive governance range from climate mitigation and adaptation and the building of social networks to new capabilities of disaster management, crisis prevention and conflict resolution. Several examples are presented showing how transition and transformation processes can be analysed with an agent-based model framework.

Keywords: Adaptive governance, anthropocene, climate, complexity, conflict, cooperation, crisis, migration, social networks, sustainability transition, sustainable peace, transformation, viability.

13.1   Introduction

Since the report to the Club of Rome on *The Limits to Growth* was published in 1972, human–environment interactions have become ever more complex (see chapter 16 by Sjovaag in this volume). The report played a prominent role in helping us understand the world as a complex dynamic system where natural boundaries are violated by uncontrolled human interventions. It has been one of the drivers in promoting the concept of complexity, which evolved in the 1980s as a new paradigm in science. With the chaotic breakdown of the East–West conflict in 1989, complexity also served as a framework for transitions in society. While established scientific concepts based on linear systems, rational choice and simple two-player games were the dominant paradigms of the cold war, they reached their limits in the new emerging world order characterized by rapid changes and transitions in the international system that were marked by shifting pathways and transformation processes (see chapter 1 by Brauch/Oswald Spring in this volume). Although complexity science (see chapter 18 by Mesjasz in this volume) is challenging the dominant rationalist, realist and reductionist framework, the new understanding still needs to move from the academic realm into the day-to-day world of policy-making (Geyer/Pickering 2011). The world's complexity is apparently growing and there is a need to develop new practical approaches to address this complexity.

The 1989 turning point in world history was followed by a period of disorder and a transformation

1   Prof. Dr. Jürgen Scheffran, Institute of Geography, CliSAP Research Group Climate Change and Security, Center for Earth System Research and Sustainability, University of Hamburg; email: <juergen.scheffran@uni-hamburg.de>.

towards a fractal and fragile international landscape that continues to be unstable and full of surprises. Numerous factors and actors are interrelated in complex networks involving national, subnational and transnational actors in complex crises and conflicts. When everything is interconnected, seemingly small changes in one part of the world could have significant impacts in other parts. The tight couplings may lead to cascading crises that spiral out of control (Kominek/Scheffran 2012, Scheffran 2015a), such as the global economic crisis of 2008, the Arab Spring of 2011, the wars in Iraq, Afghanistan, Libya and Syria, the division and civil war in Ukraine in 2014, the Greek debt crisis from 2010 to 2015, the European refugee crisis of 2015, and recent terror attacks in Beirut, Paris, Brussels and elsewhere. These events are interconnected in many ways and through multiple channels that are often invisible (Scheffran 2016b).

In this complex network of crises, environmental change is connected with other problem areas through multiple linkages from local to global levels. Irrespective of when, where and how the 'limits to growth' take effect, the continued expansion of human activities in the anthroposphere has become a driving force that transforms the earth system into a new geological epoch, the 'Anthropocene', with multiple consequences such as climate change, land degradation, resource scarcity and biodiversity loss. In this nexus of overlapping and interconnected problem areas that creates a "climate of complexity" (Rothe 2015), the world may continue on a slippery slope of escalating risk cascades of environmental destruction, poverty and violent conflict, running full speed into natural boundaries and their forces. The challenge of the twenty-first century is whether humankind can anticipate and avoid hazardous pathways by counteracting forces that slow down and change course towards a more sustainable, peaceful and viable world, while at the same time taking into account natural boundaries (Scheffran 2015a). Along these lines, this chapter is based on the following structure:

- Drawing on various research activities by the author over three decades, this chapter will focus on the systemic issues of the current expansive growth-oriented pathways and related tipping points and risk cascades, in the context of complexity science (13.2).
- The next section highlights linkages between climate change as a potential risk multiplier in the world's complex crises, emergencies and disasters through interactions between climate stress, environmental change, human responses and social

conflicts (13.3). Basic human needs and values (such as the availability of water, food, energy, health and wealth) will be used to illustrate the vulnerability to environmental changes, which may lead to social disruption through instability events (such as forced displacement, riots, insurgencies, urban violence and war).
- The author will further discuss the role of social dynamics in transformation (13.4) and conceptual issues relevant to transformation (13.5), including stability, resilience, sustainable development and peace, in order to derive the concept of viability as a framework for the analysis and governance of transition and transformation processes (13.6).
- Finally, the author will introduce the VIABLE model as a framework for the analysis of transformation processes, including examples from the cold war arms race, the complex security landscape after the cold war, climate change and related risks, and coalition formation in energy transformations (13.7).

13.2   Tipping Points and Risk Cascades in Complex Security Landscapes

13.2.1   The Role of Complexity Science

The complexity of a system reflects the difficulty of understanding, describing or representing the system in an appropriate language. This has led to numerous attempts to define complexity (for an early survey, see Scheffran 1983). Key terms in complexity theory are: chaos, bifurcation, attractor, fractal and self-organization (Mesjasz 2010; see his chapter 18 in this volume). Complexity theory is (in)famous for popularizing statements like 'everything is connected to everything' and 'small causes can have big effects'. The interplay between the complexity and stability of dynamic systems has shaped ecosystem research since the 1970s (May 1972; Casti 1979; Scheffran 1983). Evolving complex systems (e.g. biological organisms, ecosystems, social systems) are generally more robust against variations in their environment, while systems that do not use learning skills to adapt their complexity to changing environmental conditions are exposed to the risk of instability (Scheffran 2015a).

In transition processes that change the qualitative structure of systems, the complexity–stability relationship is particularly relevant, and the methods of nonlinear dynamics and self-organization can be used to analyse phase transitions. Key questions are: under

which conditions small-scale micro-level events lead to qualitative changes at the macro level, and whether there are thresholds and tipping points beyond which chain reactions and risk cascades are triggered that propagate in space and time and induce a qualitative system change. These include complex social interactions such as stock market crashes, revolutions, mass exoduses and violent conflicts (Kominek/Scheffran 2012). While systems are often robust against disturbances in the core region of stability (Held/Schellnhuber 2004), close to critical thresholds between regions of stability and instability small variations and uncertainties can decide whether systems break down or new ones are formed. This is symbolized by the famous butterfly effect in chaos theory, which may occur when a system is already 'on the edge', driven by other processes.

At tipping points the dynamics of change accelerates and induces a qualitative switch of behaviour which is sensitive to triggering events such as natural disasters, mass migrations and social movements, leading to a chain reaction of cascading sequences, e.g. when actions by one actor provoke more intense actions by other actors that undermine the stability of the whole system (Scheffran 2016b). A crucial phenomenon is path dependency (Kominek/Scheffran 2012), when social actors are locked in certain pathways of action that are self-enforcing and hard to change individually, e.g. when agents follow other agents or organizations, leading to a collective dynamics. A related term is the sensitivity of couplings between variables, which determines how changes spread in the network of interconnections (Scheffran/Link/Schilling 2012). As a result of non-linear effects, an increase in environmental variables such as global temperature and emissions above a threshold may trigger instabilities, tipping points and cascading sequences that could undermine the viability of natural and social systems. A governance challenge is to develop new approaches that stabilize the interaction, e.g. with the help of concepts such as adaptive complexity and stability (Scheffran 2015a).

One particular form of social instability is conflict emerging from incompatible actions, values, behaviours and priorities of agents who undercut each other's values and provoke responses that generate further losses and responses, thus leading to conflict escalation and waste of resources if the conflict is not resolved. The transition from conflict to cooperation requires adaptation towards common positions and mutually beneficial actions in order to stabilize the interaction.

13.2.2   The Complex Security Landscape

Human history has been shaped by complex social transformation processes, such as revolutions and the collapse of civilizations. More recent events include the end of the cold war followed by a new world (dis)order of high complexity and instability and a securitization of environmental, economic, social and human dimensions (Wæver 1997; Buzan/Wæver/de Wilde 1998; Scheffran 2008c). Initially the hostile relationship between the former superpowers was replaced by a more cooperative relationship but the positive consequences of the abandoned East–West conflict were challenged by countering trends. The unipolar dominance of the United States and NATO provoked resistance from Russia, China and other powers; conflicts in the Balkans, Africa, the Middle East and other parts of the world triggered foreign military interventions; the proliferation of nuclear weapons and missiles continued, and new arms races emerged, including that in outer space; new technologies accelerated a 'revolution in military affairs' (Neuneck 2008). 'New wars' (Kaldor 2012) and terrorism demonstrate that individuals and small groups can have a huge impact and contribute to the cycles of hatred and violence.

That small differences can matter was demonstrated by the 2000 presidential election of George W. Bush in the United States, when a few individual votes in the State of Florida changed the course of history. The 9/11 terror attacks by a small terrorist group triggered a chain reaction of violence, from the invasion of Afghanistan and Iraq to the civil war in Syria, which feeds terror attacks and refugee movements affecting the Middle East, Europe and other parts of the world.

13.2.3   The Nexus of Growth, Power and Violence

More 'tipping points' may occur in the future, in particular when the risks of environmental degradation, climate change, poverty, and hunger affect living conditions in many parts of the world; this could result in severe security threats. Especially vulnerable are societies on the edge of instability, such as 'states in transition', where the transition is from authoritarian to democratic regimes, and states that lack legitimacy and cannot protect citizens from harm. Human insecurity and personal instability could trigger social and political instability, and vice versa. The marginal impact of environmental change could undermine our

ability to solve problems and further dissolve state structures, possibly leading to their collapse. Particularly critical is the situation in fragile and failing states with social fragmentation, weak governance structures and inadequate management capacities (Milliken/Krause 2003; Rotberg 2003; Starr 2008).

Economic growth, political power differences and violent force may become drivers of crises (Scheffran 1996). While growth is a major feature of life, it can be destructive when out of balance. A population grows exponentially (proportionately to the size of the population) if the birth rate exceeds the death or mortality rate (on demographic factors of population growth, see chapter 10 in this volume by Zlotnik). Balancing birth and death rates is a precondition for preserving life. If this balance is disturbed and is not stable, then births may exceed deaths or vice versa, leading to exponential expansion or decline, with a thin dividing line between both. Growth can continue in a cancer-like chain reaction that will cause pressure, stress and destruction in its environment, until limits are reached that do not permit further growth.

Over history, the human population has grown through increasing birth rates and falling death rates. The growth principle has also applied to the expansion of capital, investments, income, technology, energy and resource flows, and to political power, as well as to violent means of destruction. Malthus's concern was that human exponential growth would result in increasing death rates once the population reached its resource limits. However, humans were able to overcome constraints on resources and to expand into new spaces by using their problem-solving capabilities and developing technical and social innovations that stretched the limits to growth, allowing more wealth to be generated on a shrinking base of natural resources. Continued expansion of the human sphere puts further pressure on natural resources and ecosystems. As we reach planetary boundaries (Rockström/Steffen/Noone et al. 2009; see chapter 2 in this volume by Dalby) in the Anthropocene, the question arises of whether a balance will be established by an increase in death rates or by the reduction of birth rates. Both represent different pathways: the first means crisis, disaster and death, while the second is associated with a global 'demographic transition', wealth creation and sustainability within natural boundaries. Before the second is discussed, the next section will associate the first pathway with the climate of complexity, focusing on possible linkages between climate change as a risk multiplier and the world's complex crises.

13.3 Climate Change as a 'Risk Multiplier' in Complex Crises

Although much is known about the effects of climate change on the components of the earth system, the interaction between the subsystems is still poorly understood. Since changes in one system can have direct or indirect effects on other systems, local events can propagate through complex causal chains and feedbacks on various spatial and temporal scales. Accordingly, climate change has been called a 'risk amplifier' and a 'threat multiplier' (CNA 2007, EU 2008, WBGU 2008).

Some critical questions are relevant in this context. What happens if climate impacts exceed the adaptive capacity of natural and social systems? Are there ranges of tolerance where systems remain stable, or outside of which turmoil, destabilization and 'tipping points' leading to qualitatively different states of the earth system are likely? Is it possible that climate change triggers regional or global risk cascades? Will critical infrastructures which are essential for the economy and society become dysfunctional? How does the risk-multiplying effect of climate change connect various problem areas? Will the stressor climate change lead to a destabilization of human–environment interaction or set reactions in motion which weaken the effects of the disturbance?

Some aspects are highlighted in the following section, based on general considerations about the complexity and stability of human–environment interaction, in particular the interaction between climate change and society[2]. The complex relationships in highly networked systems are illustrated by various types of risk, including instabilities in the climate system; hot spots of climate change and human insecurity; vulnerable infrastructures and networks; economic and financial crises; social and political instability; environmental migration; and climate change and violent conflict. As became clear during the Arab Spring, such processes have primary and secondary consequences for Europe which are mediated through mechanisms at global, regional and local levels.

---

2   This section was presented in a modified form at the Planetary Security Conference in The Hague, 2–3 November 2015 (Scheffran 2015b).

13.3.1 Instabilities in the Climate System

Weather and climate are considered primary examples of complex systems, and the Lorenz equations (a simplified mathematical model for atmospheric convection dynamics) became one of the roots of chaos theory (Sparrow 1982). Complex dynamic processes are characteristic of the climate system and are difficult to predict from knowledge of individual factors and equations. As is known from climate history, the planet went through different climate extremes, from the ice ages to warm periods, with variations occurring over short periods of time. Compared with previous abrupt climatic changes, climatic conditions in recent periods of human history have been relatively stable. Little is known about how stable the current world climate is, given the massive interference from anthropogenic greenhouse gas emissions. Furthermore, there are significant uncertainties regarding climate sensitivity and the estimation of critical stability limits, where the climate could experience a 'tipping' into unknown regions of the climate system, posing one of the gravest dangers facing mankind.

One focus of climate change research is weather extremes such as hurricanes, droughts, forest fires, floods and heatwaves, which can be described through processes of non-linear dynamics such as phase transitions, critical thresholds, and chaos; these have become paradigms in complex systems theory and in many application areas (Scheffran 1983; Bunde/Kropp/Schellnhuber 2002; Kurths/Maraun/Zhou et al. 2009; Kavalski 2015). In terms of their frequency and intensity, extreme events represent phenomena at the boundaries of the climate system. They are outside the 'normal' range and are associated with extreme circumstances that can burden the functionality and stability of the natural and social systems affected, and overwhelm their resilience and viability. The number and intensity of extreme weather events is likely to increase in the future (IPCC 2012; Rahmstorf/Coumou 2011).

In addition to single local events the climate system itself can become unstable if critical tipping points are reached, for example by exceeding certain thresholds in global mean temperature that trigger amplifying effects (Lenton/Held/Kriegler et al. 2008). These include the weakening of the North Atlantic thermohaline circulation, the rapid melting of ice shelves in Greenland and west Antarctica, the release of greenhouse gases such as methane from frozen soils in Siberia or Canada, and the change in the Asian monsoon. These phenomena and related chains

of events can lead to a global and lasting transformation in the earth system. Massive and abrupt climate change could also overwhelm the ability of the strongest states and societies to deal with the problems. Less time-critical, although globally more hazardous in the long term, is the rise in sea level that creates stress on many coastal regions and threatened islands. Given the large number of uncertainties, it is a risky experiment to move into unknown areas of the climate system, where amplification of impacts and tipping elements opens up the possibility of global destabilization.

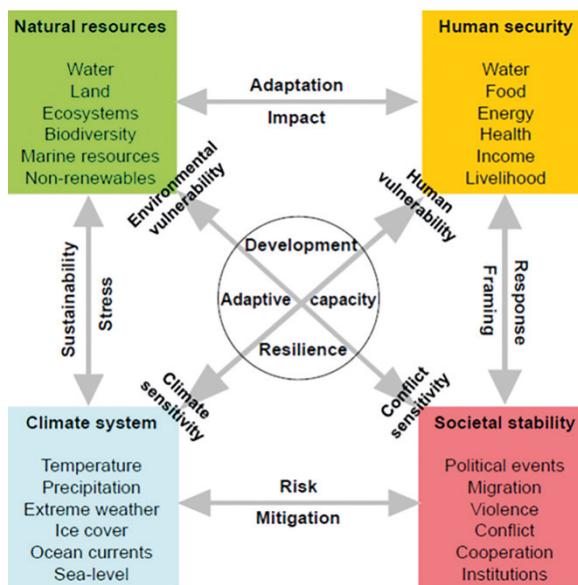
Figure 13.1: Impact chains and feedbacks in climate–society interaction. **Source**: Adapted and modified from Scheffran, Brzoska, Kominek et al. (2012a: 870).


Figure 13.1 shows an integrative framework describing the complex interactions in the earth system (Scheffran/Brzoska/Kominek et al. 2012a, 2012b). The couplings in this network can be characterized by sensitivities which each represent the impact that a change in one variable has on another variable. In the context of the climate, sensitivity is "the degree to which a system is affected, either adversely or beneficially, by climate variability or climate change" (IPCC 2007: 881). Changes in the climate system affect the functioning of ecological systems and natural resources (e.g. soil, forests, biodiversity). Depending on the vulnerability, this can have an impact on human security, e.g. by affecting the supply of water, energy, food or economic goods. Even for uncertain sensitivities the sign

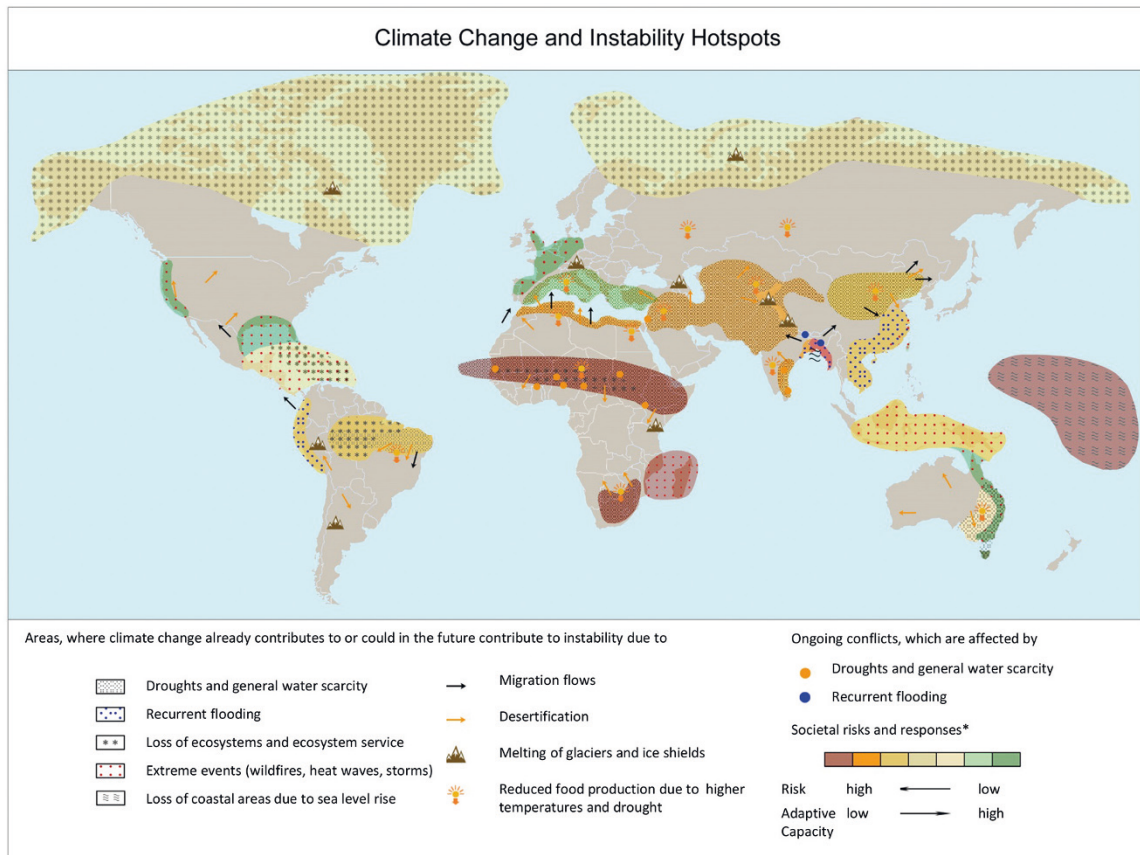
Figure 13.2: Hot spot areas where climate change impacts are critical for human security and social stability in different regions of the world. **Source**: Scheffran and Battaglini (2011): 33.


*Risk of conflict and adaptive capacity are correlated. The higher the adaptive capacity, the lower the societal risk. The risk of conflict increases from the green to the red end of the scale, while the adaptive capacity decreases.

of effects can provide valuable information that can be used to classify relevant patterns or 'syndromes' using qualitative analysis (Eisenack/Lüdeke/Petschel-Held et al. 2007).

Human reactions to environmental change can affect the stability of societal structures. This can cause conflicts and social destabilization in regional climate hot spots, and in a networked world transfer mechanisms can propagate in a domino effect. On the other hand, cooperative and sustainable response strategies for mitigation and adaptation can be initiated to weaken and mitigate the causes and consequences of climate change. The problem is to develop practical strategies that are adequate to the level of complexity and that address the challenges of climate change in order to prevent dangerous instabilities, as well as to facilitate the necessary system changes. If reached, the goals agreed in the *UN Framework Convention on Climate Change* (UNFCCC) will stabilize the climate system at a non-dangerous level. To achieve this, the underlying interactions need to be

better understood, and an anticipatory-adaptive policy framework is needed that avoids or circumvents risky pathways, as well as allowing for a timely and qualitative system transformation that takes the form of a self-organized stabilization. Some types of complex interactions are discussed below, where climate change may act as a 'risk multiplier' and trigger social destabilization in complex crises.

13.3.2   Hot Spots of Climate Change and Human Insecurity

In regions strongly affected by climate change (hot spots), there are multiple stresses on human security (figure 13.2). Hydro-meteorological disasters (storms, floods and droughts) are an immediate danger to the life and health of the most affected people (Germanwatch 2014) in both developing countries (e.g. the Indus flood in Pakistan in 2010, drought in China in 2010-11, typhoon in the Philippines in 2013) and industrialized countries (e.g. the European heatwave

of 2003; the Elbe floods in Germany in 2002 and 2013; tropical storms in the US in 2005 and 2012; wildfires in Russia in 2010). The consequences can be so severe that in the regions of concern adequate assistance is not possible and social systems become overloaded. For instance, in 2005 hurricane Katrina caused enormous damage to the south coast of the US and led to more than 1,800 deaths; it displaced hundreds of thousands of people and overwhelmed disaster management. The heatwave of 2003 in Europe left behind tens of thousands of casualties and damage to agriculture worth tens of billions of euros. The Indus flood in 2010, the worst for more than eighty years, flooded a fifth of the land area of Pakistan with consequences for twenty million people; it led to about 2,000 deaths and destroyed 1.7 million homes and a large part of the infrastructure (Gemenne/Brücker/Glasser et al. 2011).

On the other hand, climate change affects the long-term availability of natural resources, and this can contribute to shortages and an unbalanced distribution of resources. Examples include the degradation of fresh water, forests and farmlands, shortage of nutrition, the threat to biodiversity, and overfishing. Whether people are able to cope with the consequences and to limit the risks depends on their vulnerability and adaptive capacity. These are influenced by their access to resources, information and technologies, as well as by the stability and effectiveness of institutions (Adger/Lorenzoni/O'Brien 2009).

In the hot spots, climate stress causes great human suffering and significant economic and social losses, and this undermines human security. A large proportion of the risks are not only or primarily related to climate change, but are often also caused by pre-existing local problems in the affected areas. These include the destruction of ecosystems, a high level of poverty, political instability, overuse of land, and the absence of early warning systems and disaster protection. Most vulnerable to climate stress are those regions whose economies are dependent on climate-sensitive resources and where infrastructures are particularly exposed to climate change. These include developing countries with a high level of dependence on agriculture; coastal areas and river basins; and hot and dry regions. In these hot spots human security is at stake, if natural resources which are of fundamental importance for the existence of people and the satisfaction of their needs are depleted or degraded.

In many cases, the primary consequences are confined to the affected areas, but they may be connected to remote regions through humanitarian aid, civil pro-

tection or other direct interventions (including military operations). In many cases, however, indirect and secondary effects going beyond the hot spot region occur. Some reactions may further aggravate the situation, e.g. when people in need enforce the overexploitation of resources, move to other risk areas, or use violence against competitors, in order to ensure their own survival. For instance, rising land prices induce a search for cheaper land; this problem is often found in developing countries, where it leads to environmental and supply risks and displaces local users. Another example is the impact of land scarcity on the availability of water and on related crop losses. Where there are droughts in parts of Asia, Africa and America, global food markets can cause a fall in prices elsewhere. In this context, various trade-offs and exchange processes between different resources need to be taken into account. This is expressed in the nexus of water, energy and food (see the following sections).

13.3.3 Vulnerability of Infrastructure, Technical Systems and Supply Networks

Climate change may affect the viability of critical economic and social infrastructures and supply networks. These include systems for the supply of water, food and energy, goods and services, systems for the provision of communication, health, transportation and security, and human settlements and political institutions. It is not only the failure of important subsystems that matters, but also the possibility that disruption of certain system components spreads across couplings and leads to the collapse of the entire system. This is true for developing countries which depend directly on ecosystem services and agriculture and to a different degree for developed countries which rely on highly networked technical systems but have more sophisticated protection and response mechanisms. The stronger the impacts are and the more subsystems are affected, the harder it is for societies to absorb the consequences.

Corresponding relationships are examined in risk research for the failure of complex technical systems in which the combination of different events results in the loss of control mechanisms. This examination started with the debate on various spectacular accidents in high-risk technologies (Bhopal, Challenger, Chernobyl), which demonstrated that large-scale technology (chemical and nuclear engineering, biotechnology and genetic engineering, aerospace and defence technology) is not completely manageable and con-

tains a 'residual risk', comparable to natural disasters. Since not all contingencies are predictable in complex systems, it is often enough that a minor event can initiate a chain of events which appears as a 'normal accident' but leads to catastrophes in tightly coupled human–machine systems (Perrow 1984). In a globalized world these tight couplings occur not only in technical systems but in other fields as well.

A spectacular example of a risk cascade of natural and technological disasters was the earthquake in Japan on 11 March 2011, which triggered a chain of events with global effects. The tsunami flooded parts of the Japanese coast, cost many lives, and triggered the accident at Fukushima that destroyed several nuclear reactors, spreading radioactivity globally through the atmosphere and the ocean. Because of the consequences of this large-scale accident, the Japanese power grid, the nuclear industry, stock markets, oil prices and the global economy were all affected. Automobile manufacturers and electronics companies worldwide cut back production because important components were no longer being delivered from Japan. The shock waves from the nuclear disaster triggered the energy transition in Germany. This disaster impressively demonstrates how a single event can set into motion different chains of processes and can change the political environment (Kominek/Scheffran 2012; Scheffran/Burroughs/Leidreiter et al. 2015; Scheffran 2016b).

In addition to earthquakes or technological accidents, weather extremes can also hit critical nodes in the networks of business, technology and society. For industrialized countries such as Germany, whose economies and societies depend on a functioning infrastructure, the stability of a sustainable supply system in response to extreme weather events is of great importance. Weather extremes such as the 2003 heatwave, the storm surge in 2013 or the Elbe flood in 2013 lead to temporary impairments of transport or energy supply systems. From the perspective of climate research, it is important to assess whether extreme weather events that exceed the limits of adaptation of supply networks can occur over a given period. It is important to identify the critical nodes and links in the global supply network and to understand how local failures of infrastructure components affect the global supply. Network research analyses what happens in the case of the failure of network elements, how shocks propagate into the power grid, and whether chain reactions and cascading effects which can cause a collapse of the network can occur.

As an example we discuss here the failure of power grids. Since virtually all other supply networks depend on a well-functioning power grid, their failure affects all parts of society. Most hydro-meteorological disasters affect parts of the national electricity grid only temporarily, and power is then restored. However, there have also been cases in which the power supply fell victim to a large area blackout caused by minor events. In the biggest blackout in history in July 2012, over 600 million people in northern and eastern India were affected due to an overloading of the power grid. In November 1965, about thirty million people in the north-eastern United States and in many parts of Canada remained without electricity for about six days. In California, there were regular power outages caused by insufficient generation capacity and market manipulation (Brand/Scheffran 2005). During a major power blackout in Europe in November 2006, parts of Germany, France, Belgium, Italy, Austria and Spain were temporarily disconnected from the power supply. While in these cases there were various underlying causes, in other cases weather events were the trigger. In November 2005, after a heavy snowfall in North Rhine–Westphalia and Lower Saxony, one of the largest power outages in German history occurred, and some 250,000 people were without power for several days, resulting in a financial loss of about €100 million (Deutschländer/Wichura 2005). More recently, the snowstorm in North America at the turn of 2013 and 2014 caused major power cuts for hundreds of thousands of people, leading to partial failure of the communication and transport systems.[3]

If the supply system for a particular resource is hit, this often has effects on other resources, in particular the nexus of water, energy and food (Beisheim 2013; IEA 2012). Energy is needed for irrigation and for the production of food, water, and energy supply, in particular for the extraction, transportation and processing of fossil and nuclear energy. The development of unconventional gas and oil reserves (fracking, oil sands and oil shales) has led to an increasing need for water and land. In addition, renewable energy sources such as hydropower, biofuels and geothermal power need large amounts of water. Regions with low rainfall are dependent on artificial irrigation for the cultivation of plants for food and energy. Even with large solar power plants in desert areas, water supply is a

3   "Ice storm blackouts frustrate tens of thousands"; at: <http://www.cbc.ca/news/canada/ice-storm-blackouts-frustrate-tens-of-thousands-1.2476866>.

critical issue. Overall, the water demand for energy generation is estimated to rise twice as much as the demand for energy (Beisheim 2013).

Climate change affects this nexus in many ways and increases the competition between water, energy and food. For instance, nuclear power plants are vulnerable because they are dependent on the flow of cooling water. A warming of the waters or long periods of drought or floods affect power generation in developed countries, leading to critical situations when cooling water is no longer available or water in power plants is below the critical level (Beisheim 2013: 24). Through hurricane Katrina in 2005 in the Gulf of Mexico region, more than a quarter of total offshore oil production, almost a fifth of total natural gas production and almost half of available refining capacity were temporarily disabled, as well as important oil pipelines, thousands of oil rigs, and a large proportion of rail and sea transport (for an overview, see Kumins/Bamberger 2005).

Typhoon Haiyan in the Philippines 2013 destroyed part of the country's supply of renewable energy (Bradsher 2013). Since renewable energy sources (bio, hydro, wind, solar) depend on certain meteorological conditions, they are affected by climate change..

The forced cultivation of bioenergy plants as part of a climate change strategy has intensified a global resource competition as large amounts of water and land are needed that are therefore no longer available for food production (Scheffran 2010). With a shortage of resources due to climate change, market prices increase, making the expansion of agricultural production more attractive. This may lead to a rise in the demand for production factors such as water, energy, pesticides and fertilizers, which in turn are associated with increasing environmental pollution and a growing demand for land (Beisheim 2013). On the other hand, rising food prices have adverse effects on poor populations (see below). To some extent competition can be mitigated by synergistic effects, e.g. when water power plants achieve an optimal trade-off between water and energy use, solar energy is used for water desalination, organic waste is used in food production for energy purposes, and new jobs are created that contribute to development in rural areas.

It is difficult to make supply networks more resilient to climate change impacts if disruptive events occur in rapid succession and with multiple effects which hit a system simultaneously, with short time delays or in a narrow geographical area. With the increasing intensity and frequency of climate-related events, the question arises as to when the limits of capacity and resilience of infrastructure are reached and whether existing safeguards and adaptation measures are sufficient.

13.3.4 Economic and Financial Crises

Assets and economic processes such as global freight, trade and financial markets that regulate the exchange between supply and demand are also subject to climate change. Financial transactions and pricing information represent virtual transfer mechanisms which link the events with each other globally and within a very short period of time. If there is a disturbance in one place as a result of climate-related events, such as production losses, bankruptcies of companies or a fall in the stock market, it is propagated across global networks and markets.

The economic crisis of 2008 demonstrated the instability of the complex interconnected global economy. Powered by the reckless speculation and lending practices of financial institutions and short-sighted human behaviour, local events and individual responses escalated, pushing the global financial system to the brink of collapse. After the critical limit was exceeded, self-reinforcing mechanisms were triggered, leading to losses of hundreds of billions of dollars and euros worldwide. Public investment and regulatory policies were initially unable to compensate for the short-term fluctuations. The interaction between rating agencies and government responses led to an explosive situation. In Europe, the global economic crisis was followed by a crisis in southern Europe, most dramatically in Greece.

Although other factors were at work here, climate and economic crises may interact and lead to a downward spiral. According to the Stern review, abrupt and extensive changes in the climate system could wreak havoc in global trade and financial markets (Stern 2006). Since there are various links between climate change and financial markets, risk cascades can be analysed and classified (Haas 2010; Onischka 2009). In addition to the risk of direct economic damage, global impacts are possible through the loss of production, supply shortages and price increases. Thus, extreme events in one country can induce production losses in another country, and these can spread through global supply chains (Levermann 2014). While the direct damages and costs of weather extremes have been recognized for several years, the indirect economic consequences are still poorly understood. Some issues have been raised in the context of the indirect effects of bioenergy, particularly as in other

parts of the world the price and cultivation of cereals has been affected by bioenergy production (Scheffran 2010), e.g. in the so-called 'tortilla crisis' in Mexico in 2007.

In the energy sector various risks (natural disasters, infrastructure problems, strikes, riots, wars, political interventions) may lead to constraints on supply and strong market variations. High oil prices, as in 2008, are a driver for recession, social risks and willingness to accept a high level of environmental risk (Beisheim 2013). Relevant questions can be raised if production losses are observed through extreme events in a country that is a food supplier. These events include the heatwaves and related fires lasting several weeks in Russia in the summer of 2010, which resulted in an export ban on wheat (FAZ 2010). The droughts in the US in 2011 and 2012 and in China in 2010–2011 were associated with price increases in food commodities. For poorer countries the consequences of integration into the globalized economy can be as momentous as the direct effect of domestic local events. Even in developed countries such as Germany, the impacts of extreme events on the consumer are noticeable. Europe is not immune to the consequences if negative developments in the Mediterranean lead to a spiral of escalation. An economically weakened southern Europe is more vulnerable to climate-related risks and would have a lower potential for adaptation. Here problems of water and food supply could hit tourism and agriculture, lead to conflict and migration, affect neighbouring countries, and spread across continents. Some examples are discussed below.

1. *Floods in Australia* 2010–2011: In the wake of tropical cyclone Tasha, Queensland and New South Wales were affected by heavy rainfall in 2010 and 2011. The worst flooding in fifty years inundated an area the size of Germany and France combined; it included seventy cities, thirty-five people lost their lives and 200,000 people were evacuated, including from parts of the metropolitan area of Brisbane. According to media reports the damage was of the order of AUS$1 billion and the loss to GDP stood at AUS$13 billion, which had a significant impact on the economic performance of Australia. Furthermore, due to flooding about forty coal mines were temporarily closed or operated at reduced power, so that the production capacity of the largest coal exporter in the world was severely impaired. Coal mining in Queensland fell by thirty per cent; coal production fell from 471 million tonnes in the previous year to 405 mil-

lion tonnes. At times, the domestic coal industry was losing more than €70 million per day (Oldag/ Walterlin 2011). Since the cost of raw materials is more than eighty per cent of the production cost of steel, this triggered rising prices and supply bottlenecks in the steel industry. The expanding Australian chain reaction was also felt in Germany and had an impact on the automotive industry, on mechanical engineering, and on other industries (Spiegel 2011).

2. *Flood in Thailand* 2011: As a result of a violent and unusually long-lasting monsoon Thailand was hit in October and November 2011 by the worst floods in fifty years, which affected nearly twelve per cent of the country. The consequences were almost 400 deaths, property damage of more than €11 billion, substantial loss of economic growth, temporary drops in tourist numbers, and massive crop losses (a quarter below the previous year). The neighbouring countries of Cambodia and Laos were also affected. In addition to the regional consequences, the disaster had an impact on the world economy. Supply failures in electronic components led to bottlenecks in the international electronics and computer industry and a large increase in hard drive prices in Germany (Feddern/Schnurer 2011). German companies such as Volkswagen had problems with the delivery of important parts. Japan's automobile companies suffered repeated losses in production, in particular shortly after the Fukushima disaster. Although the Thai electrical and electronics industry was put back by the flooding, the industry has recovered faster than expected. With the stronger shift of production to Asia, plagued by earthquakes and floods, the consultant A. T. Kearney noted that eighty per cent of companies were adversely affected (Gärtner 2011).

3. *Drought in China in* 2010 *and* 2011: In November 2010, a once-in-a-century drought in China's eastern wheat belt threatened the winter wheat crop, which accounts for twenty-two per cent of the harvest of the world's largest producer and consumer of wheat. An area of 1.6 million hectares and more than 300 million people were affected. The severe drought hit the domestic and agricultural water supply and led to the closure of parts of the Yangtze River for navigation, as well as to the drying-up of water resources and to reduced hydropower generation. In early 2011, more than 2.2 million people and 2.73 million units of livestock nationwide suffered from a lack of water. Utilizing expe-

rience from past famines (1958–1961), the Chinese government has taken measures to reduce the risk of crop failure. They have invested in new hydro projects and bought wheat on the international market to compensate for the losses from the drought (Sternberg 2013). As a significant proportion (between six and eighteen per cent) of annual global wheat production is traded across borders (Lampietti/Michaels/Magnan et al. 2011), the decline in supply led to an increase in wheat prices and serious economic impacts in the import-dependent countries of North Africa and the Middle East (Sternberg 2013; see the following section).

13.3.5   Social and Political Destabilization

Directly or indirectly through the integration of physical, economic and geopolitical risks in a globally networked world, the impact of climate-related events could also undermine social and political stability in the regions concerned and possibly cause global turmoil. Due to globalization, combined with rapid developments in computer technology and in communication and transportation systems, people are increasingly globally connected and able to respond collectively and rapidly to local changes. Accordingly, social and political changes in one region can have significant impacts in other regions. It is possible that small groups and individuals can set in motion global chains of events that have an influence on international relations. This became clear in a spectacular way with the end of the cold war, the terrorist attacks of 11 September 2001, the Arab Spring in 2011, and the 2015 refugee crisis, where each had a significant impact on Europe. Individuals can also put solution processes in motion, as in the cases of whistle-blowers from Daniel Ellsberg to Edward Snowden, who brought sensitive information to the public in order to draw attention to deficits and problems.

The spirals of hate, terror and violence have their own dynamics across different levels. Environmental destruction, poverty and hunger affect social conditions in many parts of the world. Particularly sensitive are fragile and weak states with social fragmentation and poor governance and management capacity who cannot guarantee the core functions of government, such as law and public policy, the state's monopoly on force, welfare, participation, and basic public services in infrastructure, health and education (WBGU 2008).

Climate change may contribute to destabilization, especially where societies are in transition, for instance from authoritarian to democratic regimes. On the edge of instability, natural disasters can undermine the legitimacy and ability of states to protect their citizens from harm. If the agriculture of a developing country is severely damaged, the livelihood and existence of many people is at stake. The loss of life, income, wealth, jobs, health, family or friends provokes opposition and unrest that threaten the social contract and undermine the political order. Some of these processes act slowly and contribute to the erosion of social and political stability, others run quickly and overwhelm the problem-solving and adaptive capacity of communities. Various destabilizing processes may increase in climate hot spots and spread into neighbouring regions. With the decay of the social and political order, non-state actors (private security companies, terrorist groups, warlords) penetrate into domains opened up by the power vacuum. Countries with a low income and a low level of adaptive capacity are particularly at risk, while richer societies have more potential capacity for adaptation. However, in view of global interdependence, they cannot simply ignore the destabilization in other parts of the world which may affect them as well through complex chains.

Various natural disasters have been associated with a temporary collapse of law and order. Looting and criminal acts have occurred after heavy storms, for instance after hurricane Katrina in the US in 2005 and after the typhoon in the Philippines in 2013. After some storms and floods in southern Asia and Central America, the distribution of aid and relief goods was subject to disputes that were partly conducted violently (WBGU 2008). In addition to storms and floods with usually temporary and local impacts on the food supply, droughts have a direct and lasting impact on global food markets because of their wide spatial and temporal scale. Many people who are highly dependent on agricultural production and the local availability of water resources are affected. In contrast, it is usually the indirect influence of climate-related events and disasters on water, food and population that gives such type of disasters an international dimension.

The most significant consequences include food shortages and a consequent increase in food prices, which undermine living conditions for poor social groups. Throughout history 'bread protests' and food riots have contributed time and again to political and social change, as in the French and Russian Revolutions. This includes recent global supply crises such as those of 2008 and 2011, where food prices quickly

multiplied and the number of hungry people increased by 100 million to 1 billion (Beisheim 2013). For instance, in 2008 uprisings related to food crises provoked a change of government in Haiti, while in Cameroon twenty-four people were killed during protests and about 1,500 were arrested (Sternberg 2012).

A spectacular example is provided by the social and political upheavals in the *Middle East and North Africa* (MENA) since 2011. The series of protests and uprisings in the Arab world led to a conflagration that affected the entire region and provoked a change of regime in several countries (Johnstone/Mazo 2011). Starting with the unrest in Tunisia in early 2011 which forced the president to flee, the revolutionary impulse spread to Libya, Egypt, Syria and other MENA countries. It was accelerated and multiplied by electronic media and social networks (Kominek/Scheffran 2012), which enabled the rapid spread of protest and motivated others to join the protest movement. An example is seen in the demonstrations in Tahrir Square in Cairo and in other countries. Although supporters of the regime responded with force against the demonstrators, the self-organized resistance remained largely peaceful, forcing the resignation of President Mubarak. In the following years the situation turned violent in some countries, especially in Libya and Syria.

Which role rising food prices played here and to what proportion climate change and extreme weather events might have affected these processes is still the subject of scholarly debate. At the beginning of the revolt some media reports suggested a link with the sharp rise in food prices at the turn of 2010–2011. A collection of papers published by the Center for American Progress examined the impact of climate change on the upheavals in the Arab world (Werrell/Femia 2013). The argument was not so much that climate change was a primary cause, but rather that in an explosive political crisis the effects of climate change can act as an additional stressor that can exceed a 'tipping point'. One of the factors that occurred before the crisis was the drought in China in 2010 and 2011 (described above), which exerted pressure on the international market price of wheat and influenced the availability of food products. This coincided with other factors that further increased world food prices, including high oil prices, the development of bioenergy, and speculation on the global food markets (Johnson 2011).

The consequences affected much of the MENA region where the world's nine largest importers of food are located, seven of which saw political protests. Many households spend, on average, more than a third of their income on food (Sternberg 2013), while people in Western countries spend less than ten per cent. The dependence of Arab states on imported food makes them vulnerable to fluctuations in global commodity markets. Low incomes and high levels of resource imports and spending on food taken together affect food security. Reinforced by the sharp rise in bread prices, the existing public discontent with the government was magnified. In Egypt, the largest wheat importer in the world with a rapidly growing population, three per cent of the national income was spent on wheat subsidies (Sternberg 2013). As early as 1977 there was the 'bread intifada' in Egypt in which seventy-seven people died, and in 2008 there were bread riots. However, no protests took place in Israel or the United Arab Emirates, which have a high per capita income, a small food share of income, and better adaptive capacities.

The chain of events before, during and after the Arab Spring illustrates how in the networked world extreme events can affect international relations, mediated through economic, social and political processes. In this complex pattern of overlapping stressors (Werz/Hoffman 2013), climate change was not the main cause, but contributed to triggering the chain. The political upheavals happening today affect the stability of the Mediterranean region and coincide with the economic crisis in southern Europe. For Europe these events are quite significant, because of the civil wars in Libya and Syria and increasing migration from North Africa, the Middle East and sub-Saharan Africa (see the following sections).

13.3.6   Environmental Migration

As early as 1990, the first IPCC Assessment Report warned that changes in temperature and precipitation "could initiate large migrations of people, leading over a number of years to severe disruptions of settlement patterns and social instability in some areas" (IPCC 1990: 55). The IPCC Special Report of 2012 on extreme events and disasters stated that in the future climate extremes would have a larger impact on migration (IPCC 2012). And the most recent (fifth) Assessment Report found evidence for increased mobility or displacement in seventeen cases, while decreased mobility was found in six cases and socially differentiated mobility outcomes in five (IPCC 2014: 769).

According to the European Commission's position paper, Europe must be prepared for substantially

increased pressure from migration (EU 2008). In regions of poverty, violence, injustice and social insecurity, climate-induced stress could induce migratory movements. The *International Organization for Migration* (IOM) cites as reasons for environmental migration sudden or progressive changes in the environment that affect life or living conditions so that people are forced or choose to leave their homes temporarily or permanently (IOM 2008). In a narrow sense, Biermann/Boas (2008) define 'climate refugees' as people who leave their habitat as a result of rising sea levels, droughts and water shortages. By contrast, the *United Nations High Commissioner for Refugees* (UNHCR) (2011) argues against the use of the terms 'environmental refugee' and 'climate refugee', as they are imprecise and the term 'refugee' should be limited to political persecution and threats. As long as there are no international agreements, the legal status of climate-induced migration remains unregulated.

According to the *Internal Displacement Monitoring Centre* (IDMC), 32.4 million people have been displaced in 2012 by natural disasters (mostly weather-related), more than twice as many as in 2011. In two flood disasters in 2012 alone, 6.9 million people in Nigeria were displaced and 6.1 million people in India (IDMC 2013). The global numbers declined to 22.3 million in 2013 and to 19.3 million in 2014 (IDMC 2015). In contrast, the number of internally displaced people showed an opposite trend, from 22.8 (15.4) million in 2012, to 33.3 (16.7) million in 2013 and 38 (19.5) million in 2014 (the figures in parentheses indicate refugees). Estimates of future climate migrants in the literature vary widely, from fifty million to a billion people; the figure is disputed (Jakobeit/Methmann 2012; Foresight 2011).

Climate change is one among several possible drivers for human migration. Given a large number of possible reasons for flight and complex relationships, the impact of climate on migration is difficult to determine. Changes in the environment can not only promote but also impede migration by increasing the poverty of the rural population and thereby limiting the opportunities to escape (trapped populations). Environmental impacts and vulnerabilities can increase if people migrate to ecologically fragile and conflict-affected regions, including coastal cities which are affected by storms and sea level rise. In Europe and the United States climate migration is seen as a security problem and conflict factor, possibly leading to ethnic, religious and political tensions between the local population and immigrants. One

contributing factor is competition for scarce resources such as arable and pasture land, housing, water, jobs and social services. Media coverage of events such as the drought in Somalia, boat people in the Mediterranean and refugee movements along the Balkan route reinforce threat perceptions in Europe. With the establishment of the *European Agency for the Management of Operational Cooperation at the External Borders* (FRONTEX) the 'defence' of and against refugees—including environmental and climate migrants—is to be expanded. One response to the refugee crisis of 2015 was to increase border controls in southern Europe.

So far climate or environmental factors have not been identified as major contributions to international South–North migration. The majority of people affected by precarious environmental conditions remain in their home region or migrate to nearby urban areas. For weak and marginalized people, it is more difficult to overcome long distances or other barriers (e.g. language and cultural barriers) than it is for privileged classes. How far migration can be proved to trigger political instability and conflict is debated (Barnett/Adger 2007; Reuveny 2007). Response patterns in security policy narrow the scope of action to combatting symptoms, with the risk of a 'chain reaction' between increasing migration pressure and countermeasures (such as enhanced border protection, as observed during the 'refugee crisis' of 2015-16). Adaptation strategies and international cooperation can help overcome risks and even develop migration into an important measure of adaptation to climate change (Foresight 2011), strengthening the resistance and resilience of the affected communities. Migration networks can contribute to resilience and stable structures between source and destination countries, such as the transfer of payments, knowledge and technology (Adger/Kelly/Winkels et al.2002; Scheffran/Marmer/Sow 2012).

Industrialized countries are not spared from environmental migration. The debate became more important when hurricane Katrina in 2005 forced hundreds of thousands of people to flee New Orleans, among them a number of refugees who never returned. Risk zones vulnerable to flooding in coastal or river areas can also become uninhabitable in Europe and lead to migration, even if a larger number of domestic environmental migrants are not expected in the foreseeable future. In contrast, the debate on the immigration of refugees from conflict areas can provoke massive internal social conflicts;

this has become an issue in Europe, particularly in Germany, since the summer of 2015.

A large number of immigrants come from the MENA region (especially from Syria and Iraq), Afghanistan and the Sahel. In addition to the destabilizing remote impacts that have been mentioned in the previous section, these regions are directly affected by climate change, and this potentially increases the pressure for migration (BW 2012). Because of high population growth rates, climate change and resource depletion in large parts of Africa, availability of drinking water and arable and pasture land is expected to decline, affecting hundreds of millions of people (UNPD 2015, IPCC 2007; Schilling/Freier/Hertig et al. 2012, Busby/Raleigh/Salehyan 2013). Environmental variations increase the pressure on agriculture, fisheries and pastoralism (Werz/Hoffman 2013). Water availability in some countries is already below the threshold for water scarcity of 1,000 cubic metres per person per year. In Libya in 2009 this was only about 95.8 cubic metres and in Syria 356 cubic metres per capita, significantly lower than the figures for 2002 and well below the world average (World Bank 2013).

In the years before the rebellion Syria suffered devastating droughts (Kelley/Mohtadi/Cane et al. 2015) that hit the main growing areas of the country hardest, and many people were driven from the countryside to the cities. In 2010 alone, 50,000 Syrian families were affected. In 2002 more than thirty per cent of Syrians worked in agriculture; this had fallen to less than fifteen per cent by 2010 (Werz/Hoffman 2013). Syria has suffered from the presence of more than a million Iraqi refugees who fled after the US invasion of 2003. In Tunisia, due to urbanization, the rural population is declining despite the growth of the total population. In Algeria there have been repeated violent protests in cities, especially by unemployed immigrants from sub-Saharan Africa. Yemen suffers from the struggle over dwindling water resources and illegal water sources. Because of its growing population, the capital Sana'a could use up its groundwater in a few years. Agriculture in Morocco is particularly vulnerable to climate change (Schilling/Freier/Hertig et al. 2012). Water and food supply in Egypt depends heavily on the Nile, which is increasingly being used by upper riparian states (Link/Piontek/Scheffran et al. 2012).

Due to the growth in population and the flow of people into the cities, ethnic, religious and social tensions are increasing. Health and social services are under pressure, infrastructure and utility networks are overloaded. Frustration sparks protests, especially among the young population, and increases their willingness to leave the country to travel to the north. The problems of North Africa are linked in complex ways with those of the Sahel, which is also affected by climate change. Libya has been the destination of many migration routes from the south because of the oil revenues and related jobs. Nearly 700,000 immigrants constitute more than ten per cent of the total population. After the government was overthrown, tensions with immigrants increased, and many of those who were expelled were suspected of collaborating with Mu'ammer al-Gaddafi. Since the border became more permeable, some of the armed mercenaries who went to Mali and other countries of the Sahel have contributed to destabilization there. In sub-Saharan Africa, climate change, desertification and scarcity of resources have become connected with economic and social marginalization, political instability and violent conflict; this has undermined the livelihoods of farmers and herders and increased pressure for migration (Gemenne/Brücker/Ionesco 2013).

13.3.7 Climate Change and Violent Conflict

By altering natural and social livelihoods in many regions of the world, climate change represents a potential driver for conflict and related acts of violence. These include civil wars and military interventions that in turn are associated with various negative consequences such as famine, economic crises, refugees, resource exploitation and environmental degradation (WBGU 2008). The joint vulnerability to environmental change and violent conflict in hot spots may multiply and lead to a spiral of escalation that is difficult to control and can spread to other regions (see figure 13.2).

Different fields of conflict are relevant in the context of climate change (see chapter 12 by Ide/Link/Scheffran et al. in this volume). There is a widely held assumption that the growing consequences of global warming will increase the likelihood of conflicts that are aggravated by the destruction of human livelihoods and resources. In addition, there are potential differences over strategies for avoiding climate change as well as over the financing of these strategies, which can involve damages, costs, and the resistance of other actors. Examples include the controversy over the use of nuclear power as a contribution to CO_2 abatement or the debate about the consequences of bioenergy, which also determine the German discourse (Webersik 2010; Scheffran/Cannaday 2013). The same applies to differences on adaptation to climate change and its security implications, such as

alternative farming practices, protection measures such as dam building, and military operations in disaster management. Particularly prone to conflict are technical interventions into the climate system (geo-engineering or climate engineering) in order to remove CO_2 from the atmosphere or to influence the earth's radiation budget. Such measures raise critical issues of technical and economic feasibility, risks and responsibilities at global, national and local levels (Brzoska/Link/Maas et al. 2012). In all these consequences and responses there are concerns about justice when it comes to the distribution of the costs, benefits and risks of climate change, and this can complicate cooperative solutions.

The potential contribution of environmental change and resource use to violent conflict has been the subject of scientific controversy for more than two decades. While some studies claim that natural disasters and resource scarcity put social systems under stress, threaten their stability and make violent conflict more likely, others see no clear causality for historical events that is detectable by statistical methods, and emphasize the ability of human societies to deal with resource issues through collaboration and innovation (see reviews in Brauch 2002, 2009). So far, most environmental conflicts have been regional in scope and have presented no threat to international security (Carius/Tänzler/Winterstein 2006). The connections are regionally quite different and depend on the resource type. While for renewable resources (water, food, biodiversity) scarcity is more likely to be a conflict factor, for non-renewable resources (fossil fuels, uranium, diamonds, coltan) abundance is more likely to lead to conflict. In both cases, violent conflicts consume resources, and this can drive or restrain a spiral of violence (Scheffran/Ide/Schilling 2014).

More recent debate has addressed the links between climate change and violent conflict. This issue was raised in the fifth IPCC Assessment Report (IPCC 2014; Gleditsch/Nordas 2014). Some studies looking at long historical periods have found significant correlations between climate variability and violent conflicts, particularly in the Little Ice Age in Europe between the fifteenth and the nineteenth centuries. Research on more recent periods has produced mixed results, which depend in a complex way on the regional context and on the conflict situation (see reviews in Scheffran/Brzoska/Kominek et al. 2012a, 2012b). Studies using data selectively and studies aiming to prove the relationship between climate change and violence over all historical periods, regions of the world, forms of violence and causal mechanisms

(Burke/Miguel/Satyanath et al. 2009; Hsiang/Burke/Miguel et al. 2013) have exacerbated the controversy (Buhaug 2010; Buhaug/Nordkvelle/Bernauer et al. 2014).

Regardless of the interpretation of historical data, the impact of future climate change goes beyond previous experiences, leaving space for scenarios, plausibility considerations and speculations. It is indeed possible that societies have been able to adapt to moderate climate change over historical periods of time, but they may be overwhelmed in the future by rapid and strong climatic change that exceeds their adaptive capacities. There is a wide range of possible conflict constellations (WBGU 2008) associated with the effects of climate change on rainfall and water scarcity, land use and food security, migration and refugee movements, extreme weather events and natural disasters, and vegetation and biodiversity. All these processes can become conflict factors individually or in conjunction (see chapter 12 by Ide/Link/Scheffran et al. in this volume). In addition, the effects of climate change on infrastructure and social destabilization (see section 13.5) may become crucial and trigger societal 'tipping points', leading to social unrest, riots, violence, crime and armed conflict.

Particularly pronounced is the vulnerability of agrarian societies with a high level of population growth and a low level of development, or that are already suffering from violent conflicts (Raleigh/Urdal 2007). Whether climate change acts as a 'threat multiplier' and creates a 'climate of violence' depends largely on how people and societies respond to change, and on whether their adaptive capacities and institutional structures are adequate for maintaining stability and supporting viable solutions. While the rich industrialized countries are not spared by climate change, they may benefit from more advanced economic and institutional conditions for problem-solving and conflict management. Potential issues of conflict in Europe include tensions over territorial claims and natural resources in the Arctic and the Mediterranean (figure 13.2). The melting of the polar ice sheets affects the strategic interests of Europe, Russia and North America. Efforts between Europe, the Middle East and Northern Africa to build a power grid based on renewable energy open up the possibility of converting the Mediterranean from a region dominated by oil interests towards a region of cooperative security (Brauch 2012; Scheffran/Brauch 2014), provided that the utilization of energy is sustainable, and promotes development, peace and justice.

As an example, the importance of climate change for conflict in North and East Africa is discussed below. In the wake of the Arab spring, Syria and Libya experienced bloody unrest that led to a coup in the case of Libya, and in the case of Syria to a bloody civil war that has spread the cycle of violence to other regions. In both countries, climate change plays a dual role. With a rise in temperature and decreased precipitation water supply and agriculture are hit, affecting people's lives. The indirect consequences of conflict are mediated by the political unrest in which international food markets play a role. As in other MENA countries, both countries are facing water problems that compromise the supply of this elementary good (Schilling/Freier/Hertig et al. 2012).

For several decades, Sudan has been characterized by political instability and violent conflicts, reinforced by national power games, regional struggles and global geopolitics. Peripheral regions such as Darfur are characterized by marginalization and exclusion, and this leads to disintegration and secession. The complex nexus of problems includes population pressure, unsustainable exploitation of land and forests, declining agricultural productivity, food insecurity, and the spread of diseases such as malaria. Associated problems are environmental changes and resource degradation, which cause water shortages and the deterioration of pasture land in the northern Sahel following drought and desertification. This exacerbates competition for resources between herders and sedentary farmers. The expansion of mechanized agriculture continues to deprive nomadic peoples of their traditional migration routes, to dispossess peasants, and possibly lead to serious tensions

Attempts by the Sudanese government to set up new administrative structures have weakened traditional mechanisms of conflict resolution and resource allocation between tribal groups. This issue has become intermingled with the conflict between the government and the rebels. The resulting expulsions, killings and destructions, as well as the inflow of weapons, have increased uncertainty and fuelled the spiral of violence in Darfur. In the vicinity of crowded refugee camps further environmental and health problems have been caused by firewood collection and by infectious diseases (Scheffran/Ide/Schilling 2014).

The role of climate change as a 'conflict amplifier' in Darfur is controversial. While some observers classify Darfur as a "tragic example of a social collapse as a result of an ecological collapse" (UNEP 2007: 12–13), others are concerned about the oversimplification of the Darfur conflict (Butler 2007). They criticize the

government of Sudan for exploiting the climate argument to distract from its own responsibility (Verhoeven 2011). Overall, climate change is one of many conflict factors that reinforce each other in a complex way (for other regional case studies, see Scheffran/Brzoska/Brauch et al. 2012c; also chapter 12 by Ide/Link/Scheffran et al. in this volume).

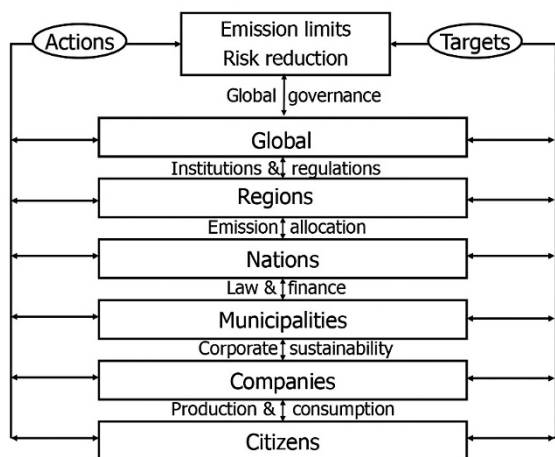
13.4 Social Dynamics in Transformative Interactions

The previous section highlights how climate change is challenging the balance between natural and social systems and interacting with other phenomena in complex crises. It is crucial that we understand how systems respond and interact to ensure their viability and survival against destabilizing consequences and avoid 'tipping points' and 'cascading breakdowns'. Natural and social systems have evolved over long historic times and developed the ability to cope with changing environmental conditions by adapting their pathways to new circumstances. Some of these pathways may aggravate problems (maladaptation), others could help to diminish harm and develop new opportunities. A key question is to what degree of climate change societies can adapt and how effective and creative they are in developing strategies that are appropriate, fast enough and sufficiently complex to cope with the speed and intensity of global change (Scheffran 2015a). Thus, to understand a 'sustainability transition' it is essential to go beyond the analysis of interactions in crisis events and to investigate social dynamics, such as social networks and collective behaviour that would support a transformation. Some initial considerations are presented in the following section, with a few examples to illustrate social transformation, without in-depth analysis.

13.4.1 Social Interactions and Networks

There are numerous agents and networks in sustainability or low-carbon transformations and they include regions, countries, businesses and citizens, each acting across multiple levels according to their interests, capabilities and rules of behaviour. At local levels, citizens and consumers are the key players; at the global level of decision-making, the main actors are the governments of nation states, or groupings among them. Local and global decision-making are connected in both directions via multiple layers of aggregation, with the intermediate national level connecting indi-

vidual citizens, governments and multinational organizations (figure 13.3). Each layer has its decision procedures for setting targets and implementing actions. To manage social dilemmas and complex crises, new rules, norms, innovations and institutions need to evolve (Ostrom 2000). In a world where national governments are still key actors, the challenge is to balance competing processes across different levels, from citizen empowerment and privatization to the formation of multinational organizations and institutions of global governance.

Figure 13.3: Micro–macro interaction between local and global levels. **Source**: Scheffran (2015a).


Social networks can promote the development of democratic and participative structures and open up opportunities for cooperation, peacekeeping and conflict resolution at local, regional and global levels. Each individual agent is a node in the network and can use its structures as power amplifiers, for destructive as well constructive purposes, to support or oppose a transformation. Social networks existed long before the Internet, though it has tremendously accelerated the formation of networks. Leaving aside climate change, there is a long history of social movements, from the workers' movement to the student, peace and environmental movements, which have played important roles in social change and political revolutions. An example is the peace movement of the early 1980s, which shaped public debate around the world and contributed to the momentous transformation that saw the end of the cold war.

In social networks, different forms of communication have been developed to deal with risks and conflicts, and these have facilitated discussions, discourses and disputes about the direction collective action should take. Protest, resistance and whistle-blowing can bring negative developments to public and political attention, help avoid unacceptable consequences and risks, and build win-win solutions. Potential linkages between climate change and the Arab Spring of 2011 have been discussed in section 13.3.5, considering food price and social media to be key factors (Kominek/Scheffran 2012). In some cases events have induced a peaceful transition, in others they have led to civil war. A large amount of research has analysed the conditions for violence and conflict. There is less research on preventing the causes of social instability and violent conflict and building social networks of resource use, conflict resolution and cooperation (Ngaruiya/Scheffran/Yang et al. 2015). In the context of 'sustainability transitions', new research is emerging on natural boundaries (Rockström/Steffen/Noone et al. 2009); forerunners in transitions (Hasselmann/Cremades/Filatova et al 2015); and the limits to the Anthropocene (Lüthje/Schäfer/Scheffran et al. 2011).

13.4.2   Collective Action and Governance

As we face common problems like climate change, without coordination and governance there is the risk that the world's more than seven billion people (2010) will waste resources, act against each other and run into conflicts. Every country, industry and citizen contributes to greenhouse gas emissions, and to driving the world into a climate of complexity. The question is whether and how quickly agents and stakeholders are learning to use their steering wheels in a coordinated manner. This is needed to develop goals and adaptive strategies that can drive the planet through the complex and foggy landscapes of climate change, where information is limited and uncertain, but continuously updated. A lack of agreement on the underlying causes, on the risks to be expected and on the actions required is impeding progress. To agree on a path that keeps the cumulative emissions and temperature changes within tolerable limits so that dangerous climate change is averted is a collective action problem. Part of the solution is to translate goals and implement agreements into rules, structures and institutions that prevent or minimize the causes, consequences and conflicts in the complex crises described above. Any substantial progress has been hampered by the expected costs and risks of transformation, by the constraints placed and the resistance by lobbying and partial interests that undermine the required cooperation.

To overcome the hurdles associated with the 'tragedy of the commons' (Hardin 1968) a multilevel process of negotiation is required (figure 13.3) that involves citizens, firms, institutions and states (Scheffran 2008). In negotiations, agents mutually restrain and adjust their actions in order to achieve joint benefits, to reduce costs, or to diminish risks. This process requires binding and verifiable agreements such as the Paris Agreement of 2015, an important stepping stone that needs to be implemented. Identifying individual emission commitments for each agent and ensuring their compliance remains a challenge (Scheffran 2016a). To address diverging preferences, some degree of cooperation is indispensable. Climate policy could help to unite the international community towards dynamic and globally coordinated actions and to achieve co-benefits with other policy fields (Ipsen/Rösch/Scheffran 2001).

To manage the technical and socio-economic transformation for sustainable development demands collective decision-making, learning and negotiation among multiple stakeholders, so that solutions can be found that bridge the differences, avoid conflicts and establish cooperative structures. Besides climate change, the transitions between conflict and cooperation have been studied extensively for fisheries management. In that domain, collective decision-making, learning and negotiation have been demonstrated to be more beneficial for both natural and social systems than individual actions of rational choice (Eisenack/Kropp/Scheffran 2007b; Bendor/Scheffran 2009). Different concepts can complement each other and enable joint action to reduce the burden on humans and nature and strengthen social skills. Governance mechanisms that strengthen human creativity and citizens' participation in democratically legitimated decisions, balance interests in stakeholder dialogues and mediation. Peaceful coexistence, cooperation and innovation are instrumental for a viable society and important for satisfying human needs and protecting livelihoods. To speed up emission reductions and technological change in the energy, agricultural and other sectors, an unprecedented degree of international action and cooperation is required. This must include the international transfer of investments and technologies to shift the composition and structure of the energy system towards emission reductions (see chapter 34 by Scheffran/Froese in this volume).

A challenge in the transition is to bridge micro–macro linkages in collective action across multiple levels of society through the formation of coalitions that acquire capabilities from individuals to generate joint values (Göbeler/Scheffran 2003; Scheffran 2006). In these coalitions agents can adapt their climate targets or merge their resources and investments to be better off by acting together rather than acting alone (Eisenack/Kropp/Scheffran 2007). Coalitions are reasonable if individual action is insufficient or inefficient, e.g. in acquiring a critical number of votes or a critical mass of investment to realize projects. Coalition formation describes the transition from individual to collective action as a bargaining process where the probability of joining a coalition increases with the values actors expect from it (Göbeler/Scheffran 2003; Scheffran 2006).

1. In resource-based coalitions actors merge their investments to generate joint benefits which are then distributed to the individual actors (Scheffran 2006). With the entry into force of the Kyoto Protocol in 2005, the international community has established a first set of cooperative instruments that address the problem of global warming. Market mechanisms are assumed to provide an efficient and cost-effective allocation between regions and businesses. Emission trading is designed to achieve emission reductions in regions and business sectors where they are least costly. The Paris Agreement of 2015 opens up opportunities for a wide range of strategies and instruments in climate policy where each state commits to individual emission reductions and related investment, so that the joint global temperature constraints can be achieved over the coming decades (see Scheffran 2016a).

2. In value-based coalitions actors seek agreement by adapting their positions and values to each other. Coalition formation is more likely among actors with similar positions. For instance, countries tend to cooperate more closely if they prefer similar levels of carbon concentration or temperature change, as can be seen in the formation of country groups in the *United Nations Framework Convention on Climate Change* (UNFCCC) and the Kyoto process. Moving beyond Kyoto has been a challenge for the policy process that is supposed to implement the longer-term objectives and manage the potentially severe implications in case of failure. While global warming affects the integrity of natural and social systems, with severe risks to their stability and security, UNFCCC Article 2 demands the stabilization of atmospheric greenhouse gas concentrations at levels that "prevent dangerous anthropogenic interference with the climate system". In Copenhagen in 2009 (COP 15)

and Paris 2015 (COP 21), this was translated into a common global goal of a global rise in temperature of less than 2°C. In this context, the Paris summit and the agreement adopted at COP 21 was a major expression and achievement of a joint global climate policy and of the emerging world civil society. More than 30,000 participants acted together, despite conflicting interests and power structures.

These issues pose a challenge for the scientific community, which is increasingly becoming involved in normative issues, value judgments and soft science; these all require innovative integrated approaches at the science–policy interface. Science can also contribute to assessment of the decision-making process by developing analytical concepts and the application of decision methods and tools (Sprinz 2005). In the following section, we discuss alternative approaches and concepts for developing a new framework appropriate for analysing social interaction, collective decision-making and governance across multiple levels.

13.5   Concepts of 'Sustainability Transitions'

Analytical concepts evaluate the evolution of complex dynamic systems according to criteria and indicators to avoid destabilizing consequences, tipping points and cascading breakdowns, and to facilitate a switch to a transformation of human–environment interaction that balances natural and social systems. After a short discussion of the concepts of stability, resilience, sustainability and peace, we focus on the concept of viability as an emerging integrative framework.

13.5.1   Stability and Resilience

The stability concept is a well-established paradigm in system dynamics and has played a significant role in international relations during the cold war (Scheffran 2011, 2015a; Scheffran/Link/Schilling 2012). In general terms stability means the ability to dampen the effect of disturbances in order to keep the essential characteristics of a system state (often an equilibrium) within boundaries. If this fails, there is the possibility of destabilization associated with systemic breakdowns, phase transitions and transformation processes. Examples include the collapse of natural and social systems under existential stress, transitions between war and peace, and the transformation from the exploitation of natural resources to their sustaina-

ble use. In the climate context it is relevant whether anthropogenic global warming leads to a destabilization of human–environment interaction, as described above, or is contained by self-stabilizing mechanisms.

Resilience often refers to the capability of a system to handle and survive external challenges and disturbances such as climate change. A 'resilient' system is able to withstand external shocks and to maintain or restore the conditions of its own existence (Holling 1973). Social resilience implies that a community is able to respond appropriately to disturbing changes (Adger/Kelly/Winkels et al. 2002). In a resilient social environment, actors cope with and withstand the disturbances caused by climate change in a dynamic way that preserves, rebuilds, or transforms their livelihood. Resilience depends on multiple abilities and characteristics, such as connectivity, innovation and creative thinking. Key resilience strategies include the building of networks, the cultivation of diversity, and the maintenance of flexibility (Scheffran 2015a). In the context of crisis management, resilience describes the "capacity over time of a system, organization, community, or individual to create, change, and implement multiple adaptive actions, procedures, and processes in the face of various types of crises" (Penuel/Statler/Hagen 2013: 811). In a changing world, individuals, communities, and organizations that are willing and able to innovate have a greater potential to confront a crisis that challenges the existing structure and to relate to it as an opportunity for further development.

13.5.2   Sustainable Development

Concepts of 'sustainable development' seek to balance economic, social and ecological issues of concern for present and future generations and integrate the human sphere (socio-sphere) into the boundaries of the natural environment (eco-sphere) (WCED 1987; Scheffran/Stoll-Kleemann 2002; see chapters 1 by Brauch/Oswald Spring and 18 by Mesjasz in this volume). The challenge is to make apparently conflicting objectives compatible (Scheffran 1997): 1. *sustain*[4] refers to *preservation* and *upholding* (in German "Erhaltung") of natural resources as the life-enabling base of society and precondition for human existence; 2. *development* means the *unfolding* of opportunities and abilities to improve human well-being and promote societal progress.[5] While the first task is to keep

---

4   The term *sustain* goes back to the Latin *sustinere* (*sub* = up, *tenere* = hold) which translates into *upholding*.

given abilities, development seeks to expand them in a progressive direction.

These goals were already suggested in the definition by the World Commission on the Environment and Development (1987): "sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs". Thus, the task is to balance the human needs and abilities of current and future generations. While 'needs' are based on human preferences and values, the term 'ability' is related to the opportunities created by natural resources (Scheffran 2011) and the capacity to act, which is a precondition for achieving needs. In a nutshell, sustainability can be defined as the ability to sustain ability. Ability has many facets related to human action, from capacity-building and Amartya Sen's (1986) 'capability approach' to the various dimensions of natural, physical, human and social capital (Scheffran/Remling 2013). While natural and physical capital determine the fundamental role of nature and technology for human capability and productivity, human capital comprises knowledge, skills and capabilities that enable human beings to act in new ways, while social capital refers to the institutions, relationships and norms that shape the quality and quantity of a society's interactions.

Integrated sustainability strategies seek to balance the two ends of the relationship between natural resource input and human value output, taking into consideration several contextual and intermediate factors (Scheffran/Stoll-Kleemann 2002). Sustainability indicators apply to human impacts on natural resources as a source (extraction for human production and consumption) and as a sink (impacts of human activity on nature). The impact of resources on humans is also twofold: resources as a production factor needed for human well-being and as a risk factor for human security. The 'Kaya identity' combines the drivers of human impact on carbon emissions and on environmental change (Kaya/Yokuburi 1997; IPCC 2014). Affecting these drivers represents different sustainability strategies: changing labour productivity, technical innovation, investment in human and social capital, resource intensity, renewable energy and sustainable lifestyles and consumption patterns, environmental protection, risk reduction and conflict management. Instead of destroying boundaries through the growing extraction and destruction of material,

energetic and biological resources, development into a multidimensional space of values would ensure the preservation of natural conditions and boundaries. The implementation of sustainable development has met various obstacles which are in conflict with competing interests and the world's power structures.

13.5.3   Peace and Sustainable Peace

In human history, visions of peace have a long tradition and have served as a model for conceptions of alternative futures of societies. Peace is often mainly associated with its negative definition as the absence of war (Galtung 1967), or in a broader sense the absence of violence (intentional destruction). Peace strategies are based on the principles of non-violence, preventing and excluding the use of violence and diminishing its potential through disarmament, transparency and confidence-building. The absence of immediate physical violence is, however, not necessarily evidence for peace. A situation could hardly be called peaceful if stronger actors were to suppress the weaker ones, who then surrender for fear of repression. This would correspond to what Johan Galtung (1969) has called 'structural violence', as a situation that encompasses severe constraints on possibilities for development. The criticism has been levied that giving violence such a broad meaning could lose focus and see anything that is interpreted as a loss compared to an ideal or desired world as violent (Scheffran/Ide/Schilling 2014). Renouncing violence as an illegitimate means of power is a more viable pathway in the pursuit of peace and sustainable development than 'just wars'. While negative peace is characterized by 'freedom from fear' of violence and hostility, positive peace rests on the freedom to develop opportunities for a satisfying and healthy life. This includes basic human rights and justice, as well as participation and conviviality in social interactions, reconciliation, healthy social relationships, prosperity in matters of social or economic welfare, and a working political order that balances the interests of all.

Like sustainable development, peace rests on two key principles with regard to the existence and development of human rights (Czempiel 1995: 170): 1. preservation and protection of the existence, integrity and identity of each individual by excluding violence; 2. self-fulfilment and unfolding of the individual through equal distribution of development opportunities. Upholding and unfolding are thus essential categories of both sustainable development and peace.

---

5   This dual role of holding and unfolding (*Erhaltung und Entfaltung*) has been recognized in Bender (1991, 1998).

Common features facilitate the joint conception of *sustainable peace* (see chapters 1 by Brauch/ Oswald Spring and 9 by Brauch in this volume). The idea of peace is accepted in political conflicts and international relations, often as a normative concept for the avoidance of violence and war. After the cold war, however, sustainable peace became a framework for global and planetary security, that would protect the earth against environmental threats and harmonize the conflicting goals of environmental and security policy. Sustainable peace addresses multiple linkages in this nexus. On the one hand, it assesses the negative interactions between armed conflict, environmental destruction and low levels of development (Scheffran/Vogt 1998). Both the lack of sustainability and peace are associated with the loss of development opportunities. If the world is more violent and less peaceful, sustainable development may also be threatened, and this could further aggravate conflicts. Degradation of sustainability undermines living conditions. This further undermines the conditions for peace and leads to violence, running into a 'vicious cycle' of a non-peaceful and unsustainable world, where the principles of non-violence, justice and preservation of life are violated, thus distracting attention from fair and equitable sustainable development.

On the other hand, positive linkages can emerge between human development, environmental protection and peace-building, leading to a 'virtuous cycle'. While sustainable development may contribute to peace, the preservation of peace may be an essential precondition for the cooperative implementation of sustainable development. As suggested above, sustainability connects the development opportunities of society to the preservation of the environment, and the development of individuals depends on the preservation of their existence in times of peace. To avoid conflicts and to strengthen the positive links between natural and social capital, it is essential that both the natural and social sciences jointly contribute to integrated sustainability strategies and that they find co-benefits, e.g. through consensus, arrangement and conflict resolution in environmental and security issues. It is important to understand how environmental degradation, low levels of development, and violence mutually influence each other; but also whether sustainable development can be achieved, even under non-peaceful conditions; and whether peace is possible, even under unsustainable conditions.

Whether positive (cooperative) or negative (conflictive) linkages will prevail depends on circumstances and human responses as well as on their speed and adequacy. While both pathways may develop in parallel, it is possible that there is a bifurcation or tipping point beyond which either pathway could prevail, following mutually enforcing mechanisms that trigger cycles of insecurity and violence or cycles of cooperation and peace (see section 13.7 below). For the time being the world may enter an undefined und uncertain path on the brink between conflict and cooperation, where small changes may drive regional development in one or the other direction. We may not know the boundary between stability and instability, how far away we are from it, how fractal its shape is, or how robust against changes it is. For the time being, the world may be moving along the edge close to a tipping point.

If seriously implemented in the mechanisms of local and global governance, the goal of sustainable peace could be an important contribution to a preventive strategy of global risk avoidance and reduction rooted in the satisfaction of basic human needs without destroying the essential conditions of life. People who are satisfied with themselves, their natural environment and their social livelihood are assumed to have less incentive to use violence or violate the social norms essential for their wealth. In this respect, sustainable peace would be an important contribution to the preservation of peace, more effective than attempts to control violence in a non-peaceful world.[6]

In addition to the two aspects of preservation and development (upholding and unfolding) already mentioned, the constructive and transformative aspects of sustainable peace can be added by reference to a third task: shaping and designing a future world. In the German language the word 'Gestaltung' can be represented by the English term 'configuring' to fit something into a proper shape, form or design, thus creating a harmonious relationship between the real and the desired world.[7] To summarize our conceptual excursion, the triangular relationship between sustainability, development and peace can be represented by the three tasks of upholding, unfolding and configuring (in German: *Erhaltung, Entfaltung, Gestaltung*, following a suggestion by Bender 1991, 1998). In short: upholding current abilities serves as a basis for unfolding enabling opportunities and configuring environmental transformation towards new pathways and spaces. The challenge is to find viable pathways that

---

6   In German, the word for 'satisfaction' is 'Zufriedenheit', which includes the word 'Frieden' meaning peace.
7   An alternative term is 'immoulding' which however is obsolete in modern English language.

transform current human–environment interactions into the desired future ones, taking into account the complex non-linear dynamics of the respective systems.

13.6   Viability as an Integrative Framework of Transformation Processes

The conceptual considerations in the previous section have laid the ground for developing the overarching integrative framework of 'viability' as a basis for analysing future transformation processes and pathways. This goes beyond established approaches, such as forward system dynamics simulations and integrated assessment modelling based on rational choice and optimal control of dynamic interactions between natural and socio-economic systems under climate change.

13.6.1   Tolerable Windows and Adaptive Control

Optimal control methods seek to maximize time-discounted utility functions (welfare), which include expected benefits, potential damages and the costs invested. Integrated assessment models use optimal growth of production functions with capital, labour and technology to design climate policies (Nordhaus 1993; Edenhofer/Lessmann/Kemfert et al. 2006), usually assuming complete knowledge utilized to select time-discounted control paths. The merits and limits of optimization-based integrated assessment have been widely recognized (see Füssel 2006). The requirements of rational choice methods such as optimal control and game theory, e.g. perfect foresight and complete information, are hardly fulfilled in decisions taken under conditions of deep uncertainty and complexity. Going beyond optimization over long-term horizons, adaptive decision-making and cooperative management allow actions and targets to be adjusted to the limited knowledge of the climate state and the capabilities of decision-makers, as well as to the complex socio-economic interactions that undermine predictability (Scheffran 2008a).

Forward-looking approaches determine a set of emission trajectories based on computer simulations in order to project future system dynamics from initial conditions by variation of scenario-dependent parameters. An alternative method is to use inverse approaches that calculate admissible 'channels' of emission trajectories compatible with a tolerable or targeted temperature range. An example is the *Tolerable Windows Approach* (TWA) and related concepts (safe landing, guard rails) that restrain and adjust the path of GHG emissions to keep average temperature change within viable bounds of natural and social systems and avoid critical risk levels (Bruckner/Petschel-Held/Toth et al. 1999; Petschel-Held/Schellnhuber/Bruckner et al. 1999). The space to manoeuvre for future climate policy is provided by assessments and judgments of climate change that take into account vulnerabilities and adaptive capacities as well as critical thresholds for phase transitions and extreme events that may cause qualitative system changes. Once the tolerable boundaries are found, control variables and regulation mechanisms for staying within these boundaries are identified.

An extension of optimal control and TWA is adaptive control, where actions are taken according to rules that respond to the actual state of a system in a prescribed direction (Scheffran 2008b). Adaptive control approaches constrain and adjust GHG emission pathways towards a target or towards staying within a viability domain of the climate system (e.g. a certain range of carbon concentration or global-average temperature change). Actors decide and act on the basis of incomplete knowledge, usually limited to a spatial and temporal window of attention. An important rule in climate policy is to stay below critical atmospheric carbon concentration and temperature thresholds. Other boundaries have been identified by Rockström, Steffen, Noone et al. (2009). Once boundaries are defined, the distance from the current position as well as the rate of change constitute drivers that are used to adjust the correcting response in order not to exceed the threshold.

Adaptive rule-based approaches are useful in complex and deeply uncertain situations where actors do not know enough about the future to calculate long-term optimization (Scheffran 2008a, 2008b). Within the range of uncertainty, a forward-looking actor can estimate whether future pathways reach the target or enter 'forbidden' areas, something which requires actions within given constraints. Continuously updated scientific information is essential for estimating whether expected future trends are tolerable within given limits or corrections are needed, just like steering and speed controls in a motor vehicle which are adapted by sight, destination and events. Similar adaptive control strategies are implemented in other contexts via decision rules and responses to a changing environment, taking into account actions taken by other actors.

Timing matters, as rapidly changing environments require faster action than long-term decision-making. For instance, impact-driven responses are too late in climate policy because of the considerable time lag of several decades between emission reductions and the visible impact of climate change (such as sea level change). In addition, the effect of policies will be delayed: for instance, the replacement of infrastructure and technology such as buildings, power stations and transport systems as part of a low-carbon transformation can take several decades. Another issue is time discounting by decision-makers, where the long-term future is given a lower value than the short-term future; this leads to 'wait and see' policies that favour short-term investment priorities. More appropriate are anticipative and adaptive strategies that are precautionary and seek to avoid risky pathways.

13.6.2 The Viability Framework of Anticipative and Adaptive Governance

Adaptive control and guard rails approaches can be embedded in a broader management framework of viability in order to analyse complex human–environment interactions and transformation processes. Since the 1980s 'viability' has emerged as a paradigm in complexity and sustainability science (Aubin 1991; Grossmann/Watt 1992; Bossel 2001; Scheffran 2015a). Originating from the Latin word 'viabilis', which combines the words *via* and *abile*, viability refers to 'able and enabling pathways' and the ability of a system, such as an organism, ecosystem or social system, to live, grow, and develop within the limits of its specific environmental conditions and boundaries. These boundaries may be transformed themselves by expansion or reduction of the available space of possibilities and opportunities.[8] If as a result of changing environmental conditions and human actions tolerable domains of viability are left, key functions of the system can be lost, and this threatens its identity and existence. Catastrophic changes and cascading events may lead to the loss of valuable functions and a breakdown of the system. To maintain viability it is essential for a system to stay within critical tolerance thresholds of its ability to exist and set up control and regulation mechanisms in time to avoid exceeding these limits (Aubin/Saint-Pierre 2007).

Viability theory provides methods and tools for adaptive management of dynamic systems within given boundaries. Mathematical viability theory studies algorithmic methods in complex uncertain systems (e.g. the biosphere, societies, markets, rural and urban areas, etc.) which develop in neither a completely deterministic nor a completely stochastic way, in conjunction with their viability constraints (Aubin/Saint-Pierre 2011).

A crucial but often neglected issue of viability is identifying the 'essential' attributes that characterize a system. While an individual system is represented by a large set of attributes, a class of systems requires only a limited set of attributes. For instance, the term 'human' is characterized by a few attributes that are typical for all humans, while a particular human being can be described in detail by numerous specific characteristics such as size, weight, location, age, name, etc. Interactions in the real world, such as moving through time and space, continuously change attributes that are less essential while existential attributes are preserved (such as the attributes that identify humans in general). Transformations change attributes along certain pathways, some of which may be essential and lead to qualitatively new systems, such as the ones that have created humans in biological evolution or that identify them in social evolution. Conceptions and constructions of identity play an essential role, as these define the key attributes and functions of the system—those that are to be maintained or achieved.

Viability combines quantitative and qualitative indicators that are partly subject to measurable data and scientific criteria (e.g. threshold for breakdown of ecosystems, number of conflicts) and partly subject to value-based judgements for the 'essential' attributes of identity or liveability of socio-ecological units (organisms, humans, societies) which can decide according to their own constructions and follow rules about when and why they change behaviour. Viability translates judgments based on value and capability into system states and trajectories that are to be achieved or avoided.

To preserve the attributes essential for a system's identity, certain capabilities are required to compensate for disturbances. Where the permissible limits are and when the viability of a system is compromised are things that are difficult to determine for complex systems. Exceeding limits means losing system functions and capabilities that are essential for their identity. If identity is based on a large number of key attributes, viability is harder to achieve if any of these attributes

---

8 Wikipedia refers to viability as the ability of a system to maintain itself or recover its potentialities. This resembles elements from the definition of resilience in a wider context.

is threatened. If critical thresholds are passed, the system is more difficult to stabilize. In particular, this is the case once a loss of crucial capabilities is experienced (such as human disabilities in walking or seeing) or pathways are pursued that provoke hostile responses from others that exceed the system's own capacity to deal with. On the other hand, additional capabilities can be gained along these pathways, e.g. by growing income or cooperative connections in social networks, thus creating mutual benefits. To meet the 'precautionary principle', early (self-)regulation mechanisms are required in order to prevent instability and maintain a system without compromising the viability of interconnected systems.

In the environmental field, viability-related approaches have been applied, for example, to the design of tolerable windows for fish harvests (Ben-Dor/Scheffran/Hannon 2009; Eisenack/Scheffran/Kropp 2006) and to guard rails for greenhouse gas concentration (Petschel-Held/Schellnhuber/Bruckner et al. 1999). Like any type of control this approach selects certain future pathways in dynamic systems and excludes others, by following normative concepts. Viability allows other concepts such as stability, resilience, sustainable development and peace to be integrated as specific representations for particular contexts, each having specific mechanisms to tackle climate change (Redman 2014). Since climate change may threaten the viability of systems and push them towards non-viable dynamics, it is important to diminish climate vulnerability and strengthen adaptation, to avoid the creation of a dangerous chain of events before it develops and becomes unstoppable.

The viability concept is closely related to the adaptive management of transformation processes in human–environment interactions (Scheffran/Link/Schilling 2012; Scheffran 2015a). Viable adaptive control is a useful instrument for designing and adjusting the complex interaction between the socio-economic, environmental and political spheres in natural resource management (see, for example, Aubin/Saint-Pierre 2007). Once political requirements or goals are defined, they can be translated into boundary conditions that allow stakeholders to identify the controls necessary to stay within sustainable limits and maintain resilience, e.g. for resource use or carbon emissions, and to avoid non-viable regions of collective human action in rural–urban interactions. Viable control and adaptive management are needed to implement actions based on locally updated information and decision rules for each actor that respond to the changing state of a system (Scheffran 2015a). In this

context a conceptual framework and a meta-model of multi-stakeholder interaction processes will be appropriate to implement the viability concept (see the VIABLE model in the next section).

Viability assessment seeks to identify non-viable areas and critical thresholds where the identity or existence of the system is threatened, for instance critical levels of water scarcity, food insecurity, poverty, mass movements, conflict escalation and ecosystem stability. The next task is to analyse dynamic pathways and consequences in the indicator space, identifying key patterns and trends in the earth system and how they could be affected by climate change projections. Using the classification of typical non-viable patterns and pathways in hot spots, possible destabilizing and conflicting pathways and responses that exceed critical thresholds and lead to non-viability would be explored, and their likely consequences discussed. Assessments can evaluate past trends and projected scenarios regarding the key indicators, including agent-based modelling of potential pathways and response patterns.

Finally, key capabilities, opportunities, rules and institutional mechanisms are identified in order to regulate and control the viability of pathways in the indicator space, avoiding or moving away from non-viable areas or crossing thresholds in either direction. Specifically, this includes variables that affect the pathways towards increasing viability of human–environment interaction; it also includes the discussion of opportunities for viable regulation and control. Examples are water, food and energy infrastructure and efficiency; possible social and technical innovations in resource use; social networks and remittances from migrants; cooperation, collective action, institutions and governance mechanisms; and strategies for disaster management, protection and resilience. The impacts of alterations in crucial couplings can be studied in order to improve viability in resource or migrant networks and possibly allow the resolution of conflicts between agents. Viability theory can be used for analysing and testing boundary conditions for various human–environment interactions.

The viability concept can be expanded to conflict studies in the context of viable adaptive networks (Scheffran/Link/Schilling 2012; Scheffran 2015a). While conflict escalation may violate essential viability conditions (e.g. through the use of violence), institutional mechanisms and regulations can maintain viability through conflict resolution and cooperation. The viability concept can also be used for analysing transformation processes between opposing pathways

of sustainability and non-sustainability, conflict and cooperation, or peace and war. In the next section, a framework is described for modelling such transitions.

13.7 The VIABLE Model Framework of Societal Transformation and Adaptive Governance

To study the complexity and stability of interactions between systems and agents, various methods and tools have been developed, including system dynamics, dynamic game theory, agent-based modelling and social network analysis. Particularly relevant for complexity thinking are adaptive networks that switch dynamically between alternative pathways in response to changing internal and external conditions. Understanding the emergence of collective behaviour and the evolution of cooperation is a dynamic field of current interdisciplinary research. Of great interest is the dynamic spread of processes and patterns across social networks, such as the diffusion of social behaviour or technical innovations (e.g. Kempe/Kleinberg/Tardos 2005; Angourakis/Santos/Galán et al. 2014). Social networks evolve through processes of interaction such as conflict, cooperation, competition, and coalition formation among a large number of participants (Flint/Diehl/Scheffran et al. 2009; Maoz 2010).

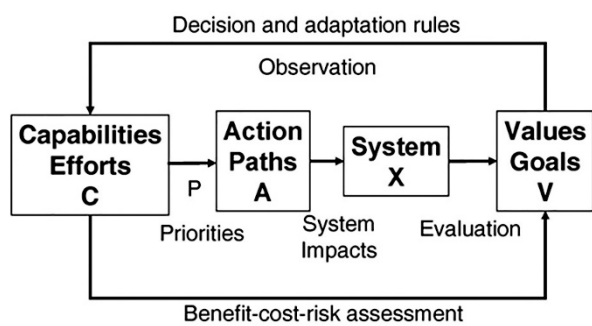
13.7.1 The VIABLE Model of Human Action and Social Interaction

In the remainder of this chapter, example cases of transformation processes are highlighted in the framework of a dynamic agent-based model of social interaction that has been developed by the author. The model framework VIABLE (*Values* and *Investments* in *Agent-B*ased interaction and *L*earning for *E*nviron-

mental systems) describes the dynamic behaviour and interaction of agents who apply (invest) proportions of their available capabilities (*C*) according to priorities (*P*) to given action pathways *(A)* that change their environment (*X*). The observed impacts are evaluated based on the agent's values and goals (*V*), which are a function of the benefits, costs, and risks of the actions taken. Over time, an agent's actions are adjusted through repeated feedback and learning cycles according to decision and adaptation rules in response to environmental changes, the actions of other agents, and the assessment of expected benefits, costs and risks associated with each action path. These actions are adjusted according to the agent's ability to evaluate the natural and social environment around them and implement their decision rules.[9] Since the choice between different action pathways and the emerging social interaction patterns (such as conflict and cooperation, social networks and coalition formation) are core elements of the VIABLE model, it offers a framework for the modelling of transformation processes. Rather than explaining the structure of the model in detail (which has been done elsewhere: Scheffran 2003; Scheffran/Hannon 2007; Bendor/Scheffran 2016), a few examples and results are given in fields where the model has actually been applied to transformation processes.


13.7.2 Ending Nuclear Deterrence: Missile Defence and Nuclear Disarmament

The VIABLE model had its origins in the analysis of the cold war arms race between the superpowers in the 1980s, starting from the question of how to end nuclear deterrence, and moving from *Mutually Assured Destruction* (MAD) to *Mutually Assured Survival* (MAS). Alternative approaches have been presented: missile defence (the Strategic Defense Initiative SDI launched by US President Ronald Reagan in March 1983) or complete nuclear disarmament (suggested by the Soviet General Secretary Mihkail Gorbachev's plan in January 1986) (see figure 13.5). Concerns about destabilization led to the failure of the Reykjavik summit in October 1986, when both strategies became incompatible.

To study the complex intricacies of these issues, the SCX Model of security, cost and armament dynamics was developed in a PhD thesis by the author between 1986 and 1989, a year of momentous transi-

---

9   Model variants such as SCX, VCX, and VCAPS have been used in different application fields.

Figure 13.5: Competing transition plans for ending nuclear deterrence in the 1980s: cost projections for Reagan's SDI plan (upper part) vs. Gorbachev's plan for the elimination of nuclear weapons. **Source**: Adapted from: (top) Pike (1985: 11); (bottom) Spiegel (1986: 98).
tions that led to the end of the cold war (Scheffran 1989).[10] Figure 13.6 shows fifty-year model runs for two selected variables (Security and Cost functions) for one of the scenarios. The results show variation of

10 The thesis was submitted in early October 1989 and the final defence took place on 21 December 1989. In between these dates, the Berlin Wall fell, and with it the East European political regimes of the Warsaw Pact, except for the Soviet Union, which disappeared in 1991.

the so-called 'worst-case parameter' between worst-case (w = -1) and best-case (w = +1) assumptions within a range of uncertainty of variables of strategic warfare (e.g. number of nuclear-armed missiles, capabilities of missile defence and space weapons, explosive yields, multiple warheads, missile accuracy, costs, etc.). The middle of the uncertainty range is represented by w = 0. It is striking that in the transition between the extreme cases a qualitative change of cascading events beyond a tipping point occurs. Moving

Figure 13.6: Simulation of the transition from negative (worst case $w = -1$) to positive (best case $w = +1$) perception of the SCX arms race model, with a chaos-like oscillation around $w = 0$. The figure shows the security function (lower part) and cost functions for the fluctuating scenario (total and variable cost, upper part) $\delta = 0$ implies no time delay in responses. **Source**: Scheffran (1989: 245).
Figure 13.7: Tipping point in global nuclear arsenals. **Source**: Scheffran/Burroughs/Leidreiter et al. 2015, based on data from the Bulletin of the Atomic Scientists.
from negative perceptions (negative security and high costs) to positive perceptions (positive security and low costs) there is a transition zone around $w = 0$ with strong chaos-like fluctuations. Thus, for the same initial strategic situation, completely different out-

comes result, depending on interpretation from hostile to friendly attitudes on both sides.

Such a shift from hostile to friendly attitudes and perceptions actually occurred between 1986 and 1989 when Gorbachev's policy of glasnost and perestroika opened the way for a new relationship between the United States and Russia. Threat perceptions declined after 1989 when the Soviet Union disappeared in 1991 and both sides significantly reduced their nuclear arsenals (figure 13.7) and even considered the complete abolition of nuclear weapons. At the same time, the United States continued to push for missile defence. This led to a hostile reaction from Russia and is one of the factors in the new climate of hostility that has slowed down progress in nuclear disarmament. This points to the fact that these issues are still relevant today.

13.7.3   Modelling Complex Conflict Landscapes and Cycles of Violence after the Cold War

After the chaotic ending of the cold war, the new conflict environment became increasingly complex, with a growing number and diversity of agents and multiple overlapping security dimensions. Within the SCX model variant of the VIABLE framework, the fractal security landscape can be represented by the bifurcation diagram in figure 13.8, which shows the range of anti-symmetric security dilemma situations for an increasing reaction (given by the so-called memory parameter) which indicates the strength of the agents' responses to an experienced change of security (for instance a strong response to security losses). For low reactivity the system shows periodic oscillations around the satisfying security state (here $S = 0$); for growing reaction the oscillation is damped and asymptotically approaches zero. With a further increase in reactivity a cascading sequence of security states emerges, which matches the famous bifurcation diagram of the logistic map in chaos theory (Jathe/Scheffran 1992). It is interesting to see that strong reactions to changing security situations may lead to overshooting in one or the other direction; this makes it hard if not impossible to predict future security transitions beyond the edge of chaos, since small events may drive the situation in one or the other direction. In a tightly coupled world of complex crises, rapidly changing security situations can emerge (as described in earlier sections of this chapter).

What adds to the complexity is the interaction of multiple agents. Going beyond two-player games, a hypothetical situation of thirty agents each is considered, with asymmetrically distributed initial conditions of security and costs (marked by crosses +) and impacts on each other in their social networks (figure 13.9). Following the dynamics of the SCX model the agents separate into those diminishing security and increasing costs (running into conflictive interactions) and those who benefit from the interaction by improving security at declining costs. Thus, the world falls apart (bifurcates) into 'winners' and 'losers', provided there are no behavioural changes, represented by shifting impact factors (Scheffran 2003). Who belongs to either group largely depends on the initial conditions and the stability of the interaction matrix, measured by its eigenvalues. While most agents who initially are in the negative or positive security domain stay there, several agents cross the divide as a result of the interaction (they either win or lose from the efforts of others).

Many conflicts are related to the 'security dilemma', where threats to the security of one agent provoke reactions that threaten the security of other agents, contributing to the 'cycle of violence' mentioned above (Scheffran/Ide/Schilling 2014). As a prominent example, this inherently unstable interaction led to cascading threats in World War 1 (Flint/Diehl/Scheffran et al. 2009). The dynamics of the conflict is driven by the interaction between motivation (incentives for survival and countering opponents) and capability (increasing losses and needs for violent force). Violence can transform (e.g. from intercommunal violent conflict to insurgencies or interstate wars) and spread to neighbouring states or regions, e.g. through (cross-border) migration, ethnic links, natural resource flows, black markets or arms exports. Societies prone to spirals of violence are those in transition or on the edge of instability, such as fragile and failing states with social fragmentation, weak governance and inadequate management capacity (Scheffran/Ide/Schilling 2015). Key variables and pathways of interaction between two actors are presented in figure 13.10. Here the resources and capabilities of each actor may be applied for productive purposes (creation of wealth assets) in cooperation or for destructive purposes (building and use of violent force) in conflict. Once critical thresholds of insecurity and violence have been passed, a self-enforcing spiral of violence may emerge when violent acts provoke more violent acts; similarly, a self-enforcing cycle of cooperation and peace can be induced (see Scheffran/Ide/Schilling 2014). Agents can choose to switch from productive to destructive purposes (and vice

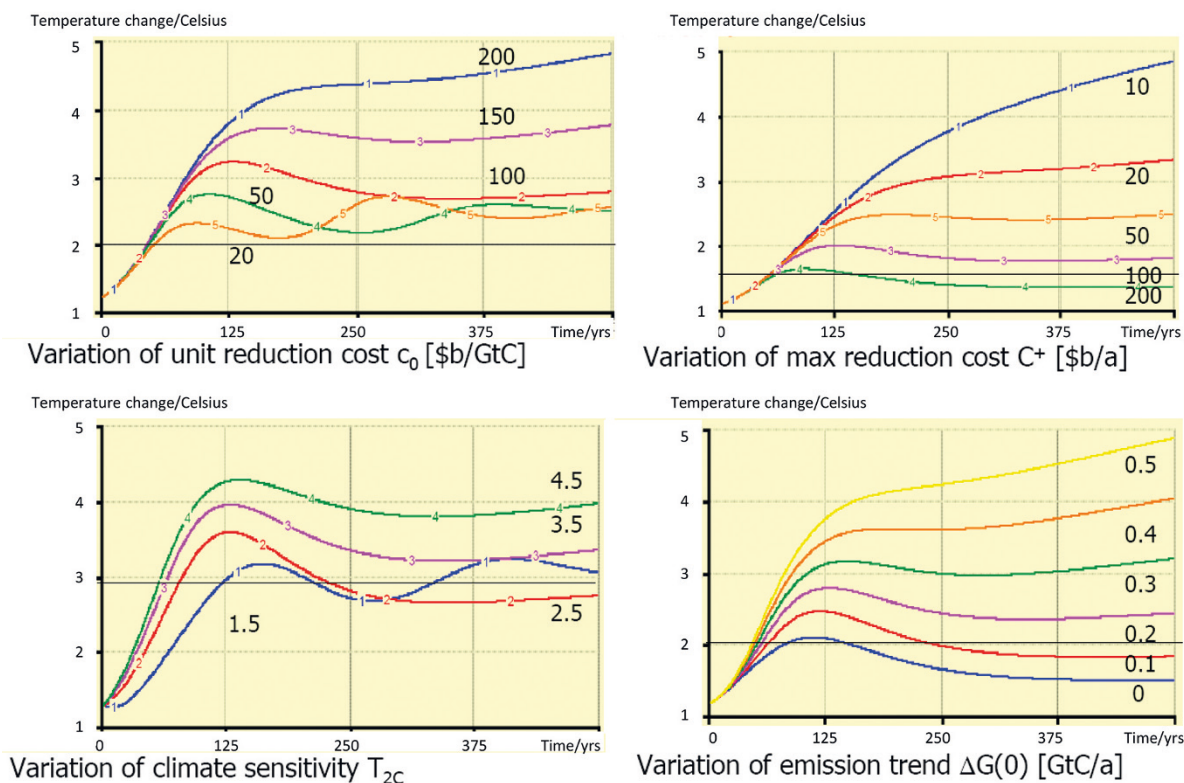
versa) according to their motivations; collective actions could drive agents into self-enforcing cycles of violence or cooperation.

13.7.4   From Climate Risk to Emission Reduction

Human–environment interaction has been extensively simulated within the VIABLE model framework (and its VCX variant for value *V*). Besides other examples, e.g. cooperative and sustainable management of fisheries (Scheffran 2000; Bendor/Scheffran 2009), modelling of energy and climate change has played an important role. In a simplified model version with adaptive control strategies the impact of parameter variations is demonstrated so that the conditions can be visualized that lead to the transition from high-emission to low-emission pathways, starting from a baseline business-as-usual scenario and a 2°C temperature limit (figure 13.11). The model is less a prediction than a demonstration tool that describes the fundamental dynamic relationship between actual and cumulative carbon emissions, atmospheric carbon concentration and global temperature change beyond pre-industrial levels for a particular parameter choice.

Figure 13.11a shows variation of the abatement costs per emission unit, which demonstrates that the target is nearly achievable for a unit cost of $20–50 billion, which will reduce the level of carbon emissions by 1 Gt (with some overshooting). For larger unit costs, temperature exceeds the limit. Variation of the maximum reduction cost shows the relevance of the total investment that the world is willing to spend on emission reductions each year (figure 13.11b). For the baseline case, $100 billion per year may stop temperature growth in about 100 years and reverse it but still misses the target, while $200 billion per year would prevent temperature from exceeding the limit and bring it back below the threshold. For high climate sensitivity (above 3.5°C) the temperature target is missed, while a lower sensitivity of 2.5°C starting from the baseline allows the temperature increase to be reversed below the threshold after temporarily overshooting (figure 13.11c). Finally, the model is sensitive to the initial trend of emission growth as a main driver of global warming (figure 13.11d).

Going beyond the world as a single agent, other simulations over fifty years are presented for two agents, called 'North' (industrialized countries: Actor 1) and 'South' (developing countries: Actor 2), modifying a basic integrated assessment model (Nordhaus

Figure 13.11: Temperature change for parameter variations of: (a) unit reduction cost; (b) maximum reduction cost; (c) climate sensitivity; (d) initial emission trend. **Source:** Scheffran and Hannon (2007).


1993) with adaptive elements from the VCX model (Scheffran/Jathe 1995, Scheffran 1999). Both regions are striving for a certain level of wealth, slightly above the present average for the North and much higher than in the South. Both invest in energy production which increases wealth but also increases the potential environmental damage (risk) from climate change, which may affect GNP negatively. The choice of the other model parameters (population growth; emissions, costs, wealth and risk effects per unit of energy; initial conditions for energy consumption, GNP, CO_2 content of the atmosphere) represent a standardized reference case, meant to correspond to the initial year 1990.

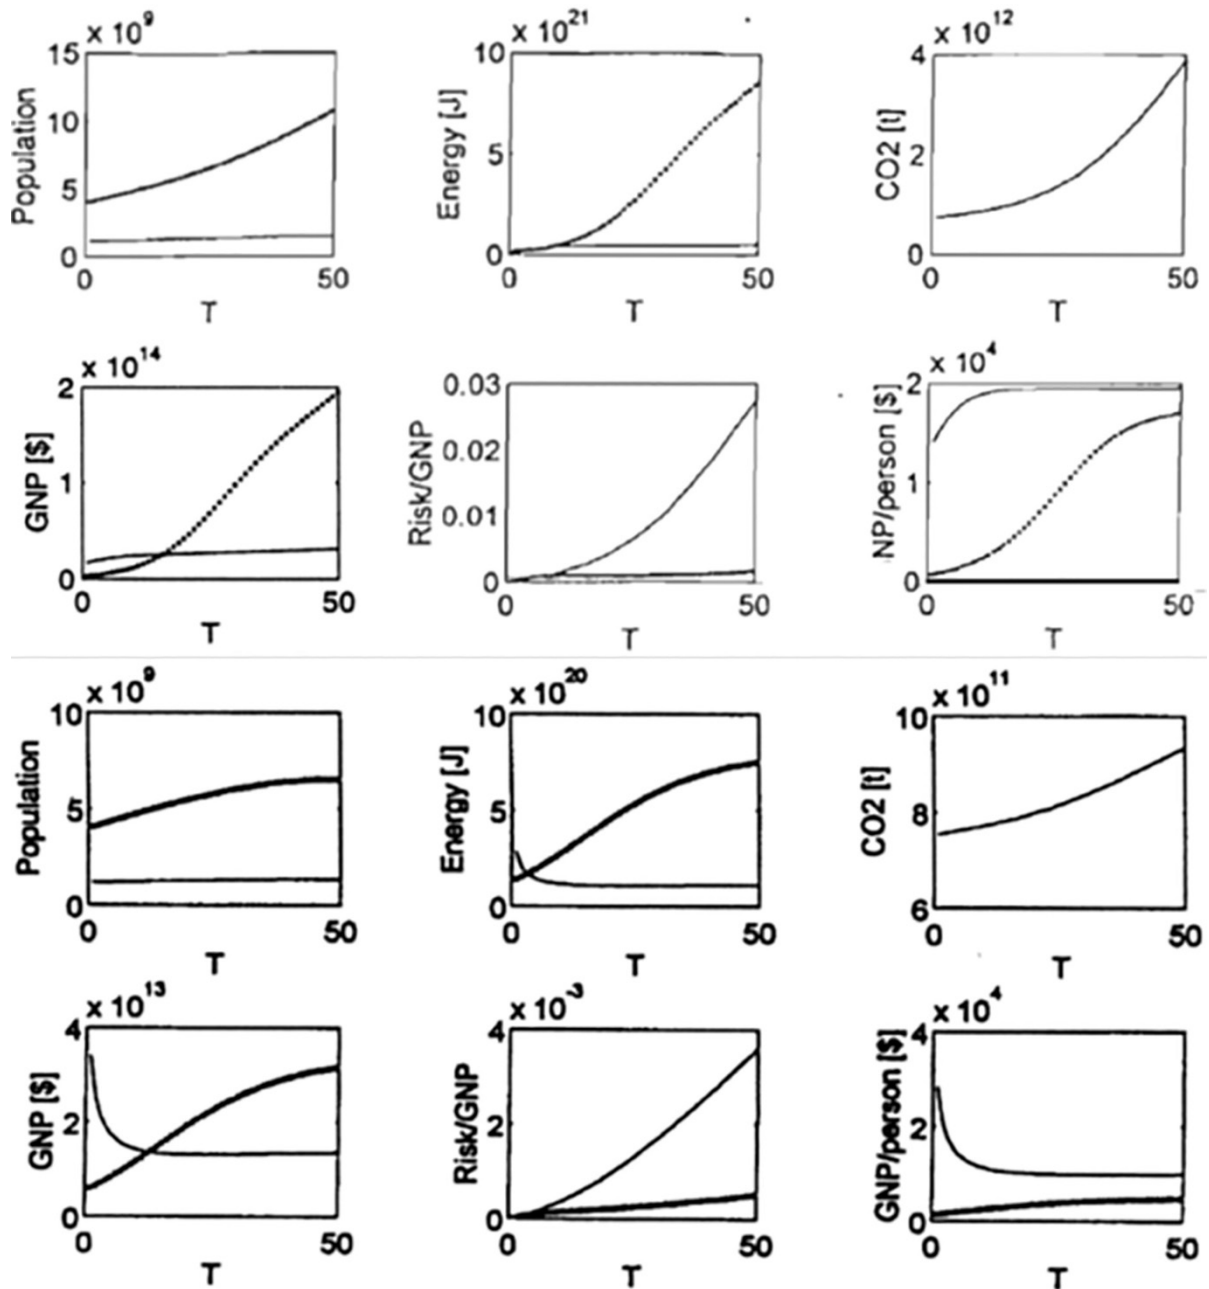
As expected, in the numerical simulation the attempt by the developing region to reach the level of wealth per capita of the industrialized region, despite a doubling of the population, leads to a dramatic increase in energy consumption and GNP to more than fifty times the present level. After about ten years, the South outstrips the North's GNP, but the North achieves the goal of GNP per capita sooner. The CO_2 content of the atmosphere increases about

fivefold, which is associated with high risks (a few per cent of GNP).

To avoid this pessimistic catastrophe scenario, a few parameters are altered: a linear decline in the population growth rate, lower and asymmetric wealth targets in North and South, technologies with fifty per cent lower CO_2 emissions, fifty per cent higher energy efficiency, and higher energy costs. Under these conditions, energy consumption in the South only grows about fourfold, while it declines by half in the North. The CO_2 concentration in the atmosphere increases to a slightly higher level than today but much lower than in the first scenario. The lower wealth goals are achieved, despite drastic increases in energy prices, with substantially less environmental damage (below one per cent of GNP).

13.7.5 Technical Innovation and Coalition Formation in Sustainable Energy Transitions

One of the greatest challenges is the transformation of the energy system from fossil and nuclear power to renewable energy sources. The key questions are

Figure 13.12: Simulation of the simplified SCX model dynamics for population, energy consumption, atmospheric CO_2 concentration, gross national product (GNP), risk/GNP and GNP/capita for two actors over fifty years (North: solid line, South: dotted line). *Upper simulation*: Catastrophe scenario if the 1990 situation continues, for high prosperity goals; *lower simulation*: Stabilization scenario for smaller population growth, lower wealth goals, lower emissions, higher efficiency and higher costs per energy unit. **Source**: Scheffran (1999).


focusing on the conditions for switching to low-carbon energy pathways, and building societal infrastructures and coalitions to support an energy transition. Integrated assessment in the VIABLE model framework couples a basic climate model to economic production with energy as a production factor, which is controlled by the allocation of investments to alternative energy technologies. Investment strategies are shaped by value functions, including utility, costs and climate damages for a given future time horizon, and these are translated into permissible emission limits for keeping atmospheric carbon concentrations and

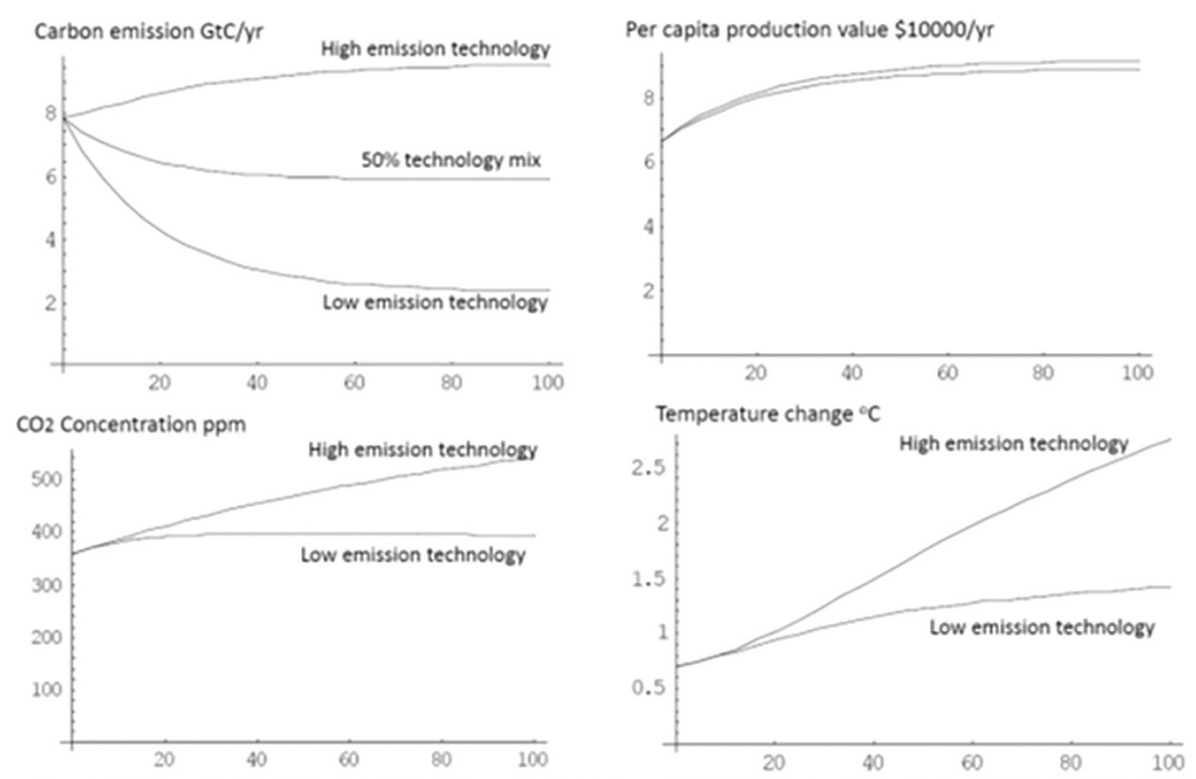
Figure 13.13: Range of variables (carbon emissions, per capita production, atmospheric CO_2 concentration, temperature change) over 100 years for low- and high-emission energy paths. **Source**: Modified from Scheffran (2008b).


Figure 13.14: Value difference between high and low emission energy technology with variation of damage factor (left) and carbon price (right). **Source**: Modified from Scheffran (2008b).
global mean temperature below a given threshold. Conditions for switching between energy paths with different costs and carbon intensities are identified, and the sensitivity of the results to variation in crucial parameters is discussed, in particular time discounting, climate damage, taxes, and time horizons for decision-making (Scheffran 2008b).

Two energy paths are compared: the established path, and a new path with twice that cost and half the emissions per energy unit. The variables in figure 13.13 are carbon emissions, per capita production, atmospheric CO_2 concentration and temperature change over a period of 100 years for high- and low-carbon pathways. While emissions show the largest variation, between 10 GtC/year for high-emission technology and 2 GtC/year for low-emission technology, per capita production varies only by a small margin of 1–2 per

Figure 13.15: Interplay between energy providers and customers for different energy paths (marked here by *A* and *B*). **Source**: Adapted and modified from Scheffran (2006).

cent. Concentration varies between around 400 and 550 ppm after 100 years, while temperature varies between 1.5°C and more than 2.5°C.

Figure 13.14 plots the annual value differences between high- and low-emission energy technologies for different time horizons of decision-making. It plots value differences against time horizons for varying damage factors (figure 13.14a) and carbon taxes (figure 13.14b). There is an initial value barrier against switching towards the low-carbon energy path, which declines with increasing damage and tax. Increasing climate damage lowers the barrier until it becomes negative. Accordingly, a tax will reduce the barrier, but much faster. A tax creates a relative incentive to switch to new technology in the near term. The example case demonstrates that timing matters. Will emission reductions and investment be delayed to a later stage, running the risk of severe climate change, or will the required action be taken earlier, at the cost of diminished near-term economic benefits? Even though the overall value may be still the same, both paths differ considerably with regard to the distribution of risks and costs in time and space.

As suggested earlier, energy transitions are driven by multi-agent interactions. These have been simulated in the VIABLE framework in order to analyse the formation of adaptive coalitions among energy providers and consumers, where the coalitions have been formed to allocate investment to different energy pathways to generate value (for model structure, see Scheffran 2006 and figure 13.15). Each coalition of energy producers receives payments from individual consumers to supply energy through different energy paths to produce value for the consumers. Here we have a triple decision situation: allocation of investment from consumers to producers and from producers to energy paths, and distribution of value to consumers. Each of the decision variables follows adjustment rules.

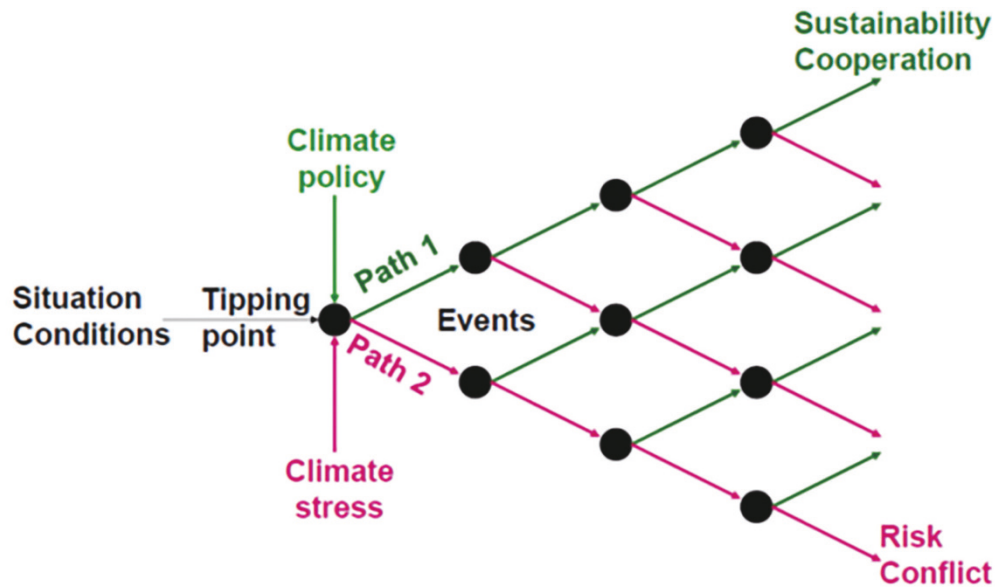
Figure 13.16 presents the hypothetical interplay between two energy providers and six customers who have the choice between two energy paths: the old technology path with high emissions and low costs, and the new one that cuts emissions by up to fifty per cent, but where unit costs are up to fifty per cent higher (Scheffran 2006). Customers differ in energy efficiency of production, where the efficiency for energy 1 declines from customer 1 to 6 and the efficiency for energy 2 increases from customer 1 to 6. The range for unit cost, efficiency and carbon emissions is a factor of two, and damages per emission unit gradually increase from the first customer to the

sixth customer. The generated value of the agents can be reinvested. The model runs in figure 13.16 show a growth in the resources of agents and coalitions, where agents $A1$ and $A6$ and coalition $C2$ have the strongest growth rates. Coalition $C1$ specializes in the old energy path and coalition $C2$ in the new energy path, where both have cost advantages. Customer $A3$ is largely indifferent between the coalitions. Customers $A1$ and $A2$ emerge as early adopters of the new energy path and prefer coalition $C2$ while customers $A4$ to $A6$ still prefer coalition $C1$ which represents the established cheaper energy path with higher emissions. In another study, the adaptive model has been applied to emission trading in eleven world regions (Scheffran 2004; Scheffran/Leimbach 2006).

13.8   Conclusions

In an increasingly interconnected world where systems are tightly coupled across different scales, stabilization of human–environment interactions under conditions of climate change is a major challenge in international relations that requires the integration of complexity science with global governance. This chapter has highlighted several cases of complex crises, where interconnected systems and cascading events have magnified individual events to the degree that they affect the stability of large systems. Climate change is considered a 'risk multiplier', which disturbs the balance between natural and social systems and amplifies the consequences through complex impact chains in interconnected systems. Through multiple pathways, climate change can affect the functioning of critical infrastructures and supply networks; intensify the nexus of water, energy and food; lead to production losses, price increases and financial crises in other regions through global markets; undermine human security, social living conditions and political stability; and trigger or aggravate migration movements and conflict situations.

Whether these linkages will materialize ultimately depends on the strengths and sensitivities of each coupling. Some effects could act over long distances, for instance through interventions or humanitarian aid in remote regions affected by violent conflict or large migration movements. Climate change as a threat multiplier could affect different security dimensions and provoke 'security dilemmas' with an increasing level of threat perceptions and armed conflicts. In the most affected states the erosion of social order and state failure could be aggravated, leading to a spiral of

Figure 13.17: Future climate pathways, tipping points and cascades between conflict and cooperation. **Source**: Modified from Scheffran (2015a).


corruption, crime and violence. To stabilize the interaction, actors could move towards mutually beneficial solutions (win–win), e.g. by resource sharing and risk management. Whether climate stress fuels a cycle of violence or climate policy drives a transition towards a cycle of cooperation and sustainable peace depends on the human and societal responses (figure 13.17).

An integrative framework of human–environment interaction can help us to analyse destabilizing developments, tipping elements and cascading risks. To survive destabilizing consequences, affected systems need to adapt to the changing circumstances to ensure their viability. Concepts of anticipative and adaptive governance influence critical decision points and adjust actions along multiple causal chains to protect human security, develop social livelihood and strengthen societal resilience. The goal is to avoid risky pathways and facilitate a qualitative and self-organized system transformation towards sustainability. Nevertheless, given the complexity and interconnectedness of affected systems, significant uncertainties exist regarding consequences and related damages, and this underscores the need for new approaches to decision-making under conditions of uncertainty and novel concepts for addressing the nexus of multiple problem areas that lead to complex crises.

To some degree, social systems have the ability to cope with the magnitude of climate change and develop possible alternative pathways of human responses and actions. To succeed, responses need to be timely and adequate compared to the speed and intensity of climate change. A key question is to what degree of climate change societies can adapt, and how effective and creative they are in developing coping strategies that are complex enough to deal with the challenges. One task is to translate environmental change into new social and political structures and institutions that avoid or minimize social instability. Rules and regulations that guarantee peaceful coexistence are characteristic of a viable society and this in turn is important for satisfying human needs.

Concepts of resilience, viability and sustainable peace can strengthen people's social capability in their effective, creative and collective efforts to handle the problems of climate change. In a resilient social environment, actors are able to cope with and withstand the disturbances caused by climate change in a dynamic way that will enable them to preserve, rebuild, or transform their livelihood. Key viability strategies, supporting a "new climate for peace" (Rüttinger/Stang/Smith et al. 2015), include climate mitigation and adaptation; the building of networks, the cultivation of diversity and the maintenance of flexibility; migrant networks that facilitate the exchange of knowledge, income and other resources; new capabilities to manage disasters; arms control, non-proliferation and disarmament; regional security concepts, crisis prevention, conflict resolution and confidence-building; and innovative institutional frameworks and legal mechanisms. The 2015 Paris Agreement offers a framework of opportunities that need to be realized.

Part IV   Initiating Research on Global (Environmental) Change, Limits to Growth and Decoupling of Growth and Resource Needs

14 The First Decade of Initiatives for Research on the Human Dimensions of Global (Environmental) Change (1986–1995)

Lourdes Arizpe[1], Martin F. Price[2] and Robert Worcester[3]

Abstract

By the end of the 1980s, very different meanings of 'global change' existed, promoted by different constituencies in the social and natural sciences (Price 1989). One could be described as anthropocentric, emphasizing the interactions between people and their institutions, primarily at scales extending to decades. This chapter presents and discusses the emergence of initiatives for research on the human dimensions of global change until the 1996 launch of the International Human Dimensions Programme on Global Environmental Change (IHDP). In 1987, the International Social Science Council (ISSC) joined with IFIAS and UNU to develop a Human Response to Global Change Programme. In 1990, ISSC launched the Human Dimensions of Global Environmental Change Programme (HDP), based on the "Framework for Research on HDGEC" (Jacobson/Price 1990), identifying seven broad areas in which research should be done. The first half of the 1990s were also characterized by the emergence and development of various national and regional (e.g., European) initiatives for research on HDGEC. In the subsequent two decades, as described elsewhere in this book, substantial advances have been made; many of them emerged from the initiatives described in this chapter.

Keywords: Social science, global environmental change, International Social Science Council, human dimensions of environmental change, land use, deforestation, industrial metabolism, social sustainability, culture and sustainability, perceptions and opinions on environmental change.

14.1 Introduction[4]

As several chapters in this volume clearly show, our planet is experiencing changes at the global scale.

The volume's title refers to 'global environmental change', but the biophysical environment is only part of the complex world in which we live, and many other parts of this are also experiencing changes at the global scale. These include social, economic and political systems and, until the early 1980s, the predominant use of the term 'global change' was by social scientists, to refer to changes in these systems. For example, the philosopher Robert Heilbroner stated that "Everybody senses that our age is one of profound turmoil, a time of deep change" (Heilbroner/Campbell 1975). He identified the proliferation of nuclear weapons, population growth and industrial growth as fundamental problems, linked to significant concerns about pol-

4 Of this chapter, section 14.1 and 14.2 rely heavily on Price, M.F. 1989: "Global change: defining the ill-defined", in: *Environment*, 31 (8), 18–20, 42–44, and Price, M.F. 1990: "Humankind in the biosphere: the evolution of interdisciplinary research", *Global Environmental Change; Human and Policy Dimensions*, 1, 3–13.

lution, inflation, energy and national security, and the possible loss of affluent lifestyles. Through the late 1970s and well into the 1980s, 'global change' continued to signify social and political change associated with similar challenges, such as international insecurity, unequal development, and decreases in the quality of life (Väyrynen 1979; Gazzo 1979; Prebisch 1980; Gati 1983; Price 1989).

In the 1980s, the concept of 'global change', now more commonly referred to as 'global environmental change', emerged, first in a study sponsored by the National Aeronautics and Space Administration (NASA), which effectively identified that we are now in the Anthropocene, referring to "changes that may affect the habitability of the earth" (Goody 1982: 3). In the following years, publications resulting from a study concluded by the US National Research Council (NRC, 1983) and a symposium sponsored by the International Council of Scientific Unions (ICSU) in 1984 (Malone/Roederer 1985) specifically referred to global change and led to the establishment of the International Geosphere–Biosphere Programme (IGBP), launched in 1986 as "A study of global change". Over the next two years, a plan for action was developed, outlining a research programme with four main components: terrestrial biosphere–atmosphere chemistry interactions; marine biosphere–atmosphere interactions; biospheric aspects of the hydrological cycle; effects of climate change on terrestrial ecosystems (IGBP 1988).[5]

Thus, by the end of the 1980s, very different meanings of 'global change' existed, promoted by different constituencies in the social and natural sciences (Price 1989). One could be described as anthropocentric, emphasizing the interactions between people and their institutions, primarily at scales extending to decades. The other could be described as geocentric, emphasizing the interacting processes of the Earth's atmosphere, biosphere, geosphere and hydrosphere, typically over far longer timescales. While people were recognised as driving forces, and also as affected by climate change and the productivity of ecosystems, they were not at all a focus, as encapsulated in a 'conceptual model of global system' published by NASA's Earth System Science Committee (ESSC 1988) in which 'human activities' were restricted to three 'bubbles' around the edge of the diagram. In this context, the goal of this chapter is to present and discuss the

emergence of initiatives for research on the human dimensions of global change–incorporating elements of both meanings–until the 1996 launch of the International Human Dimensions Programme on Global Environmental Change (IHDP).[6]

14.2   The Institutional Framework

As described below, the International Social Science Council (ISSC) launched the Human Dimensions of Global Environmental Change Programme (HDP) in 1990. This was the outcome of a long process involving a considerable number of institutions, introduced briefly in this section.

The ISSC [7] was created in 1953 as UNESCO set out to establish international non-governmental organizations (NGOs), including scientific organizations. In the aftermath of World War II, scientists were to develop their arts and sciences to reconstruct new and peaceful countries (Platt 2002: 12). Claude Lévi-Strauss became the first Secretary General of the ISSC. In accordance with its first two aims, to "advance the quality, novelty and utility of the social sciences worldwide [and] advance social science research across national and regional boundaries",[8] the establishment of disciplinary organizations and national social science associations was encouraged. By the end of the 1980s, the ISSC had more than sixty member organizations and member associations, and took the initiative to create several important research programmes.

In 1969, ICSU established the Scientific Committee on Problems of the Environment (SCOPE); its objectives included "to advance knowledge of the influence of humans on their environment, as well as the effects of these environmental changes upon people, their health and welfare".[9] While ICSU's member unions are from the natural sciences, during the 1980s, two, from the disciplines of geography and psychology, were also members of the ISSC.[10] The establishment of SCOPE derived particularly from increas-

ing awareness of the interactions of people and the biosphere, as manifested particularly by the 1972 UN Stockholm Conference on the Global Environment, for which SCOPE prepared the first report (SCOPE 1971). While many projects until the end of the 1980s focused almost exclusively on natural sciences, others involved significant numbers of both natural and social scientists (Price 1990).

A further four relevant global institutions emerged in the early 1970s, showing the increasing recognition of the need for international and interdisciplinary collaboration with regard to the challenges of global change. UNESCO's Man and the Biosphere (MAB) programme began in 1971. Its general objective was similar to those of SCOPE, but it explicitly aimed to "develop the basis within the natural and social sciences for the rational use and conservation of the resources of the biosphere and for the improvement of the global relationship between man and the environment; to predict the consequences of today's actions on tomorrow's world".[11] By 1984, MAB had some success in integrating natural and social scientists—and sometimes local decision-makers and people—in policy-relevant research (di Castri 1985). Nevertheless, the involvement of social scientists was limited (Spooner 1984).

In 1972, representatives of the Soviet Union, the US, and ten other countries from the Eastern and Western blocs established the International Institute for Applied Systems Analysis (IIASA). It created international interdisciplinary teams that used advanced systems analysis to study global challenges. In the context of this chapter, a key programme was on sustainable development of the biosphere (Clark/Munn 1986). Also in 1972, the International Federation of Institutes for Advanced Study (IFIAS) was founded; among its original objectives were "to promote and carry out joint transdisciplinary and transnational research on world problems with a special emphasis on social, ethical and humanistic aspects".[12] In the same year, the UN General Assembly adopted the decision to establish the United Nations University (UNU). Academic activities began in 1975; the first

priority programme areas were world hunger, natural resources, and human and social development.[13]

14.3 Emerging Issues in Social Science Research on Global Change

Until the 1980s, relatively few social scientists, with the exception of some anthropologists and geographers, had considered the biophysical environment as a critical constraint on the survival of human societies (Dunlap 1980). However, as the decade progressed, and building on the interdisciplinary initiatives such as those outlined above, social scientists began taking up questions of global change, and the related, but also contested, concept of sustainable development,[14] according to different disciplinary perspectives. In addition to the IIASA programme mentioned above, which included perspectives from economics, energy, geography, history, law, and management and policy studies, a few key examples are mentioned below.

In geography, researchers looked at human displacements in territorial or ecological systems, applying concepts such as risk and vulnerability (Kates et al. 1985). What kinds of micro-social models could be built in the framework of global change? Robert Kates had already developed an approach that defined decisions of social movements which decisively alter the course of a process as 'events'. 'Initial conditions' are those existing immediately prior to a major event that caused a sufficiently significant alternation of these conditions that their rippling effects can still be discerned in the present condition.

One early issue was how to define the processes under study in a global context. García (1986) proposed a three-tiered structure linking micro- to macro-processes. To analyse the dynamics of such processes, he stressed that the property of the system is not found in its components but in the relationships between them. Decision-making then becomes important to understand, for example, the emergence of famines. Researchers led by Gilberto Gallopin at the Bariloche Foundation gave a different perspective on global reality, proposing the concept of 'global impoverishment' to encompass both ecological and economic impoverishment as the central process of global change (Gallopin/Guttman/Maletta 1989; Leff, 1986). A counterpoint from more industrialized coun-

14 As early as 1989, 190 definitions existed (Pezzey 1989).

tries was provided by Udo Simonis (Simonis 1989), describing the relationships between economic structure and environmental impacts, and identifying both deficiencies of environmental policy and needs to integrating ecological dimensions into economic policy.

Sociologists and anthropologists, many of them members of research committees of the International Sociological Association and the International Union of Anthropological Sciences (both belonging to ISSC) focused on 'actions that generate social structures' through the choices made by individuals or groups. Choices are indeed made by individuals, but all such choices are embedded in exchanges. Thus, in terms of the relationship of human populations to the environment, choice is not constrained by an individual's psychological motivation but by the given range of options which that individual or group has in a given economic and social structure. Additionally, it was argued that "...human beings also have the capacity to adapt to rapidly changing environments, and so room must be left for new knowledge. Yet this gift of adaptation is based on the one single ability that people have....and that is the ability to learn from experience" (Arizpe 1989/2013: 39).

Psychologists also worked on various aspects of global change and human action. Lennart Sjöberg (Sjöberg 1989) suggested some key points with regard to: the use of cognitive and attitudinal approaches for behaviour modification; cognitive biases which tend to cause overconfidence and exaggerated belief in environmental stability; the difficulty of giving priority to the collective good and the preservation of the environment; environmental attitudes, and the difficulty of using mass media to change them; and that, while the individual perspective is important for a significant share of pollution and resource consumption, civic behaviour and organizational psychology also have potential. 'Cultural sustainability' was also taken up as perceptions of resource depletion and environmental change—not as psychological states but as expressions of cultural values in a context of accelerated social change—emerged as a major research challenge. This fundamental stratum of cultural values is the basis of assessments of options and choices made (Clark 1988). Nevertheless, the heuristic boundaries of units under analysis mean "deciding whether one culture should be considered a single unit in spite of internal diversity or whether its subcultures should be considered discrete entities" (Arizpe 1991:49). The interpretive nature of such methodological decisions in the heuristics of boundaries creates theoretical

problems and methodological issues of statistical measurement.

The examples above are all drawn from individual disciplines, but the 1980s were also a decade in which a particular aspect of global change—climate change—became an increasing focus of research attention from various social science disciplines, increasingly working together to address this complex phenomenon (e.g., Kellogg/Schware 1981; Chen et al. 1983; NRC 1983; Kellogg 1987; Glantz 1988; Parry et al. 1988). In an interdisciplinary effort, Lourdes Arizpe, Wolfgang Lutz and Robert Constanza argued that "To achieve a sustainable pattern of resource use and population we must understand and control the interactions of population and per capita resources as mediated by technology, culture and values"(Arizpe/Lutz/Constanza 1992: 61). Finally, this was a period in which boundaries between disciplines became blurred, and new hybrids emerged. To some extent, this resulted from interdisciplinary programmes and initiatives such as those mentioned above. Mattei Dogan and Robert Pahre (Dogan and Pahre 1989) identified various examples of hybridization, noting that sociology "is perhaps the most open of all social sciences... [and] interacts with all the other social sciences" (op cit. p 459), and also describing hybridization in history, political science, economics, and geography. They concluded that hybridization, through borrowing concepts, theories, and methods as well as the exchange of findings, would continue to stimulate innovate throughout the social sciences—and that this requires courage.

14.4 Towards a Research Programme on the Human Dimensions of Global (Environmental) Change

In 1986, the Sixteenth General Assembly of the ISSC adopted a resolution creating an ad hoc committee to explore the possibility of developing an international social science programme to parallel and complement the emerging IGBP, recognizing that human activities had become a significant force in global change. This decision was based in two imperatives: first, increasing recognition among social scientists that they had to advance in developing new theoretical perspectives and models to encompass all dimensions of global change; and, second, the fact that natural scientists had already begun developing the IGBP.

Even in the early discussions in the Committee, 'global change' was considered too broad a term given the many ongoing global processes, often con-

sidered as global change in the anthropogenic sense, including various processes sometimes described as 'globalization', especially in economics, political science and sociology. However, the committee also recognised the emergence of the geocentric perspective espoused by the IGBP, and the emphasis for the research programme in the social sciences increasingly focused on this perspective.

In 1987, ISSC joined with IFIAS and UNU to develop a Human Response to Global Change Programme, which soon became the Human Dimensions of Global Change Programme (HDGCP). This renaming resulted from a second conceptual discussion regarding the 'social' in the formulation of research boundaries. The members of the ad hoc committee were unwilling to emphasize disciplinary boundaries at a time when both the social sciences were insisting on revising disciplinary boundaries and the research field under discussion itself required interdisciplinary collaboration among scientists. Consequently, the terms traditionally used did not seem to be appropriate. The 'social aspects' of global environmental change would need to include in its formulation, at the very least, the social, economic, political, geographical, and cultural aspects of global change: hence, the decision to adopt 'human dimensions'. This seemed to capture the specificity of the topics that the social sciences would take up in relation to the environment, yet at the same time implied an openness to interdisciplinary work that not only left out none of the social sciences but could also include research by natural sciences which considered anthropogenic actions.

Over a one-year period, eleven meetings were held around the world in order to define the scope of the programme. These were followed by a symposium in Tokyo in September 1988 to define the programme's objectives and research initiatives (IFIAS/ISSC/UNU 1989). This initiative continued, with UNESCO joining the steering committee of the HDGCP in 1989, and a number of workshops took place under the auspices of the four (and other) organizations. Some developed themes for the proposed ISSC programme (see below), while the majority developed the research initiative derived from the Tokyo symposium, most with a policy emphasis (Price 1990).

In December 1988, the ISSC established a Standing Committee on the Human Dimensions of Global Change. The initial fourteen members of the committee included Elza Berquo (Brazil), Rene Passet (France), Ademola Salau (Nigeria), Krishnamurthy Srinivasan (India), Kerry Turner (UK), Björn Wittrock

(Sweden), and Zhang Pei Yang (China). However, these were not able to continue, and the eventual committee consisted of nine individuals, each from a specific discipline and country: Harold Jacobson (political science US, chair); Lourdes Arizpe (anthropology, Mexico); Daniel Bertaux (sociology, France); Ashish Bose (demography, India); Takashi Fuji (economics, Japan); Leszek Kosinski (geography, Canada); Kurt Pawlik (psychology, Germany); Renat Perelet (systems analysis, Russia); Robert Worcester (public opinion, UK). They met three times in 1989 and 1990, with the main task of drafting an action plan for research on what they now referred to as the human dimensions of global environmental change (HDGEC).

These ongoing processes were also influenced by the publication of 'Our Common Future' by the World Commission on Environment and Development (WCED 1987). In 1989, the NRC held a forum on 'Global change and our common future' at which the chair of the WCED, Gro Harlem Brundtland, clearly stated the convergence of the two types of global change, explicitly linking what was now becoming more widely referred to as 'global environmental change' (and particularly climate change) with sustainable development (Brundtland 1989). At the same meeting, Roberta Miller of the US National Science Foundation noted the need for social science research programmes that should not only "feed into the physical and natural science activities" (i.e, the emerging IGBP), but also "be concerned with those elements of the global change research agenda that are purely social and economic but that ultimately are as powerful determinants of environmental change as ongoing physical and biological processes" (Miller 1989: 86–87).

In November 1990, after two years of debates on research carried out in social science and in consultation with the member associations and organizations of the ISSC as well as those of ICSU, and in collaboration with UNESCO's Social Science Sector, the ISSC Standing Committee presented their output. Particularly because of the very diverse perspectives represented on the Committee, this was not an action plan, but a framework for research on HDGEC (Jacobson/Price 1990). It identified seven broad areas in which research should be carried out:

- social dimensions of resource use;
- perception and assessment of global environmental conditions and change;
- impacts of local, national, and international social, economic and political structures and institutions;
- land use;

- energy conversion and consumption;
- industrial growth; and
- environmental security and sustainable development.

The first three topics encompass the central issues involved in understanding HDGEC (Jacobson 1992). The dynamic interactions among populations, resources and technology set fundamental parameters on the anthropogenic contribution to global change. Two areas were especially signalled out for research: economics and demographic change. At that time, concerns over population growth and the need to bring about a demographic transition were priorities on the agenda of the social sciences. Importantly, in seeking a social science perspective on global environmental change, the Standing Committee emphasized that the ways in which individuals and government officials, industry managers, and the general public perceive and assess environmental changes will affect how they behave toward sources of global change and will determine steps they might take to adapt or mitigate the effects of such changes. In a forward-looking strategy, the Standing Committee was keen to draw attention to the advances in cognitive sciences that detailed the structure and function of information processing, on the one hand; and on the other hand, the understanding of the relationship between the mass media and public perception that could provide a strong base for this research.

Other members of the Standing Committee, particularly those living in what were then called 'Third World' countries, were more interested in discussing political institutions and economic policies that had direct and indirect, as well as intended and unintended, effects on global environmental change. It must be remembered that, at the time, dictatorships and *coups d'état* in Latin America and Africa and the effects of rapid modernization were the focus of attention of social scientists in these regions. Thus, they began to perceive environmental questions as the secondary objective after the development concerns of democratization and poverty alleviation, and became deeply involved in these debates. The Standing Committee, however, was able to build a broad framework that encompassed both environmental depletion as well as development needs.

Each of the first three topics demanded integrated analyses from a range of disciplines, including anthropology, economics, political science and sociology. Much discussion was devoted to debating the institutional and programmatic form that such interdisciplinary work would take. A key concern was the realiza-

tion that social science studies conducted within the borders of nation-states were not producing the data needed to understand the social aspects of global processes. As an example, a specific study group on demography was created; and this showed how national population statistics were very difficult to use in identifying global trends. Although some studies based on population statistics could show broad international trends, such as world population growth processes, they could rarely be used for comparative studies between given countries, since each established different definitions and categories of basic census data. Understanding global processes required the standardization and formalization of statistical data across countries. This became the central objective of the Human Development Project of the United Nations Development Programme which began to consolidate during the same period. Lourdes Arizpe participated in both projects, and ensured that the building of concepts and models, and the same major concerns were discussed and exchanged.

The next three themes of the framework for research on HDGEC were recognised as major proximate causes of global change—land use, energy conversion and consumption, and industrial growth—jointly responsible for the majority of greenhouse gas emissions. Understanding the dynamics of these activities was considered crucial to fully understanding the dynamics of global change. The framework explicitly linked the last topic, environmental security and sustainable development, to the report of the WCED; this was seen as embodying the normative tradition in the social science, namely, exploring the values involved in human actions. These investigations should involve description, analysis and prescription and would be an essential component of social science research on global environmental change. The costs and benefits of various strategies to adapt to global change or to mitigate its effects should be explored, and norms for dealing with issues of international and intergenerational equity should also be taken into account.

14.5   Initiatives on the Human Dimensions of Global Environmental Change, 1990–1995

The framework for research on HDGEC (Jacobson/ Price 1990) was published in November 1990. A draft work programme for the implementation of the HDGEC programme (HDP) was reviewed at a scien-

tific symposium on HDGEC held in Palma de Mallorca in the same month, in conjunction with the Eighteenth General Assembly of the ISSC, and then adopted by the Standing Committee. From this point onwards, its aim was to stimulate and encourage research among the members of the scientific organizations. Several unions already had research committees to study the processes that were changing the environment in geographical, economic and social terms. Many had already highly developed research activities on the interaction of humans and the natural environment, for example, the International Union of Anthropological and Ethnological Sciences which had a long tradition of studies of 'Man's Habitat'. The establishment of the HDP led many more member associations to create committees, study groups and research networks to study global environmental change. The then President of ISSC, Luis Ramallo, proposed that the Secretariat of the HDP be established in Barcelona, with funding from Spanish sources. It subsequently moved to Geneva, with Swiss government support, with an office and a scientific directorate which continued until August 1996 (Platt 2002: 34).

Following the lead of the IGBP and the World Climate Research Programme (WCRP), the HDP promoted interdisciplinary and international research organized on the basis of 'work programmes' to cover the two-year periods between ISSC General Assemblies (Jacobson, 1992). Given that the availability of relevant data was highlighted as crucial for research in this field, the 1991–1992 work programme (ISSC 1990) concentrated heavily on assessing available data and establishing data requirements to generate new databases in this field. Six working groups on data were therefore established. The themes, chairs, and outputs of those that published reports are listed below:

- demographic data (John Clarke, professor of geography, Durham University, UK: Clarke/Rhind 1992);
- economic data (Gary Yohe, professor of economics, Wesleyan University, US: Yohe/Segerson 1992);
- social science survey data (Robert Worcester, Senior Vice President of ISSC and former President of the World Association for Public Opinion Research (WAPOR): Worcester/Barnes 1991).

The work programme also stated that social science research on HDGEC required conceptual and methodological innovations. Seven working groups on the design and development of research, in the seven broad areas identified in the framework for research,

were therefore established, of which two published reports:

- land-use/land-cover change (jointly with the IGBP) (Billie Lee Turner, professor of geography, Clark University, US: Turner/Moss/Skole 1993);
- perceptions and assessments of global environmental conditions and change (Kurt Pawlik, professor of psychology, Hamburg University, Germany: Pawlik 1991).

In addition, most of the other working groups organized workshops. The outcomes of much of this work were reported at the second scientific symposium of the HDP, on 'Creating the Database' in 1992 and, subsequent to this, a Steering Committee, including an Executive Committee, was established. A third scientific symposium took place in 1995. By this time, four research programmes had emerged within the HDP, on attitudes and perceptions; demographic and social dimensions of resource use, industrial transformation and energy use, and land-use and land-cover change (jointly with the IGBP). The HDP had also identified two more fields for further study: institutions and environmental security; and three other areas on which further exploration was needed: human health and global environmental change, trade and environment, and the vulnerability of human populations. The papers and posters presented at the symposium addressed these very diverse themes (HDP 1996).

The late 1980s and first half of the 1990s were also characterized by the emergence and development of various national and regional (e.g. European) initiatives for research on HDGEC. In reality, the majority of funding for this research was and continues to be provided at the national level (and also, the European level). In Canada, the national global change programme included social scientists from its inception in 1985 (Braybrooke/Paquet 1987). In the US, NRC's Committee on Global Change proposed research into six areas of human dimensions in 1988 (Clark 1988), and the National Academy of Sciences and the NRC established a Committee on the Human Dimensions of Global Change in 1989. This published a substantial report in 1992 which presented the state of knowledge and proposed a national research programme on the human dimensions of global change (Stern/Young/Druckman 1992). In the same year, the Social Science Research Council appointed a Committee for Research on Global Environmental Change to foster interdisciplinary research, and the Centre for International Earth Science Information Network (CIESIN) was established as an independent NGO to provide

information that would help scientists, decision-makers, and the public better understand the changing relationship between human beings and the environment. In 1991, it organized a workshop which produced a 'social process diagram' showing the interactions between different elements of social systems, as a tool for designing research agendas concerning the causes and effects of, and responses to, different types of global change (Kuhn/Luterbacher/Wiegandt 1992). In Europe, scientific interest emerged early in Sweden, with a conference in 1988 (Svedin/Heurling 1988) and a national committee on human dimensions of global change in 1991. By 1994, various initiatives had also developed in Belgium, France, Germany, Italy, the Netherlands, Norway, Switzerland and the United Kingdom. These initiatives were summarized by Price (Price 1994) in a report designed to assist the European Commission in defining linkages between existing initiatives and its own activities in research and development programmes. The Academy of the Social Sciences in Australia began to address such topics with a conference in 1990 (Brookfield/Doube 1990).

Many of these activities were linked, to one extent or another, not only to the HDP, led by the ISSC, but to the activities of other international organizations (Price 1994). These included the European Science Foundation's project on 'Environment, Science and Society', IIASA projects on global environmental change, global economic and technological transitions, and systems methods for the analysis of global issues; various projects of the UNU and the Organization for Economic Cooperation and Development (OECD); and working groups II and III of the Intergovernmental Panel on Climate Change (IPCC).

14.6   Conclusions

The decade from 1986 to 1995 was one in which scientists from both natural and social science disciplines, as well as an increasing number of politicians and members of the public around the world, recognised the increasingly rapid rates of change in not only the biophysical, but also the human, systems of our planet. Two themes, climate change and the imperative of sustainable development, were particularly important drivers. From the scientific perspective, this implied a critical need for new ways of thinking, new types of data, and new approaches to research, often requiring collaboration across disciplinary boundaries. As Miller (Miller 1994) noted, this requires new conceptualization of research problems, agreements on measurement, and time to learn to work together. These challenges certainly characterized the development of strategies for research on the HDGEC, both in the development of the ISSC's framework for research and in its subsequent implementation. However, this was only one of many international initiatives for research on HDGEC and, equally, much of the research that needs to be undertaken in relation to HDGEC has been, and will continue to be, done by individuals and groups within and across disciplines, typically at the local, subnational, or national level. In the subsequent two decades, as described elsewhere in this book, substantial advances have been made; many of them emerged from the initiatives described in this chapter.

15   From HDP to IHDP: Evolution of the International Human Dimensions of Global Environmental Change Programme (1996–2014)

Eckart Ehlers[1]

Abstract

IHDP's performance between 1996 and 2014 can be described as a process of maturation of social science research vis-à-vis the challenges of climate and global environmental change. It is characterized by a number of independent research projects and an increasing embeddedness into joint programme developments with the natural sciences. Incorporation of IHDP into the *Earth System Science Partnership* (ESSP) and its full integration into the Future Earth initiative bear witness to these facts. The emergence of the concept of the Anthropocene, the discussions around a 'geology of mankind', and the increasingly undisputed conclusions of IPCC reports about the role of human footprints in shaping our planet by stimulating global warming and exerting deep impacts on the atmosphere, geosphere, hydrosphere and biosphere—all three observations, assumptions and related theories have greatly influenced the steadily increasing importance of the social sciences in research into global change. In 2014, IHDP joined IGBP and DIVERSITAS in merging under the umbrella of Future Earth.

Keywords: Anthropocene, Future Earth, Earth System Science Partnership, integration, Institutional Dimensions of Global Environmental Change, Industrial Transformation, human security.

15.1   Introduction

This chapter, a direct continuation of the previous one (Arizpe/Price/Worcester 2016), is a reflection of IHDP's development since its transfer from its Geneva (Switzerland) headquarters to Bonn (Germany). This transfer and reorganization falls into a period of worldwide changes, politically and ecologically. In 1989 the Berlin Wall dividing West and East Germany came down. The collapse of the former Soviet Union seemed to open a new era of cooperation between West and East and to replace the political confrontations that had dominated international politics since the end of World War II. The year 1992 saw the 'Earth Summit' in Rio de Janeiro (Brazil), a turning point for global change research. The Rio conference not only opened up insights into the global dimension of ecological and environmental

problems, but also demonstrated the necessity of increased international cooperation in order to tackle them. The 1992 Earth Summit was preceded by an increasing 'scientization' (Brauch 2009) of specific fields of climate research and its impacts on the geosphere and the biosphere. The creation of the *World Climate Research Programme* (WCRP) in 1980 (Church/Asrar/Busalacchi et al. 2011) and the establishment of the *International Geosphere–Biosphere Programme* (IGBP) in 1986 (Noone/Nobre/Seitzinger 2011) bear witness to these developments. Thus Rio 1992 and its follow-ups (Rio+10 in Johannesburg (South Africa) in 2002 and Rio+20 in 2012, again in Rio de Janeiro) became important cornerstones (Hackmann/St. Clair 2012) for the development of not only interdisciplinary research endeavours but also of international research cooperation in the fields of research into global change.

Social science research, although organizing itself from 1986 onwards, remained in a somewhat reserved and ambiguous position (see Arizpe/Price/Worcester 2016 [in this volume]). HDP/IHDP's early years are

---

1   Prof. Dr. Eckart Ehlers, University of Bonn, Department of Geography, Prof. Emeritus; email: <ehlers@giub.uni-bonn.de>.

characterized by an intensive search for a solid theoretical and methodological foundation for its specific role in research into global environmental change and for the identification of relevant themes and topics. It should, however, also be noted that the acceptance of the social science approaches by the representatives of the natural science disciplines was not always encouraging. The great challenge was to find common grounds, that is common language, common themes and topics and common projects—a tedious yet in the end successful approach. In 2014 IHDP (von Falkenhayn/Rechkemmer/Young 2011), together with IGBP (Noone/Nobre/Seitzinger 2011) and DIVERSITAS (Walther/Larigauderie/Loreau 2011), became one of the founding programmes of *Future Earth*,[2] the new programme of integrative sustainability science.

15.2 Moving from HDP to IHDP (1995–1996)

The Third HDP Scientific Symposium on "Global Change, Local Challenge", held in Geneva on 20–22 September 1995 was surely the climax of the 'old' *Human Dimensions Programme* (HDP). It was at the same time, however, the starting point of its continuation as the *International Human Dimensions of Global Environmental Change Programme* (IHDP). Led by Harold K. Jacobson (1986-1994, including its preparatory stage) and by Martin Parry (1995-96), HDP operated from its headquarters in Geneva under Ellen Wiegandt as its scientific director. Prior to HDP's 'grand finale' in September 1995, eight reports and a number of occasional papers had identified a number of social science deliverables and set the arena for IHDP's future challenges.

The Geneva symposium 1995 and its participants reads like a 'Who's Who?' of social science research on global environmental change, reflecting the broad range of themes and topics of that meeting. Plenary sessions focused on

- Risk, Uncertainties and Human Dimensions of *Global Environmental Change* (GEC);
- Population, Resources and GEC;
- Political Institutions and Global Change;
- National Programmes and International Global Change Research;
- GEC Research and Implications for Policy;
- Data Systems Demonstrations.

Plenaries were complemented by a number of focused discussion groups outlining lacunae and future needs of social science research vis-à-vis the challenges of climate and environmental changes and as a collaborator in the *World Climate Research Programme* (WCRP), the *International Geosphere-Biosphere Programme* (IGBP), and/or DIVERSITAS, the programme established to address the complex scientific questions posed by the loss in biodiversity and ecosystem services and to offer science-based solutions. The issues at stake were (among others):

- Data for Global Change;
- Developing Regionally Sensitive Energy Models;
- Environmental Security and Local Sustainability;
- Global Change and Vulnerable Regions: Coastal Zones and Small Islands;
- Integrating Science for Global Change: Research Collaboration between Natural and Social Sciences (HDP, WCRP, IGBP);
- Local Land Use Patterns and their Global Impacts;
- Individual Perceptions and National and International Environmental Policy;
- Industrial Transformation in Developed, Transitional and Developing Countries: Scenarios for Global Change;
- Regional Freshwater Resources and Global Change;
- Human Health and GEC.

As a result of this admittedly ambitious 'tour de force', the participants agreed upon a kind of manifesto in which the vision and mission of a new HDP became visible. In view of its importance as a milestone document of the human dimensions programme and as a link between the early stages of HDP and the new IHDP (from 1996 onwards), it may be appropriate to present it in full (box 15.1).

It would be going beyond the limits of this historical retrospective to dive into the details of the somewhat engaged and sometimes controversial discussions of this seminal meeting. It is, however, worth mentioning that until 1995 the situation of HDP was far from ideal in a number of ways.

15.3 IHDP 1996–2014: In Search of Stability and Sustainability

The year 1996 finally brought about substantial changes in the programme, based on two decisive decisions concerning the overall organizational structure of the programme.

---

2   See "Future Earth", at: <http://www.futureearth.org/>.

Box 15.1: Statement of the HDP Conference in Geneva, 22 September 1995. **Source**: IHDP; at: <http://www.ihdp.unu.edu/docs/Publications/Secretariat/HDP/HDP%203rd%20Scientific%20Symposium%20Sept%201995.pdf>.

The Third Scientific Symposium of the *Human Dimensions of Global Change Programme* (HDP) of the *International Social Science Council* (ISSC) was held in Geneva from 20 to 22 September 1995. Close to 200 people from nearly 40 countries from all major regions of the world attended the meeting. Representatives of national research programmes and regional networks, universities and research institutes, government funding agencies, and multinational organizations (including UNEP, WHO and EU) participated in the meeting. The purpose of the symposium was to provide an international and interdisciplinary forum for discussion of the crucial scientific challenges related to the human dimensions of global environmental change. Plenary speakers addressed a wide range of issues, including archaeological evidence of human responses to climate change in earlier periods, the relationship between population and environmental change, human health effects of global change, international environmental accords, and regional differences in vulnerability. Open discussion groups covered topics such as energy use, environmental security, data needs and policies, and the integration of social and natural science research, and developed a number of specific suggestions for future IHDP activities based on these discussions.

The symposium demonstrated a widespread and growing interest in research questions related to human dimensions of global environmental change. An increasing number of national HDP committees are being established to coordinate research at the national level. The meeting agreed that this development should be encouraged, and urged that communication be strengthened among national committees and between these committees and the HDP. Participants strongly affirmed the need for the HDP programme to promote the development of an integrated framework to facilitate inter- and transdisciplinary research, to help coordinate efforts undertaken through national, regional and disciplinary programmes, and to focus research on important gaps or particularly promising fields of study. There was a consensus that the agenda of the HDP programme covers some of the research questions considered to be most important by scientists working in this area, and that the HDP should do its best to respond also to the concerns of governmental as well as non-governmental entities trying to cope with the very complex political, economic, and social problems of global environmental change.

Geneva, 22 September 1995

First: HDP, so far under the umbrella of the *International Social Science Council* (ISSC), became co-sponsored by the *International Council of Scientific Unions* (ICSU), as ICSU was called at that time. HDP was renamed IHDP.

It would be short-sighted not to acknowledge that the inclusion of the human dimension in both ISSC and ICSU had an intellectual 'prehistory'. As early as 1991, the *International Social Science Journal* published a special issue on "Global Environmental Change. Concepts, data, methods, modelling, cooperation with natural sciences". It contains a number of very basic and fundamental articles, emphasizing the overdue cooperation between natural and social sciences. Imperatives and scientific necessities are clearly identified. Lourdes Arizpe argues in favour of a "joint agenda with the natural sciences" (Arizpe 1991). Even more explicit is J. W .M. La Rivière (1991), who stresses the need for a more or less indispensable cooperation between natural and social scientists. J. B. Robinson (1991) even proposes very specific approaches to model natural and human system interactions by combining physical flows and actor systems views. Worth mentioning is G. C. Gallopin's (1991) contribution, in which the problem of scale is outlined: how can global and local processes be combined? As a matter of fact, scaling issues were to

become one of the major methodological and practical challenges in combining natural and social science research—a problem taken up in the early years of the new IHDP (see section 15.3.2.1).

It is beyond the scope of this review to reflect the sometimes highly controversial discussions about the role of the social sciences in future global change research. The fact is that from the early 1990s onwards these discussions gained momentum and became a decisive challenge for the newly-established IHDP. The demand for much stronger participation by the social sciences in many more aspects of global change issues and the deliverance of reliable and robust data to be included in global change modelling became almost mandatory (Kates/Chen 1993).

Second: IHDP and its headquarters were transferred from Switzerland to Bonn in Germany. Thanks to generous support from German government sources as well as from the University of Bonn, IHDP moved into a spacious office right in the centre of the university's natural science departments and could be staffed in such a way that restructuring and reorganization became possible under adequate framework conditions. The author of this review was appointed jointly by the councils of ISSC and ICSU as the new chair of IHDP; Larry Kohler, a political scientist from the US who was on leave from the *International*

Labour Office (ILO) in Geneva, was appointed as IHDP's new executive director.

The official opening of the new IHDP Secretariat took place on 31 January 1997. The opening ceremony and the related expectations are described in the *ISSC Newsletter* 76 as follows: "About thirty people from the 'IHDP family' attended, including the Secretary-General of the ISSC, Professor Leszek A. Kosinski, and the executive director of the ICSU, Ms Julia Merton-Lefèvre". The report concludes modestly but also with determination "... the new IHDP, still in its 'adolescent' phase, is eager to develop its potential as the social science equivalent to the other major international programmes dealing with global environmental change, the *International Geosphere–Biosphere Programme* (IGBP) and the *World Climate Research Programme* (WCRP), and thus soon [to] become an 'adult' member of the global change research family".

15.3.1   IHDP's New Mission and Organizational Restructuring

IHDP's mission and vision as well as its objectives were defined as follows:

> IHDP is an international, interdisciplinary, social science programme to promote and co-ordinate research aimed at describing, analysing and understanding the human dimensions of global environmental change, i.e. (a) the way people and societies contribute to global environmental change; (b) the way global environmental change affects people and societies; and (c) ways and means for people and societies to mitigate and adapt to global environmental change.

Thus, the change from HDP to IHDP meant both a continuation and a new beginning. IHDP could build on the foundations laid by its HDP predecessors (Arizpe/Price/Worcester 2016 [in this volume]). On the other hand, IHDP had not only to establish entirely new organizational structures, but also to create a scientific profile of its own and develop joint ventures with existing ICSU-sponsored activities. The new IHDP *Scientific Committee* (SC) was formed, covering a broad range of social sciences and ensuring global internationality. Its members were:

- Prof. Eckart Ehlers, chair, geography, Germany;
- Prof. Arild Underdal, vice-chair, political scientist, Norway;
- Dr. Peter de Janosi, Treasurer, economics (IIASA), USA;
- Prof. Hans B. Opschoor, economics, The Netherlands;

- Prof. Mauricio T. Tolmasquim, economics, Brazil;
- Dr. Anne V. Whyte, geography, Canada.

Ex-officio members were:

- Dr. David Skole, ecology, *Land Use and Land Cover Change* (LUCC);
- Prof. Kurt Pawlik, psychology (ISSC);
- Prof. J.W. Maurits la Rivière, microbiology (ICSU);
- Prof. Peter S. Liss, environmental chemistry (IGBP);
- Prof. W.L. Gates, meteorology, climate modelling (WCRP);
- Prof. Joao M. Morais, IGBP Secretariat, Stockholm, social science liaison officer.

The overall structure of the new IHDP is summarized in figure 15.1.

The following years saw regular changes within IHDP's Scientific Committee as well as the statutory changes in the chairholders and executive directors of the programme:

Chairs:

- Eckart Ehlers, Germany (1996–1999)
- Arild Underdal, Norway (1999–2002)
- Coleen Vogel, South Africa (2002–2006)
- Oran R. Young, USA (2006–2011)
- Sir Partha Dasgupta, India (2012–2014)

Executive Directors:

- Larry Kohler, USA (1998–1999)
- Jill Jaeger (1999–2002)
- Barbara Goebel (2002–2005)
- Andreas Rechkemmer, Germany (2005–2009)
- Anantha Kumar Duraiappah, India (2010–2014)

Until the very end of IHDP in 2014 the chairs and executive directors were always accompanied by outstanding scientists and academic advisors as members of IHDP's SC, among them (to mention just a few) William C. Clark, Geoffrey Dabelko, Carl Folke, Gilberto C. Gallopin, Heinz Gutscher, Carlo Jaeger, Ruth Khasaya Oniango, Tatyana Kluvankova-Oravska, Elena Nikitina, Elinor Ostrom, Xizhe Pen, P. S. Ramakrishnan, M. A. Mohamed Salih, Roberto A. Sanchez-Rodriguez, Akilagpa Sawyer, and Paul L.G. Vlek.

While IHDP's Scientific Committee, its appointed and ex-officio members, and the representatives of IHDP's core and joint projects ensured the constant rejuvenation of the programme and its research strategies, regular 'Open Meetings' of the IHDP community took place in different parts of the world. While the early conventions attracted between 250 and 400 participants, Bonn in 2005 had more than a thousand registered social scientists from all parts of the world

(IHDP–Update 01/2006). These Open Science Meetings proved themselves valuable and almost indispensable inputs into IHDP's research portfolio and were also innovative for cooperation beyond disciplinary and cultural boundaries.

Altogether, one is probably justified in characterizing the transfer from Geneva to Bonn as a kind of rejuvenation of social science research within the GEC community. The installation of a viable administration and its equipment with highly committed staff resulted in the indicated organizational restructuring and the forceful development of research projects that soon became visible flagships of IHDP.

15.3.2   IHDP Becomes a Fully-Fledged Scientific Programme: The Decade 1996–2005/6

15.3.2.1   Project Developments

Against this background, the years from 1996 onwards saw the steady and systematic growth of IHDP and its

development into a fully-fledged programme of its own. Immediately after its establishment in Bonn and as a result of intensive discussions within the newly-established SC, it was agreed that IHDP should select three core projects to be developed as flagship activities. These were:(a) the *Institutional Dimensions of GEC* (IDGEC, led by Oran Young and Arild Underdal), (b) *Industrial Transformation* and GEC (IT, led by Pier Vellinga), and (c) *Global Environmental Change and Human Security* (GECHS, led by Steve Lonergan). These were placed on a 'priority fast track', with a view to building upon previous work in these areas by the former HDP. Based on the outcomes of preceding workshops, internal scoping reports, draft science plans and their external reviews, in 1999 IHDP was able to publish three Science Plans:

• *Science Plan: Institutional Dimensions of Global Environmental Change (IDGEC)*. IHDP Report 9, 1999.

- *Science Plan: Global Environmental Change and Human Security* (GECHS). IHDP Report 11, 1999.
- *Science Plan: Industrial Transformation (IT)*. IHDP Report 12, 1999.

Science plans are the first step in developing an innovative, integrative and also international research agenda. They formulate research needs and problems. They identify research foci and related activities. They also discuss models and methods to be applied and consider a priori programmatic links to other projects and programmes.

IHDP's endeavour to develop a visible, relevant and cross-cutting scientific profile of its own was not restricted to these three core projects alone. It also inherited joint projects with IGBP and WCRP. These included the *Land Use and Land Cover Change* (LUCC) project jointly sponsored by IHDP and IGBP. The START project [*System for Analysis, Research and Training*], another joint activity (WCRP/IGBP/IHDP), continued to pursue its goal of promoting regional research, training and capacity-building support for GEC scientists, and it is the only joint project that has maintained its independence until today.

Almost simultaneously with the three science plans of IDGEC, GECHS and IT, the LUCC project published its Implementation Strategy, specifying in detail those activities that were to fulfil the mandate outlined in its earlier science plan:

- *Implementation Strategy: Land-Use and Land-Cover Change (LUCC)*. IGBP Report 48/IHDP Report 10, 1999 (see also Lambin/Geist 2006).

However, the development of science plans and implementation strategies was only part of IHDP's new agenda. In 1998, IHDP saw the publication of two working papers, dealing with the intricate problems of "Scaling issues in the social sciences", co-authored by the later Nobel Laureate Elinor Ostrom (Gibson/Ostrom/Ahn 1998), and with "The problem of fit between ecosystems and institutions" (Pritchard/Colding/Berkes et al. 1998). Both papers were to become basic contributions not only to the newly developed core projects, but also to the general discussion on coordination between natural and social science paradigms.

This survey and reconstruction of project developments would be incomplete if one did not include those projects that developed in the later years of IHDP's first decade. They include additional core projects of IHDP such as *Urbanization and Global Environmental Change* (UGEC), focusing on the impacts of rapid global urbanization processes and their environmental and socio-economic causes and consequences. It is worth mentioning that as a by-product of this programme, nine editions of a journal-like publication "UGEC Viewpoints" (1/2008–9/2013) were produced.

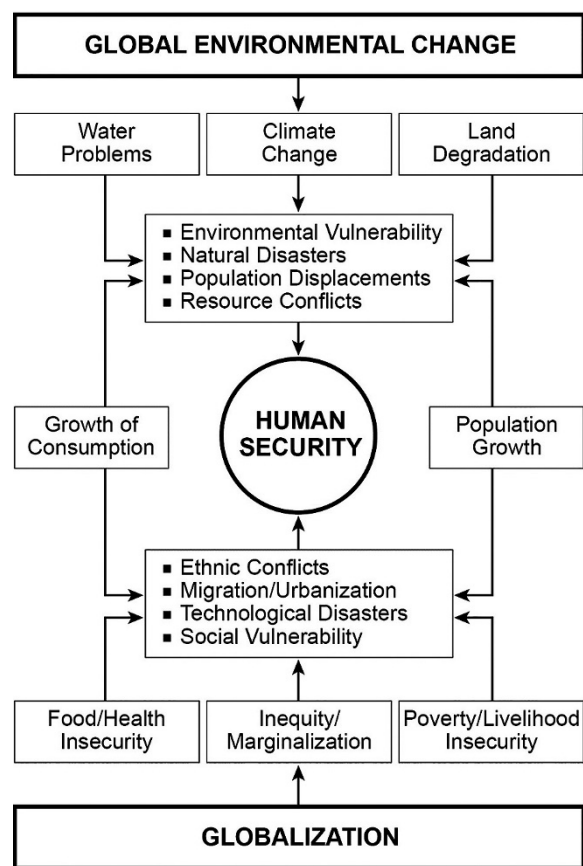
Other projects include a growing number of joint activities, especially in cooperation with IGBP. IHDP's Annual Report 2006/07 also mentions the LOICZ (*Land–Ocean Interactions in the Coastal Zone*) project and the *Global Land Project* (GLP) as core projects. Both, however, were joint activities, in operation since 1993 under the auspices of IGBP. They became a joint IGBP/IHDP initiative in 2004 and their cross-cutting aim and goal was "to provide the knowledge, understanding and prediction needed to allow coastal communities to assess, anticipate and respond to the interaction of global and local pressures which determine coastal change"–a truly multi-disciplinary challenge. The same, by the way, holds true for the GLP, successor to the LUCC and GCTE (*Global Change and Terrestrial Ecosystems*) project, inaugurated as a joint IGBP/IHDP project in 2006. Other joint activities included the continuation of the *Global Carbon Project* (GCP), the *Global Environmental Change and Food Systems* (GECAFS) project launched in 2001, and regional studies such as MAIRS (*Monsoon Asia Integrated Regional Study*) and support for capacity-building. Special mention should be made of the IHOPE (*Integrated History of People on Earth*) project, which got under way in 2005. The aim of this project, again co-sponsored by IGBP and IHDP, is to analyse co-evolution of ancient societies with their environments on different time scales (millennial, centennial, decadal)–a truly cross-cutting approach with a strong historical aspect.

15.3.2.2   From Science Plans to Syntheses

While it is impossible to go into details of IHDP's core project activities, an attempt may be made to point to the central themes, aims and goals of the three projects mentioned above and their foci within the sustainability discourse.

GECHS (Global Environmental Change and Human Security), dating back in its preliminary phase to HDP times, formulated the first draft of its Science Plan in 1997, finalizing it in 1999. It ended, after ten years of intensive research, in June 2010 under the leadership of Karen O'Brien, then GECHS–SC. She summarized GECHS's performance as follows: "GECHS research has conceptualized and characterized vulnerability, analysing what it means for the future of marginal populations and living conditions.

GECHS research has also explored the physical dimensions of challenges to human security, for example, in the context of water scarcity and food. Underlying all these challenges are the individual and social mechanisms that affect how a lack of security actually takes hold and manifests" (IHDP Update 2/2009, p. 4). Themes and topics indicate foci of GECHS research: "Sustainability in water and sanitation", "Resilience as agency", "Ethics of global environmental change", "Managing extremes" and "Sustainable adaptation: emphasizing local and global equity and environmental integrity".

Figure 15.2: Human security as a desirable goal for individuals and societies. **Source**: Bohle (2002).


In fact, human security in the broadest sense of the word and as an ultimate goal of social and environmental stability became GECHS's main research interest. The complexity of this object in view becomes apparent in figure 15.2. Human security, embedded in and endangered by the consequences of globalization and the deterioration of our natural environment, is recognized as a central and crucial aspect of humanity

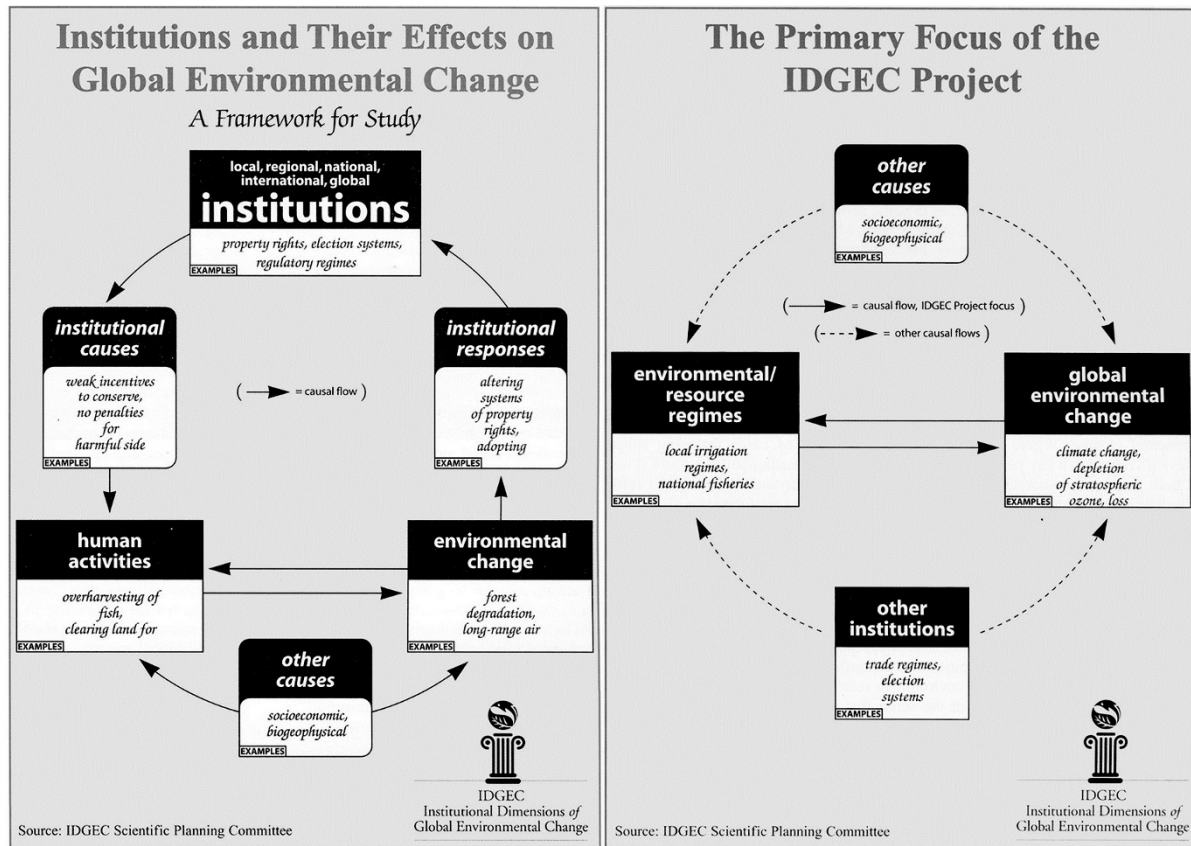
on its pathway towards sustainability. The summarizing presentation in figure 15.2 shows the intricate interactions of natural and societal impacts on human (in-)security. At the same time it indicates the core problems of vulnerabilities that will be dealt with in more detail in section 15.3.2.3.

IDGEC (Institutional Dimensions of Global Environmental Change): this project is an extremely important part of IHDP's scientific activities. It is by necessity the most cross-cutting topic, since institutions are indispensible instruments for the regulation and management of disputes; and disputes are manifold, not only over environmental and resource regimes but also over conflicting interests in social and political issues, and of course over juxtaposing views from natural and social perspectives. The IDGEC Science Plan (1999) reads like an introduction to institutional effects on GEC and the foci of IDGEC's projects (figure 15.3)

As mentioned earlier, IDGEC activities were continuously accompanied by reflections on the problems of fit, interplay and scale—problems of importance also to other IHDP projects. In view of the crucial role that institutions play in GEC as determinants of human–environment interactions, it is not surprising that several issues of IHDP Update were specifically devoted to aspects of governance and institutions: IHDP Update 3-4/2006; IHDP Update 1/2007 (with emphasis on the IDGEC Synthesis Conference), and IHDP Update 3/2009 as a special issue on Governance as a cross-cutting theme in human dimensions science.

The IDGEC Synthesis Conference in Bali (Indonesia) at the end of 2006 marked the end of a highly successful project initiative. Oran Young, long-time chair of IDGEC and for many years chair of the IHDP-SC, could sum up by saying that the project "has produced results that add to our understanding of the roles that institutions play wherever they occur …" (IHDP Update 1/2007, p. 2), and the project achieved new insights into the roles that institutions play in steering human–environment interactions.

In view of the outstanding relevance of institutions to almost all aspects of research, IDGEC's continuation beyond its termination was not surprising. The publication of the IDGEC synthesis volume in 2008 (Young/King/Schroeder 2008) marks the almost logical outset to promoting *Earth System Governance* (ESG). In October 2008 IHDP formally approved the "Earth System Governance Project" (ESGP) as a new core project. IHDP Update 3/2009 is a comprehensive tribute to this new activity. It contains a number

Figure 15.3: Institutions and their effects on global environmental change/The primary focus of the IDGEC project. **Source**: IDGEC Science Plan.


of basic articles in fields such as urban areas, health, food and their governance structures.

IT (Industrial Transformation), the third core project established in 1999, started off with three objectives: to understand complex society–environment interactions; to identify driving forces for change; and to explore development trajectories that have a significantly smaller burden on the environment (Vellinga/ Herb 1999).

Its outset was a focus on industrial production and industrial outputs that, in the past, had been completely unsustainable. The researchers' analysis, initially focused on work in industrialized countries, made it clear that technological innovations are scarcely sufficient for creating less resource-intensive and less polluting systems. Institutional and social interventions are also necessary to achieve what has been called a "social–technical system". The transfer and application of the test phase to the rapidly industrializing countries of Asia discovered the importance of "sustainability experiments", which were obvious important preconditions for more sustainable and long-term pathways.

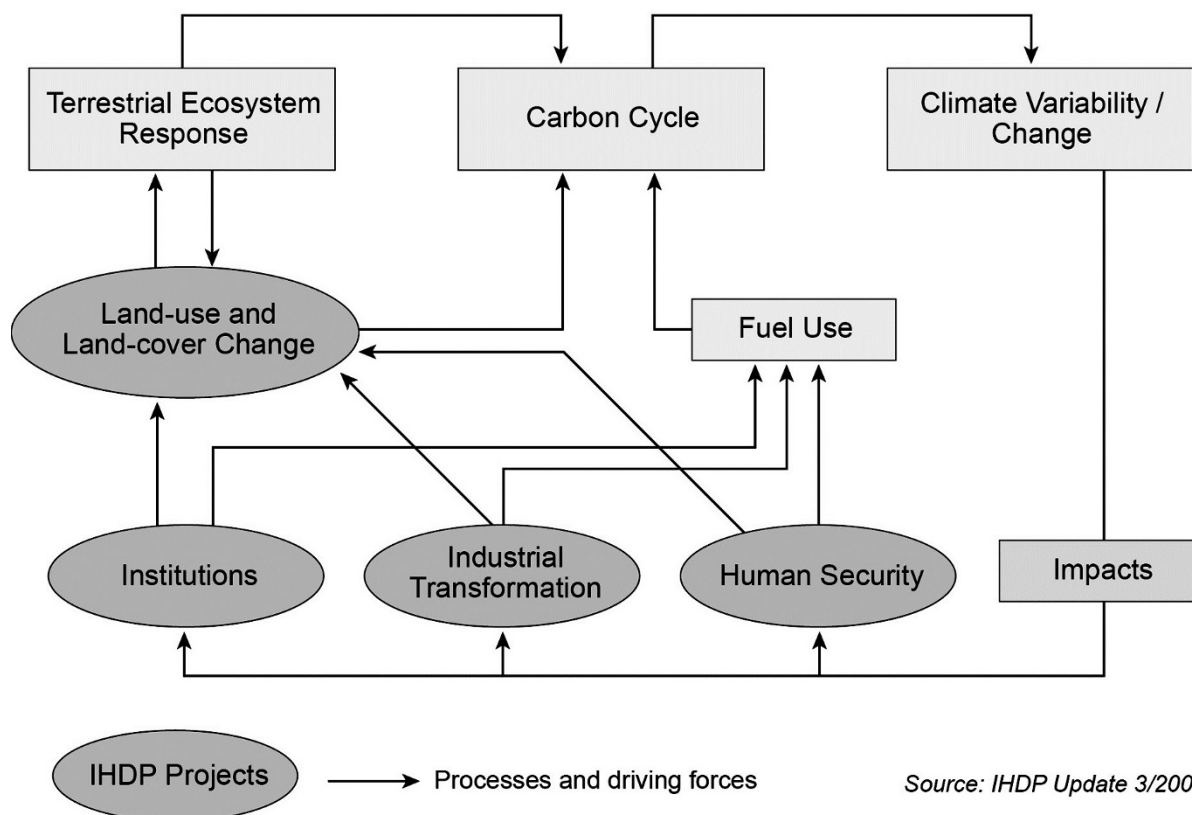
Like GECHS and IDGEC, IT cannot be viewed independently of other environmental and social factors. Urbanization, resource extraction, energy consumption and mobility: these and other phenomena are closely connected with industrial transformation. Cross-cutting activities and analyses alongside other IHDP projects and joint activities with IGBP and WCRP were practically mandatory. From the very beginning, IT has been closely connected with the Carbon Joint Project, renamed as the Global Carbon Project (GCP), of IGBP/IHDP/WCRP. In addition, IHDP's own Global Carbon Cycle Research initiative served as a basis for an international Carbon Research Framework (Gupta/Lebel/Vellinga 2001). The interactions of the IHDP projects in pursuit of this initiative are presented in figure 15.4 (see also IHDP Update 3/2000 for a special edition on the carbon cycle and its relevance for society—a collection of six articles/statements).


Figure 15.4: Industrial Transformation: Interactions within the human–environment system with respect to the global carbon cycle. **Source**: IHDP Update 3/2000.

15.3.2.3 IHDP and the Sustainability Discourse

The development of all GEC research programmes under the auspices of ICSU and ISSC are characterized by a steadily growing tendency to proceed from observation and data collection via modelling to scenario developments. The early reports of the IPCC (*Intergovernmental Panel on Climate Change*) are good examples of this kind of research and its conclusions in terms of predictions.

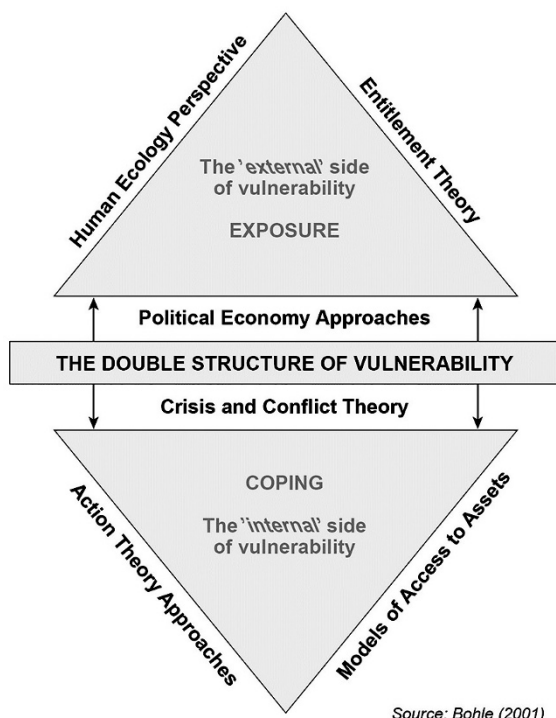
The turn of the century/millennium may also be called a turning point for GEC research. These years saw not only a number of seminal publications (Kates/ Clark/Corell et al. 2001; Kasperson/Kasperson 2001; Lubchenko 1998; NRC 1999–to name just a few), but also the propagation of the Anthropocene (Crutzen/ Stoermer 2000) and of a geology of mankind (Crutzen 2002). All this had a deep impact on IHDP's sustainability discussions and its discourses on how individuals and societies cope or are forced to cope with climate change, risks and disasters. Human security proved to be a crucial issue not only for IHDP's core projects, but also for the programmes' methodological and theoretical discussions in general. It is impressive to see just how intensive these discussions were and to what extent they also began to influence joint programmes, the activities of the ESSP, endorsed networks and capacity development initiatives. To a great extent derived from IHDP's core projects, the sustainability discourse and all its facets nevertheless developed their own agenda and produced remarkable insights in fulfilment of IHDP's original vision and mission.

It would be going far beyond the aims and scope of this report to delve into the details of these analyses. The fact is that the sustainability discourses of IHDP are closely connected with the concepts of vulnerability, risks and hazards, resilience, adaptation, mitigation, susceptibility, and coping capacity. And these are the foci of continuous academic and application-oriented discussions and further strategic developments up to today. They all deal more or less explicitly with the attempt to overcome the deep gulfs in methods, theories and practice between the natural and social sciences and to bridge the fundamental differences between them. Sustainability science as perceived by an international group of experts led them to argue: "A new field of sustainability science is

emerging that seeks to understand the fundamental character of interactions between nature and society. Such an understanding must encompass the interaction of global processes with the ecological and social characteristics of particular places and sectors ..." (Kates/Clark/Corell et al. 2001; 641).

Among the many fundamental papers that came out of IHDP's core projects, a rather short but essential and complex paper on vulnerability is Hans-Georg Bohle's "Conceptual Model for Vulnerability". This combines different social science approaches and theories as explanatory causes of vulnerability together with coping strategies to overcome the challenges and threats caused by natural or social hazards and risks. It is to a certain extent a very comprehensive approach. Bohle's external side of vulnerability covers both natural and social risks and hazards as part of human exposures. Coping strategies (e.g. adaptation or mitigation) are part of the social response to such challenges. However, Bohle's conceptual framework goes far beyond mere factual analysis. It embeds the specific cases/objects of research into a set of methodological and theoretical considerations, thus transferring the special case to a general problem. It is probably fair to say that these theoretical as well as conceptual considerations mark the increasing reliance of social science research on global environmental change.

Figure 15.5: Bohle's Conceptual Framework for Vulnerability Analysis. **Source**: Bohle (2001).

Source: Bohle (2001)


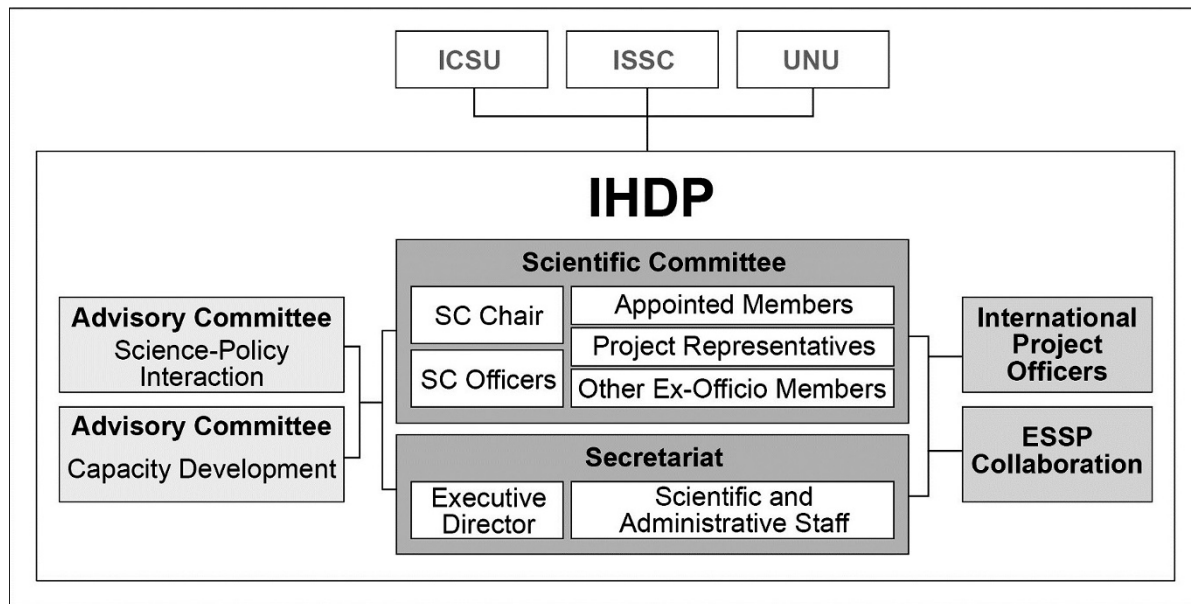
Bohle's comprehensive approach, published in IHDP Update's special issue on vulnerability (IHDP Update 2/2001), is just one example of IHDP's attempts to serve as a bridge-builder between the natural and social sciences, including the humanities. There are other and similar attempts to put the sustainability issue at the centre of IHDP's research agenda (see, for example, figure 15.2). Besides these developments, mentioned in the review of IHDP's core projects, there has been an intensive and inspiring conceptual discussion on many facets connected with the discourse on sustainability. While it is probably fair to say that IDGEC ensured, independently of its own research foci, the institutional frame for the discourse on sustainability in general, it was GECHS in particular that inspired the discussion on sustainability with a wide range of methodological and theoretical inputs. Key themes and topics were, for instance, "climate change vulnerability and adaptation, water governance issues, rural livelihoods and food security, conflicts and cooperations in trans-boundary resource management, and interactions between global environmental change and globalization" (IHDP Annual Report 2008, p. 24). GECHS's Synthesis Conference on "Human Security in an Era of Global Change" in 2009 also put the multifaceted aspects of human (in-)security including natural as well as social risks and hazards at the centre of their final discussions.

It would be going far beyond the scope of this article to try to document the scientific outcomes in detail. It must therefore suffice to point to IHDP's Updates and Annual Reports. At least until 2007, the projects' progress reports are (partly) equipped with lists of selected publications and are suggested as further reading.

15.3.3 IHDP's Second Decade (2006/7–2014): New Foci, New Directions and New Pathways towards "Future Earth"

In 2007 IHDP published a new 'Strategic Plan 2007-2015' in which, besides continuing cutting-edge research, special emphasis was given to capacity development, community building, and outreach, as well as placing a stronger focus on science–policy interactions. Figure 15.6 reflects this new strategy and the new organizational structure.

Both the programme structure of the new IHDP in 2007 and the composition of IHDP's Scientific Committee reflect the new approach. While the core of the SC covers exclusively social science disciplines and economics, its ex-officio members are mediators

Figure 15.6: IHDP's new governance structure. **Source**: IHDP's Strategic Plan 2007–2015, p. 30.


Source: IHDP's Strategic Plan 2007-2015

Box 15.6: IHDP Project Activities in 2008. **Source**: IHDP Annual Report 2008.

Core projects: IHDP currently has six core projects. Core projects are conceptualized and supported by IHDP, sometimes in partnership with various other programmes to identify and generate new, cutting-edge research activities, promote international cooperation, and build linkages between policy-makers and researchers.

- Earth System Governance (ESG)
- Global Environmental Change and Human Security (GECHS)
- Global Land Project (GLP)
- Industrial Transformation (IT)
- Land–Ocean Interactions in Coastal Zones (LOICZ)
- Urbanization and Global Environmental Change (UGEC).

ESSP Joint Projects: IHDP is currently conducting four projects in conjunction with the Earth System Science Partnership (ESSP). These projects are formed and run in a similar way to the core projects, but with support from all partners of ESSP. In addition, IHDP cooperates with ESSP to endorse other networks.

- Global Environment Change and Food Systems (GECAFS)
- Global Carbon Project (GCP)
- Global Water Systems Project (GWSP)
- Global Environmental Change and Human Health (GECHH)
- Monsoon Asia Integrated Regional Study (MAIRS)
- System for Analysis, Research and Training (START).

Initiatives: Initiatives are potential IHDP projects. These projects are in the process of preparing and reviewing a science plan to present to the IHDP Scientific Committee.

- Integrated Risk Governance (IRG)
- Integrated History of People on Earth (IHOPE)
- Knowledge, Learning and Societal Change (KLSC).

Endorsed Networks:

- Mountain Research Initiative (MRI)
- Population–Environment Research Network (PERN)
- Young Human Dimensions Researchers (YHDR).

---

of IHDP's obligations towards the natural sciences. The same holds true for IHDP's programme structure, its sponsoring institutions and its partnership with existing IGBP and WCRP activities.

The Strategic Plan 2007-2015 provides valuable background information. While some of IHDP's core projects had already terminated by 2007, others were in the final stages of the preparation of synthesis reports. Almost at the same time, in October 2008, a broadly-

based international research initiative, the *Earth System Governance Project* (ESGP), got under way and became a new core project within IHDP. ESSP also implemented four global-scale joint projects on water, food, carbon and human health, all with the strong involvement of IHDP. IHDP's extensive portfolio in 2008 is summarized in box 15.2.

All this went hand in hand with new directions in regard to IHDP's new strategies. Besides its contin-

ued involvement in research, the Strategic Plan 2007–2015 set distinctly new standards and declared "science–policy interaction a top priority for IHDP in its second decade". Science–policy interaction meant, above all, capacity development, community building and outreach. Sustainable capacity development designed as a close interaction between eminent scientists, policymakers and practitioners, and other stakeholders and beneficiaries, was to be accompanied not only by conferences and publications, but also by new major activities: specific workshops, training seminars, mentorship programmes for emerging scientists, scholarships, etc.

As indicated earlier, the last years of IHDP are somewhat difficult to reconstruct and to judge. The fact is that the programme expanded beyond its traditional cores. It became a kind of cohesive centre of the new and integrative GEC projects. It was especially under the far-sighted IHDP chairmanship of Oran Young, one of the founding fathers of the programme, that IHDP and its IDGEC programme ensured an urgently needed cohesion among IHDP's core projects and its joint activities (Young/King/Schroeder 2008). Its continuation under the umbrella of ESG is therefore a logical consequence (see: From IDGEC to ESG—Passing the Torch. 1st Synthesis book of the former IDGEC project, Delhi 2008; see also Biermann 2007). It is obvious that ESG, formally inaugurated as a new core project within IHDP in 2008, had to fulfil crucial functions and tasks for the overall GEC community, as IDGEC was now in the past. ESG is challenged by "the development of theories to understand Earth System governance, as well as strategies to advance it" (IHDP Annual Report 2008, 18). In order to achieve its interdisciplinary, international and multi-scale aims and goals, ESG's comprehensive Science and Implementation Plan was published in 2009 (Biermann/Betsill/Gupta et al. 2009).

ESSP, first discussed in Amsterdam 2001 and officially launched as an outcome of the ESSP Open Science Conference "Global Environmental Change: Regional Challenges" in Beijing in November 2006, must be seen as an important step in further fostering cooperation between WCRP, IGBP, IHDP and DIVERSITAS. This partnership is based on the conviction that the complexity and dynamics of highly sensitive socio-ecological systems needs cooperation between different programmes of GEC research and, if possible, the bottom-up development of joint projects such as GCP, GECAFS, GWSP and GECHH in order to tackle the causes and consequences of air and water pollution, water scarcity, food problems, risks and

hazards to human health—and all this under aspects such as vulnerability, resilience, and adaptation and coping strategies. Thus, and finally, DIVERSITAS, IGBP and IHDP became united under one umbrella organization, ending their experiences as ESSP and merging into the new programme called "Future Earth". Designed as a ten-year international research programme, Future Earth was launched in June 2012 at the UN Conference on Sustainable Development (Rio+20). Its initial design report (2013) includes the following statement: "Future Earth will address issues critical to poverty alleviation and development such as food, water, energy, health and human security, and the nexus between these areas and the over-arching imperative of achieving global sustainability. It will provide and integrate new insights in areas such as governance, tipping points, natural capital, the sustainable use and conservation of biodiversity, lifestyles, ethics and values. It will explore the economic implications and social transformations towards a low-carbon future. Future Earth will explore new research frontiers and establish new ways to produce research in a more integrated and solutions-oriented way."

Is it too critical or even arrogant to note that language, vision and mission as well as programme details sound rather familiar? This "familiarity" becomes even more striking if one looks at Future Earth's conceptual framework, which stresses "that humanity is an integral part of the dynamics and interactions of the Earth System and that this has important implications for global sustainability ...". It is probably not an exaggeration to state that IHDP's handwriting has had a major impact on the initial design of this executive summary.

Its ultimate aims and goals also sound somewhat familiar. Future Earth will be—in its own words—a global platform to deliver:

- *Solution-oriented* research for sustainability, linking environmental change and development challenges to satisfy human needs for food, water, energy, health;
- *Effective interdisciplinary collaboration* across natural and social sciences, humanities, economics, and technology development to find the best scientific solutions to multifaceted problems;
- *Timely information for policymakers* in generating the knowledge that will support existing and new global and regional integrated assessments;
- *Participation* of policymakers, funders, academics, and other sectors of civil society in co-designing and co-producing research agendas and knowledge; and

- *Increased capacity-building* in science, technology, and innovation, especially in developing countries, and engagement of a new generation of scientists.

It looks as if IHDP in its almost twenty years of existence must be seen as a pacemaker in bridging the gaps between the natural and social sciences and the humanities. It has done so through the cohesive power of its core and joint projects and especially through its intensive contributions in the fields of institutional and governance structures. ESSP projects and their successful implementation have been major steps towards the pursuit of serious large-scale integrative and cross-disciplinary research initiatives. The conscious inclusion of START (*Global Change System for Analysis, Research and Training*) supports IHDP's advertised interest in science–policy interactions, outreach and knowledge dissemination (IHDP Strategic Plan 2007–2015. 2007; IHDP Annual Reports 2006–2007, 2008). Thus, and for the time being, Future Earth is an important additional step forward in global (environmental) change research or, as Future Earth calls it, "a step-change in Earth system research". Its main message is that IGBP, DIVERSITAS, and IHDP have ceased to exist. Together they are now "Future Earth".

In June 2014, the IHDP headquarters and offices closed. In doing so IHDP as representative of the social sciences and the humanities within climate and global change research finished its specific mission. The legacy of IHDP will live on in Future Earth.

15.3.4   IHDP 1996–2014: A Retrospective Summary

Looking back at IHDP's institutional and organizational reforms between the late 1990s and its amalgamation with IGBP and DIVERSITAS into the new Future Earth programme in 2014, it may be appropriate to put special emphasis on the formal concomitants of IHDP's development between 1996 and 2014. Science and research would have been impossible without framework conditions, by which is meant functioning and effective communication and information structures. Equally important and basically dependent on those structures are the scientific networks beyond programme and disciplinary boundaries that emerge over time.

Central to the coherence of the international human dimensions community and its connections with its partner organizations WCRP, IGBP and DIVERSITAS was the IHDP newsletter *Update*. Over almost twenty years, *Update* developed from a meagre eight-pager to an impressive journal-like publica-

tion, consequently changing its newsletter status into that of a *Magazine of the International Human Dimensions Programme on Global Environmental Change*. The newsletter version of the *IHDP Update* in particular contains a wealth of organizational details of the programme's various activities and details of the development of the core projects and of meetings and cooperation—and, of course, policy statements and scientific articles. A reconstruction of IHDP's history from 1996/7 until early 2014 is impossible without the *IHDP Update*. The same holds true for IHDP's Annual Reports, the first of which was also published in 1997 and whose last edition was published in 2013.

However, IHDP's indispensable communication aids also underwent important organizational and structural changes. In 2007 IHDP came under the umbrella of the *United Nations University* (UNU) as an additional sponsor alongside ISSC and ICSU. The UN University and its Bonn branch has a special focus on *Environment and Human Security* (UNU-EHS),[3] and the themes and topics of UNU-EHS proved to be so close to those of IHDP that cross-cutting cooperation with IHDP was just a matter of time. In addition, UNU-EHS also agreed to host the IHDP Secretariat at its headquarters at the UN Campus in Bonn. This new affiliation with an internationally visible partner and its focus on the increasingly close interaction between nature and society granted IHDP access to many other UN agencies and secretariats located in Bonn, such as the *United Nations Framework Convention on Climate Change* (UNFCCC),[4] the *United Nations Convention to Combat Desertification* (UNCCD),[5] and others.

Formal changes in the second decade of its existence included a new format for the IHDP Update. From October 2007 onwards, this functioned as a "Magazine". As a consequence, it focused on specific themes or projects; at the same time, however, it lost its well-established functions as a newsletter in the proper sense of the word. In 2012, these functions were taken over by a short-lived publication called "The Networker". In 2012 "Update" was entirely replaced by a new journal-like publication called "Dimensions".

Taking into account the science and research in its core programmes, its growing embeddedness in joint activities, and its involvement in multidisciplinary networks, one can distinguish three distinct phases in IHDP's twenty years of existence, as follows.

15.3.4.1 The Period 1996–2001

This initial period was characterized not only by the endeavour to establish the programme logistically, but also by the development of central projects and their science plans (see 15.3.2) and by (as one of the reviewers has called it) its "success ... as a real-science driven enterprise". Both executive directors, Larry Kohler and Jill Jaeger, played crucial roles in these activities. As already indicated, and as will be addressed in further detail in chapter 15.4, these years saw the establishment of IT, GECHS and IDGEC as core projects and the development of LUCC as a joint project in cooperation with IGBP, as well as increased involvement in START activities. The Global Change Open Science Conference in Amsterdam in July 2001 may probably be considered as a turning point, since it marks the first really integrated Global Environmental Change Conference (Steffen/Jaeger/Bradshaw 2002). The "Amsterdam Declaration on Global Change" pays tribute to this integrative approach and focuses beyond doubt on the critical role of humans. The joint statement by WCRP, IGBP, IHDP, and DIVERSI-TAS notes, for example (Steffen/Jaeger/Bradshaw 2002: 206–7):

- The Earth System behaves as a single, self-regulating system made up of physical, chemical, biological and human components.
- Human activities significantly influence Earth's environment in many ways in addition to greenhouse gas emissions and climate change.
- Earth System Dynamics are characterized by critical thresholds and abrupt changes. Human activities could inadvertently trigger such changes with severe consequences for Earth's environment and inhabitants.

On the basis of these (and other) findings, the Declaration concludes:

- An ethical framework for global stewardship and strategies for Earth System management are urgently needed.
- A new system of global environmental science is required.

Amsterdam 2001 was thus a decisive event for IHDP. The role and importance of human interferences in and impacts on nature and on the environments of societies was broadly acknowledged. IHDP's science plans and implementation strategies and the rapid progress of its projects were a timely answer to these challenges.

15.3.4.2 The Period 2001–2009

This second period may—again in line with a reviewer's suggestion—be called the "real heyday of IHDP" or its "golden era". It is marked by IHDP's increasing endeavours to pursue research in line with a highly integrative and social-science-based "sustainability science" (Kates/Clark/Corell et al. 2001). Almost parallel to this short but seminal article, a number of similarly influential publications opened the pathways for the increased involvement of social science in research into global environmental change. Following a comprehensive stocktaking by the US National Research Council on "Human Dimensions of Global Environmental Change" (NRC 1999), the Stockholm Environment Institute organized an "International Workshop on Vulnerability and Global Environmental Change" and published its results (SEI 2001). Almost simultaneously, IHDP published a special issue on vulnerability (IHDP Update 2/2001).

The period from 2001 onwards is characterized by the successful progress of the IHDP research initiatives mentioned above (IDGEC, IT and GECHS), as well as by IHDP's joint projects with IGBP. In addition, new IHDP projects as well as joint projects were begun. In 2001, GECAFS (Global Environmental Change and Food Systems) was launched as a project focusing on the linkages between food security, food systems and global change; a joint project with IGBP and WCRP. As another example, in 2006 the project on Urbanization and Global Environmental Change (UGEC) got under way. LUCC merged into a new project, the Global Land Project (GLP), co-sponsored by IGBP, and the second phase of the Land–Ocean Interactions in the Coastal Zone project (LOICZ 2) became a joint effort by IHDP and IGBP.

Other outstanding achievements of this period are the publication of IHDP's Strategic Plan 2007–2015 under the chairmanship of Oran B. Young (IHDP 2007), the continued engagement in connection with the development of an Earth System Science Partnership (ESSP) inaugurated in an Open Science Conference in Beijing in November 2006; the achievements of this period culminated in the IHDP Open Meeting in Bonn 2009, with more than a thousand participants.

15.3.4.3 The Final Period 2009–2014

The third period is less easy to characterize. 'Restructuring' may be an appropriate term to describe this rather incoherent phase, but restructuring towards what? As one of the critical reviewers of this paper

noted, there were obvious "efforts to build IHDP Bonn as a research unit independent of the core projects", but there were also tendencies by the secretariat to work under the auspices of the ICSU in pursuit of the *Future Earth* (FE) programme. IHDP's decision to relocate its headquarters under the umbrella of the UNU (United Nations University) and its Bonn branch on *Environment and Human Security* (EHS) also falls into this period. Finally, in early 2012 IHDP started a new magazine *Dimensions*, which (in the words of IHDP's Executive Director Anantha Duraiappah) "will be IHDP's premier dissemination outlet for key findings from its portfolio of projects" (Dimensions 2012, p. 3)—a clear difference from IHDP's earlier and well-established information policies, and with only four issues, very short-lived. It was complemented by an equally short-lived "Quarterly Newsletter" between April 2011 and May 2014, replacing the former IHDP Update.

15.4   An Outlook: GEC Research and "Future Earth"

It is more than a mere coincidence that IHDP in its almost twenty years of existence really succeeded in bringing humankind, as one of the main triggers of both climate change and global environmental change, into the foreground of global change research. In doing so, IHDP not only fulfilled its own mission and vision (see above), but it also helped to pave the way for a basically new understanding of the intricate and dense interactions between nature and societies. The increasingly alarming results from IPCC, the postulate of a new geological era, the Anthropocene (Crutzen/Stoermer 2000; Ehlers 2008), and the propagation of a "geology of mankind" (Crutzen 2002) are milestones of a new interpretation of society–nature relationships and interactions. IHDP can take pride in the fact that it has participated in the development of these new paradigms.

Both IPCC and its warnings about the climate change impacts by human activities, and the general discussion about the 'Anthropocene', its characteristics and consequences, are durable indicators of the increasing role of the human dimension in shaping global environmental changes. The questions as to whether this is really "a new epoch of geological time" (Zalasiewicz/Williams/Haywood et al. 2012; see also Steffen/Grinewald/Crutzen et al. 2011) and whether it is "an epoch of our making" (Syvitski 2012) have greatly enhanced and fostered reflection on the importance of human interference into the nature of Planet Earth. It is especially Syvitski's ultimate statement

> Interestingly, while portions of society still refuse to acknowledge the role of humans in affecting global climate, they appear more willing to accept that the modern world is anything but pristine and strongly under the influence, if not control, of society...Humans have changed the Earth in a number of fundamental ways, many of which are far less known than global warming (Syvitski 2012: 12-13)

that underlines even stronger commitments from the social science community to cope with the increasing number of threats to our fragile Planet Earth. IHDP 1996-2014 and its projects (IDGEC, IT, GECHS, UGEC and many others) can take pride in the fact that it has been an essential promoter of these insights. IHDP was successful in raising awareness and expanding our consciousness of the causes and consequences of climate and environmental change. And, above all, it has taken up the serious and timely demands for the pursuit of a new "sustainability science" (Kates/Clark/Corell et al. 2001) and for science's responsibility for society and its well-being (Lubchenco 1998; Gibbons 1989; Lövbrand/Stripple/Widman 2009).

For millennia, humanity has lived under the threat of nature. Today, nature exists under the threat of humankind. It may therefore be appropriate to finish this review of IHDP 1996-2014 by quoting a few conclusions from a Nobel Prize Laureate symposium on Global Sustainability held in Stockholm in May 2011. Some of its key messages stress the need for new ways of thinking and include an urgent call for a new alliance between nature and society. The Nobel Prize Laureates' advice for new forms of independent social–ecological systems of global change research is as follows:

> It is time for a new social contract for global sustainability rooted in a shift of perception—from people and nature seen as separate parts to interdependent social–ecological systems. ... Most current economic and technological solutions are ecologically illiterate and too linear and single problem-orientated. ... We need a new type of 'social–ecological' innovation and technologies that work more directly for social justice, poverty alleviation, environmental sustainability and democracy ... (Third Nobel Laureate Symposium on Global Sustainability 2011).

IHDP has surely contributed to meeting these challenges. It remains to be seen how Future Earth will proceed in its efforts to achieve transformations towards sustainability.

16   From *The Limits to Growth* to 2052

Marit Sjøvaag

Abstract

This chapter summarizes the content of and the debate around *The Limits to Growth* and its updates, from 1972 until 2012. It presents the background and political context to the original 1972 study, and follows the debate in and around the four books on whether a 'fair and free market' can provide sufficient benefits for us all. The methodology of systems dynamics is briefly introduced. The analyses are presented in some detail, as are the reactions from both academia and political and economic interests following the books' publication. The two main research questions are why the debate around *Limits to Growth* became so polarized, and what we have learned about the original scenarios over the last four decades. The chapter therefore includes a synthesis of research on how the original World3 Standard run has compared to subsequent reality. Randers' forecast for the next forty years constitutes the fitting end point for this analysis.

Keywords: Limits to Growth, economic growth, polarization, system dynamics, modelling.

16.1   Introduction[1]

In 1972 a small book appeared that was to have an impact far above what its modest size indicated. It presented a set of possible scenarios for the future. *The Limits to Growth* (hereafter: LTG) (Meadows/ Meadows/Randers et al., 1972) kick-started a debate about the pros and cons of economic growth, and gave inspiration to the growing environmental movement in the industrialized world.

The hard and bitter debate that ensued is not yet concluded, but it has over the years changed in volume, intensity and character. If it is at all possible to identify one fundamental issue in a debate that has been going on for over four decades, it is first and foremost a question of whether our decision-making (mainly economic) models are capable of integrating sufficient information to ensure that the effect of human behaviour remains within the planet's carrying capacity—in other words, can we trust a free market to produce ultimate benefits for all?

Limits to Growth did not appear from nowhere. It followed an intellectual tradition that started at least

a decade previously with Rachel Carson's (year) *Silent Spring*, which highlighted the dangers to our environment of using new technologies (in her case pesticides, in particular DDT) whose consequences are unknown. But it was not only the intellectual tradition of questioning human activity's impact on the environment that was followed from *Silent Spring*. As early as the 1960s powerful industrial interests had spent large sums of money on discrediting the kind of research in *Silent Spring*, and subsequently in LTG. The battlefronts of the conflict were therefore already set and hard before LTG was published, at least in the US, where the debate was the most polarized. Once the message had been sent that the authors were 'doomsayers', 'neo-Malthusians' and 'anti-growth', it proved almost impossible to alter the impression in the public mind.

Two questions are of particular interest in this context. Firstly, why did the debate raised by the *Limits to Growth* become so polarized? And secondly, what have we learned over the last four decades about the essential questions posed by the LTG team?

In order to answer these questions this chapter will synthesize the main message from the Limits to Growth study (hereafter the LTG) as well as the two updates: *Beyond the Limits* (BLT), from 1992, and *Limits to Growth—the 30-Year Update* from 2004.

---

1   I wish to thank Prof. Jørgen Randers for helpful information and moral support throughout the writing process. Any errors are mine alone.

Finally the main findings from 2052–*A Global Forecast for the Next 40 Years* will be presented. This book can in some ways be seen as a sequel to the others, but unlike the LTG series, '2052' is presented as a forecast, not as a collection of possible futures. It will therefore be possible to empirically validate (or not) its accuracy over the next forty years.

The chapter is organized in four main parts. Part one presents the Limits to Growth from 1972 (16.2), its methodological foundations, its context, and the immediate reactions. Part two reviews the two update studies from 1992 and 2004 (16.3). Part three looks at the message and conclusions from the book 2052: *the next 40 years* (16.4), while part four offers conclusions (16.5).

16.2   The Limits to Growth—A System Dynamic Analysis of Planet Earth (1972)

The LTG was written as a 'report for the Club of Rome's project on the predicament of mankind'. The Club of Rome[2] traces its origins back to a meeting in 1968 between thirty individuals who believed that 'the major problems facing mankind are of such complexity and are so interrelated that traditional institutions and policies are no longer able to cope with them, nor even to come to grips with their full content' (Meadows/Meadows/Randers et al. 1972: 9-10).

The Club of Rome commissioned a group of young researchers at MIT under the direction of Professor Dennis Meadows to carry out 'Phase One of the Project on the Predicament of Mankind'. The intellectual inspiration for their work came from Professor Jay Forrester, an engineer who had turned his attention to management systems and to using computers in the simulation of social systems (Forrester 1989). He is the founder of system dynamics.

16.2.1   Key Concepts and Methodology

Before summarizing the findings of the LTG, it is useful to give a brief presentation of the methodological foundations upon which the study was conducted. So much has been said and opined about the LTG results that it is worth clarifying the methodological ambitions from the outset.[3]

Models[4] are 'a formalization of our assumptions about a system' (Hall/Day 1977, cited in Bardi 2011: 16). We often refer to individuals having 'mental models'. Such mental models are a representation of the surrounding world, and are crucial to our ability to make sense of our observations. Scientific models, however, should start from clear, explicit assumptions, so that others can validate their appropriateness and usefulness in different contexts. Scientific models allow us to make explicit what we assume about a system, and when the models are quantitative (i.e. mathematically formulated expressions define how various system parameters are related), they allow us to calculate how the parameters—and hence the system—will vary with time.

The assumptions may be more or less right or wrong. Large discrepancies between predictions and observations can lead us to conclude that the model is wrong, but the opposite is not true. A model is not necessarily right even if it predicts what we go on to observe. However, the more empirical data that agree with simulated results, the more we tend to 'trust' the model—we have a higher degree of confidence that it will be useful for predicting the future behaviour of the system.

System dynamics[5] emerged as a discipline in the 1950s. Initially it was used for industrial purposes, but from the 1960s it was used to model social and eco-

---

2   The Club of Rome is a "global network of independent and renowned thinkers [...that...] analyses today's challenges facing the world, their root causes and the possible futures, in a systematic and holistic manner. The Club of Rome encourages global debate in order to set in motion actions that by the middle of the century will ensure a more secure, equitable, and prosperous world." See at: <http://www.cluboffrome.org/> and <http://www.cluboffrome.org/?p=324>

3   This is not meant as an exhaustive introduction to system dynamics. For those interested, see for example Ford 2009, <http://www.public.asu.edu/~kirkwood/sysdyn/SDIntro/SDIntro.htm> or <http://www.systemdynamics.org/what-is-s/>.

4   For an excellent overview of the debate surrounding *Limits to Growth* see Ugo Bardi (2011), *Limits to Growth Revisited*. Ugo Bardi's blog can be found at: <www.cassandralegacy.blogspot.com>.

5   One typically distinguishes between linear and non-linear systems. In linear systems there are well-defined and well-known causal relationships, whereas non-linear systems involve parameters that interact, and they are often very difficult to predict over longer time spans. Cause and effect are often not well understood in non-linear systems. They are central to the group of systems called 'complex', i.e. systems that involve feedback relations.

nomic systems. System dynamics looks at several fundamental elements in a system: stocks, flows and feedback.[6] These elements vary over time and are interdependent. The stock is something's actual amount (e.g. the number of individuals in a population), whereas the flow is the variation over time of the stock (e.g. births and deaths). Feedback occurs when the intensity of a flow into a stock depends on the size of the stock. The feedback can be positive (for example, a larger population increases the number of births, if the birth rate is constant) or negative (a larger population increases the number of deaths, if the death rate is constant). However, "the fact that a system is dominated by feedback effects (...) does not imply that it is completely random. On the contrary, these systems often follow well-defined patterns" (Bardi 2011: 8), and this allows us to build models that help us analyse possible trajectories of the system's behaviour.

16.2.2 Key Scientific Approach and Messages of *The Limits to Growth* Study

LTG was a study of the Earth system using system dynamics. The research group identified what they saw as the five most central system parameters, and built a quantitative model expressing the relationship between these parameters (and some others) using mathematical expressions.

The ambition of the LTG research group was to study the interrelatedness of five basic factors that determine growth in population and ecological footprint on Earth. The question they asked was simple: how do changes in one of these factors impact on the other factors?

The five factors were:

• population
• agricultural production
• natural resources
• industrial production
• pollution.

Defining and explaining the nature of the growth of the system was a central part of the LTG study. The book goes to some length to explain the characteristics of 'exponential growth', and to emphasize how exponential growth differs from linear growth. It explains the concepts of 'doubling time' and 'positive

feedback loops'. It is hard to overestimate how difficult the human mind finds it to think about exponential growth, particularly in relation to processes that take a long time. The classic illustration used in the book is the old French riddle that visualizes the suddenness with which the 'end' is approaching:

> Suppose you own a pond on which a water lily is growing. The lily plant doubles in size each day. If the lily were allowed to grow unchecked, it would completely cover the pond in 30 days, choking off the other forms of life in the water. For a long time the lily plant seems small, and so you decide not to worry about cutting it back until it covers half the pond. On what day will that be? On the twenty-ninth day, of course. You have one day to save your pond (Meadows/Meadows/ Randers et al. 1972: page).

The LTG research group built a system dynamic model of the world, and called it World3. Like all models, it was a simplified representation of the *real* world system—this is one of the purposes of modelling—and in this case many constraints were obvious: there was insufficient knowledge about the physical processes specifying the relationships between the parameters, and it was (and is) difficult to quantify the effects of socio-psychological factors (for example, of the population's potential value change on the consumption of both industrial goods and services). The authors grouped these sources of uncertainties into three categories:

1. the relationship between economic variables that are relatively well understood,
2. the effect of socio-psychological factors that are difficult to quantify, and
3. the biological variables which are largely unknown (Meadows/Meadows/Randers et al. 1972: 103–104).

The authors were therefore aware of the shortcomings in knowledge about the system they wanted to simulate. However, rather than waiting for more research about the exact effects of socio-psychological factors or biological variables, which would take a long time in coming, they proceeded to develop the World Model, representing the world system to the best of their ability. A visual presentation of the causal links in the World Model is given in figure 16.1.

In 1972, the recent development of sufficiently sophisticated computer technology had profoundly changed our ability to handle large amounts of data simultaneously. We have become nonchalant when it comes to computing capacity, but in 1972 this was still in its infancy, and while the World Model used in the

---

6 For a highly readable introduction to the basics of system dynamics as used in the LTG study, see Bardi (2011), chapters 3 and 4.

Figure 16.1: Causal diagram of the World3 model. **Source**: Jørgen Randers presentation material; he also granted permission to use this figure.
Limits to Growth is simple from our current perspective, it was the most sophisticated in its time.

The discussion in the LTG study started from a 'standard run' of World3, where one assumed 'no significant change'[7] in the physical, economic or social relationships that were seen to govern the world system. The standard run was concurrent with historical data for the period 1900–1970. This is not surprising; the parameters of the model were chosen to ensure such a match, so the match is in itself not a sign of the correctness of the model. The model was built empirically, in some cases using historical relationships between the five basic factors to specify the equations used in the model. The standard run showed that if

continued unchanged, the exponential growth in population, food and industrial output would result in a rapidly diminishing resource base that again would lead to a slowdown in industrial growth, and subsequently (because of delays in the system) to a rapid decline in food production and population.

To investigate the effect of various policies in World3, the researchers used the 'standard run' as a baseline and simulated policy implementation by changing one or more of the input parameters. 'Policies' should here be understood as behavioural changes at the system level, rather than as a political process or pronounced ambitions (for example about recycling rates or reduction of ozone-depleting gases). The policy changes included unlimited access to nuclear energy (enabling extensive recycling and resource substitution), and controls on population and pollution. The overwhelming majority of scenarios produced futures with overshoot and collapse.

Having observed collapse, i.e. a sudden and dramatic decline in population or production, the

---

7   This important fact is often overlooked. The model was built so that it concurred with observed data in the period 1900–1970, and the standard run therefore assumed that the interdependent processes simply would continue as they had done for the previous seven decades.

researchers set themselves the task of identifying policies that would stabilize the system so that uncontrollable collapses would be avoided, and that at the same time would be capable of satisfying the basic material requirements of all people.

The input parameters were thus changed with the explicit goal of identifying a stable solution for world population with an adequate food supply and industrial output. Of course, several input combinations would be able to produce a stable system, and one set was presented in the LTG study. It consisted of:

- Stabilizing the population at 1975 levels (by setting the birth rate equal to the death rate)
- Stabilizing industrial capital at 1990 levels (by setting the investment rate equal to the depreciation rate)
- Setting resource consumption per unit of industrial output to one-fourth of its 1970 value (introduced in 1975)
- Shifting society's consumption preferences more towards services and less towards manufactured goods (starting in 1975)
- Setting pollution generation per unit of industrial and agricultural output to one-fourth of its 1970s value (introduced in 1975)
- Diverting some capital from industrial to agricultural production even if it was 'uneconomic' (to ensure proper nourishment for all)
- Maintaining soil quality through altered use of agricultural capital
- Increasing average lifetime for industrial capital.

These policies were, according to LTG, one (of several) possible sets that it was physically possible to maintain on Earth. Resource depletion would still occur, but at a rate sufficiently slow to allow for technology to adjust to changes in resource availability.

To reach this sustainable model, however, one would have to implement the above assumptions, which were highly unlikely. Simulations with less unrealistic assumptions[8] avoided collapse in the period up to 2100, whereas a simulation where policy implementation was delayed until 2000 showed collapse before 2100.

Thus, of the twelve model runs that were presented in the book, only two represented a system

that would not overshoot and collapse before 2100. Two conclusions stand out. Firstly, a free-market-oriented, liberal, individualistic world will not deliver the set of measures needed for the system to stabilize. Secondly, the later growth-reducing policies are implemented, the smaller the chances of avoiding overshoot and collapse.

The basic message from LTG can be summarized thus:

a.) The planet we live on is finite, and as the population and its ecological footprint increase in size, the relative size of the Earth system on which we depend becomes smaller.

b.) If developments in population, economic activity and use of nature's resources continue unchanged, overshoot of global carrying capacity is likely within the twenty-first century.

c.) Once in overshoot, physical contraction is inevitable. This may happen as a sudden contraction and collapse, or as a 'managed decline'.

16.2.3   Immediate Reactions—Academic and Political Debate During the 1970s

When looking at the debate that followed the publication of LTG, one should be excused for believing that the book had prophesied apocalypse and the end of humankind as we know it. However, as is often the case with highly polarized debates, the basic text seems to have been little read and even less understood. Far from being apocalyptic in its approach, the LTG study was presented as a warning signal and an invitation to think about the possible futures if the growth model we live by are to continue unchanged.

The title of the book, *Limits to Growth*, was provocative in an age where economic growth was hailed as the panacea for the world's ills. Economists, therefore, would be expected to take issue with the LTG conclusions, and they did. This academic debate was, at least initially, relatively civil in form. The LTG conclusions were out of sync with the consensual wisdom among mainstream economists and public policymakers in the 1970s, which led to questioning both of model and methodology.

One of many criticisms of the LTG came from a research team in Sussex University's *Science Policy Research Unit* (SPRU), who in 1973 published their own run of World3. Their results differed significantly from those of the LTG team. The Sussex team abolished the basic assumption of absolute resource limits, and replaced them with 'ongoing exponential increases in available resources' (Ekins 1993: 270). Thus, they

---

8 The less unrealistic assumptions were 'perfect birth control', meaning that only wanted children would be born; an average family size of two children; and industrial output stabilized at the level of average per capital output in 1975.

effectively embraced the idea that human ingenuity would develop good substitutes for non-renewable resources, and that we would learn to use existing resources much more effectively. "To postpone collapse indefinitely these rates of improvement must obviously be competitive with growth rates of population and consumption so that even if the overall growth is rapid, it is also balanced" (Cole/Freeman/Jahoda et al. 1973).

How could different scientists reach such widely different conclusions when they used the same model? Lecomber identified three points of contention that could explain the modellers' differences: their optimism regarding the rate of technical progress, how they saw future changes in the composition of output, and the possibilities of substitution. He took care, however, to emphasize that "this establishes the *logical* conceivability, not the certainty, probability or even the possibility in practice, of growth continuing indefinitely" (Lecomber, cited in Cole 1999: 89).

The economist William Nordhaus has been a vociferous participant in the debate about limits to growth since the early 1970s. In a 1973 article he criticized the World3 model, mainly on the grounds that it in his view was built on (mostly) plausible hypotheses about relationships between parameters, but that none of these relationships were empirically tested. His criticism was strongly worded:

> the dynamic theory put forward in the work represents no advance over earlier work. [...T]he economic theory put forth in *World Dynamics* is a major retrogression from current research in economic growth theory. [...W]ithout the scantest reference to economic theory or empirical data, Forrester predicts that the world's material standard of living will peak in 1990 and then decline. *Sic transit gloria* (Nordhaus 1973: 1182–1183).

Nordhaus gave voice to a widely held view among economists, namely that the researchers working with the World3 model had neglected economic research, and that they did so at their own peril. Apart from the factual error that the World3 did not *predict* the future (it merely simulated and produced scenarios based on a simplified model of the world system),[9] Nordhaus can be excused for wanting to defend economists' intellectual territory. With hindsight we may regret this lack of curiosity and mutual understanding between system dynamics and conventional economics—and conventional economists.

If reactions from the academic community were strong, they remained civil compared to some of the reactions in the public political debate. The LTG's conclusions were in many ways stark and depressing, despite the non-alarmist language used in the book. However, it is reported that none of the researchers involved in the study envisaged the uproar their publication would cause. The book's American publishers, Potomac Associates, "were arranging to present a copy of the book to every senator, representative, governor and UN ambassador" (AtKisson 2011: 10), in addition to organizing an event at the Smithsonian institute. The publication thereby received high-level political attention, reported in the American press with headlines such as "Mankind warned to curb growth or face catastrophe" (Chicago Sun Times), "Scientists warn of global catastrophe", and "Panel on growth strives to stave off world ruin" (AtKisson 2011). The subsequent debate was often hostile, polarized, and increasingly dominated by 'public legends', perceived as facts, but without root in the LTG study.

The most important of these legends is that the LTG study predicted a crisis. Far from predicting anything at all, the LTG presented twelve different scenarios based on the World3 model. The fact that an overwhelming majority of the scenarios they produced led to overshoot and collapse some time during the twenty-first century was clearly threatening to all those with a stake in the existing system. Moreover, the 'Cassandra effect', that we are reluctant to listen to bringers of bad news, may explain why many dug in to their trenches rather than participating in constructive debate about how to preserve the benefits of the existing model while attempting to change it to avoid its negative effects.

The authors of LTG were unprepared for the massive reaction the publication would create, and for the polarization that followed. If they had known the stir they would cause, maybe they would have taken greater care to emphasize that their scenarios were not predictions, but an invitation to start a debate about

---

9   The difference between a prediction and a scenario is not always obvious, and the two terms are often used interchangeably in daily speech. However, they differ both in intent and in level of precision. Whereas a 'prediction' is a statement about something that will happen in the future, and is therefore empirically testable, a scenario is one (of several possible) internally consistent stories about the future. Therefore, whilst a prediction can be said to be right or wrong once the future that was predicted has arrived, a scenario can be neither right nor wrong. Rather, the scenario is produced to inform and encourage thinking and debate about the choices we face. See also <http://www.ipcc-data.org/guidelines/pages/definitions.html>.

the paradigm within which we live our lives. This, at least, seems to be one lesson they have learned in the updated versions of the World3 simulations, which appeared in 1992 and 2004, and to which we now turn our attention.

16.2.4   Legacy: Long-Term Impact of *The Limits to Growth Study*

The LTG study was hotly debated in the 1970s, but attention receded throughout the 1980s. The general mood lifted after a decade of economic difficulties (remember the world oil crisis in 1973), and '[i]f the 1973 oil crisis had looked to many as the crisis predicted by the LTG, the end of the crisis, in the mid 1980s, seemed to be the refutation of the same predictions' (Bardi 2011: 87).

16.3   The Updates

Despite being in the business of mapping possible futures, none of the authors of the LTG had anticipated the ferocity and acerbity of the debate that followed its publication. They were scientists, not politicians or demagogues, and had not prepared for a public exchange of words on the scale of what actually happened. Two updates were published twenty and thirty years after the LTG study respectively. This part of the chapter will take a closer look at the results from these updates, and inscribe them in the political context they appeared in.

16.3.1   *Beyond the Limits*

Three of the authors of the LTG decided to publish an updated version of the World3 simulations with new numbers twenty years after the original publication. They called the new book *Beyond the Limits* (hereafter: BTL) (Meadows/Meadows/Randers 1992). In the preface they wrote:

> Much has happened in twenty years to bring about technologies, concepts, and institutions that can create a sustainable future. (...) When we began working on the present book, we simply intended to document those countervailing trends in order to update The Limits to Growth for its reissue on its twentieth anniversary. We soon discovered that we had to do more than that. As we compiled the numbers, reran the computer model, and reflected on what we had learned over two decades, we realized that the passage of time and the continuation of many growth trends had brought the human

society to a new position relative to its limits (Meadows/Meadows/Randers 1992: page).

The rerun of the World3 model with updated numbers led the authors to conclude that we had already passed the point of sustainable use of many resources and generation of many pollutants, that is, we were in 'overshoot'. Having learned from the debate following the LTG publication, they took great care to spell out that theirs was a message of hope and opportunity to do something that would improve the possibilities for choice in the future, although the latter was relatively rapidly vanishing.

The structure of BTL is very similar to the structure of the LTG. It starts with an explanation of the phenomenon of exponential growth, followed by a presentation of the limits to growth in the form of sources (renewable and non-renewable) and sinks (nature's capacity to absorb the wastes of human activity, in particular the atmosphere's reaction to greenhouse gases and some other air pollutants). The book subsequently explains the drivers of growth in the world system, including feedback loops, and finally presents a discussion of technological possibilities for solving the problems identified.

This logic underlines one important fact about their basic message, namely that the economy is a subsystem of the physical world, and therefore constrained by it. This might seem uncontroversial today, but it still proved a hard sell to many economists. The idea has been further developed by many within the field of ecological economics.[10]

Beyond the Limits was published in the year of the United Nations Conference on Environment and Development, better known as the Rio Earth Summit. This conference resulted in Agenda 21, which brought the 'sustainable development' concept on to the global political agenda.[11] Many environmentalists at the time were optimistic that world society finally would rise to the task and bring about sustainable living. But at the same time the awareness grew that the tools we had for managing these challenges were inad-

---

10 See Constanza and Daly (1987). For further information about ecological economics, see the website of the International Society of Ecological Economics: <http://www.isecoeco.org/>.

11 The concept's most common definition, 'sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs', first appeared in the report of the World Commission on Environment and Development, also known as the Brundtland Commission.

equate. To the extent that agreement was achieved on UN documents and policies, these remained vague and non-binding on the member states. This reflected the underlying old conflict about which role the state should have in the economy: on the one hand, states who were positive to global, binding regulations, and on the other, states who advocated as little state intervention as possible, in the interest of individual freedom of choice and free, unregulated markets.

BTL, like its predecessor, presented scenarios resulting from the World3 model. The 1991 run was for technical reasons carried out in a different computer language from the 1972 run, but the model itself remained unchanged. Some of the parameters were slightly altered to take into account historical data from 1972 to 1990. For example, World3 had underestimated both the (negative) impact of erosion on arable land and the (positive) effect of technological development in agriculture, and World3/91 was changed to make a better fit with observed data (Meadows/Meadows/Randers 1992: 245).[12]

However, *Beyond the Limits* is not only a product of a new run of an existing system dynamic model with adjusted numbers. It is also in many ways a communications exercise, inasmuch as it is an attempt to explain more clearly what had been misunderstood in the debate after the *Limits to Growth*. The authors emphasize that they are aware of the shortcomings of their model, and that they do not want to make predictions, but to present a set of possible futures. In the spirit of providing not only hope, but also guidance on preferred action (to answer the question 'but what can we *do*?'), they provide an 'action plan' for transition to a sustainable system. This plan consists of six elements that will improve our chances of building a sustainable society: improving the signals; speeding up response times; minimizing use of non-renewable resources; preventing erosion of renewable resources; using all resources with maximum efficiency; and slowing and eventually stopping exponential growth in population and physical capital.

William Nordhaus, one of the loudest academic critics of the 1972 book, was not convinced of the model's appropriateness despite the result from the new data. Rather, in his 1992 paper "Lethal Model 2: The Limits to Growth Revisited", he clearly ridicules what he terms the 'anti-growth movement'[13] on the grounds that the 'predicted' resource shortages never

materialized (despite this being clearly a wrong interpretation of the 1972 study). He is, however, open to the possibility that there might be physical limits to human activity. Having presented his own model for studying the future of economic growth, he concedes that "our ignorance is vast [...but...] I will hazard the guess that resource constraints are likely to be a small but noticeable impediment to economic growth over the next few decades in advanced industrial countries–although an obstacle that will continue to be surmounted by technological advance" (Nordhaus 1992: 39).

During the 1990s, not long after the publication of BTL, Mathias Wackernagel and William Rees developed a metric for measuring the ecological impact of human consumption, the now well-known 'ecological footprint'.[14] The concept of ecological footprint was clearly useful in the debate about limits to growth, as it provided a clear link between the physical environment on our planet and human consumption. It has since become a household staple in almost all debates about environmental policy in its broadest interpretation, and is incorporated in subsequent LTG studies.

16.3.2   The 30-Year Update

Limits to Growth: The 30-Year Update (Meadows/Meadows/Randers 2004) was 'the third edition in a series'. The World3 model was updated slightly. The most important changes were (1) that the cost of technology was estimated to decline more rapidly than in previous analyses, and (2) that the desired family size was set to respond more strongly to growth in industrial output, i.e. that as material welfare grew, women would choose to have fewer children, and this process was also assumed to be speedier than in previous analyses.

The preceding thirty years had seen many important developments in the public debate about sustainability and the difficulties with unlimited growth. The Brundtland Commission had brought the concept of sustainable development to the fore, and inspired much academic research around questions of nature's

---

12 Other similar changes were made. For a complete overview, see BTL appendix: Research and Teaching with World3.

13 The authors of LTG, as ecological economists, had never purported to be 'anti-growth'. They did, however, try to distinguish between material throughput and societal welfare.

14 The ecological footprint is a measure of how much land and water area is required for human activity. It is estimated that we currently (2015) use 1.5 Earths. For more information and updates, see at: <http://www.footprintnetwork.org/en/index.php/GFN/>.

constraints on human activity. This was obviously important in and of itself, but in our context it provided the authors with new concepts in their communication. In particular, the 'ecological footprint', both concept and measurements, was incorporated in their text. It also proved an invaluable tool in visualizing the meaning of 'overshoot', so central to their findings. Their new Human Welfare Index proved an effective tool for visualizing whether the future would be better or worse for those living there.

The 30-year update therefore included the variables 'human welfare' and 'ecological footprint'. The Human Welfare Index in World3 was inspired by the UN Human Development Index, and was calculated using *gross domestic product* (GDP), life expectancy and education. The Ecological Footprint Indicator in World3 was inspired by Wackernagel's 'ecological footprint' and was built using arable land used for crop production in agriculture, urban land used for urban-industrial-transportation infrastructure, and the amount of absorption land required to neutralize the emission of pollutants (Meadows/Meadows/Randers 2004: appendix 2).

The message from the third book in the series does not make cheerful reading. The language is still both clear and accessible, but the message is stark. The authors also concede that this third book is not so much about making new contributions to the debate as about providing the old debate with new numbers. Their review of the initial World3 scenarios shows that the actual development of the central parameters follow closely the standard run in World3 from 1972. The previous decade had shown that the lofty ambitions of the Earth Summit in 1992 were not being implemented.[15] Therefore, the 'action plan' from BTL was substituted by a list of 'the tools we don't yet know how to use'. These tools were: visioning; networking; truth-telling; learning; and loving.

16.3.3 Reactions to the Updates

Debate about the human condition within the physical boundaries of planet Earth had also taken on new forms since the 1970s. The strands had multiplied, and it is almost impossible to map them all. But two issues stand out: the question of limits to economic growth, and the debate about climate change.

The old question of whether there are limits to economic growth, so much ridiculed by both academics and politicians after the publication of LTG, saw a sea-change with the publication of an article by economist Matthew R. Simmons in 2000 entitled "Revisiting the Limits to Growth—could the Club of Rome have been right, after all?"[16] He compared some of the LTG scenarios within the energy sector with what had happened in the succeeding quarter of a century, and concluded that a shortage of non-renewable energy sources was a real worry. He then says: "Is there time to begin the thoughtful work which the Club of Rome hoped would take place post 1972? I would hope so. But, another 10 years of neglect to these profound issues will probably leave any satisfying solutions too late to make a difference. In hindsight, The Club of Rome turned out to be right. We simply wasted 30 important years by ignoring this work."

Graham Turner compared the last thirty years of historical developments with the LTG scenarios in 2008 (Turner 2008), and found that the LTG scenario with the closest match to historical data was the standard run of World3. His paper was another example of a re-appreciation of the LTG study in the twenty-first century, also exemplified by Hall and Day (2009) who note that "[i]f we are to resolve these issues, including the important one of climate change, in any meaningful way, we need to make them again central to education at all levels of our universities, and to debate and even stand up to those who negate their importance" (Hall/Day 2009: 237). The lower intensity of the debate in the 1980s and 1990s had allowed the hard fronts to soften, and a new generation of researchers appeared, with little or no stake in the debate from the 1970s.

This softening of the fronts in the conflict seem also to have spilt over on the mainstream macroeconomists, who are increasingly participating in the debate about environmental policy and the place of economic policy instruments in it. Moreover, social scientists of different hues have recently turned their attention to environmental problems, in particular climate change. The new voices in the debate contribute to broadening the discussions wider than simply for or against economic growth.

Since the turn of the century, and particularly after 2007, the climate policy debate has become more institutionalized and better anchored in the political

---

15 This is of course in itself a complex story, and it can be argued that some important developments took place in the global arena in the 1990s, particularly with the signing of the Kyoto Protocol in 1997.

16 See at: <http://www.resilience.org/stories/2000-09-30/revisiting-limits-growth-could-club-rome-have-been-correct-after-all-part-one>.

process both nationally and globally, and scientific knowledge about nature's processes is significantly greater than in 1972. Extreme weather events are increasingly seen as evidence of a changing climate, and the loss of biodiversity, pollution problems, and rising energy prices have all contributed to a general acceptance (among many if not all mainstream economists) that there are physical limits to what nature can sustain. This might seem rather a small achievement, but the hope is that the seed contained in this fundamental truth can flourish into a real change in how we use economic modelling, and subsequently in how modern societies arrive at decisions for collective action.

It may, of course, be a case of too little too late. As was argued both in BTL and in the 30-year update, time is running out. Humankind is already in overshoot and unless large structural changes take place, collapse seems the likely scenario. This was the background against which the book 2052–*A Global Forecast for the Next Forty Years* appeared.

16.4   2052—A Global Forecast for the Next Forty Years

There are two important differences between 2052–*A Global Forecast for the Next Forty Years* (Randers 2012) and the three other books that were discussed above. Firstly, it has only one author. Secondly, '2052' is not a scenario study, but a *forecast* of what Randers believes will actually happen by 2052. This means that the author himself has identified one scenario among several possible ones that fulfil three criteria:

- the described future must be internally consistent, i.e. the development in different variables must not cause them to contradict one another;
- the trend lines are developed based on existing data, which means that the basic assumption is *no major change* in any of the large global trends;
- the described future is what the author finds the most likely when the two first conditions are met.

The central global trends that form the basis of the forecast are GDP (based on population growth and productivity), investment, consumption, energy use, climate impacts, food production, and land use. The story is based on the same 'fairly simple' set of cause-and-effect relationships as in the World3 models, with the following important amendments:

- Urbanization leads to smaller families. This will not be because of lack of food or ill health, but

because more people will wish to have fewer children, and can better control the number of offspring because of access to education, health services and contraception.
- Labour productivity will continue to grow, but ever more slowly, because of resource depletion, pollution, climate change, and rising inequity.
- CO_2 emissions will at first increase with energy use (although at a slower rate than in many other forecasts, because of increased energy efficiency), but then gradually disconnect as the share of renewable energy accelerates. The emissions will lead to higher concentrations of greenhouse gases in the atmosphere, higher temperatures, and more climate damage to planet Earth (Randers 2012: 55ff).

A visual representation of the causal mechanisms are given in figure 16.2, where the changes from the World model are marked in red.

After defining the fundamental causal relationships, detailed forecasts are presented about both physical and non-physical variables. The first of the physical variables is population growth, which, according to Randers' forecast, will peak in 2040, at just above eight billion. This is lower than most official UN estimates,[17] and the most important driver in Randers' forecast is that women will choose to have fewer children as urbanization increases. GDP will continue to grow, but not as rapidly as hitherto, and with a significantly different distribution from what we have seen to date. The big, emerging economies will continue to grow much faster (particularly China), and the US and Europe will remain relatively stable at around 2010 levels. The rest of the world "will stay unpleasantly near their current GDP per person" (Randers 2012: 77).

When it comes to energy use, Randers forecasts that use of fossil energy sources will peak around 2030, and that renewable energy use will increase throughout the period. This will lead among other things to lower climate intensity, a process that will increase in pace after 2030 because of the higher visibility of climate change impacts on the economy. Because of the peak in fossil use, emissions from energy will also peak around 2030. This, however, is not enough to meet the two-degree target. According

---

17 But there are other institutions that forecast along the same lines, see e.g. <http://www.businessinsider.com/deutsche-population-will-peak-in-2055-2013-9>.

Figure 16.2: Causal diagram for the 2052 study-changes from the World Model marked in red. **Source**: Jørgen Randers presentation material; he also granted permission to use this figure.
to this forecast, global warming will exceed two degrees compared to pre-industrial times around the middle of the twenty-first century.

Food production will increase and peak around 2040. Food per person will follow a similar curve, but the decline in population will mean that the 'food per person' curve will decrease slower than the 'food production' curve. "Grossly simplified, my forecast to 2052 says that there will be enough energy, grain, and chicken, plus some fish—with some exception for the poor" (Randers 2012: 143).

Important elements in the 'non-material future' include stronger government, and urbanization that leads to megacities and the omnipresence of the Internet. The 'zeitgeist' will, according to Randers, focus on fragmentation, local solutions, slum urbanization, and the Internet providing fertile ground for human creativity.

The general forecast is followed by forecasts for five regions (US, OECD minus US, China, BRISE[18] (the fourteen largest 'emerging' economies), and

ROW (the *rest of the world*). The maybe most striking feature of these regional forecasts is their diversity. This underlines the large differences that will be experienced in the different regions of the world—not only because 30-cm sea level rise will have very different impacts on society depending on whether one lives on a low Pacific island or on the top of a rugged cliff, but also because the forecast describes some states that will become stronger (but have to invest more to cope with the effects of climate change), and other states that will remain unstable, unable to provide poor inhabitants with basic security and resources.

The language and style in the 2052 book is even more personal and direct than in the LTG series. The big picture depicted in 2052 is a world that is less bad than the author had feared before starting the forecasting work. It is far from his 'ideal' world, and it is a world where people are poorer than he (together

---

18 Please explain BRISE here.

Figure 16.3: World State of Affairs, 1970–2050. **Source:** Randers (2012: 232). Permission to use this figure was granted by the author.
with many economists) originally expected, but it is also a world where no major collapse will occur before the end-date of the forecast.

Randers closes his book with a list of twenty 'pieces of personal advice'. It is impossible to quote them all here, so here is a selection:

- Focus on satisfaction rather than income
- Invest in great electronic entertainment and learn to prefer it
- Live in a place that is not overly exposed to climate change
- Stop believing that all growth is good
- Remember that your fossil-based assets—suddenly one day—will lose their value
- In politics, remember that the future will be dominated by physical limits.

'2052' is the work of someone who is clearly disappointed with the world and the lost opportunities for change over the last four decades. The real disappointment is that it has proved impossible to beat short-termism, both in economics and in politics. Solving the climate challenge will mean choosing the slightly more expensive solution in the short term, and making (and keeping) electoral promises about something further than one electoral cycle away does not ensure re-election.

16.4.1   Further Resources

In spring 2014 the book was translated into seven languages. The material and analysis is rendered accessible through a website dedicated to the project (<www.2052.info>), where readers can find some of the experts' glimpses into the future and make their own forecasts based on the model.

'2052' has formed the basis for a long series of lectures and presentations,[19] and has contributed to debate in an impressive number of countries around the world. Among the many themes covered in the debates are population growth and birth control policies, environmental degradation, the future of the energy sector, and short-termism and challenges for democracy.[20]

16.5   Concluding Remarks

In the introduction two questions were raised: firstly, why did the debate about the *Limits to Growth* become so polarized, and secondly what have we

learned about the fundamental questions posed by the LTG team?

The answer to the first question can be found in the interests that felt threatened by the publication. Large industrial interests (in particular producers of fossil energy and other scarce resources) would clearly have a hard time believing that the fundamental credo and the resources from which they had created their wealth and large fortunes were to run out any time soon. Economists and politicians, who believed economic growth to be the panacea for increasing human welfare, found their world view questioned. And the population at large generally wanted and needed work and an income, and saw economic growth as the safest option for meeting these needs.

Criticism is often met with hostility. What now seems a relatively uncontroversial message about planetary boundaries was radical when it first appeared. The authors of the LTG were not prepared for the animosity their message would entail, and despite their attempt at framing their message as one of 'hope' because they presented 'possible futures', the necessary changes to bring the world to a sustainable development path were threatening for many of the established elites, economic, political and industrial.

We should also remember that the LTG was not the only environmental message that was met with hostility. The 1960s and the 1970s were decades of controversy and large societal conflict in many parts of the world, but particularly in the US.

Subsequent updates of the LTG study were also clearly presented in different lights, with more emphasis on 'hope' and 'love' (in 1992), and 'doom and gloom' (in 2004). It seems reasonable to assume that the authors chose different strategies because of their previous experiences, and because they fundamentally wanted to engage the world in a debate about where we are heading.

What has humankind learned over the last four decades?

Graham Turner has shown that the standard run of World3 seemed to be a rather good description of reality as observed thirty years after the scenario's publication.[21] Growth has continued, both in global population, production, and ecological footprint. Humankind is in a situation of overshoot with a current consumption of approximately 1.5 Earths. Every year twice as much CO2 is emitted as is being absorbed in oceans and forests, which will lead to temperature rise. Biodiversity loss and ocean acidification is happening.

The global governance system under the UN has not been able to produce a globally binding *greenhouse gas* (GHG) emission reduction treaty during the past forty years. Whether a comprehensive global agreement will occur in 2015 is still an open question, but it is highly unlikely that it will be sufficient for the world to meet its 2°C target.

This review of the four books has shown that they have all concentrated on the development of the relatively uncontroversial 'physical' variables of human development and its effect on the world around us. Discussions about wider security and social development issues have been largely non-existent. This must be characterized as one of the major shortcomings of these books. The analysis and discussion about the effects of physical changes (lower food production, climate change, biodiversity loss), i.e. how they will be felt by humans and how they will impact on social structures, stability and security, are pivotal to our possibility of grasping the real challenges. In these books it is often assumed that resource shortages may lead to social unrest, but no closer analysis or causal mechanisms are discussed.

The 2052 book only partially puts right this issue. Discussions are included about the importance of focusing on quality of life ('happiness') rather than economic growth, but the analysis is rather superficial. This is also the case for political processes, which, to the extent that they are mentioned, are criticized for not delivering policies that bring about sustainable living. Democracy is particularly vulnerable, whereas the Chinese political system gets a bit more credit for delivering on the necessities of preventing the worst causes of pollution. There is no further discussion about whether or how the political process, democratic or otherwise, can contribute to solving the *social* problems resulting from climate change.

The story of *Limits to Growth* and its aftermath is at least two different stories. One is about how global governance has been unable to take sufficient action to prevent many of the challenges that were highlighted even as early as the early 1970s. This is a story that easily leaves us feeling helpless in face of humanity's destiny. But there is another story that is sometimes forgotten. That is the story about how one slim volume managed to incite debate, raise deep ethical questions, spur a search for deeper knowledge about the world in which we live, and remain relevant for several generations.

---

21 The real test on the LTG scenarios will come over the next couple of decades, when the scenarios start to deviate.

17   Preparing for Global Transition: Implications of the Work of the International Resource Panel

Mark Swilling

Abstract

The International Resource Panel (IRP) was established as an expert scientific panel by UNEP in 2007. By using a material flow analysis perspective, the primary focus of the IRP is on global resource use and potential alternatives. The notion of a 'third great transformation' was deployed to suggest that the work of the IRP is documenting the endgame of the industrial socio-metabolic regime. Three clusters of reports were addressed: (a) global resource perspectives, with special reference to decoupling rates of economic growth from rates of resource use by focusing on the importance of resource productivity; (b) nexus themes, including cities, food, trade, and GHG mitigation technologies; and (c) specific resource challenges with respect to two clusters of issues, namely metals and ecosystem services .The conclusion reached is that a resource-use perspective adds to our understanding of the unsustainability of the current global system, complementing the outputs of climate science on the effects of anthropogenic carbon emissions and ecosystem science on the implications of biodiversity degradation. To this extent, the work of the IRP anticipates the possibility of a more resource efficient socio-metabolic order. However, the IRP has to date not addressed specifically the dynamics and modalities of transition from an institutional and macro-economic perspective.

Keywords: Decoupling, transformation, sustainable development, sustainability science, material flow analysis, long-wave theory.

17.1   Introduction

This chapter will analytically review the work of the *International Resource Panel* (IRP) from the perspective of global transition theory.[1] It will be argued that the IRP can be understood as a collaborative effort by a diverse group of researchers to document the metabolic case for why the industrial epoch has effectively reached the end of its 250-year historical cycle. Although this documentary evidence suggests that the necessary conditions are in place for a transition to a more sustainable long-term development cycle, this by no means implies that the IRP has developed a view on whether sufficient conditions exist for such a transition to happen. Now that the Sustainable Development Goals have been approved, this may provide the context for such a task. The IRP has yet to pay attention to the key factors that will determine the nature of such a transition, namely social actors, their networks and the highly complex dynamics of the institutions that embody the intentions of organized historic and current socio-economic interests.

The *International Resource Panel* (IRP) was established by the *United Nations Environment Programme* (UNEP) in 2007 (see <http://www.unep.org/resourcepanel/>). It is currently co-chaired by Dr. Ernst Ulrich von Weiszäcker and Dr. Ashok Khosla and has twenty-four members from twenty-six countries. It is not constituted like the *Intergovernmental Panel on Climate Change* (IPCC) as an *intergovernmental* expert panel. Instead, it is a panel of experts funded by governments and UNEP that also has a Steering Committee made up of government representatives who consider the scientific reports of the Panel members, but without the requirement that reports must first be approved by the Steering Committee before they are published. The Steering Com-

---

1   The arguments presented in this chapter have been developed exclusively by the author and do not in any way reflect the views of the IRP, UNEP or individual members of the IRP.

mittee, however, does have the power to approve the initiation of reports. The Panel members come from a wide range of scientific disciplines and intellectual traditions, with some closely allied to their respective governments while others are thoroughly independent and even oppositional within their domestic policy environments.

The objectives of the International Resource Panel are to:

- provide independent, coherent and authoritative scientific assessments of policy relevance on the sustainable use of natural resources and their environmental impacts over the full life cycle;
- contribute to a better understanding of how to decouple economic growth rates from the rate of resource use and environmental degradation.

17.2   Contextualizing the Work of IRP

There is growing acceptance across a wide range of audiences that 'modern society' is currently facing historically unprecedented challenges. The advent of the 'Anthropocene' comes with an all-pervasive sense that landscape pressures like climate change, resource depletion and ecosystem breakdown threaten the conditions of existence of human life as we know it (Crutzen 2002). The onset of the global economic crisis in 2007/8 has resulted in a realization that we may have come to the end of the post-World War II long-term development cycle (Gore 2010; Swilling 2013b), and there is little understanding of what will come next. Simultaneously, there are those who argue that we may have reached a metabolic turning point that marks the endgame of the industrial era (Fischer-Kowalski 2011; German Advisory Council on Global Change 2011: 81; Haberl/Fisher-Kowalski/Krausmann et al. 2011). The result of these converging industrial and metabolic crises is an interregnum Edgar Morin has usefully called a 'polycrisis' (Morin 1999: 73).

Reflecting the thought patterns and influence of Schumpeterian long-wave theory (Foxon 2011; Freeman & Louca 2001; Köhler 2012; Perez 2002; Swilling 2013b), the *German Advisory Council on Global Change* (GACGC or WBGU) has argued that we should anticipate the third 'great transformation' comparable in its historical significance to the first two 'great transformations': the Neolithic revolution some 13,000 years ago and the industrial revolution some 250 years ago (German Advisory Council on Global Change 2011). Both can be defined as great transformations because they both resulted in funda-

mental shifts in the metabolic foundations of society: for the Neolithic transformation this entailed a shift to permanently occupied land, cultivated soils, harvested biomass, animal power, clay, rocks and the basic implements of pre-industrial agriculture; and then 250 years ago a shift to fossil fuels, metals, construction minerals and massive increases in biomass use and water use with the onset of the industrial revolution (Fischer-Kowalski/ Haberl 2007). For the GACGC, the third great transformation must be about radical decarbonization and resource efficiency to "provide wealth, stability and democracy within the planetary boundaries" (German Advisory Council on Global Change 2011: 81). However, all those who use long-wave theory recognize that these transitions are by no means linear and therefore cannot be easily predicted: they are highly complex processes that manifest differently across geographical scales and historical time. Key events can coalesce unexpectedly with accumulated macro-level structural shifts and the dynamics of conjunctural realignments to open up hitherto unlikely future trajectories.

It has been argued elsewhere that the year 2009 might be such a tipping point (Swilling 2013b): the collapse of Lehman Brothers at the end of 2008 was the key event, the conjunctural realignment was the ending of the post-World War II long-term development cycle (represented by the fact that 2009 was the first year since 1945 that the global economy shrank) and the structural shifts were reflected in the gradual realization that we could be breaching planetary boundaries in dangerous ways for human survival (marked by events such as the G20 adoption of the 'green economy' concept in 2009, following on from the awarding of the Nobel Prize to the IPCC, shock events like hurricane Katrina, heatwaves and economic shifts such as the rapid acceleration of investments in renewable energy technologies that were no longer confined to innovation niches).

Following Geels (2002), it is preferable to use the notion of 'transition' to describe these major metabolic shifts rather than the notion of 'transformation', on the understanding that it is specific transformations along the way that drive an overall transition. We can thus refer to a sustainability-oriented just transition as an alternative to the notion of a 'third great transformation' (Swilling/Annecke 2012), although these notions will be used interchangeably in this chapter.

Three conditions make this transition unique, only one of which is given sufficient emphasis by the GACGC Report. The first, recognized by the GACGC,

is the fact that it is probably going to depend on the collective intent of specific constellations of actors who will need to collaborate at global, national and local levels. It is for this reason that the GACGC Report argues as follows:

"The imminent transition must gain momentum on the basis of the scientific findings and knowledge regarding the risks of continuation along the resource intensive development path based on fossil fuels, and shaped by policy-making to avoid the historical norm of a change in direction in response to crises and shocks" (German Advisory Council on Global Change 2011: 84).

This statement clearly defines the historic role of anticipatory science as key driver of the next great transformation (Poli 2014). This is why the work of the IRP, the IPCC, Future Earth and many other global scientific initiatives is significant. If they can contribute to the translation of anticipatory science into an anticipatory culture, then accumulated evidence about the risks we face and the potentials that can be exploited might just tilt the balance in favour of human survival (Poli 2014).

However, what needs greater emphasis is the implications of the *information and communication technology* (ICT) revolution that has transformed our organizational capabilities for learning and knowing–what Perez calls the fifth developmental surge that has taken place since the start of the industrial era (Perez 2009). Following Castells, just as the technologies of the combustion engine, electricity, telephony and mass production made possible the industrial revolution and its associated organizational arrangements (nation state, joint stock company, etc), so has the ICT revolution resulted in a new mode of organization, namely the network (Castells 2009). This new package of technologies and organizational modes has resulted in 'self-managed mass communications' with major implications for knowledge dissemination, innovation and collective action. For Brynjolfsson and McAffee, this provides the basis for the 'second machine age'–a new era of highly networked mutually interdependent activities that will unleash extraordinary creativity and productive potential (Brynjolfsson/McAffee 2014).

The internal informational recomposition of the industrial age that has taken place since the early 1970s has major implications for the anticipated sustainability-oriented transition. Following earlier work to address this question (Swilling 2013b), there is sufficient evidence that innovations made possible through network organization powered by ICTs will

be stimulated by the financial returns that can be made by repairing the future of the planet (see discussion of Decoupling 2 below). If the 'second machine age' makes possible low carbon and resource-intensive modes of consumption and production, then a key driver of the third great transformation begins to come into view.

The third condition that makes this transition unique is the fact that we are living in an *urbanized* Anthropocene. The majority of the world's population now lives in cities and the next 2–2.5 billion people who are expected to be living on the planet by 2050 when the population is expected to hit the 9–9.5 billion mark will land up in African and Asian cities. Demographic projections suggest that we will be constructing in cities over the four decades to 2050 more material infrastructures than what we have built over the past 400 years (Angel 2012). This harsh spatial reality has major implications for how networks coalesce to rapidly translate anticipatory science into fundamental changes in the geographies of everyday consuming and producing. What remains almost certain is that these networks will not only emerge from the networks of innovation-oriented cities that are flowering around the world, they will also be using the challenges faced by cities as the laboratories for testing the technologies that will be deployed during the next great transformation.

The co-evolutionary dynamics of anticipatory science, the network mode of organization and learning made possible by the ICT revolution, and the reconfiguration of spaces of agglomeration caused by accelerated urbanization create conditions that make it possible to consider the end of the industrial epoch and how the long-term sustainability-oriented transition—or third great transformation—could emerge (Swilling/Annecke 2012). This provides the context for understanding the enormous significance of the rapidly expanding body of work that has been generated by the IRP since 2007. At the simplest level, the IRP is providing documented evidence across a range of fields that it is no longer possible to conceive of a future for modern society that rests on the assumption that there are unlimited resources available for ensuring the well-being of over nine billion people on a finite planet by 2050. In other words, the IRP is documenting the end of the industrial socio-metabolic era and by implication anticipates a more sustainable era in the future. However, the IRP has also put in place within the global policy community a way of thinking that is different to the two other mainstream bodies of sustainability science, namely climate sci-

ence and ecosystem science. By thinking of sociotechnical and socio-economic systems as socio-metabolic systems that consume, transform and dispose of resources extracted from natural systems, the IRP has put in place a key conceptual framework for imagining the dimensions and modalities of a more sustainable epoch. The notion that we need to decouple economic development and well-being from the rising rate of resource consumption is potentially a very radical idea, especially if this implies massive reductions in resource use per capita for people living in rich countries and a redefinition of development for those policy-makers in poorer countries committed to poverty eradication. How we build a more equitable world of over nine billion people by 2050 without destroying the planet will not only depend on the mainstreaming of an appropriate political economy to replace neo-liberalism (Picketty 2014); it will also mean that a political economy that is appropriate for imagining the next great transformation will have to recognize that it will be necessary to fundamentally reconfigure the flow of non-renewable and renewable resources through our sociotechnical and socio-economic systems. When read together from the transition perspective outlined here, the research assessments generated by the IRP since 2007 provide a significant starting point and partial foundation for achieving such a synthesis.

17.3   Overview of the Work of the IRP

Unlike the IPCC, the IRP does not produce an integrated report at specific points in time. Instead, the IRP publishes reports as and when they have been produced by one or more members of the IRP and their respective research teams. This means there is no integrated synthesis of the IRP's body of knowledge. For the purposes of this chapter, the work of the panel has been divided into the following categories:[2]

- *global resource perspectives*, with special reference to decoupling rates of economic growth from rates of resource use by focusing on the importance of resource productivity (Decoupling 1 and Decoupling 2), the environmental impacts of products and materials, and the beginnings of scenario thinking;

- *nexus themes*, including cities, food, trade, and *greenhouse gas* (GHG) mitigation technologies;
- *specific resource challenges* with respect to two clusters of issues, namely metals (both stocks in use and recycling) and ecosystem services (including water and land-use/soils).[3]

The global resource perspectives define the IRP's commitment to focus on the resource inputs into the global economy, and therefore how future economic trajectories (whether growth-oriented or not) can be decoupled from the prevailing rising level of resource use over time. Without this kind of decoupling, a transition will be unlikely. Nexus themes are about specific spheres of action constituted by highly complex sociotechnical systems where the potential for decoupling exists. Specific resource challenges are about resource regimes that are both under threat from, for example, rising demand and prices, and can also be potential threats to larger systems that are dependent on them.

17.4   Global Resource Perspectives

The environmental science of pollution, climate science and ecosystem science have traditionally been the three underlying bodies of science that have supported the claims of the environmental movement. In recent years material flow analysis has emerged as the fourth body of science, with roots in industrial ecology, resource economics and political economy (Fischer-Kowalski 1998, 1999). Major historical reinterpretations of agricultural and industrial economic transitions have now been written that are clearly extremely useful for anticipating the dynamics of future transitions (Fischer-Kowalski/Haberl 2007; Giampietro/Mayumi/Sorman 2012; Smil 2014). The focus has shifted from the negative environmental impacts of the outputs of industrial processes to the material inputs into a global economy that depends on a finite set of material resources. This is the discursive framework within which the work of the IRP should be located.

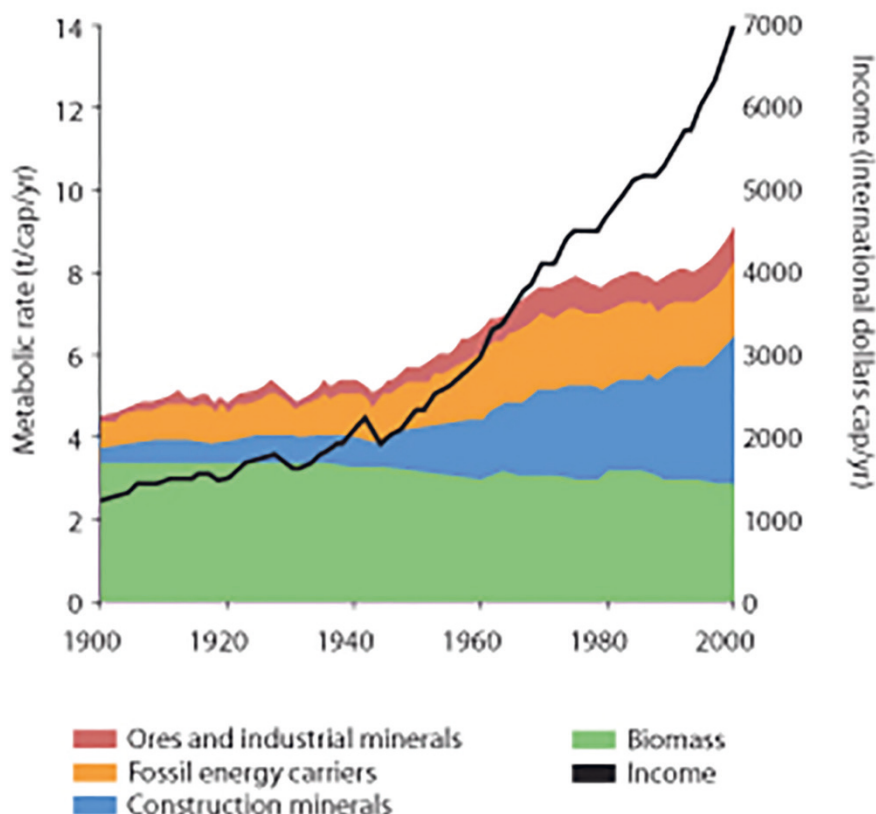
One of the first reports produced by the IRP (generally referred to as 'Decoupling 1') entitled *Decoupling Natural Resource Use and Environmental Impacts from Economic Growth* presented evidence on the use of four categories of resources: biomass (everything from agricultural products, to clothing

---

2   All completed reports referred to below are available on the IRP website at: <http://www.unep.org/ resource-panel/>.

---

3   The IRP has also produced reports on biofuels and forests, but these have not been included in this analysis.

Figure 17.1: Global metabolic rates and incomes (1900–2005), and income. **Source:** Fischer-Kowalski and Swilling (2011: 12).


material like cotton, to forest products), fossil fuels (oil, coal and gas), construction minerals (cement, building sand, etc.) and ores and industrial minerals (Fischer-Kowalski/Swilling 2011). The Decoupling 1 Report shows that by the start of the twenty-first century the global economy consumed between 47 and 59 billion metric tons of resources (which is equal to half what is physically extracted from the crust of the earth). Between 1900 and 2005 total material extraction increased over this period by a factor of 8, while GDP increased by a factor of 23 for the same period. As reflected in figure 17.1, the result is relative decoupling between rates of resource use and global growth rates.

As the Decoupling 1 Report shows, rising global resource use during the course of the twentieth century (including the metabolic shift that took place from mid-century onwards as non-renewables grew and dependence on renewable biomass declined in relative terms) corresponded with declining real resource prices—a trend that came to an end in 2000–2002. Since 2000–2002, the macro-trend in real resource prices has been upwards (notwithstanding dips along the way).

The McKinsey Global Institute report (which was published after the IRP report) generally confirms the trends identified by the Decoupling 1 Report, demonstrating that resource prices have increased by 147 per cent in the decade since 2000. As a result investments in resource productivity over the long-term can generate returns of 10 per cent, more if the US$1.1 trillion "resource subsidies" are removed (McKinsey Global Institute 2011).

A key conclusion of the Decoupling 1 Report is that a transition to a more sustainable global economy will depend on absolute resource reduction in the developed world, and relative decoupling of economic growth rates from rates of resource use in the developing world. If this is not achieved, the Report argues, the result may well be an increase in total resource use from 60 *billion tonnes* (Bt) in 2005 to 140 Bt by 2050 if all nine billion people living on the planet by then consume the equivalent of the average European (i.e. 16 *tonnes per annum per capita* (t/ cap), which is half what the average American con-

Figure 17.2: Composite resource price index (at constant prices, 1900–2000). **Source**: United States Geological Survey data cited in Fischer-Kowalski and Swilling (2011: 13).
Figure 17.3: Commodity price indices. **Source**: Fischer-Kowalski and Swilling (2011: 13).
sumes). However, if the convergence point is 8 t/cap, the total material requirement would be 70 Bt by 2050 on a planet of nine billion people. The Decoupling 1 Report suggests that the material equivalent of living in ways that will result in the emission of 2 tonnes of CO_2 per annum per capita by 2050 on a planet of nine billion people (as recommended by the IPCC) may well be 60 Bt or 6 t/cap for everyone. Although the latter is the logical consequence of the science of

the IPCC that all countries approved, it implies a 'great transformation' equal in significance to the metabolic transformations that resulted in the Neolithic and Industrial Revolutions.

Reinforcing the argument of the Decoupling 1 Report, another early IRP report entitled *Assessing the Environmental Impacts of Consumption and Production: Priority Products and Materials* (referred to as the Priority Materials Report) addressed key ques-

Figure 17.4: Major contributors to global GHG emissions, including land use and land cover change (measures in CO2 eqivalents using a 100 year global warming potential).**Source**: UNEP (2010).
Figure 17.5: Distribution of energy use across consumption categories, as identified in different studies, and total energy use measures in kW per capita. **Source**: UNEP (2010).
tions of relevance to this review, only three of which are addressed here: Which industries are the most responsible for contributing to environmental and resource pressures? What products and services have the greatest environmental impacts? Which materials

have the greatest environmental impacts across their respective life cycles? (UNEP 2010)

As indicated in figure 17.4 and related information in the Priority Materials Report, the energy industry, followed by industry and forestry (through deforesta-

Figure 17.6: Carbon Footprint of different consumption categories (tonnes of CO_2 Equivalents per capita in 2001) in 87 countries/regions as a function of expenditure ($ per capita). **Source**: UNEP (2010).
tion), are the greatest contributors to climate change, abiotic resource depletion, and sometimes eutrophication, acidification and toxicity.

As far as consumption is concerned, the Report shows that transport, housing and food are responsible for 60 per cent of all impacts (see figure 17.5). Given that these are overwhelmingly configured by urban systems, this prioritization reinforces the argument of the City-Level Decoupling Report (discussed later) that interventions that address these priorities will have to take into account their spatial contextuality.

However, even more important is the unsurprising fact that as incomes go up so do the enviromental

impacts. Figure 17.6 clearly shows that there is no decoupling when it comes to rising incomes and related environmental impacts.

As far as the environmental impacts of materials are concerned, the Priority Materials Report shows that animal products, fossil fuels and key metals (iron, steel and aluminium) have the greatest impacts. However, only integrated data for Europe exists.

The first bar in figure 17.7 shows resource use in kilograms per capita, while the second and third show the environmental impacts weighted according to their environmental impacts over the life cycle (the so-called *environmentally-weighted material consumption*, EMC). The second gives the EMC for the *global*

Figure 17.7: Normalized global warming potential of material flows and *Environmentally weighted Material Consumption* (EMC) for EU-27+1 region. **Source**: UNEP (2010).
warming potential (GWP), while the third adds up a large number of environmental impact categories such as global warming, acidification, land use competition plus others with equal weightings.

The *Priority Materials Report* concludes that future economic growth and development on a business-as-usual basis will exacerbate these trends. The impact of fossil fuels and agricultural activities are seen as the top two priorities that must be addressed if a transition to a more sustainable order is to be achieved.

In a follow-up to the Decoupling 1 Report, the IRP report entitled *Decoupling 2: Technologies Opportunities and Policy Options* (launched at Green Week, Brussels, in June 2014) argued that there are three types of decoupling (UNEP 2014):

- decoupling through maturation: found mainly in developed countries, this is a natural process caused by saturated demand, levelling off or even decline of populations, minimal new construction and a shift towards services;
- decoupling through burden shifting to other countries: by off-shoring the resource extraction and related impacts to other countries and then excluding this reality from material use calculations, it is possible for many countries to create the appearance of decoupling—in reality, as recent research has shown, if the ecological rucksacks are

attributed to the consumer and not producer, this apparent decoupling disappears (Wiedman/ Schandl/Lenzen et al. 2013);

- decoupling by intentionally improving resource productivity: as a "paradigm shift", this type of decoupling "requires technological and institutional innovations, resource-efficient infrastructure, low-material-intensity manufacturing, public awareness and appropriate attitudes and behaviours" (UNEP 2014:5).

The Decoupling 2 Report demonstrated that since 2000 metal prices have risen by 176%, rubber by 350%, energy by 260% and food by 22.4% (with some projecting an increase for food of 120–180% by 2030). Demand for water by 2030 is expected to have risen by 40%, exceeding existing capacity by 60%. Possibly even more important than price increases is price volatility and related supply shocks (UNEP 2014). The Decoupling 2 Report documents a wide range of emerging alternatives that are made possible by these price increases and argues the case for replicating radical resource productivity improvement on a global scale. Many examples are provided, including the potential to reduce energy and water demand in developed economies by 50–80% using existing energy and water efficiency technologies; how developing countries investing in new energy infrastructure could reduce energy demand by half over the next twelve

years if energy efficiency and renewable energy technologies were adopted now rather than later; and that decoupling technologies could result in resource savings equal to US$2.9 to 3.7 trillion each year until 2030 if the policy, regulatory and technological innovations are put in place (UNEP 2014).

The most significant contribution of the Decoupling 2 Report is the suggestion that radical resource productivity can be achieved by introducing a resource tax system that is used to gradually and incrementally increase real resource prices over the long term. This tax could be used to ameliorate rising prices when these occur, and to counteract declining resource prices when these occur, thus providing the market with a level of certainty over the long term. This is crucial for counteracting what is inevitably going to happen if nothing of this kind is done, namely increasing price volatility that will tend to reinforce short-term investment perspectives with limited investment in innovation. Long-term innovation-driven investments will not thrive if prices remain volatile.

Informed by the thinking reflected in the above Reports and what has emerged in the nexus and specific resource challenge reports, during the course of 2013 and 2014 IRP member Professor Tom Graedel led a group that has started to consider the formulation of future scenarios. The group has decided to adopt the GEO 4 scenarios that will be used to frame future resource use storylines. These scenarios are as follows:

- markets first—a "business-as-usual" scenario;
- policy first—a "make world greener" scenario;
- security first—an isolationist scenario of rising social, environmental, and economic tension;
- sustainability first—a new environment and development paradigm with more equitable outcomes and institutions that is, in effect, consistent with GACGC's 'third great transformation'.

If the IRP succeeds in integrating the various strands of its work into some credible scenarios using the GEO4 (or similarly well-accepted) storylines, this will contribute a new perspective to the already cluttered scenario-building scene. More importantly, it will help to bring the IRP's research firmly into the realm of the emerging science of anticipation (Poli 2014).

17.5 Nexus Themes

Each nexus theme can be defined as a complex of interrelated resource use and environmental impact issues that can be analysed by reference to a particular cross-cutting process. Cities concentrate in space in particular context-specific ways all the resource use and environmental impact issues addressed by the general global reports discussed in the previous section. Food systems are globally, regionally and locally constituted in ways that connect incredibly complex flows of nutrients, energy, water, wastes and materials. Trade is about the global flows of resources and their associated ecological rucksacks that can be attributed to the producing or consuming countries with drastically differing results. And GHG mitigation technologies are massive composites that require energy and resource inputs that are intended to produce lower carbon and more resource-efficient outputs. Although the IRP's work on these nexus themes is discussed below, only the report on cities had been published at the time of writing. This may mean the other nexus themes are dealt with more superficially.

17.5.1 City-Level Decoupling

The main aim of the Cities Working Group of the IRP is to apply the insights generated by the new literature on urban metabolism (Barles 2009; Barles 2010; Costa/Marchettini/Facchini, 2004; Farrao/Fernandez 2013; Heynen/Kaika/Swyngedouw 2006; Kennedy/Pincetl/ Bunje 2011; Ramaswami/Weible/Main et al. 2012; for the most comprehensive overview of the literature see Robinson/Musango/Swilling et al. 2013; Swilling/Robinson/ Marvin et al. 2013; Swyngedouw 2006; Weisz/Steinberger 2010) to the challenge of designing, building and operating more sustainable urban infrastructures.

The first urbanization wave took place between 1750 and 1950, and resulted in the urbanization of about 400 million people in what is now the developed world. The second urbanization wave between 1950 and 2030 is expected to result in the urbanization of close to four billion people in the developing world in less than a century. By 2007 just over fifty per cent of the global population lived in cities. Hence we should be talking about the 'urban Anthropocene'.

Based on UN population data for 1950–2050 (Department of Economic and Social Affairs, United Nations 2012), the total global urban population is expected to increase from 3.5 billion in 2010 (of which 73 per cent were in cities in developing countries) to 7.3 billion in 2050 (by which time 83 per cent will be living in cities in developing countries). This means that by 2010 the global process of urbanization that began in earnest in 1800 (see figure 17.8) had only

Figure 17.8: World Population and Urban Growth Trends (0-2010). **Source**: Angel (2012).
resulted in the urbanization of 48 per cent of households that are expected to live in cities by 2050.

Furthermore, according to the groundbreaking UN Habitat report *Challenge of Slums* (United Nations Centre for Human Settlements 2003), of the 3.5 billion who were living in cities by 2010, one billion lived in slums. In other words, 210 years of urbanization had created a decent quality of life for only two-thirds of all urban dwellers. Resolving this problem must, therefore, be seen as integral to a just urban transition by 2050.

It follows, therefore, that 52 per cent of the urban fabric that is expected to exist by 2050 must still happen over the four decades to 2050. The significant proportion of the additional urban population of nearly four billion people will end up in developing country cities, in particular Asian and African cities. If we include the one billion people who live in slums, then it follows that material infrastructures of one kind or another will need to be assembled for an additional five billion new urban dwellers by 2050.

This raises an obvious and vitally important question: what will the resource requirements of future urbanization be if business-as-usual sociotechnical systems are deployed to assemble built environments? What are the resource implications of more sustainable sociotechnical systems? Unfortunately, no one has attempted to answer these questions yet, which is why the IRP decided at its meeting Santiago in May 2014

to approve a study by its Cities Working Group that aims to address these questions.

This new study will build on the first IRP Report on cities entitled *City-Level Decoupling: Urban Resource Flows and the Governance of Infrastructure Transitions* (referred to as the City Decoupling Report) (Swilling/Robinson/Marvin et al. 2013). Noting the proliferation of reports on sustainability in cities, the core argument of this Report was that insufficient attention was paid in these reports and in the academic literature to the strategic importance of urban infrastructures. It was noted that urban infrastructures conduct resource flows (e.g. energy, waste, water and sanitation) through urban systems. It follows, therefore, that in order to transition from linear unsustainable urban metabolisms to more circular sustainable urban metabolisms it will be necessary to reconfigure urban infrastructures.

Thirty case studies of urban infrastructure transitions across all world regions were documented in order to demonstrate that there is plenty of evidence that various initiatives are under way. Furthermore, it was noted that intermediaries play a crucial role as facilitators of change. *Global technology companies* (GTCs) have emerged as new major players within the urban policy space. Companies like IBM, Siemens, Cisco, Altech and others have all mounted 'smart city' programmes, with Songdo city in South Korea the poster child for what this means in practice

(Kuecker 2013). The last time public discourse was inundated with visions of grand city-wide transformations was in the late 1800s with respect to sanitation infrastructure and in the post-World War I period during the lead-up to the highway construction programme that transformed cities around the world (Hajer/Dassen 2014). The result today is the promotion of massive global escalations in investments in urban infrastructures in cities in both developed and developing countries, sometimes but not always within a 'smart city' framework (Airoldi/Biscarini/Saracina 2010; Doshi/Schulam/Gabaldon 2007; Siemens/ PWC/Berwin Leighton Paisne 2014; World Business Council for Sustainable Development 2014). The algorithmic urbanism promoted by the GTCs holds many dangers, including the consolidation of new wealth-based digital divides and greenwashing (Hajer 2014; Luque/ Marvin/ McFarlane 2013).

Unfortunately, very little data were available about the metabolic flows before and after a given intervention. The City Decoupling Report therefore concluded that in order to assess whether urban infrastructure innovations do, indeed, result in more sustainable outcomes it would be necessary in future to use the tools of urban metabolic flow analysis in combination with systems dynamics modelling. These tools will make it possible to evaluate and, therefore, model the effect of a given set of sociotechnical innovations at two levels: at the level of design with respect to a given sectorial intervention (e.g. a public transit system or sewage treatment plant) and at the level of city-wide planning with respect to the overall resource productivity of the entire urban system.

Given that over fifty per cent of the global population now lives in cities and given the extent of future urban growth, retrofitting and building new urban infrastructures that reproduce sustainable urban metabolisms may well be the single most important driver of the third great transformation.

17.5.2   GHG Mitigation Technologies

Given that the energy transition is going to be the most important driver of the third great transformation, it follows that more needs to be known about the environmental implications of the suite of renewable energy technologies that are regarded as the cornerstone of this transition. In a draft highly-detailed 500-page report entitled *Green Energy Choices: The Benefits, Risks and Trade-offs of Low-Carbon Technologies for Electricity Production* (referred to as the Green Energy Report) the following technologies were assessed using Life Cycle Assessment: wind power, hydropower, *photovoltaics* (PV), *concentrated solar power* (CSP), geothermal power, *natural gas combined cycle power* (GCCP) with and without CO_2 *capture and storage* (CCS), and coal-fired power with and without CCS (Hertwich/Gibon/Arveson et al. 2015).[4] Bioenergy, nuclear energy, oil-fired power plants and ocean energy were not assessed.

The Green Energy Report found that wind, PV, CSP, hydro and geothermal power generate GHG emissions over the life cycle of less than 50gCO2e/ kWh. This compares favourably to coal-fired power plants that generate 800–1,000gCO2e/kWh over the life cycle and GCCP (without CCS) that generates 500–600gCO2e/kWh over the life cycle. CCS can reduce emissions of fossil power plants by only 200– 300gCO2e/kWh. As far as pollution and related health impacts are concerned, renewables reduce impacts by seventy to ninety per cent. Similarly, impacts of renewables on ecosystems are a factor of three to ten lower than fossil power plants (Hertwich/Gibon/Arveson et al. 2015).

By contrast, the Report shows, a global transition to renewables (with some GCCP for peak loading and some coal power plants) would require an increased use of steel, cement and copper in comparison to the continuation of the business-as-usual fossil-fuel-based system. Furthermore, renewables depend on various rare earth metals like indium and tellurium, as well as silver (Hertwich/Gibon/Arveson et al. 2015). There is no consensus in the literature on the security of supply of these materials. However, their concentration in China is well known.

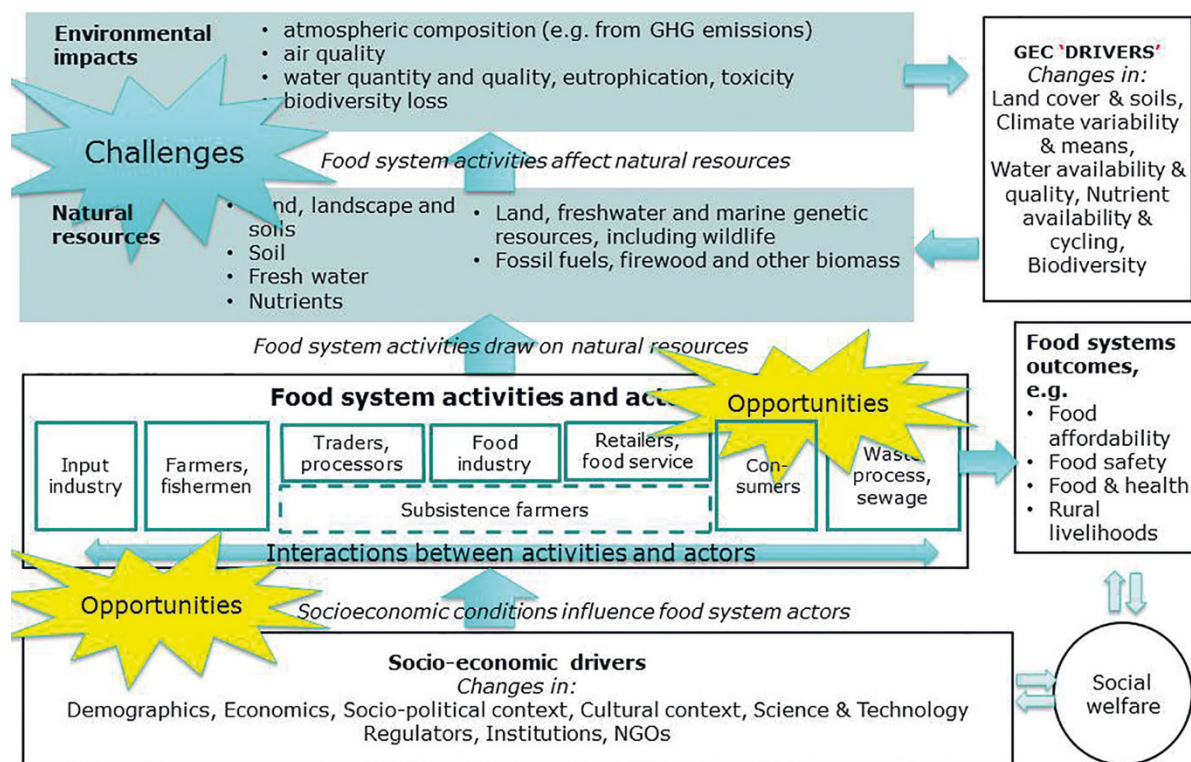
In short, from a purely technical perspective (which of course ignores institutional change, financing and learning) the environmental impacts of renewables are substantially reduced compared to fossil-fuel-based energy supply. However, the resource inputs with respect to steel, cement and copper may be greater if alternative technologies for these aspects of the clean energy infrastructure are not found. Increased requirements of bulk materials such as steel, cement and copper can easily be met with current production rates.

17.5.3   Food Systems

As argued by the *Priority Materials* Report, the food system is a major user of resources and a major con-

---

4   Note that at the time of writing this report had not gone through the UNEP peer-review process.

Figure 17.9: Conceptual Framework: Food Systems and Natural Resources. **Source**: Hajer, Westhoek, Ozay et al. (2015: 12.


tributor to negative environmental impacts. Food systems are highly complex global-local systems that are currently in deep crisis as several long-term megatrends accumulate into a perfect storm. Breaking from the dominant tendency to see food insecurity as a problem of production, the Food Working Group of the IRP adopts a food system perspective that, in turn, makes it possible to see food insecurity as a direct and persistent symptom of a flawed global food system (Hajer/Westhoek/Ozay et al. 2015). Food security is defined as a situation where all people, at all times, have physical, social and economic access to sufficient, safe and nutritious food which meets their dietary needs and food preferences for an active and healthy life (Food and Agriculture Organization 1996). Considered in terms of the distribution of dietary energy supply, 868 million people around the world were considered chronically undernourished in 2013 (FAO 2013: ix). In addition, a further two billion people experienced the negative health consequences of micronutrient deficiencies (FAO et al. 2012: 4). About 850 million of the people estimated to be undernourished live in developing countries (FAO A/B et al. 2012: 8). Food insecurity is one of the key indicators of a system incapable of responding to the pressures

that it faces. The capacity of the food system to ensure food availability and thus food security is shaped by a wide variety of factors, but the increase in population, urbanization and improved welfare are the most important (Food and Agriculture Organization 2013: ix) drivers of food system change. The conceptual framework captured in figure 17.9 represents this complex set of actors and networks.

The IRP's report on the food system essentially mounts the following argument (Hajer/Westhoek/Ozay et al. 2015). The global food system is now dominated by large-scale modern systems that have replaced localized family-farm-based food economies with large-scale globalized processing and retail activities, long value chains, regulatory standards and transnational companies. One result of neo-liberalization since the 1980s has been the shift in food governance from largely localized upstream governance systems to the big global downstream players, in particular the food processors and retailers. The result is that the food system is now primarily configured for short-term profit rather than the long-term continuity of farming systems and the ecosystems they used to depend on. Global and national governance systems tend to reinforce this orientation because it is per-

ceived to be more 'efficient'. As a result concentration in the off-farm sectors of the food value chain are high and rising: the three largest seed companies control 50 per cent of the market; the top ten agro-processors have 28 per cent of market share; and the top ten food retailers control 10 per cent of the market. It is this shift in power that is contested by the agro-ecological movements who want a return to local food bio-economies where sufficiency ensures the long-term sustainability of the underlying ecosystems.

The Food System Report goes on to argue that population growth, urbanization and improved welfare imply a ten per cent increase in food demand by 2025, with the fastest growth in demand taking place where logistical infrastructures are weakest. Given that urbanization and economic growth in developing countries implies an expanding middle class, a nutrition transition is under way from calorie-rich diets (cereals) to energy-rich diets (meat, vegetable oils and sugars). Energy-rich food requires far greater natural resource inputs, including the fact that instead of being consumed directly by humans grains are used as inputs for livestock production. This, in turn, increases the demand for land for cereal production and grazing. Furthermore, now that supermarkets have become the dominant food delivery systems in all regions where middle-class consumers are significant, energy-rich food is transported over longer distances, requires more packaging and depends on vast globally structured networks of interconnected specialized companies and value chains. The combined impact of these processes includes soil degradation as land is overexploited, depletion of acquifers and fish stocks, eutrophication due to nutrient losses (rising by twenty per cent over the next forty years) and diminished biodiversity. Climate change is expected to reduce crop production in key regions of the world (Hajer/Westhoek/Ozay et al. 2015).

The Food System Report concludes that there are significant opportunities to increase resource use efficiency in the food system, while simultaneously reducing environmental impacts. On the supply side, important options include increasing yields in certain low-yield regions with higher potential using a more balanced mixed of natural resources (including agro-ecological systems and higher input of minerals), leading to an increase in the output per unit of land, water and human labour; increased nutrient use efficiency in the food chain, and consequent reduction of nutrient losses to the environment; development of resource efficient aquaculture systems; and sustainable land and water management using agro-ecological approaches. On the demand side, the two key strategies would be reduction of food losses and wastes, and a shift to less resource-intensive diets, especially in regions with 'western' diets, by lowering the consumption of meat, dairy and eggs (Hajer/Westhoek/Ozay et al. 2015).

17.5.4 Trade

The core question of the *International Trade in Resources* report (referred to as the Trade Report) (Fischer-Kowalski/Dittrich/ Eisenmenger et al. 2015) is whether or not the global trading system contributes to greater resource efficiency and diminished environmental impacts.

The Trade Report clearly shows that although trade in volume increased by a factor of 2.5 between 1980 and 2010, trade measured in monetary terms increased dramatically to twenty-eight per cent of global GDP in 2010. Fifteen per cent of all extracted materials are traded internationally. The Report argues that while incentivizing increased extraction, one key result was increased financial revenues for poor resource-rich countries that rapidly became major exporters. In theory this should have positive developmental consequences that would need to be weighed against the environmental costs; however, as Collier has argued, in reality the more dependent on resource rents economies become the less likely they are to have the governance mechanisms to translate resource rents into developmental benefits—a dynamic known as the resource curse (Collier 2010).

The Trade Report goes on to argue that a closer look at physical trade (see figure 17.10) reveals that the total volume of materials traded between 1980 and 2010 more than doubled, with fossil fuels making up around fifty per cent of the total volume traded. However, reflecting the levelling-off of oil production and trade globally since 2005 (Murray/King 2012), growth rates in trade in oil have declined since 2005.

Figure 17.11, sourced from the Trade Report, reflects who the largest exporters and importers were in 2010. Representing a shift from twentieth-century trends, by 2010 only thirty per cent of all countries were net material suppliers while seventy per cent of all countries had become net importers—and now this was not neatly split along North-South lines. South American countries, Scandinavia, and west and central Asian countries, together with Canada, Australia and the south-east Asian islands, have become the largest suppliers of materials. The largest importers were the US, Japan and Western Europe.

Figure 17.10: Physical trade according to material composition (1980-2010). **Source**: Fischer-Kowalski, Dittrich, Eisenmenger et al. (2015).
Figure 17.11: Largest net exporters and importers by material composition of net trade in 2010. **Source**: Fischer-Kowalski, Dittrich,Eisenmenger et al. (2015).
The strategic significance of the mode of analysis in the Trade Report is that it adds another perspective to the assumptions made in the Decoupling 1 Report. Using calculations of 'domestic material extraction' (domestic extraction minus exports plus imports), Decoupling 1 effectively employed a producer perspective that allocated the ecological rucksack (i.e. materials used to produce exports) of imported goods to the exporting country. If, however, the ecological rucksack is attributed to the importing country, apparent decoupling by burden shifting is no longer possible (Wiedman/Schandl/Lenzen et al. 2013). Indeed, Wiedman, Schandl, Lenzen et al. (2013) calculated that forty per cent of the resources extracted were used to enable the exports of goods and services to other countries (Wiedman/Schandl/

Lenzen et al. 2013). The map below reflects the material footprint of nations (in t/cap) where ecological rucksacks are attributed to the consumer and not the producer. This new perspective has become the basis for the *International Trade in Resources* report.

The Trade Report argues that the twentieth-century international division of labour was characterized by declining resource prices that in general made it possible for Northern industrialized countries to act as importers of primary resources and exporters of manufactured goods, with Southern countries as the exporters of primary resources and importers of manufactured goods. The Trade Report confirms that this picture is rapidly changing in the twenty-first century. In a context of rising resource prices, some fast industrializers in the global South have become both

importers of primary resources and exporters of man-ufactured goods, and some industrialized countries like Canada and Australia have become increasingly important exporters of primary resources. In general, there are an increasing number of countries depend-ent on resource imports and a declining number of countries that are providing an ever-greater propor-tion of resource exports (Fischer-Kowalski/Dittrich/Eisenmenger et al. 2015). Trade makes physical bur-den-shifting possible, but this is unmasked if ecologi-cal rucksacks are attributed to the consumer and not the producer.

The Trade Report ends by saying that a conclusive answer to the core question about the role of trade in resource use and environmental impacts is not possi-ble at this stage, especially if a balanced view of envi-ronmental and developmental factors is taken into account. This, however, is not the question that guides the primary concerns of this chapter—this chapter is interested in the dynamics of transforma-tion. From this perspective, the declining number of countries providing more and more primary resources within the context of a long-term super-cycle of rising resource prices is clearly the most important limiting factor. The rise of 'resource nationalism' in Africa (together with rising labour costs in China which makes manufacturing through beneficiation increas-ingly viable in Africa (Swilling 2013a)) suggests that the rising state of resource prices is unlikely to be reversed in the near future, and the adoption by the EU of a Resource Efficiency strategy suggests that rich resource-importing countries will start to find ways of reducing their dependence on resource imports (European Commission 2011). Both signal new direc-tions of change with potentially transformative impli-cations.

17.6   Specific Resource Challenges

The series of IRP reports that deal with specific resource challenges have addressed metals (four reports), water (two reports), land-use and soils, and forests.[5] They all recognize that these resources will in one way or another be required by society irrespective of whether there is a sustainability-oriented transition or not. It therefore follows that it is necessary to understand the complex dynamics that will shape the availability of these resources over time and what actions will be required to ensure that these resources are managed and used in more sustainable ways as part of a wider 'great transformation' process.

17.6.1   Metals

The Metals Working Group has published four peer-reviewed reports and one working paper:[6]

- Report 1: Metal Stocks in Society (2010);
- Report 2a: Recycling Rates of Metals (2011);
- Report 2b: Metal Recycling: Opportunities, Lim-its, Infrastructure;
- Report 3: Environmental Risks and Challenges of Anthropogenic Metals Flows and Cycles (2013);
- Working Paper: Estimating Long-Term Geological Stocks of Metals.
- Future reports include:
- Report 4: Future Demand Scenarios for Metals;
- Report 5: Critical Metals and Policy Options.

All economies, no matter their level of development, depend on metals of various kinds. The rise of the information age and related increased demand for hi-tech electronic goods has resulted in rapid increases in demand for speciality (or rare earth) metals like lithium and indium. Simultaneously, the accelerated growth and rapid urbanization in the BRICS (Brazil, Russia, India, China, South Africa) -plus countries (e.g. Turkey, Mexico, Nigeria and Indonesia)—espe-cially China—has resulted in massive increases in demand for base metals. Figure 17.12 depicts the growth in demand in recent decades. In combination, these two driving forces of demand have deepened the criticality of a wide range of metals. For example, as the Metals e-Book makes clear, the future demand for zinc, copper, nickel and aluminium just for the expansion of the global energy system are in each case several magnitudes greater than current demand (e.g. demand for aluminium is expected to grow from 500 *gigagrams per year* (Gg/y) to over 5,500 Gg/y by 2050 just for non-fossil fuel infrastructure).

The increasing complexity of electronic goods is a major driver of demand for a wide range of metals to

---

5   The Reports on biofuels and forests have not been included, partly because the implications of biofuels is incorporated into the land and soil group, and the for-ests report was compiled in a way that does not quite fit into the overall orientation of the IRP.

6   A summary is contained in an e-book available on the IRP website at <http://www.unep.org/resourcepanel>. Unless alternative sources are specified, the data referred to in this section is taken from this e-book (International Resource Panel Working Group on Global Metal Flows 2013).

Figure 17.12: Growth in production of minerals, 1845–2010. **Source**: Mudd (2009), cited in International Resource
Panel Working Group on Global Metal Flows (2013).
produce the compounds required by these goods. Figure 17.13 reveals the growth in the number of elements needed to make a microchip.

Although a lack of information prevents high-confidence estimations about resource depletion (Smil 2014), what is clear from the work of the Metals Working Group is that there are also other factors that increase supply risks. These include, according to reports of this Working Group, challenging technological conditions (depth, composition of ore as ore grades decline), economic variables (adequacy of infrastructure, size of deposit), environmental constrains (natural habitats, ecosystem services), and geopolitical dynamics (trade barriers, political instability, weak states) (International Resource Panel Working Group on Global Metal Flows 2013).

Global metals production is a major contributor to environmental pollution and energy demand. The Working Group's reports shows that no less than seven to eight per cent of global energy use and therefore energy-related GHG emissions can be attributed to metals production. Whereas 20 MJ of energy is needed to make a kilogram of steel, 200,000 MJ is needed to make a kilogram of platinum (International Resource Panel Working Group on Global Metal Flows 2013). A major driver of increased future energy demand of metals production is the decline in ore quality—three times more material must be moved today to extract a kilogram of ore compared to a century ago.

Report 1 estimated the quantity of metals being used by society for the period 2000–2006. The average for aluminium was 80 kg per capita, with a range of 350–500 kg/cap for developed economies and 35 kg/cap for the least developed economies. Similarly for copper: 35-55 kg/cap is the global average, ranging from 140-300 kg/cap to 30-40kg/cap; and 2200kg/cap for iron, ranging from 7,000-14,000kg/cap to 2,000kg/cap. Obviously, the same pattern replicates itself for each metal (International Resource Panel Working Group on Global Metal Flows 2013), the implication being that global development targets aimed at eradicating poverty and achieving greater equity will entail significant increases in metals consumption in developing countries.

To diminish the environmental impact and energy requirements of metal production it will be necessary to increase the recycling rates of metals. Report 2a demonstrated that the *end of life-recycling rates* (EoL-RR) for metals are very low: EoLRR of above fifty per cent can be found for only eighteen metals.

Figure 17.13: Computer Chip Elemental Contents. **Source**: Quoted in a Powerpoint presentation by Tom Graedel, November 2013, Stellenbosch University.
The Report shows that part of the explanation for low EoLRRs is rising demand and the long in-use life of metals. However, another more important explanation is that the design of products has not hitherto taken into account the need for end-of-life recovery and reuse. Disassembly and metals recovery is not what designers have been required to do. To increase EoLRRs to fifty per cent or more for all metals as part of a wider sustainability-oriented transition, it will be necessary, the Report argues, to radically change the way products are designed (i.e. design for disassembly) and substantial investments in new collection infra-structures will be necessary (International Resource Panel Working Group on Global Metal Flows 2013). As resource prices continue to rise as demand continues to grow, driven mainly by the requirements of the information age and urbanization, the financial viabil-ity of design for disassembly will more than likely improve. This will be a crucial driver of a more funda-mental transformation.

17.6.2   Land-Use and Soils

A century of steadily declining food prices came to an end at the turn of the millennium. Since then food prices have been rising steadily and so has the number of large-scale land transactions (including so-called 'land grabbing'). Except for the first decade of the twenty-first century, there has been no decade since 1900 where there is evidence of steadily rising food prices. This pattern is expected to continue with major implications for land use and food security (Swilling/Annecke 2012: Chapter 6).

Following Scherr, the total ice-free land surface of the Earth is 13 *billion hectares* (Bha) of which 1.5 Bha is unused 'wasteland' and an additional 2.8 Bha is unused and inaccessible. This leaves 8.7 Bha which humans in the Anthropocene can choose to 'use' for a wide variety purposes, including pasture, forests and cropland. Of this, 3.2 Bha are potentially arable, the rest being marginal land from a cultivation perspective and covered by forest, grassland and permanent vege-tation.[7] Of the potentially arable land, only 1.3 Bha is deemed to be moderate to highly productive. Just under half of the 3.2 Bha of potentially arable land (1.47 Bha) is cultivated as cropland. This means that just over ten per cent of the ice-free land surface of the Earth is the resource on which humans depend

---

7   Lambin and Meyfroidt estimate that there are approxi-mately 4 Bha available for 'rain-fed agriculture' (Lambin/Meyfroidt 2011: 3466).

Figure 17.14: Agricultural inputs relative to crop yields (1961–2009). **Source**: FAO data compiled by Schutz, cited in Bringezu, Schutz, Pengue et al. (2014).
for the bulk of their food. This 1.47 Bha of cropland, plus approximately 3.2 Bha of permanent pasture and 4 Bha of permanent forest and woodland, is what makes up the 8.7 Bha of 'usable' land (Scherr 1999). Half of the developing world's arable and perennial cropland is in just five countries—Brazil, China, India (with twenty-two per cent), Indonesia and Nigeria. It is noticeable that the only African countries with very extensive or moderately extensive arable land resources are Nigeria, Ethiopia, South Africa and Sudan. The majority of African countries have limited arable land resources with high population pressures and it is estimated that sixty-five per cent of Africa's agricultural land is degraded (Scherr 1999). Yet African countries are earmarked by all the models of the future for substantial yield increases—it is also where most of the land grabs are taking place (Cotula/Vermeulen/Leonard et al. 2009).

Global land use, rising food prices, soil degradation and accelerated land transactions (as countries scramble to secure food supplies) provides the context for the IRP Report entitled *Assessing Global Land Use: Balancing Consumption with Sustainable Supply* (generally referred to as the *Land and Soils Report*) (Bringezu/Schutz/Pengue et al. 2014). Launched at the World Economic Forum in January 2014, the report raises very serious questions about the sustainability of expanding agricultural production in a world dominated by a resource inefficient food system that does not cater for the needs of the nearly billion or so people who are undernourished.

Figure 17.14 reveals that since 1961, inputs (nitrogen, phosphorus, potassium, tractors) have tended to rise at a faster rate than crop yields, and this within the context of a doubling of irrigated land area.

At the same time, soil degradation continues, with twenty-three per cent of soils degraded by 1990. Two to five million hectares are degraded per annum.

The international division of agricultural labour is clearly reflected in figure 17.15, which reveals the gap between yields in Europe and North America, where high external input intensive industrial farming is prevalent, and the yields in developing countries where soil degradation levels are high, infrastructures are poor and farming is still dominated by 400 million small farmers (only forty per cent of whom use chemical inputs).

Expanding agricultural land use is driven in part by rising demand for food and non-food biomass which cannot be compensated by higher yields. This net expansion occurs at the expense of grasslands, savannahs and forests. However, expansion is also driven by the need to compensate for expanding cities and soil degradation. This plus net expansion results in gross expansion. Based on an assessment of a wide range of studies (for sources of data cited see original diagram in *Land and Soils Report*), the dimensions of the net and gross expansion of agricultural land are represented in figure 17.16.

The Land and Soils Report shows the future land requirements to meet food supply (after exhausting yield growth potential) are estimated to be between 71 *million hectares* (Mha) and 300 Mha. The rapidly

Figure 17.15: Cereal yields by selected world regions (1961-2011). **Source**: FAO data cited in Bringezu, Schutz, Pengue et al. (2014).

Cereal yield (tonnes/ha)
expanding demand for land to grow biofuel crops is estimated to be 48 MHa to 80 Mha, and the requirements for additional biomaterials (wood, textile crops, etc) is estimated to be be 4 MHa to 115 Mha. To compensate for the expanding built environment (that tends to destroy the most valuable agricultural land), between 107 Mha and 129 Mha may be needed. Assuming that a significant proportion of degraded soils cannot be restored,[8] estimates of the requirements to compensate for degradation range from 90 Mha to 225 Mha. This means that the estimates for

gross additional agricultural land requirements to meet growing needs range between 320 Mha and 849 Mha. This suggests that the needs are much greater than FAO's estimate of 120 Mha (Bringezu/Schutz/Pengue et al. 2014).

It needs to be recognized that land-use change in favour of agriculture is one of the primary drivers of rising CO_2 emissions and biodiversity loss. We need, therefore, to accept that there are absolute limits to the quantity of global land that can be used for agriculture. Taking into account various factors, the *Land and Soils Report* proposes that the expansion of global cropland should be halted by 2020, at which point it is estimated global cropland will have expanded from about 1.5 Bha to 1.64 Bha. In other words, although an additional 140 Mha of cropland is

---

8   Although seriously degraded soils are difficult and costly to restore, there are still about 300 Mha of lightly degraded soils that can be restored mainly by changing management practices.

Figure 17.16: High and low estimates of net and gross expansion of agricultural land, 2005-2050. **Source**: Bringezu, Schutz, Pengue et al. 2014—note: for detailed references to the sources of data cited here, see original diagram in this report.

Business-as-usual expansion	Low estimate (Mha)	High estimate (Mha)
Food supply	71	300
Biofuel supply	48	80
Biomaterial supply	4	115
Net expansion	123	495
Compensation for built environment	107	129
Compensation for soil degradation	90	225
Gross expansion	320	849

bound to have very negative environmental effects, the *Land and Soils Report* nevertheless estimates that it may be possible to remain within this 'safe operating space' and thus avoid the far more negative consequences of an expansion in the range 320 Mha to 849 Mha, as suggested by the sum of existing research. To achieve this reduction in future requirements, the *Land and Soils Report* recommends the following (Bringezu/Schutz/Pengue et al. 2014):

- massively increase the existing land potential by restoring degraded soils and using existing soils optimally—how to do this is the focus of the next report on land and soils that is currently under way;
- ensure that national governments have the capacity to control expansion of agricultural land in order to avoid uncontrolled destruction of biodiversity, forests and pastures;
- limit meat/dairy consumption and change the way the food system works—again, as mentioned earlier in this chapter, this is the focus of the forthcoming IRP report.

The Report recommends the following specific sets of interventions (Bringezu/Schutz/Pengue et al. 2014):

- reducing the demand for meat/dairy products and reducing the levels of food waste could save between 96 and 135 Mha;
- halving the global biofuel targets could save between 24 and 40 Mha;
- controlling the demand for biomaterials could save up to 57 Mha;

- limiting the expansion of cities into productive agricultural by just ten per cent of the expected impact could save between 11 and 13 Mha;
- restoring a third of degraded soils could save between 30 and 74 Mha.

In short, a mix of strategies and measures to reduce overconsumption of certain foods, reduce food waste and limit the consumption of non-food biomass products while at the same time improving land management could save between 160 and 320 Mha by 2050. Cropland area would still expand to meet, in particular, the demand for increased food production to meet the needs of those who have enough, but not as much.

17.6.3   Water

According to the Water Decoupling Report (Urama 2015), integrated water resources management faces two closely interlinked obstacles—one, on the supply side, of unpolluted freshwater resources for a growing world population, and the other, on the demand side, of water for increased agricultural output, water-intensive industries and domestic use. The problems associated with the supply and demand of water, such as significant increases in water pollution and freshwater withdrawals, are driven by population increase, urbanization, rising living standards, unsustainable water governance (which includes inefficient supply and demand management), agricultural land uses (specifically irrigation), industrial production, ecosystem degradation and climate change.

The as yet unpublished but completed *Water Decoupling Report* addresses the challenge of water availability and use in light of mounting global challenges to security of supply (Urama 2015). Water withdrawals on a global scale have increased at a rate almost double the human population growth rate, from 600 billion cubic meters in 1,900 to 4,500 billion cubic meters in 2010. This could grow to between 6,350 and 6,900 billion cubic meters by 2030 if an average economic growth scenario and efficiency gains are assumed. This represents a forty per cent demand gap above currently accessible water resources, including return flows.

Table 17.1 illustrates the expected increases in water withdrawal demand for human activities by 2030. The highest incremental demand is expected to occur in sub-Saharan Africa at 283 per cent, while the lowest is expected in North America at 43 per cent.

In terms of global freshwater use to support human activities, currently 70% is used in agriculture

Table 17.1: Increases in Annual Water Demand, 2005–2030. **Source:** McKinsey (2009), cited in Urama (2015).

Region	Projected Change from 2005
China	61%
India	58%
Rest of Asia	54%
Sub-Saharan Africa	283%
North America	43%
Europe	50%
South America	95%
Oceania	109%

(output of which is estimated to increase by another 65% by 2030) of which 15–35% is considered unsustainable, especially in cases where groundwater is extracted faster than it can be recharged. An additional 22% of fresh water is used in industries (estimated to grow by an additional 25% by 2030), but this can range from as high as 60% in industrialized countries to as low as 10% in some developing countries. Lastly, 8–11% is for domestic use (estimated to grow by another 10% by 2030), at an average of about 50 litres per person per day, although also with great variability (International Water Management Institute 2007 and Gleick 2010, both cited in Urama 2015).

On the supply side, it is estimated that over the next twenty years, water supply would need to be 140% higher than in the past twenty years to meet the increasing demand and ensure accessible, reliable and sustainable provision of existing water supplies (Urama 2015). The obstacles are as follows. Readily available sources of fresh water are under significant stress already, with the shrinking of many freshwater lakes, the drying up of rivers that subsequently never reach the ocean, and the overuse of groundwater resources, something that is already occurring in many regions. Further limiting these water resources, the Water Report argues, are increasing rates of pollution with over 405 dead zones currently on record globally in coastal waters. Lastly, further water is lost due to inefficiencies in technologies, the most pertinent example being the loss of drinking water from municipal distribution systems before it even reaches the consumer, where on average thirty per cent (and in extreme cases up to eighty per cent) of water is lost. This is equivalent to over US$18 billion worth of water per year that does not generate revenue, indicat-

ing the need for efficiency and productivity gains (Urama 2015).

Figure 17.17 shows the number of people living in water-stressed areas between 2005 and 2030, as calculated by UNEP (UNEP 2011, cited in Urama 2015). The OECD estimates that nearly 3.9 billion people will experience severe water stress by 2030.

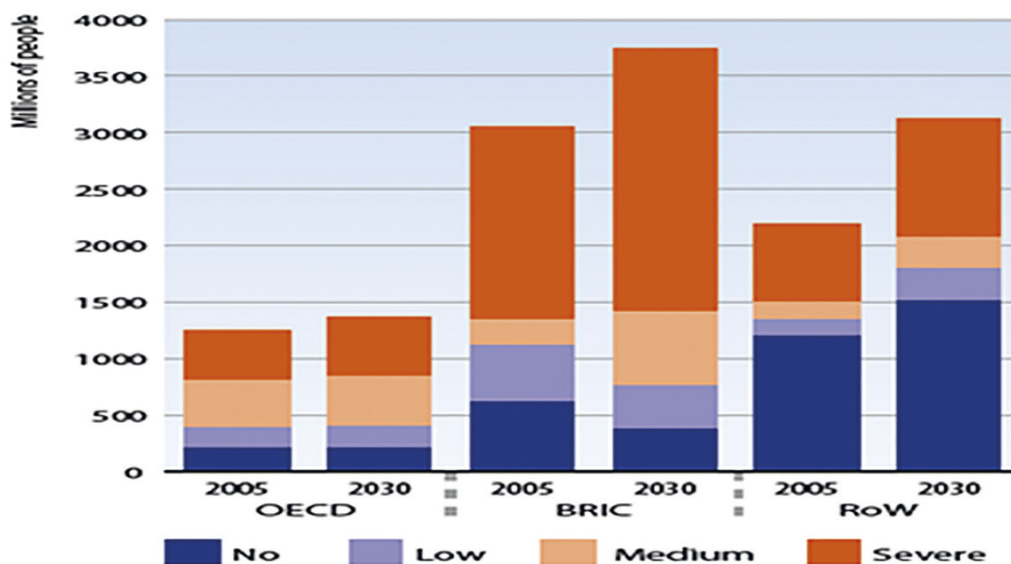
One of the greatest issues relevant to the supply of fresh water is the level of pollution through human activities. The most relevant sources include mining activities, agriculture, landfill, and industrial and urban wastewater effluents. The main pollutants from agriculture, for example, include pesticides, organic compounds and nutrients from fertilizer that end up in water bodies, causing eutrophication and ultimately leading to "dead zones" (Urama 2015). Furthermore, pollution from industrial activities is in the form of seventy per cent of untreated industrial wastes being dumped into waters (UN-Water 2009 cited in Urama 2015).

In many developing countries sanitation and wastewater treatment causes major water pollution, and scenarios have been found where as much as eighty-five to ninety-five per cent of sewage is discharged directly into rivers, lakes and coastal areas, causing large amounts of revenue to be spent dealing with waterborne diseases instead of generating new wealth (Tropp 2010 cited in Urama 2015). .

Lastly, the number of people vulnerable to water-related disasters, particularly flooding as a result of climate change, deforestation, population growth, rising sea levels, and human settlement in flood-prone lands, may reach two billion by 2050 (Urama 2015).

All these obstacles make a strong case for water decoupling, that is, using fewer units of water resources per unit of economic output, while also reducing other adverse socio-economic and environmental trade-offs downstream, such as rates of water pollution, known as impact decoupling.

Relative decoupling is shown to be beneficial to human well-being, environmental flows in river basins, and to economic growth (Urama 2015). Achieving sustainable decoupling in the water sector will require innovative structural transformations in economic pathways; integrated water management policy and practices at local, national, river-basin, and global scales; and substantive investments in improved technologies and innovations for improving water efficiency and productivity at the appropriate temporal and spatial scales. Improving technical and allocative efficiency and resource productivity in the key water use sectors could offset up to sixty per cent of the

Figure 17.17: Number of people living in water-stressed areas in 2030, by country type. **Source**: UNEP (2011), cited in Urama (2015).


anticipated growth in demand for water by 2030 (Urama 2015).

17.7   Discussion: Implications of the Work of the IRP for Global Transition Thinking

It was argued at the outset that the work of the IRP can be understood within the wider context of the so-called 'third great transformation' or more precisely a 'sustainability-oriented transition'. Following the GACGC, it was argued that a structural metabolic shift would be the distinctive feature of this transition. It should be clear from the discussion thus far that although the IRP does not address the question of transition directly, when the completed and ongoing work is read together it does provide an extraordinary body of rich empirical evidence that confirms the notion that we are experiencing the endgame of the industrial socio-ecological regime.

Although the notion of decoupling is contested on the grounds that it implies that fundamental structural change can be avoided while greening consumption (Jackson 2009), the global resource perspectives provided in the Decoupling 1, Decoupling 2 and Environmental Impacts reports all confirm that unless the global systems of production and consumption are in fact radically transformed it will not be possible to build a world without poverty where average consumption (of around six t/cap) is consistent with

what available planetary systems can provide on a sustainable basis. This message goes way beyond the carbon-centred argument of the IPCC that has succeeded in establishing the notion of a low carbon transition within the global policy community. From the perspective of the IRP, this will not be sufficient. A low carbon destruction of planetary resources is not an appropriate future trajectory.

The conclusions of the work on the various nexus themes confirm that superficial modifications to the sociotechnical systems that we depend on will not suffice. To double the extent of the world's urban settlements, it will be necessary to fundamentally change the way we design, build and operate cities. Many aspects of urban living that are taken for granted will clearly have to be replaced with information-rich alternatives that embed cities in sustainable technological and ecological cycles.

The crisis of the current highly complex tightly-coupled global food system poses a major risk to the survival of the global population, in particular the poor. Although this might be the most difficult sociotechnical system to change, fundamental changes to this system might well be driven by the social and health consequences of deepening food insecurity.

The global trade in material resources is already changing rapidly as fewer and fewer countries become increasingly important exporters of primary resources to an increasing number of industrializing and industrialized resource-importing countries. The rise of resource nationalism in many resource-rich develop-

ing countries and the resource efficiency movement in many resource-importing developed countries suggests future trajectories that will have major implications for global trade in material resources.

Finally, although the transition to renewable energy technologies will clearly have beneficial environmental impacts compared to business as usual, it would be naïve to assume that they are a panacea that will produce an environmental utopia. Like everything we humans do, resources are required that we derive from the crust of the earth in one way or another. A future world of nine billion people where we consume six t/cap and emit two tonnes of CO_2 is still a world that will require the extraction of resources on a scale equal to current levels of extraction. The IRP work on renewable energy technologies shows that the demand for certain materials may well increase if we implement the low carbon transition. This is an early warning that the sustainability-oriented transition is not a simplistic break that miraculously heals the planet.

Finally, the IRP work on the specific resource challenges in the metals and ecosystems sectors clearly shows that a sustainability-oriented transition will depend on extraordinary efforts to change the way we use the three most basic ingredients of contemporary modern living: metals (in particular for the global electronic infrastructure), water and land. However, no matter what we do, there is no way we can do without these three key resources. Indeed, it is clear from the evidence that we will need more of them all and that this will have to be done in a way that ensures that those who currently live in poverty gain greater access to these resources. The challenge, however, is to trigger new consumption and production systems that create new economic opportunities out of the need, for example, to 'design for disassembly' when it comes to metals, or to design and build decentralized urban water and sanitation systems that can use water more efficiently and recycle all waste water, or replicate on a massive scale the agro-ecological farming methods that have proved to be able to increase yields by restoring the soils and ecosystems.

This discussion raises the question about whether the IRP should go beyond its current mandate and become the global body that addresses in an integrated way the challenge of making the sustainability-oriented transition happen. For this to be possible, however, it will be necessary to embed the research done to date on resource flows within an analysis of the dynamics of the global economy. During the quarter-century leading up to the great contraction of 2009, the neo-liberalization of the global economy resulted in the rise to dominance of finance capital on the back of a wave of financial innovations made possible by the low-interest-rate regime advocated by the US Federal Reserve. The global economy is now driven by debt-driven consumption and national development strategies that measure progress in terms of GDP per capita. Indeed, without growth, fractional reserve banking systems will face a serious crisis. A key result is a highly unequal world. Not only has this triggered unprecedented social movements (Castells 2012), but the popularity of Thomas Piketty's book *Capital in the Twenty-First Century* is a clear indication that 'rule by the one per cent' of an increasingly unequal world is no longer a legitimate mode of societal governance (Piketty 2014). It is arguable that this highly complex and increasingly unstable global economic architecture is incompatible with the metabolic dynamics and requirements of the third great transformation. If this argument is correct, it will be necessary to merge the body of work thus far developed by the IRP with the emerging body of work by progressive ecological and institutional economists who have begun to consider the details of alternative future economic arrangements and trajectories that will be fundamentally different to what mainstream macro-economic theory assumes is the natural order of things.

17.8   Conclusion

In this first academic review of the IRP's body of work, it has been argued that it may be appropriate to use long-wave theories of transition to understand the contribution of the IRP to the wider field of anticipatory science. What is anticipated by those who use this perspective is that in some way the metabolic, sociotechnical and institutional regimes of the industrial epoch will be replaced over time by an alternative more sustainable epoch characterized by more sustainable metabolic flows made possible by reconfigured and transformed sociotechnical and institutional regimes. Although the IRP's work does not directly address transition per se, when read together the various strands of thought and evidence in the completed and current work do suggest that it is highly unlikely that the industrial epoch can continue into the medium- and long-term future if it depends on the continuous increase in consumption of natural resources. There are elements, of course, across the reports that could be woven into a more robust and

systematic conception of transition: the types of decoupling envisaged in the Decoupling 2 Report, the recommended dietary and land-use changes in the Land and Soils Report, the key role of cities in the City-Decoupling Report, and the unintended consequences of a transition to clean energy, to cite only a few examples.

Three broad conclusions flow from this analysis.

Firstly, when collected together, the totality of evidence mobilized by the IRP supports the notion that future well-being and development (whether growth-based or not) will have to be decoupled from rising rates of resource use. Relative decoupling is not sufficient. Absolute reductions in resource use will be necessary. To implement this idea, however, a fundamental restructuring of prevailing modes of production and consumption will be necessary. Decoupling is not simply sophisticated greenwash. It will mean significant changes for consumers in developed economies, and in developing countries committed to poverty eradication it will be necessary to replace resource-intensive development pathways with resource-efficient development pathways that end up delivering to more people a fairer deal resulting in less inequality and therefore more long-term democratic stability.

Secondly, the IRP's work reveals the futility of naïve assumptions about what will be attainable in a sustainable world populated by over nine billion people, most of whom will be living in cities. All past human activity has depended on the exploitation of natural resources in one way or another. Humans currently have technical and institutional capabilities to exploit these resources on an unprecedented scale. Anticipatory science is needed to show that this cannot continue. However, if the results from IRP research are anything to go by, massive reductions in resource use are possible, but they cannot be eliminated or reduced to insignificant levels. A world of over nine billion people without poverty may well need what was extracted from the earth in 2000. The finding made in the Green Energy Choices Report that more of certain materials might be needed is highly significant. The only question is how this will be done. Will these sociotechnical processes become part of closed-loop techno-industrial and ecological cycles or not? That will become the key longer-term question, not simply a zero-sum calculation based on how much less can be consumed. This, in turn, might make it possible to make a shift from only focusing on 'resource limits' to focusing more on 'resource potential'. This shift is already under way in a number of reports.

Thirdly, the IRP work on resource limits and potentials needs to be integrated into a wider holistic theory of economic development that is not GDP-centred. The gradual dismantling of neo-liberalism is already under way as intolerance of poverty and inequality reaches new heights in the wake of the global economic crisis and states in the developing world disassociate themselves from the hegemonies of Western thinking. This is clearly a positive movement. However, if an alternative is constructed that anticipates the great transformation that once again assumes that there is an unlimited supply of natural resources, then a major opportunity will have been missed. The economic theories informing the developmental states run the risk of making this mistake. However, this is unlikely to become a mainstream habit because the century-long decline in resource prices ended in 2002. If those who have predicted a long-term supercycle of forty to sixty years of rising resource prices prove to be correct, then we can safely anticipate that the economic theory that replaces the reductionist simplicities of neo-liberalism will indeed need to come to terms with the expanding body of work produced by the IRP. This will surely justify the efforts by those who have made this work possible.

Part V   **Developing Theoretical Approaches on Sustainability and Transitions**

18 Sustainability and Complexity: A Few Lessons from Modern Systems Thinking

Czesław Mesjasz[1]

Abstract

Sustainable development, sustainability and sustainability transition are associated with the growing complexity of sociopolitical systems and ecological systems, and of their interactions. These concepts are becoming even more intricate since in academic considerations and in policy-making the concept of complexity is not precisely defined. The term complexity usually relates to a special class of non-linear mathematical models which are relevant to phenomena described with characteristics measurable in the ratio scale which occur in nature and in social systems. It is also used as analogy and metaphor. The aim of this chapter is to identify and to assess the applications of the concepts deriving from complexity studies in the discourse on sustainability and sustainable development and on related terms—transition to sustainability and management of transition to sustainability. The main hypothesis of the chapter is that a sophisticated language dealing with complexity and applied in the narratives on sustainability and related ideas requires a profounder clarification so as to provide new insights concerning description, explanation of causal links, prediction, normative approach and influence upon societal phenomena.

Keywords: Complexity, sustainable development, sustainability transition, transition management.

18.1 Introduction

The idea of sustainable development, viewed as an action plan for achieving sustainability of the world society and of its components, has undoubtedly become one of most important social, economic and political ideas at the turn of the twenty-first century. Treated as a response to the environmental threats caused by economic development and increasing population, sustainability is viewed as a kind of ultimate objective. However, a closer look at the discourse on sustainability leads to the conclusion that very often it is defined in too general terms. In consequence of its broad meaning, 'sustainability', 'sustainable development' and associated terms can be perceived as fuzzily defined metaphors, or in other words, as a kind of linguistic variables (Zadeh 1975).

Sustainable development, sustainability and sustainability transition are associated with the growing complexity of sociopolitical systems, ecological systems, and their interactions. The concepts are becoming even more intricate since in academic considerations and in policy-making the concept of complexity is not precisely defined. The term 'complexity' is usually related to a special class of non-linear mathematical models which are relevant to phenomena described with characteristics measurable on the ratio scale and which occur in nature and in social systems. Such models, in turn, are depicted by well-known terms such as bifurcation, chaos, emergent properties, 'butterfly effect', and so on. Complexity can be also viewed as a qualitative feature of systems. In the latter case, the meaning of 'complexity' is intersubjective and is expressed with analogies and metaphors which are not always useful in scientific discourse (see chapter 13 by Scheffran).[2]

---

[1] Associate Professor dr habil., Cracow University of Economics, Cracow, Poland; Email: <mesjaszc@uek.krakow.pl>.

[2] Although metaphor is a type of analogy, in this chapter metaphor and analogy are treated separately since analogy can be of a more universal character, for example a simulated mathematical model of a social system, while metaphor is a purely linguistic vehicle.

This means that in studying the links between the complexity of socio-economic systems and of ecological systems, the Wittgensteinian language games of several concepts have to be considered (Wittgenstein 2002). Without delving into such games, it is necessary to strive for more precise definitions of such terms as 'complexity', 'sustainable development', 'sustainability', 'transition to sustainability' and 'management of transition to sustainability'. Numerous attempts have been already made to define the concepts examined in this chapter. In only a few of these attempts, however, have the links between the deeper meaning of sustainability and its associated terms, and the ideas taken from complexity studies/theory, been investigated, e.g. Jenks/Smith 2006; Loorbach 2007; Cilliers 2008; Picard 2010; Espinosa/Walker 2011. The concepts of sustainability transition and transition management are built upon various attributes of complexity, e.g. Rotmans/Kemp/van Asselt et al. 2001; Rotmans 2005; Loorbach 2007, 2008; Camaren/Swilling 2014.

The aim of the chapter is to identify and to assess the applications of the concepts deriving from complexity studies in the discourse on sustainability, sustainable development and on terms related to them—transition to sustainability and management of transition to sustainability.[3] The main hypothesis of the chapter is that despite a sophisticated language related to complexity and applied in the narratives on sustainability and related ideas, there is a need to maintain the basic classical interpretations of the characteristics of complexity as far as description, explanation of causal links, prediction, the normative approach and influence upon societal phenomena are concerned. This is of particular importance since in numerous works on the complexity of social systems and of sustainability, the narratives are based upon carelessly used analogies and metaphors, the main reason being that the subjective (intersubjective) character of social systems is not sufficiently recognized.

The analysis presented in this chapter is focused upon conceptual and linguistic considerations. It is of special importance for three reasons. First, a closer look at the concepts and definitions used in the social sciences allows for a profounder understanding and more precise operationalization. Second, the rhetoric of sustainability-related scientific discourse is often applied in political considerations on development and growth. This means that the weaknesses and imprecision of the ideas could be transferred into policy practice where they can become perceived as void 'pseudoscientific' slogans. The third element of the proposed approach is methodological. The chapter is treated as an introduction to a more rigorous quantitative research in which 'text mining' and similar methods could be used to produce a kind of 'inventory' of the applications of complexity characteristics to narratives on sustainability, which, in turn, would allow the building of typologies, the deepening of interpretations, the creation of a ground for the phenomenology of the complexity of sustainability, and subsequently, the enhancement of the effectiveness of applications in practice.

In the first part of the chapter, interpretations of sustainability and sustainable development are presented. The second part includes a survey of interpretations of the ideas of sustainability transition and transition management which have been developed in the early twenty-first century. In the third part, barriers to defining complexity and the complexity of social systems are analysed. The reasons for and examples of abuses and misuses are described. It is stressed that social systems are of subjective (intersubjective) character. Since prediction is the key element of the discourse on sustainable development, the barriers of prediction stemming from the complexity of social systems are described. In the fourth part, the links between ideas taken from complexity studies and sustainability, sustainable development, sustainability transition and transition management are surveyed and a preliminary assessment is made. The final part contains conclusions and recommendations for future research.

---

3   Because of the vagueness of the idea of complexity, in my earlier works I have refrained from using the terms 'complexity theory' and 'complexity science', although the ideas of 'emerging sciences or science of complexity' had already been proposed by Waldrop (1992) and Richardson and Cilliers (2001), and several authors use the term 'complexity theory'. Taking into account the numerous examples of the application of the terms 'complexity science' and 'complexity theory', the latter term is used in this chapter, sometimes interchangeably with 'complexity studies'. However, it would be going too far to claim that complexity theory is a developed scientific theory. The same applies to complexity science.

18.2 Systemic Characteristics of Sustainability

18.2.1 Definitions of Sustainable Development and Sustainability

18.2.1.1 Sustainable Development and Sustainability: Main Questions

The origins of the concept of sustainable development and sustainability at all levels and types of human systems, starting with local and ending with global systems, can be traced in the economic thought of the eighteenth century. In 1798, Malthus worried about how Britain's apparently inexorable rise in population could be sustained from a finite amount of land. In 1865, Jevons wondered how Britain's ever-increasing consumption of energy could be sustained from finite supplies of coal (Pezzey/Toman 2002: iv). At that time such considerations were rather a part of general reflections upon the human condition than any part of policy-oriented discussion.

In the modern era, the initial ideas associated with sustainable development emerged in the 1960s (IISD 2009). The first significant intellectual impulse for considering the sustainability of world society was delivered by the authors of the first Report to the Club of Rome in 1972 (Meadows/Meadows/Randers et al. 1972). In the Report, a relative simple computer simulation model was used. Five variables were examined in the original model: world population, industrialization, pollution, food production, and resource depletion. The authors explored the possibility of a sustainable feedback pattern for the world that would be achieved by altering growth trends among the five variables under simulated scenarios. In most of the discussions after the Report's publication its simplicity and the pessimistic conclusions partly stemming from it were often noted.

However, the meaning of both terms proved to be remarkably difficult to define, and it was similarly difficult to use the terms more precisely. The problem lies in their systemic/structural properties. This means that, when discussing sustainable development and sustainability, three questions have to be answered:

1. How can sustainability and sustainable development be defined?
2. What are the objects of reference of sustainable development and sustainability?
3. How can sustainability and sustainable development be operationalized and measured?

18.2.1.2 Survey of Definitions of Sustainable Development and Sustainability

Discussions among scholars and policymakers on sustainable development and sustainability were initiated after the publication of the report *Our Common Future* prepared under the supervision of Gro Harlem Brundtland. In the report, sustainable development was defined as development that meets the needs of the current generation, without compromising the needs of future generations (WCED 1987: 37).

Since then, an increasing wave of interpretations and applications of the concepts relating to sustainable development and sustainability has emerged. Although sometimes redundant, multiple ways of defining sustainability are useful for different situations and different purposes.

Taking into account the number and sometimes the generality and superficiality of the definitions of the two terms, it may be concluded that in some instances they have become 'buzzwords' of contemporary socio-political rhetoric, very often abused and misused in science and in policy-making.

There have been numerous attempts to define both terms and to provide a critical analysis of their interpretations. Obviously it would be a simplification to focus solely on that kind of popular use of the concepts of sustainability and sustainable development. Therefore, only a brief survey of the main ideas along with synthetic definitions of both terms are presented below.

18.2.1.3 Domains, Levels and Issues of Sustainability

There are several typologies of areas of social life where sustainability is taken into account—see tables 18.3 and 18.4. The most popular one embodies three 'pillars': social, environmental and economic (Adams 2006). There are two typologies which include various conceptions of 'four pillars'. The first specifies human, social, economic and environmental pillars, the second environmental responsibility, social equity, economic health, and cultural vitality. The following areas of sustainability and sustainable development

Table 18.1: General definitions of 'sustainability'. **Source:** The author's own research.

Definition
Sustainable: able to be used without being completely used up or destroyed; involving methods that do not completely use up or destroy natural resources; able to last or continue for a long time. Full definition of sustainability: Capable of being sustained: a: of, relating to, or being a method of harvesting or using a resource so that the resource is not depleted or permanently damaged, b: of or relating to a lifestyle involving the use of sustainable methods.[a]
A 'sustainable society' lives by the nine principles… 1. Respect and care for the community of life. 2. Improve the quality of human life. 3. Conserve the earth's vitality and diversity. 4. Minimize the depletion of non-renewable resources. 5. Keep within the earth's carrying capacity. 6. Change personal attitudes and practices. 7. Enable communities to care for their own environments. 8. Provide a national framework for integrating development and conservation. 9. Create a global alliance (IUCN/UNEP/WWF 1991: 10).
The duty imposed by sustainability is to bequeath to posterity not any particular thing with rare exceptions such as Yosemite, for example, but rather to endow them with whatever it takes to achieve a standard of living at least as good as our own and to look after their next generation similarly. We are not to consume humanity's capital, in the broadest sense (Robert Solow, quoted in Anand/Sen 2000: 2033).
Sustainability is an economic state where the demands placed upon the environment by people and commerce can be met without reducing the capacity of the environment to provide for future generations. It can also be expressed in the simple terms of an economic golden rule for the restorative economy: Leave the world better than you found it, take no more than you need, try not to harm life or the environment, make amends if you do (Hawken 1993: 139).
Sustainability is about stabilizing the currently disruptive relationship between earth's two most complex systems—human culture and the living world (Hawken 2007: 172).
A development is said to be weakly sustainable if the development is non-diminishing from generation to generation. This is by now the dominant interpretation of sustainability. "The second interpretation, known as 'strong sustainability', sees sustainability as non-diminishing life opportunities. This should be achieved by conserving the stock of human capital, technological capability, natural resources and environmental quality" (Brekke 1997: 91).
The core of mainstream sustainability thinking has become the idea of three dimensions: environmental, social and economic sustainability. These have been drawn in a variety of ways, as 'pillars', as concentric circles, or as interlocking circles. … The IUCN Programme 2005–8, adopted in 2005, used the interlocking circles model to demonstrate that the three objectives need to be better integrated, with action to redress the balance between dimensions of sustainability (Adams 2006: 2).
Four pillars of sustainability: Human, Social, Economic and Environmental: *Human sustainability* means maintaining human capital. Human capital is a private good of individuals, rather than between individuals or societies. The health, education, skills, knowledge, leadership and access to services constitute human capital. Investments in education, health, and nutrition of individuals have become accepted as part of economic development. *Social sustainability* means maintaining social capital. Social capital is investments and services that create the basic framework for society. It lowers the cost of working together and facilitates cooperation: trust lowers transaction costs. Commonly shared rules, laws, and information promote social sustainability. The widely accepted definition of *economic sustainability* is maintenance of capital, or keeping capital intact. Thus Hicks's definition of income—the amount one can consume during a period and still be as well off at the end of the period—can define economic sustainability, as it devolves on consuming value-added (interest), rather than capital. *Environmental Sustainability* itself seeks to improve human welfare by protecting Natural Capital. As contrasted with economic capital, Natural Capital consists of water, land, air, minerals and ecosystem services, hence much is converted to manufactured or economic capital.[b]
The four pillars include Environmental Responsibility, Social Equity, Economic Health, and Cultural Vitality. While it is useful to organize sustainability in terms of these four pillars, it is the integration between them that will drive sustainability, highlight opportunities for innovation and reduce duplication of efforts.[c]

Table 18.2: General definitions of 'sustainable development'. **Source:** The author's own research.

Definition
Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs. It contains within it two key concepts: – the concept of needs, in particular the essential needs of the world's poor, to which overriding priority should be given; and   – the idea of limitations imposed by the state of technology and social organization on the environment's ability to meet present and future needs (WCED 1987: 37).
Principles for Sustainable Development: "Business as usual is no longer an option—for government, private sector or individual citizens. Our soils, waters, forests and minerals are not inexhaustible. Farms, industries, homes and lifestyles must become more sustainable, in every community on our planet. To be sustainable, development must improve economic efficiency, protect and restore ecological systems, and enhance the well-being of all peoples".[a]

Table 18.3: Levels of analysis of sustainability. **Source:** Riley (1992).

Analysis of sustainability		
Level of analysis	**Typical characteristics of sustainability (cumulative)**	**Typical determinants of sustainability**
Field/production unit	Productive crops & animals; conservation of soil & water; low levels of crop pests & animal diseases	Soil & water management; Biological control of pests; use of organic manure; fertilizers; crop varieties & animal breeds
Farm	Awareness by farmers; economic & social needs satisfied; viable production systems	Access to knowledge, external inputs and markets
Country	Public awareness; sound development of agro-ecological potential; conservation of resources	Policies for agricultural development; population pressure; agricultural education, research & extension
Region/continent/world	Quality of the natural environment; human welfare & equity mechanisms; international agricultural research & development	Control of pollution; terms of trade; distribution

relating to various sociopolitical and socio-ecological systems (areas of reference) can be distinguished:

– sociopolitical sustainability,
– sustainable use of resources (environmental sustainability),
– sustainable agriculture,
– economic sustainability,
– regional sustainability,
– sustainable business and production.

The hierarchy of sustainability areas embodies the following levels: global, macro-regional, transnational, micro-regional, market-oriented corporations, agricultural units and non-market organizations. It might be worth considering the proposal to add individual persons as the fundamental (nuclear) units of sustainabil-

ity-oriented studies. Definitions of sustainability for every area and every level have been proposed in the literature. As an example, the levels of analysis of sustainability proposed by Riley (1992) are shown in table 18.3.

The selection of examples presented in tables 18.1, 18.2, 18.3 and 18.4 embodies the main interpretations which can be helpful in delving into the complexity of the idea of sustainability and the multitude of its extensions and derivative concepts.

Sustainability can be described and analysed within the framework of the four pillars. All pillars are equivalent but undoubtedly it is human economic activity which determines the present and the future of the fundamental conditions of human living that are treated as desired and sustainable. Viewed from

Table 18.4: Definitions of sustainability in specific socio-economic domains. **Source:** The author's own research.

Definition
Triple bottom line of sustainability—social, environmental (ecological), economic (financial) (three pillars, TBL, 3BL, three P's—People, Planet, Profit) (Elkington 1994).[a)]
It must be emphasized that the actor of sustainability is not an individual human being, but rather a generation of human beings making decisions. The generation metaphorically is made to function as a single being attempting to sustain a flow of imputed benefits analogous to but more inclusive than the income of the individual human being. It is this generation's ethical responsibility to 'maintain' a 'broadly defined capital stock' to sustain a 'broadly defined income' for the benefit of future generations (Brätland 2006: 10).
Corporate Sustainability is a business approach that creates long-term shareholder value by embracing opportunities and managing risks deriving from economic, environmental and social developments. Two guiding principles of corporate sustainability: – sustainable business practices are critical to the creation of long-term shareholder value in an increasingly resource-constrained world, – sustainability factors represent opportunities and risks that competitive companies must address.[b)]
Sustainable businesses are defined as follows: 1. Replace nationally and internationally produced items with products created locally and regionally. 2. Take responsibility for the effects they have on the natural world. 3. Do not require exotic sources of capital in order to develop and grow. 4. Engage in production processes that are human, worthy, dignified, and intrinsically satisfying. 5. Create objects of durability and long-term utility whose ultimate use or disposition will not be harmful to future generations. 6. Change consumers to customers through education (Hawken 1993: 144).
Sustainable Production is the creation of goods and services using processes and systems that are: – non-polluting, – conserving of energy and natural resources, – economically viable, – safe and healthful for workers, communities, and consumers, – socially and creatively rewarding for all working people. If production is sustainable, then the environment, employees, communities, and organizations—all benefit. These conditions can lead, always in the long term, and often in the short term, to more economically viable and productive enterprises.[c)]

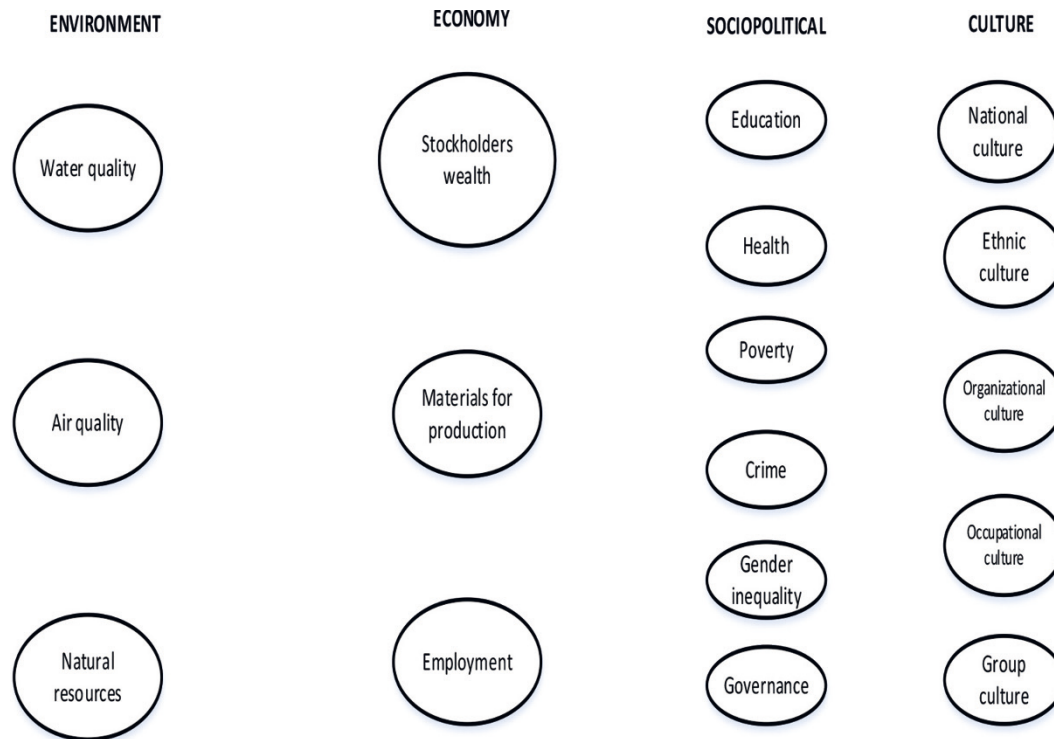
the economic perspective, the main challenge in thinking about sustainability and sustainable development is to balance the present and future needs of humanity. In economic terms this means that the following issues have to be dealt with.

The first is to define the future desired process of development, which can be viewed as self-sustainable. The process should be described with a set of parameters (variables—continuous and punctuated (discrete)). Then the interactions between subsystems must be depicted. An important element in understanding sustainable development is to capture the mechanisms of intertemporal transfer of resources, which can be seen as an element of the integration of human progress with environmental conservation.

As with other areas of sustainability theory and policy, the ideas taken from complexity studies are to a large extent a conceptual foundation of the economic facets of sustainability. They especially concern prediction and mechanisms for the transfer of resources.

The time horizon of the transfer covers one or two generations (twenty-five to fifty years) since a longer perspective in economic (and political) planning is not reasonable. A very long-term perspective is sometimes needed in ecological analyses, although a hundred-year forecast often seems very inappropriate.

As an example of analyses of inter-temporal, sustainability-oriented economic mechanisms, the ideas developed by Anand and Sen (2000) can be used as a source of inspiration. The most important issues of

Figure 18.1: Areas and elements of sustainability description and analysis (three/four pillars). **Source**: Own research based upon Adams (2006) and Goodland.


economic aspects of sustainability and sustainable development are the following:

1. The needs of future generations.
2. The volume and kind of capital which has to be left to the following generations.
3. Adequate models of economic growth.
4. Preservation of capital inherited from past generations.
5. Definition of human capital and of its growth.
6. Dilemma—to preserve or to enhance productive capabilities (broad stock capital) by the present generation with a perspective looking towards future generations.
7. Is the continuous increase in standards of living for all people achievable and justifiable?
8. Dilemma—support for the poor today vs. capital left for the future.

18.2.2 Operationalization and Measures of Sustainability and Sustainable Development

Studies of the links between the complexity of socioeconomic systems and sustainability also need to explain the methods of creating the qualitative and quantitative characteristics of sustainability. The number and variety of the definitions shown above is an obstacle to the operationalization and development of the quantitative characteristics (indicators) of sustainability and sustainable development measurable on two scales, ratio and interval. Indicators of sustainability must capture the interdependence between three, or four, 'pillars'. In addition, there is a dilemma concerning the number and quality of indicators. A large number of indicators usually leads to low precision, overlaps and correlations of indicators. Too few indicators do not allow a collection to be prepared which could be representative for description and analysis. As with other methods of assessing social systems, this dilemma remains unsolvable, and specific collections of indicators depend upon the decisions of the authors of the methods. Traditional indicators measure changes in one part of a social entity as if they were entirely independent of the other parts. Sustainability indicators reflect the fact that the elements of three (or four) different pillars are very tightly interconnected directly and indirectly. In figure 18.1, four areas and their elements are presented, and in order to make the scheme clear, no relations are modelled using lines.

There may be different methods of preparing indicators of sustainability. One of them has been proposed by the Sustainable Measures Company. Such a methodology usually derives from assumptions and questions. These are the questions proposed by this company:[4]

1. What is an indicator of sustainability?
2. What are the characteristics of effective sustainability indicators?
3. Are there any checklists that can be used to evaluate sustainability indicators?
4. How can the indicators be organized?
5. How many and what kind are needed?
6. What data sources are available for indicators?
7. Can we find examples/benchmarks of good sustainability indicators?
8. Are there any education/training materials that explain indicators and sustainability?

A survey and assessment of sets of sustainability partial indicators usually labelled as "indices" (macro-indicators) remains beyond the scope of this chapter. In order to show how different sets of indicators help to deal with the complexity of sociopolitical/socio-economic and socio-ecological systems, only the most commonly used indicators are listed. Gender-related indices are also included in this collection since a proper gender policy helps to maintain sustainability at all levels of society.

1. *American Human Development Report* (AHDR),
2. *Ecological Footprint* (EF).
3. *Gender-related Development Index* (GDI).
4. *Genuine Progress Indicator* (GPI).
5. *Gross National Happiness* (GNH).
6. *Human Development Index* (HDI).
7. *National Human Development Report* (NHDR).
8. *The Happy Planet Index* (HPI).
9. *The Index of Sustainable Economic Welfare* (ISEW).

The indicators from the above proposals have been widely discussed and assessed both positively and negatively (McGillivray 1991; Klasen 2006). From a methodological point of view they share several common features.

First, they go beyond traditional economic indicators by adding other characteristics—social, environmental, human, and political.

Second, more attention is paid to non-economic indicators, and in some cases (Ecological Footprint and gender-oriented indicators) other characteristics are considered as crucial for sociopolitical and economic development.

Third, their authors attempt to make them 'objective' by applying indicators measurable with the ratio or interval scales. Wherever possible, the basic idea behind all these approaches is to cast doubt on wealth development at any price, with the inclusion of non-market commodities, positive and negative, to yield an aggregated macro-indicator in monetary terms. This leads to a situation in which a critical approach to results stemming from the intersubjective creation of those indicators is neglected. Although their authors do not declare it openly, they are aiming at making those partial indicators measurable, not correlated and not redundant with the other indicators within the same set (index, macro-indicator).

Fourth, the development of numerous indices may contribute to confusion in policy-oriented discourse because of their lack of precision, their too high level of detail, and incommensurability of partial indicators within the indices and between the aggregate indices.

Fifth, the extension of factors and subsequently the number of indicators of sustainability and sustainable development may lead to stretching their meaning beyond the possibility of theoretical usefulness and practical applicability. It may create a situation like that of the deepening and broadening of security, which may sometimes lead to its being seen as becoming too broad and too universal and subsequently losing its theoretical and practical usefulness.

Sixth, there may also be problems resulting not only from overlaps of indicators and indices of different concepts of sustainability and sustainable development but also from overlaps with indicators applied in defining other characteristics such as resilience and robustness.

18.3 Sustainability Transition as a Theoretical and Policy-Making Concept

18.3.1 Sustainability Transition

Changing society at all levels, beginning with small groups and ending on a global scale, has always been

---

4 The questions are a modified version taken from Sustainable Measures Company (no year); at: <http://www.sustainablemeasures.com/company> (24 March 2014). The website of the Sustainable Measures Company states that it ceased its activities in 2014.

an important issue for theorists. It is not just a matter of description and understanding; there is also the challenge of how to influence the change. This leads to discussions about goals, norms and methods of change. At the micro-level, i.e. companies and non-market institutions, influencing change is mirrored in change management or project management. Theory and practice show that influencing change at that level is achievable although the expected results are never guaranteed (Kotter 1995).

There are more significant challenges in attempting to influence or even control change at higher levels of the social hierarchy—industry, a domain of social activity such as a health service or innovation, a region in a country, a country, a multi-country region, and global. In such cases the systems and the changes become more complex and policy-making requires the coordination of goals and of the activities of numerous actors. Problems at the macro-scale include security, macro-economic policy, social policy, international finance, trade, and environment.

The term transition, deriving its metaphorical sense from the phase transition in physics and chemistry, has been applied to changes at societal levels above the micro-scale, e.g. a company, and may concern such areas as energy, agriculture or regions. Usually it is equivalent to regime transformation, technological revolutions, technological transitions, system innovation, and transition management (Geels/Schot 2007).

Societal transitions are defined as processes of change that structurally alter the culture, structure and practices of a societal system. As with the case of sustainable development, these processes take a long time (one to two generations) at the level of societal systems, although partial processes (for example, fundamental changes in thinking or radical innovation) can happen almost overnight. A societal transition results from interacting changes in all societal domains (e.g. economy, ecology, institutions, technology and welfare) (Loorbach 2007: 17).

Changes in all these areas are especially significant when sustainability and sustainable development are taken into account. There are plenty of ways of assessing the characteristics of socio-economic and environmental systems, but the recommended policies, processes and methods of achieving or approaching the desired states are usually defined at a very high level of generality. One of the ways to specify more precisely not only what sustainability and sustainable development are, but how to achieve them, is the idea of sustainability transition (transition to sustainabil-ity), or even transition to sustainable development (Grin/Rotmans/Schot 2010) and transition management.

Conceptual and policy problems resulting from difficulties in defining sustainability and sustainable development also come to the fore when studying the meaning of sustainability transition and transition management. These concepts were first put forward at the beginning of the twenty-first century by theoreticians and policymakers in the Netherlands (Rotmans/Kemp/van Asselt et al. 2001; Rotmans/Kemp/van Asselt 2001). The authors of the ideas treat them as new interdisciplinary, multidisciplinary and even transdisciplinary "transition studies", begetting transition theory and even a new paradigm. These lead to new types of research: sustainability science, integrated assessment, post-normal science, and action research (Loorbach 2007: 33–34).

These have emerged over the past few years as a new approach to dealing with complex societal problems and governance in the context of such problems. In the Netherlands, the UK and Belgium, efforts have been made to develop transition policies in areas such as energy, building, health care, mobility, and water management (Loorbach/Rotmans 2010).

Transition is a process of structural societal change from one relatively stable system state to another via a co-evolution of markets, networks, institutions, technologies, policies, individual behaviour and autonomous trends. The complexity of a transition means that it has a multitude of driving factors and impacts. A transition can be accelerated by one-time events, such as big accidents or crises (such as the oil crisis). Slow changes in the external environment determine the undercurrent for a fundamental change; superimposed on this undercurrent are events such as disasters, which may accelerate the transformation process. Transitions are thus multi-causal, multi-level, multi-domain, multi-actor and multi-phase processes. In this new research field, transition processes are studied from a variety of system perspectives: sociotechnical systems, innovation systems and complex adaptive systems.

In the most general sense, the transition can be treated as a continuous process of societal change, whereby the structure of society (or a subsystem of society) changes fundamentally. This societal transformation process has the following characteristics (Loorbach 2007: 18):

– it concerns large-scale technological, economical, ecological, sociocultural and institutional develop-

ments that influence and reinforce each other,

- it is a long-term process that covers at least one generation (twenty-five years), and
- there are interactions between different scale levels (niche, regime, landscape).

The process-oriented character of the transitions approach can be depicted with the following propositions (Loorbach, 2007; Loorbach/Frantzeskaki/ Thissen 2011):

Proposition 1: Sustainability transitions are long-term processes of fundamental societal change that incorporate processes of societal, ecological, economic, cultural and technological evolution.

Proposition 2: Enabling societal processes of change (transitions) requires an integrated understanding of the dynamics of change and deliberate and reflexive strategies so as to allow for self-orientation of society towards a sustainable development pathway.

Proposition 3: Innovation and sustainable development are interlinked: to develop sustainably means to continuously innovate and redefine existing culture, structures and practices in an evolutionary manner. More specifically, a focus on sustainability could trigger innovations that comply with sustainability values as well as such innovations becoming the stimuli for the initiation of multi-domain processes for societal transitions to sustainability.

Proposition 4: Sustainability transitions are continuous open-ended processes of societal innovation. Governance for sustainability transitions has thus to secure sustainability values such as long-term orientation and intergenerational justice.

Summing up the above, it may be stated that sustainability transition constitutes a specific case of transition which results from narrowing the meaning of transition by setting a point of departure—an unsustainable state (static), or perhaps, more frequently, a more or less stable process. The purpose of the transition is to achieve a desired/expected but difficult to define state(?), unstable equilibrium, stable equilibrium(?), or process(?).

18.3.2   Transition Management

The concept of transition sustainability provides a theoretical background for the set of theoretical concepts and activities described as transition management. The goal of transition management is to enable, facilitate and guide transitions to sustainability. It tries to do so through structuring processes of governance based on the principles of complexity, transition and sustainability.[5]

Definitions of transition management have evolved since 2001 (Rotmans/Kemp/van Asselt et al. 2001; Rotmans/Kemp/van Asselt 2001; Loorbach 2007, 2008). The concept of transition management is a broad one, meaning that its definitions have many dimensions. According to Lorbach (2008: 12):

> ...transition management is a deliberative process to influence governance activities in such a way that they lead to accelerated change directed as sustainability ambitions. Transition management is thus defined as meta-governance: how do we influence, coordinate and bring together actors and their activities in such a way that they reinforce each other to such an extent that they can compete with dominant actors and practices? Transition management is thus about creating space (in a sense: governance niches) for innovative governance at all levels, as a strategy to develop alternatives to the regime. Transition management anticipates increasing pressures on the regime level (e.g. predevelopment phase) or tries to provide a more fundamental reflection and long term orientation while the process of change is underway (e.g. acceleration phase).

Transition management can be depicted with several sets of characteristics relating to its framework, governance—in Kooiman's sense (1993), levels and cycle. Loorbach (2008: 13-14) proposes the following tenets of complexity governance to be treated as a part of transition management:

1. Multi-domain, multi-actor and multi-level systems thinking is necessary.
2. Long-term thinking (at least twenty-five years) as a framework for shaping short-term policy in the context of persistent societal problems.
3. Objectives should be flexible and adjustable at the system level. The complexity of the system is at odds with the formulation of specific objectives.
4. Creating space for niches in transition arenas and transition experiments. A niche is a new structure, a small core of agents, that emerges within the system and that aligns itself with a new configuration. The new alignment is often the emergent property of the system. An emergent structure is formed around niches to stimulate the further development of these niches and the emergence of niche regimes.
5. A focus on front-runners. In this context, by front-runners we mean agents with particular competen-

---

5   The complexity of broadly defined sociopolitical governance (Jessop 2004) and of corporate governance (Goergen/Malline/Mitleton-Kelly et al. 2010) has already been studied, albeit with a predominantly qualitative approach.

cies and qualities: creative minds, strategists and visionaries.

6. Guided variation and selection.

7. Radical change in incremental steps. Radical, structural change is needed to erode the existing deep structure (incumbent regime) of a system and ultimately dismantle it. Immediate radical change, however, would lead to maximal resistance from the deep structure, which cannot adjust to radical change that happens too fast.

8. Learning-by-doing and doing-by-learning. Social learning is a pivotal aspect of societal transition processes, aimed at 'reframing', changing the perspective of the actors involved.

9. Anticipation and adaptation. Anticipating future trends and developments, taking account of weak signals and seeds of change acting as the harbingers of the future, is a key element of a proactive, long-term strategy for transition management, which has emerged over the past few years as a new approach to dealing with complex societal problems and governance in the context of these problems.

To complete this partial characterization of transition management, it should be added that four different types of governance activities can be distinguished when observing the behaviour of actors in the context of societal transitions: strategic, tactical, operational and reflexive. It is also important from the point of view of applicability that transition management can be implemented through a specific methodology (cycle) that includes the following stages (Loorbach 2008: 15):

– problem structuring, establishment of the transition arena and envisioning;
– developing a transition agenda, a vision of sustainability, and developing and deriving the necessary transition paths;
– establishing and carrying out transition experiments and mobilizing the resulting transition networks;
– monitoring, evaluating and learning.

This necessarily simplified description of transition management provides the necessary background for discussion of the links between this concept and complexity theory. More details can be found in the growing body of literature on this and associated topics; see, for example, Rotmans/Kemp/van Asselt et al. 2001; Rotmans/Kemp/van Asselt 2001; Loorbach 2007, 2008; Grin/Rotmans/Schot 2010; and Loorbach/Frantzeskaki/Thissen 2011.

18.4   The Meaning of Complexity

18.4.1   Definitions of Complexity: Models, Analogies and Metaphors

Complexity is undoubtedly one of most popular concepts used in contemporary science and policy-making. Studies of complexity are rooted in cybernetics and systems thinking.[6] The first attempts to define and study complex entities go back to the works of Weaver (1948) ("disorganized complexity" and "organized complexity"), Simon (1962)—the Architecture of Complexity, and Ashby (1963)—the Law of Requisite Variety. In his search for explaining the meaning of complexity, Lloyd (2001) identified forty-five different ways of describing complexity. A very convincing picture of the intricacy of the field of complexity science can be found in the scheme proposed by Castelani (2014). In other writings, numerous definitions of complexity have been formulated and scrutinized—Prigogine and Stengers (1984), Waldrop (1992), Gell-Mann (1995), Kauffman (1993, 1995), Holland (1995), Bak (1996), Bar-Yam (1997), Haken (1997), Prigogine (1997, 2003) and Biggiero (2001).

Unequivocal distinction of complex systems from "classical" systems is not possible. In the works by Wiener (1948/1961), Ashby (1963, defining "first-order cybernetics" and 'hard' systems thinking), and Bertalanffy (1968), complexity was treated as one of the important features of systems without considering the role of the observer. Their works were the first to list the systemic/cybernetic characteristics of systems: system, element, relation, subsystem, environment, input, output, feedback, black box, equilibrium, stability, synergy, turbulence.

Taking a preliminary approach, the complexity of systems derives from the number of elements and of their interactions. It can be also characterized by a multitude of such traits as adaptability, adaptation, attractor, autopoiesis, chaos, bifurcations, butterfly effect, closed system, co-evolution, complex adaptive systems, dynamic systems, edge of chaos, emergent properties, far-from-equilibrium states, fitness landscape, fractals, non-linearity, open system, path

---

6   There are various interpretations of the relationship between cybernetics and systems thinking but, following Bertalanffy (1968), it can be agreed that the former can be regarded as a part of the latter. To avoid unnecessary typological considerations, it is also assumed that studies of complex systems are treated as a part of systems thinking (Mesjasz 1988; Midgley 2003).

dependence, power law, reflexivity, scale-free networks, self-organization, self-organized criticality, self-reflexivity, synergy, synergetics, and turbulence. These ideas are extensively depicted in a large number of writings of which only a small fraction are quoted in this chapter.[7]

Impossibility of decomposition and incomprehensibility are also treated as important facets of complexity. Gell-Mann (1995) shows that complexity can be treated as a function of the number of interactions between the elements in a system. Nicolis and Prigogine (1989) prefer measures of complexity based on system 'behaviour' rather than on any description of system interactions. Similarly, behaviour is also fundamental to the analysis and description of *Complex Adaptive Systems* (CAS) by Holland (1995).

Ideas originating in systems thinking and complexity studies are used in the social sciences as models, analogies and metaphors. According to this distinction, the term 'model' is used only for mathematical structures. Mathematical models in complexity studies can be applied in three areas: computer-based experimental mathematics, high-precision measurements made across various disciplines and confirming the 'universality' of complexity properties, and rigorous mathematical studies embodying new analytical models, theorems and results.

Models, analogies and metaphors are instruments of theory in the social sciences and are used for description, the explanation of causal relations, prediction, anticipation, the normative approach, prescription, retrospection, retrodiction, control and regulation, or, in a modern approach, influence upon the system. It is also worthwhile adding that models, analogies and metaphors deriving from systems thinking/complexity studies are gaining a special significance in the social sciences. They are treated as 'scientific' and hence obtain supplementary political influence resulting from 'sound' normative (more specifically, prescriptive) legitimacy in any debate on security theory and policy[8].

It must be mentioned that unlike physics, chemistry and biology, where only mathematical models are used in prediction, in the social sciences it is also qualitative considerations that are used in prediction. Therefore, the role of analogies and metaphors taken from complexity studies must be taken into account with sufficient care.

One of most influential ideas of complex research are the scale-free networks developed by Barabási and Albert (1999; Barabási 2003). After finding that various networks, including some social and biological networks, had heavy-tailed degree distributions, Barabási and collaborators coined the term 'scale-free network' to describe the class of networks that exhibit a power-law degree distribution, which they presumed could describe all real-world networks of interest.

The above ideas can be called 'hard' complexity research by analogy with 'hard' systems thinking, and to some extent, with 'first-order cybernetics'. It includes the mathematical modelling of systems with well-defined and measurable characteristics in physics, chemistry, and the natural sciences, as well as in society.[9]

'Soft' complexity research, a term coined by analogy with 'soft' systems thinking and 'second-order cybernetics', includes the ideas of complexity developed in other areas—in cybernetics and systems thinking, in the social sciences, and in psychology. Its ideas can be divided into two groups. The first includes those based upon analogies and metaphors drawn from 'hard' complexity studies; these dominate in social sciences theory and practice, and are very often abused and misused (Gleick 1987; Castelani 2014). The second group includes the indigenous qualitative concepts of complexity such as those developed by Luhmann (1995).

Subjectivity is the first aspect of complexity in the 'soft' approach. Following this line of reasoning, from the point of view of second-order cybernetics, or in a broader approach, constructivism (Glasersfeld 1995; Biggiero 2001), complexity is not an intrinsic property of an object but depends on the observer. Usually it is said that "complexity, like beauty, is in the eye of the beholder".

---

7   It may be observed that the titles of the writings that include concepts such as chaos, edge of chaos, complexity, turbulence, etc., draw the additional attention of non-specialists in the field, as well as social scientists who do not have a sufficient background in the mathematical aspects of these terms, and last but not least, the general public. This extra 'appeal' of works with titles and narratives embodying these utterances is likely to be one of the reasons for the simplifications, misuses and abuses.

8   The differences between prescriptive approach based upon "common sense", and qualitative reasoning, and normative approach based upon ideal, mathematical models of rationality in decision making has been described by (Bell/Raiffa/Tversky 1988).
9   The distinction between 'soft' and 'hard' complexity was also introduced by Richardson and Cilliers (2001), though with a slightly different meaning.

As to identifying a genuine epistemological meaning of complexity, Biggiero (2001: 3), basing his approach on some properties of the relationships between observers (human or cognitive systems) and observed systems (all kind of systems), treats predictability of the behaviour of an entity as the fundamental criterion for distinguishing various kinds of complexity. He proposes three classes of complexity: (a) objects not deterministically or stochastically predictable at all; (b) objects predictable only with infinite computational capacity; (c) objects predictable only with a transcomputational capacity.

Coming from this typology, he defines '*observed irreducible complexity* (OIC)' as those states of unpredictability which allow an object to be classified in one of the three classes. This definition allows complexity to be distinguished semantically in the new sense.

The typologies presented by Biggiero lead to two conclusions that are important in studying social systems. Firstly, the first class is characterized by self-reference, relating to the many forms of undecidability and interactions between observing systems (Foerster 1982). This property, being a foundation of 'second-order cybernetics', in some sense favours the subjective interpretations of complexity. Secondly, human systems are characterized by the presence of all sources and types of complexity (Biggiero 2001: 4-6). One can summarize this by stating that human systems are the 'complexities of complexities'.

In the social sciences, and particularly in sociology, attention is given to the concepts of complexity of systems proposed by Luhmann. This is the main idea of 'soft' complexity, akin to 'second-order cybernetics'. Luhmann is one of only a few authors to have made an attempt to provide a comprehensive definition of social systems based solely on communication and on the concept of the autopoiesis (self-creation) of biological systems. According to Luhmann, a complex system is one in which there are more possibilities than can be actualized. Complexity of operations means that the number of possible relations becomes too large with respect to the capacity of elements to establish relations. It means that complexity enforces selection. The other concept of complexity is defined as a problem of observation. Now, if a system has to select its relations itself, it is difficult to foresee what relations it will select, for even if a particular selection is known, it is not possible to deduce which selections would be made (Luhmann 1990: 81).

Complexity of social systems as developed by Luhmann is strongly linked to self-reference, since reduction of complexity is also a property of the system's own self-observation, although no system can possess total self-insight. This phenomenon is representative for the epistemology of modern social sciences, where observation and self-observation, reflexivity and self-reflexivity, self-reference and subsequently intersubjectivity play an important role. According to this interpretation, social systems become self-observing, self-reflexive entities trying to solve any problems that arise through the process of adaptation (learning).

Taking an epistemological stance which might be called moderate constructivism, it should be emphasized that definitions of all categories do not have any 'objective' character, independent from the observer. This is a basic epistemological assumption in modern social sciences. Therefore, in systems thinking dealing with both 'hard' and 'soft' complexity, intersubjective interpretations of concepts are the point of departure for investigations.

The links between intersubjectivity and complexity of all kinds of systems need to be further investigated. The challenges stemming from intersubjectivity are of special importance in the discourse on 'soft' complexity, where reflexivity, self-reflexivity and self-reference are taken into consideration. This issue is thus crucial for social systems, in which the systemic properties are always the constructs of participants/observers. Paradoxically, with a few exceptions, these links have not yet been comprehensively analysed.

Intersubjectivity is one of the key issues of modern psychology and sociology, although there is no commonly accepted definition of the concept (Gillespie/ Cornish 2009). Bednarz (1984) made an initial attempt to investigate how intersubjectivity is connected with Luhmann's concept of the social system. In Bednarz's approach, Husserl's (1970) idea of transcendental intersubjectivity is treated as the source of all objectivity and meaning—including that of the world itself. Intersubjectivity should be always be borne in mind when defining and studying social systems.

18.4.2 Non-linearity, Intersubjectivity, Prediction and Complexity

There are three important aspects of complexity which have to be explained in a more detailed way in the discourse on sustainability and sustainable development: non-linearity and the limits of prediction resulting from the complexity of social systems. The main reason for choosing these characteristics is that they can be treated as the fundamental facets of the complexity of socio-economic and ecological systems which are applied in the discourse on sustainability.

Complex systems exhibit non-linear behaviour that is called positive feedback where internal or external changes to a system produce amplifying effects. Non-linear systems can generate a specific temporal behaviour which is called chaos. Chaotic behaviour can be observed in time series as data points that appear random and devoid of any pattern but which demonstrate a deeper, underlying effect. During unstable periods such as chaos, non-linear systems are susceptible to shocks (sometimes very small). This phenomenon, called 'sensitivity to initial conditions' and popularized as Lorenz's 'butterfly effect', exemplifies the cases where a small change may generate a disproportionate change (Gleick 1997). The major lesson of non-linear dynamics is that a dynamic system does not have to be 'complex' or be described by a large set of equations in order for the system to exhibit chaos. All that is needed is three or more variables and some embedded non-linearity (Ilachinski 1996: 57).

When considering non-linearity and its consequences in complex systems two phenomena should be borne in mind. Firstly, as Stanislaw Ulam once remarked, discerning non-linear phenomena and their mathematical models was "like defining the bulk of zoology by calling it the study of 'non-elephant animals'". His point, clearly, was that the vast majority of mathematical equations and natural phenomena are non-linear, with linearity being the exceptional, but important, case (Campbell 1997: 218). Secondly, it should be also mentioned that to distinguish between the statements that linear is predictable and non-linear is not predictable is a simplification. For instance, Newton's equations for the two-body Kepler problem (the Sun and one planet) are non-linear and yet explicitly solvable. It means that non-linearity does not always lead to chaos. At the same time the fundamental equation of quantum mechanics, Schrödinger's equation, is absolutely linear (Sokal/Bricmont 1998: 144–145).

Prediction is the key factor in discussions about sustainability, sustainable development and sustainability transition. It has been widely discussed in numerous works ranging from philosophy to mathematical modelling.[10] Here only a few barriers to prediction will be discussed. Leaving aside the analysis of the sense of causality and explanation, it may be stated that prediction is the key element of scientific reasoning (Popper 1974). Prediction is associated with such terms as forecasting, anticipation, predictability and prophecy. The basic meaning of prediction is a statement or claim that a particular event will occur in the future. Narrowing the sense, it may be added that the place and time of the event are known as well.

Prediction can be interpreted as the selection of one world from an infinite number of 'potential worlds' which can emerge from any given set of circumstances. This interpretation brings in the question of causality. First of all it must be stressed that causality may be interpreted as objective if proved with logical or empirical evidence. At the same time causality has an intersubjective character. Observers (participants) agree that a specific course of events has led to a specific outcome although it is not certain whether both cause and effect are unique and cannot be replaced. Prediction is also associated with anticipation, i.e. expectation or making decisions based upon the predicted states of the future, beliefs, etc.

Since social systems are 'complexities of complexities', understanding the barriers to the prediction of the behaviour of social systems requires a broader survey, including obviously the barriers of mathematical modelling.

In the most fundamental sense, in which the impact of postmodernism/post-structuralism is not incidental, social phenomena (social systems) are a mixture of a tangible component (physical and biological processes) with an intangible intersubjective component which emerges in the discourse. In a linguistically-oriented approach, the discourse on social systems in economics, management and finance includes metaphors, analogies and mathematical models. In such an approach, the barriers of prediction begin not only at the epistemological level (the future is unknown) but also at the ontological level (what is the object of which the future is to be predicted and what is the initial state of that object?). There are multiple possible futures created in the social discourse and they are shaped by various subjective factors determined by independent, 'natural' processes as well as by the actions and utterances of conscious individuals (participants/observers).

Reference to social learning brings in the main source of the complexity of social systems i.e. reflexivity and self-reflexivity. Regularities generated by social systems can be brought about by homeostatic causal loops, self-regulation through feedback and reflexive self-regulation.

The above interpretation of the prediction of the behaviour of social systems is very rudimentary but should be sufficient for further discussion on sustainability and on related ideas.

---

10 This discussion of prediction draws partly on Mesjasz (2008a).

18.5 Determinants and Main Characteristics of Complexity of Sustainability

18.5.1 Assumptions of the Survey

A closer look at the conceptual barriers to defining vague notions of sustainability, sustainable development, sustainability transition, transition management and, last but not least, complexity, allows us to conclude that paradoxically, they may be perceived as representative of both postmodernist and constructivist trends, as represented, for example, by Baudrillard (1994), Cilliers (1998), Foucault (2007), and Glasersfeld (1995), as well as for "reflexive modernity" (Beck/Giddens/Lash 1994) and "liquid modernity" (Baumann 2000). Therefore it is natural that they require a thorough, multidimensional analysis. In the theoretical assessment it is necessary to take into consideration the value of the concepts from the point of view of the already-mentioned functions of analogies, metaphors and mathematical models, i.e. description, explanation of causal links, prediction, normative approach, and the possibility of influencing societal phenomena (regulatory approach).

The above general framework of the description and assessment of the application of complexity ideas in research into and the practice of sustainability-related concepts is perfectly reflected in a self-assessment by the authors of the idea of sustainability transition (Lorbach 2007: 23):

> Sustainable development becomes rather complex when one tries to operationalize it in terms of governance strategies. After the initial optimism during the 1990s about win–win opportunities, it is increasingly understood that there are trade-offs between different values and interests in any type of development (at least in the short term) and that each development raises new problems for society. Sustainable development should therefore be considered as a continuous process in which these values and interests are discussed, negotiated and balanced. This means that sustainability in itself can never be defined objectively beforehand, but that process-conditions and contextual factors can be formulated which ensure an equal representation, pluriform debate and informed discussion. Approaching sustainable development as a continuous process of change means that it cannot be translated into a blueprint or a defined end state from which criteria could be derived and unambiguous decisions are taken to get there. Rather, it is a multi-dimensional, dynamic and plural concept that can neither be translated into the narrow terms of static optimization nor be conducive to strate-

gies based on direct control, fixed goals and predictability.

This opinion, according to which there is almost nothing constant in theoretical ideas and praxis associated with sustainability, would require a separate discussion. Looked at from the point of view of the identification and assessment of the links between complexity studies and sustainability-related theory and applications, such an approach presents a specific logical challenge. As was shown in earlier parts of the chapter, complexity cannot be defined unequivocally. This is quite common with a multitude of social ideas. However, complexity's meaning also mirrors the vagueness and impossibility of identifying and defining other concepts. There are some exceptions—more precise definitions of 'hard' complexity, according to which complex systems are simply mathematically well-defined systems with 'emergent properties', depicted as *Complex Adaptive Systems* (CAS) (Gell-Mann 1994; Holland 1995). While according to these and other authors who deal with 'hard' complexity, Complex Adaptive Systems can be precisely defined using mathematical models, other authors use the concept as a metaphor which is closer to 'soft' complexity, e.g.: "Most fundamentally, ecological and socio-economic systems are complex, adaptive systems, integrating phenomena across multiple scales of space, time and organizational complexity" (Levin 2006: 328). A similar approach is fundamental to the theory of sustainability transition, e.g. (Rotmans 2005: 32: Loorbach 2007: 55).

Remaining in the area of 'soft' complexity, it must be emphasized that it is necessary to maintain a certain 'core' set of concepts that allow for the description of complexity in a classical way, i.e. with 'classical' definitions and not just with the arbitrary use of metaphors. Otherwise, the discourse beginning "complexity is something difficult to define" is tautological and non-productive in theory and practice.

Therefore, the following point of departure for further consideration is proposed. Despite the vagueness of the ideas, methods and interpretations presented, especially in the works on sustainability transition and transition management, the traditional questions and determinants of complexity relating to description, explanation of causal links, prediction, normative approach and influence upon societal phenomena should be applied in description and assessment of the links between complexity theory and sustainability, and its related terms. It would allow for further less precise discourse and the main reason for this is simply effectiveness of communication, which in turn increases the probability of effective action.

Referring to the above survey of interpretations of complexity, it should be stressed that with the exception of precisely-defined models of social phenomena described with measurable parameters (ratio scale, and perhaps, interval scale), all other applications are based upon analogies and metaphors, or in other words, linguistic variables. It is thus necessary to consider the following factors that determine the discourse on complexity and sustainability and on related ideas:

- consequences of the intersubjective character of the systems under consideration,
- intersubjective character of complexity, especially in the 'soft' interpretation,
- limited applicability of analogies and metaphors taken from complexity theory,
- epistemological and methodological impact of contemporary trends in the social sciences (sustainability science, integrated assessment, post-normal science and action research),
- excessive relativization of ideas, objects of study, and methods,
- social/political biases of the stakeholders, especially the leaders and scientific advisors,
- cognitive/cultural biases of the stakeholders, especially the leaders and scientific advisors,
- biases of stakeholders and scientific advisors leading to tendencies of domination and politicization of the discourse,
- the necessity to prove, and at the same time the limitations to proving, what the theoretical and empirical advantages and disadvantages of narratives and operationalization dealing with complexity studies are, compared with other approaches.

The interpretations of sustainability and complexity and of all the above concepts will be scrutinized. Their relevance will then be analysed in relation to their components, operationalization and applications. First and foremost, any a priori definitions and interpretations will be assessed from the point of view of their relevance and validity. Obviously it is not possible to study all aspects of the meaning of these terms, and so a selection of characteristics and of criteria must be made.

There are significant epistemological limitations to conducting such an assessment. First and foremost, as is often stressed in transition theory and in sustainability science, which are seen as sciences without uncertainty, everything can be treated as a matter of discourse, subjectivity and intersubjectivity. Using more sophisticated terminology, the main epistemological message of all such considerations relating to inte-

grated assessment, post-normal science and action research can be and should be reduced to a few rigorously defined concepts (Loorbach 2007: 33-35).

Another epistemological limitation of the discourse on sustainability and related ideas is that it is not possible to prove empirically whether, for example the implementation of the concept of transition by the application of the narratives and methods of complexity analogies, metaphors and mathematical models is more effective than the application of narratives and methods which do not utilize such tools. Obviously, in the light of the theories proposed, it does not seem possible or necessary to conduct that kind of research, but at the same time the results of the applications *eo ipso* confirm the validity of such an approach (Lorbach/Rotmans 2010).

In consequence, the empirical scope of the description and assessment conducted in this chapter is limited and is predominantly based upon selected theoretical publications and descriptions of case studies concerning sustainability and related concepts that are available in the literature. It should be treated solely as an introduction to further, more systematic studies.

18.5.2 Complexity and Sustainability of Modern Society

Since the onset of the debate about sustainable development, complexity, more or less precisely defined, has been an indispensable element of the debate. The complexity of socio-economic and ecological systems had already been spelled out in *The Limits to Growth* in 1972 (Meadows/Meadows/Randers et al. 1972: 9, 190). In the following years, complexity became one of most important issues in sustainability discourse (Capra 1982). It was viewed as the fundamental attribute of relations between society, technology and the environment, though it was not defined precisely but rather used as a kind intuitive term referring to the number of elements, the number of their relationships, non-linearity and emergent properties. Complexity is considered at every level of the societal hierarchy and in every domain of sustainability and sustainable development.

1. Challenges of sustainability and complexity concerning the development of global systems, regions and states (Diamond 1997, 2005; Wallerstein 2000).
2. Indicators of sustainability (Meadows 1998).
3. Increasing and uncontrollable complexity of socio-economic systems (civilizations) as the reason for their collapse (Tainter 1988; 2000).

4. Holistic qualitative approach to sustainability with the use of ideas drawn from complexity studies (Capra 1982; Urry 2005; Jenks/Smith 2006; Levin 2006; Homer-Dickson 2002; Espinosa/Harnden/Walker 2008; Espinosa/Walker 2011).

5. Sustainability as a hierarchic recursive system based upon the 'Viable System Model' (Beer 1979; Schwaninger 2006; Espinosa/Harnden/Walker 2008; Espinosa/ Walker 2011).

6. Sustainability, complexity and learning systems—the emergence of a "global and sustainable learning society as an effect of coevolution of society and its environment" (Laszlo 2003: page).

7. Sustainability interpreted using a postmodernist approach based on Foucault's radical relational agency and complexity. Non-linearity as one of the main tenets of complexity in ecological considerations (Picard 2010).

In this survey of the applications of complexity-related analogies, metaphors and mathematical models in theory and policy-making concerning sustainability and sustainable development, the following functions of theory can be used as the background to a point of departure: description, identification of causal links, prediction, the normative approach, and influence upon societal phenomena (change management).

Defining in detail all the characteristics of complexity presented in this section and in the subsequent sections would require extensive description and explanation. The characteristics can be treated solely as a preliminary set of guidelines which can help to focus the discussion. There are many other questions which can be added here and in the sections concerning sustainability transition and transition management.

It must be borne in mind that research on sustainability, sustainability transition and transition management are a part of sustainability science (Kates/Clark/Corell et al. 2001), a field closely related to *Integrated Assessment* (IA) by Rotmans (2005). 'Sustainability science' is a more or less general term for a development in science as a whole towards more multi- and interdisciplinary research into complex societal issues. Sustainability science mainly deals with the field of global environmental and sustainability research, and also emphasizes the importance of the involvement of stakeholders in the knowledge development process. While IA offers concrete tools and methods for complexity and sustainability research, sustainability science redefines the role of research and researchers at an abstract level. For transition research this is relevant because the ambitions behind transition research are similar to those behind sustainability science: sci-entific and societal impact based on an active and participatory role by researchers (Loorbach 2007: 34–35).

18.5.2.1 Description

The ideas of sustainability and sustainable development are to a large extent built upon the language borrowed from both 'hard' and 'soft' complexity discourse. Analogies and metaphors dominate at higher levels of generalization. In the operationalization of more precisely defined ideas, mathematical models are applied. In the complexity-based narratives and models used to describe sustainability and sustainable development, the following issues need to be considered:

1. Identification of the systems and processes which have to be sustainable.
2. Identification of the processes leading to sustainability (methods of identification—qualitative, quantitative).
3. General definitions of sustainability.
4. Holistic approach to sustainability.
5. Relations between socio-economic systems and their environment.
6. Domains of sustainability.
7. Sustainable systems and states in the domains.
8. Methods of identification of the goals of sustainability.
9. Character of sustainability—a final stable state or just the perpetually changing state of the world (punctuated equilibria)?
10. Sustainable development as a perpetual learning process.
11. Essential variables of sustainability and methods for their definition and measurement.
12. Types of relations between sustainability of elements (subsystems) and sustainability of the systems/processes defined on any scale—economic unit (enterprise, other organizations), regional/local, national, international, regional/international, global.

18.5.2.2 Causal Relations

Causal relations within the systems constitute a foundation for studying and influencing the dynamics of sustainable development. Their identification constitutes at the same time a part of description. Identification of all monocausal and multicausal relations in a complex system is impossible. They constitute the very definition of complexity, including emergent properties. For this reason, only some example relationships can be pointed out.

1. Relations in the processes leading to sustainability (constituting sustainable development).
2. Types of causality.
3. The causal links between domains of sustainability.
4. Hierarchical and heterarchical relationships within sustainable systems.
5. Structure–agency relations in sustainable systems.
6. Self-organization as the process leading to and maintaining sustainability.
7. Loops of reflexivity in sustainability systems and processes.
8. Causal relations between sustainability of elements (subsystems) and sustainability of the systems/processes defined at any scale—economic unit (enterprise, other organizations), regional/local, national, international, regional/international, global.
9. Characteristics of the learning process—learning loops, norms of learning.

18.5.2.3 Prediction

This is the most important and at the same time the most controversial facet of the application of complexity ideas in sustainability discourse since it determines the sense of the discourse. The definition of the future sustainable state(s), processes or series of punctuated equilibria which can be representative of sustainable development is undoubtedly the key issue in the whole of sustainability discussion. Examples of determinants of the value of ideas and methods drawn from complexity studies are:

1. Expected (desired) characteristics of future sustainable states/processes.
2. Time horizon of predictions.
3. Methods and validity of predictions of long-time horizons necessary in multigenerational sustainability processes.
4. Types of causality and prediction.
5. Methods of prediction and validity of methods of prediction.
6. Quantitative and qualitative methods of prediction.
7. Prediction, learning and reflexivity.

18.5.2.4 Normative Approach

As in the case of prediction, the norms and goals of sustainability are very difficult to establish. Even if they are not defined as a stable state, the goals of sustainable development need to be determined. Usually both norms and goals are depicted as multigenerational (one to two generations) phenomena. This case echoes a classical challenge in such normative social sciences as economics, finance, management and security studies. Theoreticians and practitioners are aware that their predictive capabilities are limited, but at the same time they have to determine the goals and norms. While in classical management at the micro-level, goals resulting from the interplay between market and stakeholders are relatively easier to develop, at the higher levels of the social hierarchy the phenomena are much more difficult to grasp because of a multiplicity of elements, factors and interactions. Some examples of determinants of complexity-related normative aspects of sustainability and sustainable development are:

1. Contemporary qualitative and quantitative norms of sustainability.
2. Future norms of sustainability.
3. Patterns of selection/emergence of the norms of sustainability.
4. Norms as the result of learning process.

18.5.2.5 Influence upon Societal Phenomena

This function of theory, as well as of analogies, metaphors and mathematical models, can be understood in a twofold way. First, when traditional 'hard' systems thinking is applied, it can be reduced to simple regulation and control rooted in 'first-order cybernetics', where the observer is outside the system. Second, when 'soft' systems thinking or 'second-order cybernetics' is taken into account, the role of participant/observer and the interpretative/constructivist aspects of theory and practice must be borne in mind. However, in both approaches mathematical models drawn from 'hard' complexity as well as analogies and metaphors dealing with 'hard' and 'soft' complexity discourse should be taken into account.

1. Control parameters of processes leading to sustainability.
2. Methods of identification of control parameters.
3. Methods of direct and indirect influence.
4. Learning processes and their characteristics.
5. Influence upon learning and self-organization.
6. Balance between spontaneity and self-organization, and external influences.
7. Links between the goals and the processes of change.

18.5.3   Complexity Studies, Transition Theory and Transition Management

Concepts associated with complexity, or complexity theory or science, are the key foundation of sustainability transition theory. The narratives of sustainability transition theory and transition theory management are completely permeated with the terminology of complex systems research. Complexity studies are viewed as a 'unifying principle' (Camaren/Swilling 2014).

The following passage perfectly mirrors the complexity-related assumptions of sustainability transition and transition management.

> The basic mechanisms that underlie change in complex adaptive systems are coevolution, emergence and self-organization (Holland 1995). Societal systems can be considered as complex adaptive systems. Societal sectors consist of numerous interlinked elements (e.g. actors and institutions), there is a high degree of uncertainty about their interactions and feedback and they have an open and nested character in terms of different levels of organization. From this perspective, typical complex system behaviour can be recognized, as for example emerging structures, co-evolving (policy) domains and self-organising processes can be observed. One of the possible patterns distinguished is that of transition: a system in a relatively stable equilibrium is (suddenly) going into a phase of rapid change through a process in which self-organization and coevolution play an important role before a new equilibrium is found (Loorbach/Frantzeskaki/Thissen 2011: 77).

It must be stressed that the authors of the concepts of sustainability transition and transition management are aware of subjectivity and of the arbitrary character of their ideas. "A societal system" does not exist in reality, nor does a "regime". They clearly state that any analysis of a system is arbitrary and only valid as long as it is supported or recognized by actors operating within it. In other words, a system definition is a product of social construction and any model for analysis should support this process.... The concepts of transition theory should therefore not be regarded as goals, but rather as a means for analysis. Possibly, there are many alternative system, scale or phase models that could be of as much use. Acknowledging the limitations stemming from subjectivity and intersubjectivity, they claim that

> ...in its short existence, transition theory has proved to be of value for integrative, long term analysis of complex societal processes, and has presented a promising starting point for redefining governance in the context of these transitions.... The objective of transition research therefore is not to achieve objective analysis, but to develop coherent, integrative and long-term analytical tools that provide a basis for societal debate, policy and reflection on future development. Transition analysis should stimulate and support the necessary problem structuring processes, reflexive capacity and social learning that create the conditions for change to occur (Loorbach 2007: 22).

This reflection is essential in the analysis of the links between complexity studies and sustainability transition and transition management. It shows that applications of complexity ideas are conceptually well-grounded and the assessment will not be reduced to a simple criticism of simplifications and even ignorance, something which is, alas, too frequent in applications of complexity ideas in the social sciences. However, it also may provide grounds for justification of considerations that are too broad and superficial, especially when the statement of possible alternative systems is taken into account.

In the case of the assessment of sustainability transition, evaluation deals partly with an already-made assessment of the links between sustainability and sustainable development, and complexity. Taking into account the similar assumptions concerning analogies, metaphors, mathematical models, intersubjectivity, and so forth, a ranking of the determinants of the complexity of the systems undergoing transition through transition management can be presented.

18.5.3.1   Description

1. Identification of the systems which are the subject of transition.
2. Methods of identification of transition undergoing transitions.
3. Properties of the unsustainable initial state (stage of the process).
4. Properties of the sustainability transition which derive from the complexity of the initial state.
5. Properties of the final state (process) of the sustainability transition which derive from its complexity.
6. Characteristics of the transition process relating to its complexity.

18.5.3.2   Causal Relations

Causal relations in sustainability transition both reflect interactions within the system and emerge between various activities in the process of transition. As in in the case of sustainability, identification of all causal and multicausal relations in a complex system is impossible; only some examples of determinants of causal relationships can be pointed out.

1. Interactions in the systems in the transition process.
2. Causal links between subprocesses of transition.
3. Causal links between domains of sustainability.
4. Causal links in hierarchies and heterarchies.
5. Feedback loops.

18.5.3.3 Prediction

In predicting the results of sustainability transition it is the future state/process which has to be at least partly determined. In the case of a specific area where the sustainability transition is designed, the following determinants that concern prediction should be taken into account:

1. Characteristics of unsustainable states/processes.
2. Expected states of parameters describing the future sustainable states/processes.
3. Time horizon of predictions.
4. Methods of prediction and validity of methods of prediction.
5. Objective limitations of prediction.
6. Subjective limitations of prediction–individual specific cognitive, and collective – social, political and cultural.
7. Characteristics of the learning process—basic learning mechanisms, assumptions, norms?

18.5.3.4 Normative Approach

As explained in the earlier discussion, at the beginning of the sustainability transition process the norms and goals are unclear. Even if they are not defined as a stable state it is necessary to determine what they could be. Owing to the variety of transition projects, their time horizon may be more difficult to determine. The basic determinants of complexity are as follows.

1. Goals and norms of the transition.
2. Methods of development of the goals or methods of influence of emergence of the goals.
3. Spontaneity vs. control over development/emergence of goals and norms.
4. Characteristics of the learning process leading to emergence of goals and norms.

18.5.3.5 Influence upon societal phenomena

Determinants of complexity of description, identification of causal links, prediction and the normative approach have been described in relation to sustainability transition. Theoretical considerations and discussion concerning applications of transition management focus upon the influence of societal phenomena

(events, processes, spontaneous/non-spontaneous). The dominant characteristics of complexity of the context and of the goals of sustainability transition management have been described earlier; for sustainability transition management, only one function of analogies, metaphors and mathematical models remains: influence upon societal phenomena. Bearing in mind 'hard' and 'soft' complexity, the following questions can be asked:

1. Qualitative characteristics and quantitative control parameters of processes/phenomena   leading to sustainability.
2. Methods of direct/indirect influence upon characteristics and parameters.
3. Links between the goals and the processes of change.
4. Degrees of spontaneity and external influence upon the subprocesses of transition.

18.5.4 Understanding the Complexity of Sustainability, Sustainable Development, Sustainability Transition and Transition Management

18.5.4.1 Assumptions and Criteria of Assessment

The above considerations may constitute a point of departure for preliminary identification and assessment of the relevance of applications of complexity-related concepts to the ideas of sustainability, sustainability development, and sustainability transition and management. The assessment is by definition of an introductory character and further systematic studies are needed. It is even possible that because of the scope and intricacy of the research area, such a comprehensive evaluation is not achievable. In the assessment the following criteria should be taken into account:

1. Awareness of the subjective (intersubjective) and reflexive character of social systems and of definitions of their complexity.
2. Comprehensive understanding of the ideas of complexity ideas–'hard' and 'soft' complexity.
3. Comprehensive understanding of the meaning of analogies and metaphors drawn from complexity studies which are applied in the social sciences, including sustainability theory and policy, sustainability transition theory and sustainability management.
4. Relevance of applications of metaphors, analogies and mathematical models relating to the concepts drawn from complexity theory.

5. Comparison of advantages and disadvantages of complexity-based theory and applications of sustainability transition and transition management.
6. Misuses and abuses of complexity ideas.

When studying and assessing the applications of the utterance "complexity" in the social sciences, it is first essential to identify which characteristics of complexity are being applied and how they are used–as analogies, metaphors or mathematical models. In the majority of applications, metaphors and analogies can be found.

A deeper analysis of the uses of metaphors in theory and in practice has been conducted in several areas of the social sciences (Lakoff/Johnson 1980, 1989; Dobuzinskis 1992; Ortony 1993; Mirowski 1989, 1994; Morgan 1996). When studying the uses of metaphors, the first step is to distinguish their types and their specificity. Then it is necessary to be aware of the negative consequences of the reification of metaphors (Vandenberghe 2014). Fulfilling these two demands makes it possible to evaluate the effectiveness of the application of metaphors and analogies. Evaluation can be performed on the basis of their validity in the five functions of theory described above.

Operationalization of the characteristics of complexity is the key component of the 'hard' approach to complexity. It is usually performed in two stages. In the first stage, the verbal categories are defined in such a way as to make possible their quantification, that is, they are described using ratio or interval scales, and then either statistical processing is performed or other types of mathematical models are used. In the second stage, the model, be it statistical or of another type, is applied, and then the relevance of the model to reality is assessed.

18.5.4.2 Complexity of Sustainability and of Sustainable Development

In the considerations linking sustainability and sustainable with various characteristics of complexity all types of applications can be found: analogies, metaphors and mathematical models. The following general regularities can be observed.

Complexity is treated as an indispensable part of modern socio-economic systems and ecological systems. In a majority of cases, complexity is introduced without any deeper reflection concerning the difference between 'hard' and 'soft' complexity and its metaphorical character. In particular, no reflection on the subjectivity of the meaning is provided. The examples below are obviously not to be treated as absolutely representative but, as mentioned earlier, can be

viewed as examples that can be used to shape future, more systematic studies on the occurrence of ideas taken from complexity theory/complexity studies in the discourse on sustainability and sustainable development.

The degree of reflection on the meaning of complexity in sustainability discourse varies. Some works include a deeper reflection on complexity; examples are Espinoza/Porter (2011) and Espinosa/Walker (2011). Elsewhere, a more arbitrary approach is applied. As already mentioned, social and ecological systems and their interactions (co-evolution) are depicted as complex adaptive systems, e.g. Levin (2006). Another method of application, in which a postmodernist interpretation of ecological problems is analysed with the use of Foucault's idea of radical relational agency and complexity, employs a profounder qualitative understanding of complexity as well as an interpretation of complexity theory:

> Complex systems, however, "are not 'things' in the noun like sense but processes; nor are they 'things' in the categorical sense because nothing underwrites the linguistic academic habit of collecting them together" (Jenks/Smith 2005: 23). Complexity theory does not take complex systems to be an object of study. Rather, complexity theory describes the *processes* that occur within complexly arranged systems. That complex systems are defined by processes is consistent with a radical relational agency because it underscores the *interactions* that occur within these systems. A complex system is not defined by any innate characteristics, but by the processes enacted by the social and ecological participants that make it up. In other words, complex systems cannot be 'things' because they are *by definition* the set of complex interactions that take place between humans, nonhumans and environments (Picard 2010: 8).

The metaphor of the 'edge of chaos' seems particularly attractive, not only in security-oriented discourse and management but also in the ecological consideration. Although attempts at operationalization are made, e.g. in Carroll and Burton (2000), in most cases this phrase is used as a metaphor. A rigorous model of the 'edge of chaos' state must include a system defined with a set of measurable variables where changes to some of them represent the dynamics of the system. Otherwise, it is just a metaphor and users should be aware of its limitations.

> Ecological systems are on the edge of chaos without a 'natural' tendency towards equilibrium [...]. Indeed, many ecological systems themselves depend not upon stable relationships but upon massive intrusions, of extraordinary flows of species from other parts of the globe and of fire, lightning, hurricanes, high winds, ice storms, flash floods, frosts, earthquakes and so on. The

'normal' state of nature is not one of balance and repose; the normal state of nature is to be recovering from the latest disaster (Urry 2005: 6).

In the study of broadly defined sustainability on the global scale and on the scale of nations, the concept of complexity is applied in its basic form, even without stressing the role of emergent properties:

> Complexity [of society] is generally understood to refer to such things as the size of the society, the number and distinctiveness of its parts, the variety of specialized social roles that it incorporates, the number of distinct social personalities, and the variety of mechanisms for organizing these into a coherent, functioning whole. Augmenting any of these dimensions increases the complexity of the society (Tainter 1988: 23).

Although such an approach is a simplification which reduces complexity solely to "objective" categories in the case of systems which can be described using a mechanistic analogy, in the case of global systems it is highly valid. The system of states or other entities (regional institutions, global organizations) can and should be perceived in such a way. It both allows the application of mathematical models and provides a basis for further analyses, which may include deeper considerations on subjectivity, intersubjectivity, and the constructivist character of such collectivities.

Looking at the above examples, which obviously may not be fully representative, and confronting them with the demands of theory and policy-making, as well as with the above criteria, the following remarks can be made. First and foremost, the application of the ideas of complexity theory requires a deep and thorough investigation if it is to achieve results that will allow a comprehensive assessment. A preliminary evaluation leads to the conclusion that none of the criteria are fully applied or fulfilled in work on the complexity of sustainability and sustainable development. It is obviously impossible to achieve this in every work on sustainability, but at least some reflections need to be included. As an example of an exception that meets that requirement, the works quoted above may be mentioned (Espinosa/Harnden/Walker 2008; Espinosa/Walker 2011). Such a situation may have a number of negative consequences of a theoretical, practical and political nature. As far as theoretical considerations are concerned, it means that the validity of the discussion on sustainability can be easily weakened. Additionally, if an extended argument about sustainable development is presented without explaining what is to be sustainable and how the desired, possibly temporary, state (temporary equilib-

rium) is to be defined, then the argument is easy to bring into question.

Summarizing the above remarks and sketching a framework for future studies, it can be concluded that in almost every application of ideas relating to complexity in the discourse on sustainability, a more or less concealed mechanistic analogy drawn from physics, mechanics or biology is being applied. Such an approach is the only one possible, even when modern critical, constructivist postmodernist paradigms are taken into account. What is always obviously different is the degree to which authors are aware of the limitations of their approach, deriving as it does from the intersubjective character of all the categories applied in the discourse. Even in the case of mathematical models derived from operationalization, the choice of the model built upon the central metaphor (Lakoff 1993) is never objective, as is often claimed by the models' creators.

18.5.4.3 Complexity of Sustainability Transition and Transition Management

While discussion about the links between complexity and sustainability and sustainable development is at a very early stage and by necessity built upon only a selection of very different examples, consideration of the impact of complexity theory on sustainability transition and transition management involves two coherent theoretical and interrelated concepts.

As was shown earlier in this chapter, both the above ideas are a kind of synthesis of modern social thought on constructivism, reflexivity, holistic thinking, self-organization, governance, and a very broadly defined complexity of social and ecological systems. Undoubtedly these two concepts reflect the limits of relevant modern social thinking. Their relationship with complexity depends on the criteria formulated in the assumptions of this section.

First, as reflected in work quoted above, the reflection of the subjectivity of ideas of complexity is embedded in the theory and application of transition theory and transition management. It concerns the understanding of the systems and, to a lesser extent, of the ideas deriving from complexity studies. Second, and this can be viewed as a weakness of both ideas, is the lack of profounder interpretations of social systems and their characteristics. Although it must be emphasized that systems and their characteristics are perpetually constructed by actors during the transition process through reflection, no sufficiently precise details of such characteristics are provided. This is partly compensated for in the examples of applica-

tions where the learning processes and the emergence of systems are demonstrated (Loorbach/Rotmans 2010). It would be helpful if the norms and loops of learning were depicted in a more detailed manner. These are simply general remarks concerning ideas about systems, and they indicate further directions for reflecting upon transition to sustainability and sustainability transition.

The main focus of attention is the assessment of the application of complexity ideas in the transition to sustainability and sustainability management. In this case it must be admitted that despite the declarations of awareness of subjectivity, the ideas of complexity are sometimes applied without sufficiently profound reflection. Several examples are quoted below.

To start with, we can consider complex adaptive systems, one of the core ideas in all sustainability transition discourses. A rigorous and epistemologically valuable reference to complex adaptive systems should be supported with a detailed mapping of the ideas of operationalization, as described by Holland (2006) and others. Otherwise, the applications are simply metaphors and would require a deeper reflection on their cognitive validity. Obviously, the operationalization of some characteristics is always acceptable, but then an open question remains as to what extent such operationalization allows a full-fledged systems approach to be maintained and a system to be properly identified.

Similar reflections concern another complexity-related idea—self-organization. It is one of the main features of the complexity of social systems. It is regarded as a common trait of complex systems in both 'hard' and 'soft' approaches, and numerous examples of its use can be found in the works quoted above. However, as in all other cases, a proper identification of self-organization requires more precision in defining the system, the relationships and the determinants and patterns of *eigendynamik*, including attractors, emergence, and so forth. Taking into account the differences between understanding complexity in 'hard' interpretations and in the interpretation proposed by Luhmann, five ways of bringing self-organization into social theory are proposed. First, operationalization, i.e. identifying the 'hard' part of the system. This is measurable either on a ratio or an interval scale. Mathematical models exhibiting emergence can then be prepared. Examples of such an approach when dealing with sustainability transition have been already developed (Timmermans 2008; Timmermans/de Haan/Squazzioni 2008; Faber/Alkemade 2011). The second method, proposed by Luh-

mann (1990) and developed by Leydesdorff (2001) among others, was built upon the concept of an auto-poietic social system of meaningful communication. Having defined the social system in a relatively rigorous way, it is possible to identify the processes of self-organization in a qualitative way, optionally supported by operationalization. The fourth method is to use analogies and metaphors from the 'hard' complexity approach, without any reference to Luhmann's social autopoiesis. The fifth method, which could be seen as the most advanced approach, differs from the others by parallel applications of ideas from 'hard' and 'soft' complexity science in order to identify and analyse self-organization.

The last example reminds us that there may be references to non-linearity in the discourse on sustainability transition. As was stated above, non-linearity is a typical feature of the behaviour of different systems, and linearity is only the special case (Campbell 1997: 218). Moreover, non-linearity is not always a source of computational barriers. In order to identify a non-linear disordered behaviour, a set of well-defined parameters must be applied and relevant mathematical models developed. In other cases, as is often the case in the discourse on sustainability transition and transition management, non-linearity is used as metaphor, and so a detailed analysis of its meaning should be performed before this term is employed in theory or practice. Especially intriguing is the question of how non-linearity can be captured in a qualitative manner by the participant-observers. Obviously, positive feedback loops can be identified without mathematical formalism, but appropriate operationalization would be difficult, if not impossible, to accomplish.

Applications of other ideas drawn from complexity theory in the transition to sustainability and transition management, such as adaptation, attractor, chaos, edge of chaos, learning, and punctuated equilibria, could be scrutinized in the same manner. The methodology of assessment could be the same as in the above cases. A thorough description and evaluation of the links between complexity theory and the discourse on sustainability transition and transition management is beyond the scope of this study. However, even an evaluation made at a certain level of generality can lead to a better understanding of the complexity of sustainability transition and transition management. It is also important that the proposed level of generality enables the researcher to avoid delving into the sophisticated language of modern sociology which is used in the narratives concerning these two concepts.

The main conclusions stemming from a preliminary assessment of the applications of complexity ideas to transition to sustainability and transition management are as follows. Transition to sustainability and transition management undoubtedly constitute the most comprehensive concepts of large-scale societal change, developed on the basis of state-of-the-art studies (or theory) of differently defined complexity. As is not the case with a multitude of other applications of the various characteristics of complex systems in the social sciences, the authors of both concepts are to a large extent aware of the limitations of these applications that stem from intersubjectivity and from the constructivist character of social systems. However, while such limitations are taken into account in reflecting upon the systems, their properties and their functioning, the idea of complexity and its attributes are used with insufficiently deep reflection. In several works quoted above in this chapter, complexity and its characteristics are treated as almost a priori categories. Insufficient attempts are made to explain what the system is, how it is constructed or how it is emergent. A similar set of questions can be applied to the patterns of self-organization. By the same token, a deeper explanation is required for another feature of complex systems–the edge of chaos.

Application of the ideas taken from complexity theory in sustainability transition and transition management is affected by another weakness resulting from the need for knowledge of the genesis of the ideas connected with complexity. Without a fuller explanation, it is not possible to apply Luhmann's concept of the complexity of social systems using other ideas of complexity taken from 'hard' complexity–thermodynamics, (e.g. Prigogine/Stengers 1984; Nicolis/Prigogine 1989) or mathematical modelling of systems complexity (e.g. Waldrop 1992; Holland 1995; Bak 1996). Any attempts at operationalization or joint qualitative interpretation require a very thorough and deep understanding of both domains of the discourse on complexity.

The role of metaphors and analogies is another issue in the assessment of the links between complexity theory and sustainability transition and transition management. Although applications of metaphors are included in the ontological and epistemological foundations of sustainability transition and transition management, e.g. Loorbach (2007: 86–87) and the references to Stacey (1996) in Loorbach's work, they do not seem sufficient. Any action-oriented theories dealing with so many ideas from complexity studies should include much more profound analysis of the terms applied as analogies and metaphors. This analysis seems to be insufficient in the entire body of knowledge on sustainability transition and transition management.

There is another advantage of the use of analogies and metaphors, independent of analysis of their cognitive validity. Metaphors and analogies relating to complexity may be viewed as heuristic instruments that enhance creativity in description, explanation, prediction, setting norms and influencing social systems in the theory and practice of sustainability transition and transition management. This role of complexity theory could be utilized in prediction. Emergent phenomena in modelling systems with Complex Adaptive Systems can only serve as predictions to some extent, since they are not recurrent. However, models of CAS can deliver patterns which were 'unimaginable', and in this way they could be applied in prediction.

When choosing theoretical ideas, be they paradigm, theory or model for application in practice, it is always necessary to demonstrate their advantages over other ideas. There may be different norms and criteria for proving the superiority in an objective manner, or at least for persuading others about their advantages. In the theory of sustainability transition and transition management, the 'added value' of the complexity-based approach is insufficiently advertised. It would be worthwhile to learn what additional practical results have been and can be achieved thanks to the proposed concepts in comparison with other approaches, say, for example, systems analysis and design or traditional methodologies drawn from large-scale project management. Otherwise the proponents of new ideas are under the threat of Occam's razor.

A final remark concerns the overall character of both concepts discussed. They are built upon a reinforced ontological and epistemological rule that says–nothing is constant. Everything can be accommodated, adapted, changed after the reflections of the participant-observers. One may even pose the question: are the reflection patterns and/or loops constant or variable? Obviously, this stands in agreement with the conditions of our modern fast-changing society in flux. A question thus arises. Does changeability of the theory and practice of sustainability transition and transition management result from the fundamental ontological and epistemological limits of the objects (systems) under study, or perhaps, is it the result of the weaknesses of a theory which is not able to answer questions concerning applicability? Of course, we know that *panta rei* and we have to go 'from being to becoming', but is it possible to capture

that reality in such a comprehensive way as it is presented in the theory of transition to sustainability theory and transition management, assuming that nothing can be stable and there are no patterns which could at least make classical measurement possible? This problem was discussed by Anand and Sen (2000: 2037), who used the polarity overspecification vs. underspecification of sustainable development. The ideas of sustainability transition and transition management are somewhat unspecified, partly because of the insufficiently analysed applications of ideas drawn from complexity theory. This may lead to such high levels of relativization of ideas that it even undermines the processes of communication treated as the transfer of meaning. It may also provide arguments for the criticism that ideas, objects and methods are fuzzy to such an extent that narratives based upon broad linguistic variables, instead of discovering the very sense of the problem, may lead to its misreading and even concealment.

18.6   Conclusions

The conclusions and recommendations stemming from the above considerations can be divided into two groups. The first relates to sustainability and sustainable development and the second concerns transition and transition management.

The complexity of sustainability and sustainable development was somehow discovered at a very early stage of the development of these ideas. Initially it took the form of fuzzily described labels, but soon, together with the development of complexity science, it became one of the core issues in the discourse on sustainability. As with other vague ideas concerning social life, the terms sustainability and sustainable development cannot be defined in a precise way, and thus their meaning emerges in intersubjective exchange. The problems in defining sustainability become even more profound when ideas associated with complexity are included in research. In the works linking complexity and sustainability, applications may vary, beginning with loosely defined metaphors and analogies, and ending with various attempts at operationalization. The main advantage of the application of complexity-related concepts in the theory and practice of sustainability is the enhancement of possibilities for description, explanation of causal links, prediction and influence on social phenomena. It can be concluded that at present the theory and policy of sustainable development is to a large extent dependent upon ideas drawn from complexity theory, broadly defined.

The preliminary research on the application of complexity-related ideas in sustainability research and practice shows that, with the exception of the operationalization of some ideas taken from complexity theory, analogies and metaphors borrowed from complex systems dominate the discourse. In the majority of cases they are used without a deeper reflection on the intersubjective character of social systems and of their complexity. Social systems are the product of intersubjective discourse and the same characteristic of the discourse on complexity makes studies and actions very intricate. In many cases, the terms associated with complexity theory are misused and abused in discussions about sustainability, and the vague meaning of that and of utterances associated with it are applied as a kind of decoration, adding a 'scientific value' to the discourse.

It is obviously only a margin of applications of complexity concepts since even a purely but well-thought use of those concepts would contribute to a better understanding of the fast-changing modern world, and in consequence, should lead to the development of more effective policy measures.

While the complexity of societal and environmental phenomena has been included in the theory and policy of striving for sustainable development, ideas deriving from complexity studies have constituted the backbone of the ideas of sustainability transition and transition management. The assessment of the application of complexity-related ideas to the theoretical deliberations on those two concepts and their application leads to the following conclusions.
